
2007 Abstracts

Twenty-Ninth Annual Meeting of the American Society for Bone and Mineral Research

**Hawaii Convention Center
Honolulu, Hawaii, USA
September 16-19, 2007**

The *Journal of Bone and Mineral Research* (ISSN: 0884-0431) provides a forum for papers of the highest quality pertaining to all areas of the biology and physiology of bone, the hormones that regulate bone and mineral metabolism and the pathophysiology and treatment of disorders of bone and mineral metabolism. The *Journal of Bone and Mineral Research* is the official journal of the American Society for Bone and Mineral Research and is published monthly plus a special issue in September by the American Society for Bone and Mineral Research, 2025 M Street, N.W., Suite 800, Washington, DC 20036-3309, USA. Address reprint/offprint inquiries to the Sheridan Press at US (717) 632-8448 x 8167. Periodicals postage paid in Washington, DC, and additional offices. POSTMASTER SEND ADDRESS CHANGES TO: Journal of Bone and Mineral Research, P.O. Box 2759, Durham, NC 27715, USA. 2007 Subscription Rates: U.S.: Personal \$495.00; Institutional: \$615.00; Canada/Mexico: Personal \$515.00; Institutional \$645.00; Overseas: Personal \$570.00; Institutional: \$665.00. Single issue \$50.00. Subscription term is January - December.

Claims for missing issues will be serviced at no charge if received within six months of issue date {journal@jbmr.org, or fax (US) 919-620-8465}. Duplicate copies cannot be sent to replace issues not delivered because of failure to notify publisher of change of address. Please notify ASBMR of new address six (6) weeks in advance of moving date. All subscriptions are payable in advance in U.S. funds drawn on a U.S. bank. If not fully satisfied, notify publisher for a refund on all unmailed issues.

Address advertising and commercial reprint inquiries to Mr. Steve Kavalgian, Mill River Media LLC, 141 Boston Post Rd. Old Lyme, CT 06371-1303, USA; (860) 434-6889 (phone); (860) 434-9744 (fax); millrivermedia@aol.com (e-mail). Advertisements are subject to editorial approval.

No responsibility is assumed, and responsibility is hereby disclaimed, by the American Society for Bone and Mineral Research and the *Journal of Bone and Mineral Research* for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of methods, products, instructions or ideas presented in the *Journal*. Independent verification of diagnosis and drug dosages should be made. Discussions, views and recommendations as to medical procedures, choice of drugs and drug dosages are the responsibility of the authors. Advertisers are responsible for compliance with requirements concerning statements of efficacy, approval, licensure, and availability.

The *Journal of Bone and Mineral Research* is a **Journal Club™** selection. The *Journal* is indexed by *Index Medicus*, *Current Contents/Life Science*, *CABS (Current Awareness in Biological Sciences)*, *Excerpta Medica*, *Cambridge Scientific Abstracts*, *Chemical Abstracts*, *Reference Update*, *ScienceCitation Index*, and *Nuclear Medicine Literature Updating and Indexing Service*. Copyright © 2007 by the American Society for Bone and Mineral Research. For permission to reproduce copyrighted materials from the *Journal*, send requests to Deputy Director of Publications David Allen (david@jbmr.org), or mail the *Journal of Bone and Mineral Research*, P.O. Box 2759, Durham, NC 27715, USA; (919) 620-0681 (phone); (919) 620-8465 (fax). For libraries and other users registered with the Copyright Clearance Center, please contact the Copyright Clearance Center, 222 Rosewood Drive, Suite 910, Danvers, MA 01923, USA; www.copyright.com; (978) 750-8400 (phone); (978) 750-4470 (fax).

GUIDELINES FOR ABSTRACT READERS

The *JBMR* Supplement 1 Abstracts serves as a compiled version of the Abstracts. Authors submit their own abstracts and are charged a fee to do so. Each abstract must be sponsored by a current ASBMR member. Authors are responsible for the accuracy of the content that they post. Authors are responsible for ensuring compliance with applicable human subject and animal subject procedures. When an abstract is submitted, one person is identified as the Presenting Author, the person who is expected to present the abstract at the ASBMR Annual Meeting.

The ASBMR depends upon the honesty of the authors and presenters and relies on their assertions that they have had sufficient full access to the data to be and are convinced of its reliability. In accordance with the rules of Federation of American Societies for Experimental Biology (FASEB), the ASBMR expects that authors and presenters:

- Will disclose any conflicts of interest, real or perceived.
- Should disclose any relationship that may bias one's presentation or which, if known, could give the perception of bias.
- Will affirm, for any study funded by an organization with a proprietary or financial interest, that they had full access to all the data in the study.
- Are responsible for the content of abstracts, presentations, slides, and reference materials.
- Keep the planning, content and execution of abstracts, speaker presentations, slides, abstracts and reference materials free from corporate influence, bias, or control.
- Should give a balanced view of therapeutic options by providing several treatment options, whenever possible, and by always citing the best available evidence.
- Should disclose when any commercial product is not labeled for the use under discussion or that the product is still investigational.

The ASBMR:

- Will note those speakers who have disclosed relationships, including the nature of the relationship and the associated commercial entity.
- Peer-review the abstracts according to categories, but only to determine which will be selected for oral presentation, for poster presentations, or for any awards. Abstracts are not otherwise subject to any quality or content review by ASBMR or *JBMR*.
- Expects the audience for the Abstracts to be researchers, physicians, clinicians and other allied health professionals.
- Protects the Abstracts by copyright, and prohibits the reproduction, distribution, or transmission of the abstracts without the express written permission of ASBMR.
- Embargoes the Abstracts for public release in written, oral and electronic communications until one hour after the abstract has been presented.

Disclaimer. All authored abstracts, findings, conclusions, recommendations, or oral presentations are those of the author(s) and/or speaker(s) and do not reflect the views of the American Society for Bone and Mineral Research or imply any endorsement. No responsibility is assumed, and responsibility is hereby disclaimed, by the American Society for Bone and Mineral Research for any injury and/or damage to persons or property as a matter of products' liability, negligence or otherwise, or from any use or operation of methods, products, instructions or ideas presented in the abstracts or at the ASBMR Annual Meeting. Independent verification of diagnosis and drug dosages should be made. Discussions, views and recommendations regarding medical procedures, choice of drugs, and drug dosages are the responsibility of the authors and presenters.

AMERICAN SOCIETY FOR BONE AND MINERAL RESEARCH (ASBMR)

OFFICERS

President: Steven R. Goldring, M.D.
Past-President: Elizabeth Shane, M.D.
President-Elect: Barbara Kream, Ph.D.
Secretary-Treasurer: Keith Hruska, M.D.
Past Secretary-Treasurer: Marc Drezner, M.D.

COUNCILORS

Maria Luisa Brandi, M.D., Ph.D.	<i>Term expires 2009</i>	René Rizzoli, M.D.	<i>Term expires 2007</i>
Roberto Civitelli, M.D.	<i>Term expires 2009</i>	Janet Rubin, M.D.	<i>Term expires 2008</i>
Michael J. Econs, M.D.	<i>Term expires 2008</i>	Thomas Spelsberg, Ph.D.	<i>Term expires 2007</i>
Theresa Guise, M.D.	<i>Term expires 2007</i>	René St. Arnaud, Ph.D.	<i>Term expires 2009</i>
Mark C. Horowitz, Ph.D.	<i>Term expires 2008</i>	John Eisman, M.B.B.S., Ph.D.	<i>Ex Officio</i>

ASBMR STAFF

Greg Akroyd, <i>Marketing and Communications Manager</i>	Alison Gershen, <i>Association Coordinator</i>
David Allen, <i>Deputy Director of Publications</i>	Cara Hill, <i>Registration Assistant</i>
Gretchen Bretsch, <i>Project Manager</i>	Melissa Huston, <i>Senior Convention Manager</i>
Kimberly Buffington, <i>Exhibits Coordinator</i>	Matthew Kilby, <i>Senior Publications Assistant</i>
Angela Cangemi, <i>Senior Program Associate</i>	Kelly Marks, <i>Convention Manager</i>
Marc Charon, <i>Senior Director of Finance</i>	Earline Marshall, <i>Senior Grants Administrator</i>
Danielle Danko, <i>Marketing and Communications Associate</i>	Maureen McBride, <i>Association Associate</i>
Lisa Dittrich, <i>Director of Publications</i>	Rebecca Myers, <i>Program Manager</i>
Ann L. Elderkin, P.A., <i>Executive Director</i>	Elizabeth Nall, <i>Housing Coordinator</i>
Aaron Fennell, <i>Editorial Assistant</i>	Janine O'Donnell, <i>Senior Association Associate</i>
Douglas Fesler, <i>Associate Executive Director</i>	Wayne Horton, <i>Registration Coordinator</i>
Bill Gaskill, <i>Senior Accountant</i>

2007 PROGRAM COMMITTEE

President: Steven R. Goldring, M.D.
Program Co-Chair: Harald Jueppner, M.D.
Program Co-Chair: Juliet Compston, M.D., FRCP

Disclosures:

Dr. Compston - Consultant for Crescent Diagnostics, Procter & Gamble, Novartis, Servier, Shire Alliance for Better Bone Health, Lilly, Amgen, Pfizer, Nycomed, and Medivir, Research grant from Procter & Gamble, and Speaker's Bureau for Procter & Gamble, Servier, Alliance for Better Bone Health, Lilly, and Nycomed
Dr. Goldring - Research grants and consulting fees from Merck, Procter & Gamble Pharmaceuticals, and NPS Allelix; Speaker's bureau, Merck.
Dr. Jueppner - Nothing to disclose.

GENERAL INFORMATION

ASBMR MEETING LOCATION

All ASBMR 29th Annual Meeting sessions will take place in the Hawaii Convention Center, unless otherwise stated. The Hawaii Convention Center is located at 1801 Kalakaua Avenue Honolulu, Hawaii, USA.

COPYRIGHT

Abstracts submitted to the ASBMR 29th Annual Meeting and published in the Abstracts supplement to the Journal of Bone and Mineral Research are copyrighted by the American Society for Bone and Mineral Research. Reproduction, distribution, or transmission of the abstracts in whole or in part, by electronic, mechanical or other means, or intended use, is prohibited without the express written permission of the American Society for Bone and Mineral Research. All inquiries regarding copyrighted material or reprint orders should be directed to Lisa Dittrich, Director of Publications, American Society for Bone and Mineral Research, E-mail: lisa@jbmr.org, Tel: (919) 620-0681; Fax: (919) 620-8465, Postal Address: 3209 Guess Road, Suite 201, Durham, NC 27705, USA.

DISCLAIMER

All authored abstracts, findings, conclusions, recommendations, or oral presentations are those of the author(s) and do not reflect the views of the ASBMR or imply any endorsement. No responsibility is assumed, and responsibility is hereby disclaimed, by the American Society for Bone and Mineral Research for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of methods, products, instructions, or ideas presented in the materials herein (2007 Abstracts). Independent verification of diagnosis and drug dosages should be made. Discussions, views, and recommendations as to medical procedures, choice of drugs, and drug dosages are the responsibility of the authors.

AUDIO- AND VIDEOTAPING

ASBMR expects that attendees respect each presenter's willingness to provide free exchange of scientific information without the abridgement of his or her rights or privacy and without the unauthorized copying and use of the scientific data shared during his or her presentation. In addition, ASBMR expects that attendees will respect Exhibitors' desires not to have their products or booths photographed or videotaped.

The use of cameras, audio-taping devices, and videotaping equipment is strictly prohibited within all Scientific Sessions, the Exhibit Halls, and Poster Sessions without the express written permission of the ASBMR Convention Management. Unauthorized use of the taping equipment may result in the confiscation of the equipment or the individual may be asked to leave the session or Exhibit Hall. These rules are strictly enforced.

USE OF ASBMR NAME AND LOGO

ASBMR reserves the right to approve the use of its name in all material disseminated to the media, public and professionals. ASBMR's name, meeting name, and meeting logo may not be used without permission. Use of the ASBMR logo is prohibited without the express written permission of the ASBMR Executive Director. All ASBMR corporate supporters and exhibitors should share their media outreach plans with the ASBMR Executive Director before release.

No abstract presented at the ASBMR 29th Annual Meeting may be released to the press before its official presentation date and time. Press releases must be embargoed until one hour after the presentation. (See ASBMR Embargo Policy below).

ASBMR MEETING CONTENT AND EMBARGO POLICY

Abstracts submitted to the ASBMR 29th Annual Meeting are embargoed — that is, unavailable for public release in written, oral and electronic communications — until one hour *after* the abstract has been presented.

The ASBMR is sensitive to issues of commercial confidentiality and relevant aspects of the U.S. Securities and Exchange Commission (SEC) regulations. Therefore, the ASBMR reminds all readers that all must adhere to the U.S. Securities and Exchange Commission regulations and treat all scientific information as confidential until the embargo has been lifted – one hour after the abstract has been presented. Any reader of, or listener to, ASBMR Annual Meeting content may be viewed as an “insider” by the SEC due to knowledge of information included in abstracts, particularly clinical trial abstracts. SEC regulations may call for criminal penalties for using such information.

ASBMR'S EXPECTATION OF AUTHORS AND PRESENTERS

Through ASBMR meetings, the Society promotes excellence in bone and mineral research. Toward that end, ASBMR expects that all authors and presenters affiliated with the ASBMR 29th Annual Meeting and the 2007 Ancillary Program will provide informative and fully accurate content that reflects the highest level of scientific rigor and integrity.

The ASBMR depends upon the honesty of the authors and presenters and relies on their assertions that they have had sufficient full access to the data and are convinced of its reliability.

Furthermore, the ASBMR expects that:

- Authors and presenters will disclose any conflicts of interest, real or perceived.
- Authors and presenters describing a study funded by an organization with a proprietary or financial interest must affirm that they had full access to all the data in the study. By so doing, they accept complete responsibility for the integrity of the data and the accuracy of the data analysis.
- The content of abstracts, presentations, slides, and reference materials must remain the ultimate responsibility of the author(s) or faculty.
- The planning, content and execution of abstracts, speaker presentations, slides, abstracts and reference materials should be free from corporate influence, bias, or control.
- All authors and presenters (invited and abstracts-based oral and poster presenters) should give a balanced view of therapeutic options by providing several treatment options, whenever possible, and by always citing the best available evidence.

In addition, ASBMR's meeting evaluations will seek feedback regarding commercial bias at ASBMR Annual Meeting sessions, including the 2007 Ancillary Program.

CONTINUING MEDICAL EDUCATION CREDITS

This activity has been planned and implemented in accordance with the Essential Areas and Policies of the Accreditation Council for CME through the joint sponsorship of The Federation of American Societies for Experimental Biology (FASEB) and the ASBMR. FASEB is accredited by the Accreditation Council for Continuing Medical Education to sponsor continuing medical education for physicians.

The Federation designates this educational activity for a maximum of 38 AMA PRA Category 1 CreditsTM. Each physician should claim only those credits that he or she actually spent in the activity. CME application forms are included in the *On-site Program* book. CME forms should be sent to:

FASEB Office of Scientific Meetings and Conferences
9650 Rockville Pike
Bethesda, Maryland 20814
USA
Tel: (301) 634-7010
Fax: (301) 634-7014

CME Mission Statement and Meeting Objective

The ASBMR 29th Annual Meeting is designed to allow members to present new developments in education, research and clinical practice related to bone and mineral metabolism. The program objectives include updating attendees on the recent advances in osteoporosis and other diseases of bone and mineral metabolism, steroid hormones and receptors, calciotropic and phosphotropic hormones, cancer and bone, bone acquisition and pediatric bone disease, cartilage and connective tissue matrix, bone biomechanics and growth factors.

As a result of their attendance, participants should have enhanced their knowledge of osteoporosis, other diseases of bone, basic bone biology and its correlation to mineral metabolism, as well as their ability to treat and care for their patients. Attendees should have developed a clearer understanding of the interrelationship among basic research, clinical research and patient care through the discussions that are expected to take place. The ASBMR 29th Annual Meeting program should produce an enhanced appreciation of the investigative, diagnostic and therapeutic aspects of metabolic bone disorders.

Target Audience

The program is designed for researchers, physicians, clinicians, and allied health professionals with interests in endocrinology, physiology, cell biology, pathology, molecular biology, genetics, epidemiology, internal medicine, rheumatology, orthopedics, dentistry, nephrology, and pharmacology.

DISCLOSURE/CONFLICT OF INTEREST

The ASBMR is committed to ensuring the balance, independence, objectivity and scientific rigor of all its individually sponsored or industry-supported educational activities. Accordingly, the ASBMR adheres to the requirement set by the Federation of American Societies for Experimental Biology (FASEB) that audiences at FASEB-sponsored educational programs be informed of a presenter's (speaker, faculty, author, or contributor) academic and professional affiliations, and the disclosure of the existence of any significant financial interest or other relationship a presenter has with the manufacturer(s) of any commercial product(s) discussed in an educational presentation. When an unlabeled use of a commercial product, or an investigational use not yet approved for any purpose is discussed during the presentation, it is required that presenters disclose that the product is not labeled for the use under discussion or that the product is still investigational. This policy allows the listener/attendee to be fully knowledgeable in evaluating the information being presented. The Program will note those speakers who have disclosed relationships, including the nature of the relationship and the associated commercial entity.

All authors of submitted abstracts completed the disclosure statement in the online submission program. Invited speakers who are not required to submit an abstract received a form that they completed and returned.

Disclosure includes any relationship that may bias one's presentation or which, if known, could give the perception of bias. This includes relevant financial relationships of a spouse or partner. These situations may include, but are not limited to:

DISCLOSURE KEY

1. stock options or bond holdings in a for-profit corporation or self-directed pension plan
2. research grants
3. employment (full or part-time)
4. ownership or partnership
5. consulting fees or other remuneration
6. non-remunerative positions of influence such as officer, board member, trustee, or public spokesperson
7. receipt of royalties
8. speaker's bureau
9. other

Disclosures for invited speakers and abstract presenters are provided at the end of the session listing for invited speakers (see *On-Site Program* book) and directly after the body of an abstract for abstract submissions. If there is no conflict of interest or disclosure listed, this means that the invited speaker and/or abstract presenter indicated no conflicts to disclose.

The disclosure information will correspond to the key above. If disclosures are given, the company name, along with the respective disclosure relationship number will be listed (for example: Company Name 2, 8.)

2007 ABSTRACTS BOOK

The *2007 Abstracts* book is distributed on-site at the Annual Meeting to all ASBMR members and non-member attendees. Non-member subscribers to *JBMR* will receive the *2007 Abstracts* book by mail. ASBMR members who do not attend the Annual Meeting will receive their copy of the *2007 Abstracts* book by mail following the meeting. The entire ASBMR Scientific Program (invited speaker sessions, lectures, and abstract-based oral and poster presentation information), as well as the 2007 Ancillary Program (Working Groups and Industry-Supported Symposia), are included in full detail in the *On-Site Program* book and on the ASBMR website at www.asbmr.org. **We encourage you to make use of the 2007 Abstracts On-line that is accessible via the ASBMR website at www.asbmr.org. A complimentary hard copy of the 2007 Abstracts book in PDF format will be available for download for all ASBMR members and pre-registered attendees via the ASBMR website as well.**

2007 ABSTRACTS-ON-CD-ROM (ABSTRACTS 2VIEW™)

Supported by an educational grant from Amgen, Inc.

The Abstracts on CD-ROM is also a search tool which allows customized searches of the ASBMR abstracts. The CD-ROM will be included in the ASBMR Annual Meeting delegate bags.

ASBMR ABSTRACTS ONLINE

*Supported by an educational grant from the Alliance for Better Bone Health
(Procter & Gamble Pharmaceuticals and sanofi-aventis)*

The Abstracts Online program, which is accessible through the ASBMR website at www.asbmr.org, is an Internet-based search tool. The program allows the creation of a personalized itinerary for the ASBMR 29th Annual Meeting program and allows customized searches of abstracts.

AWARD PRESENTATIONS

The following ASBMR Awards will be presented immediately following the morning Plenary Symposia and Plenary Lectures in Kamehameha Hall III in the Hawaii Convention Center - the ASBMR Gideon A. Rodan Excellence in Mentorship Award, the Fuller Albright Award, the Louis V. Avioli Founders Award, the Frederic C. Bartter Award, the William F. Neuman Award, and the Shirley Hohl Service Award. Please refer to the schedule found in the inside cover of this book for award presentation times.

ASBMR VIRTUAL EXHIBIT HALL

The ASBMR Virtual Exhibit Hall (www.asbmrexhibits.com) showcases Exhibitors and their products, many of which are present at this year's ASBMR 29th Annual Meeting. Visitors to the ASBMR Virtual Exhibit Hall are able to learn more about Exhibitor's products and services, easily contact them for further information, and enjoy an Exhibit Hall experience at their leisure year-round.

CYBER CAFÉ

Supported by Eli Lilly and Company

The Cyber Café, located in the Exhibit Hall, has full Internet capability and enables attendees to search the Internet and check their email. The Cyber Café will be open during published Poster Hall hours.

NIH LOUNGE

If you are looking for another opportunity to ask U.S. National Institutes of Health and Center for Scientific Review staff about your grant proposal or idea, please plan to visit the Meet-the-NIH Lounge in Kamehameha Hall I & II (Exhibit Hall) of the Hawaii Convention Center and get your questions answered. Program staff from the National Institute and Musculoskeletal and Skin Diseases (NIAMS), the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), the National Cancer Institute (NCI), the National Institute of Dental and Craniofacial Research (NIDCR), National Institute on Aging (NIA), Center for Scientific Review (CSR), National Institute of Child Health and Human Development (NICHD), and more will be on-hand, by appointment, to meet with you. Be sure to sign up for open time slots on-site.

YOUNG INVESTIGATOR LOUNGE

All Young Investigator Annual Meeting attendees are cordially invited to drop by the Young Investigator Lounge located in Kamehameha Hall I and II (Exhibit Hall) of the Hawaii Convention Center. Expand your network of colleagues and make new friends.

RECEPTION FOR NEW INVESTIGATOR/NEW MEMBER/FIRST-TIME ATTENDEES

Sponsored by the ASBMR Membership Development Committee

The New Investigator/New Member/First-Time Attendee Reception will be held concurrently with the Welcome Reception and the Plenary Poster session in the Young Investigators Lounge located in the Poster area of Kamehameha Hall I and II (Exhibit Hall) in the Hawaii Convention Center. ASBMR leadership and Senior Investigators will be in attendance for a meet and greet. The purpose of this event is to assist attendees with opportunities to meet other new attendees as well as familiarize themselves with ASBMR leadership. The event has been organized to promote interactions among junior investigators. Wine and cheese will be available.

NEW INVESTIGATOR/NEW MEMBER BREAKFAST

*Sponsored by the ASBMR Membership Development Committee
Supported by an educational grant from Merck & Co., Inc.*

The New Investigator/New Member Breakfast will be held on Monday, September 17, 2007, from 7:00 am to 8:00 am, in Room 316AB of the Hawaii Convention Center. New Investigators (those early in their careers) and new ASBMR members are invited to join the ASBMR Membership Development Committee and colleagues for an informational breakfast. Highlights will include opening remarks by ASBMR President, Dr. Steven Goldring, an overview of the Annual Meeting program by Program Co-Chairs: Drs. Juliet Compston and Harald Jueppner, and a special presentation by Women in Bone and Mineral Research Committee (WBMRC) Chair Dr. Nicola Partridge. Program directors from U.S. NIH Institutes and Centers, along with ASBMR member senior scientists, and representatives from several ASBMR committees will be available for discussion at specially marked tables. Attendees should look for table signs advertising a specialty or NIH Institute or Center of interest, which include: National Institute on Aging (NIA), National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institute of Child Health and Human Development (NICHD), National Institute of Dental and Craniofacial Research (NIDCR), National Cancer Institute (NCI), National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), and Center for Scientific Review (CSR). Or attendees can make their own signs to join with colleagues who have similar interests. New Investigators and first time attendees are encouraged to pick up a "New Investigator/ First Time Attendee" ribbon, which will be distributed at the entrance to the room. Breakfast will be provided.

JOINT ECTS/ASBMR SESSION ON OSTEONECROSIS OF THE JAW

This joint session organized by ASBMR and the European Calcified Tissue Society (ECTS) will take place on Tuesday, September 18, 2007, from 12:30 pm to 2:00 pm in Kamehameha Hall III of the Hawaii Convention Center. This unique and timely symposium will feature talks on “ONJ, Fear of ONJ and the Treatment of Osteoporosis,” “The Influence of ONJ on the Use of Bisphosphonates in Cancer Patients” and “Possible Pathophysiological Mechanisms in ONJ: Separating Fact from Fiction.”

SPECIAL SESSION FOR ALLIED HEALTH PROFESSIONALS Featuring an overview of the 29th Annual Meeting by Lawrence G. Raisz, M.D.

Supported by an educational grant from Roche and GSK

This session will be held on Monday, September 17, 2007, from 12:00 noon to 2:00 pm, in Room 313A of the Hawaii Convention Center. This special session is of interest to allied health professionals, first time meeting attendees, individuals new to the field, nurses, clinical research study coordinators, physical therapists and/or those seeking guidance in navigating through the extensive ASBMR program. An overview of the ASBMR 29th Annual Meeting will be given along with lectures on “Bisphosphonates: New Insights into Mechanisms of Action and Therapy Potency” and “Bisphosphonate Therapy: Common Clinical Issue.” There is no additional fee or registration required for this session, nor will food and beverages be served. However, you are welcome to purchase lunch from the concession area in Kamehameha Hall I and II (Exhibit Hall) of the Hawaii Convention Center.

THE “INS AND OUTS” OF RESEARCH FUNDING

Co-Sponsored Career Workshop Session by the ASBMR Education and Membership Development Committees

The Career Workshop Session will be held on Wednesday, September 19, 2007, from 12:30 pm to 2:00 pm, in the Kalakaua Ballroom C of the Hawaii Convention Center. This year's program is titled, “The Ins and Outs of Research Funding.” U.S. and international new investigators (those early in their research careers) and attendees with an interest in learning more about research funding are urged not to miss this workshop on the “ins and outs” of funding—from the National Institutes of Health (NIH) and minority opportunities available to new researchers—to insight on the peer-review process, strategies for writing a successful grant and how career paths can affect prospects for funding. There is no additional fee or registration required for this session, nor will food and beverages be served. However, you are welcome to purchase lunch from the concession area in Kamehameha I & II (Exhibit Hall) of the Hawaii Convention Center.

CLINICAL ROUNDTABLES/CLINICAL SESSION

The Clinical Roundtables/Case Conferences feature a focused discussion on topical issues of clinical relevance for the practicing clinician. Each session features two speakers and includes a panel discussion. Clinical sessions include topical issues of clinical relevance, followed by either a clinical roundtable or point/counterpoint discussion. The Clinical Roundtable/Case Conference sessions include: “Sequential Therapy: Antiresorptives Before and After Anabolics” and “Management of Bone Disease in Patients Undergoing Organ Transplantation.” See the schedule for session times and location. There is no additional fee or registration required for these sessions. Food and beverages will not be served; however, you are welcome to purchase lunch from the concession area in Kamehameha I & II (Exhibit Hall) of the Hawaii Convention Center.

Special Debate

This year's special Clinical Session will be in a debate format on the topic of “Excessive Suppression of Bone Remodeling by Antiresorptive Agents - Fact or Fiction?” argued by Ego Seeman, M.D, FRACP and Socrates Papapoulos, M.D. The session will take place on Sunday, September 16, 2007, from 1:00 pm to 2:00 pm in Kamehameha Hall III of the Hawaii Convention Center.

MEET-THE-PROFESSOR SESSIONS

The Meet-the-Professor Sessions are a series of informal sessions designed to provide an opportunity for meeting attendees to interact with experts in an intimate setting and discuss specific clinical and research topics. The Meet-the-Professor program has been expanded in order to increase the number of attendees who are able to participate in these sessions. The schedule allows for many Meet-the-Professor sessions to be given twice during the program.

New this year, registration will not be required, however space is extremely limited. There are no additional fees for these sessions. Interested individuals are welcome to attend these sessions on a first-come, first-served basis. Room restrictions and professor preferences will dictate number of attendees. Food and beverages will not be served; however, you are welcome to purchase lunch from the concession area in Kamehameha Hall I & II (Exhibit Hall) of the Hawaii Convention Center.

THE WOMEN IN BONE AND MINERAL RESEARCH EVENT

Sponsored by the ASBMR Women in Bone and Mineral Research Committee

Supported by educational grants from Merck & Co., Inc.

The Women in Bone and Mineral Research Event will be held on Tuesday, September 18, from 7:00 pm to 8:00 pm in Room 316 AB of the Hawaii Convention Center. This event is open to all attendees interested in furthering women's participation in the bone and mineral research field, and in the ASBMR. The ASBMR Women in Bone and Mineral Research Committee (WBMRC) was established in 2005. This committee is charged with mentoring women in the Society with respect to career advancement, academic promotions, combining a career with family, etc. This year's event will feature Dr. Diane Wara from the University of California, San Francisco, who will be speaking on issues of women in leadership and implementing institutional change for women. Dinner and wine will be served. Advanced registration and a fee are required for this event, so sign up at your earliest convenience on-site at the Registration Desk in the Main Lobby of the Hawaii Convention Center.

CHALLENGES AND OPPORTUNITIES FACING NIH PEER REVIEW: A VISION FOR INSURING ITS STRATEGIC NATIONAL VALUE

U.S. National Institutes of Health (NIH) Center for Scientific Review (CSR) Director Antonio Scarpa, M.D., Ph.D. will be making a presentation on the changes the CSR is initiating in the NIH peer review system on Sunday, September 16, 2007, from 3:45 pm to 4:45 pm in Kalakaua Ballroom C of the Hawaii Convention Center. The CSR is the portal for NIH grant applications and its review for scientific merit, receiving nearly 80,000 applications a year and recruiting more than 18,000 external experts to review them in study sections and advisory councils. The CSR mission is to see that NIH grant applications receive fair, independent, expert and timely reviews-free from inappropriate influences-so that NIH can fund the most promising research. Dr. Scarpa's presentation will describe the new efforts CSR is instituting to shorten the review process, recruit and retain the best reviewers and foster a culture more favorable to innovative applications.

NIH CENTER FOR SCIENTIFIC REVIEW: WHAT REALLY HAPPENS AT STUDY SECTION?

This workshop will take place on Monday, September 17, 2007, from 1:30 pm to 2:30 pm in Room 311 of the Hawaii Convention Center and will provide an overview of the NIH grant review process and insights into what happens at study section and council, who can review, the skills needed to serve as an effective grant reviewer and what is involved in a grant review. Through this workshop and other activities, the U.S. NIH Center for Scientific Review (CSR) hopes to increase the pool of experienced investigators willing to serve on study sections and review different types of bone-related grants, including basic, translational and clinical grants. The discussion at this informal, interactive session will be led by a panel of bone grant study section chairs and NIH representatives.

WELCOME RECEPTION AND PLENARY POSTER SESSION

Supported by an educational grant from Merck & Co., Inc.

On Sunday, September 16, 2007, from 5:00 pm to 6:45 pm, attendees and registered guests are invited to attend the ASBMR Welcome Reception and Plenary Poster Session in Kamehameha Hall I & II (Exhibit Hall) of the Hawaii Convention Center. Simply display your badge for admission. Guests may purchase a badge for \$30 at registration, which will allow entrance to the Welcome Reception and Exhibit Hall.

ASBMR SOCIAL EVENT

The ASBMR Social Event will take place at 8:00 pm on Tuesday, September 18, 2007, at the Royal Hawaiian Hotel, a legendary Waikiki Beach hotel known as "The Pink Palace of the Pacific." The social event will feature a live band and unique cultural entertainment. Drinks, light hors d'oeuvres and desserts will be served.

Tickets are required and can be purchased for \$30, if available tickets remain. The Royal Hawaiian Hotel is within walking distance to the ASBMR hotels. Shuttle busing will be provided only at the conclusion of the event to the Hilton and Ala Moana Hotels. The event will take place outside on the Ocean Lawn and inside the Monarch Ballroom. Appropriate shoes are recommended.

ASBMR FUN RUN/WALK

Supported by Novartis Pharmaceuticals Corporation

On Wednesday, September 19, 2007, from 6:00 am to 7:00 am delegates and guests of the ASBMR 29th Annual Meeting will have an opportunity to participate in a 5K Fun Run/Walk. Whether participants choose to walk or run, they will find this event a terrific way to begin a busy day. There is no cost to participate. Tickets are required and are available at the ASBMR meeting registration area in the Hawaii Convention Center. Please stop by the Hospitality Desk in the ASBMR meeting registration area on Tuesday, September 18, 2007, from 11:00 am to 6:30 pm to pick up your T-shirt (first 250 ticket holders), sign a waiver form and learn more about transportation.

REGISTRATION HOURS

All on-site registration will take place in the Main Lobby of the Hawaii Convention Center.

Saturday, September 15, 2007	9:00 am - 5:00 pm
Sunday, September 16, 2007	7:00 am - 6:30 pm
Monday, September 17, 2007	7:00 am - 5:30 pm
Tuesday, September 18, 2007	7:00 am - 5:30 pm
Wednesday, September 19, 2007	7:00 am - 5:30 pm

EXHIBIT HALL HOURS

The Exhibit Hall is located in Kamehameha Hall I & II of the Hawaii Convention Center. For meeting attendees, lunch will be available for purchase in the hall during Exhibit hours.

Sunday, September 16, 2007	5:00 pm - 6:45 pm
Monday, September 17, 2007	9:30 am - 4:30 pm
Tuesday, September 18, 2007	9:30 am - 4:30 pm
Wednesday, September 19, 2007	9:30 am - 4:30 pm

ASBMR TELEPHONE NUMBERS

Management Office	Tel: (808) 792-6521
Registration Desk	Tel: (808) 792-6520
Media Office	Tel: (808) 792-6522
Media Office	Fax: (808) 792-6525

SPEAKER READY ROOM

Supported by an educational grant from Mission Pharmacal Company

Speakers must check into the Speaker Ready Room 24 hours in advance of their presentation. At that time, speakers may review their slides. The Speaker Ready Room is located in Manoa 304A of the Hawaii Convention Center. Review of slides must occur at least 24 hours prior to your presentation. The Speaker Ready Room will be open during the following times:

Speaker Ready Room Hours

Saturday, September 15, 2007	9:00 am – 5:00 pm
Sunday, September 16, 2007	7:00 am – 6:00 pm
Monday, September 17, 2007	7:00 am – 6:30 pm
Tuesday, September 18, 2007	7:00 am – 6:00 pm
Wednesday, September 19, 2007	7:00 am – 6:00 pm

SPEAKER LOUNGE

*Supported by an educational grant from the Alliance for Better Bone Health
(Procter & Gamble Pharmaceuticals and sanofi-aventis)*

The Speaker Lounge will be located in Makiki 302AB of the Hawaii Convention Center. The lounge provides a relaxing atmosphere for the oral presenters and invited speakers to rest, mingle with one another, and to catch up on office work. The room will be equipped with computers, fax, copier, phone/modem lines, snacks and beverages, sofas and chairs. The Speaker Lounge will be available from Sunday, September 16, to Monday, September 17, from 7:00 am to 4:00 pm. and Tuesday, September 18, to Wednesday, September 19, from 7:00 am to 5:00 pm.

POSTER SESSIONS

All poster sessions will be held in Kamehameha Hall I & II (Exhibit Hall) of the Hawaii Convention Center. Authors must be at their posters for one hour and a half of the designated poster sessions on Monday through Wednesday and must be available to answer questions during this period. Authors of odd-numbered posters should be present from 11:30 am to 1:00 pm on their designated days. Authors of even-numbered posters should be present from 1:00 pm to 2:30 pm.

Poster numbers are listed in the *2007 Abstracts* book prefixed with a letter that denotes the day of presentation, i.e., M (Monday), T (Tuesday), W (Wednesday). These letters are not posted on the boards. **Presenters should mount their posters on the board bearing their assigned numbers, disregarding the letter prefix. ASBMR accepts no liability for posters or poster materials and will not adjudicate disputes between abstract presenters.**

Plenary Poster presenters and Young Investigator Award recipients presenting posters should mount their posters on Sunday, September 16, 2007, between 3:00 pm and 4:45 pm. Plenary Poster presenters and Young Investigator Award recipients presenting posters are expected to be present during the Welcome Reception and Plenary Poster Session on Sunday, September 16, from 5:00 pm to 6:45 pm. Plenary Poster presenters and Young Investigator Award recipients presenting posters will follow the odd/even hours for presenters during Poster Session I on Monday, September 17, 2007. Plenary Posters will remain posted until Monday, September 17 at 6:30 pm. Young Investigator Award posters will remain posted for the duration of the meeting.

Please note that children 12 years of age and under will not be permitted in the poster area or the Exhibit Hall at any time.

Presenter Check-in:

Since only poster presenters are allowed in the Exhibit/Poster Hall during the below poster set-up and dismantle hours, please go to the Poster Presenter Check-in Table to receive a security pass. The table will be located in front of Kamehameha Hall II of the Hawaii Convention Center. To speed the check-in process, please have your poster board number ready.

- **NOTE: Posters remaining after Poster Dismantling times will be discarded.**
- **Young Investigator Award Posters remain up through Wednesday, September 19.**

Please adhere to these scheduled times to maximize interaction for other attendees:

POSTER PRESENTATION SCHEDULE

	Poster Set-Up	Posters Open	Authors Present	Dismantle Posters
Sunday, Sept. 16 Welcome Reception/ Plenary Poster Session	3:00 - 4:45 pm	5:00 pm – 6:45 pm	5:00 - 6:45 pm Plenary Posters & YIA Award Posters	Do not dismantle.
Monday, Sept. 17 Poster Session I	7:30 – 8:00 am	8:00 am – 6:30 pm	11:30 am - 1:00 pm for Odd # 1:00 pm - 2:30 pm for Even #	6:30 – 7:00 pm Monday Posters Plenary Posters

ASBMR MEMBERSHIP

The ASBMR Exhibit Booth is #704 in the Exhibit Hall. Come by and meet the ASBMR staff, pick up information about the Society, check out the online version of the *Journal of Bone and Mineral Research*, and order copies of the 6th Edition of the *Primer on Metabolic Bone Diseases and Disorders of Mineral Metabolism*.

The ASBMR Membership Counter will be located in the ASBMR meeting registration area in the Main Lobby of the Hawaii Convention Center and will be prepared to accept 2008 ASBMR membership renewal payments.

ASBMR JOB PLACEMENT SERVICE

The ASBMR Job Placement Service is easily accessible year-round online. You can access the most up-to-date job and candidate listings using the ASBMR Job Placement Service Website. Simply submit your resume or job announcement using the online forms at **www.asbmr.org**. After your forms are submitted and payment is received, you will be able to use your self-assigned login name and password to access the Online Placement Service database anytime you wish.

Employers enrolled in the service will be entitled to display unlimited job announcements online and onsite at the meeting on the bulletin board located in the ASBMR meeting registration area in the Main Lobby of the Hawaii Convention Center. In addition, employers will have access to candidates' Curricula Vitae.

Employers and candidates may request further information by accessing the ASBMR Online Job Placement Service at www.asbmr.org.

ASBMR MEDIA OFFICE

The ASBMR Media Office will be in operation during the ASBMR 29th Annual Meeting to facilitate media-related activities during the meeting. The Media Office will be located in Palolo 306A in the Hawaii Convention Center.

Media Office - Hours of Operation

Saturday, September 15, 2007	2:00 pm - 5:00 pm
Sunday, September 16, 2007	8:00 am - 5:00 pm
Monday, September 17, 2007	8:00 am - 5:00 pm
Tuesday, September 18, 2007	8:00 am - 5:00 pm
Wednesday, September 19, 2007	8:00 am - 5:00 pm

SPECIAL NOTICES — SAFETY TIPS

- Remove your convention badge outside the meeting sites. Do not wear your badge outside or advertise that you're a visitor and not familiar with your surroundings.
- Walk with another person rather than alone. Avoid alleys, walkways between buildings, and deserted parking lots.
- Remain alert, be aware of your surroundings, and carry your handbag in front of you.
- While in your hotel room, always lock your door. Know where emergency exits are in your hotel.
- Place any valuables in a hotel safety deposit box rather than leaving them in your room or carrying them with you.
- Keep a copy of your passport and travel papers in a safe place.

DOES THE ASBMR HAVE YOUR EMAIL ADDRESS?

All important ASBMR Annual Meeting materials can be found on the ASBMR Website... and we will broadcast email to everyone on our correspondence list early notice of the Call for Abstracts, *Preliminary Program*, Registration and Housing information, Abstracts Online, and more! **So you don't miss out** on early notices and regular updates, please send all your contact information to the ASBMR, including your email address.

American Society for Bone and Mineral Research

HOW THE PROGRAM WAS SELECTED

The President and Program Co-Chairs began the process of developing the program for this meeting in the second quarter of 2006. During this process we have greatly appreciated the advice and suggestions of the previous President, Elizabeth Shane, and the previous Program Co-Chairs Andrew Arnold and Susan Greenspan. We also extend our thanks to the Chairs and Panels of each Abstract Review Category who played a major role in formulating the program for our meeting.

Program overview

As in previous years, the program will contain a combination of oral presentations, poster sessions, symposia, State-of-the-Art Lectures, Meet-the-Professor sessions and workshops. There will be a total of 324 oral presentations selected from the 1,878 abstracts submitted. The 15th Gerald D. Aurbach Memorial lecture will be given by Sir Michael Berridge, FRS, whose discovery of the molecule inositol triphosphate (IP3) and its role in the calcium signaling pathway was a major breakthrough in scientific research. The Louis V. Avioli Memorial Lecture will be given by Tatsuo Suda, D.D.S., Ph.D., who has made numerous key contributions to our current knowledge of bone biology, particularly with regard to osteoclast maturation and function.

New features

This year's program contains two new features. First, there will be a session of "oral posters," in which 24 abstracts (12 clinical and 12 basic science) will be presented in parallel sessions on Sunday. The purpose of these sessions will be to provide the authors of the highest-ranked posters a unique opportunity to present the major findings of their work in a fast-paced oral session. Each speaker will be given three minutes (and will be allowed no more than four slides) to present the key findings of his/her abstract, followed by two minutes of discussion. These oral poster sessions are a well-tried format in some national and international meetings and we hope that they will be well received at the forthcoming Honolulu meeting.

The second new feature of our meeting is that we are staging a debate on Sunday to address the very topical issue of whether long-term suppression of bone turnover has adverse effects on bone strength. The title of this debate is "Excessive Suppression of Bone Remodeling by Anti-resorptive Agents - Fact or Fiction?" and the discussants will be Ego Seeman, M.D., FRACP and Socrates Papapoulos, M.D.

MTP sessions

Based on feedback that was received after last year's meeting, we are continuing with the large number of Meet-the-Professor Sessions (18 clinical, repeated once, and 13 basic science). Feedback indicated that the system of reserving attendance in advance was unsatisfactory because many individuals who had signed up for the session did not attend, which left seats unfilled and those without tickets either waiting in line outside the rooms or deciding not to attend because they assumed they would not be able to participate without a ticket. This year we have therefore decided that attendance should be on a "first-come, first-serve" basis, which hopefully will ensure fairer access. There are also two Clinical Workshops, one on the management of bone disease after organ transplantation and on combined or sequential anabolic and anti-resorptive therapy.

Symposia and State-of-the-Art Lectures

This year there will be seven symposia (three plenary, two clinical and two basic) and two State-of-the-Art Lecture sessions. The topics of the Plenary symposia will be imaging, bone quality and drug development and all three will cover a broad range of clinical and scientific aspects. The State-of-the-Art Lectures will cover the role of stem cells in bone research and the regulation of mineral ion homeostasis and bone metabolism in chronic kidney disease. In choosing the topics for the symposia and State-of-the-Art lectures we have used feedback from the 2006 meeting and advice from its Program Committee. We also have a joint session with the ECTS on Tuesday, which is focused on osteonecrosis of the jaw and will address the pathophysiology and management of this disorder.

How the abstracts and posters were selected

Categories for abstract submission were similar to those of last year, although some modifications were made based on the numbers of abstracts previously submitted within individual categories. 1883 abstracts were submitted, but only 1878 were reviewed due to withdrawals. The abstracts were split evenly between clinical and basic categories. A Poster and Category Chairperson and a panel of approximately 10 reviewers for each category were selected by the President and the Program Co-Chairs. The assigned category of all submitted abstracts was checked by the Category Chair and reassignment made, where appropriate, by the Program Co-Chairs. All reviewers were blinded to the authorship and affiliations of the abstracts and a 5 point score system was used. Reviewers were instructed to refrain from reviewing abstracts for which they were in conflict. Scores were tabulated by Coe-Truman Technologies, ASBMR's abstract processing vendor; these scores were then used to select the oral program by the Program Co-Chairs and the President, along with the President-Elect, Barbara Kream, and next year's Annual Meeting Co-Chairs, Rajesh Thakker and Phil Osdoby.

The over-arching principle in assembling the oral program was to select abstracts based on their scores. The highest-rated abstracts within each category were selected for the concurrent oral sessions unless the authors preferred a poster presentation; and the next tiers of highly ranked abstracts were assigned to the Oral Poster sessions and Plenary Poster Sessions, respectively. Each category had representation on the oral program that was based on the number of abstracts submitted, which resulted in roughly similar numbers with only minor differences in the spread of scoring in the different categories.

Awards

The Society, assisted by corporate support and donations, offers a number of awards, such as the ASBMR Young Investigator Awards, including the new Shun-Ichi Harada Young Investigator Awards, the ASBMR Outstanding Abstract Award, the ASBMR Award for Outstanding Research in the Pathophysiology of Osteoporosis, and the ASBMR President's Book Award. As in previous years, these awardees have been selected based on abstract score and eligibility.

Disclosure of potential conflicts of interest

The 2007 Program Committee and ASBMR staff worked together to comply with the Updated Standards for Commercial Support of the U.S. Accreditation Council for Continuing Medical Education (ACCME). The ASBMR receives its Continuing Medical Education (CME) credits through the Federation of American Societies for Experimental Biology (FASEB), which is accredited by the ACCME. All speakers, session chairs and Program Committee members are required to provide a disclosure of potential conflicts of interest.

Acknowledgements

We are extremely grateful to the ASBMR office staff for their invaluable help and support in planning the program, particularly Rebecca Myers, Angela Cangemi, Melissa Huston and Karen Hasson. We would also like to thank Judie Spalding of Coe-Truman Technologies (ASBMR's abstract processing vendor) for her assistance. We wish to thank the Category Chairs, Poster Chairs, and reviewers for the quality and timeliness of their reviewing and the President and Co-Chairs of the 2006 and 2008 ASBMR meeting for their support and helpful advice. All these individuals have made major contributions to the planning of what we believe is an outstanding scientific program for the 2007 meeting. We hope that you enjoy it as much as we have putting it together!

Sincerely,

Steven R. Goldring, M.D., *President*

Harald Jueppner, M.D., *Program Co-Chair*

Juliet Compston, M.D., FRCP, *Program Co-Chair*

ABSTRACT PRESENTATION KEY

Abstract #	Session Type	Date	Presentation Time	Room
1001-1006	Concurrent Oral 1	Monday, Sept. 17, 2007	10:00 – 11:30 am	Kalakaua Ballroom C
1007-1012	Concurrent Oral 2	Monday, Sept. 17, 2007	10:00 – 11:30 am	Kamehameha Hall III
1013-1018	Concurrent Oral 3	Monday, Sept. 17, 2007	10:00 – 11:30 am	Kalakaua Ballroom AB
1019-1024	Concurrent Oral 4	Monday, Sept. 17, 2007	10:00 – 11:30 am	Room 312
1025-1030	Concurrent Oral 5	Monday, Sept. 17, 2007	10:00 – 11:30 am	Room 313 A
1031-1036	Concurrent Oral 6	Monday, Sept. 17, 2007	10:00 – 11:30 am	Room 311
1037-1042	Concurrent Oral 7	Monday, Sept. 17, 2007	2:30 – 4:00 pm	Room 312
1043-1048	Concurrent Oral 8	Monday, Sept. 17, 2007	2:30 – 4:00 pm	Room 313 A
1049-1054	Concurrent Oral 9	Monday, Sept. 17, 2007	2:30 – 4:00 pm	Kalakaua Ballroom AB
1055-1060	Concurrent Oral 10	Monday, Sept. 17, 2007	2:30 – 4:00 pm	Kamehameha Hall III
1061-1066	Concurrent Oral 11	Monday, Sept. 17, 2007	2:30 – 4:00 pm	Kalakaua Ballroom C
1067-1072	Concurrent Oral 12	Monday, Sept. 17, 2007	2:30 – 4:00 pm	Room 311
1073-1080	Concurrent Oral 13	Monday, Sept. 17, 2007	4:30 – 6:30 pm	Kalakaua Ballroom AB
1081-1088	Concurrent Oral 14	Monday, Sept. 17, 2007	4:30 – 6:30 pm	Kalakaua Ballroom C
1089-1096	Concurrent Oral 15	Monday, Sept. 17, 2007	4:30 – 6:30 pm	Kamehameha Hall III
1097-1104	Concurrent Oral 16	Monday, Sept. 17, 2007	4:30 – 6:30 pm	Room 311
1105-1112	Concurrent Oral 17	Monday, Sept. 17, 2007	4:30 – 6:30 pm	Room 312
1113-1120	Concurrent Oral 18	Monday, Sept. 17, 2007	4:30 – 6:30 pm	Room 313 A
1121-1126	Concurrent Oral 19	Tuesday, Sept. 18, 2007	10:00 – 11:30 am	Kalakaua Ballroom C
1127-1132	Concurrent Oral 20	Tuesday, Sept. 18, 2007	10:00 – 11:30 am	Kalakaua Ballroom AB
1133-1138	Concurrent Oral 21	Tuesday, Sept. 18, 2007	10:00 – 11:30 am	Room 312
1139-1144	Concurrent Oral 22	Tuesday, Sept. 18, 2007	10:00 – 11:30 am	Kamehameha Hall III
1145-1150	Concurrent Oral 23	Tuesday, Sept. 18, 2007	10:00 – 11:30 am	Room 311
1151-1156	Concurrent Oral 24	Tuesday, Sept. 18, 2007	10:00 – 11:30 am	Room 313 A
1157-1162	Concurrent Oral 25	Tuesday, Sept. 18, 2007	2:30 – 4:00 pm	Kamehameha Hall III
1163-1168	Concurrent Oral 26	Tuesday, Sept. 18, 2007	2:30 – 4:00 pm	Kalakaua Ballroom AB
1169-1174	Concurrent Oral 27	Tuesday, Sept. 18, 2007	2:30 – 4:00 pm	Room 311
1175-1180	Concurrent Oral 28	Tuesday, Sept. 18, 2007	2:30 – 4:00 pm	Kalakaua Ballroom C
1181-1186	Concurrent Oral 29	Tuesday, Sept. 18, 2007	2:30 – 4:00 pm	Room 313 A
1187-1192	Concurrent Oral 30	Tuesday, Sept. 18, 2007	2:30 – 4:00 pm	Room 312
1193-1198	Concurrent Oral 31	Wednesday, Sept. 19, 2007	10:00 -11:30 am	Room 311
1199-1204	Concurrent Oral 32	Wednesday, Sept. 19, 2007	10:00 -11:30 am	Kalakaua Ballroom AB
1205-1210	Concurrent Oral 33	Wednesday, Sept. 19, 2007	10:00 -11:30 am	Kamehameha Hall III
1211-1216	Concurrent Oral 34	Wednesday, Sept. 19, 2007	10:00 -11:30 am	Room 313 A
1217-1222	Concurrent Oral 35	Wednesday, Sept. 19, 2007	10:00 -11:30 am	Room 312
1223-1228	Concurrent Oral 36	Wednesday, Sept. 19, 2007	10:00 -11:30 am	Kalakaua Ballroom C
1229-1234	Concurrent Oral 37	Wednesday, Sept. 19, 2007	2:30 – 4:00 pm	Kamehameha Hall III
1235-1240	Concurrent Oral 38	Wednesday, Sept. 19, 2007	2:30 – 4:00 pm	Kalakaua Ballroom C
1241-1246	Concurrent Oral 39	Wednesday, Sept. 19, 2007	2:30 – 4:00 pm	Room 311
1247-1252	Concurrent Oral 40	Wednesday, Sept. 19, 2007	2:30 – 4:00 pm	Kalakaua Ballroom AB
1253-1258	Concurrent Oral 41	Wednesday, Sept. 19, 2007	2:30 – 4:00 pm	Room 313 A
1259-1264	Concurrent Oral 42	Wednesday, Sept. 19, 2007	2:30 – 4:00 pm	Room 312
1265-1270	Concurrent Oral 43	Wednesday, Sept. 19, 2007	4:30 - 6:00 pm	Kamehameha Hall III
1271-1276	Concurrent Oral 44	Wednesday, Sept. 19, 2007	4:30 - 6:00 pm	Kalakaua Ballroom AB
1277-1282	Concurrent Oral 45	Wednesday, Sept. 19, 2007	4:30 - 6:00 pm	Room 311
1283-1288	Concurrent Oral 46	Wednesday, Sept. 19, 2007	4:30 - 6:00 pm	Kalakaua Ballroom C
1289-1294	Concurrent Oral 47	Wednesday, Sept. 19, 2007	4:30 - 6:00 pm	Room 312
1295-1300	Concurrent Oral 48	Wednesday, Sept. 19, 2007	4:30 - 6:00 pm	Room 313 A
O21-O504	Oral Posters (Clinical and Basic)	Sunday, Sept. 16, 2007	3:45 pm - 4:45 pm	Basic: Kalakaua Ballroom AB Clinical: Kamehameha Hall III
S001-S535	Plenary Posters	Sunday, Sept. 16, 2007 Monday, Sept. 17, 2007	5:00 pm - 6:45 pm	Kamehameha Hall I & II

M001-M535	Poster Session I	Monday, Sept. 17, 2007	Odd: 11:30 am – 1:00 pm Even: 1:00 pm – 2:30 pm	Kamehameha Hall I & II
T001-T521	Poster Session II	Tuesday, Sept. 18, 2007	Odd: 11:30 am – 1:00 pm Even: 1:00 pm – 2:30 pm	Kamehameha Hall I & II
W001-W521	Poster Session III	Wednesday, Sept. 19, 2007	Odd: 11:30 am – 1:00 pm Even: 1:00 pm – 2:30 pm	Kamehameha Hall I & II
WG1-WG3	Vitamin D Working Group	Sunday, Sept. 16, 2007	7:00 pm – 10:00 pm	Room 313 C
WG4-WG8	Pediatric Bone and Mineral Working Group	Sunday, Sept. 16, 2007	7:00 pm – 10:00 pm	Room 316 C
WG9-WG12	Physical Activity and Falls Working Group	Sunday, Sept. 16, 2007	7:00 pm – 9:10 pm	Room 313 A
WG13-WG20	Adult Bone and Mineral Working Group	Monday, Sept. 17, 2007	7:00 pm – 10:00 pm	Room 316 AB
WG21-WG23	Working Group on Osteoporosis and Rheumatic Diseases	Monday, Sept. 17, 2007	7:00 pm – 9:00 pm	Room 313 C
WG24-WG33	Musculoskeletal Rehabilitation in Patients with Osteoporosis Working Group	Wednesday, Sept. 19, 2007	6:30 pm – 9:30 pm	Room 316 C
WG34-WG39	Working Group on Patient Education and Adherence to Treatment	Wednesday, Sept. 19, 2007	6:30 pm – 9:30 pm	Room 312
WG40-WG41	Muscle and Bone Working Group	Monday, Sept. 17, 2007	7:00 pm – 10:00 pm	Room 316 C

FRIDAY, SEPTEMBER 14, 2007

DAY-AT-A-GLANCE

Time/Event/Location

**ANCILLARY PROGRAM - THE INTERNATIONAL
SOCIETY FOR CLINICAL DENSITOMETRY (ISCD)**

Separate registration and fee required

7:00 am - 7:30 am

ISCD Registration and Continental Breakfast

HILTON: South Pacific Ballroom Foyer

7:30 am - 11:00 am

**ISCD Bone Densitometry Course: Clinician and Technologist Courses -
General Session**

HILTON: South Pacific Ballroom III & IV

11:00 am - 5:30 pm

ISCD Bone Densitometry Clinician Course

HILTON: South Pacific Ballroom III & IV

11:00 am - 5:45 pm

ISCD Bone Densitometry Technologist Course

HILTON: South Pacific Ballroom II

SATURDAY, SEPTEMBER 15, 2007

DAY-AT-A-GLANCE

Time/Event/Location

**ANCILLARY PROGRAM - THE INTERNATIONAL
SOCIETY FOR CLINICAL DENSITOMETRY (ISCD)**

Separate registration and fee required

7:00 am - 7:30 am

ISCD Registration and Continental Breakfast

HILTON: South Pacific Ballroom Foyer

7:30 am - 11:15 am

ISCD Bone Densitometry Clinician Course

HILTON: South Pacific Ballroom I

7:30 am - 11:00 am

ISCD Bone Densitometry Technologist Course

HILTON: South Pacific Ballroom II

11:45 am - 2:00 pm

ISCD Bone Densitometry Clinician Certification Exam

HILTON: South Pacific Ballroom I

11:45 am - 1:00 pm

ISCD Bone Densitometry Technologist Exam

HILTON: South Pacific Ballroom II

12:30 pm - 6:15 pm

ISCD Vertebral Fracture Assessment Course

HILTON: South Pacific Ballroom III & IV

ASBMR REGISTRATION

9:00 am - 5:00 pm

**Hawaii Convention Center
Registration Area**

SUNDAY SEPTEMBER 16, 2007

DAY-AT-A-GLANCE

Time/Event/Location

(All events will be held at the Hawaii Convention Center, unless otherwise noted.)

7:00 am - 6:30 pm

Registration Open

Main Lobby

8:00 am - 9:30 am

Plenary Symposium I: Emerging Technologies in Functional Bone Imaging

Kamehameha Hall III

9:30 am - 11:00 am

Symposium A (Basic): Novel Insights into Bone Metabolism through Genetics

Kalakaua Ballroom AB

9:30 am - 11:00 am

Symposium B (Clinical): Inhaled Steroids, Aromatase Inhibitors, and TZDs: All Bad for the Bone?

Kamehameha Hall III

11:00 am - 11:15 am

Break

Main Lobby

11:15 am - 11:20 am

Presentation of the Shirley Hohl Service Award

Kamehameha Hall III

11:25 - 11:30 am

Presentation of the Louis V. Avioli Memorial Founders Award

Kamehameha Hall III

11:30 am - 12:30 pm

Louis V. Avioli Memorial Lecture

Kamehameha Hall III

12:30 pm - 1:30 pm

Meet-the-Professor Sessions

Rooms 301-309

No ticket required.

1:00 pm - 2:00 pm

Debate: Excessive Suppression of Bone Remodeling by Antiresorptive Agents - Fact or Fiction?

Kamehameha Hall III

2:00 pm - 3:30 pm

Symposium C (Basic): Osteocytes and the Regulation of Phosphorous Homeostasis

Kalakaua Ballroom AB

2:00 pm - 3:30 pm

Symposium D (Clinical): Anabolics: Pathways for the Future

Kamehameha Hall III

3:30 pm - 3:45 pm

Break

Ballroom Lobby and Main Lobby

3:45 pm - 4:45 pm

Oral Posters (Basic)

Kalakaua Ballroom AB

3:45 pm - 4:45 pm

Oral Posters (Clinical)

Kamehameha Hall III

3:45 pm - 4:45 pm

Challenges and Opportunities Facing NIH Peer Review: A Vision for Insuring Its Strategic National Value

Kalakaua Ballroom C

5:00 pm - 6:45 pm

Welcome Reception & Plenary Poster Session

Kamehameha Hall I & II

5:00 pm - 6:45 pm

Posters Open

Kamehameha Hall I & II

5:00 pm - 6:45 pm

Exhibits Open

Kamehameha Hall I & II

5:00 pm - 6:45 pm

New Investigator/New Member/First-Time Attendee Reception

Kamehameha Hall I & II, Young Investigators Lounge

Ancillary Program - Working Groups

7:00 pm - 9:00 pm

***In Vivo* Working Group**

Room 312

7:00 pm - 10:00 pm

Vitamin D Working Group

Room 313 C

7:00 pm - 9:30 pm

Nutrition and Bone Health Working Group

Room 316 AB

7:00 pm - 10:00 pm

Pediatric Bone and Mineral Working Group

Room 316 C

7:00 pm - 9:10 pm

Physical Activity and Falls Working Group

Room 313 A

SUNDAY SEPTEMBER 16, 2007
DAY-AT-A-GLANCE

Time/Event/Location

(All events will be held at the Hawaii Convention Center, unless otherwise noted.)

Ancillary Program - Industry-Supported Symposia (ISS)

7:00 pm - 9:15 pm

**Osteoporosis Assessment and Treatment: New Evidence
and Future Directions**

Sheraton Waikiki: Maui Ballroom

7:00 pm - 10:00 pm

**Providing Quality Osteoporosis Therapy: Navigating the
Shifting Landscape of Bisphosphonates**

Hilton: Tapa Ballroom and Palace Lounge

7:00 pm - 10:00 pm

**Current Standards and Novel Understandings in the
Management of Bone Loss: The RANK/RANKL/
OPG Pathway and Its Clinical Potential**

Sheraton Waikiki: Kauai Ballroom

MONDAY, SEPTEMBER 17, 2007
DAY-AT-A-GLANCE

Time/Event/Location

(All events will be held at the Hawaii Convention Center, unless otherwise noted.)

7:00 am - 5:30 pm

Registration Open

Main Lobby

7:00 am - 8:00 am

New Investigator/New Member Breakfast

Room 316 AB

8:00 am - 6:30 pm

Posters Open

Kamehameha Hall I & II

8:00 am - 8:10 am

Welcome and Announcements

Kamehameha Hall III

8:10 am - 8:15 am

Presentation of the Gideon A. Rodan Excellence in Mentorship Award

Kamehameha Hall III

8:15 am - 9:45 am

Plenary Symposium II: Bone Quality: Age-Related Changes in Collagen and Mineral

Kamehameha Hall III

9:30 am - 4:30 pm

Exhibits Open

Kamehameha Hall I & II

9:45 am - 10:00 am

Break

Kamehameha Hall I & II

10:00 am - 11:30 am

Concurrent Oral Sessions

1) Cancer and Bone I

Kalakaua Ballroom C

2) Osteoporosis Treatment (Preclinical) I

Kamehameha Hall III

3) Osteoporosis Pathophysiology I

Kalakaua Ballroom AB

4) Mouse Mutants and Bone

Room 312

5) VDR and Other Regulators of Calcium Transport

Room 313 A

6) Genetic Disorders

Room 311

11:30 am - 12:30 pm

Meet-the-Professor Sessions

Rooms 301 - 309

No ticket required.

11:30 am - 2:30 pm

Poster Session I

(Presentations M001 - M536)

11:30 am - 1:00 pm Odd numbers

1:00 pm - 2:30 pm Even numbers

Kamehameha Hall I & II

12:00 pm - 2:00 pm

Special Session for Allied Health Professionals: Featuring an Overview of the 29th Annual Meeting by Lawrence G. Raisz, M.D.

Room 313 A

12:30 pm - 1:30 pm

Clinical Roundtable/Case Conference

Kamehameha Hall III

1:30 pm - 2:30 pm

NIH Center for Scientific Review Workshop: What Really Happens at Study Section?

Room 311

1:30 pm - 2:30 pm

Meet-the-Professor Sessions

Rooms 301 - 309

No ticket required.

2:30 pm - 4:00 pm

Concurrent Oral Sessions

7) Bone Acquisition and Pediatric Bone Disease I

Room 312

8) Osteocyte Biology

Room 313 A

9) Epidemiology I: Hip Fractures

Kalakaua Ballroom AB

10) Osteoporosis Treatment (Clinical) I: Bisphosphonates

Kamehameha Hall III

11) Chondrogenesis and Osteogenesis

Kalakaua Ballroom C

12) Bone and Stem Cells

Room 311

4:00 pm - 4:30 pm

Break

Kamehameha Hall I & II

MONDAY, SEPTEMBER 17, 2007
DAY-AT-A-GLANCE

Time/Event/Location

(All events will be held at the Hawaii Convention Center, unless otherwise noted.)

4:30 pm - 6:30 pm

Concurrent Oral Sessions

13) Osteoporosis Assessment I

Kalakaua Ballroom AB

14) Bone Biomechanics and Quality I

Kalakaua Ballroom C

15) Osteoporosis Treatment (Clinical) II: Combination Therapy

Kamehameha Hall III

16) Osteoclastogenesis

Room 311

17) Bone and Cartilage

Room 312

18) Calcium and Phosphate Regulation

Room 313 A

Ancillary Program - Working Groups

7:00 pm - 10:00 pm

Adult Bone and Mineral Working Group

Room 316 AB

7:00 pm - 10:00 pm

Biochemical Markers of Bone Turnover Working Group

Room 313 A

7:00 pm - 10:00 pm

Bone Remodeling and Stress Fracture Working Group

Room 312

7:00 pm - 9:10 pm

Non-Invasive Assessment of Bone Microarchitecture Working Group

Room 311

7:00 pm - 9:00 pm

Working Group on Osteoporosis and Rheumatic Diseases

Room 313 C

7:00 pm - 10:00 pm

Muscle and Bone Working Group

Room 316 C

Ancillary Program - Industry-Supported Symposia (ISS)

7:00 pm - 10:00 pm

Critical Challenges and Landmark Advances in Osteoporosis

Hilton: Tapa Ballroom

7:00 pm - 9:30 pm

Osteoporosis: Opportunity for Better Outcomes

Hilton: Coral Ballroom, Salons 3-5

7:00 pm - 9:00 pm

When Osteoporosis Is the Wrong Diagnosis: New Insights Linking Vitamin D, PTH, and Bone to Cardiovascular Health

Sheraton Waikiki: Maui & Kauai Ballrooms

TUESDAY, SEPTEMBER 18, 2007

DAY-AT-A-GLANCE

Time/Event/Location

(All events will be held at the Hawaii Convention Center, unless otherwise noted.)

7:00 am - 5:30 am

Registration Open

Main Lobby

8:00 am - 6:00 pm

Posters Open

Kamehameha Hall I & II

8:00 am - 8:05 am

Presentation of the William F. Neuman Award

Kamehameha Hall III

8:10 am - 8:15 am

Presentation of the Fuller Albright Award

Kamehameha Hall III

8:20 am - 8:25 am

Presentation of the Frederic C. Bartter Award

Kamehameha Hall III

8:30 am - 9:30 am

Gerald D. Aurbach Memorial Lecture

Kamehameha Hall III

9:30 am - 10:00 am

Break

Kamehameha Hall I & II

9:30 am - 4:30 pm

Exhibits Open

Kamehameha Hall I & II

10:00 am - 11:30 am

Concurrent Oral Sessions

19) Osteoporosis Treatment (Preclinical) II

Kalakaua Ballroom C

20) Osteoporosis Treatment (Clinical) III: New Approaches

Kalakaua Ballroom AB

21) Osteoporosis Pathophysiology II

Room 312

22) Osteoblast Regulation I

Kamehameha Hall III

23) Osteoclast Signaling I

Room 311

24) Disease Mechanisms

Room 313A

11:30 am - 12:30 pm

Meet-the-Professor Sessions

Rooms 301 - 309

No ticket required.

11:30 am - 2:30 pm

Poster Session II

(Presentations T001 - T521)

11:30 am - 1:00 pm Odd numbers

1:00 pm - 2:30 pm Even numbers

Kamehameha Hall I & II

12:30 pm - 2:00 pm

Joint ECTS/ASBMR Session on Osteonecrosis of the Jaw

Kamehameha Hall III

1:30 pm - 2:30 pm

Meet-the-Professor Sessions

Rooms 301 - 309

No ticket required.

2:30 pm - 4:00 pm

Concurrent Oral Sessions

25) Epidemiology II: :Men

Kamehameha Hall III

26) Osteoporosis Assessment II

Kalakaua Ballroom AB

27) Cancer and Bone II

Room 311

28) Bone and Cartilage Development

Kalakaua Ballroom C

29) Chondrocyte Regulation

Room 313 A

30) PTH/PTHrP

Room 312

4:00 pm - 4:30 pm

Break

Kamehameha Hall I & II

4:30 pm - 6:00 pm

State-of-the-Art Lectures A (Basic): Bone and Stem Cells

Kalakaua Ballroom C

4:30 pm - 6:00 pm

State-of-the-Art Lectures B (Basic/Clinical): Mineral Ion Homeostasis and Early Stages of Chronic Kidney Disease

Kalakaua Ballroom AB

6:00 pm - 7:00 pm

ASBMR Annual Business Meeting

Room 312

7:00 pm - 8:00 pm

The Women in Bone and Mineral Research Committee Event

Room 316 AB

8:00 pm - 11:00 pm

ASBMR Social Event

Royal Hawaiian Hotel, 2259 Kalakaua Avenue

WEDNESDAY, SEPTEMBER 19, 2007

DAY-AT-A-GLANCE

Time/Event/Location

(All events will be held at the Hawaii Convention Center, unless otherwise noted.)

6:00 am - 7:00 am

ASBMR Fun Run/Walk

Ala Moana Beach Park

7:00 am - 5:30 pm

Registration Open

Main Lobby

8:00 am - 4:30 pm

Posters Open

Kamehameha Hall I & II

8:00 am - 9:30 pm

Plenary Symposium III: How Can We Find New Drugs for the 21st Century?

Kamehameha Hall III

9:30 am - 10:00 am

Break

Kamehameha Hall I & II

9:30 am - 4:30 pm

Exhibits Open

Kamehameha Hall I & II

10:00 am - 11:30 am

Concurrent Oral Sessions

31) Bone Acquisition and Pediatric Bone Disease II

Room 311

32) Epidemiology III: Genetic and Hormonal Factors

Kalakaua Ballroom AB

33) Osteoporosis Treatment (Clinical) IV: Anti-resorptives

Kamehameha Hall III

34) Bone Cell Development

Room 313 A

35) Sex Steroids and Bone

Room 312

36) Mouse Genetic Models

Kalakaua Ballroom C

11:30 am - 12:30 pm

Meet-the-Professor Sessions

Rooms 301 - 309

No ticket required.

11:30 am - 2:30 pm

Poster Session III

(Presentations W001 - W521)

11:30 am - 1:00 pm Odd numbers

1:00 pm - 2:30 pm Even numbers

Kamehameha Hall I & II

12:30 pm - 1:30 pm

Clinical Roundtable/Case Conference

Kamehameha Hall III

12:30 pm - 2:00 pm

The "Ins and Outs" of Research Funding

Kalakaua Ballroom C

1:30 pm - 2:30 pm

Meet-the-Professor Sessions

Rooms 301 - 309

No ticket required.

2:30 pm - 4:00 pm

Concurrent Oral Sessions

37) Osteoporosis Treatment (Preclinical) III

Kamehameha Hall III

38) Osteoporosis Pathophysiology III

Kalakaua Ballroom C

39) Bone Biomechanics and Quality II

Room 311

40) Osteoblast Regulation II

Kalakaua Ballroom AB

41) Regulators of Bone Formation

Room 313 A

42) Metabolic Bone Disorders

Room 312

4:00 pm - 4:30 pm

Break

Kamehameha Hall I & II

4:30 pm - 6:00 pm

Concurrent Oral Sessions

43) Osteoporosis Treatment (Clinical) V: Effects on Bone Quality

Kamehameha Hall III

44) Epidemiology IV: Postmenopausal Women

Kalakaua Ballroom AB

45) Osteoporosis Assessment III

Room 311

46) Osteoblast Regulatory Mechanisms

Kalakaua Ballroom C

47) Osteoclast Signaling II

Room 312

48) Hormones and Bone

Room 313 A

WEDNESDAY, SEPTEMBER 19, 2007
DAY-AT-A-GLANCE

Time/Event/Location

(All events will be held at the Hawaii Convention Center, unless otherwise noted.)

Ancillary Program - Working Groups

6:30 pm - 8:30 pm

DISCLOSURE/CONFLICT OF INTEREST

The ASBMR is committed to ensuring the balance, independence, objectivity and scientific rigor of all its individually sponsored or industry-supported educational activities. Accordingly, the ASBMR adheres to the requirement set by the Federation of American Societies for Experimental Biology (FASEB) that audiences at FASEB-sponsored educational programs be informed of a presenter's (speaker, faculty, author, or contributor) academic and professional affiliations, and the disclosure of the existence of any significant financial interest or other relationship a presenter has with the manufacturer(s) of any commercial product(s) discussed in an educational presentation. When an unlabeled use of a commercial product, or an investigational use not yet approved for any purpose is discussed during the presentation, it is required that presenters disclose that the product is not labeled for the use under discussion or that the product is still investigational. This policy allows the listener/attendee to be fully knowledgeable in evaluating the information being presented. The Program will note those speakers who have disclosed relationships, including the nature of the relationship and the associated commercial entity.

All authors of submitted abstracts completed the disclosure statement in the online submission program. Invited speakers who are not required to submit an abstract received a form that they completed and returned.

Disclosure includes any relationship that may bias one's presentation or which, if known, could give the perception of bias. This includes relevant financial relationships of a spouse or partner. These situations may include, but are not limited to:

DISCLOSURE KEY

- 1) stock options or bond holdings in a for-profit corporation or self-directed pension plan
- 2) research grants
- 3) employment (full or part-time)
- 4) ownership or partnership
- 5) consulting fees or other remuneration
- 6) non-remunerative positions of influence such as officer, board member, trustee, or public spokesperson
- 7) receipt of royalties
- 8) speaker's bureau
- 9) other

Disclosures for invited speakers and abstract presenters are provided at the end of the session listing for invited speakers (see On-Site Program book) and directly after the body of an abstract for abstract submissions. If there is no conflict of interest or disclosure listed, this means that the invited speaker and/or abstract presenter indicated no conflicts to disclose.

The disclosure information will correspond to the key above. If disclosures are given, the company name, along with the respective disclosure relationship number will be listed (for example: Company Name, 2, 8.).

Identification of a Novel TGF- β Dependent-Prometastatic Signature Mediating Bone Colonization. I. Garcia-Tunon^{*1}, S. Vicent^{*1}, D. Luis-Ravelo^{*1}, I. Anton^{*1}, C. Zandueti^{*1}, S. Martinez^{*1}, J. De Las Rivas^{*2}, F. Lecanda¹. ¹Division of Oncology, Center for Applied Medical Research, Pamplona, Spain, ²Bioinformatics, CIC, Salamanca, Spain.

Bone represents a frequent target organ of metastasis in a variety of solid tumors including lung. We have recently developed a rapid and selective model in which to identify genes implicated in bone metastasis of lung cancer. After intracardiac inoculation (i.c.) in nude mice, highly metastatic subpopulations (HMS) were selected with increase prometastatic activity. Microarray expression analysis revealed a novel metastatic gene signature of differentially expressed genes in HMS vs parental. Four overexpressed genes in all HMS were further validated by real time qPCR. These genes encode signaling molecules (such as TCF4 and PRKD3) and cell anchorage related proteins (MCAM, and putative adhesion molecule SUSD5). To delineate their functional contribution in metastatic activity we assessed metastatic area by X-ray image analysis and μ CT scan of retrovirally transduced simple, double and triple gene combinations. I.c. of single overexpressors TCF4, PRKD3 or SUSD5 induced a significant increase in metastatic area as compared to mock cells ($p < 0.01$). Furthermore, i.c. of triple overexpressors in nude mice synergistically induced a dramatic increase in prometastatic activity, with prominent osteolytic lesions and metastatic area ($p < 0.001$), whereas cell homing activity to bone was unaltered. This multigenic signature was also ineffective promoting cell proliferation and subcutaneous tumor growth. By contrast, intratibial injection of triple overexpressors induced aggressive bone colonization leading to overt osteolytic lesions as compared to mock cells ($p < 0.001$). These results were correlated with high osteoclastogenic activity induced by conditioned medium of triple overexpressors. Furthermore, TCF4 and SUSD5 were strongly up-regulated in a coculture system mimicking in vivo tumor-stroma interactions, an effect that was further abrogated by an anti-TGF- β peptide. Interestingly, after i.c. of HMS, in vivo treatment with a specific anti-TGF- β peptide severely reduced tumor burden (X-ray analysis and μ CT scans) and osteolytic activity of tumor cells (osteoclast number) compared to an irrelevant peptide and vehicle treated animals. These studies identified a novel signature involving several genes that act cooperatively promoting strong osseous colonization, partially mediated by high osteoclastogenic activity. This multifunctional program is strongly enhanced by TGF- β , which plays a critical role in perpetuating a "vicious cycle" involved in metastatic progression.

Osmosensing Receptor TRPV4 Mediates Cancerinduced Bone Pain. H. Wakabayashi^{*1}, L. Wang^{*2}, T. Matsubara^{*2}, A. Mizuno^{*3}, M. Suzuki^{*3}, A. Uchida^{*1}, T. Yoneda¹. ¹Orthopaedic Surgery, Mie University Graduate School of Medicine, Tsu, Japan, ²Biochemistry, Osaka University Graduate School of Dentistry, Suita, Japan, ³Pharmacology, Jichi Medical School, Tochigi, Japan.

Bone pain is becoming a major clinical problem as survival of cancer patients is extended. Bone pain can be caused by noxious chemical and/or mechanical stimuli produced by cancer cells and associated inflammatory cells. H^+ is among such a noxious chemical stimulus. It has been shown that the acidic microenvironment caused by H^+ release by bone-resorbing osteoclasts induces bone pain through an activation of the acid sensing receptors such as transient receptor potential vanilloid 1 (TRPV1). TRPV4 is a transducer of hypo-osmotic stimuli in primary nociceptive afferents. Recent studies using TRPV4^{-/-} mice suggest a critical role of TRPV4 in mechanosensing. Since TRPV4 has 45% homology with TRPV1, we reasoned that TRPV4 is also involved in the pathogenesis of cancer-induced bone pain. In the present study, we investigated the role of TRPV4 in the induction of bone pain associated with cancer colonization in bone. We established an animal model of cancer-induced bone pain in which cancer cells were directly inoculated into the marrow cavity of tibiae. Three behavioral assays including the measurement of paw withdrawal latency, grip force and hind-limb lifting (flinching) were employed to evaluate bone pain. Tumor-inoculated hind-limbs displayed hyperalgesia, decreased grip force and increased flinching as the tumor enlarged, whereas non-tumor-bearing hind-limbs showed no changes. Of note, there was significant reduction in paw withdrawal latency, grip force and flinching in tumor-inoculated hind-limbs in TRPV4^{-/-} mice compared with WT mice, despite that tumor growth and area of osteolytic lesions did not differ between TRPV4^{-/-} and WT mice.

The expression of immunoreactive neurons for pERK, a widely-used molecular marker for neural activation by noxious stimuli, was increased in the ipsi-lateral dorsal root ganglia (DRG) compared with the contra-lateral DRG in WT mice. p-ERK immunoreactive neurons were significantly decreased in the DRG in TRPV4^{-/-} mice compared with WT mice. Hypo stimuli increased p-ERK expression in neuron-like F11 cells that expressed TRPV4 mRNA but not TRPV1 by RT-PCR. Ruthenium red, which is a non-selective TRPV4 inhibitor, decreased p-ERK expression induced by hypo stimuli. In conclusion, our results suggest that TRPV4 as well as TRPV1 plays an important role in inducing bone pain associated with cancer cell colonization in bone. TRPV4 might be a new molecular target for the development of novel analgesics in cancer-induced bone pain.

Role of Hypoxia in Cancers that Metastasize to Bone: HIF1 α Enhances TGF β Signaling and Expression of Prometastatic Factors CXCR4 and VEGF. L. A. Kingsley, P. G. J. Fournier, J. M. Chirgwin, T. A. Guise. Internal Medicine, University of Virginia, Charlottesville, VA, USA.

Several cancers frequently metastasize to bone, where the microenvironment is hypoxic and rich in growth factors, such as transforming growth factor (TGF) β . TGF β stimulates tumor secretion of proteins that activate osteoclastic bone resorption, angiogenesis and tumor homing to bone. Many of the same proteins are also regulated by hypoxia-inducible factor (HIF)1 α . We hypothesized that hypoxia-induced HIF1 α enhances the effects of TGF β on cancer metastases to bone.

First, we determined that bone metastases were hypoxic. Mice with MDA-MB-231 breast cancer bone metastases were injected prior to euthanasia with pimonidazole, which forms insoluble adducts in hypoxic cells. Immunohistochemical staining of decalcified sections showed that tumor cells adjacent to bone were hypoxic. Next, we determined by Western blot that hypoxia (1% O₂) culture conditions induced the expression of HIF1 α by TGF β -responsive cancer cells which metastasize to bone: MDA-MB-231, PC-3 prostate cancer and 1205Lu melanoma.

Effects of hypoxia and TGF β on promoters of bone metastatic factors VEGF and CXCR4 were studied using luciferase constructs. Both factors are known to be increased by hypoxia. MDA-MB-231 cells and HepG2 hepatocarcinoma cells were treated \pm 5ng/ml TGF β and \pm 1% O₂ and lysates assayed for luciferase after 24hrs. Activity of both promoters was increased by TGF β or 1% O₂. Combined treatment resulted in further promoter activation. Promoter activities correlated with increased mRNAs by quantitative real-time PCR (Q-PCR). These results suggest that TGF β and HIF1 α cooperatively regulate prometastatic gene expression.

We cotransfected cDNAs for HIF1 α and the TGF β signaling proteins Smads 2, 3, 4 and assayed for CXCR4 and VEGF promoter activity. Overexpression of HIF1 α and Smads resulted in greater than 10-fold activation of the promoters by combined treatment with TGF β and 1% O₂, providing further evidence for crosstalk between TGF β and hypoxia signaling pathways. Finally, TGF β target gene expression in MDA-MB-231 cells treated \pm TGF β and \pm 1% O₂ was surveyed by Q-PCR. Hypoxia decreased two negative regulators of TGF β signaling, Smad7 and SnoN, in addition to upregulating VEGF and CXCR4. Thus, hypoxia may potentiate TGF β actions by down-regulating inhibitors of the Smad signaling pathway. Our results provide evidence for HIF1 α and TGF β crosstalk in vitro and suggest that these two pathways may cooperatively promote bone metastasis in vivo.

Osteoclasts in Myeloma Are Derived From Gr-1+CD11b+ Mononuclear Cells of the Bone Marrow Niche. J. Zhuang¹, L. Yang^{*2}, J. R. Edwards¹, C. M. Edwards¹, G. R. Mundy¹. ¹Vanderbilt Center for Bone Biology, Nashville, TN, USA, ²Cancer Biology, Vanderbilt University, Nashville, TN, USA.

When cancer cells are resident in bone, they initiate a vicious cycle with osteoclasts (OCs) which perpetuates their growth and aggressive behavior. OCs are critical for the maintenance of the vicious cycle, since they control not only bone destruction associated with cancer, but also the aggressive behavior of tumor cells. It has recently been recognized that tumor cells grow in distant sites because they induce non-malignant cells to establish a "pre-metastatic niche" for tumor cells to later engraft. But nothing is yet known for bone. Primitive bone marrow mononuclear cells, called myeloid immune suppressor cells (MISCs), which suppress immune reactivity, are important niche components. MISCs belong to the myelomonocytic lineage with surface markers of CD11b and Gr-1. We hypothesize that MISCs are precursors of OCs recruited by tumors to assist in the establishment of the vicious cycle. To test this hypothesis, we used the well-characterized 5TGM1 murine myeloma model. 5TGM1-GFP transfected myeloma cells were inoculated by tail vein injection. MISCs were assessed by FACS at weeks 1, 2, 3, 4 after tumor cell inoculation. The percentage of Gr-1+CD11b+ cells in marrow, spleen and blood in the tumor group began to increase significantly on week 2 compared with the control group. On week 4, this increase was much greater (60.9 \pm 7.8% vs 37.7 \pm 8.6% $p < 0.05$ in marrow; 21.1 \pm 4.84% vs 2.4 \pm 0.85% $p < 0.05$ in spleen; 23.1 \pm 4.27% vs 5.4 \pm 1.1% $p < 0.05$ in blood) and paralleled the myeloma burden in bone and spleen. We sorted the Gr-1+CD11b+ cells from the spleen of tumor and non-tumor bearing mice. MISCs were induced into multinucleated TRAP positive OCs in medium containing M-CSF (25ng/ml) and RANKL (50ng/ml). The number of OCs derived from tumor MISCs was dramatically greater than those from control mice after 2 weeks of culture (13 \pm 2 per x200 field vs no more than 3). MISCs lost the Gr-1 and CD11b markers and gained CD51 and calcitonin receptor as they differentiated into mature OCs. These cells caused resorption pits on dentine discs, demonstrating they were functional OCs. We co-cultured sorted MISCs with 5TGM1 cells in a transwell plate (8um pore). MISCs markedly stimulated migration of GFP+ myeloma cells at 24h compared with non-MISCs (12.5 \pm 2.08 vs 3.75 \pm 0.83 per x200 field, $p < 0.05$). Our data suggest that MISCs are increased significantly in marrow, spleen and blood of myeloma-bearing mice and parallel the appearance of lytic bone lesions. These MISCs differentiate avidly and rapidly into functional OCs. These results have a number of implications, including the possibility of reducing bone lesions in myeloma and other malignancies by depleting specific subpopulations of osteoclast precursors.

Collapse of the Vascular Bone Remodeling Compartment Is a Key Process in the Development of Myeloma-induced Osteolysis. T. L. Andersen^{*1}, T. E. Sondergaard^{*1}, K. Søe^{*1}, T. Plesner^{*2}, J. Delaisse¹. ¹Clinical Cell Biology (KBC), Vejle Hospital, Southern Denmark University, Vejle, Denmark, ²Department of Hematology, Vejle Hospital, Southern Denmark University, Vejle, Denmark.

Bone remodeling is a tightly coupled process where bone formation follows bone resorption to maintain the integrity of the bones throughout life. Bone remodeling occurs in a specialized vascular bone remodeling compartment (VBRC), separated from the marrow compartment by a cellular wall. In the case of myeloma-induced osteolysis, bone formation does not follow and compensate for the increased bone resorption. This uncoupling is a major hallmark of multiple myeloma (MM). Here we report that VBRCs often are disrupted in MM and that this destabilization correlates with: 1) an uncoupling of bone resorption and bone formation, 2) the presence of bone osteolysis as shown by x-rays, 3) direct cell contact between MM cells coming from the marrow compartment and osteoclasts, leading to the formation of myeloma-osteoclast hybrid cells.

We have established through bone histomorphometric analysis of the VBRC, eroded surfaces (ES), and osteoid surfaces (OS), that MM patients showing less than 75% ES in VBRC have a significantly increased ES/BS (20% vs 11%) and a significantly decreased OS/BS (15% vs 26%) compared to patients with more than 75% ES in VBRC. Interestingly, the collapse of VBRCs correlated significantly with the number of osteolytic lesions demonstrated by X-ray, as patients with no osteolytic lesions showed 80% of the ES in VBRC, while patients with more than 5 osteolytic lesions showed only 58% of the ES in VBRC.

We have previously reported that the myeloma-osteoclast hybrid cells account for more than 35% of the osteoclasts present in MM patients by identifying nuclei within osteoclasts having translocations specific for the MM cell clone. Here we show that the disruption of VBRC is a critical event in the generation of hybrid cells. This allows a direct contact between the MM cells of the marrow compartment and the resorbing osteoclast resulting in fusion of these two cell types.

In vitro, we mimicked the VBRC wall by establishing a confluent G₀-arrested mono-layer of MC3T3 cells and tested its response to TGFβ or MM cells. Both addition of TGFβ and co-cultures with MM cells disrupted the confluent layer of MC3T3 cells mimicking the destabilization of the VBRC wall.

In conclusion the VBRC is a micro-anatomical structure that is important for the integrity of the bone remodeling process and its collapse is a key event in the development of MM bone disease. The VBRC is disrupted in MM, potentially both directly and indirectly by MM cells, favoring the development of osteolytic lesions and the formation of myeloma-osteoclast hybrid cells.

Accelerated Bone Resorption, Due to Dietary Calcium Deficiency, Promotes Tumor Growth in a Murine Model of Breast Cancer Bone Metastasis. Y. Zheng, H. Zhou, J. R. K. Modzelewski^{*}, R. Kalak^{*}, J. M. Blair^{*}, M. J. Seibel, C. R. Dunstan. Bone Research Program, ANZAC research Institute, University of Sydney, Sydney, Australia.

The skeleton is a major site of breast cancer metastases. High bone turnover increases risk of disease progression and death. However, there is no direct evidence that high bone turnover is causally associated with the establishment and progression of metastases. In this study, we investigate the effects of high bone turnover on tumor growth in a rodent model of bone metastasis.

Female nude mice were fed a diet containing normal (0.6%) ('Normal-Ca') or low (0.1%) ('Low-Ca') calcium content starting on day -3. Mice were concurrently treated with vehicle or recombinant osteoprotegerin (OPG; 1mg/kg/day sc; n = 16/group). Three days later (day 0), 50,000 TxSA cells (a bone-seeking variant of MDA-MB-231 cells) were implanted by intra-tibial injection and mice were followed until day 17.

On day 0, mice receiving 'Low-Ca' had increased serum PTH and TRAcP5b levels, indicating secondary hyperparathyroidism and high bone turnover, which was maintained until day 17. Treatment with OPG increased serum PTH but profoundly reduced bone resorption. On day 17, in mice receiving 'Low-Ca' alone, lytic lesion area, tumor area and cancer cell proliferation increased by 43%, 24% and 24%, respectively compared to mice receiving 'normal Ca' (p < 0.01). In contrast, OPG treatment completely inhibited lytic lesions, reduced tumor area, decreased cancer cell proliferation and increased cancer cell apoptosis.

We conclude that increased bone turnover, due to dietary calcium deficiency, promotes tumor growth in bone, independent of the action of PTH. These findings have clinical implications as breast cancer patients, much like the older population in general, frequently have a low dietary calcium intake and high bone turnover.

ATF4 Is Required for the Anabolic Actions of PTH on Bone In Vivo. S. Yu¹, M. Luo^{*1}, R. T. Franceschi², D. Jiang^{*3}, J. Zhang¹, K. Patrene^{*1}, K. D. Hankenson⁴, G. D. Roodman¹, G. Xiao¹. ¹Medicine, University of Pittsburgh, Pittsburgh, PA, USA, ²Periodontics and Oral Medicine, University of Michigan, Ann Arbor, MI, USA, ³Periodontics and Oral Medicine, University of Michigan, Ann Arbor, MI, USA, ⁴University of Pennsylvania, Philadelphia, PA, USA.

Parathyroid hormone (PTH) is a potent stimulator of bone formation and a proven anabolic agent for the treatment of osteoporosis. However, the mechanism whereby PTH increases bone formation remains poorly understood. Activating transcription factor 4 (ATF4) is a critical factor for bone formation during development and throughout postnatal life. This study examined if ATF4 is required for the anabolic actions of PTH on bone using an Atf4^{-/-} mouse model. Five-day-old wt and Atf4^{-/-} mice were given daily subcutaneous injections of vehicle (saline) or hPTH(1-34) (0.04 µg/g body weight) for 28 days. In wt mice, µCT analyses of femurs show that this PTH regimen significantly increased bone volume/tissue volume (BV/TV, 4.3-fold), trabecular thickness (Tb.Th, 50%), trabecular numbers (Tb.N, 1.5-fold), cortical thickness (Cort.Th, 77%), and cross sectional area (CSA, 24%) and decreased trabecular spacing (Tb.Sp, 1.7-fold). These PTH effects were dramatically reduced or completely abolished in the absence of ATF4. Histological analyses show that PTH displayed potent anabolic effects on tibiae, vertebrae, and calvariae, which were significantly reduced in Atf4^{-/-} mice. At the molecular level, PTH markedly increased levels of osteocalcin (Ocn) and bone sialoprotein (Bsp) mRNA of long bones as measured by quantitative real-time RT/PCR. This increase was completely abolished in the absence of ATF4. This study demonstrates that ATF4 is required for the anabolic actions of PTH on bone in vivo and also suggested that modulation of the levels and activity of ATF4 may have therapeutic significance for the treatment of metabolic bone diseases such as osteoporosis.

Disclosures: S. Yu, None.

Rac2 Knockout Mice Have an Augmented Anabolic Response to PTH. T. Kawano^{*}, B. Sun^{*}, J. Wu^{*}, I. Karl. Department of Medicine, Yale University, New Haven, CT, USA.

Rac2 is a small GTPase that is required for CSF1-dependent osteoclast chemotaxis. Rac2^{-/-} mice have increased bone mass, and osteoclast-like cells prepared from these animals have reduced basal resorptive capacity. Histomorphometric analysis has demonstrated a trend towards increased numbers of osteoclasts while osteoblast number is normal. Recent studies have suggested that cells of the osteoclast lineage are necessary for the full anabolic effect of PTH to be manifest. We hypothesized that since osteoclast precursors would be normal or increased in Rac2^{-/-} animals while mature osteoclast function was impaired, the anabolic effect of PTH might be enhanced in these animals. To test this idea, adult Rac2^{-/-} mice and wild-type C57Bl/6 mice were treated with either a single daily sc injection of h(1-34) PTH (80ng/g body weight) or vehicle for 4 weeks, and BMD measured after 0, 2 and 4 weeks of treatment. At the end of 2 weeks the PTH-treated Rac2^{-/-} mice showed a greater increase in spine, femur and total body BMD compared to baseline than did the wild-type mice (3.9±6.8% vs. 1.6±6.5%, 9.0±5.7% vs. 5.8±5.3% and 7.2±3.1% vs. 4.9±2.5%; spine, femur, total body respectively; M±SD). After 4 weeks of treatment this difference was the same or greater (7.4±4.1% vs. 3.7±6.6%, 23.6±9.0% vs. 7.4±6.5% and 13.5±3.4% vs. 5.4±2.6%; spine, femur, total body respectively; M±SD). Further, when compared to vehicle-treated Rac2^{-/-} animals, the PTH-treated Rac2^{-/-} mice showed significantly greater mean increases in bone mass as compared to the increment in BMD observed in PTH-treated wild-type compared to vehicle-treated wild-type mice (6.7% vs. 1.8%; 16.2% vs. 3.8%; and 9.5% vs. 3.5% spine, femur and total body). Consistent with our hypothesis, serum CTX at 4 weeks was significantly lower in the PTH-treated Rac2^{-/-} animals than in the PTH-treated wild-type mice (13.8±2.9 vs. 22.4±9.5 ng/ml; M±SD). While the detailed cellular mechanisms that underlie this effect are not yet clear, these data support the notion that subtly altering osteoclast function may be a feasible way to improve the anabolic response to PTH. Further, since Rac2 is restricted in its expression to hematopoietic tissue it could represent a reasonable target for drug discovery.

Disclosures: T. Kawano, None.

RANK Ligand Inhibition by Denosumab Prevents Cortical Bone Loss in a Murine Model of Glucocorticoid-induced Osteoporosis. L. C. Hofbauer¹, U. Zeitze², M. Schoppert¹, M. Skalic², M. Stolina³, P. J. Kostenuik³, R. G. Erben². ¹Philipps-University, Marburg, Germany, ²University of Veterinary Medicine, Vienna, Austria, ³Amgen Inc., Thousand Oaks, CA, USA.

Osteoporosis is a frequent and severe complication of systemic glucocorticoid therapy, and in vitro studies suggest that RANK ligand (RANKL) represents a potential mediator. We examined the ability of Denosumab (DMab), a fully human monoclonal antibody against RANKL, to prevent glucocorticoid-induced osteoporosis in mice. DMab does not inhibit murine RANKL, so knockin mice were created by replacing exon 5 of the murine RANKL gene with a chimeric 5th exon (murine non-coding and human coding regions). These mice exclusively express a chimeric RANKL protein that is inhibited by Denosumab. Male huRANKL mice (8 months old) received slow-release pellets containing either vehicle or prednisolone (PRED, 5 mg) which was released at a mean dose of 2.1 mg/kg/d over 4 weeks. HuRANKL mice were treated with denosumab (10 mg/kg, twice/week, s.c.) or vehicle (PBS) starting 3-4 days after pellet implantation. In addition, two groups of wild-type mice (Black Swiss/129) were treated with subcutaneous slow release pellets containing vehicle or PRED. Four weeks later all mice were killed after in vivo double fluorochrome labeling. Renal handling of sodium, potassium, and phosphate was unchanged by PRED or denosumab in huRANKL mice. However, PRED increased renal excretion of calcium in wild-type and huRANKL mice. PRED treatment also significantly increased urinary deoxypyridinoline (DPD) excretion as well as serum and bone TRAP5b activity, and denosumab treatment prevented these increases. For example, protein extracts of the whole humerus contained 11.7 ± 2.7 , 17.3 ± 5.1 , and 7.7 ± 7.5 U/g TRAP5b activity (mean \pm SD) in huRANKL mice receiving vehicle, PRED, or PRED + denosumab, respectively (all $P < 0.05$). Quantitative computed tomography (pQCT) revealed that PRED induced significant bone loss in the axial and appendicular skeleton mainly by thinning of cortical bone, consistent with increased endocortical bone resorption. Trabecular BMD and cancellous bone area remained unchanged in PRED-treated mice. Treatment with denosumab completely prevented PRED-induced cortical bone loss in the L4 vertebrae and in the distal femoral metaphysis without impairing biomechanical properties as determined by three-point bending tests in femurs. In summary, PRED treatment caused cortical bone loss that was consistent with increased osteoclastic bone resorption. Treatment of huRANKL knock-in mice with denosumab, a fully human anti-RANKL antibody, prevented glucocorticoid-induced bone loss in association with suppression of bone resorption.

A Small Molecule Inhibitor of the Wnt Antagonist Secreted Frizzled-Related Protein (SFRP)-1 Stimulates Bone Formation. P. V. Bodine¹, B. Stauffer¹, H. Ponce-de-Leon¹, R. A. Bhat¹, A. Mangine¹, L. M. Seestaller-Wehr¹, R. A. Moran¹, J. Billiard¹, S. Fukayama², B. S. Komm³, K. Pitts³, G. Krishnamurthy³, A. Gopalsamy³, M. Shi³, J. C. Kern⁴, T. J. Commons⁴, M. A. Wilson⁴, G. S. Welmaker⁴, E. J. Trybulski⁴, W. J. Moore⁴. ¹Women's Health & Musculoskeletal Biology, Wyeth Research, Collegeville, PA, USA, ²Women's Health & Musculoskeletal Biology, Wyeth Research, Cambridge, MA, USA, ³Chemical & Screening Sciences, Wyeth Research, Pearl River, NY, USA, ⁴Chemical & Screening Sciences, Wyeth Research, Collegeville, PA, USA.

Canonical Wnt signaling has been demonstrated to increase bone formation by enhancing osteoblast proliferation, differentiation and activity, while suppressing apoptosis. Consequently, Wnt pathway components have been pursued as potential drug targets for metabolic bone diseases like osteoporosis. Deletion of the Wnt antagonist SFRP-1 in mice activates canonical signaling in bone and increases trabecular bone formation in aged animals. We have developed small molecules that bind to and inhibit SFRP-1 in vitro and demonstrate robust anabolic activity in an ex vivo organ culture assay. A library of over 400,000 compounds was screened for inhibitors of human SFRP-1 using a cell-based functional assay that measured activation of canonical Wnt signaling with an optimized T cell factor (TCF)-luciferase reporter gene assay. One of the hits in this screen, a diarylsulfone sulfonamide, bound to human SFRP-1 with a $K_d = 0.3$ μ M in a tryptophan fluorescence quenching assay. This compound inhibited human SFRP-1 with an $EC_{50} = 2.2$ μ M in the cell-based functional assay, but did not impede other SFRP family members. Moreover, the compound did not antagonize the activity of a SFRP-1 construct that lacked the C-terminal netrin domain, suggesting that this region contains the binding site. The compound also increased total bone area in a murine calvarial ex vivo assay at a concentration of 1.0 μ M. Optimization of this high throughput screening hit for binding and functional potency as well as metabolic stability and other pharmaceutical properties led to improved lead compounds. One of these leads bound to SFRP-1 with a $K_d = 0.08$ μ M and inhibited SFRP-1 with an $EC_{50} = 0.7$ μ M. Moreover, it increased total bone area in the murine calvarial ex vivo assay at concentrations as low as 0.001 μ M. Low oral bioavailability of this compound limited its in vivo evaluation in mice and rats. This work demonstrates the feasibility of developing small molecules that inhibit SFRP-1 and stimulate canonical Wnt signaling to increase bone formation.

A Bisphosphonate Analog that Lacks Anti-Remodeling Activity Prevents Osteocyte and Osteoblast Apoptosis In Vivo. L. I. Plotkin, J. Goellner, K. Vyas^{*}, R. S. Shelton^{*}, R. A. Wynne^{*}, R. S. Weinstein, S. C. Manolagas, T. Bellido. Center for Osteoporosis and Metabolic Bone Diseases, Univ Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

A major effect of bisphosphonates (BPs) on bone is inhibition of resorption resulting from their ability to induce osteoclast death or interfere with osteoclast function. Nonetheless, BPs also prevent osteocyte and osteoblast apoptosis in vitro and in vivo, but the contribution of the latter property to the overall beneficial skeletal effects of these agents remains unknown. We compared herein the effect of IG9402, a BP analog that preserves osteoblast and osteocyte viability but does not induce osteoclast apoptosis in vitro, with that of alendronate, a classic BP that affects osteoclasts as well as osteoblasts and osteocytes. Swiss Webster mice (7-8 per group) were implanted with placebo or prednisolone (GC) pellets (2.1 mg/kg/d) for 10 days, and were injected daily with saline or 2.3 μ mol/kg/d alendronate or IG9402, starting 3 days prior to pellet implantation. Alendronate decreased the serum levels of C-telopeptide and osteocalcin, markers of bone resorption and formation, respectively, as well as the levels of osteocalcin and collagen1A1 mRNA in vertebral bone. On the other hand, IG9402 did not affect serum levels of C-telopeptide or osteocalcin nor bone mRNA levels of osteocalcin or collagen1A1. Moreover, whereas alendronate decreased cancellous bone formation rate from 0.43 ± 0.25 to 0.09 ± 0.03 μ m²/ μ m/d ($p < 0.05$), IG9402 did not affect it significantly (0.39 ± 0.04 μ m²/ μ m/d). These findings are consistent with a decrease in bone remodeling resulting from inhibition of resorption by alendronate but not by IG9402. Furthermore, the increase in osteoblast and osteocyte apoptosis induced by GC (from 5.6 ± 2.5 to $15.1 \pm 6.0\%$ and 3.1 ± 1.7 to $7.1 \pm 1.1\%$, respectively, $p < 0.05$) was prevented not only by alendronate, as previously shown, but also by IG9402. In addition, GC induced a significant decrease in the load required to break the 6th lumbar vertebra (68.1 ± 11.6 to 47.1 ± 8.5 N, $p = 0.006$) and a decrease that was non-significant in the compression stress (27.8 ± 5.3 to 21.2 ± 4.9 in MPa $p = 0.095$); and both alendronate and IG9402 prevented the decreased ability of the vertebrae to sustain load induced by GC. We conclude that preservation of osteoblast and osteocyte apoptosis by bisphosphonates is an important, but heretofore unappreciated, mechanism of the beneficial effect of these drugs on bone. Preservation of bone strength without inducing osteoclast apoptosis by IG9402 opens new possibilities for the treatment of bone fragility in conditions in which a decrease in bone remodeling is undesirable.

VDRM 1: A Tissue-Selective, Non-Secosteroidal Vitamin D Receptor Modulator with Improved Therapeutic Window of Bone Efficacy over Hypercalcemia. Y. L. Ma, Y. K. Yee^{*}, Q. Zeng^{*}, A. Schmidt^{*}, D. E. Coutant^{*}, R. J. Barr^{*}, L. I. Boone^{*}, S. R. Chintalacharuvu^{*}, J. A. Dodge^{*}, H. U. Bryant, M. Sato. Eli Lilly and Company, Indianapolis, IN, USA.

The active form of vitamin D3 and analogs have been shown to be beneficial for osteoporosis, autoimmune diseases and cancer treatment in animal models; however, the narrow therapeutic window between therapeutic efficacy and hypercalcemia has limited their clinical utility. We have identified an orally active, tissue selective, non-secosteroidal, VDR ligand to be a potent agonist in bone, while having modest calcemic effects in vivo. When compared to 1,25(OH)2D3 in vitro, VDRM 1 was 10 fold less potent in inducing RXR-VDR heterodimerization (3.9 and 38 nM, respectively) and 100 fold less potent in inducing osteocalcin expression in a reporter gene assay (0.2 and 20 nM, respectively), but VDRM 1 was >300 fold less active than 1,25 (OH)2D3 in inducing epithelial cell calcium channel 2 (CAT1) gene expression in Caco-2 cells (3.3 and 1062 nM, respectively). In 7 months old, one month post ovariectomized (Ovx), osteopenic rats, two months of VDRM 1 treatment dose dependently restored Ovx induced loss of vertebral BMD to Sham levels at 0.73 μ g/kg/d. Hypercalcemia was not observed until about 4.6 μ g/kg/d in these animals. Biomechanical analyses showed that VDRM 1 improved bone strength (ultimate load) of lumbar vertebra, femoral midshaft and the femoral neck to significantly above Sham control levels. Static and dynamic histomorphometry showed a dose dependent reduction of both resorption and formation activity in the proximal tibial metaphysis; however a dose-dependent stimulation of the periosteal bone formation rate of > 2 fold was observed on the cortical surface. Histopathology evaluation indicated a 17 fold separation between the bone efficacy and soft tissue calcification in these Ovx rats. Taken together, these animal data suggest that VDRM 1 may have promise to treat postmenopausal women with osteoporosis.

Disruption of Hypoxia Inducible Factor-1 α in Osteoblasts Exacerbates Ovariectomy Induced Bone Loss in Mice. L. Deng^{*1}, X. Liu^{*1}, C. Wan², J. Wang^{*1}, J. Qi^{*1}, T. Luo^{*1}, J. Wang^{*1}, Q. Zhou^{*1}, Y. Zhu^{*1}, L. Wei^{*1}, T. L. Clemens². ¹Shanghai Institute of Traumatology and Orthopaedics, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China, ²Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Postmenopausal and senile osteoporosis are associated with decreased skeletal blood flow, reduced capillary networks and impaired endothelial cell function. Vasoactive agents can attenuate oophorectomy-induced bone loss, suggesting that estrogen normally regulates the vascular supply to bone. Angiogenesis during bone development and repair is controlled by the hypoxia inducible factor-1 α (HIF-1 α) which transcriptionally activates VEGF and other proangiogenic proteins. In this study, we examined the contribution of the HIF-1 α pathway on estrogen action in mouse bone in vitro and in vivo. Treatment of wild-type primary mouse osteoblasts with estradiol increased HIF-1 α and VEGF protein expression in a time and concentration dependent manner; these effects were more pronounced under hypoxic conditions. To examine the role of HIF-1 α on osteoblast differentiation, primary osteoblasts carrying floxed HIF-1 α alleles were infected with adenovirus constructs expressing Cre to disrupt HIF-1 α . Osteoblasts lacking HIF-1 α had reduced the levels of VEGF, Runx2, OC and ALP, and decreased RANKL mRNA levels consistent with recent reports that hypoxia regulates osteoclast activity through HIF-1-RANKL interactions. To examine the role of HIF-1 α in vivo, mice carrying an osteoblast specific mutation of HIF-1 α were subjected to ovariectomy. At baseline, HIF-1 α mutants had modestly reduced bone volume, mineral apposition rate, osteoblast numbers, and increased osteoclast numbers relative to control mice. Following ovariectomy, HIF-1 α mutants exacerbated bone loss by histomorphometry and microCT (BV/TV -1.33 fold, trabecular thickness -1.27 fold, and mineral apposition rate -1.13 fold, n=4, P<0.05) and an increase in osteoclast numbers (+1.20 fold) versus controls. These results support the hypothesis that estrogen normally regulates HIF-1 α and that loss of proangiogenic HIF-1 α signaling exacerbates bone loss following ovariectomy.

Deletion of PYK2 Led to High Bone Mass Through a Positive Balance Between Bone Formation and Resorption in Aged Mice. M. Li, D. T. Crawford^{*}, H. Qi^{*}, H. A. Simmons, Y. Li^{*}, D. R. Healy^{*}, E. A. Smith, L. Buchbinder, T. A. Brown. Cardiovascular and Metabolic Diseases, Pfizer Global Research and Development, Groton, CT, USA.

We have recently found that PYK2, a tyrosine kinase, plays an inhibitory role in bone formation. Genetic deletion of PYK2 (PYK2^{-/-}) resulted in increased bone formation and bone mass in adult mice. However, it is not known if the PYK2^{-/-} phenotype persists with age and how the bone performs biomechanically. Therefore, we characterized the skeletal phenotype of female PYK2^{-/-} mice at 12 months of age. There were no differences in body weight and femur length between PYK2^{+/+} and PYK2^{-/-} mice, demonstrating that PYK2 is not essential for bone growth. Three dimensional μ CT analysis of trabecular bone of 2nd lumbar vertebra showed that trabecular bone volume per total volume, trabecular number, thickness, and connectivity density were significantly increased in PYK2^{-/-} mice by +300%, +74%, +149%, and +80%, respectively. In contrast, trabecular separation was significantly decreased by -36% in PYK2^{-/-} mice. These data indicate that PYK2^{-/-} mice had higher cancellous bone mass and improved microarchitecture than PYK2^{+/+} controls. Histomorphometric analysis was performed on the 5th lumbar vertebral bodies. Consistent with μ CT findings, cancellous bone volume, trabecular number and thickness were significantly higher whereas trabecular separation was lower in the PYK2^{-/-} mice than those of PYK2^{+/+} controls. Osteoclast surface and number were significantly lower by -40% and -39%, respectively, suggesting a decrease in bone resorption in the PYK2^{-/-} mice. However, these mice had a +36% and +69% significant increase in tissue referent bone formation rate and ratio of mineralizing surface/osteoclast surface, respectively, which combined with the increased bone mass suggested a positive balance between bone formation and resorption in PYK2^{-/-} mice. Biomechanical properties were examined in the femoral diaphysis, a cortical bone site, and lumbar vertebra body, a cancellous bone site, by four point bending and compression tests, respectively. Maximum load and stiffness were significantly increased by +27% and +24%, respectively in the femurs of PYK2^{-/-} mice. Similarly, maximum load and energy were significantly higher in the lumbar vertebra of PYK2^{-/-} mice. These data indicate that PYK2^{-/-} mice not only had high bone mass but superior structural properties than PYK2^{+/+} controls in both cancellous and cortical bone sites. In summary, deletion of PYK2 caused a positive balance between bone formation and resorption, resulting in augmentation of bone mass and biomechanical properties. Our findings in aged mice indicate that the positive impact of PYK2 inhibition persists with aging.

β -adrenergic Signaling Requires Bone Matrix Protein OPN to Suppress Bone Formation and to Activate Bone Resorption. M. Nagao^{*1}, Y. Saita^{*1}, J. Nagata^{*1}, Y. Izu^{*1}, T. Hayata^{*1}, H. Hemmi^{*2}, Y. Ezura^{*1}, K. Nakashima^{*1}, H. Kurosawa^{*3}, M. Noda^{*1}. ¹Dept Morecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, Chiyoda-ku, Tokyo, Japan, ²MTT Program, Tokyo Medical and Dental University, Chiyoda-ku, Tokyo, Japan, ³Orthopedics, Juntendo University School of Medicine, Bunkyo-ku, Tokyo, Japan.

Sympathetic nervous system controls bone mass through the action of β -adrenergic signals that suppress bone formation and stimulate bone resorption. Sympathetic tone would exert its effects through the activation of osteoclast differentiation and in part facilitation of hematopoietic cell progenitor mobilization. Osteopontin (OPN), one of the major components of noncollagenous matrix proteins in bone, has been shown to promote cell adhesion and negatively regulate stem cell niche. However, the role of OPN in bone loss induced by sympathetic signaling via β -adrenergic receptors is unknown. We therefore investigated how signaling of a β -adrenergic agonist, isoproterenol (ISO) signaling, interacts with OPN signaling in bone. MC3T3E-1 cells were treated with 10uM isoproterenol and this treatment decreased OPN expression levels after 2 hours and it reached down to one-third of initial levels after 8 hours, whereas expression levels of RANKL were increased about 20 folds at 2 hours. These observations suggest that OPN may play a role in ISO-induced bone loss. Therefore, to explore the involvement of OPN in ISO-induced bone loss in vivo, ISO was administered into 9 weeks old wild type (WT) and OPN^{-/-} mice. Administration of ISO for 3 weeks reduced trabecular bone mass (BV/TV) in WT mice based on uCT analysis. In contrast, such reduction was not observed in OPN^{-/-} mice. Histomorphometric analysis showed that ISO treatment decreased bone formation rate(BFR) and mineral apposition rate(MAR) in WT mice. In contrast, OPN deficiency suppressed ISO-induced reduction in BFR and MAR. Since OPN is involved in bone resorption, we examined osteoclasts in OPN^{-/-} mice. ISO treatment increased the number and surface of TRAP positive cells in WT mice. In contrast, OPN deficiency suppressed ISO treatment-induced increase in these parameters of osteoclasts. These data indicated that deficiency of OPN blocks β -stimulant-induced bone loss. In conclusion, OPN plays a critical role in β -adrenergic signaling-induced bone loss in vivo via modulation of both bone formation and bone resorption.

The Basis for Osteoporosis in the Aldehyde Reductase Knockout Mouse. K. H. Gabbay^{*1}, K. M. Bohren^{*1}, R. Morello², J. Song^{*1}. ¹Pediatrics, Baylor College of Medicine, Houston, TX, USA, ²Molecular & Human Genetics, Baylor College of Medicine, Houston, TX, USA.

The aldehyde reductase enzyme (AKR1A4 - GR) knockout (GRKO - GR^{-/-}) mouse develops an age-related (>1 year) osteoporosis phenotype with spontaneous fractures that preferentially affect females. There is a marked acceleration of the phenotype in GR^{-/-} males after castration (CX) and in females after ovariectomy (OVX), and upon induction of streptozotocin diabetes. Both GR and a related enzyme, aldose reductase (AR) are able to reduce D-glucuronate to L-gulonate which is converted to ascorbic acid (ASC) by gulonolactone oxidase (GULO). Our data identify GR as the main source of L-gulonate for ASC synthesis in the mouse. AR has a secondary role indicated by a double knockout model, AR/GRKO, which recapitulates the clinical features of the GULO knockout model (GULO KO) with rapid onset of scurvy in both genders and death at 8-10 weeks of age. While the AR/GRKO and GULO KO models have absolute deficiencies, the GR^{-/-} mice have a moderate ASC deficiency. They show a marked decrease of trabecular (Tb) bone with hypertrophy of dysplastic mesenchymal cell masses, and absence of osteoblasts (Ob) at the growth plate. These cell masses (presumably dysplastic Ob) resolve and form disorganized osteoid after ASC feeding. Serial DEXA measurements in CX GR^{-/-} mice placed on regular diet (ASC content =0) show a statistically significant (p<0.001) decrease in bone mineral density (BMD). The bone phenotype is prevented by dietary ASC. Quantitative bone histomorphometry shows statistically significant decreases in bone volume, trabecular thickness and number with a marked increase in osteoclast (Oc) activity and number in CX GR^{-/-} mice after 3 weeks on regular diet. ASC administration after CX significantly suppresses Oc activity and number below those observed in intact GR^{-/-} levels on regular diet. We propose that the limited ASC synthesis in the GR^{-/-} mouse is adequate for normal skeletal development, but results in an uncoupling of bone homeostasis (formation and resorption) when the mice are subjected to stress. Thus, CX, OVX, or diabetes in the GR^{-/-} mice increase bone resorption in the face of reduced ASC availability, resulting in severe osteoporosis and fractures. ASC suppresses Oc activity and number in addition to promoting the differentiation of Ob. We suggest that oxidative stress in CX, OVX and diabetes is the common effector pathway for osteoclastogenesis. The GRKO model permits differentiation between the pro-osteoblastic activity of ASC and its additional anti-oxidant properties. This mouse model is relevant to understanding the role of ASC in bone homeostasis and the development of osteoporosis in normal and diabetic populations.

Risedronate Prevents Bone Loss in Breast Cancer Survivors: A Two-Year, Randomized, Double-Blind, Placebo-Controlled Clinical Trial. S. L. Greenspan¹, K. T. Vujevidich¹, R. Bhattacharya², S. Perera³, A. Brufsky¹, B. C. Lembersky¹, V. Vogel¹. ¹Medicine, University of Pittsburgh, Pittsburgh, PA, USA, ²Medicine, University of Kansas, Kansas City, KS, USA, ³Medicine/Biostatistics, University of Pittsburgh, Pittsburgh, PA, USA.

Chemotherapy induced menopause and aromatase inhibitors (AI) are associated with bone loss and increased risk for osteoporotic fractures in breast cancer survivors. Little data are available on the efficacy of oral antiresorptive therapy to prevent this. The REBBeca Trial was a single center, 2-year, randomized, double-blind, placebo-controlled trial to evaluate the efficacy of once weekly oral risedronate (RIS) 35mg, for the prevention of bone loss in newly postmenopausal women, following chemotherapy induced menopause for nonmetastatic breast cancer. All received calcium and vitamin D. Outcomes included changes in spine and hip bone mineral density (BMD, Hologic Discovery A) and bone resorption assessed by urinary NTX. 97% of the 87 women (mean age 50 years) randomized had normal or low bone mass by WHO criteria. At baseline, 71% were on tamoxifen and 16% were on an AI. Baseline clinical characteristics and BMD were similar between the 2 groups. During year 2, 49% of women were started on an AI by their oncologist. After 24 months, women in the PLB group had significant losses of BMD at the spine and hip sites ($p<0.05$) that were not observed in the RIS group (Table). At 24 months, BMD was significantly higher at the lateral spine and hip sites in women on RIS compared to PLB (2.3-2.4%, $p<0.05$; Table). In a secondary analysis we compared the response in women ever on an AI (+AI, $n=47$) and never on an AI (No AI, $N=40$) to their respective PLB group. Women on RIS No AI or RIS + AI had BMD 1.5 and 4.0% greater at the hip compared to women in the PLB No AI or PLB + AI groups respectively ($p<0.05$; Table). Women on RIS No AI had BMD 3.7% greater at the lateral spine compared to women in the PLB No AI group ($p<0.05$). Bone resorption was significantly lower in the women on RIS. We conclude that once weekly oral RIS improves BMD and prevents excess bone resorption in breast cancer survivors, even in women on an AI.

Table: Mean percent change \pm standard error in BMD or Marker at 24 months

	Spine	Lateral Spine	Total Hip	Trochanter	NTX
RIS all	0.4 ± 0.8	0.1 ± 1.1	0.9 ± 0.6	1.1 ± 0.8	-6.5 ± 10.4
PLB all	-1.2 ± 0.7	$-2.4 \pm 1.1^*$	$-1.6 \pm 0.4^{**}$	$-1.4 \pm 0.4^{**}$	$39.4 \pm 14.4^{**}$
Adjusted Difference all	1.4 ± 0.8	$2.3 \pm 1.2^+$	$2.4 \pm 0.5^{++}$	$2.4 \pm 0.7^{++}$	$-33.8 \pm 14.4^*$
Adjusted Difference No AI	1.1 ± 1.2	$3.7 \pm 1.8^+$	$4.0 \pm 0.8^{++}$	$3.6 \pm 1.0^{++}$	-26.3 ± 21.5
Adjusted Difference +AI	1.9 ± 1.0	1.8 ± 1.5	$1.5 \pm 0.7^+$	$1.8 \pm 0.9^+$	$-43.4 \pm 18.6^+$

* $p<0.05$, ** $p<0.01$ from baseline, + $p<0.05$, ++ $p<0.01$ RIS vs. PBO

XXY Mice Have an Osteoporotic Phenotype. P. Y. Liu¹, R. Kalak², Y. Lue³, K. Erkkila³, U. Simanainen¹, H. Zhou², A. Hikim³, D. Handelsman¹, M. Seibel², C. Wang³, R. Swerdloff³, C. Dunstan². ¹Andrology, ANZAC Research Institute, Concord, Australia, ²Bone Biology, ANZAC Research Institute, Concord, Australia, ³Endocrinology, Harbor UCLA Medical Center, Los Angeles, CA, USA.

Klinefelter's syndrome is the most common chromosomal aneuploidy in men (XXY karyotype, 1:600 live births) and is characterised by infertility and androgen deficiency, cognitive impairment and osteoporosis. The extent to which skeletal changes are due to sex hormone deficiency or arise directly from gene over-dosage cannot be easily determined in humans. To answer this question, we generated XXY mice through a complex 4-generation breeding scheme.

Eight intact XXY mice and 9 XY littermate controls, and 8 castrated XXY mice and 8 castrated XY littermate controls, were sacrificed at one year of age. Castration occurred 6 months prior to sacrifice. Tibiae were harvested and examined by mCT and histomorphometry. Blood testosterone was assayed by radioimmunoassay.

Compared to intact XY controls, XXY mice had a lower bone volume (6.8 ± 1.2 vs $8.8 \pm 1.7\%$, mean \pm SD, $P=0.01$) and trabeculae were thinner (50 ± 4 vs 57 ± 5 mm, $P=0.007$). Trabecular separation (270 ± 20 vs 270 ± 20 mm), osteoclast number relative to bone surface (2.4 ± 1.0 vs 2.7 ± 1.5 / mm²) and blood testosterone concentrations (5.3 ± 4.7 vs 2.5 ± 3.9 ng/mL) did not differ significantly. These mCT, histomorphometric and blood parameters were similar between castrated XXY and castrated XY mice. As expected, castration drastically decreased relative bone volume ($P<0.001$), trabecular thickness ($P=0.05$), trabecular separation ($P<0.01$) and blood testosterone concentrations ($P<0.001$) with equivalent effects in XY and XXY mice.

In conclusion, XXY mice replicate many features of human Klinefelter's syndrome making them a useful model for studying bone, as well as testis and behaviour (1). Testosterone deficiency may not fully explain the bone phenotype in the non-castrate state as XXY mice show both reduced bone volume and similar blood testosterone levels. These data suggest that novel genes, that escape X inactivation, contribute to bone loss, and when identified, may provide unique molecular targets for the management of osteoporosis.

(1) Lue Y, et al 2005 XXY mice exhibit gonadal and behavioral phenotypes similar to Klinefelter syndrome. *Endocrinology* 146:4148-4154

A Stone Mouse: Transgenic Expression of an Engineered Gs-coupled Receptor in Osteoblasts Produces Increased Bone Mass. E. C. Hsiao¹, B. Boudignon², P. W. Chang¹, M. Benscik², J. Peng², C. Manalac¹, B. Halloran², B. Conklin¹, R. Nissenson². ¹Gladstone Institutes, University of California, San Francisco, CA, USA, ²Endocrine Unit, VA Medical Center, San Francisco, CA, USA.

Activation of the G-protein coupled PTH/PTHrP receptor (PPR) in osteoblasts can elicit a marked increase in bone formation and bone mass. The PPR is capable of activating multiple G protein pathways; however the specific signals responsible for the anabolic effects of the PPR are not fully understood. To address this problem, we engineered a novel GPCR ("Rs1") that activates the Gs/cyclic AMP pathway and displays constitutive Gs-linked signaling in transfection experiments of cultured cells. Rs1 was targeted to osteoblasts in vivo using a ColI 2.3kb promoter fragment combined with the TetO/TetA (TetOff) system. Expression of Rs1 in maturing osteoblasts from conception was sufficient to induce a dramatic anabolic skeletal response. Mutant mice displayed a 2-5 fold increase in femoral bone volume as compared to age and sex-matched littermate controls at 3 weeks. Whole body DEXA demonstrated a 3-fold increase in BMD in 9-week-old mice over controls (0.14 g/sq cm vs. 0.05 g/sq cm, respectively); microCT imaging confirmed a massive and generalized increase in mineralized bone by 9 weeks of age. Histomorphometry showed a marked increase in bone cellularity and osteoid with disorganized trabecular bone and loss of the cortical shell. Serum markers of bone metabolism were elevated in the mutant mice as compared to wildtype controls, including alkaline phosphatase at 3 weeks (970.6 ± 306.8 vs 251.6 ± 27.1 IU/L), and osteocalcin (507.2 ± 86.6 vs 131.6 ± 45.3 ng/ml) and pyridinoline cross links (2.45 ± 0.64 vs 1.28 ± 0.07 nmol/ml) at 9 weeks. No skeletal phenotype was observed in mice where Rs1 expression was suppressed by doxycycline administration from conception through the first 4 weeks of postnatal life. Our results indicate that Gs-GPCR signaling in osteoblasts during the first 4 weeks of life can produce a massive and progressive increase in bone formation and bone mass. The observed phenotype of these mice differs significantly from that of fibrous dysplasia and of transgenic mice expressing a constitutively-active form of the PPR, suggesting that G-protein signaling may interact with other crucial pathways to regulate bone formation. Our model provides a novel approach to activating the Gs pathway in osteoblasts and may indicate an anabolic pathway that could be used to maximize acquisition of peak bone mass for the treatment of osteoporosis.

Impaired Bone Formation in Mice Lacking the G Protein Subunit Gs α in Early Osteoblasts Leads to Marked Bone Fragility. J. Y. Wu¹, S. Rodda², N. A. Sims³, I. J. Poulton³, M. Chen⁴, L. S. Weinstein⁴, A. P. McMahon², H. M. Kronenberg¹. ¹Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, ²Department of Molecular and Cellular Biology, Harvard University, Cambridge, MA, USA, ³St. Vincent's Institute of Medical Research, Fitzroy, Australia, ⁴Metabolic Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, USA.

Gs α is a ubiquitous heterotrimeric G protein subunit that mediates signaling downstream of numerous G protein-coupled receptors, including the parathyroid hormone (PTH)/PTH-related peptide (PTHrP) receptor (PPR). We have deleted Gs α in osteoblast progenitors expressing osterix, a transcription factor expressed early in osteoblastogenesis. Osterix-Cre:Gs α (fl/fl) mice have markedly decreased trabecular and cortical bone mass, and experience fractures of the posterior ribs and long bones by the first day of life, leading to early postnatal lethality. Histomorphometric analysis reveals a significant (70%) reduction in trabecular bone volume, with reduced trabecular thickness and number, and osteoblast surface and numbers are dramatically diminished by 87% in mutant mice. We have previously shown that micro-computed tomography of cortical bones revealed increased cortical porosity in Gs α conditional knockout mice. Double calcein labeling demonstrates abnormal woven cortical bone in the absence of Gs α . Sirius red staining followed by analysis under polarized light confirms a striking absence of lamellar bone in cortical bones from mutant mice. Similarly, calvariae of conditional knockout mice are notable for markedly increased porosity and aberrant persistence of woven bone. TRAP staining of trabecular, cortical and calvarial bones do not demonstrate any increase in osteoclasts, and serum TRACP 5b levels are significantly reduced in mutant mice, suggesting that this phenotype cannot be attributed to enhanced bone resorption. Furthermore, osteoclast surface and numbers are not increased in mutant mice. Taken together, these results suggest that mice lacking Gs α early in the osteoblastic lineage have abnormal and/or inadequate bone formation affecting both intramembranous and endochondral bones. The resulting failure to remodel woven bone into lamellar bone may underlie the profound fragility of Gs α -deficient bones.

Designer G Protein Coupled Receptors Suggest Opposing Roles for Gs and Gi Signaling in Osteoblasts. S. M. Millard¹, J. Peng¹, M. Bencsik¹, A. Storer¹, W. Lu¹, T. J. Wronski², B. Conklin³, R. A. Nissenson¹. ¹Endocrine Research Unit, Veteran's Affairs Medical Center, San Francisco, CA, USA, ²Department of Physiological Sciences, University of Florida, Gainesville, FL, USA, ³Department of Medicine, University of California, San Francisco, San Francisco, CA, USA.

Designer GPCRs are powerful tools for dissecting the functional roles of specific G protein signaling pathways. We utilized two such receptors, Ro1 which signals through the Gi pathway and Rs1 which signals through the Gs pathway, to examine the role of these pathways in osteoblasts. Transgenic expression of Ro1 in osteoblasts using the 2.3 kb-Col1 promoter resulted in a dramatic osteopenic phenotype. Histomorphometric analysis of the proximal tibia revealed no change in the numbers of osteoblasts or osteoclasts on the bone surface, but decreased mineral apposition and bone formation rates were evident in Ro1 mice compared to littermate controls (Male BFR: 23.98 \pm 3.83 vs 36.46 \pm 1.44, Female BFR: 31.88 \pm 2.47 vs 44.32 \pm 4.57, p values <0.001). Osteoblast specific Ro1 transgene expression was tet-regulatable (tet-off system), allowing for the controlled expression of Ro1 in primary bone marrow stromal cell (BMSC) cultures. Induction of Ro1 expression in BMSC failed to influence osteoblast specific gene expression or formation of mineralized colonies, even in the presence of spiradoline, a synthetic agonist that activates Gi signaling by Ro1. These findings indicate that Gi signaling in osteoblasts in vivo has a marked negative effect on bone formation, apparently independent of cell autonomous inhibition of osteoblast function. To examine the role of Gs/cAMP signaling in osteoblasts, we have employed Rs1, a modified 5HT4 receptor that signals through Gs/cAMP in response to the synthetic drug RS23597, but not in response to 5HT (serotonin). The ability of Rs1 signaling to mimic cAMP dependent PTH responses was assessed in the osteoblast-like cell line Ros17/2.8. RS23597 induced an increase in intracellular cAMP, increased mRNA expression of the cAMP early response gene, ICER, and repressed Dickkopf1 mRNA expression in cells transiently transfected with Rs1. Neither 5HT treatment nor treatment with RS23597 in the absence of Rs1 expression produced these effects. This demonstrates that Rs1 is a suitable designer GPCR for assessing the role of Gs signaling in osteoblasts. Transgenic expression of Rs1 in osteoblasts in vivo produces a marked increase in bone mass, implying that the Gs/cAMP pathway is a major positive anabolic signaling pathway in osteoblasts. The contrasting phenotypes of the osteoblast-specific Ro1 and Rs1 transgenic mice are suggestive of critical and opposing roles for Gi and Gs signaling in osteoblast biology, the mechanisms of which are yet to be clearly delineated.

Severe Osteopenia in PERK-Knockout Mice Is Due to Impaired Osteoblast Differentiation Associated with Reduction of Type II RUNX2 Expression. J. Wei^{*}, X. Sheng^{*}, B. McGrath^{*}, D. R. Cavener. Biology, Penn State University, University Park, PA, USA.

PERK deficiency in human (Walcott-Rallison Syndrome) causes multiple skeletal dysplasias and severe osteopenia. As revealed by Micro-CT analysis, PERK deficient mice show a remarkable reduction in trabecular bone mineralization and cortical bone thickness as early as postnatal day 2. The expression of osteoblast markers (Alkaline phosphatase, Osteocalcin and Type I Collagen) was found to be significantly down-regulated in Perk KO mice by ~60-70% compared to wild-type littermates, and osteoclast markers were also reduced. To aid in the in situ identification of mature osteoblasts, the Col2.3GFP transgene was introduced into Perk KO mice. We found that the reduction in the expression of the osteoblast markers in Perk KO mice was the result of fewer mature osteoblasts and lower expression of osteoblast-specific genes per osteoblast. No increase in cell death was observed in KO mice, thus indicating that major defect in Perk-/- osteoblasts was abnormal or incomplete differentiation. A reduction of osteoblast markers was also seen in osteoblast-specific Col2.3 Perk KO mice, suggesting that PERK intrinsically regulates osteoblast differentiation. PERK is well known as a positive translational regulator of certain genes, including the transcription factor ATF4, which contain 5' upstream open reading frame (uORF) in their mRNAs. ATF4 was recently shown to be important in bone development and in regulating amino acid metabolism genes in osteoblasts. However, we found that in bone tissue of Perk KO mice, ATF4 mRNA and protein are normally expressed as well as its downstream amino acid metabolism genes. Another potential candidate for PERK-dependent regulation is RUNX2-type II, which contains five uORFs in its 5' UTR. In Perk-/- primary osteoblast culture, protein level of RUNX2-II is 50-30% of WT, while mRNA level is 80-90% of WT. Furthermore, DTT, a ER stress inducer, can strongly up-regulate RUNX2-II expression in both MC3T3-E1 and WT primary osteoblast, but only mild induction is seen in Perk-/- osteoblast, suggesting translation of RUNX2-II is PERK dependent. In summary our results illustrate that PERK is essential to normal osteoblast differentiation and reduction of type II RUNX2 possibly accounts for the osteoblast defects observed in Perk-/- mice. Supported by NIH AR49816 (D.R.C.).

Bone Cell Autonomous Effects of Osteoactivin/Gpnmb In Vivo. J. Y. Belcher¹, M. C. Rico¹, I. Arango-Hisijara¹, S. Salihoglu¹, K. B. Buck¹, S. Abdelmagid¹, A. Sanjay¹, M. C. Nakamura², S. N. Popoff¹, F. F. Safadi¹. ¹Anatomy and Cell Biology, Temple University, Philadelphia, PA, USA, ²University of California, San Francisco, San Francisco, CA, USA.

Osteoactivin/Glycoprotein nmb (OA/gpnmb) is a transmembrane glycoprotein. The protein is synthesized, processed and heavily glycosylated by osteoblasts. Its expression is associated with increased osteoblast differentiation and matrix mineralization. We have previously shown that OA/gpnmb expression in osteoblasts is regulated by BMP-2 through the Smad-1 signaling pathway. In this study, we used a mouse model with a naturally occurring mutation in the OA/gpnmb gene resulting from a premature stop codon that leads to the production of a truncated OA/gpnmb protein with no biological functions. OA/gpnmb mutant mice develop osteoporosis with age when compared to normal, wild type (WT) littermates. Histological and micro-CT measurements of femurs in mutant mice revealed a decrease in bone volume (BV/TV), trabecular number (Tb.N), and trabecular thickness in OA/gpnmb mutants compared to WT controls. Primary osteoblasts were generated from newborn OA/gpnmb and WT mice and examined for their differentiation ex vivo. All markers for early (alkaline phosphatase activity and collagen type I expression) and late (nodule formation, matrix mineralization and osteocalcin production) osteoblast differentiation were significantly reduced in the OA/gpnmb mutant osteoblasts compared to controls. We also examined bone marrow stromal cells isolated from OA/gpnmb and WT mice and testing their ability to differentiate into osteoblasts. Colony forming unit-fibroblasts (CFU-F) and CFU-osteoblasts (OB) (determined by alkaline phosphatase staining) were significantly reduced in mutant compared to WT mice. These data suggest that OA acts as positive regulator of osteoblast differentiation and function in vivo. We next examined osteoclast differentiation using a co-culture system established using normal osteoblasts as feeder cells and bone marrow (monocyte/macrophage) obtained from either OA/gpnmb mutant or WT mice in the presence of 1,25(OH)₂ vitamin D₃ and PGE2. Osteoclast formation/differentiation was determined by TRAP-staining and actin ring formation. Co-culture of bone marrow cells isolated from OA/gpnmb mutant mice and WT osteoclasts showed marked increase in osteoclast numbers and size when compared to osteoclasts generated from normal bone marrow cells and normal osteoblasts. These data suggest the OA/gpnmb acts as a negative regulator of osteoclast formation in vivo. Collectively, these data suggest that OA/gpnmb acts to regulate bone remodeling by positively affecting osteoblastogenesis and negatively regulating osteoclastogenesis in vivo.

Characterization of Osteoblast-Specific capn4 Knockout Mice. M. Shimada¹, P. A. Greer^{2*}, A. P. McMahon^{3*}, E. Schipani¹. ¹Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA, ²Pathology, Queen's University, Kingston, ON, Canada, ³Molecular & Cellular Biology, Harvard University, Cambridge, MA, USA.

We have previously demonstrated that the calpain small subunit directly binds the intracellular C-terminal tail (C-tail) of the PTH1R at a site near its N-terminus, and it cleaves PTH1R at its C-tail in a calcium- and ligand- dependent manner in cell lysates and in intact cells. Moreover, the absence or reduction of calpain activity reduces PTH-mediated intracellular cAMP accumulation in both embryonic fibroblasts expressing PTH1R and MC3T3-E1 cells.

The universal knockout mice of capn4, a gene encoding the calpain small subunit, are embryonic lethal. Thus, to investigate calpain's role in cells of osteoblast lineage which express PTH1R, in vivo, we established osteoblast-specific capn4 knockout mice by mating capn4fl/fl mice with mice expressing Cre under the control of osterix promoter (osx-cre). Thereafter, capn4fl/fl and capn4+ indicate floxed and wild-type alleles of capn4, respectively. Efficiency of Cre recombinase, as assessed by real-time PCR of genomic DNA, was approximately 85%. Osx-cre;capn4fl/fl mice were phenotypically normal at birth and fertile. Whole skeletal analysis of newborn mice showed that osx-cre;capn4fl/fl mice had no patterning defect, but they displayed smaller body size and a delay in mineralization of calvaria compared to either control or osx-cre;capn4fl/+ littermates. Body weight of osx-cre;capn4fl/fl mice stayed significantly lower than those of osx-cre;capn4+/+ and capn4fl/fl mice at least up to 12 weeks of age. Detailed histological analyses showed that tibias of osx-cre;capn4fl/fl mice had reduced trabecular bone and lower expression of both osteoblast-specific markers including type I collagen, collagenase 3, osteopontin and osteocalcin, and osteoclast makers such as tartrate-resistant acid phosphatase in comparison to control littermates. Consistent with these data, bone mineral density, as measured by dual-energy X-ray absorptiometry, was also significantly lower in femurs of osx-cre;capn4fl/fl male mice than in controls at 12 weeks old. Preliminary histomorphometric analysis confirmed that osx-cre;capn4fl/fl mice had significantly lower bone volume/total volume ratio and trabecular number with concomitant increase in trabecular spacing when compared to control littermates. Collectively, these results suggest that capn4 plays a critical role in bone development and remodeling in vivo.

Overexpression of Human VDR in the Intestine Rescues the Hypocalcaemia-Related Phenotype of VDR Knockout Mice. Y. Xue^{*}, J. C. Fleet. Dept. of Foods and Nutrition, Purdue University, West Lafayette, IN, USA.

Vitamin D Receptor (VDR) knockout mice have reduced intestinal calcium absorption (Ca Abs) and develop severe hypocalcaemia and rickets when fed a standard 0.72% Ca chow diet. A highly bioavailable, 2% Ca, 20% lactose rescue diet that bypasses the transcellular Ca Abs pathway partially rescues this phenotype and reveals the importance of vitamin D-regulated intestinal Ca Abs in whole body Ca metabolism. To further study the role of VDR-mediated intestinal Ca absorption in Ca and bone metabolism, we generated transgenic (TG) mice with intestine-specific expression of hemagglutinin-tagged human VDR (HA-hVDR) driven by a 12.4 kb fragment of the villin promoter. Two TG lines, HV1 and HV2, were characterized. HA-hVDR mRNA and protein expression was detected from duodenum (Dd) to colon in TG mice; intestinal VDR protein was increased by 2- and 8- fold in HV1 and HV2, respectively, compared to the wild-type (WT) mice. In contrast a small level of HA-hVDR mRNA was seen in kidney of HV1 and HV2 and no HA-hVDR mRNA was seen in any other tissue. The HV2 line was used to examine whether TG expression could recover the VDR knockout (-/-) mouse phenotype. VDR +/-, TG +/- (control), VDR -/-, TG +/- (recovered KO or TG/KO) and VDR -/-, TG -/- (KO) mice were fed a standard chow diet for 8 or 12 weeks. At the 12 weeks of age, KO mice were growth arrested, developed alopecia, and had severe rickets. TG/KO mice also developed alopecia but growth and bone density were completely recovered. Serum Ca and PTH in TG/KO mice were completely restored to control levels. Serum 1,25(OH)₂D₃ and renal CYP27B1 mRNA levels were dramatically elevated in KO (100X and 400X above control, respectively). In TG/KO, these endpoints were restored to normal (CYP27B1 mRNA) or near normal (serum 1,25(OH)₂D₃, 7X above control levels). Intestinal expression of calbindin D_{9k} and TRPV6 mRNA levels were reduced in KO but recovered in TG/KO mice. In contrast, renal CYP24 mRNA levels were only partially recovered (25% control levels) in TG/KO. At 8 wks, basal Ca Abs in the Dd of TG/KO was 26% higher than controls and both lines increased Ca Abs after treatment with 1,25 (OH)₂D₃ (25 ng/100g body, 9 h; 29.94% vs. 51.46% in controls; 37.81% vs. 52.36% in TG/KO). Surprisingly, while 1,25 (OH)₂D₃ treatment significantly induced CYP24 (Dd, kidney), calbindin D_{9k} (Dd), and TRPV6 (Dd) mRNA in both control and TG/KO, the response in TG/KO was blunted. Our data demonstrate that restoration of active VDR-mediated Ca Abs throughout the intestine is necessary to recover the phenotype of VDR KO mice. This further shows the critical importance of the intestine in controlling whole body Ca metabolism.

Studies Using Nullmutant Mice Reveal Active Intestinal Calcium Transport in the Absence of Calbindin-D_{9k} or TRPV6. B. S. Benn^{1*}, P. Dhawan^{1*}, A. Porta^{1*}, X. Peng^{1*}, M. Hediger^{2*}, J. Peng^{3*}, G. Oh^{4*}, S. Christakos¹. ¹Biochemistry and Molecular Biology, UMDNJ- New Jersey Medical School, Newark, NJ, USA, ²Institute of Biochemistry and Molecular Medicine, University of Berne, Berne, Switzerland, ³Department of Medicine, University of Alabama, Birmingham, AL, USA, ⁴Laboratory of Cardiovascular Genomics, Ewha Woman's University, Seoul, Republic of Korea.

To study the role of the calcium binding protein calbindin-D_{9k} and the epithelial calcium channel TRPV6 in intestinal calcium absorption, calbindin-D_{9k} and TRPV6 nullmutant mice were generated. Nullmutation was verified by RT-PCR and Western blot analyses. When fed a standard rodent chow diet, TRPV6 knockout (KO) mice and calbindin-D_{9k} KO mice have serum calcium levels similar to those of wild type (WT) mice (~ 9 mg Ca⁺⁺/dl). In the TRPV6 KO mice, however, there is a 3 fold increase in serum PTH and 2.4 fold increase in serum 1,25(OH)₂D₃ levels. Levels of calbindin-D_{9k} mRNA and protein in intestine were not significantly different in TRPV6 KO mice compared to WT nor were levels of intestinal TRPV6 mRNA significantly different in calbindin-D_{9k} KO mice compared to WT. However, in calbindin-D_{9k} KO mice there is a significant 2-3 fold increase in renal calbindin-D_{28k} mRNA and protein (vs. WT), suggesting that renal calbindin-D_{28k} is compensating for the lack of renal calbindin-D_{9k}. Active intestinal calcium absorption was measured using the everted gut sac method and the first 5 cm of the duodenum of WT or nullmutant mice. Under low dietary calcium conditions [mice were fed a low calcium (0.02%) diet from weaning for 4 weeks] there was a 4.4, 4.1 and 2.8 fold increase in calcium absorption in the duodenum of WT, calbindin-D_{9k} and TRPV6 KO mice respectively [n=5-18/group; p>0.1 WT vs. calbindin-D_{9k} KO and p<0.05 WT vs. TRPV6 KO on the low calcium diet]. Duodenal calcium absorption was increased 2.2 +/- 0.1 fold in the calbindin-D_{9k}/TRPV6 double knock out mice fed the low calcium diet (p<0.05 WT vs. double KO). Calcium absorption was not stimulated by low dietary calcium in the ileum of the WT or KO mice. In addition to low dietary calcium, 1,25(OH)₂D₃ administration (three injections of 1,25(OH)₂D₃ 100ng/100g body weight; 48, 24 and 12h prior to sacrifice) to vitamin D deficient mice also resulted in a significant increase in duodenal calcium absorption (1.8 - 2.4 fold; p<0.05 compared to vitamin D deficient mice and p>0.1 among all groups) in WT, calbindin-D_{9k}, and TRPV6 KO mice. This study provides evidence for the first time using nullmutant mice that significant active intestinal calcium transport occurs in the absence of calbindin-D_{9k} or TRPV6, thus challenging the dogma for the need for calbindin-D_{9k} and TRPV6 for vitamin D induced active intestinal calcium transport.

Novel Mechanism of Vitamin D Receptor (VDR) Activation: Histone H3 Lysine 9 Methyltransferase Is a Transcriptional Coactivator for VDR. Y. Zhong^{*}, S. Christakos. Biochemistry and Molecular Biology, UMDNJ-New Jersey Medical School, Newark, NJ, USA.

Acetylation of core histone tails plays an essential role in transcriptional activation by nuclear hormone receptors. In addition to acetylation, methylation also occurs on core histones. The H3 specific lysine 9 methyltransferase G9a has been reported to function as a co-repressor of transcription by associating with transcriptional repressors. Here we report a novel mechanism of VDR receptor activation where G9a functions as a transcriptional activator in the 1,25(OH)₂D₃ regulation of 25-hydroxyvitamin D₃ 24 hydroxylase (24(OH)ase). Using COS-7 cells transfected with VDR and the rat 24(OH)ase promoter (-298/+74) and treatment with suboptimal 1,25(OH)₂D₃, increasing concentrations of G9a (0.02 - 0.2 ug) alone or in combination with the H3 specific arginine methyltransferase CARM1/PRMT4 (0.2 ug) had little effect on VDR mediated transcription. Expression of GRIP-1 (a p160 coactivator) alone (0.05 ug) or in combination with CARM1 (0.2 ug) or G9a (0.2 ug) stimulated transcription a maximum of 3 fold above the 1,25(OH)₂D₃ induced response. However transfection of G9a (0.2 ug) in combination with GRIP-1 (0.05 ug) and CARM1 (0.2 ug) resulted in a significantly greater enhancement of 1,25(OH)₂D₃ induced 24(OH)ase transcription 7- 8 fold above the 1,25(OH)₂D₃ induced response (p<0.01 compared to each enzyme alone or in combination or compared to activation with GRIP-1; maximal 1,25(OH)₂D₃ induced transcription was 60-70 fold). The synergy was dependent on 1,25(OH)₂D₃ and VDR. When either a mutant of CARM1, E267Q, or a mutant of G9a, that lacked enzymatic activity, was transfected, synergistic coactivator function was reduced. *In vitro* translation and co-immunoprecipitation studies have indicated that GRIP-1 binds directly to CARM1 and indirectly to G9a. When the GRIP-1 mutant AAD2 (which lacks the binding site for CARM1) was used, synergy was not observed, indicating a critical role of GRIP-1 in recruiting the secondary coactivators for VDR mediated transcriptional activation. Results of ChIP assays indicated that G9a is associated with the 24(OH)ase VDRE (-151/-137). Using the mouse 1α hydroxylase promoter and transfection in AOK-B50 kidney cells, we found that G9a can act as a repressor of PKA activation. These findings suggest that the histone modification induced by GRIP-1 can result in G9a acting as a transcriptional activator and that activation or repression depends on the context of transcription factors at a specific promoter. Our findings also suggest, for the first time, that cooperativity between histone methyltransferases and p160 coactivators may play a fundamental role in VDR mediated transcriptional activation.

Intracrine Synthesis and Action of 1,25-dihydroxyvitamin D Rescues Toll-like Receptor Suppression of Innate Immunity. S. Ren¹, L. Nguyen^{*1}, P. Liu^{*2}, R. L. Modlin^{*2}, J. S. Adams¹, M. Hewison¹. ¹Endocrinology, Diabetes and Metabolism, Cedars-Sinai Medical Center, Los Angeles, CA, USA, ²Division of Dermatology, UCLA, Los Angeles, CA, USA.

Vitamin D can act as a versatile modulator of the immune system by suppressing adaptive T-cell responses whilst stimulating macrophage innate immunity. We have shown recently that the latter involves toll-like receptor (TLR)-mediated induction of the enzyme 1 α -hydroxylase (CYP27b1) and concomitant autocrine metabolism of 25-hydroxyvitamin D (25D₃) to 1,25-dihydroxyvitamin D₃ (1,25D₃) by macrophages. This enhances innate immunity by stimulating expression of the antibacterial protein cathelicidin (LL37). Here we have used human macrophages cultured in the presence of autologous human serum to assess the effects of circulating 25D₃ levels on LL37 and beta-defensin 4 (DEFB4), another antibacterial peptide associated with innate immunity. Peripheral blood mononuclear cells were isolated from the patients as part of an established IRB protocol. Adherent monocytic cells were then isolated from non-adherent lymphocytes in serum-free medium and re-cultured in medium containing 10% of the patient's own serum. Under these conditions treatment with ligand to either TLR2 (19 kDa lipoprotein [19 kDa], 1ng/ml) or TLR4 (LPS, 100 ng/ml) suppressed expression of LL37 20-fold (p<0.001, n=9) and 32-fold (p<0.001, n=6) respectively. Analysis of patient vitamin D metabolites showed that suppression of LL37 by 19 kDa was inversely correlated with the patient's serum 25D₃ level (R=-0.801, p=0.009), indicating that intracrine conversion of patient 25D₃ to 1,25D₃ protected against inhibition of LL37. Monocytes cultured in autologous serum showed relatively high levels of CYP27b1 expression, and addition of exogenous 25D₃ (100 nM) alone increased expression of mRNA for LL37 (17-fold, p<0.001, n=10). Furthermore, co-treatment with exogenous 25D₃ (100 nM) rescued the suppressive effects of 19 kDa and LPS on LL37 expression (68-fold and 75-fold respectively for 19 kDa and LPS relative to cells treated with TLR ligand alone). Parallel analysis of DEFB4 showed that, in contrast to LL37, expression of this innate immunity gene was induced by either 19 kDa or LPS (349- and 86-fold respectively), and this response was unaffected by co-treatment with 25D₃. In summary, we have shown that high concentrations of TLR ligands act to suppress expression of antibiotic LL37, possibly as a mechanism by which pathogens can evade innate immunity. However, increased serum levels of 25D₃ protect against this pathogenic evasion mechanism. These data emphasize further the importance of intracrine metabolism of 25D₃ as a pivotal mechanism for normal human innate immunity.

Barrier Site Metabolism of Vitamin D: A Mechanism for Protection Against Inflammatory Bowel Disease. S. Wu, L. Nguyen*, S. Ren, R. F. Chun, J. S. Adams, M. Hewison. Endocrinology, Diabetes and Metabolism, Cedars-Sinai Medical Center, Los Angeles, CA, USA.

The active form of vitamin D, 1,25-dihydroxyvitamin D₃ (1,25(OH)₂D₃) is a versatile immunomodulator. In addition to suppression of adaptive T-cell responses, 1,25(OH)₂D₃ is also a potent inducer of innate antibacterial activity in macrophages. Both of these mechanisms are dependent on localized synthesis of 1,25(OH)₂D₃ via the enzyme 1 α -hydroxylase (CYP27b1). We have postulated that this autocrine/paracrine response is crucial to innate and adaptive immune responses at 'barrier sites' where cells have routine contact with pathogen-associated molecular patterns. To test this hypothesis we have used dextran sodium sulfate (DSS) to induce a gastrointestinal barrier challenge in mice, thereby generating symptoms of inflammatory bowel disease (IBD). Wild type (+/+) BL6 mice treated with 2.5% DSS in water for 7 days followed by 2 days recovery showed a decrease in weight of 8.0 \pm 4.4% compared to weight at day 0. Analysis of colonic tissue from these animals showed no change in expression of the Th2 cytokine interleukin-10 (IL-10), but there were increased levels of mRNA for the inflammatory cytokine, IL-1 (14.4-fold, p<0.001). This was associated with a parallel rise in CYP27b1 expression, at the level of mRNA (2.1-fold, p=0.003) and protein (the latter defined by immunohistochemistry). Analysis of sera from the DSS-treated animals showed no change in circulating levels of 25-hydroxyvitamin D₃, but these mice exhibited significantly lower levels of 1,25(OH)₂D₃ (42 pg/ml) when compared to untreated mice (58 pg/ml) (p=0.013). DSS-treatment of mice +/- for the CYP27b1 gene resulted in a similar loss of weight to WT mice (7.1 \pm 5.2% compared to 6.5 \pm 0.6% weight gain in control mice). By contrast, mice with ablation of the CYP27b1 gene (-/-) exhibited a striking weight loss of 23.8 \pm 3.9% when treated with DSS, compared to 2.1 \pm 2.0% weight gain in untreated -/- mice. The enhanced sensitivity of CYP27b1 -/- mice to DSS treatment was associated with increased colonic expression of mRNA for both IL-1 (20-fold compared to DSS-treated +/- mice) and IL-10 (8-fold compared to DSS-treated +/- mice). Increased expression of IL-1 and IL-10 in DSS-treated CYP27b1 -/- mice relative to +/- mice was also observed in spleens from these animals but not kidneys. This study provides further evidence of a role for vitamin D in protecting against the onset of IBD. In particular, our data show that a crucial determinant of this protective effect is the expression of CYP27b1 in affected tissues, including both the colonic epithelium and immune system.

Molecular Mechanisms of 1 α ,25(OH)₂ Vitamin D₃-induced ATP Release in Osteoblasts. P. Biswas*, L. P. Zanello*. Biochemistry, UC,Riverside, Riverside, CA, USA.

Steroid hormones including 1 α ,25(OH)₂ vitamin D₃ (1,25D) are known to modulate bone cell populations and their activities. Changes in osteoblast to osteoclast ratios have

been identified as a possible cause of some bone diseases. Some therapeutic approaches aim at reduction of osteoclast generation or activity, which to a large extent is governed by factors released by osteoblasts. One such factor is ATP. ATP released by osteoblasts at localized sites, exerts autocrine/paracrine signaling and modulates osteoclast functions. However, molecular mechanisms of ATP release and its regulation are not fully known. Our study describes rapid exocytotic release of ATP induced by the steroid hormone 1,25D in osteoblastic rat ROS 17/2.8 and human Saos-2 cells. Single exocytotic events were monitored in real time with time-lapse videomicroscopy on live osteoblasts stained with quinacrine, which has high affinity for ATP stores. Physiological concentrations of 1,25D (1-10 nM) caused a 3 fold and 5 fold increase of ATP release respect to vehicle in ROS 17/2.8 cells and Saos-2 cells respectively. We found that 1,25D-induced ATP release is vesicular. Pretreatment of cells with 1 mM NEM and 100 μ M monensin, both agents known to interfere with vesicular transport and release, almost completely abolished 1,25D-induced ATP exocytosis. By means of siRNA silencing of the vitamin D receptor (VDR), we demonstrated that a classic VDR is required for 1,25D potentiation of Ca²⁺ and Cl⁻ channels coupled to ATP exocytosis. In addition, we found that an increase in intracellular Ca²⁺ induced by 1,25D is also required for 1,25D-mediated ATP secretion. The L-type Ca²⁺ channel blocker nifedipine (2 μ M) reduced 1,25D induction of ATP exocytosis by about 80%, while the L-type Ca²⁺ channel agonist S(-) BayK8644 (0.5 μ M) and depletion of internal calcium stores with thapsigargin (3 μ M) caused a significant increase in ATP release. Involvement of 1,25D-induced increase in intracellular Cl⁻ in 1,25D-mediated ATP release was determined by pretreatment of cells with the Cl⁻ channel blocker DIDS (200 μ M). We found that DIDS almost completely inhibited the 1,25D-induced ATP secretion. Furthermore, siRNA silencing of the CIC-3 voltage-gated chloride channel in ROS 17/2.8 cells significantly reduced 1,25D-stimulation of ATP release. Our findings provide for the first time, a signaling mechanism for the rapid release and increase of localized ATP concentrations in bone, and its regulation by the steroid hormone 1,25D.

Dominant-Negative GCMB Mutations Cause Hypoparathyroidism. M. Mannstadt¹, G. Bertrand^{*2}, B. Grandchamp^{*2}, H. Jueppner¹, C. Silve². ¹Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, ²Faculté de Médecine, Hôpital Xavier Bichat, Paris, France.

Glial cells missing (GCM), which was first discovered in the fruit fly, belongs to a small family of transcription factors that are key developmental regulators. The rodent GCM ortholog, Gcm2, is exclusively expressed in parathyroid glands and was shown to be a key regulator of parathyroid gland development since mice homozygous for ablation of Gcm2 fail to form parathyroid glands and consequently develop hypocalcemia and hyperphosphatemia; heterozygous animals are phenotypically normal. Consistent with these findings, homozygous mutations in GCM2, the human homolog of Gcm2, provided a plausible explanation for several cases of familial autosomal recessive hypoparathyroidism; importantly, heterozygous carriers of these mutations were healthy. We now report the identification of heterozygous GCM2 mutations as the cause of autosomal dominant hypoparathyroidism in two unrelated families with several affected members; in both families, mutations in the genes encoding parathyroid hormone and the calcium-sensing receptor were excluded. Because of the dominant mode of inheritance, we therefore considered the possibility of dominant negative GCM2 mutations. Indeed, direct nucleotide sequence analysis of GCM2 led to the identification of two novel, heterozygous mutations in genomic DNA of the affected, but not in the unaffected individuals in each family. Both heterozygous GCM2 mutations are single nucleotide deletions within GCM2 exon 5 (c1389delT and c1399delC) that introduce a frame-shift resulting in the truncation of the C-terminal GCM2 region, which contains the putative transactivation domain. To further elucidate the mechanism through which these heterozygous GCM2 mutations cause autosomal dominant hypoparathyroidism, we tested in HEK and DF-1 cells whether the mutant GCM2 inhibits the actions of the wild-type transcription factor using a GCM2-activated luciferase reporter. These experiments demonstrated that both GCM2 mutants impaired dose-dependently the transactivation capacity and thus the biological activity of wild-type GCM2; when expressed alone, the mutants exhibited a reduced capacity to activate the reporter. These findings strongly indicate that the newly discovered GCM2 mutants have dominant-negative properties.

Luciferase reporter assay using chicken fibroblast DF-1 cells. Results from triplicate wells; bars denote standard deviation.

TβRI Inhibitor Rescues Uncoupled Bone Resorption and Formation Caused by TGF-β1 Mutations in Camurati-Engelmann Disease. X. Wu¹, Y. Tang¹, W. Lei^{*1}, W. Van Hul², T. R. Nagy^{*3}, M. Wan¹, X. Cao¹. ¹Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, ²Medical Genetics, University of Antwerp, Antwerp, Belgium, ³Nutrition Sciences, University of Alabama at Birmingham, Birmingham, AL, USA.

TGFβ1, the most abundant cytokine deposited in bone matrix, plays a critical role in bone, but its exact function in the bone milieu is still unclear. Previously, we found that TGF-β1 is activated during bone resorption to induce migration of osteoprogenitors for bone formation as a coupling factor. Camurati-Engelmann Disease (CED) is an inherited bone disease associated with amino acid substitutions in the latency-associated peptide (LAP), but not in the mature TGFβ1 peptide. In examining cellular function of six different CED-derived TGFβ1, we found that mutations in LAP cause premature release of mature TGFβ1 upon secretion. As a result, TGFβ1 mutants exhibit much more potent effects on migration of osteoprogenitors than WT TGFβ1, suggesting its potential disturbance of coupling of bone resorption and formation. Indeed, CED TGFβ1 mutants are hyperactive for inducing phosphorylation of Smad2 and luciferase transcription activity. To examine whether premature release of active TGFβ1 uncouples bone resorption and formation, we generated a CED mutant and WT TGFβ1 transgenic mice driven by 2.3 kb Col I osteoblast-specific promoter. High levels of active TGFβ1 were detected only in bone marrow and matrix of the TGFβ1 mutant mice. A typical progressive diaphyseal dysplasia was observed in the tibia of one month-old TGFβ1 mutant mice. More than 95% mice had tibial fractures by 3 months of age. X-ray and μCT analysis revealed that very high bone density was present at certain areas whereas severe bone resorption was shown at other regions, indicating that bone resorption and formation is uncoupled. No significant differences were observed in bone mineral density (BMD), osteoclast and osteoblast activity between WT and CED transgenic mice, suggesting that premature release of active TGFβ1 interrupts coupling in TGFβ1 mutant mice. Most importantly, treatment of TGFβ1 mutant mice with the inhibitor of TGFβ type I receptor (TβRI) for 6 weeks rescued the uncoupled bone resorption and bone formation and completely prevented tibial fractures in TGFβ1 mutant mice. Taken together, CED-derived TGFβ1 mutations cause premature release of active TGFβ1 as well as uncoupling bone resorption and bone formation. TβRI inhibitor could be used as a potential agent for the treatment of CED patients.

RUNX2 Trinucleotide Repeat Mutations Are Associated with Decreased Bone Density and Altered Protein Function. A. Stephens^{*1}, J. Doecke^{*1}, S. Ralston², R. Prince³, G. Nicholson⁴, P. Sambrook⁵, M. Osato^{*6}, N. Morrison¹. ¹School of Medical Science, Griffith University, Gold Coast, Australia, ²Rheumatic Diseases Unit, University of Edinburgh, Edinburgh, United Kingdom, ³Department of Endocrinology and Diabetes, University of Western Australia, Perth, Australia, ⁴Department of Medicine, Geelong Hospital, University of Melbourne, Geelong, Australia, ⁵Department of Rheumatology, Royal North Shore Hospital, St Leonards, Australia, ⁶Institute of Molecular and Cell Biology, Proteos, Singapore.

The RUNX2 transcription factor is essential for osteoblast differentiation and chondrocyte maturation. Rare mutations within RUNX2 cause the dominantly inherited skeletal disorder cleidocranial dysplasia which is characterized by gross dysgenesis of the skeleton. A unique feature of RUNX2 is the polyglutamine and polyalanine (poly Q/A) domain encoded by a trinucleotide repeat sequence. Such repeat sequences are prone to strand slippage resulting in high mutation rates. We hypothesized that mutations within the RUNX2 poly Q/A domain would exist and these variants would be associated with altered bone density and protein function. 4361 DNA samples were obtained from multiple epidemiological studies of bone density. Bone density was measured by DEXA and ultrasound and expressed as Z-scores around the appropriate age-adjusted mean. A total of 21 subjects were identified as being heterozygous for a wild type 23Q/17A allele and a poly Q/A repeat variant allele. Deletions (15Q and 16Q) and insertions (30Q and 23A) were identified. Collectively Q/A repeat variants presented with significantly lower Femoral Neck BMD (DEXA) displaying a 0.65 SD decrease ($n = 21$, $p = 0.0004$) and lower bone density as measured by quantitative ultrasound of similar magnitude (-0.79 SD, $n = 8$, $p = 0.031$). To understand the mechanism via which the rare mutations were decreasing bone density, functional analyses were carried out on 23Q (WT), 16Q and 30Q RUNX2. The ability of the proteins to bind to the RUNX2 DNA binding site was assessed by EMSA. The analysis did not reveal any obvious changes in the DNA binding capacities of the mutant proteins. However, reporter gene analysis using the mouse osteocalcin promoter revealed significant decreases in the transactivation function of 16Q and 30Q. Finally, the ability of the proteins to localise to the nucleus was assessed. Subcellular analysis revealed the 16Q and 30Q proteins displayed defective nuclear localisation compared to WT. We have identified a new class of functionally relevant RUNX2 variants that occur at collective frequency of ~0.5%. These mutations are associated with significantly lower bone density and altered protein function.

A Constitutively Activated BMP Receptor, ALK2, Induces Heterotopic Bone Formation in Patients with Fibrodysplasia Ossificans Progressiva (FOP). T. Fukuda¹, M. Kohda^{*2}, K. Kanomata^{*1}, J. Nojima¹, J. Kamizono^{*3}, H. Oda^{*4}, K. Nakayama^{*5}, A. Ohtake^{*6}, K. Miyazono^{*7}, E. Jimi⁸, I. Owan^{*9}, Y. Okazaki^{*2}, T. Katagiri¹. ¹Division of Pathophysiology, Saitama Medical Univ., RCGM, Saitama, Japan, ²Division of Translational Research, Saitama Medical Univ., RCGM, Saitama, Japan, ³Department of Pediatric Emergency, Kitakyusyu city Yahata Hospital, Fukuoka, Japan, ⁴Department of Orthopedic Surgery, Saitama Medical Univ., Saitama, Japan, ⁵Department of Endocrinology and Diabetes, Saitama Medical Univ., Saitama, Japan, ⁶Department of Pediatrics, Saitama Medical Univ., Saitama, Japan, ⁷Department of Molecular Pathology, Univ. of Tokyo, Tokyo, Japan, ⁸Department of Bioscience, Kyushu Dental College, Fukuoka, Japan, ⁹Department of Orthopedic Surgery, Univ. of Ryukyus, Okinawa, Japan.

Fibrodysplasia Ossificans Progressiva (FOP) is a rare autosomal dominant disorder of skeletal malformations and progressive heterotopic bone formation in muscle. Particularly, heterotopic bones were markedly induced in traumatic injury and inflamed area. Recently, the 617G>A and its related mutations were identified in ALK2, one of the BMP type I receptors, in patients with FOP. However, the functional changes of the mutant ALK2 proteins were not elucidated. In the present study, we examined genetic mutations of the ALK2 gene in Japanese patients with FOP and analyzed biochemical alterations of the mutant ALK2. The identical 617G>A heterozygous mutation, which causes a substitution mutation of Arg206 to His, was found in the ALK2 gene in all of the patients examined. Transient overexpression of ALK2(R206H) in C2C12 myoblasts induced phosphorylation and nuclear accumulation of Smad1/5/8 and transactivation of their target gene, Id1. ALK2(R206H) inhibited maturation of myoblasts to myosin heavy chain-positive myocytes. In contrast, ALP activity was synergistically induced by co-expression of ALK2(R206H) and Smad1 or Smad5 in C2C12 myoblasts. Treatment of C2C12 cells overexpressing ALK2(R206H) with BMP-4 or BMP-7 further increased the ALP activity. Co-transfection of Smad7, but not Smad6, suppressed the induction of ALP activity by ALK2(R206H). Moreover, we found that expression of the BMP signaling molecules were up-regulated during muscle regeneration *in vivo*. Taken together, these results clearly indicated that ALK2(R206H) is an active BMP receptor and constitutively transduces intracellular signaling of BMPs. It was also suggested that ALK2(R206H) cooperatively induces the heterotopic bone formation with BMP ligands and/or BMP signaling molecules induced at the sites of muscle regeneration. Smad7 might be a therapeutic target of FOP to inhibit BMP signaling induced by ALK2(R206H).

Regulation of the Transcription Factor Pitx1 and its Role in Osteoarthritis Pathogenesis. C. Picard^{*1}, B. Azeddine^{*1}, D. Wang^{*1}, J. Martel-Pelletier^{*2}, J. Fernandes^{*3}, F. Moldovan^{*4}, A. Moreau⁵. ¹Research Center CHU Sainte-Justine, Montreal, PQ, Canada, ²Osteoarthritis Research Unit, CHUM Hôpital Notre-Dame, Montreal, PQ, Canada, ³Research Center, Hôpital du Sacré-Coeur, Montreal, PQ, Canada, ⁴Department of Stomatology, Université de Montréal, Research Center CHU Sainte-Justine, Montreal, PQ, Canada, ⁵Department of Stomatology & Biochemistry, Université de Montréal, Research Center CHU Sainte-Justine, Montreal, PQ, Canada.

The presence of Pitx1, a homeodomain transcription factor, during development of periparticular regions giving rise to the hip and knee joints prompted us to investigate its putative role in Osteoarthritis (OA) pathogenesis. Our previous study demonstrated that partial inactivation of Pitx1 gene led to a progressive formation of OA-like lesions in aging Pitx1^{+/−} mice. Indeed, a loss of Pitx1 expression was observed only in cartilage of OA patients when compared to controls. The purpose of this study is to identify the mechanisms responsible for the down regulation of Pitx1 expression in primary OA. Search for mechanisms turning off Pitx1 expression led us to identify a mutation (−3727 C→T) present only in OA patients and localized into an E2F-response element within the human pitx1 promoter. Electrophoretic mobility shift assays were performed with nuclear extracts prepared from OA and matched control articular chondrocytes and allowed the detection of a protein complex bound to either the wild-type probe or the probe containing the mutated E2F-like site. Off-rate analysis revealed that such mutation increased the stability of the bound complex. To identify proteins part of this complex, we performed DNA pull down assays followed by peptide digestion coupled to mass spectrometry analysis, which allowed the detection of Prohibitin (PHB-1), Prohibitone (PHB-2) and BCL-6 interacting co-repressor (BCoR). PHB-1 plays a role in the maintenance of mitochondrial function and localizes as well as in the nucleus where it facilitates cellular senescence by recruiting specific co-repressors to inhibit E2F target genes. The pathophysiological relevance of PHB-1 was further supported by the detection of an aberrant nuclear accumulation of PHB-1 by immunohistochemistry methods only in OA articular chondrocytes, while the co-localisation *in vivo* of PHB-1 and BCoR on this E2F site was confirmed in OA articular chondrocytes by ChIP assays. The recruitment of this repressor complex was independent of the presence of the mutation suggesting that nuclear accumulation of PHB-1 could be a primary mechanism leading to OA onset. Collectively, these data define an unrecognized and crucial role for Pitx1 in OA pathogenesis and the recruitment of a novel repressor complex switching off its expression in OA.

Mice with a Truncation Mutation Affecting the UBA Domain of SQSTM1 Develop Several Phenotypic Features Paget's Including Focal Lytic Lesions, and Increased Bone Turnover In Vivo. J. A. Rojas^{*1}, A. Daroszewska^{*1}, R. Layfield^{*2}, M. Helfrich³, R. J. Van't Hof^{*1}, S. H. Ralston¹. ¹Rheumatic Diseases Unit, University of Edinburgh, Edinburgh, United Kingdom, ²Institute of Neuroscience, University of Nottingham, Nottingham, United Kingdom, ³Bone Research Group, University of Aberdeen, Edinburgh, United Kingdom.

Introduction: Paget's disease of bone (PDB) is characterized by focal increases in bone turnover and mutations affecting the Sequestosome 1 gene (SQSTM1) are an important cause of this condition.

Methods: Here we report upon our preliminary analysis of the skeletal phenotype of mice with a truncating mutation at codon 409 (S409X) of the SQSTM1 gene which deletes most of the UBA domain.

Results: We studied 6 wild type and 11 mutant mice carrying a S409X mutation of SQSTM1. Five were heterozygous and 6 were homozygous for the mutation. The age range of animals was 13.5 ± 0.25 months (range 12-15 months). Analysis of the femur and tibia by microCT examination ex-vivo showed large focal lytic lesions in 3/5 heterozygotes and 2/6 homozygotes, although smaller lytic lesions were observed in other mutants such that 9/11 of the animals which carried mutations (81.8%) had lytic lesions of the lower limbs. Three animals had more than one lytic lesion. Lesions of the type seen in the S409X mutant mice were not observed in control littermates. Histological analysis of lesions revealed evidence of increased bone turnover. Moreover bone histomorphometry of the tibial metaphysis showed a dramatic increase in bone turnover in homozygous mutants. There was a 3-fold increase in osteoclast number from 1.2 ± 0.5 /mm² in WT to 4.5 ± 0.8 /mm² in mutant ($p < 0.01$) and a two fold increase in eroded surface from 6.1 ± 2.0 % to 13.2 ± 1.8 % ($p < 0.01$). Osteoblast numbers were also increased from 15.2 ± 4.0 /mm² in WT to 37.5 ± 5.0 /mm² in mutant ($p < 0.01$). Studies in vitro showed a 8.6 ± 14.4 % increase in RANKL-induced osteoclast formation in mutant mice compared with WT ($p = 0.03$), but there was no difference in osteoblast growth between genotypes.

Conclusions: Mice carrying a S409X truncating mutation of the SQSTM1 gene exhibit several features that are reminiscent of PDB including increased bone turnover, focal lytic lesions in the lower limbs, and show increased osteoclast formation in vitro. Further studies are in progress to conduct more detailed characterisation of these mice but our data suggest that the S409X mutant mice may represent an animal model of PDB.

Is Bone Strength a Simple Function of Muscle, or Does Other Mechanical Loading Play a Role? J. N. Dowthwaite¹, P. P. E. Flowers^{*2}, J. A. Kanaley^{*3}, R. M. Hickman^{*1}, J. A. Spadaro¹, T. A. Scerpeila¹. ¹Orthopedic Surgery, SUNY Upstate Medical University, Syracuse, NY, USA, ²Engineering, Syracuse University, Syracuse, NY, USA, ³Exercise Science, Syracuse University, Syracuse, NY, USA.

Many researchers tout muscular forces as the primary impetus for bone formation, but weight-bearing and impact-loading may also yield bone adaptations. We hypothesize that childhood gymnastic loading is linked to high arm BMC, bone diameter and bone strength, independent of arm lean mass (FFM), a surrogate for muscle size.

The Institutional Review Board of SUNY Upstate Medical University approved the project, and subjects/guardians assented/consented to participation. Total body DXA and pQCT radius scans were performed on 33 post-menarcheal girls. Non-dominant arm FFM and BMC were measured by DXA (Hologic QDR 4500W). Non-dominant polar strength-strain indices (SSI) and total bone cross sectional areas (CSA) were measured by pQCT at 4% and 33% distal radius sites. Forearm length was measured with a ruler. Calcium intake was assessed by food frequency questionnaire. Gynecological age was calculated as time from menarche to scan date. Focal outcomes were: non-dominant total arm DXA BMC; pQCT SSIs, total bone CSAs and fall SSIs (SSI/ (weight * forearm length)) at 4% and 33% radius sites. Gymnasts and ex-gymnasts (ex/gymnasts) had spent at least 5 hours per week in gymnastic training for at least 2 years out of the past 10 years. ANOVA compared means for ex/gymnasts (n= 19) vs. non-gymnasts (n= 14); ANCOVA adjusted for gynecological age, calcium intake and arm FFM.

Age, maturity, body size and calcium intake did not differ by gymnastic group. Arm FFM was a strong, consistent correlate of bone outcomes ($R > 0.53-0.79$, $p < 0.003$). All bone outcomes were greater in ex/gymnasts than non-gymnasts with large effect sizes (all $p < 0.02$, Cohen's $d > 0.98$). Gymnastics effects were large regardless of ANCOVA adjustment ($p < 0.05$, Cohen's $d > 0.78$), but arm FFM adjustment tempered 4% CSA significance ($p = 0.08$, large $d = 0.67$). Muscle and bone properties are closely related, and arm FFM is a useful gauge of upper extremity bone characteristics. However, gymnastic exposure acts as an independent factor in bone growth, linked to elevated bone accrual, geometry and strength. Thus, mechanical loading from non-muscular sources is a distinct and important determinant of human skeletal structure.

Negative Effect of Dietary Protein Intake on Bone Mass Accretion in Chinese Pubertal Girls with Low Calcium Intake. Q. Zhang^{*1}, H. Greenfield^{*2}, G. S. Ma^{*1}, K. Zhu², X. Q. Du^{*2}, L. H. Foo^{*2}, X. Q. Hu^{*1}, C. T. Cowell^{*3}, D. R. Fraser^{*2}. ¹Chinese Center for Disease Control and Prevention, Beijing, China, ²University of Sydney, Sydney, Australia, ³Children's Hospital at Westmead, Sydney, Australia.

The aim of this study was to assess the relationship between background nutrient intakes and bone mass accrual in a longitudinal study including two-year milk supplementation trial and three-year follow-up study in Chinese pubertal girls.

Total 757 girls (aged 10.1 yr) were divided into three groups, supplied with either 330 ml calcium fortified milk (n=238) or milk fortified with calcium and vitamin D (n=260) on each school day for 24 mo, or consuming habitual diet without milk supplementation as controls (n=259). Over 24 mo, each subject consumed 144 ml/d supplementary milk on average, containing calcium 245 mg/d with/without vitamin D 3.33µg/d. Of 698 subjects completing the supplementation trial, 504 subjects agreed to be re-examined at 36 mo after supplement cessation.

All indices were measured at 0, 12, 24, 48 and 60 mo from the baseline. Bone mass of the forearm and whole body was measured with dual energy X-ray absorptiometry (DXA, Norland XR-36). Nutrient intakes were assessed by a three-day food record (including two weekdays and one weekend day).

Continuous variables were logarithm-transformed to observe the proportional association after adjustment for corresponding baseline value, pubertal development at baseline, age at each survey, physical activity percentage distribution at each survey, and clustering by schools. A linear mixed model in SAS program was used with $P < 0.1$ as the standard for retention in backward elimination regression. Subjects from all groups and subjects from the control groups (representing typical urban girls in China at puberty) were analyzed separately to identify the influential components.

Most positive effects of milk supplementation on total body and proximal forearm became significant after 24 mo supplementation, and disappeared at two or three yr after supplementation withdrawal. During the five-year study, the background calcium intake (440 mg/d on average, independently of that from the milk supplement) positively influenced bone mineral content (BMC) at total body (TB), proximal forearm (PF) and distal forearm (DF), bone area (BA) at PF and DF, as well as bone mineral density (BMD) at DF. However, negative associations were observed between protein intake (55 mg/d on average) and BMC at TB, PF and DF, BA at PF, as well as BMD at DF.

In summary, besides the effects of milk supplementation, a higher background calcium intake had a positive effect on bone mass accrual, while higher protein intakes appeared to diminish bone mass accrual in Chinese pubertal girls perhaps in association with their low calcium intakes.

Sexual Dimorphism in Radial and Longitudinal Bone Growth Differ by Tempo and Magnitude: A Study in Male-Female Co-twins Pairs. S. Iuliano-Burns¹, J. Hopper^{*2}, R. Zebaze¹, E. Seeman¹. ¹Endocrinology, Austin Health / University of Melbourne, West Heidelberg, Australia, ²Epidemiology, University of Melbourne, Parkville, Australia.

An individual's bone trait position on the sample distribution influences fracture risk. Fracture risk is lower in males than females, in part due to sex differences in bone achieved during growth. We studied within pair differences in bone structure and mass in 61 dizygotic (DZ) boy-girl twin pairs aged 7 - 18 years to test the hypothesis that sexual dimorphism in bone traits emerge at puberty and are negligible prior to puberty. Total body and posterior anterior lumbar spine (LS) BMC and mid-femoral shaft (FS) dimensions were measured using DEXA. Regional BMC was acquired for the total body scan. Height was measured using a Holtain Stadiometer, and limb lengths using a Harpenden anthropometer. 41 twin pairs were pre- and 20 pairs were or peri/post-pubertal based on Tanner staging (pubic hair, genital development). Within pair comparisons were performed using unpaired t-tests. Contrary to the hypothesis, sexual dimorphism in bone structure and BMC was evident before puberty. BMC was 2-8% greater in the male than female depending on the site measured ($p < 0.05$). LS width (not height) was greater in boys than girls before puberty (3.3 ± 0.03 v 3.0 ± 0.03 mm, $p < 0.001$). Similarly, mid-FS periosteal widths (not femoral length) were higher in boys than girls (15.6 ± 0.3 v 14.5 ± 0.3 mm, $p < 0.01$), resulting in greater slenderness (bone width / length) at the femur in females than males ($p < 0.1$, NS). These existing differences remained during and after puberty. Sexual dimorphism in BMC and structure is detectable prior to puberty challenging the notion that the dimorphism is driven only by differences in sex hormones.

Disclosures: S. Iuliano-Burns, None.

A School-based Physical Activity Intervention Positively Affects Change in Imax in Pre- and Early Pubertal Boys. H. M. Macdonald^{*1}, D. M. L. Cooper¹, S. A. Kontulainen², H. A. McKay¹. ¹Orthopaedics, University of British Columbia, Vancouver, BC, Canada, ²University of Saskatchewan, Saskatoon, SK, Canada.

Bone structural adaptations to physical activity during growth are not well understood. We previously reported a strong trend for greater gain in peripheral QCT (pQCT)-derived bone strength (density-weighted polar section modulus, SSI) at the tibial midshaft in boys who participated in a school-based physical activity intervention compared with control boys.¹ The objective of the present study was to further explore the structural adaptations underpinning the trend for bone strength gains. Participants were 202 boys aged 9-11 years from 10 schools that were randomly assigned to control (CON, 3 schools, n = 63 boys) and intervention (INT, 7 schools, n = 139 boys) groups. Boys in INT schools participated in 60 minutes of additional classroom physical activity each week, which included a simple, progressive, high-impact bone-loading program (Bounce at the Bell), over 11 months. We used ImageJ (1.37v) with a threshold of 480 mg/cm³ to process the grayscale pQCT images (XCT-2000) from the tibial midshaft (50% site) and determine the maximum and minimum second moments of area (Imax, Imin, mm⁴) and the cortical area (CoA, mm²) by quadrant (anterior, medial, lateral and posterior). The quadrants were defined according to the pixel coordinates about the cross-sectional centroid. We used a mixed linear model (group = fixed effect, school = random effect) to compare change in Imax, Imin and CoA (by quadrant) between CON and INT boys after adjusting for baseline bone value, change in tibial length and maturity at followup. Boys were 10.2 ± 0.6 years at baseline and the majority (60%) were prepubertal (Tanner stage 1). Boys in the INT group had a significantly greater gain in Imax than CON boys ($+ 365.7$ mm⁴; 95% CI: 83.5 to 647.9). Boys in the INT group also tended to have a greater gain in Imin, but the difference between groups was not statistically significant ($+ 109.3$ mm⁴; 95% CI: -25.4 to 243.9). Underpinning the greater gain in Imax in INT boys was a slightly greater gain (1-1.5%) in CoA in the anterior, medial and posterior quadrants although the differences between groups were not statistically significant. Change in CoA in the lateral quadrant was similar between CON and INT boys. Our school-based intervention effectively increased bending strength (Imax) at the tibial midshaft in young boys. Together with the tendency for quadrant-specific changes in CoA, these data suggest regional variation in the bone response to AS! BC. Our findings are consistent with expected patterns of bone formation induced by bending loads in the anterior-posterior direction.

High Protein Intake Enhances the Positive Influence of Physical Activity on Bone Mineral Content in Pre-Pubertal Boys. T. Chevalley, S. Ferrari, J. P. Bonjour, R. Rizzoli. Service of Bone Diseases, Department of Rehabilitation and Geriatrics, Geneva University Hospitals, Switzerland.

Physical activity is an important lifestyle determinant of bone mineral mass acquisition. Its influence during childhood can be modulated by nutrition, particularly by protein and calcium intakes. We analyzed the relationship between physical activity levels and protein intake, as compared to calcium intake, on bone mineral mass in 232 healthy pre-pubertal boys (age: 7.4 ± 0.4 yrs; standing height: 125.7 ± 5.9 cm; body weight: 25.3 ± 4.6 kg, mean \pm SD). Bone mineral content (BMC) was measured by dual X-Ray absorptiometry (DXA) at 6 skeletal sites: radial metaphysis; radial diaphysis; femoral neck; trochanter; femoral diaphysis and L2-L4 vertebrae. Physical activity, protein and calcium intakes were 242 ± 94 kcal.d⁻¹, 1.79 g.kg BW.d⁻¹ (a value about twice the usual recommended dietary allowance), and 752 ± 263 mg.d⁻¹, respectively. In univariate analysis, correlation coefficients r between physical activity, protein and calcium intakes, and the BMC sum of the 6 skeletal sites were 0.33 ($p=0.0001$), 0.26 ($p=0.0001$), and 0.16 ($p=0.013$), respectively. By multiple regression analysis, physical activity (β adjusted = 0.292, $p < 0.0001$) and protein intake (β adjusted = 0.224, $p=0.007$) remained correlated to BMC, whereas calcium intake was not (β adjusted = -0.027 $p=0.740$). Very similar results were found at the 6 individual skeletal sites. Within the group with protein intake above the median (2.0 g.kg BW.d⁻¹), increased physical activity from 168 to 321 kcal.d⁻¹ was associated with greater total BMC Z-score ($+0.6$, $p=0.0005$). In contrast, in the group with protein intake below the median (1.5 g.kg BW.d⁻¹) increased physical activity from 167 to 312 kcal.d⁻¹ was not associated with a significantly greater total BMC Z-score ($+0.2$, $p=0.371$). The interaction between physical activity and protein intake was close to statistical significance for total BMC Z-score ($p=0.055$) and total radius BMC ($p=0.054$), and significant for femoral neck BMC ($p=0.012$). In keeping with the results derived from multiple regression analysis, the increased physical activity on total BMC Z-score was not influenced by difference in calcium intake (above the median: i.e. 945 mg d⁻¹; below the median: i.e. 555 mg d⁻¹). No significant interaction ($p=0.754$) was detectable for total BMC Z-score as well as for any of the 6 skeletal sites between physical activity and calcium intake. In conclusion, in healthy pre-pubertal boys the influence in increased physical activity on bone mineral content appears to be enhanced by protein intake within a range above the usual recommended allowance.

Determinants of Bone Mass and Fracture in Adolescent Children: Early Life, Prepubertal and Current Factors. G. Jones, K. L. Hynes^{*}, S. Foley, J. Flynn^{*}. Menzies Research Institute, Hobart, Australia.

Fractures are common in children while variation in peak bone mass contributes approximately two thirds of fracture risk in later life. Reports in prepubertal children suggested that maternal smoking during pregnancy, breastfeeding and birth weight were all determinants of early bone mass and/or fracture but it is unclear if this persists through puberty. The aim of this study was to examine the role of early life, prepubertal and current factors in the determination of bone mass and fracture in adolescent male and female children.

During 2004/5, 415 16 year old Southern Tasmanian children were studied. Early life factors were available from a 1988 study of risk factors for SIDS (smoking during pregnancy, weight gain, age at birth, birthweight, duration of breastfeeding, period of gestation, anthropometrics and socioeconomic variables). Data were also available from age 8 (bone mass and body composition by DXA, physical activity, sun exposure). Bone mass was assessed at age 16 at the total body, femoral neck and spine using an Hologic Delphi densitometer and at the heel by a Sahara ultrasound densitometer. Fractures were collected by questionnaire (site, age, circumstances) with confirmation from medical records.

Of the 415 children, 160 (39%) had a fracture. In multivariate analysis, bone mass at age 16 was predicted by breastfeeding (3% higher at hip and total body), birth weight (hip and total body), lean mass, sports participation, shuttle run and standing long jump at age 8 (hip and total body) as well as bone mass at age 8. Fracture (particularly those involving the upper limb) was predicted by breastfeeding (HR yes v no 0.69, $p=0.02$) (but not birth weight) and bone mass at age 8 (total body and spine, HR 1.5-2.5/SD). No significant associations with either bone mass or fracture were present for maternal smoking during pregnancy or sun exposure at age 8. Both DXA and heel ultrasound measures at age 16 were also able to discriminate those with and without prevalent fracture (especially those involving the upper limb, OR 1.3-1.8/SD).

These unique data provide strong support to indicate that bone mass in adolescence can be influenced by environmental factors both breastfeeding in early life as well as during childhood where physical activity is most important. In addition, both breastfeeding during early life and bone mass assessed by DXA at age 8 were strong predictors of fracture while heel ultrasound is also reduced in those with fracture. These results suggest that osteoporosis and fracture prevention programs should commence very early in the life cycle.

Targeted Deletion of E11/gp38 in Osteocytes Results in Increased Skeletal Size and Bone Mineral Density. D. Guo^{*1}, Y. Mishina^{*2}, J. Feng¹, M. Ray^{*2}, G. Scott^{*2}, M. Harris³, L. Bonewald¹. ¹Oral Biology, UMKC, Kansas City, MO, USA, ²Molecular Developmental Biology, NIEHS, Research Triangle Park, NC, USA, ³Department of Periodontics, UTHSCSA, San Antonio, TX, USA.

As the osteoblast differentiates into an osteocyte, a dramatic change in morphology occurs from polygonal to dendritic. E11/gp38 is a membrane glycoprotein highly expressed in the embedding osteocyte that appears to be responsible for dendrite formation and elongation due to fluid flow shear stress. Therefore, we hypothesized that a reduction of E11 in the osteocyte would be detrimental as the cell would have less capacity for communication and viability. Conventional deletion results in lethality at birth due to a lung defect, therefore to determine function in osteocytes, postnatal targeted deletion of the E11 gene was performed by generation of E11 flx/flx mice (5' loxp site in SacI of exon 1 non-coding region, 3' loxp site in BstEII of intron 1) crossed with mice expressing the osteocalcin promoter driving CRE. The first cKO mouse showed approximately 10% greater body weight than its control littermate at 1 to 3 months of age. Bone mineral density was also 10–20% higher in the E11cKO mouse as determined by PIXIMUS analysis, confirmed by microCT and radiography. Histomorphometric analysis showed a 10% reduction in osteocyte density in ulnar cortical bone compared to control. To validate that E11 was deleted in bone, immunostaining was performed showing dramatic reduction in expression in bone. Furthermore, scanning electron microscopy of acid-etched ulnae embedded in resin revealed an irregular lacuno-canalicular network dramatically different from the uniformly distributed lacunae in control cortical bone. In addition to fewer lacunae, fewer canaliculi per lacunae were observed in the E11 cKO. These observations further support the role of E11 in dendrite formation, however suggest that a reduction in dendrite formation may actually maintain the osteoblast in the matrix producing stage for an extended time before embedment in matrix resulting in greater bone mass.

Dynamic Imaging of Fluorescently Tagged Osteoblast and Osteocyte Populations Integrates Mineralization Dynamics with Osteoblast to Osteocyte Transition. S. L. Dallas¹, P. A. Veno^{*1}, L. F. Bonewald¹, D. W. Rowe², I. Kalajzic^{*2}. ¹Univ. of Missouri Kansas City, Kansas City, MO, USA, ²Univ. of Connecticut Health Ctr, Farmington, CT, USA.

A well accepted model of osteocyte differentiation proposes that the osteoblast becomes trapped within an osteoid matrix, followed by mineralization of the matrix to entomb the osteocyte within its lacuna. Thus, osteocyte differentiation and bone mineralization occur simultaneously and may be interrelated. As a model to understand the dynamic process of osteocyte to osteoblast transition and how this integrates with mineralization, we have performed automated time lapse imaging in mineralizing bone cell cultures from transgenic mice with fluorescently tagged osteoblast and osteocyte populations. Calvarial cells from neonatal mice expressing a Dmp1-GFP transgene as a marker for osteocytes, a 3.6kb Col1a1-DsRed transgene as a marker for osteoblasts or both transgenes together, were cultured with ascorbate and β -glycerol phosphate (β GP) to promote mineralization. Mineral deposition was monitored using differential interference contrast optics or using alizarin red as a vital stain for calcium. Mineral deposition was found to occur exclusively at sites where small clusters of 4–20 cells expressed the Dmp1-GFP transgene and the boundary of the mineralized area followed the boundary of the GFP+ve cell clusters. The kinetics of mineralization were quantified by time lapse imaging in conjunction with thresholding of image stacks. After addition of β GP there was a lag phase of 10–20h followed by a rapid period of mineral deposition that lasted 10–14h before reaching a plateau. A large amount of membrane ruffling and mitosis within the nodule preceded mineral deposition. There was also a high degree of cell motility within the nodule, with a subpopulation of Dmp1-GFP+ve cells, presumably representing embedded cells, remaining stationary throughout the imaging period. A large number of cells switched on Dmp1-GFP expression just prior to or during mineralization, suggesting transition from an osteoblast to an osteocyte-like phenotype. The osteocytic nature of these cells was confirmed by immunostaining for the early osteocyte marker, E11. Interestingly, the Col1a1-DsRed and Dmp1-GFP transgenes identified two distinct cell populations with little overlap. The majority of cells that turned on the Dmp1-GFP osteocyte marker during mineralization were derived from a cell type that did not express high amounts of the Col1a1-DsRed transgene. Together, these data suggest that mineralization is directed by a cell type that is already transitioning into an osteocyte and suggest that mineralization and osteocyte differentiation are simultaneous, interrelated and possibly non-extricable processes.

Dynamic Imaging in Living Calvaria Reveals the Motile Properties of Osteoblasts and Osteocytes and Suggests Heterogeneity of Osteoblasts in Bone. P. A. Veno¹, D. P. Nicoletta², I. Kalajzic³, D. W. Rowe³, L. F. Bonewald¹, S. L. Dallas¹. ¹Univ. of Missouri Kansas City, Kansas City, MO, USA, ²Southwest Res. Inst., San Antonio, TX, USA, ³Univ. of Connecticut Health Ctr, Farmington, CT, USA.

Osteocytes, once thought to be quiescent cells, are now known to be mechanoresponsive, capable of modifying their microenvironment and play a key role in phosphate homeostasis. We have shown that osteocytes within their lacunae may be highly dynamic and show motions of their cell body and dendrites. To determine the dynamic interactions between osteoblasts and osteocytes and understand the role of cell motility in their function we have performed dynamic imaging using mice with fluorescently tagged osteocyte and osteoblast populations.

Calvarial explants from 5–12 day old mice expressing a Dentin matrix protein 1-GFP (Dmp1-GFP) transgene in osteocytes, a 3.6kb Col1a1-DsRed transgene in osteoblasts or both together, were imaged by time lapse fluorescent microscopy. Osteoblasts on the bone surface were highly motile and continually moved randomly with a mean velocity of 5.3 μ m/h. We have previously shown that this motility drives assembly of extracellular matrix proteins. Three distinct motile cell populations were observed on the bone surface. The majority of motile cells were red only (Col1a1DsRed+ve) with smaller populations that were green only (Dmp1GFP+ve) or red and green (GFP/DsRed dual expressing). 65% of the osteocytes showed motions of their cell bodies within their lacunae, with deformations between 4–12% and 98% of the osteocytes extended and retracted their dendrites. Alizarin red staining confirmed that these motions occurred in osteocytes within mineralized lacunae. Transient dendritic connections appeared to be made between adjacent osteocytes and between osteocytes and surface cells. Osteocytes also extended dendrites beyond their canaliculi into vascular channels and resorption pits and appeared to contact cells in these spaces. Osteocytes exposed during bone resorption underwent cell death or migrated out of their lacunae into the resorbed area. Dynamic imaging was next combined with immunostaining to correlate expression of specific markers with the motile history of the cell. In the case of E11, an early osteocyte marker, this revealed distinct cell populations. 75% of Dmp1-GFP+ve surface motile cells and 100% of the partially embedded osteocytes with dendrite motion expressed E11. In contrast, 14% of embedded osteocytes with dendrite motion were E11+ve.

These data suggest that osteocytes and osteoblasts are more motile than previously known and suggest heterogeneity of osteoblasts on the bone surface. A surface motile cell expressing Dmp1-GFP and E11 appears to represent a precursor cell that is destined to become an osteocyte.

Control of the SOST Bone Enhancer by PTH Via MEF2 Transcription Factors. O. Leupin^{*1}, I. Kramer^{*1}, N. M. Colette^{*2}, G. G. Loots^{*2}, F. Natt^{*1}, M. Kneissel¹, H. Keller¹. ¹Musculoskeletal Disease Area, Novartis Institutes for BioMedical Research, Basel, Switzerland, ²Chemistry, Materials and Life Sciences Directorate, Lawrence Livermore Laboratory, Livermore, CA, USA.

The SOST gene encodes for sclerostin, an osteocyte-secreted key inhibitor of bone formation. SOST expression is restricted to osteocytes in adult bone and requires the presence of a distant enhancer that is deleted in Van Buchem disease patients, which are characterized by a generalized progressive bone overgrowth. Parathyroid hormone (PTH) has been shown to suppress endogenous SOST expression in UMR-106 bone cells and in adult bone in vivo. Recently, we have reported that PTH completely inhibited the transcriptional activity of the SOST bone enhancer, but only marginally affected the proximal promoter using transient transfection reporter gene assays in UMR-106 cells. Footprint and functional mutation analysis revealed a myocyte enhancer factor 2 (MEF2) response element that is essential for enhancer activity. Furthermore, gel retardation assays and antibody-induced supershifts demonstrated direct binding of MEF2 transcription factors. Here, we show that the MEF2 response element is sufficient for enhancer activity. It conferred comparable enhancer activity as the full length enhancer sequence. Moreover, its activity was fully suppressed by PTH in a manner similar to the full length enhancer sequence. Expression of MEF2 transcription factors in bone was detected by quantitative RT-PCR and in situ hybridization. Expression levels of MEF2A, B, C and D in femur and UMR-106 cells were similar to those in heart and brain, two known MEF2-expressing tissues. Furthermore, immunohistochemistry demonstrated co-expression of MEF2s and sclerostin in UMR-106 cells and in osteocytes of adult bone in vivo. Overexpression of MEF2C in reporter gene assays had no effect on the activity of the proximal SOST promoter, but stimulated the SOST enhancer activity about 3-fold. Conversely, co-expression of a dominant negative MEF2C mutant protein inhibited enhancer activity by 55% in UMR-106 cells. Finally, siRNA-mediated knockdown of MEF2A, C and D suppressed endogenous SOST expression by 65, 59 and 84%, respectively, in UMR-106 bone cells. Combinations of siRNAs against MEF2A&C, A&D, C&D led to increased inhibition of SOST expression reaching levels similar to those observed with SOST-specific siRNAs. These data suggest that MEF2 transcription factors control SOST expression in osteocytes and mediate PTH responsiveness. Hence, MEF2 transcription factors are implicated in the regulation of adult bone mass.

Target Ablation of PTH/PTHrP Receptor in Osteocytes. P. P. Divieti¹, W. F. Powell^{*1}, T. Kobayashi¹, S. E. Harris², F. Bringhurst¹. ¹Endocrine Unit, Mass General Hospital, Harvard Medical School, Boston, MA, USA, ²Department of Periodontic, University of Texas Health Center at San Antonio, San Antonio, TX, USA.

Osteocytes are the most abundant cells in bone, but their relative inaccessibility and the lack of good in vitro cell models have impeded progress in understanding their functional roles. Parathyroid hormone (PTH) is known to act upon osteocytes via both PTH/PTHrP receptors (PPRs), specific for the amino-terminal PTH (and PTHrP) sequence, and CPTHrPs, which recognize amino-truncated forms of the hormone.

To study the role of PTH and PTHrP activation of PPRs in osteocytes we have conditionally ablated PPRs in osteocytes using the Cre-LoxP technique. We first generated three independent lines of transgenic mice in which the tamoxifen inducible Cre-recombinase (Cre-ERT2) is driven by an osteocyte-specific promoter (the 10Kb region of DMP1 promoter). The function, induction and specificity of the DMP1-Cre-ERT2 transgene was evaluated by mating male and female transgenics with homozygous Rosa26R Cre-reporter mice. The dams were injected with tamoxifen (2 mg) at day 17.5 dpc, and X-Gal staining was performed in newborn pups. All osteocytes were positive for the X-Gal staining demonstrating that the promoter was functional and Cre-dependent recombination could be fully induced upon tamoxifen injection. Cre-recombinase mRNA expression was confirmed by RT-PCR analysis of RNA from newborn calvarial bones. Two 10Kb-DMP1-Cre-ERT2 lines were mated with PPR(f/f) animals to create double heterozygotes, which then were mated with PPR(f/f) mice to generate DMP1-Cre/PPR(f/f) animals. To assess for PPR deletion in osteocytes we assessed down regulation of SOST expression in 4 and 8 week old mice (WT and PPRKO) fed a low calcium diet (0.2% Ca) for 1 or 2 weeks to induce secondary hyperparathyroidism. All animals were injected with tamoxifen (0.5 mg every 2 days for up to 2 weeks), and ionized and total calcium were measured at the end of the study period. Long bones and calvaria were fixed, decalcified and analyzed by immunohistochemistry for SOST expression. As expected, SOST expression remained readily detectable in KO mice but was greatly suppressed in WT animals, consistent with successful deletion of the PPR in osteocytes. Further studies to evaluate message levels of SOST and other PTH-regulated genes are currently underway. In summary, we have established a mouse model in which PPR expression can be specifically ablated in osteocytes. These mice will provide an excellent model to dissect the roles of PPRs in osteocytes. Furthermore, the 10Kb-DMP1-Cre-ERT2 mice can be used to delete additional genes of interest from this specific bone cell population

Mutations in LRP5 β -Propeller 1 Block Sclerostin (SOST) Mediated Inhibition of the LRP5-Wnt-TCF Signals in U2OS Osteoblast-like Cells. B. M. Bhat, V. E. Coleburn*, P. J. Yaworsky*, P. V. N. Bodine, S. Harada. Women's Health & Musculoskeletal Biology, Wyeth Research, Collegeville, PA, USA.

Loss of function mutations in the Sclerostin (SOST) gene are linked to Sclerosteosis and van Buchem disease which exhibit progressive growth of dense bone that can lead to clinical complications. However, heterozygous SOST mutations are clinically normal despite having high bone mass (HBM). The specific effect of SOST on bone formation was further demonstrated by increased bone mineral density in SOST knockout mice, osteopenia in SOST transgenics and complete reversal of ovariectomy induced bone loss in rats by SOST antibodies. Osteocyte secreted SOST was considered to be an antagonist of BMP-signaling, but recent studies indicate that this effect is preceded by the inhibition of LRP5-Wnt signaling. It is now well established that an HBM trait in humans is associated with mutations in LRP5 β -propeller 1, among its four β -propellers. Additionally, by in vitro studies we have shown along with others that the HBM-like mutations in LRP5 confer resistance to Dkk1, a secreted inhibitor of LRP5-Wnt- β -catenin signaling. Interestingly, Dkk1 interacts with LRP5 propellers 3 and 4 region while SOST binds to propellers 1 and 2. To investigate the LRP5-SOST interaction further, we studied several LRP5 mutants generated within all four β -propellers. These included the HBM-mutant LRP5G171V, and its structurally equivalent site mutants created within and outside the propeller 1. The analysis involved transient co-transfection assays using a Wnt- β -catenin responsive TCF-reporter and LRP5 or its mutant cDNAs in U2OS bone cells. In addition, we compared the potential role of Kremen2 in modulating Dkk1 and SOST function. Our results indicate that Kremen2 is essential for the inhibition of the LRP5-mediated TCF signal by Dkk1 while SOST mediated inhibition is Kremen independent. It is interesting to observe that Dkk1 and Kremen2 inhibited TCF activity of all three Wnts (1, 3a & 10b) tested while SOST inhibited only Wnt1 and Wnt10b. Out of the eight LRP5 mutants, only those in β -propeller 1 showed resistance to SOST and further supports the specificity of the SOST interaction with β -Propeller 1. In conclusion, the study demonstrates that inhibition of LRP5-Wnt- β -catenin signaling can be dependent on the co-expression of Kremens and the antagonists Dkk1 or SOST. Moreover, the analysis shows the importance of LRP5 β -propeller 1 and specific Wnts in SOST function. Continued investigations would lead to better understanding of LRP5 signaling and the role of different antagonists in maintaining bone homeostasis.

Increased Mortality in Patients with a Hip Fracture - Effect of Pre-morbid Conditions and Post-fracture Complications. P. Vestergaard^{*1}, L. Rejnmark², L. Mosekilde². ¹The Osteoporosis Clinic, Aarhus Amtssygehus, Aarhus, Denmark, ²Department of Endocrinology and Metabolism C, Aarhus Amtssygehus, Aarhus, Denmark.

Background: Patients with a hip fracture have a significant excess mortality. However, it remains unclear if the mortality is linked to the pre-morbid conditions or to complications to the fracture.

Aim: To investigate the causes of mortality after a hip fracture.

Material and methods: All subjects with a hip fracture in Denmark between 1977 and 2001 compared with three age- and gender-matched subjects from the general population. Co-morbidity at the time of fracture and causes of death were evaluated.

Design: Historic cohort study.

Results: A total of 169,145 fracture cases were compared to 524,010 controls. The cases had a much higher prevalence of co-morbidity than the controls. The mortality rate was twice as high in fracture cases compared with controls (HR=2.26, 95% CI: 2.24-2.27). Adjustments for confounders only changed the excess mortality risk little. The mortality after the hip fracture was divided into two categories: an excess mortality of 19% within the first year following the fracture (relative survival=0.81 compared to controls), and an excess mortality of 1.8% per year (relative survival 0.982) for every additional year following the fracture. The major causes of the excess mortality were due to complications to the fracture event (70.8% within the first 30 days). Elderly hip fracture patients were more likely to die from trauma related factors than younger patients.

Conclusions: Patients with a hip fracture have a pronounced excess mortality risk. The major cause was linked to the fracture event and not to pre-existing co-morbidity.

Risk of Subsequent Fracture Depends on Bone Mineral Density and Fracture Type: A 15-Year Prospective Study. D. Bliuc, N. Nguyen, T. V. Nguyen, J. A. Eisman, J. R. Center. Bone and Mineral Program, Garvan Institute of Medical Research, Sydney, Australia.

Half of all fractures occur in people with non-osteoporotic BMD (T-score > -2.5). Any osteoporotic fracture increases re-fracture risk, yet, there is no information on re-fracture risk for different T-scores and how normal or osteopenic BMD affects that risk. This study therefore aimed to examine re-fracture risk according to BMD for all types of osteoporotic fractures in 1374 women and 871 men aged 60+ from the Dubbo Osteoporosis Epidemiology Study (April 1989 - May 2005).

BMD was measured at baseline at spine and hip, and all osteoporotic fractures and deaths were recorded. Fractures were classified into hip, vertebral, major (proximal humerus, distal femur, proximal tibia, pelvis, multiple rib) and minor (all other peripheral fractures excluding digits). Subsequent fracture rates were calculated according to gender, fracture type, and BMD T-score and compared with initial fracture rate of a BMD-matched group. There were 520 incident fractures in women (35% osteopenia and 57% osteoporosis) and 198 in men (44% osteopenia and 25% osteoporosis) during 14,203 and 9,709 person-years, respectively. Following initial fracture 176 women and 48 men had subsequent fractures (2683 and 808 person-years, respectively).

Absolute re-fracture risks were highest for women and men with osteoporosis [86 (72-103) and 135 (87- 209); RR: 1.4 (1.1- 1.7) and 2.9 (1.7- 4.9), respectively] and still increased for osteopenia [40 (30- 55) and 52 (32- 83); RR: 1.5 (1.1- 2.1) and 2.5 (1.5- 4.3) respectively], but for those with normal BMD there was no significant increase in re-fracture risk [RR: 2.1 (0.9- 4.6) and 1.7 (0.8- 3.7) respectively]. As for overall re-fracture risk the increase in relative risk was 2-fold higher for men than women.

In women and men with hip and vertebral fracture¹, re-fracture risk was increased irrespective of BMD, except in the few men with normal BMD where over 50% died within 3 years.

There was an overall increased re-fracture risk following initial fracture in women and men with osteopenia and osteoporosis. Hip and vertebral fractures were associated with the highest re-fracture risk. Neither women nor men with normal BMD had an increased re-fracture risk following minor fractures. These results should help guide physicians in treatment decisions following initial fracture.

Decline in Age Adjusted Hip Fracture Incidence but a Drastic Increase in Hip Fractures Among the Very Oldest. Hip Fracture Curve Is Right-shifting. U. Bergström¹, Y. Gustafson², H. Jonsson¹, U. Pettersson¹, O. Svensson¹. ¹Dept of Orthopaedics, Umeå, Sweden, ²Dept of Community Med. and Rehab. Geriatric Medicine, Umeå, Sweden.

Introduction: Hip fracture incidence decreases in Europe and N. America. Is there a decreasing trend in all age groups or is just the fracture curve drifting?

Material and methods: This population-based material includes all hip fracture patients 1993-2005, ≥50 years, admitted to Umeå University Hospital: a total of 2,919 (31% men). The absolute numbers of fractures and incidence were mean value over the time periods 93-96 and 01-05.

Results: The overall hip fracture incidence was showing a declining trend, for the periods 93-96, 97-00 and 01-05: for women (men) 706 (390), 709 (314), and 625 (317) hip fractures per 100,000. However, the absolute numbers of hip fractures per year did not change over time. A 50% increase in absolute fracture rate was noted in women age 90 or older (11.5 hip fractures/year (93-96) and 24.6 hip fractures/year (01-05). The latter fracture rate can be compared with the absolute number of hip fractures in women age 75-79 (27.2 fractures/year 01-05) (Table 1). The incidence was also increasing during this period of time, from 2700/100,000 to 3900/100,000 among the women ≥ 90 years (Table 2). In men there were a declining trend in both incidence and absolute numbers, only a small increase of absolute fractures were noted among men ≥ 90 years.

Conclusion: Though the absolute incidence shows a declining secular trend, the absolute fracture rate and incidence are increasing among the very oldest. Women ≥ 90 now account for the same number of hip fractures every year as women 75-79 years. There seems to be a right shift and skewing of the hip fracture distribution towards the very oldest. This is probably due to the increased number of the octo- and nonagenarians, perhaps also to a better general- and bone health among the septuagenarians. This changed pattern will further strain the scarce orthopaedic and geriatric resources- surgery is more technically demanding, and local and general complications are much more common than in younger.

Disclosures: U. Bergström, None.

Ethnic Variations in Hip Geometry Among Women at Baseline from the Women's Health Initiative. D. A. Nelson¹, T. J. Beck², C. E. Lewis³, T. Bassford⁴, J. A. Cauley⁵, M. S. LeBoff⁶, S. B. Going⁴, Z. Chen⁴. ¹Wayne State University, Detroit, MI, USA, ²Johns Hopkins University, Baltimore, MD, USA, ³University of Alabama, Birmingham, AL, USA, ⁴University of Arizona, Tucson, AZ, USA, ⁵University of Pittsburgh, Pittsburgh, PA, USA, ⁶Brigham and Women's, Boston, MA, USA.

The risk of osteoporotic fracture varies among ethnic groups in the U.S., presumably due to differences in bone mechanical strength. African Americans suffer fewer osteoporotic fractures than whites although fracture susceptibility is less well studied in other groups. Our objective was to describe ethnic differences in bone geometry, and possible contributing factors, using hip structure analysis (HSA) of the femoral neck (FN), shaft (FS) and intertrochanteric (IT) regions based on data from the Women's Health Initiative (WHI). Baseline data included DXA of bone and soft tissue, body size, lifestyle, and medical history in 10,516 women representing four ethnic groups (non-Hispanic White-NHW, African-American-AA, Mexican-American-MA, Native-American-NA), ages 50 to 79. Geometry was adjusted for age, height, weight and % lean mass (see FN results in Table).

Hip geometry measurements in FN region (adjusted)	NHW (N=8206)		AA (N=1476)		MA (N=704)		NA (N=130)	
	Mean	SD	Mean	SD	Mean	SD	Mean	SD
Cross sectional area (cm ²)	2.04	0.003	2.15*	0.008	2.03	0.012	2.07	0.028
Outer diameter (cm)	3.02	0.216	2.98*	0.005	3.02	0.008	3.01	0.018
Section modulus (cm ³)	0.916	0.002	0.948*	0.004	0.904	0.006	0.916	0.015
Buckling ratio	12.6	2.937	11.7*	0.070	12.6	0.100	12.4	0.23

*P<0.001 vs. NHW

Compared to NHW, AA women had consistently narrower femora with smaller buckling ratios at all regions. Geometric strength differences were variable: bending resistance (section modulus) was higher in FN but lower in IT and FS, while axial resistance (bone cross-sectional area) was higher in the FN and IT and lower in the FS. Neither MA nor NA women differed from NHW at the FN, but both had higher axial and bending resistance at the IT. MA women had slightly higher bending resistance at the FS. There appear to be ethnic differences in size adjusted femur strength parameters but the clearest advantage for AA women is in their lower buckling ratio. This suggests that they may be less susceptible to loss of strength due to local buckling compared to NHW. Geometric strength differences in MA and NA compared with NHW are less clear and are reduced by adjustment for selected skeletal dimensions in the hip.

Disclosures: D.A. Nelson, None.

Risk Factors for Falls in Older Community-dwelling Women. K. A. Faulkner¹, J. A. Cauley¹, J. M. Zmuda¹, D. P. Landsittel², S. R. Cummings³, S. A. Studenski⁴, M. C. Nevitt³. ¹Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, ²Duquesne University, Pittsburgh, PA, USA, ³University of California San Francisco, San Francisco, CA, USA, ⁴University of Pittsburgh, Pittsburgh, PA, USA.

Identifying risk factors for a single fall is difficult due to accidents. The purpose of the study is to identify risk factors for more frequent incident falls among women with no recent history of falling. Study participants included 9,704 older community-dwelling women who were enrolled in the Study of Osteoporotic Fractures. The analysis sample consisted of 6,750 women (70% of median age (IQR) =72 years (67-75) who had no history of falls in past 12 months. A wide range of potential risk factors were assessed at baseline including 1) age, body mass index (BMI), height and education, 2) medical conditions, 3) medications, 4) lifestyle and 5) neuromuscular function. Data on the number of falls were self-reported every four months using post-card mailings over four years (97% complete) and fall rates were calculated (# falls/woman-years). Poisson regression models with Generalized Estimating Equations were used to calculate the Risk Ratio (RR), or ratio of fall rates. Step-wise building of a multivariate model was performed from 46 potential risk factors that all were minimally adjusted for age, clinic, height, BMI, and education. In the analysis sample including non-fallers at baseline, the average annual fall rates were 344 falls per every 1,000 woman-years. We identified the several risk factors for more frequent falls (p<0.05 for all), including having a high school education (RR= 1.03, vs. no high school education), higher number of Instrumental Activities of Daily Living (IADLs) with difficulty (RR=1.14, per 1 IADL), faster usual-paced walking speed (RR=1.07, per 1 SD), self-reported physician diagnosis of arthritis (RR=1.11), self-reported fear of falling (RR=1.22), and the current use of antidepressants (RR=1.25) and anticonvulsants (RR=1.46). Protective factors for more frequent falls (p<0.05 for all) included taller height (RR= .95, per 2 inches) and a higher number of step-ups completed in 10 seconds (RR=.93, per 1 SD). The RR indicates the increased risk (or decreased risk) in the average rate of falling that is associated with a given factor. Hence, the use of antidepressant and anticonvulsant medications is associated with fall rates 22% and 46% higher, respectively, compared to not using the medications. In conclusion, among older women with no recent history of falls, potentially modifiable risk factors for more frequent falls include the use of antidepressant and anticonvulsant medications, fear of falling, weaker muscle power and poorer functional status.

Age Effects on Hip Structure: Results in 636 WOMEN AGED 20 to 97. J. K. Brown¹, C. E. Cann^{*1}, R. L. Prince². ¹Mindways Software Inc., Austin, TX, USA, ²Sir Charles Gairdner Hospital, Perth, Australia.

The effects of age on three dimensional bone structure remains uncertain. 636 women, recruited from ten centres across the USA, had a standard, clinical, whole-body CT scan to develop reference data for QCT for regulatory purposes. Slices were taken at 2.5 - 3.0 mm intervals, pixel size 0.75mm and results normalized using a proprietary phantom. Images were analysed using Mindways CTXA Hip Version 3 software with partial volume correction. The CV error for the various measures was under 3%. The data relating bone structure to age is shown in the table.

Total Hip Site	Age Standardised Coefficient	Age ⁻¹ Standardized Coefficient	R ²
Total Mass	0.69 ^{xx}	-1.02 ^{xxx}	0.12
External volume	0.70 ^{xx}	NS	0.12
Total volumetric density	NS	-0.64 ^{xxx}	0.38
Cortical mass	0.66 ^{xx}	-1.02 ^{xxx}	0.19
Cortical volume	0.52 ^{xx}	-0.93 ^{xxx}	0.19
Cortical volumetric density	0.93 ^{xxx}	-0.79 ^{xxx}	0.04
Trabecular mass	0.47 ^{xx}	-0.60 ^{xxx}	0.30
Trabecular volume	0.47 ^{xx}	NS	0.30
Trabecular volumetric density	-0.47 ^{xx}	NS	0.44

^{xx} P < 0.01, ^{xxx} P < 0.001

Bone mass in the various compartments decreased with age as a quadratic by about 40% from age 20. The external bone volume and trabecular (marrow) volume increased with age linearly from age 20 by about 30%, while the cortical volume decreased with age as a quadratic. Volumetric density decreased with age in the total and trabecular compartment, but the cortical volumetric density data increased slightly with age. The changes at the total hip were representative of the changes at the femoral neck, trochanter and intertrochanter sites except for trochanter trabecular mass which was constant with age.

Bone mass at the hip falls from age 20 but the rate increases with age probably reflecting an effect of estrogen deficiency at menopause. However the external size of the hip increases from age 20 likely independent of changes in sex hormone levels. The cortical mass and volume decrease with age in such a way that there is little apparent change in cortical density consistent with thinning of the cortex with age.

Thus age effects on hip bone mass differ in critical respects to age effects on bone volume. Increases in external volume throughout life may increase bone strength and delay the onset of hip fracture.

Efficacy and Safety of Zoledronic Acid 5 mg in Preventing Fractures in Men and Women With Prevalent Hip Fracture: The HORIZON-Recurrent Fracture Trial. K. Lyles¹, C. Colon-Emeric^{*1}, J. Magaziner², J. Adachi³, C. Pieper^{*1}, L. Hyldstrup^{*4}, C. Mautalen⁵, C. Recknor⁶, K. Moore^{*1}, C. Lavechia^{*7}, J. Zhang^{*7}, P. Mesenbrink^{*7}, E. Eriksen⁸, S. Boonen⁹. ¹Duke Univ Med Ctr, Durham, NC, USA, ²Univ of Maryland, Baltimore, MD, USA, ³McMaster Univ, Hamilton, ON, Canada, ⁴Hvidovre Hospital, Univ of Copenhagen, Copenhagen, Denmark, ⁵Centro de Osteopatias Medicas, Buenos Aires, Argentina, ⁶United Osteoporosis Centers, Gainesville, GA, USA, ⁷Novartis Pharmaceuticals Corp, East Hanover, NJ, USA, ⁸Novartis Pharma AG, Basel, Switzerland, ⁹Univ of Leuven, Leuven, Belgium.

Hip fractures put patients at risk for future fracture and increased mortality. HORIZON-RFT is an international, multicenter, randomized, double-blind, placebo-controlled, parallel group trial assessing whether zoledronic acid (ZOL) 5 mg reduces subsequent clinical fractures in men and women ≥50 yrs of age with a prevalent hip fracture. Inclusion/exclusion criteria as previously described (Colon-Emeric et al. CMRO 2004;20:903). Patients received loading dose vitamin D2 or D3 and daily supplements of 800-1200 IU vitamin D3 and 1000-1500 mg elemental calcium. Patients were followed until 211 had experienced confirmed new clinical fractures (the primary efficacy endpoint). Of 2127 patients randomized, 2111 were treated with once-yearly IV infusions of ZOL 5 mg (N=1054) or placebo (PBO; N=1057). Baseline characteristics were similar between groups. Median age was 76 yrs (range, 50-98); 76% were women. Clinical fractures occurred in 231 patients (92 ZOL, 139 PBO) for a 2-yr cumulative event rate of 8.59% (ZOL) and 13.88% (PBO), based on Kaplan-Meier estimates, and a relative risk reduction of 35% (HR=0.65; 95% CI: 0.50-0.84; P=.0012). ZOL reduced risk for clinical vertebral and non-vertebral fractures relative to PBO by 46% (HR=0.54; 95% CI: 0.32-0.92; P=.0210) and 27% (HR=0.73; 95% CI: 0.55-0.98; P=.0338), respectively. ZOL reduced risk of hip fractures by 30% relative to PBO (HR=0.70; 95% CI: 0.41-1.19; P=.1815 [NS]). Overall incidence of AEs and SAEs was comparable between treatment groups. No significant differences were seen in any cardiovascular parameters or long-term renal function. No cases of ONJ were reported. Death occurred in 101/1054 ZOL patients (9.58%) vs 141/1057 PBO patients (13.34%), yielding a 28% lower mortality risk in ZOL relative to PBO (HR=0.72; 95% CI: 0.56-0.93, P=.0117). In conclusion, this trial showed that subjects with a prevalent hip fracture treated with an annual IV infusion of ZOL experienced significantly fewer clinical fractures compared with placebo. In addition, ZOL had a favorable safety profile and was well tolerated. Finally, this is the first trial to demonstrate a mortality benefit for an antiresorptive agent.

Risk Factors for Serious Adverse Events (SAEs) of Atrial Fibrillation in the HORIZON-PFT Trial of Zoledronic Acid. S. R. Cummings¹, P. Mesenbrink^{*2}, E. F. Eriksen³, R. Eastell⁴, D. M. Black⁵. ¹San Francisco Coordinating Center, C.P.M.C. Research Institute and University of California, San Francisco, San Francisco, CA, USA, ²Novartis Pharmaceuticals Corp, East Hanover, NJ, USA, ³Novartis Pharma AG, Basel, Switzerland, ⁴University of Sheffield, Sheffield, United Kingdom, ⁵San Francisco Coordinating Center, University of California San Francisco, San Francisco, CA, USA.

Findings from 2301 HORIZON-PFT Trial of zoledronic acid in postmenopausal women with osteoporosis (but not the 2310 Trial in elderly women with hip fracture) and from the Fracture Intervention Trial (FIT) of alendronate raise a possibility that use of bisphosphonates (BPs) might be associated with an increased risk of atrial fibrillation SAEs (defined as events resulting in hospitalization, disability, or judged to be life-threatening).

The 2301 Trial included 7714 women with osteoporosis treated with annual infusions of 5 mg of zoledronic acid or placebo for 3 years. Women who had taken a bisphosphonate for ≥1 year must have stopped for at least 2 years before enrollment. Previous bisphosphonate use was reported by 1161 or 14.5% of participants (type, dose and duration were not recorded). Arrhythmias were adjudicated by a panel of cardiologists. In an exploratory analysis using this dataset, we selected the best set of risk factors for atrial fibrillation by building stepwise proportional hazards models from age, baseline cardiovascular history, prior BP use and other potential risk factors after fixing treatment and study stratum into the model.

Significant risk factors for atrial fibrillation SAEs included congestive heart failure (CHF), tachyarrhythmia, age and previous use of bisphosphonates. The incidence of atrial fibrillation SAEs was 2.2% with prior BP use vs. 1.6% for no use. In an additional analysis, prior bisphosphonate use was not significantly associated with all (serious and non-serious) atrial fibrillation AEs.

Risk Factors for Atrial Fibrillation Serious Adverse Events		
Factor	Hazard Ratio (95% CI)	P-value
Treatment*	2.35 (1.43, 3.88)	0.001
Age (per year)	1.07 (1.02, 1.11)	0.002
CHF	2.86 (1.12, 7.25)	0.028
Tachyarrhythmia	6.01 (3.23, 11.2)	<0.001
Past BP use	1.81 (1.05, 3.13)	0.034

*Assignment to zoledronic acid vs. placebo

Older women with CHF and tachyarrhythmias have an increased risk of atrial fibrillation. This observational analysis suggests that women who have previously used bisphosphonates might have an increased risk for atrial fibrillation SAEs. This possibility needs additional investigation.

Efficacy of Continued Alendronate for Fractures in Women without Prevalent Vertebral Fracture: The FLEX Trial. A. V. Schwartz¹, D. C. Bauer¹, J. A. Cauley², K. E. Ensrud³, L. Palermo¹, R. B. Wallace^{*4}, M. C. Hochberg⁵, A. C. Feldstein⁶, A. Lombardi⁷, S. R. Cummings⁸, D. M. Black¹. ¹University of California, San Francisco, San Francisco, CA, USA, ²University of Pittsburgh, Pittsburgh, PA, USA, ³VA Medical Center & University of Minnesota, Minneapolis, MN, USA, ⁴University of Iowa, Iowa City, IA, USA, ⁵University of Maryland, Baltimore, MD, USA, ⁶Kaiser Permanente Northwest Center for Health Research, Portland, OR, USA, ⁷Merck & Co. Inc., Rahway, NJ, USA, ⁸California Pacific Medical Center, San Francisco, CA, USA.

The Fracture Intervention Trial (FIT) found that 4 years of alendronate (ALN) in women without prevalent vertebral fracture reduced the risk of non-vertebral fractures (NVF) in those with femoral neck (FN) T-score ≤ -2.5 but not in those with higher BMD. In the main results of the FIT Long Term Extension trial (FLEX), 10 years of ALN did not significantly reduce the risk of NVFs, compared with 5 years of ALN. Continuing ALN reduced the risk of clinical vertebral fractures but not the risk of x-ray defined vertebral fractures. We tested whether the long term effect of ALN on fracture among women without a prevalent vertebral fracture differs by FLEX baseline FN T-score.

In FLEX, 1099 women randomized to ALN in FIT (mean previous duration 5 years) were re-randomized to placebo (40%) or ALN 5 (30%) or 10 (30%) mg/d for an additional 5 years. The ALN groups were combined in these analyses. At FLEX baseline, 723 women (66%) did not have a prevalent vertebral fracture. We analyzed fracture results in this group, excluding 3 women without baseline hip BMD. Interaction models used continuous FN T-score.

Among women without vertebral fracture at FLEX baseline, we found significant

interactions between FLEX baseline FN T-score and treatment for NVF (table). Continuation of ALN reduced NVF in women with FLEX baseline FN T-score ≤ -2.5 but not in women with T-score > -2 . Results for clinical vertebral or morphometric vertebral fracture did not differ significantly by FN T-score at FLEX baseline.

Risk (95% CI) of Non-Vertebral Fracture among Women without Prevalent Vertebral Fracture			
FLEX Baseline FN T-score	N	Risk Difference	Relative Risk
FN T > -2	333	4.01% (-3.22, 11.24)	1.41 (0.75, 2.66)
-2.5 $<$ FN T ≤ -2	203	-3.46% (-13.30, 6.39)	0.79 (0.37, 1.66)
FN T ≤ -2.5	184	-13.32%* (-25.46, -1.18)	0.50* (0.26, 0.96)
Interaction (p-value)		0.049	0.019

*p<0.05

This post hoc analysis suggests that continuing alendronate for 10 years instead of stopping after 5 years reduces the risk of non-vertebral fracture in women without prevalent vertebral fracture whose FN T-score, achieved after 5 years of ALN, is ≤ -2.5 , but does not reduce risk of NVF in women whose T-score is > -2 . These results are similar to those previously reported for 4 years of ALN use.

Giant Osteoclast Formation After Long-Term Oral Aminobisphosphonate Therapy for Postmenopausal Osteoporosis. R. S. Weinstein, T. M. Chambers*, E. A. Hogan*, W. W. Webb*, C. A. Wicker*, S. C. Manolagas. Center for Osteoporosis, Central Arkansas Veterans Healthcare System, Univ of Ark for Med Sci, Little Rock, AR, USA.

Treatment of postmenopausal osteoporosis with aminobisphosphonates leads to progressive increases in bone density and a reduction in the incidence of new fractures. The efficacy of these drugs is believed to result from their ability to promote osteoclast apoptosis. However, bone specimens taken from non-human primates and patients treated with long-term aminobisphosphonates often show little or no effect of the drugs on the number of osteoclasts. We examined bone biopsies from 26 women with postmenopausal osteoporosis after a 3-yr double-blind, randomized, placebo-controlled trial of 10 mg/d of oral alendronate (ALN) for the prevention of postmenopausal bone loss. We report that in the subjects receiving ALN, osteoid perimeter, bone formation rate and biochemical markers of bone remodeling decreased whereas bone density increased as expected. Strikingly, osteoclast number was significantly increased in the subjects receiving ALN compared with those receiving placebo: 0.114 osteoclasts per mm cancellous perimeter \pm 0.078 SD, $n = 9$ vs. 0.059 \pm 0.038, $n = 17$, $p = 0.012$. In the ALN group, most of the osteoclasts were in superficial resorption cavities. Unexpectedly, giant osteoclasts were present in 4 out of the 9 (44%) of the ALN-treated subjects. Specifically, in these 4 subjects, 19% (13/68) of the osteoclasts observed were unusually large and had as many as 15 to 30 nuclei, as compared to 3 to 8 nuclei in the normal-sized osteoclasts of the placebo group. None of the subjects receiving placebo exhibited such cells (0/91). The atypical osteoclasts were partially detached from bone and they were clearly separated from the cancellous bone by unidentified mononuclear cells interspersed between them and the bone surface. In addition, the ruffled borders of the giant cells were distorted or missing. Further, the giant osteoclasts demonstrated positive nuclear in situ end labeling (ISEL) indicative of apoptosis, as well as nuclear condensation, fragmentation and peripheral beading. We conclude that long-term treatment with ALN decreases osteoclast resorptive ability rather than number, possibly by disrupting the ruffled border. Moreover, such treatment gives rise to a previously unrecognized cell phenotype: an apoptotic, excessively nucleated, colossal osteoclast, with apparent resistance to the phagocytosis that normally results from the detachment of cells from the bone matrix. Although these abnormal cells may well be dysfunctional and of no direct danger to the patient, awareness of the condition is crucial because giant osteoclasts could lead to a mistaken diagnosis of Paget's disease or hyperparathyroidism.

Effect of Daily Oral Minodronate on Vertebral Fractures in Japanese Postmenopausal Women with Established Osteoporosis: A Randomized Placebo-Controlled Double-Blind Study. T. Matsumoto¹, H. Hagino², M. Shiraki³, M. Fukunaga⁴, T. Nakano⁵, K. Takaoka⁶, H. Morii⁶, Y. Ohashi⁷, T. Nakamura⁸. ¹University of Tokushima Graduate School of Health Biosciences, Tokushima, Japan, ²Tottori University, Yonago, Japan, ³Research Institute and Practice for Involuntional Diseases, Nagano, Japan, ⁴Kawasaki Medical School, Okayama, Japan, ⁵Tamana Central Hospital, Kumamoto, Japan, ⁶Osaka City University, Osaka, Japan, ⁷University of Tokyo, Tokyo, Japan, ⁸University of Occupational and Environmental Health, Kitakyushu, Japan.

Minodronate (ONO-5920/YM529), a potent bisphosphonate, has been shown to increase the lumbar bone mineral density (BMD) of postmenopausal women with established osteoporosis. However, its efficacy in reducing osteoporotic fractures has not been evaluated. The present study was undertaken to examine the efficacy and safety of daily oral minodronate on the risk of vertebral and other fractures in subjects with established osteoporosis.

Seven hundred and four postmenopausal Japanese women at 55 to 80 years of age with one

to five vertebral fractures and BMD below 80% of the young adult mean were enrolled in this study. The subjects were randomly assigned to receive either daily 1 mg minodronate ($n=359$) or placebo ($n=345$) for 26 months. All the participants received daily supplements of 600 mg calcium and 200 IU vitamin D₃. Daily oral 1 mg minodronate for 26 months, compared with placebo, reduced the cumulative incidence of new vertebral fractures (10.4 vs 24.0%; $p<0.0001$) by 58.9% (95% CI, 36.6-73.3%) over 26 months. Because a large number of vertebral fractures occurred during the first 6 months in both groups (20 and 27 in minodronate and placebo groups, respectively), the cumulative incidence of new vertebral fractures from 6 to 26 months was reduced by 74.1% (4.7% vs 16.6%; $p<0.0001$) by minodronate treatment. A non-significant reduction in the incidence of overall clinical fractures was observed by 26 months of minodronate treatment (9.4 vs 13.8%). Minodronate treatment also reduced height loss both after 12 months (1.2 mm vs 3.4 mm in placebo) and 26 months (3.7 mm vs 6.8 mm). Bone turnover markers were suppressed by about 50% after 6 months of minodronate treatment, and remained suppressed thereafter. The overall safety profile including gastrointestinal safety was similar between the two groups. These results demonstrate that daily oral minodronate is safe, well-tolerated, and is effective in reducing vertebral fracture incidence in postmenopausal women with established osteoporosis. Because the dose of minodronate in reducing fracture incidence was low, further studies are warranted to evaluate the efficacy of intermittent administration of higher oral doses of minodronate on osteoporotic fractures.

Efficacy of Clodronate on Fracture Risk in Women Selected by 10-year Fracture Probability. E. McCloskey¹, H. Johansson^{*1}, A. Oden^{*1}, S. Aropuu^{*2}, T. Jalava^{*2}, J. Kanis¹. ¹University of Sheffield, Sheffield, United Kingdom, ²Bayer Schering Pharma, Berlin, Germany.

Treatments for osteoporosis are commonly targeted to patients with low bone mineral density. The WHO tool for fracture prediction estimates an individual's probability of fracture in the next 10 years from clinical risk factors, with or without BMD measurement. To determine if patients identified at high risk by the algorithm are responsive to anti-resorptive treatment, we examined the effects of the bisphosphonate, clodronate, on fracture incidence during 3 years of treatment across the range of fracture probabilities estimated by the WHO tool.

5212 women aged 75 years and older, randomly selected from the local population were randomised, regardless of the presence or absence of osteoporosis, to receive 3 years of therapy with clodronate (BONFOS[®]) 800mg daily p.o. or an identical placebo. The 10-year probability of fracture in each woman was computed using baseline clinical risk factors including BMI, prior fracture, glucocorticoid use, parental hip fracture, smoking, alcohol and secondary osteoporosis. Femoral neck BMD measurements were also obtained at baseline. The interaction between probability of fracture and treatment efficacy to reduce the incidence of all osteoporosis-related fractures was determined using Poisson regression analysis.

Complete clinical risk factor data were available in 3974 women (76.2% of the cohort). The 10-year probability for osteoporotic fracture without BMD was 20.0 \pm 7.3% (mean \pm SD) with the range 7.3-72.8%. The probability for osteoporotic fracture with BMD was 18.1 \pm 8.6% (mean \pm SD) with the range 1.4-73.0%. The interaction between fracture probability and treatment efficacy was not significant when probability was assessed either with or without BMD ($p=0.098$ and $p=0.11$ respectively). A non-significant trend was observed for greater fracture reduction at higher fracture probability, with or without the use of BMD. For example, women lying at the 75th percentile of fracture probability in the absence of BMD had a fracture probability of 24% and treatment reduced the risk of fracture by 23% over 3 years (HR 0.77, 95%CI 0.63-0.95). In those with a fracture probability of 30% (90th percentile), the fracture risk reduction was 31% (HR 0.69, 0.53-0.90). We conclude that the estimation of an individual's 10-year probability of fracture identifies patients at high risk of fracture who will respond to bisphosphonate therapy.

Central Control of Bone Remodelling by Neuromedin U: A Mediator of the Leptin-dependent Regulation of Bone Formation. S. Sato^{*1}, S. Takeda¹, R. Hanada^{*2}, M. Iwasaki^{*1}, H. Inose¹, A. Kimura^{*1}, K. Kangawa^{*3}, M. Kojima^{*2}, K. Shinomiya^{*1}. ¹Orthopaedic Surgery & 21COE Program, Tokyo Medical and Dental University, Tokyo, Japan, ²Molecular Genetics, Institute of Life Science, Kurume University, Kurume, Japan, ³Biochemistry, National Cardiovascular Center Research Institute, Osaka, Japan.

Leptin inhibits bone formation through a hypothalamic relay and the sympathetic nervous system (SNS). However, hypothalamic target molecule of leptin remains to be elucidated. Neuromedin U (NMU) is an anorexigenic neuropeptide whose expression is induced by leptin. In this study, we investigated the role of NMU on bone remodelling and the possible crosstalk between NMU signalling pathway and leptin-SNS pathway. NMU deficient mice (NMU^{-/-} mice) exhibited a 30% increase in bone mass compared to wild-type (wt) mice. Bone formation in NMU^{-/-} mice was increased as revealed by higher bone formation rate and osteoblast surface. Indeed, in vivo, osteoblast mitotic index analyzed by BrdU incorporation was significantly increased in NMU^{-/-} mice. In contrast, bone resorption parameters of NMU^{-/-} mice were comparable to those of wt mice. In vitro, differentiation or proliferation of primary osteoblasts isolated from NMU^{-/-} mice was similar to those from wt mice. In addition, treatment with varying concentrations of NMU did not affect osteoblast function, suggesting the lack of direct effect of NMU on osteoblast. In contrast, continuous intracerebroventricular infusion (ICV) of NMU to NMU^{-/-} mice decreased bone volume significantly, indicating the central nature of NMU's action on bone formation. Leptin ICV decreased bone volume and bone formation in wt mice, as previously reported. However, and surprisingly, leptin ICV paradoxically increased bone formation and osteoblast number in NMU^{-/-} mice. Likewise, injection of isoproterenol, a beta agonist, reduced bone mass in wt mice. However, NMU^{-/-} mice were resistant to the antiosteogenic activity of isoproterenol. Furthermore, NMU/Adrb2 (gene encoding beta2 adrenergic receptor) double heterozygote mice had higher bone mass than Adrb2 single heterozygote mice or NMU single heterozygote mice. Collectively, our study shows that NMU inhibits osteoblast proliferation and bone formation through the central nervous system. Moreover, it suggests that NMU mediates the antiosteogenic action of the leptin-SNS pathway.

ECM1, a Direct Targeting Molecule of PTHrP, Is a Novel Potent Mediator of Chondrogenesis. L. Kong^{*1}, Y. Zhang^{*1}, B. Jiang^{*2}, Y. Xie^{*2}, J. Q. Feng², T. Kobayashi^{*3}, H. M. Kronenberg³, C. Liu¹. ¹Department of Orthopaedic Surgery, New York University, New York, NY, USA, ²Department of Biomedical Sciences, Baylor College of Dentistry, Texas A&M University System Health Science Center, Dallas, TX, USA, ³Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

Chondrogenesis is controlled by cellular interactions with surrounding matrix proteins and growth factors that mediate cellular signaling pathways. In a functional genetic screen for proteins associating with cartilage oligomeric matrix protein, we identified a novel extracellular matrix protein, ECM1 (extracellular matrix protein 1), a molecule that had previously been linked to lipid proteinosis and lichen sclerosis, a common chronic inflammatory condition. We verified this novel interaction using in vitro pulldown and in vivo coimmunoprecipitation assays and demonstrated that these two proteins colocalized on the cellular surface of primary human chondrocytes. Using RT-PCR and western blotting assays, we showed that both mRNA and protein levels of ECM1 were upregulated during differentiation of chondrocytes. ECM1 significantly inhibited mRNA levels of both early and later genes critical for chondrogenesis such as Sox9 (78% reduction), collagen type II (82% reduction), and collagen X (90% reduction) and repression of ECM1 via the siRNA silencing markedly enhanced the expression of Collagen X in the course of chondrogenesis (22 and 5 fold in ADTC5 and 10T1/2 mesenchymal stem cells respectively). To determine the potential mechanisms by which ECM1 negatively regulates chondrogenesis, we studied the effects of ECM1 on PTHrP (an essential negative regulator for later chondrogenesis) and IHH (a positive regulator of chondrogenesis). ECM1 induced PTHrP 5- to 18-fold and inhibited IHH (50% reduction) during chondrogenesis. We further showed that PTHrP induced mRNA levels of ECM1 (28-fold) in chondrocytes. Importantly, knocking down ECM1 mRNA levels via the siRNA silencing or blocking ECM1 protein activity via anti-ECM1 antibodies completely abolished the effects of PTHrP on chondrogenesis in vitro. Using an immunohistochemistry assay, we showed that ECM1 was expressed throughout the chondrocyte zone of growth plates and articular cartilage and that ECM was no longer detectable in PTHrP null growth plates at day E18.5 in vivo. Last, we demonstrated that both mRNA and protein levels of ECM1 were upregulated in arthritis using microarray, real-time PCR and western blotting assays. Our findings demonstrate for the first time that ECM1, a direct downstream molecule of PTHrP in cartilage, is a novel negative regulator of chondrocyte differentiation and suggest that ECM1 may also plays an important role in the pathology of arthritis.

Regulation of Chondrocyte Hypertrophy and Bone Mineral Density by Matrilin-3 Through Modulating Bone Morphogenetic Protein Signaling Pathways. X. Yang^{*1}, L. van der Weyden^{*2}, L. Wei^{*1}, Z. Wang^{*1}, A. Bradley^{*2}, Q. Chen¹. ¹Brown University, Providence, RI, USA, ²Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

Regulation of the entrance to and the exit from the hypertrophic stage of chondrocyte differentiation during endochondral ossification is crucial to the normal development and mineralization of a long bone. Mis-regulation of hypertrophy leads to chondrodysplasia. Important regulators of chondrocyte hypertrophy include growth factors such as bone morphogenetic proteins (BMPs) and extracellular matrix (ECM) proteins. Matrilin-3 (MATN3) is a member of the matrilin family, a group of the adhesive ECM proteins. Mutations in the human gene of MATN3 result in a variety of skeletal diseases including multiple epiphyseal dysplasia, spondylo-epi-metaphyseal dysplasia, and hand osteoarthritis. To determine the function of matrilin-3 in endochondral ossification, we examined the consequences of both knocking out MATN3 and over-expressing MATN3 in hypertrophic chondrocytes. In MATN3 KO mice, the hypertrophic zone of the embryonic tibial growth plate was expanded in comparison to its wildtype littermates. Thus, the lack of matrilin-3 leads to mis-regulation of chondrocyte differentiation in the developing epiphyseal growth plate. By 18 weeks of age MATN3 null mice had a significantly higher total body and knee joint bone mineral density (BMD) than wild-type littermates. Aged MATN3 null mice were much more predisposed to develop severe osteoarthritis than their wild-type littermates. Conversely, Over-expression of MATN3 in embryonic chondrocytes during their transition to hypertrophy led to reduced expression of Col X mRNA, a marker of chondrocyte hypertrophy. Deletion of the cis-acting element in the Col X promoter indicated that the 5' distal region containing BMP responsive elements was necessary and sufficient to mediate the inhibitory effect of MATN3 on Col X. This suggests that MATN3 inhibition of Col X expression is mediated by the BMP pathways. Immunoprecipitation pull-down assay detected BMP-2 in a complex with MATN3 in the conditioned medium of MATN3 transfected cells, suggesting MATN3 may inhibit BMP signaling by interacting and sequestering BMP-2 extracellularly. Interestingly, increased BMP signaling in MATN3 KO mice was indicated by an increase of phosphorylated Smad1 in the growth plate. Our data revealed that MATN3 plays a negative role in regulating chondrocyte hypertrophy by modulating BMP signaling. It suggest a novel pathological mechanism by which matrix defects lead to abnormal BMP signaling that ultimately affects ossification, bone mineral density, and skeletal development and aging.

Perlecan Modulates FGF and VEGF Signaling and Is Essential for Vascularization in the Development of the Cartilage Growth Plate. M. Ishijima¹, E. Arikawa-Hirasawa^{*2}, K. Hozumi^{*1}, N. Suzuki^{*1}, K. Kosaki^{*1}, T. Matsunobu^{*1}, Y. Yamada^{*1}. ¹Laboratory of Cell and Developmental Biology, National Institute of Dental and Craniofacial Research, National Institute of Health (NIH), Bethesda, MD, USA, ²Research Institute for Diseases of Old Age, Juntendo University School of Medicine, Tokyo, Japan.

Perlecan (Perl) is a heparan sulfate proteoglycan that is expressed in all basement membranes and in cartilage. Perl-deficiency in mice and humans causes lethal chondrodysplasia, indicating that Perl is essential for cartilage development. However, the precise function of Perl in cartilage development is unknown. The purpose of this study is to investigate the mechanism of Perl functions in growth plate development. Here, we describe the critical role of Perl in FGF/VEGF signaling and angiogenesis in growth plate formation. The Perl^{-/-} growth plate is short with severely impaired endochondral bone formation. Chondrocyte proliferation is reduced, and the hypertrophic matrix is disorganized. Although chondrocytes are differentiated, the expression of FGF downstream genes is dysregulated. We found that both FGFR3 and FGFR1 were activated in the Perl^{-/-} growth plate. Expression of VEGF, a FGF/FGFR target gene, was upregulated by Perl^{-/-} hypertrophic chondrocytes, suggesting that the lack of vascularization into the hypertrophic zone is not due to the reduced VEGF expression. We demonstrated that Perl bound VEGFR but not VEGF. Expression of the Perl transgene specifically in cartilage of Perl^{-/-} mice rescued the perinatal lethality of Perl^{-/-} mice, and vascularization into the growth plate was restored, indicating that perlecan in the growth plate is critical in this process. These results suggest that Perl in the growth plates activates VEGFR signaling of endothelial cells for vascularization into the growth plate. Thus, we conclude that perlecan plays a critical role in endochondral bone formation via modulating FGF/VEGF signaling and promoting angiogenesis.

Genetic and Pharmacologic Activation of the Hypoxia Inducible Factor Pathway Promotes Angiogenesis and Accelerates Bone Regeneration. C. Wan¹, S. R. Gilbert², Y. Wang¹, X. Cao^{*1}, X. Shen^{*1}, G. Ramaswamy^{*3}, K. A. Jacobsen^{*4}, Z. S. Alaql^{*4}, L. C. Gerstenfeld⁴, T. A. Einhorn⁴, A. W. Eberhardt^{*3}, L. Deng^{*1}, T. L. Clemens¹. ¹Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, ²Orthopaedic Surgery, University of Alabama at Birmingham, Birmingham, AL, USA, ³Biomedical Engineering, University of Alabama at Birmingham, Birmingham, AL, USA, ⁴Boston University School of Medicine, Boston, MA, USA.

Angiogenesis is critical for bone formation and occurs in close spatial and temporal association with osteogenesis during skeletal development and regeneration. Osteoblasts sense fluctuations in oxygen tension and respond to hypoxia by activating the hypoxia-inducible factor-1 α (HIF-1 α) pathway, which in turn activates vascular endothelial growth factor (VEGF) and other angiogenic gene programs. In this study, we applied genetic and pharmacologic strategies to manipulate HIF-1 α levels in osteoblasts and determine its role in bone regeneration. Overexpression of HIF-1 α was achieved by deleting VHL, a key component of the E3 ubiquitin degradation pathway. Mice overexpressing HIF-1 α (Δ VHL) or lacking HIF-1 α (Δ HIF-1 α) in osteoblasts were subjected to distraction osteogenesis (DO) and bone vascularity and regeneration were measured by angiography and CT. HIF overexpressing Δ VHL mice showed increased vascularity (2.4 fold in vessel volume/total volume, VV/TV), increased VEGF expression and CD31 staining and markedly increased (1.6 fold) BV/TV after consolidation compared with control littermates. Three point bending testing showed increased peak load to failure (3.5 fold) of the Δ VHL bones compared with controls. Concomitant treatment of the Δ VHL mice with VEGF receptor 1 and 2 neutralizing antibodies during distraction markedly attenuated both the angiogenic and osteogenic phases of the repair process. By contrast, Δ HIF-1 α mice exhibited decreased vascularity (2 fold in VV/TV) and decreased bone volume (1.7 fold) in the distraction gap after consolidation compared to control littermates. To pharmacologically induce HIF-1 α , we screened a series of prolyl hydroxylase inhibitors for their ability to activate a HIF-responsive reporter gene. Two compounds, desferrioxamine (DFO) and L-mimosine were then evaluated for their bone regenerative efficacy by local injection in the DO model. Wild type mice receiving DFO, but not L-mimosine, exhibited significantly increased vascularity (2.3 fold in VV/TV) and increased bone (1.5 fold in BV/TV) in the distraction gap compared to vehicle treated mice. We conclude that activation of the HIF pathway accelerates bone healing by stimulating both angiogenesis and osteogenesis. Our results demonstrate the feasibility of developing HIF-1 α activating agents to facilitate bone regeneration.

Over-expression of Runx2 in Mesenchymal Cells Enhanced Bone Formation but Inhibited Cartilage Formation and Limb Development. C. A. Yoshida^{*}, T. Maeno^{*}, N. Kanatani^{*}, T. Fujita^{*}, S. Izumi^{*}, T. Komori^{*}. Department of Cell Biology, Unit of Basic Medical Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

Runx2 is an essential transcription factor for skeletal development. Although the roles of Runx2 in osteoblast differentiation and chondrocyte maturation have been extensively studied, the functions of Runx2 at an early developmental stage, when multipotent mesenchymal cells commit to the osteoblastic or the chondrocytic cell lineage, still remain to be investigated. To clarify this issue, we prepared Runx2 transgenic mice using a 2.5kb Prx1 promoter, which drove Runx2 expression to mesenchymal cells in calvarium, limb primordia, maxilla, mandible, and neck. At embryonic day (E) 13.5 skeletal preparations of Runx2 transgenic mice, but not wild-type mice, displayed calcification of calvarial tissues. At E15.5 Runx2 transgenic mice showed brain hernia due to a fusion of the frontal, parietal, and occipital bones. Furthermore, at this stage, the absence of the sternum, resulted in heart and liver hernia. Histological examination of transgenic mice at E12.5, revealed abnormal Col1 α expression and mineralization in the calvarium and neck. Development of the limbs in Runx2 transgenic mice was clearly inhibited, and the level of inhibition ranged from mild to a complete abrogation of cartilage formation. Limb buds of Runx2 transgenic embryos at E10.5 showed reduced or undetectable expression levels of Fgf8, Shh, and Fgf4 but augmented apoptotic cells in the ectoderm compared to those of wild type mice, indicating that apical ectodermal ridge formation was inhibited. These data demonstrate that Runx2 is able to induce differentiation of mesenchymal cells into osteoblasts in presumptive regions of bone formation and even in ectopic areas but to inhibit the differentiation of mesenchymal cells into chondrocytes. Further, our findings indicate that Runx2 can disturb limb development by inhibiting the formation of apical ectodermal ridge.

Targeted Deletion of a Distant Transcriptional Enhancer of the RANKL Gene Reduces Bone Remodeling and Increases Bone Mass. C. Galli¹, P. E. Cazer^{*1}, L. A. Zella², J. A. Fretz^{*2}, J. W. Pike², R. S. Weinstein¹, S. C. Manolagas¹, C. A. O'Brien¹. ¹Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA, ²Department of Biochemistry, University of Wisconsin, Madison, WI, USA.

Previous in vitro studies, using BAC-based transcriptional reporter constructs and ChIP-on-chip assays, indicated that PTH and 1,25(OH) $_2$ D $_3$ stimulate murine RANKL expression in stromal/osteoblastic cells via an evolutionarily-conserved transcriptional enhancer. This enhancer is located 76 kb upstream from the transcription start site and is designated the RANKL distal control region (DCR). To determine the significance of this enhancer for control of RANKL expression and bone homeostasis, we created knock-out (KO) mice in which the 2 kb DCR was eliminated by gene targeting. DCR null mice were viable, fertile, and, in contrast to RANKL KO mice, were not osteopetrotic. Nonetheless, deletion of the DCR reduced PTH- and 1,25(OH) $_2$ D $_3$ -stimulation of RANKL mRNA and osteoclast formation in primary bone marrow cultures. Consistent with this, stimulation of RANKL mRNA in bone by a single injection of either PTH or 1,25(OH) $_2$ D $_3$ was blunted in DCR KO mice. DCR deletion also reduced basal RANKL mRNA levels in bone, thymus, and spleen. Spinal and femoral bone mineral density (BMD) was elevated in both male and female mice lacking the DCR beginning at 2 months of age and remained elevated up to at least 6 months of age, with the difference in BMD between genotypes remaining relatively constant during this time period. The increase in spinal BMD was approximately 9% in 5-month-old mice and was associated with a 28% increase in vertebral compression strength. Histomorphometric analysis of lumbar vertebra revealed reduced osteoclast and osteoblast formation leading to a low rate of bone remodeling similar to that observed in humans and mice with hypoparathyroidism. Moreover, deletion of the DCR increased trabecular number and thickness and decreased trabecular separation, suggesting that reduced remodeling of the primary spongiosa during growth may be responsible for the increase in bone volume. Consistent with this finding, DPD excretion in urine was reduced in DCR KO mice. However, circulating calcium and PTH levels were similar in wild-type and DCR-deficient mice, demonstrating that PTH control of RANKL is not required for calcium homeostasis under basal conditions. Taken together, these findings demonstrate that PTH control of RANKL expression via the DCR is a critical determinant of the rate of bone remodeling and provide new insights into the relationship, or lack thereof, between the calcium regulating actions of PTH and its effects on the skeleton.

Oncostatin M Is an Essential Stimulus of Bone Formation and Osteoclastogenesis. N. A. Sims, E. C. Walker^{*}, I. J. Poulton^{*}, N. E. McGregor^{*}, M. T. Gillespie, T. J. Martin. St. Vincent's Institute of Medical Research, Melbourne, Australia.

The gp130 receptor is common to many cytokines, including IL-6, IL-11, LIF and cardiotrophin-1 (CT-1) which are all important for regulating bone mass in vivo. Murine oncostatin M (OsM) signals through gp130 bound to a specific receptor, OsMR. Osteoblasts express OsMR, and OsM has been reported to increase osteoclast formation by dramatically increasing their RANKL production. The effects of OsM on bone formation however, are not clearly defined.

To determine whether OsM action is essential for bone formation in vivo, we studied the bone phenotype of 10 week-old OsMR deficient mice. While cortical dimensions and density were not altered, male and female OsMR null mice demonstrated a 75% increase in trabecular bone volume in the distal tibia and 4th lumbar vertebrae. Femoral trabecular BMD was also elevated (by 40%) in both males and females. This was associated with a significant (30%) reduction in osteoclast surface and reduced bone resorption, consistent with the known effect of OsM on osteoclast generation in co-cultures. Bone formation was also significantly reduced, evidenced by low osteoid thickness (reduced to 30%), osteoblast surface (reduced to 60%) and bone formation rate (halved). In contrast, the number of marrow adipocytes was elevated ~4 fold.

To determine the effects of OsM on bone formation, Kusa 4b10 murine stromal cells were treated with OsM (1.25-10ng/ml) for 14 to 21 days. Under mineralising conditions, OsM treatment dose-dependently increased mineralisation; doses as low as 1.25 ng/ml more than doubled alkaline phosphatase activity and alizarin red staining compared to untreated controls. In contrast, under adipogenic conditions adipocyte formation was more than halved. Both the reduced adipogenesis and increased bone formation with OsM treatment are consistent with the opposite observations in OsM-deficient animals.

To identify targets of OsM, we studied its effects on gene expression by undifferentiated Kusa4b10 cells and Kusa4b10 cells differentiated along the osteoblast lineage for 17 days. In both systems, there was a 90% reduction in PPARgamma at 24 hours and a rapid 20-fold increase in C/EBPdelta (but no change in C/EBPbeta) expression within 1 hour of OsM administration. Since C/EBPdelta has been shown to synergise with runx2 to enhance osteocalcin transcription we investigated the effect of OsM on a 6xOSE-luciferase reporter construct in UMR106-06 cells. We detected a dose-dependent increase in reporter activity in response to OsM that was maximal by 6 hours and equivalent to levels observed with 1,25D3 and CT-1.

This reveals a critical role for OsMR in maintaining normal levels of bone resorption and bone formation in vivo, as well as an inhibitory role in adipocyte differentiation.

Zfp521, a D2DFosB-interacting Protein, Regulates Chondrocyte Differentiation Downstream of PTHrP. D. Correa, R. Kiviranta, L. Neff*, W. C. Horne, R. Baron. Orthopaedics, Yale University, New Haven, CT, USA.

Chondrocytes are derived from mesenchymal precursor cells through a tightly regulated differentiation process. The paracrine factor PTHrP and the transcription factor Runx2 are key regulators in this program and have opposing actions in prehypertrophic chondrocytes, with PTHrP inhibiting and Runx2 favoring chondrocyte differentiation. We identified the zinc finger protein Zfp521, a 180 kDa protein consisting of 30 kruppel-like zinc fingers, as a $\Delta 2\Delta$ FosB-interacting protein in a yeast-two hybrid screen of an osteoblast cDNA library. In situ hybridization with a Zfp521-specific probe showed that Zfp521 is expressed in mesenchymal condensations as early as day E12.5 and in the developing growth plates of long bones, as well as in osteoblasts. Immunostaining detected Zfp521 mainly in PTHrP receptor (PTH1R)-expressing prehypertrophic chondrocytes. In the well-established ATDC5 cell model of in vitro chondrogenesis, the endogenous expression of Zfp521 was observed primarily at the stage of transition from prehypertrophic to hypertrophic chondrocytes, with a peak around the third week of culture, sharing again a similar pattern of expression with the PTH1R. Transient overexpression of Zfp521 in the ATDC5 cells inhibited chondrogenic differentiation, with decreased Alcian Blue staining and impaired cartilage nodule formation at day 12 of culture. This effect was comparable to the inhibitory effect of PTHrP(1-34). Treatment with PTHrP(1-34) did not increase the Zfp521-induced inhibition of nodule formation in these cells, suggesting that PTHrP and Zfp521 might share the same signaling pathway. Consistent with this hypothesis, stimulation of ATDC5 cells with PTHrP(1-34) and Forskolin promoted Zfp521 expression, regardless of the stage of differentiation, and inhibited chondrocyte progression from prehypertrophic to hypertrophic stages. In contrast, PTHrP(7-34), a known competitive antagonist of PTHrP(1-34), downregulated Zfp521 expression suggesting that it blocked the auto/paracrine effect of PTHrP(1-34), including its positive influence on Zfp521 expression. Additionally, PTHrP(1-34) but not PTHrP(7-34) had a negative effect on Runx2 expression during the differentiation of the ATDC5 cells. Therefore, based on Zfp521's negative effect on chondrogenesis, its pattern of expression in the growth plate and in the ATDC5 model, and its upregulation by PTHrP(1-34), we propose that Zfp521, which antagonizes the transcriptional activity of Runx2, lies downstream of PTHrP at the control point of the progression from prehypertrophic to hypertrophic chondrocytes in the growth plate.

Insulin Promotes Osteoblast Differentiation Independent from IGF-1 Signaling and Its Receptor Is Required for Normal Post Natal Bone Acquisition. K. Fulzele*, Z. Liu*, C. Wan*, W. Zhang*, J. Bruening*, T. L. Clemens*. ¹Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, ²Department of Mouse Genetics and Metabolism, Institute for Genetics, Center of Molecular Medicine, University of Cologne, Cologne, Germany.

Defective bone formation is common in patients with insulin-dependent diabetes mellitus, suggesting that insulin normally exerts anabolic actions in bone. Previous studies suggested that insulin might exert direct effects on osteoblast proliferation and apoptosis. However, because insulin can cross-activate the IGF-1 receptor (IGF-1R), which also functions in bone, it has been difficult to establish direct (IGF-1 independent) actions of insulin in osteoblasts. In this study, we first compared the effects of insulin and IGF-1 on differentiation of primary osteoblasts in vitro. Primary calvarial mouse osteoblasts expressing normal levels of IGF-1R (WT) or deficient in IGF-1R (IGF-1R KO) were differentiated in osteogenic medium with or without insulin or IGF-1. In WT osteoblasts, expression of IGF-1R mRNA declined with differentiation whereas insulin receptor (IR) mRNA remained constant. WT osteoblasts treated with insulin differentiated more rapidly than those treated with IGF-1, as evidenced by increased ALP activity and von Kossa staining. Insulin induced robust activation of Akt and GSK3 β that were not dependent on IGF-1R since they were also observed in IGF-1R KO osteoblasts. Moreover, insulin, but not IGF-1, upregulated expression of Runx2 in WT and KO cells suggesting that insulin promotes differentiation of the primary osteoblasts via the Akt-Runx2 pathway. To investigate the effects of insulin in bone in vivo, we selectively disrupted the IR in osteoblasts using Cre-loxP recombination. Mice carrying floxed IR alleles were mated with a mouse expressing the Cre recombinase driven by the human osteocalcin promoter to generate IR osteoblast-specific knock out mice. Micro-CT analysis of femurs from 3-week-old male OC-Cre IR floxed mice (N=4) showed that bone volume was significantly decreased in IR KO mice compared with IR-floxed littermates. Taken together, our results suggest that insulin exerts direct actions on osteoblasts and signaling through its receptor is required for normal post-natal bone acquisition in vivo. We predict that the loss of insulin action in osteoblasts during states of insulin resistance may contribute to defective bone formation seen in patients with diabetes.

Osteogenic Stem Cell Homing to Sites of Endochondral Bone Formation. C. M. Foulletier-Dilling*, A. M. Wada*, Z. Lazard*, M. E. Dickinson*, A. R. Davis¹, F. H. Gannon², M. H. Heggeness^{3,4}, E. A. Olmsted-Davis¹. ¹Cell and Gene Therapy, Baylor College of Medicine, Houston, TX, USA, ²Molecular Physiology, Baylor College of Medicine, Houston, TX, USA, ³Orthopedic Surgery and Pathology, Baylor College of Medicine, Houston, TX, USA, ⁴Orthopedic Surgery, Baylor College of Medicine, Houston, TX, USA.

Using a model of de novo bone, we recently demonstrated the recruitment of bone marrow derived cells of myeloid lineage to undergo chondrogenesis and osteogenesis. Their differentiation program appears to be dictated by the local micro-environment established in the tissues prior to stem cell engraftment. However, these cells must first mobilize from the bone marrow into the circulation and target the site of new bone formation. This process requires the cells to pass through the vessel wall, known as extravasation, into the target tissue. Receptor/integrins on the stem cell surface specifically bind corresponding molecules on specialized endothelial cells. We induce endochondral bone formation in the mouse hind limb by delivery of cells transduced with adenovirus to express BMP2. Immunohistochemical analysis of tissues isolated from the model prior to bone/cartilage formation, revealed the synthesis of new vessels simultaneous with specific temporal expression of several molecules known to be involved in extravasation. Microarray analysis of the tissue surrounding the bone induction site confirmed a specific enhancement in these genes including SDF-1, CXCR4, CD44, Mac1, and E-selectin. To further confirm the formation of new vessels, we utilized mice possessing a cassette consisting of the VEGF receptor (flk-1) promoter driving the expression of nuclear yellow fluorescent protein (YFP). Previous reports suggest that flk1 expression is somewhat restricted to endothelial cells present on smaller newly forming vessels. Our initial characterization of these mice confirmed YFP expression on subpopulations of CD31⁺ endothelial cells. Quantification of the flk-H2B:YFP⁺ in tissues isolated from either the region receiving cells transduced with either AdBMP2 or a control adenovirus, showed a significant increase in YFP expression as compared to the control. We observed this increase as early as two days after induction prior to the appearance of stem cells within the tissues. The results collectively suggest the ability of BMP2 to both recruit the necessary chondro-osseous stem cells but also establish the essential vasculature for extravasation and engraftment into the tissues. This is the first report demonstrating a specific mechanism for stem cell homing for the production of endochondral bone, a process that is essential for tissue engineering, but also provides novel targets for treatment of heterotopic bone formation, and bone metastases.

TGF β 1 Induces Migration of Mesenchymal Stem Cells in Coupling Bone Resorption and Formation. Y. Tang, X. Wu, S. Xie*, L. Zhao*, C. Wan*, Z. Shi*, X. Feng, X. Peng*, M. Wan, X. Cao. Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Bone is continuously remodeled by the balanced processes of bone resorption and concomitant bone formation. The recruitment of osteoprogenitors to the site of bone resorption is the initial event necessary for coupling of bone resorption and formation. However, such factor(s) for the coupling process is not clear. Here we demonstrate that TGF β 1 released from bone matrix during osteoclastic bone resorption induces migration of stro-1⁺ primary human bone marrow mesenchymal cells (MSCs). Migration of MSCs was examined in coupling with in vitro osteoclastic bone resorption. Osteoclastic bone resorption-conditioned medium (CM) stimulates migration of MSCs, whereas CM from monocytes/macrophage or osteoclasts without bone slices had no effect. Importantly, addition of an antibody against TGF β 1 inhibited the migration, but antibodies against TGF β 2, TGF β 3, FGF-1, FGF-2, FGF-3, or noggin did not affect the migration. Western blot analysis revealed that only bone resorption-CM contains active TGF β 1. In addition, bone resorption-CM prepared from TGF β 1^{-/-} mice did not induce migration of MSCs. The results indicate that TGF- β 1 released and activated during osteoclastic bone resorption is a key factor in inducing MSCs migration.

In characterization of the mechanism of TGF β 1-induced migration of MSCs, we found that Smad signaling promotes cell migration through TGF β 1 type I receptor (T β RI). T β RI specific inhibitor (SB-431542) blocks the migration. Importantly, injection of the T β RI inhibitor in the rat tibia reduced bone formation dose-dependently as demonstrated by X-ray, μ CT and histomorphometry. TGF β 1 activates RhoA which induces formation of focal adhesion and results in reduction of migration of MSCs. Injection of RhoA inhibitor (Y-27632) in the rat tibia stimulated bone formation. The T β RI-mediated migration mechanisms were also confirmed in MSCs isolated from either T β RII or Smad4 conditional knockout mice. Finally, the TGF β 1^{-/-} mice was crossed with immuno-deficient Rag2^{-/-} mice to prevent the early death of the TGF β 1^{-/-} mice due to organ failure of with inflammatory disease. The adult TGF β 1^{-/-} mice exhibited smaller trabecular bone volume and thickness, and larger trabecular bone space. Histology staining showed lack of preosteoblasts at the surface of trabecular bone. Moreover, TRAP staining of mature osteoclasts confirmed an absence of preosteoblasts around the mature osteoclasts on the surface of trabecular bone. Thus, TGF β 1^{-/-} mice exhibit significant bone loss with features characteristic of uncoupled bone resorption and formation, which indicates that TGF β 1 functions as a primary coupling factor for bone formation and resorption.

Bone Turnover Markers and Prediction of Fracture: Nine-Year Follow-Up Study of 1040 Elderly Women. K. K. Ivaska, P. Gerdhem, K. Åkesson, K. J. Obrant. Department of Orthopaedics, Lund University, Malmö, Sweden.

High level of bone turnover has been suggested to be a risk factor for future fracture. The aim of this study was to investigate if biochemical markers of bone turnover are associated with long-term incidence of fracture in elderly women followed prospectively for a mean of nine years.

The ability of bone turnover markers to predict future fracture was studied in a population-based sample of 1040 randomly recruited elderly women, all 75-years of age at inclusion (the Malmö OPRA study). Six bone turnover markers (S-TRACP5b, S-CTX-I, S-OC[1-49], S-TotalOC, S-boneALP, urinary osteocalcin (U-OC)) were measured at baseline and after a new sampling one year later, at the age of 76. Prospective fractures were recorded and verified.

During the mean follow-up of 9.0 years (range 7.4 -10.9), a total of 364 women sustained prospectively at least one fracture, including 116 hip fractures and 103 clinical vertebral fractures. Women in the highest tertile for S-TRACP5b, S-CTX-I or U-OC had significantly greater risk for sustaining fracture when compared to women in the lowest tertile. The hazard ratio for any prospective fracture was 1.3-1.4 ($p<0.05$), depending on marker. The results were consistent when we analyzed resorption markers measured at one-year follow-up visit and the incidence of any prospective fracture during the remaining follow-up time of mean 7.9 years (range 6.3 - 9.9). Similar tendency for increased risk was observed when hip fractures or vertebral fractures were analyzed separately, but it did not reach statistical significance. The associations to hip or vertebral fracture became, however, significant with hazard ratios up to 2.0 ($p<0.05$), when we used the average value of two marker measurements (baseline and one-year visit). Bone formation markers S-OC[1-49], S-TotalOC and S-boneALP were not associated with prospective fractures.

We conclude that elevated levels of bone resorption markers S-TRACP5b, S-CTX-I and U-OC are consistently associated with increased fracture risk for up to a decade in elderly women.

Biochemical Markers of Bone Turnover, Hip Bone Loss and Non-spine Fracture in Men: A Prospective Study. D. C. Bauer¹, P. Garnero², S. L. Harrision³, J. A. Cauley⁴, R. Eastell⁵, K. E. Ensrud⁶, E. Barrett-Connor⁷, E. S. Orwoll⁸. ¹UCSF, San Francisco, CA, USA, ²Synarc, Lyon, France, ³CPMC Research Institute, San Francisco, CA, USA, ⁴University of Pittsburgh, Pittsburgh, PA, USA, ⁵University of Sheffield, Sheffield, United Kingdom, ⁶University of Minnesota, Minneapolis, MN, USA, ⁷UCSD, San Diego, CA, USA, ⁸OHSU, Portland, OR, USA.

Previous studies have found that biochemical markers of bone turnover are independently associated with fracture risk in older women, but few prospective data exist in men.

We performed a nested case-cohort analysis within the Osteoporotic Fractures in Men (MrOS) study to determine if men with higher levels of bone turnover had accelerated bone loss or an elevated risk of fracture. Among the 5,995 MrOS subjects enrolled at baseline (mean age: 72.2 \pm 6.1), 440 men had documented non-spine fractures during a mean follow-up of 5.1 yr. Hip BMD (Hologic QDR4500) was measured at baseline and after a mean follow-up of 4.6 yr. Using fasting baseline serum stored at -190C, bone turnover (PINP, Roche Diagnostics; TRACP 5b, SBA-Sciences; and beta CTX, Roche Diagnostics) was measured on 428 fracture cases (including 82 hip fractures) and 943 randomly selected men. Bone loss (in the randomly selected men) and fracture outcomes were examined in multivariate models adjusted for age and clinic.

Hip bone loss was greater among men in the highest quartile of PINP (>45.6 ng/mL), TRACP 5b (>3.7 U/L) or CTX (> 0.494 ng/mL). For example, total hip bone loss was 0.6% per year among those in the highest quartile of PINP and 0.4% per year among those in the lower 3 quartiles ($p=0.002$). Compared to men without fracture, those with one or more non-spine fracture during follow-up were older (75.5 yr. vs. 73.7) and had lower total hip BMD (0.89 gm/cm² vs. 0.96), but had similar BMI (27.2 kg/m² vs. 27.3). Elevated PINP, but not TRACP 5b or CTX, was associated with an increased risk of fracture, particularly in the highest quartile (Table). Further adjustment for baseline hip BMD attenuated the associations between PINP and fracture, and they were no longer statistically significant.

We conclude that higher levels of bone turnover are associated with greater hip bone loss in older men, but increased turnover is not independently associated with the risk of hip or non-spine fracture. Our findings suggest that a single serum measurement of bone turnover may not be useful to predict hip or non-spine fracture risk in this population.

	RH (95% CI)		RH (95% CI)	
	adjusted for age and clinic (highest vs. 3 lower quartiles)		adjusted for age, clinic and BMD (highest vs. 3 lower quartiles)	
	Non-spine	Hip	Non-spine	Hip
PINP	1.42 (1.10, 1.84)	2.17 (1.29, 3.65)	1.19 (0.91, 1.56)	1.23 (0.65, 2.32)
TRACP 5b	1.07 (0.81, 1.40)	0.91 (0.52, 1.59)	0.93 (0.70, 1.24)	0.65 (0.35, 1.20)
beta CTX	1.15 (0.88, 1.49)	1.45 (0.87, 2.40)	0.93 (0.71, 1.22)	0.89 (0.50, 1.59)

Quantitative Ultrasound Predicts Incident Vertebral and Hip Fractures at Least as Strongly as DXA: The OPUS Study. C. C. Glüer¹, R. Barkmann¹, T. Blenk^{2*}, A. Stewart^{3*}, S. Kolta^{4*}, J. Finigan^{5*}, C. Graeff¹, J. v. d. Gabelentz^{2*}, R. Eastell³, D. M. Reid³, C. Roux⁴, D. Felsenberg². ¹Medical Physics, Diagnostic Radiology, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany, ²Charité Universitätsmedizin, Berlin, Germany, ³University of Aberdeen, Aberdeen, United Kingdom, ⁴René Descartes University, Paris, France, ⁵University of Sheffield, Sheffield, United Kingdom.

In the Osteoporosis & Ultrasound (OPUS) study we recruited a population-based sample of 2409 women (ages 55 to 81 years) from 5 European cities. Baseline examinations included dual-x-ray absorptiometry (DXA) of the lumbar spine and the total hip and Quantitative Ultrasound (QUS) of the heel using 4 devices (Lunar Achilles+, Osteometer DTU-one, Quidel/Metra QUS-2, and DMS UBIS 5000) and of the finger using one device (IGEA DBM Sonic BP). At baseline and 6 years later 1566 women underwent repeat spinal radiography for assessment of incident vertebral fractures and reported hip fractures since the baseline visit. Incidence of osteoporotic vertebral fractures was centrally assessed in Berlin according to standard radiological and semiquantitative assessment (vertebral height reduction $>20\%$). We examined the association of the baseline measurements with incident fractures by calculating standardized odds ratios (sOR, per one SD decrease of population variance, adjusted for age) from logistic regression models. There were 67 incident vertebral osteoporotic fractures and 11 incident hip fractures (no major trauma). Prediction based on Speed of Sound (SOS) results was somewhat stronger than for Broadband Ultrasound Attenuation (BUA) or DXA but the differences were not significant (ROC analysis). Finger measurements did not show significant associations with incident fractures. In multivariate age-adjusted vertebral fracture models including both SOS and BMD, only spinal BMD but not total hip BMD contributed independently of SOS (e.g. sOR=1.6, $p<0.03$ for DTU-one SOS and sOR=1.3, $p<0.04$ for DXA spine BMD).

Predictor variable	Age-adj. sOR Vert Fr	Age-adj. sOR Hip Fr
DXA spine BMD	1.5 (1.2-1.8)***	1.3 (0.8-2.1)
DXA total hip BMD	1.5 (1.5-2.0)**	2.6 (1.4-5.0)**
Achilles+ BUA	1.4 (1.04-1.8)*	1.9 (1.1-3.5)*
DTU-one BUA	1.5 (1.2-1.8)***	2.0 (1.3-3.2)**
UBIS 5000 BUA	1.5 (1.2-1.8)**	1.8 (1.0-3.0)*
QUS-2 BUA	1.6 (1.2-2.1)**	2.0 (1.1-3.4)*
Achilles+ SOS	1.7 (1.2-2.3)**	2.9 (1.4-6.4)**
DTU-one SOS	1.8 (1.4-2.4)****	2.9 (1.4-6.4)**
UBIS 5000 SOS	1.6 (1.3-2.2)***	2.7 (1.2-5.7)*
Achilles+ Stiffness Index	1.6 (1.2-2.1)**	2.5 (1.2-5.1)**
DBM BP AD-SoS	1.1 (0.9-1.3)	1.2 (0.8-1.8)

* $p<0.05$, ** $p<0.01$, *** $p<0.001$, **** $p<0.0001$

Conclusion: Calcaneal QUS methods, best evaluated based on SOS, predict incident vertebral and hip fractures at least as well as central DXA approaches.

Abdominal Aortic Calcification (AAC) on Vertebral Fracture Assessment (VFA) Images Predicts Incident Myocardial Infarction and Stroke Independent of Clinical Cardiovascular Disease Risk Factors. J. T. Schousboe¹, B. C. Taylor², D. P. Kiel³, K. E. Ensrud², K. E. Wilson⁴, E. V. McCloskey⁵. ¹Park Nicollet Health Services, Minneapolis, MN, USA, ²Minneapolis VAMC, Minneapolis, MN, USA, ³Hebrew SeniorLife, Harvard Medical School, Boston, MA, USA, ⁴Hologic, Inc, Bedford, MA, USA, ⁵University of Sheffield, Sheffield, United Kingdom.

The risk for cardiovascular disease (CVD) among older women is not adequately captured by traditional clinical CVD risk factors. Lateral spine images obtained on bone densitometers intended for VFA can detect abdominal aortic calcification, an important additional subclinical marker of CVD.

Objective: To estimate the association between AAC scored on VFA images and subsequent MI and stroke in women age 75 years or older participating in a randomized trial of clodronate versus placebo after adjustment for traditional risk factors.

Methods: 408 women sustaining either a fatal or non-fatal MI or stroke during the median 4-year study follow-up period were selected as cases, and an equal number of controls were randomly selected from the remainder of the study population. 732 (89.7%) had a baseline VFA with adequate space visualized anterior to the lumbar spine such that AAC could be scored by a single reader using a previously validated 24-point scale and a simplified 8-point scale, blinded to case status and covariate data. Covariates were systolic BP, LDL and HDL cholesterol, triglycerides, smoking, presence of diabetes, renal function, self-reported diagnoses of hypertension, angina, prior stroke, and health status. Missing covariate data was statistically imputed.

Results: Using logistic regression models, the multivariate-adjusted odds ratios of incident MI/stroke for the top and middle tertiles compared to the bottom tertile of AAC score were;

Outcome Measure	Odds Ratio (95% Confidence Interval) vs. Bottom Tertile (reference)	
	Middle Tertile	Top Tertile
AAC-24	1.14 (0.79 - 1.65)	1.74 (1.19 - 2.56)
AAC-8	1.42 (0.98 - 2.05)	1.76 (1.22 - 2.55)

Results for the subset with complete covariate data (n=420) were very similar.

Conclusion: AAC scored on lateral VFA images is a predictor of incident MI and stroke independent of other clinical risk factors. Since bone densitometry is indicated for all women age 65 and older, VFA imaging offers an opportunity to measure this subclinical indicator of cardiovascular disease in the female population at very little marginal cost.

Clinical Risk Factors for Incident Vertebral Fractures: Data from the Six-Year Prospective OPUS Study. K. Briot¹, C. Roux¹, S. Kolta¹, R. Eastell², D. M. Reid³, D. Felsenberg⁴, C. C. Gluer⁵. ¹Rheumatology, Cochin Hospital, Paris, France, ²University of Sheffield clinical sciences centre, Sheffield, United Kingdom, ³Department of Medicine and Therapeutics, University of Aberdeen, Aberdeen, United Kingdom, ⁴Diagnostic Radiology, Free University Berlin, Berlin, Germany, ⁵Medical Physics, Department of Diagnostic Radiology, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany.

Fractures related to osteoporosis represent a strong public health burden. Low bone mineral density explains only a part of the fracture risk; clinical risk factors play an important role. Many clinical risk factors are identified, but responsibility of some of them needs to be clarified. The objective of the study was to identify clinical risk factors for incident vertebral fractures. Using the 6-years data from the Osteoporosis and Ultrasound study (OPUS), a multi-centre wide study, 2409 European postmenopausal ambulatory women 55-81 years old with baseline clinical risk factors assessment (age, weight, current smoking, personal or familial previous fracture, corticosteroids, medical diseases, physical activity), and bone mineral density (BMD) measurements, were included in the analysis. Spine X-rays were performed using standardized procedures and assessed in a central facility. Incident vertebral fractures (defined as >20% vertebral height reduction and radiological signs of osteoporotic fracture) occurred in 67 women during the six years of follow-up. We performed logistic regression analysis on each of the potential risk factors, with adjustment for age. We chose for multivariate analysis those risk factors that were statistically significant ($p \leq 0.05$). In the age-adjusted multivariate analysis, several clinical factors were significantly associated with incident vertebral fractures, independently of BMD value: age (per 10 years) (sOR=1.7; 95% CI, 1.0-2.7; $p<0.04$), previous fall (sOR=1.4; 95% CI, 1.0-1.9; $p<0.04$), previous paternal hip fracture (sOR=3.0; 95% CI, 1.5-5.9; $p<0.002$), and current intake of proton pump inhibitor therapy (omeprazole) (sOR=1.9; 95% CI, 1.2-2.9; $p<0.006$). There was a trend for an association with previous low traumatic fracture (sOR=1.3; 95% CI, 1.0-1.8; $p<0.08$). Using data from a cohort of ambulatory postmenopausal European women, we showed that few clinical risk factors are associated with an increase risk of incident vertebral fracture over 6 years; two of them (paternal hip fracture and current intake of omeprazole) have not been observed in prospective studies before. This 6-year prospective study results confirm recent data from case-control studies: proton pump inhibitor therapy appeared to be associated with an increase risk of vertebral fractures.

Validation of Ten-Year Fracture Risk Prediction in a Large Clinical Cohort. W. D. Leslie¹, J. F. Tsang², L. M. Lix³. ¹Dept of Medicine, University of Manitoba, Winnipeg, MB, Canada, ²University of Manitoba, Winnipeg, MB, Canada, ³Manitoba Centre for Health Policy, University of Manitoba, Winnipeg, MB, Canada.

Absolute 10-year fracture risk is the preferred method for fracture risk assessment. The validity of applying published fracture rates from one population to another population is uncertain.

Women age 47.5 y or older at the time of baseline femoral neck BMD (N=20579, 1990-2002) were identified in a database containing all clinical DXA test results for the Province of Manitoba, Canada. Individual 10 y fracture risk was predicted from age-only and age+BMD (NHANES-III femoral neck T-score) using published 10 y fracture risk for Swedish women. Health service records were assessed for the presence of non-trauma 'osteoporotic' fracture codes (hip, clinical spine, wrist, humerus) subsequent to BMD testing (86447 person-y follow up, 1173 patients with osteoporotic fractures). Fracture rates were derived for subgroups stratified by age (5 y strata) and estimated risk (5% strata). 10 y fracture rates were computed directly by the Kaplan-Meier method (10 y continuous data) and by the actuarial method (two 5 y periods with adjustments for aging, death and expected BMD loss). Direct and actuarial methods gave nearly identical point estimates, but the latter were more precise.

There was a strong linear correlation between predicted and observed fracture rates based upon age-only (weighted $r=0.95$) and age+BMD (weighted $r=0.99$). For age strata 50 to 75, and for estimated risk strata from 0-5% to 20-25%, the confidence intervals overlapped the line of identity. For women age >77.5 or estimated risk >25%, observed exceeded estimated fracture rates. This is explained by healthy selection bias whereby elderly women referred for BMD testing have lower mortality than expected, hence more years at risk for fracture. Corrected for survival bias, women age >77.5 had observed fracture rates no different than predicted.

In conclusion, Swedish 10-year fracture risk data are generally applicable to the Canadian female population referred for BMD testing, though fracture rates may be underestimated in the oldest and highest risk subgroups due to healthy selection bias.

Figure: Predicted 10-year fracture risk versus observed fracture rates (actuarial method) for age-only (left, 5 y age strata from 50 to 85) and age+BMD (right, 5% risk strata for estimated risk, from 0-5% to >30%). Dotted line is the line of identity.

Bone Mineral Density and Hip Fracture: A Revisit with Time-varying Effects. T. V. Nguyen, N. D. Nguyen, S. A. Frost^{*}, J. R. Center, J. A. Eisman. Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

All previous studies of association between BMD and fracture were based on a single measurement, and assumed that BMD do not change. The assumption is clearly untenable since BMD is known to decrease with advancing age. The present study sought to estimate the magnitude of association between BMD and hip fracture risk taking into account the time-dependent bone loss.

A cohort of 782 women and 566 men aged 60+ years who have had at least two BMD measurements preceding a hip fracture was studied. The individuals have been followed-up for a median period of 15 years with an average of 5 BMD measurements (GE Lunar DPX) per subject. During the follow-up period, 77 women and 23 men had sustained at least one hip fracture. The Cox's proportional hazards model with time-varying covariates was used to evaluate the absolute risk of fracture for an individual conditioned on the individual's age, history of prior fracture and fall, and BMD measurements.

For a given risk profile, in addition to baseline BMD, bone loss further increased the risk of hip fracture in an individual. For example, a 70-year old woman with baseline BMD T-score of -2.0, and with a prior fracture and a fall is estimated to have the 5-year and 10-year risk of hip fracture of 6.8% and 10.6%, respectively. However, conditional on an annual bone loss is 1%, her 5-year and 10-year risks of hip fracture increase to 7.7% and 14.3%, respectively. Using this time-varying approach, it is possible to construct a full profile of BMD and fracture risk.

These data suggest that to accurately assess the risk of hip fracture in an individual, the dynamic nature of BMD should be considered. The present model takes into account the time-varying effect of BMD, and can therefore be used for individualizing the risk of hip fracture for any given unique risk profile

Clinical Validation of a Simplified Absolute Fracture Risk Algorithm in Canadian Women. W. D. Leslie¹, J. F. Tsang², L. M. Lix³. ¹Dept of Medicine, University of Manitoba, Winnipeg, MB, Canada, ²University of Manitoba, Winnipeg, MB, Canada, ³Manitoba Centre for Health Policy, University of Manitoba, Winnipeg, MB, Canada.

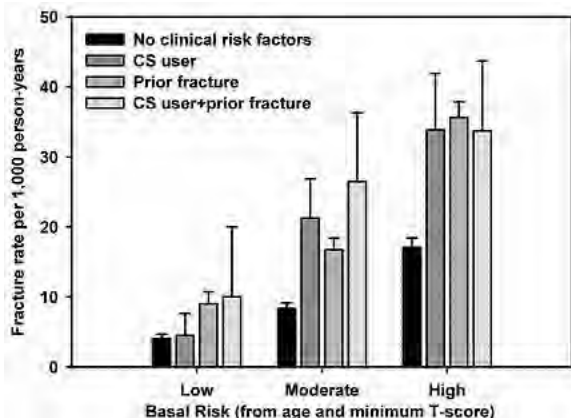

Absolute 10 y fracture risk based upon multiple factors is the preferred method for assessment. A simplified risk assessment system from gender, age, minimum T-score, and two clinical risk factors (CRFs) - prior fracture and systemic corticosteroid (CS) use - has been used in Canada since 2005. The current study was undertaken to validate this system in the Canadian female population.

16,205 women of white ethnicity age 50 y or older at the time of baseline BMD (1998-2002) were identified in a population-based database containing all clinical DXA test results for the Province of Manitoba, Canada. Individual basal 10 y fracture risk (from age and minimum T-score lumbar spine, femur neck, trochanter, total hip) was categorized as low (<10%), moderate (10-20%) or high (>20%). Health service records since 1987 were assessed for non-craniofacial non-trauma fracture codes prior to BMD (N=5,224). CS use was defined as possession for 90d or more during the year prior to BMD testing at a prednisone-equivalent mean daily dose of 7.5mg or greater (N=616). Fracture rates (per 1,000 person-y) after BMD testing were calculated from non-trauma fracture codes for the hip, clinical spine, wrist, or humerus (collectively designated 'osteoporotic', N=757).

In women without CRFs, fracture risk predicted from age and BMD alone showed a significant gradient in observed fracture rates (low 4.1±0.6, moderate 8.4±0.8, high 17.1±1.3 per 1,000 person-y; p-for-trend <.0001). There was an incremental increase in incident fracture rates from a prior fracture (13.9 per 1,000 person-y, p<.0001) or recent CS use (8.4 per 1,000 person-y, p=.0077). Site of prior fracture further stratified fracture risk ('osteoporotic' 25.9 vs all other sites 5.5 per 1,000 person-y, p<.0001). Lower dose CS use (<7.5mg daily) had no observed effect on fracture rates. A Cox proportional hazards model gave: HR basal risk moderate 1.94 (1.61-2.34) and high 4.51 (3.73-5.45) vs low (ref); CS use 1.54 (1.16-2.05); prior 'osteoporotic' fracture 2.68 (2.26-3.17) vs other fracture 1.41 (1.17-1.71).

This simplified fracture risk assessment system provides an assessment of fracture risk that is broadly consistent with observed fracture rates.

Figure: Observed fracture rates (SE bars) in relation to age, BMD and two clinical risk factors.

Leptin-deficient (ob/ob) Mice Exhibit Increased Bone Mechanosensitivity and Corresponding Osteoblasts Show Increased Anabolic Shear Stress Responses In Vitro. K. H. W. Lau¹, S. Kapur¹, M. Amoui¹, X. Wang¹, C. Kesavan¹, S. Mohan¹, D. J. Baylink². ¹Loma Linda VAMC, Loma Linda, CA, USA, ²Loma Linda Univ., Loma Linda, CA, USA.

We sought to test the hypothesis that the leptin receptor (Lepr) pathway plays an important role in bone mechanosensitivity based on the rationales that Lepr is located within one of the mouse genetic loci that showed mechanosensitivity modulating effects and that Lepr signaling is essential for skeletal maturation and metabolism. To test this hypothesis, the osteogenic response to loading (in the form of 2-week four-point bending) in tibia of adult female ob/ob mice [in C57BL/6J (B6) background] was compared with those in adult female B6 tibia. To adjust for the 14% greater bone size in ob/ob mice, the load was adjusted to produce similar levels of mechanical strain (2129 $\mu\epsilon$ at 9N for ob/ob mice vs. 2500 $\mu\epsilon$ at 6N for B6 mice). This mechanical strain was insufficient to produce a bone anabolic response in B6 mice; whereas in ob/ob mice this strain increased total BMC (16%), cortical area (22%), content (29%), and thickness (28%), and BMD (8%) [p<0.05 for each]. To further test if leptin deficiency would enhance osteogenic response to mechanical stimuli, the effects of a 30-min fluid shear (20 dynes/cm²) on [³H]thymidine incorporation (TdR) and Erk1/2 phosphorylation in ob/ob osteoblasts were compared to those of wild-type (WT) littermates and B6 mice. While the shear stress increased TdR and Erk1/2 in osteoblasts of B6 and WT littermates (each by ~2-fold, p<0.05), the stimulation in ob/ob osteoblasts was greater (> 3-fold, p<0.05 vs. B6 osteoblasts). In addition, 2-hr pretreatment of ob/ob osteoblasts with 100 ng/ml of leptin completely abrogated the enhanced mitogenic response. Because it has been reported that the mechanism whereby mechanical stimuli act to stimulate proliferation involves upregulation of genes of the IGF-I, Wnt, BMP/TGF β , and estrogen receptor pathways, we next determined whether the Lepr pathway acts upstream to these 4 pathways by assessing the effects of the fluid shear on the expression levels of representative genes of these pathways in ob/ob and B6 osteoblasts (by real-time PCR). The upregulation of each test gene of the 4 pathways in ob/ob osteoblasts was much greater (p<0.05) than those in B6 osteoblasts. The 2-hr leptin pretreatment also abrogated the shear stress-induced upregulation of these genes in ob/ob osteoblasts. Conclusions: 1) In vivo, the Lepr pathway inhibits the anabolic responses to mechanical loading which is consistent with increased basal values for bone size in the ob/ob mouse, 2) In vitro, the Lepr pathway also has a negative modulating role in the mechanosensitivity of mouse osteoblasts, and 3) The Lepr pathway acts upstream of 4 selected major anabolic pathways to modulate mechanosensitivity.

Denosumab (AMG 162), a Fully Human RANKL Antibody, Improves Cortical and Cancellous Bone Mass and Bone Strength in Ovariectomized Cynomolgus Monkeys. M. S. Ominsky¹, J. Schroeder¹, S. Y. Smith², D. J. Farrell¹, J. E. Atkinson¹, P. J. Kostenuik¹. ¹Amgen Inc., Thousand Oaks, CA, USA, ²Charles River Laboratories Preclinical Services Montreal, Inc., Montreal, PQ, Canada.

Denosumab, a fully human monoclonal antibody that inhibits RANKL, decreases bone resorption and increases bone mineral density (BMD) in postmenopausal women participating in clinical studies. Denosumab was shown to cause similar responses in adult ovariectomized (OVX) cynomolgus monkeys (cynos). We now describe the consequences of these changes on bone strength.

One month after OVX or sham surgery, OVX cynos (9 to 16 years old) were treated with vehicle (OVX-Veh) or denosumab (25 or 50 mg/kg, SC, once/month) for 16 months (n=14 to 20/group). Sham controls were treated with vehicle (n=17). After sacrifice, ex vivo DXA and pQCT scans were taken of the intact right femur, L3-L4 vertebral bodies, and L5-L6 vertebral 5mm cancellous cores. Destructive testing was performed by 3-point bending of the femur diaphysis and humeral cortical beams, shearing of the femur neck, and compression of the lumbar vertebral specimens. Statistically significant differences between the denosumab and OVX-Veh groups are reported as P<0.05 by ANOVA.

Compared with OVX-Veh, both doses of denosumab were associated with greater BMC at the femur neck (+19% to 22%), L3-L4 bodies (+23% to 25%), L5-L6 cores (+29% to 30%), and femur diaphysis (+10% to 11%). Both doses of denosumab were associated with significantly greater peak load for femur neck (19% to 34%), L3-L4 bodies (54% to 55%), and L5-L6 cores (69% to 82%), compared with OVX-Veh. Both doses of denosumab were associated with significantly greater stiffness for femur neck (21% to 26%), L3-L4 bodies (39% to 46%), L5-L6 cores (61% to 62%), and femur diaphysis (15% to 16%), compared with OVX controls. Intrinsic (material) properties for cortical sites were derived from geometric data and extrinsic (whole bone) strength parameters. Intrinsic strength parameters of femur diaphysis and humerus cortical beams were similar in OVX-Veh and treatment groups, and the relationship between femur diaphysis vBMC and peak load was strong and similar among all groups ($r^2=0.79$ to 0.91). For the lumbar vertebral bodies and cancellous cores, significant positive correlations were found between vBMC and yield load for all groups ($r^2=0.57$ to 0.84).

In summary, long term (16-month) denosumab therapy increased bone mass and density at both cortical and cancellous sites in ovariectomized cynomolgus monkeys. These increases were highly correlated with improvements in the extrinsic strength of cortical and cancellous sites. The results suggest that in this study, denosumab improves bone strength primarily by increasing bone mass.

Concerted Growth of Bone Length and Width - Influence of Sex Hormones, IGF-1 and Muscle Size. S. Cheng¹, Q. Wang¹, P. Rakkila^{*1}, M. Alen^{*1}, A. Mahonen^{*2}, H. Kröger², H. Suominen¹, A. Lyytikäinen¹, E. Völgyi^{*1}, U. M. Kujala^{*1}, F. Tylavsky³, E. Seeman⁴. ¹Univ. of Jyväskylä, Jyväskylä, Finland, ²Univ. of Kuopio, Kuopio, Finland, ³Univ. of Tennessee, Memphis, TN, USA, ⁴Univ. of Melbourne, Melbourne, Australia.

Bone growth is determined by genetic and environmental factors. The effect of mechanical loading on growth in bone width and length has not been specifically addressed. We hypothesized that 1) sex hormones and IGF-I correlate with bone growth prior to puberty, since hormone levels are changing rapidly, but correlate less well after puberty when levels vary less; and 2) loading, as reflected by muscle size, correlates with bone width and length throughout growth. 258 girls aged 11.2 yrs at baseline were followed on average for 6.5 years. Left tibial shaft was scanned using pQCT (XCT2000). Tibial length (TL) was determined from whole body DXA scans. Serum 17 β -estradiol (E2), testosterone (Te) and IGF-I concentrations were assessed using immunofluorometry and serum sex hormone binding globulin (SHBG) using time-resolved fluoroimmunoassays.

In hierarchical multiple regression models the growth of tibial length, total cross-sectional area (tCSA), bone marrow cavity area (bmCSA) and cortical thickness (cTh) were explained by E2, Te, IGF-I, SHBG, muscle cross-sectional area (mCSA), and time relative to menarche (TRM). The results of these models are summarized in the Fig. There was no correlation between E2 and bone size measures either before or after menarche. mCSA correlated positively with IGF-I and negatively with SHBG both before and after menarche. Te was positively associated with TL, tCSA and cTh before menarche. Of the hormones studied none were associated with bone variables after menarche. Interestingly, TRM was negatively associated with the bmCSA but was not associated with tCSA after menarche. This implies increased periosteal apposition in the long bone shaft as the girls age. The moderate correlation found between TL and tCSA ($r^2=0.44$) was partly due to growth asynchrony between the two.

The results support our hypothesis that before and after menarche bone growth in length and width are influenced differently by hormones and mechanical loading. Mechanical loading is the dominant factor throughout the pubertal period. Hormones may have an indirect influence on bone growth via their regulatory role on muscle mass based on our results.

Role for Estrogen Receptor-Beta in Trabecular Bone Mechanotransduction. A. B. Castillo¹, J. M. Doyle^{*1}, M. R. Allen², C. H. Turner¹. ¹Biomedical Engineering, Indiana University Purdue University, Indianapolis, IN, USA, ²Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA.

Recent studies suggest that estrogen receptor beta (ERb) plays a role in bone mechanotransduction at cortical bone sites. To determine whether ERb plays a role in trabecular bone mechanotransduction, 16-wk-old wildtype and ERb^{-/-} female mice were subjected to 28 days of tail suspension (TS). Age-matched, normally-loaded (NL) mice served as controls. Trabecular bone microarchitecture in the distal femur was evaluated using high-resolution computed tomography (vivaCT40, Scanco Medical), and the following parameters were calculated: bone volume/total volume (BV/TV), connectivity density (Conn.D), trabecular number (Tb.N, 1/mm), trabecular thickness (Tb.Th, mm), trabecular spacing (Tb.Sp, mm) and structure model index (SMI). Data were checked for normality and constancy of variance and analyzed using a 2-factor ANOVA with a Fisher's PLSD post-hoc analysis. TS had a significant factor effect on all variables ($p<0.001$) and resulted in significantly different BV/TV, Conn.D, Tb.N and SMI in TS wildtype and ERb^{-/-} when compared to NL controls (Table I). Genotype had a significant factor effect on BV/TV ($p=0.029$), Tb.Sp ($p=0.029$) and SMI ($p<0.001$). TS wildtype and ERb^{-/-} mice exhibited a 38% and 60% decrease in BV/TV, an 8% and 24% increase in Tb.Sp, respectively, when compared with NL controls. Disuse results in a decrease in osteoblast number and activity with no change in osteoclastic activity in most cases. Estrogen inhibits bone turnover by suppressing both osteoblastogenesis and osteoclastogenesis. The fact that TS ERb^{-/-} mice showed a greater loss in BV/TV compared to wildtype mice implies that signaling via ERb may normally inhibit disuse-related osteoclastic activity in the trabecular bone compartment. The role of ERb in disuse-related osteoclastic activity remains unclear. Taken together, these data implicate a role for ERb^{-/-} in disuse bone loss

and suggest that ERb plays a role in trabecular bone mechanotransduction.

Effects of One Year Treatment with PTH (1-34) on Bone Microstructure at the Ultradistal Radius. S. Kirmani, M. Holets*, S. Khosla. Mayo Clinic, Rochester, MN, USA.

Previous studies have shown a beneficial effect of PTH (1-34) on bone density and fracture rate reduction in women with osteoporosis. Compared to placebo, a 13% and 6% increase in areal BMD (aBMD) using DXA was seen at the spine and hip, respectively (NEJM 344: 1434, 2001). At the distal radius, there was no significant effect on aBMD with the 20 μ g/d dose, but at the 40 μ g/d dose, there was a 2% decrease as compared to placebo. Using pQCT, a subset of women from the same trial had a 5-7% increase in cortical bone area, but no significant change in cortical vBMD or cortical thickness (JBMR 18:539, 2003). Despite these data on changes in BMD, there are sparse data on possible effects of PTH therapy on bone microstructure, and the available data are limited to studies using bone biopsies from the iliac crest. Thus, to further define effects of PTH on bone microstructure, we used high resolution 3D-pQCT (XtremeCT, Scanco AG, voxel size ~90 microns) to measure bone microstructural variables at the ultradistal radius in 7 women with osteoporosis (mean age, 74 yrs) at baseline and 1 yr after initiation of 20 μ g/d of PTH (1-34) (Forteo) for osteoporosis. None of the women suffered a fracture during the 1 year of treatment. Compared to baseline, we noted a 6.9% increase in bone volume/tissue volume (BV/TV) (Table, $P = 0.035$). This was similar in magnitude to the 5.7% change noted at the iliac crest in women treated for 3 years with PTH (JBMR 16:1846-1853). Two-thirds of this increase in BV/TV was due to an increase in trabecular thickness (Tb.Th), and only one-third due to an increase in trabecular number (Tb.N). There was a trend towards a decrease in cortical thickness (C.Th) and cortical volumetric BMD (vBMD). In summary, these data represent the first assessment of trabecular microstructure at the wrist following PTH therapy, and they demonstrate that (1) changes in trabecular parameters seen at the radius are very similar to those previously reported at the iliac crest; and (2) the beneficial effects of PTH (1-34) on trabecular bone seem to result primarily from increased trabecular thickness, with the minor apparent increase in trabecular number seen likely due to coalescence of the thickened trabeculae.

Glucocorticoids, Aging and Bone Hydration: New Insights into Qualitative Aspects of Bone Strength. R. S. Weinstein, J. Goellner, T. M. Chambers*, E. A. Hogan*, S. B. Berryhill*, R. Shelton*, W. W. Webb*, C. A. Wicker*, S. C. Manolagas. Central Arkansas Veterans Healthcare System, Center for Osteoporosis, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Both aging and glucocorticoid excess are associated with a decline in bone strength that is greater than the decline in bone mass. In addition, both conditions may decrease the water content of bone, as determined by the intensity of an inert aqueous fluorescent tracer (Procion red), which provides a visible outline of the lacunocanalicular network, following injection into the tail vein. Prompted by these lines of evidence, we obtained femora (including bone marrow) from 15 C57BL/6 mice at 4 months of age and placed them in a vacuum chamber for 50 hours at 4° C. Contralateral femora from the same animals were maintained in normal saline at the same temperature. Compared to zero time, there was a $58.7 \pm 3.0\%$ (SD) reduction of total weight in the femora, as early as 24 hours, and weights remained stable thereafter, indicating that maximum water removal was accomplished by this time point. We next determined the biomechanical properties of the femora during 3-point bending of the wet versus the vacuum dried femora taken from the same animals. Loss of wet weight reduced the average breaking stress by 33.7% and toughness (i.e. the work required to break the bone) by 59%. In agreement with this line of evidence, prednisolone administration to 8 month old C57BL/6 mice ($n = 3$) for 7 days (a time period insufficient to affect bone mass) decreased Procion fluorescence by 71%, as compared to placebo control. This effect was prevented in transgenic mice overexpressing the enzyme 11β -HSD2 in the context of an OG2 promoter, a model for deflecting glucocorticoid action from osteoblasts. In a second experiment with C57BL/6 mice ($n = 16$), crystallinity determined by Fourier transformation infrared microscopy (FTIRM) as well as strength decreased in mice receiving prednisolone for 28 days; and the two measures were directly correlated ($r = 0.53$; $p < 0.03$). Moreover, both the decrease in crystallinity and strength were prevented in the 11β -HSD2 transgenic animals. Lastly, Procion red epifluorescence was decreased by more than 40% in 31 month old as compared to 4 month old female or male C57BL/6 animals ($p < 0.001$). In addition, the mRNA levels in bone of 11β -HSD1 - the enzyme that locally amplifies glucocorticoid action, was increased by 1.8 fold between 8 and 31 month old mice and were inversely related to strength ($r = -0.67$, $p < 0.05$). These results lend strong support to our working hypothesis that skeletal water volume may protect against mechanical failure by means of hydraulic stiffening; and that both aging and glucocorticoid excess compromise bone strength, in part by decreasing skeletal hydration.

Effects of Mechanical Loading and Estrogen Are Structurally Distinct. J. Jokihaara¹, I. Pajamäki¹, H. Sievänen^{*2}, P. Kannus^{*2}, T. Vuohelainen^{*1}, T. L. N. Järvinen^{*1}. ¹University of Tampere, Tampere, Finland, ²UKK-Institute, Tampere, Finland.

The objective was to study the effects of effects of estrogen and locomotion on trabecular bone structure. We hypothesized that the independent and potentially interactive effects of these two factors should become distinct after separate or simultaneous inclusion of their influence; i.e. using the classic 2×2 factorial study design.

Accordingly, 30 three-week old littermates of female rats were first randomly assigned into bilateral ovariectomy (E-) or sham surgery (E+), after which the left hindlimb of each rat was cast immobilized (L-) while the contralateral (right) hindlimb served as normally loaded control (L+). After eight-week study period, trabecular structure of the distal femoral metaphysis was analyzed with micro-computed tomography. To eliminate the inherent bias arising from comparisons between animals differing in body weight and size, all data pertaining to bone mechanical competence was equalized in terms of the animal's apparent loading environment by using the body weight and femoral length as covariates. Loading increased bone size ($P=0.002$), while estrogen was not associated with changes in bone size ($P=0.280$). Both factors displayed a significant stimulatory effect on trabecular bone volume ($P=0.001$ and $P=0.003$, respectively). Further, both factors increased trabecular number ($P=0.006$ and $P=0.007$, respectively) while only loading increased trabecular thickness ($P<0.001$ and $P=0.244$, respectively) and only estrogen decreased trabecular separation ($P=0.775$ and $P=0.004$, respectively).

The anabolic effects of loading and estrogen were shown to be independent and the mechanisms of action of these two factors were distinct: loading alone (E-L+) resulted in thickening of individual trabeculae and estrogen effect (E-L-) was discernible as a denser (less spacing) trabecular meshwork. Moreover, when the factors were combined (E+L+), the effects add up. In conclusion, our results show that there is a structural dimorphism in the skeletal actions of estrogen and loading so that the actions of these two factors are independent and additive in nature.

Transgenic Overexpression of OPG Results in Increased Bone Mass and Strength and Decreased Bone Turnover in One-Year-Old Female Rats. M. S. Ominsky, F. J. Asuncion, M. Barrero, Q. Niu*, T. J. Corbin*, D. Dwyer*, K. S. Warmington*, M. Grisanti, H. Tan*, X. Li, M. Stolina, P. J. Kostenuik. Metabolic Disorders and Laboratory Animal Research, Amgen Inc., Thousand Oaks, CA, USA.

RANK ligand (RANKL) is an essential mediator of bone resorption, and its activity is inhibited by osteoprotegerin (OPG). We created transgenic (Tg) rats to study the long-term impact of increased circulating levels of OPG on bone turnover, volume, density, and strength. CD rats were engineered to overexpress full-length soluble rat OPG via a liver promoter. Serum OPG levels in female Tg rats ($n=32$) were up to 260-fold greater than the mean value (257 ± 16 pg/ml) found in wildtype (WT) controls ($n=23$). At 1 year of age, rats were injected with fluorochrome labels for dynamic histomorphometry, bled for biomarker analyses, scanned by DXA, and sacrificed. Lumbar vertebra 2 (L2) was used for histomorphometry, and L5 was scanned by microCT and subjected to destructive mechanical testing.

In normal WT rats, there were no significant correlations between log serum OPG levels and lumbar BMD, serum TRAP-5b, serum osteocalcin, bone formation rate, or bone strength parameters. In contrast, log serum OPG in OPG-Tg rats had significant ($P<0.01$) and positive linear correlations with lumbar BMD ($r^2=0.53$), BV/TV ($r^2=0.77$), trabecular number ($r^2=0.93$), and peak load ($r^2=0.54$). Log serum OPG in OPG-Tg rats had significant ($P<0.01$) and negative linear correlations with serum TRAP-5b ($r^2=0.64$), serum osteocalcin ($r^2=0.35$), and bone formation rate ($r^2=0.51$).

Tg rats with the highest levels of serum OPG (OPG-hi, 50- to 260-fold greater than the mean value for WT controls; $n=15$) had 70% lower osteoclast surface and 91% lower bone formation rates in L2 compared with WT controls ($P<0.001$). Despite the profound suppression of bone turnover, the vertebra of the OPG-hi rats had 56% greater peak load, 62% greater stiffness, and 53% greater energy absorption compared with WT controls ($P<0.01$). To approximate material properties, apparent strength parameters were derived by normalizing to bone volume. Apparent toughness was similar between WT and Tg groups, while apparent strength was significantly higher in the OPG-hi group versus WT ($P<0.01$).

In summary, 1 year of OPG overexpression led to marked changes in bone turnover, volume, density and strength that were consistent with the suppression of bone resorption. The dose-dependent suppression of resorption in OPG-Tg rats was accompanied by a secondary coupling-related suppression of bone formation. Rats with the highest levels of OPG overexpression had the greatest reductions in bone turnover parameters, and the greatest improvements in extrinsic bone strength with no evidence of impairment of material properties.

Comparison of the Effects of Teriparatide and Alendronate on Parameters of Total Hip Strength as Assessed by Finite Element Analysis: Results from the Forteo and Alendronate Comparison Trial. T. M. Keaveny¹, P. F. Hoffmann^{*2}, D. L. Kopperdahl², D. W. Donley^{*3}, K. Krohn³, E. V. Glass^{*3}, B. H. Mitlak³. ¹University of California, Berkeley, CA, USA, ²O.N. Diagnostics, Berkeley, CA, USA, ³Eli Lilly and Company, Indianapolis, IN, USA.

Biomechanical computed tomography (BCT) uses finite element analysis of QCT scans to provide non-invasive measures of femoral strength and density plus a strength: density ratio that can be considered a measure of bone "quality". Teriparatide [rPTH (1-34), TPTD] 20 µg/d and alendronate 10 mg/d (ALN) were previously shown to have positive effects on vertebral strength as assessed by BCT during a randomized, double-blind, 18-month study in postmenopausal women with osteoporosis. The purpose of the present analysis was to extend these studies to analysis of proximal femoral strength for a simulated sideways fall. Using the QCT scans, volumetric density from QCT and strength from BCT were determined for the total hip and for the trabecular and cortical compartments, and a strength: density ratio was calculated. In the TPTD group, whole total hip density was not significantly different from baseline at any time point, however, at 18 months trabecular density significantly increased 5.1% and cortical density significantly decreased 1.0% from baseline. In the ALN group, density was not significantly different from baseline at any time point for any compartment. Total hip strength significantly increased 5.9% from baseline at 18 months in the TPTD group, and strength did not significantly change from baseline at any time point in the ALN group. No significant changes were seen in the strength measures associated with isolated changes in the cortical or trabecular compartments. The strength: density ratio significantly increased 4.1% from baseline at 18 months in the TPTD group, whereas no significant changes were seen for ALN. In conclusion, total hip strength at 18 months significantly increased in the TPTD group and did not significantly change in the ALN group. This significant biomechanical effect for TPTD was associated with a significant decrease in cortical density and a somewhat larger increase in trabecular density.

Table: Median percent change from baseline (Interquartile range) at 6 and 18 months

	Alendronate 10mg/day		Teriparatide 20µg/day

Prediction of 24 Month Change in BMD on PTH Followed by Alendronate: The PaTH Study. D. M. Black¹, D. C. Bauer¹, L. Palermo¹, C. J. Rosen², S. L. Greenspan³, J. P. Bilezikian⁴. ¹UC San Francisco, San Francisco, CA, USA, ²MECORE, St. Joseph Hospital, Bangor, ME, USA, ³University of Pittsburgh, Pittsburgh, PA, USA, ⁴Columbia University, New York, NY, USA.

We previously reported the PaTH study results for postmenopausal women on 2 years of parathyroid hormone (PTH 1-84, 100 µg daily) used either alone or in combination with alendronate (ALN, Black et al., NEJM, 2005). The treatment group that received 1 year of PTH (1-84) followed by 1 year of ALN had the largest mean spine BMD change of 12%, but response varied, with 17% of women having BMD increases over 20%. Previous PaTH analyses have examined predictors of 1 year BMD change while on PTH therapy. This analysis aimed to identify early predictors of response over 2 years in women taking 1 year of PTH followed by 1 year of ALN.

This analysis included 53 women assigned to 1 year of PTH 1-84 followed by 1 year of ALN. The main endpoint was 2 year change in (DXA) spine BMD. Potential predictors included baseline variables (age, BMI, bone marker levels (serum CTX, PINP, Bone ALP), serum chemistries) and early 1- and 3-month on-treatment bone marker values. We used univariable analyses (logistic regression) with change in BMD (>20%) as the outcome adjusted for significant covariates. Bone markers were categorized into highest quartile vs. lower 3 quartiles combined.

The following baseline factors had weak, but significant relationships to the 24-month change in BMD: age, BMI and serum calcium. Baseline bone markers were not significantly associated, but bone marker values at 1 and 3 months after start of treatment were very strongly related to BMD change at 24 months. While all 3 bone markers were associated with 24 month BMD change, PINP was most strongly correlated. The figure

compares 24 month % change in spine BMD in those with 1 month PINP levels in the highest quartile (>142ng/ml) vs. those in the lower 3 quartiles (≤142ng/ml):

The data show that those in the highest quartile of PINP at 1 month were 10 times more likely to show an increase in DXA BMD of ≥20% at 24 months. This relationship was confirmed with multivariable adjustment. In addition to 1-month bone marker values, the 3-month values and change from baseline to 1 and 3 months were similarly predictive of 2 year BMD change. In conclusion, a single measurement of PINP as early as 1 month after initiation of PTH therapy strongly predicts 2 year spine BMD response to 1 year of PTH followed by 1 year of ALN.

Patients Previously Treated with Risedronate Demonstrate Greater Responsiveness to Teriparatide than Those Previously Treated with Alendronate: The OPTAMISE Study. P. Miller¹, R. Lindsay², N. Watts³, S. Meeves^{*4}, T. Lang^{*5}, P. Delmas⁶, J. Bilezikian⁷. ¹Colorado Center for Bone Research, Lakewood, CO, USA, ²Helen Hayes Hospital and Columbia University, West Haverstraw, NY, USA, ³University of Cincinnati College of Medicine, Cincinnati, OH, USA, ⁴sanofi-aventis US Inc., Bridgewater, NJ, USA, ⁵Center for Molecular and Functional Imaging, University of California, San Francisco, CA, USA, ⁶Inserm Research Unit 831 and Université de Lyon, Lyon, France, ⁷Columbia University College of Physicians and Surgeons, New York, NY, USA.

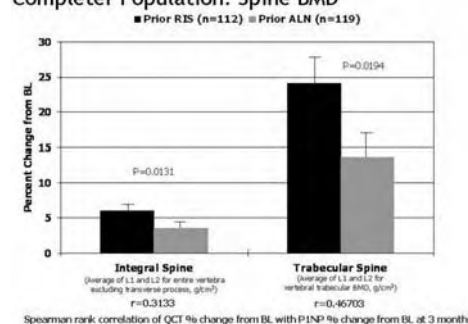

Previous or simultaneous treatment with alendronate (ALN) has been shown to blunt or delay the anabolic response to teriparatide (TPTD). It is not known if the effect is the same with other bisphosphonates. OPTAMISE evaluated the anabolic effect of TPTD in postmenopausal women previously treated for ≥24 months with risedronate (RIS) or ALN.

Post-RIS (n=146) and post-ALN (n=146) subjects were stratified by duration of prior therapy, discontinued their bisphosphonate and were treated with TPTD (20 µg/d SQ) for 12 months. We measured bone turnover markers (BTMs) and bone mineral density (BMD) by DXA and QCT. At baseline, BTMs were higher in the post-RIS group (P<0.05); otherwise, the groups were comparable for key characteristics including BMD by DXA and QCT. Compared with post-ALN subjects, post-RIS changes in BTMs were significantly greater at Months 1-5 (P<0.05, including primary endpoint of PINP change at Month 3), and for BMD by DXA at Month 12 at the spine (P<0.05) and hip (P<0.01). Results were not related to duration of prior bisphosphonate therapy, baseline BTMs, or baseline BMD. Post-RIS subjects showed a 76% greater increase in QCT of trabecular bone at the spine (24.1% vs 13.7%, P=0.0230; Figure). Spine QCT changes correlated with PINP changes at 3 months (r=0.47). TPTD was well-tolerated with a similar incidence of adverse events between groups.

When switched to teriparatide, subjects previously treated with risedronate showed a greater QCT response that correlated with a more pronounced, early increase in PINP as compared with those previously treated with alendronate. Our findings support differences between these bisphosphonates that affect subsequent response to the anabolic effects of teriparatide.

Bone Turnover Markers Demonstrate Greater Earlier Responsiveness to Teriparatide Following Treatment with Risedronate Compared with Alendronate: The OPTAMISE Study. P. Delmas¹, N. Watts², P. Miller³, D. Cahall⁴, J. Bilezikian⁵, R. Lindsay⁶. ¹Inserm Research Unit 831 and Université de Lyon, Lyon, France, ²University of Cincinnati College of Medicine, Cincinnati, OH, USA, ³Colorado Center for Bone Research, Lakewood, CO, USA, ⁴sanofi-aventis, Bridgewater, NJ, USA, ⁵Columbia University College of Physicians & Surgeons, New York, NY, USA, ⁶Helen Hayes Hospital and Columbia University, West Haverstraw, NY, USA.

Previous treatment with alendronate (ALN) has been shown to blunt or delay the anabolic response to teriparatide (TPTD). It is not known if the effect is the same with other bisphosphonates. OPTAMISE evaluated the anabolic effect of TPTD on bone turnover markers (BTM) in postmenopausal women previously treated for ≥ 24 months with risedronate (RIS) or ALN.

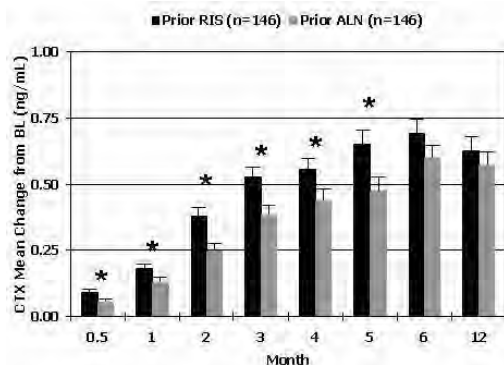

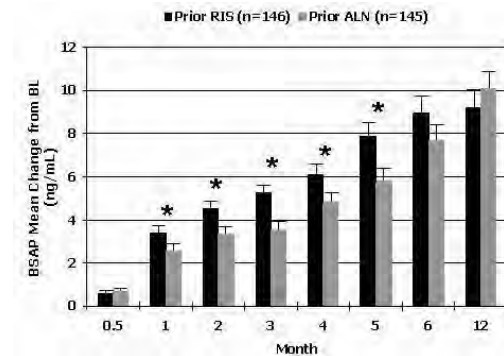

Post-RIS (n=146) or post-ALN (n=146) patients were stratified by duration of prior bisphosphonate therapy, and after discontinuation were treated with TPTD (20 μ g/d SQ) for 12 months. We measured N-terminal propeptide (P1NP, primary endpoint change at Month 3), bone-specific alkaline phosphatase (BAP), osteocalcin (OC), serum CTX and urine NTX in both groups.

Baseline BTMs were significantly higher in the post-RIS group ($P<0.05$); otherwise the groups were comparable for key characteristics, including duration of prior therapy. Absolute changes in P1NP were significantly greater for post-RIS than post-ALN groups during Months 1-5 (Figure 1). Comparable results were observed for BAP, OC, CTX and NTX (Figure 2). Results were consistent regardless of duration of prior therapy or baseline BTMs. TPTD was well-tolerated with a similar incidence of adverse events between groups.

In response to treatment with TPTD, subjects previously treated with RIS showed greater increases in BTMs compared with those previously treated with ALN. The increase in the resorption markers occurred as early as the increase in formation markers, but to a lesser extent. Our findings suggest differences between these bisphosphonates in which RIS allows the skeleton to be more responsive to the anabolic properties of TPTD.

Teriparatide Reduces Bone Microdamage Accumulation in Postmenopausal Women Previously Treated with Alendronate. H. Dobnig¹, J. J. Stepan², D. B. Burr³, A. F. Fahrleitner-Pammer¹, J. Li³, A. Sipos⁴, M. Sato⁴, I. Pavo⁴. ¹Endocrinology and Nuclear Medicine, Medical University of Graz, Graz, Austria, ²Institute of Rheumatology, Charles University Faculty of Medicine, Prague, Czech Republic, ³Department of Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, ⁴Lilly Research Laboratories, Indianapolis, IN, USA.

Suppression of bone turnover by bisphosphonates is associated with increased bone microdamage accumulation in animal models. It has been demonstrated at the baseline analysis of the present study, that after adjustment for potential confounders, crack density (Cr.D) was elevated in alendronate (ALN) treated patients compared with treatment naïve (TN) patients. In addition, an association of microdamage accumulation with low bone mineral density was only present in ALN treated patients. To assess effects of bone formation on bone quality, our objective was to investigate the change in microdamage accumulation in iliac crest biopsies by teriparatide (TPTD) in these previously TN patients and in those switched from ALN to TPTD. Sixty-six postmenopausal women with osteoporosis (mean age of 68.0 years and mean BMD T-score of -1.7 at total hip and -2.8 at lumbar spine; 62% with prevalent fractures) entered this prospective, non-randomized study and started with 24-month 20 µg/day subcutaneous TPTD treatment in monotherapy: thirty-eight stopped previous ALN treatment (10 mg/day or 70 mg/week for a mean duration of 63.6 months) and switched to TPTD while twenty-eight were treatment naïve (TN) previously. Paired biopsies with two intact cortices were collected and analyzed for microdamage accumulation at baseline and after 24-month TPTD administration in 13 TN and 18 ALN treated patients. A within-group t-test comparing the mean percent change was carried out on log-transformed data. Following 24 months of teriparatide treatment, Cr.D, crack surface density (Cr.S.D) and crack length (Cr.L) were decreased in previously ALN treated patients while only Cr.L was reduced in former TN patients (Table). The changes in microdamage accumulation parameters were not statistically different between the two groups. Our data indicate that TPTD reduces microdamage accumulation in iliac crest biopsies of patients previously treated with ALN.

All mean+/-SD, %change on log-transformed data				
		Baseline	After TPTD	P-value
Crack Density (/mm ²)	Treatment naïve (N=13)	0.56+/- 0.6	0.71+/-0.6	0.33
Crack Density (/mm ²)	ALN (N=18)	0.91+/-0.7	0.66+/-0.8	0.05
Crack Surface Density (µm/mm ²)	Treatment naïve (N=13)	28.7+/-35	26.7+/-24	0.79
Crack Surface Density (µm/mm ²)	ALN (N=18)	44.5+/-33	28.3+/-43	0.01
Crack Length (µm)	Treatment naïve (N=13)	46+/-10	36+/-5	0.01

Year 3 Effects on Bone Mass in Women using Bisphosphonates after PTH Therapy: Follow-up Results from the PaTH II Study. T. F. Hue¹, J. P. Bilezikian², K. E. Ensrud³, S. L. Greenspan⁴, C. J. Rosen⁵, L. Palermo¹, T. F. Lang¹, D. M. Black¹. ¹University of California, San Francisco, San Francisco, CA, USA, ²Columbia University, New York, NY, USA, ³University of Minnesota, Minneapolis, MN, USA, ⁴University of Pittsburgh, Pittsburgh, PA, USA, ⁵Maine Center for Osteoporosis Research & Education, St. Joseph Hospital, Bangor, ME, USA.

We previously reported the results of the 2-year PaTH trial of 238 postmenopausal women comparing 1 year of therapy with either parathyroid hormone (PTH 1-84, 100 µg daily) alone, the bisphosphonate, alendronate (ALN), alone or the two in combination, followed by 1 year of ALN or placebo (Black et al., NEJM, 2004; NEJM, 2005). At 24 months, 1 year of PTH followed by 1 year of ALN resulted in the largest increases in areal bone mineral density (BMD) at the spine and hip, by dual-energy x-ray absorptiometry (DXA). This group also showed the greatest BMD increase in trabecular spine BMD by quantitative computed tomography (QCT). PaTH II was a 1-year observational study designed for a 3rd year of follow-up in women originally randomized into PaTH (from 4 sites: ME, MN, NY, and PA) to assess if BMD continues to increase or is maintained in those treated with PTH followed by a bisphosphonate. After completion of PaTH, 60% (n=109) of the 182 women in follow-up were prescribed a bisphosphonate (ALN or resoridronate). In addition, 90% of the 182 remained on calcium/vitamin D supplements. Results are presented for the 109 participants who used a bisphosphonate (BIS) during year 3 (months 25-36).

Women who used Bisphosphonates in year 3 (n=109): BMD Mean Percent Changes by DXA and QCT[†]

Treatment Group	PaTH				PaTH II			
	% Changes from baseline to year 2				% Changes from baseline to year 3			
Yr 1 Treatment	PTH	PTH	PTH/BIS	BIS	PTH	PTH	PTH/BIS	BIS
Yr 2 Treatment	Placebo	BIS	BIS	BIS	Placebo	BIS	BIS	BIS
Yr 3 Treatment					BIS	BIS	BIS	BIS
DXA BMD								
Spine	+5.9*	+11.2*	+7.9*	+8.1*	+8.9*	+11.5*	+10.1*	+9.4*
Total hip	+0.05	+4.6*	+3.4*	+3.0*	+1.7	+5.1*	+3.3*	+3.7*
QCT BMD								
Trabecular spine	+19.6*	+29.7*	+9.0*	+3.5	+10.7	+26.6*	+8.1	+3.3
Trabecular hip	+7.8	+13.9*	+14.7*	+5.8	-4.8	+15.1*	+15.1*	+2.4
Cortical hip	-2.6*	-1.4	-1.3	-1.4	-3.6*	-3.5*	-3.2*	-3.4*

* Mean change within group, p-value < 0.05

† QCT scans were not measured in participants at the New York site. PaTH (months 0-24), n= 95;

PaTH II (months 25-36), n=76.

The results suggest that BMD increases were maintained with BIS use in year 3 (for groups B & C), after 1 year of PTH followed by 1 year of BIS or the two in combination, followed by 1 year of BIS. However, women (in group A) who received PTH for 1 year, had no treatment the following year, and then took BIS in year 3, lost approximately 50% of their previous gain (from months 0-24) in trabecular spine BMD. Group A also had a loss of all gains in trabecular hip BMD and reverted to below the mean baseline level. We conclude that treatment of up to 2 years with bisphosphonate, immediately following 1 year of daily PTH, appears to maintain bone mass gains from the initial anabolic therapy in postmenopausal osteoporotic women.

Teriparatide Improves Bone Microarchitecture in Postmenopausal Women Previously Treated with Alendronate. J. Li¹, D. B. Burr¹, J. J. Stepan², H. Dobnig³, A. Fahrleitner-Pammer³, A. Sipos⁴, T. Mullarney⁴, M. Westmore⁴, M. Sato⁴, I. Pavo⁴. ¹Department of Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, ²Institute of Rheumatology, Charles University Faculty of Medicine, Prague, Czech Republic, ³Department of Internal Medicine, Medical University of Graz, Graz, Austria, ⁴Lilly Research Laboratories, Indianapolis, IN, USA.

Teriparatide stimulates mineral apposition resulting in increased trabecular bone volume and cortical thickness in postmenopausal women with osteoporosis who were not treated previously with antiresorptive agents. Patients previously on alendronate (ALN) may have a delayed response to teriparatide (TPTD) as measured by an increase in serum levels of biochemical markers of bone formation activity and bone mineral density (BMD). Our aim was to investigate the effect of teriparatide on bone microarchitecture in patients after long-term ALN treatment. Sixty-six postmenopausal women with osteoporosis (mean age of 68.0 years and mean BMD T-score of -1.7 at total hip and -2.8 at lumbar spine; 62% with prevalent fractures) entered a prospective, non-randomized study. Thirty-eight had been switched from previous ALN treatment (10 mg/day or 70 mg/week for a mean duration of 63.6 months) while twenty-eight were treatment naïve (TN). All patients were subsequently treated with TPTD (20 µg/day, subcutaneously) as monotherapy for 24 months. Iliac crest bone biopsies were collected at baseline and endpoint and were analyzed by two-dimensional (2D) histomorphometry (N=35) and three-dimensional (3D) microcomputed tomography (µCT, N=45). Mean activation frequency, an indicator of bone turnover was increased from baseline in both TN and ALN treated patients (mean change, mean % change, within-group p-value: 0.165 cycles/year, 138%, p=0.002 and 0.212 cycles/year, 359%, p<0.001 for TN and ALN respectively). The more accurate µCT 3D indices demonstrated an increase in both trabecular and cortical thickness (Table). There was no difference in 3D changes between the two patient groups. Our results show that after 24 months of treatment, TPTD therapy improves bone microstructure in patients, irrespective of whether they had received prior ALN antiresorptive therapy.

	Treatment naïve (N=16)		Alendronate treated (N=29)

Unusual Osteoclast Morphology in Teriparatide-treated Patients Who Have Been Pretreated with Alendronate. D. W. Dempster¹, H. Zhou¹, J. W. Nieves¹, N. Barbuti^{*1}, M. Bostrom^{*2}, F. Cosman¹, R. Lindsay¹. ¹Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, ²Hospital for Special Surgery, New York, NY, USA.

It has long been established that osteoblasts signal to osteoclasts. Recent observations suggest that signaling also occurs in the opposite direction, from osteoclasts to osteoblasts (Karsdal et al, JBMR 2007). Such signaling almost certainly plays an important role in mediating the stimulatory effect of anabolic agents, such as teriparatide (TPTD) on bone formation and may also be influenced by prior treatment with antiresorptive agents such as bisphosphonates. The purpose of the present study is to define better the effects of TPTD and prior treatment with the bisphosphonate alendronate on osteoclasts. We recruited 37 women with osteoporosis (16 treatment naïve; 21 pretreated with alendronate for at least one year. The two groups were randomized to control or TPTD (20 mcg/day). Iliac crest biopsies were taken either prior to TPTD treatment (n=11), after 7.5 weeks (n=13), or after 7.5 months (n=13). Biopsies were analyzed without knowledge of treatment assignment. During the morphometric analysis, osteoclasts with unusual morphology were observed in a number of subjects. These cells were approximately twice the size of normal osteoclasts, and contained many more nuclei (up to 27 per cell profiles). They were frequently not attached to the bone surface or were separated from it by lining cells. They were often not associated with Howship's lacunae, or the lacunae were shallow. We refer to them as large, inactive osteoclasts (LI.Oc). LI.Oc were observed in only 1 of 13 subjects at 7.5 weeks but were commonly seen on cancellous, endocortical or both surfaces at 7.5 months.

Group	Number of Subjects	Number of Subjects with LI.Oc
Alendronate Pre-TPTD	6	2
Alendronate Post-TPTD	8	8
Naïve Pre-TPTD	5	1
Naïve Post TPTD	5	1

LI.Oc were observed in 33% of ALN treated patients prior to TPTD treatment, in 100% of patients in whom ALN was followed by TPTD, and in only 20% of naïve patients both before or after TPTD treatment. We conclude that treatment with ALN followed by TPTD results in an increase in LI.Oc. We hypothesize that, by 7.5 months, TPTD enhances osteoclast recruitment, but the resorptive capacity of these osteoclasts is inhibited by ALN. Osteoclast nuclear number and size increase as a compensatory response to inhibition of activity. While resorptive function is inhibited, signaling to osteoblasts remains intact as bone formation is markedly increased by TPTD in ALN-treated subjects (see abstract from our group, this meeting)

The Aging Associated Gene SIRT-1 Regulates Osteoclast Formation and Bone Mass In Vivo. J. R. Edwards¹, K. Zainabadi^{*2}, F. Eleftheriou¹, L. Connelly³, F. Yuli^{*3}, T. S. Blackwell^{*3}, E. Alt^{*2}, L. Guarente^{*2}, G. R. Mundy¹. ¹Center for Bone Biology, Vanderbilt University Medical Center, Nashville, TN, USA, ²MIT, Cambridge, MA, USA, ³VUMC, Nashville, TN, USA.

Progressive bone loss is a universal accompaniment of aging and involves multiple mechanisms. As the aging process has a powerful genetic component we questioned if genes associated with aging had a direct role in controlling bone mass. We examined the role of the longevity gene Sir2 which directly regulates lifespan in *S. cerevisiae*, *C. elegans* and *Drosophila*, in the control of vertebrate bone remodeling. The mammalian homolog of Sir2 is the highly conserved histone deacetylase Silent Information Regulator T-1 (SIRT-1). We examined the phenotype of SIRT-1 null mice using Piximus, μ CT scanning, histomorphometric analysis, bone resorption and cell proliferation assays of primary bone cells from SIRT-1 null and WT mice. In addition, the effect of SIRT-1 agonists and inhibitors on normal osteoclast formation and Nf κ B activity were studied using a GFP-tagged Nf κ B-reporter (NGL) mouse model, and q-PCR used to assess SIRT-1 expression in bone extracts from the SAM P6 osteoporotic mouse model. The phenotype of these mice was striking. Skeletal tissues from 1, 4 and 11 month SIRT-1 null mice showed up to 40% decrease in BV/TV by μ CT analysis (p<0.001) and 46% decrease in BMD (p<0.01) compared to WT. Histomorphometric analysis of undecalcified SIRT-1 null L3-4 vertebrae supported μ CT data showing up to 44% decrease in BV/TV (p<0.001). TRAP staining demonstrated a 27% increase in osteoclast surface/bone surface compared to WT animals (p<0.05). When cells extracted from normal bone marrow were treated with M-CSF (30ng/ml), RANKL (50ng/ml) and the SIRT-1 inhibitor Nicotinamide (10mM) the number and size of VNR+, TRAP+ multinucleated cells formed and resorption of dentine slices was significantly increased. The SIRT-1 agonist Resveratrol (1uM) demonstrated a decrease in osteoclast formation (p<0.05). In agreement with pharmacological data, primary bone marrow cells isolated from SIRT-1 null mice also formed TRAP+ multinucleated cells at significantly increased rates compared with WT cells. Isolated bone marrow cells from NGL mice treated with M-CSF, RANKL and Nicotinamide showed a x10 increase in fluorescence (p<0.05). Resveratrol treatment reduced GFP expression to a level lower than that of RANKL treatment alone (p<0.05) suggesting that Nf κ B is a downstream target of SIRT-1. In addition, bone extracts from SAM P6 mice showed a 7.5 fold decrease in SIRT-1 expression compared to SAM R1 controls (p<0.001). This data suggests that SIRT-1 activity regulates osteoclast formation and bone mass through the release of Nf κ B from SIRT-1 inhibition. These findings identify a new molecular link between aging and osteoporosis.

Functional Analysis of Bcl-xL in Osteoclasts by Osteoclast-Specific Deletion of bcl-x Gene in Mice. M. Iwasawa¹, Y. Nagase¹, T. Miyazaki¹, T. Akiyama¹, Y. Kadono¹, M. Nakamura¹, Y. Oshima¹, T. Yasui^{*1}, T. Nakamura^{*2}, S. Kato^{*2}, K. Nakamura¹, S. Tanaka¹. ¹Department of Orthopaedic Surgery, The University of Tokyo, Tokyo, Japan, ²The Institute of Molecular and Cellular Biosciences, The University of Tokyo, Tokyo, Japan.

Osteoclasts undergo rapid apoptosis without trophic factors, such as macrophage colony-stimulating factor (M-CSF) and receptor activator of NF- κ B ligand (RANKL). However, the molecular events implicated in these processes still remain elusive. Bcl-2 family proteins are central regulators of apoptosis, and include pro- and anti-apoptotic members. Bcl-xL is an anti-apoptotic member of the Bcl-2 family, which is generated by alternative splicing of bcl-x gene, and suppresses apoptosis in many cell types. To investigate the role of Bcl-xL in osteoclasts, we generated osteoclast-specific Bcl-xL knock-out (cKO) mice by mating bcl-x flox/flox mice with Cathepsin K-Cre mice, in which Cre recombinase gene was knocked into a single allele of the cathepsin K gene locus. Expression of Bcl-xL was specifically reduced in osteoclasts derived from cKO mice (-/-OCs) compared to those from wild-type littermates (+/+OCs), but not in osteoblasts or other tissues. Osteoclasts differentiated normally from cKO mouse bone marrow cells in the presence of RANKL and M-CSF. However, -/-OCs exhibited increased cell death and Caspase-3 activity after cytokine withdrawal. In spite of their susceptibility to apoptosis, -/-OCs showed higher bone-resorbing activity than +/+ OCs as determined by pit formation assay. These phenotypes of -/-OCs were restored by adenoviral introduction of Bcl-xL. We further analyzed the effect of Bcl-xL deficiency in osteoclast differentiation using RNA interference technique, and found that osteoclast differentiation was not affected by Bcl-xL knockdown. cKO mice were alive at birth and were obtained at predicted Mendelian frequencies. Although they grew normally with no apparent morphological abnormalities, they exhibited a decrease in trabecular bone volume after 8 weeks, and developed significant osteopenia at 1 year of age as determined by radiological (soft X-ray and bone densitometry) and histological analysis. Histomorphometric analysis of distal femur revealed that the eroded surface/bone surface (ES/BS) was significantly increased in the cKO mice, while bone formation markers were equivalent to those of wild-type mice. From these observations, we conclude that Bcl-xL deficiency in OCs leads to decrease of bone volume through increased bone resorbing activity, despite of increased apoptosis. Bcl-xL plays a pivotal role in both survival and bone-resorbing activity of osteoclasts, thus creating a novel link between anti-apoptotic molecule and skeletal homeostasis.

ADAM8 Binds $\alpha_9\beta_1$ to Increase OCL Formation and Function by Interacting with Pyk2 and Activating Paxillin. G. Lu¹, K. Patrene^{*1}, V. Garcia-Palacios¹, J. Anderson^{*1}, C. Boykin^{*2}, D. Del Prete^{*3}, J. J. Windle^{*2}, G. D. Roodman⁴. ¹Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, ²Human Genetics, Virginia Commonwealth University, Richmond, VA, USA, ³Human Anatomy & Histology, University of Bari Medical School, Bari, Italy, ⁴Medicine/Hem-Onc, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

We have previously identified ADAM8 (A Disintegrin and Metalloproteinase 8) as a novel osteoclast (OCL) stimulator whose disintegrin domain mediates its stimulatory effects. Further, we identified integrin $\alpha_9\beta_1$, which is expressed both on OCLs and their precursors, as a receptor of ADAM8. Since α_9 integrin only forms heterodimers with β_1 , and β_1 knockout (KO) mice are embryonic lethal, we determined whether there are other receptors for ADAM8 by assessing osteoclastogenesis in α_9 -/- mice, as well as in human bone marrow cells infected with an α_9 integrin shRNA lentivirus. Bone marrow cells from α_9 -/- mice and human OCL precursors infected with α_9 shRNA formed decreased numbers of OCL which were small and had disrupted actin rings. When bone marrow non-adherent cells and spleen cells from 7-day-old α_9 -/- mice were infected with a full length human α_9 construct, normal numbers of OCLs formed. Further, bone marrow cells from α_9 -/- mice failed to respond to treatment with soluble ADAM8, whereas, wild type bone marrow cells formed OCLs in the presence of soluble ADAM8. These data suggest that expression of full length α_9 integrin can rescue the α_9 KO phenotype in OCL formation. To determine the mechanisms responsible for the stimulatory effects of ADAM8 on osteoclastogenesis, we used an ADAM8 disintegrin domain GST fusion protein to identify the proteins that interact with ADAM8. This GST fusion protein can stimulate osteoclast formation to the same level as the full length ADAM8. GST ADAM8 protein pull-down assays with OCL precursor lysates demonstrated that protein tyrosine kinase 2 (Pyk2) formed a complex with the ADAM8 disintegrin domain. The identity of Pyk2 in the complex was confirmed by peptide mass fingerprinting (MS/MS). Further, we found that treatment of wild type OCL cultures with ADAM8 for 5 to 10 minutes induced transient tyrosine phosphorylation (pY118) of paxillin. Paxillin phosphorylation was not detected in α_9 -/- OCL cultures. These results demonstrate that α_9 is the only receptor for ADAM8, and suggest that ADAM8/ $\alpha_9\beta_1$ increases OCL formation and function through interacting with Pyk2 and signaling through paxillin.

RANKL Stimulates Osteoclasts to Release the Lymphatic Growth Factor, VEGF-C, and Enhances Osteoclastic Bone Resorption Through an Autocrine Mechanism. R. Guo, Q. Zhang, Y. Lu*, E. M. Schwarz, B. F. Boyce, L. Xing. University of Rochester, Rochester, NY, USA.

Osteoclasts (OCs) are bone-resorbing cells, which mediate normal bone remodeling and pathologic bone loss, such as in rheumatoid arthritis (RA). Recent studies indicate that OCs also function as immunomodulators and secrete cytokines that contribute to inflammation and autoimmunity. To investigate if OCs produce angiogenic factors in RA, we performed microarray analysis using purified CD11b⁺/Gr-1⁻ osteoclast precursors (OCPs) from blood and bone marrow of TNF transgenic (TNF-Tg) arthritic mice and wt littermates. Among 50 angiogenic factors examined, VEGF-C expression was significantly increased in TNF-Tg mice (6-fold vs wt cells). VEGF-C is a recently identified lymphatic growth factor, but little is known about its role in bone. Here, we examined if osteoclastogenic cytokines regulate VEGF-C production by OCs and if VEGF-C affects OC function. We cultured wt spleen cells with M-CSF for 3 days to generate OCPs, treated them with RANKL or TNF, and examined expression of VEGF members by real-time RT-PCR. Both RANKL (12.1 \pm 0.5 fold) and TNF (3.5 \pm 0.2 fold) stimulated OCP expression of VEGF-C, but not of other VEGFs. RANKL also stimulated mature OCs to produce VEGF-C (40 \pm 1 fold). RANKL failed to induce VEGF-C expression in NF- κ B p50/p52 double knockout OCPs. In an EMSA assay, RANKL promoted nuclear protein binding to a putative NF- κ B binding sequence from the mouse VEGF-C promoter. To determine if VEGF-C affects OC function, we treated OCPs with VEGF-C or over-expressed VEGF-C by retrovirus infection and cultured them on bone slices. VEGF-C increased OC resorption pit area, but not OC numbers. To test if VEGF-C works as an autocrine factor, OCPs were treated with RANKL plus the VEGF-C specific receptor inhibitor, VEGFR3-Fc, or VEGFR2-Fc, which inhibits other VEGFs. VEGFR3-Fc, but not VEGFR2-Fc, reduced RANKL-mediated OC pit formation (pit area (mm²)/slice: IgG 2.1 \pm 0.25; VEGFR3-Fc 0.8 \pm 0.1; VEGFR2-Fc 2.1 \pm 0.22) and had no effect on OC numbers. Furthermore, immunostaining of joint sections from RA patients or TNF-Tg mice showed that OCs expressed high levels of VEGF-C and that lymphatic vessel numbers were increased in joints of the TNF-Tg mice. In summary, RANKL stimulates OCs and OCPs to release large amounts of VEGF-C, which enhances OC bone resorption by binding to the VEGF-C receptor on OCPs and OCs. Thus, VEGF-C is a RANKL-induced autocrine factor for OC function. Importantly, our study indicates that RANKL and OCs may directly affect lymphangiogenesis through VEGF-C signaling, which will require further investigation given the importance of the lymphatic system in inflammation and tumor metastasis.

TRPV4 Affects Bone Remodeling by Regulating Calcium Signaling Required for Osteoclast Activity. R. Masuyama¹, J. Vriens², S. Torrekens¹, K. Moermans¹, A. Vanden Bosch¹, R. Bouillon¹, B. Nilius², G. Carmeliet¹. ¹Laboratory of Experimental Medicine & Endocrinology, Katholieke Universiteit Leuven, Leuven, Belgium, ²Department of Cell Biology, Division of Physiology, Katholieke Universiteit Leuven, Leuven, Belgium.

Intracellular calcium [Ca²⁺]_i signaling is necessary for osteoblast and osteoclast function implying that calcium permeable channels are implicated in local bone remodeling rather than in systemic calcium homeostasis. TRPV4 is a widely expressed Ca²⁺ entry channel of the "Transient Receptor Potential" (TRP) family of cation channels. We detected TRPV4 expression in both osteoblasts and osteoclasts. To elucidate whether TRPV4-mediated [Ca²⁺]_i signaling is important for bone, TRPV4 deficient mice were investigated. Lack of TRPV4 did neither affect systemic calcium homeostasis nor endochondral bone development. However, an increased bone mass (+60%) was observed by histomorphometry in 12-week-old TRPV4^{-/-} tibiae (P<0.01), which was associated by a decreased osteoclast surface (-40%) compared to WT mice (P<0.05). In addition, calcitonin receptor mRNA levels were decreased in TRPV4^{-/-} femora (P<0.05), consistent with decreased serum CTX levels (P<0.05). At the other hand, osteoblast function was not different between genotypes as evidenced by unaltered serum osteocalcin levels and dynamic bone histology. Also, RANKL/OPG mRNA expression in the femur was not altered. These data suggest that TRPV4 promotes osteoclastogenesis cell-autonomously. Accordingly, multinuclearity evaluated by the number of mature osteoclasts containing more than 10 nuclei was decreased in cultures of TRPV4^{-/-} bone marrow-derived hematopoietic cells (P<0.01) treated with RANKL and MCSF. This was associated with decreased resorption activity (-60%) in TRPV4^{-/-} osteoclasts compared to WT osteoclasts (P<0.05) assessed by culturing osteoclasts on apatite-coated disks. In these polarized osteoclasts on apatite disks, TRPV4 localized at the apical membrane as shown by vertical reconstruction of confocal microscope scanning images. Furthermore, the TRPV4-specific agonist, 4 α -PDD, evoked [Ca²⁺]_i influx specifically in large mature WT osteoclasts, but not in small WT osteoclasts containing less than 5 nuclei or TRPV4^{-/-} osteoclasts. Noteworthy, TRPV4 inactivation resulted in lower basal [Ca²⁺]_i in osteoclasts measured at 37°C. In addition, treatment with TRPV4 agonists induced NFATc1 mRNA expression accompanied by increased calcitonin receptor mRNA expression in cultured WT osteoclasts.

In summary, our findings provide evidence that TRPV4 maintains [Ca²⁺]_i homeostasis, osteoclast maturation and function, and therefore contributes to normal bone remodeling.

Cell-cell Fusion of Osteoclasts Is Stimulated in DC-STAMP Transgenic Mice. R. Iwasaki^{*1}, T. Miyamoto², H. Kawana^{*3}, T. Nakagawa^{*3}, T. Suda^{*4}. ¹Department of Cell Differentiation, Dentistry and Oral Surgery, Keio University School of Medicine, Tokyo, Japan, ²Department of Cell Differentiation, Musculoskeletal Reconstruction and Regeneration Surgery, Keio University School of Medicine, Tokyo, Japan, ³Department of Dentistry and Oral Surgery, Keio University School of Medicine, Tokyo, Japan, ⁴Department of Cell Differentiation, Keio University School of Medicine, Tokyo, Japan.

Osteoclasts are multinuclear giant cells derived from hematopoietic stem cells in the presence of M-CSF and RANKL. The multinucleation of osteoclasts is induced by a cell-cell fusion of mononuclear osteoclasts. Recently, we have isolated DC-STAMP (Dendritic Cell Specific Transmembrane Protein), a seven transmembrane protein, as an essential molecule for osteoclast cell-cell fusion. Osteoclasts in DC-STAMP deficient mice show complete lack of cell-cell fusion in osteoclasts (J. Exp Med, 2005). Since the osteoclast differentiation molecules such as TRAP and CathepsinK, and the transcriptional factors such as c-fos and NFATc1 were not suppressed in DC-STAMP deficient compared with wild-type osteoclasts, DC-STAMP is specifically required for osteoclast cell-cell fusion. However, it is not yet characterized the mechanisms of cell-cell fusion via DC-STAMP. Here we generated DC-STAMP transgenic mice (Tg) under the control of an actin(CAG) promoter to express DC-STAMP ubiquitously in vivo. 95 lines of offspring were generated by the embryo microinjection, and the presence of the transgene in the offsprings was tested by PCR of tail DNA using transgene specific primers. 10 transgenic founder lines were established, and DC-STAMP expression was detected in various tissues of DC-STAMP Tg mice such as liver, muscle and brain, all of which do not express DC-STAMP physiologically. Interestingly, ectopic cell-cell fusion was not observed in liver and muscle, and the multinucleation of myotube was not stimulated by the forced expression of DC-STAMP in Tg mice.

Indeed defects of osteoclast cell-cell fusion in DC-STAMP deficient mice was rescued by crossing with DC-STAMP Tg mice in vivo and in vitro. In vitro osteoclast formation assay, the number of multinuclear cells as well as the number of nuclei in each multinuclear cell were significantly upregulated in osteoclasts of Tg mice compared with that of wild-type littermates. The cell-cell fusion was not induced even in the cells derived from Tg bone marrow in the presence of M-CSF alone, while the addition of RANKL in turn induced hyper-multinucleation of osteoclasts. Taken together our results suggest that DC-STAMP promotes cell-cell fusion in a tissue specific manner, and DC-STAMP induces a cell-cell fusion downstream of RANKL-RANK cascade in osteoclasts.

Disclosures: R. Iwasaki, None.

Characterization of Osteoclast Inhibitory Peptide-1 (OIP-1/hSca) Binding to Fc Gamma Receptor II B (Fc γ R₂) on Osteoclast Precursor Cells. S. Shanmugarajan¹, C. Beeson^{*2}, S. V. Reddy¹. ¹Charles P. Darby Children's Research Institute, Charleston, SC, USA, ²Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC, USA.

We have previously identified and characterized the osteoclast inhibitory peptide-1 (OIP-1/hSca) as an autocrine/paracrine inhibitor of osteoclast differentiation. OIP-1 is also known as RIG-E or TSA-1, a member of Ly-6 gene family. We have recently demonstrated that mice targeted with the OIP-1/hSca expression to the osteoclast lineage develop osteopetrosis bone phenotype. We have also shown that OIP-1 c-peptide region is critical for osteoclast (OCL) inhibitory activity; however a cognate receptor/membrane protein which interacts with OIP-1 in osteoclast precursor cells is unknown. Evidence suggests a functional physical association between TSA-1 and Fc gamma receptor II B (Fc γ R₂) on the surface of activated B-cells. Immunoreceptor tyrosine-based activation motif (ITAM) bearing adapter proteins such as Fc γ R₂ and DAP12 play a critical role in OCL development. We therefore, hypothesized that OIP-1 binding to Fc γ R₂ on osteoclast precursor cells inhibit OCL differentiation. We examined binding of the OIP-1 c-peptide to RAW 264.7 osteoclast progenitor cells using FACS analysis. Fluorescein conjugated OIP-1 c-peptide (10 μ M) binds to these cells indicating the presence of a surface receptor or membrane protein partner in these cells. Co-immune precipitation and subsequent mass spectrometric analysis identified OIP-1 associated to Fc γ R₂ expressed in RAW264.7 cells. Confocal microscopy analysis demonstrated co-localization of fluorescein conjugated OIP-1 c-peptide with Fc γ R₂ expressed on the cell membrane in osteoclasts formed in RAW 264.7 and OIP-1 mouse bone marrow cultures. An ELISA binding assay confirmed that the OIP-1 c-peptide forms a 1:1 complex with recombinant Fc γ R₂ protein characterized by an equilibrium dissociation constant of K_d = 5 \pm 1 μ M. We further examined if OIP-1 signals through Fc γ R₂ to inhibit OCL differentiation. siRNA suppression of Fc γ R₂ expression in RAW 264.7 cells rescues OIP-1 c-peptide inhibition of RANKL stimulated OCL differentiation in vitro. We further show that OIP-1 c-peptide (100 ng/ml) treatment of RAW 264.7 and OIP-1 transgenic mouse bone marrow derived preosteoclast cells suppresses (6-fold) RANKL induced ITAM phosphorylation. Taken together, our results suggest OIP-1 binding to Fc γ R₂ in preosteoclasts inhibits osteoclast differentiation through suppression of ITAM phosphorylation. Thus, OIP-1 is an important physiologic regulator of osteoclast development and may have therapeutic utility for bone diseases with high bone turnover such as osteoporosis and Paget's disease of bone.

Calcium and Phospholipase C γ 2 Signaling Regulates RANKL-induced Osteoclastogenesis. Y. Chen¹, X. Wang², L. Di³, G. Fu³, Y. Chen³, L. Bai³, J. Liu¹, H. Liu¹, L. Ma¹, X. Feng¹, Y. He³, R. Wen³, J. M. McDonald⁴, D. Wang³, H. Wu². ¹Pathology, MCP, University of Alabama at Birmingham, Birmingham, AL, USA, ²Pediatric Dentistry, University of Alabama at Birmingham, Birmingham, AL, USA, ³Blood Research Institute of Wisconsin, Milwaukee, WI, USA, ⁴Pathology and VA medical center, University of Alabama at Birmingham, Birmingham, AL, USA.

Activation of calcium and phospholipase γ (PLC γ) signaling has been demonstrated in osteoclastogenesis stimulated by the receptor activator of NF κ B ligand (RANKL). Inhibition of PLC γ blocks RANKL-induced Ca²⁺ release from intracellular stores. PLC γ 1 is ubiquitously expressed, whereas its highly homologous PLC γ 2 is primarily expressed in hematopoietic cell lineages, including osteoclasts. With the use of the PLC γ 2 knock out (PLC γ 2^{-/-}) mice, we investigated the role of PLC γ 2 on bone homeostasis in vivo and RANKL-induced osteoclastogenesis in vitro.

Bone morphology of mice was characterized by dual-energy X-ray absorptiometry, MicroCT and histomorphometry analyses. Increased bone mineral density was demonstrated in PLC γ 2^{-/-} relative to wild-type mice. Quantitative measurements of the ratio of trabecular bone volume to tissue volume showed a 2-fold increase in PLC γ 2^{-/-} mice. Bone perimeter and trabecular numbers were increased and trabecular space was decreased in PLC γ 2^{-/-} mice. The increased bone volume was associated with a decreased number of osteoclasts and decreased relative osteoclast surface. Moreover, upon stimulation by RANKL in vitro, the PLC γ 2^{-/-} bone marrow macrophage precursors showed increased expression of early osteoclast markers tartrate-resistant acid phosphatase (TRAP) and Cathepsin K (Cath K), but failed to differentiate into mature multinucleated osteoclasts with expression of the later osteoclast marker calcitonin receptor (CTR). Moreover, lack of PLC γ 2 severely impaired RANKL-induced activation of NF- κ B, AP-1, and NFATc1, the transcription factors involved in osteoclastogenesis. Thapsigargin that is known to increase calcium induced the expression of TRAP, CathK and CTR, and partially restored the RANKL-induced osteoclastogenesis, indicating that PLC γ related calcium signaling is critical for the late stages of RANKL-induced osteoclastogenesis. Further, a retrovirus-mediated gene transduction of PLC γ 2 but not PLC γ 1 restored RANKL-induced osteoclastogenesis of PLC γ 2^{-/-} cells. Therefore, PLC γ 2 plays an important and unique role in RANKL-mediated osteoclastogenesis.

Taken together, PLC γ 2 is essential for RANKL signaling, and its deficiency leads to defective osteoclastogenesis. Characterization of the role of PLC γ 2 in RANKL-induced osteoclastogenesis is important for osteoporosis prevention and therapy.

Nell-1, a Key Functional Mediator of Runx2, Partially Rescues Craniofacial Defects in Runx2 Haploinsufficient Mice. X. Zhang¹, K. Ting¹, C. M. Cowan², H. Lee³, J. Wong¹, T. Hsu¹, D. Pathmanathan¹, S. Kuroda³, C. Soo⁴. ¹Dental&Craniofacial Research Institute, University of California, Los Angeles, Los Angeles, CA, USA, ²Department of Bioengineering, University of California, Los Angeles, Los Angeles, CA, USA, ³Department of Structural Molecular Biology, Institute of Scientific and Industrial Research, Osaka University, Osaka, Japan, ⁴Department of Plastic and Reconstructive Surgery, University of Southern California, Los Angeles, CA, USA.

Mesenchymal stem cell commitment to an osteochondroprogenitor lineage requires Runx2. Heterozygous Runx2 mice (Runx2^{+/-}) manifest delayed membranous bone development/ossification, causing open anterior and posterior fontanelles, a phenotype similar to cleidocranial dysplasia (CCD) in humans. We have recently demonstrated that craniosynostosis associated protein, Nell-1, is a direct transcriptional target of Runx2. The purpose of this study was to investigate the functional relationship of Nell-1 and Runx2 in craniofacial bone development via in vitro, ex vivo and in vivo experiments. To determine if Nell-1 could functionally compensate for Runx2 absence, Runx2^{-/-} calvarial cells were infected with adenoviral (Ad) Nell-1 (AdNell-1). To determine if Nell-1 was required for Runx2 activity, Nell-1 siRNA were applied on wild-type calvarial cells infected with AdRunx2. Osteoblastic differentiation was assessed by real-time PCR, ALP activity, and von Kossa. To determine if Nell-1 could stimulate mineralization on explanted Runx2^{+/-} mice calvaria, in situ calcein deposition was monitored after recombinant Nell-1 (rNell-1) application. Lastly, to determine if Nell-1 could compensate for Runx2 haploinsufficiency, Nell-1 overexpression mice (Nell-1^{overexp}) were mated to Runx2^{+/-} mice and the progenies were evaluated by skeletal staining, micro-CT, histology, and immunohistochemistry. The results show that Nell-1 induced delayed Alp and Opn upregulation, but no mineralization in Runx2^{-/-} calvarial cells. Meanwhile, Nell-1 siRNA inhibited Alp and Ocn upregulation, ALP activity, and mineralization in AdRunx2 infected wild-type calvarial cells. Furthermore, rNell-1 significantly increased ossification in calvarial explants from Runx2^{+/-} mice. Finally, increased calvarial bone growth as evidenced by smaller anterior fontanelle, narrower sagittal suture width and significantly thicker parietal bone plate were apparent in the Nell-1^{overexp}/Runx2^{+/-} progenies. In conclusion, Nell-1 serves as a key functional mediator of downstream Runx2 effects in supporting full preosteoblastic calvarial cell differentiation and inducing craniofacial bone development.

Role of BMP2 in Postnatal Bone Biology: Conditional Knock-Out (cKO) of BMP2 Using the 3.6 Collagen Type IA1 - Cre Model. W. Yang¹, D. Guo², J. Gluhak¹, M. A. Harris¹, A. Lichtler³, B. Kream³, J. Edwards⁴, G. R. Mundy⁴, Y. Mishina⁵, S. E. Harris¹. ¹UTHSCSA, San Antonio, TX, USA, ²UMKC, Kansas City, MO, USA, ³UCONN Health Center, Farmington, CT, USA, ⁴Vanderbilt U, Nashville, TN, USA, ⁵LRDT, NIEHS/NIH, Research Triangle Park, NC, USA.

BMP2 is expressed in early and late osteoblasts and has been shown to accelerate bone regeneration in adults. Genetic data have demonstrated an association of polymorphisms in the BMP2 gene with increased fracture risk and osteoporosis. However, the postnatal function and mechanism of endogenous BMP2 in bone formation has not been established due to the embryonic lethality of BMP2-null mice at 10.5dpp. Thus to define the function of BMP2 in skeleton postnatally, we created a BMP2 floxed mouse model with loxP sites flanking exon 3. Mice embryos with the BMP2 floxed homozygous allele and with the Mox2-Cre allele, which is active at the blastula stage, have the same phenotype as the global BMP2-null model, lethal around 10.5 dpc along with the absence of chorion and defective heart development. This BMP2 floxed model now allows us to remove BMP2 spatiotemporally with various Cre-Loxp recombination models. With 3.6Colla1-Cre recombinase that target early collagen type 1 expressing osteoblasts, BMP2 expression is not detected in osteoblasts and osteocytes in the BMP2 cKO mice. Removal of BMP2 from osteoblasts postnatally results in skeletal defects in vertebrae, ribs, craniofacial bones, and long bones. BMP2 cKO mice show a pronounced osteopenia with reduced radio-opacity and a 12-25% reduced BMD in bones from 2 weeks to 6 months of age. The vertebrae and humeri are revealed to be the most sensitive bones to the removal of BMP2 in osteoblasts. Quantitation μ CT analysis on tibia of 1-month BMP2 cKOs has shown a 33% reduction in the vBV/TV and a 24% reduction in the trabecular number. Furthermore by histology evaluation, we observed the reduction of the trabecular bone and decreased amounts of mineralized bone matrix. Reduced osteoclast activity and number were also detected in BMP2 cKO mice at 1 month. This suggests that deletion of BMP2 in osteoblasts is linked to disruption of bone remodeling. Deletion of BMP2 and a 30% reduction of Osterix expression were also determined in bone extracts from calvaria, humeri, and femurs by Northern analysis. By in situ hybridization, we detected reduced mRNA expression levels of BMP4, Osterix and DLX5 in bone associated osteoblasts. Further investigation on dynamic bone formation rates and detailed histomorphometric analysis is underway. Collectively, our results suggest BMP2 action is upstream of BMP4 in these collagen producing osteoblasts and BMP2 is necessary but not sufficient for the continued differentiation of osteoblasts to stages required for production of mineralized bone postnatally.

Targeted Disruption of Ephrin B1 in Osteoblasts Reduces Bone Size in Mice. W. Xing, K. Govoni, A. Kapoor*, S. Mohan, J.L. Pettis VA Medical Center and Loma Linda Univ, Loma Linda, CA, USA.

Mutations of Ephrin B1 (Efnb1), a ligand for Ephrin B tyrosine kinase receptors, in humans caused craniofrontonasal syndrome while deletion of Efnb1 gene in mice resulted in perinatal lethality and defects in skeletal patterning. Based on these findings that Efnb1 is required for survival of mice and bone development, we hypothesized that Efnb1 produced by osteoblasts plays a key role in the attainment of peak bone mass. To test this hypothesis, we used a Cre-loxP approach to disrupt Efnb1 specifically in osteoblasts (Obs). Transgenic mice expressing Cre recombinase under the control of the promoter/enhancer unit of Col1a2 gene were crossed with Efnb1 loxP mice to generate Cre+ (Efnb1 disruption) and Cre- (control) loxP homozygous mice. Cre expression was limited to type I collagen producing cells of mesenchymal origin. Western blot confirmed that Efnb1 was expressed in Obs isolated from calvariae of Cre- mice, but not Cre+ mice. The skeletal phenotypes of mice (n = 10 to 19) were characterized by PIXImus measurements at 3 & 8 weeks of age as shown below. An asterisk indicates a significant difference between Cre+ and Cre- mice (P < 0.05).

pQCT analysis of femurs at 8 weeks of age revealed that periosteal and endosteal circumferences were reduced by 22 and 16%, respectively, in the femurs of Cre+ mice vs. corresponding littermate control mice (P < 0.01). In contrast, total volumetric BMD was not affected indicating that the reduction in aBMD by PIXImus was caused by reduced bone size. Because ephrin ligands are known to regulate tissue renewal and tumor cell progression, we tested the prediction that Efnb1 regulates bone size by influencing cell proliferation. Accordingly, overexpression of Efnb1 in MC3T3-E1 cells increased cell number by 32% compared to GFP control (P < 0.05). In summary: 1) Targeted disruption of efnb1 in Obs results in decreased peak bone mass caused predominantly by reduced bone size; 2) Overexpression of Efnb1 in Obs increased cell number. In conclusion, our data provide the first experimental evidence that efnb1 is a critical regulator of bone size in mice and may be an important regulator of osteoblast proliferation.

mTOR Signaling: A Novel Molecular Mechanism Underlying Wnt's Anabolic Effects on Osteogenesis. H. Ouyang¹, K. Inoki^{2*}, X. Zhang¹, T. Zhu^{2*}, C. Bennett^{3*}, C. Lindvall⁴, B. O. Williams⁴, O. A. MacDougald³, K. Guan^{2*}. ¹Cardiology, Restorative Sciences and Endodontics (CRSE), University of Michigan, Ann Arbor, MI, USA, ²Life Sciences Institute, University of Michigan, Ann Arbor, MI, USA, ³Department of Molecular and Integrative Physiology, University of Michigan, Ann Arbor, MI, USA, ⁴Laboratory of Cell Signaling and Carcinogenesis, Van Andel Research Institute, Grand Rapids, MI, USA.

The canonical Wnt signaling plays a critical role in regulating osteogenesis. It inhibits GSK3, resulting in stabilization of β -catenin, a transcription factor important for cell growth-related gene expression. Little knowledge exists as to whether Wnt signaling also regulates protein synthesis, in addition to its role in gene transcription. The mammalian target of rapamycin (mTOR) is a serine/threonine kinase that controls cell growth and protein translation via phosphorylating the molecular components of translation apparatus, such as S6K, S6 and 4EBP. TSC2 is an upstream inhibitor for mTOR; mutation in TSC2 causes tuberous sclerosis complex, an autosomal dominant genetic disorder featured by hamartoma formation in multiple tissues. Here, we reported that Wnt signaling stimulated the mTOR signaling in osteoblasts, both in vivo and in vitro. Wnt3a increased phosphorylation of S6K and S6 in a time- and dose-dependent manner in osteoblasts. Wnt10b stable expression in mouse bone marrow stromal cells also activated mTOR. Consistently, Wnt10b transgenic mice displayed greater mTOR activities than the wild type animals, in vivo. These inductions occurred in a β -catenin-independent manner. Overexpression of a constitutively active form of β -catenin failed to induce mTOR activities, and Wnt3a stimulated mTOR signaling in MEF cells null for β -catenin. Moreover, GSK3 phosphorylated TSC2 in a manner dependent on AMPK, a serine/threonine kinase that acts as a sensor for intracellular energy level. Such phosphorylation enhanced TSC2 inhibition on mTOR. Wnt stimulated the mTOR signaling via inhibiting

GSK3 phosphorylation of TSC2. Importantly, inhibition of mTOR by rapamycin, a specific inhibitor for mTOR, blocked Wnt signaling-induced osteoblastic proliferation and biomineralization, in vitro. Taken together, these results show that Wnt stimulates protein translation machinery and cell growth by activating mTOR signaling. Furthermore, they reveal a role of TSC2/mTOR signaling in Wnt-induced osteogenesis, therefore suggesting a therapeutic value of rapamycin in treating osteosclerotic dysplasia associated with activated Wnt signaling. IGF-I Signaling Is Required for Postnatal Growth Plate Development. Y. Wang¹, H. Z. ElAlieh^{1*}, E. Nakamura^{2*}, M. Nguyen^{2*}, S. Mackem^{2*}, D. D. Biale¹, W. Chang¹. ¹Endocrine Unit, University of California, San Francisco/VA Medical Center, San Francisco, CA, USA, ²Laboratory of Pathology, Center for Cancer Research, NCI, NIH, Bethesda, MD, USA.

Studies of mice with global knockouts genes encoding the insulin-like growth factor-I (IGF-I) and IGF-I receptor (IGF-IR) support a critical role for IGF-I signaling in skeletal development. These mice are born dwarf with severely deformed skeletons and with a high perinatal mortality rate. It is assumed that the lack of local IGF-I/IGF-IR signaling is the main cause for much of the skeletal phenotype in these mice, but systemic derangements are likely to contribute as well. To investigate the role of IGF-I signaling in postnatal GP development, we generated mice ($Tam^{Cre}IGF-IR^{-/-}$) with tamoxifen (Tam)-inducible, cartilage-specific knockout of IGF-IR gene by breeding floxed IGF-IR mice with mice carrying a cDNA encoding Cre recombinase fused to a mutated estrogen responsive element. The transcription of this cDNA is controlled by a type II collagen promoter. $Tam^{Cre}IGF-IR^{-/-}$ mice were viable and fertile without injection of tamoxifen. To knockout the IGF-IR postnatally, we injected the $Tam^{Cre}IGF-IR^{-/-}$ mice with tamoxifen (0.2 mg/mouse) at day 5, day 7, day 9 and day 11 after birth. Bones from the $Tam^{Cre}IGF-IR^{-/-}$ mice and their wild-type littermates (WT) were harvested at day 14 for analysis. Tamoxifen-injected $Tam^{Cre}IGF-IR^{-/-}$ mice were smaller in size (70% of WT) at day 14. Histology showed disorganized proliferating zone, shortened hypertrophic zone (62% of WT), and reduced proliferation (by 60%) in the proliferating zone in tibial GPs of the $Tam^{Cre}IGF-IR^{-/-}$. The protein levels of chondrocyte differentiation markers type II collagen and type X collagen, and the levels of chondrocyte differentiation regulator Indian Hedgehog (Ihh) were also decreased in these mice as assessed by immunohistochemistry. Our data indicate that IGF-I/IGF-IR signaling pathway regulates postnatal GP development by stimulating chondrocytes proliferation and differentiation, support the idea that local IGF-I/IGF-IR signaling is essential for the growth and maturation of chondrocytes in the postnatal periods, and is required for the orderly progression of GP maturation.

Beta Blockade Mitigates Bone Loss During Energy Restriction Partially via Leptin. K. Baek*, J. Stallone*, S. Bloomfield. Department of Health & Kinesiology and Department of Nutrition, Texas A&M University, College Station, TX, USA.

Leptin is a candidate for responsible for linking energy metabolism to bone mass. In previous work, we demonstrated that energy restriction (ER) is a major contributor to the bone loss during global food restriction. Also, we observed decreased serum leptin during mild food restriction, which may be due to reduced adipocyte number/size and/or sympathetic nervous system (SNS) activation of beta-adrenoreceptors during ER, inhibiting release of leptin from adipocytes. In the present study, we tested whether beta-adrenoreceptor blockade attenuates bone loss during energy restriction and whether such an effect is associated with changes in serum leptin level and leptin localization in bone tissues. Female, 4-mo-old Sprague-Dawley rats were acclimatized to new AIN-93M purified diet for 8 weeks, then assigned into four groups (n=10 each): 2 groups of 40% energy restriction treated with vehicle (ERVEH; saline) or beta-blocker (ERBB; DL-propranolol, Sigma; 250 μ g/kg \cdot hr) via drinking water during 12 weeks, and 2 groups of ad-lib fed controls treated with the same 2 agents (CONVEH, CCBB, respectively). On days 0 and 84, peripheral computed tomography (pQCT) assessed proximal tibial volumetric bone mineral density (vBMD) and geometry, and dual energy X-ray absorptiometry (DXA) assessed total body fat, lean mass, and total body and spine BMD. Sagittal sections of proximal femur were analyzed by standard immunohistochemistry for assessing leptin expression in marrow adipocytes and leptin localization in bone cells. All animal procedures were approved by Texas A&M University Laboratory Animal Care Committee. Over 84 days, CONVEH and CCBB rats gained, but ERVEH and ERBB rats lost body fat mass (+4.8%, +10.08% vs -14.4% and -11.9%, respectively), but lean mass did not change in any group. Reduction in serum leptin (by ELISA) in ERVEH rats was mitigated in ERBB rats (-5.32 vs -1.15ng/ml, respectively). The decline in proximal tibia cancellous vBMD observed in ERVEH rats was attenuated in ERBB rats (-85.24 vs -53.94 mg/cm³, respectively). Spine BMD (by DXA) did not change in any group over 84 days. More leptin expression was observed in bone marrow adipocytes in groups showing higher serum leptin level and higher cancellous vBMD. In the same groups, more bone lining cells, osteocytes and chondrocytes in cartilage also stained positive for leptin. In conclusion, beta blockade mitigated metaphyseal bone loss during energy restriction and also attenuated reductions in serum levels and bone tissue-specific localization of leptin. These data suggest a contributory role for beta-adrenoreceptor signaling via adipocytes in the bone response to energy restriction.

Collagen/Annexin V Interactions Regulate Growth Plate Chondrocyte Mineralization. H. Kim, T. Kirsch, Orthopaedics, University of Maryland School of Medicine, Baltimore, MD, USA.

Mineralization of growth plate cartilage is crucial for normal bone formation. Therefore, an understanding of the mechanisms regulating mineralization is important. We have shown that annexins (II, V and VI) form Ca^{2+} channels in growth plate chondrocytes enabling the initiation of mineralization. In addition, binding of annexin V to types II and X collagen stimulates annexin V Ca^{2+} channel activities. In this study we hypothesized that type II or type X collagen matrix stimulates mineralization of growth plate chondrocytes via binding and activating annexin V channel properties resulting in increased intracellular Ca^{2+} concentration, $[\text{Ca}^{2+}]_i$. Increased $[\text{Ca}^{2+}]_i$ then stimulates mineralization related events. To test this hypothesis, we treated growth plate chondrocytes with vitamin C to stimulate collagen synthesis in the absence or presence of 3,4-dehydro-L-proline (inhibitor of collagen fibril formation and secretion). On the other hand we cultured growth plate chondrocytes on type I or type II collagen coated dishes in the absence or presence of an annexin V specific Ca^{2+} channel blocker (K-201). We measured $[\text{Ca}^{2+}]_i$, expression of mineralization-related genes, alkaline phosphatase (APase) activity and the degree of mineralization. Vitamin C stimulated type II and X collagen synthesis, APase activity and mineralization of growth plate chondrocytes, whereas 3,4-dehydro-L-proline inhibited the stimulation of these events in vitamin C-treated cells. Vitamin C also led to an increase of $[\text{Ca}^{2+}]_i$ in growth plate chondrocytes, whereas 3,4-dehydro-L-proline inhibited this increase. Flow cytometric and co-immunoprecipitation experiments revealed that annexin V is cell surface exposed and interacts with types II and X collagen. Culturing growth plate chondrocytes on type I or type II collagen coated dishes increased $[\text{Ca}^{2+}]_i$, APase activity and the degree of mineralization compared to the levels of cells cultured on non-coated dishes. K-201, a specific annexin V channel blocker, inhibited increase of $[\text{Ca}^{2+}]_i$ of growth plate chondrocytes cultured on type II collagen coated dishes but not on type I collagen coated dishes. Furthermore, overexpression of full length annexin V, which binds to types II and X collagen, was more effective in stimulating APase activity, MMP-13 expression and mineralization of growth plate chondrocytes than overexpression of N-terminus deleted mutant annexin V, which binds to type X collagen but not to type II collagen. In conclusion, our findings reveal that types II and X collagen via binding to annexin V stimulate annexin-mediated Ca^{2+} influx, thereby regulating growth plate chondrocyte Ca^{2+} homeostasis and ultimately mineralization events.

Runx1, Co-activator of Sox5, Sox6 and Sox9 (the Sox trio) Regulates Chondrogenic Differentiation. F. Yano¹, T. Ikeda¹, T. Saito², N. Ogata¹, S. Takeda³, A. Kimura³, S. Ohba¹, F. Kugimiya², K. Nakamura², T. Takato¹, H. Kawaguchi², U. Chung¹. ¹Division of Tissue Engineering, Faculty of Medicine, University of Tokyo, Tokyo, Japan, ²Department of Sensory and Motor System Medicine, Faculty of Medicine, University of Tokyo, Tokyo, Japan, ³Department of Orthopedics, Tokyo Medical and Dental University, Tokyo, Japan.

Aiming at clinical applications to cartilage regeneration, we previously screened natural and synthetic compound libraries and found that a thienindazole derivative small compound T-198946 (TM) strongly induced chondrogenic differentiation without inducing hypertrophy. To clarify its transcriptional targets and signal transduction mechanism, we screened for the target molecules of TM by a microarray analysis using undifferentiated mesenchymal C3H10T1/2 cells treated with TM for 48 hours. Compared to the control, 581 genes were up-regulated by TM, among which Runx1, Sox5, and Sox6 were especially markedly induced. Real-time RT-PCR analysis confirmed that expressions of Runx1, Sox5, and Sox6 were strongly induced by TM treatment. To investigate the functional contribution of Runx1 to chondrocyte differentiation, Runx1 was adenovirally overexpressed, but it did not induce endogenous expression of chondrogenic markers in C3H10T1/2 cells. However, when Runx1 was combined with Sox5, Sox6 and Sox9 (the Sox trio), it enhanced induction of chondrogenic differentiation and cartilage matrix synthesis without inducing hypertrophy, mimicking effects of TM treatment. On the other hand, silencing of Runx1 reduced effects of TM on chondrogenic differentiation. We analysed the effects of Runx1 on the human type II collagen promoter containing putative binding motif for Runx family transcriptional factors. Luciferase-reporter assay using several deletion constructs identified the region containing the binding site of Runx1 at -293 to -288bp, which is highly conserved among species in the proximal promoter and distinct from the Sox9 responsive element. Immunoprecipitation analysis showed that Runx1 physically associated with Sox 5, 6 and 9 proteins. Immunohistochemistry revealed that Runx1, Sox5, 6, and 9 were co-localized in the proliferative and pre-hypertrophic chondrocytes of the mouse growth plate. These data suggest that Runx1 cooperatively works with the Sox trio to induce chondrogenic differentiation. Elucidation of the molecular network of TM targets may help realize to the realization of the regenerative medicine of permanent cartilage.

A Homozygous Missense Mutation in Human KLOTHO Causes Severe Tumoral Calcinosis, but not Premature Aging. S. Ichikawa^{*1}, E. A. Imel¹, M. L. Kreiter^{*2}, X. Yu¹, D. S. Mackenzie^{*1}, A. H. Sorenson^{*1}, R. Goetz^{*3}, M. Mohammadi^{*3}, K. E. White¹, M. J. Econs¹. ¹Indiana University School of Medicine, Indianapolis, IN, USA, ²Children's Memorial Hospital and Feinberg School of Medicine, Northwestern University, Chicago, IL, USA, ³New York University School of Medicine, New York, NY, USA.

Familial tumoral calcinosis is a rare metabolic disorder characterized by ectopic calcifications and hyperphosphatemia. The known genetic causes of tumoral calcinosis are inactivating mutations in the genes encoding fibroblast growth factor 23 (FGF23) and GalNAc transferase 3 (GALNT3). Klotho (KL)-deficient mice were originally reported to model early aging; however, these mice manifest a biochemical phenotype similar to Fgf23-null mice and tumoral calcinosis patients.

We examined a 13-year-old girl with severe tumoral calcinosis with significant dural and carotid artery calcifications. This patient had defects in mineral ion homeostasis with marked hyperphosphatemia, hypercalcemia, and elevated parathyroid hormone (PTH). Serum FGF23 concentrations were markedly elevated [16,140 pg/mL intact (NL<71 pg/mL) and 10,900 RU/mL C-terminal (NL<149 RU/mL)], suggesting resistance to the actions of FGF23 as the cause of the observed hyperphosphatemia. However, there were no features of premature aging.

Mutational analysis was performed for the calcium sensing receptor (CASR), FGF23, GALNT3, and KL. We identified a homozygous missense mutation (His193Arg) in the KL gene of the patient. Analysis of the mutation in the context of published glycosidase structures revealed that the mutated histidine 193 is at the base of the catalytic site. Substitution of the histidine residue to arginine should destabilize the tertiary folding of the KL domain, attenuating the production of membrane-bound and secreted KL. Indeed, compared to wild-type KL, cell surface expression and secretion of mutant KL was drastically reduced in vitro. Immunoprecipitation analysis of the FGF23-KL-FGFR1 ternary complex revealed that only minute amounts of mutant KL bound to FGF23. Furthermore, stimulation of HEK293 cells expressing wild-type KL with FGF23 resulted in a 56-fold increase in mRNA of early growth response-1 (EGR1), a downstream mediator of FGF23 signaling, whereas EGR1 expression was reduced by ~80% in cells expressing mutant KL (p<0.0001).

In summary, our clinical and molecular findings demonstrate that human loss-of-function mutations in KL impair the bioactivity of FGF23 to signal via its cognate FGF receptors and lead to severe tumoral calcinosis, rather than premature aging as previously reported in the KL-deficient mice. Thus, KL plays an essential role in FGF23-mediated phosphate and vitamin D metabolism in humans.

Disclosures: S. Ichikawa, None.

Phosphate-Independent Effects of Fgf-23 on Skeletogenesis. D. Sitara¹, C. Bergwitz², S. Kim^{*1}, R. Erben³, H. Jüppner², B. Lanske¹. ¹Developmental Biology, Harvard School of Dental Medicine, Boston, MA, USA, ²Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA, ³Natural Sciences, University of Veterinary Medicine, Vienna, Austria.

Phosphate homeostasis is regulated by hormones such as parathyroid hormone (PTH), 1,25-dihydroxyvitamin D₃ (1,25(OH)₂D₃) and fibroblast growth factor-23 (Fgf23). Each of these factors can modulate directly or indirectly the activity of sodium-dependent phosphate co-transporter proteins (NaPi) located in kidney and intestine, affecting both renal and intestinal phosphate handling and thereby influencing overall mineral ion homeostasis. Fgf23 ablation leads to a complex phenotype, including hyperphosphatemia, elevated 1,25(OH)₂D₃ and suppressed PTH serum levels, accompanied by enhanced renal tubular phosphate reabsorption through NaPi2a and NaPi2c, leading to abnormal bone mineralization and soft tissue calcifications.

Using genetically modified mice we have now demonstrated an inverse correlation between Fgf23 and NaPi2a; homozygous ablation of NaPi2a from Fgf23^{-/-} mice to generate Fgf-23^{-/-}/NaPi2a^{-/-} double mutants resulted in urinary phosphate-wasting and hypophosphatemia at 6 weeks of age but normal phosphate levels at 3 weeks, despite significantly elevated 1,25(OH)₂D₃ serum levels. This data suggest that altered phosphate homeostasis in Fgf23^{-/-} mice is a NaPi2a-dependent process. Histological analysis of tibial bone sections from Fgf23^{-/-}/NaPi2a^{-/-} double mutants revealed a close resemblance to the findings in Fgf23^{-/-} bones, i.e. hypermineralization of the primary spongiosa together with severe osteoidosis in secondary spongiosa and cortical bone. To further investigate these findings, we examined the expression of genes associated with skeletal development. In Fgf23^{-/-} bones, we observed an up-regulated expression of osteopontin and dental matrix protein-1 (Dmp-1), two sibling proteins known to affect bone mineralization; expression of these genes in Fgf23^{-/-}/NaPi2a^{-/-} double mutants is currently underway.

We are furthermore in the process of evaluating NaPi2c expression, which may be up-regulated to compensate for the loss of NaPi2a in the double mutants, leading to normal serum phosphate levels in Fgf23^{-/-}/NaPi2a^{-/-} double mutants at 3 weeks of age. Moreover, since PTH is known to decrease NaPi2a expression, we are studying the in vivo role of PTH in Fgf23-mediated phosphate homeostasis and skeletogenesis.

In conclusion, our current findings suggest that Fgf23 not only exhibits endocrine functions by regulating phosphate homeostasis through its actions on the kidney, but it also affects skeletogenesis through yet undefined autocrine/paracrine actions.

Disclosures: D. Sitara, None.

The Role of the Type IIc Sodium-dependent Phosphate Transporter (Npt2c), which Is Involved in Hereditary Hypophosphatemic Rickets with Hypercalciuria (HHRH). H. Segawa^{*1}, A. Onitsuka^{*1}, M. Kuwahata^{*1}, E. Aramaki^{*1}, J. Furutani^{*1}, I. Kaneko^{*1}, Y. Tomoe^{*1}, S. Kuwahara^{*1}, N. Amizuka², M. Matsumoto^{*3}, K. Miyamoto¹. ¹Molecular Nutrition, Health Biosciences, The Univ. of Tokushima Graduate School, Tokushima, Japan, ²Center for Transdisciplinary Research, Niigata University, Niigata, Japan, ³Molecular Immunology, Enzyme Research, University of Tokushima, Tokushima, Japan.

Primary loss of inorganic phosphate (Pi) from the kidneys results in hypophosphatemia, the severity of which is directly related to the degree of secondary bone mineralization defects. Two transporters (Npt2a and Npt2c) are expressed exclusively in the proximal convoluted tubule and are regulated by Pi intake, PTH, and FGF23 levels. The type IIa Na/Pi cotransporter (Npt2a) play a major role in reabsorption (70-80%), while type IIc Na/Pi transporter (Npt2c) is more important in weaning animals and less so in adult animals. While the renal Npt2a play a major role in renal Pi reabsorption, Npt2a null (Npt2a^{-/-}) mice do not exhibit rickets/osteomalacia. More recently, linkage analyses have suggested that hereditary hypophosphatemic rickets with hypercalciuria (HHRH) may arise from mutation(s) in the NPT2c/SLC34A3 gene. The goal of the present study was to characterize the role of renal Pi wasting in bone disorders by studying mice deficient in the Npt2c gene, which is the pathogenic protein involved in HHRH. Homozygous mutants (Npt2c^{-/-}) mice are viable, fertile and do not display any gross physical or behavioral abnormalities. Npt2c^{-/-} mice exhibit hypercalcemia, hypercalciuria, and elevation of plasma 1,25-dihydroxyvitamin D3 levels. Interestingly, the levels of plasma fibroblast growth factor 23 (FGF23) levels were significantly reduced in Npt2c^{-/-} mice. However, histologic examination of bone samples from Npt2c^{-/-} mice failed to identify typical features of advanced rickets. Since Npt2c KO mice exhibited abnormally phosphate/calcium homeostasis, our results support that Npt2c may be involved in phosphate/calcium homeostasis.

The further studies required to clarify the mechanism of rickets/osteomalacia which caused by Npt2c-genetic abnormality.

Disclosures: H. Segawa, None.

Molecular Analyses of DMP1 Mutants Causing Autosomal Recessive Hypophosphatemic Rickets (ARHR). E. G. Farrow¹, S. I. Davis^{*1}, X. Yu¹, L. M. Ward², K. E. White¹. ¹Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA, ²Pediatrics, Children's Hospital of Eastern Ontario, Ottawa, ON, Canada.

Heritable disorders of hypophosphatemia involving FGF23 result from mutations in several genes. We previously demonstrated that the recessive mutations M1V (A1>G) and 1484-1490 deletion (del) in Dentin Matrix Protein-1 (DMP1) cause the novel disorder autosomal recessive hypophosphatemic rickets (ARHR), associated with elevated serum FGF23. The goals of the current studies were to understand the effects of the ARHR mutations on DMP1 and to test the regulation of DMP1 expression. Western analyses of wild type DMP1 following transient transfection into cells demonstrated that DMP1 is normally expressed equally in the cellular lysates and the media. In contrast, the ARHR 1484-1490del mutant was primarily detected in the media whereas the M1V mutant was only detected in the cellular lysates. In order to investigate the ARHR mutations on DMP1 intracellular trafficking, transfected cells were fluorescently co-stained for DMP1 in parallel with staining for the trans-golgi network (TGN), ER, and nucleus. Wild type and 1484-1490del mutant DMP1 localized to the TGN, consistent with their cellular secretion. The M1V mutant did not localize to the TGN but filled the entire cell due to loss of the highly conserved DMP1 signal peptide. We obtained the same results with these constructs produced as fusion proteins with V5 tags or untagged, in HEK293, UMR106, and MC3T3 cells. The last 18 amino acids of DMP1 are highly conserved and are replaced by 33 novel residues due to a frameshift caused by the 1484-1490del mutation. We deleted the last 18 DMP1 residues to determine the role of the C-terminus in processing. This truncated DMP1 acted the same as the wild type species, and had balanced intra- and extracellular expression. Therefore, the unbalanced expression of 1484-1490del DMP1 is a function of the 33 novel residues, and not a consequence of deleting the last 18 native residues. UMR-106 cells were treated with excess phosphate or with 1,25(OH)₂ vitamin D (1x10⁻⁷M) for 4 h to test endogenous DMP1 response. qRT-PCR showed a 2-3 fold increase in DMP1 mRNA compared to control cells with both treatments. In summary, our studies of the ARHR DMP1 mutants illustrate that modifications to the signal peptide and to the C-terminus of DMP1 affect cell processing, and that DMP1 is responsive to metabolites that also control FGF23 production. The alterations in DMP1 secretion due to the ARHR mutations provide unique insight into domains of DMP1 critical for normal biological function.

Vascular Calcification and Aortic Gene Expression Are Consistent with Hyperphosphatemia in OPG-Deficient Mice. S. Morony¹, Z. Zhang^{*2}, Y. Tintut², P. J. Kostenuik¹, L. L. Demer². ¹Amgen Inc., Thousand Oaks, CA, USA, ²Medicine, UCLA, Los Angeles, CA, USA.

Osteoprotegerin (OPG) is a cytokine that suppresses bone resorption by inhibiting the catabolic effects of receptor activator of NF-kappaB ligand (RANKL). OPG-deficient mice [opg^{-/-}] are osteoporotic and exhibit medial calcification of the aorta. This vascular phenotype in opg^{-/-} mice was the first evidence suggesting a protective role for OPG in the vasculature. However, the mechanism of this effect has not been determined and could be an indirect result of high turnover, or the direct result of RANKL or OPG actions within the vasculature. We evaluated these possibilities by assessing vascular calcification, serum calcium/phosphate levels, and aortic gene expression in opg^{-/-} mice and wildtype (WT) controls.

We quantified vascular calcification in opg^{-/-} mice by analyzing aortas ex vivo, using a high-resolution digital radiographic system. Radiographs were scored semi-quantitatively (0 to 5) based on the extent of mineralization, by an investigator blinded to genotype, sex, or age of the mice. No evidence of aortic mineralization was noted in any of the 24 WT aortas; whereas all 27 aortas were calcified in opg^{-/-} mice (mean calcification score = 2.7 ± 1.2). Aortic calcium content was quantified biochemically from a subset of mice, and was elevated 12-fold in opg^{-/-} mice compared to WT controls (p < 0.05).

We found increased serum phosphate (11.5 ± 1.4 mg/dL vs. 9.6 ± 1.1 mg/dL; p < 0.01) and calcium/phosphate product (114 ± 16 mg/dL vs. 94 ± 13 mg/dL; p < 0.01), but normal serum calcium levels (9.9 ± 0.5 mg/dL vs. 9.7 ± 0.4 mg/dL; p = 0.12) in opg^{-/-} mice compared to WT controls. The hyperphosphatemia in opg^{-/-} mice is likely related to increased bone resorption, as RANKL (926 ± 397 vs. 21 ± 22 pg/ml; p < 0.01), TRAP5b (0.10 ± 0.02 vs. 0.05 ± 0.02 AU; p < 0.001), and osteopontin (1736 ± 312 vs. 374 ± 91 pg/ml; p < 0.01) levels were elevated relative to WT controls.

Quantitative PCR was used to evaluate aortic gene expression between opg^{-/-} and WT mice and no difference was noted in expression of bone/cartilage transcription factors, BMP/TGF signaling molecules, or mineral binding/matrix factors. However, consistent with hyperphosphatemia, expression of matrix GLA protein (MGP) in opg^{-/-} mice was increased 90% (p < 0.01) while mRNA for alkaline phosphatase (akp2) was decreased 94% (p < 0.02). Interestingly, mRNA for ectonucleotide pyrophosphatase phosphodiesterase 1 (enpp1), which generates inorganic pyrophosphate (PPi), a mineralization inhibitor, was not increased in opg^{-/-} mice. Thus, the lack of enpp1 induction, together with remodeling-related hyperphosphatemia, may be important etiological factors in the development of vascular calcification in opg^{-/-} mice.

Reduced Kidney-stone Formation and Altered Renal Phosphate-homeostasis in Mice Over-expressing Murine-MEPE. A. Martin¹, V. David¹, L. W. Fisher², A. Hedge^{*1}, P. S. N. Rowe¹. ¹Internal Medicine, Kansas University Medical Center, Kansas City, KS, USA, ²NIDCR-NIH, Bethesda, MD, USA.

Transgenic-mice constitutively over-expressing recombinant murine-MEPE (Col1a1 2.3kb promoter) were used to study the role of MEPE in phosphate mineral-metabolism. Ten 19 week-old transgenic (TGC) male C57Bl6 mice were compared to ten age-matched wild-type (WT) male mice on a high 1% phosphate diet. Biochemical measurements were performed on sera and urine. RT-PCR, western-blots and immunohistochemistry were performed on kidneys to analyse the expression of different markers involved in phosphate-regulation. Computed 3D-microtomography (uCT) was used to assess kidney-stone formation.

Remarkably, despite a low bone-mass phenotype induced by MEPE over-expression, an increase in serum phosphate (WT: 8.1 mg/dL vs. TGC: 11.4 mg/dL, p<0.01) and a mild hypocalcemia (WT: 9.95 mg/dL vs. TGC: 8.96 mg/dL, p<0.05) occurred. Consistent with the increased serum-PO₄, the fractional excretion of phosphate decreased by 66% (p<0.01) and serum PTH decreased by 33% (170 pg/mL to 120 pg/mL, p<0.05). Interestingly, despite a mild hypocalcemia, serum 1,25-(OH)₂-Vit-D₃ was significantly increased (18 pg/mL to 40 pg/mL, p<0.05). Also, increased renal NPT2a Na-dependent co-transporter mRNA levels (+267%, p<0.01) and protein (as measured by western-blots and immunohistochemistry) occurred in transgenic mice, again consistent with the hyperphosphatemia. In contrast transgenic-mice had significantly decreased renal NTP2b and NPT2c mRNA levels (75% and 80% reduction respectively, p<0.05). Phex expression dramatically increased by 4X (p<0.05) in TGC mice. Compared with WT, TGC mice displayed a 700% increase in MEPE expression (protein and mRNA) in the kidney (p<0.05) and a reciprocal decrease in DMP-1 expression (76% decrease, p<0.05). This in combination resulted in a decrease in kidney stones induced by the high-phosphate diet as assessed by 3D-uCT (figure 1; 97% decrease, p<0.05).

In summary, over-expression of MEPE under a Col1a1 2.3kb promoter markedly alters renal-phosphate homeostasis and dramatically influences susceptibility to renal-calcification. Also, these data show an association between MEPE, renal sodium-phosphate co-transporters and susceptibility to kidney-stone formation.

Phospholipase C Signaling via the PTH/PTHrP Receptor Is Essential for Normal Full Response to PTH in both Bone and Kidney. J. Guo¹, M. Liu^{1*}, C. C. Thomas¹, D. Yang¹, M. L. Bouxsein², E. Schipani¹, F. R. Bringhurst¹, H. M. Kronenberg¹. ¹Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA, ²Orthopedic Biomechanics Laboratory, Beth Israel Hospital and Harvard Medical School, Boston, MA, USA.

To study role of signaling by distinct second message systems in vivo, we have constructed "knock-in" mice with mutant PTH/PTHrP receptors (PTHR) that can activate adenyl cyclase normally but cannot activate phospholipase C (PLC). We have previously shown that hypertrophic differentiation of chondrocytes is delayed in these so-called DSEL mice. To better understand role of PLC signaling via the PTHR in bone modeling and remodeling we examined the bone phenotype in DSEL mice that were fed either a standard diet or a calcium-deficient diet. Levels of serum PTH, phosphate and total calcium in DSEL mice fed a standard diet were not significantly different from those observed in wild type (WT) mice. Histomorphometric and uCT analysis demonstrate reduced trabecular bone (decreased by 15-20%) in DSEL mice fed a standard diet, and this decrease is associated with a decrease in trabecular number and an increase in trabecular spacing. The mechanisms underlying the low bone mass is not fully understood, since histomorphometric parameters of cell number and bone formation rate are normal in the secondary spongiosa of DSEL tibiae. The decreased bone mass may reflect abnormal modeling, as suggested by indices of increased osteoclast activity in the primary spongiosa, such as increased TRAP activity and mRNAs encoding TRAP and MMP9. Interestingly, DSEL mice fed a low calcium diet was able to develop secondary hyperparathyroidism including elevated serum PTH and substantial bone loss but exhibited a strikingly curtailed peritrabecular stromal cell response (peritrabecular bone marrow fibrosis), whereas WT mice exhibited extensive peritrabecular stromal cell responses to the low calcium diet. Such stromal cells express mRNAs encoding $\alpha 1(I)$ collagen, osteocalcin, and osteopontin, suggesting that they are preosteoblasts. In addition, the mutant mice fed low calcium diet were hyperphosphatemic, in contrast to the fall in blood phosphate in the WT control mice. The DSEL mice also exhibited an attenuated elevation of 1 α -hydroxylase mRNA, despite dramatic elevation of serum PTH in both groups. No significant change in mRNA levels of NaPi2a and NaPi2c was observed in the mutant mice in response to low calcium diet. Levels of FGF23 fell in response to the low calcium diet in both WT and DSEL mice, but on both diets FGF23 levels were not affected by the DSEL mutation. Our findings show that in both kidney and bone, PLC signaling through the PTHR in response to PTH are needed for the normal full responses; molecular analysis of the abnormalities is in progress.

Deletion of the Calcitonin/CGRP Gene Causes a Profound Cortical Resorption Phenotype in Mice. R. F. Gagel, A. O. Hoff, S. E. Huang*, G. J. Cote*. Endocrine Neoplasia & Hormonal Disorders, University of Texas M.D. Anderson Cancer Center, Houston, TX, USA.

There has been confusion regarding the long-term biological effects of calcitonin (CT) deficiency. Prior studies describing CT/CGRP gene or CT Receptor knockout models have provided contradictory phenotypes. To address these inconsistencies we have bred the knockout model (J Clin Invest 2002; F3 generation) into a pure C57/B6 mouse background (F10 generation). In this mouse model exons 2-5 of the mouse CT/CGRP were deleted in the germline by targeted disruption. Analysis of C57/B6 CT/CGRP KO mice (F10 generation) demonstrated a striking phenotype characterized by increased trabecular remodeling, trabecular & cortical thinning, and cortical porosity. The cortical thinning leads to morphological changes of vertebral bodies characterized by a 5% reduction of the height/width ratio ($p < 0.05$) in 12 and 18 month-old animals. The earliest indication of increased remodeling is the presence of a trabecular thinning in 3 & 6 month-old animals.

By 12 months of age a striking phenotype has emerged characterized by trabecular and cortical thinning (25%) with evidence of cortical tunneling (see Figure), collections of osteoclasts, and a 1.5-2-fold increase of serum C-telopeptide. The phenotype is most striking in 12 and 18 month females. Analysis of expressed genes (Affymetrix chip) derived from flushing of marrow with extraction buffer showed > 2-fold increases in CSF2Ra, CSF2Rb2, CCR2, Flotilin 2, Vimentin and > 1.5-fold increases of Prokineticin 2 and NFATc1, all genes involved in monocyte or osteoclast differentiation.

Conclusions: CT/CGRP deficient C57/B6 F10 mice have a profound and progressive phenotype characterized by increased trabecular thinning and cortical remodeling. These mice retain the greater calcemic response to PTH described earlier. Although there is evidence of these effects in 3 & 6 month-old animals, the major histologic effects are observed in older animals, possibly accelerated by gonadal steroid deficiency. The emergence of this phenotype argues persuasively for an important role of the CT/CGRP in the prevention of age-related bone loss and regulation of trabecular remodeling. The modulation of genes important in monocyte and osteoclast differentiation in the CT/CGRP KO indicates a previously unknown regulatory function of calcitonin.

PTH-Regulated Gene Expression in the Mouse Skeleton Suggest a Role for Ephrins in PTH Anabolism versus Catabolism. E. N. Bianchi*, R. Rizzoli, S. L. Ferrari. Div. of Bone Diseases, Geneva University Hospital, Geneva, Switzerland.

Intermittent PTH (i.PTH) induces a positive bone mineral balance while continuous PTH (c.PTH) does the opposite, particularly in the cortical bone compartment. The molecular mechanisms for PTH anabolism versus catabolism however remain poorly understood. Bidirectional ephrin signaling mediated by the binding of ephrinB2 ligand (EfnB2) to the ephrinB4 receptor (EphB4) was recently reported to induce osteoblast differentiation and reciprocal inhibition of osteoclast differentiation. This led us to hypothesize that ephrins expression could be up- and down-regulated by, respectively, i.PTH and c.PTH. Using gene expression profiling (Affymetrix Mouse 430A 2.0 Array) of PTH-stimulated primary osteoblasts from neonatal mouse calvariae, we first delineated a set of ephrin ligands (Efn) and receptors (Eph) that was expressed in bone cells. Then, we investigated PTH effects on skeletal gene expression of ephrins in both adult C57/B6J mice and beta-arrestin2 (Arrb2) KO mice, which lack a regulatory protein for PTH-mediated signaling. For this purpose, mice were treated with either daily (s.c.) or continuous (Alzet pump) PTH (80 μ g/kg/day) or vehicle ($n=4$ /gr) for 1 week. RNA was extracted separately from the femur cortical diaphysis (Dia) after flushing of the bone marrow and trabecular metaphysis-epiphysis (Met) region. Targeted gene expression levels of Efn B1 and B2, and Eph A3, A4, B2, B3 and B4, first identified by gene chips analysis in vitro, were analyzed by qRT-PCR (TaqMan MGB probes). Intermittent PTH up-regulated EfnB1, EphB2 and EphB3 1.4 to 1.5 fold in both trabecular and cortical bone compartments, whereas c.PTH did not. In contrast, in Arrb2 KO mice, i.PTH down-regulated the expression of EphA3 and EphA4 in Dia (-1.5x). Moreover, in these mice, c.PTH down-regulated expression of all Efn and Eph (except EphB4) in Dia (-1.4 to -2.5x.) and of EphA3, EphA4 and EphB3 in Met (-1.4 to -1.6x). Interestingly, the profile of EfnB1, EphB2 and EphB3 gene expression induced by PTH paralleled the profile of osteoprotegerin gene (OPG) expression, namely an up-regulation of OPG by i.PTH (2x in Met), but not by c.PTH, in WT mice and a down-regulation (-1.4x in Met and -1.7x in Dia) by c.PTH in KO mice. In summary PTH regulates skeletal gene expression of ephrins and their receptors, which depends on the mode of PTH administration and signaling regulation by beta-arrestins. In turn, up-regulation of ephrins/ephrins receptors, such as EphB3, and OPG by i.PTH should promote osteoblast differentiation and inhibition of osteoclastogenesis. Thereby ephrins could play a role in i.PTH anabolism on both trabecular and cortical bone compartments, while down-regulation of the ephrins system by c.PTH could favor catabolism.

Treatment with an Anti-Sclerostin Antibody Increased Bone Mass by Stimulating Bone Formation Without Increasing Bone Resorption in Aged Male Rats. X. Li, K. S. Warmington*, Q. Niu*, M. Grisanti, H. Tan, D. Dwyer*, M. Stolina, M. S. Ominsky, W. S. Simonet, P. J. Kostenuik, C. Paszty, H. Z. Ke. Amgen Inc., Thousand Oaks, CA, USA.

Male osteoporosis is becoming more common as the population ages, and decreased bone formation appears to be one of the characteristics of this condition. We previously reported that treatment with an anti-sclerostin antibody (Scl-Ab) stimulated bone formation, restored bone mass and bone strength in aged ovariectomized rats. We now describe the effects of Scl-Ab treatment on bone formation and bone mass in aged gonad-intact male rats. Sixteen-month-old male SD rats were treated s.c. with vehicle or Scl-Ab at 5 or 25 mg/kg, twice a week, for 5 weeks (9-10/group). In vivo bone mineral density (BMD) measurements by DXA showed that rats treated with Scl-Ab at 5 or 25 mg/kg had significantly higher BMD at lumbar vertebrae (+16%; +27%), distal femur (+15%; +20%) and femur-tibia (+9%; +11%) compared with vehicle control. Serum osteocalcin, but not serum CTX-1, was significantly increased in Scl-Ab treated rats as compared with control. Histomorphometric analysis at the proximal tibial metaphysis showed that rats treated with 5 or 25 mg/kg Scl-Ab had significantly greater trabecular bone volume (BV/TV, +133% and +166%, respectively), trabecular thickness, and a significant decrease in trabecular separation compared with vehicle controls. Scl-Ab treated rats had significantly greater osteoblast surface but not osteoclast surface compared with vehicle control. Furthermore, Scl-Ab treated rats had significantly greater mineralizing surface (MS/BS), mineral apposition rate (MAR) and bone formation rate (BFR/BS, +252% and +374% for 5 and 25 mg/kg, respectively) in trabecular bone of proximal tibia. At the tibial shaft increases in endocortical and periosteal bone formation were seen at both the 5 and 25 mg/kg doses, with greater increases seen at the endocortical surface (for 25 mg/kg dose: MS/BS +383% vs +130%, BFR/BS +852% vs +285%). In summary, inhibition of sclerostin by a Scl-Ab increased bone mass and increased bone formation on trabecular, periosteal and endocortical surfaces without evidence of increased bone resorption in aged male rats. These results suggest that anti-sclerostin antibody represents a novel anabolic therapy for age related bone loss in males.

Gαq Signaling in Osteoblasts Inhibits Bone Formation. N. Ogata¹, Y. Shinoda¹, F. Yano¹, N. Wettschureck^{*2}, S. Offermanns^{*2}, G. V. Segre³, K. Nakamura¹, H. Kawaguchi¹. ¹Sensory and Motor System Medicine, University of Tokyo, Tokyo, Japan, ²Pharmakologisches Institut, University of Heidelberg, Heidelberg, Germany, ³Endocrine Unit, MGH, Boston, MA, USA.

Gas/CAMP/PKA and Gαq/PLC/PKC are known to be the two major signal pathways of PTH. Although accumulated evidence has revealed the anabolic role of the Gas signaling in bone formation, little is known about that of Gαq. To study the role of the Gαq signaling, we initially produced transgenic (Tg) mice that overexpressed the constitutively active Gαq gene exclusively in osteoblasts under the control of 2.3-kb type I collagen α1 chain (COL1A1) promoter. The Tg mice exhibited osteopenia in trabecular and cortical bones with decreased bone formation parameters. Cultured calvarial osteoblasts from the Tg mice showed impairment of differentiation and matrix formation, which was restored by addition of a PKC inhibitor GF109203X. To further explore the role of endogenous Gαq-mediated signaling in bone, we established double knockout (DKO) mice with osteoblast-specific ablation of Gαq and global ablation of Gα11, a Gαq subfamily member that also activates PLC; we did this by crossing Cre transgenic mice under the control of the COL1A1 promoter above (COL1-Cre^{+/+}) and mice with the Gαq gene flanked with loxP / global ablation of Gα11(Gαq^{fl/fl};Gα11^{-/-}). The DKO (COL1-Cre^{+/+};Gαq^{fl/fl};Gα11^{-/-}) mice developed and grew normally without abnormality of major organs. In addition, bone densitometry, 3D-μCT, and histomorphometric analyses showed no significant difference of bone volume or formation in DKO as compared with hetero-knockout of either Gαq (COL1-Cre^{+/+};Gαq^{fl/fl};Gα11^{-/-}) or Gα11 (COL1-Cre^{+/+};Gαq^{fl/fl};Gα11^{-/-}), or the wild-type (COL-Cre^{+/+};Gαq^{fl/fl};Gα11^{+/+}) littermates at 4-20 weeks of age under physiological condition. However, when rhPTH (1-34) (0.08 mg/kg x 5 times x 4 weeks) or the vehicle was subcutaneously injected to 8-week-old mice of all genotypes (n=10/group), the bone densities of the femur, tibia, and L2-5 vertebrae of the PTH group were 12.2, 11.3, and 5.0% higher than the vehicle group (p<0.01 PTH vs. vehicle) in wild-type mice. Although the PTH effect in the Gα11 hetero-knockout mice (12.4, 11.7, and 5.5%) was comparable to WT, it was moderately enhanced by the Gαq hetero-knockout (13.7, 13.1, and 6.7%, P<0.10 vs. wild-type) and significantly by the DKO (15.3, 14.9, and 8.5%, P<0.05 vs. wild-type), indicating dose-dependent stimulation by the Gαq deficiency, but not by Gα11. Taken together, both the gain- and the loss-of-functions of Gαq in osteoblasts clearly demonstrated the inhibitory role of the Gαq signaling in bone formation. Suppression of the Gαq signaling to enhance the PTH anabolic action may lead to a novel treatment of osteoporosis.

Disclosures: N. Ogata, None.

Adenosine and Osteoporosis: Adenosine A₁ Receptor Blockade Reverses Bone Loss in Ovariectomized Mice and Deletion of Adenosine A_{2A} Receptors Leads to Diminished Bone Density. F. M. Kara^{*1}, S. B. Doty^{*2}, A. Boskey^{*2}, B. Fredholm^{*3}, B. N. Cronstein¹. ¹Medicine, NYU School of Medicine, NYC, NY, USA, ²Hospital for Special Surgery, NYC, NY, USA, ³Karolinska Institute, Stockholm, Sweden.

Adenosine regulates a wide variety of physiological processes via interaction with one or more of four G protein-coupled receptors. Because we have previously reported that adenosine A₁ receptors promote fusion of stimulated human monocytes to form giant cells whereas A_{2A} receptor activation inhibits in vitro giant cell formation we determined whether there was a similar requirement for A₁ & A_{2A} receptor occupancy in osteoclast formation.

Spleens were harvested from C57BL/6 female mice (or A₁R knockout mice and their wild type littermates) and splenocytes were cultured in the presence of M-CSF (30 ng/ml) and RANKL (30 ng/ml) with or without various concentrations of the A₁R antagonist DPCPX for 7 days. Cells were stained for tartrate-resistant acid phosphatase (TRAP). The number of TRAP-positive multinucleated cells/well was then enumerated. Histological examination of bones from A₁R, A_{2A} knockout and wild type mice was carried out with both standard (H&E) and immunohistologic (TRAP & Cathepsin K) stains and electron microscopy of bone sections was also carried out. A₁KO and A_{2A} KO mice were analyzed by DEXA (PIXImus) to measure the BMD and by MicroCT. Four week old C57BL/6 mice underwent ovariectomy (OVX) or SHAM surgery; those mice were treated with DPCPX (50 mg/kg/day) or vehicle (VEH) for 5 weeks.

The A₁R antagonist DPCPX inhibits osteoclast formation by as much as 93% in a dose-dependent fashion (P= 0.0012). splenocytes from A₁R KO mice formed almost no osteoclasts in response to M-CSF and RANKL. Histological, pQCT and PIXImus examination from A₁R KO mice shows osteopetrosis, where A_{2A} KO mice shows Osteoporosis. Immunohistological demonstrates that although osteoclasts are present in the A₁R KO mice the osteoclasts are smaller and often not associated with bone. Electron microscopy from A₁KO femur shows an absence of ruffled borders of osteoclasts and resorption of bone. Where A_{2A} mice shows that the osteoclasts are pretty actively in resorbing bone, pQCT and PIXImus scan measurements indicated that by 5 weeks of DPCPX treatment trabecular bone density (TbBD) in the proximal femur increased in both OVX and SHAM compared to VEH. Ex vivo analysis of whole mice by DXA (PIXImus) scan confirmed increased BMD in DPCPX treated mice.

These results indicate that endogenously-released adenosine plays a critical role in regulating bone turnover via interaction with adenosine A₁ & A_{2A} receptors on osteoclasts and their precursor cells. Moreover the A₁ & A_{2A} receptors may be useful targets in treating diseases characterized by excessive bone turnover such as osteoporosis.

Effects of Cyclic and Daily PTH in Combination with OPG. A. Iida-Klein¹, S. Johnston^{*1}, Y. Shen², F. Cosman³, R. Lindsay³, D. W. Dempster¹. ¹Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, ²MDS Services Inc., Bothell, WA, USA, ³Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

We recently demonstrated that combination of PTH with the anti-resorptive agent alendronate markedly enhances bone strength as well as bone density in mice (Iida-Klein et al, NOF, 2007). Accordingly, we address whether another anti-resorptive agent osteoprotegerin (OPG) has similar effects to alendronate on bone strength as well as density when added to daily or cyclical PTH regimens. We treated 20-week-old, female C57BL/6 mice (n=10/group) for 7 weeks with the following: 1) vehicle [control], 2) OPG-Fc 10 mg/kg/day 2 days/week [OPG], 3) hPTH (1-34) 40 mcg/kg/day [daily PTH], 4) daily PTH in addition to OPG [daily PTH + OPG], 5) PTH and vehicle alternating weekly [cyclic PTH], 6) cyclic PTH in addition to OPG [cyclic PTH + OPG]. We examined the effects of these regimens on femoral and vertebral BMD, bone markers and cortical bone structure of the femur assessed by DXA, biochemical assays and pQCT, respectively. At 7 weeks, all treatment groups markedly increased BMD, and the combination of PTH and OPG additively increased BMD (Table). The positive effect of OPG on vertebral BMD was more marked in the cyclic PTH + OPG group. PTH significantly increased osteocalcin (OC) and mTRAP, while OPG significantly decreased OC and mTRAP. Furthermore, OPG blunted the stimulatory effects of PTH on OC and mTRAP. PTH significantly increased periosteal circumference while OPG tended to decrease endosteal circumference. This effect of OPG at the endocortical site was further enhanced in the presence of PTH as shown by significant decreases in endosteal circumference in the combined groups. At the periosteal site, OPG slightly blunted the PTH-stimulated periosteal expansion. Cortical thickness significantly increased in all groups.

The current study suggests that combination of PTH and OPG may work in a complementary fashion. Combination of these 2 agents in an appropriate protocol in humans may potentially produce more beneficial effects on bone than treatment with either agent alone.

Table 1. Percent increase from control in femoral and vertebral BMD, femoral bone structure and bone markers

	BMD		Osteocalcin	mTRAP	Cortical Thickness	Endosteal Circ.	Periosteal Circ.
	Femur	LV1-6					
OPG	9.1% ^a	16.5% ^b	-42.4% ^b	-65.4% ^b	4.7% ^a	-1.8%	-0.1%
Daily PTH	14.8% ^b	11.8% ^b	472.9% ^b	81% ^b	14.0% ^b	0%	4.9% ^b
Daily PTH + OPG	23.9% ^b	30.1% ^b	-6.8%	-56.3% ^b	22.1% ^b	-5.4% ^b	4.2% ^b

A Comparison of Denosumab and Alendronate in Combination with PTH in Ovariectomized Knockin Mice Expressing Humanized RANKL. S. L. Ferrari¹, D. Pierroz¹, N. Bonnet¹, D. Dwyer², M. Stolina², P. Kostenuik². ¹Div. of Bone Diseases, WHO Collaborating Center for Osteoporosis Prevention, Geneva University Hospital, Geneva, Switzerland, ²AMGEN Inc., Metabolic Disorders Research, Thousand Oaks, CA, USA.

Denosumab (DMab, a human Ab versus RANKL), was shown to improve bone volume, density and strength in ovariectomy (OVX) models. The antiresorptive action of DMab typically leads to a secondary increase in serum PTH, which might contribute to Dmab effects on bone. We explored this possibility by examining the endogenous PTH response to DMab or alendronate (ALN), the effects of those therapies on bone density and architecture, and the effects of adding daily PTH to those regimens.

DMab does not inhibit murine RANKL, so studies were performed in knockin mice that express a humanized RANKL gene wherein murine exon 5 was replaced by a human sequence. Adult huRANKL mice (4 months) were sham-operated or OVX, and treated twice weekly (sc) with ALN (100 ug/kg) or Dmab (10 mg/kg) or vehicle (VEH) (n=14-16/group) for 8 weeks. After 4 weeks, half the animals in each group were co-treated with PTH (80 ug/kg/d) or VEH for the remaining 4 weeks. BMD was assessed by DXA at weeks 4 and 8, and trabecular (Tb) and cortical (Ct) microarchitecture of the distal femur was assessed by ex vivo micro-CT at week 8.

Compared to sham, OVX induced a significant loss of whole body (WB) BMD, Tb BV/TV (-74%), number (TbN, -43%), thickness (TbTh, -12%), connectivity (ConnD, -90%) and Ct width (-18%). ALN significantly improved WB BMD, BV/TV and TbN compared to VEH, whereas ALN plus PTH was significantly better than ALN alone on these parameters as well as on TbTh and ConnD. Dmab was statistically superior to ALN alone and equivalent to ALN plus PTH on all Tb bone parameters. Dmab also significantly increased Ct width (+17%), which ALN +/- PTH did not.

The addition of daily PTH to Dmab at week 4 did not significantly change any DXA/microCT parameters compared to 8 weeks of Dmab alone. The lack of additive effects may have been related to the pronounced effects of Dmab monotherapy, which increased WB BMD, BV/TV, TbN and ConnD to levels significantly greater than sham controls. Moreover, Dmab caused a significantly greater increase in serum PTH (1-84) (+250%) and lower serum phosphate at week 4 vs ALN. Circulating PTH levels correlated positively with WB BMD (r=0.62, P<0.001) and Tb BV/TV (r=0.59, p<0.001).

In summary, Dmab was superior to ALN and similar to ALN plus PTH in preventing OVX-related changes of WB BMD, Tb and Ct microarchitecture in huRANKL mice. Intermittent PTH did not further improve Dmab effects, while Dmab induced a significant increase in PTH (1-84) levels and activity. These results support the possibility that endogenous PTH response to Dmab may contribute to its ability to improve bone mass and architecture.

GLP-2 Significantly Increases Hip BMD in Postmenopausal Women: A 120-Day study. D. Henriksen¹, P. Alexandersen², B. Hartmann¹, I. Byrjalsen³, J. J. Holst⁴, C. Christiansen¹. ¹Sanos Bioscience A/S, Roedovre, Denmark, ²Center for Clinical & Basic Research, Ballerup, Denmark, ³Nordic Bioscience A/S, Herlev, Denmark, ⁴Department of Medical Physiology, University of Copenhagen, Copenhagen, Denmark.

Glucagon-like peptide-2 (GLP-2) is an intestinal hormone released in response to food intake. We have earlier shown that treatment with GLP-2 for 14 days caused a significant post-administration reduction of bone resorption. This effect was not followed by a change in bone formation and s-osteocalcin levels were unaffected by treatment.

We now present a randomized, placebo-controlled 120-day phase II trial with 160 postmenopausal women. The aim was to test the sustainability of above findings over a longer treatment period and to evaluate the potential for long-term treatment with GLP-2. The study subjects were osteopenic (BMD T-score, -2.5 < T ≤ -1.0) at one or more of the regions: lumbar spine, femoral neck, or total hip. The objectives were relative change from baseline of total hip and spine BMD, as well as pharmaco-dynamic changes in bone resorption (s-CTX) and formation (s-osteocalcin) over the 120 days. Subjects received daily bedtime injections of 0.4, 1.6, or 3.2 mg GLP-2, or placebo. All subjects received supplements of calcium and vitamin D. Treatment with GLP-2 resulted in a dose dependent increase in total hip BMD from baseline, which reached statistical significance (p=0.006) in the 3.2 mg GLP-2 group compared to placebo. This dose dependent relationship in BMD was also seen at the trochanter, (p=0.01, 3.2 mg group). All GLP-2 doses levels elicited an acute and sustained reduction of the nocturnal rise in s-CTX seen in the placebo group. The reduction in the s-CTX level was greater at Day 120 than at Day 1 indicating an overall improved suppression of bone resorption during the 120 days treatment. At Treatment Day 120, all GLP-2 groups had a greater, and highly statistically significant, (p<0.0001) reduction in AUC_{0-4h} for s-CTX compared to placebo.

None of the study participants developed any detectable antibodies against GLP-2 and no tachyphylaxis was observed. Overall, it was concluded that the treatment with GLP-2 for 120 consecutive days was effective, well-tolerated and safe. In conclusion, the results suggest that GLP-2 acutely disassociates the two processes of bone remodelling and thereby increases the bone calcium (ossification) balance, particularly at the hip. The favourable effect of GLP-2 on the BMD of the hip suggests that an agent with this mode of action could prove a valuable new treatment for osteoporosis.

A Randomized, Double-Blind, Placebo-Controlled Study of a Cathepsin-K Inhibitor in the Treatment of Postmenopausal Women with Low BMD: One Year Results. H. G. Bone¹, M. McClung², N. Verbruggen³, A. Rybak-Feiglin⁴, C. DaSilva⁴, A. C. Santora⁴, A. Ince⁴. ¹Michigan Bone and Mineral Center, Detroit, MI, USA, ²Oregon Osteoporosis Center, Portland, OR, USA, ³Merck Research Laboratories, Brussels, Belgium, ⁴Merck Research Laboratories, Rahway, NJ, USA.

Cathepsin K, a cysteine protease abundantly expressed in osteoclasts, is necessary for bone collagen degradation. MK-0822, a selective inhibitor of cathepsin K, has been shown to rapidly and reversibly decrease bone resorption in both preclinical and short-term clinical studies. In order to evaluate the safety, tolerability and efficacy of weekly doses of placebo, 3, 10, 25 or 50 mg of MK-0822 on BMD and biochemical indices of bone turnover, a 1+1 year dose-ranging trial is ongoing in postmenopausal women with low BMD. We present 12-month data here. Postmenopausal women (N=399) with BMD T-scores ≤ -2.0 and ≥ -3.5 at lumbar spine (LS), femoral neck (FN), trochanter, or total proximal femur were randomized to receive placebo or 1 of 4 doses of MK-0822. Mean age was 64.2 ± 7.8 years. The mean LS T-score was -2.2 ± 0.8, the FN T-score was -1.9 ± 0.7, and the urinary N-telopeptide/creatinine ratio was 44.1 ± 21.2 nmol/mol. Treatment produced dose-related increases in BMD from baseline. The highest dose of MK-0822 tested (50 mg) resulted in a 3.4% increase in LS BMD (Figure), a 2.5% increase in femoral neck BMD, and a 58% reduction in uNTx/Cr. The safety profile of MK-0822 was generally favorable. There were no dose-related trends in any adverse experiences (AEs). Rash was reported in 8.4% and 3.8% of those in the placebo and 50 mg arms, respectively. Among participants in the placebo arm, 9 discontinued the study due to AEs, and 4 discontinued due to AEs considered drug-related. By contrast, 4 and 0 participants in the 50 mg arm were in each of these AE categories, respectively. In summary, 12 months of MK-0822 treatment was generally safe and well-tolerated and increased LS and FN BMD in postmenopausal women with low BMD.

Anti-Sclerostin Antibody Increases Markers of Bone Formation in Healthy Postmenopausal Women. D. Padhi¹, B. Stouch¹, G. Jang¹, L. Fang¹, M. Darling¹, H. Glise², M. Robinson³, S. Harris⁴, E. Posvar¹. ¹Amgen Inc, Thousand Oaks, CA, USA, ²UCB SA (Pharma), Braine-l'Alleud, Belgium, ³UCB-Celltech, Slough, United Kingdom, ⁴Seaview Research, Miami, FL, USA.

Genetic evidence, along with gene expression, cell biology and pharmacology data, demonstrate that the osteocyte-secreted protein, sclerostin, negatively regulates osteoblasts and plays a key role in controlling bone formation and bone mass throughout life. In this blinded, placebo-controlled, rising single dose study, 48 healthy postmenopausal women were randomized (3:1) to receive a single SC dose (0.1, 0.3, 1, 3, 5, or 10 mg/kg) of a sclerostin neutralizing monoclonal antibody (scl-mAb) or placebo. Blood samples were collected up to 85 days postdose for determination of serum scl-mAb, BSAP, osteocalcin, P1NP and CTx concentrations.

Scl-mAb pharmacokinetics (PK) were non-linear with dose (eg. for the 30-fold increase in dose from 0.1 to 3 mg/kg, mean exposure based on the maximum serum scl-mAb concentrations or area under the serum concentration-time curve increased approximately 60- to 100-fold). Preliminary pharmacodynamic (PD) data for doses of 0.1 to 10 mg/kg scl-mAb are available. Dose-related increases in the bone formation markers P1NP, osteocalcin and BSAP were observed (relative to placebo), with mean percentage change from baseline for these markers of approximately 60 to 100% at 3 mg/kg by 21 days. A trend of dose-related decreases in serum CTx was also observed.

In conclusion, scl-mAb PK following SC administration in healthy postmenopausal women was nonlinear with dose, as observed with other mAbs. Single doses of scl-mAb resulted in significant increases in bone formation markers relative to placebo and a trend of dose related decreases in serum CTx. Scl-mAb was well tolerated following administration of single SC doses. These data support continued clinical investigation of sclerostin inhibition as a potential therapeutic strategy for conditions that will benefit from increased bone formation.

Ostabolin-CTM Increases Lumbar Spine and Hip BMD after 1 Year of Therapy: Results of a Phase II Clinical Trial. A. Hodsman¹, H. Bone², C. Gallagher³, D. Kendler⁴, J. P. Brown⁵, S. Greenspan⁶, C. L. Barclay⁷, P. Morley⁸, R. Anderson⁷, B. R. MacDonald⁸. ¹St. Joseph's Hospital, London, ON, Canada, ²Michigan Bone and Mineral Clinic, Detroit, MI, USA, ³Creighton University, Omaha, NE, USA, ⁴ProHealth Clinical Research Center, Vancouver, BC, Canada, ⁵Laval University, Quebec, PQ, Canada, ⁶University of Pittsburgh, Pittsburgh, PA, USA, ⁷Zelos Therapeutics, Ottawa, ON, Canada, ⁸Zelos Therapeutics Inc., West Conshohocken, PA, USA.

Ostabolin-C (OC) is a cyclic analogue of parathyroid hormone (PTH) (1-31) that has demonstrated marked increases in bone mineral density (BMD) and bone strength in long term preclinical studies, without inducing hypercalcemia. 261 postmenopausal women aged 45-75 years with a BMD T score at lumbar spine (LS) or femoral neck ≤ -2 were randomized into a double blind, placebo controlled dose ranging study investigating the safety and efficacy of 4 months of treatment with OC. Subjects received placebo, 7.5, 15, 30 or 45 $\mu\text{g/day}$ by subcutaneous injection. 198 study subjects elected to continue into a blinded extension study of 8 additional months. The primary endpoint was change in LS-BMD at 1 year. Secondary measures included change in BMD at the hip, biomarkers of bone turnover, and safety measures, including the occurrence of hypercalcemia. OC caused a striking, dose-dependent increase in LS-BMD that was evident by month 4. 79% of subjects in the 45 μg group had an early BMD response (defined as $\geq 3\%$ increase after 4 months). BMD measurements at all proximal femur sites were also increased at 4 months in the 45 μg group. At month 12, LS-BMD was further increased in all active treatment groups with a maximum mean % increase of 11.0 % in the 45 μg group compared to a 0.17 % increase in placebo ($p < 0.001$). At month 12, 97% of subjects in the 45 μg group had an increase in LS-BMD of $\geq 3\%$. At month 12, total hip BMD increased by 2.4% in the 45 μg group compared to a 1.2% decrease in placebo ($p < 0.001$). The BMD effects at all doses were accompanied by commensurate significant increases in biomarkers of bone formation that were detectable at the earliest measured timepoint (4 weeks). Mean % change in P1NP was $> 120\%$, and osteocalcin was $> 100\%$, above baseline throughout the study. Compliance with study drug was $> 93\%$ in all dose groups. The most commonly reported adverse event was mild nausea, as seen with other PTH analogues. This adverse event usually occurred early in the treatment period. Few serious adverse events occurred. Most episodes of hypercalcemia were mild. Hypercalcemia $> 11.0 \text{ mg/dL}$ was infrequent, and only observed with higher incidence than placebo in the 45 μg group. The observed clinical profile, including a marked early BMD response at both hip and spine, indicates that OC has the potential to be a highly effective treatment for osteoporosis.

Dose-dependent Increases in Endogenous Parathyroid Hormone Concentrations After Administration of a Calcium Sensing Receptor Antagonist to Normal Volunteers: Potential for an Oral Bone Forming Agent. D. Ethgen¹, J. Phillips¹, C. Baidoo¹, C. Matheny¹, A. Roshak¹, R. Marquis¹, G. Stroup², S. Kumar¹, P. Bhatnagar¹, W. F. Huffman¹, V. S. Kitchen¹, M. Gowen², L. A. Fitzpatrick¹. ¹GlaxoSmithKline, Collegeville, PA, USA, ²GlaxoSmithKline, King of Prussia, PA, USA.

Brief antagonism of the calcium-sensing receptor (CaR) in the parathyroid gland results in transient stimulation of endogenous parathyroid hormone (PTH) release, a profile known to stimulate bone formation. SB-423557 is an ethyl ester precursor of SB-423562. Upon administration, SB-423557 is converted into its corresponding acid, SB-423562. Both molecules are potent calcium-sensing receptor antagonists that are being investigated for the treatment of osteoporosis as a novel oral bone forming agent. This first clinical study administering SB-423557 orally to healthy male volunteers was designed as a single-blind, placebo-controlled, crossover, randomized (with respect to placebo), dose-rising study. Fifty-four subjects participated in two study sessions separated by ≥ 7 days. In random order, subjects received placebo in one study session, and single oral dose SB-423557 in the other. Dose levels were 5, 10, 20, 50, 100, 200, 400 and 500 mg ($n=5-6$, except $n=12$ for 50 mg group). Blood samples for pharmacokinetic and pharmacodynamic analyses were obtained over a 24-h period after each dose. Elevations in plasma PTH closely followed the time-course of SB-423562 concentrations in blood (SB-423557 generally was undetectable). The duration of PTH elevation (defined as PTH levels \geq twice the pre-dose level) was usually under 8 hours. At SB-423557 doses of 100 mg and above, PTH exposure ($\text{AUC}_{0-24 \text{ h}}$) was on average, 10% to 48% higher compared to placebo. The mean maximum post-dose PTH concentration ranged from 38% to 285% higher relative to placebo; median time to maximum concentration (T_{max}) ranged from 1.01 h to 2.26 h. At doses of 50 mg and higher, relative to placebo, a 1.8- to 4.2-fold increase in PTH levels compared to baseline was noted at the T_{max} . There were no significant effects on serum calcium levels. SB-423557 was generally well tolerated at all doses and no serious adverse events were reported. There were no notable differences among regimens with regard to adverse events frequency, safety laboratory values, vital signs or 12-lead ECG interval values outside the threshold ranges. In conclusion, the observed transient rises in PTH after single oral doses of a CaR antagonist, SB-423557, constitutes an early proof-of-concept in man, and provides the basis for further development of this class of compounds for delivering an oral bone forming treatment to osteoporotic patients.

A Single Dose of ACE-011 Is Associated with Increases in Bone Formation and Decreases in Bone Resorption Markers in Healthy, Postmenopausal Women. J. Ruckle¹, M. Jacobs¹, W. Kramer², R. Kumar³, K. Underwood³, R. S. Pearsall³, A. Pearsall³, J. Seehra³, C. Condon³, M. L. Sherman³. ¹Covance Clinical Research, Honolulu, HI, USA, ²Kramer Consulting, LLC, North Potomac, MD, USA, ³Accelaron Pharma, Inc., Cambridge, MA, USA.

ACE-011 is a fusion protein consisting of the extracellular domain of the human type II activin receptor IIA (ActRIIA) linked to the Fc portion of human IgG1. ACE-011 binds to activin with a K_d of 50 pM. Nonclinical studies in ovariectomized mice treated with ActRIIA fused to the Fc region of a murine IgG have shown improvements in bone architecture and strength. Histomorphometry studies have demonstrated an anabolic effect. A randomized, double-blind, placebo-controlled study was conducted to evaluate ACE-011 administered to healthy, postmenopausal women. Forty-eight subjects were randomized in cohorts of 6 to receive either a single dose of ACE-011 or placebo (5 active:1 placebo). Dose levels ranged from 0.01 to 3.0 mg/kg intravenously and 0.03 to 0.1 mg/kg subcutaneously. All subjects were followed for 120 days. Subjects were excluded from study participation if they took medications affecting bone metabolism within 6 months of study entry. Safety evaluations were conducted following each cohort to determine dose escalation. In addition to pharmacokinetic (PK) analyses, the biologic activity of ACE-011 was also assessed by measurement of biochemical markers of bone formation and resorption, and FSH levels. No serious adverse events were reported in this study. Adverse events (AEs) were generally mild and transient. Preliminary analysis of AEs included headache, elevated laboratory values, cold symptoms, emesis or vomiting, intravenous infiltration, and hematoma at injection site. PK analysis of ACE-011 displayed a linear profile with dose, and a mean half-life of approximately 25-32 days. The absorption after SC dosing was essentially complete. ACE-011 caused a rapid, sustained dose-dependent increase in serum levels of bone-specific alkaline phosphatase, and a dose-dependent decrease in C-terminal type 1 collagen telopeptide and tartrate-resistant acid phosphatase 5b levels. These bone biomarker changes were sustained for at least 29 days at the highest dose levels tested. There was also a dose-dependent decrease in serum FSH levels consistent with inhibition of activin.

A single dose of ACE-011 given to healthy postmenopausal women was safe and well-tolerated for the range of dose levels tested. The prolonged PK and pharmacodynamic effects suggest that intermittent dosing would be appropriate for future studies. ACE-011 is a first-in-class novel osteoanabolic agent with biological evidence of both an increase in bone formation and a decrease in bone resorption.

Compromised Bone Marrow Perfusion in Osteoporosis. J. F. Griffith¹, D. K. W. Yeung¹, P. K. Tsang¹, K. C. Choi², T. C. Y. Kwok³, A. T. Ahuja¹, K. S. Leung⁴, P. C. Leung⁵. ¹Diagnostic Radiology and Organ Imaging, The Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, Hong Kong, ²School of Public Health, The Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, Hong Kong, ³Community and Family Medicine, The Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, Hong Kong, ⁴Orthopaedics and Traumatology, The Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, Hong Kong, ⁵Jockey Club Centre for Osteoporosis Care and Control, The Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, Hong Kong.

Background: There may be a link between bone blood flow and osteoporosis. This study of the proximal femur investigates the relationship between bone mineral density (BMD), bone fat content, bone and muscle perfusion.

Methods: 120 healthy female subjects (mean age, 74 years) underwent DXA, proton (¹H) MR spectroscopy, and dynamic contrast-enhanced MRI. Marrow fat content was measured at the femoral head, neck and shaft. Perfusion indices (maximum enhancement, E_{max} and enhancement slope, E_{slope}) in the proximal femur (head, neck, shaft and acetabulum) and adductor muscle were measured. Correlation between T-score, fat content and perfusion indices was examined.

Results: Perfusion indices were significantly reduced in subjects with osteoporosis (Table) compared to subjects with osteopenia or normal BMD (Figure).

Adductor muscle perfusion was not affected by change in BMD (E_{max} , $r = -0.061$; E_{slope} , $r = -0.057$). As marrow perfusion decreased in the proximal femur, marrow fat increased. For normal BMD subjects, perfusion parameters in the femoral head were 1/3 those in the femoral neck or shaft and 1/5 those in the acetabulum.

Conclusion: Perfusion in the proximal femur is reduced in osteoporotic subjects compared to osteopenic and normal subjects. This reduction in perfusion occurs only within the bone and not in the extrasosseous tissues.

Pearson correlation coefficient between T-score, perfusion indices and fat content.			
		Vs. T-score	Vs. Fat content

Neuropeptide Y Protects the Skeleton from Stress-induced Bone Loss. P. A. Baldock^{*1}, S. Allison^{*1}, T. Karl^{*2}, D. Pierroz³, D. Lin^{*2}, A. Sainsbury^{*2}, R. Enriquez^{*1}, S. Ferrari³, H. Herzog^{*2}, J. Eisman¹. ¹Bone Program, Garvan Institute of Medical Research, Sydney, NSW, Australia, ²Neuroscience Program, Garvan Institute of Medical Research, Sydney, NSW, Australia, ³Service and Laboratory of Bone Diseases, Geneva University Hospital, Geneva, Switzerland.

Bone responses to stress are not well studied beyond corticosteroid-related effects. Neuropeptide Y has anxiolytic actions, attenuating the psychological effects of stress. Interestingly, the major Y-receptor mediating these anti-stress actions is the Y2 receptor, also known to control bone mass. We therefore investigated how the NPY pathway may modulate skeletal responses to physiological stress.

Behavioral stress responses in NPY^{-/-} mice were examined using established models. Skeletal response to stress was examined at 14 weeks in male NPY^{-/-} and wild type mice after 4 week low and high stress protocols. All mice were kept in a low stress environment until the age of 9 weeks. Following this, the "stress" groups were involved in a protocol that necessitated regular handling and other known stressors in mice, including rectal temperature, glucose tolerance test, 24h fasting and metabolic cage studies. Control mice remained in the lower stress environment.

Anxiety-like behaviours in the open field and light-dark tests, both standard methods for determination of explorative and anxiety-related parameters, were much greater in NPY^{-/-} mice.

As expected, whole body, femoral (53 ± 2 mg/mm² vs 65 ± 2 , $p < 0.05$) and tibial BMD was greater in NPY^{-/-} mice compared to wild type in low stressed group, coincident with greater cortical volume and thickness. Greater cancellous bone volume in distal femoral ($16.7 \pm 1.5\%$ vs 11.6 ± 0.9 , $p < 0.01$), and lumbar vertebral metaphyses was coincident greater mineral apposition rate in NPY^{-/-} mice (1.9 ± 0.1 μ m/d vs 2.8 ± 0.1 , $p < 0.0005$).

In the "stressed" groups, body weight was reduced in NPY^{-/-} mice (30.1 ± 1 g vs 25.5 ± 1 g, $p < 0.0001$), with decrements in lean and fat mass, with no decrease in wild type. A mild cancellous response was evident in wild type mice, with trabecular number reduced but no significant loss of cancellous bone volume. However, in "stressed" NPY^{-/-} mice there was a marked decrease in cancellous bone volume compared to low stressed NPY^{-/-} mice ($16.7 \pm 1.5\%$ vs 13.2 ± 0.7 , $p < 0.01$), again associated with reduced trabecular number. Importantly, mineral apposition rate was also reduced in "stressed" NPY^{-/-} mice, but still remained greater than wild type (1.6 ± 0.1 μ m/d vs 2.4 ± 0.1 , $p < 0.0001$).

In summary, these data suggest that NPY plays a powerful role in regulating the effects of stress. Diminishing levels of NPY may enhance the bone loss induced by stress. This may explain a mechanism for bone loss associated with stress in otherwise healthy individuals.

Fat-1 Gene Prevents Ovariectomy Induced Bone Loss by Modulating Osteoclastogenesis. M. M. Rahman, A. Bhattacharya*, J. Banu, G. Halade*, G. Fernandes*. Medicine/CI, UTHSCSA, San Antonio, TX, USA.

Consumption of n-3 fatty acids (FA) positively influences on calcium and bone metabolism. Beneficial effects of n-3 FA on bone mineral density (BMD) have been reported in mice, rats and humans, but the precise mechanisms involved have not been described. In this study, we investigated the effect of fat-1 gene on ovariectomy induced bone loss. fat-1 gene encodes for an n-3 desaturase enzyme that can synthesize n-3 FA from n-6 FA. Ovariectomized (OVX) and sham operated wild type (WT) C57BL/6 (B6) mice and fat-1 transgenic B6 mice were fed a diet containing 10% CO. After 24 weeks on diets, BMD was analyzed by dual energy x-ray absorptiometry. fat-1 OVX mice had significantly higher BMD in distal femoral metaphysis, proximal tibial metaphysis, femoral diaphysis, and lumbar vertebra as compared to WT OVX mice. Pro-inflammatory cytokines TNF-alpha, IL-6 and IL-1 beta and anti-inflammatory cytokine IL-10 were analyzed in LPS stimulated bone marrow (BM) culture supernatant by ELISA. Significantly lower level of IL-1 beta, TNF-alpha and IL-6, and higher level of IL-10 expression was found in fat-1 OVX mice compared to WT OVX mice. LPS stimulated NF-kappaB activation was also analyzed in BM cells. NF-kappaB activation was found significantly less in fat-1 OVX mice compared to WT OVX mice. We also examined the LPS stimulated inducible nitric oxide synthase (iNOS) expression and nitric oxide (NO) production in BM cells. Interestingly, LPS treated NO production in BM culture supernatant and iNOS protein expression in BM cells was significantly higher in fat-1 OVX mice as compared to WT OVX mice. Moreover, fat-1 transgenic, nontransgenic and WT BM cells were cultured in the presence of n-6 fatty acid (linoleic acid) with RANKL to differentiate into TRAP +ve cells. Interestingly, fat-1 transgenic BM cells generated significantly less TRAP +ve osteoclast like cells compared to fat-1 nontransgenic and WT B6 BM cells. We offer further the mechanisms involved in preventing the bone loss in OVX mice by n-3 FA using a fat-1 transgenic mouse model.

A CD40L Mediated Cross-talk Between T Cells and Stromal Cells Is Required for Estrogen Deficiency and PTH to Induce Bone Loss. Y. Gao, M. Terauchi, K. Page*, X. Yang*, F. Grassi, S. Galley, E. Shah*, M. R. Ryan, M. N. Weitzmann, R. Pacifici. Division of Endocrinology, Metabolism and Lipids, Emory University School of Medicine, Atlanta, GA, USA.

Activated T cells induce bone loss in inflammation and estrogen (E) deficiency by secreting RANKL, TNF, and IFN γ . T cells also regulate bone marrow (BM) stromal cells (SCs) via surface receptors, but the relevance of T cell membrane signals in bone diseases is unknown. Herein we investigated a) if T cells regulate the capacity of SCs to support osteoclast (OC) formation through CD40L, a T cell costimulatory molecule which binds to SC expressed CD40 receptors, and b) the role of CD40L/CD40 signaling in the bone loss induced by ovariectomy (ovx) and in vivo continuous PTH treatment (cPTH). As compared to T cell replete controls, SCs from nude mice and WT mice immunodepleted of T cells in vivo produce less M-CSF, RANKL, and TNF and supported the formation of fewer OCs when cocultured with BM macrophages (BMMs) from WT mice. Moreover, ovx and cPTH upregulate the osteoclastogenic activity of SCs from control, but not T cell deficient mice, demonstrating that E and PTH regulate SC function through T cells. OvX and cPTH upregulate the T cell expression of CD40L and the SC expression of CD40 by 2-3 fold. CD40 expression is equally increased by IFN γ and TNF, cytokines produced in large amounts by T cells of ovx mice, suggesting that ovx upregulates CD40 expression through these factors. PTH induced OC formation in cocultures of BMMs and SCs is equally enhanced by soluble CD40L and WT T cells, while CD40L -/- T cells are ineffective. Moreover, neutralizing anti CD40L mAb blocks the T cell potentiation of PTH induced OC formation, and the capacity of T cells from ovx mice to increase the formation of OCs in cocultures of SCs and BMMs from intact mice, demonstrating a role for CD40L in PTH and ovx induced OC formation. Analysis by μ CT reveals that CD40L -/- mice are completely protected against the loss of trabecular and cortical bone induced by ovx and cPTH, respectively. Thus, CD40L plays a key role in both ovx and PTH induced bone loss. When T cells from WT and CD40L -/- mice were adoptively transferred into TCR β -/- mice, a strain lacking $\alpha\beta$ T cells, cPTH stimulated bone resorption leading to cortical bone loss in hosts reconstituted with WT T cells, but not in those reconstituted with CD40L -/- T cells, thus demonstrating the specific role of T cell expressed CD40L. In summary, CD40L/CD40 costimulation is a novel pathway by which T cells regulate SC function and OC formation. Upregulation of the osteoclastogenic activity of SCs by T cell expressed CD40L is pivotal for the osteoclastogenic response to PTH and E deficiency. Understanding the cross-talk between T cells and SCs may thus yield novel therapeutic strategies for postmenopausal and PTH induced bone loss.

Ovariectomy Decreases Bone Mass in Young and Old Female Athymic Mice. W. M. Kozlow, K. Mohammad, C. R. McKenna*, H. Walton*, M. Niewolna*, T. A. Guise. Internal Medicine, University of Virginia, Charlottesville, VA, USA.

Ovariectomy (OVX) has been reported to have no effect on trabecular bone mass in female athymic (nude) mice because these mice lack T cells⁽¹⁾. However, recent data has demonstrated trabecular, but not cortical, bone loss 4 weeks after OVX in 6-week-old female nude mice⁽²⁾. The effect of OVX on bone mass in female nude mice may be related to mouse age at the time of surgery.

To determine the effect of mouse age (at the time of OVX) on bone mass, 4-week-old (young) and 16-week-old (old) female BALB-c nude mice were randomized to OVX or sham surgery (sham). Bone mineral density (BMD), as assessed by Lunar PIXImus, was assessed at baseline and every 2 weeks thereafter. At 20 weeks, the young OVX mice had decreased BMD at the total body ($p=0.0056$), spine ($p<0.0001$) and proximal tibia ($p<0.0001$) compared to the sham mice. Decreased BMD was noted as early as 2 weeks after OVX in the total body and proximal tibia, and by 4 weeks after OVX in the lumbar spine. Although there was no difference in BMD at the distal femur, BMD was surprisingly increased at the mid femur ($p<0.0001$) in the OVX mice compared to the sham mice. However, histomorphometry demonstrated no difference in trabecular bone volume at the distal femur or proximal tibia between the OVX mice and sham mice.

Twenty weeks after surgery, the old OVX mice had decreased BMD at the total body ($p=0.0048$), spine ($p<0.0001$), mid femur ($p=0.0409$) and distal femur ($p<0.0001$) as compared to the sham mice. Decreased BMD was noted as early as 2 weeks after OVX in the total body and distal femur, and by 4 weeks after OVX in the lumbar spine and mid femur. There was no difference in BMD at the proximal tibia.

At 20 weeks, differences between the OVX and sham mice were greater in the young mice versus the old mice: 3.4% versus 1.5% total body; 18.3% versus 9% spine; 9.2% versus 1.1% mid femur; 3.8% versus 6.1% distal femur; 20.1% versus 6.6% proximal tibia.

Bone marrow cultures from OVX mice exhibited a greater number of colony forming unit (CFU)-fibroblasts ($p<0.0001$ for young and old), CFU-osteoblasts ($p<0.0001$ young, $p=0.0001$ old) and TRAP-positive osteoclasts ($p=0.0005$ young) compared to sham mice.

These experiments show that OVX does have an effect on bone mass at multiple sites in female nude mice. OVX-induced decreases in bone mass were seen in both young and old female nude mice, but the differences between the OVX and sham mice were more profound in the younger mice as compared to the older mice. Bone marrow cultures revealed that the lower bone mass was associated with increased bone turnover.

IGF-I Carrier Components Determine Skeletal Integrity Via Direct and Indirect Mechanisms. S. Yakar¹, W. Mejia^{*1}, Y. Kawashima^{*1}, H. Sun^{*1}, M. L. Bouxsein², C. J. Rosen³. ¹Mount Sinai School of Medicine, New York, NY, USA, ²Beth Israel Deaconess Medical Center, Boston, MA, USA, ³The Jackson Laboratory, Bar Harbor, ME, USA.

Serum IGF-I is secreted mainly by the liver and circulates bound to IGF-binding proteins (IGFBPs, predominantly IGFBP-3) in binary complexes and bound to IGFBP-3 and the acid labile subunit (ALS) in a ternary complex. To delineate the role of IGF-I circulatory complexes in skeletal integrity, we employed three mouse lines that have reduced circulating IGF-I: liver-specific IGF-I deficient (LID) mice; ALS knockout (ALSKO) mice, and IGFBP-3 knockout (BP3KO) mice. Bone micro-architecture is profoundly affected in the different IGF-I mutants; LID mice exhibit minor reductions in trabecular BV/TV% (~10%), but significantly lower areal BMD and mid-diaphyseal cortical thickness. In contrast, gene inactivation of the ALS, leads to a marked decrease in trabecular BV/TV% (~20%), with no changes in cortical thickness and reduced cross-sectional area. In contrast to both LID and ALSKO mice, BP3KO mice have ~30% decreases in trabecular bone volume fraction with no changes in cortical bone thickness or diaphyseal cross-sectional geometry. To determine what mechanisms may be operative in the skeleton of the IGF-I deficient mice we studied marrow cells and their ability to form osteoblasts(OB) and osteoclasts (OC). ALSKO and BP3KO exhibited an increase in OB differentiation as assessed by alkaline phosphatase staining, whereas marrow stromal cells from LID mice did not differ from controls. OC differentiation was enhanced in BP3KO mice as reflected by increased TRAP positivity compared to control mice. In contrast, ALSKO mice exhibited reductions in OC number and activity as assessed by pit formation assay. In support of the latter, real time PCR for OC markers revealed a decrease in TRAP and cathepsin K expression in ALSKO cultures consistent with impaired differentiation of macrophage precursors. Taken together, these results suggest direct yet diverse effects of ALS and IGFBP-3 on OB and OC differentiation and activity. Alternatively it is conceivable that ALS and IGFBP-3 may have indirect effects on bone via alterations in the hematopoietic-monocytic lineage that are modulated by marrow stromal cells.

Evidence for Lineage Dependent Non-canonical Wnt Signal Transduction by Bone Cells. G. J. Spencer*, P. G. Genever*. Department of Biology, University of York, York, United Kingdom.

Wnt signaling has emerged as an important determinant of bone mass, regulating osteoblast and osteoclast formation and activity. Most studies have focused on the transcriptional effects of canonical Wnt signaling although Wnts are also known to signal through non-canonical pathways, evoking changes in intracellular calcium and activation of protein kinase signaling cascades. Using a combination of Affymetrix microarray analysis and RT-PCR we have identified expression of Wnt ligands (Wnt5a), Fzd receptors (Fz 1, 3 and 7) and PKC isoforms required for non-canonical Wnt signal transduction in human mesenchymal stem cells (MSCs). Exposure of MSCs to the prototypical non-canonical Wnt ligand Wnt5a (conditioned medium, 10-50%) during osteogenic differentiation induced by dexamethasone, ascorbate and β -glycerol phosphate, significantly reduced cell numbers ($p<0.001$) and increased alkaline phosphatase activity ($p<0.01$), supporting a role for non-canonical signaling in stimulating osteogenesis. In contrast, exposure to the canonical ligand Wnt3a stimulated proliferation and inhibited osteogenesis. By confocal imaging, western blotting and immunolocalization we demonstrated that exposure of MSCs to Wnt5a (10-500ng/ml) caused a rapid, thapsigargin-sensitive increase in intracellular calcium and potentially stimulated the phosphorylation of PKC isoforms PKC δ , PKC α/β and PKD/PKC μ . Wnt5a also stimulated the phosphorylation and nuclear translocation of the transcription factor CREB without affecting p42/44 MAPK activity. Significantly, using cultures of rat primary calvarial osteoprogenitors we were unable to demonstrate any stimulatory effect of Wnt5a on intracellular calcium, proliferation or osteogenic differentiation, although Wnt3a remained inhibitory. These data strongly suggest that uncommitted MSCs respond to non-canonical signals to promote osteogenesis with loss of responsiveness soon after the onset of differentiation, while anti-osteogenic effects of Wnt3a are independent of lineage commitment state. As potential anabolic therapies depend on their specificity for osteogenesis we determined whether cells of the osteoclast lineage also respond to non-canonical Wnts. Using RAW264.7 cells we showed that exposure to Wnt5a (10-500ng/ml) potentially increased p42/44 MAPK activity and phosphorylation of JNK, PKC α , PKC α/β and PKD/PKC μ , without affecting CREB. These data have wide implications for our understanding of Wnt signaling in bone; non-canonical Wnts promote osteogenesis but also have potential to affect osteoclastogenesis and bone resorption through common activation of PKC isoforms but differential effects on the activity of CREB, MAPK and JNK.

Reciprocal Regulation of Dkk1 Gene Transcription by Msx2 and c/EBP α . S. Cheng, O. L. Sierra, D. A. Towler. Division of Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA.

Msx2 plays an important role in craniofacial bone formation, osteoblast gene transcription, and osteogenic-adipogenic differentiation. We previously demonstrated that Msx2 inhibits gene transcription via 3 mechanisms: (a) antagonistic protein-protein interactions with a multiprotein complex containing Runx2, Ku antigen, and MINT, (b) inhibitory interactions with TFII-F, a PolII-dependent transcription initiation and elongation factor, and (c) inhibitory protein-protein actions with c/EBP α that preclude PPAR γ 2 expression and adipogenic differentiation. We also demonstrated that Msx2 promotes calvarial osteogenesis in part via suppression of Dkk1, with concomitant activation of canonical Wnt signaling. Msx2 pro-osteogenic actions are abrogated by treatment with Dkk1 protein or transduction with a Dkk1-expressing retrovirus. We wished to examine the mechanisms that mediate Msx2 inhibition of Dkk1. Using 10T1/2 cells transduced with Msx2 retrovirus or primary calvarial osteoblasts from CMV-Msx2 transgenic mice, we find that Msx2 suppresses Dkk1 gene expression. Western blot analyses confirm reduction of Dkk1 levels in Msx2-expressing cells (30% of control). Conversely, "knock-down" of endogenous Msx2 levels in 10T1/2 cells with Msx2 siRNA enhances Dkk1 transcription. Msx2 variants with either increased (P148H) or absent (T147A) intrinsic DNA binding activity demonstrate that Msx2 inhibits Dkk1 transcription via antagonistic protein-protein interactions. Systematic 5'- and 3'-deletion analyses of the Dkk1 promoter (LUC reporter) mapped Msx2-dependent suppression to nucleotides +165 to +234 relative to the transcription initiation site. Increased expression of the adipogenic transcription factor c/EBP α sequesters Msx2, and upregulates Dkk1 gene transcription. Chromatin immunoprecipitation (ChIP) assays demonstrate that Msx2 reduces the stable interaction of PolII with Dkk1 gene. Inhibition is distinctly enhanced with distance downstream of the transcription initiation site, indicating that both initiation and elongation must be affected by Msx2. Thus, Msx2 promotes osteogenesis and prevents adipogenic gene expression in part via paracrine Dkk1 signals. Msx2 suppression of Dkk1 promotes canonical Wnt signaling and osteogenic differentiation. Conversely, inhibition of Msx2 by c/EBP α upregulates Dkk1, inhibits canonical Wnt signaling, and promotes adipogenic differentiation. Stable association of PolII with the Dkk1 gene is negatively regulated by Msx2, and represents an important transcriptional regulatory step during osteogenic differentiation of calvarial mesenchymal progenitors.

ERK1 and ERK2 Are Essential for Osteoblast Differentiation. T. Matsushita^{*1}, G. Landreth^{*2}, S. Murakami¹. ¹Orthopaedics, Case Western Reserve University, Cleveland, OH, USA, ²Neurosciences, Case Western Reserve University, Cleveland, OH, USA.

To examine the roles of ERK MAPK in bone formation, we inactivated ERK2 using the Cre-loxP system. Inactivation of ERK2 in mesenchymal cells using the Prx1-Cre transgene in the ERK1-null background caused severe bone defects in the limbs and calvaria. In severely affected long bones, no distinct cortical bone was formed. The lambdoid suture in calvaria failed to close postnatally. While normal levels of Runx2, Osterix, Atf4, and Col1a1 expression were observed in situ hybridization, Osteocalcin expression was abolished. These observations indicate that osteoblast differentiation was blocked after Osterix expression and before differentiation into fully mature osteoblasts. Furthermore, loss of ERK1 and ERK2 caused ectopic cartilage formation in the perichondrium, strongly suggesting that osteo-chondroprogenitor cells in the perichondrium were arrested in their differentiation into osteoblasts and instead differentiated into chondrocytes. Immunohistochemical analysis showed decreased beta-catenin protein levels in the perichondrium, suggesting reduced Wnt signaling. Loss of ERK1 and ERK2 in chondrocytes also resulted in severe disorganization of the epiphyseal cartilage. While the cartilage anlage was normally formed, chondrocytes failed to form columnar structures in the growth plate. There was a striking widening of the zone of hypertrophic chondrocytes. Furthermore, TRAP-positive osteoclasts were decreased, suggesting MAPK-mediated regulation of osteoclastogenesis by mesenchymal cells. Similar cartilage phenotype was observed when ERK2 was inactivated using the Col2a1-Cre transgene in the ERK1-null background. As a complementary experiment, we generated transgenic mice that express a constitutively active mutant of MEK1 under the control of a prx1 promoter. The transgene was expressed in the developing limb bud, the perichondrium and periosteum of the long bones, and the lambdoid suture in the cranium. These mice showed a delay in the formation of cartilage anlage, synostosis of long bones, fusion of carpal and tarsal bones, and accelerated closure of the lambdoid suture. These mice showed a thickening of Runx2-expressing periosteum and a dramatic increase in the cortical bone formation. Our observations indicate that ERK1 and ERK2 are essential for osteoblast differentiation, and increased MAPK signaling promotes bone formation. ERK1 and ERK2 inhibit ectopic cartilage formation in the perichondrium, and increased MAPK signaling inhibits the formation of cartilage anlage. Based on these observations, we propose that ERK1 and ERK2 play essential roles in the lineage specification of mesenchymal cells.

Polycystin-1 Selective Activation of Runx2-II Isoform Transcription Is Mediated Through the Calcium-PI3K-Akt Pathway. Z. S. Xiao, S. Q. Zhang^{*}, B. S. Magenheimer^{*}, J. P. Calvet^{*}, L. D. Quarles. The Kidney Institute, University of Kansas Medical Center, Kansas City, KS, USA.

The presence of primary cilia and polycystins 1 (PC1) and 2 (PC2) in osteoblasts and osteocytes, suggest that these molecules may form a mechanosensing complex in bone. At present, data supporting this hypothesis is limited to the observation that PC1-deficient (Pkd1 mutant) mice have osteopenia that is associated with a selective decrease in the expression of the Runx2-II isoform in bone. To further establish the role of primary cilia and polycystins in regulating bone cell function, we investigated PC1 and PC2 expression in primary cilia and examined the signal transduction pathways linking PC1 to Runx2-II expression in osteoblasts. Using immunofluorescent staining with antibodies to PC1, PC2, and the primary cilium marker alpha tubulin, we found that PC1 and PC2 co-localize to primary cilia in MC3T3-E1 osteoblasts. To further establish the role of Runx2-II in mediating PC1 effects on bone, we crossed heterozygous Pkd1 and Runx2-II mutant mice to create double heterozygous mice that are deficient in both PC1 and Runx2-II. Double heterozygous Pkd1 and Runx2-II mice exhibited a significantly greater reduction in bone mineral density than their heterozygous littermates, supporting the functional role of Runx2-II as a downstream signal for PC1 regulation of osteoblast function in vivo. To investigate the intracellular pathways linking PC1 to Runx2-II, we examined the effects of over-expressed PC1 C-tail constructs on P1 and P2 promoter-luciferase activity, intracellular calcium levels and PI3K/Akt pathways in MC3T3E1 osteoblasts. We found that PC1 C-tail constructs resulted in a significant increase in intracellular calcium and Runx2 P1 but not P2 promoter activity. Site-directed mutagenesis of critical amino acids in the coil-coil domain of the PC1 C-tail construct necessary for coupling to PC2 completely abolished PC1 C-tail-stimulated Runx2-II P1 promoter activity. Moreover, both PI3K (LY294002) and Akt inhibitors blocked the ability of PC1 C-tail constructs to increase Runx2-II P1 promoter activity. Additional promoter analysis identified a PC1 responsive region in an area between positions -420 to -350 that contains both putative NF1 and AP-1 binding sites. These findings indicate that a primary cilia-polycystin complex is present and is selectively coupled to Runx2-II gene expression in osteoblasts through intracellular calcium and PI3K-AKT signaling pathways.

Identification of the Homeobox Protein, Prx1 (MHox), as a Regulator of Osterix Expression and Mediator of TNF Action. X. Lu^{*1}, G. R. Beck², L. C. Gilbert^{*1}, T. P. Conrads^{*3}, M. J. Kern^{*4}, M. S. Nanes¹. ¹Div Endocrinology, Dept Medicine, Emory Univ / VAMC, Atlanta, GA, USA, ²Div Endocrinology, Dept Medicine, Emory Univ, Atlanta, GA, USA, ³Div Clin Pharm, Hillman Cancer Inst, Univ Pittsburgh, Pittsburgh, PA, USA, ⁴Dept Cell Biology and Anatomy, MUSC, Charleston, SC, USA.

A network of transcription factors (TF) regulates the commitment of pluripotent mesenchymal cells to the osteoblast lineage. Identifying these factors is key to understanding skeletal development and lifelong renewal of bone forming cells. Osterix (Ox, SP7) is an important TF required for late chondrocyte and osteoblast differentiation as deletion results in a cartilaginous skeleton. We recently described the transcriptional regulation of Ox by defining 2 upstream promoters that direct synthesis of 2 mRNA species. A potent TNF/MAPK sensitive suppressor region was identified within the Ox promoter that was highly protein bound, inactivated by mutation, and functionally transferable to another promoter. We considered that identification of the proteins bound to the suppressor would reveal early TF regulators of osteoblast differentiation. Nuclear extracts from TNF-treated and untreated mesenchymal cells (C3H) were incubated with a DNA-Sepharose probe containing the 18 bp suppressor sequence. Tryptic fragments of the bound proteins were analyzed using tandem mass spectroscopy. Candidate TF were identified by subtraction analysis of identified protein fragments from the 2 treatment groups. 7 transcription factors were found among 62 unique nuclear proteins in the murine genome database. ChIP assay confirmed specific binding of some but not all of these to the Ox promoter suppressor region. One TF, the paired related homeobox protein (Prx1, MHox), had previously been shown to have a critical role in skeletal development and a compound loss of Prx1/Prx2 (S8) function was reported to have limb deformation, impaired ossification, and facial defects (Martin Genes Dev 1995; Lu Dev Biol 1999; Peterson Dev Dyn 2005). PCR revealed expression of Prx1 in primitive mesenchymal cell lines including C3H, C2C12, and MC3T3. TNF induced a 2 fold increase in Prx1 expression without affecting expression of Prx2. To determine the role of Prx1 in the TNF suppression of Ox, C3H cells were treated with a silencing RNA to Prx1 (siPrx1). siPrx1 specifically silenced basal Prx1 mRNA and blocked TNF stimulation of Prx1. Treatment of C3H cells with siPRX1 completely abrogated TNF suppression of Ox mRNA expression. In MC3T3, siPRX1 increased basal Ox expression 6 fold and partially prevented inhibition by TNF. These results identify Prx1 as an important inhibitor of Ox transcription and a mediator of TNF/MAPK inhibition of Ox expression in early osteoblast progenitors.

TIEG: A Novel Mediator of Runx2 Expression and Activity in Osteoblasts. J. R. Hawse¹, M. Subramaniam¹, D. G. Monroe¹, J. B. Lian², G. S. Stein², A. J. van Wijnen², M. J. Oursler¹, T. C. Spelsberg¹. ¹Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, ²Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA.

TGFβ Inducible Early Gene-1 (TIEG) is a member of the Kruppel-like family of transcription factors that is highly expressed and regulates a multitude of genes in osteoblasts. Through the development of TIEG-null mice (TIEG^{-/-}), we have identified a critical role for TIEG in bone as these animals display a severe osteopenic phenotype. TIEG^{-/-} calvarial osteoblasts have reduced expression levels of Runx2 and other important osteoblast marker genes as well as significant defects in their mineralization capacity. Through the use of transient transfection and ChIP assays, we have demonstrated that TIEG directly binds to, and activates, the Runx2 promoter, and we have shown that the DNA binding domain of TIEG is necessary for this regulation. Since TIEG is known to be targeted for proteasomal degradation by SIAH, an E3 ubiquitin ligase, we created 2 point mutations in the TIEG protein that abolishes the interaction of TIEG with SIAH and ultimately increases its stability. Interestingly, this mutation results in further activation of the Runx2 promoter indicating that the stability of TIEG plays a critical role in the regulation of Runx2 expression. Additionally, transfection of wild-type calvarial osteoblasts with a TIEG specific siRNA significantly decreases the expression of Runx2 and conversely, overexpression of TIEG induces Runx2 transcription. Runx2 adenoviral infection of TIEG^{-/-} osteoblasts restores Runx2 expression and significantly increases their mineralization capacity. Through the use of co-immunoprecipitation studies, we have demonstrated that TIEG is also capable of interacting with Runx2. This interaction is further confirmed through the use of transient transfection assays in which TIEG co-activates Runx2 binding elements (OSE₂) in the presence of Runx2 protein. Since Runx2 regulates the expression of important osteoblast marker genes such as osterix and osteocalcin, and since these genes exhibit decreased expression in TIEG^{-/-} osteoblasts, these studies imply that TIEG may play an important role in co-activating their expression in concert with Runx2. Collectively, these data demonstrate that TIEG directly regulates the expression and activity of Runx2 in osteoblasts and suggest that the decreased expression of Runx2 in TIEG-null mice is, at least in part, responsible for the observed osteopenic phenotype. Finally, a novel mechanism for the regulation and modulation of Runx2 expression and activity in osteoblasts is revealed.

Transcription Factor IRF-8 Is a Negative Regulator of Osteoclast Differentiation In Vitro and In Vivo. B. Zhao^{*1}, M. Takami¹, A. Yamada^{*1}, X. Wang^{*1}, K. Nakao^{*2}, T. Tamura^{*3}, K. Ozato^{*4}, H. Takayanagi⁵, R. Kamijo¹.

¹Department of Biochemistry, School of Dentistry, Showa University, Tokyo, Japan, ²Laboratory for Animal Resources and Genetic Engineering, Center for Developmental Biology, RIKEN, Kobe, Japan, ³Department of Physiology, Osaka City University Graduate School of Medicine, Osaka, Japan, ⁴Laboratory of Molecular Growth Regulation, National Institute of Child Health and Human Development, NIH, Bethesda, MD, USA, ⁵Department of Cell Signaling, Graduate School, Tokyo Medical and Dental University, Tokyo, Japan.

RANK signaling regulates the expressions of various transcription factors involved in osteoclast differentiation including NFATc1. However, little is known about transcription factors that negatively regulate osteoclast differentiation. In this study we identified a transcription factor, IRF-8 (also referred to as ICSBP), which is controlled by RANK signaling. IRF-8 was expressed in bone marrow or spleen-derived macrophages that are capable of differentiating into osteoclasts in response to RANKL stimulation. When the macrophages were stimulated with RANKL, the expression level of IRF-8 decreased within 8 hours, which is earlier than the increase of NFATc1 expression. Overexpression of IRF-8 in macrophages by retrovirus vectors completely inhibited RANKL-induced osteoclast differentiation, indicating that IRF-8 is a negative regulator of osteoclast differentiation. In IRF-8 deficient mice, a significant increase in osteoclast number and severe osteoporosis due to high turnover of bone metabolism were observed. Macrophages prepared from IRF-8 deficient mice differentiated into osteoclasts by stimulation with 1/20-1/4 of the concentrations of RANKL used for wild type. Cocultures of osteoblasts with IRF-8-deficient bone marrow cells produced a significantly larger number of osteoclasts than that with wild-type bone marrow cells. Analysis using immunoprecipitation, EMSA and promoter assay revealed that IRF-8 interacted with NFATc1 and attenuated transcriptional activity of NFATc1 by interfering with the binding of NFATc1 to its target DNA sequence. Furthermore, toll-like receptor ligands such as LPS, CpG ODN, peptidoglycan and poly(I:C)RNA inhibited osteoclast differentiation by macrophages prepared from wild-type mice although the ligands failed to inhibit that prepared from IRF-8 deficient mice. These results suggest that IRF-8 is a critical negative regulator reduced by RANK signaling in the early phase of osteoclast differentiation. Since IRF-8 deficient mice showed severe osteoporosis, IRF-8 also contributes to physical bone homeostasis in vivo. Furthermore, our data imply that IRF-8 plays an important role in inflammatory bone destruction induced by virus and bacterial infection.

The Small GTPase cdc42 Enhances Osteoclastogenesis and Bone Resorption. Y. Ito¹, Y. Zheng^{*2}, J. F. Johnson^{*2}, L. Yang^{*2}, S. L. Teitelbaum¹, F. P. Ross¹, H. Zhao¹. ¹Department of Pathology and Immunology, Washington University, St. Louis, MO, USA, ²Division of Experimental Hematology, University of Cincinnati, Cincinnati, OH, USA.

Osteoclasts (OCs) degrade bone by polarized secretion of protons and cathepsin K, a process requiring cytoskeletal reorganization. Cdc42, a small GTPase, is hypothesized to control formation of the OC actin cytoskeleton. Since global deletion of cdc42 leads to early embryonic lethality its impact on bone biology cannot be evaluated directly. Our observation, however, that the osteoclastogenic cytokines M-CSF and RANKL activate cdc42 led us to investigate further. Cycling of cdc42 between inactive GDP-bound and active GTP-bound forms is regulated by specific guanine nucleotide exchange factors that enhance GDP/GTP exchange and GTPase-activating proteins (GAPs) that stimulate its intrinsic GTPase activity, respectively. To define the role of cdc42 in OCs we examined first cdc42 gain-of-function mice, which were produced by deleting cdc42GAP globally. The animals die soon after birth, precluding direct analysis of their OC phenotype. To overcome this problem we transplanted WT or cdc42GAP-deficient OC precursors present in fetal liver cells into irradiated WT mice and sacrificed them after four months. Compared to WT controls cdc42GAP^{-/-} bone marrow macrophages (BMMs) undergo accelerated proliferation in response to M-CSF and differentiate into increased numbers of OCs in the presence of M-CSF and RANKL. Furthermore, cdc42GAP null mature OCs exhibit less apoptosis and OCs cultured on bone exhibit greater resorptive capacity than WT cells (medium CTx levels). Confirming a role for cdc42 in organizing the OC cytoskeleton, the number of RANKL-induced actin rings at the sealing zone of cdc42GAP^{-/-} OCs cultured on bone is greater than in WT cells. Last, RANKL induces formation of a Par3/Par6/APK complex downstream of cdc42 activation. Reflecting these in vitro observations, mice containing cdc42GAP^{-/-} OC precursors have lower bone mass, more osteoclasts and higher levels of bone resorption. Having established a cdc42 gain of function phenotype, we turned to OCs lacking cdc42. To this end, we isolated BMMs from cdc42^{flx/flx} mice and deleted the small GTPase by transduction in vitro with retroviral Cre. In contrast to gain of function cells, proliferation of cdc42 null BMMs is decreased in response to M-CSF, apoptosis is increased in pre-OCs and M-CSF/RANKL-induced differentiation largely absent. Given these obverse phenotypes we conclude that cdc42 a) increases OC precursor proliferation and differentiation; b) suppresses apoptosis in pre- and mature OCs; c) promotes organization of the OC actin cytoskeleton on bone and hence d) enhances bone resorption.

IkB α -Deficient Mice Display Increased Osteoclast Formation and Activity and Bone Loss In Vivo. J. R. Edwards¹, L. Connelly², W. Han^{*3}, L. C. Dumitrescu¹, T. S. Blackwell^{*3}, E. Yull^{*2}, G. R. Mundy¹. ¹Center for Bone Biology, Vanderbilt University Medical Center, Nashville, TN, USA, ²Cancer Biology, VUMC, Nashville, TN, USA, ³Immunology, VUMC, Nashville, TN, USA.

The Rel-NF κ B transcription factor family regulates numerous growth factors including those that control osteoclast (Oc) formation. Rel dimers are sequestered in the cytoplasm by inhibitor κ B (IkB) proteins, predominantly IkB α . As this vital regulatory molecule mediates the transcriptional activity of NF κ B, we hypothesized that IkB α may directly regulate bone mass by controlling Oc formation. The bone phenotype of IkB α -genetically modified mice was examined by whole body imaging, histomorphometric analysis, bone resorption and cell proliferation assays, molecular and protein analysis of primary bone cells and purified immortalized macrophages. IkB α ^{-/-} mice die shortly after birth. Alizarin red/alcian blue whole body preparations of 4 day pups showed a severe skeletal growth defect and μ CT scanning revealed a 23% decrease in BV/TV compared to +/+ pups. Mature 4mth IkB α ^{+/-} mice were compared to +/+ animals using histomorphometry, Pixmap and μ CT scanning. IkB α ^{+/-} mice showed a profound decrease in BMD and BV/TV ($p < 0.01$). Histomorphometric analysis of undecalcified IkB α ^{+/-} L3-4 vertebrae supported μ CT data showing a BV/TV of 9.2 ± 0.3 compared to 15.4 ± 1.6 in +/+ mice ($p < 0.05$). The Oc surface/bone surface ratio in +/+ mice was 6.3 ± 2.4 while +/+ mice displayed 4.3 ± 0.4 ($p < 0.05$). In vitro culture of +/+ marrow cells showed increased dentine resorption and Oc formation rates than +/+ cells. TRAP staining of +/+ cells stimulated with M-CSF (30ng/ml) and RANKL (50ng/ml) formed 48.6 TRAP+ cells/well, while +/+ cells formed 33.5 TRAP+ cells/well over 5 days ($p < 0.05$). To accurately study Oc formation in IkB α KO cells, we immortalized macrophages isolated from IkB α ^{-/-} and +/+ pups. While IkB α +/+ macrophages appeared typically small and spherical the morphological appearance of IkB α ^{-/-} cells were larger and often multinucleated. Calcitonin receptor, NFATc1 and c-src mRNA expression were increased in IkB α ^{-/-} cells which proliferated at twice the rate of +/+ cells ($p < 0.001$). Gel zymography showed a 2-fold increase in MMP-9 in media conditioned by IkB α ^{-/-} macrophages compared to +/+ cells. M-CSF decreased proliferation of -/- cultures by 71% ($p < 0.001$) and increased TRAP+ multinucleated cells by 30% while +/+ cell proliferation increased 33% ($p < 0.005$). RANKL and M-CSF treatment increased TRAP+ multinucleated cells in both cell lines, indicating that RANKL augments Oc formation in precursor cells with constitutive NF κ B activation through alternative pathways. We conclude that IkB α deletion increases Oc formation and activity and decreases bone mass in vivo by its effects on bone resorption.

NF- κ B2 Limits TNF-induced Osteoclastogenesis Through Precursor Cell Cycle Regulation. Z. Yao, L. Xing, B. Boyce. Pathology, University of Rochester, Rochester, NY, USA.

RANKL and TNF are the only cytokines known to directly induce osteoclastogenesis without stromal cells in vitro. However, TNF consistently generates fewer and smaller osteoclasts (OCs) than RANKL and stimulates fewer OCs than RANKL in vivo, suggesting that it may work through different mechanisms from RANKL or induce inhibitors in osteoclast precursors (OCPs) during culture. Both cytokines activate the canonical (p65 and p50) and non-canonical (p52 and RelB) NF- κ B pathways, which typically control different biologic processes by regulating transcription of different target genes. In the non-canonical pathway p52 is generated from its precursor protein, p100 (NF- κ B2), but the role of this pathway in OC formation has not been fully investigated. To address this issue, we examined the expression of NF- κ B p65, p50, p52 and RelB during TNF- and RANKL-induced OC differentiation from 4 to 96 hrs, in which mature OCs started to form at ~48 hrs. Both cytokines increased mRNA expression of p65 and p50 temporarily from 1 to 4 hours and of p52 and RelB from 4 hrs to 72 hrs, and these gradually decreased thereafter. TNF and RANKL induced a similar pattern of p65, p50 and RelB protein expression. RANKL increased protein levels of p52, but not p100. In contrast and importantly, TNF increased both p52 and p100 protein levels in whole cell lysates from 8 to 72 hours. Previous studies have shown that exit from the cell cycle is a necessary step for OC terminal differentiation and involves NF- κ B. TNF also activates cyclin D1 through NF- κ B p52/RelB to stimulate cell proliferation. To determine if TNF induction of fewer OCs than RANKL requires NF- κ B2 and involves cyclin D1, we first treated OCPs from wt and NF- κ B2^{-/-} mice that lack both p52 and p100 expression with TNF or RANKL. TNF induced significantly fewer OCs from wt cells than RANKL (120 ± 13 vs 585 ± 29) and significantly more TRACP-negative cells. Importantly, TNF generated similar OC numbers (365 ± 20 vs 410 ± 18) and resorption pit area/bone slice (2.5 ± 0.6 vs 2.8 ± 0.8) and fewer TRACP-negative cells than RANKL from NF- κ B2^{-/-} spleen cells. Furthermore, TNF induced more OCs from cyclin D1^{-/-} than wt OCPs (369 ± 40 vs 173 ± 18 per well). We conclude that TNF limits differentiation of OCPs through mechanisms involving NF- κ B2 and cyclin D1. Thus, NF- κ B2 may function as a negative regulator of osteoclastogenesis by controlling proliferation of OCPs to limit excessive bone resorption mediated by TNF in various bone diseases.

Wnt5a Enhances RANKL-induced Osteoclastogenesis. K. Maeda^{*1}, Y. Kobayashi^{*2}, T. Mizoguchi^{*2}, Y. Nakamichi², T. Yamashita², S. Kinugawa^{*2}, N. Udagawa³, K. Marumo^{*1}, N. Takahashi². ¹Department of Orthop. Surg., The Jikei Univ., Tokyo, Japan, ²Institute for Oral Science, Matsumoto Dental Univ., Shiojiri, Japan, ³Department of Biochemistry, Matsumoto Dental Univ., Shiojiri, Japan.

Wnts exert two types of signals, β -catenin (β -cat)-dependent (canonical) and β -cat-independent (non-canonical) pathways. Combinations of their putative receptors, frizzleds and their co-receptors, LRP5/6 or Ror2, determine which pathway to use. The β -cat pathway has been reported to suppress bone resorption due to up-regulation of OPG expression and suppression of RANKL expression in osteoblasts. However, the roles of the non-canonical pathway in bone resorption are not elucidated. Here, we analyzed the effect of Wnt5a, a non-canonical Wnt ligand, on osteoclast formation. (1) Wnt5a enhanced RANKL-induced osteoclast formation from mouse bone marrow macrophages (BMM ϕ), RAW264.7 cells and human CD14-positive monocytes in a dose-dependent manner. (2) Wnt5a activated c-Jun N-terminal kinase and protein kinase C, but failed to increase the cytoplasmic accumulation of β -cat in BMM ϕ . (3) The role of Ror2, a co-receptor of Wnt5a, in osteoclast formation was examined using short hairpin RNA interference. The knockdown of Ror2 abolished the stimulatory effect of Wnt5a on RANKL-induced osteoclast formation in the BMM ϕ culture. (4) GST-soluble Ror2 (sRor2) specifically bound to Wnt5a in a pull down assay. Addition of sRor2 to the BMM ϕ culture also abolished the stimulatory effect of Wnt5a on RANKL-induced osteoclast formation. (5) Semi-quantitative RT-PCR analysis revealed that the expression level of Wnt5a mRNA was much higher in osteoblasts than in BMM ϕ . (6) sRor2 inhibited $1\alpha,25$ -dihydroxyvitamin D₃-induced osteoclast formation in co-cultures of osteoblasts and BMM ϕ in a dose-dependent manner. These results suggest (1) that Wnt5a activates the non-canonical pathway but not the canonical one in BMM ϕ , and (2) that Wnt5a secreted by osteoblasts promotes osteoclast formation through Ror2. Rheumatoid arthritis (RA) synovium has been shown to strongly express Wnt5a. Taken together, our results indicate that Wnt5a is involved not only in physiological bone remodeling but also in pathological bone loss in RA. Wnt5a represents a potential novel therapeutic target for RA to suppress excessive bone loss.

Osteoclast Formation and Osteolysis Are Promoted by the AMP-activated Protein Kinase (AMPK) Activator Aminoimidazole-4-carboxamide Ribonucleoside (AICAR) In Vivo. J. M. W. Quinn¹, S. Tam^{*2}, N. A. Sims¹, H. Saleh^{*1}, N. E. McGregor^{*1}, I. J. Poulton^{*1}, B. E. Kemp^{*3}, M. T. Gillespie¹, B. J. W. van Denderen^{*1}. ¹St. Vincent's Institute, Fitzroy, Australia, ²Dept of Medicine, The University of Melbourne, Fitzroy, Australia, ³CSIRO Molecular and Health Technologies, Parkville, Australia.

AMPK serves to maintain whole body and cellular energy balance in response to hormonal and metabolic stress signals. We have investigated the effect of pharmacological activation of AMPK by AICAR on osteoclast (OC) formation and function in vitro and in vivo.

AICAR (200uM) increased OC formation by approximately 40% in murine bone marrow cell cultures maximally stimulated by RANKL (100ng/ml) and MCSF (30ng/ml); with lower RANKL levels (20ng/ml) AICAR increased OC formation up to 50-fold. Osteoclast formation was not increased by adenosine, adenosine antagonists or re-uptake inhibitors, consistent with AICAR acting independently of the adenosine signaling pathway. Increased OC formation with AICAR was also observed in RANKL stimulated cultures of spleen cells, bone marrow macrophages, RAW264.7 cells and in osteoblast/bone marrow co-cultures stimulated by dihydroxy vitamin D₃. AICAR stimulated phosphorylation of the AMPK substrate acetyl-CoA carboxylase in bone marrow macrophages. However, AICAR did not alter OC survival or the amount of dentine resorbed per OC.

We investigated AICAR actions in vivo, using a protocol previously employed to investigate AMPK activation in skeletal muscle. Male C57Bl/6 mice (12 weeks old) received daily intraperitoneal injections of AICAR (500mg/kg) or saline (controls) and their tibia examined by histomorphometry at 28 days. We found significantly reduced (49.5%) trabecular bone mass (BV/TV) in AICAR treated mice, with 2.2-fold greater OC numbers (OcS/BS). Trabecular number (Tb.N) was much decreased but trabecular thickness (Tb.Th) was not altered. Osteoblast numbers (ObS/BS) were also 2.8-fold higher with AICAR treatment and osteoid surface increased.

In summary, AICAR promotes OC progenitor differentiation, and causes high turnover osteopenia in vivo that is consistent with increased OC formation and a coupled increase in osteogenesis. These results are consistent with AMPK playing a role in bone physiology by modulating bone cell differentiation.

Activation of BMP Signaling by the FOP ACVR1 R206H Mutation. Q. Shen^{*1}, M. Xu^{*1}, S. C. Little^{*2}, F. S. Kaplan¹, M. C. Mullins^{*2}, E. M. Shore¹. ¹Orthopaedics, University of Pennsylvania, Philadelphia, PA, USA, ²Cell and Developmental Biology, University of Pennsylvania, Philadelphia, PA, USA.

Fibrodysplasia ossificans progressiva (FOP), a rare genetic disorder of heterotopic ossification, results in profound decreased mobility of affected individuals. ACVR1, a bone morphogenetic protein (BMP) type I receptor, is mutated in FOP, with a single recurrent missense mutation in the GS activation domain (c.617G>A; R206H) in all patients with classic disease features (malformation of the great toe and progressive heterotopic ossification). In order to examine the functional effects of the FOP ACVR1 mutation, His-tagged control (c.617G) and mutant (c.617A) ACVR1 constructs were generated. Expression in COS-7 cells was confirmed by immunoblot analysis. As expected, cells transfected with control ACVR1 showed ligand-dependent activation of BMP signaling with increased phosphorylation of Smad1/5/8. Signaling occurred specifically through the BMP/Smad pathway. By contrast, cells transfected with mutant ACVR1 showed ligand-independent activation of BMP pathway signaling in Smad phosphorylation and luciferase reporter assays. To investigate the interaction of mutant ACVR1 with FKBP12, a GS domain binding protein that prevents leaky type I BMP receptor activation in the absence of ligand, we co-transfected COS-7 cells with FKBP12 and control or mutant ACVR1 constructs, followed by co-immunoprecipitation with FKBP12 antibodies and immunoblot analysis for ACVR1. We found reduced binding of FKBP12 to mutant ACVR1, suggesting that increased BMP pathway activity in cells with mutant ACVR1 is due at least in part to decreased binding of the inhibitory factor FKBP12. To complement these in vitro studies, in vivo functional analyses tested the ability of ACVR1 to rescue the zebrafish Alk8 (homolog of human ACVR1) knockout (lost-a-fin). Transient expression of control ACVR1 RNA in zebrafish embryos partially rescued (~75%) the lost-a-fin phenotype. However, mutant ACVR1 induced a ventralized phenotype in the embryos, demonstrating an over-compensation of the knockout phenotype and indicating hyper-activation of BMP signaling. In conclusion, these data show that the FOP ACVR1 c.617G>A mutation causes elevated ligand-independent activity of the BMP pathway and support that decreased binding of the FKBP12 inhibitory protein to the mutant receptor is a mechanism leading to increased BMP signaling and heterotopic ossification in FOP.

Measles Virus Nucleocapsid Gene Expression Is Required for Abnormal Osteoclast Activity in Paget's Disease of Bone. N. Kurihara¹, Y. Hiruma¹, K. Yamana², C. Rousseau^{*3}, J. Morissette^{*3}, J. P. Brown³, G. D. Roodman⁴. ¹Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, ²Biomedical Research, Teijin, Tokyo, Japan, ³CHUL Res Center, Laval University, Quebec City, PQ, Canada, ⁴Medicine/Hem-Onc, VA Pittsburgh Healthcare System and University of Pittsburgh, Pittsburgh, PA, USA.

Paget's disease (PD) is one of the most exaggerated examples of abnormal bone remodeling, but its etiology is unclear. Both a genetic and a viral etiology for PD have been suggested. The viral etiology is based on: 1) the detection of Measles Virus Nucleocapsid (MVNP) mRNA and protein in osteoclasts (OCL) from PD lesions, 2) studies showing that transfection of normal human OCL precursors with the MVNP gene results in formation of PD-like OCL, and 3) transgenic mice expressing MVNP targeted to the OCL lineage (TRAP-MVNP mice) develop PD-like bone lesions. However, the role of MVNP in the abnormal OCL formation present in PD patients is unclear. To determine the requirement of MVNP for the abnormal OCL activity in PD, we tested MVNP mRNA expression by RT-PCR in OCL precursors from bone marrow of normals and PD patients and the effect of a previously validated antisense construct targeted to 5' end of the MVNP mRNA (AS-MVNP, J Inf Dis 176:258,1997) on OCL formation, bone resorption, and the enhanced $1,25$ -(OH)₂D₃ responsiveness in OCL precursors from patients carrying the most common genetic mutation linked to PD (p62^{P392L}). OCL precursors from 5 of 8 PD patients expressed MVNP, and MVNP was not detected in 6 normals. AS-MVNP transduced OCL precursor cells from 2 patients with PD that expressed MVNP or normals were cultured in methylcellulose with recombinant GM-CSF and G418. G418-resistant CFU-GM-derived cells were then cultured with varying concentrations of $1,25$ -(OH)₂D₃ or RANKL. OCL precursors from PD were hyper-responsive to $1,25$ -(OH)₂D₃, RANKL and TNF- α compared to normals. AS-MVNP transduced OCL precursors from PD patients treated with $1,25$ -(OH)₂D₃ or RANKL formed 60-70% fewer OCL and had lower nuclear numbers compared to OCL formed from scrambled antisense transduced OCL precursors. AS-MVNP had no effect on normal OCL formation compared to scrambled antisense controls, and scrambled antisense transduced PD cells formed PD-like OCL. Further, expression of TAF_{II}17 mRNA, a VDR coactivator present in PD but not normal OCL, was decreased by 70% with transfection of AS-MVNP compared to scrambled vector transduced PD OCL precursors. These data demonstrate that AS-MVNP blocked the abnormal OCL formation in cultures from patients with PD and decreased the hyper-sensitivity of PD OCL precursors to $1,25$ -(OH)₂D₃ and RANKL. These results support a pathologic role for MVNP in PD.

TSH Is Both Anti-Resorptive and Anabolic In Vivo. L. Sun¹, J. Iqbal^{1*}, L. L. Zhu^{1*}, K. Yamoah^{1*}, A. Arabi^{1*}, B. S. Moonga^{1*}, T. F. Davies^{1*}, H. C. Blair², E. Abe¹, M. Zaidi¹. ¹Mount Sinai Bone Program, Department of Medicine, Mount Sinai School of Medicine, New York, NY, USA, ²Department of Pathology, University of Pittsburgh, VA Medical Center., Pittsburgh, PA, USA.

We have shown that the deletion of the TSH receptor (TSHR), even in a haploinsufficient state, causes high-turnover bone loss (Abe et al. Cell, 2003). We have further demonstrated that this osteoporosis and enhanced osteoclastogenesis is reversed by genetically ablating TNF α in double TSHR^{-/-}/TNF α ^{-/-} mutants. In vitro, we showed that TSH inhibits osteoclast formation and function, as well as TNF α expression (Hase et al., Proc. Natl. Acad. Sci. 2006). Here, we show that the in vivo administration of recombinant human TSH (Genzyme), 0.7 μ g/mouse, three times a week prevents bone loss following ovariectomy, as well as increases bone mass in sham-operated controls. A lower dose of TSH (0.07 μ g/mouse) increased bone mass in sham-operated controls, but not in ovariectomized mice. The effect of high dose TSH, 0.7 μ g/mouse, was however, less marked, reflecting persistent elevations in serum thyroid hormones. Identical results were obtained by administering estrogen pellets (0.56 μ g/mouse) or daily recombinant human PTH (0.56 μ g/mouse). Ex vivo cultures of bone marrow cells 8 weeks post-cessation showed highly significant reductions in osteoclast formation and expression of the osteoclast differentiation markers TRAP, integrin β_3 , cathepsin K, calcitonin receptor and NFATc1. We also found evidence for an anabolic action ex vivo in bone marrow stromal cell cultures; CFU-F and CFU-OB formation were dramatically increased with 0.07 and 0.7 μ g/mouse doses, again 8 weeks post-cessation. To further substantiate the anti-resorptive component of TSH action, we investigated mice with functionless TSH receptors, TSHR^{hwt} mice. Ex vivo osteoclast formation was significantly enhanced in both TSHR^{hwt} mutants and heterozygotes. This enhanced osteoclast differentiation was suppressed by TSH in heterozygous and wild type mice, but not in homozygous mutants, thus confirming TSH-specificity. In conclusion, TSH exhibits both anti-resorptive and anabolic actions in vivo.

Atorvastatin Inhibits Lipid Induced Aortic Valve Calcification and Osteoporosis via the Lrp5/Wnt Mediated Pathways in Vivo and In vitro. N. M. Rajamannan¹, F. C. Caira^{1*}, A. L. Flores^{1*}, C. P. Dolehide^{1*}, L. B. Arterburn^{1*}, M. Subramaniam², T. C. Spelsberg². ¹Cardiology, Northwestern University, Chicago, IL, USA, ²Biochemistry, Mayo Clinic, Rochester, MN, USA.

Atherosclerosis and osteoporosis are the leading causes of morbidity and mortality in the aging population in the United States. Evidence indicates that hyperlipidemia plays a paradoxical role in these disease processes. However, the hyperlipidemic mechanisms of atherosclerotic calcification and decrease bone mass are not well understood. We hypothesize that hyperlipidemia plays a role in cardiovascular calcification and osteoporosis. We propose to test this hypothesis in an experimental hypercholesterolemia model and further test if statins play a protective role in this process. LDLR^{-/-} mice (n=100) were treated with Group I (n=20) normal diet, Group II (n=20) 1.25% chol diet (w/w), and Group III (n=20) 1.25% (w/w) chol diet+atorv, to determine the development of calcification in the hearts and osteoporosis in the bones. The aortic valve and aorta (AVA) was examined for myofibroblast cell proliferation, calcification, and bone matrix markers by immunohistochemistry and RTPCR. Bone formation was assessed by micro Computed Tomography (microCT), calcein injection, osteocalcin, cbfa-1 and osteopontin expression. We also have an in vitro model of aortic valve (AV) myofibroblasts cells and bone MC3T3 cells treated with osteogenic media to determine the expression of bone development and measure the signaling markers in these ossifying cells. The cholesterol diet induced complex bone formations by microCT in the calcified AVA with an increase in cellular proliferation, osteopontin, osteocalcin and cbfa-1 expression. Atorvastatin reduced bone formation, cellular proliferation and cbfa-1 levels and calcification in the AVA. Ex vivo analysis of calcein label demonstrated an increase in calcein label (4+) in the hypercholesterolemia AVA and the periosteal femoral bone surface with attenuation of the calcein label (1+) with atorvastatin therapy in the AVA and the femoral bones. (Calcein Scale =1-4, 4+=severe label, 1+=minimal label). The in vitro aortic valve myofibroblast cells and MC3T3 cells developed bone in the presence osteogenic media at 40 days. Cbfa1, Lrp5 and Osteopontin are increased in the osteogenic treated AV and MC3T3 cells as compared to the controls. Alizarin Red confirmed the presence mineralizing nodules in culture. Experimental hypercholesterolemia induces cardiovascular calcification and increased bone turnover which is attenuated by atorvastatin and mediated in part by an osteoblast pathway in the cardiovascular tissues. This model may have future implications in the treatment of cardiovascular calcification and osteoporosis with statin therapy.

Degradation of MEPE, DMP1 & Release of SIBLING ASARM-peptides (minhibins): ASARM-peptide(s) Are Directly Responsible for Defective Mineralization in HYP. V. David¹, A. Martin¹, J. Laurence^{1*}, M. D. McKee², L. W. Fisher³, A. Hedge^{1*}, P. S. N. Rowe¹. ¹Kansas Uni Med Center, Kansas City, KS, USA, ²McGill University, Montreal, PQ, Canada, ³NIDCR, Bethesda, MD, USA.

Binding of MEPE to PHEX results in proteolytic protection and prevents release of a small protease resistant MEPE-peptide (ASARM peptide). This peptide is a potent inhibitor of mineralization (minhibin) in vivo and in vitro and also occurs in DMP1, a related SIBLING protein. Thus, in Hyp, increased osteoblastic-proteases and the absence of PHEX may contribute to increased ASARM-peptide release from DMP1 and MEPE. We therefore evaluated the effects of ASARM-peptide and a small synthetic PHEX-Peptide (SPR4; 4.2 kDa) on mineralization of co-cultures of HYP and wild-type (WT) bone marrow stromal cells (BMSCs). The ASARM peptide binds to the PHEX Zn-binding motif as confirmed by surface plasmon resonance (SPR) and 2D H1/N15 NMR. Also, SPR4 peptide mimics the minimal PHEX Zn-motif site and binds specifically to the ASARM peptide. Interactions between SPR4 and ASARM peptide largely determine the bound conformation, whereas the ASARM-phosphate moieties stabilize the interaction, increasing the binding strength. When cultured individually for 21 days, Hyp BMSCs displayed reduced mineralization compared to WT (-87%; p<0.05). When co-cultured, both Hyp and WT cells failed to mineralize. ASARM-peptide induced a similar pattern in WT cells (-78%), and treatment with SPR4 peptide or an anti-ASARM neutralizing-antibodies completely corrected the mineralization defect. SPR4-peptide had no effect on WT mineralization without ASARM-PO4 peptide. In HYP BMSCs, SPR4-peptide increased mineralization nodules by >66%. Anti-ASARM neutralizing antibodies had similar effects to the SPR4 peptide. Moreover, ASARM treatment also decreased PHEX mRNA expression in WT-cells (-72%; p<0.05) and protein as detected by immunohistochemistry (-80%; p<0.05). SPR4 co-treatment reversed this by preventing ASARM binding to PHEX. Also, western-blots of Hyp calvariae revealed massive degradation of both MEPE and DMP1 protein as compared to the WT. Similar results were obtained by immunohistochemistry in Hyp and ASARM BMSCs treated cultures and a significant correction occurred after SPR4 peptide co-treatment or treatment. We conclude that degradation of MEPE and DMP-1 and release of acidic ASARM-peptides are chiefly responsible for the mineralization defect in HYP.

Effect of ASARM and SPR4 on mineralization

Circulating Osteogenic Precursor Cells of Hematopoietic Origin. R. J. Pignolo¹, R. K. Suda^{1*}, D. Porter^{1*}, E. M. Shore², F. S. Kaplan³. ¹Medicine, University of Pennsylvania, Philadelphia, PA, USA, ²Genetics and Orthopaedic Surgery, University of Pennsylvania, Philadelphia, PA, USA, ³Medicine and Orthopaedic Surgery, University of Pennsylvania, Philadelphia, PA, USA.

Mesenchymal precursors with osteogenic potential reside in a variety of tissues. We previously demonstrated that circulating osteogenic precursor (COP) cells can be identified from peripheral blood as a population of CD 14/type I collagen⁺/CD 45⁺ mononuclear adherent cells that can produce bone in vivo upon subcutaneous injection into immunodeficient mice. We further showed that higher numbers of COP cells occur in patients with fibrodysplasia ossificans progressiva (FOP) who had recent episodes of ectopic bone formation, compared to either patients with stable disease or unaffected individuals. We now show that human COP cells are of hematopoietic origin. COP cells isolated from patients who underwent sex-mismatched bone marrow transplantation (BMT), including one FOP patient, were examined for both X and Y chromosomes by fluorescence in situ hybridization (FISH) and for COP cell-specific markers by immunofluorescence using antibodies against type I collagen/CD34, type I collagen/CD45, or type I collagen/CD13. Virtually 100% of circulating cells that became adherent in culture were of donor origin. Of these cells, 79-89% expressed markers consistent with their identity as COP cells. We also demonstrated by immunofluorescence the presence of type I collagen⁺/CD45⁺ COP cells in lesions of heterotopic ossification found in FOP. Our

data suggest that bone-formation is not exclusively derived from cells of the mesenchymal lineage, but that circulating cells of hematopoietic origin can also serve as osteogenic precursors.

Arterial Oxygen Saturation During Sleep and the Risk of Fractures, Falls and Mortality in Older Men. J. A. Cauley¹, T. Blackwell², S. Redline³, D. Bauer⁴, K. Ensrud⁵, S. Ancoli-Israel⁶, E. Haney⁷, H. Fink⁸, E. Orwoll⁷, K. Stone². ¹University of Pittsburgh, Pittsburgh, PA, USA, ²California Pacific Medical Center, San Francisco, CA, USA, ³Case Western Reserve University, Cleveland, OH, USA, ⁴University of California San Francisco, San Francisco, CA, USA, ⁵University of Minnesota, Minnesota, MN, USA, ⁶University of California, San Diego, San Diego, CA, USA, ⁷Oregon Health Sciences University, Portland, OR, USA, ⁸Veterans Affairs Medical Center, Minneapolis, MN, USA.

Low arterial oxygen saturation has been linked to poor neuromuscular function and could be a risk factor for falls and fractures.

To test this hypothesis, we studied 2,911 men (mean age 76.4 y) enrolled in the Osteoporotic Fractures in Men (MrOS) Sleep study. Oxygen saturation (SaO₂) during sleep was measured by finger pulse oximetry (Nonin, MN) during a home polysomnography test over one night. Sleep time was assessed by neurophysiological monitoring and staged using standard criteria. Men were divided into groups based on the percent of sleep time that SaO₂ was below 90%: <1% (referent); 1 to <3.5%; 3.5 to <10% and ≥10%. Incident falls were reported every four months for 1 year; recurrent falls defined as ≥ 2 falls. Incident non-spine fractures and deaths were ascertained during 2.2 years of ≥95% complete follow-up. Logistic regression (falls) and Cox Proportional Hazards models (fractures/deaths) were used to estimate the Relative Risk (RR) and 95% Confidence Interval. We initially adjusted for age, weight, race and clinic.

819(28.1 %) men reported at least one fall; 396(13.6%) men reported two or more falls; 94(3.2%) men experienced an incident fracture and 75(2.6%) men died over the follow-up period. More time at SaO₂ <90% (i.e., more time spent at lower levels of oxygen saturation) was associated with an increased risk of falls, recurrent falls, non-spine fractures and death, Table. Additional adjustment for BMD, history of COPD, smoking, neuromuscular function and self-reported health status had little effect on our results (data not shown). Further adjustment of the fracture models for falls in the past 12 months did not appreciably change the results.

We conclude that greater time spent at nocturnal desaturation levels below 90% is an independent risk factor for falls, fractures, and death in older men. Further trials should determine if identification of these men for treatment could reduce these clinical events.

Asymmetry in Leg Power Increases Non-spine and Hip Fracture Risk in Older Men: The Osteoporotic Fractures in Men (MrOS) Study. P. M. Cawthon¹, T. L. Blackwell¹, B. Chan², K. Winters-Stone², E. Barrett-Connor³, K. Ensrud⁴, E. S. Orwoll². ¹Research Institute, California Pacific Medical Center, San Francisco, CA, USA, ²Oregon Health and Science University, Portland, OR, USA, ³University of California, San Diego, CA, USA, ⁴University of Minnesota, Minneapolis, MN, USA.

In older men, decreased leg power is associated with an increased risk of falls and fractures. Asymmetry, or the difference in power between the left and right legs, may also influence fall and fracture risk in older men.

To test the hypothesis that greater asymmetry in leg power increases the risk of fracture, we measured leg power (Nottingham Power Rig) in the right and/or left leg in 5,443 men age ≥65. Men were followed for an average of 1 year for falls and 4.7 years for non-spine fractures. Asymmetry was calculated as the absolute percent difference in maximal leg power between the right and left legs, and categorized into quartiles. Men in the highest quartile of asymmetry (quartile 4, most difference between legs) were compared to men with less difference in leg power (quartiles 1-3, referent group). Men who were unable to complete the leg power measures on one leg due to injury or weakness were included in the highest asymmetry group. During follow-up, 387 non-spine fractures (including 63 hip)

were validated. Frequent fallers (N=596) were men who fell two or more times in the year after baseline. Proportional hazards models estimated fracture risk; logistic regression was used for falls outcomes. Confounding variables were selected using backward selection. Total hip bone mineral density (BMD) was measured by dual x-ray absorptiometry (DXA). Average maximal leg power was 208.3 watts. Average asymmetry was 9.8% (range: 0% - 86%). 95 men (1.7%) completed leg power measures on only one leg. A difference in leg power of 13.5% or higher represented the highest quartile of asymmetry. In multivariate models, men with greatest asymmetry had a 73% increased risk of hip fracture and a 28% increased risk of non-spine fracture. Men with the greatest asymmetry had a modest increase in risk for frequent falls in age-adjusted models, but in multivariate models this association was smaller in magnitude and no longer reached significance. (Table) In summary, asymmetrical leg power was found to be a novel risk factor for fractures in older men. Assessment of asymmetry in leg power may be worth pursuing when evaluating fracture risk in older men.

Table. Likelihood of falls and relative hazard of fracture for men with asymmetrical leg power

	Frequent faller	Non-spine fracture	Hip Fracture
Age, clinical center adjusted	1.29 (1.07, 1.55)	1.36 (1.10, 1.68)	1.96 (1.19, 3.22)
Multivariate adjusted*	1.16 (0.96, 1.41)	1.28 (1.04, 1.59)	1.73 (1.04, 2.88)

Falls models adjusted for age, clinical center, walking for exercise, diabetes, osteoarthritis, stroke, overall leg power, self-rated health and physical activity score.

Non-spine fracture models adjusted for age, clinical center, walking for exercise, BMI, race, overall leg power, total hip BMD.

Hip fracture models adjusted for age, clinical center, BMI, heart attack, stroke, overall leg power, total hip BMD.

*Referent group is men with more symmetrical leg power

SSRI Use Is Associated with Increased Risk of Fracture Among Older Men. E. M. Haney¹, N. Parimi², S. J. Diem³, K. E. Ensrud³, J. A. Cauley⁴, E. S. Orwoll¹, M. M. Bliziotes¹. ¹Department of Medicine, Oregon Health & Science University, Portland, OR, USA, ²California Pacific Medical Center, San Francisco, CA, USA, ³University of Minnesota, Minneapolis, MN, USA, ⁴University of Pittsburgh, Pittsburgh, PA, USA.

Selective serotonin reuptake inhibitors (SSRIs) have the potential for direct effect on bone because they block the serotonin transporter that is present in osteoclasts, osteoblasts, and osteocytes. SSRI use has been associated with lower bone mineral density (BMD) in men. The purpose of this analysis was to examine the association between SSRI use and fracture.

MrOS is a prospective cohort study of 5,995 U.S. men ages 65 and older from six clinical sites. This analysis used data from 4,156 men who participated in the baseline visit and Visit 2, approximately 4 years later. SSRI users were defined as those participants reporting SSRI use at either baseline or Visit 2. Combination antidepressant users and those using another antidepressants were excluded. We performed Cox-proportional hazards regression. Initially, we included variables that were significantly associated with SSRI use in univariate analyses. Then we restricted the covariates to those that influenced the parameter estimate for SSRIs and fracture in order to achieve the most parsimonious model.

236 (6.3%) men reported use of SSRIs at either baseline or Visit 2. 323 (7.6%) men had at least one fracture. Adjusting for age, race, weight, clinic site, hip BMD, and depressive symptoms using the baseline SF-12 mental summary score, SSRI use was associated with an increased hazard rate of any non-spine fracture (HR=2.2, 1.6-3.0, p<0.0001). Multivariate models including the above variables plus all significant covariates also indicated an increased HR for SSRIs (HR 2.2, 1.6-3.1, p<0.0001). Excluding users of benzodiazepines, non-benzodiazepine anticonvulsants, and osteoporosis medications and substituting the Geriatric Depression Scale measured at Visit 2 for the SF-12 mental summary score did not change the results. The final model included SSRI use, age, weight, total hip BMD, history of fracture, and history of falls (HR 1.8, 1.2-2.6, p=0.003).

Our results suggest that SSRI use in a population of community-dwelling elderly men is associated with fracture. Given the widespread use of these drugs, further investigation into the mechanism for this association is important.

Aortic Calcifications Correlate with Volumetric Bone Mineral Density and Bone Microstructure in Men: A Population-Based Study. J. T. Chow^{*1}, S. Khosla¹, L. J. Melton², E. J. Atkinson^{*3}, A. E. Kearns¹. ¹Endocrinology, Mayo Clinic College of Medicine, Rochester, MN, USA, ²Epidemiology, Mayo Clinic College of Medicine, Rochester, MN, USA, ³Biostatistics, Mayo Clinic College of Medicine, Rochester, MN, USA.

Calcification of the vasculature has been epidemiologically linked with bone loss and osteoporosis. Data in men has been sparse, with studies primarily utilizing conventional radiography and absorptiometry for calcification and bone density determination, respectively. We herein present the first population-based assessment relating volumetric bone mineral density (vBMD) and bone microstructure to aortic calcification (AC) in men, utilizing advanced imaging techniques.

Using QCT, vBMD and calcification in the abdominal aorta were quantified in 321 men from an age-stratified sample of Rochester, Minnesota residents. High-resolution 3-D pQCT imaging at the radius was used to define trabecular bone volume/tissue volume (BV/TV), trabecular thickness (Tb.Th), trabecular number (Tb.N), and trabecular separation (Tb.Sp). Subjects were analyzed in 2 groups based on age: <50 or ≥50 years.

AC was present in 285 subjects (89%), with the prevalence rapidly increasing after age 50. In men ≥50 years of age, but not <50 years of age, AC correlated with lower vertebral and femur neck vBMD. The negative correlation was not significant after adjustments for age, body mass index (BMI), and smoking status (ever). In subjects ≥50, AC correlated with lower BV/TV and Tb.Th, but not after multivariate adjustment, while a negative correlation with Tb.N persisted after adjustment. Conversely, AC correlated with higher Tb.Sp, and this relationship also continued to be significant after multivariate adjustment. Our findings support an age-dependent association between AC and vBMD in men. This population-based study of men may provide a more accurate representation of vascular and bone biology, as potential confounding factors in women such as menopause are not present. We also present the novel finding of a relationship between vascular calcification and bone microstructure beyond the 5th decade of life. The association of AC to lower Tb.N and higher Tb.Sp is especially interesting, given our previous observation that Tb.N and Tb.Sp appear to be constant throughout life in a general population of men. Further studies are required to establish the pathophysiologic process leading to this association.

Table 1 - Unadjusted and Age/BMI/Smoking Status-Adjusted Correlation Coefficients Relating AC with vBMD and Microstructural Parameters

Diabetes and Fracture Risk in Older Men: The Osteoporotic Fractures in Men (MrOS) Study. A. V. Schwartz¹, E. S. Strotmeyer², T. Dam^{*3}, D. E. Sellmeyer¹, D. C. Bauer¹, K. E. Ensrud⁴, A. R. Hoffman^{*5}, L. M. Marshall⁶, E. Barrett-Connor⁷, L. Palermo¹, E. S. Orwoll⁶, S. R. Cummings⁷. ¹University of California, San Francisco, San Francisco, CA, USA, ²University of Pittsburgh, Pittsburgh, PA, USA, ³University of California, San Diego, La Jolla, CA, USA, ⁴VA Medical Center & University of Minnesota, Minneapolis, MN, USA, ⁵VA Palo Alto Health Care System, Palo Alto, CA, USA, ⁶Oregon Health & Science University, Portland, OR, USA, ⁷California Pacific Medical Center, San Francisco, CA, USA.

In older women type 2 diabetes (DM) is associated with increased fracture risk in spite of average or higher BMD compared with non-diabetic women. Since limited data are available for men, we investigated DM and fracture risk in participants from the Osteoporotic Fractures in Men (MrOS) Study, a cohort of community dwelling, ambulatory men aged ≥65 years recruited at 6 U.S. sites during 2000-2002. DM was defined as self-report of a previous physician diagnosis or use of hypoglycemic medication. Men who first reported DM at a follow-up visit were excluded (N=288). Of the remaining 5,707 participants, 663 (11.6%) had DM at baseline, including 80 who reported insulin use (Ins DM). Those with DM were less likely to be white (78% Ins DM, 82% No Ins DM, 90% non-DM), had higher total hip BMD (0.99 g/cm² Ins DM, 1.00 No Ins DM, 0.95 non-DM) and BMI (29.5 kg/m² Ins DM, 28.9 No Ins DM, 27.1 non-DM) and were more likely to have fallen in the previous year (44% Ins DM, 25% No Ins DM, 20% non-DM). Average age (73.7 ± 5.9 yrs) was similar. During an average follow up of 5.3 years, 420 men reported at least one non-vertebral fracture. Incidence rates (per 100 person-years) were 3.00 (Ins DM), 1.40 (No Ins DM), and 1.37 (non-DM). The most common fractures were rib, hip and wrist. Risk of first non-vertebral fracture was assessed with proportional hazards models, adjusted for age, race, clinic, total hip BMD, BMI, use of bone-active medications, and then falls. Risk estimates were not reduced by excluding 153 men who reported thiazolidinedione use, associated with fracture risk in diabetic women, at any visit.

Model adjusted for:	Insulin use	Oral hypoglycemic use, no insulin	No hypoglycemic use
Age, race, clinic	2.64 (1.48, 4.71)	1.08 (0.75, 1.58)	1.04 (0.57, 1.90)
+ potential confounders	2.49 (1.38, 4.49)	1.01 (0.66, 1.53)	1.05 (0.52, 2.12)
+ falls	2.18 (1.21, 3.95)	0.97 (0.64, 1.47)	1.04 (0.51, 2.10)

Compared with non-diabetic men, fracture risk was increased in older diabetic men on insulin therapy but not among others with diabetes, even after adjusting for more frequent falls. Insulin use may be a marker of increased diabetes-related complications in older men.

Mapping the Prescripiome to Fractures in Men: A National Analysis of Prescription History and Attributable Risk. B. Abrahamsen¹, K. Brixen².

¹Department of Medicine F, Copenhagen University Hospital Gentofte, Hellerup, Denmark, ²Department of Endocrinology, Odense University Hospital, Odense, Denmark.

Despite the large number of pharmaceutical products on the market, studies linking exposure to medicines to fracture risk are generally undertaken in a manner similar to candidate gene studies and not to the more conservative genetic mapping, despite the risk of mass significance. To stress the similarity between pharmacoepidemiology and genetics, we coined the term prescripiome to describe the entire complement of prescription drugs redeemed by an individual.

We identified all men aged 50+ years who presented with a fracture at any hospital in the country in the year 2000 and retrieved information about prescriptions redeemed in the preceding 5y in fracture patients (n= 15,716) and matched controls (n=47,149). All level-4 ATC groups were included as independent variables in the same logistic regression analysis with fracture as the dependent variable.

The greatest increase in hip fracture risk was observed in patients exposed to antiepileptics (odds ratio OR 1.80, 95% CI [1.53-2.12], population attributable risk PAR 1.4%), opioids (1.40 [1.23-1.59], PAR 1.4%), dopaminergics (1.87 [1.46-2.39], 0.6%), hormone antagonists (2.20 [1.14-4.28], 0.1%), anti-depressants (1.53 [1.37-1.71], 3.5%), insulin (1.87 [1.50-2.33], 1.2%), loop diuretics (1.37 [1.20-1.57], 3.6%) and anti-psychotics (1.51 [1.26-1.80], 1.0%). The risk of spine fractures were particularly increased in users of most classes of analgesics, cardiac glycosides, systemic and topical glucocorticoids and hormone antagonists.

Medications predisposing to hip fracture differed from those associated with increased risk of spine fractures. Most classes of analgesics were more widely used in patients who subsequently sustained fractures, but drugs affecting the nervous system were key contributors to hip fracture risk while anti-hormonal agents were more important as predictors of vertebral fracture. The advantage of this type of analysis is that it provides a conservative approach, while facilitating discovery of new associations between prescription history and subsequent fracture. The disadvantage of the method is that weak associations may be missed, especially where drugs belonging to the same level-4 ATC class have opposite effects on risk.

Skeletal Size and Fracture Risk in a Large Clinical Cohort. W. D. Leslie¹, J. F. Tsang^{*2}, L. M. Lix^{*3}. ¹Dept of Medicine, University of Manitoba, Winnipeg, MB, Canada, ²University of Manitoba, Winnipeg, MB, Canada, ³Manitoba Centre for Health Policy, University of Manitoba, Winnipeg, MB, Canada.

DXA is affected by skeletal size with smaller bones giving lower areal BMD (aBMD) despite equal volumetric BMD. Whether this size effect confounds the use of aBMD as a diagnostic and fracture risk assessment tool is unclear.

We identified 16205 women of white ethnicity age 50 y or older undergoing baseline hip assessment with DXA (1998-2002) from a population-based database which contains all clinical DXA test results for the Province of Manitoba, Canada. Total hip aBMD and T-scores (NHANES-III) were categorized according to quartile in total hip area (Q1=smallest, Q4=largest). Longitudinal health service records were assessed for the presence of non-trauma 'osteoporotic' fracture codes (hip, clinical spine, wrist, humerus) during mean 3.1 y after BMD testing (757 osteoporotic fractures, 186 hip fractures).

Total hip area strongly affected diagnosis with much higher rates in Q1 (15.5%) than Q4 (8.9%). However, incident fracture rates in women with T≤-2.5 were constant across area quartiles. Age was a potential confounder that correlated positively with area (r=0.12, p<.0001). When age was not included in a Cox regression model, Q1 appeared to have a lower rate of osteoporotic fractures (HR 0.80, 95% CI 0.66-0.98, reference Q4) and hip fractures (HR 0.63, 95% CI 0.43-0.94) for a given aBMD. In age-adjusted regression models, aBMD was strongly predictive of osteoporotic fractures (HR per SD 1.83, 95% CI 1.68-1.99) and hip fractures (HR per SD 2.80, 95% CI 2.33-3.35) but there no independent effect of bone area (categorical or continuous). Including height and/or weight as covariates did not change the results. Models that assessed bone area and BMC covariates together, or simple volume-adjustments, were no better than aBMD alone for fracture prediction.

We conclude that aBMD categorizes a substantially higher fraction of women with smaller bone area as being osteoporotic despite younger age. Observed fracture rates correlate equally well with aBMD across all bone area quartiles when adjusted for age.

Table: Osteoporosis diagnosis (T≤-2.5) and fracture rates (for osteoporotic women)

according to total hip area quartile (Q1=smallest, Q4=largest).

	Q1 (N=4052)	Q2 (N=4051)	Q3 (N=4050)	Q4 (N=4052)	p-for-trend
Osteoporosis diagnosis	15.5%	11.0%	9.8%	8.9%	<.0001
Any osteoporotic fracture	13.5%	11.9%	14.1%	13.4%	NS
Hip fracture	4.8%	5.4%	5.6%	5.6%	NS

High Resolution Peripheral Quantitative CT (HRpQCT) of the Radius Reflects Iliac Crest Biopsy Measures of Microstructure and Mechanical Competence. A. Cohen¹, D. W. Dempster², R. Mueller³, X. E. Guo¹, X. H. Zhang^{*1}, A. J. Wirth^{*3}, G. H. van Lenthe^{*3}, D. J. McMahon¹, H. Zhou^{*2}, M. R. Rubin¹, J. P. Bilezikian¹, R. R. Recker⁴, E. Shane¹. ¹Columbia University, New York, NY, USA, ²Helen Hayes Hospital, West Haverstraw, NY, USA, ³University of Zurich, Zurich, Switzerland, ⁴Creighton University, Omaha, NE, USA.

The newly available HRpQCT instrument (Scanco Medical AG) has sufficiently high resolution (<100µm) to permit in vivo assessment of trabecular (Tb) architecture at the radius (RAD) and tibia (TIB). Finite element analysis (FEA) can be applied to HRpQCT data to quantify bone mechanical competence (Young's moduli; E), where E is a surrogate for bone strength.

Study goal: To evaluate relationships between structural parameters and Young's moduli assessed by HRpQCT of the RAD and TIB and those measured by 2D histomorphometry (2DH) and 3D microCT (Scanco µCT40) of iliac crest biopsies, and to determine whether HRpQCT images accurately reflect histomorphometric analyses.

Biopsies and HRpQCT scans were performed in 37 individuals (10 men, age 22-76) with normal BMD, or with osteoporosis or hypoparathyroidism. Cortical thickness (CtWi) was measured by 2DH and HRpQCT, while Tb indices, including Tb bone volume (BV/TV), number (TbN), thickness (TbTh), separation (TbSp) were assessed by 2DH, microCT and HRpQCT. In a subset (n=24), FE models created by voxel-to-element conversion were used to calculate apparent E (longitudinal) for microCT and E in 3 directions for HRpQCT. Structural Measures: BV/TV, TbN, TbTh, and TbSp by 2DH correlated well with comparable microCT measures on biopsies (r=0.85, 0.82, 0.71, 0.80, respectively; all p<0.0001). RAD HRpQCT measures of BV/TV, TbN and TbSp correlated significantly with 2DH of biopsies (r=0.47, 0.41, 0.42; p<0.02). In contrast, at the TIB only BV/TV correlated significantly with 2DH of biopsies (r=0.37, p<0.05). CtWi by 2DH correlated with RAD (r=0.42; p=0.01) and TIB (r=0.54; p<0.001) HRpQCT. MicroCT measurements of BV/TV, TbN and TbSp correlated with similar RAD (r=0.41, 0.50, 0.63; all p<0.02), but not TIB, HRpQCT.

Mechanical competence: Apparent E (longitudinal) calculated from microCT correlated with E in three directions calculated from RAD (r=0.65; p<0.001) but not TIB (r=0.17; NS) HRpQCT.

In summary, there are strong relationships between comparable measures performed on iliac crest biopsies by 2DH and 3D microCT, and also between most 2DH and microCT parameters at the iliac crest and HRpQCT of the RAD. Parameters from TIB HRpQCT did not correlate well with biopsies. E calculated on biopsies correlated well with E calculated on RAD, but not TIB HRpQCT.

We conclude that RAD HRpQCT correlates well with bone biopsy structural parameters and can be considered as a non-invasive surrogate measure of bone strength.

QCT and High Resolution CT Are Better Surrogate Measures of Bone Strength than DXA for Patients on Teriparatide Treatment: Results from the EUROFOR Study. C. C. Glüer¹, C. Graeff¹, T. Nickelsen^{*2}, P. Zysset^{*3}.

¹Med. Phys., Diagn. Radiology, UKSH, Kiel, Germany, ²Eli Lilly, Europe, Bad Homburg, Germany, ³Inst. for Lightweight Design and Struct. Biomechanics, Vienna University of Technology, Wien, Austria.

The deficiencies of DXA for monitoring osteoporosis treatment are well established. Treatment induced increases in BMD only partially reflect reductions in fracture risk. As an alternative approach, structural strength of the vertebrae can be estimated by digital finite element analysis (FEA). We investigated (1) whether this performance problem of DXA would manifest itself as a reduction in the correlation between DXA and structural strength in teriparatide (TPTD) treated compared to untreated patients and (2) whether QCT or High Resolution CT (HRCT) might show more consistent correlations in treated and untreated patients, indicating that they would be better techniques for monitoring treatment effects.

In the Eurofors multi-center study, a subset of 23 patients on 24 months of treatment with TPTD (20 µg per day) was measured with DXA (L1-4), QCT (L1-3), and HRCT (T12). FEA of the T12 vertebrae was used to calculate ultimate load under axial compression. Using StructuralInsight software developed in-house, regions of the vertebral cortical rim (outer 3mm) and inner trabecular volume were segmented. Volumetric BMD (QCT) and structural measures (apparent BV/TV, from HRCT) were calculated for T12. QCT analyses on L1-3 were performed by Mindways QCTPro.

At baseline DXA explained 40% of bone strength but this was reduced to only 14% after 2 years of TPTD treatment. QCT based BMD and HRCT based BV/TV associations with bone strength were maintained or even shown improvements: at 24 months these measures explained 43-76% of bone strength.

We conclude that in patients on teriparatide treatment DXA loses its ability to estimate bone strength but that QCT and HRCT maintain a high correlation with bone strength. Our results indicate that CT based assessments may offer substantial advantages over DXA in assessing treatment effects on bone strength, specifically for TPTD.

Development of a Clinical Nomogram for Individualizing 5-year and 10-year Risks of Fracture. N. D. Nguyen, S. A. Frost*, J. R. Center, J. A. Eisman, T. V. Nguyen. Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Although many risk factors of fracture have been identified, the translation of these risk factors into a prognostic model that can be used in primary care setting has not been well realized. The present study sought to develop a nomogram that incorporates non-invasive risk factors to predict 5-year and 10-year absolute risks of fracture for an individual man and woman.

The Dubbo Osteoporosis Epidemiology Study was designed as a community-based prospective study, with 1358 women and 858 men aged 60+ years as at 1989. Baseline measurements included femoral neck bone mineral density (FNBM), prior fracture, a history of falls and body weight. Between 1989 and 2004, 426 women and 149 men had sustained a low-trauma fracture. Two prognostic models based on the Cox's proportional hazards analysis were considered: model 1 included age, BMD, prior fracture and falls; and model 2 included age, weight, prior fracture and falls.

Analysis of the area under the receiver operating characteristic curve (AUC) suggested that model 1 (AUC=0.75 for both sexes) performed better than model 2 (AUC = 0.72 for women and 0.74 for men). Using the models' estimates, various nomograms were constructed for individualizing the risk of fracture for men and women. If the 5-year risk of 10% or greater is considered "high risk", then virtually all 80 years old men with BMD T-scores < -1.0 or 80 years old women with T-scores < -2.0 were predicted to be in the high risk group. A 60 years old woman's risk was considered high risk only if her BMD T-scores ≤ -2.5 and with a prior fracture; however, no 60 years-old men are in the high risk regardless of their BMD and risk profile.

These data suggest that the assessment of fracture risk for an individual can not be based on BMD alone, since there are various combinations of factors that could substantially elevate an individual's risk of fracture. The nomograms presented here can be useful for individualizing the short- and intermediate-term risk of fracture and identifying high-risk individuals for intervention to reduce the burden risk of fracture in the general population.

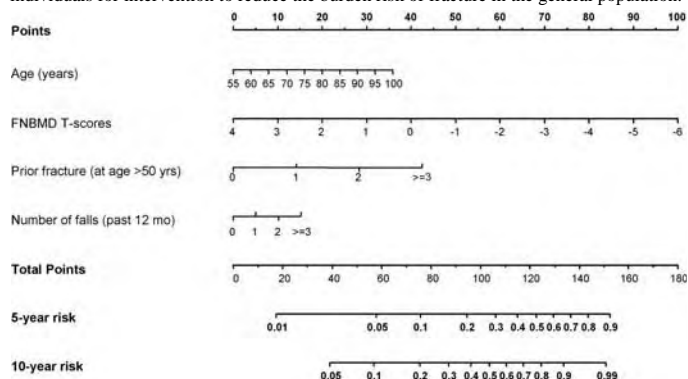

Figure: Nomogram for predicting 5-year and 10-year probability of any osteoporotic fracture for individual women

Ten-year Probability of Osteoporotic Hip Fracture in Elderly Women Combining Clinical Factors and Heel Bone Ultrasound: A New Model From the EPISEM Prospective Cohort. C. Durosier^{*1}, M. Krieg², A. Schott^{*3}, J. Kanis^{*4}, D. Hans¹. ¹Nuclear Medicine, University Hospital, Geneva, Switzerland, ²Outpatient Clinic, University Hospital, Lausanne, Switzerland, ³Medical Information, Hospices Civils of Lyon, Lyon, France, ⁴WHO Collaborating Centre for Metabolic Bone Diseases, Sheffield University, United Kingdom.

Many independent clinical risk factors (CRF) have been identified that contribute to the osteoporotic hip fracture risk above that reflected by BMD. However, DXA is not always available. Prospective studies shown that heel bone ultrasound (HBU) predicts hip fracture equally well as hip BMD. In addition we demonstrated that combining CRF with HBU improves the 10-year probability of hip fracture (ASBMR 2006). The aim of our study is to recalculate the probability considering additional CRF present in the current WHO model for central DXA.

We built a database "EPISEM" (12958 women aged 70 to 97 years) by grouping the EPIDOS (French) and SEMOF (Swiss) cohorts. At baseline, all women had been measured by the HBU Achilles+ (GE-Lunar), and questioned for their osteoporosis CRF. During a mean follow-up of 3.2 ± 0.9 years (\pm SD), 307 women reported a hip fracture. Covariates included age and time since start of follow-up. The association of risk factors with the risk of hip fracture and possible interactions were examined using a Poisson regression model, which included only the significant ones. Stiffness HBU was expressed as Z-scores. Gradient of risk per standard deviation of the model was calculated as well as the 10-year probability of hip fracture of all possible combination of selected CRF and Stiffness HBU. The following independent predictors were kept: Stiffness HBU, BMI, past fracture, fall within a year, chair test, past HRT, current smoking, current corticoids intake and hip fracture in mother. Gradient of risk of the model per one standard deviation decrease varies from 1.5 to 2.7 when considering a baseline age of 70 up to 95 years. An example of probability of a 70-year-old woman is given in the figure below according to the number of risk factors (sum-up).

The association of CRF and HBU clearly improves the detection of elderly women at high risk. Thresholds corresponding to an equivalent of -2.5 T-score of the femoral neck are been defined enabling the identification of women likely to benefit of a treatment initiation. Clinical evaluation is underway to further validate such model.

Establishing a Reference Range for Bone Turnover Markers in 635 healthy, Young, Pre-menopausal Women from UK, France, Belgium and the USA. S. J. Glover¹, M. Gall², O. Schoenborn-Kellenberger³, P. Garnero⁴, S. Boonen⁵, J. A. Cauley⁶, D. M. Black⁷, P. D. Delmas⁸, R. Eastell¹. ¹Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, UK, United Kingdom, ²Novartis Pharmaceuticals Incorporated, East Hanover, NJ, USA, ³Novartis Pharma AG, Basel, Switzerland, ⁴SYNARC, Lyon, France, ⁵Leuven University Center for Metabolic Bone Diseases & Division of Geriatric Medicine, Katholieke Universiteit Leuven, Leuven, Belgium, ⁶University of Pittsburgh, Pittsburgh, PA, USA, ⁷Department of Epidemiology and Biostatistics, University of California, San Francisco, CA, USA, ⁸INSERM Research Unit 831, University of Lyon, Lyon, France.

Bone turnover markers (BTMs) are important in determining fracture risk in women with postmenopausal osteoporosis. Robust reference ranges are required for the interpretation of BTMs in large phase III fracture trials, such as the Horizon-PFT study of zoledronic acid. The aims of the study were to: a) establish reference intervals for crosslinked C-telopeptides of type I collagen (beta CTX), crosslinked N-telopeptides of type I collagen (NTX), bone alkaline phosphatase (bone ALP) and procollagen type I N propeptide (PINP) in healthy young pre-menopausal women; and b) study the effect of geographical location on BTMs. We recruited 635 women from 4 countries that participated in the Horizon-PFT study (UK, France, Belgium, US). The women were 30 to 40 years of age (mean 34.6), with regular cyclic menses. Subjects completed a medical and lifestyle questionnaire. The reference ranges are shown in the table and were obtained using the IFCC methodology.

Measurement	Reference interval, 95% CI	Lower limit, 90%CI	Upper limit, 90%CI
Serum CTX, ng/mL	0.114 - 0.628	0.100 ; 0.131	0.548 ; 0.721
Urinary NTX/Cr, nmol/mmol Cr	9.22 - 51.81	8.03 ; 10.57	45.16 ; 59.44
Serum bone ALP, ug/L	5.15- 15.32	4.48 ; 5.92	13.33 ; 17.61
Serum PINP, ug/L	16.3 - 78.2	15.5 ; 17.3	74.0 ; 82.7

Beta CTX was significantly higher in France than UK ($p=0.01$) and PINP was higher in France and Belgium than UK ($p<0.001$) and higher in France than US ($p<0.01$) by ANOVA. We found several differences between countries in BMI, previous numbers of pregnancies, and in the proportion of women who were current smokers, regular exercisers and consuming alcohol regularly (ANOVA, all $p<0.05$), which might explain the differences in BTMs. The proportion of current smokers was higher in France than in UK ($p<0.01$) and smoking was associated with significantly higher levels of beta CTX and PINP ($p<0.05$). In conclusion we have established reference ranges for 4 BTMs based on an international study of pre-menopausal women and have identified differences in BTMs, BMI, smoking habit, pregnancies, exercise and alcohol consumption between countries.

Specific Inhibition of the VEGF Homologue Placental Growth Factor Is Protective Against Osteolytic Bone Metastasis in Mice. L. Coenegrachts^{*1}, C. Maes¹, I. Stockmans^{*1}, T. Guise², R. Bouillon¹, P. Carmeliet^{*3}, G. Carmeliet¹. ¹Laboratory of Experimental Medicine and Endocrinology, K.U.Leuven, Leuven, Belgium, ²Dept. of Internal Medicine, University of Virginia, Charlottesville, VA, USA, ³Center for Transgene Technology and Gene Therapy, VIB, K.U.Leuven, Leuven, Belgium.

Osteolytic bone metastasis comprises of several stages including tumor cell migration, tumor growth, angiogenesis and bone resorption. Bone marrow (BM) stromal cells and osteoclasts contribute to metastasis progression and both cell types express VEGFR-1, the receptor for the VEGF homologue Placental Growth Factor (PlGF). We recently reported that PlGF is important for fracture repair by stimulating angiogenesis and bone remodeling. Given this multi-functionality of PlGF in bone pathology, we investigated its role in osteolytic metastasis.

MDA-MB231 human breast cancer cells, which express VEGFR-1, were intracardiac injected in nude mice treated for 3 weeks with an anti-murine PlGF antibody (mPlGF-Ab) or an isotopic control antibody (a kind gift of Thrombogenics NV, Leuven, Belgium).

Administration of mPlGF-Ab significantly reduced the number of mice with osteolytic lesions as analyzed by radiography (mPlGF-Ab: 7/13 vs. control: 11/11; $p<0.05$). In particular, the number of affected bones was significantly reduced by mPlGF-Ab treatment (mPlGF-Ab: 0.92 vs. control: 3.54, of 4 bones (tibia-femur) analyzed per mouse; $p<0.001$). Histomorphometry confirmed these results and additionally showed that tumor size in mPlGF-Ab treated mice with osteolytic lesions was reduced compared to the control group. These data suggest that preferentially early phases of bone metastasis and tumor growth are inhibited by mPlGF-Ab treatment.

Mechanistic investigation revealed that murine BM stromal cells expressed increased PlGF mRNA and protein levels (species-specific qRT-PCR, ELISA) when cultured in vitro adjacent to human MDA-MB231 cells for 3 and 6 days ($p<0.001$) but not when cultured separated by a membrane. This observation can explain the significantly increased mPlGF mRNA expression in bone, 2 weeks after tumor cell injection, the time when metastases become histological detectable. In addition, already one week after tumor cell injection, osteoclast surface (TRAP) was decreased in mPlGF-Ab treated mice compared to control treatment. In agreement, C-telopeptide serum levels, a bone resorption marker, were significantly reduced in mPlGF-Ab treated mice 3 weeks after tumor cell injection. Moreover, osteoclast differentiation in vitro was significantly impaired by inhibition of PlGF activity.

In conclusion, these data suggest that mPlGF promotes osteolytic bone metastasis by affecting tumor growth and by stimulating bone resorption.

Imatinib Mesylate Suppresses Bone Metastases by Inhibiting Osteoclasts through Blockade of M-CSF Signals. T. Hiraga, H. Nakamura. Histology and Cell Biology, Matsumoto Dental University, Nagano, Japan.

Imatinib mesylate (imatinib), also known as Glivec or STI-571, is a potent and selective inhibitor of the tyrosine kinases, Bcr-Abl, c-Kit and platelet-derived growth factor receptors (PDGFRs), and is widely and successfully used for the treatment of chronic myeloid leukemia and gastrointestinal stromal tumor. Recently, it has been reported that imatinib also targets the macrophage colony-stimulating factor (M-CSF) receptor c-Fms. M-CSF signals are critical for the differentiation of osteoclasts. Furthermore, it is widely accepted that osteoclasts play central roles in the development and progression of bone metastases. These findings led us to hypothesize that imatinib may have beneficial effects on bone metastases. Co-immunoprecipitation assays showed that imatinib inhibited the M-CSF-induced phosphorylation of c-Fms in the osteoclast precursor cells, RAW264.7 and mouse bone marrow macrophages (BMM ϕ), as well as the PDGF-induced PDGFR phosphorylation in MDA-MB-231 human breast cancer cells. Imatinib also suppressed osteoclast-like cell formation in BMM ϕ cultures treated with RANKL/M-CSF and mouse bone marrow cultures treated with parathyroid hormone-related protein (PTHrP) in a dose-dependent manner. However, imatinib did not affect the RANKL-induced cell signals, phosphorylation of I κ B α and ERK, in RAW264.7 and BMM ϕ , and the PTHrP-induced RANKL expression in mouse primary bone marrow stromal cells, suggesting that the imatinib-decreased osteoclast-like cell formation was caused by the blockade of M-CSF signals but not RANKL signals. Of note, imatinib also inhibited osteoblast differentiation determined by alkaline phosphatase activity and alizarin red staining; however, the minimum effective dose was approximately 10 times higher than the dose required to inhibit osteoclast differentiation. Finally, we examined effects of imatinib on bone metastases using a well-characterized animal model. Radiographic and histomorphometric analyses demonstrated that imatinib significantly decreased the bone metastases of MDA-MB-231 in a dose-dependent manner. Consistent with the *in vitro* results, osteoclast number was significantly reduced in the bone metastases in imatinib-treated animals. The development of MDA-MB-231 tumors in the mammary fat pad was also suppressed by the imatinib treatment. In conclusion, these results suggest that imatinib reduced bone metastases by inhibiting osteoclasts through the blockade of M-CSF signals, in addition to the direct anti-tumor effects through the inhibition of known tyrosine kinases. The results also suggest that imatinib may have a protective effect against cancer treatment-induced bone loss.

Treatment with Heparanase III Inhibits the Growth of Myeloma Tumors in Bone. Y. Yang^{*1}, L. Suva², Z. Shriver^{*3}, G. Venkataraman^{*3}, R. Sasisekharan^{*4}, J. Epstein^{*5}, S. Yaccoby⁵, J. Shaughnessy^{*5}, R. Sanderson^{*1}. ¹Pathology, UAB, Birmingham, AL, USA, ²Orthopedic Surgery, UAMS, Little Rock, AR, USA, ³Momenta Pharmaceuticals, Inc., Cambridge, MA, USA, ⁴Division of Bioengineering and Environmental Health, MIT, Cambridge, MA, USA, ⁵Myeloma Institute for Research and Therapy, Little Rock, AR, USA.

Bacterial heparinase III (HepIII) is an enzyme that degrades heparan sulfate and has anti-tumor activity in animal models of melanoma and lung carcinoma. We tested HepIII for its effect against myeloma tumors because the syndecan-1 heparan sulfate proteoglycan is expressed by all myeloma tumors and is shed into the myeloma microenvironment where it binds to and regulates the activity of numerous growth factors. Through these activities, syndecan-1 plays a major role in promoting myeloma growth, metastasis and angiogenesis. Recombinant HepIII was purified to homogeneity, cleared of endotoxins and tested for anti-myeloma activity utilizing two *in vivo* models of the disease; a subcutaneous model in which cells of the CAG human myeloma cell line were injected into SCID mice and a SCID-hu model in which primary tumor cells isolated from myeloma patients were injected into fragments of human bone implanted in SCID mice. In addition to treatment with the recombinant HepIII enzyme, we also tested the anti-tumor activity of fragments of heparan sulfate generated by treating purified syndecan-1 with HepIII. Treatment of tumor-bearing animals with HepIII (15 mg/kg/day) or HepIII-generated fragments of heparan sulfate (0.8 mg/kg/day) was accomplished by twice daily injections for 4 weeks. The levels of human immunoglobulin light chain in murine sera were assessed as an indicator of tumor burden. The results demonstrated that treatment with either Hep III or Hep III-generated heparan sulfate fragments significantly inhibited tumor growth of both the cell line (subcutaneous model) and primary tumors (SCID-hu model). All 8 myeloma patient samples tested were inhibited by the treatment, with Hep III and Hep III-generated heparan sulfate fragments reducing tumor burden by 83% (P=0.003) and 78% (P=0.02), respectively. MicroCT scanning of the human bones revealed that inhibition of tumor growth by Hep III was associated with prevention of the bone destruction associated with myeloma. Importantly, the treated animals showed no sign of adverse side effects. We conclude that Hep III and Hep III-generated fragments of heparan sulfate significantly inhibit tumor growth and cancer-related bone resorption *in vivo*. These results indicate that targeting heparan sulfate may be an effective therapeutic approach for myeloma.

Intermittent PTH Treatment Inhibits Development and Progression of Primary Myeloma by Promoting Bone Formation in the SCID-rab Model. A. Pennisi^{*}, X. Li^{*}, M. Zangari^{*}, S. Yaccoby. Myeloma Institute for Research and Therapy, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Myeloma (MM) is associated with severe bone disease that likely contributes to tumor progression. We have previously demonstrated that whereas osteoclasts support MM growth osteoblasts have negative impact on survival of MM cells (Yaccoby et al., Haematologica 2006). The aims of the study were to investigate the effect of intermittent parathyroid hormone (PTH 1-34) treatment on bone formation and MM growth, and the consequences of PTH pretreatment on MM progression in our SCID-rab model for primary MM (Yata & Yaccoby, Leukemia 2004). SCID-rab mice were engrafted with MM cells from 5 patients. Upon establishment of MM growth, as monitored by measurement of human monoclonal immunoglobulins (hIg) in mice sera and by x-rays, mice were subcutaneously injected with PTH (0.3 mg/kg/day) or saline for 4-6 weeks. Overall, whereas BMD of the myelomatous bones in saline-treated hosts was markedly reduced by 22 \pm 7% (p<0.03), it was increased by 6 \pm 6 % from pretreatment level in PTH-treated hosts (p<0.02 saline vs. PTH-treated hosts). The bone anabolic effect of PTH was evident in 4 of 5 experiments and was associated with reduced MM growth only in hosts whose implanted bone had increased BMD from pretreatment level (242 \pm 87 vs. 875 \pm 186 μ g/ml hIg in controls, p<0.01). PTH, however, significantly increased BMD of the nonmyelomatous, uninvolved, murine femur by >12% (p<0.017) from pretreatment level in all experiments, regardless of tumor burden level in the remote myelomatous implanted bone. In additional experiments hosts received PTH or saline (10 mice/group), 4 weeks prior to and 8-12 weeks after the injection of 3 patient's derived MM cells. PTH pretreatment prior to injection of MM cells increased BMD of the nonmyelomatous implanted bones by 48 \pm 11% (p<0.001). Following inoculation of MM cells, BMD of the implanted bone in PTH-treated hosts remained significantly higher than in saline-treated hosts (p<0.002). In all 3 set of experiments, pretreatment with PTH resulted in delayed engraftment and growth of MM cells. We further confirmed by qRT-PCR that type-1 PTH receptor was not expressed by MM cells. *In vitro* PTH had no direct effect on MM cell growth and in contrast to Saos-2 osteosarcoma cells PTH did not protect MM cells from serum starvation-induced growth inhibition, indicating that PTH inhibitory effect on MM is indirectly mediated through creation of an inhospitable environment for MM cells. We conclude that increased bone formation by PTH contributes to controlling MM growth and that pretreatment with PTH, in addition to improving skeletal complications, may be a promising approach to prevent MM progression.

Anti-myeloma Response of the Proteasome Inhibitor, Bortezomib, Is Associated with Reduced Osteoclastogenesis and Increased Osteoblastogenesis and Bone Mass in Myelomatous Bones. A. Pennisi^{*}, X. Li^{*}, B. Barlogie, M. Zangari^{*}, S. Yaccoby. Myeloma Institute for Research and Therapy, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

The ubiquitin-proteasome pathway regulates differentiation of bone cells and myeloma (MM) growth. Bortezomib is a novel proteasome inhibitor with promising efficacy, even in patients with refractory MM. We recently reported that anti-MM response of bortezomib is associated with increased circulating alkaline phosphatase in MM patients (Zangari et al., BJH 2005). The aim of this study was to investigate the effect of bortezomib on bone remodeling and tumor growth in our SCID-rab model for primary MM (Yata & Yaccoby, Leukemia 2004). SCID-rab mice were engrafted with MM cells from 14 patients. MM growth was monitored by measurement of human monoclonal immunoglobulins (hIg) in mice sera, by x-rays and by live animal imaging using luciferase-expressing MM cells. MM-bearing mice were injected subcutaneously with bortezomib (0.5 mg/kg twice a week) or saline for 4-8 weeks. Whereas all control mice had increased hIg levels, bortezomib reduced hIg in 7/14 experiments by 70 \pm 7% from pretreatment levels and delayed growth in additional 3 experiments. Overall, tumor burden in control- and bortezomib-treated mice was increased by 519 \pm 85% and 202 \pm 68% from pretreatment, respectively (p<0.003). Whereas in control mice BMD of the implanted bone was reduced by 15.2 \pm 5.7%, in bortezomib-treated hosts it increased by 5.4 \pm 11% from pretreatment (p<0.03). Increased bone formation by bortezomib was more profound in responding hosts (r=-0.58 between BMD and hIg changes in responding hosts) and was not observed in hosts responding to melphalan. Furthermore, clinical response and bone histomorphometric changes (assessed by micro-CT) in patients who received bortezomib as a single agent were consistent with bortezomib's effects in mice engrafted with MM cells from those patients. Histological examination revealed increased numbers of osteocalcin-expressing osteoblasts (34 \pm 7 vs. 13 \pm 3 in controls, p<0.03) and reduced numbers of multinucleated TRAP-expressing osteoclasts (10 \pm 3 vs. 28 \pm 7 in controls, p<0.02) in myelomatous bones from bortezomib-treated hosts. We further demonstrated that bortezomib (2.5-5 nM) directly induced differentiation of human MSCs into osteoblasts and prevented formation of TRAP-expressing multinucleated osteoclasts (p<0.03) via downregulation of NF-kappaB activity in osteoclast precursors. We conclude that bortezomib promotes bone formation in MM by simultaneously inhibiting osteoclastogenesis and stimulating osteoblastogenesis, and thus, is a potent agent for treating MM and its associated bone disease.

WISP-1/CCN-4 a Novel Target for Inhibiting Prostate Cancer Growth in Bone. C. I. Inkson*, T. M. Kilts*, L. W. Fisher, M. F. Young. Craniofacial and Skeletal Diseases Branch, National Institute of Dental and Craniofacial Research, Bethesda, MD, USA.

WISP-1/CCN-4 is a member of CCN family of cysteine-rich secreted proteins implicated in the progression of breast, colonic and gastric cancers. Recent studies indicate that WISP-1 can regulate osteogenic progenitor cell function in vitro and in vivo. The goal of our study was to examine WISP-1 expression in prostate tumors, and then to test the possibility that by inhibiting WISP-1 we could reduce prostate tumor growth. We have developed an antibody to WISP-1 which was used to localize WISP-1 expression in various grades of prostate cancer and normal prostate tissue. WISP-1 expression was found predominantly in early to mid stage cancers, mostly localized to large areas of stromal tissue within these tumors that co-localized with areas of alpha-SMA expression. Expression was also apparent in some transformed ductal epithelial cells and small blood vessels. However, only weak expression of WISP-1 could be observed in normal prostate tissue. Next we tested whether our antibody could block WISP-1 activity thereby preventing tumor growth of the PC3 prostate cancer cells in vivo. To do this, PC-3 cells containing a luciferase gene (PC3-luc) were incubated with 100ug/10,000 cells WISP-1 affinity purified antibody (ab), an iso-type control ab, or PBS for 1 hour and then injected subcutaneously to form tumors in nude mice. The extent of tumor development was analysed by measurement of growth dimensions using callipers, as well as by measurement of luciferase expression using the Xenogen Live Bioluminescent Imaging System. Twice weekly intra-peritoneal (IP) injections of 100ug WISP-1 ab suppressed the size and growth rate of these subcutaneous growths in comparison to mice treated with 100ug of a control ab or PBS. In a second approach, we used an intra-cardiac (IC) injection model to test the possibility that by inhibiting WISP-1 we could obstruct growth of circulating prostate cells in the bone microenvironment. PC3-luc cells were pre-treated with 100ug/10,000 cells WISP-1 ab, control ab or PBS and then administered via IC injection into nude mice (N=6 per treatment). Bioluminescence was analyzed over a 4 week period to determine tumor formation and growth. Cells pre-incubated with the WISP-1 ab had significantly less tumor establishment than PBS or control ab pre-treated cells, and unlike the untreated cells, tumors were limited to the craniofacial region. Furthermore, twice weekly IP injection of 100ug WISP-1 antibody suppressed the growth rate of these tumors compared to control ab or PBS-injected mice. Our data implies WISP-1 may play a role in prostate cancer growth in bone and may prove a novel target for future therapeutics.

Hypoxia-Inducible Factor 2 α Induces Type X Collagen and Promotes Hypertrophic Differentiation of Chondrocytes. T. Saito¹, T. Ikeda^{*2}, A. Higashikawa¹, Y. Kawasaki¹, A. Kan¹, M. Ushita¹, S. Ohba², F. Yano², K. Nakamura¹, U. Chung², H. Kawaguchi¹. ¹Sensory & Motor System Medicine, University of Tokyo, Tokyo, Japan, ²Division of Tissue Engineering, University of Tokyo, Tokyo, Japan.

Although hypertrophic differentiation of chondrocytes is a crucial process in endochondral ossification, the underlying molecular mechanism remains unclear. The present study initially performed the screening of transcription factors using HeLa cells transfected with a luciferase-reporter construct containing a 1.2 kb human promoter of type X collagen (COL10A1), the representative marker for hypertrophic chondrocytes. Among over 200 transcription factors known to be expressed in chondrocytes, we identified hypoxia-inducible factor 2 α (HIF2A) as the strongest transactivator of the COL10A1 promoter. The activity was more than twice that of Runx2, a representative transcription factor of COL10A1. In vivo expression of HIF2A was shown by immunohistochemistry to be localized in the pre-hypertrophic and hypertrophic chondrocytes of the mouse growth plate. In addition, during differentiation of cultured mouse chondrogenic cell line ATDC5 in the presence of insulin, the HIF2A mRNA level determined by real-time RT-PCR was increased simultaneously with that of COL10A1. To investigate the functional relevance of HIF2A to chondrocyte hypertrophy, we established stable lines of ATDC5 cells overexpressing HIF2A or the dominant negative (DN) HIF2A mutant through retroviral introduction. The COL10A1 mRNA level, as well as ALP and Alizarin red stainings, were increased by the HIF2A overexpression, whereas all were decreased by the DN mutant overexpression, as compared with respective GFP-introduced control cells. We further examined the mechanism of induction of COL10A1 by HIF2A. Among several hypoxia-responsive elements in the COL10A1 promoter, site-directed mutagenesis analysis determined the responsive region of HIF2A in intron 1. Electrophoretic mobility shift assay revealed specific binding of in vitro-translated HIF2A protein with the oligonucleotide probe of the region, but not with the mutated probe. The competition assay using unlabeled probes and the super-shift assay using the antibody to HIF2A confirmed the specific binding of HIF2A and the region. Furthermore, the chromatin immunoprecipitation assay confirmed their in vivo binding. In conclusion, the present study identified HIF2A as a potent transcription factor for COL10A1 and hypertrophic differentiation of chondrocytes. Elucidation of the signaling related to the HIF2A / COL10A1 axis will lead to further understanding of the molecular network of chondrocyte differentiation during endochondral ossification.

Expression of Ca²⁺ Receptors in Cartilage Is Essential for Embryonic Skeletal Development In Vivo. C. Tu*, H. Elalieh*, T. Chen*, B. Liu*, M. Hamilton*, D. Shoback, D. Bikle, W. Chang. Endocrine Research Unit, VAMC, University of California San Francisco, San Francisco, CA, USA.

The Ca²⁺ receptor (CaR), a G-protein coupled receptor, is expressed in the growth plate with highest levels in the mineralizing hypertrophic zone. In cultured growth plate chondrocytes (GPCs), CaRs are critical for promoting terminal differentiation. Their impact on growth plate development in vivo is unclear. GPCs from a general CaR-knockout mouse (^{CaR}^{-/-}) (Ho et al, Nature Med, 1993) express alternatively spliced CaRs lacking exon 5 and respond to changes in the extracellular [Ca²⁺] ([Ca²⁺]_e) comparable to wild-type (wt) GPCs -- suggesting an incomplete knockout. Severe hypercalcemia and hyperparathyroidism and early death have precluded definitive assessment of CaR function in postnatal growth unless the hyperparathyroidism was corrected. To address this, we generated cartilage-specific CaR^{-/-} (^{CaR}^{CaR}^{-/-}) mice using Cre/lox recombination by inserting loxP sites flanking CaR exon 7, which encodes the transmembrane and intracellular loops of the CaR, and injecting the construct into mouse ES cells. CaRs transcribed from CaR exon 1-6 cDNA did not reach the membrane, respond to high [Ca²⁺]_e, or block signaling by wt CaRs. Germline transmission of the floxed-CaR (CaR^{lox/lox}) was achieved. Cre recombinase (Cre) could excise CaR exon 7 when CaR^{lox/lox} GPCs were infected with adenoviruses expressing Cre. ^{CaR}^{CaR}^{-/-} mice were made by breeding CaR^{lox/lox} mice with transgenic (Tg) mice expressing Cre driven by a Col(II) promoter [Col(II)-Cre] and backcrossing to CaR^{lox/lox} mice to generate homozygous knockouts. Homozygous knockout is embryonic lethal: no ^{CaR}^{CaR}^{-/-} mice were born alive in 25 litters (~200 pups) or found at embryonic (E) stages 14-16 (6 litters). In 56 embryos (6 litters for E12 and E13), only 2 homozygous ^{CaR}^{CaR}^{-/-} mice were found. Both showed delayed formation of primary ossification centers and unmineralized calvariae and long bones. To study the role of CaRs in postnatal growth, we bred CaR^{lox/lox} mice with Tg ^{CaR}^{ER^{Cre}} mice which express cDNA encoding a fusion protein (Cre-ER^{Tam}) containing Cre and a mutated ligand-binding domain of the estrogen receptor conferring tamoxifen (Tam) sensitivity. The Cre-ER^{Tam} is controlled by a mouse Col(II) promoter for cartilage-specific expression. Homozygous ^{CaR}^{Cre-ER^{Tam}}/CaR^{lox/lox} mice are viable and fertile. Two consecutive maternal injections of 4OH-Tam 2-4 days before birth induced excision of CaR exon 7 in neonates. Analyses of Tam-induced ^{CaR}^{CaR}^{-/-} mice are in progress. This work shows for the first time a non-redundant role for CaRs in growth plate development in vivo and indicate that exon 5-less CaRs can compensate for the loss of full-length CaR in the ^{CaR}^{CaR}^{-/-} mice.

Conditional Deletion of Fibronectin in Osteoblasts Reveals Distinct Roles in Orchestrating Assembly of Bone ECM Proteins and in Osteoblast Differentiation. Q. Chen¹, J. Zhao^{*1}, M. R. Dallas^{*1}, D. M. Pacicca^{*2}, R. Fassler^{*3}, S. L. Dallas¹. ¹Univ. of Missouri, Kansas City, Kansas City, MO, USA, ²Children's Mercy Hospitals & Clinics, Kansas City, MO, USA, ³Max Planck Institute of Biochemistry, Martinsried, Germany.

Fibronectin (FN) is an extracellular matrix (ECM) glycoprotein that is expressed at sites of bone formation and is important for osteoblast function. Conventional knockout of the FN gene is early embryonic lethal and therefore its role in the skeleton is unclear. Previous studies using FN-null embryonic fibroblasts differentiated with BMP2 have shown that FN was required for osteoblast mineralization, through its role in controlling assembly of multiple bone ECM proteins. To further determine the role of FN in the skeleton we have used an in vivo and in vitro conditional knockout approach. Mice with a deletion of FN in osteoblasts (FNcKO) were generated by crossing FN floxed mice with mice expressing Cre recombinase driven by the 3.6kb Col1a1 promoter. The numbers of FNcKO live births were 60% less than expected, suggesting lethality. Surviving FNcKO mice were fertile but were smaller than control littermates, with a 10-35% reduction in body weight. At 6wks, the FNcKO mice showed a 3-10% reduction in the length and width of the tibia and femur and reduced cortical thickness. Bone mineral density and bone mineral content of the whole body, spine, femur and tail vertebrae were significantly decreased. 100% of the FNcKO mice showed a kinky tail phenotype, ranging from involvement of a single vertebra to involvement of all tail vertebrae. Occasionally, a curved spine phenotype was also observed, resembling congenital scoliosis. Decreased FN in the skeleton was associated with decreased staining for type I collagen and decorin. A key role for FN in bone ECM assembly was confirmed in FN floxed primary osteoblast cultures infected with adenovirus expressing Cre (Ad-CMV-Cre) to achieve an in vitro deletion of FN. The Ad-CMV-Cre-infected cultures showed a 90% reduction of FN compared to untreated or Ad-CMV-GFP treated controls. Lack of FN was associated with reduced alkaline phosphatase (AlkP) and impaired assembly of bone ECM proteins, including type I collagen, decorin, biglycan, LTBP1 and fibrillin-1, a known regulator of BMPs. Both AlkP expression and assembly of ECM proteins were rescued by addition of intact FN to the cultures, but not by a panel of shorter FN fragments, covering the complete FN molecule. BMP2 alone rescued AlkP expression but not the assembly of bone ECM proteins. These data suggest that FN is critical for normal development of the skeleton and for normal osteoblast function and is a key regulator of assembly of bone ECM proteins. The effects of FN on differentiation may be mediated by BMP2, while those on ECM assembly may be BMP2-independent.

Connective Tissue Growth Factor (CTGF) Causes Osteopenia In Vivo. A. Smerdel-Ramoya, S. Zanotti, L. Stadmeier*, E. Canalis. Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

CCN are highly conserved proteins, which include Cyr 61, connective tissue growth factor (CTGF). Nephroblastoma overexpressed (Nov) and Wnt induced secreted proteins. CCN proteins are expressed in skeletal cells and ctgf null mutations have demonstrated that CTGF plays a role in developmental chondrogenesis in vivo. However, the function of CTGF in the post natal skeleton is not known. To define the function of CTGF in the skeleton in vivo, we created transgenic mice expressing CTGF under the control of a 3.8 kilobase fragment of the human osteocalcin promoter in an FVB genetic background. Two transgenic lines were established. Four week old CTGF transgenic mice were compared to wild type littermate controls of identical age, sex and genetic composition. CTGF overexpression was confirmed in calvarial extracts by real time RT-PCR, which revealed 150 times higher levels of CTGF mRNA in transgenics than control mice. CTGF transgenics exhibited osteopenia, with a 50% decrease in trabecular bone volume, due to a decrease in trabecular number. This phenotype was analogous in male and female CTGF transgenics. There was a 20% increase in osteoclast surface/bone surface and osteoclast number/perimeter, and a tendency toward an increase in eroded surface/bone surface, without a compensatory increase in mineral apposition rate or bone formation rate. Osteoblast number/perimeter and surface were not changed. To examine the mechanism for the lack of a bone forming response, marrow stromal cells from CTGF transgenics were studied. Confirming the BMP antagonistic activity of CTGF, cells from CTGF transgenics displayed a reduced response to BMP on mothers against decapentaplegic (Smad) 1/5 phosphorylation, and a modest reduction in alkaline phosphatase activity. In conclusion, CTGF overexpression in vivo causes osteopenia, by enhancing bone resorption and preventing a bone forming response, possibly by antagonizing BMP signaling.

Selective Deletion of Fibronectin in Osteoblasts Affects Bone Density and Osteoblast Function. A. Bentmann*, N. Kawelke*, I. Nakchbandi².

¹University of Heidelberg, Heidelberg, Germany, ²University of Heidelberg and Max-Planck Institute for Biochemistry, Heidelberg, Germany.

Bone extracellular matrix consists mainly of collagen (90%), with fibronectin consisting only a small portion. In vitro data however have established an absolute requirement for fibronectin for the assembly of collagen to take place. We therefore postulated a defect in matrix assembly that may affect bone density in mice in which fibronectin is deleted in the osteoblasts.

Mice that are homozygous for fibronectin die in utero. We therefore used the Cre-loxP strategy to produce mice that are deficient in fibronectin produced by the osteoblasts. Mice with the genotype collagen alpha1(I)-Cre (1.6 kb)/+ were mated with mice carrying the fibronectin floxed gene (fibronectin floxed/floxed) over two generations to obtain mice with the following genotype: alpha1(I)-Cre (1.6 kb)/+ _fibronectin floxed/floxed. These mice will delete fibronectin in cells that express collagen alpha1(I); i.e., osteoblasts. At 4 months of age female mice were euthanized and bones harvested for further analysis.

There was a significant decrease in bone mineral density of the femur in conditional knockout mice (cKO) as measured using peripheral quantitative computer tomography in total bone (6% decrease in bone mineral density compared to controls; n=14 for controls and 8 for cKO, p<0.01), and in trabecular bone (12% decrease, p<0.05). Histomorphometry showed a 50% increase in osteoblast number adjusted to bone surface (27 ± 2 in cKO vs. 17 ± 1 in controls, n=5 for both, p<0.05), a 34% increase in osteoid surface adjusted to bone surface (p<0.01), a 15% decrease in the osteoid surface per osteoblast (p<0.005), and a 64% increase in mineralization lag time (p<0.05).

In summary, production of fibronectin by osteoblasts is required for a normal bone mineral density in female mice. In the absence of fibronectin production each osteoblast lays down less osteoid than a normal osteoblast, but due to the presence of a larger number of osteoblasts more osteoid gets laid down. This osteoid lags behind in its mineralization confirming in vitro data that fibronectin is required for normal mineralization by osteoblasts (Moursi A. et al. 1996 and Chen Q et al. 2006).

These data suggest that fibronectin production by osteoblasts via a feedback loop regulates osteoblast number, production of matrix and mineralization. Thus we were able to prove in vivo a role for locally produced fibronectin in modulating osteoblasts, and to show that fibronectin production by collagen alpha1(I) expressing osteoblasts mediates 6% of bone mineral density of the total bone and 12% of trabecular bone density in adult female mice.

Mis-expressions of SOX9 During Skeletogenesis Lead to Accelerated Adipogenesis in Transgenic Mice. B. Liang¹, D. Chen^{*1}, B. Lee², G. Zhou¹.

¹Department of Orthopaedics, Case Western Reserve University, Cleveland, OH, USA, ²Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA.

During development mesenchymal cells can differentiate into adipocytes, chondrocytes, myoblasts, and osteoblasts as determined by different cell-type specific transcription factors. Among them SOX9 is a positive regulator for chondrogenesis while RUNX2 acts as a transcriptional activator essential for osteoblasts differentiation and chondrocytes maturation. RUNX2 also represses adipocytes differentiation and RUNX2 deficiency in chondrocytes showed enhanced adipogenesis. We have previously reported that SOX9 could severely inhibit RUNX2 function in the osteoblasts of a Col1a1-SOX9 transgenic mouse model in which SOX9 was specifically expressed in osteoblasts by a 2.3kb Col1a1 promoter. In this study to investigate the effects of SOX9 on mesenchymal stem cells (MSCs) differentiation, we isolated MSCs from the bone marrows of Col1a1-SOX9 transgenic mice and induced adipocytes and osteoblasts differentiation in vitro. While there were no significant differences in the number of osteoblast precursor cells by alkaline phosphatase assay between wild-type and transgenic mice, Col1a1-SOX9 MSCs exhibited decreased osteogenic differentiation by Alizarin Red staining. Interestingly Col1a1-SOX9 MSCs also displayed enhanced adipocytes differentiation by Oil Red-O staining. To directly investigate inhibitory effects of SOX9 on RUNX2 during chondrocytes hypertrophy, we have also generated a novel Col10a1-SOX9 transgenic mouse model in which SOX9 is specifically expressed in hypertrophic chondrocytes driven by a 10kb Col10a1 promoter. In monolayer culture of rib hypertrophic chondrocytes (HC) isolated from 6-day-old mice, expression of Col10a1, a downstream target of RUNX2, was decreased by 55% in Col10a1-SOX9 transgenic mice by quantitative RT-PCR. Additionally mineralized hypertrophic cartilage areas were significantly reduced by 10% (p<0.05) in 10-week-old proximal tibia of Col10a1-SOX9 transgenic mice by von Kossa staining. Furthermore in comparison with wild-type mice, Col10a1-SOX9 HC culture also displayed increased adipogenesis with more lipid droplets accumulation by Oil Red-O staining and higher expression levels of adipogenic genes including C/EBPα, PPARγ2, SCD1 and Glut4. In conclusion, our work suggests that during mesenchymal cells differentiation repression of RUNX2 function by SOX9 not only results in impaired osteogenesis and hypertrophic cartilage mineralization, it also leads to enhanced adipogenesis via relieving RUNX2 inhibition of adipocytes differentiation.

Molecular Interaction Between Bcl-xL and Bnip3 Determines the Cell Fate of Hypertrophic Chondrocytes. Y. Oshima¹, T. Akiyama^{*1}, M. Iwasawa¹, Y. Nagase¹, L. Hennighausen^{*2}, K. Nakamura¹, S. Tanaka¹.

¹Orthopaedic Surgery, The University of Tokyo, Tokyo, Japan, ²Laboratory of Genetics and Physiology, National Institutes of Health, Bethesda, MD, USA.

During endochondral ossification, chondrocytes undergo hypertrophic differentiation and die by apoptosis. The level of inorganic phosphate (Pi) elevates at the site of cartilage mineralization, and previous studies have proposed that Pi entry into hypertrophic chondrocytes may act as an apoptogen. The Bcl-2 family proteins, which consist of pro- and anti-apoptotic members, are major regulators of mitochondria-initiated apoptosis. To investigate their role in determining the cell fate of chondrocytes, we used chondrogenic ATDC5 cells that differentiate into hypertrophic state in the presence of insulin. When differentiated ATDC5 cells were treated with Pi, they mineralized the surrounding matrix and underwent rapid apoptosis as evidenced by nuclear condensation, Caspase-3 & 7 activation, and Lamin proteolysis. With this system, we analyzed the role of pro- and anti-apoptotic Bcl-2 members in chondrocyte apoptosis. Among 15 pro-apoptotic Bcl-2 members, 7 molecules increased their expression levels during the course of hypertrophic differentiation, and two in response to Pi stimulation. Of these, gene silencing of a proapoptotic BH3-only molecule bnip3 by RNA interference significantly suppressed Pi-induced apoptosis. Conversely, among anti-apoptotic members examined, overexpression of bcl-xL suppressed, and its knockdown promoted apoptosis. The susceptibility to apoptosis by bcl-xL knockdown was partially restored by simultaneous silencing of bnip3. Pi treatment markedly upregulated the protein level of Bnip3 without affecting Bcl-xL levels. Bnip3 was associated with Bcl-xL and attenuated its anti-apoptotic effect in chondrocytes. Immunohistological examination of murine growth plates revealed that Bcl-xL expressed uniformly in the growth plate chondrocytes, whereas Bnip3 expression was exclusively localized in the hypertrophic chondrocytes. Finally, we generated chondrocyte-specific bcl-xL knockdown mice using the Cre-loxP recombination system, and provided evidence that the hypertrophic chondrocyte layer was markedly shortened in those mice owing to massive chondrocyte apoptosis and that the mice exhibited dwarfism as a result. Furthermore, Bnip3 expression was decreased in hypertrophic chondrocytes in mice fed with a low phosphate diet, and the abnormalities in the growth plate were almost completely rescued. In summary, increase in Pi levels in hypertrophic zone causes upregulation of Bnip3 in chondrocytes, which binds to Bcl-xL and consequently impairs its anti-apoptotic effect, and finally causes apoptosis of the cells.

p63 Plays a Central Role in Cartilage Development by Directly Regulating Key Genes for Chondrogenesis. T. Ikeda¹, H. Kawaguchi², T. Saito², A. Kan², F. Yano¹, M. Ushita², Y. Kawasaki², K. Nakamura^{*2}, U. Chung¹. ¹Div of Tissue Engineering, Graduate School of Medicine, The Univ of Tokyo, Tokyo, Japan, ²Orthop Surg, Graduate School of Medicine, The Univ of Tokyo, Tokyo, Japan.

To understand the molecular network underlying chondrogenic differentiation, we identified the embryonic SOX6 promoter and its core enhancer CES6. Using the 4 x CES6 as bait for bio-panning of cartilage-derived phage display libraries, we identified a p53 family gene p63 as a CES6-binding transcription factor. Luciferase-reporter assay revealed that p63 transactivated not only SOX6 promoter, but also promoters of type II collagen (COL2A1) and SOX9. Among the three alternative splicing variants α , β and γ , p63 β exhibited the strongest activity. When multi-tissue expression was evaluated by real-time RT-PCR, p63 was mainly expressed in the tracheal cartilage, testis and prostate. Overexpression of p63 in non-chondrogenic cell line HeLa caused rapid induction of SOX6 and COL2A1 expressions, which were 2-3 fold greater than that by overexpression of SOX9, the representative transcription factor for chondrogenesis. Furthermore, retroviral overexpression of p63 into de-differentiated mouse costal cells after a long period of culture induced their re-differentiation to chondrocytes with enhanced Alcian blue staining and increased COL2A1, SOX6 and SOX9 mRNA levels. By combining luciferase-reporter assay, electrophoretic mobility shift assay, and chromatin immunoprecipitation, we identified the direct binding sites of p63 β in CES6 of SOX6 and in the proximal promoters of the SOX9 and COL2A1. The identified sequences were 1-2 bp different from the known p53 binding motif "RRRCWWGYYY". To further learn the endogenous function of p63, we investigated the skeleton of p63 knockout (p63^{-/-}) mouse embryos that exhibited severe short limb deformities. The expressions of SOX6, SOX9 and COL2A1 were rarely detectable in limb buds of p63^{-/-} embryos around E12-13 by whole mount in situ hybridization. Although a small cartilage was barely formed after E17, the SOX6, SOX9 and COL2A1 expressions were decreased compared to those in the wild-type littermates. Since BrdU uptake was comparable between p63^{-/-} and wild-type limb buds, the impaired cartilage development by the p63 deficiency may be due to a defect in chondrogenic differentiation, but not in proliferation, of mesenchymal cells. In conclusion, we identified a novel chondrogenic transcription factor p63 which may play a central role in cartilage development by directly regulating key genes for chondrogenesis like SOX6, SOX9 and COL2A1. Further understanding of molecular network related to p63 will herald a new era of cartilage regenerative medicine.

Atf4 Regulates Chondrocyte Proliferation and Differentiation by Direct Targeting Indian Hedgehog Transcription. W. Wang^{*}, X. Yang. Center for Bone Biology, Departments of Medicine and Pharmacology, Vanderbilt University, Nashville, TN, USA.

Indian Hedgehog plays a critical role in growth plate biology, and understanding the regulation of its expression is important for our understanding of endochondral bone formation. In studies on Atf4, a CREB-related transcription factor required for osteoblast differentiation and function (Yang & Karsenty, 2004), we noted evidence that Atf4 also affects cartilage biology. For example, Atf4-deficient (Atf4^{-/-}) mice are small in size with shorter limbs suggesting a defect in endochondral bone formation. We found that Atf4 whose cell-specificity is regulated at protein level (Yang et al., 2004) is expressed in chondrocytes by Western blot analysis using an antibody against Atf4. To determine whether Atf4 mutant mice display abnormalities of growth plate chondrocytes, we examined Atf4^{-/-} newborns in details by histological analysis, BrdU-labeling of dividing cells, and in situ hybridization. Compared to their wildtype counterparts, Atf4^{-/-} newborns exhibit 1) a delay in hypertrophic mineralization, 2) an expansion of the hypertrophic zone, 3) a decrease in BrdU positive proliferating chondrocytes, and 4) a dramatic decrease in the expression of the Indian Hedgehog (Ihh), a key regulator coordinating the chondrocyte proliferation and differentiation in endochondral bone formation in the prehypertrophic chondrocytes. Consistent with these in situ hybridization results, we also detected a decrease in Ihh mRNA expression in the Atf4^{-/-} chondrocytes. Based on these observations we hypothesize that Atf4 may play a central role in controlling chondrocyte proliferation and differentiation by direct targeting Ihh transcription. To test this hypothesis, we cloned a 5 kb promoter fragment of the Ihh gene from a BAC genomic DNA clone and made 5 Ihh promoter driven-luciferase reporter constructs that contain different lengths of the Ihh promoter sequences. Co-transfection assays using these reporter constructs and Atf4 expression vector showed that ATF4 indeed was able to transactivate the Ihh promoter with maximal observed activation in a reporter construct containing 742 base-pairs of the Ihh proximal promoter sequence, pIhh742-Luc. By visual scanning we found 9 putative Atf4 binding sites (A1 to A9) within this fragment. Gel retardation assays showed that Atf4 bound strongly to A9 and weakly to A1 to A8. Deletion of A9 led to a decrease in ATF4 transactivation activity on the pIhh742-Luc by 60%, suggesting that Atf4 activates the Ihh gene through A9. Taken together, our findings identify Atf4 as a physiological activator of Ihh gene and a regulator of chondrocyte proliferation and differentiation by directly targeting Ihh gene transcription.

Trps1 Transcription Factor Regulates Chondrocyte Hypertrophy and Perichondrial Mineralization through Repression of Runx2. D. Napierala¹, K. Sam^{*1}, R. Morello¹, T. Bertin^{*1}, Q. Zheng¹, T. Sibai^{*1}, R. Shivdasani^{*2}, B. Lee¹. ¹Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, ²Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA, USA.

Mutations involving the TRPS1 gene cause tricho-rhino-phalangeal syndrome (TRPS) characterized by short stature, cone-shaped epiphyses, premature closure of growth plates and distinctive craniofacial appearance. During mouse skeletal development Trps1 is highly expressed in chondrogenic mesenchymal condensations, prehypertrophic chondrocytes, joint mesenchyme and perichondrium. Trps1 is a transcription repressor that contains nine zinc-fingers including GATA-type and Ikaros-type domains. To elucidate the role of Trps1 in endochondral bone formation, we analyzed Trps1 mutant mice deleted for the GATA DNA-binding domain (Trps1 Δ GT mice). Histological analysis of long bones of E18.5 embryos showed reduced size of bone marrow cavity due to expansion of cartilaginous part in homozygous Trps1 Δ GT mice. Morphometric analyses and RNA in situ hybridization demonstrated that zones of proliferating, prehypertrophic and hypertrophic chondrocytes are elongated in Trps1 Δ GT mice in comparison with WT littermates. Moreover, the Trps1 mutant mice demonstrated advanced mineralization of perichondrium. Both mineralization and chondrocytes maturation are regulated by the Runx2 transcription factor, therefore we tested the potential interaction of Trps1 and Runx2 in vitro. Cotransfection experiments demonstrated that Trps1 can repress the Runx2-mediated transactivation of the target reporter. Moreover, the C-terminal part of the Trps1 protein physically interacts with the runt domain of Runx2 in the GST pull-down assay. In conclusion, our data indicate that Trps1 regulates the growth plate mineralization and chondrocyte hypertrophy, and that could be partially through the repression of the Runx2 protein function.

Identification of a Novel Chondrogenic Factor Sorting Nexin 19 Using a Real-Time Fluorescence Monitoring Cell Line ATDC5-S2RD5. A. Kan, T. Ikeda, T. Saito, U. Chung, H. Kawaguchi. Sensory & Motor System Medicine, Tissue Engineering, University of Tokyo, Tokyo, Japan.

To identify chondrogenic factors, the present study initially attempted to establish a monitoring system that could detect chondrogenic differentiation in a precise, noninvasive and real-time manner. For this purpose, we identified a 49 bp region including a SOX9 binding enhancer in intron 1 of type II collagen (COL2A1) gene, which was highly conserved among human, mouse and rat. We then established several lines of mouse chondrogenic ATDC5 cells stably transfected with four tandem copies of the 49 bp region cloned upstream of the COL2A1 promoter and DsRed2 fluorescence reporter gene. Among them, we selected a clone ATDC5-S2RD5 that fluoresced not only upon chondrogenic stimulation by insulin, but also by BMP-2, TGF β , and SOX9 / SOX6 co-transfection. This cell line was confirmed to show increases in COL2 mRNA level and Alcian blue staining by the stimulations above. We then created retroviral expression libraries from human tracheal cartilage and mouse embryos, and applied the ATDC5-S2RD5 cell line to the expression cloning for their screening. Among several genes that caused fluorescence in the system, sorting nexin (SNX) 19, a member of the SNX family, intracellular transportation proteins whose insufficiency causes skeletal dysplasia in human, exhibited strong fluorescence. Multi-tissue expression analysis by real-time RT-PCR confirmed the SNX19 expression in cartilage, and the subcellular localization was shown to be limited in the cytoplasm by immunostaining with an anti-myc-FITC antibody in HeLa cells overexpressing myc-SNX19. To learn the functional relevance of SNX19 to chondrogenic differentiation, we established ATDC5 cells and mouse primary costal cells overexpressing SNX19 or the siRNA through retroviral transfection. COL2 mRNA level by real-time RT-PCR and the promoter activity by luciferase-reporter assay were increased by the SNX19 overexpression, whereas they were decreased by the knockdown. Among signaling molecules ERK, p38 MAPK, JNK, Akt, I κ B, Smads and GSK3 β , the SNX19 overexpression enhanced phosphorylation of p38. SB203580, a specific inhibitor of p38, suppressed COL2 expression induced by the SNX19 overexpression. In conclusion, we established a real-time fluorescence monitoring cell line for chondrogenesis ATDC5-S2RD5. Using it, we identified a novel chondrogenic factor SNX19 which was a cytoplasmic protein related to the p38 signaling. Further screening of molecules using this monitoring cell line will elucidate the molecular network underlying chondrogenic differentiation.

Osteal Macrophages: Novel Regulators of Bone Formation. L. J. Raggatt¹, M. K. Chang^{*1}, K. A. Alexander^{*1}, J. S. Kuliwaba², N. L. Fazzalari², D. A. Hume^{*1}, A. R. Pettit¹. ¹Institute for Molecular Bioscience, Cooperative Research Centre for Chronic Inflammatory Diseases, University of Queensland, Brisbane, QLD, Australia, ²Institute of Medical and Veterinary Sciences and Hanson Institute, University of Adelaide, Adelaide, SA, Australia.

Resident tissue macrophages are an integral component of many tissues and are important in immunity, homeostasis and repair. Macrophages have been implicated in both bone destruction and osteophyte formation in bone diseases, suggesting these cells may also be associated with osteal tissues. We report here that resident tissue macrophages (referred to as OsteoMacs) are present on the endosteal surface of human trabecular bone. We have extended these observations using the murine tissue macrophage marker F4/80 to investigate fully the anatomical distribution of OsteoMacs in mouse bones. Immunohistochemistry demonstrated F4/80⁺ OsteoMacs are intercalated in bone lining tissues. OsteoMacs were also closely associated with bone remodelling units in the secondary spongiosa but are not TRAP⁺ mononuclear osteoclast precursors. Importantly, OsteoMacs formed a cell layer over bone forming osteoblasts (OB, collagen type 1⁺ and osteocalcin⁺) on growing cortical surfaces. Histomorphometric analysis showed that on cortical endosteal surfaces 75.9±5.3% of the OB bone surface was covered by a F4/80⁺ cell 'canopy', indicating that OsteoMacs and OB are intimately associated in vivo and that OsteoMacs may regulate OB function. We examined the effect of OsteoMacs on OB functional responses to elevated extracellular calcium (eCa²⁺), as eCa²⁺ is unique to the bone microenvironment and induces macrophage expression of the osteo-inductive molecule BMP-2. Using a co-culture system of macrophages with OB, in either direct contact or separated using transwells, we demonstrated that OB mineralization occurred in response to eCa²⁺ only in the presence of macrophages. At no stage were OB exposed to the classical differentiation agents ascorbate and beta-glycerolphosphate, yet macrophage enhanced OB mineralization occurred rapidly (7 days). Conditioned medium from eCa²⁺ stimulated macrophages also induced mineralization of OB cultures, indicating that macrophages produce a soluble factor that enhances OB mineralization. However addition of recombinant noggin or soluble BMPRI to co-cultures did not inhibit macrophage-induced OB mineralization, indicating that BMP-2 is not the osteo-inductive molecule. These observations suggest macrophages detect changes in eCa²⁺ and consequently produce soluble factor(s) that drive OB mineralization. We propose that OsteoMacs are an integral component of osteal tissues and play a novel role in bone homeostasis through regulating OB function and orchestrating bone formation.

Upregulation of Calcium-sensing Receptor Gene Expression by the Proinflammatory Cytokine, Interleukin-6: In Vivo and In Vitro Studies. L. Canaff^{*}, K. Schorr^{*}, G. N. Hendy. Medicine, McGill University, Montreal, PQ, Canada.

Increased calcium-sensing receptor (CASR) expression in parathyroid gland, thyroid C-cells, and kidney tubule leads to a decrease in the extracellular calcium set-point, thereby reducing parathyroid hormone (PTH) secretion and renal calcium reabsorption and increasing calcitonin secretion resulting in reduced circulating calcium levels. Hypocalcemia is common in critically ill patients with burn injury and/or sepsis. In such patients, circulating levels of cytokines are increased, with those of interleukin-6 (IL-6) being most marked. In the present study, we have examined the ability of IL-6 to affect the expression of the CASR. In vivo, in the rat, parathyroid, thyroid and kidney CASR mRNA levels increased after intraperitoneal injection of IL-6. Peak values occurred at 16h and remained elevated at 24h. This was associated with decreased circulating calcium and PTH levels. Further in vitro studies were conducted. The human CASR gene has two promoters (P1 and P2) yielding transcripts having alternative 5' untranslated regions (1A and 1B), but encoding the same receptor protein. Activities of human CASR P1 and P2 promoter/luciferase reporter constructs transfected into proximal tubule HKC cells and TT thyroid C-cells were stimulated ~2-3 fold by IL-6. The P1 construct contains 1439 bp upstream of the transcription start (+1), the 638 bp exon 1A and 242 bp of exon 2 before the ATG translation start site. Transfection of P1 deleted and mutated constructs into TT cells revealed that a Stat element within exon 1A accounted for ~70% of the induction by IL-6. Cotransfection of Stat1 (Y701F) or Stat3 (Y705F) dominant negative constructs markedly reduced (~70%) IL-6-stimulated upregulation of the P1 promoter. Pretreatment of TT cells with the MAPK pathway inhibitor U0126 (10 microM) led to significant loss (~30%) of IL-6 upregulation of all the P1 promoter constructs including an exon 1A Stat mutant. The P2 construct has 460 bp upstream of the transcription start (+1), the 259 bp exon 1B and 242 bp of exon 2 before the ATG translation start site. Transfection of P2 deletion constructs into TT cells showed that sequence within -341 to +220 is required for IL-6 responsiveness. There are no Stat elements in the P2 promoter or exon 1B but Sp1 elements are present at the transcription start site (+1). Cotransfection of Sp1 and/or Stat1 or Stat3 dominant negative constructs abolished IL-6 responsiveness of the P2 promoter. In conclusion, a variety of elements in the CASR gene promoters mediate transcriptional upregulation by IL-6, with Stat and MAPK independently and additively controlling promoter P1, and Stat regulating promoter P2 via Sp1.

The Role of Caspase-3 in the Anabolic Actions of PTH in Bone. J. Yamashita¹, D. Yang¹, K. Yamashita^{*1}, E. T. Keller², L. K. McCauley¹. ¹University of Michigan School of Dentistry, Ann Arbor, MI, USA, ²University of Michigan Medical School, Ann Arbor, MI, USA.

Caspase-3 is a crucial component in the signaling of programmed cell death, cell survival, and cell cycle in a variety of cells. It has been reported that caspase-3 functions in osteogenic differentiation of bone marrow stromal cells and that the activation of caspase-3 is essential for osteoclast differentiation. Intermittent PTH is a powerful bone anabolic agent, but the exact mechanisms of PTH action are unclear. It has been hypothesized that PTH may extend the life span of osteoblasts by suppressing apoptosis and the long-living osteoblasts would contribute to enhanced mineral matrix deposition. Because caspase-3 is a pro-apoptotic factor, suppression of caspase-3 could enhance the anabolic effect of PTH in bone. However, the role of caspase-3 in PTH actions is not known. In this study we tested the hypothesis that inhibition of caspase-3 enhances anabolic actions of PTH in bone. Caspase-3 deficient mice were genotyped and the expression of caspase-3 protein verified by Western blotting of spleen lysate. Histomorphometric analysis of the tibiae of day-21 mice showed no significant difference in bone area (%) between caspase-3 wild type (+/+) and knockout (-/-) mice. Calvarial osteoblasts were isolated from caspase-3 +/+ and -/- mice. Cell enumeration showed no difference between caspase-3 +/+ and -/- osteoblasts over the 9 day culture period. To characterize apoptosis of osteoblasts, cells were treated with staurosporine and relative cell numbers versus control were assessed. Caspase-3 -/- osteoblasts ex vivo showed more resistance to staurosporine-induced cell death than +/+, suggesting an important role of caspase-3 in osteoblast survival. To determine the role of caspase-3 in bone formation in response to PTH, daily administration of PTH (50µg/kg/day) was performed on +/+ and -/- mice from day-4 to day-21 of age. Peripheral quantitative computed tomography and histomorphometric analyses showed that both caspase-3 +/+ and -/- mice responded to PTH with substantially increased bone area when compared to vehicle-control groups. Such increased bone mass was more significantly pronounced in caspase-3 -/- mice than +/+ (p<0.05). To further determine whether the inhibition of caspase-3 augments anabolic effect of PTH in osteoporotic bone, caspase-3 +/+ and -/- mice (9 weeks old) were ovariectomized and PTH (80µg/kg/day) administered for 21 days. Daily PTH administration significantly increased bone mass in both genotypes with greater anabolic effect in -/- than +/+ bone. These results suggest that the inhibition of caspase-3 may enhance the anabolic actions of PTH in bone. Caspase-3 could be a target for the prevention and treatment of osteoporosis in conjunction with PTH therapy.

Dissection of the Mechanisms of PTH-mediated Inhibition of Sodium-dependent Phosphate Transport Using a Long-acting PTH(1-28) Analog. S. Nagai, M. Okazaki^{*}, J. T. Potts, H. Jüppner, T. J. Gardella. Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

PTH reduces the reabsorption of inorganic phosphate (Pi) largely through its effects on sodium-dependent phosphate transporters (NaPi-IIa and NaPi-IIc) in renal proximal tubule (PT) cells. The mechanisms by which PTH regulates transporter function in these cells are not clear, particularly in terms of the signaling and protein-trafficking pathways utilized. We now investigated these processes by utilizing a new PTH analog, [Ala^{1,2}, Aib³, Gin¹⁰, Har¹¹, Trp¹⁴, Arg¹⁹]hPTH(1-28)NH₂ {M-PTH(1-28)} that binds to the PTH receptor more stably than does PTH(1-34). The capacity of the analog to inhibit phosphate uptake in opossum kidney (OK) cells, a model PT cell line, was first assessed by a routinely used 4-hour incubation protocol. M-PTH(1-28) inhibited Pi uptake to the same extent (~60%) as did PTH(1-34) (ligand concentrations = 1x10⁻⁷ M). Phosphate transport was then assessed at various time points after incubating the cells with ligand for only 10 minutes followed by extensive rinsing before measuring Pi uptake. Using this protocol, Pi uptake was maximally inhibited by PTH(1-34) two hours after wash-out and returned to basal by 24 hours. In cells treated with M-PTH(1-28), Pi uptake was again maximally inhibited at 2 hours, but remained suppressed for at least 24 hours. Analysis of cAMP production showed that the response to PTH(1-34) diminished to basal by 1 hour after wash-out, whereas that of M-PTH(1-28) continued for at least 6 hours. PTH(1-34) is known to induce the removal of NaPi-IIa from the surface of OK cells; confocal microscopy showed that whereas NaPi-IIa surface expression was restored by 24 hours in cells treated with PTH(1-34), it was completely absent in cells treated with M-PTH(1-28). To explore these differences in ligand activity in vivo, PTH(1-34) and M-PTH(1-28) were injected subcutaneously into mice, and serum Pi was measured. Both ligands suppressed Pi levels maximally at 2 hours, but where Pi levels returned to normal by 4 hours in PTH(1-34)-treated mice, they remained suppressed for 6 hours in M-PTH(1-28)-treated mice. The data show that persistent binding of a PTH agonist to the PTH receptor in renal PT cells can lead to sustained cAMP signaling and sustained down-regulation of NaPi-IIa. The mechanisms by which PTH regulates NaPi-IIa expression and function in PT cells are incompletely understood, but the formation of cAMP appears to be a key signaling event. Moreover, the recovery process occurs more slowly than expected, particularly when assessed with the new analog, M-PTH(1-28). This new PTH analog should be useful in exploring the underlying mechanisms further.

Analysis of PTH-PTH Receptor Interaction Mechanisms Using a New, Long-Acting PTH(1-28) Analog Reveals Selective Binding to Distinct PTH Receptor Conformations and Biological Consequences In Vivo. M. Okazaki*, S. Nagai, T. Dean*, J. T. Potts, T. J. Gardella. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

The PTH/PTHrP receptor (PTHR) is likely to exist in multiple protein conformations. This raises the possibility that different PTH or PTHrP ligands could bind selectively to distinct PTHR conformations and thereby produce different biological effects. Based on recent radioligand binding data, we hypothesize that the PTHR can adopt a novel PTHR conformation, termed R0, that is uncoupled from heterotrimeric G protein but yet can form highly stable complexes with certain PTH ligands, including PTH(1-34). In contrast, PTHrP(1-36) and M-PTH(1-15) (M = Aib1,3,Gln10,Har11,Ala12,Trp14), bind only poorly to R0, and instead bind predominantly to PTHRs in a G protein-coupled conformation (RG). We further hypothesize that R0 can isomerize to RG, and thus contribute to ligand activity. For example, stable binding of a ligand to R0 could result in signaling responses in cells long after the initial ligand-binding event. To test these hypotheses, we investigated the structural features in the ligand and receptor that underlie stable binding to R0 in vitro, and we explored the biological relevance of such binding in vivo. One analog to emerge from the studies was [Ala1,12,Aib3,Gln10,Har11,Trp14,Arg19]hPTH(1-28)NH2 (M-PTH(1-28)). In R0 binding assays, performed using membranes expressing the rat PTHR, 125I-PTH(1-34) tracer radioligand, and in the presence of GTPγS, M-PTH(1-28) bound with 80-fold higher affinity than did PTH(1-34), and more than 200-fold higher than did M-PTH(1-15) or unmodified PTH(1-28). In ROS17/2.8 cells, M-PTH(1-28) produced a more prolonged cAMP response than did the latter three peptides. When injected subcutaneously into mice (50 nmole/Kg), M-PTH(1-28) produced a more prolonged hypercalcaemic response than did PTH(1-34): blood Ca++ induced by PTH(1-34) peaked at 2 hours and returned to vehicle control at 4 hours; whereas, that induced by M-PTH(1-28) peaked at 3 hr, and did not return to control until at least 6 hours. Overall, the studies support the hypothesis that the PTHR can form a stable R0 conformation, and that the extent to which a ligand (e.g. PTH or PTHrP) binds this conformation can determine the biological actions of that ligand in vivo. The capacity of a ligand to bind to R0 requires interaction to the both the juxtamembrane and N-terminal regions of the PTHR, because both the "M" modifications and the 16-28 segment of M-PTH(1-28) are required. Further exploration of the conformational states possible for the PTHR should improve our understanding of how this receptor functions in normal and pathological physiology.

Parathyroid Hormone Expression Is Negatively Regulated by FGF23 in Primary Bovine Parathyroid Cells. T. Krajisnik¹, P. Björklund², R. Marsell², O. Ljunggren¹, G. Akerstrom², K. B. Jonsson², G. Westin², T. E. Larsson¹. ¹Uppsala University Hospital, Dept. of Medical Sciences, Uppsala, Sweden, ²Uppsala University Hospital, Dept. of Surgical Sciences, Uppsala, Sweden.

Fibroblast Growth Factor-23 (FGF23) is a circulating protein that regulates serum levels of inorganic phosphate as well as 1,25(OH)2D3. FGF23 is elevated in chronic kidney disease (CKD), as a response to the prevailing hyperphosphatemia. In addition, high serum FGF23 in CKD is a predictor of future secondary hyperparathyroidism, although the reason for this association is unknown. The objective of the current study was to investigate the effect of FGF23 on parathyroid glands in vitro. For this purpose, we used primary isolates of bovine parathyroid cells. Recombinant FGF23 was produced by transient transfection of the hFGF23(R176Q)-pcDNA3.1-V5-His-TOPO plasmid into COS-7 cells. Conditioned serum-free medium was collected and analyzed for intact FGF23 concentration using an intact FGF23 ELISA. Control medium was obtained by transfection of the pcDNA3.1(+) expression vector. Importantly, we found that Klotho, a FGF23 receptor co-factor, was abundantly expressed in bovine parathyroid cells, as detected by RT-PCR. FGF23-stimulation of parathyroid cells at concentrations of 400-2000 pg/mL was followed by a 2-7-fold increase in Egr-1 mRNA level, a marker of FGF23 signaling (p<0.05). FGF23 potently and dose-dependently decreased the PTH mRNA level within 12 hours in the concentration range 400-2000 pg/mL (p<0.01). In agreement, FGF23 dose-dependently decreased PTH protein secretion into conditioned media at concentrations 700-2000 pg/mL (p<0.05). Finally, FGF23 did not alter cell viability or apoptosis, as determined by flow cytometry analysis. A small but significant increase in cell proliferation was observed (p<0.001), as measured by tritium-labelled thymidine incorporation. We conclude that FGF23 is a potent negative regulator of PTH mRNA expression and protein secretion. Our data indicate that increased FGF23 levels in CKD may, in part, inhibit secondary hyperparathyroidism. This potentially defines a novel function of FGF23 in CKD, besides the previously established role in ameliorating hyperphosphatemia by promoting renal Pi excretion.

Geranylgeranylation Promotes Osteoblast Survival and Is Involved in Anti-apoptotic Effects of PTH. T. Yoshida*, P. H. Stern. Department of Molecular Pharmacology and Biological Chemistry, Northwestern University Feinberg School of Medicine, Chicago, IL, USA.

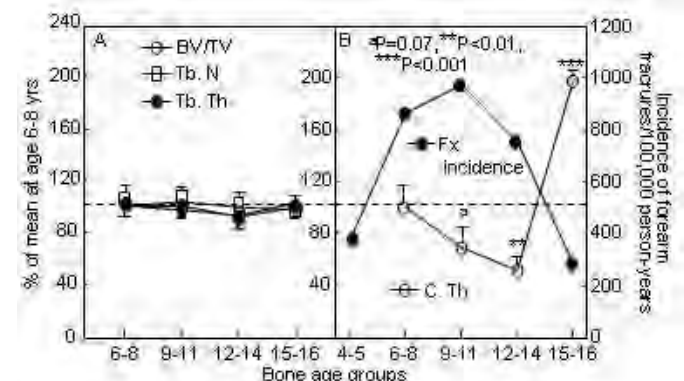

We have previously described a Gα12/Gα13-RhoA-phospholipase D pathway in osteoblastic cells, and found that the pathway is stimulated by parathyroid hormone (PTH). It was therefore of interest to determine the role of the pathway in osteoblast cell function and in parathyroid hormone action on osteoblasts. Studies in other tissues indicate that the pathway is involved in cell survival and influences the apoptotic cascade. Covalent attachment of geranylgeranyl moieties from the donor geranylgeranylpyrophosphate (GGPP) leads to the activation of RhoA, and several studies show that reducing the cellular pool of GGPP by inhibition of HMG-CoA reductase leads to apoptosis. These reports led us to investigate whether the pathway, and specifically geranylgeranylation, could be involved in osteoblast survival and in the anti-apoptotic effects of PTH. We used the geranylgeranyl group donor geranylgeraniol (GGOH) and the geranylgeranyltransferase inhibitor GGTI-2166 as tools to study this. Preosteoblastic MC3T3-E1 cells were seeded at a density of 250,000 cells/well in 6-well plates, and serum starved for 24 hr, a stimulus leading to apoptosis and elevated caspase-3 activity, a central step in the apoptosis cascade. Subsequent treatment with PTH for 6 hr markedly decreased caspase-3 activity. Effects were seen at PTH concentrations as low as 10 pM. In contrast to the effects of short-term exposure, overnight treatment with PTH was not effective. The response to PTH was density-dependent and was attenuated in higher density cultures. GGOH (10 μM) mimicked the effect of PTH, decreasing caspase-3 activity in serum-starved cells. The effects of PTH or fetal bovine serum to decrease caspase-3 activity were antagonized by GGTI-2166, 10 and 30 μM. In cultures of primary mouse osteoblasts, PTH promoted cell survival after serum starvation, as measured by trypan blue exclusion, and the geranylgeranyltransferase inhibitor GGTI-2166 antagonized the protective effect of PTH. These results suggest that GGPP is critical for osteoblast survival. In addition to direct effects through Gα12/Gα13-coupled receptors, we speculate that the PTH effect on survival and on PLD could be mediated through increases in a cellular pool of GGPP.

Decreases in Cortical Thickness, and not Changes in Trabecular Microstructure, Are Associated with the Pubertal Increase in Forearm Fractures in Girls. S. Kirmani, L. McCready*, M. Holets*, P. R. Fischer*, B. L. Riggs, L. J. Melton, S. Khosla. Mayo Clinic, Rochester, MN, USA.

We previously demonstrated that forearm fractures in girls peak between age 8 and 11 years, during the time of maximal pubertal growth (JAMA 2003;290:1479). The structural basis for this increase is unclear but may be related to the transient cortical thinning and increased porosity related to increased calcium demands during maximal growth. It is also possible that there may be alterations in trabecular microstructure during puberty that reduce bone strength. To address these possibilities, we used high-resolution 3D pQCT (XtremeCT, Scanco, voxel size ~90 microns) to assess trabecular and cortical bone parameters in healthy girls aged 7-16 yrs (n=46) without a prior history of fracture. Subjects were classified into 4 groups based on bone age (BA) assessed using hand and wrist x-rays: Group I (BA, 6-8 yrs, n = 8), Group II (BA, 9-11 yrs, n = 15), Group III (BA, 12-14 yrs, n = 13), and Group IV (BA, 15-16 yrs, n = 10). There were no significant differences (P > 0.2) in trabecular parameters (bone volume/total volume, BV/TV; trabecular number, Tb.N; or trabecular thickness, Tb.Th) through the course of puberty, expressed as a percentage of the mean value in Group I (Panel A of figure). By contrast, there were marked but transient decreases in cortical thickness (C.Th) which decreased by 50% during puberty (P < 0.005 for group I vs. group III, P = 0.07 for group I vs. group II) before rising sharply by 89% at the end of puberty (P < 0.005 for group I vs. group IV). This pattern was a mirror image of the previously described rise in distal forearm fractures in this population (Panel B), and there were similar changes in cortical vBMD (data not shown).

Our findings, which represent the first direct assessment of trabecular and cortical structure during growth in children, thus demonstrate that: (1) perhaps surprisingly, puberty is associated with minimal changes in trabecular microstructure, suggesting that these parameters may be established very early in life; and (2) the transient increase in distal

forearm fractures during growth in girls is largely explained by temporary cortical thinning (and perhaps increased cortical porosity). Further studies are needed to define the mechanisms underlying these alterations in cortical parameters as well as preventive measures that may attenuate these changes and, hence, distal forearm fractures during growth.

Vitamin D Receptor Gene Polymorphisms Modulate the Musculo-Skeletal Response to Vitamin D Supplementation in Healthy Girls. A. Arabi¹, Z. Mahfoud^{1,2}, L. Zahed³, J. Maalouf¹, M. Nabulsi⁴, M. Choucair¹, G. El-Hajj Fuleihan¹. ¹Calcium Metabolism and Osteoporosis Program, American University of Beirut, Beirut, Lebanon, ²Epidemiology and Population Health, American University of Beirut, Beirut, Lebanon, ³Pathology and Laboratory Medicine, American University of Beirut, Beirut, Lebanon, ⁴Pediatrics, American University of Beirut, Beirut, Lebanon.

Associations between Vitamin D receptor (VDR) genotypes and bone mass have been reported. Our group showed a beneficial effect of vitamin D (Vit D) supplementation on bone mass in girls¹. This effect was mediated by changes in height, bone area and lean mass¹. Whether the musculo-skeletal response to Vit D is modulated by polymorphisms in VDR gene has not been previously assessed.

The relationship between VDR gene polymorphisms and the musculo-skeletal response to Vit D supplementation was evaluated in 168 girls (10-17 years), randomly assigned to placebo (n=55), Vit D3 1400 IU/week (n=58) or Vit D3 14000 IU/week (n=55), for one year¹. Calcium intake was similar between groups¹.

VDR genotypes were determined using BsmI, TaqI and ApaI restriction enzymes. Bone mass at the spine (LS), hip, forearm (FA) and total body (TB), and lean mass were measured by DXA at baseline and at one year.

Because the response to Vit D3 was not dose dependent¹, Vit D3 groups (low and high dose) were combined in the analyses. VDR gene polymorphisms using BsmI restriction enzyme were associated with percent changes in height, LS BMC, femoral neck BMC (FN BMC) and TB BMC, FN area, TB area, TB BMD and FA BMD in the Vit D3 group but not in the placebo group. The least increments were observed in the BB genotype (Table). There was no difference in changes in lean mass between genotypes. The relationship between VDR genotypes and changes in BMD and BMC remained significant after adjustment for menarcheal status, changes in lean mass, in height or in bone area.

Similar relationships between skeletal response and VDR were obtained with TaqI restriction enzyme. The least increments were observed in the tt genotype. No such relationship was observed when VDR genotypes were determined using ApaI restriction enzyme.

In conclusion, polymorphisms in the VDR gene may modulate the skeletal response to vitamin D supplementation in healthy adolescent girls.

Growth and Response to Active Vitamin D and Phosphorus Treatment Is Highly Associated with Haplotype of the Vitamin D Receptor Promoter in X-linked Hypophosphatemic Rickets. F. Jehan, M. Nguyen*, O. Walrant-Debray*, C. Sinding*, M. Garabedian*. Hopital Saint Vincent de Paul, Inserm U561, Paris, France.

X-linked hypophosphatemic rickets is a monogenic disease characterized by bone deformities, growth retardation, dental anomalies, urinary phosphate wasting, low serum 1,25-dihydroxyvitamin D3 and hypocalciuria. Treatment with phosphorus and 1-hydroxylated forms of vitamin D cures, or prevents, bone deformities, and improves calcium/phosphorus status. However, its beneficial effect on growth retardation remains controversial, mainly due to wide variations of individual expressivity of the disease. We have hypothesized that natural genetic variations (polymorphisms and/or haplotypes) could explain some of the variability in growth impairment and treatment responses. We considered variants in the promoter region of the vitamin D receptor (VDR) gene as a good target, since we found association between VDR promoter variants and growth in healthy adolescents girls (d'Alesio et al., Hum Mol Genet, 2005 14: 3539-48), and since variants influencing VDR expression are likely to influence responses to vitamin D treatment in hypophosphatemic patients.

Methods. We analyzed the VDR promoter haplotype structure in a large cohort of hypophosphatemic rickets patients treated since early childhood with phosphate and 1-hydroxylated vitamin D derivatives (n=52 including 16 patients now adults), that we have clinically and biologically followed from diagnosis on.

Results: 1) A clear association was observed between adult height (expressed as SD scores) and VDR Hap1 haplotype (Hap1+: -0.82±0.40, Hap1-: -2.59±0.26; mean ± SE; p<0.004). The Hap1 effect on growth was highly significant as early as 4 years of age (p<0.004). It was independent of the gender, vitamin D and phosphate daily dosages, and age at onset of treatment. No such effect was observed by breaking the cohort with the two other major haplotypes of the VDR promoter.

2) Urinary calcium excretion increased with the 1-(OH)D dosage in all patients during childhood. But the sensitivity to treatment was clearly Hap1 dependent. With 1 microgram per day of 1-OH vitamin D, the mean urinary calcium/creatinine ratio for each patient was normal in Hap1+ children (0.36±0.20 mmol/mmol, n=26) and already elevated in Hap1- children (0.76±0.35, n=10, mean ± SD, p<0.0001 vs. Hap1+). Other biological values were similar in the two Hap1 groups (serum calcium, phosphorus, 25-(OH)D, and 1,25-(OH)2D).

Conclusion: variations in the clinical and biological expressivity of the hypophosphatemic rickets may be explained, at least in part, by natural genetic variants on the VDR promoter that may regulate the VDR protein expression, and hence the patient sensitivity to vitamin D treatment.

Sequencing of Collagen I in Three Patients with Multiple Fractures of Unknown Aetiology Reveals Novel Mutations Causing Osteogenesis Imperfecta with Normal to High BMD. K. Lindahl*, H. Brändström, A. Kindmark*, Ö. Ljunggren*. Medical Sciences, Endocrinology, Uppsala, Sweden.

Osteogenesis imperfecta (OI) is a heterogeneous genetic disorder with an incidence of approximately 1/15 000 individuals. In general, patients with OI have low Bone Mineral Density (BMD) and an increased susceptibility to fracture. Clinical features of OI also include blue sclerae, dentinogenesis imperfecta, deafness and hyper mobile joints. Phenotypes range from mild to lethal. In more than 90% of cases the disorder is due to a dominant mutation in one of the two genes that encode collagen type I, COL1A1 and COL1A2. Mild OI is usually the result of a mutation that leads to a premature stop codon, which subsequently leads to too little, but structurally normal collagen. In contrast, the more severe OI phenotypes are often de-novo mutations leading to an exchange of a glycine residue for an amino acid with a bulkier side chain. Patients with multiple fractures, but no other clinical signs of OI, pose a diagnostic problem, especially when BMD is normal. It is debated whether collagen sequencing should be performed as a routine in these cases.

In this study, we have sequenced COL1A1 and COL1A2 in three patients who had suffered more than 15 fractures, but had a BMD in the normal to high range. None of the patients had any clinical signs of OI and despite extensive investigation neither of the patients had a clinical diagnosis explaining their fragile bones.

DNA was extracted from whole blood using a commercially available kit. Exons and flanking intron sequences of COL1A1 and COL1A2 were sequenced using standardised sequencing with ABI3130XL using 110 primer pairs.

Three novel mutations were found: Asp1219Asn, was detected at the splice site of the carboxy-terminal propeptide of the COL1A1 gene, Gln1206Termination in COL1A1 and Gly757Ser in COL1A2. Control sequence ruled out the possibility of a naturally occurring polymorphism and the mutations were not previously reported in the collagen database.

These findings indicate that sequencing of collagen type I is valuable in patients with multiple fractures of unknown aetiology. Furthermore, BMD is not necessarily low or strictly correlated to bone strength in OI.

Bone Traits Are Determined Early in Life but Adapt During Growth to Accommodate Local Loading Circumstances. Q. Wang¹, S. Cheng², E. Seeman¹. ¹Medicine/Austin Health, University of Melbourne, Melbourne, VIC, Australia, ²Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland.

Bone structure determines the loads tolerated but the loads imposed also determine its structure. We hypothesized that: 1) the position of an individual's bone trait is established prior to puberty and remained in the position, 2) bone shape changes to accommodate prevailing loads, 3) bone strength and the loads imposed increase in proportion with age so their ratio is independent of age. In 258 10-13yrs healthy girls, peripheral quantitative computed tomography (Stratec XCT-2000) was used to determine the cross sectional structure of the left tibial shaft and muscle size during 2 years. Mothers of 108 of these girls were also studied. Height, lower leg length, bone traits such as total tibial cross sectional area (CSA) and cortical thickness increased with age but trait variances - the magnitude of the dispersion around the age-specific mean did not. The relative position of bone trait, whether at the 5th, 50th or 95th percentile, was established prior to puberty. In 60-70% individuals their bone traits remained in their percentile after 2 years; the other 30-40% individuals their bone trait's percentile increased or decreased. The change in the percentile of muscle CSA or in lean tissue mass (from DXA) correlated with the change in the percentile of bone traits ($r=0.5-0.6$). Periosteal apposition added more than twice the amount of bone anteriorly (18 mg) and posteriorly (10 mg) than medially (5 mg) and laterally (4 mg) increasing tibial ellipticity. Bending strength of tibial shaft thus increased more in the antero-posterior (Imax) than medio-lateral direction (Imin); the ratio Imax/Imin increased by 7% over the 2 years ($p<0.001$) and was 13% higher in the mothers than in girls at baseline ($p<0.001$) (Fig). Imax increased with age and correlated with the estimated load imposed (tibial length X weight) ($r=0.73$). The ratio Imax/estimated load was independent of age reflecting proportional age-related increases in the structural determinants of bone strength and the load imposed. In conclusion, we infer that skeletal structure in one individual as a result of genetic variability is already expressed before puberty. In this setting, skeletal development is adaptive throughout growth so that load applied modifies bone shape accommodating that load efficiently.

Extraction Socket Healing in Pediatric Patients Treated with Pamidronate: A Retrospective Chart Review. C. J. Chahine^{*1}, M. Cheung^{*2}, T. W. Head^{*1}, S. Schwartz^{*3}, F. Rauch², F. H. Glorieux². ¹Oral and Maxillofacial Surgery, McGill University, Montreal, PQ, Canada, ²Genetics Unit, Shriners Hospital for Children, Montreal, PQ, Canada, ³Pediatric Dentistry, Montreal Children's Hospital, Montreal, PQ, Canada.

Osteonecrosis of the jaw (ONJ) has been described in adults who have received bisphosphonates, but its occurrence in children has not been reported. In the present study we evaluated whether ONJ has occurred in any of the pediatric patients who received pamidronate therapy at the Shriners Hospital for Children in Montreal. 338 patients had received pamidronate treatment. Dental follow up data were obtained on 49 patients (16 females) who had undergone tooth extraction (age at last follow up: 2 to 24 years, mean 12.8 years). The indication for pamidronate use included osteogenesis imperfecta (N = 46), fibrous dysplasia (N = 1), hypercalcemia (N = 1), and muscular dystrophy (N = 1). A total of 181 teeth had been extracted (145 primary teeth, 36 permanent teeth). 19 of the teeth required surgical extraction with flap elevation, bone removal, and tooth sectioning. Prophylactic antibiotic use was implemented in 10 patients. The indication for dental extraction was impacted teeth (N = 16), fractured teeth (N = 11), decay or odontogenic abscess (N = 38), retained primary teeth (N = 67), and ectopic eruption or pre-orthodontic therapy (N = 49). The mean cumulative dose of pamidronate prior to dental extraction was 40.6 mg/kg. The mean duration of pamidronate treatment prior to dental extraction was 4.5 years. 100 teeth were extracted during active treatment. The mean interval of time between the last pamidronate dose prior to dental extraction and first pamidronate dose following dental extraction was 55 and 61 days, respectively. 81 teeth were extracted an average of

1.6 years after the last dose of pamidronate. All of the patients were followed post-operatively with a mean of 2.6 years (range: 1 month to 10 years). Adequate healing as judged by the treating dentist's clinical evaluation was noted on post-operative visits in all patients. There was no evidence of delayed healing, exposed bone, or ONJ in any patient. In conclusion, we did not detect any cases of ONJ in this large pediatric patient population with long-term pamidronate exposure.

Large-scale Analysis of Association Between Polymorphisms in the LRP-5 and -6 Genes and Bone Mineral Density and Fracture. J. B. J. van Meurs^{*1}, T. A. Trikalinos^{*2}, S. H. Ralston^{*3}, F. Rivadeneira^{*1}, J. P. A. Ioannidis^{*2}, A. G. Uitterlinden^{*1}, The Genomos Study Group^{*4}. ¹Internal Medicine, Erasmus Medical Center, Rotterdam, The Netherlands, ²Hygiene and Epidemiology, University of Ioannina, Ioannina, Greece, ³Rheumatic Diseases, University of Edinburgh, Rotterdam, United Kingdom, ⁴For more information: Http://www.genomos.eu/, The Netherlands.

Objective: Mutations in the low-density lipoprotein receptor-related protein 5 (LRP5) gene cause rare syndromes characterized by altered bone mass. Common LRP5 variants may affect bone mass and fracture risk, but the magnitude of the association has been debated. The objective of this study was to generate large-scale evidence on whether common variants of LRP5 and its close homologue LRP6 are associated with bone mineral density (BMD) and fracture-risk.

Methods: We performed a prospective meta-analysis of participant-level data from 18 centers on 37,760 men and women. We assessed the association of common LRP5 (Val667Met, Ala1330Val) and LRP6 (Ile1062Val) variants with lumbar spine (LS) BMD, femoral neck (FN) BMD, all prevalent fractures, and prevalent vertebral fractures. Genotyping was standardized across centers. Unadjusted analyses with generalized linear mixed models allowed for random effects across center-gender strata. Adjustments for sex, age, weight, height, menopausal status and hormone replacement therapy were also performed. Fracture risks were also adjusted for BMD.

Results: LS-BMD decreased by 0.02 g/cm² per 667Met allele copy ($p=3.3 \times 10^{-8}$), and by 0.014 g/cm² per 1330Val copy ($p=2.6 \times 10^{-9}$). The corresponding decrease for FN-BMD was 0.011 and 0.008 g/cm² ($p=5.0 \times 10^{-6}$ and $p=3.8 \times 10^{-5}$). For both LS and FN this corresponds to approximately 0.1 SD difference in BMD. For fractures, the strongest association was seen for vertebral fracture risk (OR=1.26 [95%CI: 1.05-1.24] and 1.12 [95%CI: 1.01-1.24] per allele for Val667Met and Ala1330Val, respectively), but an effect was present also for all fractures (OR 1.14 [95%CI: 1.05-1.24] and 1.06 [95%CI: 1.01-1.12] per allele, respectively). The fracture risks were partly attenuated by adjustment for differences in BMD. Haplotype analysis of the two LRP5 variants indicated independent effects of both variants on BMD. The LRP6 Ile1062Val polymorphism was not associated with any of the phenotypes.

Conclusions: In this very large genetic association study of more than 37,000 subjects we show that common variants of the LRP5-gene are consistently associated with both BMD and fracture risk across different Caucasian populations. The magnitude of the effect is modest, but highly significant. LRP5 is the first gene to reach a genome-wide significance level for a phenotype related to osteoporosis.

Serum DHEA Is Independently of Estradiol and Testosterone Related to Incident Fractures in Elderly Men - The MrOS Sweden Study. C. Ohlsson¹, L. Vandenput¹, A. Holmberg², H. Mallmin³, E. Orwoll⁴, A. Oden^{*5}, A. Eriksson¹, M. Lorentzon¹, M. Stenstrom^{*1}, M. K. Karlsson², Ö. Ljunggren⁶, F. Labrie^{*7}, D. Mellström¹. ¹Center for Bone Research at the Sahlgrenska Academy, Dpts of Internal Medicine and Geriatrics, Gothenburg University, Gothenburg, Sweden, ²Dpt of Orthopaedics, Malmö University Hospital, Lund University, Malmö, Sweden, ³Dpt of Surgical Sciences, Uppsala University, Uppsala, Sweden, ⁴Bone and Mineral Unit, Oregon Health and Sciences University, Portland, OR, USA, ⁵Consulting Statistician, Gothenburg, Sweden, ⁶Dpt of Medical Sciences, Uppsala University, Uppsala, Sweden, ⁷Laboratory of Molecular Endocrinology and Oncology, Laval University, Quebec, PQ, Canada.

The enzymes required to transform adrenal-derived dehydroepiandrosterone (DHEA) into androgens and/or estrogens are expressed in several peripheral target tissues such as bone and muscle. The impact of serum DHEA for bone health in elderly men is unclear. The aim of the present study was to determine the relationship between serum DHEA and incident fractures in elderly men of MrOS Sweden (n=3014, 75.4 ± 3.2 years). Incident X-ray verified fractures at major non-vertebral osteoporosis-related sites (hip 39, distal radius 29, proximal humerus 16 and pelvis 8 fractures) were identified in 82 subjects with an average follow-up of 3.3 years. Serum levels of DHEA, estradiol and testosterone were analyzed by validated gas chromatography/mass spectrometry assays (n=2640). Serum SHBG was measured using an immunoradiometric assay.

Multivariate proportional hazards regression analysis was used to assess the independent relationship of DHEA to fracture risk. In age-adjusted analyses, baseline DHEA was inversely related to incident fracture risk (hazard ratio (HR) per SD decrease in DHEA = 1.43; CI 1.17-1.75). As serum estradiol and serum testosterone were inversely and SHBG was directly related to incident fracture risk, these parameters were included in the

analyses of the independent relationship between DHEA and incident fracture risk. Interestingly, the relationship between DHEA and incident fracture risk was not affected by adjustment for estradiol, testosterone and SHBG (HR per SD decrease in DHEA = 1.40; CI 1.13-1.74). Neither inclusion of total hip BMD (HR per SD decrease in DHEA = 1.36; CI 1.11-1.67) nor inclusion of BMI (HR per SD decrease in DHEA = 1.45; CI 1.18-1.77) in the model affected the association between DHEA and incident fractures.

In conclusion DHEA is an independent predictor of incident non-vertebral fractures at major osteoporosis-related sites in elderly men. Because this association was independent from changes in BMD, one may speculate that adrenal-derived DHEA could influence neuromuscular function and thereby fracture risk in elderly men.

Enhancement of Prognosis of Osteoporotic Fractures by Genetic Marker: Contribution of the Collagen I alpha 1 Gene. B. H. Tran*, N. D. Nguyen, S. A. Frost*, J. R. Center, J. A. Eisman, T. V. Nguyen. Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia.

Given the time-invariant nature of the genetic information and BMD and age-related nature of fracture risk, a short-term absolute risk approach is more meaningful and appropriate than a relative risk-based approach. The present study was aimed at developing a prognostic model for predicting 5-y and 10-y of fracture risks in elderly women by incorporating genetic marker information.

COL1A1 genotypes (GG, GT and TT) were determined in 915 women of Caucasian background aged 60+ years as at 1989, who have been followed for up to 17 years (1989-2006). Low trauma, non-pathological fractures were recorded. Femoral neck bone mineral density (FNBMD) was measured by dual energy X-ray absorptiometry (GE-LUNAR DXA) at baseline and expressed as T-scores. A series of nomograms for predicting 5-year and 10-year risk of fractures including any fracture, hip and vertebral fractures for an individual woman were developed by using Cox's proportional hazards model.

The proportion of individuals with GG, GT and TT genotypes in the population of 63%, 32% and 5%, respectively, which was consistent with Hardy-Weinberg equilibrium law. In the multivariable Cox's proportional hazards model, the risk ratio for COL1A1 TT (vs. G allele) and any, hip and vertebral fractures were 3.07 (1.47-6.43), 7.07 (2.37-21.14) and 4.45 (1.89-10.47), respectively, after adjusting for age and FNBMD. The area under the curves for prediction models for any fracture, hip and vertebral fractures were 0.68, 0.85 and 0.69, respectively. Using the models' parameters, various nomograms were constructed for individualizing the risk of any, hip and vertebral fractures. A woman with the TT genotype had an absolute fracture risk equivalent to a 20-year older counterpart without the TT genotype independence of BMD. Similarly, a woman homozygous for the T allele had an absolute risk approximately equivalent to a woman with the same age without the genotype but with 1SD lower in FNBMD.

These data suggest that in women the effect of COL1A1 TT genotype (5% in the population) is equivalent to an effect of 20-year increase in age or one SD lower in BMD. The incorporation of COL1A1 genotypes could enhance the short-term prognosis of osteoporotic fracture in women.

Figure: 5-y risk of any fracture in women, stratified by age, BMD and COL1A1 genotype

Serum 25 Hydroxy Vitamin D 25(OH) and the Risk of Hip Fractures: The Women's Health Initiative (WHI). J. A. Cauley¹, A. LaCroix², L. Wu³, J. Lee⁴, M. Horowitz⁵, D. Bauer⁶, R. Jackson⁷, M. Danielson⁸, M. LeBoff⁹, F. Stranczyk¹⁰, S. Cummings¹¹. ¹University of Pittsburgh, Pittsburgh, PA, USA, ²University of Washington, Seattle, WA, USA, ³University of California, Davis, Davis, CA, USA, ⁴University of California San Francisco, San Francisco, CA, USA, ⁵Ohio State University, Ohio, OH, USA, ⁶Harvard University, Cambridge, MA, USA, ⁷University of Southern California, Los Angeles, CA, USA, ⁸University of San Francisco, San Francisco, CA, USA.

Vitamin D deficiency is common in older persons, especially in home based populations, in general medical inpatients and in women with acute hip fracture. To test the hypothesis that serum measures of 25(OH)D predict the likelihood of hip fracture in

community dwelling women, we performed a nested case control study in the WHI Observational Study Cohort. We excluded women who had a history (hx) of hip fracture or used hormones or other osteoporosis medications at baseline. A total of 39,793 women met these criteria. We randomly chose 400 women who had an incident hip fracture, confirmed by medical record over a median of 7.1 y. A control was selected for each case, matched on baseline age (+/- one year), race/ethnicity and date of blood draw (within 75 days). 25(OH)D was measured in fasting baseline serum using DiaSorin kits. The sensitivity of the assay was 1.5ng/ml; interassay coefficients of variation ranged 8.6% to 12.5%. Conditional logistic regression models were conducted to evaluate the association between hip fractures and Vitamin D. Odds ratio (OR) with 95% confidence intervals (CI) were estimated per SD and across quartiles of 25(OH)D (defined by the distribution in controls) with p values for tests of linear trend. We adjusted for potential confounders. The mean age of cases and controls was 70.8 years; 95% were White. 25(OH)D levels ranged from 3.7 to 48.6 ng/ml. The mean (SD) Vitamin D level (ng/ml) in the cases was 22.4 (8.1) and 23.8 (7.2) in the controls, p=0.007. The risk of hip fractures was 77% higher among women whose 25(OH)D was <19ng/ml (Table). Additional adjustment for other risk factors for fracture had no effect. In conclusion, low serum 25(OH)D levels are an independent prognostic risk factor for hip fracture in community dwelling postmenopausal women.

Odds ratio (95% CI) for hip fracture

Variation in the FLNB Gene Regulates Bone Density in Two Populations of Caucasian Women. S. G. Wilson¹, B. H. Mullin², M. R. Jones³, I. M. Dick⁴, F. Dudbridge⁵, T. D. Spector⁶, R. L. Prince⁷. ¹Endocrinology, Sir Charles Gairdner Hospital, Nedlands, Australia, ²MRC Biostatistics Unit, Cambridge, United Kingdom, ³Twin Research and Genetic Epidemiology, King's College London, London, United Kingdom, ⁴Medicine and Pharmacology, The University of Western Australia, Nedlands, Australia.

Based on our previous linkage data showing that genes in the chromosome 3p14-21 region are associated with osteoporosis¹ and data that mutations of the Filamin B (FLNB) gene are the cause of osteochondrodysplasias including Larsen's Syndrome, Boomerang Dysplasia and atelosteogenesis type I & III, recently confirmed by KO studies in mice, we have undertaken a detailed study of the effects of variation in the FLNB gene sequence on bone structure. Filamin B is a cytoskeleton protein involved in actin polymerisation and participates in its interaction with signal transduction pathways. Thus the aim of this study was to evaluate the role of variation in the FLNB gene in regulating bone mass and the propensity to osteoporotic fracture. This hypothesis was tested in two large cohorts, firstly 771 women from the GENOS sib-pair study, identified on the basis of an osteoporotic proband and previously used in linkage analysis, and secondly a population-based cohort of 1192 unrelated Caucasian women from the CAIFOS/CARES study. Hip bone density was measured by DXA (Hologic QDR 4500). Genotyping for the family study was by GoldenGate Assay (Illumina Inc.) and in the population study used MALDI-ToF (Sequenom Inc.). Association between BMD and genotype in the family study was assessed using the FBAT program and in the population-based cohort used ANOVA. Genotype effect on fracture rate was examined using a Chi-square test. Haplotype analysis was undertaken using UNPHASED software. Nine SNPs covering the LD in the FLNB gene were studied in the family-based cohort, of which four (rs7637505, rs9822918, rs2177153 and rs2001972) showed an association with age corrected BMD at both femoral neck (P = 0.02-0.0002) and total hip (P = 0.02-0.0006). Six SNPs were taken forward to the population-based replication study of which, rs9822918 (P = 0.02-0.003) and rs2177153 (P = 0.02) showed association with BMD. The difference in mean BMD for alleles of rs2177153 was 3.9-44.9%. Fewer prevalent fractures were observed in individuals homozygous for the G allele of rs2177153 (P = 0.015). Our data shows that genetic variation in the FLNB gene is associated with differences in bone mass and this has been replicated in two independent cohorts of Caucasian women. These results suggest that understanding the mechanism may lead to greater insight into bone cell biology and new therapies.

Genetic and Environmental Effects on Muscle Cross-Sectional Area and Structural Strength of Tibia in Older Female Twins. T. Mikkola^{*1}, S. Sipilä^{*2}, T. Rantanen^{*1}, H. Sievänen³, H. Suominen¹, J. Kaprio^{*4}, M. Koskenvuo^{*4}, M. Kauppinen^{*2}, A. Heinonen¹. ¹Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland, ²Finnish Centre for Interdisciplinary Gerontology, University of Jyväskylä, Jyväskylä, Finland, ³Bone Research Group, UKK Institute for Health Promotion Research, Tampere, Finland, ⁴Department of Public Health, University of Helsinki, Helsinki, Finland.

The aims of this study were to estimate to what extent individual differences in cross-sectional area of the lower leg muscles (mCSA), bending strength of tibial shaft (BSIb) and compressive strength of distal tibia (BSIc) are influenced by genetic and environmental factors in older women, and to investigate whether the associations between these traits are due to common genetic or environmental factors.

The mCSA, BSIb and BSIc values were measured with peripheral quantitative computed tomography from 102 monozygotic (MZ) and 113 dizygotic (DZ) 63-76-year-old female twin pairs. Quantitative genetic models were used to decompose the phenotypic variances into common and trait-specific additive genetic (A), shared environmental (shared by the sisters, C) and individual environmental (unique to each sister, E) factors.

The pairwise correlations of the MZ and DZ twins were 0.73 and 0.42 for mCSA, 0.73 and 0.50 for BSIb and 0.73 and 0.56 for BSIc, respectively. The age-adjusted multivariate independent pathway model showed that the total relative contributions of A, C and E were 75%, 0% and 25% for mCSA, 55%, 20% and 25% for BSIb and 40%, 37% and 23% for BSIc, respectively. In addition, the model showed that a genetic factor, common to all three traits accounted for 75% (95% CI: 66-82%) of the variance in mCSA, 17% (8-27%) of that in BSIb and 8% (2-17%) of that in BSIc. BSIb and BSIc had a shared environmental factor in common which accounted for 20% (9-35%) and 37% (20-53%) of the variances in BSIb and BSIc, respectively. A common individual environmental factor accounted for 5% (2-11%) of the variance in mCSA, 22% (13-33%) of that in BSIb and 13% (7-22%) of that in BSIc. The remaining variances were attributable to trait-specific genetic factors and trait-specific individual environmental factors.

In older women, cross-sectional area of the lower leg muscles, tibial bending strength and tibial compressive strength share common genetic and environmental effects. The total influence of genes is strong on muscle area and weaker on tibial strength indices. These results suggest that in older women the same genetic and environmental factors may predispose to or protect from both sarcopenia and bone fragility.

Effect of Denosumab on Bone Mineral Density and Bone Turnover Markers: 48-Month Results. P. Miller¹, M. Bolognese^{*2}, E. M. Lewiecki^{*3}, M. McClung⁴, B. Ding^{*5}, Y. Liu⁵, J. San Martin⁵. ¹Colorado Center for Bone Research, Lakewood, CO, USA, ²Bethesda Health Research Center, Bethesda, MD, USA, ³New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA, ⁴Oregon Osteoporosis Center, Portland, OR, USA, ⁵Amgen Inc., Thousand Oaks, CA, USA.

Denosumab is an investigational fully human monoclonal antibody that reduces bone turnover by inhibiting RANKL, an essential mediator of osteoclast formation, function, and survival. An ongoing phase 2 study in postmenopausal women with low bone mineral density (BMD) showed that denosumab increased BMD and reduced bone turnover markers (BTM) during the first 24 months of therapy. We report 48-month results of denosumab continuous treatment, discontinuation, and rechallenge.

After 24 months, subjects were reassigned. Those who continued on denosumab were switched from other denosumab dosing regimens to 60 mg Q6M (continuous treatment). Those who received denosumab 210 mg Q6M were switched to placebo (PBO) for the rest of the study (discontinuation), and those on 30 mg Q3M were switched to 12 months of PBO followed by 12 months of 60 mg Q6M (rechallenge). Subjects in the PBO arm remained on PBO, and those in the alendronate (ALN) arm discontinued ALN and were followed. Changes in BMD, BTM, and safety were assessed at 48 months.

BMD data from 229 subjects were available for this interim analysis. After 48 months, continuous denosumab treatment resulted in sustained BMD gains from baseline. Lumbar spine BMD % change from baseline at month 48 was 10.6% for denosumab vs -2.7% for PBO (between-group difference: 13.4%, $P < .001$). BMD also increased at the total hip with denosumab (5.8% vs -2.9%; between-group difference: 8.7%, $P < .001$; Figure). Denosumab discontinuation was associated with a BMD decrease to values near baseline. Rechallenge with denosumab increased BMD to an extent similar to initial therapy. In subjects who discontinued ALN, a slight decline of BMD was observed. Continuous denosumab therapy led to sustained reduction of BTM from baseline. BTM increased upon denosumab discontinuation and decreased with rechallenge. Adverse event rates were similar among treatment groups over 48 months.

These data indicate that RANKL inhibition with denosumab led to continued gains in BMD and suppression of BTM relative to PBO over 48 months, which appeared to be reversible with discontinuation and responsive with rechallenge.

Efficacy of Bazedoxifene in Reducing New Vertebral Fracture Risk in Postmenopausal Women with Osteoporosis: Results From a 3-Year, Randomized, Placebo- and Active-Controlled Clinical Trial. S. L. Silverman¹, C. Christiansen², H. K. Genant³, J. R. Zanchetta⁴, I. Valter^{*5}, T. J. de Villiers^{*6}, G. Constantine^{*7}, A. A. Chines⁷. ¹Osteoporosis Medical Center, Clinical Research Center, Beverly Hills, CA, USA, ²Center for Clinical and Basic Research (CCBR), Ballerup, Denmark, ³University of California, San Francisco, and Synarc, San Francisco, CA, USA, ⁴University of El Salvador, Metabolic Research Institute, Buenos Aires, Argentina, ⁵CCBR, Tallinn, Estonia, ⁶Panorama MediClinic, Capetown, South Africa, ⁷Wyeth Pharmaceuticals, Collegeville, PA, USA.

Bazedoxifene (BZA), a novel selective estrogen receptor modulator (SERM), is currently in clinical development for the prevention and treatment of postmenopausal osteoporosis. We report the results of a 3-year, Phase III study that evaluated the effect of BZA therapy on the incidence of new vertebral fracture compared with placebo (PBO) and raloxifene (RLX) in postmenopausal women with osteoporosis.

This study enrolled generally healthy postmenopausal women aged 55-85 years with lumbar spine (LS) or femoral neck (FN) T-scores ≤ -2.5 and no prevalent vertebral fractures or LS or FN T-scores

≥ -4.0 with prevalent vertebral fractures. Participants were randomized to receive 20 mg/d or 40 mg/d BZA, 60 mg/d RLX, or PBO and received supplemental calcium (1200 mg) and vitamin D (400 IU). The primary efficacy outcome was the incidence of new vertebral fractures after 36 months; secondary outcomes included non-vertebral fractures (NVFs).

A total of 7492 women (mean age \pm SD, 66.4 \pm 6.7 years) were randomized and received ≥ 1 dose of study medication. At baseline, mean LS T-score was -2.4, mean total hip T-score was

-1.4, and 56% of women had ≥ 1 prevalent vertebral fracture (mostly mild). The 3-year incidences of new vertebral fracture, based on Kaplan-Meier estimates, were 2.3%, 2.5%, 2.3%, and 4.1% in the BZA 20 mg, BZA 40 mg, RLX 60 mg, and PBO groups, respectively, with a relative risk reduction for new vertebral fracture of 42% ($P=0.015$), 37% ($P=0.031$), and 42% ($P=0.012$), respectively, versus PBO. There was overall no treatment effect on NVFs. In a post-hoc analysis of women with FN T-score ≤ -3.0 or ≥ 1 moderate or multiple vertebral fracture ($n=1782$), NVF incidence was 3.0%, 3.8%, 5.9% and 6.3% in BZA 20 mg, 40 mg, RLX 60 mg and PBO groups, respectively. Relative to PBO, BZA 20 mg reduced NVF incidence by 52% ($P=0.045$). Similar reduction was observed when both BZA doses were combined (46% reduction, $P=0.037$).

We conclude that BZA treatment significantly reduces the risk of new vertebral fractures, and in subjects at higher risk for fractures, BZA is associated with a significant reduction in NVFs.

The Effect of Calcium plus Vitamin D Supplement on Hip Geometric Structures: Results from the Women's Health Initiative CaD Trial. Z. Chen¹, T. J. Beck², N. C. Wright¹, A. Z. LaCroix³, J. A. Cauley⁴, C. E. Lewis⁵, T. Bassford^{*1}, M. S. LeBoff⁶, R. D. Jackson^{*7}. ¹U of Arizona, Tucson, AZ, USA, ²Johns Hopkins Univ., Baltimore, MD, USA, ³Fred Hutchinson Cancer Research Center, Seattle, WA, USA, ⁴U of Pittsburgh, Pittsburgh, PA, USA, ⁵U of Alabama, Birmingham, AL, USA, ⁶Brigham and Women's Hospital, Boston, MA, USA, ⁷Ohio State Univ., Columbus, OH, USA.

A previous report has shown that calcium and vitamin D (CaD) supplementation caused a small but significantly improvement in bone mineral density (BMD) among healthy postmenopausal women who participated in the CaD trial of the U.S. nationwide Women's Health Initiative Study (WHI). The purpose of this study was to investigate the effect of CaD intervention on femoral bone strength as measured by hip structure analysis (HSA) in the same sample. The WHI CaD trial was designed for women to take either the CaD supplement (containing calcium carbonate (500 mg as elemental calcium) with vitamin D₃ (200 IU)) or matching placebo twice daily (GlaxoSmithKline Consumer Healthcare, Parsippany, NJ) depending on their randomization assignment. The analysis included participants (n = 1,731) at three WHI bone density centers. HSA in the femoral narrow neck (FNN), intertrochanter (IT), and femoral shaft (FS) regions were done using the validated Beck's method on hip scans from dual-energy x-ray absorptiometry. Women in the CaD arm were similar to women in the placebo arm in baseline characteristics, such as age (62.2 vs. 62.3 year), height (161.81 vs. 161.75 cm) and body weight (76.2 vs. 75.2 kg). Percent changes in HSA measurements at FNN from baseline to year3 are presented in the Figure. Results from multiple linear regression analysis after adjusting for baseline HSA measure suggest significant CaD intervention effects on HSA measurements in the FNN region during the first three years of the intervention (p<0.05). Overall CaD reduced the expansion of outer diameter (OD) and increased buckling ratio (BR). Meanwhile, section modulus (SM) and cortical thickness (CT) were significantly improved by CaD intervention. Higher cross-sectional area (CSA) were also observed in the CaD arm, but the intervention effect was not statistical significant. Adjusting for hormone interventions did not change the findings. Interestingly, the CaD effect on bone strength was limited to the FNN region. In conclusion, CaD intervention has significant and skeletal-site specific benefits on bone strength.

Figure 1. Percent change in HSA measurements by intervention from baseline to year 3

Denosumab Increases Bone Mineral Density in Patients with Rheumatoid Arthritis: 12-month Results. R. K. Dore^{*1}, E. Hurd^{*2}, W. Palmer^{*3}, W. Shergy^{*4}, N. Lane^{*5}, S. Cohen^{*6}, L. Zhou^{*7}, R. Newmark⁷, W. Tshuji^{*7}. ¹Robin K. Dore, Inc., Anaheim, CA, USA, ²Arthritis Centers of Texas, Dallas, TX, USA, ³Westroads Medical Group, Omaha, NE, USA, ⁴Rheumatology Associates of North Alabama, Huntsville, AL, USA, ⁵UC Davis Medical Center, Sacramento, CA, USA, ⁶Metroplex Center for Clinical Research, Dallas, TX, USA, ⁷Amgen, Inc., Thousand Oaks, CA, USA.

Rheumatoid arthritis (RA) is characterized by articular and periarticular bone erosions and systemic bone loss. RANKL is a key factor implicated in the bone destruction associated with many diseases, including RA. In clinical studies, denosumab, a fully human monoclonal antibody, inhibits RANKL and increases bone mineral density (BMD) in postmenopausal women with low bone mass. As part of a study to determine the effects of denosumab on joint destruction in patients with RA, the effect of denosumab on systemic bone loss was examined. Patients with mild to moderately active RA for at least 6 months with manifest erosions and maintained on methotrexate (MTX) were randomly assigned to treatment with subcutaneous injections of placebo or denosumab (60 or 180 mg) every 6 months. BMD was measured by dual-energy x-ray absorptiometry (DXA) at baseline, 1 month, 6 months, and 12 months. Adverse events were monitored throughout the study. A total of 227 patients were enrolled in the study (78 placebo, 73 denosumab 60 mg, 76

denosumab 180 mg). Average lumbar spine BMD T-score at baseline was (mean \pm SD) -0.50 \pm 1.58. Approximately one-third of patients used steroids at screening and one-fifth of all patients used bisphosphonates during the study; uses of both were balanced among groups. An additional 5% of patients in each treatment group had previously used bisphosphonates. At 12 months, denosumab significantly increased BMD at the lumbar spine, total hip, femoral neck, and trochanter compared with placebo (Table). Adverse events occurred with similar frequency among the treatment groups. Flare of RA was the most common adverse event.

All statistical comparisons were based on a repeated-measures model adjusting for treatment, visit, baseline use of steroid, previous use of biologic, baseline value, and visit by treatment interaction.

In summary, denosumab treatment increased BMD in patients with RA at 12 months and showed similar frequency and severity of adverse events across treatment groups. These results are consistent with those observed at 6 months.

Least-Squares Mean (\pm SE) Percent Change from Baseline in BMD at 12 Months			
Skeletal site	Placebo (n = 74)	Denosumab 60 mg (n = 70)	Denosumab 180 mg (n = 71)
Lumbar spine	0.76 \pm 0.39	3.01 \pm 0.38 ^a	4.05 \pm 0.39 ^a
Total hip	-0.35 \pm 0.29	1.60 \pm 0.28 ^a	1.75 \pm 0.28 ^a
Femoral neck	-0.61 \pm 0.44	1.28 \pm 0.44 ^b	1.48 \pm 0.44 ^b
Trochanter	-0.30 \pm 0.44	2.05 \pm 0.44 ^a	2.20 \pm 0.44 ^a

^a P \leq 0.001 versus placebo
^b P = 0.010 and 0.004 versus placebo for the 60-mg and 180-mg groups, respectively

Efficacy of Bazedoxifene for Prevention of Postmenopausal Osteoporosis: Results of a 2-Year, Phase III, Placebo- and Active-Controlled Study. P. D. Miller¹, C. Christiansen², H. C. Hoek^{*2}, D. L. Kendler³, E. M. Lewiecki⁴, G. Woodson⁵, M. Ciesielska^{*6}, A. A. Chines⁶, G. Constantine^{*6}, P. D. Delmas⁷.

¹University of Colorado Medical Center, Denver, CO, USA, ²Center for Clinical and Basic Research, Ballerup, Denmark, ³Osteoporosis Research Centre, Vancouver, BC, Canada, ⁴New Mexico Clinical Research & Osteoporosis Center, Inc, Albuquerque, NM, USA, ⁵Atlanta Research Center, Decatur, GA, USA, ⁶Wyeth Pharmaceuticals, Collegeville, PA, USA, ⁷University of Lyon and INSERM Research Unit 831, Lyon, France.

Bazedoxifene (BZA) is a novel selective estrogen receptor modulator (SERM) currently in clinical development as monotherapy for prevention and treatment of postmenopausal osteoporosis and in combination with conjugated estrogens for the treatment of menopausal symptoms and prevention of postmenopausal osteoporosis. In preclinical studies, BZA maintained skeletal mass without stimulation of the mammary gland or endometrial tissue. This 2-year, Phase III study was designed to assess the efficacy and safety of 3 BZA doses compared with placebo (PBO) and raloxifene (RLX) in the prevention of postmenopausal osteoporosis.

Healthy postmenopausal women (N=1583; mean age: 57 y) with lumbar spine or femoral neck BMD T-scores no less than -2.5 (mean: -1.2) were randomized to 1 of 5 groups: BZA 10, 20, or 40 mg, PBO, or RLX 60 mg. All women received 600 mg elemental calcium. The primary outcome was percent change in lumbar spine BMD at 24 months; secondary outcomes included BMD at other skeletal sites and serum bone turnover markers.

All BZA doses and RLX prevented bone loss, whereas PBO was associated with significant reductions in BMD. The difference in percent change of lumbar spine BMD from baseline to 24 months relative to PBO was 1.08%, 1.41%, 1.49%, and 1.50% for 10 mg, 20 mg, 40 mg BZA and 60 mg RLX, respectively (P<0.001 for all comparisons). Comparable BMD responses were observed with BZA at other skeletal sites. Significant decreases in serum osteocalcin and C-telopeptide levels from baseline and relative to PBO were observed as early as 3 months and remained sustained through study end (P<0.001). By month 24, median serum osteocalcin levels decreased from baseline by 21%, 22%, 22%, and 27% with BZA 10, 20, and 40 mg, and RLX, respectively, and 6% with PBO (P<0.001 vs baseline for each); median serum C-telopeptide levels decreased by 25%, 24%, 22%, and 32% with respective BZA doses and RLX and 13% with PBO (P<0.001 vs baseline for each). Overall, BZA was well tolerated and exhibited a favorable safety profile.

In conclusion, this study demonstrated that treatment with BZA, a new SERM, prevented bone loss, reduced bone turnover, and was generally well tolerated in postmenopausal women with normal or low BMD.

The Effect of a Single Large Oral Dose of Cholecalciferol on Serum 25-hydroxyvitamin D Levels in Humans. M. Ilahi, L. A. G. Armas, R. P. Heaney. Endocrinology, Diabetes & Metabolism, Creighton University Medical Center, Omaha, NE, USA.

We report results of work to quantify the response of 25-hydroxyvitamin D to a large oral dose of cholecalciferol. Large intermittent doses of vitamin D have been shown to reduce fracture risk and to elicit good patient compliance. However, the time course of the serum 25(OH)D response has never been measured and hence both the safety and the optimum frequency of dosing are uncertain.

This study included two groups, an older group of 20 subjects (age 61-84 yrs, 15 females, 5 males) and a younger group of 10 subjects (age 27-47yrs, 6 females, 4 males). The subjects were healthy with limited sun exposure. Data were collected from October to March. Subjects were dosed at baseline with 100,000 IU of cholecalciferol as a single oral dose. Blood for 25-hydroxyvitamin D was drawn throughout the ensuing 16 weeks. Blood for calcium was drawn through the first 5 days.

Baseline levels of 25(OH)D were 59.4 nmol/L (median; interquartile range 55.6-75.1) in the older group and 63.7 nmol/L (median; interquartile range 57.1-78.4) in the younger group. 25(OH)D increased to 92.1 nmol/L (median; interquartile range 81.1-104.6) in the older age group, and to 102.8 nmol/L (median; interquartile range 91.6-126.2) in the younger age group. Both groups reached peak 25(OH)D levels at day 7. In most of the subjects the mean 25(OH)D remained above 80 nmol/L for 70 days. Only two subjects in the older age group did not reach 80 nmol/L throughout the study. The incremental rise of 25(OH)D in the older age group was 28.7 nmol/L (median; interquartile range 24.0-37.9). In the younger age group the incremental rise of 25(OH)D was 36.5 nmol/L (median; interquartile range 28.0-52.1). Calcium at baseline for both the older and younger group was 9.5 mg/dl (median; interquartile range 9.4-9.8). Calcium levels during the first week of supplementation remained below baseline.

In summary, one large oral dose of 100,000 IU of cholecalciferol raises and maintains 25(OH)D above 80 nmol/L in most subjects for 70 days without raising serum calcium levels. No subject achieved a 25(OH)D level above what would commonly be found in outdoor workers at the end of summer. Even a dose this large will not raise 25(OH)D above 80 nmol/L in more severely vitamin D deficient subjects. We conclude that doses of 100,000 IU cholecalciferol are safe and that the optimum frequency of dosing is at least every 60-70 days.

Akt1 Contributes to Maintenance of Bone Mass and Turnover by Inhibiting Apoptosis of Osteoblasts Through FoxO3a/Bim Axis. N. Kawamura, F. Kugimiya*, T. Kadowaki*, K. Nakamura, U. Chung, H. Kawaguchi. Sensory & Motor System Medicine, Tissue Engineering, and Metabolic Diseases, University of Tokyo, Tokyo, Japan.

We found that mice lacking a phosphoinositide-dependent serine-threonine protein kinase Akt1 (Akt1^{-/-}) exhibited low-turnover osteopenia through dysfunctions of osteoblasts and osteoclasts: the former through increased susceptibility to apoptosis and decreased differentiation with impaired transactivity of Runx2, and the latter through suppressed RANKL expression in osteoblasts and cell-autonomous defects in osteoclasts. This study sought to learn the molecular mechanism underlying the enhanced apoptosis in Akt1^{-/-} osteoblasts. Among apoptosis-related molecules that are known to be possible substrates of Akt, transcription factors FoxO3a and FoxO1 were expressed in primary osteoblasts and MC3T3-E1 cells. Although these factors showed nuclear entry after serum deprivation, only that of FoxO3a was enhanced in Akt1^{-/-} osteoblasts as compared to wild-type (WT) osteoblasts. Meanwhile, overexpression of the constitutively active form of Akt1 (Akt1CA) in osteoblasts stimulated the cytoplasmic FoxO3a phosphorylation and inhibited the nuclear entry. The increased apoptosis and caspase-3 activity of Akt1^{-/-} osteoblasts after serum deprivation were restored by introduction of a dominant-negative form of FoxO3a (FoxO3aDN). Among the candidate molecules of the transcriptional target of FoxO3a: Fas ligand, Bim, and Bcl-xL, only Bim mRNA and protein levels were increased after serum deprivation, followed by the induction of cleaved caspase-3, in osteoblasts. The cleaved caspase-3 induction was suppressed by silencing of Bim through RNA interference. Actinomycin D canceled the Bim increase after serum deprivation, indicating the transcriptional regulation. The Bim promoter activity determined by luciferase-reporter assay was enhanced by FoxO3a, and endogenous Bim expression was stimulated by overexpression of FoxO3a while inhibited by FoxO3aDN, indicating that Bim is a transcriptional target of FoxO3a in osteoblasts. Akt1CA overexpression suppressed the Bim transactivation by FoxO3a and endogenous Bim induction after serum deprivation. The Bim induction which was higher in Akt1^{-/-} osteoblasts than WT was restored by the FoxO3aDN transfection. We therefore conclude that Akt1 inhibits osteoblast apoptosis through phosphorylation of FoxO3a and prevention of the nuclear entry, leading to impaired transactivation of pro-apoptotic Bim. Taken all together, Akt1 was established as a crucial regulator of osteoblasts and osteoclasts to maintain bone mass and turnover via several pathways.

Dimorphic Effects of Notch Signaling in Bone Homeostasis. F. Engin¹, T. Yang¹, G. Zhou¹, T. Bertin^{*1}, M. Jiang^{*1}, Y. Chen^{*1}, L. Wang², H. Zheng^{*1}, Z. Yao³, B. Boyce³, B. Lee⁴. ¹Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, ²Pediatrics, Baylor College of Medicine, Houston, TX, USA, ³Pathology and Laboratory Medicine, University of Rochester, Rochester, NY, USA, ⁴Molecular and Human Genetics, Baylor College of Medicine, Howard Hughes Medical Institute, Houston, TX, USA.

Evolutionarily conserved Notch signaling plays a critical role in diverse developmental and physiological processes including cell fate determination, differentiation, proliferation, and apoptosis. Dysregulation of Notch pathway has been associated with many different diseases including spondylocostal dysostosis and cancer. However, its in vivo function during mesenchymal cell differentiation, and specifically in bone homeostasis remains largely unknown. Here, we show that osteoblast-specific gain of Notch1 function results in severe osteosclerosis. Transgenic mice over-expressing Notch1 intra cellular domain (N1ICD) from the Col1a1 promoter have increased proliferation of immature osteoblasts that produce immature woven bone. Under these pathological conditions, Notch stimulates early osteoblastic proliferation by up-regulating Cyclin D, Cyclin E and Osterix. Notch also regulates osteoblastic terminal differentiation by directly binding Runx2, an essential transcription factor for osteoblastogenesis, and repressing its transactivation function. Consistent with this proliferative effect, human osteosarcomas show evidence of increased Notch signaling and its inhibition by a gamma-secretase inhibitor in vitro decreases the proliferation of human osteosarcoma cells. In contrast, loss of all physiologic Notch signaling in osteoblasts, generated by deletion of Presenilin 1 and 2 in osteoblasts, is associated with late onset, age-related osteoporosis. Double knock-out mice show decreased expression of Osteoprotegerin (Opg) expression indicating an increased osteoblast-dependent osteoclastic activity. Moreover, co-culture and flow cytometric analyses reveal increased differentiation of osteoclast precursors explaining the low bone mass phenotype in these mice. Together, these findings highlight the potential dimorphic effects of Notch signaling in bone homeostasis, and importantly, they may provide direction for novel therapeutic applications.

Osteoblasts in Adult Bone use Slug for Regeneration and Repair but not Remodelling. J. G. Mount*, S. Allen*, M. Muzylak*, L. E. Lanyon, A. Goodship*, I. M. McGonnell*, J. S. Price. Veterinary Basic Sciences, Royal Veterinary College, London, United Kingdom.

The zinc finger transcription factor Slug was first described as a marker of pre-migratory and migratory neural crest in the embryo. It is a member of the highly conserved Snail family of transcription factors, originally thought to be involved exclusively in developmental functions. Snail family members have not been identified in adult bone and have not been ascribed any function in osteoblasts. We recently identified a range of neural crest markers, including Slug, in the periosteum from which deer antlers regenerate (these are the only bones that repeatedly regenerate in adult mammals). This led us to further explore the role of Slug in bone. We also studied the relationship between Slug and Wnt signaling since there is a LEF/TCF binding site in Slug's promoter and during development it is regulated by Wnts.

Immunocytochemistry was used to co-localize Slug and activated β -catenin (β cat) in mesenchymal progenitors in the foetal primordia of antlers and in osteoblasts on the frontal bone on which antlers develop. Slug and β cat also co-localized in osteoblasts in foetal long bones. Slug could not be detected in any adult deer or rodent bones, however, in healing adult rat fractures it was identified in periosteal progenitors. Similarly, in regenerating adult antlers Slug and β cat localized in mesenchymal progenitors and in osteoblasts. This suggests that Slug may have distinct roles at early and late stages of skeletal cell differentiation. Interestingly, Slug was not detected in cartilage in regenerating antlers, nor in cartilage in fracture callus. This indicates that its down-regulation is required for chondrogenesis.

In order to investigate the relationship between Slug expression, osteogenesis and chondrogenesis, periosteum-derived progenitor cells (PDPs) were cultured under osteogenic or chondrogenic conditions. Slug expression increased as osteoblast differentiation increased (determined by changes in Osterix and Runx-2 expression), whereas its expression decreased with chondrocyte differentiation (determined by changes in Sox9 and type II collagen). Wnt/ β catenin signaling is known to control cell fate determination in mesenchymal cells and in PDP cells activation of Wnt signaling by LiCl decreased Slug expression.

In conclusion, we have shown, to our knowledge for the first time, that in adults Slug has a role in osteoblasts during bone regeneration and repair, but not remodeling. We also present evidence that Slug is involved in the regulation of mesenchymal cell fate by Wnt/ β catenin signaling. The study also affirms that in adults developmental mechanisms are recapitulated during bone regeneration and fracture repair.

MicroRNA Expression Profiling and Function During In Vitro Osteogenesis. G. J. Spencer*, P. G. Genever*. Department of Biology, University of York, York, United Kingdom.

Understanding molecular mechanisms that control osteogenic differentiation is central to the development of novel therapies aimed at bone remodelling such as osteoporosis. Many studies have successfully identified critical factors involved in initiating and maintaining lineage-specific transcriptional changes although the role of post-transcriptional gene silencing during osteoblast differentiation remains unclear. MicroRNAs (miRNAs) are a superfamily of evolutionary conserved, small non-coding RNAs that bind to the 3' UTR of mRNAs inhibiting protein translation and influencing a broad range of biological roles, instrumental in conferring tissue identity and function. In this study we aimed to determine expression and investigate the function of miRNAs during osteogenesis in vitro. Expression was determined by microarray analysis of 984 known and predicted miRNAs using RNA isolated from undifferentiated rat primary calvarial osteoblast progenitors or cells induced to differentiate in the presence of osteogenic supplements (dexamethasone, ascorbic acid and β -glycerolphosphate) over 21 days. Differentiation was confirmed by induction of alkaline phosphatase, von-Kossa positive mineralization and qRT-PCR, revealing temporally relevant changes in expression of osteogenic markers (cbfa-1, alkaline phosphatase, type-I collagen, osteopontin and osteocalcin). Analyses revealed constitutive expression of 20 miRNAs, 5 miRNAs specifically expressed in osteoblast progenitors but down regulated during osteogenesis and 35 miRNAs absent from progenitors and expressed in mature osteoblasts. The functional role of miRNAs was determined using anti-mir microRNA inhibitors transfected into rat calvarial osteoblast progenitors before osteogenic stimulation. Inhibition of miRNA, let7i, constitutively expressed throughout osteogenesis, significantly reduced alkaline phosphatase activity and impaired osteoblast differentiation as determined by changes in gene expression by qRT-PCR. In contrast, inhibition of progenitor specific mir298 promoted osteoblast differentiation and reduced osteoblast numbers as determined by viability assays. Bioinformatic analyses of let7i and mir298 targets using predictive algorithms revealed components of the Wnt, Notch and BMP signaling pathways, suggesting the endogenous function of let7i in promoting osteoblast differentiation, and mir298 in inhibiting differentiation and promoting proliferation may be mediated by specific regulation of these signaling pathways. Together these data provide evidence for an important functional role of miRNAs during osteogenesis which may have pervasive implications for our understanding of bone biology.

Pericytes Derived from Adipose Tissue; Characterization and Evaluation of their Osteogenic Potential. I. Kalajzic¹, L. Wang¹, X. Jiang^{*1}, K. Lamothe^{*2}, L. H. Aguila^{*2}, D. W. Rowe¹. ¹Dept. of Reconstructive Sciences, Uni. of Conn. Health Center, Farmington, CT, USA, ²Dept. of Immunology, Uni. of Conn. Health Center, Farmington, CT, USA.

We have shown that pericytes/myofibroblast expand following osteoblast ablation. This was assessed by a dramatic increase in a population of cells within the bone marrow that was positive for smooth muscle actin (SMAA), SM22 and exhibited a myofibroblastic phenotype. To further substantiate these observations and test the hypothesis that pericytes from non-calcified tissues have osteoprogenitor potential we have obtained SMAA-GFP transgenic mice that direct GFP towards smooth muscle cells and pericytes. We have characterized the GFP expression in bone and other tissues. A few SMAA-GFP positive cells detected in bone were localized to microvasculature in the periosteum and in a few locations within the trabecular area within bone marrow space. We have confirmed the close relationship of SMAA+ cells in periosteum with the underlying endothelial cells by CD31 immunohistochemistry. Utilizing SMAA-GFP, we observed rich vascular network in muscle and adipose tissue. In adipose tissue, two levels of SMAA+ cells were closely associated with CD31+ staining; a smooth muscle layer of blood vessels, and extensive capillary network.

Phenotypic analysis against cell surface markers expressed in mesenchymal progenitor cells showed that 50% of freshly isolated SMAA-GFP+ cells from adipose tissue were CD45-/Sca1+. Culturing for 6 days enriched this CD45-/SMAA+/Sca1+ mesenchymal progenitor population to 80%. In addition, SMAA+ cells were negative for c-kit and CD11b.

Bone marrow and adipose derived stromal cells isolated from SMAA-GFP mice were purified by FACS to generate SMAA-GFP+ and GFP- populations. Following induction to osteogenesis and adipogenesis, expression of bone and fat markers was restricted to SMAA-GFP+ population. This in vitro data confirmed that SMAA-GFP+ cells differentiated into osteoblasts and adipocytes. To confirm the ability of SMAA-GFP positive cells derived from adipose tissue to generate mature osteoblasts in an in vivo model, we have utilized dual transgenic mice obtained by breeding a SMAA(green) with osteoblast specific Col2.3(blue). Following FACS isolation, pure SMAA-GFP+/2.3GFP- cells were transplanted by direct intra marrow injection into GFP negative recipient mice. One month after the injection histological analysis of transplanted bones reveals the presence of numerous osteoblasts (Col2.3GFP+) localized to bone surface and closely associated with new bone formation as detected by underlying deposition of xylenol orange. Our result confirms that a pericyte population from adipose tissue has osteoprogenitor potential with the ability to generate mature bone lineage cells.

Oxidative Stress-induced Vascular Calcification Is Associated with Increased Expression of Receptor Activator of Nuclear Factor κ B Ligand (RANKL). C. Byon^{*1}, X. Feng¹, T. L. Clemens¹, J. M. McDonald², Y. Chen¹.

¹Pathology, MCP, University of Alabama at Birmingham, Birmingham, AL, USA, ²Pathology and VA medical Center, University of Alabama at Birmingham, Birmingham, AL, USA.

Oxidative stress plays a critical role in the pathogenesis of atherosclerosis, including the development of atherovascular calcification, a prominent feature of atherosclerosis. Enhanced osteogenic differentiation of vascular smooth muscle cells (VSMC) is associated with oxidative stress in vitro. Further, increased expression of RANKL is present in calcified vessels. Thus, we determined the effects of oxidative stress on the expression of RANKL and its role in VSMC calcification.

VSMC were explanted from the aorta of C57BL6 mice and the smooth muscle (SM) cell identity was confirmed by immunofluorescent staining with SM α -actin antibody. VSMC were exposed to osteogenic media for 3 weeks and mineralization was determined by von Kossa staining. H_2O_2 , at concentrations of 0.05 mM to 0.4 mM, were used to induce oxidative stress. The expression of RANKL, alkaline phosphatase (ALP), type I collagen (Col I), and osteocalcin (OC) was determined by real-time PCR and RT-PCR. The effect of oxidative stress on RANKL promoter activity was determined with a series of deletion mutants of RANKL promoter-luciferase reporters. All experiments were performed with VSMC at passage 5 to 8. H_2O_2 increased intracellular peroxide production in VSMC as determined by dichlorofluorescein fluorescence. VSMC mineralization was induced by H_2O_2 in a dose-dependent manner (fold increase at 0.05 mM=1.5 \pm 0.7, 0.3 mM=6.0 \pm 1.4, and 0.4 mM=16.0 \pm 1.4 compared with control, n = 4, p<0.05). Increased expression of bone-associated proteins including ALP, Col I and OC and decreased expression of SM- α actin were demonstrated when VSMC were exposed to 0.4 mM H_2O_2 (fold increase in ALP=8.7 \pm 1.2, Col I=6.6 \pm 0.9, and OC=5.3 \pm 1.4 compared with control, n = 4, p<0.05). In addition, a 33-fold increase in the expression of RANKL and no change in osteoprotegerin (OPG) was demonstrated in VSMC exposed to 0.4 mM H_2O_2 (n = 4). Luciferase-reporter assay revealed an oxidative stress-responsive region between -400 and -200 in RANKL promoter. Addition of RANKL (100 ng/ml) or OPG (50 ng/ml) protein into the osteogenic media did not affect VSMC calcification; and oxidative stress-enhanced calcification was not blocked in VSMC from RANKL knock out mice.

In summary, oxidative stress decreased the expression of SM α -actin and increased the expression of bone-associated proteins and calcification in VSMC. Oxidative stress induced the expression of RANKL via its promoter region located between -400 and -200. Elevation of RANKL during VSMC calcification did not mediate the effect of oxidative stress on VSMC calcification.

Androgens Act Directly via the Androgen Receptor in Mineralizing Osteoblasts to Regulate Bone Turnover and Maintain Trabecular Bone in Male Mice. R. A. Davey¹, M. Chiu^{*1}, C. Chiang^{*1}, A. J. Moore^{*2}, E. Doust^{*1}, C. Ma^{*1}, T. L. Clemens³, H. A. Morris³, J. D. Zajac³.

¹Medicine, AH, University of Melbourne, Heidelberg, Victoria, Australia, ²Hanson Institute, Adelaide, Australia, ³Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Androgens play a key role in skeletal growth and bone maintenance, however the relative contribution of their actions via the androgen receptor (AR) versus the estrogen receptor (ER) remains unclear. Our recent data using Collagen 1a1 2.3kb-AR knockout mice (KO) provides strong evidence for a role of androgens acting directly via the AR in mature osteoblasts to maintain trabecular bone (1). The aim of this study was to define the target cells of androgen action via the AR in bone using mice in which the DNA-binding actions of the AR are deleted specifically in terminally differentiated, mineralizing osteoblasts (mOBL-ARKOs).

mOBL-ARKO mice were generated by breeding mice with a floxed exon 3 of the AR gene (2) with osteocalcin-Cre mice. The phenotype of male mOBL-ARKOs and littermate controls (wild-type, AR floxed, osteocalcin-Cre) was assessed by histomorphometry in the distal femoral metaphysis at 6, 12 and 24 wks of age (n=10/group).

mOBL-ARKOs had normal femur length, body weight, testis and seminal vesicle mass compared to controls. Deletion of the AR specifically in mineralizing osteoblasts resulted in 22-38% decreases in trabecular number (TbN) at 6, 12 and 24 wks of age (P<0.05) in the secondary spongiosa. At 6 wks of age, this loss of TbN resulted in a 36% decrease in trabecular bone volume (BV/TV) (P<0.01). In contrast, BV/TV in mOBL-ARKOs did not differ from controls at 12 and 24 wks of age, as they were able to maintain or increase trabecular thickness (P<0.05), suggesting a compensatory mechanism to prevent further bone loss in the absence of AR action in mineralizing osteoblasts. The loss of TbN observed at all ages is likely to be due to increased bone resorption, evident from 12 wks of age as measured by serum X-laps (P<0.05). Although the mean X-laps was higher in mOBL-ARKOs at 6 wks of age (mean \pm SE; wild-type: 92 \pm 6; mOBL-ARKO: 122 \pm 15, n=10), this did not reach significance (P=0.07). Trabecular bone parameters in the primary spongiosa were unaffected in mOBL-ARKOs indicating that the accrual of new bone is not dependent on the DNA-binding actions of the AR in mineralizing osteoblasts.

Our findings conclusively demonstrate that in addition to the well-established actions of androgens via aromatization to estrogen, androgens also act directly via the AR in osteoblasts. We have now shown that androgens also act directly via the AR in mineralising osteoblasts to maintain trabecular bone mass by regulating bone turnover.

Local Over Expression of Aromatase in Osteoblasts Leads to Clearly Increased Bone Mass. K. Sjogren*, N. Andersson, S. Movérare-Skrtic*, C. Swanson, C. Ohlsson. Division of Internal Medicine, Medicine, Goteborg, Sweden.

Testosterone (T) is of importance for the regulation of peak bone mass and age-dependent bone loss in males. The effects of T on bone can either be direct or mediated via local aromatization of T to estrogen (E2), followed by activation of estrogen receptors (ERs) in osteoblasts.

To investigate the importance of high local formation of E2 in osteoblasts, we developed a transgenic mouse model that over-expresses the human aromatase gene under the control of the rat type I alpha I procollagen promoter (Coll-Aro mice). This promoter will direct the aromatase expression to late osteoblasts in bone.

Measurements of aromatase expression in bone by quantitative real-time PCR showed that the system works and that Coll-Aro mice have a high and specific expression of human aromatase in bone. The bone specific expression of aromatase was supported by that serum E2 levels were unaffected in both male and female Coll-Aro mice and that the uterine weight was unaffected in female mice. At 11 weeks of age, male Coll-Aro mice exhibited a dramatic increase in cortical bone mineral content as analysed in the diaphyseal region in femur (+28%, $p < 0.001$) while there was no effect in female mice as measured by peripheral quantitative computed tomography (pQCT). The increased cortical bone mineral content in the male Coll-Aro mice was mainly due to increased cortical thickness (+21%, $p < 0.001$) but also to a slightly increased cortical volumetric BMD (+6%, $p < 0.001$). Detailed analysis of the tibia by μ CT revealed an increase in trabecular thickness (+9%, $p < 0.05$) in male Coll-Aro mice.

In conclusion, we show that bone-specific anabolic estrogenic effects can be achieved without systemic adverse effects by increasing the expression of aromatase specifically in bone. Based on the fact that aromatase expression in osteoblasts and breast/uterus is dependent on different promoters one may speculate that development of tissue specific inducers of aromatase expression in bone might result in bone-anabolic effects without systemic adverse effects.

Modulation of Mouse RANKL Gene Expression by Runx2 and Vitamin D3. R. Kitazawa, K. Mori, T. Kondo, S. Kitazawa. Division of Pathology, Kobe University, Graduate School of Medicine, Kobe, Japan.

The expression of receptor activator of nuclear factor- κ B ligand (RANKL) in osteoblastic cells is regulated by bone-seeking hormones such as PTH and vitamin D3. Runx2 is a master gene for osteoblastic differentiation and, at the same time, modulates osteoclastogenesis by regulating RANKL gene through the proximal (-378/-354, -214/-194 and -200/-180) and the distal (conserved noncoding sequence located 76 kb upstream of exon 1) runx2 sites. To elucidate the precise mechanism whereby runx2 and vitamin D3 regulate RANKL expression, we studied the function of runx2 on chromatin structure and on the proximal binding sites using mouse osteoblastic cell lines derived from normal (ST2) and runx2-deficient mice (C6).

Quantitative RT-PCR revealed that although the expression of RANKL mRNA in the steady-state was higher in runx2-deficient C6 cells than in ST2, it increased 20-fold in ST2, but only 1.8-fold in C6 by an 8-hour D3 treatment. Additionally, runx2 knock down in ST2 by siRNA resulted in an increase in the steady-state expression of RANKL mRNA and a decrease in the inducible effect of D3. Conversely, restoration of Runx2 by the Tet-On system in C6 decreased steady-state RANKL expression and increased the inducible effect of vitamin D3.

The exogenous transfected 2 kb promoter-reporter construct (2k-luc) showed 60% of the steady-state activity in C6 compared with that in ST2. Vitamin D3 increased the promoter activity of 2k-luc in ST2, but not in C6. Forced expression of runx2 by Tet-On system in C6 increased the steady-state activity of 2k-luc and its response to D3. Transfection of the mutated constructs with any one, two or all of the three proximal runx2 sites, depending on the number of mutated sites, decreased both the steady-state activity and the inducible effect of vitamin D3 in ST2, but not in C6. These data suggest that runx2 may exert a positive effect on the activity of the proximal 2kb promoter and its response to vitamin D3. We then assessed the acetylation status of the area spanning 40 kb upstream of the basic promoter in ST2 and C6 by ChIP assay with anti-acetylated H3 and H4 histone antibodies. Whereas H3 and H4 histone acetylation was detected even in the steady-state in C6, it was detected only in the presence of vitamin D3 in ST2, suggesting that constitutive histone acetylation of the 5' flanking region of the RANKL gene due to runx2-deficiency in C6 may cause its higher expression at the steady-state than in ST2.

Although runx2 may suppress RANKL gene by condensing chromatin structure, it exerts a positive effect in D3-induced RANKL transcription when the proximal runx2 sites are accessible to runx2 by D3 treatment. Thus, RANKL expression in stromal/osteoblastic cells is keenly regulated in response to vitamin D3 by transactivating the gene at two different levels.

Sex Steroids Hormone Receptors in Osteoclasts Mediate Osteoprotective Effects by Regulating Its Life Cycle. Y. Imai¹, T. Nakamura², T. Matsumoto^{3*}, S. Takeda⁴, K. Igarashi^{5*}, T. Fukuda^{6*}, Y. Yamamoto^{2*}, J. Kanno^{5*}, K. Takaoka⁶, T. J. Martin⁷, P. Chambon^{8*}, S. Kato³. ¹Laboratory of Nuclear Signaling, Institute of Molecular and Cellular Biosciences, The University of Tokyo, Department of Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Tokyo, Japan, ²Laboratory of Nuclear Signaling, Institute of Molecular and Cellular Biosciences, The University of Tokyo, Tokyo, Japan, ³Laboratory of Nuclear Signaling, Institute of Molecular and Cellular Biosciences, The University of Tokyo, ERATO, JST, Tokyo, Japan, ⁴Tokyo Medical and Dental University, Tokyo, Japan, ⁵Division of Cellular and Molecular Toxicology, National Institute of Health Sciences, Tokyo, Japan, ⁶Department of Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan, ⁷St. Vincent's Institute of Medical Research, Fitzroy, Australia, ⁸Institut de Genetique et de Biologie Moleculaire et Cellulaire and Institut Clinique de la Souris, Illkirch, France.

Sex steroids, estrogen and androgen, have the osteoprotective effect and prevents bone loss such as post-menopausal osteoporosis. However the molecular mechanism of how these are accomplished remains to be elucidated. Here we report critical roles of osteoclastic androgen receptor (AR) in males and osteoclastic estrogen receptor alpha (ER α) in females in mediating the actions of sex steroids on bone.

We selectively ablated AR and ER α in differentiated osteoclasts (AR^{ΔOC/Y} and ER^{ΔOC/ΔOC}) using Cathepsin K-Cre knock-in mice. AR^{ΔOC/Y} males exhibited clear bone loss in plain X-ray and 3D-CT, similar to the osteoporotic bone phenotype. Also in DEXA, femurs of AR^{ΔOC/Y} males showed low bone mineral density. Bone histomorphometric analysis revealed significant increase of osteoclast surface, osteoclast number and eroded surface in AR^{ΔOC/Y} males when compared to the control. In addition, MAR and BFR were increased in AR^{ΔOC/Y} males, these results suggested that AR^{ΔOC/Y} males had a high turnover osteoporotic phenotype. In *in vitro* study, quantitative RT-PCR showed that mRNA expression of Fas ligand (FasL) was facilitated in AR-overexpressed primary cultured osteoclasts treated with DHT, although the expression of Fas was not altered. Likewise, osteoclastic ER α appeared to mediate the osteoprotective estrogen action in females, but not males.

From these findings, we presume that the osteoprotective actions of sex steroids are mediated at least in part through osteoclastic AR in male and ER α in female, and that sex steroids regulate the life span of mature osteoclasts by controlling Fas/FasL related cell death signaling.

Control of Estradiol-Directed Gene Transactivation by an Intracellular Estrogen Binding Protein and an Estrogen Response Element Binding Protein. H. Chen, M. Hewison, J. S. Adams. Endocrinology, Diabetes and Metabolism, Cedars-Sinai Medical Center, Los Angeles, CA, USA.

Experiments of nature have helped to illuminate the key pathways associated with metabolism and signal transduction of steroid hormones. In recent studies we have used the steroid hormone resistance exhibited by New World primates (NWP) to identify entirely novel mechanisms associated with intracellular trafficking and DNA targeting of steroid hormones. NWP exhibit resistance to estrogens that is associated with overexpression of an estrogen response element binding protein (ERE-BP) and an intracellular estradiol binding protein (IEBP). The NWP ERE-BP shows homology with human heterogeneous nuclear ribonucleoprotein C like protein, whilst IEBP shows homology with human hsp27. Although ERE-BP acts as a competitor for ERE occupancy by liganded estrogen receptor-alpha (ER), the function of IEBP/hsp27 is less clear. In new studies using human breast cells we show that IEBP/hsp27 can regulate estrogen signaling: 1) as a protein chaperone for ER; 2) as a cytosolic decoy for estradiol (E₂) binding; 3) by binding to ERE-BP and modulating the temporal organization of ERE occupancy by the ER and ERE-BP. IEBP/hsp27 was able to bind E₂ with relatively high affinity (K_d=0.25 nM). This was similar to that observed with estron (0.1 nM), whereas the selective estrogen receptor modulator tamoxifen showed no binding to IEBP/hsp27. Studies using ER^{ΔVE} MCF-7 cells showed that, in the absence of E₂, IEBP/hsp27 and ER were localized predominantly in the cytoplasm, with both translocating to the nucleus in the presence of E₂. GST-pulldown analyses confirmed binding of ER to IEBP/hsp27 but also revealed indirect association between ER and ERE-BP. Protein-protein interaction of IEBP/hsp27 and ERE-BP was confirmed by immunolocalization, as well as yeast 2-hybrid and GST-pulldown analyses. These studies also showed that normal E₂ responses in MCF-7 cells involve cycling of the IEBP/hsp27-ERE-BP complex between the cytosol and nucleus. Over-expression of either IEBP/hsp27 or ERE-BP suppressed E₂-mediated transcription in ER^{ΔVE} cells. This was associated with abnormal subcellular distribution of the IEBP/hsp27-ERE-BP complex, which resulted in concomitant dysregulation of ERE occupancy by ER and ERE-BP as determined by chromatin immunoprecipitation. We hypothesize that IEBP/hsp27 and ERE-BP not only cause hormone resistance in NWP but are also crucial to normal estrogen signaling in human cells. In particular, protein-protein interaction between IEBP/hsp27 and ERE-BP in both cytosolic and nuclear compartments appears to be essential to the regulation of their individual actions on ER signaling.

Estradiol Mediates Rescue of the Dominant-negative Effects of Estrogen Response Element-binding Protein In Vivo. H. Chen, M. Hewison, L. Nguyen*, J. S. Adams. Endocrinology, Diabetes and Metabolism, Cedars-Sinai Medical Center, Los Angeles, CA, USA.

Biological responses to estrogens are dependent on the integrated actions of various proteins, including the estrogen receptor (ER), that regulate the transcription of estrogen response element (ERE)-containing target genes. We have identified a naturally occurring antagonist of this mechanism that functions by competing with ER for ERE occupancy. The hnRNP-like protein, termed an ERE-binding protein (ERE-BP), is constitutively over-expressed in cells from estrogen-resistant New World primates. In order to verify that ERE-BP legislates estrogen resistance *in vivo*, we generated transgenic mice that specifically over-express varying levels of ERE-BP in breast tissue under the control of whey acidic protein gene promoter. Female transgenic mice with high levels of ERE-BP were unable to nurse their pups, none of which survived to weaning unless were fostered. Mice expressing intermediate and low levels of ERE-BP in breast had progressively more estrogen-driven breast development and lactational capacity. We hypothesized that escape from the dominant-negative action of ERE-BP on the breast was dictated by relative balance in ERE-BP expression levels and the concentration of estrogen available to the dominant-positive-acting ER. To test this hypothesis, four-week-old ERE-BP-high female mice were implanted subcutaneously with a capsule containing 7.2mg/21day-release estradiol (E2) or placebo. Analysis of 8-week-old mice breast whole-mounts and histology showed that E2-treated ERE-BP mice exhibited a 4.5-fold increase in mammary gland branch number ($p<0.001$) and 3.7-fold increase in duct number ($p<0.05$) compared with the placebo-infused controls. Analysis of postpartum breast whole-mounts and histology showed that E2-treated ERE-BP mice demonstrated more than a doubling in milk-containing lumina and a 3.0-fold increase in lobule-alveolae and duct formation ($p<0.02$) compared to placebo-infused ERE-BP mice, consistent with improved mammary gland differentiation. These data emphasize that 1) ERE-BP is a potent attenuator of estrogen-directed bioactivity and 2) increased circulating levels of E2 can rescue the host from the suppressive effects of ERE-BP *in vivo*, confirming *in vitro* data from our group. In summary, we have shown for the first time that there exists a reciprocal, dominant-positive:dominant-negative relationship between E2-liganded ER and ERE-BP *in vivo*. Although our experiments have focused on breast tissue, we hypothesize that ERE-BP is a crucial determinant of ERE-directed estrogen responses throughout the body.

Bax-deficient Mice Exhibit Marked Increase in Callus Size and Cartilage During Endochondral Repair of Femur Fractures. C. H. Rundle, X. Wang*, J. E. Wergedal, M. H. C. Sheng, R. M. Porte*, K. H. W. Lau, S. Mohan. Research (151), J.L. Pettis VAMC, Loma Linda, CA, USA.

While it is clear that endochondral bone formation during fracture repair involves the spatial and temporal regulation of the proliferation and differentiation of multiple cell types, there is suggestive evidence that the spatial and temporal regulation of apoptosis is also critical. Accordingly, this study evaluated the effects of Bax (a pro-apoptotic gene) deficiency on fracture repair. Healing of femoral fractures (created by three-pointed bending) in adult Bax KO [in a C57BL/6 (B6) genetic background] and B6 control mice was monitored by pQCT and histomorphometry. Bax KO mice developed larger calluses with increased cartilage area [3-fold at 7 days ($p<0.003$); 2-fold at 14 days ($p<0.05$)]. The bone mineral content (BMC) of Bax KO calluses was also greater than B6 calluses [\sim 2-fold each at 14 days ($p<0.004$), 21 days ($p<0.04$), and 28 days ($p<0.0008$)]. Cell counts within the cartilage area of the healing calluses showed that the enlarged cartilage in the Bax KO callus was due to an increase in chondroblast number and not cell size. To evaluate whether the BAX deficiency-related impairment of apoptosis accounted for the difference, the number of apoptotic cells in the cartilage within the healing callus was determined by the TUNEL assay. There was no significant difference in the percentage of apoptotic cells, indicating that the large increase in chondroblast number could not be due to differences in chondroblast apoptosis alone and suggesting that Bax deficiency also increased chondroblast proliferation during early fracture healing. There were also more osteoclasts on the woven bone surfaces of Bax KO mice during callus remodeling at 21 days (25%, $p<0.004$) and 28 days (33%, $p<0.05$). The callus size and BMC of Bax KO mice returned to B6 levels at 35 days. To identify a mechanism for the increase in chondroblasts, whole genome gene expression analysis was performed at 14 days post-fracture. There were no significant expression changes in genes associated with mitochondrial apoptosis, with the exception of the Bik-like gene (2.3-fold increase, $p<0.05$), suggesting a compensatory function for this gene. Consistent with the greater prehypertrophic chondrocyte content of early fracture cartilage, the expression of collagen-2 and collagen-9 (3-fold, $p<0.05$ for each), but not collagen-10, was elevated. Conclusions: 1) Bax deficiency enhanced cartilage formation, bone formation and remodeling during fracture repair, suggesting that Bax is a negative regulator of these processes, and 2) Bax deficiency increased chondroblast proliferation, suggesting that Bax may regulate fracture repair through a mechanism independent of its pro-apoptotic action.

Type III Sodium-Dependent Phosphate Transporter Controls Endochondral Ossification Through Regulating Chondrocyte Apoptosis. A. Sugita¹, S. Kawai¹, T. Hayashibara^{*1}, H. Yoshikawa², T. Yoneda¹.

¹Biochemistry, Osaka University Graduate School of Dentistry, Suita, Japan,

²Orthopedics, Osaka University Graduate School of Medicine, Suita, Japan.

Previous studies reported that phosphate levels in growth plate increased as chondrocyte differentiation advances. Cartilage differentiation is markedly disturbed in X-linked hypophosphatemia (XLH), a dominant disorder of phosphate homeostasis. These results suggest a critical role of phosphate in chondrocyte differentiation. Extracellular phosphate is incorporated into cells through the sodium-dependent phosphate transporter (NPT). Growth plate chondrocytes express type IIa NPT (Npt2a) and type III NPT (Pit-1). It is therefore likely that these NPTs are involved in the regulation of chondrocyte differentiation. However, which NPT is a major player is currently unknown. Phosphonoformic acid (PFA), a non-selective competitive inhibitor of NPT, reduced ³²P uptake and suppressed apoptosis in mouse primary rib chondrocytes. PFA also inhibited chondrocyte apoptosis *in vivo*. Of interest, PFA decreased intracellular levels of ATP, which is essential for the activation of caspase-9 and caspase-3, leading to the progression of apoptosis. To investigate the specific role of phosphate in chondrocyte apoptosis, we knocked-down Npt2a or Pit-1 using small interfering double-stranded RNA (siRNA). siPit-1 significantly decreased ³²P uptake, intracellular ATP levels, caspase-9 and caspase-3 activity, followed by reduced apoptosis. As a consequence, calcification of chondrocytes was diminished. In contrast, siNPT2a showed no effects. Both siPit-1 and siNPT2a did not affect early stages of chondrocyte differentiation. Finally, we examined the effects of Pit-1 overexpression on apoptosis in chondrocytes of Hyp mice that are a mouse homologue of human XLH and exhibit reduced Pit-1 expression and apoptosis in cartilage compared with wild-type mice. Overexpression of Pit-1 significantly increased ³²P uptake in Hyp chondrocytes. In conjunction, it also increased intracellular ATP levels, caspase-9 and caspase-3 activation and apoptosis in Hyp chondrocytes. In conclusion, our results suggest phosphate uptake through Pit-1 specifically modulates the activation of ATP-dependent caspase signaling pathway, which in turn controls apoptosis and calcification of chondrocytes, thereby regulates endochondral ossification.

The 7B2 Protein Regulates FGF-23 Degradation and Production in X-linked Hypophosphatemia (XLH). B. Yuan*, M. Takaiwa*, Y. Xing*, J. J. Meudt*, M. K. Drezner*. Department of Medicine, Endocrinology Section, University of Wisconsin, Madison, WI, USA.

The mechanism by which inactivating PHEX mutations increase serum FGF-23 remains unknown. However, FGF-23 may be processed at a subtilisin-like proprotein convertase (SPC) cleavage site (RXXR). Indeed, we reported mice treated 5 days with an SPC inhibitor, Decanoyl-Arg-Val-Lys-Arg-chloromethyl ketone (Dec), develop inhibition of FGF-23 degradation and elevation of serum FGF-23, as well as abnormal Pi homeostasis and vitamin D metabolism, characteristic of XLH. Yet, these studies did not reveal increased FGF-23 mRNA, failing to recapitulate the mechanism underlying abnormal serum FGF-23 in XLH. Thus, we further investigated if abnormal SPC activity can create both aberrant FGF-23 cleavage and production. Initially, we explored if SPC2 and helper protein 7B2 truly alter FGF-23 degradation, using HEK293 cells transfected with recombinant FGF-23 cDNA and co-transfected with SPC2 and 7B2 alone or together. After 48 hours Western blotting indicated neither SPC2 nor 7B2 alone altered FGF-23 degradation. However, transfection with SPC2 and 7B2 increased C-terminal fragments of FGF-23 in cell culture medium (2.14 ± 0.18 vs 1.0 ± 0.08 ; $p<0.01$) and decreased intact FGF-23 in cell lysates (0.48 ± 0.4 vs 1.02 ± 0.2 ; $p<0.05$), confirming that diminished SPC2/7B2 activity may increase serum FGF-23 levels. Subsequently, we explored if SPC2/7B2 inhibition altered FGF-23 mRNA production. Incubation of immortalized osteoblasts with 25 μ M Dec for 12h inhibited FGF-23 degradation, but more importantly increased FGF-23 mRNA (3.9 ± 0.9 vs 1.2 ± 0.2 ; $p<0.001$). Surprisingly, altered FGF-23 degradation and production corresponded with decreased 7B2 active protein (0.53 ± 0.01 vs 1.77 ± 0.1 ; $p<0.001$) and mRNA (0.61 ± 0.09 vs 1.04 ± 0.14 ; $p<0.001$). These observations suggest that decreased 7B2 not only reduces FGF-23 degradation but up-regulates production. To confirm this possibility we assessed 7B2 in hyp-mice, the murine homolog of XLH. The hyp-mice have decreased osseous production of 7B2 mRNA (0.45 ± 0.02 vs 1.06 ± 0.05 ; $p<0.01$) and reduced 7B2 active protein (0.68 ± 0.04 vs 1.0 ± 0.08 ; $p<0.01$). Further, we found that administration of 25 μ M Dec to normal mice for 12-days not only resulted in the HYP biochemical phenotype, but in a significant decrease in osseous 7B2 mRNA (0.84 ± 0.05 vs 1.0 ± 0.12 ; $p<0.05$), an expected decrease of FGF-23 degradation and an increase in FGF-23 mRNA (2.23 ± 0.12 vs 1.16 ± 0.02 ; $p<0.01$). Our observations indicate that decreased 7B2 production and accordingly 7B2 active protein in osteoblasts result in the sustained elevation of circulating FGF-23 in XLH due both to the direct effects of SPC2/7B2 on FGF-23 cleavage and to likely downstream effects of SPC2/7B2, which increase FGF-23 mRNA production.

Abnormal Bone Mineralization, Osteoclastogenesis & Bone Turnover in Transgenic Mice Overexpressing MEPE. V. David¹, A. Martin¹, L. W. Fisher², A. Hedge¹, P. S. N. Rowe¹. ¹Internal Medicine, Kansas University Medical Center, Kansas City, KS, USA, ²NIDCR-NIH, Bethesda, MD, USA.

Matrix extracellular phosphoglycoprotein (MEPE) is a SIBLING-protein involved in bone-mineralization. Although increased MEPE expression occurs in several bone-mineral and renal-phosphate handling diseases, its precise physiological role is unknown.

In this study, we constructed transgenic-mice overexpressing murine-MEPE (Col1a1 2.3kb promoter) and used them as a model-system to test whether MEPE influences bone-mineralization in vivo. We analyzed bone-phenotypes of male-transgenic (TGC) and wild type (WT) C57BL6 newborn, 5 week-old and 19 week-old adult mice (n=10).

Protein (western-blot) and mRNA (RT-PCR) measurements confirmed a 50X over-expression of MEPE in bone. Newborn mice overexpressing MEPE displayed a low bone-mass phenotype (see figure, 53% decrease in BMD, $p<0.001$). Abnormal bone-growth also occurred at 5 weeks as assessed by femur length (5% decrease, $p<0.01$) and growth plate width (+26%; $p<0.05$). In older animals, X-ray densitometry and 3D-microtomography analyzes (uCT) showed MEPE over-expression results in a lower tibial bone-mineral density (6% decrease, $p<0.01$) and cortical thickness (10% decrease, $p<0.01$). In contrast, TGC mice had a significantly reduced vertebral trabecular bone-volume (8%, $p<0.05$). Despite an increase in PHEX (+300%, $p<0.05$) and other osteocyte and osteoblast specific markers, MEPE over-expression resulted in reduced bone-remodeling. Specifically, TGC mice displayed lowered bone-formation rate (34% decrease in BFR/BS, $p<0.05$), reduced osteoclast number (33% decrease N.Oc/B.Pm, $p<0.01$), as well as serum and urinary bone-resorption markers (CTX and PYD, -50%, $p<0.05$). Also, BMSCs from MEPE transgenic-mice failed to mineralize in vitro as measured by alizarin-red staining. Interestingly, a 5X increased mRNA expression of DMP1 (a related SIBLING-protein) occurred in transgenic bone.

In summary, our findings show bone over-expression of MEPE negatively impacts bone-mineralization, hinders bone-growth and reduces bone-resorption and modeling age-dependently. Also, an indirect or direct negative effect on osteoclastogenesis plays a key role in the transgenic phenotype.

FGF Receptors 3 and 4 Are Not Physiologically Relevant FGF23 Targets in the Kidney. S. Liu, L. Vierthaler*, W. Tang*, J. Zhou*, L. D. Quarles. Internal Medicine/The Kidney Institute, University of Kansas Medical Center, Kansas City, KS, USA.

Fibroblast growth factor 23 (FGF23) is a phosphaturic factor that exerts its biological effects on the kidney proximal tubule, leading to suppression of the sodium-dependent phosphate transport and production of 1,25(OH)₂D and to rickets/osteomalacia. FGF23 activation of target tissues appears to require the co-expression of FGF receptors and klotho, a transmembrane beta-glucuronidase. Klotho binds to the c splice isoforms of FGF receptors 1, 3 and 4, and the resulting FGF receptor:klotho complex creates the functional FGF23 receptor. The proximal tubule restricted location of the FGF receptor 3c implicates this receptor as the physiologically relevant target for FGF23 in the kidney. To confirm the role of FGF receptor 3 in mediating FGF23-dependent kidney effects, we crossed Hyp mice, which have elevated circulating FGF23 levels due to an inactivating Phe mutation, onto FGFR3-null mice. Consistent with their high circulating FGF23 levels, Hyp mice compared to wild-type (WT) littermates exhibited low serum phosphate (5.5 ± 0.2 mg/dL in Hyp vs. 8.9 ± 0.2 mg/dL in WT, $P < 0.01$) and serum 1,25 (OH)₂D levels (132 ± 25 pM in Hyp vs. 197 ± 23 pM in WT, $P = 0.08$), reduced Npt2a expression in the proximal tubules, and low bone mineral density (BMD) due to the presence of osteomalacia. In contrast, neither the serum phosphate nor 1,25(OH)₂D levels were altered in FGF receptor 3 null mice. More importantly, ablation of the FGF receptor 3 in Hyp mice failed to correct

the hypophosphatemia, aberrant 1,25(OH)₂D levels, reduced Npt2a expression or decreased BMD. In similar studies, ablation of FGF receptor 4 in Hyp mice also failed to correct the effects of excess FGF23. To explore the role of FGFR1 and klotho in mediating the proximal tubule response to FGF23, we performed immunohistology of mouse kidneys using FGFR1 and klotho specific antibodies. Consistent with previous reports, we found that both FGFR1 and klotho are predominately expressed in the distal rather than the proximal tubule. Our findings suggest that neither FGFR3 nor FGFR4 are responsible for the renal actions of FGF23. Moreover, the co-localization FGFR1 with klotho in the distal tubule would require the presence of a distal to proximal tubular autocrine pathway to explain FGF23 inhibition of renal phosphate absorption and 1,25(OH)₂D production by the proximal tubule. Further studies are needed to determine whether FGFR1c in the distal tubule or a novel receptor in the proximal tubule mediate the renal effect of FGF23.

Alox5 Null Mice Have Reduced Cortical Bone Density, Altered Bone Turnover and Low Serum IGF-I. V. E. DeMambro¹, L. G. Horton¹, C. L. Ackert-Bicknell¹, W. G. Beamer¹, M. C. Horowitz², C. J. Rosen¹. ¹The Jackson Laboratory, Bar Harbor, ME, USA, ²Yale University School of Medicine, New Haven, CT, USA.

We previously reported that a congenic mouse strain, B6.C3-6T, which carries a 30 cM QTL region from C3H on Chr 6. B6.C3-6T, has reduced serum IGF-1, decreased areal BMD and low trabecular BV/TV, with enhanced marrow adiposity. A candidate gene in this QTL is Alox5 (Lipoxygenase 5), which by sequencing in 6T, has a truncated 3'UTR. Alox5 was also reported to be a prime candidate gene for BMD and fat mass in a B6 x DBA analysis, although phenotyping was limited in the Alox5 nulls (-/-) by small numbers of mice(1). To test the hypothesis that Alox5 polymorphisms could contribute to the 6T phenotype, we raised Alox5-/- (n=20) mice on a pure B6 background and compared them with littermate +/- (n=20) controls. At 16 weeks, male and female Alox5-/- had decreased aBMD ($p<0.05$) by DXA; % body fat was lower in the male -/- vs +/- ($p<0.05$) but did not differ in the females. Femoral pQCT revealed that both male and female Alox5-/- mice had decreased total vBMD, reduced periosteal and endosteal circumferences, and thinner cortices ($p<0.05$ vs gender matched +/-). Femur length was not affected. MicroCT40 of the femur revealed a decrease in both Bone Area and Bone Surface at the midshaft of female and male -/- mice, while analysis of the distal femur showed that male Alox5-/- mice had slightly reduced BV/TV ($p=0.08$ vs +/-) due to a decrease in trabecular thickness ($p<0.05$ vs +/-), without changes in trabecular number. Female Alox5-/- mice had an increase in distal femoral BV/TV ($p<0.05$ vs +/-) and connectivity density ($p<0.05$ vs +/-) with a trend towards increased trabecular number and decreased trabecular spacing. Histomorphometry of female -/- tibias at 8wks of age showed decreased osteoblasts/osteoid perimeter ($p=0.02$ vs +/-) and a slightly reduced Bone Surface/Bone Volume ($p=0.10$ vs +/- controls). Both male and female Alox5-/- had a 15-20% reduction in serum IGF-1 ($p<0.05$ vs +/-) while osteocalcin levels tended to be lower in the females -/- ($p=0.10$ vs +/-) but not in the males -/-. In vitro studies of marrow stromal and bone marrow cells from 10wk Alox5-/- females demonstrated reduced CFU-AP+ colonies ($p<0.05$ vs +/-), as well as less TRAP+ multinucleated osteoclasts compared to controls. In summary, Alox5-/- mice have in vivo and in vitro evidence of altered bone turn over, as well as compartment specific changes in the skeleton. Polymorphisms in the Alox5 gene may contribute to the unique skeletal phenotype of 6T, and may be important in peak bone acquisition.

Weekly Administration of a Novel Parathyroid Hormone - Collagen Binding Domain Fusion Protein Increases Bone Mineral Density by More Than 15 Percent in Normal Mice. T. Ponnappakkam¹, O. Matsushita^{2*}, J. Sakon³, R. C. Gensure¹. ¹Pediatrics, Ochsner Clinic Foundation, New Orleans, LA, USA, ²Microbiology and Parasitology, Kitasato University School of Medicine, Tokyo, Japan, ³Chemistry and Biochemistry, University of Arkansas, Fayetteville, AR, USA.

Parathyroid hormone (PTH) is an anabolic bone agent which has been shown to be superior to bisphosphonate compounds in the treatment of osteoporosis; however, bisphosphonates are currently the first line treatment for this disorder primarily because of dosing convenience and more favorable side-effect profile. Bisphosphonates accumulate in the bone, allowing them to be efficacious with weekly/monthly oral dosing or yearly intravenous dosing. PTH, on the other hand, is quickly metabolized in the bloodstream and must therefore be given by daily subcutaneous injection. To prolong the retention of PTH in the bone, and thus prolong its duration of action and minimizing systemic side-effects, we have synthesized a fusion protein (PTH-CBD) of human PTH(1-33) and the collagen binding domain of ColH collagenase, derived from Clostridium histolyticum. In-vitro collagen binding assays indicate that the PTH-CBD fusion protein retains its ability to bind collagen. PTH-CBD also stimulates cAMP accumulation with similar potency and efficacy to human PTH(1-34) in LL-CPK cells stably transfected with the parathyroid hormone receptor (PTH-CBD: Kd = 2×10^{-8} M, Emax = 390 ± 54 pmol/well; PTH(1-34): Kd = 1.5×10^{-8} M, Emax = 357 ± 60 pmol/well). Weekly injections of PTH-CBD in normal young female C57BL/6J mice (Jackson Laboratories) for 8 weeks resulted in a 16.7 ± 4.5 percent ($p<0.01$, N=6) increase in spinal bone mineral density (BMD), vs. 7.3 ± 7.1 percent for PTH(1-34) (NS, N=6) and 4.9 ± 6.7 percent for vehicle control (NS, N=8). BMD was also measured in excised spines after sacrifice, and there was again a significant increase seen after PTH-CBD treatment vs. vehicle control (15.4% increase, 74.8 ± 3.0 vs. 64.9 ± 1.5 mg/cm², $p<0.05$). The PTH(1-34) group showed no significant change in BMD vs.

vehicle control (67.7 \pm 2.5 vs. 64.9 \pm 1.5 mg/cm², NS). There were no side effects observed in either treatment group; the animals did not develop hypercalcemia and there was no evidence of bone tumors in whole-body DEXA scans or in excised bone tissues at the end of the study. In-vivo efficacy of longer (i.e. monthly) dosing intervals of PTH-CBD is currently being assessed. This novel fusion protein represents an application of a new concept in drug design, combining individual protein domains to create an agent with unique properties. PTH-CBD allows the superior anabolic effect of parathyroid hormone in the treatment of osteoporosis to be obtained with a more convenient dosing interval, at least in mice.

ACE-011, A Soluble Activin Receptor Type IIA Fusion Protein, Increases BMD and Improves Microarchitecture in Cynomolgus Monkeys. R. J. Fajardo¹, M. L. Bouxsein¹, A. E. Pearsall², A. Grinberg², M. Davies², T. Monnell², J. Ucran², M. Barazza², C. Kelly², D. Khanzode², K. Underwood², R. Kumar², R. S. Pearsall². ¹Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA, ²Accelaron Pharma, Cambridge, MA, USA.

Until recently, the role of activin, a member of the TGF- β superfamily, in bone metabolism was unclear. We have reported that treatment with an activin antagonist, a soluble form of the extra cellular domain of activin type IIA receptor (ActRIIA) fused to a murine IgG-Fc fragment, increases bone formation in normal mice and reverses bone loss in OVX mice. However, the pharmacokinetics of human ActRIIA-IgG-Fc (ACE-011) and its effects on bone mass in a larger animal model with a physiology more similar to humans has been lacking. To address this, female young adult Cynomolgus monkeys were used 1) to assess the pharmacokinetic (PK) properties and tolerability of ACE-011, and 2) to assess skeletal effects of ACE-011 treatment. In the PK study, a single dose of ACE-011 (1, 10 and 30 mg/kg) was administered by subcutaneous (SC) injection. Tolerability and PK parameters were assessed over a 28-day period. ACE-011 showed linear pharmacokinetic parameters across the 3 dose levels tested in the 28-day study. The half-life of ACE-011 was found to be 7 to 10 days. A single subcutaneous dose of ACE-011 up to 30 mg/kg was well tolerated, as were multiple doses (7) at 10 mg/kg over a 3-month period. In the efficacy study, monkeys were treated with ACE-011 (10 mg/kg, SC, bi-weekly) or VEH for 3 months (n=5/gr). At the conclusion of the study bones were harvested for ex vivo assessment of bone density and structure using DXA, pQCT, and μ CT. Compared to VEH, 3-months treatment with ACE-011 administration significantly increased BMD, trabecular bone density and structure in the axial and appendicular skeleton. BMD of the 5th lumbar vertebral body by DXA was 13.2% higher in ACE-011 vs. VEH (p<0.01). MicroCT analysis of the same bone revealed that ACE-011 treatment led to an increase in trabecular BV/TV (+16.2%, p<0.01), trabecular number (+13%, p=0.07), and a decrease in structure model index (7 fold decrease, p<0.01) relative to VEH. At the distal femur, compared to VEH, BMD by DXA was increased 15.3% (p=0.052), whereas trabecular bone density by pQCT was increased 79.5% (p<0.01). In summary, these results indicate that soluble ActRIIA (ACE-011) has a PK profile consistent with intermittent dosing, and that biweekly treatment with ACE-011 significantly improves bone density and structure at multiple skeletal sites in monkeys. These data provide strong rationale for further investigations into the use of ACE-011 as a new anabolic agent for the treatment of skeletal fragility.

Treatment with an Anti-Sclerostin Antibody Directly Stimulates Bone Formation in a Dose-Dependent Manner in Ovariectomized Rats with Established Osteopenia. X. Li, K. S. Warmington*, Q. Niu*, M. Grisanti, H. Tan, W. S. Simonet, P. J. Kostenuik, C. Paszty, H. Z. Ke. Amgen Inc., Thousand Oaks, CA, USA.

We previously reported that sclerostin inhibition via an anti-sclerostin antibody (Scl-Ab) increased bone formation, restored bone mass and bone strength in aged ovariectomized (OVX) rats with established osteopenia. In the present study, using osteopenic OVX rats, we examined the effects of various Scl-Ab doses on bone mass and bone formation. Six-month-old female SD rats were sham-operated or OVX and left untreated for 5 months. OVX rats were then treated with vehicle or Scl-Ab at 1, 2.5, 5, 10, 25 mg/kg (twice a week, s.c.) for 5 weeks (10/group). Xylenol orange (XO, 90 mg/kg) was injected s.c. the day before and the day of treatment initiation in order to detect mineralization and bone formation for the initial effects of treatment. Calcein and tetracycline were injected s.c. 12 and 2 days before necropsy, respectively. Histomorphometric analysis at the 2nd lumbar vertebral body showed that Scl-Ab treated groups had greater trabecular bone volume (BV/TV, +14 to +69%) in a dose-dependent manner compared with OVX control. There was a significantly higher osteoblast surface in OVX rats treated with 5 or 25 mg/kg of Scl-Ab compared with OVX control. However, osteoclast surface did not differ significantly between all doses of Scl-Ab treated OVX rats and OVX control. Qualitatively, OVX rats treated with Scl-Ab had more bone surface labeled with XO than Sham or OVX rats treated with vehicle. Almost all of the XO labeled bone surface in Scl-Ab treated animals was followed by new bone formation and calcein-tetracycline labels, indicating that Scl-Ab directly stimulates the trabecular bone formation without prior activation of bone resorption. Scl-Ab treated OVX rats had greater mineralizing surface (MS/BS, +76 to +288%), mineral apposition rate (MAR, +8 to +60%) and bone formation rate (BFR/BS, +101 to +546%) according to the measurement of calcein-tetracycline labels in a dose-dependent manner compared with OVX control. Qualitatively, an "over-filling" in trabecular bone remodeling was observed, illustrating that Scl-Ab increases bone formation on trabecular remodeling surfaces. These results

reveal that treatment with a Scl-Ab in OVX rats increases the formation mode of trabecular bone modeling and also increases bone formation on trabecular remodeling surfaces without increasing bone resorption.

Sclerostin Inhibition Leads to Increased Periosteal and Endocortical Bone Formation as well as Decreased Cortical Porosity in Aged Ovariectomized Rats. Q. Niu^{*1}, K. S. Warmington^{*1}, M. Grisanti¹, H. Tan¹, M. S. Ominsky¹, W. S. Simonet¹, M. Robinson^{*2}, P. J. Kostenuik¹, H. Z. Ke¹, C. Paszty¹, X. Li¹. ¹Amgen Inc., Thousand Oaks, CA, USA, ²UCB-CellTech, Slough, United Kingdom.

We previously reported that treatment with a sclerostin antibody (Scl-Ab) stimulated trabecular bone formation, restored bone mass and bone strength in aged ovariectomized (OVX) rats. Cortical bone is known to be a major contributor to bone strength, so we used dynamic histomorphometry to examine the effects of sclerostin inhibition on cortical bone formation. Six-month-old female SD rats were sham-operated or OVX and left untreated for 13 months. OVX rats were then treated s.c. with vehicle or a Scl-Ab at 25 mg/kg, twice a week, for 5 weeks (9-12/group). Calcein and tetracycline were given by s.c. injection 10 and 3 days before necropsy, respectively. Left femurs were collected and femoral midshaft cross-sections were prepared for dynamic histomorphometry. Scl-Ab treated OVX rats had decreased marrow cavity area (-17%) and increased cortical bone area (+14%) compared with OVX controls. Mineralizing surface (MS/BS), mineral apposition rate (MAR) and bone formation rate (BFR/BS) were determined. Scl-Ab-treated OVX rats had significantly greater bone formation on periosteal (MS/BS +155%, MAR +84%, BFR/BS +339%) and endocortical surfaces (MS/BS +372%, MAR +145%, BFR/BS +913%) compared with OVX controls. In addition to examining periosteal and endosteal surfaces, we looked at the effect of Scl-Ab treatment on intracortical surfaces. Cortical porosity was quantitated by determining the total porosity area for all pores with a diameter greater than 40 μ m. Expressed as percent of cortical area (Ct.Ar), the OVX control group had increased porosity area (Po.Ar/Ct.Ar, +1124%) as compared to sham controls. As compared to OVX control rats, Scl-Ab treatment decreased porosity area (to sham levels) and significantly increased MS/BS (+205%), MAR (+49%) and BFR/BS (+504%) on the intracortical surfaces. These results suggest that the decreased porosity in Scl-Ab treated OVX rats is due to increased bone formation on the intracortical surfaces. In summary, sclerostin inhibition stimulated periosteal and endocortical bone formation, and also reduced cortical porosity by increasing bone formation on intracortical surfaces of aged OVX rats with established osteopenia. These results suggest that treatment with anti-sclerostin antibody has the potential to improve cortical geometry and bone strength by promoting bone formation on periosteal, endocortical and intracortical surfaces in patients with low bone mass.

Comparison of a Soluble Activin Receptor Type IIA (ACTRIIA), PTH and Zoledronate, for Treatment of Established Bone Loss in OVX Mice. E. Rosen^{*1}, E. Canalis², L. Stadmeier^{*2}, E. Cory^{*1}, V. Glatt¹, R. S. Pearsall³, M. L. Bouxsein^{*1}. ¹Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA, ²St. Francis Hospital and Medical Center, Hartford, CT, USA, ³Accelaron Pharma, Cambridge, MA, USA.

We previously reported that treatment with an activin antagonist, a soluble form of the extra cellular domain of activin receptor type IIA fused to a murine IgG-Fc fragment (RAP-011), induced new bone formation and reversed bone loss in OVX mice. Here, we compare the skeletal effects of RAP-011 to known anabolic (PTH(1-34)) and antiresorptive (zoledronate, ZOL) therapies. 8-wk old female C57BL/6 mice were OVX or SHAM-OVX, and allowed to lose bone for 8 wks. OVX mice were then randomized to receive RAP-011 (10 mg/kg, I.P. 2x/wk), PTH (80 μ g/kg, s.c. 5x/wk), ZOL (single I.P. injection, 20 μ g/kg) or vehicle (VEH, I.P., 2x/wk) for 6 weeks (n=8-10/gr). In two other groups (VEH and RAP-011), treatment was stopped after 6 wks, and mice were sacrificed 6 wks later. Skeletal response was assessed by PIXImus, microCT and histomorphometry. Total body BMD increased significantly in PTH, RAP-011, and ZOL versus baseline but was unchanged in VEH and SHAM. By microCT, trabecular (Tb) BV/TV at the distal femur was higher than VEH in RAP-011 and ZOL, but not PTH. Histomorphometry of the distal femur revealed that bone formation rate was increased only in RAP-011 (1.4-fold, p=0.03 vs VEH). Osteoblast number increased in PTH (1.4-fold, p=0.014) but not in RAP-011 or ZOL, while osteoclast number decreased in RAP-011 (p=0.03) and ZOL (p<0.01), but not PTH. Eroded surface was increased in PTH, but not other treatments. At the 5th lumbar vertebral body, Tb BV/TV was significantly greater in RAP-011 (+30%), PTH (+35%) and ZOL (+21%) than VEH (p<0.001 for all). Tb number was increased in PTH and RAP-011, but not ZOL. Vertebral compressive strength was higher in all treatment groups compared to VEH (p<0.001 for all), whereas work-to-failure was significantly increased by PTH and RAP-011, but not ZOL. Six weeks after cessation of treatment, vertebral and femoral Tb BV/TV remained increased in RAP-011 vs VEH. Altogether these data indicate that in adult OVX mice with established bone loss, treatment with an activin antagonist (RAP-011) increases bone volume, trabecular number and bone formation rate without enhancing bone resorption. The pattern of skeletal response to RAP-011 differed from PTH and from ZOL, suggesting that activin inhibition represents a novel mechanism for restoration of bone mass following estrogen deficiency.

Intermittent PTH Has Increased Anabolic Effects in Cyclooxygenase-2 Knockout Mice. M. Xu, Q. Gao*, O. Voznesensky*, S. Choudhary, V. Diaz-Doran*, L. Raisz, C. Pilbeam. Endocrine Division and Musculoskeletal Institute, University of Connecticut Health Center, Farmington, CT, USA.

Because PTH induces cyclooxygenase (COX)-2 and prostaglandin (PG) E_2 production and because PGE $_2$ and PTH can both increase bone formation, we hypothesized that COX-2 knockout (KO) mice would have decreased anabolic response to PTH compared to wild type (WT) mice. Five-month old male WT (27) and KO (24) mice in a CD-1 background were injected with vehicle (control) or PTH (80 µg/kg, 1-34 hPTH) daily for 22 d and euthanized 3 h after the last injection. Bone mineral density (BMD) was measured by DXA in vivo at beginning and end. KO mice weighed 10% less than WT mice ($p < 0.01$) and had 20% less body fat than WT mice ($p < 0.01$). There was no difference in femur BMD between WT and KO before PTH. Comparing each mouse to itself, PTH increased femur BMD 6.0% ($p < 0.01$) in WT mice and 11.4% ($p < 0.01$) in KO mice, and the increase was significantly greater ($p < 0.05$) in KO mice. PTH increased the BMD of ex vivo vertebrae (L1-L5) 11% ($p < 0.05$) in KO mice but only 6% (NS) in WT mice. On µCT of ex vivo bones no change in BV/TV was seen in PTH-treated WT or KO mice. However, PTH increased trabecular thickness in vertebrae and distal femurs 15-20% ($p < 0.01$) in WT mice and 21-25% ($p < 0.01$) in KO mice. Femur cortical thickness ($p < 0.01$) and area ($p < 0.05$) were less in KO (0.25 mm, 1.15 mm 2) compared to WT mice (0.29 mm, 1.28 mm 2). PTH increased cortical thickness and area 25-30% ($p < 0.01$) in KO mice but the increase (3-7%) in WT was not significant. Dynamic histomorphometry of the distal femur showed that, compared to controls, PTH significantly ($p < 0.01$) increased (1) MAR from 0.85 to 1.85 µ/d in WT mice and from 0.78 to 2.46 µ/d in KO mice and (2) BFR/BS from 0.23 to 0.77 µ 3 /µ 2 /d in WT mice and from 0.24 to 1.32 µ 3 /µ 2 /d in KO mice. PTH increased resorption similarly in WT and KO mice. Compared to controls, PTH increased (1) osteoclast surface in WT (7.4% vs 17.9%, $p < 0.01$) and KO mice (6.7% vs 13.0%, $p < 0.01$); (2) serum calcium 10% ($p < 0.05$) in both WT and KO mice; and (3) serum TRAP levels 1.8- to 2-fold ($p < 0.01$) in both WT and KO mice. Analysis of mRNA in tibiae by real time PCR at end of experiment showed no differences in COX-1 in any group. Alkaline phosphatase, Runx2, and RANKL mRNA were increased and OPG mRNA decreased by PTH in both WT and KO mice. Compared to controls, PTH decreased SOST mRNA in KO mice (RQ values, 8.0 vs 2.6, $p < 0.01$) but not significantly in WT mice (RQ values, 6.7 vs 4.1). In summary, PTH increased BMD of femur and spine to a greater degree in COX-2 KO mice than in COX-2 WT mice. Effects of PTH on trabecular bone volume were similar in WT and KO mice. We speculate that absence of COX-2 expression may increase the anabolic response to PTH primarily in cortical bone.

Deletion of Steroid Receptor Coactivator-2 (TIF-2) Results in Skeletal Resistance to Estrogen but a High Bone Mass Phenotype Due to Concomitant Resistance to PPAR γ . U. I. Moedder¹, D. G. Fraser¹, A. Sanyal¹, M. Gehin², P. Chambon², B. W. O'Malley³, C. J. Rosen⁴, T. C. Spelsberg¹, S. Khosla¹. ¹Mayo Clinic, Rochester, MN, USA, ²Institut de Génétique et de Biologie Moléculaire et Cellulaire, Illkirch, France, ³Baylor College of Medicine, Houston, TX, USA, ⁴Jackson Labs, Bar Harbor, ME, USA.

Both the estrogen receptor (ER) and PPAR γ regulate bone metabolism and there is increasing evidence for cross-talk between these receptors. Clinically, PPAR γ agonists are associated with increased bone loss and fractures in postmenopausal women, but not in men. Since steroid receptor coactivator (SRC)-2 enhances both ER and PPAR γ activity, we examined the consequences of deletion of SRC-2 on bone using SRC-2 knock out (KO) mice. To assess the skeletal response to estrogen (E), wild type (WT) or SRC-2 KO mice ($n = 7-10$ per group) were studied following sham surgery, ovariectomy (ovx) or ovx following treatment with a physiological concentration of E $_2$ (2.5 µg/kg/d) for 2 months. While both WT and SRC-2 KO mice lost similar amounts of bone following ovx, the same dose of E $_2$ was much less effective in preventing ovx-induced bone loss in the SRC-2 KO compared to the WT mice (Figure).

Despite this defect in E action, SRC-2 KO mice clearly had a high bone mass phenotype under basal conditions (BV/TV [mean \pm SEM] at the femur metaphysis of 22.2 ± 3.4 %, vs. 12.4 ± 1.3 % for the WT, $P = 0.02$) with a marked decrease in bone marrow adipocytes (AV/TV of 0.6 ± 0.1 % vs. 1.3 ± 0.3 % for the WT, $P = 0.03$). These data suggest that, in the SRC-2 KO mice, endogenous PPAR γ ligands may be less effective at inhibiting bone formation. Consistent with this, in the presence of the PPAR γ agonist, rosiglitazone (1µM), bone marrow cultures from SRC-2 KO mice formed significantly more mineralized nodules (by 93 ± 34 %, $P = 0.02$) compared to cultures from WT mice. Collectively, these findings demonstrate that SRC-2 may be a key coregulator linking ER and PPAR γ signaling pathways in bone. While loss of SRC-2 leads to skeletal E resistance, the concomitant resistance to PPAR γ appears to be dominant, resulting in a net increase in bone mass and reduction in bone marrow adipocytes. To the extent that the ER and PPAR γ may compete for limiting cellular concentrations of SRC-2, loss of E following the menopause may lead to the observed susceptibility to thiazolidinediones (TZD)-induced bone loss in postmenopausal women by increasing the availability of SRC-2 to enhance PPAR γ signaling in bone.

Increased Bone Mineral Density in Transgenic Mice Over-expressing Tissue-nonspecific Alkaline Phosphatase. M. C. Yadav¹, S. Narisawa¹, K. Johnson², R. Terkeltaub², N. Pleshko Camacho³, J. L. Millan¹. ¹Oncodevelopmental Biology, Burnham Institute for Medical Research, La Jolla, CA, USA, ²VAMC/UCSD, La Jolla, CA, USA, ³The Hospital for Special Surgery, New York, NY, USA.

We have recently reported that the rickets and osteomalacia characteristic in tissue-nonspecific alkaline phosphatase (TNAP)-deficient mice (Akp2 $^{-/-}$ mice) results from highly increased levels of the calcification inhibitor PPI, a natural substrate of TNAP, and from the concomitant increase in the expression of skeletal osteopontin (OPN), another calcification inhibitor. These studies suggested the possibility of manipulating the PPI/OPN axis as a means of affecting calcification. In this paper, we have tested this axis by surmising that transgenic mice over-expressing TNAP might be able to achieve tissular expression of TNAP sufficiently high to be able to lower circulating PPI and OPN concentrations to enhance bone mineral density (BMD) in these animals. Transgenic mice were generated by expressing human TNAP cDNA under control of the Apolipoprotein E promoter, which drives expression of TNAP primarily in the post-natal liver. We examined the expression levels of TNAP in tissues from mice carrying one copy or two copies of the ApoE-Tnap transgene and also from [Akp2 $^{-/-}$; ApoE-Tnap] mice, and examined the ability of their primary osteoblasts to calcify in culture. MicroCT analysis was used to measure BMD in long bones, vertebrae and calvaria. TNAP expression in ApoE-Tnap mice was major in the liver and kidney as expected, with lower but yet detectable levels in bone, brain and lung. Serum AP concentrations were 10 to 50-fold higher than age-matched sibling control wild-type (WT) mice. As predicted, serum levels of PPI and OPN were reduced in the transgenic animals. Furthermore, microCT analysis of femur, vertebrae and calvaria revealed higher BMD in cancellous bone of ApoE-Tnap+ and ApoE-Tnap+/+ mice compared to WT mice. Thus, we show that increases in tissular and circulating levels of TNAP lead to higher BMD by reducing the effective levels of the calcification inhibitors PPI and OPN. These data provide a mechanistic interpretation for the correlation between AP and BMD that has been observed in humans and mice. Furthermore, these studies suggest that administering recombinant TNAP may serve as a novel therapeutic approach for osteoporosis.

The Retinoblastoma-Related Pocket Protein Rbl2 Is a Candidate Gene for a Quantitative Trait Locus Affecting Peak Bone Mass and Strength in Mice. R. F. Klein, E. A. Larson*, W. J. Wagoner*, D. A. Olson*, A. S. Carlos*. Bone and Mineral Unit, Oregon Health & Science University, Portland, OR, USA.

We previously identified a QTL on chromosome 8 (Chr 8) associated with variation in peak bone mineral density (BMD) in C57BL/6 (B6) and DBA/2 (D2) mice. A chromosomal fragment containing the Chr 8 QTL interval (61.6 Mb - 111.7 Mb) was transferred from D2 onto a B6 genetic background by selective breeding. Comparison of the resulting congenic strain (B6.D2^{DM231.113}) with the background B6 strain, established that the D2 interval on Chr 8 conferred increased bone mass and strength. Peak whole body, femoral and vertebral BMD (determined by DXA in 20-wk-old male mice) were, respectively, 11%, 23% and 16% greater in the congenic (D2 allele-bearing; $n=10$) mice compared to the background B6 ($n=9$) mice (all t-tests $p < 0.0001$). MicroCT analysis of mid-shaft femoral geometry revealed 18% greater cross-sectional area, 10% greater cortical thickness and 47% increased moment of inertia in congenic mice compared to background mice (all $p < 0.0001$). Consistent with the increased bone density and geometry, femoral failure load (determined by 3-point bending) of the congenic mice was increased 40% compared to the background mice ($p < 0.0001$). The Chr 8 introgressed region is homologous with a human genomic region (16q11.1-q23) linked with variation in both bone density and circulating osteocalcin levels suggesting that the effects on bone mass at this chromosomal region may be mediated through genes affecting bone remodeling. Serum osteocalcin levels (determined by RIA) were increased 53% (92 ± 5 ng/ml vs. 60 ± 4 ng/ml, $p < 0.0001$) in the B6.D2^{DM231.113} congenic strain compared to the

background strain. Based on synteny between human genome sequence and the murine Chr 8 introgressed region, we identified Rbl2 (residing at 16q12.1 in the human genome and at 94 Mb on Chr 8 in the mouse genome), which encodes the retinoblastoma p130 pocket protein, as a positional candidate gene for the observed variation in bone traits. Sequencing of the Rbl2 gene identified 5 nonsynonymous amino acid variants, one of which (exon 20; position 1023) involved a substitution of alanine (B6) for serine (D2). The transcriptional activity of p130 is influenced by post-translational phosphorylation at serine and threonine residues raising the possibility that this polymorphism may alter p130 function. Given the important role the family of retinoblastoma proteins plays in coordinating skeletal development through their effects on osteogenic differentiation, we hypothesize that Rbl2 is an important determinant of bone mass in mice and that inherited variation in the activity of retinoblastoma proteins may explain some proportion of the natural variation in peak bone density and strength in humans.

Activation of Renin-Angiotensin System Induces Osteoporosis Independently of Hypertension. Y. Asaba^{*1}, M. Ito², K. Watanabe¹, S. Takeshita¹, J. Ishida^{*3}, Y. Nimura^{*4}, A. Fukamizu^{*3}, K. Ikeda¹. ¹Department of Bone and Joint Disease, National Center for Geriatrics and Gerontology (NCGG), Obu, Japan, ²Department of Radiology, Nagasaki University School of Medicine, Nagasaki, Japan, ³Center for Tsukuba Advanced Research Alliance (TARA), University of Tsukuba, Tsukuba, Japan, ⁴Department of Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan.

Osteoporosis and cardiovascular disease are major health problems worldwide. Although low BMD has been associated with deaths from stroke, the relationship between blood pressure and BMD is controversial and the underlying mechanism remains elusive. We have studied the role of the renin-angiotensin system (RAS) in bone metabolism using Tsukuba Hypertensive Mice (THM) overexpressing the human renin and angiotensinogen genes. THM exhibited elevated circulating angiotensin II (Ang II), high blood pressure (140 +/- 10 mmHg vs. 118 +/- 10 mmHg in WT) and low trabecular bone volume, as determined by microCT-40, at 3 and 6 months old. The trabeculae of THM were characterized by microarchitectural alterations such as decreases in trabecular thickness and connectivity and increases in trabecular separation and structure model index. Bone histomorphometry at the proximal tibia revealed the number of osteoclasts and eroded surface were significantly elevated compared with wild-type mice, and the bone formation rate was also increased, pointing to a state of high bone turnover. Interestingly, single transgenic mice overexpressing the human renin gene were normotensive but exhibited lower bone mass. Together with the expression of angiotensin converting enzyme (ACE) in bone by RT-PCR, it was suggested that local RAS is sufficient to induce osteoporosis independently of hypertension. Ang II had no direct effect on osteoclastogenesis from isolated bone marrow macrophages (with RANKL/M-CSF), but stimulated the formation of TRAP-positive osteoclasts in co-cultures of bone marrow cells and osteoblasts, pointing to an indirect mechanism through osteoblasts. Both the AT1 and AT2 receptors were expressed in osteoblasts, in which Ang II had increased RANKL and VEGF expression. Knockdown of AT2 by siRNA inhibited osteoclastogenesis in co-culture, while that of AT1 caused a paradoxical increase, suggesting a functional interaction between the 2 receptors. Accordingly, treatment of THM mice in vivo with an ACE inhibitor (enalapril) improved but an AT1 blocker (losartan) exacerbated osteoporosis. In conclusion, activated RAS is a contributing factor to the pathogenesis of osteoporosis, and certain anti-RAS drugs may be an effective therapy for the co-morbidity of hypertension and osteoporosis with aging.

Effects of Testosterone and Estrogen on Bone Resorption Markers and RANKL mRNA Levels in Bone Marrow Osteoblastic Cells in Men. A. Sanyal, K. Hoey*, J. Peterson*, E. Atkinson*, L. McCready*, M. Oursler, S. Khosla. Mayo Clinic, Rochester, MN, USA.

Previous studies have shown that in men, estrogen (E) may be a more potent inhibitor of bone resorption than testosterone (T), although this remains controversial. In addition, while it is clear that RANKL is a key regulator of bone resorption, possible effects of T and E on RANKL production in men have not been defined. Thus, to characterize further possible differential effects of T and E on bone resorption and on RANKL production in vivo, we studied 59 elderly men (mean age, 67 yrs) using a previously validated experimental paradigm in which the men were made hypogonadal with GnRH, endogenous E production was suppressed with the aromatase inhibitor letrozole, and sex steroid levels maintained with exogenous T or E supplementation. Following serum collections for the bone resorption markers, CTx and TRAP 5b, the men had withdrawal of both T and E (-T, -E), were replaced with T alone (+T, -E) but with continuation of letrozole to block aromatization of T to E, E alone (-T, +E) or both (+T, +E) for 3 weeks and the serum collections were repeated. In addition, bone marrow aspirates were performed and osteoblast lineage cells isolated by magnetic activated cell sorting (MACS) using an antibody against alkaline phosphatase (AP). RNA was extracted from the cells and RANKL mRNA levels quantified using quantitative PCR. Panel A shows the percent changes in serum CTx, panel B shows the percent changes in serum TRAP 5b, and panel C shows the relative RANKL mRNA levels in the AP positive cells isolated from the subjects in the 4 groups.

As is evident, while there were clear effects of E on both resorption markers, T did not regulate either marker. The pattern of changes in RANKL mRNA levels in the AP positive cells was similar to the changes in the bone resorption markers, although due to the variability of these measurements, there was only a trend for an E effect. Collectively, these findings are consistent

with the hypothesis that, at physiological concentrations, E has greater suppressive effects on bone resorption than T and that these differences are likely mediated, at least in part, by regulation of RANKL production. The use of more highly purified cell populations (e.g., additional purification using fluorescent activated cell sorting following MACS) should reduce the variability of the mRNA assessments and allow for clearer definition of the mediators of sex steroid action in vivo.

Increased Plasma Osteoprotegerin (OPG) Concentrations Are Associated with Indices of Bone Strength of the Hip: The Framingham Study. E. J. Samelson^{*1}, K. E. Broe¹, S. Demissie^{*2}, E. J. Benjamin^{*3}, R. S. Vasan^{*3}, J. Massaro^{*3}, S. Kathiresan^{*3}, C. J. O'Donnell^{*3}, T. J. Beck^{*4}, D. Karasik^{*1}, D. P. Kiel^{*1}. ¹Inst for Aging Research, Hebrew SeniorLife, Boston, MA, USA, ²Biostatistics, BUSPH, Boston, MA, USA, ³Framingham Heart Study, Framingham, MA, USA, ⁴Johns Hopkins, Baltimore, MA, USA.

OPG is an important regulator of bone turnover though its effects on osteoclastogenesis, yet little is known about the significance of circulating OPG concentrations with respect to bone strength in humans. Therefore, we evaluated the cross-sectional association between plasma OPG and femoral neck bone density (FN BMD) and geometry in a large cohort of women and men.

Participants included 1379 post-menopausal women and 1165 men, age 50+ years, in the Framingham Offspring Study. Information was obtained from exams performed 1996-2001. DXA (Lunar DPX-L) scans were used to evaluate FN BMD and geometry. Hip structure analysis was used to determine subperiosteal width, section modulus (bending strength), cross-sectional area (compression strength), and BMD at the narrow neck (NN) region. Plasma OPG concentrations were measured by ELISA (Biomedica, Austria). Sex-specific analysis of covariance was used to calculate means and assess linear trend in BMD and geometry values across OPG quartiles, adjusted for age, height, body mass index, current smoking, diabetes, coronary heart disease, osteoporosis medications, estrogen use (women), and NN BMD (for geometry outcomes).

Mean age of participants was 64 years (range, 50-89 years). OPG concentrations were greater in women (median 5.75 pmol/L; interquartile range (IQR) 4.85-6.84) than men (median 5.32; IQR 4.38-6.47) and increased with age. Multivariable-adjusted mean FN BMD in women increased from the lowest to the highest OPG quartile (Table; trend, p<0.01). However, no linear trend between FN BMD and OPG was observed in men (trend, p=0.34). Section modulus, width, and cross-sectional area increased with OPG in men (trend, p<0.01), whereas no association between hip geometry indices and OPG was observed in women.

Increased OPG concentrations were associated greater bone density in women and with favorable geometry features in men. These results suggest that higher OPG concentration may indicate greater skeletal strength in women and men, possibly through reducing bone loss in women and through increasing periosteal apposition in men.

Coadaptation Among Trabecular and Cortical Traits Contribute to Genetic Variation Affecting Bone Size in Recombinant Inbred Mouse Vertebral. S. M. Tommasini¹, B. Hu^{2*}, J. H. Nadeau³, K. J. Jepsen². ¹CUNY Graduate Center, New York, NY, USA, ²Mount Sinai School of Medicine, New York, NY, USA, ³Case Western Reserve University School of Medicine, Cleveland, OH, USA.

A previous study showed that randomization of A/J (A) and C57BL/6J (B) genomic regions resulted in adult Recombinant Inbred (RI) mice having mechanically functional femora with different sets of morphological and tissue-quality traits. This suggested that multiple traits were coordinated to ensure mechanical functionality. Analysis of RI strains has the potential for determining if similar biological controls exist for the construction of vertebrae. To test the hypothesis that trabecular, cortical, and compositional traits of the vertebral body are functionally related, we examined vertebrae from 20 genetically randomized female AXB/BXA RI mouse strains (n=5/genotype; age=16wks). Trabecular traits (bone volume fraction, Tb BV/TV; number; thickness; spacing), cortical traits (cortical thickness, CtTh), tissue mineral density (TMDn), and total vertebral volume (TtV = bone vol + marrow vol) of the L4 vertebral body were measured using micro-CT (GEMS). A correlation analysis using the mean values for each RI strain revealed that 30% of the correlations examined were significant. Thus, many bone traits covaried after genetic randomization. A Path Analysis was conducted using the mean Z-scores of each RI strain. Directed paths (Fig 1) identified important interactions among total vertebral size, cortical thickness, and mineral density similar to that observed in femora, such that larger vertebrae (greater TtV) tended to have thinner cortices with lower mineral content, whereas smaller vertebrae had thicker cortices with higher mineral content. Further, the Path Analysis highlighted important functional relationships between cortical and trabecular components such that vertebrae with thicker cortices had higher Tb BV/TV and Tb TMDn, and vertebrae with thinner cortices had lower Tb BV/TV and Tb TMDn. These results suggest that there are critical biological controls that co-adapt the set of cortical, trabecular, and compositional bone traits so that vertebrae are sufficiently stiff for daily loading. Therefore, this approach provides important new insight showing how genetic variation in trabecular architecture is functionally related to genetic variation in cortical traits.

Fig 1. Path analysis showing causal (straight arrows) and non-causal (curved arrows) relationships among body weight, total vertebral volume (TtV), cortical thickness (CtTh), cortical tissue mineral density (Ct TMDn), trabecular bone volume fraction (Tb BV/TV), and trabecular tissue mineral density (Tb TMDn). Path coefficients based on Z-transformed data.

$$CtTh = 0.92 \text{ Weight} - 0.13 \text{ TtV}, R^2 = 0.67$$

$$Ct \text{ TMDn} = 0.77 \text{ CtTh} + 0.34 \text{ Weight} - 0.24 \text{ TtV}, R^2 = 0.84$$

$$Tb \text{ BV/TV} = 0.57 \text{ CtTh} - 0.01 \text{ Ct TMDn}, R^2 = 0.32$$

$$Tb \text{ TMD} = 0.36 \text{ Tb BV/TV} + 0.31 \text{ CtTh} + 0.39 \text{ Ct TMD}, R^2 = 0.87$$

$$\text{Chi-square} = 1.30, \text{ df} = 4, \text{ p-value} = 0.86, \text{ RMSEA} = 0.00$$

Correlation Between Growth Patterns and Material Composition Leads to Preferred Sets of Adult Bone Traits. C. Price, H. W. Courtland, K. J. Jepsen. Mount Sinai School of Medicine, New York, NY, USA.

The specific combination of bone size, shape, and material composition observed in adulthood is predictive of whole bone mechanical properties and fracture risk. However, it is unknown how certain combinations of adult bone traits arise. Knowledge of how specific trait combinations arise is important because while most sets of bone traits satisfy the mechanical demands of daily loading certain sets are preferred under extreme loading conditions. Therefore, the goal of this investigation was to determine how different combinations of adult bone traits develop in inbred mouse femora. Variability in periosteal and endosteal surface growth results in different combinations of adult bone traits. To determine how surface movement influences bone shape and size we plotted femoral polar moment of inertia (J_0) against cortical area (CtAr) for A, B6, and C3H inbred mice from 1 to 112-days of age. Power law regression analysis ($J_0 = A \cdot CtAr^B$) demonstrated that B6 mice constructed femora in a more "structurally efficient" manner resulting in a greater femoral J_0 for a given CtAr. A and C3H femora exhibited similar structural efficiencies of growth that were reduced in comparison to B6. Analysis of bone surface movement demonstrated that strain-specific differences in the structural efficiency

of growth resulted from variability in the relative rates of periosteal and endosteal expansion.

To test if the structural efficiency of growth could be extrapolated from adult data sets we validated a generalized power law regression with a fixed exponent ($J_0 = A \cdot CtAr^{1.44}$) that utilized only adult bone CtAr and J_0 values. We observed significant variability in structural efficiency of growth (A) among a cohort of 8 inbred mouse strains and 18 A, B6, and C3H reciprocal cross offspring/founders. Using this panel we also identified a significant correlation between the structural efficiency (SE) of growth and measures of ash content ($\text{ash} = -0.09 \cdot SE + 0.70, r^2 = 0.30, p < 0.01$). Thus, femora with more efficient growth patterns exhibited lower ash content values than those with less efficient growth patterns. This correlation between measures of material composition and structural efficiency was further confirmed by an analysis of previously published data including 29 different inbred mouse strains [1]. Together, these results suggest that surface growth patterns and material composition are co-adapted during bone growth. This investigation also provides new insight into bone adaptation and bone fragility and suggests mechanisms by which growth patterns can be used to establish preferred sets of (or robust) adult bone traits (high CtAr, high J_0 , and low ash).

Heritability of Bone Microstructure in Women. S. L. Ferrari, T. Chevalley, J. P. Bonjour, R. Rizzoli. Div. of Bone Diseases, WHO Collaborating Center for Osteoporosis Prevention, Geneva University Hospital, Geneva, Switzerland.

Areal bone mineral density (BMD) has a 60-80% heritability (h^2) in humans. Bone microarchitecture, another major constituent of bone strength, is also highly heritable in inbred strains of mice. Because bone microstructure is difficult to assess in humans, the proportion of the population-based variance for trabecular and cortical bone traits explained by additive genetic factors is currently unknown. We measured cortical (Ct) and trabecular (Tb) bone structure at distal radius and tibia in 103 mother-daughter pairs using high-resolution (82 microns) peripheral computed tomography (HR-pQCT, Scanco, Switzerland). BMD was evaluated by DXA at radius, hip and spine. H^2 (%) was calculated as twice the beta coefficient of the linear regression between maternal and offspring values. The sample consisted of 103 young European-Caucasian females (mean age \pm SD, 20.4 \pm 0.6 yrs) and their mothers, of whom 53 were pre- (48.1 \pm 3.2 yrs) and 50 post-menopausal (53.3 \pm 3.2 yrs; 5.0 \pm 3.4 yrs since menopause, YSM). H^2 estimates for body weight, height and BMD were in the expected range, from a lowest 42% and 50% for total and ultradistal (UD) radius BMD, to a highest 70% and 84% for total hip and trochanter BMD, respectively. Heritability of cross-sectional area (CSA), as evaluated by HR-pQCT, was 62% at radius and as high as 96% at tibia, a weight-bearing site. Concerning tibia bone microstructure, h^2 values equal or greater than 50% were found for Tb bone density (BV/TV), Tb number (TbN), as well as Tb and Ct thickness (TbTh, CtTh), whereas h^2 was much lower for cortical volumetric density (D.Ct). However, TbTh and D.Ct had h^2 values of 79% and 48%, respectively, in daughters with pre-menopausal mothers, but of less than 20% in those with post-menopausal mothers, indicating that increased bone turnover may promptly overcome genetic effects on these traits. At radius, h^2 of 50% or greater was found for Tb BV/TV and TbN in all pairs, and for CtTh and D.Ct in pre-menopausal mother-daughter pairs only. Since DXA and HR-pQCT evaluate the same ROI at distal radius, bone microstructural traits were then adjusted by multiple linear regressions for UD radius BMD in addition to height, weight, age and YSM, leading to the following adjusted h^2 values at radius: BV/TV, 52%, TbN, 49%, CtTh, 58%, CSA, 44%, D.Ct 32% and TbTh < 10%.

In summary, we report for the first time the heritability of bone microstructure in humans, including the evidence that additive genetic effects may contribute specifically to these traits, i.e. independently of body size and BMD. Heritability for BMD, CSA and TbTh being more robust at weight-bearing sites, it suggests a genetic influence on the skeletal response to loading.

Spatio-Temporal Dynamics of a Single Bone Remodeling Unit. M. D. Ryser^{*1}, N. Nigam^{*1}, S. V. Komarova². ¹Mathematics and Statistics, McGill University, Montreal, PQ, Canada, ²Dentistry, McGill University, Montreal, PQ, Canada.

Bone remodeling occurs asynchronously at multiple sites in the mature skeleton and involves bone resorption by osteoclasts, followed by formation of new bone by osteoblasts. At each location, osteoclasts and osteoblasts are organized in Bone Remodeling Units (BRUs), which contain 10-20 osteoclasts in the leading front followed by 1000 - 2000 osteoblasts. BRUs exist much longer than individual osteoclasts and osteoblasts, traveling for 2-6 mm at a rate of 20-40 μ m/day. To analyze BRU progression, we developed a mathematical model that describes changes in osteoclast and osteoblast numbers in time and space while taking into account autocrine and paracrine interactions among these cells. We assumed that basal level of a pro-resorptive cytokine RANKL may change locally due to microfracture or external stimulus. The changes in osteoclast numbers were modeled to result from osteoclast formation, death and movement via diffusion and convection in response to RANKL field. The cutting cone was modeled as a free-boundary value problem with appropriate Stefan conditions. The changes in osteoblast numbers were modeled to result from osteoblast formation and death, whereas the necessity for osteoblast active movement was investigated. RANKL antagonist OPG was modeled to be produced by mature osteoblasts and to diffuse with different rates both through bone tissue and

through the liquid interface between osteoblasts and osteoclasts. The evolution of the cutting cone arising from this model was studied using numerical simulations. We have found that our model successfully recapitulates spatial and temporal dynamics observed in vivo in a cross-section of the bone. The formation and movement of osteoclasts were most strongly affected by RANKL produced by cells resident to quiescent bone, such as lining cells, osteocytes and stromal cells. Coupling of osteoclasts to osteoblasts allowed for sufficient recruitment of osteoblasts to remodeled surfaces, in such way that a diffusion term describing the directional movement of osteoblasts was not necessary. OPG diffusion through bone was critical in determining the direction of BRU movement. RANKL produced by osteoblasts was found to have little effect on activation of BRU, but was most important in preventing OPG from diffusing through the liquid interface between osteoblasts and osteoclasts, and inhibiting osteoclast activation. Thus, our model demonstrates that taking into account spatial organization of BRUs provides new insights into the roles of RANKL and OPG in regulating bone turnover. In the future, this model will allow in silico analysis of the impact of cytokines, growth factors and potential therapies on the process of bone remodeling.

Rapamycin Differentially Alters the Skeletal Response to PTH and Mechanical Loading. P. J. Niziolek^{*1}, S. M. Murthy^{*2}, S. N. Ellis^{*2}, K. B. Sukhija^{*3}, T. A. Hornberger^{*3}, C. H. Turner¹, A. G. Robling². ¹Department of Biomedical Engineering, Purdue University, Indianapolis, IN, USA, ²Department of Anatomy, Indiana University, Indianapolis, IN, USA, ³Department of Bioengineering, University of California - San Diego, San Diego, CA, USA.

Exercise-induced skeletal muscle hypertrophy requires signaling through the mTOR pathway. Likewise, bone cells may respond to exercise through the mTOR pathway, but this hypothesis has not yet been tested. PTH-induced bone hypertrophy requires IGF signaling (an upstream effector of mTOR), but the downstream components of this PTH-stimulated cascade are less certain. We investigated whether the bone-building effects of intermittent PTH require functional mTOR signaling, by treating mice with rapamycin, a selective inhibitor of mTOR activity, during a 6-wk course of daily PTH. We also investigated whether the anabolic effects of mechanical stimulation in bone require functional mTOR signaling, as they do for skeletal muscle, by subjecting mice to ulnar loading in the presence of rapamycin.

Female C57BL/6J mice were implanted with sustained-release rapamycin (or placebo) pellets, then treated with [A] either 0 (vehicle), 30, 60, or 90 µg/kg PTH 1-34 7dy/wk for 6 wk, or [B] mechanical loading of the right ulna for 3 consecutive days, (2 Hz; 2400 µε). PTH treated mice were measured for skeletal effects using DEXA, pQCT, and µCT; serum Trap 5b was measured via ELISA. Loaded mice were measured for MS/BS, MAR, and BFR/BS in the right and left ulnar midshaft via fluorochrome histomorphometry.

Rapamycin reduced BMC modestly but significantly. PTH induced significant dose-responsive gains in bone mass in the presence of rapamycin, albeit to a lesser degree than in placebo pellet animals. Trabecular bone mass and morphology in the distal femur (BV/TV, Tb.N, vBMD) followed similar trends as was observed for whole-body DEXA. Serum Trap 5b measurements indicated that resorption was enhanced significantly in the rapamycin-treated mice, particularly in those given PTH. Mechanical loading increased mineralizing surface similarly in rapamycin and non-rapamycin treated mice, but rapamycin treatment significantly suppressed load-induced mineral apposition rates and bone formation rates by 34% and 38% (p<0.05), respectively.

The anabolic effects of PTH appear to occur in the presence of rapamycin. Most of the disparity in PTH-induced bone gain between rapamycin and non-rapamycin treated mice can be attributed to the enhanced resorptive response induced by rapamycin. The reduced osteogenic response to mechanical loading in the rapamycin-treated mice suggests that mTOR participates in bone cell mechanical signal transduction cascades. Our data indicate that bone and muscle share a common exercise-induced pathway.

Temporal Pattern of Gene Expression and Histology of Stress Fracture Healing in the Rat Ulna-Loading Model. L. J. Kidd^{*1}, A. Stephens^{*1}, J. S. Kuliwaba^{*2}, N. L. Fazzalari², M. R. Forwood¹. ¹School of Biomedical Science, The University of Queensland, Brisbane, Australia, ²Division of Tissue Pathology, Institute of Medical and Veterinary Science and Hanson Institute, Adelaide, Australia.

Rat ulnar loading has become a central tool in the investigation of bone fatigue injury and remodelling, however this model has not yet been fully characterised. The aim of this study was to undertake a detailed examination of the histology, histomorphometry and gene expression of the healing and remodelling process initiated by rat ulnar fatigue-loading. In a group of 30 female Wistar rats cyclic ulnar loading was stopped at a fatigue level of 10% increase in displacement. Ulnae were harvested 2, 4 or 6 weeks following loading. All animals developed a fatigue fracture of the distal diaphysis of the loaded ulna. These were of a consistent configuration and position with a "U" shaped, incomplete, "stress" fracture on the medial cortex of the bone. Fracture healing involved direct remodelling that progressed along the fracture line as well as woven bone proliferation at the site of the fracture. Remodelling was greatest at 2 weeks and it originated at the region of the fracture line closest to the periosteal exit.

Real-time PCR was performed on the ulnae from 40 rats in which a stress fracture was created. Rats were euthanized following 4 hours, 24 hours, 4 days, 7 days and 14 days (n=8/group). A control group did not undergo loading. At 4 hours post fracture there was peak increased mRNA expression (p<0.05), compared to non-loaded controls, for IL-6 (400 fold increase), OPG (11 fold), COX-2 (6 fold) and VEGF (2 fold). At 24 hours there was peak mRNA expression of IL-11 (48 fold). At 4 days there was a significant increase in mRNA expression of SDF-1 (4 fold), SOST (3 fold), and BMP-2 (6 fold). At 7 days there was peak mRNA expression of RANK-L (12 fold). Other genes that showed a marginal increase in mRNA expression were BAX, Bcl-2, Collagen 10, COX-1, IGF-1, Runx-2, TNFα and IL-1, all with 2-3 fold increases, peaking at 4 days post fracture. mRNA expression of RANK-L, OPG and COX-2 was also increased in the opposite, unloaded, left limb suggesting a systemic response in bones distant to the site of injury.

These results show that rat ulna-loading is an excellent model for creating stress fractures and initiating remodelling. The gene expression results demonstrated a clear temporal cascade of important signalling events that occurred during fracture healing and remodelling. Dramatic, early up-regulation of IL-6 and IL-11 suggests their central role in initiating later signalling events. Prominent, up-regulation of COX-2, VEGF, OPG, SDF-1, BMP-2 and SOST prior to peak expression of RANK-L indicates the likely importance of these factors in mediating and possibly co-ordinating directed remodelling.

GSK-3β Inhibits Osteoblastic Bone Formation Through Suppression of Runx2 Transcriptional Activity by the Phosphorylation at a Specific Site. M. Hirata, F. Kugimiya, N. Kawamura, S. Ohba, K. Nakamura*, H. Kawaguchi, U. Chung. Sensory & Motor System Medicine & Tissue Engineering, University of Tokyo, Tokyo, Japan.

GSK-3β is known to be a kinase involved in bone formation signalings like Wnt and Akt. To investigate the role of GSK-3β in bone, we initially investigated the skeletal phenotype of GSK-3β-deficient mice. Although the homozygous deficient mice were embryonically lethal, the heterozygous deficient (Gsk-3β^{+/-}) mice developed and grew normally; however, bone densitometry, 3D-μCT, and histomorphometric analyses revealed that Gsk-3β^{+/-} mice showed increased bone mass with enhanced bone formation as compared to the wild-type littermates. In Gsk-3β^{+/-} calvarial osteoblast cultures, the differentiation and function determined by ALP, Alizarin red and von Kossa stainings, and mRNA levels of osteoblastic markers were enhanced, while the proliferation was unaffected. Similarly, addition of lithium chloride or SB216763, selective inhibitors of GSK-3β, stimulated the bone formation parameters above. Meanwhile, overexpression of wild-type GSK-3β or a constitutively active form of GSK-3β (CA-GSK-3β) suppressed the parameters, although the kinase-inactive form of GSK-3β (KI-GSK-3β) overexpression did not affect it. Neither CA-GSK-3β overexpression, genetic GSK-3β insufficiency, nor GSK-3β inhibitors altered the expression or subcellular localization of Runx2, a master gene for osteoblast differentiation. However, the luciferase reporter assay revealed that the Runx2-dependent transcription was attenuated by wild-type GSK-3β or CA-GSK-3β overexpression, but not by KI-GSK-3β, whereas it was enhanced by GSK-3β inhibitors. Binding with the oligonucleotide probe of OSE2 / osteocalcin promoter by electrophoretic mobility shift assay was enhanced in nuclear extracts from Runx2-overexpressing osteoblasts from Gsk-3β^{+/-}, as compared to those from wild-type. To learn the contribution of phosphorylation of Runx2 by GSK-3β, we generated phosphorylation-deficient mutants of Runx2 at the five consensus sites, and found that a specific mutant at S369-S373-S377 cancelled the inhibition of Runx2 transactivity by CA-GSK-3β. Finally, when Runx2^{+/+} mice were crossed with Gsk-3β^{+/-} mice to generate the compound deficient mice (Gsk-3β^{+/-};Runx2^{+/+}) or were administered lithium chloride from E7.5, the cleidocranial dysplasia was significantly rescued, confirming the interaction between Runx2 and GSK-3β in vivo as well. In conclusion, GSK-3β was shown to inhibit the Runx2 transcriptional activity through the phosphorylation at S369-S373-S377, causing the suppression of osteoblast differentiation and bone formation.

Overexpression of DeltaFosB Decreases Adipose Mass in a Non-Cell Autonomous Manner by Increasing Energy Expenditure Independently of Bone Cells. G. C. Rowe^{*1}, L. Neff^{*1}, T. Green^{*2}, H. Saito^{*1}, C. Choi^{*3}, G. Shulman^{*3}, E. Nestler^{*2}, W. Horne¹, R. Baron¹. ¹Orthopaedics, Yale University, New Haven, CT, USA, ²Psychiatry, University of Texas Southwestern Medical Center, Dallas, TX, USA, ³Internal Medicine, Yale University, New Haven, CT, USA.

Overexpression of Δ FosB in mice under the control of the enolase 2 promoter (ENO2), which drives expression in bone, fat and the brain, results in increased bone formation and decreased adipose mass, due to a reduction of the size of the individual adipocytes and not their number. To determine whether this effect on fat was linked to the bone phenotype, we generated mice which overexpress Δ FosB under the control of the osteocalcin promoter (OG2). These mice failed to recapitulate the adipose phenotype, demonstrating that the effect on adipocytes is independent of the increased bone formation. Since differentiation of the adipocytes was unimpaired we then explored whether the function of the adipocyte or the metabolic status of the ENO2- Δ FosB mice may be altered. To determine if the decrease in adipose mass was due to a cell autonomous effect within the adipocyte we generated a mouse overexpressing Δ FosB under the control of the adipocyte protein 2 promoter (aP2). Again, these mice did not recapitulate the decrease in adipose mass observed in the ENO2- Δ FosB mice, eliminating the possibility that the decrease in size of the adipocytes was due to a cell-autonomous defect. These results lead us to explore the metabolic status of the ENO2- Δ FosB mice: in contrast to the OG2- Δ FosB and aP2- Δ FosB mice, the ENO2- Δ FosB mice exhibited an improved glucose tolerance and an increased sensitivity to insulin. Furthermore metabolic analysis of the ENO2- Δ FosB mice revealed an increase in energy expenditure that was not present in the aP2- Δ FosB mice. Since the effect of Δ FosB on the regulation of adipose mass and energy expenditure was not due to its expression in either the osteoblast or adipocyte lineages, these results opened the possibility of a central effect of Δ FosB. We found that Δ FosB is overexpressed in the arcuate nucleus (ARC) of the hypothalamus in the ENO2- Δ FosB mice. Since the hypothalamus has been identified as a key regulator of both adipose and bone mass, we then examined the possibility of Δ FosB regulating adipose mass centrally. Stereotaxic injections were performed using adeno-associated viruses to target Δ FosB to the ARC of the hypothalamus. Six weeks post injection the mice injected with Δ FosB exhibited a significant reduction in body weight compared to control injected mice. This suggests that Δ FosB is able to alter adipose mass in a non-cell autonomous manner by altering the hypothalamic regulation of energy expenditure independent of the osteoblast.

Inhibition of Wnt Signaling by Osterix. C. Zhang¹, J. Lyons^{*2}, K. Sinha^{*1}, P. McCrea^{*2}, X. Zhou^{*1}, B. de Crombrughe¹. ¹Molecular Genetics, University of Texas MD Anderson Cancer Center, Houston, TX, USA, ²Biochemistry and Molecular Biology, University of Texas MD Anderson Cancer Center, Houston, TX, USA.

During mouse embryonic development both the osteoblast-specific transcription factor Osterix (Osx) and Wnt/ β -catenin signaling are required for osteoblast differentiation. To explore whether Osx also plays a role in control of osteoblast proliferation, we compared BrdU incorporation in wild type and Osx-null E18.5 calvaria and examined the proliferation rates of primary calvarial cells isolated from wild type and Osx-null E18.5 embryos. BrdU incorporation in calvaria and proliferation of calvarial cells were markedly increased in Osx-null mice. In addition, overexpression of Osx in C2C12 mesenchymal cells resulted in slower growth. These experiments suggested the hypothesis that Osx could control osteoblast proliferation.

A microarray comparison of RNA expression profiles of wild type and Osx-null calvarial cells from E18.5 embryos revealed that expression of the Wnt inhibitor, Dkk1, which is high in wild type osteoblasts, was abolished in calvarial cells of Osx-null embryos. Moreover, expression of several Wnt target genes such as c-Myc and cyclin D1 increased in Osx-null calvarial cells. These findings suggested the hypothesis that Osx might inhibit Wnt pathway activity. Several lines of evidence, indeed, support this hypothesis. In vitro transfection studies in HEK293 cells demonstrated that Osx activated the Dkk1 promoter. In other transfection experiments Osx inhibited expression of the β -catenin-induced TOPFLASH reporter. In addition, Osx also inhibited β -catenin-induced secondary axis formation in Xenopus embryos. Moreover, in calvaria of Osx^{-/-} mice, which harbor the TOPGAL reporter transgene, β -galactosidase activity of the reporter was increased, suggesting that Osx inhibits the Wnt pathway in osteoblasts in vivo. Coimmunoprecipitation experiments showed that Osx interacted with Tcf, a DNA-binding partner of β -catenin. Gel shift assay indicated that Osx was able to disrupt Tcf binding to DNA. Thus our observations suggest that Osx has the ability to inhibit Wnt/ β -catenin signaling through several mechanisms. We speculate that the proposed inhibition by Osx of osteoblast proliferation might be a consequence of the Osx-mediated control of Wnt/ β -catenin activity.

Zfp521, a D2D FosB-interacting Protein, Is a Novel Inhibitor of Runx2 Activity with Opposite Effects on Osteoblasts and Bone Formation In Vitro and In Vivo. E. Hesse, M. Wu^{*}, G. C. Rowe^{*}, L. Neff^{*}, W. C. Horne, R. Baron. Orthopaedics and Cell Biology, Yale University School of Medicine, New Haven, CT, USA.

The identification of novel molecules or pathways that contribute to the regulation of bone formation in vivo is essential for the development of future anabolic drugs. Overexpression of Δ FosB leads to a striking osteosclerotic phenotype in vivo and to the increased expression of osteoblast (OB) markers and bone nodule formation in vitro (Sabatatos, Nat Med, 6:985, 2000). We recently reported that the further N-terminally truncated and AP1 transcription-inactive isoform Δ 2 Δ FosB induces the same phenotype as Δ FosB in vivo. We therefore proceeded to a yeast two-hybrid screen and identified the zinc finger protein Zfp521, a 180 kDa protein consisting of 30 kruppel-like zinc fingers, as a Δ 2 Δ FosB-interacting protein. In situ hybridization and immunocytochemistry showed that Zfp521 is expressed at the periphery of mesenchymal condensations as early as day E12.5. At later stages of bone development, Zfp521 is strongly expressed in chondroblast and OB precursors in the perichondrium and periosteum, as well as in prehypertrophic chondrocytes, OB and osteocytes. In vitro, Zfp521 expression repressed, whereas RNAi-mediated depletion of Zfp521 enhanced, in vitro OB differentiation, nodule formation and mineralization. Co-immunoprecipitation studies revealed that Runx2 interacts with Zfp521, and we identified zinc fingers 6-10 and 26-30 as interacting sites. Moreover, in vitro overexpression of Runx2 dose-dependently rescued the Zfp521 induced repression of the OB phenotype, suggesting that Zfp521 acts as a Runx2 antagonist. Consistent with this hypothesis, Zfp521 strongly repressed the transcriptional activity of Runx2 in a reporter assay as well as the expression of Runx2 target genes (Runx2 itself, alkaline phosphatase, and other OB markers). Surprisingly, and despite the fact that Zfp521 inhibits OB differentiation in vitro, over-expressing Zfp521 in transgenic mice under the control of the OB-specific osteocalcin promoter resulted in a marked increase in bone volume and bone formation as measured by histomorphometry. Therefore, based on the well known functional duality of Runx2, which is required for OB differentiation at early stages of bone development while inhibiting OB maturation at later stages (Liu, J Cell Biol, 155:157, 2001; Geoffroy, Mol Cell Biol, 22:6222, 2002), we propose that Zfp521 both inhibits early OB differentiation and promotes late stages of OB maturation and bone formation by antagonizing Runx2 activity. Thus, the balance between Zfp521 and Runx2 could determine the rate of osteoblast differentiation and bone formation during development and in the adult skeleton.

Cox-2 Deficiency Impairs Periosteal Progenitor Cell Activation and Differentiation Rescued by Ep4 Agonist. X. Zhang, C. Xie^{*}, M. Xue^{*}, A. Naik^{*}, E. Schwarz, R. J. O'Keefe. Orthopaedics, University of Rochester, Rochester, NY, USA.

We previously showed that genetic ablation of cyclooxygenase-2 (COX-2) resulted in delayed and defective fracture healing in mice. In this study, we evaluated COX-2 expression in the bone repair microenvironment and its critical role for activation and expansion of local progenitor cells following skeletal injury. In a stabilized femoral fracture healing model, COX-2 mRNA was increased at day 3 prior to chondrogenesis and peaked at day 7 in early chondroprogenitors and proliferating chondrocytes. Coincident with COX-2 expression, initiation and completion of periosteum mediated endochondral bone repair was markedly delayed in COX-2^{-/-} mice, as evidenced by delayed appearance of PCNA positive periosteal progenitor cells at day 3, marked reduction of Col2a1 gene expression at day 5, and deficient angiogenesis and osteogenesis at day 14. The deficient activation of periosteum bone repair in COX-2^{-/-} mice resulted in the development of fibrotic non-unions in live 4mm segmental cortical bone graft transplantations. Minimal periosteal response was found on the wild-type (WT) or COX-2^{-/-} (KO) graft when transplanted into a KO host. In contrast, the transplantation of a wild type live graft into a wild type host defect resulted in abundant bone formation and neovascularization on grafted surface. An intermediate amount of periosteal bone formation with increased amount of cartilage formation was found on the graft when transplanting a KO graft into a WT host, suggesting the requirement of COX-2 in the local microenvironment for the normal initiation and progression of periosteal bone repair. To rescue the deficient periosteal response in COX-2^{-/-} mice, an EP4 agonist CP-734432 was administered via periosteal injection. The delivery of EP4 agonists during the early phase of fracture healing reversed the impaired fracture healing in COX-2^{-/-} mice. PGE2 and agonists of EP2 or EP4 receptor potentially increased phosphorylation of ERK1/2 in mouse bone marrow stromal cells and primary sternal chondrocyte cultures. The activation of the MAPK/ERK pathway led to rapid induction of early growth response gene (EGR-1). Treatment with PGE2 and EP agonists also induced the phosphorylation of GSK3 β at serine 9 in the same cultures with further induction of the active form of β -catenin. Taken together, our data strongly suggest that transient induction of COX-2 functions as an essential early signal for initiation and completion of endochondral bone healing through targeting of the periosteal progenitor cell population. These signals are necessary for early events in repair and are a potential target for the treatment of impaired skeletal healing.

TRIP-1: An Important Co-Regulator of Bone Formation in Skeletal Remodeling. D. Metz-Estrella*, T. Sheu*, R. Mroczek*, J. Puzas. Orthopaedics, University of Rochester, Rochester, NY, USA.

TGFbeta receptor interacting protein (TRIP-1) is an intracellular signaling cofactor with high affinity for fragments of tartrate resistant acid phosphatase (TRAP). TRAP, when bound to TRIP-1 activates the TGFbeta signaling pathway and leads to an increase in markers of bone formation in osteoblasts. This may be one way that osteoblasts recognize resorption lacunae during remodeling. Pull down assays also show that TRIP-1 interacts with intermediates of the BMP pathway (i.e. Smad1) and that this interaction is inversely related to the level of activation in the pathway. Based on these findings we hypothesize that TRIP-1 is a pleiotropic regulator of Smad-dependent pathways during bone remodeling.

To further investigate the mechanism by which TRIP-1 influenced signaling we identified regions in the Smads that bind to TRIP-1. Our results show that the MH1 domain of Smad3 is mainly involved in the physical interaction with TRIP-1 and that this interaction leads to a large increase in its phosphorylation.

In regard to its pleiotropic nature TRIP-1 also activates a BMP-specific reporter in osteoblasts. When this same reporter is transfected into Smad4-deficient cells, TRIP-1 expression leads to a greater than 50 fold induction. Moreover, co-localization experiments have shown that TRIP-1 associates with phosphorylated Smad1, 5, 8 in the nuclei of osteoblasts.

To understand the *in vivo* role of TRIP-1 we used a mouse model in which TRIP-1 can be over expressed in osteoblasts using the TetOn system. In these mice, induction of TRIP-1 expression in the calvarium led to an approximate three fold increase in bone volume ($p<0.001$) and a three fold increase in mineral apposition rate ($p<0.001$).

These results provide evidence to conclude that TRIP-1 is an important co-regulator of the Smad pathways and may control, in part, bone formation at sites of remodeling.

Serum IGFBP-2 (IGF binding protein-2) Is a Marker of Bone Turnover; In Vivo Evidence from the IGFBP-2 Null Male Mouse. V. E. DeMambro¹, D. Clemmons², W. G. Beamer¹, M. L. Bouxsein³, E. Canalis⁴, C. J. Rosen¹. The Jackson Laboratory, Bar Harbor, ME, USA, ²University of North Carolina, Chapel Hill, NC, USA, ³Beth Israel Deaconess Medical Center, Boston, MA, USA, ⁴St. Francis Hospital & Medical Center, Hartford, CT, USA.

IGFBP-2 is a 36kD IGF binding protein with strong affinity for hydroxyapatite and extracellular Matrix proteins. It circulates in relatively high concentrations, and increases with age, and malnutrition. IGFBP-2 is expressed in most tissues including bone and combined with IGF-I can stimulate bone formation in experimental animals. A recent study highlighted a direct correlation between serum IGFBP-2 and bone turnover markers in both men and women. However, the mechanism of this effect is unknown. To understand the role of IGFBP-2 in the mammalian skeleton we generated IGFBP-2 null (-/-) mice that were backcrossed 10 generations onto C57BL/6J. We then performed skeletal and metabolic phenotyping at 8 and 16 weeks and compared the nulls to +/+ littermates. Male BP2-/- mice had shorter femurs at 16 wks and had greater % body fat than +/+ ($p<0.05$). However, they were not insulin resistant and had normal glucose tolerance. Serum IGF-I in the BP2-/- mice was 10% higher than +/+ ($p<0.05$) at 8 but not 16 wks. Hepatic expression of IGFBP-1,3,4,5,6 was higher in the -/- at 6wks than +/+ mice ($p<0.05$). BP2-/- mice at 8 weeks had reduced total bone area and cortical thickness by microCT with a 17% reduction in trabecular BV/TV vs +/+ ($p<0.01$). This was almost entirely due to reduced trabecular thickness ($p<0.01$) rather than change in trabecular #. Serum osteocalcin was suppressed by 40% in BP2-/- vs +/+ ($p<0.01$) and both CFU-AP+ pre-OBs and TRAP+ osteoclasts were significantly less abundant *in vitro* than +/+ cells from littermates. Moreover, null mice have 20% smaller spleens and less B220+ mononuclear cells in marrow and spleen than +/+. Histomorphometry at 16 wks revealed there were significantly less osteoblasts/BPm ($p<0.01$) and less osteoclasts/BPm ($p<0.05$) in BP2-/- than +/+ mice. Mineralizing surface/bone surface in BP2-/- was markedly reduced ($p<0.001$), as was the overall bone formation rate/BSd (-45%, $p<0.001$) but MAR was not different. In summary, IGFBP-2 null mice have a skeletal phenotype that is directly related to bone turnover and mostly likely begins with impaired OB recruitment. Recent work suggests that IGFBP-2 can bind to the $\alpha_v\beta_3$ integrin receptor, independent of IGF-I, and may suppress PTEN expression. Conversely, IGFBP-2 may mediate its action by transporting IGF-I to its receptor on stromal cells leading to enhanced OB differentiation. Studies are ongoing to assess whether recombinant IGF-I or IGFBP-2 can rescue the *in vitro* or *in vivo* phenotypes. Nonetheless, circulating IGFBP-2 may become a useful marker of bone turnover.

Chemokine Receptor CCR-1 Deficient Mice Have a High Turnover Osteoporosis that Is Greater in Females than in Males. J. Lorenzo, J. Kalinowski*, S. Jastrzebski*, S. K. Lee*. Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Chemokine receptor CCR1 is expressed on osteoclasts and binds the ligands CCL3 (macrophage inflammatory protein 1 α , MIP-1 α) and CCL9 (MIP-1 γ). Previous *in vitro* results demonstrated that MIP-1 α and MIP-1 γ stimulate osteoclast formation and mobility. To better understand the *in vivo* effects of CCR1 and its ligands on bone, we examined mice that were globally deficient in CCR1 (CCR1 KO). Animals were examined for changes in bone mass, bone turnover and the ability of bone marrow cells to form osteoclast-like cells (OCL) *in vitro*. CCR1 KO and wild type (WT) mice were in a C57BL/6 background. Bone mass was measured by micro-CT. Changes in bone cells were determined by histomorphometry. Global bone turnover was assessed by measuring serum c-terminal telopeptide (CTX), a measure of bone resorption, and osteocalcin (OCN), a measure of bone formation. *In vitro* osteoclastogenesis was assayed in bone marrow cultures, treated with M-CSF and RANKL (30 ng/ml for each) for 4 days. Mice were examined at 9-10 weeks of age and females (F) and males (M) were analyzed separately. Based on the previous *in vitro* data, we anticipated that CCR1 KO mice would have increased bone mass and low turnover. Instead we found that both F and M CCR1 KO mice had decreased vertebral trabecular bone mass, with the greatest effect in females (BV/TV was decreased 15.8% in F and 8.4% in M, trabecular thickness was decreased 12.2% in F and 3% in M, $p<0.05$ for all). Femoral cortical bone thickness was also significantly decreased in F and M CCR1 KO mice by 10% for both ($p<0.05$). There was no significant difference in femoral trabecular bone mass between either F or M CCR1 KO and WT. In the femurs of F mice there were increases in the osteoclast surfaces (29.2%), the number of osteoclasts per unit bone surface (22.8%) and osteoblast surfaces (43.3%) ($p<0.05$ for all). In the femurs of M mice there were no significant differences in histomorphometric indices between CCR1 KO and WT. CCR1 KO mice also had increased serum turnover markers. In F CCR1 KO mice serum CTX was 36% greater while OCN was increased by 49% over WT ($p<0.05$ for both). Increases in serum CTX and OCN in M CCR1 KO mice were also seen but were less (20% and 39%, respectively, $p<0.05$ for both). OCL formation *in vitro* in bone marrow cell cultures was similar in F CCR1 KO and WT cultures. In contrast, in M cells, there was an 18% decrease in OCL formation relative to WT cells ($p<0.05$). These results demonstrate that CCR1 KO mice have a high turnover osteoporotic phenotype, which is markedly greater in female than in male mice. These findings imply that complex mechanisms, which are not dependent on the ability of CCR1 ligands to stimulate osteoclasts, are responsible for the observed bone phenotype of CCR1 KO mice.

Selective Deletion of the Membrane-bound Colony Stimulating Factor 1 Isoform In Vivo Does Not Affect Estrogen-deficiency Bone Loss in Mice. G. Yao, J. Wu*, K. Insogna. Yale University, New Haven, CT, USA.

It has been reported that a neutralizing antibody to CSF1 completely prevents ovariectomy (OVX)-induced bone loss in mice. There are two isoforms of CSF1, soluble (sCSF1) and membrane-bound (mCSF1), but their individual biological functions are unclear. It has been reported that estrogen-withdrawal increases levels of IL-1 and TNF in bone marrow, which induce the formation of a stromal cell population producing high levels of secreted CSF1. However, others have found that estrogen-withdrawal selectively up-regulates expression of mCSF1 and down-regulates sCSF1 expression in rat bone marrow cultures. To explore the role of CSF1 isoforms in estrogen-deficiency bone loss, we have generated mCSF1 knock-out mice. Isoform-specific RT-PCR confirmed the absence of transcripts for mCSF1 in bone tissue isolated from these animals and western blot analysis demonstrated similar amounts of sCSF1 secreted by osteoblasts isolated from mCSF1 k/o and wild-type mice. The mCSF1 k/o mice had higher femur BMD than wild-type controls. Five month-old mCSF1 k/o and wild-type female mice underwent ovariectomy (OVX) or sham-OVX. One month after surgery, femoral and spinal BMD (determined by DEXA) were reduced by 7% and 5% respectively in OVX-wild-type animals as compared to sham-OVX wild-type mice. OVX mCSF1 k/o mice showed similar 5% and 8% reductions in femoral and spinal BMD respectively compared to sham-OVX mCSF1 k/o animals. We next used real time PCR to quantitate expression of transcripts for mCSF1 and sCSF1 in RNA isolated from bones of OVX or sham-OVX wild-type mice. When data from three separate experiments were analyzed, OVX induced a significant 4-fold increase in the expression of sCSF1 while mCSF1 expression was either unchanged or changed minimally. In summary, our findings indicate important non-redundant functions for the two isoforms of CSF1. In particular, it appears that the mCSF1 isoform is not involved in estrogen-deficiency bone loss although this isoform is essential for normal bone remodeling since, in its absence, bone density is increased. In contrast our data suggest that sCSF1 could play a key role in estrogen-deficiency bone loss.

Point Mutation of Endofin at PP1c-Binding Domain (F872A) Stimulates Bone Formation in Transgenic Mice: A Negative Feedback Regulation of BMP Signaling. F. Zhang^{*1}, W. Shi^{*1}, T. Qiu¹, X. Wu¹, J. Chen^{*2}, J. Si^{*3}, M. Wan¹, X. Cao¹. ¹Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, ²Pharmacology, Tongji Medical School, Wuhan, China, ³Pathology, Shihezi University School of Medicine, Shihezi, China.

Smad anchor for receptor activation (SARA) facilitates TGF β signaling by recruiting and presenting Smad2/3 to the receptor complex. SARA does not bind Smad1 and hence does not enhance bone morphogenetic protein (BMP) signaling. We identified Endosome-associated FYVE-domain protein (endofin) acts as a Smad anchor for receptor activation in BMP signaling. We have shown that endofin binds Smad1 preferentially and enhances Smad1 phosphorylation and nuclear localization upon BMP stimulation. Silencing of endofin by RNAi resulted in a reduction in BMP-dependent Smad1 phosphorylation. We also demonstrate that endofin contains a protein-phosphatase-binding motif, which recruits protein phosphatase 1 (PP1c) to negatively modulate BMP signals through receptor dephosphorylation of BMP type I receptor. Point mutation of endofin at PP1c-binding domain (F872A) almost abolished the interaction between PP1c and endofin. As a result, BMP signaling was sensitized and osteoblast differentiation was enhanced.

To further determine whether this endofin mutant affects osteoblast activity and bone formation in vivo, transgenic mice were generated in which this mutant (F872A) was overexpressed in osteoblasts driven by 2.3 kb Col I promoter. Significant bone formation in transgenic mice was observed. The expression of the mutant endofin (F872A) was detected in 4 different transgenic lines with Western blot. X-ray analysis revealed that bone density of the entire skeleton is elevated at 4-month-old age of all 4 transgenic lines. Analysis of femur by μ CT shows that trabecular volume (BV/TV) is increased by 11 percent more in comparison to their wild type littermates. Consistently, the trabecular bone thickness and number are also significantly increased, whereas the trabecular bone separation is decreased. To examine whether the effect of this endofin mutant on bone formation is due to BMP signaling change, Smad1 phosphorylation was detected in osteoblasts. Immunostaining of tibia sections demonstrate that the level of phosphorylated Smad1 was enhanced in osteoblasts from the transgenic mice. Taken together, the recruitment of PP1c to endofin functions as a negative feedback regulation of the BMP signaling pathway. Disruption of PP1c binding motif of endofin by point mutation leads to an elevated level of phosphorylated Smad1 and augment of bone formation in transgenic mice.

Molecular Mechanisms for BMP-2 Transcription by the Hedgehog Pathway. M. Zhao¹, R. L. Chandler^{*2}, J. Liu^{*1}, G. R. Mundy¹, D. P. Mortlock^{*2}. ¹Medicine/Clinical Pharmacology, Vanderbilt University, Nashville, TN, USA, ²Molecular Physiology & Biophysics, Vanderbilt University, Nashville, TN, USA.

The Hedgehog pathway is essential for normal developmental patterning from drosophila to man. This pathway mediates effects via the Gli family of transcriptional activators, and one of its major downstream target genes is BMP-2. We have previously examined the molecular mechanisms by which Gli2 transactivates BMP-2 through the 5' flanking promoter region from -2712 to +165 (Zhao et al., 2006, MCB), but did not find good evidence for discrete functional binding sites. We have thus now examined much larger genomic regions flanking the murine BMP-2 gene. Two BAC clones, namely 5'BAC-LacZ and 3'BAC-LacZ, spanning from -185 to +53kb and -2.7 to +207kb of upstream and downstream respectively of the gene, were modified by inserting a LacZ reporter cassette in the place of exon 3 of BMP-2 coding region. Using transgenic mice which contain the BAC-LacZ genes, we have found that each BAC clone directs distinct BMP-2 expression patterns. Strikingly, we found that the regulatory sequence located more than 53kb 3' to the promoter is required for BMP-2 expression in osteoblast progenitors during skeletal development. To refine the location of the osteoblastic element, we have generated transgenics that carry 3'BAC-LacZ with different deletions. We found that deletion of +132 to +168kb region completely abolished LacZ-positive osteoblasts in long bones. Finally, a conserved 656bp region, namely ECR1, located within +155 to +160kb from the BMP-2 promoter, was identified as an osteoblast-specific enhancer of BMP-2 expression, shown by LacZ staining in both endochondral and intramembranous bones of ECR1 transgenic mice. Sequence analysis of the ECR1 fragment shows a putative Gli-response element. Thus, we examined the effect of Gli2 on ECR1 regulation of BMP-2 transcription. We made two chimeric reporter constructs by linking ECR1 to the BMP-2 promoter (2.7kb) or SV40 promoter (0.2kb). Luciferase assays showed that ECR1 addition increased Gli2 stimulation of BMP-2 promoter activity. We also found that Gli2 significantly enhanced the activities of 3'BAC-LacZ and ECR1-LacZ genes that were stably transfected into the osteoblastic MC3T3-E1 cells. These results strongly suggest that the 3' genomic sequence from +155 to +160kb of BMP-2 gene, covering a cis-enhancer ECR1, is required for osteoblast progenitor-specific BMP-2 expression, and the Hedgehog signaling mediator Gli2 enhances BMP-2 transcription in osteoblasts through this region. The identification of this enhancer should clarify regulatory mechanisms that control BMP-2 transcription in osteoblasts during skeletal development and postnatal bone formation.

Absence of sFRP1, an Antagonist of Wnt Signaling Accelerates Fracture Healing. T. Gaur¹, J. J. Wixted^{*2}, S. Hussain^{*1}, D. Ayers^{*2}, P. V. N. Bodine³, G. S. Stein¹, J. B. Lian¹. ¹Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA, ²Department of Orthopedics, University of Massachusetts Medical School, Worcester, MA, USA, ³Women's Health and Musculoskeletal Biology, Wyeth Research, Collegeville, PA, USA.

Bone fractures are the frequent consequence of trauma and pathological bone conditions (osteoporosis, diabetes and cancer). Fracture healing is a complex regenerative process and delayed process in aging and diseased bone results in clinical complications. Several clinical studies as well as transgenic mouse models have shown that the Wnt pathway supports bone formation. We examined the role of Wnt signaling in improving fracture repair using a knockout mouse model for the Wnt antagonist secreted frizzled related protein 1 (sFRP1-KO). We also used the chemical inducer LiCl to activate canonical Wnt signaling in wild type mice. A transverse fracture in the right tibia was generated in WT and sFRP1-KO mice. Healing was monitored at regular intervals by radiographic analyses. Bone samples were collected at 7, 11, 14, 21 and 28 days post fracture for histological and gene expression analyses for assessing the progression of bone formation and remodeling. Fracture healing was achieved completely in WT mice by 28 days post fracture but significantly accelerated in the sFRP1-KO mouse with appearance of new bone formation beginning at day 11. Both radiographic and histological analyses showed that on day 7, the initial callus appeared similar, but by day 11, reduced callus formation with increased cartilage tissue and trabecular bone bridging the fracture occurred in sFRP1-KO mice. After day 11, bone remodeling (by TRAP staining) was much more robust in the sFRP1-KO. Radiography identified union of the fracture by day 21 in the sFRP1-KO mice, in contrast to the WT fracture which still exhibited presence of cartilaginous callus along with formation of new bone. Enhanced fracture healing was observed in WT mice treated with LiCl. Gene expression analyses using RNA from callus tissues showed reduced TNF α levels suggesting less inflammation in KO mice fractures. Lower levels of chondrocyte proliferation markers (Col2a1 and Sox9) and mild induction of bone markers (Runx2, osteocalcin, osteopontin and Colla1) were observed in sFRP1-KO mice, consistent with less chondroid tissue and more bone formation in sFRP1-KO mice by histology. Bone remodeling markers, MMP9, TRAP and VEGF were slightly elevated in sFRP1-KO mice, suggesting mechanisms for accelerated healing. Our studies establish a direct improvement of fracture repair by increasing Wnt signaling and also provide a possibility for modulation of the Wnt pathway to achieve better fracture healing in compromised clinical cases.

Enzyme Replacement Therapy for Murine Hypophosphatasia. J. L. Millan¹, S. Narisawa^{*1}, I. Lemire^{*2}, T. P. Loisel^{*2}, G. Boileau^{*3}, P. Leonard^{*2}, M. D. McKee⁴, P. Crine², K. Johnson^{*5}, R. Terkeltaub^{*5}, N. Pleshko Camacho⁶, M. P. Whyte⁷. ¹Oncodevelopmental Biology, Burnham Institute for Medical Research, La Jolla, CA, USA, ²Enobia Pharma, Inc., Montreal, PQ, Canada, ³University of Montreal, Montreal, PQ, Canada, ⁴McGill University, Montreal, PQ, Canada, ⁵VAMC/UCSD, La Jolla, CA, USA, ⁶The Hospital for Special Surgery, New York, NY, USA, ⁷Shriners Hospitals for Children and Washington University, St. Louis, MO, USA.

Hypophosphatasia (HPP) is the inborn-error-of-metabolism that features rickets or osteomalacia due to loss-of-function mutation within the tissue-nonspecific alkaline phosphatase (TNALP) gene. Consequently, there is extracellular accumulation of the mineralization inhibitor inorganic pyrophosphate (PPI), one of TNALP's natural substrates. HPP features a remarkable range of severity spanning (most severe to mildest) perinatal, infantile, childhood, adult, and odontohypophosphatasia forms, classified (historically) according to age at diagnosis. TNALP null mice (Akp2^{-/-}) phenocopy infantile HPP remarkably well, as they are born with a normally mineralized skeleton, but develop radiographically apparent rickets at about 6 days of age, and die between day 12-16 suffering severe skeletal hypomineralization and episodes of apnea and epileptic seizures attributable to disturbances in pyridoxal 5'-phosphate (vitamin B6) metabolism. There is no established medical therapy for HPP. Case reports of enzyme replacement therapy (ERT) using intravenous (i.v.) infusions of ALP-rich plasma from Paget's bone disease patients and purified placental ALP have described failure to rescue affected infants. It seems that ALP activity must be increased not in the circulation, but in the skeleton itself. This hypothesis is supported by beneficial outcomes for two girls with infantile HPP following marrow cell transplantation where perhaps some TNALP-containing cells were introduced throughout the skeleton. Here, we report survival without significant skeletal or dental disease or seizures in TNALP knockout mice undergoing enzyme replacement therapy (ERT) from birth with a bone-targeted form of recombinant TNALP (sALP-FcD10). Short-term and long-term efficacy studies with daily s.c. injections of 1, 2, or 8.2 mg/kg sALP-FcD10 for 15, 19 and 52 days showed homing of sALP-FcD10 to bone tissue and normal circulating PPI concentrations with preservation of skeletal and dental architecture (assessed by radiographs, microCT, and histology) as well as increased life span and well-being. This bone-homing, recombinant form of human TNALP prevents lethal HPP in TNALP knockout mice. Our findings represent the first successful use of ERT for a heritable primary disease of the skeleton, and are a foundation for therapeutic trials for human HPP.

Treatment of Osteogenesis Imperfecta in Adults with Teriparatide: Results of an 18-month Prospective Observational Trial. J. D. Ringe¹, H. Faber^{*1}, P. Farahmand^{*1}, T. N. Nickelsen². ¹Medizinische Klinik IV, Klinikum Leverkusen, Leverkusen, Germany, ²Medical Department, Lilly Deutschland GmbH, Bad Homburg, Germany.

Osteogenesis imperfecta (OI) is a genetic disorder of connective tissue characterized by brittle bones and a susceptibility to fracture from normal impacts of daily living or inadequate trauma. It has been shown that an antiresorptive therapy with bisphosphonates has beneficial effects on the clinical outcome of OI, especially in children. So far there is a lack of data on the use of osteoanabolic drugs in this disorder.

The aim of the ongoing "Teriparatide in Osteogenesis Imperfecta" trial (TOI-trial) is to study the efficacy of an anabolic treatment with teriparatide (rPTH-1-34) in adults with clinically symptomatic disease. In this 18-month prospective, observational, single center trial we included 10 patients (6 men, 4 women) above the age of 30 years (mean age 44.9) with a T-score <-3.0 at the lumbar spine and <-2.0 at the total hip, and at least one prevalent vertebral and one non-vertebral fracture. Fluoride, bisphosphonates or alfacalcidol had been used previously over different intervals, but during the last 6 months only calcium and vitamin D were given. During the study, all patients received daily subcutaneous injections of 20µg teriparatide plus oral supplements of 1200 mg calcium and 800 IU vitamin D per day.

Baseline characteristics of patients included a mean height of 154.1 cm, mean weight 66.3 kg, average T-scores of -4.03 at the lumbar spine and -3.24 at the hip, and a mean number of 1.5 new vertebral and 0.8 non-vertebral fractures per patient during the last year before intervention.

BMD measured at 6-month intervals showed highly significant increases at both sites and amounted to an average gain of 10.8% at the lumbar spine and 8.4% at the total hip after 18 months. During the 18 months we observed only one new vertebral and two non-vertebral fractures. This is remarkable in relation to the respective average fracture rates during the last year before starting teriparatide injections. There was a significant decrease in back pain. Moderate, transient adverse events occurred in 5 of 10 patients.

All patients will be followed during a subsequent antiresorptive therapy up to month 36. These very positive preliminary results should encourage further, controlled trials with an anabolic therapy in osteogenesis imperfecta.

Mutations in CRTAP or P3H1 Cause Dysregulation of Prolyl-3-hydroxylation and Recessive Osteogenesis Imperfecta. D. Baldrige^{*1}, U. Schwarze^{*2}, R. Morello¹, J. Lenington^{*1}, T. K. Bertin^{*1}, D. R. Eyre², M. Weis^{*2}, A. Green^{*3}, J. Walsh^{*3}, D. Lambert^{*3}, D. Krakow^{*4}, D. L. Rimoin^{*4}, D. H. Cohn^{*4}, P. H. Byers^{*2}, B. Lee¹. ¹Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, ²University of Washington, Seattle, WA, USA, ³Our Lady's Hospital, Dublin, Ireland, ⁴Cedars Sinai Medical Center, Los Angeles, CA, USA.

Osteogenesis imperfecta (OI) or brittle bone disease is a genetic condition caused by mutations in the type I collagen genes (COL1A1 or COL1A2). Quantitative or structural type I collagen alterations lead to recurrent fractures. Prolyl 3-hydroxylases, such as P3H1, are recently identified enzymes that hydroxylate a unique proline residue in the α -helical domain of fibrillar collagens like type I collagen. CRTAP, or cartilage-associated protein, interacts with P3H1, and Crtp null mice display an OI-like phenotype and lack fibrillar collagen prolyl 3-hydroxylation. The purpose of this study is to identify additional genetic causes of osteogenesis imperfecta.

In our study of 70 OI subjects we report a spectrum of recessively-inherited phenotypes, including OI types II and III, caused by mutations in either CRTAP (two patients) or mutations in P3H1 (six patients). The latter group includes a mutation in the Irish Traveller population, a community with a high degree of consanguinity and which has a prevalence of OI of approximately 2%. The mutations lead to loss-of-function, including premature termination, frameshift, and splice site alterations that result in a severe decrease of mRNA, as well as decreased collagen prolyl-3-hydroxylation by mass spectrometry, as demonstrated in patient fibroblasts. MS analysis of collagen from bone shows a 50% decrease in prolyl-3-hydroxylation in a patient with a P3H1 mutation, while a patient with a CRTAP mutation shows a 95% reduction. This suggests that there may be partial functional redundancy among the family of prolyl-3-hydroxylase enzymes and therefore as yet undiscovered less severe phenotypes from loss of function of each of these genes. However, expression of the cofactor CRTAP may be essential for complete enzymatic activity of the complex in vivo. Clinically, one patient with a P3H1 mutation was treated with IV bisphosphonates and showed prolonged survival. Hence, osteoclastic inhibition may be a viable strategy for treatment of OI due to abnormal 3-prolyl-hydroxylation. These results demonstrate a genetic basis for recessive OI and help to explain the apparent recurrence of OI to unaffected parents previously attributed primarily to germline mosaicism. In summary, loss of function of CRTAP or P3H1 leads to the severe OI phenotype including types II and III.

Expression of Osteocalcin by Circulating Endothelial Progenitor Cells Predicts Endothelial Dysfunction or Structural Coronary Artery Disease. U. I. Moedder, M. Gössl^{*}, A. Lerman^{*}, S. Khosla. Mayo Clinic, Rochester, MN, USA.

Increasing evidence indicates a link between bone and the vasculature, and bone marrow as well as circulating cells with osteogenic potential have been identified by staining for the osteoblastic marker, osteocalcin (OCN). Endothelial progenitor cells (EPCs) contribute to vascular repair, but repair of vascular injury may result in calcification, which is also a marker for future coronary events. A previous preliminary study (Bull Exp Biol Med. 139:266, 2005) found that circulating cells staining for another bone-related protein, osteonectin, were present in the circulation of 7 subjects with coronary artery disease (CAD) but absent from the circulation of 4 control subjects. Thus, in the present study, we tested whether patients with coronary atherosclerosis had increases in circulating EPCs expressing an osteogenic phenotype, as assessed by OCN staining. We studied 59 patients undergoing invasive coronary assessment. Subjects were defined as controls (no significant structural coronary lesions, normal endothelial function, n = 11) versus two groups with coronary atherosclerosis: early coronary atherosclerosis (defined as no significant structural coronary lesions but abnormal endothelial function, n = 19) and late coronary atherosclerosis (defined as severe, multi-vessel coronary artery disease [CAD], n = 29). Peripheral blood mononuclear cells were analyzed using flow cytometry following staining for EPC markers (CD133, CD34, vascular endothelial growth factor receptor 2/kinase insert domain receptor [KDR]) and OCN. Compared to controls, patients with early or late coronary atherosclerosis had significantly higher percentages of EPCs which co-stained for OCN, particularly in the population containing relatively late EPCs (CD133-/CD34+/KDR+, by 8- and 5-fold, P = 0.0006 and 0.012, respectively). In unadjusted logistic regression models, a doubling of these OCN positive EPCs was associated with an odds ratio of 1.8 (95% confidence interval, 1.2-2.7) for having CAD; following adjustment for age, sex, and statin use, the corresponding odds ratio was 4.2 (95% confidence interval, 1.5-12.1); by comparison, the analogous odds ratios for the currently used marker for coronary atherosclerosis, high sensitivity C-reactive protein, were 0.9 (0.7-1.3) and 1.2 (0.7-1.9), unadjusted and age, sex, and statin use adjusted, respectively. Thus, a higher percentage of EPCs co-stains for OCN in patients with coronary atherosclerosis as compared to subjects with normal endothelial function and no structural CAD. These findings have potential implications for the mechanisms of vascular calcification and for the development of novel markers for coronary disease.

Disclosures: U.I. Moedder, None.

A Novel Central Mechanism in Uremic Bone Disease. W. Cheung^{*1}, C. Vanek², U. T. Iwaniec^{*3}, R. T. Turner^{*3}, R. Klein^{*2}, R. Mak^{*1}. ¹Pediatrics, University of California at San Diego, La Jolla, CA, USA, ²Bone and Mineral Unit, Oregon Health and Science University, Portland, OR, USA, ³Nutrition and Exercise Sciences, Oregon State University, Corvallis, OR, USA.

Bone disease is common in patients with uremia. In this study, we tested whether leptin signaling, via the hypothalamic melanocortin system, is an important cause of uremic bone disease. We performed sub-total nephrectomy (N) or sham operation (S) in 8-week-old wild-type (WT, C57BL/6J), leptin deficient (ob/ob), leptin receptor deficient (db/db) and melanocortin receptor 4 knockout (MC4-RKO) mice. Additional WT-N mice were treated with agouti-related protein (AgRP, a MC4-R antagonist) or vehicle (V). Secondary hyperparathyroidism in uremic mice was minimized by administering a low phosphorus and high calcium diet. WT-N mice were fed ad libitum and all other mice were pair-fed to WT-N mice. Changes in whole body composition were assessed by DXA at the beginning and at the end of the 6-week study. Excised left femoral composition was determined by DXA and x-ray microtomographic scanning. Femoral strength was assessed by 3-point bending. Architecture of right femora was analyzed by mCT. WT-N, ob/ob-N, db/db-N, MC4-RKO-N, WT-N/V and WT-N/AgRP mice were uremic based on increased blood urea nitrogen and creatinine levels. WT-N mice displayed a uremic bone phenotype characterized by decreased femoral length, bone mineral content/density and failure load. mCT evaluation demonstrated reduced total femoral volume, cortical area and thickness in WT-N mice. The uremic bone phenotype was attenuated in ob/ob and db/db mice; nephrectomy in these animals did not result in significant differences in femoral bone composition and architecture compared to controls. Uremic bone disease was also attenuated by central MC4-R deficiency. MC4-RKO-N mice had no change in bone parameters compared with MC4-RKO-S mice. We also tested the effect of central MC4-R antagonism in the WT-N mice. Uremic bone disease in WT-N was ameliorated by central administration of AgRP. In summary, leptin signaling through the central melanocortin system may play an important role in the pathogenesis of uremic bone disease. These findings may have significant clinical and pharmacotherapeutic implications.

Threonine 137 Is an Important Determinant of Sodium-Phosphate Co-transport in Human NaPi-IIc. G. Jaureguiberry^{*1}, T. O. Carpenter², S. Forman^{*3}, H. Jüppner¹, C. Bergwitz¹. ¹Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, ²Dept. of Pediatrics and Endocrine Unit, Yale School of Medicine, New Haven, CT, USA, ³Dept. Anesthesiology, Massachusetts General Hospital, Boston, MA, USA.

We recently reported homozygous and compound heterozygous loss-of-function mutations in SLC34A3/NaPi-IIc, as the cause for hereditary hypophosphatemic rickets with hypercalciuria (HHRH). A previously reported male affected by HHRH (Pediatrics 1989; 84:276-280) was found to carry a novel SLC34A3 mutation, T137M c.410C>T(p.T137M), on the maternal allele and the deletion g.4225_50del on his paternal allele. In addition to rickets and typical biochemical abnormalities, he also suffered from recurrent kidney stones prior to therapy with phosphate or vitamin D analogs. His mother, who is a heterozygous carrier of T137M, also had one renal stone during pregnancy, but both parents were otherwise healthy. To permit functional analysis of T137M and g.4225_50del in vitro, we generated expression plasmids encoding enhanced green-fluorescence protein (EGFP) followed, in-frame, by cDNAs encoding wild-type or mutant human NaPi-IIc, i.e. EGFP-hNaPi-IIc, EGFP-[M137]hNaPi-IIc, or EGFP-[V446Stop]hNaPi-IIc. The V446Stop mutant showed a complete loss-of-function when assayed for surface expression and sodium-dependent [33P]-uptake in *Xenopus* oocytes. Conversely, EGFP-[M137]hNaPi-IIc was well expressed in apical patches, the renal brush border membrane equivalent of opossum kidney cells, and it was properly inserted into the cell membrane when the mutant cRNA was injected into oocytes. However, when quantified by confocal microscopy, oocyte membrane fluorescence was reduced to 50% compared to EGFP-hNaPi-IIc. After correction for surface expression, the rate of [33P]-uptake by oocytes mediated by EGFP-[M137]hNaPi-IIc was decreased by an additional 60%. In comparison to wild-type, function of this NaPi-IIc mutant was thus reduced to 30%, which, taken together with complete loss-of-function by g.4225_50del on his second allele appears to be sufficient to explain the phenotype in our patient. Two-electrode studies indicated that EGFP-[M137]hNaPi-IIc is non-electrogenic and the stoichiometry of simultaneous [33P]- and [22Na]-uptake was unaltered when compared to EGFP-hNaPi-IIc. However, EGFP-[M137]hNaPi-IIc displayed a significant phosphate-independent inward-directed sodium-leak, which appears to be insensitive to phosphonoformic acid (PFA) and changes in extracellular pH, factors known to inhibit sodium-dependent phosphate co-transport. M137 may thus reduce the rate of phosphate uptake by uncoupling sodium-phosphate co-transport, suggesting that this amino acid residue has an important functional role in human NaPi-IIc.

Alendronate Impairs Angiogenesis and Bone Formation During the Early Stages of Bone Healing in an Animal Model for Osteonecrosis of the Jaw. J. I. Aguirre, S. M. Vanegas*, M. K. Altman*, S. E. Franz*, M. E. Leal, T. J. Wronski. Physiological Sciences, University of Florida, Gainesville, FL, USA.

Osteonecrosis of the jaw (ONJ) is a bone disorder characterized by persistent areas of exposed, necrotic bone in the oral cavity after jaw trauma, dental surgery, or tooth extraction. ONJ is most frequently observed in cancer patients that receive high doses of nitrogen-containing bisphosphonates (BPs) IV to inhibit bone metastases. It has also been reported to occur, although with lower incidence, in postmenopausal women undergoing treatment for osteoporosis with lower doses of orally-administered BPs. Despite the association of BPs with ONJ, the pathophysiology of this condition is not well understood. Since tooth extraction has been identified as a risk factor for ONJ, we propose to use BP-treated rats as a novel animal model to test the hypothesis that BPs inhibit angiogenesis and delay filling of the root socket with new bone after tooth extraction. Intact female rats at 2.5 months of age were injected SC twice weekly with either vehicle, a low dose of alendronate (15 µg/kg bw), or a high dose of alendronate (150 µg/kg bw). The 10-fold difference in these doses is roughly equivalent to the difference between osteoporosis and oncology doses for other BPs. Treatments were administered for 3 weeks before the first mandibular molar was extracted in each rat, and continued during a post-extraction period of 10 days. The left mandibles were then collected to assess the effects of alendronate on bone healing by determining osteo- and angiogenesis within the distal root socket by quantitative histomorphometry. We found that both the low and high doses of alendronate decreased woven bone volume within the root socket by approximately 50% compared to vehicle-treated rats. In addition, alendronate induced significant decreases in osteoid and osteoblast surfaces by approximately 45% and 30% at the low and high doses, respectively. In contrast, no significant difference was observed in osteoclast surface with either dose. Remarkably, both the low and high doses of alendronate decreased blood vessel area by 30% and 45%, and blood vessel number by 40% and 35%, respectively. Along the mesial and distal alveolar bone surfaces at the margins of the distal root socket, both doses of alendronate significantly decreased mineralizing surface, but no difference was observed in osteoclast surface. These findings indicate that alendronate impairs angiogenesis and bone formation during the early stages of bone healing after tooth extraction in female rats. Furthermore, these findings provide evidence for use of tooth extraction in rats as an animal model for BP-associated ONJ.

Nitrates and BMD Among Canadian Men and Women. S. A. Jamal¹, D. Goltzman², D. A. Hanley³, A. Papaioannou⁴, J. C. Prior⁵, R. G. Josse¹. ¹Medicine, University of Toronto, Toronto, ON, Canada, ²Medicine, McGill University, Montreal, PQ, Canada, ³Medicine, University of Calgary, Calgary, AB, Canada, ⁴Medicine, McMaster University, Hamilton, ON, Canada, ⁵Medicine, University of British Columbia, Vancouver, BC, Canada.

Cross sectional studies suggest that compared to nonusers, postmenopausal women using nitrates have higher BMD and a decreased fracture risk. We used data from a population-based cohort study, The Canadian Multicentre Osteoporosis Study (CaMos), to determine the relationship between nitrate use and bone loss among men and women in a prospective manner. Subjects were 50 years and older, not using bone active agents at the baseline visit. Medication use was assessed by questionnaire at baseline and subjects classified as nitrate users if they used any of: isosorbide dinitrate, mononitrate or nitroglycerin at least once a day every day. We excluded subjects who reported use of nitroglycerin (tablet or spray) exclusively on an "as needed" (prn) basis. BMD at the lumbar spine, total hip and femoral neck was measured at baseline and five years later.

We used linear regression models, stratified by gender and adjusted for age and weight to determine the change in BMD at the total hip, femoral neck and lumbar spine (L1 to L4) from baseline. Results are expressed as the annualized percent change in nitrate users compared with nonusers.

BMD measurements were obtained in 1449 men; 14 men reported nitrate use. BMD measurements were obtained in 2682; 35 women reported nitrate use. The majority of the cohort was Caucasian (95%). The mean age of the men in our cohort was 66.3 ± 9.5 years; the mean age of the women was 68.2 ± 9.3 years. The men weighed 81.2 ± 13.8 kg and the women weighed: 68.9 ± 13.9 kg. Among both men and women, nitrate users were significantly older and weighed significantly less than nonusers.

At all BMD sites and among both men and women, nitrate users lost less bone mass than nonusers. For example, among men, nitrate users had a 1.3% (95% Confidence Interval [CI]: 0.6 to 3.7) annual increase in total hip BMD while nonusers lost 0.9% (95% CI: 0.5 to 1.1) at the total hip. At the lumbar spine nitrate users had a 1.2 % (95% CI: 0.5 to 4.1) increase in BMD while nonusers gained 0.6% (95% CI: 0.3 to 1.1) at the lumbar spine. Women who used nitrates had a 2.8% (95% CI: 0.4 to 5.2) increase in total hip BMD compared to nonusers who lost 1.9% (95% CI: 1.7 to 2.1). Nitrate users also had a 1.4 % (95% CI: 1.1 to 4.0) increase in lumbar spine BMD compared to nonusers who gained 0.5% (95% CI: 0.4 to 0.7).

Our analysis demonstrates that nitrate use is associated with increases in BMD among both men and women 50 years and older. These findings are consistent with earlier studies and strengthen the need for a randomized trial to determine the effects of nitrates on fracture.

Bone Apposition in Patients on Teriparatide Treatment Is Preferably Directed to Skeletal Regions of Local Structural Weakness: Assessment by High Resolution CT Based Finite Element Analysis In Vivo. C. Graeff¹, P. Zysset^{*2}, F. Marin^{*3}, C. C. Glüer¹. ¹Medical Physics, Diagnostic Radiology, Universitätsklinikum Schleswig Holstein, Campus Kiel, Kiel, Germany, ²Institute for Lightweight Design and Structural Biomechanics, Vienna University of Technology, Vienna, Austria, ³Medical Research, Eli Lilly & Co, Europe, Madrid, Spain.

The concepts of skeletal adaptation to loads, such as Wolff's law and Frost's mechanostat, are well established. High resolution computed tomography (HRCT) combined with finite element (FE) analysis technique provide new tools to study these concepts non-invasively in vivo. We investigated at which locations within vertebral bodies new bone is preferentially added under teriparatide treatment, hypothesizing that bone apposition induced by teriparatide is not solely governed by existing bone material acting as a scaffold but is controlled by mechanical needs, e.g. happens preferentially in areas of high strain.

In 27 patients participating in the EUROFORs study we studied the relationship of local baseline strain and subsequent increases in bone mass during 6 months of teriparatide (TPTD, 20 µg per day) treatment. HRCT scans of T12 were performed at 0 and 6 months. Voxel by voxel, we correlated baseline FE-calculated strains (and, for comparison, local apparent bone volume as assessed by HRCT, appBV/TV) with subsequent locally site-matched increases in bone mineral density (BMD) by employing image registration methods. For the FE analysis the entire segmented vertebrae were converted into finite elements of 1.3 mm isotropic resolution and relative von Mises strains were calculated by dividing local strain by global strain applied to the whole vertebra.

Results shown in figure 1 confirm our hypothesis: a sharp increase in BMD with increasing local strain, then converging (left) and a less pronounced upturned U-shaped relation to baseline app.BV/TV

Effects of 2 Year Teriparatide Treatment on 3-D Femoral Neck Bone Distribution, Geometry and Bone Strength: Results from the Eurofors Study. J. Borggrefe^{*1}, C. Graeff¹, T. N. Nickelsen², F. Marin^{*2}, J. del Pino^{*3}, J. Kekow^{*4}, R. Mörcke^{*5}, C. C. Glüer¹. ¹Med. Phys., Diagn. Radiology, UKSH, Kiel, Germany, ²Eli Lilly & Co, Bad Homburg, Germany, ³Internal Medicine, Hospital ClAnico, Salamanca, Spain, ⁴Fachkrankenhaus Rheumatologie, Vogelsang, Germany, ⁵Endokrinolog. Praxis, Magdeburg, Germany.

A DXA-based analysis of treatment-induced changes in bone strength of the proximal femur has limitations due to the complex 3-D bone structure, the projectional imaging and limited spatial resolution. We studied teriparatide (TPTD) induced changes in bone distribution, geometry (periosteal apposition occurring?), and bone strength based on 3-D QCT of the femoral neck.

We examined 53 patients treated for 24 months with TPTD (20 µg/d) in the EUROFORs study with 3 subgroups of women, based on prior antiresorptive treatment: treatment-naïve; pre-treated; and pre-treated with inadequate response. In addition to DXA femoral neck BMD (aBMD [g/cm³]), CT scans of the proximal femur were obtained at 0, 6, 12, and 24 months and were analyzed with Mindways' QCTPRO BIT software. The QCT neck region was defined semiautomatically by six reformatted 1mm slices positioned perpendicular to the neck axis and with a consistent position along that axis based on neck excentricity criteria. Cortical (vBMDcor [mg/cm³]) and trabecular (vBMDtra [mg/cm³]) bone density were evaluated in regions segmented by a fixed threshold. Minimum section modulus (Z1 [cm³]) was calculated as measure of bending strength, buckling ratio (BR) as measure of risk of buckling (high risk if BR>10), and cross sectional area (CSA [cm²]) to evaluate geometric changes.

Strength in bending and buckling did not change in the first 12 months and improved significantly at 24 months, independent of type of pre-treatment. No significant change in periosteal bone geometry was observed. Treatment effects were more favourable in individuals at higher baseline risk: the improvement in Z1 was larger at lower baseline Z1; absolute BR reduction over 2 years was -0.8 in high risk subjects (baseline BR>10) compared to -0.2 in other subjects (p<.05), resulting in a 29% reduction of subjects (16 vs 21) in the high risk category.

We conclude that 24 months of TPTD treatment improves bone strength of the proximal femur both with regard to bending and buckling, with larger protective effects in subjects at higher risk.

Table 1: Baseline data and TPTD-induced changes. ^{ns}:p<0.2, ^{*}:p<.05, ^{**}:p<.01, ^{***}:p<.001

	aBMDfin	vBMDcor	vBMDtra	CSA	Z1	BR

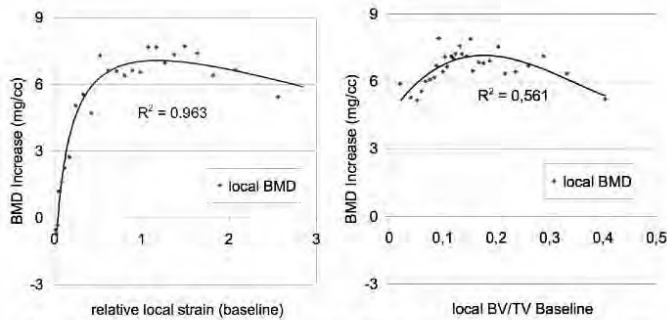

Figure 1: BMD changes as function of baseline strain (left) and appBV/TV (right). Each point represents 2.5% of the total number of voxels.

We conclude that bone apposition under TPTD treatment is not uniform but directed to skeletal regions of local structural weakness. This represents a microstructural, non-invasive, visual and quantitative demonstration of the validity of the biomechanical concepts of bone tissue response to local strains, in accordance with Wolff's law and Frost's mechanostat.

Changes in Circulating Osteoblast Lineage Cells Following PTH (1-34) Therapy and Correlation with Changes in Trabecular Bone Mass. S. Kirmani, M. Drake, U. Moedder, J. Peterson*, S. Khosla. Mayo Clinic, Rochester, MN, USA.

Using flow-cytometry, we previously demonstrated a five-fold increase in circulating osteoblast progenitor cells in pubertal boys compared to adult males (NEJM 352:1959-1966). We recently further classified these osteocalcin (OCN) positive cells into two distinct populations: small, relatively agranular cells that co-stained for the stem cell marker, CD34 (OCN^{small}, which may represent a less differentiated cell population), and larger, more granular cells that were CD34 negative (OCN^{gran}, which may represent a more differentiated cell population) (Bone 40:1370-1377). To evaluate the effects of PTH therapy on these cells, we studied 8 women at baseline, 3 months and 12 months after starting 20 mcg/day rh 1-34 PTH (Forteo). All 8 subjects completed the baseline and 3 month visit, and 7 of the 8 completed the 12 month visit. Panel A in the figure shows the changes in the OCN^{small} and OCN^{gran} cells. At 3 months, there was no significant change in the OCN^{small} cells, but a trend for an increase (of 26%, P = 0.14) in the OCN^{gran} cells. However, at 12 months, this pattern was reversed, with the OCN^{small} cells showing a marked increase (of 64%, P = 0.016), and the OCN^{gran} showing a decrease back to baseline levels. Interestingly, the percent change in OCN^{gran} cells between 0 and 12 months was highly positively correlated (R = 0.82, P = 0.02) with changes in bone volume/tissue volume (BV/TV) as assessed by high resolution 3D-pQCT (Xtreme CT, Scanco) in these patients (Panel B). The mean (± SEM) increase in BV/TV in the subjects who had an increase in the OCN^{gran} cells between baseline and 12 months was 10.8 ± 3.25% as compared to 1.7 ± 0.6% in the subjects who had a decrease in these cells (P = 0.066). To the extent that the OCN^{small} cells and OCN^{gran} cells represent less as compared to more differentiated osteoprogenitor populations, respectively, our findings suggest that PTH initially expands the population of more mature osteoprogenitor cells, whereas over a longer period of time this effect wanes, and more immature cells are recruited along the osteoblast pathway. Sustained increases in the more differentiated cells appear to be predictive of larger gains in trabecular bone volume, although further studies characterizing the relative osteoblastic differentiation of the OCN^{small} vs. OCN^{gran} are needed to test this hypothesis.

Effect of Vitamin-D3 and Calcium on Fracture Risk in 65-71 Year Old Women in a 3-Year Randomized Clinical Trial - Preliminary Results of the OSTPRE-Fracture Prevention Study. K. T. J. Salovaara¹, M. Tuppurainen¹, T. Rikonen¹, M. Kärkkäinen^{*1}, J. Sirola^{*1}, R. Honkanen^{*1}, E. Alhava^{*2}, H. P. Kröger³. ¹Bone and Cartilage Research Unit, University of Kuopio, Kuopio, Finland, ²Department of Surgery, University Hospital of Kuopio, Kuopio, Finland, ³Department of Orthopedic, Trauma and Handsurgery, University Hospital of Kuopio, Kuopio, Finland.

Although Ca+Vitamin D supplementation has been shown to prevent fractures in the elderly, the effect of such a supplementation on fracture prevention in younger ambulatory postmenopausal women is still debatable. The aim of this population level intervention was to determine whether daily Vitamin-D3 800 IU and Ca 1000 mg administered in two daily doses (Calcichew-D3 forte 500 mg/400IU, Leiras Nycomed Ltd. Finland) could decrease the incidence of fractures in postmenopausal women.

The women within the OSTPRE-cohort who were 65 years or older on 30.11.2002 (n = 5553) were asked regarding their willingness to participate in a randomized controlled trial with questions about medications, health disorders and health behaviour. Of the questionnaires that were adequately completed with written consent, 3432 subjects were randomized to have either Ca+Vit D supplementation (n=1718) or no supplementation (n=1714) for 3 years. Primary end points were number of falls and fractures. Fracture data was collected from the entire cohort by telephone interviews once a year and also from a subsample every 4 months. All self reported fractures were included in the analysis. Risk of fracture (HR) was calculated using Cox proportional hazards model. The study was approved by the local ethics committee.

Mean age of women was 67.4 (SD 1.8, range 65-71). At baseline (n = 3432) there were no statistically significant differences in age, weight, bone mineral density, HRT-use, hormonal status, age at menopause, smoking habits, alcohol use or functional capacity. A total of 290 fractures were reported including 144 osteoporotic fractures (vertebral n=26, hip n=10, distal forearm n=82 and humerus n=26). The incidence of distal forearm fractures was lower (1.86 %) in the intervention group compared to the control group (2.68%) (p = 0.107, chi square test). In the Cox regression model (n = 2946) the hazard ratios (HR with 95% CI) in the intervention group compared to the control group were 0.84 (0.65-1.08) for all fractures, 0.74 (0.51-1.06) for osteoporotic fractures and 0.60 (0.37-0.98) for distal forearm fractures, respectively.

In conclusion, this population level intervention study suggests that daily Vitamin-D3 and Calcium supplementation has a trend towards fracture reduction in all fractures and particularly osteoporotic fractures in postmenopausal women.

Long Term Risk Factors for Incident Vertebral Fractures In Healthy Older Women After 15 Years of Follow-up: The Study of Osteoporotic Fractures. T. A. Hillier¹, J. A. Cauley², M. C. Nevitt³, J. H. Rizzo^{*1}, K. L. Pedula^{*1}, K. K. Vesco^{*1}, M. C. Hochberg⁴, S. R. Cummings³. ¹Center for Health Research, Kaiser Permanente, Portland, OR, USA, ²U Pittsburgh, Pittsburgh, PA, USA, ³CPMC Research Institute and UCSF, San Francisco, CA, USA, ⁴U Maryland, Baltimore, MD, USA.

Vertebral fractures (Vfx) are associated with morbidity and mortality in older white women, yet little is known about their long-term risk factors.

We therefore performed a comprehensive assessment of potential risk factors in 2,286 women age 65 or older without baseline Vfx enrolled in the Study of Osteoporotic Fractures. Women who returned after 15 years of follow-up represented 76% (3572/4702) of survivors, 64% (2286/3572) of whom had repeat lateral thoracic and lumbar spine films. Incident Vfx were defined as $\geq 20\%$ and $\geq 4\text{mm}$ decrease in vertebral height at any level. More than 50 risk factors were evaluated, including known short-term predictors of vertebral fractures and long-term predictors of non-spine fracture. Risk factors associated univariately with incident Vfx (p<0.10) were further tested using backward stepwise regression to determine the final multivariable logistic regression model.

During a mean of 15 (SD 0.70) years of follow-up, 324 (14%) of women developed an incident vertebral fracture. Age, BMD, history of fracture since age 50, and falls remained significant risk factors (p<0.05) for incident Vfx (Table). DXA BMD at total hip and spine were both significantly associated with incident Vfx; spine BMD had a higher point estimate and was used in the final model. Other risk factors for non-spine fracture, such as alcohol, smoking, physical activity, and estrogen or glucocorticoid use, were not independent predictors.

Long-Term Incident Vfx Risk Multivariable model:	Odds Ratio (95% CI)
Age (per 5 years)	1.6 (1.4, 1.9)
Spine BMD*	1.8 (1.6, 2.1)
Fall during first year of follow-up	1.4 (1.1, 1.9)
Fracture since age 50	1.5 (1.2, 1.9)

*per standard deviation decrease

Among women who survived to age 80 and above, only four factors were independent predictors of new Vfx during 15 years of follow-up. Our results suggest a single BMD is highly predictive of long-term vertebral fracture risk, and that efforts to prevent vertebral fracture in healthy older women should focus on BMD and on falls.

Is Antidepressant Use Associated with Bone Loss or Fractures in Postmenopausal Women? L. Spangler^{*1}, D. Scholes¹, R. Brunner^{*2}, J. Robbins^{*3}, S. Reed⁴, K. Newton^{*1}, J. Melville^{*4}, A. LaCroix⁵. ¹Group Health, Seattle, WA, USA, ²University of Nevada, Reno, NV, USA, ³University of California, Sacramento, CA, USA, ⁴University of Washington, Seattle, WA, USA, ⁵Fred Hutchinson Cancer Research Center, Seattle, WA, USA.

A link between depression and bone outcomes has been postulated. The association may be the result of common physiologic systems, similar risk factors, or medication use. Literature on the association between antidepressant medication (ADM) use and BMD is limited and most research on the association with fracture relies on automated data.

We assessed these associations in 93,676 postmenopausal women (50 to 79 years old) enrolled in the WHI Observational Study, followed an average of 7.4 years. Participants brought current medications to the interviews and ADM was recorded. We further categorized ADM as selective serotonin reuptake inhibitors (SSRIs) and all other types for some analyses. To assess self-reported fractures of the hip (adjudicated), spine, wrist, and "other" skeletal sites we used Cox survival models controlling for exercise, cardiovascular disease, analgesic use, and fracture history. To assess 3-year changes in hip, spine, and whole body BMD in 6441 women enrolled at the 3 densitometry clinics we used linear regression models that included baseline BMD and hormone therapy. In addition, all models adjusted for depressive symptoms (Burnam's screen), age, menopause duration, race, physical function, smoking, height and weight.

At baseline, 8% of women were using ADM (4% SSRI). Overall, no significant associations were seen between ADM and 3-year changes in BMD at any skeletal site after adjustment. There was a positive association between ADM and increase risk of self-reported spine fractures (HR for SSRI =1.25 CI .96 - 2.05; HR for other ADM = 1.45 CI 1.17-1.81) and fractures at other skeletal sites (HR for SSRI = 1.32 CI 1.21 - 1.45; HR for other ADM =1.16 CI 1.06 -1.27) (Table 1). Controlling for falls had little effect on these associations. No associations were observed between ADM and hip or wrist fracture. The results from this sizeable study of generally healthy postmenopausal women provide additional evidence for an association between ADM and increased risk of fracture at some skeletal sites.

Table 1. Antidepressants use (ADM) and adjusted hazard ratios for fracture

Anatomic site of fracture	Adjusted hazard ratio for fracture (referent group =women not using antidepressants)	p-value	95% Confidence interval
Hip (1,132 hip fractures)	1.14	0.28	0.90 to 1.45
Spine (1,607 spine fractures)	1.36	0.001	1.14 to 1.63
Wrist (2,867 wrist fractures)	1.15	0.06	0.99 to 1.33
Other sites (11,128 fractures at other skeletal sites)	1.24	<0.001	1.15 to 1.32

Functional Decline after Incident Wrist Fracture: The Study of Osteoporotic Fractures. B. J. Edwards¹, D. Dunlop^{*1}, J. Song^{*1}, H. A. Fink², J. Cauley³. ¹Medicine, Feinberg School of Medicine, Northwestern University, Chicago, IL, USA, ²Medicine, Geriatric Research Education and Clinical Center, Veterans Affairs Medical Center, Minneapolis, MN, USA, ³Medicine, University of Pittsburgh, Pittsburgh, PA, USA.

Wrist fractures are common fractures that occur in post-menopausal women. Little is known about the effect of wrist fractures on functional decline. Analyses included 7,694 participants of the Study of Osteoporotic Fractures (SOF), a multicenter observational study of women aged > 65 years. Functional activity was by self-report and measured ability to perform five activities: walking, climbing stairs, preparing meals, shopping, and doing heavy housework. The items are rated on a four point scale from no difficulty (0), mild (1) and moderate difficulty (2), to unable to perform (3). We calculated global function (0-15), and targeted upper extremity function (0-9 from cooking, heavy housekeeping and shopping).

Participants who did not sustain a vertebral or hip fracture or wrist fracture prior to baseline and participated in as at least one (range 1-5) follow-up visits through 1998. (N=7,694) We track wrist fracture status at each visit to utilize longitudinal information and to include records from women who contribute function data both prior to and following an incident wrist fracture. Longitudinal multiple regression analyses with generalized estimating equations (GEE) are used to estimate annual decline in function

over time.

Age-adjusted average annual rates of global functional decline were almost 3 times greater following a wrist fracture and remained significantly higher controlling for BMI, and health status (Table 1). Similarly, wrist fractures resulted in significantly greater decline in upper extremity function (Table 2)

Table 1 Average Annual Decline in Global Function by Incident Wrist Fracture Status

Adjustment Factors	Sustained Incident Wrist Fracture		Comparison of average decline in function for women with and without wrist fracture
	Yes	No	
Age	0.37	0.13	p=0.003
Age+BMI+Health	0.27	0.02	p=0.001

Table 2: Average Annual Decline in Upper Extremity Function by Incident Wrist Fracture Status

Adjustment Factors	Sustained Incident Wrist Fracture		Comparison of average decline in function for women with and without wrist fracture
	Yes	No	
Age	0.58	0.34	p=0.002
Age+BMI+Health	0.46	0.20	p=0.007

Women with incident wrist fractures had statistically significant functional decline independent of age, BMI and baseline health.

Fracture Risk Increases after Cancer Diagnosis in Postmenopausal Women: Results from the Women's Health Initiative. Z. Chen¹, M. Maricic¹, A. K. Aragaki², C. P. Mouton³, A. M. Lopez⁴, L. A. Arendell¹, T. Bassford⁵, R. T. Chlebowski⁵. ¹Univ. of Arizona, Tucson, AZ, USA, ²Fred Hutchinson Cancer Research Center, Seattle, WA, USA, ³Howard University, Washington, DC, USA, ⁴Arizona Cancer Center, Tucson, AZ, USA, ⁵UCLA, Los Angeles, CA, USA.

The primary aim of this study was to investigate changes in fracture and fall risk after breast cancer (BC) or other cancer (OC) diagnosis. This was a prospective study in the Women's Health Initiative (WHI) cohort. Participants included 145,886 postmenopausal women who had no cancer history at baseline and were enrolled in either the Observational Study (OS) or the Clinical Trials (CT). They were followed up to 9 years and classified into no-cancer, incident BC and incident OC group. Hip fractures were adjudicated for both OS and CT, while the remaining fractures were only adjudicated in the CT group. Falls were self-reported. Hazards ratio (HR) and confidence interval (CI) were computed from Cox Proportional Hazards Models. The results suggest that fracture and fall risk increases after cancer diagnosis (Table 1). In comparison to women without a cancer history, hip fracture risk was significantly higher after BC diagnosis (HR =1.51 CI(1.13-2.54)) or OC diagnosis (HR = 2.03 (1.62-2.54)), but the annual incidence rates of hip fractures before a cancer diagnosis were comparable between groups after adjusted for age, hormone use, health and other lifestyle factors. Risk of fall also increased with either a BC (HR = 1.16 (1.08-1.25)) or OC diagnosis (HR = 1.27 (1.19-1.36)). Although fall was a risk factor for fracture, the increased number of falls did not explain the elevated hip fracture risk. The relative risk for vertebral, forearm or total fractures were all elevated after either BC or OC diagnosis; however, the increased risk reached statistical significant (p<0.05) only for vertebral and total fractures in the other cancer group. In conclusion, postmenopausal women have a significantly elevated risk for fracture and fall after a cancer diagnosis. However, the increased risk of fall is not the major contributor to this higher fracture risk observed in the incident cancer cases. Future study should investigate the impact of cancer prognosis and cancer treatment on the observed increased risk of fracture and fall associated with cancer.

Table1. Age-adjusted Annualized Percentages of Fractures and Falls Before and After Cancer Diagnosis (n=146,959)

		Annualized Percent				
	Phase	Hip Fracture	Forearm Fracture	Vertebral Fracture	Total Fracture	>= 2 Falls
No Cancer (N = 132840)		0.15%	0.47%	0.19%	1.24%	4.72%

Impact of Adherence to Osteoporosis Medications on Fracture Rates: A Population-based Study. S. Jaglal¹, D. Thiruchelvam², G. Hawker³. ¹Rehabilitation Science, University of Toronto, Toronto, ON, Canada, ²Institute for Clinical Evaluative Sciences, Toronto, ON, Canada, ³Medicine, University of Toronto, Toronto, ON, Canada.

The purpose of this study was to examine if current efforts at managing osteoporosis led to a reduction in fracture in elderly men and women in Ontario, Canada. Specifically we determined the impact of differing levels of adherence to osteoporosis medications on subsequent fracture in a population-based study. Ontario residents over the age of 65 have universal access to Medicare and to certain osteoporosis medications. We identified all persons aged 67 and older who initiated an osteoporosis medication between April 1, 2002 - March 31, 2004 and who did not have a drug claim for an osteoporosis medication (bisphosphonate or SERM) during the 2 years prior to initiation date (N=90,723). We excluded patients with erroneous records (prescribed 1 pill for 1 day, n=866 or adherence > 120%, n = 4,605), prescription for salmon calcitonin (n=687), history of Paget's, epilepsy, cancer, pathological fracture (n=163), discharged to nursing home (n=2,458) or died before the end of the 2 year followup period from medication initiation (n=7,859) for a final cohort of 74,085 patients. The main predictor was fracture in the period after the initiation of medication. The Medication Possession Ratio (MPR) defined as the no. days supplied from first to last prescription / length of followup (730 days). This was defined at 4 cut-offs, 30%, 50%, 67% and 80%. The outcome was fracture in the period after the initiation of medication. There were 1751 (2.4%) fractures. Logistic regression analyses were conducted for each refill compliance cut-off adjusted for age, sex, BMD, no. of non-osteoporosis medications, and no. of physician visits in 2 year period prior to initiation of treatment, BMD after initiation of treatment, and Charlson co-morbidity index. Only 80% and 67% refill compliance were statistically significantly associated with fracture reduction: Odds ratio (80%) = 0.85, p = 0.046; Odds ratio (67%) = 0.85, p = 0.013. Age <75 (OR = 0.63), being female (OR = 0.54), having had a BMD prior to treatment (OR = 0.85) and one after (OR = 0.89) were also statistically significantly associated with fracture reduction. In conclusion, patients who are at least 67% adherent with their osteoporosis medications over a two-year period are less likely to fracture. Other factors associated with fracture reduction are younger age, female sex, and BMD testing. These are important findings, which confirm at a population level previous reports based on selected clinical trials patients. We now have evidence to show decision-makers that if we continue our efforts to monitor treatment and increase adherence even bigger gains in fracture reduction might be possible.

Clinical Low-Trauma Fractures Cluster in Time in Postmenopausal Women. P. Geusens¹, T. van Geel², G. Dinant². ¹Internal Medicine/Rheumatology, University Hospital Maastricht and UHasselt, Maastricht, The Netherlands, ²Department of General Practice, University Maastricht, Maastricht, The Netherlands.

Objective. Postmenopausal women with a fracture history have an increased risk for new fractures. Some studies indicate that this risk is highest immediately after a fracture. We assessed during a 10-year follow-up the time relation between a first and second clinical fracture.

Study design. Population-based study in 10 general practice centers, including 4203 postmenopausal women, aged between 50 and 80 years at baseline, who completed a questionnaire about the incidence of radiographically confirmed clinical low-trauma fractures, analysed by multiple Cox regression.

Main outcome measures. The time frame between start of menopause, a first and second low-trauma clinical fracture.

Results. 924 women sustained at least one fracture after menopause, of whom 243 had a second fracture. The fracture probability for a first fracture within 1, 5, 10 and 20 years from the menopause on was 1.0 (0.7-1.3), 3.5 (3.0-4.1), 7.9 (7.1-8.7) and 19.0% (17.6-20.3). The fracture probability for a second fracture within 1, 5, 10 and 20 years following a first fracture was 6.1 (4.5-7.6), 15.9 (13.4-18.4), 27.1 (23.8-30.5) and 40.2% (35.4-45.0), respectively.

Of all first fractures, 4.3% (3.0-5.6) occurred within one year after menopause, 15.5% (13.2-17.8) within 5 years and 33.9% (30.9-36.9) within 10 years. Of all second fractures, 22.6% (17.7-27.5) occurred within one year after a first fracture, 53.9% (48.1-59.8) within 5 years and 79.8% (75.2-84.5) within 10 years.

Conclusion. In postmenopausal women, low-trauma clinical fractures cluster in time. Twenty percent of second fractures occur within 1 year after a first fracture, half within 5 years and 80% within 10 years. Prevention of a second fracture is therefore indicated soon after a first fracture has occurred.

Tri-partite Relationships Between Bone, Cartilage and Adipogenic Changes Contribute to Bone Loss. N. H. Kulkarni^{*1}, T. Wei^{*1}, B. Han^{*1}, M. A. Schreivweis^{*1}, K. A. Brune^{*1}, T. A. Christopher^{*1}, J. A. Wolos^{*1}, A. Harvey^{*1}, D. L. Sterchi^{*1}, B. Gitter^{*1}, S. Chandrasekhar^{*1}, T. J. Martin², H. U. Bryant¹, Y. L. Ma¹, P. G. Mitchell^{*1}, J. E. Hale^{*1}, J. E. Onyia¹. ¹Eli Lilly and Company, Indianapolis, IN, USA, ²SVIMR, Fitzroy, Victoria, Australia.

Ovariectomy (Ovx) or estrogen withdrawal leads to an increase in bone turnover resulting in osteopenia. A hallmark of this process includes changes in bone, cartilage and adipogenic markers. While the bone markers are well studied in osteopenia, the regulation of cartilage and adipogenic markers remain poorly understood. Here, we present a comprehensive longitudinal evaluation of the anatomical (BMD), biochemical and molecular changes in bone, cartilage and adipogenic markers in rat Ovx model. Female, 6-month old rats were Ovx or sham-operated and sacrificed at 2, 4, 6, 8 and 12 weeks post-Ovx. The left femur was analyzed for BMD and the right metaphyseal femora were used for mRNA analysis of bone, cartilage and adipogenic/lipid metabolism markers. Biochemical markers of bone and cartilage turnover (PINP, CTX-I, CTX-II) and leptin, an adipogenic marker, were measured in the serum. Ovx-induced decrease in distal metaphyseal BMD was evident at 2 weeks with a steady decline over 12 weeks and was consistent with observed histological decrease in bone volume and increase in marrow adiposity. Serum PINP, CTX-I and CTX-II robustly increased 3.5-, 1.8-, and 4.7- fold respectively in 2 weeks and returned to near sham levels by 12 weeks. The levels of serum leptin increased, most evident in 6 weeks and was sustained over time consistent with increased adiposity. The mRNA levels of 15 osteogenic markers (alkaline phosphatase, collagens α_1 (I), α_1 (V), osteocalcin, etc) initially increased with maxima at 6 weeks and thereafter decreased below sham levels; whereas the expression levels of osteoblast-derived resorption indicator (OPG/RANKL ratio) steadily declined reminiscent of BMD. Interestingly, a steady decrease in the expression levels of chondrocytic markers (collagen α_1 (II), (X), aggrecan, COMP, cdnap) were observed. In contrast, markers of 7 adipogenic/lipid metabolism (LPL, FABP4, SCD1, PEPCK, leptin, etc) increased significantly and persisted with time. Overall, gene expression changes in these markers were consistent with biochemical markers and pathological changes in Ovx-induced osteopenia. Gene expression markers (bone, cartilage and adipogenic) independently showed a correlation of $r^2=0.55$; 0.58; 0.52 respectively to BMD, whereas a combination of these markers increased the correlation to $r^2=0.91$. These results suggest that the relationship between bone, cartilage, and adipogenic changes underscore osteopenia and should together be leveraged as markers to better model the disease process.

Bone Mineral Density in Hip and Spine by Quantitative CT and Previous History as Predictors of Incident Low Trauma Fractures in Elderly Men and Women. K. Siggeirsdottir^{*1}, T. Aspelund^{*1}, G. Sigurdsson¹, B. Jonsson^{*2}, B. Mogensen^{*3}, G. Eiriksdottir^{*1}, S. Sigurdsson^{*1}, L. Launer^{*4}, T. Harris^{*4}, T. F. Lang⁵, V. Gudnason^{*1}. ¹Icelandic Heart Association, IS-201 Kopavogur, Iceland, ²University Hospital, Malmö, Sweden, ³University of Iceland, IS-101 Reykjavik, Iceland, ⁴National Institute on Aging, Bethesda, MD, USA, ⁵University of California, San Francisco, CA, USA.

The experience with QCT in prospective population studies is limited. We have studied the predictive power of QCT of hip and lumbar spine in the AGES-REYKJAVIK Study, a cohort of 67-85 year old men (n=829) and women (n=1088) drawn from an established population based cohort. 4 detector Siemens CT system with 1 mm slices was used and for this analysis integral BMD in femoral neck and vertebral centrum in L₁+L₂ was used. All low trauma fractures during 3.7 years follow-up were validated by medical and radiological records, altogether 44 fractures in 36 men and 121 fractures in 104 women. Baseline information on previous fractures, falls during the last twelve months, medications, body mass index and measured grip strength were among several variables included in a Cox-proportional hazards model (see table).

Significant variables	Hazard ratio (95% CI)	
	Females	Males
Δ 5-years in age	NS	1.6** (1.0-2.3)
Femoral neck BMD/SD	1.8** (1.4-2.3)	2.0** (1.4-2.8)
Previous fracture	1.7** (1.1-2.6)	2.9** (1.4-6.0)
Falling/12 months	2.2** (1.4-3.4)	2.9* (1.4-6.2)
Grip strength/SD	1.7* (1.1-2.5)	NS

*p<0.05, **p<0.01

The results show that the risk of all osteoporotic fractures almost doubled in both sexes per one standard deviation below the mean in femoral neck BMD whereas lumbar spine BMD did not add further to the prediction. Increase in age after 67 seems to be mainly a risk factor amongst men. Previous osteoporotic fractures and falling during the last twelve months were strong risk factors in both sexes whereas grip strength reached only significance in women. The area under the ROC curve (aROC) was 0.83 (0.78-0.88) for men, using the above variables, and 0.72 (0.76-0.77) for women. Using hip BMD increased the aROC curve significantly both for men (p=0.03) and women (p=0.0230). Grip strength did not improve diagnostic capacity. We conclude that volumetric BMD at the femoral neck measured by QCT is an important risk factor for all osteoporotic fractures.

Fracture Risk Index After Falling: A Selection Strategy for Fracture Reduction Through Falls Prevention in the Frail Elderly. P. N. Sambrook¹, J. S. Chen^{*1}, L. M. March¹, J. M. Simpson^{*2}, M. J. Seibel³. ¹Institute of Bone & Joint Research, University of Sydney, Sydney, Australia, ²School of Public Health, University of Sydney, Sydney, Australia, ³ANZAC Research Institute, University of Sydney, Sydney, Australia.

This study aims to develop and evaluate a fracture risk index after falling for use in the frail elderly. We assessed risk factors at baseline and prospectively recorded falls and falls-related fractures in 2005 institutionalized older people. Each fall was treated as a study unit and a fracture as an outcome. To account for within-subject correlation between falls, the generalized estimating equations approach (specified a binomial distribution and a log link) was used to identify fracture predictors after falling. Relative risk (RR) for a risk factor was assigned as a weight. A baseline weighting of one was given if a resident did not have the risk factor. Fracture score was calculated by multiplying the weights of all independent risk factors in a person. The score is a RR compared to residents without the risk factors. The subjects (1532 females & 473 males) were older and frail, with a mean age of 87 (SD = 7.1) years and 45% living in nursing homes. Over a mean of 1.55 years, 6646 falls were reported by 1342 subjects and 308 fractures by 270 subjects, giving an incidence rate of 214 and 9.9 per 100 person years for falls and fractures respectively. The independent risk factors were lower broadband ultrasound attenuation, lower weight, longer lower leg length, better balance, intermediate-care residence, a history of fracture and lack of report of a fall in the past year. The risk score corresponded well with fracture risk. Fracture rate was 1.1 per 100 falls for 13.8% of falls with a mean score of 3.1 compared to a rate of 9.9 for 14.4% of falls with a mean score of 20.0, a multiplicative increase of 8.8. In order to identify residents who would be at high risk of both falls and fractures from baseline, the risk score was multiplied by a falls risk score calculated using the falls risk index proposed by the Fracture Risk Epidemiology in the frail Elderly (FREE) study (Chen et. al. A multivariate regression model predicted falls in residents living in intermediate hostel care. J Clin.Epidemiol. 58:503-508, 2005). The results showed that 34% of highest risk residents (i.e. highest combined score) had incidence rates of 249 and 16.2 per 100 person years for falls and fractures respectively and accounted 56% of the total fractures. The rates were 30% and 125% higher in falls and fractures respectively compared to the rest of the sample. Prevention strategies on fracture reduction through fall prevention should be directed to those at highest risk in both falls and fractures. The index could help to rationalize the provision of falls prevention programs in the frail elderly.

Finite Element Analyses Based on In Vivo HR-pQCT Images of the Radius Tend to Improve Wrist Fracture Prediction. S. Boutroy^{*1}, B. Van Rietbergen^{*2}, E. Sornay-Rendu^{*1}, F. Munoz^{*1}, M. L. Bouxsein³, P. D. Delmas¹. ¹INSERM Unit 831 and Université de Lyon, Lyon, France, ²Department of Biomedical Engineering, Eindhoven University of Technology, Eindhoven, The Netherlands, ³Orthopedic Biomechanics Laboratory, Beth Israel Deaconess Medical Center, Boston, MA, USA.

We recently reported that attributes of cortical (Ct) and trabecular (Tb) architecture contribute to skeletal fragility, partially independently of areal BMD (Sornay-Rendu, JBMR 2007; Boutroy, JCEM 2005). Integrated assessment of bone strength by finite element analysis (FEA) may further contribute to the prediction of fracture risk. To test this, we performed FEA on in vivo HR-pQCT images of the distal radius (XtremeCT, Scanco Medical AG) in 33 women (73 ± 6 yrs) who previously sustained a fragility fracture of the wrist (fx) and 33 age-matched controls, from the OFELY cohort. We found that areal BMD; total, Tb and Ct volumetric BMD; Tb number, separation, thickness and distribution; as well as Ct thickness were significantly worse in fx cases than controls, ranging from -6% to 73%. FEA-derived stiffness, apparent modulus and estimated failure load were 15-16% lower in fx than in controls (p < 0.05). In both groups, the load was mostly carried by the cortex, from 60% (distal region) to 91% (proximal region). Tb bone carried 9 to 22% more load in controls than in fx, implying that the load distribution was more uniform in controls. To reduce the number of variables, we conducted a principal components (PC) analysis with varimax rotation in the 66 women. The first PC included stiffness, apparent modulus, estimated failure load, areal and volumetric BMD and Ct thickness, explaining 51% of the variance. PC2 combined Tb architecture: number, separation and distribution, and explained 13% of the variance. An additional 10% of the variance was explained by the distribution of the load between Ct and Tb bone (PC3). We used univariate logistic regression to compute odds ratio (OR) for the PC: PC1=2.27 [1.16-4.44], PC2=2.22 [0.97-5.09] and PC3=2.21[0.99-4.98]. The OR for combination of PC1 and PC2 was 4.72 [1.54-14.28], but the addition of PC3 did not reach significance (p=0.27). Altogether these results indicate that FEA may provide information about skeletal fragility and fracture risk not assessed by BMD or architecture measurements alone. In particular, the load distribution between Ct and Tb bone, assessed by FEA, seems very promising for improving wrist fracture prediction independently of BMD and microarchitecture. These data provide strong rationale for additional studies testing the ability of FEA based on HR-pQCT to predict fracture risk.

Height Loss Predicts Fractures in Middle Aged and Older Men and Women: European Prospective Investigation Into Cancer-Norfolk Population Cohort Study. A. Moayyeri^{*1}, A. Welch^{*1}, R. N. Luben^{*1}, N. J. Wareham^{*2}, S. Bingham^{*3}, K. T. Khaw^{*1}. ¹Department of Public Health and Primary Care, Institute of Public Health, School of Clinical Medicine, The University of Cambridge, Cambridge, United Kingdom. ²MRC Epidemiology Unit, The University of Cambridge, Cambridge, United Kingdom. ³MRC Dunn Human Nutrition Unit, The University of Cambridge, Cambridge, United Kingdom.

With effective interventions available for fracture prevention, a major clinical issue is identification of individuals at greatest fracture risk for preventive interventions. Height loss among middle aged men and women can be easily measured in outpatient clinics and may contribute to fracture risk prediction. We aimed to assess measured height loss and fracture incidence in a prospective observational population study. Height was measured in men and women in the Norfolk cohort of the European Prospective Investigation into Cancer (EPIC-Norfolk) between 1993 and 1997 and was repeated between 1997 and 2000. Incident fractures up to 2006 were ascertained by hospital record linkage. Height loss and known risk factors of fracture were entered into Cox proportional hazards models to determine their independent contribution to the risk of fracture. In 14,921 men and women aged 42-82 years, during follow-up period of 7.1 (SD 0.7) years, there were 390 fractures, including 122 hip fractures. Annual height loss in the group of fracture sufferers (1.8 mm, SD 0.3) was significantly greater than other participants (0.9 mm, SD 0.2; $p < 0.001$). Participants with annual height loss > 0.5 cm had an age and sex-adjusted hazard ratio of any fracture of 1.76 (95%CI 1.16-2.67) and of hip fracture of 2.08 (95%CI 1.07-4.05) compared to those with no height loss. In multivariate models, 1 cm of height loss per year was associated with a hazard ratio of 1.86 (95% CI 1.28-2.72) for all fractures and 2.24 (95%CI 1.23-4.09) for hip fracture independent of age, sex, past history of fracture, smoking, body mass index, alcohol intake, and heel ultrasound measures. Annual height loss of 1 cm was comparable to having a past history of fracture and equivalent to being about 14 years older in chronological age in terms of magnitude of relationship with fracture risk. Middle aged and older men and women with annual height loss > 0.5 cm are at increased risk of hip and total fracture. Serial height measurements can easily be incorporated in routine clinical practice and may contribute to the development of practical fracture risk assessment tools.

Hip Muscle Cross-Sectional Area and Attenuation: Association with Hip Fracture. T. F. Lang¹, X. Cheng^{*2}, C. Li^{*1}, A. Koyama^{*1}, T. Harris^{*3}, Y. Lu^{*1}. ¹Radiology, University of California, San Francisco, San Francisco, CA, USA, ²Radiology, Beijing Ji Shui Tan Hospital, Beijing, China. ³Epidemiology and Biometry, National Institute on Aging, Bethesda, MD, USA.

Purpose: Falling is an important risk factor for hip fracture, and the strength of the hip musculature is crucial for recovery of stability after loss of balance. We hypothesized that the size (cross-sectional area (CSA)) of hip muscle from hip QCT and adipose infiltration of muscle (defined by CT x-ray attenuation of the hip muscles), acting as surrogate measures for hip muscle function, would correlate with hip fracture independently of age and body size.

Methods: To test the hypothesis, we compared CT scans of the contralateral hip in 45 women (mean age 74.71 ± 5.94) imaged within 48 hours of their hip fractures to 66 age-matched control subjects (mean age 70.70 ± 4.66). A volumetric CT scan encompassing the proximal part of the femur was analyzed for total percentage of fat tissue in the in the CT field of view and for the CSA and lean tissue Hounsfield Unit (HU) values of the hip extensor, abductor, adductor and flexor muscles. The CT scan was also analyzed to compute areal bone mineral density (aBMD) of the hip bone. Logistic regression analyses were employed to determine differences between fracture subjects and controls in body composition measures after adjustment for age, height, and BMI. Receiver-operator curve (ROC) analyses were employed to determine if combinations of aBMD and body composition were better discriminators of hip fracture than aBMD alone.

Results: Subjects with hip fractures were on average 5 years older ($p < 0.001$) had 8% lower BMI ($p < 0.05$), 8% lower percentage fat ($p < 0.0001$) and roughly 20% lower extensor and adductor CSA values than controls ($p < 0.0001$). Despite having lower total adiposity, they had higher muscle adiposity as indicated by lower lean tissue attenuation in all four muscle groups, with statistically significant differences in the adductor, abductor and flexor groups ($0.00001 < p < 0.02$). After adjustment for age and BMI, the fracture subjects had lower total % fat, smaller extensor and adductor CSA values, and greater adipose infiltration (lower attenuation) in the adductor ($0.001 < p < 0.05$). ROC analyses showed that models combining percent fat, muscle CSA and muscle attenuation values with aBMD had higher AUC values than models containing only aBMD (0.97 vs 0.88 , $p < 0.001$).

Conclusions: Reduced total adiposity and increased hip muscle adiposity appear to be independent correlates of hip fracture, and combination of skeletal and body composition variables appears to enhance diagnostic efficacy compared to skeletal variables alone.

Deletion of Subunit b1 in Osteoblast Reveals Novel Role for Calcineurin in Bone Formation. A. R. Venn^{*}, H. Yeo^{*}, J. M. McDonald, T. L. Clemens, M. Zayzafoon. Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

We recently reported that the pharmacological inhibition of calcineurin (Cn) by low concentrations of Cyclosporin A increases osteoblast differentiation in vitro and bone mass in vivo. To determine whether Cn exerts direct actions in osteoblasts, we generated mice lacking Cnb1 (Cn regulatory subunit) in osteoblast ($\Delta Cnb1^{OB}$) using Cre-mediated recombination methods. Transgenic mice expressing Cre-recombinase, driven by human osteocalcin promoter, were crossed with homozygous mice that express loxP-flanked-Cnb1 ($Cnb1^{flf}$). Micro-CT analysis of tibiae at three months showed that $\Delta Cnb1^{OB}$ mice had dramatic increases in bone mass compared to controls. Histomorphometric analysis showed significant increases in mineral apposition rate (67%), bone volume (32%), trabecular thickness (29%) and osteoblast numbers (68%), as well as 40% decrease in osteoclast numbers as compared to the values from control mice. To delete Cnb1 in vitro, primary calvarial osteoblasts, harvested from $Cnb1^{flf}$ mice, were infected with adenovirus expressing the Cre-recombinase. Cre-expressing osteoblast had a complete inhibition of Cnb1 protein levels, but differentiated and mineralized more rapidly than control, GFP-expressing cells. Deletion of Cnb1 increased expression of osteoprotegerin and decreased expression of RANKL. Co-culturing Cnb1-deficient osteoblast with wild type osteoclast demonstrated that osteoblast lacking Cnb1 failed to support osteoclast differentiation in vitro. Taken together, our findings demonstrate that the inhibition of Cnb1 in osteoblasts increases bone mass by directly increasing osteoblast differentiation and indirectly decreasing osteoclastogenesis.

Conditional Knockouts in Early and Mature Osteoblasts Reveal a Critical Role for Ca^{2+} Receptors in Bone Development. W. Chang¹, C. Tu^{*1}, T. Chen^{*1}, B. Liu^{*1}, H. Elalieh^{*1}, M. Dvorak¹, T. Clemens², B. Kream³, B. Halloran¹, D. Bikle¹, D. Shoback¹. ¹Endocrine Research Unit, VAMC, University of California San Francisco, San Francisco, CA, USA, ²University of Alabama, Birmingham, AL, USA, ³University of Connecticut Health Center, Farmington, CT, USA.

Ca^{2+} receptors (CaRs), which detect changes in extracellular $[Ca^{2+}]$ ($[Ca^{2+}]_e$) in parathyroid and kidney cells, are also expressed in osteoblasts (OBs) during differentiation. In vitro studies support a role for CaRs in mediating high $[Ca^{2+}]_e$ -induced changes in proliferation, chemotaxis, and gene expression in OBs, but their impact on skeletal development in vivo is unclear. We generated mice with conditional knockout of CaRs in early committed or mature OBs by breeding a novel mouse line carrying floxed-CaR ($CaR^{flox/flox}$) gene alleles with transgenic mice expressing Cre recombinase (Cre) under the control of 2.3 kb type 1 collagen ($2.3Col1-Cre$) or 3.5 kb human osteocalcin (OC) promoters ($OC-Cre$), respectively. Resulting $2.3Col1-Cre/CaR^{flox/flox}$ and $OC-Cre/CaR^{flox/flox}$ mice were born in normal Mendelian ratios with the $2.3Col1-Cre/CaR^{flox/flox}$ mice demonstrating severe growth retardation, clearly visible by 3 days of age. At 21 days of age, weights of $2.3Col1-Cre/CaR^{flox/flox}$ mice were $\approx 30\%$ of their wild-type (wt) littermates. They had smaller, undermineralized skeletons by whole-mount alcian blue and alizarin red staining with significant reductions in bone volume (BV) and bone mineral density (BMD) in femur and vertebrae by micro-computed tomography (μ CT). Goldner and von Kossa staining revealed excessive amounts of unmineralized osteoid in both metaphyses and diaphyses of the long bones from $2.3Col1-Cre/CaR^{flox/flox}$ vs wt mice. Defective mineralization was evident in newborns and persisted postnatally in $2.3Col1-Cre/CaR^{flox/flox}$ mice suggesting that CaRs are essential for both prenatal and postnatal bone development. Quantitative real-time PCR demonstrated significant reductions in OC RNA level (by $\approx 50-65\%$) and increases in RUNX2 and RANKL expression (by $\approx 50\%$) in calvariae and humeri from $2.3Col1-Cre/CaR^{flox/flox}$ vs wt mice without changes in RNA expression of Col1 and osteopontin, supporting a role for CaRs in OB maturation. Width of the hypertrophic zone in growth plate was reduced in $2.3Col1-Cre/CaR^{flox/flox}$ mice, indicating delayed growth plate development which could contribute to their growth retardation. In contrast, growth curves of $OC-Cre/CaR^{flox/flox}$ mice were comparable to wt littermates. Analyses of bone micro-architecture by μ CT revealed no significant changes in BV, BMD, and structure parameters in the $OC-Cre/CaR^{flox/flox}$ mice. These studies confirm a critical role for CaRs at early stages of bone development potentially by promoting OB maturation.

Inadequate Bone Adaptation in Bone Cell Specific Connexin43 Deficient Mice. Y. Zhang*, A. F. Taylor*, E. M. Paul*, A. Davison*, S. K. Bronson*, H. J. Donahue. Penn State University, College of Medicine, Hershey, PA, USA.

Previous in vitro studies suggest that gap junction (GJ) deficiency affects bone metabolism possibly resulting in osteopenia. We examined the hypothesis that connexin 43 (Cx43), the predominate Cx in bone, deficiency in murine osteoblasts and osteocytes results in osteopenia. Osteoblast/osteocyte specific Cx43 knockout (KO) mice were generated by breeding Cx43 null mice (Cx43^{-/-}) with mice expressing Cre recombinase under the control of the human osteocalcin promoter (OC-Cre) and with mice in which the Cx43 gene is flanked by two loxP sites (Cx43^{fl/fl}). Our breeding strategy resulted in littermates with Cx43 deleted from osteoblasts (conditional knockout, KO, Cx43^{fl/fl};OC-Cre), a single functional allele of Cx43 in osteoblasts (heterozygous equivalent, HET, Cx43^{fl/+};OC-Cre), or with two functional alleles in all cell types (wild type equivalent, WT, Cx43^{fl/fl}). All mice examined were 3 weeks old. GJ intercellular communication (GJIC) was dramatically reduced in osteoblastic cells isolated from KO relative to HET or WT, suggesting that we had indeed deleted Cx43 expression in osteoblastic cells. MicroCT of humeri and femora revealed that bones from KO mice were osteopenic, relative to WT or HET mice. KO displayed periosteal expansion, cortical thinning, increased porosity and an approximately 8% and 26% reduction in bone mineral density and bone volume over total volume, respectively. More importantly, three point bending revealed that the failure stress of femora from KO mice was reduced approximately 41% and 27% relative to WT and HT, respectively. Our results demonstrate successful conditional deletion of the Cx43 gene in osteoblasts and osteocytes and confirm previous in vitro data suggesting that Cx43 is largely responsible for GJIC between osteoblastic cells. More importantly, microCT and mechanical testing revealed osteopenia in osteoblast/osteocyte specific Cx43 deficient mice. The exact mechanism by which Cx43 deficiency results in osteopenia was not investigated in this study. However, the remarkable similarity between bones from KO mice and those from mice experiencing disuse osteopenia, together with our previous in vitro data demonstrating that GJIC contributes to bone cell response to load induced biophysical signals, suggests that bones from KO mice were unable to properly adapt to loads engendered during normal ambulation, which, as confirmed by behavioral studies, all genotypes examined were experiencing. In any case, these in vivo data confirm in vitro data suggesting Cx43 mediated GJIC is critical for normal bone adaptation and emphasize the physiological relevance of GJs in bone.

Low Bone Mass in Mice with Null Mutation in TG-interacting Factor (TGIF): Impaired Osteoblast Function. M. K. Crook¹, K. S. Mohammad¹, G. A. Clines¹, L. Bartholin², T. Melhuish², C. R. McKenna¹, M. Niewolna¹, L. J. Suva³, A. Carver³, D. Wotton², T. A. Guise¹. ¹Department of Internal Medicine, University of Virginia, Charlottesville, VA, USA, ²Department of Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA, USA, ³University of Arkansas for Medical Sciences, Little Rock, AR, USA.

TGIF (TG interacting factor) is a transcriptional corepressor of both TGF β and retinoic acid signaling. Mutations in the TGIF gene can lead to holoprosencephaly, a severe defect in craniofacial development. TGIF-null mice had developmental and skeletal abnormalities including growth retardation, domed skulls, twisted noses, and defects in vertebrae, ribs and sternum. Loss of TGIF may enhance responses to TGF β and retinoic acid, both of which can adversely affect bone. Therefore, we studied bone remodeling in TGIF^{-/-} and wild-type (WT) littermates in the C57BL/6J mice. Skeletal assessment revealed that the TGIF^{-/-} mice had significantly less trabecular bone by DXA (PIXImus), microCT and histomorphometry. Low bone mass was associated with increased osteoclast activity, reduced osteoblast number and bone formation rates. Primary osteoblasts from TGIF^{-/-} compared to WT mice had reduced expression of two late markers, osteocalcin and bone sialoprotein, and increased expression of the early marker Col1A, assessed by quantitative real-time PCR, suggesting that complete osteoblast differentiation was impaired in TGIF^{-/-} mice. To evaluate if the low bone mass seen in TGIF^{-/-} mice was due to enhanced TGF β signaling, we treated TGIF^{-/-} and WT mice for 10 weeks with a small molecule inhibitor of the TGF β receptor I kinase, which significantly reduces TGF β 1-dependent phosphorylation of Smad proteins and increase bone mass in normal mice. As expected, inhibitor treatment versus vehicle significantly increased bone mineral density (BMD) in WT mice at total body (p=0.0005), tibia (p<0.0001), femur (p=0.0046) and spine (p=0.0005). In contrast, BMD was not increased at any site in the TGIF^{-/-} mice treated with inhibitor versus vehicle. There was no difference in phosphoSmad2 staining in the bones of TGIF^{-/-} compared to WT mice.

The data suggest that reduced bone mass in TGIF^{-/-} mice is due to impaired osteoblast differentiation and increased osteoclast activity. We hypothesized that the effects were due to enhanced activity of TGF β and/or retinoic acid due to loss of TGIF repression. However, we found no evidence of increased TGF β signaling, nor were the bone abnormalities reversed by a TGF β receptor kinase inhibitor. The mechanism responsible for the abnormal bone remodeling requires further elucidation and may involve increased retinoic acid signaling.

Skeletal Phenotype in Transgenic Mice Over-Expressing CTGF in Cells of the Osteoblast Lineage. J. A. Arnott, E. Nuglozeh*, K. B. Buck*, F. F. Safadi, S. N. Popoff. Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA.

CTGF has recently emerged as an important growth factor in osteogenesis, demonstrated by its ability to promote proliferation, matrix production and differentiation in cultures of osteoblasts. Since most of the data concerning the role of CTGF in osteogenesis has come from in vitro studies, in this study we generated transgenic mice in which CTGF is over-expressed under control of the truncated 3.6kb collagen type I (pOBCol3.6) promoter (CTGF^{pOBCol3.6} mice). This promoter was chosen because it is expressed early during osteoblast differentiation. The targeting vector used to generate transgenic mice also contained LacZ (to identify cells expressing the transgene) and an enhancer element to boost CTGF expression. The presence of the transgene was determined by PCR of tail DNA using transgene specific primers. Six lines were established by mating founder mice with C57/Blk6 wild type (WT) mice. Multiple tissues were used to examine specificity of transgene expression using PCR with transgene specific primers, followed by confirmation of CTGF mRNA expression levels by Northern blot analysis. Transgene expression was highest in long bone and calvaria, with lower levels of expression in other type I collagen producing tissues (lung and skin). Two of the transgenic lines with different CTGF expression levels were used for analysis of the skeletal phenotype. Mice from one line survive, however, mice from the other line die within a few days after birth. Line one showed a 3-4 fold (moderate expression) increase and line two showed a >7-8 fold (high expression) increase in CTGF protein levels in bone when compared to age matched WT mice. Histological and morphometric examination of the distal femoral metaphysis from TG mice with moderate over-expression of CTGF exhibited significant increases in trabecular bone volume associated with increased osteoid thickness and osteoblast activity/numbers compared to WT mice. Increased thickness of the periosteum with increased numbers of osteoprogenitor cells was also observed in TG compared to WT bone. Primary cultures of osteoblasts derived from these TG mice also exhibited enhanced differentiation (ALP staining and mineralization) compared to WT cultures. Surprisingly, examination of bones from transgenic mice over-expressing CTGF at very high levels demonstrated an increase in osteoclast number and size. These data suggest that the precise effects of CTGF on bone cell differentiation and function depend on the magnitude of CTGF over-expression. Moderate levels of CTGF have a direct effect on osteoblasts to promote bone formation, while high levels favor the formation of osteoclasts, perhaps indirectly through a RANK-L dependent mechanism.

The Human Type 1a2 Procollagen Nuclear Targeting Sequence Together with Human Runx2 Enhancer Elements Drives Robust Expression in Transgenic Mouse Osteoblasts. D. D. Strong*, C. Strivers*, K. Howard*, S. Kleinman*, T. A. Linkhart. MDC, J.L. Pettis Memorial VA Med Ctr., Loma Linda, CA, USA.

Translocation of plasmid DNA into the nucleus is an important rate-limiting step affecting transgene expression levels in non-dividing cells. Inclusion of a SV40 viral DNA nuclear targeting sequence (DTS) in plasmid vectors enhances nuclear import efficiency and increases transgene delivery and expression in vitro and in vivo. Plasmid nuclear import involves cellular transcription factors that bind in the cytoplasm to viral DTSs and translocate the DNA by a nuclear localization signal/importin dependent process. We identified a sequence in the human type 1 alpha 2 procollagen promoter (hCol1a2) (-312 to +45) that stimulated osteoblast (Ob) specific nuclear entry of plasmid DNA but not into the nuclei of fibroblasts or chondrocytes. We used this hCol1a2-based nuclear import sequence together with an enhancer sequence derived from the human Runx2 promoter to increase Ob-specific promoter activity and retain nuclear entry activity. We found that the hRunx2-hCol1a2 promoter linked to the luciferase reporter (pGL3Basic vector) demonstrated three-fold more activity than the hCol1a2 promoter alone in transient transfection assays of Obs. To test the specificity and strength of expression of the hCol1a2 and hRunx2-hCol1a2 promoters in vivo we took advantage of Cre-loxP technology and created transgenic (Tg) mouse lines to characterize expression patterns of the promoters in the postnatal skeleton. Specifically the Cre recombinase (Cre) transgene was linked to either the hCol1a2 or the hRunx2-hCol1a2 promoter in the pTurbo-Cre vector (T. Ley) that expresses Cre fused to a nuclear localization signal sequence to facilitate recombination. Multiple lines of Tg mice were prepared and Cre expression was assessed by crossing Cre Tg mice with Rosa26LacZ (R26R) reporter mice to allow expression of beta-galactosidase following Cre activation. Using these mice, we found Cre activity in distinct cell populations in skeletal tissues, including Obs lining the bone surface and in osteocytes. The Runx2-hCol1a2 promoter expressed higher levels of Cre than the hCol1a2 promoter and Cre expression levels and patterns were comparable to mCol1a1-Cre Tg animals (from Dr. Karsenty) crossed to R26R animals and analyzed in parallel. The Tg lines showed that the Ob-specific nuclear entry sequence (\pm hRunx2 enhancer) was also a strong promoter in Ob lineage cells. The hCol1a2 promoter not only contains a novel Ob-specific DTS, useful for development of nonviral expression vectors to increase transgene expression in Obs but also acts as a strong promoter in vivo to drive Ob-specific transgene expression in skeletal tissues.

Tec Tyrosine Kinases Are Essential For Osteoclast Differentiation. M. Shinohara*, T. Koga*, K. Okamoto*, H. Takayanagi. Cell Signaling, Tokyo Medical and Dental University, Tokyo, Japan.

Osteoclasts are multinucleated cells that originate from bone marrow-derived monocyte/macrophage precursor cells (BMMs). The differentiation of BMMs to osteoclasts is mainly regulated by three signaling pathways activated by receptor activator of nuclear factor κ B ligand (RANKL), macrophage colony-stimulating factor (M-CSF) and immunoreceptor tyrosine-based activation motif (ITAM). RANKL and its costimulatory receptors of the immunoglobulin superfamily cooperatively stimulate the tyrosine phosphorylation of ITAM in DNAX-activating protein 12 (DAP12) and Fc receptor common γ subunit (FcR γ). However it has been unclear how RANKL contributes to the activation of the tyrosine kinase cascade downstream of ITAM. In this study, a genome-wide screening for non-receptor tyrosine kinases revealed selective expression of Tec and Btk, which are essential for B cell development. Notably, Tec^{-/-}Btk^{-/-} mice exhibited an osteopetrotic phenotype due to severe impairment of osteoclast differentiation. In vitro analysis demonstrated that Tec and Btk are essentially required for the osteoclast differentiation in a cell autonomous manner. Tec kinases are activated by RANKL stimulation and recruited to a lipid raft to form an osteoclastogenic complex with RANK, adaptor proteins such as BLNK and ITAM-harboring adaptors, which mediates the activation of PLC γ -calcium signaling-NFATc1 pathway. Furthermore, Tec^{-/-}Btk^{-/-} mice are resistant to ovariectomy-induced bone loss. Thus, this study identifies the importance of Tec kinases in the osteoclast differentiation and may provide a molecular basis for a novel therapeutic strategy for bone diseases.

Regulation of Skeletal Homeostasis by Anti-apoptotic Molecule Bcl-2. Y. Nagase¹, M. Iwasawa¹, T. Akiyama¹, Y. Kadono¹, T. Miyamoto², Y. Oshima¹, M. Nakamura¹, T. Yasui¹, K. Nakamura¹, S. Tanaka¹. ¹Orthopaedic Surgery, University of Tokyo, Tokyo, Japan, ²Orthopaedic Surgery, Cell differentiation, Keio University School of Medicine, Tokyo, Japan.

Anti-apoptotic molecule Bcl-2 resides on mitochondrial outer membrane, and inhibits apoptosis by suppressing cytochrome c release from mitochondria. Although several studies have uncovered the importance of Bcl-2 in maintaining skeletal integrity, detailed cellular and molecular mechanisms still remain elusive. We investigated the role of Bcl-2 on bone metabolism by analyzing bcl-2-deficient mice. Bcl-2^{-/-} (KO) mice were dwarf at 3 weeks of age compared to wild type (WT) littermates, and radiographic analysis of long bones showed a sclerotic lesion at the metaphysis and an atrophic change at the diaphysis. The histomorphometric study revealed that KO mice showed an increase in primary spongiosa due to a decrease in the number of osteoclasts and eroded surface. Many KO osteoclasts were found unattached to primary spongiosa, whereas WT osteoclasts were largely juxtaposed to bone in vivo. The proportion of osteoclast precursors in bone marrow cells which were positive for c-Fms, Mac1 and c-Kit was not different between KO mice and WT littermates as determined by flow cytometry. However, NFATc1 induction in response to RANKL stimulation was impaired in M-CSF-dependent osteoclast precursors obtained from KO mice, which led to a delayed differentiation into mature osteoclasts. KO osteoclasts exhibited an increased cell death and higher Caspase-3 activity after cytokine withdrawal, and their bone-resorbing activity was impaired as determined by pit formation assay as compared to WT osteoclasts in spite of their normal actin ring formation. These abnormalities were restored by retroviral introduction of Bcl-2. In addition to such cell-autonomous defect in bone resorption, bone formation of KO mice was also impaired, which caused an atrophic bone lesion at the diaphysis and reduced calcein double labeling. KO mice exhibited a decrease in osteoblast surface/bone surface, mineral apposition rate and bone formation rate by histomorphometric analysis. KO osteoblasts exhibited an increased cell death, and expression of osteoblastic markers such as type I collagen, alkaline phosphatase and osteocalcin was reduced in primary osteoblasts obtained from KO mouse calvaria, and their mineralization was attenuated. Serum deprivation induced Caspase-3 activation in KO osteoblasts at higher levels, which indicated an increased susceptibility to apoptosis. Collectively, Bcl-2 promoted the differentiation, activity and survival of both osteoclasts and osteoblasts, and plays an essential role in maintaining skeletal homeostasis.

Distinct Roles of ITAM Signaling in Bone Remodeling in Various Bony Microenvironments. Y. Wu¹, J. Torchia², W. Yao³, N. E. Lane³, L. L. Lanier¹, M. C. Nakamura², M. B. Humphrey⁴. ¹Microbiology and Immunology, University of California, San Francisco, San Francisco, CA, USA, ²Medicine, VA Medical Center, San Francisco, CA, USA, ³Medicine, University of California, Davis, Sacramento, CA, USA, ⁴Medicine, University of Oklahoma Health Science Center, Oklahoma City, OK, USA.

Immunoreceptor tyrosine-based activation motif (ITAM) signaling mediated by DAP12 or Fc ϵ receptor γ chain (FcR γ) has been shown to be critical for osteoclast differentiation and maturation under normal physiological conditions. Their function in pathological conditions is unknown. We studied the role of ITAM signaling during rapid bone remodeling induced by

ovariectomy (OVX) in wild-type (WT), DAP12^{-/-}, FcR γ ^{-/-} and DAP12^{-/-}FcR γ ^{-/-} mice. Six weeks after OVX, DAP12^{-/-}FcR γ ^{-/-} mice showed resistance to lumbar vertebral body (LVB) trabecular bone loss, while WT, DAP12^{-/-} and FcR γ ^{-/-} had significant LVB bone loss. In contrast, all ITAM-deficient mice responded to OVX with bone loss in both femur and tibia of approximately 40%, relative to basal bone volumes (Table 1). DAP12^{-/-}FcR γ ^{-/-} mice showed the greatest absolute loss of trabecular bone after OVX, losing more than twice as much bone volume as WT, DAP12^{-/-} and FcR γ ^{-/-} (Table 1). Only WT mice developed significant cortical bone loss after OVX. In vitro studies showed microenvironmental changes induced by OVX are indispensable for enhanced osteoclast formation and function. Cytokine changes, including TGF β and TNF α , were able to induce osteoclastogenesis independent of RANKL in bone marrow-derived macrophages (BMMs) from WT but not DAP12^{-/-} and DAP12^{-/-}FcR γ ^{-/-} mice. Follicle-stimulating hormone (FSH) stimulated RANKL induced osteoclast differentiation from BMMs in WT, but not DAP12^{-/-} and DAP12^{-/-}FcR γ ^{-/-} mice.

Our study demonstrates that whereas ITAM signaling is critical for normal bone remodeling, estrogen deficiency induces an ITAM-independent bypass mechanism allowing for enhanced osteoclastogenesis and activation in specific bony microenvironments.

Table 1. Bone loss in distal femur, six weeks after OVX, n=5 in each group.

	Wild-type	DAP12 ^{-/-}	FcR γ ^{-/-}	DAP12 ^{-/-} FcR γ ^{-/-}
BV/TV _{SHAM}	5.7%	20.6%	11.7%	56.3%
BV/TV _{OVX}	2.9%	12.1%	6.7%	35.0%
Δ	-2.8%	-8.4%	-5.0%	-21.3%
Δ / BV/TV _{SHAM} (x100%)	-49	-41	-43	-38

Osteoclast Specific Ablation of Dicer Suppresses Bone Resorption and Increases Bone Mass. F. Mizoguchi¹, T. Nakamura², T. Hayata¹, H. Hemmi³, Y. Ezura¹, K. Nakashima⁴, N. Miyasaka⁴, B. Harfe⁵, S. Kato², M. Noda¹. ¹Molecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, 21st Century COE Program, Tokyo, Japan, ²Institute of Molecular and Cellular Biosciences, University of Tokyo, Tokyo, Japan, ³MTT Program, Tokyo Medical and Dental University, Tokyo, Japan, ⁴Department of Medicine and Rheumatology, Tokyo Medical and Dental University, Tokyo, Japan, ⁵Department of Molecular Genetics and Microbiology, University of Florida College of Medicine, Gainesville, FL, USA.

Micro RNAs (miRNA) are endogenous non-coding RNAs of ~22 nucleotides in length. miRNAs regulate the expression of genes by binding 3'-UTR regions of the targets, and have been reported to be involved in fine tuning of biological events, such as cell proliferation, differentiation and cell death in both physiological and pathological conditions. Osteoclastogenesis is a complex process where multiple transcription factors and cytokines are involved. However, the role of miRNAs in osteoclastogenesis is totally unknown. It was reported that simple loss-of-function approaches will be less fruitful for studying miRNA function due to their high level of possible redundancy (B. Harfe. PNAS 2005). RNaseIII enzyme Dicer is one of the key molecules that process pre-miRNAs to mature miRNAs while dicer knock out mice are embryonic lethal. To examine the role of miRNAs in osteoclastogenesis, we specifically knocked out dicer in these cells by crossing conditional allele (Dicer flox) with Cathepsin K-Cre knock-in allele. Mutant mice survived normally during perinatal period. However, during the growth period, body weight gain was less and body size was smaller by about 20 % than control Cre-negative littermates at the age of 7 weeks. Bone mineral density (BMD) levels at the distal 1/3 of the femora in mutant mice were increased by about 20 % than control littermates. In contrast, BMD levels of whole femora were similar between mutant mice and control mice. Thus, the effects of dicer KO appears to be more in cancellous bone. In fact, 3-dimensional micro CT analyses revealed that dicer deficiency in osteoclasts increased BV/TV levels by about 20% compared to control littermates. Further analyses revealed that 3D-thickness of the trabecular bone was specifically increased in mutant mice, while the levels in the number of trabeculi in mutant mice were similar to those in control mice. Histological analysis revealed that TRAP positive cells in trabecular bone (Oc/BS, N.Oc/BS) were decreased in mutant mice by about 30% compared to control littermates. These results indicated that dicer is required for the maintenance of osteoclastic activities in bone. Thus, miRNAs play a regulatory role in these cells to determine the levels of bone resorption.

Rab3D Recruits the Dynein Complex to Secretory Vesicles in Osteoclasts Through Direct Interaction with Tctex-1. N. J. Pavlos¹, J. Xu¹, A. Carrello^{*1}, R. Jahn^{*2}, M. H. Zheng¹. ¹Department of Orthopaedic Surgery, The University of Western Australia, Perth, Australia, ²Department of Neurobiology, The Max Planck Institute for Biophysical Chemistry, Goettingen, Germany.

Targeted intracellular trafficking of osteolytic enzymes and degraded bone matrix substrates to and from the ruffled border of bone-resorbing osteoclasts requires coordinated interplay between carrier vesicles, motor proteins and the cytoskeletal network. We have previously shown that Rab3D, an exocytic-related small GTPase, regulates a post-TGN vesicle transport step that is required for the maintenance of the ruffled border membrane and bone resorption (1). Here, to investigate the complement of effectors through which Rab3D elicits its biological function, we have employed a yeast two-hybrid system to screen for candidate Rab3D-interacting proteins. Using the N-terminal of Rab3D as "bait" we identified Tctex-1, a 14 kDa light chain of the cytoplasmic dynein motor complex, as a putative effector molecule. Specific interaction between Rab3D and Tctex-1 was confirmed by GST-pull-down, immunoprecipitation and colocalization studies. Furthermore, yeast two-hybrid analysis demonstrated that Tctex-1 specifically associates with Rab3 family members via an interaction with the Switch II/GTP-binding motif. Consistently, bioluminescence resonance energy transfer (BRET) analyses demonstrated that Tctex-1 preferentially binds to the active (GTP-bound) forms of Rab3 GTPases *in vivo*. Moreover, overexpression of wild-type and constitutively active Rab3D led to the recruitment of Tctex-1 and other subunits of the dynein/dynactin complex to secretory vesicle membranes. Disruption of cytoplasmic dynein by dynamin overexpression redistributed Golgi-associated Rab3D to peripheral vesicles. Similarly, depolymerization of microtubules with nocodazole altered the spatial distribution Rab3D-bearing vesicles and impaired Rab3D-Tctex-1 interaction *in vivo*. These data demonstrate that Tctex-1 is a bona fide Rab3 binding protein and that Tctex-1 may cooperate with Rab3D to recruit the dynein motor complex to membrane micro-domains, thereby regulating the sorting and microtubule-dependent targeting/recycling of post-Golgi secretory vesicles to/from the ruffled border during osteoclast-mediated bone resorption.

Mice with a Myeloid Lineage-Specific Deletion of IKK β Demonstrate Both In Vivo and In Vitro Defects in Osteoclastogenesis. J. E. Otero^{*1}, M. Al-hawagri^{*1}, S. Dai^{*1}, J. Vacher^{*2}, M. Pasparakis^{*3}, Y. Abu-Amer¹. ¹Orthopedic Surgery and Cell Biology & Physiology, Washington University School of Medicine, Saint Louis, MO, USA, ²Institut de Recherches Cliniques de Montreal, Montreal, PQ, Canada, ³Molecular Biology, EMBL, Monterotondo, Italy.

Nuclear Factor kappa B (NF- κ B) is a family of transcription factors that regulates various cellular and physiological processes such as inflammatory signaling, immune system development, and cell survival. NF- κ B activity is controlled by two upstream kinases, IKK α and IKK β . NF- κ B is also essential for osteoclast development and survival, evidenced by the osteopetrotic phenotype displayed by mice doubly deficient in subunits NF- κ B1 and NF- κ B2. The significance of upstream regulation of NF- κ B in the context of osteoclastogenesis *in vivo* has been unclear given the embryonic and early postnatal lethal phenotypes of mice deficient in IKK β and IKK α , respectively. Furthermore, the only published report of a conditional deletion of IKK β relevant to osteoclastogenesis utilizes an inducible system, in which specificity of deletion is uncertain. We report for the first time that a myeloid lineage-specific deletion of IKK β using the Cre-loxP system renders mice defective in both *in vivo* and *in vitro* osteoclastogenesis. Cre recombinase driven by the promoter for myeloid-specific marker, CD11b, deletes loxP-flanked IKK β in bone marrow macrophages to a degree sufficient to drastically reduce the IKK β mRNA level compared to that observed in CD11b Cre-negative, loxP-flanked IKK β controls. Furthermore, IKK β protein levels are undetectable in both bone marrow and spleen osteoclast precursors from CD11b Cre-positive, loxP-flanked IKK β mice. The defect in osteoclastogenesis appears to be due to developmental and survival defects, since knockout bone marrow macrophages form less osteoclasts in response to RANKL and are also more sensitive to RANKL and pro-inflammatory cytokine, TNF- α , induced apoptosis. Furthermore, retroviral transduction of a dominant-negative form of IKK β into wild-type bone marrow macrophages blocks basal and TNF- α stimulated osteoclastogenesis. Interestingly, although IKK β protein is undetectable in spleen macrophages, no defect in *in vitro* osteoclastogenesis has been observed, which suggests that the microenvironment of macrophages in the spleen pre-programs osteoclast precursors to differentiate into osteoclasts independently from IKK β activity. These findings support the conclusion that IKK β is required for osteoclast development and survival in a cell-autonomous manner. Furthermore, our results substantiate IKK β as a target in the treatment of inflammatory bone loss and validate the CD11b promoter as a tool for transgenic expression of genes in cells of the myeloid lineage.

Conditional Ablation of Parathyroid Hormone Related Peptide (PTHrP) in Mammary Epithelial Cells Inhibits Breast Cancer Progression. J. Li^{*1}, A. Karaplis², P. Siegel^{*1}, V. Papavasiliou^{*1}, W. Muller^{*1}, R. Kremer¹. ¹Dept. of Medicine, McGill University Health Centre, McGill University, Montreal, PQ, Canada, ²Dept of Medicine, Jewish General Hospital, McGill University, Montreal, PQ, Canada.

Breast cancer, the second leading cause of cancer death in women, is frequently associated with increased circulating PTHrP levels in late stage of the disease. However, a causal relationship between breast tumor progression and PTHrP has not yet been established. Here, we used the Cre/LoxP recombination system to disrupt PTHrP function in the mammary epithelium of a transgenic mouse model of human breast cancer (PyVMT). In this model hyperplasia occurs at 4-5 weeks, adenocarcinoma at 7-8 weeks and pulmonary metastasis at 12-13 weeks in 100% of animals. Mice carrying a conditional PTHrP allele in which the fourth coding exon was flanked by LoxP recombination sites were backcrossed on an FVB background. These mice were first crossed with the PyVMT mammary tumor model and then with a separate transgenic strain expressing Cre in the mammary epithelium (MMTV/Cre) both on an FVB background. Targeted excision of the PTHrP allele was confirmed using molecular and histological approaches. Ablation of PTHrP in normal FVB animals did not interfere with the initial stages of mammary ductal outgrowth. Ablation of PTHrP in PyVMT animals significantly delayed tumor onset as demonstrated by Kaplan Meier analysis. At age 50 days, 50% of control animals (PyVMT-PTHrP^{fllox/fllox}-Cre⁻ and PyVMT-PTHrP^{fllox/+}-Cre⁻) had a palpable tumor as compared to age 67 days ($p < 0.005$) in heterozygous (PyVMT-PTHrP^{fllox/+}-Cre⁺) and 78 days ($p < 0.001$) in homozygous (PyVMT-PTHrP^{fllox/fllox}-Cre⁺) animals. In addition tumor growth slowed significantly over time with a significant reduction observed in both PyVMT^{fllox/+}-Cre⁺ and PyVMT-PTHrP^{fllox/fllox}-Cre⁺ animals at all time points. Tumor weight at sacrifice (13 weeks) was significantly reduced in homozygous ($67 \pm 5\%$ reduction, $p < 0.001$) and heterozygous animals ($48 \pm 8\%$ reduction, $p < 0.005$) as compared to controls. Finally, metastatic spread to lungs at sacrifice was seen in 14/14 control animals, 0/13 homozygous animals and 6/14 heterozygous animals. Molecular and immunohistochemical analysis of tumor tissues revealed an 80% inhibition of markers of tumor progression including cyclin D1, Neu/Erb2 and Ki67 in homozygous PyVMT-PTHrP^{fllox/fllox}-Cre⁺ animals and a 40% reduction in heterozygous PyVMT-PTHrP^{fllox/+}-Cre⁺ animals as compared to controls.

In summary these studies provide a direct demonstration that PTHrP is critical for the initiation and progression of mammary tumorigenesis *in vivo*.

The 57 kDa C-terminal Fragment of Dentin Matrix Protein 1 (DMP1) Retains All Biological Activity: Osteocytic Regulation of Pi Homeostasis Through FGF23. Y. Lu¹, S. Liu², S. Yu³, Y. Xie^{*3}, J. Zhou^{*2}, L. D. Quarles², L. F. Bonewald¹, J. Q. Feng³. ¹Oral Biology, School of Dentistry, UMKC, Kansas City, MO, USA, ²The Kidney Institute, KU Medical Center, Kansas City, KS, USA, ³Baylor College of Dentistry, Dallas, TX, USA.

Patients with Autosomal Recessive Hypophosphatemic Rickets (ARHR) were found to have mutations in DMP1. Like Dmp1-null mice, these patients exhibit osteomalacia, renal Pi wasting and elevated FGF23 expression in osteocytes. The intact DMP1 protein has never been purified from bone, only 37 kDa N-terminal and 57 kDa C-terminal fragments. To determine if one of these fragments is biologically active, we re-expressed the 57 kDa C-terminal fragment of DMP1 in Dmp1-null animals using the 3.6 kb Col 1 promoter. Re-expression of the full-length DMP1 was performed as a control. To validate successful re-expression in osteoblasts/osteocytes, *in situ* hybridization and immunohistochemistry were performed showing highly elevated expression in osteoblasts/osteocytes as compared to endogenous DMP1 which is more highly expressed in osteocytes. The Dmp1-null phenotype was fully corrected with introduction of either the full-length molecule (two independent lines) or the 57 kDa fragment (two independent lines). Defects in the Dmp1-null mice such as shortened long bones, disorganized growth plate, diffuse fluorochrome labeling of matrix, disorganized osteocyte lacuno-canalicular network, etc. where found to be corrected in either the full-length or the 57 kDa fragment rescued mice using approaches such as X-ray, uCT, procion red injection, TEM, backscatter SEM, von Kossa, and resin-casted SEM approaches. Biochemical analysis further confirmed that high FGF23 (13-fold elevation in Dmp1-null mice as compared to controls), low serum Pi (40% decrease), and low serum calcium (8.9% decrease) levels were restored to control levels in both full-length and 57 kDa animals by 7 weeks of age. Preliminary studies suggest DMP1 regulation of FGF23. In summary, our findings show that the 57 kDa fragment is the biologically active form of DMP1. We are in the process of determining if the biological activity of DMP1 resides in the carboxy terminus as mutations were identified in the last 20 amino acids of DMP1 in the ARHR patients.

Parathyroid Hormone Activates β -catenin Signaling Through LRP5/6. M. Wan, C. Yang*, H. Yuan*, X. Wu*, C. Lu*, C. Chang*, X. Cao. Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Parathyroid hormone (PTH) plays a primary role in regulating calcium homeostasis and is the only anabolic treatment for osteoporosis in clinical. PTH (1-84) or its analog PTH (1-34) binds to the PTH/PTHrP receptor (PTH1R) and activates Gas and G α q, leading to the activation of PKA and PKC respectively. However, the mechanism accounting for the anabolic actions of PTH on bone is still not clear. Here we show that PTH induces the recruitment of LRP5/6, coreceptors of Wnt canonical signaling, to PTH1R to stabilize β -catenin, which is known to positively regulate osteoblast activity and bone formation. PTH stimulated β -catenin-responsive luciferase reporter and elevated the levels of β -catenin protein in both cytoplasm and nucleus in osteoblastic UMR106 cells and embryonic kidney epithelial HEK 293 cells, indicating that treatment of PTH stabilizes β -catenin protein and promotes its nucleus translocation. To further clarify the mechanism, immunoprecipitation assays demonstrated that PTH induced the interaction of PTH1R with LRP5/6 as well as the formation of ternary complex of PTH ligand, PTH1R and LRP5/6. The extracellular domains of LRP5 or LRP6 act as dominant negative mutants to inhibit the formation of the triple complex. PTH-induced recruitment of LRP5/6 resulted in phosphorylation LRP5/6 at their intercellular PPPSP motifs, which is required for the subsequent binding of Axin to LRP5/6. Interestingly, addition of the inhibitors of either PKA or PKC blocked PTH-induced LRP5/6 phosphorylation, indicating that both PKA and PKC signals are required for optimal activation of LRP5/6 signaling. Moreover, PTH-induced activation of LRP5/6 was confirmed in xenopus system. Coinjection of PTH and PTH1R mRNAs significantly enhanced the efficiency of secondary axis induction by LRP5 and LRP6 to 18% and 25%, respectively.

Activation of LRP5/6- β -catenin signaling by PTH was also examined in vivo. Injection of PTH in rats stimulated phosphorylation of LRP5/6 in 30 minutes and peaked at 8 hours. Levels of both β -catenin and phosphorylated LRP5/6 were significantly increased in the osteoblasts of trabecular bone sections when PTH was intermittently administered for 28 days in mice, correlating with increased bone formation. Neither β -catenin nor phosphorylated LRP5/6 level was stimulated with continuous PTH treatment for the same period of time. These findings reveal that coreceptors LRP5/6 mediate PTH-activated β -catenin signaling in a similar way as in canonical Wnt pathway in osteoblasts, and imply that this pathway is one of the key elements in mediating the anabolic bone effect of PTH.

T-lymphocytes Amplify the Anabolic Action of Intermittent PTH Treatment by Regulating Osteoclast Formation. M. Terauchi, Y. Gao, S. Galley, X. Yang*, K. Page*, E. Shah*, M. N. Weitzmann, R. Pacifici. Division of Endocrinology, Metabolism and Lipids, Emory University School of Medicine, Atlanta, GA, USA.

Intermittent PTH treatment (iPTH) stimulates bone formation by targeting stromal cells (SCs) and osteoblasts (OBs), but osteoclasts (OCs) are now known to be the source of a key permissive signal, as iPTH fails to exert its anabolic activity in the absence of OCs. T cells have been shown to be required for continuous PTH treatment to induce OC formation and bone resorption, suggesting the possibility that T cells may regulate the anabolic activity of iPTH by modulating OC formation. To investigate this hypothesis 5 week-old C57BL/6 T cell receptor β knock-out mice (TCR β -/-), a strain which lacks $\alpha\beta$ T cells, were treated with iPTH by injecting sq human PTH 1-34, 80 μ g/kg/day for 4 weeks. Prospective in vivo BMD measurements by DXA revealed that iPTH caused a larger increase in femur BMD in congenic WT controls than in TCR β -/- mice (45.5% vs. 33.8%, $p < 0.05$). μ CT analysis of the femoral metaphysis showed that iPTH induces a greater increase in trabecular BV/TV in WT than in TCR β -/- mice (25.0% vs. 16.8%; $p < 0.05$). Trabecular number, separation and thickness were also differentially affected by iPTH in WT and TCR β -/- mice. The blunted response of TCR β -/- mice to iPTH was confirmed by 4-point bending tests which showed that iPTH increases femoral stiffness in WT, but not in TCR β -/- mice. Measurements of serum levels of osteocalcin, a marker of bone formation, and of CTX, a marker of resorption revealed that iPTH stimulates both bone formation and resorption in WT mice while it had no effect in TCR β -/- mice. Furthermore, in vivo iPTH treatment failed to stimulate the formation of CFU-ALP, an index of the number of SCs with osteogenic potentials, in whole bone marrow (BM) from TCR β -/- mice. PTH also caused a 3-fold lower increase in ex vivo formation of OCs in TCR β -/- mice as compared to WT mice. These findings demonstrate that T cells potentiate the capacity of iPTH to stimulate OB and OC formation. Additional FACS studies revealed that in vivo iPTH treatment increases by 2-fold intracellular RANKL levels in BM CD4+ and CD8+ T cells, while in vitro PTH treatment upregulates T cell RANKL expression in cocultures of T cells and SCs, but not in purified T cells alone. Thus, PTH stimulates T cell RANKL expression by targeting SCs. In summary, the data demonstrate that PTH stimulated SCs induce the production of RANKL by T cells, suggesting that T cell produced RANKL contributes to PTH induced osteoclastogenesis, and indicating that T cells potentiate the bone anabolic activity of iPTH by promoting the formation of OCs, a lineage required for iPTH to stimulate bone formation.

Movements Within the Parathyroid Hormone Receptor (PTH1R) Upon PTH Binding. B. E. Thomas¹, A. Wittelsberger¹, P. Monaghan^{*1}, D. F. Mierke^{*2}, M. Rosenblatt¹. ¹Tufts University School of Medicine, Boston, MA, USA, ²Department of Molecular Pharmacology, Brown University, Providence, RI, USA.

Defining the nature of the parathyroid hormone (PTH)-PTH receptor (PTH1R) interaction is key to understanding the role of PTH in physiology, disease, and facilitating the discovery of therapeutic agents which work through the PTH1R. The PTH-PTH1R interaction leads to receptor (Rc) activation, signal transduction, and expression of PTH bioactivity. Since the hormone docks distant from intracellular G proteins, changes resulting from PTH binding to the extracellular face of PTH1R must converge into a conformational shift at the cytoplasmic PTH1R-G protein interface. We set out to determine the motions of transmembrane (TM) domains of PTH1R induced by PTH and the sequence of events that trigger Rc activation. We engineered Cys-substitutions into TMs postulated to play a critical role in Rc activation. Promotion of disulfide crosslinking by PTH indicates that two TMs are brought sufficiently close to form a linkage not possible in the "inactive" state. We chose to study the dynamics of TM2 and TM7 motion by creating a series of PTH1R mutants, each of which contains a Cys pair with potential to span TM2 to TM7 superimposed on a PTH1R template which contains a c-myc "tag" for purposes of detection and a Factor Xa (FXa) cleavage site. The PTH1R template displays binding and PTH-stimulated adenylyl cyclase activity comparable to native PTH1R. PTH1R mutants were exposed to PTH-(1-34), followed by Factor Xa cleavage. The appearance/disappearance of a low MW band (~23 kDa) was monitored using anti-c-myc antibody. A decreased quantity of the band indicates new disulfide formation. For one TM2/TM7 pair, F238C/F447C, mild oxidation promoted disulfide formation. But addition of PTH decreased disulfide linkage, indicating that the Cys pair in TM2 and TM7 are near each other in the inactive state of Rc, but move apart upon binding PTH. These data are supported by molecular modeling insights: bound PTH causes disruption of interaction between residues at position 238 in TM2 and 447 in TM7, suggesting that F238 and F447 move apart to accommodate the bound hormone. For the K240C/F447 pair, disulfide linkage is promoted by PTH binding, indicating that the Cys pair moves even closer. One experiment provides demonstration of the sensitivity of this approach: placement of Cys in TM2 at position 241 instead of 240 precludes disulfide formation with Cys 447. Since the TMs have a helical structure, insertion of Cys one position removed places the sulfhydryl function one-third way around the helix, away from the favorable spatial arrangement of the 240/447 pair. These studies begin to elucidate the molecular mechanisms by which PTH triggers activation of PTH1R.

Bone Mineralization and Vitamin D Inadequacy. Histomorphometric Analysis of Iliac Crest Bone Biopsies and Circulating 25-hydroxyvitamin D in 648 Patients. M. Priemel¹, T. Kladde^{*1}, S. Kessler^{*1}, S. Seitz^{*1}, K. Püschel^{*2}, T. Schinke¹, M. Amling¹. ¹Trauma Surgery and Center of Biomechanics, University Medical Center Hamburg, Hamburg, Germany, ²Forensic Medicine, University Medical Center Hamburg, Hamburg, Germany.

The estimated required circulating 25-hydroxyvitamin D (25[OH]D) to maintain skeletal health range between 12 and 40 ng/ml. This wide range is based on many studies that have used the relationship between low 25[OH]D and increased secretion of parathyroid hormone (PTH) to determine a plausible threshold. PTH is however only one measurable index of skeletal health and we reasoned, that histomorphometric analysis of iliac crest bone biopsies would be another and even more direct approach to assess bone health. Thus to get an answer as to the circulating levels of 25[OH]D that should be ensured, and to assess the prevalence of vitamin D insufficiency we measured 25[OH]D serum levels and performed transiliac crest bone biopsies (8mm diameter) in 648 patients (388 males, mean age: 58.8 years, and 260 females, mean age: 68.6 years) who had no signs of secondary osteopathies at autopsy. All biopsies were undecalcified embedded and histologically processed. Static structural analysis was performed using the Osteomeasure system according to ASBMR standard. Analysis included bone volume (BV/TV), osteoid volume (OV/BV), osteoid surface (OS/BS), trabecular thickness (Tb.Th), trabecular number (Tb.N), and trabecular separation (Tb.Sp). Statistical analysis consisted of testing for the lack of correlation and the similarity of the correlation coefficient in males and females. The histologic results demonstrate an unexpected high prevalence of mineralization defects. Indeed 37.35% of the analyzed patients presented with an OS/BS of more than 20%. Based on the definition described by Delling in 1975 that an OV/BV of >1.2% is pathologic 46.76% of the biopsies presented with manifest skeletal mineralization defects. Even a more conservative threshold with a pathologic increase in OV/BV of > 2% was detected in 27.62% of the patients. Most interestingly these mineralization defects were found independent of BV/TV, throughout all ages and affected both sexes. While we could not establish a minimum 25[OH]D level that was inevitably associated with manifest mineralization defects, we did not find pathologic accumulation of osteoid in any patient with circulating 25[OH]D levels above 30ng/ml. Therefore our data demonstrate that the prevalence of vitamin D deficiency and manifest mineralization defects is extremely high in the European population. In case of vitamin D supplementation, the dose given should ensure that circulating levels of 25[OH]D reach a threshold of 30 ng/ml.

Marrow Adipogenesis and Osteoblastogenesis Reflect Global Energy Utilization Through Activation of PPARG and Modulation by 'Clock' Genes in a Genotype Specific Manner. C. L. Ackert-Bicknell¹, V. E. DeMambro¹, M. L. Bouxsein², M. C. Horowitz³, E. Canalis⁴, C. J. Rosen¹. ¹The Jackson Laboratory, Bar Harbor, ME, USA, ²Beth Israel Deaconess Medical Center, Boston, ME, USA, ³Yale University School of Medicine, New Haven, CT, USA, ⁴St. Francis Hospital and Medical Center, Hartford, CT, USA.

The relationship between marrow adipogenesis and bone formation is critical for understanding osteoporosis. We generated a congenic mouse (6T) with C3H alleles from a QTL on mouse Chr 6 introgressed on a 99.5% C57BL/6J(B6) background. 6T have reduced BMD, impaired osteoblast(OB) differentiation, more marrow adiposity, but low body temp, and unresponsiveness (i.e. thermal output) to stimulation by a $\beta 3$ agonist. An inversion in C3H, and polymorphisms in genes at the break point [115.38-116.38 Mb between Pparg and Alox5], prompted us to hypothesize that genes in this region influence OB and adipocyte(Ad) function. To test this, we fed 3 wk B6 and 6T mice an 11%(LF) or 60% fat(HF) diet for 13 wks and studied metabolic and skeletal parameters. On a HF diet, B6 gained wt and became insulin resistant with no change in BV/TV by μ CT, while 6T showed no change in wt or insulin secretion, but lost trabecular bone ($p<0.001$ vs B6). Histomorphometry comparing HF to LF diets revealed that B6 had suppressed bone formation, reduced osteoclast #, increased marrow Ads (2.1 fold higher), but no change in BV/TV. In contrast 6T on HF had a 1.5 fold increase in OB#, but no change in Ad #, despite a 30% reduction in BV/TV. Expression profiling (using a 2x2 statistical design:genotype x diet)revealed that 21 genes were differentially regulated in liver; and 64 in bone (marrow+bone). Most were histones, but in 6T liver on HF, Ccrn4l (a 'clock' gene) was 2 fold up-regulated; $p=1.0 \times 10^{-6}$, while in 6T bone, uncoupling protein-1(Ucp-1) was increased nearly 3 fold; $p=1.0 \times 10^{-6}$. 2 candidate genes within the 1Mb region on Chr 6 were suppressed in 6T bone on the HF diet: March 8, a membrane protein ($p<0.0005$, vs B6) and Raf1 ($p<0.007$ vs B6). In the liver, two downstream targets of Pparg, Fasn, and Srebp, as well as ephrinA1 and SOCS-2, were increased by a HF diet in 6T($p<0.05$ vs B6). In summary, we found genotype-specific skeletal and marrow responses to HF. In 6T, HF caused bone loss despite recruitment of more OBs, but in B6, even with marrow adipogenesis, and a reduced bone formation rate, BV/TV was preserved. Expression profiles demonstrated that a HF diet activated Pparg in a strain-specific manner, likely through recruitment of co-activators that differentially influenced Ad and OB function. In 6T, greater UCP-1 expression (a marker of brown fat), and enhanced insulin sensitivity imply distinct physiologic roles for marrow fat (i.e. energy use:6T vs storage: B6) influenced by Chr 6 genes and modulated by 'clock' proteins.

Estrogen Receptor α Is Required for Strain-Related β -Catenin Signaling in Osteoblasts. V. J. Armstrong*, M. Muzylak*, A. Sunter*, G. Zaman*, L. K. Saxon, J. S. Price, L. E. Lanyon. Veterinary Basic Sciences, The Royal Veterinary College, London, United Kingdom.

Wnt/ β -catenin signaling has been implicated in the regulation of bone mass through its involvement in bone cells' response to their mechanical environment [1]. Since Estrogen Receptor α (ER α) is also involved in bones' response to loading [2], we investigated whether strain induced signaling through ER α uses the same pathway as β -catenin. Western blot and immuno-cytochemical analysis showed that in ROS 17/2.8 cells a short period of dynamic strain in vitro increased the levels of activated β -catenin (β cat) in the cytoplasm and within 1 hour stimulated its translocation to the nucleus. These changes in β cat were paralleled by inhibitory phosphorylation of GSK-3 β . Strain, and the GSK-3 β inhibitor LiCl, also induced a significant increase in TCF/LEF transcriptional activity. In contrast, estrogen had no influence on the level or distribution of β cat, nor any effect on TCF/LEF activation. Nuclear translocation of β cat and TCF/LEF activation stimulated by both strain and LiCl were inhibited by the ER modulator ICI 182,780, which also reduced strain-induced nuclear accumulation of ER α . The ER modulator Tamoxifen also inhibited LiCl stimulated nuclear translocation of β cat.

In primary cultures of osteoblast-like cells derived from the long bones of Wild Type mice and those lacking ER β , β -catenin was similarly activated and translocated to the nucleus in response to strain and LiCl. In these cells this response was blocked by ICI 182,780. In contrast, in cultures of osteoblast-like cells from mice lacking ER α neither strain nor LiCl stimulated nuclear accumulation of β cat. ICI 182,780 had no effect in these cells.

These data show that in osteoblastic cells exposure to strain causes similar activation of β -catenin, its translocation to the nucleus, and regulation of transcription as GSK-3 β inhibition by LiCl. These changes require ER α but not ER β . To our knowledge these are the first data to demonstrate that in osteoblasts ER α is required for these cells' responses to strain involving Wnt/ β -catenin. Reduced effectiveness of bone cells' responses to bone loading, associated with decline in bio-available estrogen and ER α , may contribute to the failure to maintain structurally appropriate bone mass in osteoporosis in both men and women. This failure may in part be due to reduced effectiveness of Wnt/ β -catenin signaling.

Expression of OCZF Directed by the Cathepsin K Promoter Affects Bone Mass and Osteoclast Formation in Transgenic Mice. T. Shobuiké*, T. Kukita², K. Nagata^{*2}, J. Teramachi^{*2}, M. Asagiri³, H. Takayanagi³, A. Kukita¹. ¹Saga University, Saga, Japan, ²Oral Biological Science, Kyushu University, Fukuoka, Japan, ³Cell Signaling and COE Program, Tokyo Medical and Dental University, Tokyo, Japan.

We previously isolated the OCZF cDNA encoding Kat-6 antigen specifically expressed in rat osteoclast. The OCZF gene product is a member of POK protein family that contains two domains of POZ/BTB and zinc finger in their N- and C-terminal region respectively, and that is shown to be involved in various cellular processes. Suppression of OCZF by antisense RNA inhibits osteoclast differentiation in vitro, indicating that OCZF is involved in osteoclastogenesis, but in vivo role in the process is not clear. To this end we generated transgenic mice, which expressed OCZF under the control of mouse cathepsin K promoter. Nine transgenic mice were identified among the offspring by PCR and Southern blot analysis of mouse tail genomic DNA. Transgene expression was verified by RT-PCR using osteoclasts differentiated in vitro from bone marrow at 10 weeks of age. Two lines of the transgenic animals exhibited relatively high transgene expression, and were further investigated. The c-fos and NFATc1 protein exhibit higher levels during differentiation into osteoclasts in vitro from bone marrow of the transgenic mice than that of normal littermates. Micro-CT and peripheral quantitative CT (pQCT) analyses and histomorphometry of femur were performed in mice at 6 weeks of age. Micro-CT imaging demonstrates a reduction in trabecular bone volume in the transgenic mice relative to normal littermates. pQCT analyses also demonstrate a reduction in bone mineral density and bone mineral content especially in trabecular bone with a decrease in strength strain index, whereas those in cortical bone were slightly affected. Consistently, von Kossa staining shows a smaller mineralized area in the transgenic mice than in normal littermates. Histological analyses with tartrate-resistant acid phosphatase staining and calcein labeling indicate an increase in the number of osteoclast, whereas bone formation rate did not significantly change. These results suggest that OCZF has an important role in osteoclastogenesis in vivo.

Transgenic Overexpression of Osteoclastic Protein-tyrosine Phosphatase, PTP-oc, in Cells of Osteoclastic Lineage Led to Increased Bone Resorption and Marked Reduction in Trabecular Bone Mass and Density in Adult Mice. M. H. C. Sheng, M. Amoui*, A. K. Srivastava, J. E. Wergedal, K. H. W. Lau, Loma Linda VAMC, Loma Linda, CA, USA.

Past in vitro studies have suggested that the structurally unique osteoclastic transmembrane PTP-oc acts as a positive regulator of osteoclast activity. This study sought to determine whether transgenic (TG) overexpression of PTP-oc in cells of osteoclastic lineage would increase (\uparrow) bone resorption and decrease (\downarrow) bone mass or density (BMD) in adult mice. To generate TG mice, a TG construct containing the rabbit PTP-oc cDNA driven by a tartrate-resistant acid phosphatase (TRACP)-1C promoter was injected into the pronucleus of fertilized ova, which were implanted into pseudo-pregnant B6D2F1 mice. TG founders, identified by a PCR-based genotyping assay using primers that span unique regions of TRACP-1C promoter and rabbit PTP-oc sequence, were bred with C57BL/6J mice to produce F2 mice. Ten-week-old male F2 progenies were extensively followed for pQCT, histological, and serum resorption marker analyses. The body weight of TG mice was 10% less ($p<0.05$, $n=8$ each) than that of wild-type (WT) littermates. pQCT analyses of the femur revealed that TG mice had 30% \downarrow in trabecular BMD ($p<0.002$). Histologic analyses at the secondary spongiosa in the femur of 9 TG and 7 WT littermates confirmed that TG mice showed 35% \downarrow in trabecular surface (Tb.Pm, $p<0.01$), 27% \downarrow in % trabecular area (Tb.Ar, $p<0.05$), 11% \downarrow in trabecular number (Tb.N, $p<0.05$), and 36% \uparrow in trabecular separation (Tb.Sp, $p<0.005$). The lumbar vertebra of 12 TG mice, when compared to 8 WT littermates, also showed 20% \downarrow in Tb.Pm ($p<0.005$), 17% \downarrow in Tb.N ($p<0.003$) and 35% \uparrow in Tb.Sp ($p<0.004$). Consistent with an \uparrow in bone resorption, the serum c-telopeptide level of TG mice ($n=14$) was 25% ($p<0.05$) higher than that of littermates ($n=11$). That the number of osteoclasts and the length of TRACP-labeled bone surface per total bone surface were not different suggested that TG overexpression of PTP-oc increased osteoclast activity rather than osteoclast differentiation. The same phenotype was confirmed in a second TG line. In congruent with an \uparrow in osteoclastic activity, the average pit area created by osteoclasts derived from bone marrow cells of 10-week-old male TG mice in response to RANKL and MCSF in the pit formation assay was $\sim 50\%$ greater ($p=0.008$) than those by osteoclasts of WT littermates ($n=8$ each). However, the TRACP activity per cellular protein in osteoclasts derived from the two groups of mice was not different. In summary, TG overexpression of PTP-oc in cells of osteoclastic lineage led to a marked reduction in trabecular bone mass in adult mice due to an \uparrow in osteoclastic activity. These findings provide compelling in vivo evidence that PTP-oc is a positive regulator of osteoclastic activity.

CITED1 Ablation Impairs Endochondral Bone Formation During Embryonic Development. D. Yang, J. Guo*, R. Bringham*. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

CITED1 (CBP/P300 interacting Transactivator with Glutamic Acid [E]/ Aspartic Acid [D]-Rich C-terminal domain) is a transcriptional cofactor located on the X chromosome. We previously observed that CITED1 expression is rapidly and transiently induced by PTH1R activation in osteoblasts and that cultured osteoblasts from mice lacking CITED1 display abnormal differentiation in vitro. To determine the possible role of CITED1 in early bone development, we have analyzed endochondral bone formation in tibiae from CITED1-knockout (KO) embryonic mice in which the CITED1 gene is replaced with a functional LacZ/Neo cassette and bred into the 129Sv background for five generations. The tibiae of CITED1 KO mice were shorter than those of wild type (WT) littermates, and bone volume and the extent of trabeculae in CITED1 KO tibiae at E18.5 and post-natal day 1 (P1) were significantly reduced, as shown by von Kossa staining and histology. At E15.5, the regions of overall chondrogenesis and of chondrocyte hypertrophy, demonstrated by Col II and Col X expression respectively, were not different in WT and KOs; but bone formation, shown by Col I in situ analysis, appeared slightly earlier inside the tibia and expanded wider in perichondral region in the WT. Osteopontin (OPN) is expressed by late hypertrophic chondrocytes and osteoblasts within the primary and secondary spongiosa. Relative to WT, the length of the central region of OPN expression was reduced in all KO bones from E15.5 through P1, accounting for the foreshortening of the overall bone length. In situ hybridization and LacZ staining analysis showed strong expression of CITED1 in this same central region of the developing bones but not in adjacent chondrocytes. We conclude that CITED1 expression, probably by cells of the osteoblast lineage, is important for normal endochondral bone formation and that loss of functional CITED1 expression leads to a reduction in the rate of bone formation. Whether this defect reflects impaired activity of osteoblasts that normally express CITED1 and/or loss of an indirect effect on chondrocyte proliferation and/or differentiation, which could involve PTHrP, remains to be investigated.

Biglycan and Fibromodulin Control Bone Mass by Regulating Osteoclast Differentiation Through Bone Marrow Stromal Cells. Y. Bi*, T. M. Kilts*, A. C. Griffin*, M. F. Young. National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD, USA.

Members of the Small Leucine-Rich Proteoglycan (SLRP) family populate numerous sites in the musculoskeletal system including tendon, cartilage and bone, but, their precise role in these tissues is still unclear. Previous work showed that mice with combined deficiencies in two SLRPs, biglycan (bgn) and fibromodulin (fmod), acquire osteoarthritis and ectopic tendon ossification. Here we show that the bgn-0/fmod-/- mice have delayed bone formation during development judged by alizerin red/alcian blue staining and severe age-dependent osteopenia determined by X-ray and microCT analyses. In order to understand the molecular basis for this osteopenia, osteogenic bone marrow stromal cells (BMSCs) were isolated and examined. Colony-forming unit fibroblastic (CFU-F) analysis, which estimates the number of osteogenic stem cells, showed no significant differences between WT and bgn-0/fmod-/- mice. Further, in vitro osteogenesis assays showed that Ca2+ accumulation was increased in the bgn-0/fmod-/- BMSC cultures compared to WT BMSCs. Western analysis of the BMSC protein extracts showed that the bgn-0/fmod-/- cells had increased levels of Runx2 compared to WT controls. The bgn-0/fmod-/- BMSCs also had increased BMP-2 and TGF-beta1 signaling indicated by increased levels of p-smad1 and p-smad2/3 in the presence of BMP-2 and TGF-beta1 compared to WT BMSCs, respectively. Furthermore, in vivo bone formation was not significantly different between WT and bgn-0/fmod-/- BMSCs transplanted subcutaneously into immuno-compromised mice. From these data, we concluded that the decreased bone mass in bgn-0/fmod-/- mice was not primarily due to a defect in osteogenesis. We next determined whether the osteopenia in bgn-0/fmod-/- mice could be due to increased differentiation and/or activity of osteoclasts. To test this, sections of long bone and BMSC transplants were stained for Tartrate-Resistant Acid Phosphatase (TRAP), an osteoclast marker. The number of TRAP positive cells was higher in bone and in vivo BMSC transplants from bgn-0/fmod-/- mice. Osteoclastogenesis was assessed by adding bone marrow suspensions to plates in which BMSC had formed individual colonies and showed that greater numbers of colonies in the bgn-0/fmod-/- cultures supported formation of TRAP-positive multinucleated cells compared to WT. In summary, we have shown that bgn and fmod when depleted in combination have a negative influence on bone mass by increasing osteoclast formation and function and thereby pointing to the possibility that these SLRPs could be novel targets to modulate bone turnover.

Rescue of MT1-MMP Expression in Cartilage Increases Survival, Chondrocyte Proliferation and Bone Formation in MT1-MMP Deficient Mice. L. Szabova*, S. Yamada*, K. Holmbeck*. CSDB/MMPU, NIDCR, Bethesda, MD, USA.

Membrane type-1 matrix metalloproteinase (MT1-MMP) is a potent collagenase essential for proper remodeling of collagen rich tissues. Mice deficient for MT1-MMP (KO) are dwarfs with severe fibrosis of connective tissues, bone loss and retention of embryonic cartilages in the skull due to impaired degradation of unmineralized type I and II collagens. Here we define the contribution of disrupted cartilage remodeling in the development of the MT1-MMP-deficient phenotype. Specifically, we created transgenic mice where MT1-MMP expression was selectively re-introduced in cartilage tissues using a transgene driven by the type II collagen promoter/enhancer. We have bred these mice into the MT1-MMP-deficient background and evaluated the developmental effects of MT1-MMP expression in the cartilage tissue of otherwise MT1-MMP deficient mice. Cartilage specific MT1-MMP expression in KO mice resulted in complete rescue of the pre-weaning death observed in KO mice, increased body weight and prolonged survival. Transgenic KO mice further displayed increased bone formation in the skull compared to KO mice. Strong expression of the MT1-MMP transgene increased chondrocyte proliferation in the epiphyseal growth plate, which resulted in increased growth of the long bones. Increased bone formation quite unexpectedly coincided with expression of the transgene in a subset of bone cells. Expression of type II collagen was documented in bone cells of normal mice using in situ hybridization and immunostaining thus documenting that transgene expression was not ectopic, but mirrored the normal expression pattern of type II collagen. This finding explains the increased bone formation observed in transgenic KO mice since MT1-MMP is necessary for maintaining the bone formation. In conclusion, reintroduction of MT1-MMP in the cartilage of MT1-MMP KO mice results not only in cartilage specific expression, but also directs transgene expression in a subset of bone cells thereby facilitating increased bone formation. These bone cells are most likely the descendants of a common progenitor of bone cells and chondrocytes expressing type II collagen and support our previous observation that some chondrocytes can differentiate into bone cells. Our data suggest that MT1-MMP provides type II expressing chondrocytes and bone cells with the necessary collagenolytic activity required for chondrocyte proliferation and bone formation in vivo.

Sclerostin Overexpression Impairs Limb Patterning. N. M. Collette*, R. M. Harland*, G. G. Loots*. Biosciences and Biotechnology Division, Lawrence Livermore National Laboratory, Livermore, CA, USA, ²Department of Molecular and Cellular Biology, University of California, Berkeley, CA, USA.

Sclerostin (SOST) is a negative regulator of bone formation that has been described as both a BMP- and WNT- antagonist. Loss of SOST function causes sclerosteosis (MIM 269500), a condition of severe progressive bone overgrowth. Using transgenic mice expressing human SOST from a bacterial artificial chromosome (BAC) we have demonstrated that SOST over-expression causes decreased bone formation and results in osteopenia, similar to the over-expression of other BMP antagonists such as Noggin and Gremlin. These mice also exhibit severe limb patterning defects that are dose-dependent and range from the loss of a single posterior digit to the loss and/or fusion of many distal limb skeletal elements. The apical ectodermal ridge (AER) relays cell-cell signals to the underlying differentiating limb mesenchyme, a place of SOST expression initiated as early as E9.5. To determine how elevated levels of SOST impair proper limb patterning, we have examined AER and cartilage markers by measuring mRNA levels by in situ hybridization. We find FGF8, a major AER signaling molecule and underlying mesenchymal markers BMP2, Gli1, Pax1, HoxD12 and gremlin expression to be perturbed in SOST transgenic mice. In addition, skeletal analysis of double mutant animals show that over-expression of SOST fails to complement loss of BMP antagonists (Gremlin and Noggin) essential for limb patterning and chondrogenesis, resulting in more dramatic skeletal defects than single mutants alone, suggesting that SOST action in the limb parallels the BMP-pathway. TNF- α Upregulates Aortic BMP2-Msx2-Wnt Signaling in Diabetic LDLR-/- Mice. J. S. Shao, C. F. Lai, Z. Al-Aly*, J. Cai*, E. Huang*, S. L. Cheng, D. A. Towler. Dept. of Internal Medicine, Washington University School of Medicine, St. Louis, MO, USA.

Aortofemoral calcification is prevalent in type II diabetes (T2DM), tracking metabolic syndrome parameters and increasing the risk for lower extremity amputation. LDLR-/- mice fed high fat diets (HFD) develop obesity, T2DM, and accumulate aortic calcium - the latter mediated via osteogenic mechanisms that resemble craniofacial mineralization. HFD upregulate aortic BMP2 and Msx2-Wnt signaling cascades that promote mineralization in neural crest-derived skeletal tissues. Administration of recombinant purified BMP2 augments aortic Msx2-Wnt signaling in TOPGAL reporter mice, and promotes aortic calcium deposition in LDLR-/- mice. Low-grade inflammation, including elevated circulating TNF- α , is characteristic of obesity with T2DM, therefore, we examined the relationships between TNF- α and aortic BMP2-Msx2-Wnt signaling in the LDLR-/- model. HFD feeding promotes obesity, hyperglycemia, and hyperlipidemia -- and upregulated serum TNF- α and haptoglobin in male LDLR-/- mice. Oxidative stress, reflected in serum 8-F- α -isoprostane (8-IsoP) levels, was increased, with concomitant upregulation of aortic BMP2 (2.5-fold), Msx2 (2.5-fold), Wnt3a (10-fold), and Wnt7a (14-fold) gene expression (all $p < 0.01$, 2-tailed t-test). Treatment of diabetic LDLR-/- mice with the TNF- α antagonist infliximab (10 μ g / gm twice weekly, 5 animals per group) did not reduce obesity, hyperleptinemia, or hyperglycemia; however, serum 8-IsoP and haptoglobin levels were significantly decreased. Moreover, aortic BMP2, Msx2, Wnt3a, and Wnt7a expression and aortic calcium accumulation were concomitantly and significantly reduced by infliximab treatment (all $p < 0.05$). Administration of sodium salicylate, an alternative anti-inflammatory strategy, also reduced serum haptoglobin and aortic Msx2 gene expression. Finally, C57BL/6 mice with arterial smooth muscle TNF- α expression augmented by a SM22- TNF- α transgene accumulate significantly higher levels of aortic BMP2, Msx2, Wnt3a, and Wnt7a mRNAs vs. their non-transgenic sibling cohorts. Furthermore, 80% of SM22-TNF α ; TOPGAL mice exhibit aortic betagalactosidase reporter staining vs. 0% of their non-transgenic TOPGAL siblings ($p=0.05$ with Yates' chi-square correction), indicating net enhanced mural Wnt signaling by the SM22-TNF α transgene. Thus, inflammatory TNF- α signals promote pro-calcific BMP2-Msx2-Wnt programs in the aortic tissues of diabetic LDLR-/- mice. Strategies that inhibit inflammation-induced arterial BMP2-Msx2-Wnt signals may improve aortofemoral physiology and reduce lower extremity amputation risk in T2DM.

Conditional Ablation of the Osteoblast Calcium-Sensing Receptor Causes Abnormalities in Skeletal Development and Mineralization. M. M. Dvorak¹, C. Tu^{*1}, H. Elalich^{*1}, T. Chen^{*1}, B. Liu^{*1}, B. E. Kream^{*2}, D. D. Bikle¹, W. Chang¹, D. M. Shoback¹. ¹Department of Medicine, University of California, San Francisco, CA, USA, ²Department of Medicine, University of Connecticut Health Center, Farmington, CT, USA.

The calcium-sensing receptor (CaR) is a G protein-coupled receptor essential for maintenance of calcium homeostasis. Defining the role for the osteoblast CaR in vivo, using global full-length CaR knockout models, is complicated by metabolic disturbances and the potential for compensation by a CaR splice variant identified in these mice. To circumvent these issues, we generated Flox-CaR^{+/+} mice, in which loxP sites flank exon 7 that encodes the transmembrane and signaling domains of the receptor. Osteoblast-specific inactivation of the CaR was achieved by mating Flox-CaR^{+/+} mice to transgenic mice expressing Cre-recombinase, under control of the 3.6 kb fragment of the rat $\alpha 1(I)$ collagen promoter (Col1-Cre). Col1-Cre^{+/+}/Flox-CaR^{+/+} mice exhibited growth delay from birth and died within four weeks. At 21 days, the skeletal phenotype was hallmarked by hypomineralization, evident by von Kossa staining and micro-computed tomography (μ CT) analysis, which revealed significant reductions in bone volume/tissue volume (BV/TV; $\downarrow \sim 75\%$), bone mineral density (BMD; $\downarrow > 90\%$), segmented BMD ($\downarrow \sim 20\%$), trabecular number ($\downarrow \sim 40\%$), trabecular thickness ($\downarrow \sim 30\%$) and connectivity density ($\downarrow \sim 80\%$) in the secondary spongiosa of the distal femur ($n=6$, $p<0.05$, ANOVA), compared to controls. The changes were comparable, although less extensive in the L4 vertebra. The cortical compartment of the femur was also affected, with significant decreases in BV ($\downarrow \sim 60\%$), cortical thickness ($\downarrow \sim 70\%$), BMD ($\downarrow \sim 45\%$), and segmented BMD ($\downarrow \sim 15\%$) and markedly increased cortical porosity ($\sim 70\%$), compared to controls ($n=6$, $p<0.05$, ANOVA). Histology of femora from Col1-Cre^{+/+}/Flox-CaR^{+/+} mice revealed severe hyperostoidosis (Goldner staining) as well as trabeculation of the cortex (Von Kossa staining). Reduced mineral content could be secondary to increased turnover, with inadequate mineralization of newly made osteoid. This is consistent with quantitative real-time PCR (qPCR) analysis of humeri and calvaria that indicate significant increases in markers of proliferation (cncd1), osteoblast differentiation (collagen I, alkaline phosphatase, osteopontin), mineralization (anklylosis protein, ectonucleotide pyrophosphatase/phosphodiesterase 1) and regulators of osteoclastogenesis (RANK-L, osteoprotegerin); ($n=3-5$, $p<0.05$, ANOVA). Our findings indicate a critical role for the skeletal CaR in the control of bone mineralization in early postnatal skeletal development.

Novel Vitamin D3 Analogs (DLAMs) Antagonize Bone Resorption Via Suppressing RANKL Expression in Osteoblasts. M. Inada, K. Tsukamoto*, M. Takita, M. Hirata, A. Hoshino*, T. Tominari*, K. Nagasawa*, C. Miyaura. Department of Biotechnology and Life Science, Tokyo University of Agriculture and Technology, Koganei, Tokyo, Japan.

Active vitamin D3, 1 α , 25(OH)2D3 (D3), has been proposed to regulate bone remodeling through bone formation and resorption that is maintaining calcium levels in blood serum. Recently new aspects of D3 activities have been reported in bone resorption, inhibition of osteoclast differentiation via interference of c-fos and NFATc1 expression. The other aspect was found in D3 analogs, synthetic modification at C2 position of D3 that is enhancing bone formation and bone mass. Here we show newly synthesized analogs, 1 α ,25(OH)2D3-26,23-lactam, (23S,25S)-DLAM-1P and DLAM-2P, that has a lactam moiety in the side chain, perfectly antagonized D3-induced osteoclast (Oc) differentiation. In computer docking simulation estimated DLAM-1P bind to VDR, lactam moiety in DLAM-1P may interfere VDR helix-12 folding at the site of Phe-422 (ligand binding domain). Oc formation was assessed by mouse co-culture system. We first examined antagonistic effects of DLAMs on Oc formation induced by D3. When simultaneous treatment of DLAM-1P (10-7M to 10-5M) and D3 (10-8M), DLAM-1P clearly suppressed the number of TRAP+ Ocs in a dose-dependent manner. To understand the mechanism of action of DLAM-1P, we analyzed mRNA expression of RANKL, a sole molecule for Oc differentiation. DLAM-1P clearly suppressed the D3-induced expression of RANKL mRNA in osteoblasts. In organ culture using mouse calvaria, bone resorbing activity (calcium release) induced by D3 was clearly suppressed by adding DLAM-1P that is associated with less induction of RANKL mRNA. The other analog DLAM-2P has shown similar activities to DLAM-1P. Therefore, DLAM analogs act on osteoblasts as an antagonist of D3 to suppress RANKL dependent Oc differentiation in the cell and the organ, suggesting the DLAMs are novel candidate for the treatment of pathological bone loss such like osteoporosis. Further modification will require for the therapeutic compound, enhancing bone formation and inhibition of RANKL expression beside minimum modification in DLAMs structure, e.g. installing substituents on its C2 position.

Characterization of the Bone Phenotype in CIC-7 Deficient Mice. A. V. Neutzsky-Wulff^{*1}, K. Henriksen¹, A. Snel^{*1}, T. J. Jentsch^{*2}, J. Fuhrmann^{*2}, P. Lange^{*2}, C. Christiansen³, M. A. Karsdal¹. ¹Nordic Bioscience, Herlev, Denmark, ²MDC/FMP, Berlin, Germany, ³CCBR, Ballerup, Denmark.

Loss of the chloride channel CIC-7 leads to severe osteopetrosis. CIC-7 is believed to play a role in the ability of the osteoclasts to acidify the resorption lacuna, and thereby their ability to resorb bone. We therefore examined the bone phenotype of CIC-7 knockout (KO) mice in vitro and in vivo in detail, and compared it to the phenotype of oc/oc mice.

CIC-7 KO, oc/oc mice, and their corresponding wildtype littermates (WT) were sacrificed at 4-5 weeks of age. Bones and spleens were dissected and used for isolation of osteoclasts. The isolated cells were differentiated into mature osteoclasts on bone using M-CSF and RANKL. Cell culture supernatants were collected for measurements of CTX-I, TRACP and gelatinase activity by zymography. Cells were fixed and TRACP stained and the resorption pits were counted. Biochemical markers of resorption (CTX-I), osteoclast number (TRACP 5b), and osteoblast activity (ALP) were measured in serum of CIC-7 KO, oc/oc mice and the corresponding WT. Osteoblastogenesis in vitro was investigated using calvarial osteoblasts. In addition, bones were used for histological examination of TRACP positive osteoclasts with respect to number and morphology. Furthermore, osteoblast numbers and morphology were examined.

The osteoclasts from the CIC-7 KO mice were unable to resorb bone, as measured by CTX-I and by counting of resorption pits. Measurements of TRACP activity, as well as TRACP staining, showed the presence of equal numbers of osteoclasts in WT and KO cultures. Gelatinase activity was similar in both genotypes. Furthermore, the morphology of the KO cells was normal. Histological investigation of TRACP stained bone sections of both CIC-7 KO and oc/oc mice, indicated an elevated number of large osteoclasts present compared to WT. The serum TRACP levels were increased by 250% in CIC-7 KO and oc/oc mice, whereas the resorption per osteoclast was reduced to 50% of the WT level. Finally, the serum ALP level in KO and oc/oc mice was increased by 30%, whereas no differences in osteoblast function were observed in vitro.

In summary, the osteoclasts from CIC-7 KO mice differentiate normally and form actin rings, but fail to resorb bone in vitro. In vivo, the osteoclasts are larger and more numerous, however, show no signs of resorption. Interestingly, an elevation of TRACP, a marked reduction in resorption per osteoclast, and elevated ALP level were observed in serum from both CIC-7 KO and oc/oc mice, showing increased signs of bone formation despite the low resorption. These findings indicate that the osteoclasts, and not their activity, control osteoblastic activity.

Parathyroid Hormone-Related Protein Induces Bone Pain Through Stimulation of Proton-Secretion in Osteoclasts. L. Wang*, H. Wakabayashi*, T. Hiraga*, T. Yoneda. Department of Biochemistry, Osaka University Graduate School of Dentistry, Osaka, Japan.

Bone pain is the most common complication associated with bone metastases. Of note, clinical studies reported that inhibitors of osteoclasts such as bisphosphonates (BPs) efficiently reduced bone pain, suggesting a causative role of osteoclasts. Parathyroid hormone-related protein (PTH-rP), a potent stimulator of osteoclasts, has been implicated in bone metastasis. Activated osteoclasts are known to release protons via the $\alpha 3$ type vacuolar- H^+ -ATPase ($\alpha 3$ V- H^+ -ATPase) to dissolve bone minerals, thereby inducing acidosis in the neighboring environment. Acidosis is a well-known cause of pain. These results collectively suggest that PTH-rP is associated with bone pain through stimulating osteoclastic bone resorption. Repeated subcutaneous injections of PTH-rP caused increased osteoclastic bone resorption in the metatarsal bones and hyperalgesia in the hind-paw. Immunohistochemical examination revealed that the hyperalgesia was associated with increased protein expression of the transient receptor potential channel-vanilloid subfamily member 1 (TRPV1) and phosphorylated-ERK (p-ERK) in the ipsi-lateral dorsal root ganglions (DRGs) and c-Fos in the spinal dorsal horn. The hyperalgesia and elevated protein expression were significantly reduced by a most potent BP zoledronic acid, recombinant human OPG, a specific inhibitor of the V- H^+ -ATPase FR167356 and an antagonist of TRPV1 activation I-RTX, respectively. Finally, TRPV1 knockout mice exhibited reduced PTH-rP-induced hyperalgesia. Relevant to bone pain in bone metastases of breast cancer, we developed an animal model in which the MDA-MB-231 human breast cancer cells that produces large amounts of PTH-rP were directly inoculated into the tibial marrow cavity in nude mice. These mice showed hyperalgesia in the ipsi-lateral hind-paw and a monoclonal antibody to PTH-rP reduced the hyperalgesia. These results suggest that PTH-rP produced by metastatic cancer cells plays a part in causing bone pain through stimulation of proton-secretion in osteoclasts, thereby activating the acid-sensing receptors such as TRPV1 that are expressed in the nociceptive neurons innervating bone.

Myeloma Cells Decrease EphB4 Expression in Osteoblasts; A Novel Mechanism for Regulation of Bone Formation in Multiple Myeloma. A. L. Bates*, G. R. Mundy, C. M. Edwards. Vanderbilt Center for Bone Biology, Vanderbilt University, Nashville, TN, USA.

Multiple myeloma is associated with a destructive osteolytic bone disease, characterized by an increase in osteoclastic bone resorption and a reduction in osteoblastic bone formation. The increase in bone resorption in myeloma is well characterized; however the precise cellular and molecular mechanisms which mediate the reduction in bone formation and the uncoupling of bone resorption from bone formation are poorly understood. Recently, a novel mechanism has been suggested for coupling between osteoblasts and osteoclasts during normal bone homeostasis due to bidirectional signaling between the ligand ephrin B2, expressed by osteoclasts, and its receptor EphB4, expressed by osteoblasts. The interaction between EphB4 and ephrin B2 resulted in inhibition of osteoclast activity by reverse signaling through ephrin B2 on osteoclasts and stimulation of osteoblast differentiation and bone formation by forward signaling through EphB4 on osteoblasts (Zhao et al. 2006). Since the normal coupling of bone resorption to bone formation is dysregulated in multiple myeloma, we hypothesized that this may be mediated by modifications in the EphB4/ephrin B2 receptor/ligand interaction. To study bone formation in multiple myeloma in vivo, we used the 5TGM1 murine model of myeloma. 5TGM1 myeloma cells were inoculated by i.v. injection into C57BL/6J mice, resulting in homing of myeloma cells to the bone marrow, and development of an osteolytic bone disease. In addition to the well characterized increase in osteoclastic bone resorption, the bone disease was associated with a significant reduction in osteoblast number and rates of bone formation ($p < 0.01$). Real time PCR demonstrated expression of EphB4 mRNA in 5TGM1 myeloma cells, C2C12 and 2T3 osteoblasts, with a 2-fold increase in expression in 5TGM1 myeloma cells when compared with C2C12 or 2T3 cells. Western blotting demonstrated expression of EphB4 protein in C2C12 and 2T3 cells. Treatment of C2C12 or 2T3 cells with conditioned media from 5TGM1 myeloma cells resulted in a significant reduction in expression of EphB4 in both C2C12 and 2T3 cells, suggesting that myeloma cells release a soluble factor which down-regulates EphB4 in osteoblasts. In conclusion, we have shown that the development of myeloma bone disease in the 5TGM1 murine model of myeloma is associated with a reduction in bone formation, and that 5TGM1 myeloma cells can down-regulate EphB4 expression in osteoblasts. This raises the possibility that the reduction in bone formation associated with myeloma bone disease is mediated by a reduction in EphB4 expression and thus disruption of the normal coupling of bone resorption and bone formation.

Endogenous Sex Hormones and Incident Fracture Risk in Older Men: The Dubbo Osteoporosis Epidemiology Study. C. Meier¹, T. V. Nguyen², D. J. Handelsman^{3,4}, C. Schindler^{4,5}, M. M. Kushnir^{6,7}, A. L. Rockwood^{8,9}, W. A. Meikle^{6,7}, J. R. Center², J. A. Eisman², M. J. Seibel⁷. ¹Division of Endocrinology, University Hospital Basel, Switzerland, ²Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia, ³Department of Andrology, ANZAC Research Institute, Sydney, Australia, ⁴Institute of Social and Preventive Medicine, University of Basel, Switzerland, ⁵ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, UT, USA, ⁶Department of Medicine and Pathology, University of Utah, Salt Lake City, UT, USA, ⁷Bone Research Program, ANZAC Research Institute, Sydney, Australia.

One third of osteoporotic fractures occur in men. Data on the influence of gonadal hormones on incident fracture risk in elderly men are limited. The present study examined the prospective relationship between serum levels of testosterone (T) and estradiol (E2) and future fracture risk in elderly men as part of the long-term observational Dubbo Osteoporosis Epidemiology Study of community-dwelling men over 60 years followed prospectively since 1989. This analysis included men who had serum samples for baseline measurements ($n=609$, 70.6%) with follow-up of 5.8 years (up to 13 yrs) closing in 2005. Clinical risk factors, including bone mineral density (BMD) and lifestyle factors were assessed at baseline. Serum T and E2 were measured by tandem mass spectrometry (LC-MS/MS). The incidence of low-trauma symptomatic fracture was ascertained by X-ray record.

During follow-up, 113 men suffered at least one low-trauma fracture. Fracture risk was increased in men with reduced T levels (hazard ratio [HR] 1.33; 95%CI: 1.09, 1.62). After adjustment for SHBG, both low serum T (HR 1.48; 95%CI: 1.22, 1.78) and serum E2 (HR 1.21; 95%CI: 1.00, 1.47) were associated with increased overall fracture risk. After further adjustment for major fracture risk factors (age, weight or BMD, fracture history, smoking status, calcium intake and SHBG), lower T was still associated with increased risk of hip (HR 1.88; 95%CI: 1.24, 2.82) and non-vertebral (HR 1.32; 95%CI: 1.03, 1.68) fracture. By contrast, lower E2 was only associated with increased fracture risk in the presence of body weight (HR 1.25; 95%CI: 1.02, 1.54), but not at any site after adjustment for BMD (HR 1.19; 95%CI: 0.69, 1.03).

In community-dwelling men over 60 years of age, serum T, but not E2, is an independent predictor of osteoporotic fracture and its measurement may provide additional clinical information for the assessment of fracture risk in elderly men.

Respiratory Function Is Associated with Bone Ultrasound Measures and Hip Fracture: European Prospective Investigation Into Cancer-Norfolk Population Cohort Study. A. Moayyeri¹, R. N. Luben², S. Bingham^{2,3}, A. Welch¹, N. J. Wareham³, S. Kaptoge¹, J. Reeve¹, K. T. Khaw¹. ¹Department of Public Health and Primary Care, Institute of Public Health, School of Clinical Medicine, The University of Cambridge, Cambridge, United Kingdom, ²MRC Dunn Human Nutrition Unit, The University of Cambridge, Cambridge, United Kingdom, ³MRC Epidemiology Unit, The University of Cambridge, Cambridge, United Kingdom.

Forced expiratory volume in 1 second (FEV1), an easily obtainable measure of respiratory function in clinics, has been shown to be associated with physical activity. We hypothesized that FEV1 is linked with bone health. In the context of the European Prospective Investigation into Cancer-Norfolk study, 14,800 participants aged 42-81 in 1997-2000 were evaluated by spirometry and heel ultrasound and were followed for fracture outcomes up to July 2007. After excluding participants with history of pulmonary diseases, among 5,555 men and 6,935 women (mean age 62.1 \pm 9.0), FEV1 significantly correlated with heel broadband ultrasound attenuation (BUA; Pearson $r=0.403$; $p<0.001$) and velocity of sound (VOS; $r=0.269$; $p<0.001$). The association remained significant in sex-stratified linear regression models after adjustment for age, history of fracture, height, body mass index, smoking status and alcohol consumption (standardized Beta coefficient -0.057 and $p<0.001$ in men; Beta -0.075 and $p<0.001$ in women). Mean adjusted FEV1 among 109 hip fracture patients (2.00 \pm 0.60 liter) was significantly lower than that of other participants (2.49 \pm 0.71 liter; t -test $p<0.001$). In a Cox proportional hazards regression model, FEV1 was a significant predictor of hip fracture after adjustment for age, sex, history of fracture, height, body mass index, smoking and alcohol consumption (hazard ratio for 1 standard deviation [700 ml in 1 second] decrease in FEV1 -1.39 , 95%CI 1.03-1.88, $p=0.029$). Among 6197 current and former smoker participants, hazard ratio for 1 standard deviation decrease in FEV1 was 1.67 (95%CI 1.11-2.57, $p=0.014$). Middle aged and older men and women with lower respiratory function appear to be at increased risk of osteoporosis and hip fracture. The observed association might be related to the level of physical activity or deformities in thoracic spine related to osteoporosis. Given the feasibility and affordability of spirometry in general practices, it can be used to improve the identification of high risk groups at the first point of care.

Changes in Hip Geometric Structures with Aging--Longitudinal Data Analysis from the Women's Health Initiative Observational Study. T. Bassford^{*1}, T. J. Beck², G. Wu^{*1}, J. A. Cauley³, A. Z. LaCroix^{*4}, C. E. Lewis⁵, Z. Chen¹. ¹University of Arizona, Tucson, AZ, USA, ²Johns Hopkins University, Baltimore, MD, USA, ³University of Pittsburgh, Pittsburgh, PA, USA, ⁴Fred Hutchinson Cancer Research Center, Seattle, WA, USA, ⁵University of Alabama-Birmingham, Birmingham, AL, USA.

Fracture risk increases with age. In addition to bone loss, change in the distribution of bone mass is another significant factor associated with bone fragility. The objective of this study was to investigate the relationship between aging and changes in hip geometry derived from hip structure analysis (HSA). A prospective study in an ethnically diverse subcohort of 5,856 postmenopausal women enrolled in the Observational Study of the Women's Health Initiative was conducted. Eligible subjects were between 50 and 79 years of age and had completed bone scans using Dual-energy X-ray Absorptiometry (DXA). The Beck HSA software was used to estimate bone mineral density (BMD), cross-sectional area (CSA), outer diameter (OD), section modulus index (SM), average cortical thickness (CT) and buckling ratio (BR) for the femoral narrow neck (FNN), intertrochanter (IT) and proximal femoral shaft regions (FS). Analyses showed that BMD, CSA, SM and CT were all significantly lower and the OD and BR measures were significantly higher in the older age group in comparison to the younger age group at baseline ($p < 0.01$). Results from paired t-test indicated significant changes in all HSA measures from baseline to year 6 (Table). Interestingly, both the bone bending strength (SM) and the likelihood of cortical failure under compression (BR) increased significantly over this same time frame, suggesting a complex process with changes in the hip geometry associated with aging. The rates of changes in HSA measures varied by age group and by femoral site. For example, OD expansion in all regions was significantly larger in the 60-69 or 70-79 years age group in comparison to the 50-59 years age group. While significant age differences in the change of other HSA measures were only observed in the FNN region. In conclusion, hip geometric structures change significantly with aging and the rate of changes varies by age and femoral site. The impacts of these changes on hip bone strength are complicated and remained to be investigated.

FNN	Baseline	Year 6	Change	*P-value
BMD (g/cm ²)	0.719 ± 0.130	0.713 ± 0.136	-0.006 ± 0.070	<0.001
CSA (cm ²)	0.204 ± 0.365	0.205 ± 0.391	0.007 ± 0.208	0.037
Outer diameter (cm)	2.997 ± 0.209	3.033 ± 0.228	0.035 ± 0.139	<0.001

Oral Treatment with the Calcium Receptor Antagonist SB-423557 Causes PTH Release in Multiple Species and Positive Bone Forming Effects in the Rat. S. Kumar¹, X. Liang¹, J. A. Vasko^{*1}, G. B. Stroup², S. J. Hoffman¹, V. R. Vaden^{*2}, H. Haley^{*2}, J. Fox³, E. F. Nemeth³, A. M. Lago^{*2}, J. F. Callahan^{*2}, P. Bhatnagar^{*1}, W. F. Huffman^{*1}, M. Gowen². ¹GlaxoSmithKline, Collegeville, PA, USA, ²GlaxoSmithKline, King of Prussia, PA, USA, ³NPS, Salt Lake City, UT, USA.

Antagonists of the parathyroid calcium receptor (calcilytics) stimulate the secretion of PTH. Previously, we demonstrated the ability of an orally active calcilytic compound to cause sustained increases in circulating levels of endogenous PTH and to stimulate bone formation and resorption (without a net increase in bone formation) in the ovariectomized (OVX) rat. In the present study, a prodrug approach has been used to preserve oral bioavailability and yield a calcilytic with a shorter half-life in vivo. SB-423557 is the ethyl ester prodrug of SB-423562 that, when administered orally to rats, dogs or monkeys, caused a dose-dependent, transient increase in circulating levels of endogenous PTH. In order to examine the bone forming effect of SB-423557, six-month-old female rats received OVX or sham surgery and were untreated for 6 weeks to allow osteopenia to develop and then treated orally daily with either vehicle, SB-423557 (50 mg/kg), or with rat PTH(1-34) (5 µg/kg SC) for 12 weeks. Plasma levels of PTH peaked at 10-60 min following oral administration of 50 mg/kg SB-423557 (3-fold, C_{max} of 40-60 pM) and returned to baseline by 2-3 hours. SC administration of rat PTH(1-34) resulted in a systemic C_{max} of 127-240 pM at 10 minutes post-injection. SB-423557 significantly and completely prevented additional OVX-induced loss of BMD in the lumbar spine and partially prevented trabecular BMD loss in the proximal tibia by 39% (ns) compared to OVX controls. Histomorphometric analysis indicated greater trabecular bone area (36%, ns) in the spine and increased cortical area (72%) and endocortical bone formation rate (220%) with no effect on the eroded perimeter of the distal tibia in the SB-423557 treated rats compared to vehicle-treated OVX animals. Serum osteocalcin increased (ns) with SB-423557 treatment with no effect on urinary deoxypyridinoline levels. In addition, treatment with SB-423557 resulted in greater ultimate strength (ns), toughness, and elastic modulus of a lumbar vertebral body and at the femoral diaphysis compared to OVX controls. Treatment with PTH(1-34) also completely prevented the OVX-induced loss in bone mass, BMD, and strength. These data provide a proof of principle for stimulation of bone formation following daily brief antagonism of the calcium receptor in the OVX rat and support the potential use of these agents to treat disorders of bone metabolism such as osteoporosis.

β2 Adrenergic Receptor Deficiency Enhances Bone Mass in by Antagonizing Against Aging-induced Bone Loss and Blunts Anabolic Effects of PTH on Osteoblasts. R. Hanyu^{*1}, Y. Saita^{*1}, J. Nagata^{*1}, Y. Izu^{*1}, T. Hayata^{*1}, H. Hemmi^{*2}, S. Takeda^{*3}, Y. Ezura^{*1}, K. Nakashima^{*1}, H. Kurosawa^{*4}, M. Noda^{*1}. ¹Department of Molecular Pharmacology, 21st Century COE Program, MRI, Tokyo Medical and Dental University, Chiyoda-ku, Tokyo, Japan, ²MTT Program, MRI, Tokyo Medical and Dental University, Chiyoda-ku, Tokyo, Japan, ³Department of Orthopedics, 21st Century COE Program, Tokyo Medical and Dental University, Chiyoda-ku, Tokyo, Japan, ⁴Department of Orthopedics, Juntendo University school of Medicine, Bunkyo-ku Tokyo, Japan.

Soaring of the aged population in modern world increases the fraction of aged population with diseases and thus in bone field, leads to increase in osteoporosis incidence. Loss of bone mass is accelerated with age regardless of gender. Osteoporotic patients with their bone mass levels at their nadir require treatment to increase bone mass through the activation of bone formation. PTH has been proven to be efficacious in increasing bone mass. However, its efficacy in the highly aged population such as those over 80 years of age in human have not yet been fully elucidated. In mice, aged models of over one year old, indicate lower bone mass than younger adult animals regardless of the gender. Recently, sympathetic nervous system was reported to regulate bone mass in mice. However, these reports always indicate the effects of adrenergic system on young adult mice. Therefore, the purpose of this paper is examine the effects of β2 adrenergic system and PTH on the bone mass in aged mice. Aged (54 weeks old) female mice null for β2 adrenergic receptor (Adrb2^{-/-}) and wild type (WT) were used. Mice were treated with vehicle or PTH (80µg/kg/day sc) for 4 weeks (5 days/week). The base line bone mass levels in these aged mice were significantly reduced compared to young adult mice. Aged Adrb2^{-/-} mice exhibited higher total body BMD, trabecular bone volume fraction(BV/TV), cortical bone volume compared with aged WT mice. In WT, PTH treatment significantly increased the levels of total body BMD, 3D-BV/TV, mineral apposition rate (MAR) and bone formation rate (BFR). In contrast, in aged Adrb2^{-/-} mice, PTH failed to increase the levels of BMD and BV/TV. Analyses on aged Adrb2^{-/-} mice also revealed that PTH failed to enhance BFR and MAR. Importantly, Adrb2 deficiency increased cortical bone volume compared to WT while this parameter was no longer enhanced by PTH in the mutant mice. Regarding bone resorption side, Oc.S/BS, N.Oc/BS were similar regardless of the genotype or PTH treatment. In conclusion, we found that in one year old aged female mice, β2 adrenergic receptor signal operates to reduce bone mass, while β2 adrenergic signaling is required for the anabolic actions of PTH on bone formation.

Decreased Bone Turnover and Porosity Are Associated with Improved Bone Strength in Ovariectomized (OVX) Cynomolgus Monkeys Treated with Denosumab, a Fully Human RANKL Antibody. M. S. Ominsky¹, J. Schroeder^{*1}, J. Jolette^{*2}, S. Y. Smith², D. J. Farrell^{*2}, J. E. Atkinson¹, P. J. Kostenuik¹. ¹Amgen Inc., Thousand Oaks, CA, USA, ²Charles River Laboratories Preclinical Services Montreal, Inc., Montreal, PQ, Canada.

Denosumab (DMab), a fully human monoclonal antibody against RANKL, was previously shown to decrease biochemical markers of bone turnover and increase bone mineral density in adult OVX cynomolgus monkeys. We now report from that study the effects of DMab on bone turnover at the histologic level, and their relationships with bone strength. One month after surgery, OVX cynos (9-16 years old) were treated with either vehicle (OVX-Veh) or DMab (25 or 50 mg/kg, SC, once/month) for 16 months (n=14-20/group). Sham controls were treated with vehicle (n=17). Double fluorochrome labels were injected prior to iliac and rib biopsies (at month 6 and 12), and prior to sacrifice. Histomorphometry was performed on these biopsies, the tibial diaphysis, and cancellous bone in L2 vertebra and the proximal femur. Cancellous bone turnover was increased in OVX-Veh animals, based on significantly greater mineralizing surface (MS/BS), bone formation rate (BFR), and activation frequency at the lumbar spine, iliac crest, and femur neck ($P < 0.05$ vs Sham). Both doses of DMab fully prevented these OVX-related changes while reducing values significantly below those of sham controls ($P < 0.05$). Osteoclast and osteoblast surfaces were 78-100% lower in the lumbar spine, iliac crest, and femur neck of DMab groups, while eroded surface was decreased by 45-93% ($P < 0.05$ vs OVX-Veh). Cortical bone turnover was also increased in OVX-Veh cynos, as shown by significantly greater cortical porosity, labeled perimeter, and BFR at the endocortical and haversian surfaces of the tibial diaphysis and rib ($P < 0.05$ vs Sham). Both doses of DMab fully prevented these OVX-related changes, while reducing labeled perimeter and BFR significantly below sham control levels ($P < 0.05$). Prolonged DMab-related turnover suppression was associated with significant increases in strength parameters at the lumbar vertebrae, femur neck, and femur diaphysis ($P < 0.05$ vs OVX-Veh). Regression analysis of all groups combined demonstrated significant inverse relationships between the strength of L5-L6 cores (yield load) and mineralizing surface ($r^2 = 0.44$) or eroded surface in L2 ($r^2 = 0.37$; $P < 0.001$). Cortical porosity in the tibia was negatively correlated with peak load at the femur diaphysis ($r^2 = 0.21$; $P < 0.001$). In summary, denosumab treatment of OVX cynos was associated with significant decreases in histomorphometric indices of bone turnover. These changes were accompanied by significant improvements in bone strength at cortical and cancellous sites.

Efficacy of Adding Teriparatide versus Switching to Teriparatide in Postmenopausal Women with Osteoporosis Previously Treated with Raloxifene or Alendronate. F. Cosman¹, R. A. Werners², C. Recknor³, K. F. Mauck^{*2}, L. Xie^{*4}, E. V. Glass^{*4}, J. H. Krege⁴. ¹Helen Hayes Hospital, West Haverstraw, NY, USA, ²Mayo Clinic, Rochester, MN, USA, ³United Osteoporosis Centers, Gainesville, GA, USA, ⁴Eli Lilly and Company, Indianapolis, IN, USA.

In patients previously treated long term with antiresorptive drugs, information regarding the relative efficacy of adding teriparatide (TPTD, 20 mcg/d) versus switching to TPTD is not available. Postmenopausal women with osteoporosis previously treated for at least 18 months with alendronate (ALN, 70 total mg/week, median treatment duration 37.3 months) or raloxifene (RLX, 60 mg/d, median treatment duration 36.9 months) were randomized to either add TPTD or switch to TPTD for 6 months. A preplanned 12-month extension of this study is currently ongoing. Efficacy results included markers of bone turnover and DXA BMD. Baseline BMD and other characteristics were well matched with the exception that previous ALN patients had lower baseline bone turnover than previous RLX patients (Table). Adding TPTD conferred smaller increases in bone turnover versus switching to TPTD; these differences were more marked between the groups previously treated with ALN. However, adding TPTD conferred greater increases in BMD versus switching to TPTD; these differences were again more marked between the groups previously treated with ALN. All regimens were well tolerated. In conclusion, an anabolic response to TPTD was observed in patients previously treated with ALN or RLX regardless of whether the previous antiresorptive drug was continued or discontinued. In general, greater bone turnover was achieved by switching from antiresorptive to TPTD, while greater BMD increase was achieved by continuing antiresorptive during TPTD treatment.

Table: Baseline and change from baseline after 6 Months of TPTD Treatment.

Variable	Alendronate Pretreated			Raloxifene Pretreated		
	TPTD (N=50)	TPTD+ALN (N=52)		TPTD (N=49)	TPTD+RLX (N=47)	
BL	6-Mo Δ	BL	6-Mo Δ	BL	6-Mo Δ	BL
PINP (μg/L)	27.101.5 (400.9%*)	30.21.5 (69.1%*)	43.103.0 (245.7%*)	42.62.5 (125.4%*)		
BSAP (U/L)	5.11.9 (73.3%*)	0.3.1 (16.1%*)	25.9.7 (38.6%*)	27.8.1 (30.6%*)		
CTx (ng/ml)	0.10.40 (231.0%*)	0.10.05 (28.6%*)	0.30.37 (136.1%*)	0.20.14 (64.6%*)		
LS DXA BMD (g/cm ²)	0.80.012 (1.9%*)	0.80.033 (4.5%*)	0.80.034 (4.2%*)	0.80.037 (4.6%*)		
FN DXA BMD (g/cm ²)	0.60.0001 (0.1%)	0.60.004 (0.7%)	0.60.002 (0.3%)	0.60.012 (1.9%*)		
TH DXA BMD (g/cm ²)	0.7-0.007 (-0.8%)	0.70.009 (1.4%*)	0.70.003 (0.5%)	0.70.013 (1.8%*)		

For bone markers, values are median baseline, median absolute change from baseline (% change). For BMD, values are mean baseline, mean absolute change from baseline (% change). BL, baseline; PINP, amino-terminal propeptide of type I collagen; BSAP, bone specific alkaline phosphatase; CTx, C-terminal telopeptide of type I collagen; LS, lumbar spine; FN, femoral neck; TH, total hip. P-values are based on percent changes. *P<0.001 and **P<0.05 within group from baseline; †P<0.001 and ‡P<0.05 between groups within a stratum.

Mechanistic Bases of Bone Mineral Density Increase During Alendronate Therapy. D. Vashishth¹, P. Chavassieux², G. Boivin², P. D. Delmas². ¹INSERM Unite 831 Universite de Lyon France & Rensselaer Polytechnic Institute, Troy, NY, USA, ²INSERM Unite 831 Universite de Lyon, Lyon, France.

An increase in the mean degree of tissue mineralization (DMB) occurring through secondary mineralization has been proposed to increase bone mineral density (BMD) during bisphosphonate (BP) therapy [1]. In this study we conducted additional analyses on human iliac crest biopsies obtained as part of alendronate (ALN) clinical trials [2] to identify the mechanistic bases of BMD increase.

Out of a group of 16 patients on a three-year ALN-therapy [1], we identified two groups of 5 patients each showing lower (8.5 %) and higher (13.3%) bounds of BMD increase but no difference in baseline BMD. For all 10 patients, previously prepared microradiographs were reanalyzed to measure the mean degree of tissue mineralization (DMB) at the osteonal and interstitial compartments in both cortical and cancellous bone tissues. Based on a moving average analysis, six fields each of cortical and cancellous bone tissues were randomly selected for measurement from each biopsy. The average values for patients in each group within osteonal and interstitial compartments were compared between and across cortical and cancellous bone tissues. All DMB measurements were also tested for correlation with standard histomorphometric measures of bone structure (BV/TV, Tb.Th, Tb. Separation, Tb.N), osteoclast activity (EV/BV, E-Depth, Oc#/BS), osteoid (OS/BS, OV/BV, OTh), and bone formation (MAR, BFR/BS, FP) reported previously [2].

The low-BMD-gain group demonstrated no difference between the osteonal and interstitial bone compartments within cortical or cancellous bone tissues but demonstrated a higher DMB in cancellous than in cortical tissue (p<0.05). In contrast, the high-BMD-gain group showed higher DMB in interstitial than in osteonal compartment for both cortical and cancellous tissues as well as a higher DMB in cancellous than in cortical tissue (p<0.05). Out of all the DMB measures in cortical and cancellous tissues, only cortical bone interstitial level DMB correlated to bone formation rate (BFR/BS) (r = -0.86; p = 0.006) and formation period (FP) (r = -0.75; p = 0.04). In conclusion, this study demonstrates that the effects of ALN-therapy are more evident in

cancellous than in cortical bone. Moreover since the interstitial level DMB is at least partially dependent on the duration of secondary mineralization, and negatively correlated to formation parameters, slow bone formation rate and longer bone formation period produce conditions conducive to complete secondary mineralization and consequently larger BMD gain.

Thioredoxin-1 Overexpression Attenuates Streptozotocin-induced Diabetic Osteopenia in Mice: A Novel Role of Oxidative Stress and Therapeutic Implications. Y. Hamada^{*1}, H. Fujii^{*1}, R. Kitazawa², S. Kitazawa², M. Fukagawa¹.

¹Division of Nephrology and Kidney Center, Kobe University School of Medicine, Kobe, Japan, ²Division of Molecular Pathology, Department of Biomedical Informatics, Kobe University School of Medicine, Kobe, Japan.

Diabetes mellitus is associated with increased risk of osteopenia and bone fracture. However, the mechanisms accounting for diabetic bone disorder still remain to be clarified. Moreover, there are few effective treatments for this disease. We have previously reported that streptozotocin-induced diabetic mice develop low turnover osteopenia associated with increased oxidative stress in diabetic condition (BONE 2007). Therefore, in order to determine the role of oxidative stress in the development of diabetic osteopenia, we investigated the effect of thioredoxin-1 (TRX) overexpression, a major intracellular antioxidant, on the development of diabetic osteopenia using TRX transgenic mice (TRX-Tg). TRX-Tg was C57BL/6 mice that carry the human TRX transgene under the control of β-actin promoter.

Eight-week-old male TRX-Tg and wild type littermates (WT) were intraperitoneally injected with either streptozotocin or vehicle alone. Mice were classified into four groups: 1) non-diabetic WT, 2) Non-diabetic TRX-Tg, 3) diabetic WT, and 4) diabetic TRX-Tg. After 12 weeks of streptozotocin treatment, the physical properties of femora, and the parameters of bone histomorphometry of tibiae were assessed. Oxidative stress in the whole body as well as in the bone was evaluated.

TRX overexpression did not affect either body weights or hemoglobin A1c levels both in the diabetic mice and in the non-diabetic mice. There were no significant differences in renal function, and serum levels of calcium, phosphate, and intact parathyroid hormone among four groups. Urinary excretion of 8-hydroxydeoxyguanosine (8-OHdG), a marker of oxidative DNA damage, was significantly elevated in diabetic WT, which was attenuated in diabetic TRX-Tg. Immunohistochemical staining for 8-OHdG was clearly intensified in the bone tissue of diabetic WT compared with non-diabetic WT. In contrast, staining was attenuated in diabetic TRX-Tg. TRX overexpression partially restored reduced bone mineral density and prevented the suppression of bone formation (OV/BV, OS/BS, Ob.S/BS, O.Th, MAR, and BFR/BS) observed in diabetic WT. These results suggest that increased oxidative stress in diabetic condition contributes to the development of diabetic osteopenia. Furthermore, our findings indicate that suppression of increased oxidative stress by TRX induction can be a therapeutic approach for treatment of diabetic osteopenia.

Time Sequence of Secondary Mineralization and Microhardness of Bone in an Ewe Model. Y. Bala^{*}, D. Farlay^{*}, C. Simi^{*}, P. J. Meunier, P. D. Delmas, G. Boivin. INSERM Unité 831, Université de Lyon, Lyon, France.

The degree of mineralization is a major determinant of the mechanical resistance of bone (Follet et al. 2004, Bone 34:783-9). Mineralization begins by a rapid primary mineralization followed, after the full completion of the Basic Structural Units (BSUs), by a secondary mineralization phase, i.e., a slow and gradual maturation of the mineral component leading to complete mineralization of newly formed BSUs (Meunier & Boivin 1997, Bone 21:373-7). The duration of primary mineralization has been evaluated by several authors but the time sequence of secondary mineralization is still poorly investigated [Fuchs et al. 2005, J Bone Miner Res 20 (Suppl.1):325]. Our aim was to determine the time course of secondary bone mineralization in ewe, an animal model having an Haversian bone tissue with a remodeling activity close to the Human one (Chavassieux et al. 1997, Bone 20:451-5). 18 ewes (4.5±0.4 years, INRA, Theix, France) received every six months for 30 months fluorescent labelings following the schedule: T0 double tetracycline, T6 single fluorescein, T12 triple tetracycline, T18 double fluorescein, T24 single tetracycline, T30 double alizarin labeling in order to date the age of the BSUs. Transiliac bone samples have been taken on each ewe after T18 and T30 labelings, then embedded in methyl methacrylate. Microradiography (Boivin & Meunier 2002, Calcif Tissue Int 70:503-11) performed on 100±1 μm-thick sections allowed the measurement of the focal Degree of Mineralization of Bone (DMB g/cm³) on 505 different BSUs in which the duration of the mineralization was precisely determined by labeling. Microhardness using a Vickers indenter under a load of 25g for 10s (Hv kg/mm²) was measured on 367 among the 505 BSUs [Bala et al. 2006, J Bone Miner Res 21(suppl.1):S332]. DMB measured at primary mineralization (0.76±0.10 g/cm³) significantly increased during the first 6 months (+26%, p<0.0001). Then, DMB increased more slowly until 30 months to reach a mean of 1.20±0.12 g/cm³. DMB measured at the end of the primary mineralization corresponded to 64% of the final mineralization. DMB after 6 and 12 months were 85% and 91% of the final DMB, respectively. Secondary mineralization is thus the fastest during the first year. Hv followed a similar trend, with a rapid increase during the first six months (+32%, p<0.0008), then a slow increase until 30 months. Hv and DMB are strongly and positively correlated (r²=0.52, p<0.0001). The time course of secondary mineralization can be divided into two parts having separated trends, a rapid increase during the first year then a slowdown of mineralization until 30 months. Mineralization explains a great part of the hardness of bone at BSU level.

Oxidized Metabolites of Polyunsaturated Fatty Acids Stimulate Osteoblast Apoptosis via both PPAR γ -dependent and -independent Mechanisms. R. L. Jilka, M. Almeida, R. Wynne*, L. Han, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Age-related loss of bone mass and strength in mice is accompanied by increased reactive oxygen species (ROS) in the bone marrow, increased osteoblast apoptosis, and decreased osteoblast number; but the underlying mechanisms are unknown. The level of expression of the lipoxygenase Alox15, and the nuclear hormone receptor PPAR γ , is inversely related to bone mass in mice; and the expression of these genes increases with aging. Alox15, as well as ROS, oxidize polyunsaturated fatty acids (PUFAs) to generate PPAR γ ligands such as 9-hydroxyoctadecadienoic acid (9-HODE) and 12-hydroxyicosatetrenoic acid (12-HETE). Oxidized PUFAs are further metabolized to form 4-hydroxynonenal (4-HNE), which can form pro-apoptotic protein and DNA adducts, and can further increase oxidative stress. Here, we examined the impact of these PUFA metabolites on the apoptosis of C2C12 uncommitted osteoblast progenitor cells and OB-6 osteoblastic cells. We found that 9-HODE or 12-HETE stimulated apoptosis of C2C12 cells after 6 hours and of OB-6 cells after 16 hours, as measured by caspase-3 activity. This effect required 0.5 to 5 μ M of 9-HODE or 12-HETE, which is near their binding constant for PPAR γ 2. Using osteoblastic OB-6g2 cells that express PPAR γ 2 under the control of the tet-OFF promoter, we found that the pro-apoptotic effect of both metabolites required the presence of this transcription factor. Six hours of treatment with 4-HNE also stimulated apoptosis of C2C12 and OB-6 cells at physiologic concentrations (10–40 μ M). Unlike 9-HODE and 12-HETE, however, the pro-apoptotic effect of 4-HNE did not require PPAR γ 2. Using pharmacologic inhibitors, we further determined that 4HNE-stimulated apoptosis required p38 MAP kinase, and that neither MEK nor JNK MAP kinases were involved. 4-HNE-induced apoptosis was prevented by the antioxidant N-acetyl cysteine. Moreover, treatment of C2C12 cells with 40 μ M 4-HNE for 1 hour increased phosphorylation of p66^{Sbc}, a ROS-sensitive adaptor protein known to directly activate apoptosis. Based on these findings, we hypothesize that an age-related increase in the production of oxidized lipids such as 9-HODE and 13-HETE stimulate apoptosis of osteoblasts and osteoblast progenitors via activation of PPAR γ 2; and downstream PUFA metabolites like 4-HNE further increase oxidative stress and stimulate apoptosis of these cells. In view of the role of lipid oxidation in atherosclerosis and increasing epidemiologic evidence linking atherosclerosis and osteoporosis, it is tempting to speculate that these diseases share a common pathologic basis.

The Role of Fas/Fas Ligand System in Estrogen Deficiency-induced Osteoporosis. N. Kovacic¹, V. Grubisic^{*1}, K. Mihovilovic^{*1}, I. K. Lukic¹, D. Grcevic^{*2}, V. Katavic^{*1}, P. Croucher³, A. Marusic^{*1}. ¹Department of Anatomy, Zagreb University School of Medicine, Zagreb, Croatia, ²Department of Physiology and Immunology, Zagreb University School of Medicine, Zagreb, Croatia, ³Academic unit of Bone Biology, University of Sheffield Medical School, Sheffield, United Kingdom.

The aim of this study was to estimate the role of Fas/Fas ligand system in vivo in the pathogenesis of estrogen deficiency induced bone loss.

We first analyzed the expression of Fas gene by quantitative PCR in bones and bone cell cultures from wild-type mice, four weeks after the ovariectomy (ovx). Then we performed ovx in mice deficient for Fas gene (Fas^{-/-}) and their wild-type controls. After four weeks we analyzed: 1) standard histomorphometric parameters of their femora, 2) differentiation of osteoblast (Obl) and osteoclasts (Ocl) in vitro from their bone marrow progenitors. Obl and Ocl differentiation was estimated histochemically (number of alkaline phosphatase positive Obl colonies, and number of TRAP-positive Ocl-like cells), and according to the expression of Obl (Runx2, alkaline phosphatase, osteocalcin and osteoprotegerin) and Ocl (RANK, calcitonine receptor) differentiation genes.

Our results showed that after four weeks, gene expression of Fas was increased in bone and mature Obl cultures from ovx (0.36 \pm 0.06 and 2.6 \pm 0.05 respectively) compared to sham operated animals (0.31 \pm 0.01 and 1.8 \pm 0.76, p<0.05). A mild decrease in Fas expression was also observed in the Ocl cultures from ovx animals. Trabecular bone volume was generally significantly higher in Fas^{-/-} mice (p=0.01, t-test) than in wild-type controls. Furthermore, trabecular volume significantly decreased in wild-type mice four weeks after ovx (p=0.01, t-test), and remained unaltered in Fas^{-/-} mice (p=0.67, t-test). Mean number of TRAP-positive Ocl on bone surface of wild-type mice increased four weeks after ovx (p=0.03), whereas this number was unchanged in Fas^{-/-} mice (p=0.27). OvX also significantly increased osteoclastogenesis in vitro in wild-type animals but this effect was absent in Fas^{-/-} mice. Osteoblastogenesis in vitro was stimulated by ovx in both animal strains, but this effect was more pronounced in Fas^{-/-} mice. Obl differentiation genes were had similar expression patterns in sham operated and ovx mice, although Fas^{-/-} mice Obls generally had higher expression levels of Obl differentiation genes compared to wild-type controls. Our findings point to the conclusion that Fas/Fas ligand system may have an important role in the pathogenesis of postmenopausal osteoporosis and modulation of its effects on bone cells may contribute to the development of new strategies for osteoporosis treatment.

Osterix as a Regulator of Bone Formation and Maintenance. J. Kim¹, W. Baek^{*1}, M. Lee^{*1}, H. Akiyama^{*2}, Z. Zhang^{*3}, B. de Crombrughe³. ¹Department of Molecular Medicine, Kyungpook National University School of Medicine, Daegu, Republic of Korea, ²Department of Orthopaedics, Kyoto University, Kyoto, Japan, ³Department of Molecular Genetics, University of Texas M. D. Anderson Cancer Center, Houston, TX, USA.

Osterix (Osx) is a zinc-finger containing transcription factor which is essential for osteoblast differentiation and bone formation. Osx null mutant by gene targeting shows a complete absence of intramembranous and endochondral bone formation. Disruption of Osx has led to perinatal lethality, hence preventing the study for the importance of Osx in bones that are developing or formed. Here, we examined the role of Osx in developing bones after bone collar formation using the time-specific and site-specific Cre/loxP system. Osx was inactivated in osteoblasts by Col1a1-Cre with the activity of Cre recombinase under the control of 2.3-kb collagen promoter. Low bone mass was observed in mouse bones at the age of 2 months. Bone forming rate by Calcein double labeling was shown a remarkable reduction, while single labeling surface was increased in endosteum and trabecular of mouse lumbar. The analysis of Deoxyypyridinoline (DPD) crosslinks in the urine, which reflects osteoclast activity in vivo, was not significantly changed in Osx-inactivated mice. These results demonstrated that Osx inactivation decreased the function of osteoblasts to synthesize and regulate the deposition and mineralization of bone extracellular matrix, whereas it was not affected to osteoclast differentiation and activity in vivo. We also studied the role of Osx in intact bones after birth by generating Osx inactivation in osteoblasts using inducible Cre system. Bone volume was decreased and bone forming rate was reduced in mice which Osx was inactivated in osteoblasts of already formed bones after birth by 4-OHT administration. Thus, this study suggests that Osx plays a significant role in regulating bone formation and maintenance. To better understand the role of Osx in cellular mechanisms, we are investigating the interrelation between osteoblasts and osteoclasts derived from Osx-inactivated mice.

Overexpression of Osteoblast Specific Angiopoietin1 Increases Bone Mass. T. Suzuki^{*1}, T. Miyamoto², N. Fujita^{*3}, M. Yagi^{*3}, K. Ninomiya^{*1}, R. Iwasaki^{*4}, Y. Toyama^{*3}, T. Suda^{*3}. ¹Cell Differentiation and Orthopaedics Surgery, Keio University, Tokyo, Japan, ²Orthopaedics Surgery and Musculoskeletal Reconstruction and Regeneration Surgery, Keio University, Tokyo, Japan, ³Orthopaedics Surgery, Keio University, Tokyo, Japan, ⁴Department of Dentistry and Oral Surgery, Keio University, Tokyo, Japan, ⁵Cell Differentiation, Keio University, Tokyo, Japan.

Angiogenesis has been considered to play an important role in the bone formation. However, relationship between angiogenesis and bone formation is poorly understood. Angiopoietin1 (Angpt1) is an essential molecule of angiogenesis, is expressed in osteoblasts. To understand the effect of Angpt1 on bone formation in vivo, we generated a transgenic mouse overexpressing Angpt1 in osteoblasts under the control of mouse 2.3kb alpha 1 collagen promoter. 51 lines of offspring were generated by the embryo microinjection. The presence of the transgene in the offsprings was tested by PCR of tail DNA using transgene specific primers. 16 transgenic founder lines were established by mating founders with C57/BL6 wild type mice. Angpt1 expression was confirmed by RT-PCR with mRNA extracted from long bones, and Western blotting with protein extracted from calvaria. CD31-positive endothelial cells were increased in tibial trabecular area of 6-weeks-old Angpt1 transgenic mice compared with wild-type controls. Microcomputed tomography analysis showed that bone mineral density and bone volume/total volume were significantly increased, while trabecular spacing was significantly decreased in 8-weeks-old Angpt1 transgenic mice compared with wild-type controls. Immunohistochemistry using alkaline phosphatase (ALP) antibody showed increase of ALP activity in femoral trabecular area of 8-weeks-old Angpt1 transgenic mice compared with wild-type controls. Furthermore, tartrate resistant acid phosphatase (TRAP) staining showed TRAP activity of 8-weeks-old transgenic mice femoral trabecular area is higher than wild-type controls. Overall, these data showed that Angpt1 overexpression in osteoblasts induced angiogenesis of the trabecular area, which results in increased bone mass in vivo.

Marrow Adipogenesis and Osteoblastogenesis Reflect Global Energy Utilization Through Activation of PPARG and Modulation by 'Clock' Genes in a Genotype Specific Manner. C. L. Ackert-Bicknell¹, V. E. DeMambro¹, M. L. Bouxsein², M. C. Horowitz³, E. Canalis⁴, C. J. Rosen¹. The Jackson Laboratory, Bar Harbor, ME, USA, ²Beth Israel Deaconess Medical Center, Boston, ME, USA, ³Yale University School of Medicine, New Haven, CT, USA, ⁴St. Francis Hospital and Medical Center, Hartford, CT, USA.

The relationship between marrow adipogenesis and bone formation is critical for understanding osteoporosis. We generated a congenic mouse (6T) with C3H alleles from a QTL on mouse Chr 6 introgressed on a 99.5% C57BL/6J(B6) background. 6T have reduced BMD, impaired osteoblast(OB) differentiation, more marrow adiposity, but low body temp, and unresponsiveness (i.e. thermal output) to stimulation by a $\beta 3$ agonist. An inversion in C3H, and polymorphisms in genes at the break point [115.38-116.38 Mb between Pparg and Alox5], prompted us to hypothesize that genes in this region influence OB and adipocyte(Ad) function. To test this, we fed 3 wk B6 and 6T mice an 11%(LF) or 60% fat(HF) diet for 13 wks and studied metabolic and skeletal parameters. On a HF diet, B6 gained wt and became insulin resistant with no change in BV/TV by μ CT, while 6T showed no change in wt or insulin secretion, but lost trabecular bone ($p<0.001$ vs B6). Histomorphometry comparing HF to LF diets revealed that B6 had suppressed bone formation, reduced osteoclast #, increased marrow Ads (2.1 fold higher), but no change in BV/TV. In contrast 6T on HF had a 1.5 fold increase in OB#, but no change in Ad #, despite a 30% reduction in BV/TV. Expression profiling (using a 2x2 statistical design:genotype x diet)revealed that 21 genes were differentially regulated in liver; and 64 in bone (marrow+bone). Most were histones, but in 6T liver on HF, Ccrn4l (a 'clock' gene) was 2 fold up-regulated; $p=1.0 \times 10^{-6}$, while in 6T bone, uncoupling protein-1(Ucp-1) was increased nearly 3 fold $p=1.0 \times 10^{-6}$. 2 candidate genes within the 1Mb region on Chr 6 were suppressed in 6T bone on the HF diet: March 8, a membrane protein ($p<0.0005$, vs B6) and Raf1 ($p<0.007$ vs B6). In the liver, two downstream targets of Pparg, Fasn, and Srebp, as well as ephrinA1 and SOCS-2, were increased by a HF diet in 6T ($p<0.05$ vs B6). In summary, we found genotype-specific skeletal and marrow responses to HF. In 6T, HF caused bone loss despite recruitment of more OBs, but in B6, even with marrow adipogenesis, and a reduced bone formation rate, BV/TV was preserved. Expression profiles demonstrated that a HF diet activated Pparg in a strain-specific manner, likely through recruitment of co-activators that differentially influenced Ad and OB function. In 6T, greater UCP-1 expression (a marker of brown fat), and enhanced insulin sensitivity imply distinct physiologic roles for marrow fat (i.e. energy use:6T vs storage: B6) influenced by Chr 6 genes and modulated by 'clock' proteins.

Osterix Mediates Mesenchymal Progenitor Cell Differentiation into Osteoblasts Downstream of PTH During Bone Repair. L. A. Kaback*, Y. Jiang*, A. Naik*, C. Hock*, E. M. Schwarz, S. Bukata, R. J. O'Keefe, H. Drissi. Orthopaedics, University of Rochester, Rochester, NY, USA.

We investigated the mechanisms underlying the effects of PTH on bone repair. We hypothesize that PTH accelerates fracture healing through induction of the zinc finger transcription factor Osterix (Osx), thereby inducing mesenchymal stem cell (MSC) commitment towards osteogenesis. Our real time RT-PCR data show that Osx transcripts are up-regulated upon intermittent PTH treatment of osteoblast progenitors 24, 36 and 72 hours in culture compared to untreated controls, concomitant with that of osteoblast phenotypic genes. Continuous PTH treatment strongly inhibits Osx mRNA levels and osteoblast markers at all time points. Daily injections of mice with the anabolic PTH drug, Forteo, or saline for up to 14 days was performed. Bone marrow derived MSCs cultured from Forteo treated and control mice revealed accelerated osteoblast maturation with increased alkaline phosphatase and Von Kossa staining. Analyses of RNA extracted from these MSCs shows that Osx expression in marrow cultures from Forteo treated mice was dramatically up-regulated compared to control samples. Furthermore, Runx2 levels were also up-regulated in the Forteo treated samples along with markers of osteoblast differentiation. Together, these results indicate that in vivo treatment with Forteo mimics the anabolic effects of PTH observed in vitro. The cellular distribution of Osx during fracture repair was determined immunohistochemically in response to Forteo. Our results show that after 7 days of Forteo exposure, Osx protein is maintained in the periosteal cells and confined in the immature chondrocytes while absent from the hypertrophic chondrocytes in the fracture callus. By 10 to 14 days post-fracture, Osx persists in mesenchymal progenitor cells as well as in the immature chondrocytes, and in osteoblasts embedded in the newly formed bone in the control calluses. However, this representation of Osx is intensified in the Forteo treated animals. We harvested RNA from fracture callus of mice treated or not with Forteo. Our real time RT-PCR data show a progressive induction of Osx transcripts which becomes maximal after 10 days of treatment, but is down-regulated 14 and 21 days post-fracture. Additionally, while Runx2 regulation parallels that of Osx in these calluses, type I collagen and osteocalcin continue to be up-regulated 14 days post-fracture. Together, our results suggest that PTH may accelerate fracture repair through MSC differentiation into mature osteoblasts in response to Osx enhanced expression. Signaling and transcriptional mechanisms behind this PTH mediated regulation of Osx is currently under investigation.

Analysis of Krox20 Gene Regulation Reveals Srf Function in Bone and Cooperation with NFAT1. M. Frain^{*1}, A. Nordheim^{*2}, P. Charnay^{*1}. ¹Ecole Normale Supérieure, Inserm U 784, Paris, France, ²Department of Molecular Biology, Tuebingen University, Institute of Cell Biology, Tuebingen, Germany.

The Krox20 gene encodes a zinc finger transcription factor that plays a key role in regulating bone formation. We have shown that Krox20 is expressed in a subpopulation of growth plate hypertrophic chondrocytes and in differentiating osteoblasts and that Krox20 conditional knockout mice develop severe osteopenia.

To investigate the mechanisms of Krox20 transcriptional regulation in bone, we have used a transgenic mice approach and identified a bone-specific enhancer in the 5' flanking region of the mouse Krox20 gene which spans 860 bp and recapitulates Krox20 expression during bone development. Combining phylogenetic footprinting analyses and in vitro and in vivo experiments, we have defined three types of regulatory elements within the enhancer: Krox20 binding sites involved in a direct positive autoregulatory loop, Runx2 binding sites modulating Krox20 expression and a 13 bp A/T rich essential for Krox20 activation in both osteogenic and chondrogenic cells. This key regulatory element is conserved among vertebrates and contains partially overlapping canonical binding sites for two transcription factors: Srf (Serum Response Factor) and NFAT (Nuclear Factor of Activated T-cells) known to control several developmental processes. Gel-shift, transfection experiments and mutational analyses have shown that Srf and NFAT1/c2 are both required for initiation of Krox20 expression in the two bone-forming cells. Our data are consistent with recent studies showing that NFAT1 controls endochondral bone formation (Koga et al, Nat Med 8, 880-5, 2005). We have pursued our studies by establishing Srf spatio-temporal expression pattern in the developing bone. We have found that Srf is expressed in hypertrophic chondrocytes and in differentiating osteoblasts and precedes Krox20 activation in these cell types. To genetically establish that Srf lies upstream of Krox20 in the regulatory cascade, we have created a Srf conditional mutant inactivating Srf in hypertrophic chondrocytes and differentiating osteoblasts. We have found that the Srf conditional mutant shows a reduced level of Krox20 expression in the developing bone.

Altogether, our studies demonstrate that Srf and NFAT1 constitute upstream regulators of Krox20 in bone and highlight a novel role for Srf in regulating skeletogenesis.

Role of Dlx3 in Bone: Study of Inducible Cre Mediated Dlx3 Inactivation in Mice. M. Islam^{*1}, X. Jiang^{*1}, H. Li^{*1}, M. S. Kronenberg^{*1}, D. J. Adams^{*1}, M. M. Morasso^{*2}, A. C. Lichtler¹. ¹University of Connecticut Health Center, Farmington, CT, USA, ²NIAMS, National Institute of Health, Bethesda, MD, USA.

Dlx3 is a member of Dlx family of transcription factors. Trichodonto osseous dysplasia, a human genetic anomaly, is caused by mutation of Dlx3 gene. This condition has distinct bone findings, which suggests that Dlx3 has a role in bone formation and metabolism. Studies in our lab also show that Dlx3 is highly expressed in mature osteoblast and osteocytes. Universal knock out of the gene causes embryonic lethality, so we have created a bone specific Dlx3 null mice using cre-LoxP recombination. We have used a transgenic mouse model in which a 3.6 kb type I collagen promoter drives constitutive or tamoxifen inducible (CreERT2) cre. In the constitutive model, cre is active in multiple tissues including bone, skin and tendon, and sometime in early embryonic development. Because of this lack of specificity, we focused on inducible cre mediated floxed Dlx3 knockout mouse model. Here the cre transgene is fused to a mutated estrogen receptor gene. Although cre activity in this model should require tamoxifen; we found that inducible cre transgenic mice show strong bone specific cre activity without tamoxifen in vivo and in calvarial osteoblast (mCOB) and bone marrow stromal cell (BMSC) cultures. Dlx3 mutant mice show distinct trabecular and cortical bone changes. In a microCT study of femur, there was a trend of increase bone volume fraction (BV/TV) and trabecular number while trabecular spacing and thickness was decreased in the mutant mice compared to age matched controls. Femoral cortical bone in microCT showed a trend of age related increase in cortical porosity in the mutant mice starting at 3 weeks of age. In histological bone sections it appeared that there were more osteocytes in the femoral cortical bone. Dynamic histomorphometry did not show a difference in mineral apposition rate (MAR), but did show a significant decrease of mineralized surface in the trabecular compartment of mutant mice. Expression of bone marker genes is currently being studied. We believe that Dlx3 plays a role towards the end stages osteoblast differentiation pathway, hence downstream to Runx2 and osterix transcription factors.

OASIS, an Endoplasmic Reticulum Stress Transducer, Is Involved in Normal Bone Formation. T. Murakami¹, S. Kanemoto^{*1}, S. Kondo^{*1}, A. Wanaka^{*2}, K. Imaizumi^{*1}. ¹Division of Molecular and Cellular Biology, Department of Anatomy, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan, ²Department of Anatomy and Neuroscience, Nara Medical University, Nara, Japan.

OASIS (Old Astrocyte Specifically Induced Substance) is a basic leucine zipper (bZIP) transcription factor of the CREB/ATF family with a transmembrane domain that allows it to associate with the ER. In our previous report, we identified OASIS as a novel endoplasmic reticulum (ER) stress transducer in astrocytes. The molecule is cleaved at the membrane in response to ER stress, and its cleaved amino-terminal cytoplasmic domain, which contains the bZIP domain, translocates into the nucleus where it activates the transcription of target genes such as GRP78/BiP. To assess the role of OASIS in vivo, we generated OASIS knockout mice. OASIS^{-/-} mice were viable, but exhibited growth retardation. In macroscopic observation on OASIS^{-/-} mice, they exhibited deformity of limb bones and swellings in joint. Analysis of in situ hybridization showed that OASIS mRNA was detected not only in astrocytes but also in bones. From the results of histopathological examination of osseous tissues, OASIS deficiency resulted in abnormal bone formation with significant loss of bone mass. Electron microscopic analysis indicated the expansion of rough ER and accumulation of a large amount of secreted materials in the ER lumen in OASIS^{-/-} osteoblast. In contrast, none of the structural changes were observed in osteocytes, osteoclasts and chondrocytes. These results suggested that abnormality of bone formation in OASIS^{-/-} mice was caused by disturbance of production or secretion of bone matrix in osteoblasts. Next, we examined expression, production and secretion of bone matrix in primary osteoblast. OASIS proteins were highly expressed in primary osteoblasts. Secretion rate of osteopontin was decreased in ^{-/-} osteoblasts compared with WT, while that of osteocalcin was increased. These results showed that OASIS^{-/-} osteoblasts were disturbed production and secretion of bone matrix. Taken together, these findings indicate that OASIS is required for normal bone formation and its deficiency causes osteogenesis imperfecta.

Identification of a Novel Wnt/ β -Catenin Response Element in the Osteoprotegerin Gene Promoter and its Regulation with Bone Morphogenetic Protein-2 Signaling. M. Sato^{*1}, A. Nakashima^{*1}, M. Nashimoto^{*2}, A. Ishisaki^{*1}, Y. Yawaka^{*3}, M. Tamura¹. ¹Biochemistry and Molecular Biology, Grad. Sch. Dent. Med., Hokkaido University, Sapporo, Japan, ²Department of Applied Life Sciences, NUPALS, Niigata, Japan, ³Dentistry for Children and Disabled Person, Grad. Sch. Dent. Med., Hokkaido University, Sapporo, Japan.

Wnt/ β -catenin signaling plays a role in the developing skeletal system. However, the exact mechanisms by which Wnt/ β -catenin signaling regulates bone remodeling remain to be elucidated. Our previous studies demonstrated that an interaction between β -catenin and Smad was crucial for Wnt-mediated regulation of the BMP-2 responsive gene expression, and that BMP-2 up-regulated Wnt-induced lymphoid enhancing factor 1/T cell factor (Lef1/Tcf)-dependent TopFlash transcriptional activity in the C2C12 cell line. Also, Wnt/ β -catenin signaling regulates expression of osteoprotegerin (OPG) and receptor activator of NF κ B ligand (RANKL) in osteoblasts. In this study, we investigated the mechanism of how OPG expression is induced by Wnt/ β -catenin signaling in osteoblasts. OPG expression was induced by over-expression of Wnt3a or activated β -catenin in mesenchymal pluripotent C2C12 cells or osteoblastic MC3T3-E1 cells. In these cultures, BMP-2 synergistically enhanced OPG expression. Silencing of glycogen synthase kinase-3 β by siRNA or sgRNA (tRNAseZL-utilizing gene silencing method) also increased OPG levels in the culture supernatant from C2C12 cells estimated by ELISA assay. To investigate the mechanisms of the Wnt/ β -catenin signaling activated OPG gene transcription, we have cloned an approximately 1.5-kilobase pair genomic DNA fragment corresponding to the 5'-flanking promoter region of the murine OPG gene. Activated β -catenin results in a 10-15 fold increase in reporter gene transcription activity of the 1.5-kilobase fragment by transient transfection assay performed in C2C12 cells. Deletion analyses revealed that a proximal 253-base pair region in the promoter was required for Wnt/ β -catenin responsiveness. In this region, we identified four putative Lef1/Tcf binding sites, which meet with a consensus sequence reported to be recognized by Lef1/Tcf proteins. Using site-directed mutation analyses, functional Lef1/Tcf binding site was identified in these regions. Smad protein was involved and interacted with the Wnt/ β -catenin responsive element on the OPG promoter in response to BMP-2 stimulation. A chromatin IP assay indicated that β -catenin regulates transcription of OPG via a promoter region at their site. These results show that OPG is a target gene for Wnt/ β -catenin signaling and that its induction is mediated by a novel Wnt/ β -catenin response element of the OPG gene promoter.

Expression of a Hypomorphic Allele of FIAT (Factor Inhibiting ATF4-mediated Transcription) Improves Long Bone Mechanical Properties. V. W. C. Yu^{*}, R. St-Arnaud. Genetics Unit, Shriners Hospital for Children, Montreal, PQ, Canada.

We have recently cloned and characterized FIAT, a 66 kDa leucine zipper protein that dimerizes with the basic domain-leucine zipper transcription factor ATF4 to form inactive dimers that cannot bind DNA. Overexpression of FIAT in osteoblasts of transgenic mice inhibited osteocalcin gene transcription and reduced osteoblastic activity, leading to osteopenia (J Cell Biol 169: 591; 2005). Reciprocally, inhibition of FIAT expression in osteoblasts, using siRNA technology, results in a higher transcriptional activity from the osteocalcin promoter, augmented collagen type I secretion, and enhanced mineralization. Together, these results support the role of FIAT in regulating ATF4 activity in osteoblasts and confirm the importance of FIAT in the modulation of osteoblast activity. To further assess the physiological role of FIAT, we have used the technique of homologous recombination in ES cells to engineer an allele of FIAT in which the first exon, containing the translational start site, was flanked by lox P sites. Mice carrying the floxed FIAT allele were crossed to transgenic mice expressing the Cre recombinase under the control of the collagen type I promoter (Col I-Cre) for osteoblast-specific inactivation. Since the FIAT gene maps to the X chromosome, initial characterization of the mutant phenotype was performed in Col I-Cre;FIAT^{Y/f} male mice. Mutant mice showed only 20% reduction of FIAT expression as measured by RT-qPCR, suggesting that we have engineered a hypomorphic allele and not a true null. The reduction in FIAT expression was statistically significant, however. Despite this moderate reduction in FIAT mRNA levels, the mutant mice showed significantly increased osteocalcin gene transcription and a trend towards increased bone volume. When the biomechanical properties of the mutant bones were tested using three-point bending, we measured significant increases in ultimate force and work to failure. These results show that even a small reduction in FIAT expression significantly improves long bone mechanical properties and suggest that FIAT represents an interesting target for therapeutic intervention to increase bone strength in osteoporotic patients.

Mechanical Loading Induced Wnt/ β -catenin Signaling Is Compromised in ER α -/- Mouse Tibia- In Vivo Microarray Analysis. G. Zaman^{*}, L. K. Saxon, M. Muzylak^{*}, J. S. Price, L. E. Lanyon. Basic Sciences, The Royal Veterinary College, London, United Kingdom.

Postmenopausal osteoporosis represents a failure of bone cells to adapt bone mass and architecture to withstand loading without fracture. A number of studies have shown that the adaptive response of bone to mechanical loading is deficient in the absence of estrogen receptor associated with estrogen deficiency. Wnt/ β -catenin signalling is one of the pathways shown to regulate bone formation during growth and in response to mechanical load.

In order to identify the genes and signal pathways responsible for the loading-related osteogenic response, we used the RNG-MRC 25k mouse microarray analysis to compare differential gene expression in the right and left (loaded, 12N at 2Hz for 60 cycles and not loaded) tibiae of WT and ER α -/- mice after a single period of dynamic axial loading. This transient exposure to dynamic strain change has been shown to produce an osteogenic response in mice.

RNA was extracted at 3, 8, 12 and 24 hours after loading from control and loaded tibiae. In WT mice there were 663, 539, 173 and 33 differentially regulated genes at 3, 8, 12 and 24 hours respectively after loading. Lists of differentially regulated genes were loaded into Ingenuity Pathways Analysis software. Canonical pathway analysis of the sets of genes differentially regulated showed that a number of catabolic and anabolic pathways were affected. Six genes previously reported to be involved in the Wnt/ β -catenin pathway (WNT2B, FZD2, GNAQ, PPP2R3A, CREBBP, RAR γ) were differentially expressed in loaded versus control bones 3 hours after treatment (expression of 10 genes changing over a period of 24 hours). This differential expression was less evident at 8 and 12 hours after loading and returned to the levels observed in the contra-lateral control limb 24 hours after treatment.

In ER α -/- mice the number of differentially regulated genes was much lower at each time point after loading (17, 122 and 8 genes at 3, 8 and 24 hours respectively). Only one Wnt/ β -catenin related gene (RAR γ) in ER α -/- mice showed a change in its expression between loaded and control bones at 3 hours and none at 24 hours. The gene expression profile in response to mechanical loading in WT mice confirms the regulation of a number of genes involved in Wnt/ β -catenin signalling. The reduction in the number of Wnt/ β -catenin-related genes differentially regulated by loading in the absence of ER α suggests a role for ER α in early loading-related activation of the Wnt/ β -catenin signalling in bone cells. Diminished effectiveness of loading-related Wnt/ β -catenin activity due to reduced ER α activity, as would occur with estrogen deficiency, may contribute to less effective control of structurally appropriate bone mass in osteoporosis in both men and women.

Prostaglandin E₂ (PGE₂) Increases a Specific Subset of Primitive Hematopoietic Cells In Vivo. B. J. Frisch*, B. J. Gigliotti*, J. M. Weber*, R. J. O'Keefe, C. T. Jordan*, L. M. Calvi. University of Rochester School of Medicine, Rochester, NY, USA.

Parathyroid Hormone (PTH) stimulates osteoblastic cells (OBs) in the bone marrow (BM) microenvironment, expanding hematopoietic stem cells (HSCs) through activation of the Notch receptor. Similarly, we previously demonstrated that PGE₂ increases the Notch ligand Jagged1 in OBs, and does so through Protein Kinase A (PKA) activation. Therefore, we hypothesized that PGE₂ could also expand HSC in vivo. To test whether PGE₂ regulates HSC, we treated mice with intermittent intraperitoneal PGE₂ or vehicle. Several schedules were tested to maximize the PGE₂ effect on the HSC-enriched lineage-Sca-1+ c-kit+ (LSK) cells in BM. At the end of each treatment, peripheral blood (PB) was analyzed and mice were euthanized (n=8 mice per treatment group). BM was harvested from one of the hindlimbs, while the contralateral limb was fixed for microCT and histologic analysis. Flow cytometric analysis demonstrated a time and dose dependent increase in BM LSK, which was maximal at day 16 with bid PGE₂ vs vehicle (0.11 vs 0.04% BM mononuclear cells, P=0.0061). At this dose, there was no significant PGE₂-dependent bone anabolic effect either histologically or by micro-CT. Maximal LSK expansion was superior to PTH-dependent HSC stimulation (approximately 350 vs 100% increase in LSK). When the more mature hematopoietic progenitor population was quantified using the CFU-C assay in vitro, there was no difference between PGE₂- and vehicle-treated animals. Similarly, there were no significant PGE₂ effects on Hct, Plts or WBC counts compared to vehicle. Therefore PGE₂-dependent cell expansion was not global across differentiated subsets, but was restricted to primitive hematopoietic cells, similar to the effects of PTH in vivo. Competitive transplantation of irradiated recipients was then performed to assess the engraftment, proliferation, and self-renewal properties which define HSC. Cells derived from PGE₂-treated mice demonstrated superior contribution to all hematopoietic lineages at 3 weeks after transplantation (33.3 vs 23.5% PB mononuclear cells, P=0.0045), but this increase was not persistent at 12 weeks. This surprising result suggests that PGE₂ selectively expands a subpopulation of HSC, the short-term HSCs (or ST-HSCs), which have highly proliferative properties, but limited self-renewal. Further studies will determine if this effect is mediated by osteoblastic Jagged1 or by other niche components. This finding implicates for the first time the existence of specialized niches regulating subsets of HSC. These novel data therefore increase our understanding of the HSC niche, which could be exploited clinically for specifically targeted ST-HSC expansion.

Cell Cooperation Between Human OsteoProgenitor Cells and Endothelial Cells in Tissue Engineering. M. Grellier*, C. Bourget*, R. Bareille*, P. L. Granja*, M. A. Barbosa*, J. Amédée*. INSERM U577 - University V. Segalen Bordeaux 2, Bordeaux, France, ²INEB - Instituto de Engenharia Biomédica - University of Porto, Porto, Portugal.

Bone is a dynamic tissue that constantly undergoes remodelling which requires interactions between bone cells. However, the intimate association of the vascular endothelium with osteogenic cells appears necessary to modulate bone formation and degradation balance. The purpose of this work is to study the cell communication between osteoblast and endothelial cells before to apply this strategy for bone tissue engineering. To investigate that, Human OsteoProgenitor (HOP) and Human Umbilical Vein Endothelial Cells (HUVEC) were co-cultured in direct contact and compared to isolated cultures. We analysed the regulation of cell communication, studying the expression of Connexin 43 and VE-cadherin, by Quantitative-PCR and the localization of beta-catenin, by immunostaining. We investigated genes involved in extracellular matrix organisation (ECM) such as MMP-1, TIMP-1, VEGF and TGFbeta-1. We followed cell migration by time lapse. We used an extrusion system to encapsulate cells inside beads of alginate. After 24 hours of co-culture, HOP and HUVEC form specific multicellular networks which suggest an ECM reorganisation and cell migration. The expression of Connexin 43 is up-regulated while VE-cadherin expression is down regulated in co-culture compared to HUVEC culture. We observed a modification of the beta-catenin distribution when cells are in direct contact: beta-catenin is cytoplasmic in HOP culture and localised to the membrane after 6 hours of co-culture while its expression, analysed by western blot, was unchanged. MMP1 and TIMP1 results suggest that the co-culture could enhance a production of an ECM and both VEGF and TGFbeta-1 are upregulated in co-culture. We observed by time lapse that HUVEC are able to migrate through HOP filopodes. These results suggest that ECM remodelling occurred when endothelial and osteoblastic cells are in direct contact. This mechanism could be due either to a regulation of cell communication between HOP and HUVEC or/and to a production of growth factors involved in cell migration and ECM remodelling. A better knowledge of this cell to cell cross-talk will be helpful for the development of a vascularised bone tissue for tissue engineering. Preliminary data obtained using alginate microspheres revealed that these cells entrapped inside such beads are still able to proliferate after one week of culture and their implantation into a critical size bone defect allows us to evaluate this newly bone regeneration strategy.

Progressive Ankylosis Gene (ank) Regulates Osteoblast Differentiation. T. Kirsch¹, H. Kim¹, J. A. Winkles². ¹Orthopaedics, University of Maryland School of Medicine, Baltimore, MD, USA, ²Surgery, University of Maryland School of Medicine, Baltimore, MD, USA.

The progressive ankylosis gene (ank) is a transmembrane protein that transports intracellular pyrophosphate (PP_i) to the extracellular milieu. Human mutations of ank lead to craniometaphyseal dysplasia (CMD), a disease, which is characterized by the overgrowth of craniofacial and long bones, suggesting that Ank plays a role in the regulation of osteoblast differentiation. To determine the role of Ank in osteoblast differentiation, we suppressed Ank expression in osteoblastic MC3T3 cells using siRNA or studied the osteoblastic differentiation of bone marrow stromal cells isolated from the bone marrow of ank/ank mice, which express a truncated, non-functional Ank protein, or wild type littermates. MC3T3 cells mineralized within 20 days after the addition of vitamin C and β-glycerolphosphate. Ank gene and protein expression in these cells was the highest at 3 days and declined afterwards, whereas alkaline phosphatase (APase) expression and activity increased on day 8 and was the highest between day 17 and day 20. Suppression of Ank expression in MC3T3 cells using siRNA led to a decrease of APase expression and activity. Suppression of Ank expression in these cells also resulted in a decrease of the expression of bone-related genes, including type I collagen, bone sialoprotein, and osteocalcin. In addition, the expression of the transcription factor osterix was downregulated in Ank expression suppressed MC3T3 cells, whereas runx 2 expression in these cells was upregulated. Bone marrow stromal cells isolated from bone marrow of ank/ank mice and wild type littermates were cultured in the presence of 100 μg/ml ascorbate phosphate for various days and analyzed by staining for APase enzyme activity and van Kossa to determine mineralized colonies. The number of APase activity positive and van Kossa stained colonies was markedly reduced in bone marrow stromal cell cultures from ank/ank mice compared to the number of APase activity and van Kossa positive colonies in bone marrow stromal cell cultures from wild type littermates. These findings suggest that Ank is a positive regulator of differentiation events towards a mature osteoblastic phenotype and Ank appears to act upstream of osterix. Loss of Ank function in osteoblastic precursor cells results in an arrest of cells in a premature osteoblastic stage, in which they express high levels of runx2 and low levels of osterix.

Wnt5A Signals Through Ror2 to Promote Osteoblastogenesis. Y. Liu, B. Rubin*, P. V. N. Bodine, J. Billiard. Women's Health and Musculoskeletal Biology, Wyeth Research, Collegeville, PA, USA.

Wnts are a large family of growth factors that regulate important cellular events by signaling through both canonical/beta-catenin pathway and non-canonical pathways. While activation of canonical Wnt signaling has been implicated in osteoblast physiology, very little is known about the role of non-canonical pathways in osteoblasts. Ror2 is an orphan receptor tyrosine kinase that induces osteogenic commitment and differentiation of pluripotent mesenchymal stem cells (MSCs). We and others have shown that both canonical and non-canonical Wnts bind Ror2, but their ability to activate Ror2 signaling has not been examined. Here we tested if canonical or non-canonical Wnts induce downstream signaling of the Ror2 receptor and lead to increased osteogenesis. We used purified recombinant non-canonical Wnt5A and canonical Wnt3A that bound Ror2 equally well in pull-down assays. We found that Wnt5A, but not Wnt3A, induced homo-dimerization of Ror2 and stimulated tyrosine phosphorylation of the Ror2 substrate 14-3-3β scaffold protein. Treatment of pluripotent human MSCs with Wnt5A dose-dependently induced formation of the mineralized extracellular matrix, which is the ultimate phenotype of an osteogenic tissue. Down-regulation of Ror2 expression by short hairpin RNA greatly inhibited Wnt5A-induced mineralization, indicating that Wnt5A effect is mediated at least in part through activation of the Ror2 receptor. Finally, using mouse calvarial ex vivo organ culture model, we demonstrated that treatment with Wnt5A results in significantly increased bone formation in this complex system.

In summary, we identify Wnt5A as the ligand that activates the Ror2 receptor tyrosine kinase signaling pathway and promotes osteogenic commitment and differentiation of pluripotent stem cells.

Growth Inhibition of Osteoblast Progenitors by Runx2 Depends on Its C-Terminal Regulatory Domain and Is Accompanied by Changes in G-Protein Coupled Signaling Pathways. N. Teplyuk, M. Galindo*, V. Teplyuk*, D. W. Young*, D. Lapointe*, M. van der Deen*, J. Pratap, S. K. Zaidi*, A. Javed, J. L. Stein*, J. B. Lian, G. S. Stein, A. J. van Wijnen. Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA.

The runt-related transcription factor Runx2 mediates osteogenic cell fate determination, as well as stimulates anabolic activities and inhibits the proliferative potential of osteoblasts. The levels of Runx2 change during the cell division cycle, and preferential expression of Runx2 in G1 may control the responsiveness of osteoblasts to extracellular signals that influence commitment to enter a new proliferative cycle. Runx2 elicits biological responses in osteoblasts by acting as the end-point effector of multiple signaling axes, including the Src/Yes-Yap, TGF β /BMP-Smad and CDK-cyclin pathways, which each converge at nuclear matrix-associated transcriptional sites. Here we addressed what functions of Runx2 protein are required for cell growth suppression, and what genes are regulated by Runx2 to control osteoblast growth. We first examined the biological phenotypes of osteoblastic progenitors upon introduction of Runx2 proteins with mutations that affect interactions with co-factors that transduce cell signals and/or control transcriptional activation or repression. These Runx2 point mutants were introduced into Runx2 null mouse calvarial cells using adenoviral vectors that permit efficient transient expression of Runx2 proteins. Wild type Runx2 or point mutants that can not interact with Yap or Smad or the nuclear matrix each inhibit growth of Runx2 null cells. Thus, several key signaling pathways are dispensable for growth suppression by Runx2. A point mutation in the runt-homology DNA binding domain establishes that cell growth control requires direct regulation of putative Runx2 target genes. Deletion of the C-terminal VWRPY repressor domain reduces but does not abolish growth suppressive potential indicating that both gene activation and repression contribute to the anti-proliferative effect of Runx2. Affymetrix gene expression profiling shows that the C-terminus of Runx2 is required for the induction of its classical targets (e.g., osteocalcin, osteopontin, MMP13), but also a number of genes involved in cell cycle related pathways, including multiple components of G-protein coupled receptor signaling. Because defects in Gs-signaling have been linked to fibrous dysplasia (FD), our data suggest that Runx2 may contribute to the hyper-proliferation of mesenchymal cells characteristic of FD.

Regulation of Osteoblast Differentiation by MicroRNA. H. Inose¹, S. Takeda², A. Kimura^{*2}, S. Sato^{*1}, K. Shinomiya^{*1}. ¹Department of Orthopaedics, Tokyo Medical and Dental University, Tokyo, Japan, ²TICOE, Tokyo Medical and Dental University, Tokyo, Japan.

MicroRNAs (miRNA) regulate the expression of genes by binding and modulating the translation of specific mRNAs. They have been shown to be critical in the development of organisms and cell proliferation. However, their role in osteoblast differentiation remains to be elucidated. In this study, we aimed to identify miRNAs expressed in osteoblasts and investigate their role in osteoblast differentiation. C2C12 cells were induced to differentiate into osteoblasts by BMP2 treatment. Using miRNA microarray, we performed comprehensive analysis of miRNAs. Most of the known miRNAs were expressed in C2C12 cells. Among these, we focused on several miRNAs whose expression was reduced during the course of osteoblast differentiation as potential negative regulators for osteoblast differentiation. We confirmed that they were also expressed in primary osteoblasts and their expression was downregulated along differentiation. To address their physiological role, we manipulated their expression in osteoblasts and examined the effect. Indeed, forced expression of those miRNAs in primary osteoblasts significantly repressed osteoblast differentiation as demonstrated by reduced alkaline phosphatase activity and expression of osteoblastic genes. Conversely, inhibition of the activity of those miRNAs by antisense miRNA oligonucleotide promoted osteoblast differentiation. We further examined their potential target using in silico approach and verified that those candidates are, bona fide, target genes of the miRNAs by in vitro experiments. Taken together, our results suggest that miRNA is a physiological regulator of osteoblast differentiation and manipulating their activity would lead to a development of a novel therapy for increasing bone formation.

Mesenchymal Stem Cells from Aging C57BL/6 Exhibit Increased Oxidative Stress and Defective Replication: Correction of Both by Provision of an Extracellular Matrix from Young Mice. X. Chen, C. M. Skinner*, E. Ambrogini*, L. Han, M. Almeida, S. C. Manolagas, R. L. Jilka. Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. of Arkansas for Medical Sciences, Little Rock, AR, USA.

The supply of osteoblasts depends on the replication of mesenchymal stem cells (MSCs) and their commitment to the osteoblast lineage. It has been shown previously that a cell-free extracellular matrix (ECM) made by marrow stromal cells greatly increases the frequency of MSCs by promoting their replication and restraining their differentiation. And, it has been reported that age-related bone loss in C57BL/6 mice is associated with decreased osteoblast number and bone formation, as well as increased oxidative stress in the bone marrow. Here, we have examined whether aging and oxidative stress negatively impact the number and ex vivo replication of MSCs using femoral marrow cells from 3-month old (young) and 18-month old (old) female C57BL/6 mice. We report that the number of MSCs in marrow from old mice, measured by their ability to form a colony of osteoblastic cells (CFU-OB), was 5-10% lower as compared to young mice. Moreover, MSCs from old mice exhibited a replication defect during 6 days of culture on plastic, as measured subsequently upon re-plating and determination of CFU-OBs. Thus, whereas CFU-OB from young mice increased during this period by 1.8 fold, MSCs from old mice did not. As a result, the frequency of CFU-OB in the expanded population of cells from old mice was only 30% of that of young mice. In parallel cultures of marrow cells maintained for 6 days on an ECM made by marrow stromal cells from 2 month old mice, the number of CFU-OB from both young and old mice increased indistinguishably (14 \pm 2, and 16 \pm 2 fold, respectively). Further, the intracellular level of reactive oxygen species (ROS), quantified using dichlorodihydrofluorescein diacetate, was 20% higher in cultures from old mice, as compared to young, when the cultures were performed on plastic. Fascinatingly, ROS levels in cultures from young and old mice were reduced by 30% and 50%, respectively, when cells were maintained on the ECM. Consistent with these ex vivo results, oxidative stress induced by administration of buthionine sulfoxide to 6-month old C57BL/6 mice for 4 weeks reduced femoral CFU-OB number by 30-50%. Based on these findings, we hypothesize that the increased oxidative stress associated with old age exhausts a limited pool of MSC osteoblast progenitors, and that the old ECM itself, and/or the factors embedded in it, may contribute to the increased oxidative stress. Moreover, we suggest that culture of aging MSCs on an ECM may improve their number and quality, thereby optimizing the effectiveness of autologous MSC administration for therapeutic applications.

AMP-kinase Activator (AICAR) and Rho-kinase Inhibitor (hydroxyfasudil) Induce the Differentiation and Mineralization of Osteoblastic MC3T3-E1 Cells via Inhibiting the Mevalonate Pathway and Enhancing BMP-2 Expression. I. Kanazawa*, T. Yamaguchi, S. Yano, M. Yamauchi, M. Yamamoto, T. Sugimoto. Internal Medicine 1, Shimane University Faculty of Medicine, Izumo, Japan.

AMP-activated protein kinase (AMPK) and Rho kinase (ROK) have recently attracted widespread attention due to their beneficial anti-diabetic and anti-atherosclerotic effects. AMPK is known to modulate the mevalonate pathway via suppressing HMG-CoA reductase, and ROK comprises this pathway and acts in its downstream. Although the inhibition of the mevalonate pathway by statins is well known to stimulate bone formation via enhancing BMP-2 expression, the effects of AMPK activator and ROK inhibitor on bone metabolism by modulating the pathway are still unclear. We investigated the effects of pharmacological AMPK activator (5-amino-imidazole-4-carboxamide-riboside; AICAR) and ROK inhibitor (hydroxyfasudil; HF) on the differentiation and mineralization of osteoblastic MC3T3-E1 cells. AMPK activation by AICAR (0.1-0.5mM) was confirmed by Western blot. AICAR significantly stimulated ALP activity, and promoted mRNA expressions of both collagen-I and osteocalcin (OC) by real-time PCR as well as mineralization by von Kossa and Alizarin Red stainings. Moreover, AICAR significantly stimulated BMP-2 mRNA expression in dose- and time-dependent manners. Simultaneous addition of either mevalonate or geranyl-geranyl pyrophosphate (GGPP), which also comprise the mevalonate pathway and act in the downstream of HMG-CoA reductase, significantly antagonized BMP-2 and OC mRNA expressions and mineralization enhanced by AICAR. On the other hand, inhibition of ROK by HF (10-5-10-4M) also stimulated OC mRNA expression and mineralization through enhancing BMP-2 mRNA expression in dose- and time-dependent manners. In conclusion, the suppression of mevalonate pathway by AICAR and HF promoted the differentiation and mineralization of osteoblastic MC3T3-E1 cells via enhancing BMP-2 expression. Our present findings suggest that modulation of the mevalonate pathway might be useful for not only creating anti-diabetic or anti-atherosclerotic drugs but also developing new drugs promoting bone formation for the treatment of osteoporosis.

Molecular Mechanisms of Lysophosphatidic Acid-Stimulated Osteoblastic Cell Chemotaxis. S. A. Karagiosis*, L. K. Opreko*, W. B. Chrisler*, N. J. Karin. Biological Sciences Division, Pacific Northwest National Laboratory, Richland, WA, USA.

Our focus is the understanding of molecular mechanisms of lysophosphatidic acid (LPA)-induced osteoblastic cell chemotaxis. We hypothesize that LPA exerts anabolic effects on bone mass through the stimulation of pre-osteoblast migration, and that LPA is therefore a factor that supports bone repair. Osteoblast progenitor cells must migrate to injury sites where they elaborate mineralized matrix in the compromised region. LPA is released by activated platelets at the site of injury, and we have shown that this lipid factor is a potent chemotactic agent for MC3T3-E1 pre-osteoblasts [Masiello et al. (2006) Bone 39:72-82]. LPA-stimulated MC3T3-E1 cells exhibit dramatic changes in morphology and F-actin architecture, including robust stress fiber formation. We investigated the role of phosphatidylinositol-3 kinase (PI3K), which is essential in many other cells for driving the initial cytoskeletal rearrangements and cell polarization required for cell locomotion. We found a dose-dependent reduction in LPA-induced migration upon treatment with the PI3K inhibitor, LY294002. The distribution of two actin regulatory proteins, zyxin and arp2/3, was also consistent with our hypothesis. Zyxin was enriched at the newly-formed stress fibers in LPA-treated pre-osteoblasts and to focal adhesions and filopodia tips. The arp2/3 complex immunolocalized to sites of dynamic F-actin assembly in lamellipodia and filopodia. The propagation of ERK1/2 activation is required for the coordinated-migration of cells during epithelial wound healing [Matsubayashi et al. (2004) Curr. Biol. 12:731-735]. MC3T3-E1 cell ERK1/2 exhibited two waves of phosphorylation upon LPA stimulation: a rapid transient wave and a more sustained wave. Using live cell imaging of osteoblasts expressing low levels of ERK1-GFP, we observed ERK1 nuclear translocation upon LPA addition. LPA-induced cell motility was not blocked by an inhibitor of ERK1/2 activation. Additionally, we demonstrate that LPA-induced ERK1/2 activation and migration are independent of EGF receptor transactivation in osteoblasts. We conclude that PI3K-associated cytoskeletal changes, but not ERK1/2 phosphorylation or EGF receptor transactivation, are essential for LPA-stimulated MC3T3-E1 cell migration.

Proliferation and Differentiation of Periosteal Osteoblast Progenitors Are Differentially Regulated by Sex Steroids and Intermittent PTH Administration. M. Ogita, E. Dworakowski*, J. P. Bilezikian, S. Kousteni. Division of Endocrinology College of Physicians & Surgeons, Department of Medicine, Columbia University Medical Center, New York, NY, USA.

The periosteum is recognized as a homeostatic and therapeutic target for actions of sex steroids and intermittent parathyroid hormone (PTH) administration. However, the mechanisms by which estrogens suppress but androgens and PTH promote periosteal expansion are not known. In this report, we show that intermittent PTH(1-34), within 16 days of treatment, upregulates the expression and activity of alkaline phosphatase (AP) in periosteal cells isolated from the surface of murine or rat long bones. Similar to PTH, dihydrotestosterone (DHT) dose-dependently stimulates AP activity. The stimulatory action of PTH or DHT on AP activity is suppressed by inhibitors of ERKs, BMP-2 and Wnt signaling. In contrast, 17 β -estradiol (E_2) has no effect by itself; but dose-dependently attenuates PTH- or BMP-2-induced stimulation of AP expression or activity. E_2 also attenuates the stimulatory effect of PTH or BMP-2 on AP, osteocalcin, as well as Smad6 and axin2 expression in primary periosteal cells. In agreement with these in vitro observations, administration of intermittent PTH (40 ng/g) or a bone protective dose of DHT (300 ng/g) to ovariectomized adult C57BL/6 mice, induces, within 1 hour, phosphorylation of Smad1/5/8 in the periosteum as assessed by western blot analysis of femoral periosteal lysates. A replacement dose of E_2 (30 ng/g) has no effect by itself but suppresses PTH-induced phosphorylation of Smads. None of the 3 hormones affect Smad phosphorylation in trabecular bone from the femurs of the same experimental animals. In contrast to its pro-differentiating effects, PTH suppresses proliferation of primary periosteal osteoblast progenitors. E_2 , not only promotes proliferation, but attenuates the anti-proliferative effect of PTH. Finally, all 3 hormones protect periosteal osteoblasts from apoptosis induced by etoposide, TNF α or dexamethasone. These observations suggest that the different effects of sex steroids and PTH on the periosteum result from opposing actions on the recruitment of early periosteal osteoblast progenitors. Intermittent PTH and androgens promote osteoblast differentiation from periosteum-derived mesenchymal progenitors by actions that require ERK, BMP and Wnt signaling. Estrogens promote the expansion of early osteoblast progenitors but inhibit their differentiation by osteogenic agents such as PTH or BMP-2. The property of estrogens to increase periosteal osteoblast precursor number, yet retain them in an undifferentiated state may reflect actions of the hormone on a cell population distinct from that affected by PTH.

P2X7 Receptors on Osteoblasts Couple to Production of Lysophosphatidic Acid: A Novel Signaling Axis Promoting Osteogenesis. N. Panupinthu¹, J. T. Rogers¹, L. Zhao², F. Possmayer², S. M. Sims¹, S. J. Dixon¹. ¹CIHR Group in Skeletal Development and Remodeling, The University of Western Ontario, London, ON, Canada, ²Obstetrics & Gynaecology, The University of Western Ontario, London, ON, Canada.

Nucleotides are released in response to mechanical stimuli and signal through P2 receptors. P2X7 receptors are ATP-gated cation channels that, under certain conditions, induce formation of large membrane pores. Targeted disruption of the gene encoding the P2X7 receptor diminishes periosteal bone formation and impairs response of the skeleton to mechanical loading. Our goal was to investigate the pathways underlying the actions of P2X7 receptors on osteogenesis. Benzoylbenzoyl-ATP (BzATP, an agonist more potent than ATP at P2X7 receptors) induced pore formation in live cells on the surface of calvariae from wild-type (WT), but not P2X7 receptor knockout (KO) mice. When rat calvarial cells were differentiated to form bone-like nodules in vitro, BzATP induced pore formation in cells associated with these nodules. These data indicate that functional P2X7 receptors are present in cells of the osteoblast lineage. BzATP, but not equivalent concentrations of UTP (P2Y agonist) or inorganic phosphate, accelerated the appearance of alkaline phosphatase activity and promoted mineralization in rat calvarial cell cultures. Moreover, expression of genes encoding osteocalcin and osteonectin was significantly enhanced in BzATP-treated cultures. Next, calvarial cells from WT and KO mice were differentiated in the absence of exogenous nucleotides. Alkaline phosphatase activity and mineralization were markedly reduced in KO compared to WT cultures, without significant difference in cell numbers. Transcript levels of osteocalcin, osteonectin and osteocalcin were also suppressed in KO compared to WT cultures. These changes were accompanied by increased levels of the adipocyte markers PPAR γ and lipoprotein lipase. Using thin layer chromatography, we found that BzATP activates production of the potent lipid mediator lysophosphatidic acid (LPA) through activation of phospholipases D and A₂. The specific LPA receptor antagonist VPC-32183 suppressed LPA-induced elevation of cytosolic free calcium in rat calvarial cells. Importantly, the same concentration of VPC-32183 abolished the stimulatory effects of BzATP on mineralization and expression of osteocalcin and osteonectin. We conclude that P2X7 receptors on osteoblasts enhance bone formation through a cell autonomous mechanism. Furthermore, a novel signaling axis links P2X7 receptors to production of LPA, which in turn stimulates osteogenesis. These findings explain the role of P2X7 receptors in skeletal development and mechanotransduction.

Estrogen Receptor α Is Required for Strain-Related β -Catenin Signaling in Osteoblasts. V. J. Armstrong*, M. Muzylak*, A. Sunter*, G. Zaman*, L. K. Saxon, J. S. Price, L. E. Lanyon. Veterinary Basic Sciences, The Royal Veterinary College, London, United Kingdom.

Wnt/ β -catenin signaling has been implicated in the regulation of bone mass through its involvement in bone cells' response to their mechanical environment [1]. Since Estrogen Receptor α (ER α) is also involved in bones' response to loading [2], we investigated whether strain induced signaling through ER α uses the same pathway as β -catenin. Western blot and immuno-cytochemical analysis showed that in ROS 17/2.8 cells a short period of dynamic strain in vitro increased the levels of activated β -catenin (β cat) in the cytoplasm and within 1 hour stimulated its translocation to the nucleus. These changes in β cat were paralleled by inhibitory phosphorylation of GSK-3 β . Strain, and the GSK-3 β inhibitor LiCl, also induced a significant increase in TCF/LEF transcriptional activity. In contrast, estrogen had no influence on the level or distribution of β cat, nor any effect on TCF/LEF activation. Nuclear translocation of β cat and TCF/LEF activation stimulated by both strain and LiCl were inhibited by the ER modulator ICI 162,780, which also reduced strain-induced nuclear accumulation of ER α . The ER modulator Tamoxifen also inhibited LiCl stimulated nuclear translocation of β cat. In primary cultures of osteoblast-like cells derived from the long bones of Wild Type mice and those lacking ER β , β -catenin was similarly activated and translocated to the nucleus in response to strain and LiCl. In these cells this response was blocked by ICI 162,780. In contrast, in cultures of osteoblast-like cells from mice lacking ER α neither strain nor LiCl stimulated nuclear accumulation of β cat. ICI 162,780 had no effect in these cells. These data show that in osteoblastic cells exposure to strain causes similar activation of β -catenin, its translocation to the nucleus, and regulation of transcription as GSK-3 β inhibition by LiCl. These changes require ER α but not ER β . To our knowledge these are the first data to demonstrate that in osteoblasts ER α is required for these cells' responses to strain involving Wnt/ β -catenin. Reduced effectiveness of bone cells' responses to bone loading, associated with decline in bio-available estrogen and ER α , may contribute to the failure to maintain structurally appropriate bone mass in osteoporosis in both men and women. This failure may in part be due to reduced effectiveness of Wnt/ β -catenin signaling.

Effects of PTH(1-34) on Primary Osteocytes. S. Banerjee^{*1}, S. Shaheen^{*1}, S. E. Harris², F. R. Bringhurst¹, P. Divieti¹. ¹Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, ²Department of Periodontic, University of Texas Health Center, San Antonio, TX, USA.

Parathyroid hormone (PTH) induces a plethora of effects on bone cells, depending on the mode and timing of administration. While continuous PTH in vivo induces catabolic effects, including rapid bone turnover, intermittent treatment increases bone mass (anabolic effect). At the cellular level, continuous treatment with PTH inhibits osteoblast differentiation while intermittent treatment promotes it. Osteocytes play a major "mechanosensory" role and PTH is known to influence the output of this mechanosensory response and to delay osteocyte apoptosis. PTH exerts its classical effects via activation of a G-protein coupled receptor, the PTH/PTHrP receptor (PPR) that recognizes and is fully activated by the first 34 amino acids of the hormone. Osteocytes also express CPTHRS, which recognize amino-truncated forms of the hormone.

In this study we compared the effects of continuous vs intermittent activation of PPRs in osteocytes in vitro. Cells were isolated enzymatically from calvariae of 4-day-old transgenic mice in which the green fluorescent protein (GFP) is driven by the 8Kb promoter of dentin matrix protein 1 (DMP1). Primary bone cells cultured for 10 days before sorting them for GFP+ (osteocytes) and GFP- (predominantly osteoblasts) populations.

We have previously shown that both PPRs and CPTHRS were expressed in GFP+ cells and that their expression was 2-3 fold higher than in GFP- cells, suggesting that both PPRs and CPTHRS might play an important role in osteocyte functions. Cyclic AMP accumulation in response to PTH(1-34) was also present in these cells. The expression of selected osteocytic marker proteins - Sclerostin (SOST), DMP1 and the membrane mucoprotein Podoplanin (E11) was analyzed following intermittent vs continuous PTH treatment in vitro. Unsorted calvarial cells were treated with 10nM PTH(1-34) for 2 hr every second day (intermittent) or continuously (refed with fresh PTH every 2 days) for 10 days before FACS analysis. Continuous PTH reduced the percentage of GFP+ cells, increased expression of SOST and reduced that of DMP1 and E11 in the GFP+ population. Intermittent PTH decreased SOST and E11 but increased DMP1. We conclude that terminal differentiation of osteoblasts is inhibited by continuous PTH exposure in vitro and that the osteocyte phenotype is sensitive to different temporal patterns of PTH exposure.

Rho GTPase Signaling Pathways in Osteoclasts: Wrch1/rho Role In Cell Adhesion and Osteolysis. A. Blangy, H. Brazier^{*}, S. Ory^{*}, S. Stephens^{*}, G. Pawlak^{*}. CNRS UMR 5237 CRBM, CNRS Montpellier France

Rho GTPase signaling pathways regulate essential aspects of osteoclast biology through the regulation of actin cytoskeleton dynamics. In particular they control osteoclast adhesion by regulating podosome organization and sealing zone architecture, thereby modulating osteolysis. We established the expression pattern of all Rho GTPases and Rho GTPase activator during osteoclast differentiation, identified novel genes induced during osteoclastogenesis and confirmed their importance in osteoclast by retrovirus-mediated RNA interference (Brazier et al., 2006, JBM, 21(9) 1387-1398).

In particular we reported that the expression of Wrch1/RhoU is highly induced during osteoclastogenesis but absent in macrophages, suggesting an specific role for the GTPase in osteoclasts. Using retrovirus-mediated infection of osteoclast precursors, we now report that Wrch1/RhoU localizes to osteoclast adhesion structures: it colocalized with vinculin around isolated podosomes and the podosome belt. Furthermore, when osteoclasts were seeded on mineralized matrices, we observed Wrch1/RhoU association with the sealing zone. The distribution of Wrch1/RhoU was identical in RAW264.7 cell or mouse bone marrow derived osteoclasts. We expressed constitutively active (Q107L) and inactive (T63N) mutants of Wrch1/RhoU in osteoclasts and showed that the GTPase associates with the podosomes and the sealing zone requires in its active GTP bound form. We next examined the influence of Wrch1/RhoU on adhesion structure and sealing zone formation. Using dynamic imaging on live cells, we have shown that Wrch1/RhoU influences the distribution and amount of adhesion structures, that it modifies integrin linked signaling and affects cell migration. We will also present how the modification of Wrch1/RhoU activity by mutant expression or lentivirus-mediated gene silencing in osteoclasts affects their migration and osteolytic activity on mineralized matrix.

Our results show that Wrch1/RhoU associates with osteoclast adhesion structures and the sealing zone and affect their ability to migrate and to resorb mineralized matrix. To establish its importance in the maintenance of bone homeostasis, we are currently generating mouse strains bearing a conditional knock out of Wrch1/RhoU gene in the osteoclast lineage.

An Osteoclast Niche Is Composed of 5-FU-insensitive Osteoclast Precursors In Vivo. T. Mizoguchi^{*1}, A. Muto^{*2}, A. Hosoya^{*3}, T. Yamashita¹, Y. Kobayashi^{*1}, T. Ninomiya^{*1}, Y. Nakamichi¹, N. Udagawa⁴, M. Ito^{*1}, N. Takahashi¹. ¹Institute for Oral Science, Matsumoto Dental Univ., Shiojiri, Japan, ²Department of Periodontology, School of Dentistry, Aichi Gakuin Univ., Nagoya, Japan, ³Department of Oral Histology, Matsumoto Dental Univ., Shiojiri, Japan, ⁴Department of Biochemistry, Matsumoto Dental Univ., Shiojiri, Japan.

We have shown that cell cycle progression and subsequent cell cycle arrest in osteoclast precursors are required for their differentiation into osteoclasts. The quiescent osteoclast precursors were named "postmitotic osteoclast precursors (pOCPs)" (JBM 21 Suppl 1: F259, 2006). We also showed that osteoblasts prepare the osteoclast niche, which supports a long-term survival of pOCPs. pOCPs in the osteoclast niche differentiated into osteoclasts without cell cycle progression in response to several stimuli including RANKL administration. These findings suggest that, like hematopoietic stem cells, pOCPs should be resistance to 5-fluorouracil (5-FU), which induces apoptosis of cells having high proliferative potential. Here, we examined effects of 5-FU administration in mice on the osteoclast differentiation from pOCPs in bone. 5-FU was administered intravenously to mice for 6 days. Mice received intraperitoneal injections of 2MD (a highly potent analog of $1\alpha, 25(\text{OH})_2\text{D}_3$) for additional 2 days. To discriminate between proliferating and quiescent cells, mice were given 5'-bromo-2'-deoxyuridine (BrdU) in drinking water during the period of 2MD administration. Tibiae and serum samples were collected from mice. Bone marrow cells were recovered from tibiae and subjected to cellular analysis. Sections of tibiae were subjected to histological analysis using TRAP and BrdU staining. TRAP5b activity, a marker of osteoclastic activity, and calcium concentrations in serum were measured using the respective assay kits. (1) The number of monocytes and lymphocytes in the bone marrow was markedly decreased by 5FU administration. (2) 2MD administration scarcely affected the bone marrow cellularity, but significantly increased the number of TRAP-positive osteoclasts in tibiae even after treatment with 5FU. None of the nuclei in osteoclasts incorporated BrdU. In contrast, BrdU-positive nuclei in chondrocytes were detected in growth plates. (3) Serum TRAP5b activity was significantly increased in mice injected with 2MD even after administration of 5-FU. Serum calcium levels were also increased in response to 2MD in the 5-FU-treated mice. These results suggest that osteoclasts, induced by administration of 2MD, differentiated from 5-FU-insensitive pOCPs. Our observations support the hypothesis that quiescent pOCPs exist in the osteoclast niche.

The RANK Cytoplasmic Motif, IVVY⁵³⁵⁻⁵³⁸, Plays an Essential Role in TNF α - and IL-1-induced Osteoclastogenesis. J. Jules, Z. Shi^{*}, W. Liu^{*}, S. Wang^{*}, X. Feng. Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

RANKL and its cognate receptor RANK play a pivotal role in osteoclastogenesis. RANK, a member of the TNFR family, possesses three cytoplasmic motifs that recruit various TNFR-associated factors (TRAF) to transmit downstream signaling pathways to regulate osteoclastogenesis. Recently, a TRAF-independent RANK cytoplasmic motif (IVVY⁵³⁵⁻⁵³⁸) was shown to play an essential role in osteoclastogenesis by committing bone marrow macrophages (BMMs) to the osteoclast lineage. Notably, both TNF α and IL-1 utilize TRAFs to activate signaling, but they are unable to mediate osteoclastogenesis in the presence of M-CSF. However, TNF α and IL-1 can induce osteoclastogenesis from BMMs exposed to permissive levels of RANKL in the presence of M-CSF, indicating that TNF α -/IL-1-mediated osteoclastogenesis requires prior priming of BMMs by RANKL. Therefore, we hypothesize that it is the RANK motif IVVY⁵³⁵⁻⁵³⁸ that plays a role in priming BMMs in TNF α -/IL-1-mediated osteoclastogenesis. To address the issue, we used a previously established chimeric receptor approach. The receptor comprises human Fas external domain linked to the transmembrane and cytoplasmic domains of mouse RANK. When the chimera was expressed in BMMs from C3H mice, the clustering of the chimera induced by a human Fas activating antibody (hFas-AB) activates the RANK intracellular domain of the chimera without affecting its endogenous RANK on the BMMs. Since hFas-AB recognizes only human Fas, it does not activate endogenous mouse Fas on BMMs. We developed two chimeric receptors: Ch-1 and Ch-2. While Ch-1 comprises the human Fas external domain linked to the transmembrane and intracellular domains of normal RANK, Ch-2 contains an inactivating mutation in the RANK motif. BMMs expressing Ch-1 or Ch-2 were pre-treated with hFas-AB for 18 hours in the presence of M-CSF, followed by treatments with TNF α or IL-1 in the presence of M-CSF for 96 hours. The assays showed that only the chimeric receptor containing the normal RANK motif (Ch-1) was able to incite osteoclastogenesis, indicating that the RANK motif IVVY⁵³⁵⁻⁵³⁸ plays an important role in priming BMMs in TNF α -/IL-1-mediated osteoclastogenesis. To further address the issue, we are currently inserting a RANK fragment containing IVVY⁵³⁵⁻⁵³⁸ to TNFR1. If the addition of the RANK fragment renders TNFR1 to be able to mediate osteoclastogenesis, the data will provide firm proof that IVVY⁵³⁵⁻⁵³⁸ is involved in TNF α -/IL-1-mediated osteoclastogenesis. Significantly, these studies may establish IVVY⁵³⁵⁻⁵³⁸ as a potent therapeutic target for bone loss in rheumatoid arthritis.

Dok-1 and Dok-2 Deficiency Enhances Bone Resorption and Modulates the Geometry of Bone In Vivo. A. Kawamata¹, A. Inoue², Y. Ezura³, K. Nakashima¹, T. Amagasa³, Y. Yamanashi², M. Noda¹. ¹Department of Molecular Pharmacology, 21st Century COE Program, MRI, Tokyo Medical and Dental University, Tokyo, Japan, ²Department of Cell Regulation, MRI, Tokyo Medical and Dental University, Tokyo, Japan, ³Maxillofacial Surgery, Tokyo Medical and Dental University, Tokyo, Japan.

Dok-1 and Dok-2 are adaptor proteins acting downstream of protein tyrosine kinases (Yamanashi et al. Cell 1997). Both Dok-1 and Dok-2 are mainly expressed in the cells of hematopoietic lineage (DiCristofano et al. JBC 1998) and suppress Ras-Erk signaling (Yasuda et al. JEM 2004). Dok-1 and Dok-2 also suppress TLR4 signaling in innate immunity (Shinohara et al. JEM 2005). Recently, defects in Dok-7, another family member were shown to be involved in congenital myasthenic syndromes (Beeson et al. Science 2006). However, the functions of Dok-1 and Dok-2 in bone are not understood. The aim of this paper is to elucidate the role of Dok-1 and Dok-2 in bone metabolism. Dok-1 or Dok-2 single deficient mice did not show overt phenotypes possibly because of overlapping functions of Dok-1 and its closest family member, Dok-2. Thus, we analyzed bone in Dok-1 and Dok-2 double-deficient (dKO) mice. Dok-1/2 double deficient mice revealed reduction in the levels of cortical bone thickness and cortical bone volume in the femora of 9-week-old mice compared to wild type (WT). In addition, Dok-1/2 deficiency increased periosteal perimeters and endosteal perimeters in the mid shaft of femora. Possibly as a result of these changes, bone mineral density levels in femur of dKO mice were similar to those in WT. For cancellous bone envelope, bone volume and mineralized nodule formation in ex vivo bone marrow cultures were similar between dKO and WT. Histomorphometrical analysis of the dynamic bone parameters indicated that the levels of mineral apposition rate (MAR) and bone formation rate (BFR) in cortical bone of Dok-1/2 dKO mice were similar between dKO and WT. To understand the role of Dok-1/2 in bone resorption, we measured urine deoxypyridinoline (Dpyr), a marker of bone resorption. Double Dok-1/2 deficiency significantly increased Dpyr levels in urine. Intriguingly, the levels of the number of TRAP positive cells per bone surface were similar between dKO and WT, suggesting that Dok-1 and Dok-2 would be involved in the suppression of osteoclastic function specifically without altering osteoclast number. In conclusion, we identified that the novel signaling molecules Dok-1 and Dok-2 suppress bone resorption and are involved in the maintenance of bone geometry.

RNA Interference Machinery Is Essential for Osteoclastogenesis. T. Sugatani, K. A. Hruska. Department of Pediatrics, Washington University Medical School, St. Louis, MO, USA.

RNA interference (RNAi) is an evolutionarily conserved pathway, central to a broad spectrum of biological phenomena, including development, stem cell differentiation, transcriptional gene silencing, heterochromatin formation, and transposon silencing. RNAi is triggered by small RNAs such as microRNAs and small interfering RNAs (siRNAs) that regulate gene expression by translational inhibition and mRNA degradation. However, the biological function of the RNAi-related pathway in osteoclastogenesis is not completely understood. Here we show that RNAi machinery is essential for osteoclastogenesis. Moreover, microRNA-223 expression in bone marrow macrophages (BMMs) is critical for osteoclastogenesis. To investigate whether RNAi machinery is a key function in osteoclastogenesis, we focused on the function of Dicer and Argonaute 2 in the RNAi-related pathway. Endogenous small non-coding microRNAs are processed by Dicer from precursor microRNAs. Then, these small double-stranded RNAs assemble into the RNA-induced silencing complex (RISC), which contains Ago 2, Dicer and other cellular factors. Activated RISC finds its target mRNA and affects mRNA translation or stability. We employed a retroviral system for delivery of Dicer or Ago 2 siRNA into primary BMMs, and osteoclasts were induced by RANKL. The knockdown of Dicer or Ago 2 expression attenuated cell proliferation in BMMs. Moreover, the knockdown of Dicer or Ago 2 expression in BMMs suppressed the number of TRAP-positive multinucleated osteoclasts formed compared with scrambled siRNA as a control. However, TRAP expression was not blocked by the knockdown of Dicer or Ago 2 expression. These results indicate that RNAi machinery regulates TRAP-positive multinucleated osteoclast formation. We have reported that microRNA-223 is expressed in RAW264.7 cells, and the overexpression of precursor microRNA-223 in cells blocks TRAP-positive multinucleated osteoclast formation and bone resorption. Here, we examined the effect of the overexpression of microRNA-223 in primary BMMs using a retroviral system. The overexpression of precursor microRNA-223 in BMMs suppressed the number of TRAP-positive multinucleated osteoclasts formed, demonstrating that the continuous expression of microRNA-223 in BMMs results in the inhibition of TRAP-positive multinucleated osteoclast formation. Thus, we provide the first evidence that the Dicer and Ago 2-related RNAi machinery is important for the formation of TRAP-positive multinucleated osteoclasts. In particular, the regulation of microRNA-223 expression in osteoclast precursors during osteoclastogenesis may be critical for osteoclast differentiation and function.

The Mechanism of RANKL-evoked $[Ca^{2+}]_i$ Oscillations Mediated by RGS10 in Osteoclast Differentiation. S. Yang, Y. Li. Cytokine Biology, The Forsyth Institute, Harvard School of Dental Medicine, Boston, MA, USA.

Increased osteoclastic resorption leads to many bone diseases, including osteoporosis and rheumatoid arthritis. To better understand the mechanisms underlying osteoclast-based diseases and design relevant therapies, it is necessary to unveil the molecular basis of osteoclast differentiation and function as well as the regulatory mechanisms of osteoclast signaling. In our previous work, we have characterized RANKL-induced signaling protein, Regulator of G-protein Signaling 10 (RGS10) and found it is predominantly expressed in osteoclasts. Impaired osteoclast differentiation in RGS10-deficient ($RGS10^{-/-}$) mice with severe osteopetrosis indicates the essential role of RGS10 for RANKL-evoked $[Ca^{2+}]_i$ oscillations in osteoclast differentiation. However, the mechanism underlying how RGS10 regulates the RANKL-evoked $[Ca^{2+}]_i$ oscillations and NFATc1 expression in osteoclast differentiation still remains unclear. In this study, we focused on the mechanism of RANKL-evoked $[Ca^{2+}]_i$ oscillations mediated by RGS10 in osteoclast differentiation. Our data demonstrated that RGS10 interacts with calmodulin in a Ca^{2+} -dependent manner. Ca^{2+} /calmodulin complexes are formed at high $[Ca^{2+}]_i$ and compete for the PIP₃ binding site on the RGS10 protein to regulate $[Ca^{2+}]_i$ oscillations and activity of PLC γ . Calcineurin inhibitor, FK506, inhibited the rescue effect of RGS10 reintroduction in RANKL-induced $RGS10^{-/-}$ BMMs and the formation of TRAP⁺ cells from $RGS10^{-/-}$ BMMs driven by RGS10 ectopic expression without RANKL induction. Ectopic expression of NFATc1 rescues impaired osteoclast differentiation in $RGS10^{-/-}$ mice, indicating that RGS10 acts upstream of Calcineurin and NFATc1. Our results revealed a working model: PIP₃ specifically binds RGS10 at low $[Ca^{2+}]_i$ to inhibit RGS10 activity. When RANKL activates ITAM and PLC γ , which hydrolyzes PIP₂ to generate inositol 3-phosphate (IP₃), Ca^{2+} /calmodulin complexes are formed at high $[Ca^{2+}]_i$ and the complexes compete for the PIP₃ binding site on the RGS10 protein to restore RGS10 activity, which in turn regulates PLC γ activity. The dual regulation of RGS10 activity can cause $[Ca^{2+}]_i$ oscillations, implying the mechanism for RGS10-mediated modification of intracellular $[Ca^{2+}]_i$ oscillations that activate calcineurin (CN) and NFATc1 for osteoclast terminal differentiation. To our knowledge, this is the first in vivo model revealing the mechanism of $[Ca^{2+}]_i$ oscillation regulation by RGS10. The essential role of RGS10 selectively involved in RANKL-induced $[Ca^{2+}]_i$ oscillations in osteoclast differentiation may offer a very specific and powerful therapeutic target for treatment of bone diseases caused by excessive bone resorption.

A Dramatic Increase in Hematopoiesis and Angiogenesis in Bone Marrow of Rescued RANKL-Deficient Mice by Expression of Soluble RANKL Transgene. H. Yasuda¹, A. Minamida², J. M. Penninger³, Y. Iwakura².

¹Nagahama Institute for Biochemical Science, Oriental Yeast Co., Ltd., Shiga, Japan, ²Institute of Medical Science, University of Tokyo, Tokyo, Japan, ³Institute of Molecular Biotechnology of the Austrian Academy of Sciences, Vienna, Austria.

Receptor activator of NF- κ B ligand (RANKL) is a key regulator of osteoclastogenesis, lymphocyte development and lymph node (LN) organogenesis. RANKL is a membrane-bound ligand but its soluble form is released from different type of cells by shedding. In humans increases of serum sRANKL level were reported in patients with rheumatoid arthritis and juvenile Paget's disease. RANKL knockout (KO) mice showed severe osteopetrosis, with no osteoclasts, marrow spaces, or tooth eruption, and exhibited profound growth retardation. These mice also showed defects in early differentiation of T and B cells, and lacked all LNs. We previously reported that most of all abnormalities in RANKL KO mice were rescued by expression of soluble RANKL (sRANKL) transgene by mating the KO mice with sRANKL transgenic (TG) mice. The purpose of this study is to analyze the bone marrow cells appeared in the rescued mice (hereafter called TG/KO mice). The histological analysis of the TG/KO mice revealed that a dramatic increase in hematopoiesis and angiogenesis in their bone marrow cavities. The ratio of Ter119+ cells (erythroid cells), Mac1+ cells (macrophages), Gr-1+ cells (granulocytes), and Thy1.2+ cells (T cells) increased in the flow cytometry, respectively. In contrast, the ratio of B220+ cells (B cells) decreased. These results suggested the possibility of a lineage shift from B cells to others. The increase in hematopoiesis and angiogenesis was observed only in TG/KO mice, but not in TG mice, suggesting that the phenotypic changes were not directly caused by overexpression of sRANKL. RT-PCR analysis revealed that the sRANKL transgene was expressed in T-cells, B-cells, and macrophages, but not in osteoblasts in the TG/KO and TG mice. Numerous TRAP+ multinucleated cells were formed in bone marrow macrophage culture of TG/KO and TG mice in the presence of M-CSF without addition of sRANKL. Addition of OPG inhibited the osteoclast formation. Together, these results suggest that sRANKL acts on bone marrow macrophages in an autocrine fashion. TRAP+ cells were observed only in the bone surface in TG/KO mice, suggesting that the hypothetical factors besides RANKL regulated the localization of osteoclasts. In conclusion, the TG/KO mice showed a marked increase in hematopoiesis and angiogenesis accompanied with a lineage shift from B cells to other cell populations in the rescued bone marrow cavities and these mice would represent a good animal model studying the formation of bone marrow.

Expression of OCZF Directed by the Cathepsin K Promoter Affects Bone Mass and Osteoclast Formation in Transgenic Mice. T. Shobuiké^{*1}, T. Kukita², K. Nagata^{*2}, J. Teramachi^{*2}, M. Asagiri³, H. Takayanagi³, A. Kukita¹. ¹Saga University, Saga, Japan, ²Oral Biological Science, Kyushu University, Fukuoka, Japan, ³Cell Signaling and COE program, Tokyo Medical and Dental University, Tokyo, Japan.

We previously isolated the OCZF cDNA encoding Kat-6 antigen specifically expressed in rat osteoclast. The OCZF gene product is a member of POK protein family that contains two domains of POZ/BTB and zinc finger in their N- and C-terminal region respectively, and that is shown to be involved in various cellular processes. Suppression of OCZF by antisense RNA inhibits osteoclast differentiation in vitro, indicating that OCZF is involved in osteoclastogenesis, but in vivo role in the process is not clear. To this end we generated transgenic mice, which expressed OCZF under the control of mouse cathepsin K promoter. Nine transgenic mice were identified among the offspring by PCR and Southern blot analysis of mouse tail genomic DNA. Transgene expression was verified by RT-PCR using osteoclasts differentiated in vitro from bone marrow at 10 weeks of age. Two lines of the transgenic animals exhibited relatively high transgene expression, and were further investigated. The c-fos and NFATc1 protein exhibit higher levels during differentiation into osteoclasts in vitro from bone marrow of the transgenic mice than that of normal littermates. Micro-CT and peripheral quantitative CT (pQCT) analyses and histomorphometry of femur were performed in mice at 6 weeks of age. Micro-CT imaging demonstrates a reduction in trabecular bone volume in the transgenic mice relative to normal littermates. pQCT analyses also demonstrate a reduction in bone mineral density and bone mineral content especially in trabecular bone with a decrease in strength strain index, whereas those in cortical bone were slightly affected. Consistently, von Kossa staining shows a smaller mineralized area in the transgenic mice than in normal littermates. Histological analyses with tartrate-resistant acid phosphatase staining and calcein labeling indicate an increase in the number of osteoclast, whereas bone formation rate did not significantly change. These results suggest that OCZF has an important role in osteoclastogenesis in vivo.

Potential Role of Rab3D-Calmodulin Interaction in Osteoclastic Bone Resorption. J. Xu, T. Cheng*, N. Pavlos*, E. Ang*, M. H. Zheng. Orthopaedic Surgery, The University of Western Australia, Nedlands, WA, Australia.

Osteoclastic bone resorption is a highly dynamic process that requires the tight ordering of intracellular trafficking events in order to maintain the structural and functional polarization of the ruffled border and basolateral domains. Rab3 proteins are a subfamily of GTPases, known to mediate membrane transport in eukaryotic cells and play a role in exocytosis. Our recent data indicates that Rab3D modulates a post-TGN trafficking step that is required for osteoclastic bone resorption (1). Here, to identify down-stream regulatory molecules of Rab3D, we have performed a yeast two-hybrid screen. Amongst several candidate Rab3D-interacting proteins identified, Rab3D was found to associate with calmodulin, an established regulator of osteoclastic bone resorption. As an initial effort to better define the interaction between Rab3D and calmodulin, we generated several mutants of Rab3D which interfere with the GDP/GTP nucleotide exchange (Rab3DQ81L, Rab3DNI35I) and/or membrane attachment of Rab3D (Rab3D-CXC). By in vivo bioluminescence resonance energy transfer (BRET) assay, Calmodulin was found to associate equivalently with wild-type Rab3D as well as Rab3DNI35I and Rab3DCXC variants. Overexpression of constitutively-active Rab3D (Rab3DQ81L) enhanced this interaction suggesting that the active form of Rab3D (i.e. GTP-bound) might recruit additional effector molecules which further potentiate its binding to calmodulin. In an attempt to address the impact of calmodulin activity on Rab3D-calmodulin interaction and osteoclastic bone resorption, we performed complementary BRET and in vitro bone resorption assays in the presence of the calmodulin inhibitor, calmidazolium chloride. Interestingly, we show that suppression of calmodulin activity via calmidazolium chloride impairs the association of Rab3D with calmodulin, an affect that correlates with a disruption in osteoclastic bone resorption. We propose that the recruitment of calmodulin by Rab3D might be an important requirement for osteoclast-mediated bone resorption. 1. TNFR1 and 2 Differentially Regulates Inflammatory Bone Resorption Induced by LPS In Vivo. M. H. Mian^{*1}, K. Aoki², N. Alles^{*1}, H. Saito^{*2}, K. Ohya². ¹Center of Excellence program for Frontier Research on Molecular Destruct. and Reconst. of Bone, Tokyo Medical and Dental University, Tokyo, Japan, ²Department of Hard tissue Engineering, Section of Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan.

Chronic bone infection is often complicated by severe osteolysis. It has been reported that TNF receptors differentially regulate osteoclastogenesis, where TNFR1 accelerate and TNFR2 inhibit osteoclastogenesis (Abu-Amer et al, J Biol Chem, 2000). But whether these receptors influence bone resorbing activity of osteoclast differentially is yet to be

elucidated. The purpose of this study was to investigate bone resorbing activity through TNFR1 and TNFR2 in vitro as well as to clarify the role of these receptors on inflammatory bone resorption in vivo. We examined the roles of TNF receptors using bone marrow cells in vitro as well as in LPS induced local bone resorption model in vivo. For in vitro study, pit formation assay in dentin slices using a confocal microscope was performed to check the functional osteoclast activity of TNFR1 and TNFR2 upon stimulation of TNF- α . Average pit depth in Wild type (WT) and TNFR1 deficient (KO) culture influenced by TNF- α were not significantly changed, but significant increase in average pit depth were observed in TNFR2 KO culture. For in vivo study, 10 mg/kg LPS was injected subcutaneously on calvaria of TNFR1KO, TNFR2 KO, and their WT mice, sacrificed on day 5 after the LPS injections. Calvariae, tibiae and femurs were dissected. The calvarial BMD measured by DXA in LPS-injected group was significantly decreased in WT and TNFR2 KO mice compared to the control. In contrast, there was no significant decrease of calvarial BMD in TNFR1 KO mice. On the other hand, the significant decrease on the BMD of tibiae and femurs measured by peripheral quantitative computed tomography (pQCT) was observed in TNFR2 KO mice, but no significant decrease was observed in WT and TNFR1 KO mice. The results of urinarydeoxyypyridinoline reflected these resorption and histomorphometric analyses of tibia shows the significant increase of osteoclast number in TNFR2 KO mice by LPS injection. These BMD data were confirmed by μ -CT analyses. The present data indicate that TNFR1 plays the pivotal role for inducing local bone resorption induced by LPS and TNFR2 might have a protecting role in inflammatory bone resorption process.

Transgenic Overexpression of Osteoclastic Protein-tyrosine Phosphatase, PTP-oc, in Cells of Osteoclastic Lineage Led to Increased Bone Resorption and Marked Reduction in Trabecular Bone Mass and Density in Adult Mice. M. H. C. Sheng, M. Amoui*, A. K. Srivastava, J. E. Wergedal, K. H. W. Lau. Loma Linda VAMC, Loma Linda, CA, USA.

Past in vitro studies have suggested that the structurally unique osteoclastic transmembrane PTP-oc acts as a positive regulator of osteoclast activity. This study sought to determine whether transgenic (TG) overexpression of PTP-oc in cells of osteoclastic lineage would increase (\uparrow) bone resorption and decrease (\downarrow) bone mass or density (BMD) in adult mice. To generate TG mice, a TG construct containing the rabbit PTP-oc cDNA driven by a tartrate-resistant acid phosphatase (TRACP)-IC promoter was injected into the pronucleus of fertilized ova, which were implanted into pseudo-pregnant B6D2F1 mice. TG founders, identified by a PCR-based genotyping assay using primers that span unique regions of TRACP-IC promoter and rabbit PTP-oc sequence, were bred with C57BL/6J mice to produce F2 mice. Ten-week-old male F2 progenies were extensively followed for pQCT, histological, and serum resorption marker analyses. The body weight of TG mice was 10% less ($p < 0.05$, $n = 8$ each) than that of wild-type (WT) littermates. pQCT analyses of the femur revealed that TG mice had 30% \downarrow in trabecular BMD ($p < 0.002$). Histologic analyses at the secondary spongiosa in the femur of 9 TG and 7 WT littermates confirmed that TG mice showed 35% \downarrow in trabecular surface (Tb.Pm, $p < 0.01$), 27% \downarrow in % trabecular area (Tb.Ar, $p < 0.05$), 11% \downarrow in trabecular number (Tb.N, $p < 0.05$), and 36% \uparrow in trabecular separation (Tb.Sp, $p < 0.005$). The lumbar vertebra of 12 TG mice, when compared to 8 WT littermates, also showed 20% \downarrow in Tb.Pm ($p < 0.005$), 17% \downarrow in Tb.N ($p < 0.003$) and 35% \uparrow in Tb.Sp ($p < 0.004$). Consistent with an \uparrow in bone resorption, the serum c-telopeptide level of TG mice ($n = 14$) was 25% ($p < 0.05$) higher than that of littermates ($n = 11$). That the number of osteoclasts and the length of TRACP-labeled bone surface per total bone surface were not different suggested that TG overexpression of PTP-oc increased osteoclast activity rather than osteoclast differentiation. The same phenotype was confirmed in a second TG line. In congruent with an \uparrow in osteoclastic activity, the average pit area created by osteoclasts derived from bone marrow cells of 10-week-old male TG mice in response to RANKL and mCSF in the pit formation assay was ~50% greater ($p = 0.008$) than those by osteoclasts of WT littermates ($n = 8$ each). However, the TRACP activity per cellular protein in osteoclasts derived from the two groups of mice was not different. In summary, TG overexpression of PTP-oc in cells of osteoclastic lineage led to a marked reduction in trabecular bone mass in adult mice due to an \uparrow in osteoclastic activity. These findings provide compelling in vivo evidence that PTP-oc is a positive regulator of osteoclastic activity.

The CaMK-CREB Pathway Regulates Osteoclast Differentiation and Function. A. Suematsu¹, K. Sato^{*2}, T. Nakashima^{*1}, S. Takemoto-Kimura^{*3}, K. Aoki⁴, K. Ohya⁴, A. Yamaguchi⁵, T. A. Chatila^{*6}, H. Bito^{*3}, H. Takayanagi¹. ¹Department of Cell Signaling, Tokyo Medical and Dental University, Tokyo, Japan, ²Division of Rheumatology and Applied Immunology, Saitama Medical University, Saitama, Japan, ³Department of Neurochemistry, University of Tokyo, Tokyo, Japan, ⁴Department of Hard Tissue Engineering, Tokyo Medical and Dental University, Tokyo, Japan, ⁵Department of Oral Pathology, Tokyo Medical and Dental University, Tokyo, Japan, ⁶The David Geffen School of Medicine at the University of California at Los Angeles, Los Angeles, CA, USA.

Calcium (Ca^{2+}) signaling is critical for the regulation of various cellular events. Intracellular Ca^{2+} binds to calmodulin, and the Ca^{2+} /calmodulin complex activates Ca^{2+} /calmodulin-dependent kinases (CaMKs) as well as phosphatases such as calcineurin. We

revealed the importance of calcineurin-nuclear factor of activated T cells (NFAT) pathway in osteoclastogenesis. However, it remains unclear whether CaMKs play a crucial role in bone homeostasis. Here we examined the role of CaMKs in osteoclast differentiation and function. Because knockdown of CaMKIV had a suppressive effect on RANKL-induced osteoclastogenesis, we analyzed the bone phenotype of CaMKIV-deficient mice. We observed an increase in bone volume in CaMKIV-deficient mice, which resulted from the reduction in osteoclast number. In vitro osteoclastogenesis in CaMKIV-deficient cells stimulated with RANKL was also reduced. We focused on cAMP response element (CRE)-binding protein (CREB) as a physiological substrate of CaMK in the osteoclast differentiation. CREB was phosphorylated and activated through CaMKIV after RANKL stimulation. The pharmacological inhibition of CaMKs suppressed osteoclast differentiation and downregulated the expression levels of c-fos, which is required for the induction of NFATc1. Furthermore, CREB together with NFATc1 induced the expression of osteoclast-specific genes. Finally, we explored the possibility whether modulation of CaMK activity can be used as therapeutic target in an ovariectomy (OVX) mice. The reduction in bone volume associated with an increase in osteoclast number in OVX mice was ameliorated by systemic administration of CaMK inhibitor. These results indicate that both kinases and phosphatases downstream of Ca^{2+} signaling cooperatively regulate the transcriptional program of osteoclast differentiation and function. Thus, inhibition of the CREB-CaMK pathway may be a new therapeutic target for various bone diseases.

Thyroid Hormone-induced Terminal Differentiation of Growth Plate Chondrocytes Involves IGF-1 Modulation of Canonical Wnt Signaling. L. Wang^{*1}, Y. Y. Shao^{*1}, R. T. Ballock². ¹Department of Biomedical Engineering, Cleveland Clinic, Cleveland, OH, USA, ²Departments of Orthopaedics and Biomedical Engineering, Cleveland Clinic, Cleveland, OH, USA.

Thyroid hormone is a potent regulator of skeletal maturation in the growth plate. Wnt signaling has also been recognized as an important signal transduction pathway in regulating terminal differentiation of growth plate chondrocytes into hypertrophic cells. Wnt ligands and β -catenin have been shown to promote chondrocyte maturation in the chick growth plate. Since thyroid hormone is a known stimulator of IGF-1 receptor expression, and IGF-1 has been described as a stabilizer of β -catenin in other cell types, we hypothesize that thyroid hormone may regulate terminal differentiation of growth plate chondrocytes in part by stimulating Wnt/ β -catenin signaling pathway through the modulation of IGF-1/IGF-1R signaling.

Three-dimensional pellet cultures of 2-day old rat growth plate chondrocytes were maintained in serum-free medium. Thyroid hormone treatment upregulated Wnt-4 mRNA expression, increased the accumulation of β -catenin and upregulated β -catenin target gene Runx2/cbfa1. Both Wnt4 conditioned medium and adenovirus expressing stabilized β -catenin increased the markers of hypertrophy alkaline phosphatase (ALP) activity and Col10a1 mRNA expression in growth plate chondrocytes. Blocking Wnt ligand/receptor interactions with Wnt inhibitors Frzb/sFRP3 or DKK1 decreased the T3-induced increases of β -catenin accumulation and inhibited the maturation-promoting effects of T3 in growth plate cells. IGF-1R mRNA expression was upregulated by thyroid hormone treatment in growth plate cells. Incubation of the cells with recombinant IGF-1 protein or IGF-1R adenovirus not only resulted in increases of β -catenin accumulation and upregulation of Wnt4 and Runx2 mRNA expression, but also increased ALP activity and Col10a1 mRNA expression in growth plate chondrocytes. The IGF-1 receptor inhibitor picropodophyllin (PPP) inhibited T3-induced increases of Wnt4 mRNA as well as T3-mediated hypertrophy of growth plate chondrocytes.

These data demonstrate that thyroid hormone promotes terminal differentiation of growth plate chondrocytes in part through IGF-1 modulation of the canonical Wnt signaling pathway.

Proteasome Inhibition Induces Permanent Growth Retardation and Apoptosis in Growth Plate Chondrocytes. E. E. Eriksson, F. Zaman^{*}, A. S. Chagins^{*}, D. Chrysis^{*}, L. Sälvendahl^{*}. Women and Child Health, Pediatric Endocrinology, Stockholm, Sweden.

Proteasome inhibitors, a new class of anti-cancer drugs has recently been approved for multiple myeloma treatment in adults and is under clinical trial in pediatric cancers. However, any specific side effects on normal bystander tissues in children are unknown. The objective of this research was to study the effects of the proteasome inhibitors, MG262 and the clinically used proteasome inhibitor, Velcade on linear bone growth in young mice (male, 5 weeks old) and in fetal rat metatarsal bones. To address this question, C57B and NMRI mice were treated with the proteasome inhibitors, Velcade and MG262, in a clinical relevant dose. We followed the linear bone growth of the mice longitudinally and observed permanent growth retardation. To elucidate the underlying mechanisms, we used a transgenic mouse model expressing a green fluorescent protein reporter allowing monitoring the ubiquitin/proteasome system. MG262 treatment results in accumulation of the green fluorescent protein in the growth plate and increased apoptosis in stem-cell like chondrocytes. To further prove local effect of proteasome inhibition on linear growth, fetal rat metatarsal bones were cultured in presence of either Velcade or MG262. These experiments also showed bone growth retardation and increased chondrocyte apoptosis. To understand the apoptotic pathways induced by proteasome inhibitors in chondrocytes, we used rat- and human chondrocytic cell lines that both were found to undergo apoptosis upon proteasome inhibitor treatment. A pan-caspase inhibitor (Z-VAD-fmk) suppressed MG262-mediated apoptosis by 32% in rat and 35% in human chondrocytes. Together with

early up-regulation of p53 and apoptosis inducing factor (AIF) these observations suggest involvement of both caspase-dependent and independent apoptosis. Indeed, apoptosis was suppressed by 30% employing p53-sequence specific siRNA. In short, we conclude that impairment of the ubiquitin/proteasome system causes permanent growth retardation by inducing massive apoptosis in chondrocytes in vivo and in vitro, an effect which is both dependent and independent of caspases. Our findings suggests that proteasome inhibitors have to be cautiously used in growing children and that involvement of p53 in chondrocyte apoptosis opens targets for new potential ways to rescue growth.

The Regulation of Chondrocyte Proliferation, Function, and Differentiation by Akt Signaling Pathways. T. Fujita^{*}, S. Rokutanda^{*}, N. Kanatani^{*}, C. Yoshida^{*}, T. Komori^{*}. Cell Biology, Nagasaki university, Nagasaki, Japan.

Akt is a broadly expressed multifunctional protein, but its roles in chondrocytes still remain to be clarified. We investigated chondrocyte proliferation, function, and differentiation in transgenic mice expressing myristoylated Akt (myrAkt) by Col2a1 promoter. Chondrocyte proliferation was enhanced in the reservoir zone, but it was reduced in the proliferative zone, in which an increase in matrix production was observed. Chondrocyte maturation was enhanced in the spine and sphenoid but inhibited in the long bones. Accelerated chondrocyte proliferation by IGF-I was inhibited by FoxO3a, and an inhibitory effect of Akt on chondrocyte proliferation was abolished by rapamycin, a mTOR specific inhibitor, suggesting that Akt-FoxO and Akt-mTOR axes functioned as a proliferative pathway in the reservoir zone and as an anti-proliferative pathway in the proliferative zone, respectively, in myrAkt transgenic mice. The enhanced matrix synthesis by myrAkt was blocked by rapamycin, indicating that Akt-mTOR pathway plays an important role in matrix synthesis. FoxO3a overexpression mildly enhanced chondrocyte maturation, and lithium, a GSK3 inhibitor, inhibited it in long bone of wild-type mice. Further, the stimulatory effect of Akt on chondrocyte maturation in spine was abolished by rapamycin. These results indicate that Akt-FoxO and -GSK3 β pathways are involved in the negative regulation of chondrocyte maturation in long bone but Akt-mTOR pathway is involved in the positive regulation of chondrocyte maturation in spine. These results demonstrate that Akt regulates chondrocyte proliferation, matrix synthesis, and chondrocyte maturation depending on the skeletal elements and the maturational stages of chondrocytes.

Disclosures: T. Fujita, None.

Transcriptional Regulation of Type X Collagen by Runx2: Molecular Network Underlying Chondrocyte Hypertrophy Causing Osteoarthritis. A. Higashikawa, T. Saito, S. Kamekura^{*}, S. Ohba, T. Ikeda, K. Nakamura, U. Chung, H. Kawaguchi. Sensory & Motor System Medicine, University of Tokyo, Tokyo, Japan.

Chondrocyte hypertrophy is essential not only for physiological skeletal development and growth, but also for pathological disorders like osteoarthritis (OA). When we created an experimental mouse OA model by producing instability in the knee joint through surgical transection of the medial collateral ligament and resection of the medial meniscus, Runx2 expression determined by immunostaining and real-time RT-PCR was induced in chondrocytes at the superficial and middle layers of joint cartilage as early as 2 weeks, which was not observed in the sham-operated joint. Most of the Runx2-positive chondrocytes then expressed type X collagen (COL10), the representative marker of hypertrophic differentiation, at 2-4 weeks, and thereafter produced collagenases causing degradation of the cartilage matrix. In heterozygous Runx2-deficient mice, however, COL10 expression, as well as the subsequent collagenase expression and matrix degradation, was suppressed under the OA induction, indicating that Runx2 contributes to the pathogenesis of OA through chondrocyte hypertrophy. COL10 mRNA level, as well as Alizarin-red and von Kossa stainings, were markedly increased by the Runx2 overexpression, whereas they were decreased by the dominant negative Runx2 overexpression, in the cultures of respective stable lines of mouse chondrogenic ATDC5 cells. In HeLa cells transfected with a luciferase-reporter gene construct containing a 4.5 kb fragment of the human COL10 promoter region, the transcriptional activity was enhanced by co-transfection with Runx2. Deletion analysis using a series of 5'-deletion constructs of the COL10 promoter identified the core responsive element to Runx2 to be within 10 bp around the -80 bp region (HY-box). The transcriptional activity of Runx2 was suppressed by a site-directed mutagenesis in the HY-box. The tandem-repeat constructs responded to Runx2 depending on its repeat number. Electrophoretic mobility shift assay showed specific binding of nuclear extracts from Runx2-overexpressed COS7 cells with the wild-type HY-box oligonucleotide probe, but not with the mutated probe. Cold competition with an excess of unlabelled wild-type probe, but not with the unlabelled mutated probe, suppressed formation of the complex. In addition, the complex underwent a supershift by the antibody to Runx2, confirming the specific binding of the HY-box and Runx2. In conclusion, we identified the Runx2-responsive region HY-box in the COL10 promoter. Studies on molecules related to Runx2 / HY-box will lead to elucidation of the molecular network underlying chondrocyte hypertrophy and OA pathogenesis.

Inhibitory Smad6 and Smad7 Differently Regulate Cartilage Formation. T. Iwai¹, J. Murai^{*1}, H. Yoshikawa¹, N. Tsumaki². ¹Orthopaedic Surgery, Osaka University Graduate School of Medicine, Osaka, Japan, ²Cartilage and Bone Biology, Osaka University Graduate School of Medicine, Osaka, Japan.

TGF- β / BMP signals are mediated by Smad proteins. Biochemical studies have revealed that Smad6 inhibits BMP signaling, whereas Smad7 inhibits both TGF- β and BMP signaling. Transgenic / knockout mouse studies showed that BMP signals are definitely necessary for cartilage formation, whereas importance of TGF- β signals in cartilage formation is controversial. In this annual meeting last year, we reported generation of conditional transgenic mice overexpressing Smad7 in cartilage. Smad7 overexpression inhibited cartilage formation and delayed chondrocyte hypertrophy. In the present study, we further clarified roles of Smads 6 and 7. In situ hybridization analysis revealed that the expression levels of both Smad6 and Smad7 were low in cartilage compared with those in surrounding soft tissues and bone. To investigate the importance of this Smad7 down-regulation in cartilage during endochondral bone formation, we analyzed transgenic mice (Tg) overexpressing Smad 6 or Smad7. In situ hybridization analysis showed elevated expression of Smad 6 in cartilage of Smad6 Tg and elevated expression of Smad7 in cartilage of Smad7 Tg. Cartilage size was normal in Smad6 Tg, but significantly reduced in Smad7 Tg. We next cultured mesenchymal cells derived from 12.5 d.p.c. limb buds and induced cartilaginous nodule formation in the presence of rhBMP2 in micromass system. Cartilaginous nodule formation induced by exogenous BMP2 was prohibited in mesenchymal cells prepared from Smad7 Tg, but not in those from Smad6 Tg. Real-time RT-PCR analysis of the cells in micromass culture showed that the Smad6 expression level in Smad6 transgenic mesenchymal cells was 1.7 times higher than wild-type mesenchymal cells and that the Smad7 expression level in Smad7 Tg was 1.8 times higher. The expression level of Sox9 was normal in Smad6 transgenic cells, but dramatically reduced in Smad7 transgenic cells. Cartilaginous nodule formation induced by rhBMP2 in wild-type mesenchymal cells was inhibited by addition of the SB203580 (inhibitor of p38 MAPK pathway), but not by addition of the SB431542 (inhibitor of TGF- β pathway). Immunoblot analysis of ATDC5 cells showed that BMP-induced phosphorylation of ATF2 was repressed by overexpression of Smad7 but not by overexpression of Smad6. In general, BMP stimulate cartilage formation and chondrocyte hypertrophy. Smad6 Tg showed that BMP signals for chondrocyte hypertrophy is mediated by Smad 1/5/8 that Smad6 blocks. The present results suggest that BMP signals for cartilage formation are mediated by Smad-independent pathways. This pathways could be inhibited by Smad7 but not Smad6. The p38 MAPK pathways may be one of candidates for this pathway.

Analysis of the Role of Runx1 in Chondrocyte Differentiation using Chondrocyte-specific Runx1 Deficient Mice. A. Kimura^{*1}, S. Takeda^{*1}, S. Sato^{*2}, M. Iwasaki^{*2}, H. Inose^{*1}, K. Sinomiya^{*1}. ¹21COE, Dept. of Orthopedics, Tokyo Medical and Dental University, Tokyo, Japan, ²Dept. of Orthopedics, Tokyo Medical and Dental University, Tokyo, Japan.

Chondrocyte differentiation is a multistep process essential for endochondral bone formation.

The transcription factor Runx family is involved in chondrocyte differentiation. Namely, Runx2 accelerates chondrocyte differentiation and Runx3 also regulates chondrocyte maturation in collaboration with Runx2. However, the physiological role of the other member Runx1 in chondrocyte differentiation remains to be elucidated. We previously reported that all Runx genes are expressed in cells of chondrocyte lineage in mouse embryo. In this study, we tried to address the role of Runx1 in chondrocyte differentiation, in vivo, by generating mice deficient for Runx1 specifically in chondrocyte, since mice lacking Runx1 die in the midgestation stage.

We generated Runx1-floxed mice (Runx1^{fl/fl}) harboring loxP sites surrounding exon4 which encodes DNA binding domain of Runx1 by gene targeting. By crossing them with Col1a1-Cre transgenic mice that drive cre expression by chondrocyte-specific Col1a1 promoter, we obtained chondrocyte-specific Runx1 deficient (Col1a1-Cre/Runx1^{fl/fl}) mice.

Successful deletion of Runx1 in Col1a1-Cre/Runx1^{fl/fl} mice was confirmed by southern blot analysis of genomic DNA. Unexpectedly, Col1a1-Cre/Runx1^{fl/fl} mice were grossly normal. By skeletal preparation at birth, Col1a1-Cre/Runx1^{fl/fl} mice were indistinguishable from wild-type mice, namely the size of the body and calcification of the skeleton were similar. Histologically, Col1a1-Cre/Runx1^{fl/fl} embryos showed no overt abnormality. We also analyzed them by In situ hybridization analysis using molecular markers expressed in chondrocytes such as Col1a1, ColXa1 and Indian hedgehog, but we did not detect any abnormality.

Taken together, this study show that Runx1 is not necessary for chondrocyte differentiation and the absence of Runx1 may be compensated by Runx2 and Runx3.

Osteoprotegerin Negatively Regulates Chondroclast Formation and Recruitment in Endochondral Ossification. N. Ota¹, H. Takaishi^{*1}, J. Takito^{*1}, T. Kimura^{*2}, Y. Okada^{*2}, K. Matsuzaki¹, H. Yasuda^{*3}, H. Kawaguchi⁴, Y. Toyama^{*1}. ¹Orthopaedic Surgery, Keio University School of Medicine, Tokyo, Japan, ²Pathology, Keio University School of Medicine, Tokyo, Japan, ³Nagahama Institute for Biochemical Science, Oriental Yeast, Shiga, Japan, ⁴Orthopaedic Surgery, University of Tokyo, Tokyo, Japan.

Osteoprotegerin (OPG) is a decoy receptor for receptor activator of NF- κ B ligand (RANKL). It has been suggested that RANKL expression in hypertrophic chondrocytes is involved in the formation and activation of chondroclasts, which function in resorption of cartilaginous matrix at the growth plates. The fracture repair process closely resembles normal development of the skeleton during embryonic bone formation. We previously reported the accelerated fracture healing in OPG deficient mice (OPG KO) via the rapid resorption of cartilaginous callus due to the enhanced chondroclast recruitment. The purpose of the present study was to further investigate the role of OPG in endochondral ossification using the chondrocytes obtained from OPG KO and wild type (WT). Newborn rib chondrocytes were disseminated as feeder cells in the presence of 1,25-dihydroxy vitamin D3 and PGE2, and cocultured with spleen cells, in order to examine inducing effects of chondrocytes on the chondroclast formation. Strikingly, OPG KO-derived chondrocytes induced numerous TRAP positive multinucleated cells in a coculture system with spleen cells isolated from WT. In contrast, WT-derived chondrocytes could not induce any TRAP positive cells. Addition of recombinant OPG to the coculture system decreased the chondroclastogenesis in a concentration dependent manner. RT-PCR analysis showed that WT chondrocytes increased RANKL mRNA in response to PTHrP, FGF-18, PGE2, IL-1 and TNF- α . On the other hand, TGF- β increased the expression of OPG. Next, we examined whether the chondrocytes fully differentiated in atelocollagen pellets could induce chondroclastogenesis. Cartilage pellets from OPG KO cocultured with RAW 264.7 cells induced TRAP positive multinucleated cells in the presence of 10 ng/ml RANKL, while WT cartilage pellets did not. ELISA measurements indicated that the OPG KO-derived cartilage pellets produced the significant level of soluble RANKL. Finally, the transplantation assay of the cartilage pellets under the kidney capsules of adult OPG KO revealed the remarkable recruitment of TRAP positive cells around the OPG KO-derived cartilage pellets, which were subsequently replaced by osseous tissues. These observations suggest that RANKL and OPG expression in chondrocytes is regulated by various cytokines and inflammatory mediators, and OPG might controls the process of endochondral ossification as a negative regulator of chondrocyte dependent chondroclastogenesis.

CITED1 Ablation Impairs Endochondral Bone Formation During Embryonic Development. D. Yang, J. Guo^{*}, R. Bringhurst^{*}. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

CITED1 (CBP/P300 interacting Transactivator with Glutamic Acid [E]/ Aspartic Acid [D]-Rich C-terminal domain) is a transcriptional cofactor located on the X chromosome. We previously observed that CITED1 expression is rapidly and transiently induced by PTH1R activation in osteoblasts and that cultured osteoblasts from mice lacking CITED1 display abnormal differentiation in vitro. To determine the possible role of CITED1 in early bone development, we have analyzed endochondral bone formation in tibiae from CITED1-knockout (KO) embryonic mice in which the CITED1 gene is replaced with a functional LacZ/Neo cassette and bred into the 129Sv background for five generations. The tibiae of CITED1 KO mice were shorter than those of wild type (WT) littermates, and bone volume and the extent of trabeculae in CITED1 KO tibiae at E18.5 and post-natal day 1 (P1) were significantly reduced, as shown by von Kossa staining and histology. At E15.5, the regions of overall chondrogenesis and of chondrocyte hypertrophy, demonstrated by Col II and Col X expression respectively, were not different in WT and KO; but bone formation, shown by Col I in situ analysis, appeared slightly earlier inside the tibia and expanded wider in perichondral region in the WT. Osteopontin (OPN) is expressed by late hypertrophic chondrocytes and osteoblasts within the primary and secondary spongiosa. Relative to WT, the length of the central region of OPN expression was reduced in all KO bones from E15.5 through P1, accounting for the foreshortening of the overall bone length. In situ hybridization and LacZ staining analysis showed strong expression of CITED1 in this same central region of the developing bones but not in adjacent chondrocytes. We conclude that CITED1 expression, probably by cells of the osteoblast lineage, is important for normal endochondral bone formation and that loss of functional CITED1 expression leads to a reduction in the rate of bone formation. Whether this defect reflects impaired activity of osteoblasts that normally express CITED1 and/or loss of an indirect effect on chondrocyte proliferation and/or differentiation, which could involve PTHrP, remains to be investigated.

A Spontaneous Mutation (Dhe) in the Mouse Lmna Gene Results in Hypoplastic Cranial Sutures and Under-mineralization of the Skeleton. L. R. Donahue¹, D. Liu^{*1}, M. Curtain^{*1}, J. Hurd^{*1}, C. Marden^{*1}, C. A. MacKay^{*2}, P. R. Odgren^{*2}. ¹The Jackson Laboratory, Bar Harbor, ME, USA, ²University of Massachusetts Medical School, Worcester, MA, USA.

The Lmna gene encodes the nuclear lamins A and C, which, along with lamin B, constitute the proteinaceous nuclear envelope. Lmna mutations are associated with connective tissue disorders, including cardiomyopathies, muscular dystrophies, lipodystrophies, progeria and bone abnormalities. We discovered a new mutation in mouse Lmna that demonstrates a critical role for Lmna in cranial suture development and skeletal mineralization. Dhe, (Dominant hair and ears) is a semi-dominant mutation in exon 1 of Lmna (L52R). Dhe/+ mice exhibit a sparse coat, small ear pinnae, hypoplastic cranial sutures, and under-mineralization of the skeleton.

To assess suture formation we used X-ray, histological, and in situ analyses. Skeletal mineralization was measured by DEXA and X-ray.

DEXA showed that areal BMD is lower in Dhe/+ than in controls (Dhe/+ 0.037; +/- 0.045 g/cm²). Under-mineralization can be seen in radiographs of axial and appendicular skeleton. In X-rays of Dhe/+ skulls, the premaxillary/maxillary and cranial vault sutures, and the entire parietal bone, are clearly visible and radiolucent, indicating severe hypomineralization.

Microscopic examination revealed severely hypomorphic sutures in Dhe/+ skulls. The bony plates fail to overlap, the cells and connective tissue connecting the bones are loosely organized and hypoplastic, and suture material is poorly attached.

Extracellular matrix gene expression by in situ hybridization assessed with probes for expression of type I collagen mRNA in bone matrix and type III collagen mRNA in the fibrous suture matrix revealed gross deficiency of collagen gene expression. In controls, rows of osteoblasts on bone surfaces were intensely stained for col I. Bone synthesis was highly polarized, with active bone synthesis confined to specific surfaces, indicating a high degree of site specificity to the production of bone in the cranium. In contrast, Dhe/+ mice had extremely low levels of col I mRNA at the cranial sutures, consistent with a pronounced deficiency of bone synthesis. In +/- mice, the fibroblastic cells inhabiting the suture expressed high levels of col III, consistent with the production of dense connective tissue in the suture proper. In Dhe/+, the level was extremely low, consistent with the loose strands of connective tissue connecting the cranial bones. These observations provide evidence that there is a severe loss of extracellular matrix synthesis at the cellular level in osteoblasts and sutural fibroblasts. Thus, Lmna is critical to normal cranial bone and suture formation and to skeletal mineralization.

Body Mass Influences Bone Mass Independent of Leptin Signaling. U. T. Iwaniec¹, S. Boghossian^{*2}, R. T. Turner¹, S. P. Kalra^{*2}. ¹Nutrition and Exercise Sciences, Oregon State University, Corvallis, OR, USA, ²Neuroscience, University of Florida, Gainesville, FL, USA.

Skeletal growth and turnover are coupled to energy balance via incompletely understood mechanisms. Anorexia is associated with low bone mass, whereas obesity correlates with increased bone mass. Leptin, a hormone produced by fat cells, functions as a sentinel of energy balance and may be a potential mediator of the effects of fat mass on bone mass. The objective of this study was to determine whether increased weight due to increased fat intake increases bone mass, and, if so, whether this requires central leptin signaling. Leptin-deficient ob/ob mice were used in the experiment. In order to replete hypothalamic leptin, 8-10 week-old ob/ob mice were injected in the hypothalamus with a recombinant adeno-associated virus containing the leptin gene (rAAV-lep) or a control vector, rAAV-GFP (green fluorescent protein). The mice were maintained on a regular control diet (RCD) for 7 weeks and then subdivided into groups (n=8-9/group) and either continued on the RCD or fed a high fat diet (HFD, 45 kcal% fat; D12451, Research Diets) for 8 weeks. Bone mass and architecture were evaluated by μ CT. Administration of rAAV-lep resulted in decreased body weight, increased femur length and total femur volume, and reduced cancellous bone volumes in the distal femur and lumbar vertebra, indicating that leptin affects multiple aspects of bone growth and architecture. Body weight increased (P<0.003) with high fat intake (+18%), irrespective of rAAV treatment; mice administered rAAV-GFP weighed 56 \pm 2g on RCD and 66 \pm 2g on HFD, while mice administered rAAV-lep weighed 28 \pm 3g on RCD and 33 \pm 2g on HFD. Total femur bone volume increased with HFD in leptin-deficient rAAV-GFP mice (P<0.001, 14.3 \pm 0.6 mm³ vs. 18.2 \pm 0.4 mm³) and there was a tendency for an increase in total femur bone volume in HFD-fed rAAV-lep-treated mice (P<0.06, 16.2 \pm 0.2 mm³ vs. 17.1 \pm 0.4 mm³). Distal femur and vertebral cancellous bone volume were not altered by diet. There was a significant correlation between body weight and total femur bone volume in wildtype mice fed normal diets (data not shown). Taken together, these findings suggest that increased body weight has a positive effect on total femur bone mass that is independent of dietary fat and leptin signaling.

Phenotypic Analysis of the Crtp^{-/-} Mice: The First Animal Model for Recessive Osteogenesis Imperfecta. R. Morello¹, J. N. Lenington^{*2}, S. Kakuru^{*1}, M. Jiang^{*3}, Y. Chen^{*3}, D. R. Keene^{*4}, B. Lee³. ¹Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, ²Pediatrics, Baylor College of Medicine, Houston, TX, USA, ³Howard Hughes Medical Institute, Houston, TX, USA, ⁴Shriners Hospital for Children, Portland, OR, USA.

We recently described the phenotype of the Crtp^{-/-} mice. These mice exhibit a severe osteochondrodysplasia, with low bone mass, kyphosis and shortening of the long bones. Crtp interacts with prolyl 3-hydroxylase 1 (P3h1) and is essential for proper type I and II collagens post-translational modification. Importantly, the phenotype of Crtp^{-/-} mice closely resembles that of OI patients and mutations in the CRTAP gene cause recessive osteogenesis imperfecta (OI). In this study we extended the phenotypic analysis of our mutant mice in order to obtain a better understanding of the Crtp role during development and adulthood. Adult skeletal preparations showed marked craniofacial abnormalities in the Crtp null mice, consisting of shortening and compression of the anterior portion of the cranium with occasional asymmetry causing malocclusion and overgrowth of the incisor teeth. The skin showed increased laxity compared to WT littermates: a histological analysis revealed a decreased thickness of the dermis while at the ultrastructural level, areas of decreased matrix density as well as collagen fibrils with increased diameter were visible. Histological analysis of visceral organs showed evidence of abnormal lung morphology, with alveolar dilatation associated with thinning of the alveolar walls. Moreover, the kidney glomerular basement membrane appeared to have an expanded lamina lucida at the expenses of the lamina densa, suggesting perhaps an additional Crtp role in the regulation of type IV collagen modification. Finally, loss of Crtp causes a chondrodysplasia with rhizomelic shortening of long bones. Interestingly, BrdU incorporation studies of the growth plate point to a slight increase in chondrocyte proliferation in the zeugopod growth plates of E15.5 Crtp null mice compared to controls. Our studies point to a broad spectrum of connective tissue disease that can arise from loss of CRTAP and altered collagen 3-prolyl-hydroxylation.

Female, But Not Male, TIEG-Null Mice Display Severe Osteopenia and Abnormal Cancellous Bone Microarchitecture. M. Subramaniam¹, J. R. Hawse¹, U. T. Iwaniec², S. F. Bensamoun^{*3}, K. D. Peters^{*1}, N. M. Rajamannan⁴, M. J. Oursler¹, R. T. Turner², T. C. Spelsberg¹. ¹Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, ²Department of Nutrition and Exercise Sciences, Oregon State University, Corvallis, OR, USA, ³Genie Biologique, Universite de Technologie de Compiègne, Compiègne, France, ⁴Department of Cardiology, Northwestern University Medical School, Chicago, IL, USA.

TGF β Inducible Early Gene-1 (TIEG), also classified as Krüppel-like transcription factor-10 (KLF-10), was originally cloned from human osteoblasts and has been shown to play an important role in osteoblast growth and differentiation. To better understand the biological role of TIEG in the skeleton, we generated TIEG-null (TIEG^{-/-}) mice. Calvarial osteoblasts isolated from TIEG^{-/-} mice express reduced levels of Runx2 and other important osteoblast marker genes and have significant defects in their mineralization capacity relative to wild-type (WT) controls. Through the use of PIXImus and pQCT analysis, we have demonstrated that the femurs and tibias of two-month-old C57Black6 female TIEG^{-/-} mice display significant decreases in numerous bone parameters including total bone mineral content, density and area, relative to WT littermates. However, no differences were observed for any of these bone parameters in male mice. In order to further characterize the bone phenotype of female TIEG^{-/-} mice, we performed mechanical 3-point bending tests. These studies revealed that the femurs of TIEG^{-/-} mice are much weaker when compared to WT littermates. Micro-CT analysis of femurs of two-month-old TIEG^{-/-} and WT mice revealed a highly significant 9% decrease in total femur bone mass (cortical + cancellous bone) in the TIEG^{-/-} mice compared to WT littermates. Histomorphometric evaluation of the distal femur revealed that TIEG^{-/-} mice also display a 31% decrease in cancellous bone area, which is primarily due to a 22% decrease in trabeculae number. At the cellular level, TIEG^{-/-} mice exhibit a 42% reduction in bone formation rate which is almost entirely due to a reduction in double labeled perimeter. Differences in the mineral apposition rate were not detected between WT and TIEG^{-/-} mice. Interestingly, we have demonstrated that TIEG is regulated by estrogen in an ER β isoform-specific manner in osteoblasts. Since ER β is primarily expressed in cancellous bone, and since TIEG^{-/-} mice display significant defects in cancellous bone in a gender specific manner, we speculate that the estrogen regulation of TIEG may play a vital role in this phenomenon. Taken together, these findings suggest that TIEG^{-/-} mice are osteopenic mainly due to a decrease in total osteoblast number and support a critical role for TIEG in skeletal development and/or homeostasis.

Biglycan and Fibromodulin Control Bone Mass by Regulating Osteoclast Differentiation Through Bone Marrow Stromal Cells. Y. Bi*, T. M. Kilts*, A. C. Griffin*, M. F. Young. National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD, USA.

Members of the Small Leucine-Rich Proteoglycan (SLRP) family populate numerous sites in the musculoskeletal system including tendon, cartilage and bone, but, their precise role in these tissues is still unclear. Previous work showed that mice with combined deficiencies in two SLRPs, biglycan (bgn) and fibromodulin (fmod), acquire osteoarthritis and ectopic tendon ossification. Here we show that the bgn-0/fmod-0 mice have delayed bone formation during development judged by alizerin red/alcian blue staining and severe age-dependent osteopenia determined by X-ray and microCT analyses. In order to understand the molecular basis for this osteopenia, osteogenic bone marrow stromal cells (BMSCs) were isolated and examined. Colony-forming unit fibroblastic (CFU-F) analysis, which estimates the number of osteogenic stem cells, showed no significant differences between WT and bgn-0/fmod-0 mice. Further, in vitro osteogenesis assays showed that Ca²⁺ accumulation was increased in the bgn-0/fmod-0 BMSC cultures compared to WT BMSCs. Western analysis of the BMSC protein extracts showed that the bgn-0/fmod-0 cells had increased levels of Runx2 compared to WT controls. The bgn-0/fmod-0 BMSCs also had increased BMP-2 and TGF- β 1 signaling indicated by increased levels of p-smad1 and p-smad2/3 in the presence of BMP-2 and TGF- β 1 compared to WT BMSCs, respectively. Furthermore, in vivo bone formation was not significantly different between WT and bgn-0/fmod-0 BMSCs transplanted subcutaneously into immuno-compromised mice. From these data, we concluded that the decreased bone mass in bgn-0/fmod-0 mice was not primarily due to a defect in osteogenesis. We next determined whether the osteopenia in bgn-0/fmod-0 mice could be due to increased differentiation and/or activity of osteoclasts. To test this, sections of long bone and BMSC transplants were stained for Tartrate-Resistant Acid Phosphatase (TRAP), an osteoclast marker. The number of TRAP positive cells was higher in bone and in vivo BMSC transplants from bgn-0/fmod-0 mice. Osteoclastogenesis was assessed by adding bone marrow suspensions to plates in which BMSC had formed individual colonies and showed that greater numbers of colonies in the bgn-0/fmod-0 cultures supported formation of TRAP-positive multinucleated cells compared to WT. In summary, we have shown that bgn and fmod when depleted in combination have a negative influence on bone mass by increasing osteoclast formation and function and thereby pointing to the possibility that these SLRPs could be novel targets to modulate bone turnover.

Implication of Two Matrix Proteins in Bone Healing: Osteopontin (OPN) and Bone Sialoprotein (BSP). L. Monfoulet*, J. Fricain*, L. Malaval*, J. Aubin*, O. Chassande*. ¹INSERM U577 - Univ Victor Segalen Bordeaux2, bordeaux, France, ²INSERM U890 - Univ Jean Monnet, St Etienne, France, ³Medical Genetics and Microbiology, Faculty of Medicine, University of Toronto, Toronto, ON, Canada.

Bone fracture healing involves a well characterized cascade of events that includes: hematoma, inflammation, "soft" callus, neovascularization, callus mineralization and remodelling of the "hard" callus to generate mature lamellar bone. This complex sequence of biological processes is controlled by chemotactic factors, growth factors and bone matrix proteins. Our study is focused on two major non-collagenous bone matrix proteins belonging to the Small Integrin-Binding Ligand N-linked Glycoprotein (SIBLING) family: osteopontin and Bone Sialoprotein. OPN promotes angiogenesis, inhibits bone mineralization, and regulates osteoclast function. BSP is involved in osteoclast adhesion and differentiation, in matrix mineralization, and mediates endothelial cell migration and angiogenesis. Together, these data suggest that BSP and OPN can play an important role in bone fracture healing. To investigate the role of these proteins of bone healing, we used mice knockout for the OPN or BSP genes. We developed a new model of bone healing in mice which consists in a 0.9 mm diameter cortical defect in the femoral diaphysis. Micro-computed tomography was used to quantify mineralization at 14 and 21 days. Histology (at 14 and 21 days) and quantitative RT-PCR (at 10 days) were used to evaluate cellular functions related to ECM formation, bone formation and remodelling. We also established primary cultures of osteoblasts from mutant and wild type bone marrow, characterized by quantitative RT-PCR and alkaline phosphatase activity. Using micro-CT, we have demonstrated in BSP-0 mice a significant delay of bone healing as showed by a slower decrease of the Bone Volume / Tissue Volume (BV/TV) volume within the defect. At 10 days, RT-PCR analysis reveals a lower expression of osteocalcin mRNA in BSP-0 mice compared to wild-type mice. These preliminary results suggest that the delay in bone healing observed in BSP-0 mice could be due to a decreased osteoblast activity. In contrast, the OPN-0 mice show an advanced bone healing in comparison with wild-type. We have also developed primary cultures of mouse Bone Marrow Stromal Cells to investigate the role of this bone matrix protein on osteoblast differentiation. The first results tend to show that OPN deficiency accelerates differentiation into mature osteoblasts. This early differentiation could explain the advanced bone healing observed by microCT in OPN-0 mice. In summary, our results reveal antagonist roles for these two major bone matrix proteins during the process of bone healing.

Delayed Cartilage and Bone Remodeling During Fracture Healing in Matrix Metalloproteinase 13 Null Mutant Mice. C. Colnot¹, D. J. Behonick², S. Lieu¹, Z. Xing¹, R. Marcucio¹, Z. Werb², T. Miclau¹. ¹Orthopaedic Surgery, University of California San Francisco, San Francisco, CA, USA, ²Anatomy, University of California San Francisco, San Francisco, CA, USA.

Adult bone does not heal through the production of scar tissue rather through a regenerative process, that recapitulates early skeletal development. Matrix metalloproteinase 13 (MMP13, collagenase-3) is an extracellular matrix (ECM) protease whose preferred substrates include the major components of cartilage and bone ECM. MMP13 has been shown to be important for skeletal development via endochondral ossification (1). This observation led us to question the role of MMP13 in skeletal repair. We compared bone healing in Mmp13^{-/-} and wild type mice during non-stable, stable fracture repair and cortical defect healing. In order to understand which cell types were affected by the Mmp13^{-/-} mutation, we examined the expression profile of Mmp13 during bone healing using in situ hybridization. In addition, we transplanted bone marrow from wild type mice into Mmp13^{-/-} mice and compared healing to Mmp13^{-/-} mice, which received bone marrow from a Mmp13^{-/-} donor. Tissues were analyzed by cellular, molecular and histomorphometric analyses on paraffin tissue sections.

We show that MMP13 is required for proper resorption of hypertrophic cartilage and normal bone remodeling during non-stabilized fracture healing, which occurs via endochondral ossification (Fig. 1). Transplant of bone marrow from wild type mice is not sufficient to rescue the Mmp13^{-/-} healing phenotype. These results indicate that impaired healing is intrinsic to cartilage and/or bone and is not due to defects in osteoclasts. These results are consistent with the expression of Mmp13 which is restricted to hypertrophic chondrocytes and osteoblasts but absent from osteoclasts. Furthermore, Mmp13^{-/-} mice also exhibit a delay in bone remodeling during healing of stabilized fractures and cortical defects via intramembranous ossification, demonstrating that the bone phenotype is independent from the cartilage phenotype. Overall, our findings demonstrate that MMP13 is crucial for normal production and remodeling of cartilage and bone during adult fracture repair.

Rescue of MT1-MMP Expression in Cartilage Increases Survival, Chondrocyte Proliferation and Bone Formation in MT1-MMP Deficient Mice. L. Szabova*, S. Yamada*, K. Holmbeck*. CSDB/MMPU, NIDCR, Bethesda, MD, USA.

Membrane type-1 matrix metalloproteinase (MT1-MMP) is a potent collagenase essential for proper remodeling of collagen rich tissues. Mice deficient for MT1-MMP (KO) are dwarfs with severe fibrosis of connective tissues, bone loss and retention of embryonic cartilages in the skull due to impaired degradation of unmineralized type I and II collagens. Here we define the contribution of disrupted cartilage remodeling in the development of the MT1-MMP-deficient phenotype. Specifically, we created transgenic mice where MT1-MMP expression was selectively re-introduced in cartilage tissues using a transgene driven by the type II collagen promoter/enhancer. We have bred these mice into the MT1-MMP-deficient background and evaluated the developmental effects of MT1-MMP expression in the cartilage tissue of otherwise MT1-MMP deficient mice. Cartilage specific MT1-MMP expression in KO mice resulted in complete rescue of the pre-weaning death observed in KO mice, increased body weight and prolonged survival. Transgenic KO mice further displayed increased bone formation in the skull compared to KO mice. Strong expression of the MT1-MMP transgene increased chondrocyte proliferation in the epiphyseal growth plate, which resulted in increased growth of the long bones. Increased bone formation quite unexpectedly coincided with expression of the transgene in a subset of bone cells. Expression of type II collagen was documented in bone cells of normal mice using *in situ* hybridization and immunostaining thus documenting that transgene expression was not ectopic, but mirrored the normal expression pattern of type II collagen. This finding explains the increased bone formation observed in transgenic KO mice since MT1-MMP is necessary for maintaining the bone formation. In conclusion, reintroduction of MT1-MMP in the cartilage of MT1-MMP KO mice results not only in cartilage specific expression, but also directs transgene expression in a subset of bone cells thereby facilitating increased bone formation. These bone cells are most likely the descendants of a common progenitor of bone cells and chondrocytes expressing type II collagen and support our previous observation that some chondrocytes can differentiate into bone cells. Our data suggest that MT1-MMP provides type II expressing chondrocytes and bone cells with the necessary collagenolytic activity required for chondrocyte proliferation and bone formation *in vivo*.

Identification of a Novel Stem Cell for Bone and Cartilage of the Myeloid Lineage. Z. W. Lazard*, C. M. Fouletier-Dilling*, F. H. Gannon², M. H. Heggeness*, E. A. Olmsted-Davis¹, A. R. Davis¹. ¹Cell and Gene Therapy, Baylor College of Medicine, Houston, TX, USA, ²Orthopedic Surgery and Pathology, Baylor College of Medicine, Houston, TX, USA, ³Orthopedic Surgery, Baylor College of Medicine, Houston, TX, USA.

We have previously shown that osteoblasts can be derived from hematopoietic stem cells (HSC), through mesenchymal progenitors. In this study, we focused on identifying the pathway that leads from a bone marrow HSC to a mesenchymal progenitor for bone and cartilage. To better characterize this process, we used a BMP2 inductive model which recruits chondro-osseous progenitors in the mouse to a heterotopic location. In this bone formation model, cells transduced with an adenovirus expressing BMP2 were implanted into the muscle in the mouse hind limb. Bone formation occurs rapidly, with cartilage appearing within 6 days and mineralized osteoid detected by 7 days after implantation of the transduced cells. Initial characterization of the tissues isolated three days after induction showed a substantial increase in tentative progenitors. These cells possessed the marker of the donor HSCs used to repopulate the bone marrow in ablated recipients, suggesting they were bone marrow derived. Cells isolated from the day 4 tissues were capable of undergoing osteogenic or chondrogenic differentiation *in vitro*. Immunohistochemical and microarray analysis of these tissues showed specific elevation in genes associated both with mesenchymal stem cells (CD44, CXCR4) as well as myeloid cells (CD11b, CD68, CD166) in tissues receiving the AdBMP2 transduced cells as compared to those receiving cells transduced with an empty vector. To further delineate the tentative myeloid origin of these progenitors we performed heterotopic bone assays in mice which express myeloid restricted β -galactosidase. In these mice cre recombinase is expressed by the myeloid specific LysM gene promoter which can remove the intervening DNA sequence between the LacZ gene promoter and its transcriptional start site leading to permanent activation. Analysis of the tissues shows specific β -galactosidase activity in the tentative progenitors, as well as the mature chondrocytes, and osteoblasts in the heterotopic bone as well as adjacent skeletal bone. Since these bone marrow derived cells must circulate to reach the heterotopic location, we next attempted to purify these from peripheral blood. Results showed significant elevation in both myeloid and mesenchymal stem cell markers on peripheral blood mononuclear cells by 3 days after induction of bone formation. The data collectively demonstrates a novel myeloid progenitor, easily isolated from peripheral blood, that is recruited for endochondral bone formation.

BMP Canonical Signaling Through Receptor Smads 1 and 5 Is Required for Endochondral Bone Formation. K. N. Retting*, R. R. Behringer*, K. M. Lyons¹. ¹Orthopaedic Surgery, UCLA, Los Angeles, CA, USA, ²Molecular Genetics, University of Texas M.D. Anderson Cancer Center, Houston, TX, USA.

Transforming growth factor- β (TGF β) superfamily members including bone morphogenetic proteins (BMP) play multiple roles during endochondral bone formation. It is believed that TGF β superfamily members signal predominantly through canonical Smad pathways during chondrogenesis. The BMP family activates Smads 1, 5 and 8. We have found nuclear localization of BMP R-Smads in proliferating and differentiating chondrocytes in the growth plate and in primary cultures. These and other studies establish that BMP signaling is required for chondrogenesis. R-Smads share structural homology, yet the extent to which Smad proteins are functionally redundant, regulate distinct targets, and control endochondral bone formation *in vivo* is unknown. To study the role of BMP R-Smads during chondrogenesis, we generated knockout models of Smads 1, 5 and 8 individually and in combination. It has been reported that Smad8 null mice have no obvious defects. Because mice null for either Smad1 or 5 die too early in embryogenesis for chondrogenesis analysis, we conditionally deleted Smads 1, 5 and 8 in endochondral elements utilizing the cartilage-specific collagen II-Cre. Cartilage-specific loss of Smad1 as well as the combined loss of Smads1 and 8 results in apparently normal mice. However, Smad1 (fx/fx);Smad5 (fx/fx);Col2Cre mutant mice exhibit severe chondrodysplasia, resulting in lethality at birth. Smad1/5^{CKO} mutants display little to no mineralization of the axial skeleton. The dramatically shortened limbs lack an organized growth plate and display excessive growth in the bone collar. These data demonstrate that canonical Smad signaling is required for endochondral bone formation, and suggest that Smads 1 and 5 exhibit functional redundancy. The phenotype is more severe than that seen in Smad4 (fx/fx);Col2Cre mice, challenging the dogma, at least in chondrocytes, that co-Smad4 is required to mediate Smad signaling through TGF β and BMP pathways. Furthermore, skeletal defects in the Smad1/5^{CKO} are not as severe as the cartilage-specific knockout of BMP receptors, indicating that BMP signaling is not completely abolished. We are currently testing these hypotheses. Overall, these data demonstrate the importance of the BMP canonical Smad pathway in chondrogenesis and answer the questions of functional redundancy of Smads1, 5 and 8.

Absence of endochondral bone formation in Smad1 (fx/fx);Smad5 (fx/fx);Col2Cre mice. Wild type (A,C) and mutant (B,D) littermates at P0; MicroCT scan (A,B); proximal tibia stained with Alcian blue and nuclear fast red (C,D).

Role of TROY in Tooth Development. N. Yamaguchi¹, H. Ichioka^{*1}, S. Toyosawa^{*2}, H. Harada^{*3}, R. Nishimura¹, T. Yoneda¹. ¹Biochemistry, Osaka University Graduate School of Dentistry, Suita, Japan, ²Oral Pathology, Osaka University Graduate School of Dentistry, Suita, Japan, ³Oral Anatomy 2, Iwate Medical University School of Dentistry, Morioka, Japan.

Mutations of ectodysplasin (Eda), a member of TNF family, cause hypohydrotic ectodermal dysplasia (HED), characterized by ectodermal abnormalities, including sweat glands defects, impaired hair formation, anodontia/oligodontia, and amelogenesis imperfecta. It is also demonstrated that the receptor for Eda/Edar and an adaptor protein of Edar EDARADD are responsible for HED. Spontaneous mutations of the Eda, Edar or EDARADD gene in mice also develop HED like phenotype. These results indicate a critical role of Eda/Edar/EDARADD signal in the tooth development. Eda/Edar/EDARADD transduces signals into cytoplasm through TRAF6. Mice deficient in TRAF6 gene showed more severe ectodermal abnormalities than tabby mice which have a mutation in the Eda gene. We therefore hypothesized that an additional pathway plays a role in the tooth development through TRAF6. Because a TNF receptor family member, TROY, which has 33% homology to Edar and directly binds to TRAF6, is expressed in tooth germ, we examined whether TROY plays a critical role in tooth development associated with TRAF6.

We first determined the expression of TROY in tooth germs. RT-PCR analyses demonstrated the expression of TROY in tooth germs of E13 or 14 days mouse embryos. In addition, we also found that Nogo Receptor 66-1 and LINGO-1, both of which function as co-receptors of TROY, were expressed in tooth germs, suggesting an involvement of TROY in the tooth development. To understand the role of TROY in the tooth development, we generated soluble TROY (sTROY), which consists of only an extracellular domain of TROY, and thus is expected to function as a decoy receptor for TROY, and determined its effect on the development of tooth germs of mice in organ culture system. Treatment with sTROY clearly impaired growth of tooth germs. Furthermore, sTROY markedly inhibited expression of phenotypic markers of ameloblast such as ameloblastin, amelogenin, and Sp6. These results suggest that TROY is involved in ameloblast differentiation. To determine downstream pathways of TROY involved in the tooth development, we next examined whether p38 and JNK pathways, which are well-known downstream pathways of TRAF6, are involved in the tooth development. We observed that p38 inhibitor (SB203580) and JNK inhibitor (SP600125) dramatically inhibited the development of tooth germs and reduced expression of ameloblastin at transcriptional level. In conclusion, our data suggest that TROY plays an important role in the tooth development, especially in ameloblast differentiation, presumably through p38 and JNK pathways.

Sclerostin Overexpression Impairs Limb Patterning. N. M. Collette^{*1}, R. M. Harland^{*2}, G. G. Loots¹. ¹Biosciences and Biotechnology Division, Lawrence Livermore National Laboratory, Livermore, CA, USA, ²Department of Molecular and Cellular Biology, University of California, Berkeley, CA, USA.

Sclerostin (SOST) is a negative regulator of bone formation that has been described as both a BMP- and WNT- antagonist. Loss of SOST function causes sclerosteosis (MIM 269500), a condition of severe progressive bone overgrowth. Using transgenic mice expressing human SOST from a bacterial artificial chromosome (BAC) we have demonstrated that SOST over-expression causes decreased bone formation and results in osteopenia, similar to the over-expression of other BMP antagonists such as Noggin and Gremlin. These mice also exhibit severe limb patterning defects that are dose-dependent and range from the loss of a single posterior digit to the loss and/or fusion of many distal limb skeletal elements. The apical ectodermal ridge (AER) relays cell-cell signals to the underlying differentiating limb mesenchyme, a place of SOST expression initiated as early as E9.5. To determine how elevated levels of SOST impair proper limb patterning, we have examined AER and cartilage markers by measuring mRNA levels by in situ hybridization. We find FGF8, a major AER signaling molecule and underlying mesenchymal markers BMP2, Gli1, Pax1, HoxD12 and gremlin expression to be perturbed in SOST transgenic mice. In addition, skeletal analysis of double mutant animals show that over-expression of SOST fails to complement loss of BMP antagonists (Gremlin and Noggin) essential for limb patterning and chondrogenesis, resulting in more dramatic skeletal defects than single mutants alone, suggesting that SOST action in the limb parallels the BMP-pathway. This work is supported by NIH RO1 HD047853 and the work has been performed under the auspices of the U.S. Department of Energy by the University of California, Lawrence Livermore National Laboratory Contract No. W-7405-Eng-48. Lysophosphatidic Acid Induces Osteocyte Dendrite Outgrowth. S. A. Karagiosis^{*}, N. J. Karin. Biological Sciences Division, Pacific Northwest National Laboratory, Richland, WA, USA.

Osteocytes form an extensive mechanosensory network in bone matrix and communicate intercellularly via gap junctions established at dendrite termini. These membrane extensions are thought to be essential for osteocyte function, but the mechanisms that govern dendrite formation are not known. We previously demonstrated that osteoblasts, the progenitors of osteocytes, are highly responsive to the lipid growth factor lysophosphatidic acid (LPA). LPA-treated MC3T3-E1 osteoblastic cells developed membrane structures that resemble osteocyte dendrites [Masiello et al. (2006) Bone 39:72-82], and we predicted that LPA would promote osteocyte membrane outgrowth. We developed a method to measure osteocyte dendritogenesis in vitro using a modified transwell assay and determined that LPA is a potent stimulator of dendrite outgrowth in MLO-Y4 osteocytes. The stimulatory effects were dose-dependent with maximal outgrowth observed within a physiological range of LPA. The LPA-induced increase in dendrite formation was blocked by the specific LPA-receptor antagonist K16425 and by pertussis toxin. LPA-treated osteocytes exhibited distinct rearrangements of the actin cytoskeleton and a more stellate morphology than control cells. These data are the first evidence for the regulation of dendrite formation by a soluble factor. Osteocytes in vivo are encased in bone matrix, rendering them non-motile. However, LPA promoted MLO-Y4 cell chemotaxis, suggesting that commonalities exist between the intracellular signaling pathways that regulate dendrite outgrowth and cell motility. Bone cells in vivo encounter platelet-derived LPA in regions of bone damage, and we postulate that this lipid factor is important for re-establishing osteocyte connectivity during fracture repair. We also found that MC3T3-E1 cells, primary mouse calvarial osteoblasts and MLO-Y4 osteocytes express autotaxin, a lysophospholipase that catalyzes the generation of LPA. This indicates that bone cells may be exposed to LPA under conditions other than the response to bone damage, and that this lipid growth factor may have broader roles in the control of skeletal homeostasis.

TNF-alpha Upregulates Aortic BMP2-Msx2-Wnt Signaling in Diabetic LDLR-/- Mice. J. S. Shao, C. F. Lai, Z. Al-Aly^{*}, J. Cai^{*}, E. Huang^{*}, S. L. Cheng, D. A. Towler. Dept. of Internal Medicine, Washington University School of Medicine, St. Louis, MO, USA.

Aortofemoral calcification is prevalent in type II diabetes (T2DM), tracking metabolic syndrome parameters and increasing the risk for lower extremity amputation. LDLR-/- mice fed high fat diets (HFD) develop obesity, T2DM, and accumulate aortic calcium - the latter mediated via osteogenic mechanisms that resemble craniofacial mineralization. HFD upregulate aortic BMP2 and Msx2-Wnt signaling cascades that promote mineralization in neural crest-derived skeletal tissues. Administration of recombinant purified BMP2 augments aortic Msx2-Wnt signaling in TOPGAL reporter mice, and promotes aortic calcium deposition in LDLR-/- mice. Low-grade inflammation, including elevated circulating TNF-alpha, is characteristic of obesity with T2DM, therefore, we examined the relationships between TNF-alpha and aortic BMP2-Msx2-Wnt signaling in the LDLR-/- model. HFD feeding promotes obesity, hyperglycemia, and hyperlipidemia -- and upregulated serum TNF-alpha and haptoglobin in male LDLR-/- mice. Oxidative stress, reflected in serum 8-F-alpha-isoprostane (8-IsoP) levels, was increased, with concomitant upregulation of aortic BMP2 (2.5-fold), Msx2 (2.5-fold), Wnt3a (10-fold), and Wnt7a (14-fold) gene expression (all p < 0.01, 2-tailed t-test). Treatment of diabetic LDLR-/- mice with the TNF-alpha antagonist infliximab (10 ug / gm twice weekly, 5 animals per group) did not reduce obesity, hyperleptinemia, or hyperglycemia; however, serum 8-IsoP and haptoglobin levels were significantly decreased. Moreover, aortic BMP2, Msx2, Wnt3a, and Wnt7a expression and aortic calcium accumulation were concomitantly and significantly reduced by infliximab treatment (all p < 0.05). Administration of sodium salicylate, an alternative anti-inflammatory strategy, also reduced serum haptoglobin and aortic Msx2 gene expression. Finally, C57BL/6 mice with arterial smooth muscle TNF-alpha expression augmented by a SM22- TNF-alpha transgene accumulate significantly higher levels of aortic BMP2, Msx2, Wnt3a, and Wnt7a mRNAs vs. their non-transgenic sibling cohorts. Furthermore, 80% of SM22-TNFalpha; TOPGAL mice exhibit aortic beta-galactosidase reporter staining vs. 0% of their non-transgenic TOPGAL siblings (p=0.05 with Yates' chi-square correction), indicating net enhanced mural Wnt signaling by the SM22-TNFalpha transgene. Thus, inflammatory TNF-alpha signals promote pro-calcific BMP2-Msx2-Wnt programs in the aortic tissues of diabetic LDLR-/- mice. Strategies that inhibit inflammation-induced arterial BMP2-Msx2-Wnt signals may improve aortofemoral physiology and reduce lower extremity amputation risk in T2DM.

IGF-I Engineered Bone Marrow Mesenchymal Stem Cells Improve the Fracture Healing Process. F. Granero-Molto¹, J. A. Weis¹, L. D. O'Rear¹, M. I. Miga², A. Spagnoli¹. ¹Pediatrics, Vanderbilt University, Nashville, TN, USA, ²Biomedical Engineering, Vanderbilt University, Nashville, TN, USA.

Healing failure occurs in 20% of the fractures. The reasons why fractures do not heal are mostly unknown. Limitations in adult stem cells (MSC) and growth factor imbalance play critical roles. The purpose of this study is to determine the regenerative ability of bone marrow (BM) MSC engineered to express IGF-I in a rodent fracture healing model. MSC, isolated from BM of syngenic FVB male mice, were retrovirally infected and selected either to stably express human des-IGF-I (MSC-IGF-I) or empty vector (MSC). Syngenic female mice (8-10 weeks old) were subjected to a three point bending stabilized tibia fracture and then transplanted either with 10⁶ MSC-IGF-I or MSC by IV tail injection. Fractured females were also used as controls (no cells). Fractured tibias were analyzed longitudinally by μ CT scan (Scanco 40 μ m). Fracture mechanoproperties were determined by distraction biomechanical testing (BMT) (ELF 3100, Bose). Callus cross-sections were subjected to histological and in-situ hybridization studies for cartilage and bone markers. As shown in Table I, fractured mice transplanted with MSC-IGF-I showed a significant improvement of the biomechanical properties of the callus with an increase in peak force, modulus of elasticity and energy to peak compared to controls.

	MSC-IGF-I (n=3)	MSC (n=4)	No cells (n=4)
Peak Force (N)	5.00 \pm 1.32 ^{*#}	2.63 \pm 0.96	1.86 \pm 0.55
Modulus of Elasticity (N/mm)	41.12 \pm 1.02 ^{*#}	11.95 \pm 9.76	19.39 \pm 9.35
Energy to Peak (N*mm)	0.36 \pm 0.18 ^{*#}	0.49 \pm 0.11	0.14 \pm 0.05

Table I. MSC-IGF-I transplant improves fracture healing. BMT performed 14 days after fracture/transplant. *p<0.05 vs MSC; #p<0.05 vs no cells.

As determined by μ CT analyses, fractured mice transplanted with MSC-IGF-I showed a significant increase in total, new high and low mineralized bone volumes (Table II).

	MSC-IGF-I (n=3)	MSC (n=3)	No cells (n=2)
New High Mineralized Bone (NH) (mm ³)	2.71 \pm 0.45 ^{*#}	2.02 \pm 0.47	1.93 \pm 0.07
New Low Mineralized Bone (NL) (mm ³)	6.91 \pm 2.24 [#]	3.43 \pm 0.61	3.69 \pm 1.26
Total Bone Volume (B+NH+NL) (mm ³)	13.72 \pm 2.22 [*]	9.32 \pm 1.15	9.26 \pm 1.32

Table II. MSC-IGF-I transplant increases callus bone mineralized volumes. μ CT analyses performed 14 days after fracture/transplant. *p<0.05 vs MSC; #p<0.05 vs no cells.

In-situ hybridization showed that in mice transplanted with MSC-IGF-I, the increase in biomechanical properties and bone callus volumes was associated with an increase of collagen-1 and 10 expression. We conclude that MSC-IGF-I transplant improves fracture repair increasing the fracture mechanoproperties, bone volumes and bone/cartilage gene expression. Our studies provide critical data to implement a novel therapeutic approach in patients with fracture healing failure transplanting MSC engineered to express IGF-I.

E-Selectin Ligand 1 Negatively Regulates TGF β in the Golgi During Skeletogenesis. T. Yang¹, R. Mendoza-Londono¹, H. Lu¹, K. Li¹, B. Keller¹, M. Jiang¹, Y. Chen¹, T. Bertin¹, B. Dabovic², D. B. Rifkin³, J. Hick⁴, A. L. Beaudet¹, B. Lee¹. ¹Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, ²Department of Cell, New York University Medical Center, New York, NY, USA, ³New York University Medical Center, New York, NY, USA, ⁴Dept. Pathology, Baylor College of Medicine, Houston, TX, USA.

Transforming growth factor β (TGF β) signaling is critical for the regulation of growth and differentiation during development and disease. Its context dependent action is specified by numerous control mechanisms at the extracellular level and downstream of ligand-receptor interactions, but little is known about the regulation of its post-translational trafficking. E-Selectin Ligand-1 (ESL-1), the cysteine rich protein originally isolated as a ligand for E-Selectin, was found to interact with FGFs and to be co-purified with TGF β 1 in a large protein complex. To elucidate the in vivo function of ESL-1, we mutated Esl-1 gene in mice by conventional knock-out strategy. The newborn and adult Esl-1^{-/-} mice are notably smaller with narrow chests and generalized shortening and thinning of the long bones, ribs and spine. By histological analysis, P1 Esl-1^{-/-} mice showed shortening of the growth plates in both the proliferating zone and hypertrophic zone. Further molecular biology assays show that ESL-1 acts as a negative regulator of TGF β production by binding TGF β precursors in the Golgi in a cell autonomous fashion. In vivo, loss of ESL-1 function causes increased TGF β signaling resulting in decreased cell proliferation and delayed terminal differentiation in the cartilaginous growth plate, independent of effects on BMP and FGF signaling. Moreover, in vivo genetic models of gain vs. loss of TGF β signaling in the growth plate confirm this effect. These data identify a novel cellular mechanism for regulating TGF β during skeletogenesis and cartilage homeostasis.

Klotho Ablation Completely Reverses the Biochemical and Skeletal Alterations in FGF23(R176Q) Transgenic Mice. X. Bai, H. Fu*, D. Qiu*, D. Goltzman, A. C. Karaplis. Department of Medicine, McGill University, Montreal, PQ, Canada.

Recently, we described the generation of a murine model of FGF23(R176Q) overexpression (FGF23^{tg}) and the associated biochemical and bone histological changes consistent with abnormal vitamin D metabolism and rickets. In this study, we have sought to use the mouse genetic approach to clarify the role of Klotho in the metabolic derangements associated with FGF23(R176Q) overexpression. To this end, we have crossed mice heterozygous for the hypomorphic Klotho allele (Kl^{-/-}) and Fgf23^{tg} mice to obtain Fgf23^{tg} transgenic mice homozygous for the Kl-hypomorphic allele (Fgf23^{tg}/Kl^{-/-}). Mice were sacrificed on day 50 post partum and serum, urine, and tissues were procured for analysis and comparison to Fgf23^{tg} WT, and Kl^{-/-} controls. From 4 weeks onward, Fgf23^{tg}/Kl^{-/-} mice were clearly distinguishable from Fgf23^{tg} mice and exhibited a striking phenotypic resemblance to the Kl^{-/-} controls. Their average body weight was 12.5 g \pm 0.7 (N=12), similar to that of Kl^{-/-} mice (12.7 g \pm 0.6; N=12) and significantly different from Fgf23^{tg} (18.6 g \pm 0.3; N=12) and WT controls (23.5 g \pm 0.5; N=12). Similarly, their average life span was dramatically diminished compared to Fgf23^{tg} mice (59.6 days vs. ~2 years) but comparable to that of Kl^{-/-} mice (62.4 days). Serum analysis for calcium (12.04 \pm 0.30 vs. 11.19 \pm 0.12 vs. 10.27 \pm 0.11 mg/dl), phosphorus (13.74 \pm 0.66 vs. 15.87 \pm 0.44 vs. 6.43 \pm 0.27 mg/dl), PTH (46.67 \pm 0.58 vs. 48.24 \pm 1.19 vs. 84.23 \pm 11.37 pg/ml), 1,25(OH)₂ vitamin D₃ (164.30 \pm 13.71 vs. 159.3 \pm 14.11 vs. 73.33 \pm 8.49 pg/ml), and alkaline phosphatase activity (163.30 \pm 15.59 vs. 125.40 \pm 26.20 vs. 611.3 \pm 66.04 IU/L) further confirmed the serum biochemical resemblance between the Fgf23^{tg}/Kl^{-/-} and Kl^{-/-} mice and their distinct difference from that of Fgf23^{tg} controls, respectively. Serum intact FGF23 levels also paralleled this pattern (371,500 \pm 16,500 vs. 336,000 \pm 32,300 vs. 2,544 \pm 463 pg/ml) among animals of the three genotypes. The characteristic bony changes associated with FGF23(R176Q) overexpression were also dramatically reversed by the absence of Klotho. Hence, frontal view of 3D reconstructed proximal end of Fgf23^{tg}/Kl^{-/-} tibia obtained using microCT showed complete reversal of the wide, unmineralized growth plate observed in the Fgf23^{tg} mice. Improved skeletal mineralization was also confirmed on histological sections of the Fgf23^{tg}/Kl^{-/-} epiphyseal region of femurs with complete absence of the profound osteomalacic changes apparent in trabecular and cortical bone in animals expressing FGF23(R176Q). In summary, our findings confirm the pivotal role of Klotho in the mechanism of action of FGF23 as its concomitant ablation fully reverses the complete spectrum of biochemical and skeletal disturbances attributed to FGF23.

1,25(OH)₂D₃ Inhibits Bone Nodule Mineralization Through the FGF23-Mediated ERK Pathway in Rat Calvaria Osteoblast Cultures. T. Minamizaki¹, Y. Yoshiko¹, H. Wang¹, S. Suzuki¹, K. Kozai², J. E. Aubin³, N. Maeda¹. ¹Oral Growth & Developmental Biology, Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan, ²Pediatric Dentistry, Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan, ³Molecular and Medical Genetics, University of Toronto, Toronto, ON, Canada.

Vitamin D, or its active metabolite 1,25-dihydroxyvitamin D₃ (1,25(OH)₂D₃), plays a major role in the regulation of mineral homeostasis and affects bone metabolism, but separating direct effects on osteoblasts and bone from indirect effects via other cell types and organs has been difficult in humans and animal models. However, osteoblasts possess a specific receptor for 1,25(OH)₂D₃ and 1,25(OH)₂D₃ affects many osteoblast functions including proliferation, extracellular matrix synthesis, etc. In the well-established rat calvaria (RC) osteoblast model, we found that 1,25(OH)₂D₃ inhibits bone nodule mineralization, concomitant with upregulation of production of fibroblast growth factor (FGF)23, a phosphate-regulating factor responsible for several phosphaturic disorders; we also found that overexpression of FGF23 in RC cells inhibits bone nodule mineralization. We therefore hypothesized that FGF23 may be involved in 1,25(OH)₂D₃-dependent mineralization defects in the RC osteoblast model. To test this hypothesis, we first confirmed that RC osteoblasts expressed Klotho, a senescence-related protein and FGF receptor (FGFR)s, which together are necessary for FGF23-specific signaling. 1,25(OH)₂D₃ (0.1~10 nM) upregulated FGF23 production in nodule-forming osteoblastic cells but not proliferating progenitor cells, and this activity was enhanced by 10 mM β -glycerophosphate, a stimulator of mineralization. We next prepared conditioned media from 10 nM 1,25(OH)₂D₃-treated (CM-D; FGF23, \geq 10,000 pg/ml) and -untreated (CM-C; FGF23, approx. 20 pg/ml) RC osteoblast cultures. As predicted, CM-D but neither CM-C nor 1,25(OH)₂D₃ at reduced concentrations in CM-D (\leq 0.4 nM) inhibited bone nodule mineralization in a dilution dependent manner (1:50-1:200). Neutralizing anti-FGFR antibody, SU5402 (an inhibitor of tyrosine kinase activity of FGFR1) and U0126 (an inhibitor of extracellular signaling-related kinase (ERK)) all rescued the mineralization defects seen in both CM-D and 1,25(OH)₂D₃ (10 nM)-treated RC osteoblast cultures. These effects were, at least in part, mimicked by either small interfering (si)RNA knockdown of FGF23 or siRNA knockdown of Klotho. Thus, our observations suggest that 1,25(OH)₂D₃ inhibits bone nodule mineralization through an FGF23-induced ERK pathway in RC osteoblast cultures.

FGF-7 Is a Potent In Vivo Phosphaturic Agent in Rats. A. Shaikh*, T. Berndt*, R. Kumar. Nephrology Research, Mayo Clinic Rochester, Rochester, MN, USA.

FGF-7 has been identified as a tumor-derived phosphatonin on the basis of its ability to inhibit Na⁺ dependent phosphate uptake in cultured renal epithelia. Its bioactivity in vivo is unknown. The purpose of this study was to compare the phosphaturic effect of fibroblast growth factor-7 (FGF-7) to that of FGF-23 in rats with intact parathyroid glands. Rats were anesthetized and prepared for clearance studies to determine the glomerular filtration rate and fractional excretion of phosphate following infusion of protein or vehicle. After a 90-minute stabilization period, a control 30-minute clearance sample was collected and then either vehicle (saline, n=8), recombinant FGF-7 (0.1nmol/kg/hr, n=4) or recombinant FGF-23 (1 nmol/kg/hr, n=8) were infused intravenously. Glomerular filtration rate remained stable in all groups. The fractional excretion of phosphate (FEP) was unchanged in rats receiving vehicle alone (control vs. experimental period, 21±4 to 26±4%). Infusion of full length FGF-23 at a dose of 1 nmol/kg/hr increased FEP from 14±3% to 32±5%. Infusion of 0.1 nmol/kg/hr of FGF-7 increased FEP from 25±7% to 42±5%.

We conclude that FGF-7 increases phosphate excretion in vivo at a 10-fold lower dose than FGF-23. FGF-7 is likely to be responsible for the abnormal phosphate metabolism seen in some patients with tumor-induced osteomalacia in which tumors elaborate FGF-7 but not FGF-23.

The Role of Npt2c in Renal Pi Reabsorptive Process of Npt2a KO Mice. Y. Tomoe*, H. Segawa*, S. Sugino*, M. Ito*, S. Tatsumi, M. Kuwahata*, K. Miyamoto. Molecular Nutrition, Health Biosciences, The University of Tokushima Graduate School, Tokushima, Japan.

The proximal tubule is the major site of renal Pi reabsorption. The rate-limiting step in Pi reabsorption is a sodium-dependent step that occurs in the luminal brush border membrane (BBM). Two transporters (Npt2a and Npt2c) are expressed exclusively in the proximal convoluted tubule and are regulated by Pi intake, PTH, and FGF23 levels. The type IIa Na/Pi cotransporter (Npt2a) play a major role in reabsorption (70-80%), while type IIc Na/Pi transporter (Npt2c) is more important in weaning animals and less so in adult animals. Recently, mutation of the human Npt2c gene has shown to cause hereditary hypophosphatemic rickets with hypercalciuria (HHRH), implicating that the NPT2c plays an important role in renal Pi reabsorption in human and may be a key determinant of plasma Pi concentration. In this study, we examined administration of FGF23, which is a strong Pi diuresis factor, to Npt2a KO mice to determine the role of Npt2c in renal Pi reabsorptive process using naked DNA methods. As described previously, the levels of plasma FGF23 concentration were kept extremely low in the Npt2a KO mice when compared with wild-type (WT) mice. The levels of plasma FGF23 protein was markedly increased in Npt2a KO mice injected FGF23R179Q. FGF23R179Q induced severe hypophosphatemia, and markedly decreased renal Na/Pi transport activity, and Npt2c protein levels in Npt2a KO mice when compared with WT mice (FGF23R179Q group) 4 days after administration. FGF23R179Q suppressed the levels of intestinal Na/Pi transport activity in WT mice. However, intestinal Na/Pi transport activity were similar when compared Npt2a KO (FGF23R179Q group), and Npt2a KO (Mock group). These results suggested that Npt2a KO mice retain the capacity to reabsorb Pi at a rate that can be explained by the presence of Npt2c. Renal Npt2c is a major Na/Pi transporter in Npt2a KO mice.

Protein-PTH mRNA Interactions that Determine PTH mRNA Stability in Secondary Hyper- and Hypoparathyroidism. M. Nechama*, I. Z. Ben-Dov*, J. Silver, T. Naveh-Manly. Minerva Center for Calcium and Bone Metabolism, Hadassah Hebrew University Medical Center, Jerusalem, Israel.

Hypocalcemia, uremia and hypophosphatemia regulate PTH gene expression, PTH secretion and parathyroid cell proliferation. Gene expression can be regulated at the transcriptional or post-transcriptional level. Serum Ca²⁺ and P regulate PTH gene expression post-transcriptionally by changes in mRNA stability. A low serum Ca²⁺ and uremia result in increased protein-PTH mRNA binding of a stabilizing complex and increased PTH mRNA levels in vivo. A low P has the opposite effects. We have previously identified two trans acting proteins, AU rich binding factor 1 (AUF1) and Upstream of N-ras (Unr) that bind a specific conserved cis element in the PTH mRNA 3'- untranslated region (UTR) and stabilize PTH mRNA. Here we use both in vitro degradation assays with rat parathyroid extracts and transfected heterologous cells to characterize the mechanisms of PTH mRNA decay and to identify the ribonucleases that determine PTH mRNA stability. mRNA decay can be exonucleolytic from either the 5' or 3' end of the mRNA or endonucleolytic by cleavage in the mRNA body. We show that PTH mRNA is endonucleolytically cleaved by parathyroid extracts and is a substrate for the endonuclease PMR1. PMR1 co-immunoprecipitates with the 3' to 5' exonucleolytic complex, the exosome. Knock-down of an exosome component by siRNA prevents PMR1-mediated degradation of PTH mRNA. Similarly, exosome immunodepletion in parathyroid extracts prevents PTH mRNA endonucleolytic degradation. PMR1 also interacts with the mRNA decay-promoting protein KSRP that binds PTH mRNA and decreases PTH mRNA levels in transfected cells. Significantly, the association of KSRP with PTH mRNA is increased in parathyroid glands from rats fed a phosphorus restricted diet where PTH mRNA is unstable, compared to parathyroid glands from rats fed a calcium-restricted diet or uremic rats, where PTH mRNA is stable. We suggest that KSRP recruits a degradation complex to

degrade PTH mRNA and determine PTH mRNA stability and levels in response to changes in Ca²⁺ and P. Phosphorous restriction increases PTH mRNA association with KSRP generating a degradation complex that accelerates PTH mRNA decay and decreases PTH mRNA levels. Calcium depletion and uremia lead to formation of a stabilizing complex on PTH mRNA, consisting of AUF1 and Unr. This complex competes for the association of PTH mRNA with the degrading complex and leads to increased PTH mRNA stability and levels. This is the first identification of the molecular mechanisms whereby protein-RNA interactions determine PTH mRNA stability and levels in response to changes in serum Ca²⁺ and P and experimental uremia.

The Calcium-Sensing Receptor Regulates PMCA2 Activity in Mammary Epithelial Cells: A Mechanism for Calcium-Stimulated Calcium Transport into Milk. J. N. VanHouten, J. J. Wysolmerski. Yale University, New Haven, CT, USA.

Milk contains a great deal of calcium. Mammary epithelial cells secrete calcium into milk via a high capacity transepithelial transport system that is only partly understood. Prior experiments have demonstrated that calcium can stimulate its own transport from the maternal circulation into milk. Activation of the calcium-sensing receptor (CaR) at the basolateral surface of mammary epithelial cells promotes transepithelial calcium transport and also stimulates bulk milk production in mice. In this study, we investigated the mechanism by which CaR signaling affects calcium transport across mammary epithelial cells. The plasma membrane calcium ATPase, isoform 2 (PMCA2), has been reported to be the major calcium pump responsible for the transport of calcium into milk. We confirmed that expression of the PMCA2bw splice variant is upregulated in the mammary gland during lactation. Immunofluorescence and immuno-electron microscopy demonstrated that PMCA2 is found only at the apical surface of mammary epithelial cells. Milk calcium was reduced by 70% in homozygous Dfw-2J mice, which carry a loss-of-function mutation in the PMCA2 gene (Atp2b2). These data confirm that PMCA2 is critical for calcium transport into milk. Therefore, we sought to determine whether PMCA2 is a downstream target of CaR signaling in mammary epithelial cells. In cultured primary and EpH4 mouse mammary epithelial cells, CaR stimulation by extracellular calcium or the calcimimetic, gadolinium, had no discernable effect on PMCA2 expression, mRNA splicing, or localization. However, activation of the CaR increased calcium-dependent ATPase activity in mammary epithelial cell plasma membrane preparations. Knockdown of PMCA2 expression with siRNA showed that PMCA2 accounts for the preponderance of calcium-ATPase activity in mammary epithelial cells. Furthermore, siRNA-mediated ablation of CaR expression in mammary epithelial cells eliminated the ability of extracellular calcium or gadolinium to elicit an increase in plasma membrane calcium-dependent ATPase activity. These results demonstrate that activation of the CaR on the basolateral aspect of mammary cells increases PMCA2 activity in the apical membrane and provide a mechanism for the regulation of transepithelial calcium transport by calcium in the lactating mouse mammary gland.

Conditional Ablation of the Osteoblast Calcium-Sensing Receptor Causes Abnormalities in Skeletal Development and Mineralization. M. M. Dvorak*, C. Tu*, H. Elalieh*, T. Chen*, B. Liu*, B. E. Kream*, D. D. Bikle*, W. Chang*, D. M. Shoback*. ¹Department of Medicine, University of California, San Francisco, CA, USA, ²Department of Medicine, University of Connecticut Health Center, Farmington, CT, USA.

The calcium-sensing receptor (CaR) is a G protein-coupled receptor essential for maintenance of calcium homeostasis. Defining the role for the osteoblast CaR in vivo, using global full-length CaR knockout models, is complicated by metabolic disturbances and the potential for compensation by a CaR splice variant identified in these mice. To circumvent these issues, we generated Flox-CaR^{+/+} mice, in which loxP sites flank exon 7 that encodes the transmembrane and signaling domains of the receptor. Osteoblast-specific inactivation of the CaR was achieved by mating Flox-CaR^{+/+} mice to transgenic mice expressing Cre-recombinase, under control of the 3.6 kb fragment of the rat $\alpha 1(I)$ collagen promoter (Col1-Cre). Col1-Cre^{+/+}/Flox-CaR^{+/+} mice exhibited growth delay from birth and died within four weeks. At 21 days, the skeletal phenotype was hallmarked by hypomineralization, evident by von Kossa staining and micro-computed tomography (μ CT) analysis, which revealed significant reductions in bone volume/tissue volume (BV/TV; \downarrow 75%), bone mineral density (BMD; \downarrow 90%), segmented BMD (\downarrow 20%), trabecular number (\downarrow 40%), trabecular thickness (\downarrow 30%) and connectivity density (\downarrow 80%) in the secondary spongiosa of the distal femur (n=6, p<0.05, ANOVA), compared to controls. The changes were comparable, although less extensive in the L4 vertebra. The cortical compartment of the femur was also affected, with significant decreases in BV (\downarrow 60%), cortical thickness (\downarrow 70%), BMD (\downarrow 45%), and segmented BMD (\downarrow 15%) and markedly increased cortical porosity (~70%), compared to controls (n=6, p<0.05, ANOVA). Histology of femora from Col1-Cre^{+/+}/Flox-CaR^{+/+} mice revealed severe hyperostoidosis (Goldner staining) as well as trabeculation of the cortex (Von Kossa staining). Reduced mineral content could be secondary to increased turnover, with inadequate mineralization of newly made osteoid. This is consistent with quantitative real-time PCR (qPCR) analysis of humeri and calvaria that indicate significant increases in markers of proliferation (ccnd1), osteoblast differentiation (collagen I, alkaline phosphatase, osteopontin), mineralization (anklylosin protein, ectonucleotide pyrophosphatase/phosphodiesterase 1) and regulators of osteoclastogenesis (RANK-L,

osteoprotegerin); (n=3-5, p<0.05, ANOVA). Our findings indicate a critical role for the skeletal CaR in the control of bone mineralization in early postnatal skeletal development.

Calcium Sensing Receptor Plays Significant Role in Protection Against Hypercalcemia. L. Kantham¹, S. Quinn^{*1}, O. Egbuna¹, J. Pang^{*1}, R. Butters^{*1}, M. Pollak^{*2}, E. M. Brown¹. ¹Medicine / Endocrine, Brigham & Women's Hospital, Boston, MA, USA, ²Medicine / Renal division, Brigham & Women's Hospital, Boston, MA, USA.

The calcium sensing receptor (CaR) plays a pivotal role in controlling the secretion of parathyroid hormone (PTH), which, in turn, via its direct and indirect actions on kidney, bone and intestine restores and maintains normal extracellular ionized calcium levels. To date, there is only limited understanding of the functions of CaR expressed in tissues other than the parathyroid. Mice homozygous for knockout of the CaR were unsuitable for such studies as they die from lethal hyperparathyroidism. As an alternative, we employed single and double knock out (KO) mouse models, specifically mice lacking PTH alone (CaR^{+/+}PTH^{-/-}), both CaR and PTH (CaR^{-/-}PTH^{-/-}), and wild type (CaR^{+/+}PTH^{+/+}) of the same genetic background for studies to gain insight into CaR-specific functions in the absence of confounding actions of CaR-mediated changes in PTH.

In the first set of experiments, 3-4 month old adult male mice were fed ad lib with regular chow containing 0.8% calcium and 0, 1 or 2% CaCl₂ containing water for one week. Measurement of serum calcium (SCa) levels revealed marked differences between the three genotypes. As expected, CaR^{+/+}PTH^{+/+} mice maintained their SCa levels close to 9.5 mg/dL under all conditions. The CaR^{+/+}PTH^{-/-} and CaR^{-/-}PTH^{-/-} mice were hypocalcemic, showing SCa of 6.8 and 6.2 mg/dL, respectively, in the absence of added calcium in the water. However, the SCa level rose to 8.3 in the CaR^{+/+}PTH^{-/-} mice and to over 10 mg/dL in the CaR^{-/-}PTH^{-/-} mice when they received water containing 1% CaCl₂. On 2% CaCl₂ water, the CaR^{+/+}PTH^{-/-} mice showed a SCa (9.5 mg/dL) in the normal range. In contrast the SCa increased markedly to 14 mg/dL in the CaR^{-/-}PTH^{-/-} mice. The results indicate that despite the lack of PTH, CaR is able to defend the mice against hypercalcemia in the face of an increased oral load of calcium. It is known that severe phosphate deficiency induces hypercalcemia and we tested the response of these mice to a phosphate deficient diet (containing 1% calcium) and plain water for one week. Once again we noted significant differences between mice expressing the CaR and those that did not. The wild type and CaR^{+/+}PTH^{+/+} mice maintained near normal SCa levels of 9-10 mg/dL, whereas those in the CaR^{-/-}PTH^{-/-} mice reached 15 mg/dL. Further investigation revealed that the calcitonin response to hypercalcemia induced by increased oral calcium load was normal in the control mice but was severely blunted in the CaR^{-/-}PTH^{-/-} mice. Thus the CaR defends effectively against hypercalcemia induced by a calcium load even in the absence of CaR-mediated changes in PTH secretion. Ongoing studies are directed at further characterization of the mechanism(s) by which it does so.

The Small GTPase RhoA and its Effector Kinase ROCK Mediate Actin Cytoskeleton Reorganization Leading to Osteocyte Anoikis by Glucocorticoids. L. I. Plotkin, K. Vyas*, S. C. Manolagas, T. Bellido. Center for Osteoporosis and Metabolic Bone Diseases, Univ Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

Glucocorticoids (GC) induce osteocyte apoptosis by activating the focal adhesion-related kinase Pyk2 and its downstream target, the kinase JNK, which in turn counteract pro-survival signaling mediated by the focal adhesion kinase FAK. This results in osteocyte detachment-induced apoptosis or anoikis. We report herein that the retraction of osteocyte cytoplasmic processes and cell rounding that precede GC-induced apoptosis of osteocytic MLO-Y4 cells are associated with rapid disruption of stress fibers and formation of peripheral actin rings, as visualized by confocal microscopy of cells stained with Alexa Fluor-conjugated phalloidin. The small GTPase family of proteins has been shown to transduce extracellular signals into actin cytoskeleton reorganization, ultimately controlling cell morphology and diverse cellular functions, including apoptosis. Consistent with a role of small GTPases in GC actions on osteocytes, the GC-induced apoptosis, changes in cell shape as well as actin reorganization were abolished by pharmacological inhibition of the small GTPase RhoA or its effector kinase ROCK with p75^{NTR} or Y-27632, respectively. On the other hand, inhibition of another small GTPase Rac1 with NSC23766 did not prevent GC effects. Furthermore, whereas GC did not induce apoptosis in cells expressing a kinase deficient dominant negative Pyk2 (K-Pyk2), expression of a constitutively active (ca) RhoA mutant, as well as two different ca JNK mutants, rescued GC-induced apoptosis in cells expressing K-Pyk2. These results indicate that Pyk2 activation by GC results in activation of both RhoA and JNK. Moreover, the ca RhoA rescued GC-induced apoptosis in cells expressing a dn JNK mutant, whereas the ca JNK mutants were unable to rescue GC-induced apoptosis in cells treated with the ROCK inhibitor. These results indicate that activation of JNK precedes RhoA/ROCK activation. We conclude that the small GTPase RhoA and its downstream kinase ROCK act downstream of Pyk2 and JNK activation by GC in a pathway that leads to rapid reorganization of the actin cytoskeleton. The resulting changes in cell morphology lead to osteocyte detachment-induced apoptosis or anoikis.

Col3.6-HSD2 Transgenic Mice: A Glucocorticoid Loss-of-Function Model Spanning Early and Late Osteoblast Differentiation. M. Yang^{*1}, J. R. Harrison², D. J. Adams³, B. E. Kream¹. ¹Medicine, University of Connecticut Health Center, Farmington, CT, USA, ²Craniofacial Sciences, University of Connecticut Health Center, Farmington, CT, USA, ³Orthopaedic Surgery, University of Connecticut Health Center, Farmington, CT, USA.

Glucocorticoids (GC) exhibit complex regulatory effects on bone remodeling. To elucidate the role of endogenous GC signaling in mature osteoblasts, we previously developed Col2.3-HSD2 transgenic (TG) mice in which a 2.3-kb Col1a1 promoter fragment drives expression of 11 β -hydroxysteroid dehydrogenase type 2 (11 β -HSD2), which metabolizes biologically active GC. Col2.3-HSD2 TG mice showed decreased vertebral trabecular and femoral cortical bone mass, due in part to impairment of osteoblast differentiation. The goal of the present study was to characterize the bone phenotype of Col3.6-HSD2 TG mice in which a longer 3.6-kb Col1a1 promoter fragment drives 11 β -HSD2 expression more widely in the osteoblast lineage. Serum corticosterone was unchanged in 7-week-old TG females. Skeletal parameters were assessed by dual energy X-ray absorptiometry and microcomputed tomography. Compared to WT littermates, TG mice showed reductions of 20% in vertebral trabecular bone volume, 10-17% in femoral and tibial sub-periosteal area, and 20-40% in sub-endosteal area. TG calvarial osteoblast (mCOB) and bone marrow stromal cell (BMC) cultures had decreased alkaline phosphatase and mineral staining, and reduced pOBCol3.6-GFP transgene expression, a marker of early osteoblast differentiation. Northern blot and real time PCR showed that Col1a1, bone sialoprotein and osteocalcin expression were decreased by 56%, 73% and 72%, respectively, in TG cultures. To study osteoclast formation, BMCs were treated with RANKL and mCSF for 3-7 days. Col3.6-HSD2 TG cells showed lower osteoclast number at day 4, but higher osteoclast number at day 6 and 7, suggesting delayed osteoclast formation and/or suppression of osteoclast apoptosis. To determine gene pathways affected by 11 β -HSD2 transgene, RNA of 7-week-old WT and TG female vertebrae was assessed by microarray analysis. Modest (1.5- to 2-fold) but significant effects were seen on genes of the TGF β , IGF and FGF pathways. TG bone had increased cathepsin K and c-fms expression, markers of the osteoclast lineage. In summary, Col2.3-HSD2 and Col3.6-HSD2 mice showed a similar low bone mass phenotype and impaired ex vivo osteoblast differentiation; in addition, Col3.6-HSD2 mice showed an altered tempo of ex vivo osteoclast formation. Based on the phenotypic similarities between the Col2.3-HSD2 and Col3.6-HSD2 models, we conclude that endogenous GC signaling is required for optimal bone mass acquisition by acting primarily on the later stages of osteoblast differentiation.

Intermittent PTH Stimulates Osteoblastic Cells Even in the Absence of Osteoclasts. P. H. Luiz de Freitas¹, M. Li², T. Ninomiya^{*3}, M. Nakamura^{*3}, K. Oda^{*4}, R. Takagi^{*1}, N. Udagawa^{*3}, T. Maeda^{*5}, N. Amizuka². ¹Oral and Maxillofacial Surgery, Niigata University, Niigata, Japan, ²Center for Transdisciplinary Research, Niigata University, Niigata, Japan, ³Institute for Oral Science, Matsumoto Dental University, Shiojiri, Japan, ⁴Biochemistry, Niigata University, Niigata, Japan, ⁵Oral and Maxillofacial Anatomy II, Niigata University, Niigata, Japan.

PTH anabolic actions affect both components of the bone remodeling cycle. We aimed to determine if the increase on osteoblastic activity seen after intermittent PTH treatment in vivo is solely result of the hormone's actions on osteoblasts, or if it also depends on coupling to, and/or enhancement of, osteoclastic activities. Eight-week-old ICR male mice were divided in control and PTH injection groups. Age-matched c-fos knockout female mice, an osteopetrotic strain without osteoclasts, were similarly grouped. Injection groups received PTH (120 μ g/kg, sc) daily for 14 days, while controls received only saline. Under anesthesia, animals were fixed with an aldehyde solution and had their bones extracted for histological processing, i.e., tartrate-resistant acid phosphatase (TRAP) reaction, alkaline phosphatase (ALP) and PTH/PTHrP receptor (PTH-R) immunohistochemistry, as well as for transmission electron microscopy (TEM). The picture of PTH treatment in ICR mice was one of increased bone content with longer, thicker and interconnected trabeculae. Compared to their controls, injection samples had a thicker ALP-positive preosteoblastic layer lining their bone surfaces. Number of TRAP-positive cells did not differ considerably between control and injection groups, while PTH-R positivity was increased in the latter. TEM imaging revealed at least two categories of cells of the preosteoblastic layer according to their morphology: endoplasmic reticulum (ER)-rich cells and ER-poor ones. Collated to their controls, PTH-injected c-fos knockouts exhibited more ALP-positive cells on their bone surfaces. It has been suggested that osteoclastic cells may play an active role on the anabolic actions of PTH, but our data pointed to another direction: PTH-driven osteoblastic anabolism seems to be independent of osteoclast presence and/or activity, yet the outcomes of hormonal administration might be less dramatic when bone resorption is hindered. We have shown that intermittent PTH stimulates cells of the osteoblastic line even if osteoclasts are ablated, substantiating the idea that anabolic effects of PTH are independent of osteoclastic presence.

Ablation of IGF-I Signaling Disrupts the Communication Between Osteoblasts and Osteoclasts. Y. Wang¹, H. Z. ElAlich^{*1}, W. Chang¹, T. L. Clemens², D. D. Bikle¹. ¹Endocrine Unit, University of California, San Francisco/ VA Medical Center, San Francisco, CA, USA, ²Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

We and others have shown that insulin-like growth factor-I (IGF-I) has been regulates the functions of both osteoblasts (OB) and osteoclasts (OCL). Our previous studies demonstrated that IGF-I was required for normal OBs proliferation, differentiation and stimulated osteoclastogenesis both directly and/or through the interaction between OBs and OCL precursors to support OCL formation. Furthermore, IGF-I signaling is required for PTH stimulation of bone formation, an action that appears to require the OCL as well as IGF-I. However, the mechanisms by which IGF-I signaling is responsible for the cellular communication between OBs and OCLs has not been evaluated. Recent studies identified bidirectional signaling between OBs and OCLs mediated by ephrin B2 in OCLs and EphB4 in OBs. To address whether such signaling was involved in IGF-I action, we used Cre-mediated conditional gene targeting techniques to delete IGF-I receptor (IGF-IR) in vitro and in vivo. Bone marrow stromal cells (BMSC) were isolated from the mice bearing the loxP-flanked IGF-I receptor (IGF-IR) alleles in exon 3 (IGF-IR floxed mice). To inactivate IGF-IR, BMSCs were infected with 10 PFU/cell recombinant adenoviruses expressing a functional Cre (Cre-ADV) at day 12 for 2 days. Quantitative real-time PCR (Q-PCR) analysis demonstrated that the mRNA levels of IGF-IR in the BMSCs were reduced by 95% with Cre-ADV infection. mRNA levels of ephrin B2 and Eph B4 were decreased by 78% and 71%, respectively in the cultures infected by Cre-ADV (IGF-IR^{-/-}). PTH treatment (100 ng/ml, 2 hrs) significantly increased the mRNA levels of both ephrin B2 (2.6 fold) and EphB4 (4 fold) in the cultures infected by vehicle (IGF-IR^{+/+}), but these effects were abolished in the IGF-IR^{-/-} cultures. For the in vivo studies, 3 month old mice with a bone specific IGF-IR null mutation (OB IGF-IR^{-/-}) (floxed IGF-IR x osteocalcin promoter driven Cre recombination) and their normal littermates (controls) were treated with vehicle or PTH (80 µg/kg bw/day for 2 weeks). As analyzed by Q-PCR, mRNA levels of ephrin B2 and EphB4 were decreased by 44% and 48% respectively in bone tissue of the OB IGF-IR^{-/-} mice. PTH significantly increased the mRNA levels of ephrinB2 and EphB4 in the control mice (1.6 fold and 3.5 fold, respectively), but induced no changes in the mRNA levels of these 2 molecules in the OB IGF-IR^{-/-} mice. Our data indicate that the IGF-IR is critical for the communication between OBs and OCLs mediated by bidirectional ephrin signaling to stimulate OBs differentiation and osteoclastogenesis, suggest that this action is required for PTH stimulated bone turnover.

Androgenic Effects on Bone and Body Composition Depend on Concerted and Additive Activation of both AR and ERα: Evidence from a New Male Mouse Model with Combined Disruption of both AR and ERα. F. Callewaert^{*}, K. Venken^{*}, J. Ophoff^{*}, K. De Gendt^{*}, S. Boonen, R. Bouillon, G. Verhoeven^{*}, D. Vanderschueren. Katholieke Universiteit Leuven, Leuven, Belgium.

During puberty, androgens increase bone and muscle mass but lower fat mass. Both androgen receptor (AR) and estrogen receptor-α (ERα) activation are likely to be involved in these characteristic male phenotypic changes, but the relative contribution of these sex steroid receptors is unclear. In the present study, we characterized bone and body phenotype of male AR-ERα double KO (AR-ERαKO) mice in comparison with ARKO, ERαKO and wildtype (WT) littermates. Tibial bone mineral density and geometry and whole-body composition were assessed weekly by in vivo pQCT and DEXA, respectively, until 16 weeks of age. Results were analyzed by repeated measures ANOVA and expressed as % difference vs. WT. Disruption of the AR decreased body weight gain (-14%, $p < 0.01$) without additional effect of ERα disruption. Interestingly, body composition was independently affected in ARKO or ERαKO mice; ERα disruption (but not AR disruption) increased fat mass in ERαKO or AR-ERαKO mice from 8 weeks of age (+36% and +30%, resp., $p < 0.01$), whereas combined AR and ERα disruption caused additive reductions of lean body mass (-24%, $p < 0.01$). However, ARKO and ERαKO mice showed divergent effects on trabecular BMD; disruption of the AR or ERα decreased (-64%, $p < 0.01$) and increased (+14%, $p < 0.01$) cancellous bone density, respectively. The cancellous bone gain in ERαKO mice appeared entirely AR dependent since no increase was observed in AR-ERαKO mice. In contrast, cortical bone mass acquisition was impaired in ARKO or ERαKO mice as reflected by a significantly decreased cross-sectional area (-8% and -6%, resp., $p < 0.01$) and periosteal perimeter (-4% and -3%, resp., $p < 0.01$). Moreover, combined disruption of the AR and ERα further reduced cortical bone expansion; an additional decrease in cross-sectional area (-14%, $p < 0.01$), periosteal perimeter (-5%, $p < 0.01$) and strength strain index (-29%, $p < 0.01$) was observed in AR-ERαKO mice. Disruption of the ERα, not AR, also lowered serum IGF-I in ERαKO (-23%, $p < 0.01$) and AR-ERαKO mice (-10%, $p < 0.01$), which may explain its additive negative impact on periosteal bone expansion. Our data indicate that combined disruption of the AR and ERα has an additive effect on cortical bone growth as well as lean body mass compared to ARKO or ERαKO mice. Therefore, we conclude that activation of both AR and ERα are needed for optimal acquisition of cortical bone mass and lean mass. However, AR activation alone is able to maintain cancellous bone mass, whereas ERα activation lowers fat mass and increases serum IGF-I.

Factors Produced in Ovary Inhibit Musculoskeletal Growth and Promote Adipogenesis During Puberty: Potential Mediation by Non Estrogenic Actions. K. E. Govoni, R. B. Chadwick^{*}, J. E. Wergedal, S. Mohan, J. L. Pettit VAMC and Loma Linda University, Loma Linda, CA, USA.

To test if the pubertal surge in estrogen is essential for the increased growth hormone (GH)/insulin-like growth factor (IGF) action and bone accretion during puberty, we evaluated the consequence of ovariectomy in prepubertal mice on skeletal changes and GH/IGF axis during puberty. C57BL/6J mice were ovariectomized (OVX) or SHAM operated at 3 weeks of age ($n = 6$ to 7) and skeletal changes measured prior to and 3 weeks after surgery. A 57% reduction ($P = 0.01$) in uterine size confirmed the effectiveness of OVX. Prepubertal OVX caused a 12% increase in the body weight ($P = 0.01$), 15% increase in lean total body mass ($P < 0.01$), and 18% reduction in percent total body fat ($P < 0.01$). Abdominal body fat was reduced by 43% in OVX group ($P = 0.01$). PIXImus analysis revealed a 12% increase in total body BMC and bone area ($P < 0.02$). pQCT analysis of femur mid diaphyseal region revealed an 8% increase in cross sectional area ($P = 0.07$), but no effect on vBMD. Femur length was increased by 3% ($P < 0.01$). We next determined if the absence of ovarian hormones during puberty influences puberty-induced increase in serum IGF-I level. We found that neither serum level of IGF-I (298 ± 21 vs. 277 ± 19 ng/ml in SHAM vs. OVX, respectively) or local IGF-I expression (1.12 ± 0.14 and -1.23 ± 0.13 fold change vs. SHAM in bone and muscle, respectively) were altered in OVX mice at 3 weeks post surgery ($P \geq 0.30$). To identify the potential pathways by which ovarian factors negatively regulate their effects on the musculoskeletal system, we performed a whole genome microarray analysis of mRNA from the femurs of OVX and SHAM mice at 3 weeks post surgery. A total of 223 genes were significantly ($P \leq 0.05$) regulated in the bones of OVX mice. We observed significant upregulation ($P \leq 0.05$) of expression of regulators (osterix, ephrinA1, formin2) and markers (Colla2, thrombospondin2, lumican) of osteoblast differentiation in the bones of OVX mice. In contrast, OVX resulted in significant downregulation ($P < 0.05$) of genes (lipoprotein lipase, stearyl-Coenzyme A desaturase 1, caveolin1) which are known to be upregulated in adipocytes. In conclusion: 1) Female mice exhibit male-like features (bone, muscle and adipose) in the absence of ovarian hormones during puberty; 2) The increase in GH/IGF production during puberty is not dependent on estrogen production; 3) Expression of genes involved in osteoblast and adipocyte differentiation was altered in OVX mice during puberty; and 4) Based on these data and the published data that bone size is not increased in estrogen receptor-α knockout female mice, we speculate that factors besides estrogen may be responsible for the inhibitory effects of ovarian factors on the musculoskeletal system during puberty.

The Purinergic P2X₇ Receptor Is Responsible for Ovariectomy-induced Bone Loss in Mice. S. Petersen^{*1}, S. Syberg^{*1}, Z. Henriksen^{*1}, P. Schwarz², J. B. Jensen^{*1}, O. H. Sorensen^{*1}, N. R. Jorgensen¹. ¹Endocrinology and Clinical Biochemistry, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark, ²Research Center for Ageing and Osteoporosis, Copenhagen University Hospital Glostrup, Glostrup, Denmark.

The purinergic P2X₇ receptor is an ATP-gated cation channel that is primarily expressed in cells of hematopoietic origin such as osteoclasts and macrophages, but also in mature osteoblasts. It has been shown to have important functions both in the regulation of osteoblastic bone formation and in the formation and activity of osteoclasts. The aim of this study was to elucidate possible gender-differences in bone mass between P2X₇ genotypes as well as the role of the receptor in the bone loss accompanying estrogen-withdrawal.

Two groups of C57BL mice with the following P2X₇ genotype: P2X₇^{+/+} (Wt), P2X₇^{-/-} (He) P2X₇^{-/-} (Ho) were examined. The first group (A) was sacrificed at 120 days of age ($n=159$, 76 males, 83 females). The second group (B) contained all females and were ovariectomized (OVX) ($n=36$) at 120 days of age with one month additional follow up for effect of OVX. At sacrifice, both groups had determination of bone mineral density (BMD) and bone mineral content (BMC) using a PIXImus densitometer as whole body BMD/BMC and right femur BMD/BMC.

In order to determine the role of the P2X₇ receptor in gender-differences in bone mass we compared bone mass values for the genotypes in group A. For the Wt animals, males had highly significant BMC/BMD than females (p -values < 0.01), while in the P2X₇ null mice only slight differences between genders could be found, and only for BMC of the femur (Mean \pm SEM: 0.037 ± 0.001 vs. 0.035 ± 0.0005 , p -value: 0.04), despite significantly higher weight in males compared to females in all genotype groups. For group B, a significant bone loss (5%) was found one month after OVX in the Wt group compared to baseline, but no change in BMD/BMC values could be detected in the He or Ho groups in response to OVX. In conclusion, as expected differences were found in bone mass between male and female mice. Interestingly, these differences were not present in mice with a deletion of the P2X₇ receptor. Furthermore, P2X₇ null mice were protected against OVX-induced bone loss compared to their Wt littermates. Thus, the P2X₇ receptor appears to be involved in the effects of sex hormones on the regulation of bone metabolism.

Classical ER α Signaling Is Essential for Estrogen Mediated Enhancement of Osteogenesis but not for Inhibition of Adipogenesis. F. A. Syed, D. G. Fraser*, M. J. Oursler, S. Khosla. Endocrinology, Mayo Clinic College of Medicine, Rochester, MN, USA.

Previous studies have demonstrated that estrogen (E) enhances osteoblastic and inhibits adipocytic differentiation of bone marrow stromal cells (BMSCs). ER α can signal either via the "classical" pathway requiring direct binding to E response elements (EREs) or through indirect, "non-classical" pathways involving protein-protein interactions. We have previously demonstrated (JBMR 20:1992, 2005; Endocrinology 148:1902, 2007) that mice with a deleted ER α allele and a knock-in of a mutant ER α that cannot bind EREs on the other allele (ER α -/NERKI) have osteopenia and decreased bone formation rates, suggesting that ERE signaling may be essential for E effects on bone formation. Interestingly, in contrast to the generally observed inverse relationship between bone mass and marrow fat, ER α -/NERKI mice have osteopenia but no increase and, in fact, a decrease in bone marrow fat: adipocyte volume/total volume (AV/TV) at the proximal tibial metaphysis of $2.3 \pm 0.2\%$ vs. $14.6 \pm 1.6\%$ for wild type (WT) mice, $P < 0.05$, suggesting dissociation of ER α signaling on bone vs. fat. To test this, we exposed primary BMSC cultures from female WT, ER α -/ER α -, and ER α -/NERKI mice to osteogenic (dex, β -glycerolphosphate, and ascorbate) and adipogenic (rosiglitazone) media in the absence or presence of estradiol (10^{-8} M). Mineralization was assessed using von kossa staining and adipogenesis using oil red O staining. As is evident (Figure, panel A), while E clearly increased the number of osteoblastic colonies in WT cultures, it was totally ineffective in doing so in the ER α -/ER α - or ER α -/NERKI cultures. By contrast, while E inhibited adipogenesis in WT and was ineffective in the ER α -/ER α - cultures, it was able to inhibit adipogenesis in the ER α -/NERKI cultures (panel B). Collectively, our in vivo and in vitro findings demonstrate that ERE signaling is essential for E effects on enhancing bone formation but not for inhibition of adipogenesis, consistent with dissociation of the signaling pathways involved in these effects. Further studies to characterize the different pathways by which E mediates effects on osteogenesis vs. adipogenesis are currently underway.

Internalization of Vitamin D Binding Protein (DBP) by Human Monocytes. R. F. Chun, S. Ren, J. S. Adams, M. Hewison. Endocrinology, Diabetes and Metabolism, Cedars-Sinai Medical Center, Los Angeles, CA, USA.

Convention holds that 25-hydroxyvitamin D₃ (25D₃) and 1,25-dihydroxyvitamin D₃ (1,25D₃) enter target cells by passive diffusion in their 'free' form. However, recent studies have shown that DBP-bound 25D₃ can also enter cells by facilitated endocytosis. In proximal tubule and breast epithelial cells this mechanism provides a conduit for delivery of substrate 25D₃ to the vitamin D-activating CYP27b1 α -hydroxylase. Here we used fluorescent Alexa-tagged DBP, which retains the capacity to bind 25D₃ specifically, to show that DBP is also internalized by monocytes, a cell type that exhibits classical extrarenal metabolism of 25D₃ to 1,25D₃ via the 1 α -hydroxylase. Human peripheral blood mononuclear cells were cultured in the presence of granulocyte-macrophage colony stimulating factor (10 U/ml) for 1, 3 or 7 days. During this time monocytes showed increased expression and activity of the CYP27b1 α -hydroxylase with sustained Alexa-DBP uptake at levels 2-4-fold higher than control cell autofluorescence. Uptake of Alexa-DBP was observed when fluorescence-activated cell sorting (FACS) was gated for monocyte sub-populations, but no uptake was observed when cell populations were gated for lymphocyte sub-populations, indicating that uptake was specific for human monocytes. In day-1 and day-3 populations of cells DBP uptake was more pronounced in cells positive for the macrophage marker CD14. However, in day-7 populations, DBP uptake was also observed in CD14-negative dendritic cells. To determine whether uptake of DBP by monocytes was megalin-mediated, as observed in kidney and breast cells, monocytes were preincubated with receptor-associated protein (RAP), an antagonist of megalin-mediated endocytosis. RAP reduced Alexa-DBP internalization in megalin-rich BN16 rat yolk epithelial cells but had no effect on DBP uptake in monocytes, highlighting a megalin-independent means for DBP uptake in these cells. In summary, these data indicate that: 1] human monocyte/macrophages and DCs are capable of internalizing DBP by megalin-independent means; and 2] internalization of DBP occurs in monocytes, macrophages and dendritic cells. We propose that DBP-mediated uptake of 25D₃ is a crucial mechanism in defining the immunomodulatory actions of 25D₃. Furthermore, the presence of this mechanism in different types of human mononuclear cells suggests that DBP-mediated uptake of 25D₃ is important for vitamin D effects on both innate and adaptive immunity.

Curcumin: A Novel Nutritionally-Derived Ligand of the Vitamin D Receptor with Implications for Colon Cancer Chemoprevention and Bone Health. L. Bartik*, G. K. Whitfield², M. J. Kaczmarek*, C. A. Haussler², M. R. Haussler², P. W. Jurutka³. ¹Biochemistry & Molecular Biophysics, University of Arizona, Tucson, AZ, USA, ²Basic Medical Sciences, University of Arizona College of Medicine, Phoenix, AZ, USA, ³Integrated Natural Sciences, Arizona State University, Phoenix, AZ, USA.

The nuclear vitamin D receptor (VDR) mediates the actions of 1,25-dihydroxyvitamin D₃ (1,25D₃) to alter gene transcription in several target tissues, including intestine and bone. Recently, the secondary bile acid, lithocholate, was recognized as a VDR ligand. Using reporter gene and mammalian two-hybrid systems, we identified curcumin (CM), a turmeric-derived bioactive polyphenol, as a likely additional novel ligand for VDR. CM (10^{-5} M) activated transcription of a luciferase plasmid containing the distal vitamin D responsive element from the human CYP3A4 gene comparably to 1,25D₃ (10^{-8} M) in transfected human colon cancer cells (Caco-2). While CM also stimulated transcription via a retinoid X receptor (RXR) responsive element, activation of the glucocorticoid receptor by CM was negligible. Competition binding assays with radiolabeled 1,25D₃ confirmed that CM binds directly to VDR, obviating the possibility that it acts only via RXR. In mammalian two-hybrid assays employing transfected Caco-2 cells, CM (10^{-5} M) increased the ability of VDR to recruit RXR and the steroid receptor coactivator (SRC-1) by 10- and 9.6-fold, respectively, an action consistent with the promotion of transcriptional initiation of VDR-regulated genes. Small intestine and colon are important VDR-containing tissues, and frequent consumption of curry-containing foods can result in chronic, long-term exposure to significant levels of CM at these sites. Therefore, it is hypothesized that such diets can result in modest and sustained VDR/CM-mediated transcriptional activation of key target genes in the intestine. If this effect extends to genes involved in calcium transport, such as TRPV6, this may explain the beneficial effects of CM on bone, and our preliminary quantitative real time PCR (RT-PCR) data reveal CM-mediated upregulation of TRPV6 in Caco-2. Moreover, numerous studies have shown intestinal chemoprotection by CM via a variety of mechanisms; 1,25D₃ has known anticancer properties in the intestine potentially due, in part, to VDR activation of CYP-mediated xenobiotic detoxification and/or up-regulation of p21. Using RT-PCR, we demonstrate a significant increase in the levels of p21 mRNA in Caco-2 cells treated with either 1,25D₃ or CM. Thus, our results raise the novel possibility that nutritionally-derived CM facilitates intestinal chemoprotection and enhanced bone health via direct binding to VDR and activation of strategic target genes.

Molecular Analysis of Two Novel Mutations in the Vitamin D Receptor Corepressor, Hairless, and Expression of Rat Hairless in E. coli. J. C. Hsieh¹, C. A. Sheedy*, D. R. Mathern*, S. A. Slater*, G. K. Whitfield², C. A. Haussler², M. R. Haussler². ¹Biochemistry & Molecular Biophysics, University of Arizona, Tucson, AZ, USA, ²Basic Medical Sciences, University of Arizona, Phoenix, AZ, USA.

Mammalian hairless (hr) is expressed primarily in skin and brain tissues. Its gene product (Hr) is postulated to be involved in hair follicle progression and regeneration, as well as in brain development. Hr interacts with the thyroid hormone receptor (TR) and the orphan nuclear receptor, ROR α , inhibiting the ability of these receptors to activate transcription. Our recent work demonstrated that Hr also inhibits vitamin D receptor (VDR)-mediated transactivation in human keratinocytes. Two novel autosomal recessive Hr mutations, G985W and Δ AK (a C-terminal deletion), have been reported to cause hair loss in mice. The mutated residues are highly conserved in human, macaque, mouse, and rat species. To test whether the G985W and Δ AK rat Hr (rHr) mutants inhibit VDR and TR action, plasmids expressing the relevant proteins were cotransfected into COS-7 cells. Data revealed that the G985W mutation abolished the ability of Hr to repress TR- and VDR-mediated transactivation. On the contrary, the Δ AK mutant lost the ability to repress TR-mediated transactivation, but retained strong repression of 1,25-VDR-mediated transcription. Pull-down assay demonstrated that both rHr mutants interact well with human VDR. These results provide new insight into the Hr repression mechanism, including the functional, but not VDR-association, involvement of Gly985 in the repression of VDR- and TR-mediated transactivation. Second, the requirement of the C-terminal Ala-Lys residues in rHr for repression of TR- but not VDR-mediated transactivation, implies a clear difference in how Hr modulates the activity of these two nuclear receptors. Third, the hair loss phenotype exhibited by the Δ AK mutant is presumably caused by a defect in Hr function that is downstream of VDR-Hr binding. To further probe Hr-VDR interactions, we next overexpressed rHr. Previous characterization of Hr has been hampered by the limited availability of sufficient quantities of this large, labile protein. Consequently, full-length rHr was overexpressed in E. coli. A 4 kb fragment of the rHr cDNA was subcloned into the pT7-7 expression vector and transformed into E. coli BL21(DE3)pLys S cells. The 130 kDa rHr was well expressed in this bacterial system and its authenticity was confirmed by mass spectrometry. The expression yield of rHr in this system was approximately 2-3% of total protein. This E. coli-expressed rHr will provide a resource for future functional studies of the molecular mechanism whereby Hr influences VDR- and TR-mediated target gene transcription.

Novel Vitamin D3 Analogs (DLAMs) Antagonize Bone Resorption Via Suppressing RANKL Expression in Osteoblasts. M. Inada, K. Tsukamoto*, M. Takita, M. Hirata, A. Hoshino*, T. Tominari*, K. Nagasawa*, C. Miyaura. Department of Biotechnology and Life Science, Tokyo University of Agriculture and Technology, Koganei, Tokyo, Japan.

Active vitamin D3, 1 α , 25(OH)2D3 (D3), has been proposed to regulate bone remodeling through bone formation and resorption that is maintaining calcium levels in blood serum. Recently new aspects of D3 activities have been reported in bone resorption, inhibition of osteoclast differentiation via interference of c-fos and NFATc1 expression. The other aspect was found in D3 analogs, synthetic modification at C2 position of D3 that is enhancing bone formation and bone mass. Here we show newly synthesized analogs, 1 α ,25(OH)2D3-26,23-lactam, (23S,25S)-DLAM-1P and DLAM-2P, that has a lactam moiety in the side chain, perfectly antagonized D3-induced osteoclast (Oc) differentiation. In computer docking simulation estimated DLAM-1P bind to VDR, lactam moiety in DLAM-1P may interfere VDR helix-12 folding at the site of Phe-422 (ligand binding domain). Oc formation was assessed by mouse co-culture system. We first examined antagonistic effects of DLAMs on Oc formation induced by D3. When simultaneous treatment of DLAM-1P (10-7M to 10-5M) and D3 (10-8M), DLAM-1P clearly suppressed the number of TRAP+ Ocs in a dose-dependent manner. To understand the mechanism of action of DLAM-1P, we analyzed mRNA expression of RANKL, a sole molecule for Oc differentiation. DLAM-1P clearly suppressed the D3-induced expression of RANKL mRNA in osteoblasts. In organ culture using mouse calvaria, bone resorbing activity (calcium release) induced by D3 was clearly suppressed by adding DLAM-1P that is associated with less induction of RANKL mRNA. The other analog DLAM-2P has shown similar activities to DLAM-1P. Therefore, DLAM analogs act on osteoblasts as an antagonist of D3 to suppress RANKL dependent Oc differentiation in the cell and the organ, suggesting the DLAMs are novel candidate for the treatment of pathological bone loss such like osteoporosis. Further modification will require for the therapeutic compound, enhancing bone formation and inhibition of RANKL expression beside minimum modification in DLAMs structure, e.g. installing substituents on its C2 position.

Targeted Inactivation of the Vitamin D Receptor by Caspase-3. P. J. Malloy*, D. Feldman. Department of Medicine, Stanford University, Stanford, CA, USA.

Calcitriol inhibits the growth of many cells including breast, colon, ovarian, pancreatic, and prostate cancer cells by causing cell cycle arrest and in some cells by inducing apoptosis. In breast cancer cells, calcitriol induces apoptosis by a caspase independent mechanism. On the other hand, in prostate cancer cells, calcitriol induction of apoptosis involves activation of caspase activity. Calcitriol actions are mediated by the vitamin D receptor (VDR) a member of the steroid-thyroid-retinoid receptor superfamily of nuclear transcription factors. In LNCaP prostate cancer cells induction of apoptosis by staurosporine abolished [³H]1,25(OH)₂D₃-binding and VDR protein suggesting to us that the VDR might be targeted for inactivation by caspases, a family of cysteine proteases that are activated during apoptosis. We identified a potential caspase-3 cleavage site (DxxDS) in helix H2n (D₁₉₅MMDS₁₉₉) in the VDR ligand-binding domain. Mutations (D195A, D198A and S199A) were generated in the putative caspase-3 cleavage site and their effects on caspase cleavage of VDR examined. In reporter gene assays, all of the VDR mutants exhibited transactivation activity similar to the WT VDR. COS-7 cells transfected with WT and mutant VDR cDNA expression vectors were then treated with staurosporine and VDR examined by western blot. A 22 kDa cleavage fragment was detected on western blot from cleavage of the WT VDR and the S199A mutant VDR but not the D195A or D198A mutant VDRs. Addition of the caspase-3 specific inhibitor z-DEVD-FMK prevented cleavage of the WT VDR in vivo. Treatment of transfected COS-7 cells with calcitriol also resulted in cleavage of the WT VDR but not the D198A mutant VDR. Calcitriol-induced cleavage of the WT VDR was blocked with z-DEVD-FMK demonstrating that calcitriol activates caspase-3 in these cells. In vitro treatment with caspase-3 resulted in the cleavage of WT VDR and S199A but not D195A or D198A mutant VDRs. WT VDR was also cleaved by caspase-6, and -7 but not caspase-8 in vitro. In conclusion, our results demonstrate that the VDR is cleaved by caspase-3 in vivo. We further demonstrate that calcitriol induces caspase-3 activity that results in the cleavage of the VDR. Our results suggest that activation of caspase-3 by calcitriol, while contributing to apoptosis may also may limit the apoptotic effects of calcitriol in cells that express caspase-3. Since caspases also regulate the activity of many proteins under non-apoptotic conditions, the inactivation of VDR by caspases may be of general importance as a mechanism to limit calcitriol activity.

Phe377del Mutation in the Ank Gene Causes Craniometaphyseal Dysplasia (CMD)-like Phenotype in Knock-in Mice. I. Chen*, J. C. Wang*, E. J. Reichenberger. Reconstructive Sciences, UCHC, Farmington, CT, USA.

Craniometaphyseal dysplasia (CMD) is a rare craniofacial disorder characterized by progressive thickening of craniofacial bones concurrent with widened and radiolucent metaphyses in long bones. Mutations for autosomal dominant CMD have been identified in the human ANK gene (ANKH). ANK serves as a pyrophosphate (PPi) transporter regulating intra and extracellular PPi levels. To date, little is known about the pathogenesis of CMD and medical therapies of CMD show limited effect. We have generated a knock-in (KI) mouse model expressing a deletion mutation (Phe377del) in the Ank gene, the most common mutation found in our CMD patients. The purpose of this study is to characterize the progression of bone phenotype in these mice.

Ank^{-KI} and Ank^{KI/KI} mice appear normal at birth. Ank^{KI/KI} mice begin to weigh less than their respective wild type and Ank^{-KI} littermates after weaning. Within four to five weeks they develop a stiff, flat-footed gait, similar to phenotypes in Ank^{ank/ank} and Ank null mice. Decreased mobility of joints becomes more severe with age and they die around 6 months of age. Radiographically, bones from 1, 3 and 6 month-old Ank^{KI/KI} mice show increased radiopacity of cranial vault, base, facial bones, and mandibles; widening of metaphyses with increased radiolucency in femurs; fusion of joints in paws; narrowing of inter-disc space of vertebrae. Most Ank^{-KI} mice are indistinguishable from wild type mice but bones from 3 or 6 month-old heterozygous mice develop an intermediate phenotype. Skulls and jaws from 3 month-old Ank^{KI/KI} mice show significantly increased bone mineral density and bone mineral content. MicroCT results from skulls, femurs and mandibles of 3 month-old Ank^{KI/KI} mice show hyperostosis of calvariae and cranial base, narrowing of cranial neural foramina; significant decrease in trabecular number and bone volume fraction (BVf) of club-shaped femurs; increased BVf but decreased cortical density of mandibles compared to wild type and Ank^{-KI} mice. Dynamic histomorphometry analysis of femurs from 10 week-old Ank^{KI/KI} mice shows a marked decrease in mineral apposition rate. These observations suggest that the Ank mutation causing the CMD-like phenotype may be in a dose and time-dependent manner. These Ank knock-in mice can be used as a model for CMD.

Based on the similar joint phenotype to Ank null mice, we hypothesize that the CMD-causing mutant Ank is a loss of function mutation. The unique CMD-like phenotype in these mice suggests that a second molecular mechanism, rather than solely an abnormality in the extracellular pyrophosphate level, is involved in CMD pathogenesis.

BMP Signaling in Osteoblasts Negatively Regulates Canonical Wnt Signaling to Reduce Bone Mass During Embryonic Bone Development. N. Kamiya¹, L. Ye², T. Kobayashi³, Y. Mochida⁴, M. Yamauchi⁴, H. Kronenberg³, J. Feng², Y. Mishina^{*1}. ¹LRDT, NIEHS/NIH, Research Triangle Park, NC, USA, ²Oral Biology, University of Missouri-Kansas City, Kansas City, MO, USA, ³Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA, ⁴Dental Research Center, University of North Carolina, Chapel Hill, NC, USA.

Bone morphogenetic proteins (BMPs) have been believed to be osteogenic inducers over 40 years, because of their ability to induce ectopic endochondral bone formation after subcutaneous implantation. However, physiological function of BMP signaling in osteoblasts remains largely unknown, because mice with germline mutations in genes encoding BMPs or BMP receptors that are predominantly expressed in bone (i.e., BMP2, BMP4, BMPRIA, and ACVRI) die in early embryonic stages before bone development. In the present study, we focused on function of BMP signaling during embryonic bone development using loss-of-function and gain-of-function strategies for BMP receptor IA (BMPRIA) in mice. We unexpectedly found that BMP signaling in osteoblasts restrained bone mass through regulation of canonical Wnt signaling.

BMP receptor type IA (BMPRIA or ALK3) is one of three type I receptors for BMPs and is predominantly expressed in bone. Since homozygous mice for a null mutation in Bmpr1a die at embryonic day 7.5, we rescued the embryonic lethality by generating a bone-specific knockout of Bmpr1a using tamoxifen inducible Cre-loxP system. Interestingly, under the physiological loss of BMPRIA signaling in osteoblasts, bone mass was increased and osteoclastogenesis was reduced concomitantly. Moreover, canonical Wnt signaling was upregulated due to a dramatic reduction in some of the Wnt inhibitors. Treatment with one of the Wnt inhibitors ex vivo rescued the phenotype of Bmpr1a-deficient bones with concomitant reduction of canonical Wnt signaling. In addition, upregulation of BMPRIA signaling in osteoblasts increased the expression of the Wnt inhibitor and increased osteoclastogenesis through OPG/RANKL pathway. Lastly, the bone phenotype of Bmpr1a-deficient mice was rescued by upregulation of BMPRIA signaling in mice with concomitant reduction of canonical Wnt signaling and an increase in osteoclastogenesis. These data indicate that BMP signaling in osteoblasts negatively regulates canonical Wnt signaling and positively regulates osteoclastogenesis through OPG/RANKL pathway to reduce bone mass during embryonic bone development. This study provides the first evidence of the molecular mechanism how these two major signaling pathways, BMP and Wnt, interact specifically in bones. We believe this study will provide innovative understanding of the physiological function of BMP signaling in bone biology.

Characterization of the Bone Phenotype in CIC-7 Deficient Mice. A. V. Neutzsky-Wulff^{*1}, K. Henriksen¹, A. Snel^{*1}, T. J. Jentsch^{*2}, J. Fuhrmann^{*2}, P. Lange^{*2}, C. Christiansen³, M. A. Karsdal¹. ¹Nordic Bioscience, Herlev, Denmark, ²MDC/FMP, Berlin, Germany, ³CCBR, Ballerup, Denmark.

Loss of the chloride channel CIC-7 leads to severe osteopetrosis. CIC-7 is believed to play a role in the ability of the osteoclasts to acidify the resorption lacuna, and thereby their ability to resorb bone. We therefore examined the bone phenotype of CIC-7 knockout (KO) mice in vitro and in vivo in detail, and compared it to the phenotype of oc/oc mice.

CIC-7 KO, oc/oc mice, and their corresponding wildtype littermates (WT) were sacrificed at 4-5 weeks of age. Bones and spleens were dissected and used for isolation of osteoclasts. The isolated cells were differentiated into mature osteoclasts on bone using M-CSF and RANKL. Cell culture supernatants were collected for measurements of CTX-I, TRACP and gelatinase activity by zymography. Cells were fixed and TRACP stained and the resorption pits were counted. Biochemical markers of resorption (CTX-I), osteoclast number (TRACP 5b), and osteoblast activity (ALP) were measured in serum of CIC-7 KO, oc/oc mice and the corresponding WT. Osteoblastogenesis in vitro was investigated using calvarial osteoblasts. In addition, bones were used for histological examination of TRACP positive osteoclasts with respect to number and morphology. Furthermore, osteoblast numbers and morphology were examined.

The osteoclasts from the CIC-7 KO mice were unable to resorb bone, as measured by CTX-I and by counting of resorption pits. Measurements of TRACP activity, as well as TRACP staining, showed the presence of equal numbers of osteoclasts in WT and KO cultures. Gelatinase activity was similar in both genotypes. Furthermore, the morphology of the KO cells was normal. Histological investigation of TRACP stained bone sections of both CIC-7 KO and oc/oc mice, indicated an elevated number of large osteoclasts present compared to WTs. The serum TRACP levels were increased by 250% in CIC-7 KO and oc/oc mice, whereas the resorption per osteoclast was reduced to 50% of the WT level. Finally, the serum ALP level in KO and oc/oc mice was increased by 30%, whereas no differences in osteoblast function were observed in vitro.

In summary, the osteoclasts from CIC-7 KO mice differentiate normally and form actin rings, but fail to resorb bone in vitro. In vivo, the osteoclasts are larger and more numerous, however, show no signs of resorption. Interestingly, an elevation of TRACP, a marked reduction in resorption per osteoclast, and elevated ALP level were observed in serum from both CIC-7 KO and oc/oc mice, showing increased signs of bone formation despite the low resorption. These findings indicate that the osteoclasts, and not their activity, control osteoblastic activity.

Identification of Single Nucleotide Polymorphisms (SNPs) Contributing to Bone Mineral Density and Fractures: A DNA Microarray Based Study. L. Gennari¹, D. Tejedor^{*2}, D. Merlotti¹, V. De Paola¹, A. Cadaval^{*2}, G. Martini¹, F. Valleggi¹, B. Franci^{*1}, S. Campagna^{*1}, B. Lucani^{*1}, L. Simon^{*2}, A. Martinez^{*2}, R. Nuti¹. ¹Internal Medicine, Endocrine-Metabolic Sciences and Biochemistry, University of Siena, Siena, Italy, ²Progenika Biopharma SA, Derio, Spain.

Osteoporosis is a complex polygenic disorder determined by the interaction between multiple genes and environmental risk factors, each with a small to modest effect. Traditional single candidate gene approach was only able to figure out a very small fraction of the whole genetic background of bone mass and fractures. We performed a DNA microarray-based analysis allowing the simultaneous study of 113 single nucleotide polymorphisms (SNPs) of 54 genes, which have been selected by their potential impact on bone metabolism. BMD and other phenotypes relevant to the pathogenesis of osteoporosis, such as ultrasound properties of bone, bone volume, bone turnover markers and sex hormone levels were evaluated in a population-based cohort of 904 postmenopausal women and elderly men. Moreover, 125 consecutive patients with non traumatic fractures were also investigated. Relationship between the selected clinical outcomes and the patient's pattern of SNPs was analysed by logistic regression. For each clinical outcome the optimal predictive model, based on a weighted combination of SNPs and disease characteristics and aimed resulting in a very high (95%) specificity, was selected. We identified 19 major SNP associated with BMD of whom 7 were non -sex-specific and 12 sex-specific. In particular SNPs at LRP-5, CYP19, ESR2, PPARalpha, and CYP11B1 genes were preferentially involved in determining BMD in males and SNPs at ESR1, SRD5A2, AR, IGF1, and IL-6 appeared to be female specific. Moreover, in females 2 SNPs (ESR1 and IL-6) were specific for spine BMD and 2 for hip BMD (AR and SRD5A2). In males, LRP-5 and CYP19 SNPs affected both femoral and lumbar BMD, while PPARalpha SNP mainly regulated BMD at the spine. Interestingly, 7 SNPs were associated with non-traumatic fractures independently of BMD. The most consistent associations with non-vertebral fractures were observed in IntegrinBeta3 and COL1A2 SNPs. In contrast, ESR1, TNFalpha, ADRB2, COMT, IL-6, and CYP19 were associated with both vertebral and non vertebral fractures. Importantly, different associations of SNPs were able to discriminate between the presence or the absence of non-traumatic fractures in the analysed population with a specificity of 95%, sensitivity 57% or 55%, and a likelihood ratio of 11.4 or 11.0 in males and females, respectively. The validation of these associations in larger samples could result useful for the identification of patients at higher fracture risk.

Disclosures: L. Gennari, None.

Genome-Wide Measure of Pleiotropy Among Osteoporosis-Related Traits in the Framingham Study. D. Karasik¹, Y. K. Cho², L. A. Cupples^{*2}, D. P. Kiel¹, S. Demissie^{*2}. ¹IFAR, Hebrew SeniorLife, Boston, MA, USA, ²Biostatistics, BU Sch Public Health, Boston, MA, USA.

There have been no genome-wide association studies (GWAS) for osteoporosis-related traits using high-density genotyping platforms published to date. Such a GWAS may be used to examine pleiotropic associations of single nucleotide polymorphisms (SNPs) with BMD and bone geometric (BG) indices.

We used the Affymetrix 100K SNP GeneChip marker set in the Framingham Heart Study (FHS) to examine genetic associations with BMD and BG indices of the hip. We evaluated 70,987 autosomal SNPs with genotypic call rates $\geq 80\%$, HWE $p \geq 0.001$, and MAF $\geq 10\%$. In 1141 phenotyped members of FHS families (495 men and 646 women, mean age 62.5 yrs), using multivariable-adjusted residual trait values, we used linear regression analysis with generalized estimating equations (GEE), as well as family-based association tests (FBAT), to test associations between SNPs and BMD and BG traits. Variance components analysis (SOLAR) was performed to estimate genetic correlations (ρ_{Gc}) among these traits.

We searched for SNPs associated with pairs of bone traits and presented the proportion of SNPs associated with the first trait that are also associated with the second trait.

We found that at a pre-specified significance threshold α , BMD traits (measured at femoral neck, FN, and trochanter, TR) share 23% at $\alpha = 0.001$ (36% at 0.01 level) associated SNPs in GEE analysis, as is expected from the high $\rho_{Gc} = 0.84$ between them (Table). There are almost no such SNPs that share associations with both hip BMD and BG traits (femoral neck and shaft width, N and S WID, and neck length, FNL), despite substantial ρ_{Gc} among these traits (ranging -0.25 to -0.44). Also, the BG traits shared a surprisingly small percentage of associated SNPs.

In conclusion, GWAS offers an unbiased strategy to identify new candidate genes for osteoporosis, but also may be used to better understand how related phenotypes potentially share the same genetic determinants. These results need to be replicated in other GWAS samples.

LRP5 G171V Mutation and Age-Related Bone Fragility. M. P. Akhter, D. M. Cullen, R. R. Recker. Medicine, Creighton University, Omaha, NE, USA.

It is well documented that aging has significant impact on the mechanical properties of bone in the human skeleton. In an animal model, we characterized bone structural and strength properties to determine if the LRP5 G171V mutation will protect against bone loss associated with Aging. Seventy two female mice representing two genotypes [(all bred to C57BL/6 mice), WT (Lrp5+/+, wild type), HBM (High bone mass with LRP5 G171V mutation)] and three age groups (4, 18, 22 months) were used (Table). At the time of necropsy fourth lumbar (L4) vertebral bodies were collected and then scanned using micro-CT (μ CT-40, Scanco) to quantify trabecular bone structural properties. The vertebral bodies were then mechanically tested in compression (along cranial-caudal direction) at 3mm/min displacement rate using an Instron-5543 testing device. We analyzed the trabecular bone structure and strength data using the General Linear Model (SPSS, IL) for univariate analysis to test for differences ($P < 0.05$) due to age and genotype. There was age-related loss in vertebral body structure and strength (Table). By 18 months of age, vertebral body trabecular bone structure (BV/TV) declined 28% in HBM mice and 54% in WT mice. In addition, HBM (33-60% decrease) and WT (47-57% decrease) mice lost significant structural strength (ULT, YLD, STIFF) by 18 months (Table). However, the decline between the 18 and 22 month age groups was not significant for either bone structure or strength within each genotype. HBM's trabecular bone structure (BV/TV) and strength remained significantly elevated at each age group (Table). These data suggest that the HBM mice (Lrp5 G171V mutation) experienced similar rates of bone loss with age but maintained both structural and strength advantage over the WT mice.

Age (month)	4		18		22	
Variable/ Genotype	HBM	WT	HBM	WT	HBM	WT
BV/TV	0.61 \pm 0.05	0.5 \pm 0.03 ^b	0.44 \pm 0.07 ^a	0.23 \pm 0.04 ^{ab}	0.49 \pm 0.05 ^a	0.24 \pm 0.06 ^{ab}
ULT (N)	46.5 \pm 9.20	18.9 \pm 5.9 ^b	19.0 \pm 3.2 ^a	10.0 \pm 5.6 ^{ab}	24 \pm 6.1 ^a	11.0 \pm 3.6 ^{ab}
YLD (N/mm)	35.0 \pm 8.30	13.9 \pm 5.5 ^b	15.3 \pm 4.3 ^a	6.0 \pm 3.9 ^{ab}	14.7 \pm 6.4 ^a	6.9 \pm 3.4 ^{ab}

LRP5 Mutations Are Associated with Osteoporosis, Impaired Glucose Tolerance and Hypercholesterolemia. A. Saarinen^{*1}, T. Saukkonen^{*2}, M. Somer^{*3}, C. M. Laine^{*2}, S. Toivainen-Salo^{*4}, A. Lehesjoki^{*1}, O. Mäkitie^{*2}.

¹Folkhälsan Institute of Genetics, University of Helsinki, Helsinki, Finland, ²Hospital for Children and Adolescents, University of Helsinki, Helsinki, Finland, ³The Family Federation of Finland, Helsinki, Finland, ⁴Helsinki Medical Imaging Center, Helsinki University Hospital, Helsinki, Finland.

LRP5 and LRP6 are coreceptors in the Wnt signaling pathway. Homozygous mutations in LRP5 cause osteoporosis-pseudoglioma syndrome (OPPG), characterized by severe osteoporosis and blindness. Heterozygous LRP5 mutations may also result in reduced bone mass. Recently mutations in LRP6 have been associated with coronary artery disease and metabolic syndrome. We have assessed bone health and glucose and lipid metabolism in a large Finnish OPPG pedigree with several heterozygous carriers of LRP5 mutations. DNA samples were collected from 30 family members, two of whom had OPPG. The exons and exon-intron boundaries of LRP5 were sequenced. Skeletal phenotype was assessed in 29 subjects by fracture history, bone mineral density (BMD) and spinal radiographs. Fasting blood samples were collected and oral and intravenous glucose tolerance tests were performed to assess glucose and lipid metabolism in individuals with LRP5 mutations.

Two different missense mutations were identified. The subjects with OPPG (aged 52 yrs and 58 yrs) were homozygous for R570W. One subject (age 85 yrs) was a compound heterozygote for R570W and R1036Q; she had normal vision but severe osteoporosis. Six subjects were heterozygous for R570W and three, for R1036Q; their median age was 59 yrs (15 - 72 yrs) and median BMI 26 kg/m². No mutations were found in 18 family members; their median age was 48 yrs (20 - 67 yrs) and median BMI 26 kg/m². Patients with two LRP5 mutations had multiple spinal and peripheral fractures and low BMD. The nine heterozygous LRP5 mutation carriers had significantly lower median BMD Z-scores at the lumbar spine (-1.0 vs +0.4, P=0.002) and femoral neck (-0.8 vs +0.75, P=0.009), more often vertebral fractures (44% vs 17%) and more peripheral fractures than those 18 without mutations. Of the 11 subjects with LRP5 mutation(s) six subjects (55%) had abnormal glucose tolerance: five had diabetes and one, impaired glucose tolerance. Intravenous glucose tolerance tests suggested impaired beta cell function; no insulin resistance was observed. Six subjects (55%) had hypercholesterolemia; three of them were on medication.

In addition to osteoporosis we found an unexpectedly high prevalence of diabetes and hypercholesterolemia in subjects with LRP5 mutations. These results link mutations in LRP5 to risk factors of coronary artery disease and implicate LRP5 as a novel gene that plays a role in glucose dependent insulin secretion from pancreatic beta cells.

Association Study Between Polymorphism Across the Osteoprotegerin Gene and Osteoporotic Phenotypes. S. Jurado^{*1}, N. Garcia-giral^{*1}, L. Agueda^{*2}, M. Bustamante^{*2}, A. Supervia^{*1}, M. A. Checa^{*1}, L. Perez-edo^{*1}, G. Salo^{*1}, M. J. Peña^{*1}, I. Aymar^{*1}, J. M. Garces^{*1}, S. Balcells^{*2}, D. Grinberg^{*2}, L. Mellibovsky^{*1}, A. Diez-perez^{*1}, X. Nogues^{*1}. ¹URFOA IMIM Universitat Autònoma de Barcelona, Hospital del Mar, Barcelona, Spain, ²Genetics Department, Universitat de Barcelona, Barcelona, Spain.

Osteoprotegerin (OPG) is a key regulator of bone resorption in the OPG/RANK/RANKL system. Therefore, the study of polymorphisms in the OPG gene is relevant in relation to osteoporosis. The aim of the present study is to evaluate common variation across the OPG genomic region using a haplotype-based approach.

A total of 964 postmenopausal women from Hospital del Mar of Barcelona (BARCOS cohort) were recruited and anthropometric features, together with bone mineral density (BMD) and osteoporotic fracture data, were recorded. Cases were consecutive unselected women attending to the Menopause Unit outpatient clinics in our institution. Secondary causes of metabolic bone disease were ruled out. BMD was measured with HOLOGIC QDR 4500 SL at lumbar spine (LS) and femoral neck (FN) sites. Twenty four single nucleotide polymorphisms (SNPs) were selected from haplotypic blocks obtained from the second phase of HapMap (CEU). Genotyping was performed by SNPlex at CeGen facilities, Biomedical Research Park of Barcelona. Haplotype frequencies were obtained using the PHASE software. Statistical analyses included ANCOVA for BMD and logistic regression for fractures (SPSS for windows statistical package v.12.0). Additive, recessive and dominant models were considered in all cases.

Twelve out of the 24 SNPs yielded significant statistical results (p value < 0.05) for LS BMD, FN BMD and/or osteoporotic fracture. These SNPs are located between the promoter region and intron 1, and belong to five different haplotypic blocks. Haplotypes within these blocks were also found to be associated with the different bone phenotypes. While none of the SNPs was associated with the three phenotypes, three of them were associated with both FN BMD and fracture, and two with FN and LS BMD.

In conclusion, genetic variants at the promoter and intron 1 of the OPG gene were found related to BMD and fracture risk in Spanish postmenopausal women, suggesting a role for regulatory SNPs in this gene for bone mass and / or fragility determination.

Inhibition of Osteolytic Bone Metastases in Breast Cancer with a Cathepsin K Inhibitor. G. Wesolowski¹, M. Pickarski¹, G. Neusch^{*1}, P. Leung^{*1}, R. Oballa^{*2}, M. Percival^{*2}, W. Black^{*2}, L. T. Duong¹. ¹Bone Biology & Osteoporosis, Merck Res. Labs., West Point, PA, USA, ²Merck Res. Labs., Pointe-Claire-Dorval, PQ, Canada.

Breast and prostate cancer commonly metastasize to bone, resulting in bone loss, bone pain and fracture. Orally active cathepsin K inhibitors are currently being developed as potent bone resorption inhibitors for the treatment of osteoporosis. The standard of care, I.V. bisphosphonates, provides proof-of-concept for the use of potent antiresorptives for the treatment of metastatic bone disease. High expression of Cat K has also been detected in metastatic breast carcinoma, which suggests a role of Cat K in tumor invasion. L-006235 is a potent inhibitor of Cat K, with IC₅₀ of 0.2, 0.5, 12 and 22 nM against human, rabbit, rat and mouse Cat K, respectively, and of rabbit osteoclastic bone resorption, with IC₅₀ of 5 nM. Previously, L-235 was shown to be lysosomotropic, resulting to potential inhibition of other cathepsins, including Cat B, at high concentration in vivo. In this study, oral L-006235 was evaluated up to 100 mg/kg/day and compared to zoledronic acid (ZOL, 7.5 µg/kg, sc, wky) for the prevention of osteolytic lesions and tumor growth in the intra-tibial engraftment model of MDA-MB-231 breast carcinoma cells in nude rats. Progression of osteolysis and tumor burden were monitored by radiography and evaluated by µCT and histological analyses over 6 weeks. Compared to vehicle, L-006235 at 10, 30 and 100 mg/kg dose-dependently inhibited tumor-induced bone volume loss by 18%, 22%, and 43% (p<0.001), respectively, with full protection at the highest dose which was comparable to the efficacy of ZOL (45%). Compared to vehicle, L-006235 also reduced tumor growth by 29%, 40% and 63% (p<0.001), versus a 56% reduction with ZOL. In this study, L-006235 at 30 and 100 mg/kg also reduced cortical disruption, tumor necrosis, and tumor cell migration from the original injection site. Taken together, these data suggest that cathepsin K inhibitors provide potent anti-resorptive efficacy and, compared to the current standard of care, may potentially have added benefits in reducing tumor invasion, and preventing bone metastases associated with breast cancer.

Parathyroid Hormone-Related Protein Induces Bone Pain Through Stimulation of Proton-Secretion in Osteoclasts. L. Wang^{*}, H. Wakabayashi^{*}, T. Hiraga^{*}, T. Yoneda. Department of Biochemistry, Osaka University Graduate School of Dentistry, Osaka, Japan.

Bone pain is the most common complication associated with bone metastases. Of note, clinical studies reported that inhibitors of osteoclasts such as bisphosphonates (BPs) efficiently reduced bone pain, suggesting a causative role of osteoclasts. Parathyroid hormone-related protein (PTH-rP), a potent stimulator of osteoclasts, has been implicated in bone metastasis. Activated osteoclasts are known to release protons via the a3 type vacuolar-H⁺-ATPase (a3 V-H⁺-ATPase) to dissolve bone minerals, thereby inducing acidosis in the neighboring environment. Acidosis is a well-known cause of pain. These results collectively suggest that PTH-rP is associated with bone pain through stimulating osteoclastic bone resorption. Repeated subcutaneous injections of PTH-rP caused increased osteoclastic bone resorption in the metatarsal bones and hyperalgesia in the hind-paw. Immunohistochemical examination revealed that the hyperalgesia was associated with increased protein expression of the transient receptor potential channel-vanilloid subfamily member 1 (TRPV1) and phosphorylated-ERK (p-ERK) in the ipsi-lateral dorsal root ganglions (DRGs) and c-Fos in the spinal dorsal horn. The hyperalgesia and elevated protein expression were significantly reduced by a most potent BP zoledronic acid, recombinant human OPG, a specific inhibitor of the V-H⁺-ATPase FR167356 and an antagonist of TRPV1 activation I-RTX, respectively. Finally, TRPV1 knockout mice exhibited reduced PTH-rP-induced hyperalgesia. Relevant to bone pain in bone metastases of breast cancer, we developed an animal model in which the MDA-MB-231 human breast cancer cells that produces large amounts of PTH-rP were directly inoculated into the tibial marrow cavity in nude mice. These mice showed hyperalgesia in the ipsi-lateral hind-paw and a monoclonal antibody to PTH-rP reduced the hyperalgesia. These results suggest that PTH-rP produced by metastatic cancer cells plays a part in causing bone pain through stimulation of proton-secretion in osteoclasts, thereby activating the acid-sensing receptors such as TRPV1 that are expressed in the nociceptive neurons innervating bone.

Runx2 Regulates the Indian Hedgehog-PTHrP Pathway in Breast Cancer Cells. J. Pratap, J. Dobson*, A. J. van Wijnen, J. L. Stein*, G. S. Stein, J. B. Lian. Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA.

Runx2 is expressed in hypertrophic chondrocytes and osteoblasts and is essential for bone formation. However, Runx2 is also highly expressed in bone metastatic cancer cells compared to non-metastatic cells. Importantly, Runx2 upregulates several metastatic markers (MMPs and VEGF) in cancer cells and a loss of function mutation of Runx2 prevents the osteolytic lesions formed by breast cancer cells in vivo. To further understand how Runx2 participates in the osteolytic process mediated by cancer cells, we investigated the effect of Runx2 on key components of the "vicious cycle". The vicious cycle of metastatic bone disease involves overproduction of PTHrP (Parathyroid hormone related protein) by tumor cells in the bone microenvironment, resulting in osteoclastic bone resorption. The resorbed bone releases TGF- β thereby stimulating tumor-cell proliferation and consequently continuing the vicious cycle. In the growth plate chondrocytes, Indian hedgehog (IHH) regulates PTHrP expression. Here, we show, following transduction of Runx2 expressing adenovirus that Runx2 activates endogenous levels of IHH more than 10 fold compared to 3-4 fold activation of other Runx2 target genes (VEGF, MMP9, MMP13 and osteocalcin) in MDA-MB-231 cells detected by real time PCR analysis. Runx2 also increased PTHrP levels 2-3 fold. The C-terminal deletion mutant of Runx2 (lacking the activation domain) failed to induce IHH and PTHrP levels in MDA-MB-231 breast cancer cells, as well as Runx2 target genes. In a time course analysis, we find Runx2 was able to activate IHH levels within 6hr of Runx2 expression in MDA-MB-231 cells. Consistent with these findings, depletion of Runx2 by siRNA decreases endogenous IHH and PTHrP levels produced by breast cancer cells. Blocking the Hedgehog signaling pathway using cyclopamine also inhibits Runx2 mediated activation of PTHrP which suggests that PTHrP upregulation by Runx2 is via IHH signaling events. We confirmed Runx2 recruitment on the IHH promoter in breast cancer cells by chromatin immunoprecipitation assays. Runx2 binds to a proximal (-0.5Kb) and distal site (-1.4Kb) of human IHH promoter. We propose that metastatic cancer cells by having higher levels of Runx2 are able to activate components of the vicious cycle as well as target genes that promote tumor progression in bone and increases bone loss. Thus this master regulator of bone formation is also a significant mediator of the metastatic activities of cancer cells and deserves consideration for targeted inhibition in tumor cells as a therapeutic approach to prevent the osteolytic bone disease.

Osteonecrosis of Jaw Under Bisphosphonate Therapy: Patient Profile and Risk Assessment. T. I. Jung*, J. von der Gablentz*, B. Hoffmeister*, S. Mundlos*, P. Fratzl*, M. Amling*, M. J. Seibel*, D. Felsenberg*. ¹Zentrum für Muskel- und Knochenforschung (ZMK), Charité - Universitätsmedizin, Berlin, Germany, ²Clinic for Oral, Maxillofacial and Plastic Surgery, Charité - Universitätsmedizin, Berlin, Germany, ³Institute for Medical genetics, Charité - Universitätsmedizin, Berlin, Germany, ⁴Department of Biomaterials, Max Planck Institute of Colloids and Interfaces, Potsdam-Golm, Germany, ⁵Centre for Biomechanics and Skeletal Biology, University Hospital, Hamburg-Eppendorf, Germany, ⁶ANZAC Research Institute, University of Sydney, Sydney, Australia.

The objective of the ongoing German Register for Osteonecrosis of the Jaw (ONJ) was to explore the development of ONJ as a serious adverse event of bisphosphonate (BP) treatment. A standardized questionnaire was used to analyze all cases that were officially reported within Germany up until 31 Dec 2006. Focus was placed on 1) demographics, 2) primary disease incl. its therapy 3) BP intake 4) dental status 5) diagnosis of ONJ and outcome of ONJ therapy. We included cases with osteomyelitis or ONJ while cases due to radiotherapy were excluded.

In 383 reported cases, patients were 63.4 \pm 8.3 years old and women were affected twice as often. They suffered from malignant disease (78.4%), osteoporosis (8.2%), or a combination of both (13.4%). Common malignant diseases were breast cancer (46.7%), multiple myeloma (30.1%) and prostate cancer (13.5%). Patients had previously received chemotherapy (68.9%), radiotherapy (62.3%) and glucocorticosteroids (47.5%). The majority (67.2%) was treated with a single BP: Zoledronate (79.7%) or Pamidronate (12.4%). Two BPs were administered consecutively to 30.7% of the patients: Pamidronate/Zoledronate (53.5%). ONJ occurred after 23.8 \pm 17.6 (Zoledronate) or 36.4 \pm 20.0 (Pamidronate) months of BP treatment. Patients presented clinically with infection (33.3%), mucosal changes (21.4%), wound healing disturbance (21.4%), exposed bone (11.9%) and pathological dental status (46.2%). Histological signs were infection (51.9%) and osteonecrosis (34.2%) while radiologists diagnosed osteolysis (19.5%) and osteomyelitis (14.3%). Dental management included surgical (45.3%) or conventional (13.2%) methods, or a combination of both (41.6%). Success rate was highest (17.0%) for the combination therapy.

The etiopathogenesis of ONJ remains unclear but is likely to be complex. A discrete increase in osteoporotic patients was noted but high-risk patients received BPs due to their malignant disease. The occurrence of ONJ might be reduced by adjusting the guidelines of bisphosphonate treatment and by defining algorithms for the dental management of high-risk patients.

The SABRE (Study of Anastrozole with the Bisphosphonate Risedronate) Study: 12-Month Analysis. R. Eastell¹, C. Van Poznak*, R. A. Hannon¹, G. Clack³, M. Campone*, J. R. Mackey*, J. Apffelstaedt on behalf of the SABRE Investigators*, ¹Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom, ²Dept of Internal Medicine, University of Michigan, Michigan, MI, USA, ³AstraZeneca, Macclesfield, United Kingdom, ⁴Site Hospitalier Nord de Nantes, Centre René Gauducheau, Nantes, France, ⁵Dept of Oncology, University of Alberta, Edmonton, AB, Canada, ⁶Dept of Surgery, University of Stellenbosch, Tygerberg, South Africa.

The SABRE study (NCT00082277) evaluated the effects of the bisphosphonate risedronate on bone mineral density (BMD) and bone turnover in postmenopausal women with hormone receptor-positive early breast cancer treated with anastrozole. Patients were stratified according to baseline risk of fracture by lumbar spine and hip T-scores. High-risk (H) patients (T-score < -2.0 for spine or hip, or those deemed high-risk by the investigator) received anastrozole (A) 1 mg/day plus risedronate (R) 35 mg/week orally. Moderate-risk (M) patients (T-score < -1.0 for spine or hip but \geq -2.0 for both) were randomized in a double-blind manner to receive A plus either R or placebo (P). Low-risk (L) patients (T-scores \geq -1.0 at both sites) received A alone. All patients received calcium and vitamin D. Bone turnover was assessed using serum procollagen type I amino terminal peptide (PINP), bone alkaline phosphatase (bALP), and serum C-terminal crosslinking telopeptide of type I collagen (sCTX). Percentage change in BMD is shown in the table. BMD increased significantly in H and decreased significantly in L. In M, a significant difference was seen between treatment groups for lumbar spine (p < 0.0001) and total hip (p = 0.002, analysis of covariance).

In M, there was a significant difference in the percentage changes in bone markers between treatment groups (A + R sCTX -43.73, PINP -47.56, bALP -23.91 vs A + P 5.18, -7.65, 1.61 respectively; p < 0.0001 for all). Incidences of adverse events (AEs) were comparable between M treatment groups (A + R 88%, A + P 86%; serious AEs A + R 5%, A + P 5%). In postmenopausal women with breast cancer who are already at moderate to high risk of fragility fracture, and are scheduled for treatment with anastrozole, bone health can be managed according to established guidelines. In this study, for patients already at risk, risedronate at the licensed dose was sufficient to prevent a decrease in BMD and an increase in bone turnover.

	Stratum / treatment	N	Estimated % change in BMD from baseline to 12 months (95% CI)
Lumbar spine	L/A only	35	-0.62 (-1.93, 0.71)
	M/A+P	65	-0.41 (-1.11, 0.29)
	M/A+R	73	+1.71 (0.85, 2.58)
	H/A+R	36	+3.36 (2.05, 4.69)
Total hip	L/A only	35	-0.35 (-1.37, 0.68)
	M/A+P	65	-0.09 (-0.66, 0.47)
	M/A+R	73	+1.29 (0.69, 1.90)
	H/A+R	37	+1.53 (0.37, 2.71)

In Vivo Inhibition of Osteosarcoma Growth by Notch Pathway Inhibition. T. Setoguchi*, M. Tanaka*, S. Komiya*. Department of Orthopaedic Surgery, Kagoshima University, Kagoshima, Japan.

The Notch signaling pathway functions as an organizer in embryonic development. Genetic analysis has demonstrated a critical role for the Notch pathway in morphogenesis. Recent studies have shown constitutive activation of the Notch pathway in various types of malignancies. However, it remains unclear whether this pathway is activated in human bone tumor. Here, we examined the expression of the Notch pathway components by RT-PCR and immunohistochemical staining. RT-PCR and immunohistochemistry for Notch1-4, Jagged, Dll, Hes, and Hey was performed using human osteosarcoma cell lines and human osteosarcoma samples. And also, we investigated the effects of Notch pathway inhibition on osteosarcoma growth using pharmacologic inhibitors of γ -secretase (GSI) in vitro and in vivo. Cell viability was examined by MTT method. In order to determine the effects of Notch blockade in vivo, we examined the formation of tumor xenografts using osteosarcoma cell line and nude mice. RT-PCR revealed high expression of Notch-1, 2, Jagged1 Hes, and Hey in all of osteosarcoma cell lines. And also, 7 osteosarcoma human samples also showed high expression of notch signaling molecules mRNAs. In addition, immunohistochemistry showed high expression of Notch-1C in nucleus of osteosarcoma cell lines and human osteosarcoma samples. And also, expression of Jagged and Hes was observed in osteosarcoma cell lines and human osteosarcoma samples. MTT assay showed that GSI suppresses the growth of the osteosarcoma cell lines in vitro (Fig.1). In addition, intraperitoneally GSI administration dramatically inhibited the osteosarcoma xenografts growth in vivo (Fig.2). Our data indicate that the Notch pathway is a new candidate for therapeutic target of osteosarcoma.

Transforming Growth Factor β Receptor I Kinase Inhibitor Reduces the Development and Progression of Melanoma Bone Metastases. K. S. Mohammad¹, D. Javelaud², E. G. Stebbins³, M. Niewolna¹, C. R. McKenna¹, X. Peng¹, L. A. Kingsley¹, P. G. J. Fournier¹, L. S. Higgins³, D. H. Wong³, A. Mauviel², T. A. Guise¹. ¹Internal Medicine, University of Virginia, Charlottesville, VA, USA, ²INSERM U697, Paris, France, ³Scios Inc., San Francisco, CA, USA.

Melanoma often metastasizes to bone, where it is exposed to high concentrations of TGF- β . Constitutive Smad signaling occurs in human melanoma. Because TGF- β

promotes metastases to bone by several solid tumors, we hypothesized that TGF- β could promote melanoma metastases to bone. Consistent with this, overexpression of the inhibitory Smad7 blocked the capacity of 1205Lu melanoma cells to form bone metastases by preventing the TGF- β induction in vitro of genes known to mediate osteolytic breast cancer bone metastases such as PTHrP, IL-11, CXCR4 and osteopontin and by blocking the induction of TGF- β target genes PTHrP, IL-11 and CTGF in bone metastases in vivo. We next tested the effect of a small molecule inhibitor of TGF- β receptor I kinase (TGF- β RI), SD-208 on development and progression of bone metastases due to 1205Lu melanoma. This inhibitor effectively reduced bone metastases due to MDA-MB-231 breast cancer. In vitro, SD-208 blocked TGF- β induction of Smad3 phosphorylation relative activity of the TGF- β (Smad)-responsive promoter CAGA in several melanoma lines: 1205Lu, WM852, 501mel and 888mel as well as invasion through matrigel by 1205Lu. We therefore hypothesized that pharmacologic blockade of TGF- β signaling using SD-208, would be effective treatment for melanoma metastasis to bone. Nude mice were inoculated with 1205Lu melanoma cells into the left cardiac ventricle and treated with SD-208 (20 and 60 mg/kg po qd administered via oral gavage) in either prevention or treatment protocol. In the former, SD-208 (60mg/kg/d), started 2 days before tumor inoculation, prevented the development of osteolytic bone metastases compared with vehicle. In the latter, mice given SD-208 (60mg/kg/d) after confirming the presence of osteolytic lesions by radiography, had significantly smaller osteolytic lesions vs. vehicle treated mice ($p=0.0009$). These data indicate that therapeutic targeting of TGF- β may decrease the osteolytic bone metastases caused by malignant melanoma by mechanisms similar to those implicated in breast cancer osteolysis.

RANKL Inhibition Blocks Lung Cancer-induced Osteolytic Lesions and Reduces Skeletal Tumor Burden in Both RANK-Expressing and RANK-Negative Lung Cancers. R. Miller¹, J. Jones¹, M. Tometsko¹, M. Chaisson-Blake¹, M. Roudier², W. Dougall¹. ¹Department of Hematology/Oncology Research, Amgen Inc., Seattle, WA, USA, ²Department of Pathology, Amgen Inc., Seattle, WA, USA.

Bone metastasis is a serious complication of lung cancer and occurs in 30% of patients. Tumor cells interact with the bone microenvironment to induce osteoclastogenesis, leading to bone destruction and release of growth factors that have the potential to feed back to the tumor growth. RANK ligand (RANKL) is essential for osteoclast formation, function, and survival. Tumor cell-mediated osteolysis occurs ultimately via induction of RANKL within the bone stroma, and inhibition of RANKL in animal models of breast or prostate cancer bone metastasis blocks tumor-induced osteolysis and prevents the increase in bony tumor burden. Another role for RANK and RANKL in promoting metastasis to bone has recently been proposed, in which RANK-expressing tumor cells migrate into the bone environment via RANKL acting as a chemotactic factor (Holstead-Jones et al. 2006). We examined a panel of lung cancer cell lines to develop a model of lung cancer in bone. Lung cancer cell lines that expressed RANK included H146, H2107, H2108, H1975, H2126, while H526 and H1299 were negative for RANK, as determined by flow cytometry. Using bioluminescent imaging (BLI) and intracardiac challenge, we observed that several lung cancer lines became established and progressed in the bone, resulting in osteolytic lesions. The growth in bone and development of osteolytic lesions occurred with both RANK-expressing (H2126, H1975) and RANK-negative (H1299) cell lines. We treated mice bearing either H1299 (RANK-negative) or H1975 (RANK-positive) with the RANKL inhibitor OPG-Fc at early or late timepoints. OPG-Fc completely blocked the radiographically-evident osteolytic lesions induced by either cell line at all time points tested. In addition, RANKL inhibition blocked the skeletal tumor progression of the H1299 lung cancer line as determined by longitudinal BLI analysis and histomorphometry. In conclusion, these results clearly show that both RANK-expressing and RANK-negative lung tumor cells lead to bone metastasis. The ability of RANK expression on tumor cells to further promote bone metastasis will require additional studies. These results demonstrate that, irrespective of RANK expression on tumor cells, RANKL is a required factor for the tumor-induced osteolytic lesions caused by each lung cancer tested in vivo. RANKL inhibition reduced skeletal tumor burden of the H1299 lung cancer line, presumably via the indirect mechanism of blocking tumor-induced osteoclastogenesis and resultant production of growth factors from the bone microenvironment.

Myeloma Cells Decrease EphB4 Expression in Osteoblasts: A Novel Mechanism for Regulation of Bone Formation in Multiple Myeloma. A. L. Bates*, G. R. Mundy, C. M. Edwards. Vanderbilt Center for Bone Biology, Vanderbilt University, Nashville, TN, USA.

Multiple myeloma is associated with a destructive osteolytic bone disease, characterized by an increase in osteoclastic bone resorption and a reduction in osteoblastic bone formation. The increase in bone resorption in myeloma is well characterized; however the precise cellular and molecular mechanisms which mediate the reduction in bone formation and the uncoupling of bone resorption from bone formation are poorly understood. Recently, a novel mechanism has been suggested for coupling between osteoblasts and osteoclasts during normal bone homeostasis due to bidirectional signaling between the ligand ephrin B2, expressed by osteoclasts, and its receptor EphB4, expressed by osteoblasts. The interaction between EphB4 and ephrin B2 resulted in inhibition of osteoclast activity by reverse signaling through ephrin B2 on osteoclasts and stimulation of

osteoblast differentiation and bone formation by forward signaling through EphB4 on osteoblasts (Zhao et al. 2006). Since the normal coupling of bone resorption to bone formation is dysregulated in multiple myeloma, we hypothesized that this may be mediated by modifications in the EphB4/ephrin B2 receptor/ligand interaction. To study bone formation in multiple myeloma in vivo, we used the 5TGM1 murine model of myeloma. 5TGM1 myeloma cells were inoculated by i.v. injection into C57BlK^a.wRij mice, resulting in homing of myeloma cells to the bone marrow, and development of an osteolytic bone disease. In addition to the well characterized increase in osteoclastic bone resorption, the bone disease was associated with a significant reduction in osteoblast number and rates of bone formation ($p < 0.01$). Real time PCR demonstrated expression of EphB4 mRNA in 5TGM1 myeloma cells, C2C12 and 2T3 osteoblasts, with a 2-fold increase in expression in 5TGM1 myeloma cells when compared with C2C12 or 2T3 cells. Western blotting demonstrated expression of EphB4 protein in C2C12 and 2T3 cells. Treatment of C2C12 or 2T3 cells with conditioned media from 5TGM1 myeloma cells resulted in a significant reduction in expression of EphB4 in both C2C12 and 2T3 cells, suggesting that myeloma cells release a soluble factor which down-regulates EphB4 in osteoblasts. In conclusion, we have shown that the development of myeloma bone disease in the 5TGM1 murine model of myeloma is associated with a reduction in bone formation, and that 5TGM1 myeloma cells can down-regulate EphB4 expression in osteoblasts. This raises the possibility that the reduction in bone formation associated with myeloma bone disease is mediated by a reduction in EphB4 expression and thus disruption of the normal coupling of bone resorption and bone formation.

Prevention and Treatment of Hypogonadism-associated Bone Loss and Bone Metastases by OPG-Fc in a Model of Mixed Osteolytic/Osteoblastic Metastases. S. S. Padalecki¹, B. Grubbs¹, B. Goins¹, A. Soundarajan¹, G. R. Mundy², W. Dougall³. ¹UTHSCSA, San Antonio, TX, USA, ²VUMC, Nashville, TN, USA, ³Amgen, Inc., Cambridge, MA, USA.

Bone resorption plays an important role in the development of osteoblastic metastases. Osteoclastic bone resorption results in the release of potent growth factors from bone. Androgen ablation, the standard treatment for men with advanced prostate cancer, increases systemic bone resorption and releases these growth factors from bone. As a result it also likely makes the skeleton a more fertile environment for prostate cancer metastasis. We have previously shown that increased osteoclastic bone resorption due to hypogonadism causes a more fertile environment for mixed osteolytic/osteoblastic bone metastases utilizing a mouse model which mimics the clinical situation of men rendered hypogonadal as a result of treatment for prostate cancer. To investigate the potential of OPG-Fc in preventing and treating bone loss due to hypogonadism and mixed bone metastases, male nude mice underwent orchiectomy or sham surgery 4 weeks prior to intracardiac inoculation with TSU-PR1 bladder cancer cells that cause mixed bone metastases. The potential of OPG-Fc in prevention of bone loss and mixed bone metastases was assessed by treating mice 3X weekly with OPG-Fc or vehicle from the time of surgery. To determine the efficacy of treating existing bone metastases with OPG-Fc, treatments were not started until 75% of the mice had evidence of bone metastases by radiograph. Radiographs, bone mineral density, 99mTc-MDP MicroSPECT imaging and bone histomorphometry were used to assess bone turnover and tumor osteolysis. As expected, hypogonadism resulted in lower bone mineral density and increased bone turnover compared with sham-controls. This was prevented by OPG-Fc. TSU-PR1 bone metastases were increased and developed faster in hypogonadal mice treated with vehicle compared to sham-controls. OPG-Fc decreased bone metastases in hypogonadal TSU-PR1-inoculated mice when used in a preventative fashion but had no effect on soft tissue metastases or survival. When OPG-Fc was used to treat existing bone metastases, it resulted in a decrease in radiographic lesion number and area. This work provides in vivo evidence that OPG-Fc not only prevents bone loss due to androgen deprivation and reduced bone metastases in a prevention scenario, but suggests it also may lessen the severity of existing bone metastases. These data support the hypothesis that increased bone resorption due to androgen deprivation may result in a more fertile environment for the development of bone metastases. Bone resorption inhibitors, such as OPG-Fc, may benefit hypogonadal men with advanced prostate cancer to prevent and treat bone loss as well as skeletal metastases.

Serum Pentosidine Level Is Positively Associated with the Presence of Vertebral Fractures in Postmenopausal Women with Type 2 Diabetes. M. Yamamoto, T. Yamaguchi, M. Yamauchi, S. Yano, T. Sugimoto. Department of Internal Medicine 1, Shimane University Faculty of Medicine, Izumo, Japan.

Despite higher BMD than healthy subjects, patients with type 2 diabetes mellitus (2DM) have an increased risk of fractures, suggesting that BMD was not sensitive enough to assess the risk of fractures. However, there are no useful methods for assessing the bone fragility in 2DM. Recently, bone content of pentosidine, which is one of well-known advanced glycation end-products, is known to be negatively associated with bone strength. In this study, an association between serum pentosidine levels and the presence of vertebral fractures were examined in diabetic patients whose bone fractures lack their predictive markers. Ninety-four male and 76 postmenopausal female patients with 2DM within normal creatinine levels were examined by bone mineral density (BMD) at the lumbar spine, femoral neck and one-third of radius as well as spine radiographs, and by measurement of

biochemical parameters including serum pentosidine, serum bone-specific alkaline phosphatase (BAP) and urinary levels of N-telopeptide (uNTX). Thirty-three male and 20 female had vertebral fractures. Serum pentosidine level significantly increased with age in the diabetic men and women ($r = 0.232$, $p = 0.026$ and $r = 0.319$, $p = 0.006$, respectively). Comparison between diabetic subjects with and without vertebral fractures revealed no significant differences in BMD values at any sites or biochemical parameters such as BAP or uNTX in both genders. In contrast, serum pentosidine levels in women with vertebral fractures were significantly higher than in those without fractures ($0.0440 \pm 0.0136 \mu\text{g/ml}$ vs $0.0321 \pm 0.0118 \mu\text{g/ml}$, $p < 0.001$). Multivariate logistic regression analysis adjusted for age, body weight, body height, HbA1c, serum creatinine and diabetic duration showed that serum pentosidine level was identified as an independent factor associated with the presence of vertebral fractures in postmenopausal women with diabetes as shown in Table.

Associations between the presence of vertebral fractures and serum pentosidine levels in 2DM			
Pentosidine level	OR	(95% CI)	P
Male	0.76	(0.44-1.30)	0.3087
Female	3.33	(1.42-7.84)	0.0059 **

Serum pentosidine level, but not BMD, seems to be useful for assessing the risk of vertebral fractures in postmenopausal diabetic women, and may reflect bone quality in this group.

Factors Predicting Osteoporosis Treatment Initiation in a Regionally-Based Clinical Cohort. W. D. Leslie¹, J. F. Tsang², L. M. Lix³. ¹Dept of Medicine, University of Manitoba, Winnipeg, MB, Canada, ²University of Manitoba, Winnipeg, MB, Canada, ³Manitoba Centre for Health Policy, University of Manitoba, Winnipeg, MB, Canada.

BMD testing is used by many clinical practice guidelines to identify those at high fracture risk and to guide osteoporosis therapy (OTx) initiation. We hypothesized that OTx initiation would show large step increases at discrete cutoffs corresponding to proposed T-score intervention thresholds (e.g., -1.5, -2.0 or -2.5). Women age 50 y or older who had not been dispensed any OTx medication in the year prior to baseline DXA (1998-2002) were identified in a regionally-based database which contains all clinical DXA test results for the Province of Manitoba, Canada. Women with independent indications for OTx (previous glucocorticosteroid use or non-traumatic fractures of the hip, spine, wrist or humerus) were excluded. The rate of OTx initiation in the year after BMD (1 or more pharmacy dispensations) was studied using descriptive and logistic regression methods. 3826 of the 8654 women (44.2%) were dispensed OTx in the year after BMD. OTx initiation increased progressively as BMD decreased (8.2% normal, 41.0% osteopenic, 78.5% osteoporotic, p -for-trend < .00001). Contrary to expectation, there was a gradient response to OTx initiation rather than step increases at conventional T-score intervention thresholds. A small step increase occurred at a T-score of -1.0 but this is not generally considered as an OTx initiation threshold in the absence of other indications. In a logistic regression model BMD was strongly associated with OTx ($p < .00001$) while age ($p > .2$), weight or BMI ($p > .2$), and fracture (excluding hip, spine, wrist or humerus) in the last year ($p > .2$) were not. Similar results were seen when spine and hip T-scores were considered separately, or when OTx initiation was defined as 2 or more pharmacy dispensations. We conclude that physicians rely heavily on the BMD T-score to decide on OTx initiation. Although many clinical practice guidelines suggest that age in addition to other risk factors should be considered in OTx decision-making, we did not see evidence of this. More explicit methods of reporting fracture risk may be required to assist physicians in selecting patients likely to derive the largest benefit from OTx.

Figure: Osteoporosis treatment (OTx) initiation according to T-score (minimum spine and hip).

Utility of Lumbar Spine DXA Scanning in Women Undergoing Asymptomatic Osteoporosis Screening. V. Pao*, D. E. Sellmeyer, Medicine/Endocrinology, University of California San Francisco, San Francisco, CA, USA.

The International Osteoporosis Foundation recommends osteoporosis screening with bone mineral density (BMD) be conducted at the hip. The planned WHO fracture risk assessment model includes femoral neck BMD. Previous studies of research populations have suggested that lumbar BMD may be affected by degenerative changes and contribute little additional information to fracture risk assessment. To determine the utility of spine BMD in asymptomatic postmenopausal women undergoing routine clinical osteoporosis screening, we conducted a retrospective chart review of women over age 50 years who were referred for screening via dual x-ray absorptiometry (DXA) scanning at the UCSF Osteoporosis Center during 12 consecutive months. Women were excluded if they had a known secondary cause of bone loss or were on medications known to affect bone. We categorized each DXA as normal, osteopenia, or osteoporosis at the lumbar spine, femoral neck, and total hip according to the WHO T-score definitions. We also recorded patient demographics and specialty of referring physician. Patient characteristics were analyzed across categories of bone density using ANOVA.

The average age of the 744 participants was 65.7 ± 9.4 (mean \pm SD) years; 65% were Caucasian and 21% were Asian. DXA results showed 18.5% of the women had normal bone mineral density (BMD) at all three sites while 57.2% had osteopenia (T-score between -1 and -2.5) at one or more sites and 24.2% had osteoporosis (T-score < -2.5) at one or more sites. Compared to women with normal BMD, women with osteoporosis were more likely to be of Asian or Caucasian ethnicity ($p < 0.001$), have a smaller BMI ($p < 0.001$), and have a past history of back pain ($p = 0.009$). Osteoporotic patients were less likely to be taking calcium and vitamin D ($p = 0.02$) and more likely to have a history of fracture ($p = 0.003$). The majority of the patient population was referred by their primary care provider (64.1%), followed by gynecologists, endocrinologists, and rheumatologists. Orthopedic surgeons referred only 0.1% of patients. Of women who had normal BMD readings at both the total hip and femoral neck, 9.3% had osteopenia or osteoporosis at the lumbar spine. The average lumbar spine T-score among these women was -1.6 ± 0.5 . Many health care providers limit screening for osteoporosis to hip and femoral neck measurements. However, in our study a significant proportion of women had osteopenia or osteoporosis at the lumbar spine despite having normal BMD at the hip and femoral neck. These women would be expected to have an increased risk for vertebral fracture and would be missed if screening were limited to the hip site. Consideration should be given to regularly including the lumbar site when conducting routine osteoporosis screening in asymptomatic women.

In Vivo Assessment of 3-Dimensional Bone Micro Architecture with HR-pQCT in Patients with and without Fractures. H. Radspieler¹, I. Frieling², M. Neff³, R. Fischer⁴, M. Zulliger³, M. A. Dambacher⁵. ¹Center of Osteoporosis Munich, Muenchen, Germany, ²Center of Osteoporosis Hamburg, Hamburg, Germany, ³Center of Osteoporosis Zurich, Zurich, Switzerland, ⁴Klinik Eppendorf, Hamburg, Germany, ⁵ZORG, Zurich, Switzerland.

Measurement of areal bone mineral density (BMD/DXA) with derived T-scores may not be sufficient to evaluate the individual fracture risk. HR-pQCT reveals volumetric cortical and trabecular bone density and structural parameters as BV/TV, trabecular thickness and separation and cortical thickness.

We examined more than 200 women in the centres of osteoporosis in Hamburg and Munich with normal (T-Score > -1 SD), osteopenic (-2.5 SD $>$ T-score < -1.0 SD) or osteoporotic (T-score < -2.5 SD) BMD measured with DXA. In all patients volumetric BMD and trabecular architecture of the radius and tibia were measured by HR-pQCT (XtremeCT[®], SCANCO Medical AG).

Women with and without fractures showed no significant differences in height and weight but in age (68 vs. 63 y). The median T-scores from DXA measurements in women with and without fractures showed no significant differences (lumbar spine: -2.2 and -2.1, total hip: -2.2 and -2.2, neck: -2.0 and -1.8, respectively).

However, selective and region specific trabecular densities as well as structure parameters measured by HRpQCT differed significantly in osteopenic and osteoporotic women with and without fractures. The mean total density was lower in women with fracture than in women without fractures (D100, 247 vs. 291 mg/ml, $p < 0.001$), as well as the mean trabecular density (Dtrab, 94 vs. 123 mg/ml, $p < 0.001$) and the mean inner trabecular density (Dinn, 49 vs. 75 mg/ml, $p < 0.001$). Furthermore structure parameters in patients with fractures showed significantly increased trabecular separation (TbSp, 678 vs. 548 μ m, $p < 0.001$) and significantly decreased trabecular number (TbN, 1.3 vs. 1.6/mm, $p < 0.001$) as well as BV/TV (7.8 vs. 10.3%, $p < 0.001$) and significantly decreased cortical thickness (CtTh, 623 vs. 735 μ m, $p < 0.05$) with visible inhomogeneity of trabecular structure.

In conclusion, high-resolution peripheral computed tomography might help to predict fracture risk in osteopenic and osteoporotic patients. Especially in patients with osteopenia (according WHO-definition), the T-score seems to underestimate the fracture risk.

Use of DXA-Based Structural Engineering Models of the Proximal Femur to Predict Hip Fracture. L. Yang¹, N. Peel², J. Clowes¹, E. V. McCloskey¹, R. Eastell¹. ¹Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom, ²Metabolic Bone Centre, Northern General Hospital, Sheffield, United Kingdom.

Several DXA-based structural engineering models of the proximal femur have been developed to estimate stress due to sideways falls. Their usefulness in predicting hip fracture has not yet been established and we therefore evaluated these models as diagnostic tools for hip fracture.

We recruited 51 consecutive female patients presenting to the orthopaedic ward with low-trauma hip fracture (ages 58-81); 30 of the fractures had occurred at the femoral neck (FN), 17 were classified as trochanteric (TR) and 4 fracture sites were not specified. For each case we selected 3 age-height and weight-matched controls from a population-based cohort. The hip DXA scans were analysed using a special version of Hologic's software that produces a pixel-by-pixel BMC map. Curved-beam, curved composite beam and finite element (FE) models were generated and the stress calculated at each pixel. The elastic modulus and yield stress of the models were determined according to Keyak (Keyak et al. Clin Orthop Relat Res 437: 219-28). Index of fracture risk (IFR) was defined at each pixel as the stress divided by the yield stress. The maximum and mean IFR in the FN, narrowest FN, middle trochanter (MT), trochanter and total hip were calculated. The usual hip structure analysis (HSA) parameters were also calculated. Logistic regression was performed followed by ROC analysis, expressed as area under the curve (AUC), to identify the best discriminators between cases and controls. Analysis was performed regarding hip fracture as a homogeneous condition and repeated separately for FN and TR fractures.

TH BMD, FN axial length (AL), MT cortical thickness (CTH) and mean IFR (avgIFR) from the FE models were identified as best predictors. Specificity for hip fracture was consistently high (93-99%). The sensitivity and AUC are shown in the Table where * indicates AUCs that are significantly ($p < 0.05$) different from that with TH BMD alone as predictor.

In conclusion, this study suggests that HSA and FE models can enhance hip fracture discrimination over TH BMD alone. Preliminary analyses suggest their contribution may differ between FN and TR fractures but further evaluation is required.

	Model 1	Model 2	Model 3	Model 4
All hip fractures				
Sensitivity (%)	33	45	59	61

Longitudinal Rate of Change in Bone Mineral Density by Age for Men and Women. L. Langsetmo¹, C. Berger¹, D. A. Hanley², J. Prior³, W. P. Olszynski⁴, J. Brown⁵, L. Joseph⁶, A. Tenenhouse⁶, D. Goltzman⁶. ¹CaMos, Montreal, PQ, Canada, ²University of Calgary, Calgary, AB, Canada, ³University of British Columbia, Vancouver, BC, Canada, ⁴University of Saskatchewan, Saskatoon, SK, Canada, ⁵Laval University, Ste-Foy, PQ, Canada, ⁶McGill University, Montreal, PQ, Canada.

The objective of this study was to estimate the average rate of change in bone mineral density (BMD) of the lumbar spine and hip as a function of age for men and women 25-85

years old. The source population was a longitudinal cohort of 9423 community-dwelling Canadian adults recruited from randomly selected households within a 50 km radius of nine cities across Canada. BMD of the lumbar spine and hip (total hip, femoral neck, trochanter, and Ward's triangle) was measured at baseline and 5-year follow-up for all age groups and at 3-year follow-up for those 40-60 years old. The study excluded anyone without repeat BMD measurement (n=2665), over 85 years (n=179), or with more than 3 months corticosteroid use (n=211). A direct calculation or linear regression was used to estimate individual rate of change. A separate analysis was done for men and women and further stratified by use of anti-resorptives. The average rate of BMD change was calculated based on 5-year age intervals and used to construct age trajectories for the rate of bone loss.

The main age-dependent changes for women are a period of accelerated bone loss in those 40-54 years old, increased loss at hip sites in those over 70 years old, and a sustained increase in BMD of the lumbar spine in those over 65 years old. The main age-dependent changes for men are increased loss at all sites in those 25-39 years old, increased loss at hip sites in those over 65 years old, and a sustained increase in lumbar spine BMD in those over 40 years old. Different hip sites had similar but not parallel trajectories. The maximal femoral neck BMD loss for women not using anti-resorptives was an average 0.0077 (95% CI: 0.0062-0.0091) g/cm² per year in the 50-54 year age group and for men not using anti-resorptives was an average 0.0060 (95% CI: 0.0032-0.0088) g/cm² per year in the 25-29 year age group. In contrast, the femoral neck BMD loss for women using anti-resorptives was an average 0.0026 (95% CI: 0.0017-0.0035) g/cm² per year in the 50-54 year age group. Mean rates of bone loss for anti-resorptive users were lower than non-users for both men and women 50-79 years old. The differences between users and non-users were statistically significant for women but not men. The overall pattern of bone loss with age is substantially different in men and women with different periods of increased bone loss. Understanding the timing of maximal bone loss may enable better strategies in prevention and management of osteoporosis.

S339

Impact of Herbal Remedies for Menopause on Bone Mineral Density: The Herbal Alternatives for Menopause (HALT) Trial. K. M. Newton¹, A. Z. LaCroix², S. D. Reed³, L. C. Grothaus⁴, J. W. Lampe⁵, K. Ehrlich⁶. ¹Group Health Center for Health Studies, Seattle, WA, USA, ²Fred Hutchinson Cancer Research Center, Seattle, WA, USA, ³Obstetrics and Gynecology, University of Washington, Seattle, WA, USA.

While estrogen therapy is associated with decreased fracture risk, evidence regarding the effects of soy isoflavones on bone mineral density (BMD) is mixed, and the influence on BMD of herbal approaches used for menopause symptoms is unknown. The purpose of this study was to evaluate the effects of herbal approaches for menopause symptoms on hip and spine BMD.

We enrolled 351 peri and postmenopausal women, aged 45-55, in Washington state, into the HALT study, a 5-arm randomized controlled trial comparing 3 herbal therapies and hormone therapy to placebo. Entry criteria included ≥ 2 hot flashes and/or night sweats per day. Over 95% completed the month 6 BMD, 93% the month 12. Women were randomly assigned to: 1) black cohosh (160 mg daily); 2) multibotanical with black cohosh (200 mg daily) and 9 other ingredients; 3) multibotanical plus dietary soy counseling; 4) conjugated equine estrogen 0.625 mg \pm medroxyprogesterone acetate 2.5 mg daily (HT); or 5) placebo. Outcome measures were BMD of the lumbar spine and total hip measured by DXA at baseline, 6, and 12 months. We used maximum likelihood (mixed models) to compare mean percent change from baseline for herbs and hormone therapy vs. placebo, adjusted for age, body mass index (kg/m²), dietary calcium and baseline BMD. Compared to placebo, the multibotanical plus dietary soy was associated with a significant decrease in hip and spine BMD at 6, but not 12 months. Compared to placebo, HT had no significant effect on hip BMD but was associated with a significant increase in spine BMD at 6 and 12 months.

Black cohosh and the multibotanical with black cohosh had no impact on hip or spine BMD, Table 1.

Table 1. Percent BMD Change From Baseline

	Hip 6 Months	Hip 12 Months	Spine 6 Months	Spine 12 Months
Black Cohosh n=79	-0.59%	-0.22%	-1.11%	-1.72%
Multibotanical n=74	-0.72%	-1.23%	-1.57%	-2.23%
Multi + Soy n=78	-0.94%	-1.21%	-1.72%*	-2.42%
HT n=32	-0.28%	0.77%	2.10%†	1.17%‡
Placebo n=83	-0.23%	-0.54%	-0.65%	-1.48%

Change in intervention vs. change in placebo *P=0.03, †P=0.0001, ‡P=0.002

We conclude that black cohosh alone or as part of a multibotanical preparation has no impact on BMD of the total hip or lumbar spine, and that black cohosh taken in combination with other herbs and soy diet may negatively impact spine BMD.

Disclosures: K.M. Newton, None.

Effects of Functional Single Nucleotide Polymorphism in the Tissue-Nonspecific Alkaline Phosphatase Gene (787T>C) Associated with BMD. M. Goseki-Sone¹, N. Sogabe², K. Oda³, H. Nakamura⁴, H. Orimo⁵, T. Hosoi⁶. ¹Department of Food and Nutrition, Japan Women's University, Tokyo, Japan, ²Division of Biochemistry, Niigata University, Graduate School of Medical and Dental Sciences, Niigata, Japan, ³Department of Chemistry, Gakushuin University, Tokyo, Japan, ⁴Division of Molecular Genetics and Nutrition, Department of Biochemistry and Molecular Biology, Nippon Medical School, Tokyo, Japan, ⁵Department of Advanced Medicine, National Center for Geriatrics and Gerontology, Aichi, Japan.

Human alkaline phosphatases (ALPs) are classified into four types: tissue-nonspecific, intestinal, placental, and germ cell types. Previously, we identified polymorphisms of the TNSALP gene 787T>C (Y246H) associated with BMD among 501 postmenopausal women. There was a significant difference in the BMD and the score of BMD adjusted for age and body weight (Z-score) among haplotypes, which was lowest among 787T homozygotes, highest among 787T>C homozygotes, and intermediate among heterozygotes. In subgroups divided by age, haplotypes were significantly associated with the BMD in older postmenopausal women. These results indicated that the effect of haplotypes on the BMD depended on age. In the present study, we have investigated the effects of amino acid substitution on the biosynthesis and the catalytic properties of the protein translated from the 787T>C gene, and three-dimensional structure-related effects on calcium. Furthermore, we explored the possibility that the TNSALP gene may contribute to phosphate metabolism in humans by measuring serum concentrations of bone-specific ALP (BAP), osteocalcin, calcium, phosphorus, and FGF-23 (phosphatonin). As the results, TNSALP (787T) and TNSALP (787T>C) were synthesized similarly as a high-mannose-type 66-kDa form, and became an 80-kDa form in an in vitro translation system. Expression of the 787T>C TNSALP gene using mouse marrow stromal cells (ST2) demonstrated that the protein translated from 787T>C exhibited an ALP-specific activity similarly to that of 787T. Interestingly, the Km value for TNSALP in cells transfected with the 787T>C TNSALP gene was decreased significantly compared to that of cells bearing the 787T gene (p<0.01). Moreover, we demonstrated the associations among the levels of serum BAP and phosphorus in 60 healthy young males. The level of serum BAP was significantly correlated with serum phosphorus in 787T (p<0.01), but not in 787T>C homozygotes. These results suggest that TNSALP variation may be an important determinant of age-related bone loss in humans, and that the phosphate metabolism pathway may provide a novel target for the prevention and treatment of osteoporosis.

The Effect of Nutritional Calcium on the Risk of Postmenopausal Fractures Varies with Age. A 15-year Follow-up of the OSTPRE Cohort.

R. J. Honkanen¹, K. Salovaara², M. Kärkkäinen¹, M. T. Tuppurainen³, H. P. Kröger⁴, E. M. Alhava⁴. ¹BCRU, Clinical Research Center, University of Kuopio, Kuopio, Finland, ²Surgery, Kuopio University Hospital, Kuopio, Finland, ³Gynaecology, University Central Hospital of Kuopio, Kuopio, Finland, ⁴Surgery, University Central Hospital of Kuopio, Kuopio, Finland.

We have previously shown that nutritional calcium (Ca) prevents early postmenopausal distal forearm fracture (DFF). The purpose was to examine the stability of this Ca effect with age.

The study population consisted of those 9403 OSTPRE cohort women (born in 1932-41) who responded to all four enquiries: in 1989 (N=13100), in 1994 (N=11798), in 1999 (N=10977) and in 2004 (N=9403). Self-reported follow-up fractures were validated by perusal of patient records: 777 women recorded fractures in 1989-94, including 279 women with DFF and 6 women with hip fracture; the number of women with fractures in 1999-2004 was 835, including 322 women with DFF and 28 women with hip fracture. Self-reported dairy Ca intake (forming about 75 % of overall nutritional Ca intake) was used as a measure of nutritional Ca intake. Logistic regression was used as the statistical method.

Mean Ca intake was 827(SD 391) mg/day in 1989 and 848 (SD370) mg/day in 1999. Ca intake did not predict fractures in general in 1989-94 or in 1999-2004. It protected from DFF in 1989-94 (p=0.001 for continuous Ca variable) (with OR of 0.68 (95% CI 0.51-0.92) at Ca intake of 500-999 mg and OR of 0.57 (0.40-0.81)) at Ca intake >999 mg compared to women with Ca intake <500 mg) but not in 1999-2004 (p=0.353 for continuous Ca variable). However, a joint effect of high Ca intake and HRT on the incidence (%) of DFF was seen even in late postmenopausal women in 1999-2004:

	Ca intake in 1999			P value*
HRT in 1999	<500 mg	500-999 mg	>999 mg	
No	4.0 %	4.1 %	3.8 %	0.679
Yes	3.4 %	2.2 %	1.3 %	0.019

*trend test

In addition, Ca intake strongly protected from hip fracture in 1999-2004 (p=0.001 for continuous Ca variable) with OR of 0.27 (0.13-0.59) at Ca intake of <500 mg and OR of 0.08 (0.02-0.34) at Ca intake >999 mg compared to Ca intake of <500 mg. Adjusting for weight, height, fracture history, HRT, time of menopause and number of health disorders did not affect these fracture risks. Ca intake did not protect from fractures at other sites. The protective effect of nutritional Ca on distal forearm fracture risk is more easily seen in early than late postmenopausal women, whereas the effect on the risk of hip fracture becomes apparent later with increasing incidence of hip fractures.

Leg Lean Mass and Risk of Hip Fracture: The Framingham Study. M. T. Hannan, K. E. Broe*, R. R. McLean*, D. P. Kiel. HSL Institute for Aging Research, Boston, MA, USA.

While bone density is a potent risk factor for fracture, few data exist on lean muscle mass and risk of hip fracture. Low lean mass, or 'sarcopenia', has been associated with reduced muscle strength and lower functioning in elders. We examined whether leg lean mass predicted risk of hip fractures in women of the Framingham Original Cohort with the hypothesis that lower lean mass of the legs would be associated with increased hip fracture risk even after adjustment for major confounders. Men were not included as too few hip fractures occurred in men and their lean mass measures were different from women.

432 women of the Original Cohort had leg lean mass (kg) measured in 1992-93 using whole body DXA (Lunar DPX-L) and were followed for incident hip fracture. Fracture information through 12/31/2003 was provided by the Framingham Fracture Registry (incident hip fractures ascertained by interview, record reviews and confirmed by x-ray). Number of person-years was determined from DXA scan date to hip fracture, last contact, death, or end of follow-up. Cox proportional hazards regression was used to calculate hazard ratios (HR) and 95% confidence intervals (CI) estimating the risk of hip fracture for each kg increase in leg lean mass. Covariates (baseline) included age, weight, height, physical activity (PASE score), calcium and vitamin D intake and femoral neck bone mineral density (BMD).

Mean age was 78 yrs (range: 72-92 y); 49 hip fractures occurred over follow-up. Mean leg lean mass for these women was 11.38 kg (range 7.2-17.0). Leg lean mass was significantly inversely correlated with age, and significantly positively correlated with weight, height, physical activity and BMD. In Cox regression model adjusting for age, weight and height, leg lean mass predicted subsequent hip fracture, HR=1.46 (95% CI: 1.15, 1.85). Further adjustment for physical activity, calcium and vitamin D intake did not change these results. Adding femoral neck BMD to the model attenuated the risk somewhat: for each kg increase in leg lean mass in women, the risk of hip fracture increased by 30% (HR=1.30, 95% CI: 1.01, 1.67).

In sum, leg lean mass predicted hip fracture in elderly women even after adjusting for BMD. While not supporting our hypothesis, these unexpected results may reflect that those elderly women with greater lean mass were more physically active and were more apt to fall and fracture (ie, adjusting for physical activity may not have fully adjusted for increased opportunity to fall & fracture). Also, perhaps a lower fracture risk exists for middle-age adults but not the geriatric women we studied (ie, hip fracture risks change with age). Further studies should examine lean mass and fractures in men as well as change in physical activity and falls for risk of hip fractures in elders.

Burden of Hip and Wrist Fractures: Incidence Estimates of Non-traumatic Fractures in Older Women and Men in North America, Western Europe, Australia, and Japan. C. Strader*, C. W. Shinoff*, M. S. Anthony*, L. A. Fitzpatrick*. The Mattson Jack Group, St. Louis, MO, USA, ²Amgen Inc., Thousand Oaks, CA, USA.

Fractures in older men and women lead to increased risk of subsequent fractures and mortality. Current international estimates of non-traumatic fracture incidence are not readily available, but are needed to estimate the burden of osteoporotic disease. We estimated the annual incidence of non-traumatic hip and wrist fractures in women >50 and men >60 years of age. A literature review and web-search was conducted to find studies that quantified fracture incidence in the United States, Canada, United Kingdom, Germany, France, Italy, Spain, Australia, and Japan. Data from the National Health and Nutrition Examination Survey (NHANES) 1999-2002 were used to estimate the ratio of site-specific non-traumatic fractures to total hip and wrist fractures. Non-traumatic fractures were defined as a fall from standing height or less. If the country-specific fracture studies did not exclude traumatic fractures, the site-specific NHANES ratio of non-traumatic to total fractures was used to estimate site and country-specific non-traumatic fracture incidence rates. Census data were used to standardize the age-, gender-, and country-specific incidence data to the 2005 country-specific population. Non-traumatic hip fracture incidence was 1-6 fold higher and wrist fracture incidence 3-8 fold higher in women compared to men (Table 1). Hip fracture incidence was highest for women in Germany and wrist fracture rates were highest in US women. Hip and wrist fracture rates increased with age for both men and women.

Table 1. Annual Non-Traumatic Hip and Wrist Fracture Incidence Estimates in Women >50 and Men >60 Years of Age (per 10,000 population)

Country	Hip fractures		Wrist fractures	
	Women	Men	Women	Men
United States	36.8	12.7	52.9	8.1
Canada	26.0	7.6	27.5	8.2
United Kingdom	38.5	7.8	32.5	4.7
Germany	42.4	6.7	42.5	5.3
France	27.9	5.7	19.3	3.3
Italy	22.1	4.4	21.3	2.9
Spain	28.2	6.1	20.0	3.6
Australia	34.0	28.1	24.2	3.5
Japan	17.5	3.5	20.2	2.8

Fractures in older women and men represent a significant problem globally. Projected to the 2005 census, there are about 500,000 non-traumatic hip fractures and 537,000 non-traumatic wrist fractures annually in women older than 50 and men older than 60 years of age in these 9 countries. Differences in rates between countries could be due to inherent biologic differences, differences in fracture ascertainment, or differences in environmental factors, such as strategies for preventing fractures. As the population ages, these rates will continue to increase.

Chronic Proton Pump Inhibitor Use Is Not Associated with an Increased Risk of Osteoporotic Fracture. L. E. Targownik*, W. D. Leslie¹, L. M. Lix*, C. J. Metge*, H. J. Prior*, S. Leung*. ¹Internal Medicine, University of Manitoba, Winnipeg, MB, Canada, ²Community Health Sciences, University of Manitoba, Winnipeg, MB, Canada, ³Pharmacy, University of Manitoba, Winnipeg, MB, Canada.

Proton pump inhibitors (PPIs) are commonly prescribed medications used for the treatment and prevention of a variety of gastrointestinal diseases. They are believed to decrease gastrointestinal absorption of dietary calcium, and are also postulated to stimulate osteoclast activity. Therefore, PPIs are a putative risk factor for the development of osteoporosis and osteoporotic fracture. Results of studies linking PPI use to osteoporotic fracture are conflicting.

We used the Manitoba Health Research Data Repository to perform a nested case-control study. Cases, defined as patients admitted for a hip/proximal femoral fracture between 1996-2004, were matched to controls with no history of osteoporotic fracture (hip, spine, wrist) on age, sex, medical comorbidity and ethnicity (Aboriginal vs. non-Aboriginal). PPI exposure was obtained from the provincial pharmacy database, and tracked for either 1, 2, or 4 years prior to the index date. Subjects were considered to be continuously exposed to PPIs if there was documented PPI use over >70% of days in the exposure period of interest (1, 2, and 4 years prior to event), and unexposed if PPIs were used <10% of the time during the exposure period of interest. Conditional logistic regression was performed to obtain odds ratios and confidence intervals, adjusted for pertinent covariates.

Numbers of cases and controls for each exposure period and both the unadjusted and adjusted odds ratios are displayed in the table below. We did not detect an association between PPI use and hip fracture over 1, 2 or 4 years of prior exposure.

PPIs do not appear to be an important risk factor for the development of hip fracture. Further studies are required in other populations to confirm our findings.

PPI Exposure and Odds of Developing Hip Fracture				
Duration of Exposure	# Cases	# Controls	Crude Odds Ratio (95% CI)	Adjusted Odds Ratio (95% CI)
Lead-In Time			PPI exposed vs. PPI unexposed	(PPI exposed vs. PPI unexposed)
1 year	13378	40048	1.10 (1.00 - 1.23)	1.04 (0.93 - 1.16)
2 years	11067	33182	1.08 (0.95 - 1.22)	1.00 (0.88 - 1.13)
4 years	7172	21465	1.17 (0.97 - 1.40)	1.11 (0.92 - 1.35)

Vertebral Fracture Lines Are Not Smooth, but Mixtures of Multiple Schmorl's Nodes and Endplate Perforations. T. Okamoto*, S. Okamoto¹, H. Noguchi*, H. Suzuki*, N. Otsu*, A. Itabashi*. ¹SORF Okamoto Clinic, Oita, Japan, ²Noguchi Thyroid Clinic and Hospital Foundation, Beppu, Japan, ³Suzuki Orthodontic Office, Nagasaki, Japan, ⁴Saitama Center of Bone Research, Saitama, Japan.

Although vertebral fracture cannot occur without mechanical compression, discussion on what exactly is the primary causative factor of vertebral depression has been conspicuously absent. The 3-D models revealed that the vertebral endplates of fractured vertebrae are rarely smooth and are compromised with multiple Schmorl's nodes and endplate perforations. The TV X-ray fluoroscopy was performed on 2,600 female patients with osteoporosis in one outpatient clinic in Oita, Japan. Care was taken to adjust the posture of each patient to align the vertebrae in right angle to the film. Also we created computerized 3-D renderings of 1280 cases comprised of post-menopausal women aged 45-85, primarily of patients of osteoporosis and osteoarthritis, and healthy female controls aged 20-40. The digital 3-D models were constructed from helical CT data and examined for morphologic characteristics. The 3-D models revealed that the vertebral endplates of post-menopausal women are frequently compromised with perforated indentations. We calculated the ratio of the perforations to the area of the endplates and found that the there was a significant correlation between the perforation/endplate area ratio and the number of years after menopause. The space enclosing the vertebral disc actually expands while the rims of the vertebrae converge. What has conventionally been known as fish-shaped vertebral fractures may in fact be secondary to the herniation of the disk nucleus into the weakened vertebral body of the osteoporotic spine. The so-called wedge type fractures appear to be the result of rim destruction due to direct contact between the vertebral rims after narrowing of intervertebral space. The multiple perforations which appears just after menopause, and gradually enlarge, are eroding vascular pathways which nourish the vertebral disc through the vertebral medulla. To avoid inaccurate diagnosis of vertebral fractures, a better grasp of the vertebral structure as a complex three-dimensional entity is definitely necessary.

Computer Based Measure of Kyphosis Predicts Fractures in the Thoracic Spine of Postmenopausal Women. P. C. Pettersen¹, M. de Bruijne², J. Chen¹, Q. He¹, L. B. Tankó³, C. Christiansen⁴. ¹Radiology, Center for Clinical and Basic Research, Ballerup, Denmark, ²Department of Computer Science, University of Copenhagen, Copenhagen, Denmark, ³Clinical Research, Center for Clinical and Basic Research, Ballerup, Denmark, ⁴Nordic Bioscience, Herlev, Denmark.

The aim of this study is to investigate whether recently introduced computer-based measures of the degree of kyphosis and irregularities in vertebral alignment of the thoracic spine are independent contributors to fragility fractures.

This was a case control analysis including 126 healthy elderly women, 63 of whom maintained skeletal integrity, whereas 63 sustained a thoracic fracture over the mean observation period of 4.8 years. None of the women received ongoing osteoporosis treatment and the cases and controls were matched for age, follow-up, spine BMD L1-L4 (DEXA), and body weight. Lateral X-rays acquired at baseline and follow-up were digitised and the corner points on each vertebra from Th4 to L1 were marked. Spine curvature at each vertebra level was characterized by the curvature (1/radius) of the circle connecting its center with the centers of neighbors. The degree of kyphosis is defined as the mean curvature of the thoracic spine (Th5 to Th12). The sum of differences between the individual curvatures and the mean curvature defined irregularity of vertebral alignment.

Kyphosis presented a statistically significant difference between the two groups at baseline (fig1 p=0.002), and the measure of kyphosis was increased from baseline in the fracture group (p=0.02). The analyses of irregularities along the thoracic spine did not show differences between the two groups at baseline (fig1). However, the measure of irregularity of vertebral alignment increased in those sustaining a vertebral fracture (p=0.0001). The mean values and SD are shown in figure 1.

The measure of kyphosis, but not the measure of irregularity, can predict fragility fractures in the thoracic spine of postmenopausal women, independent of age, body weight and spine BMD. The observation of increasing irregularity of vertebrae alignment is considered as a consequence of irregular anterior wedge accentuation due to either remodeling or fragility fractures. Secondly, this observation indicates that the herein presented computer based diagnostic tool could be a useful supplement to existing approaches to fracture prediction.

Endogenous Sex Hormones and Incident Fracture Risk in Older Men: The Dubbo Osteoporosis Epidemiology Study. C. Meier¹, T. V. Nguyen², D. J. Handelsman³, C. Schindler⁴, M. M. Kushnir⁵, A. L. Rockwood⁶, W. A. Meikle⁶, J. R. Center², J. A. Eisman², M. J. Seibel⁷. ¹Division of Endocrinology, University Hospital Basel, Switzerland, ²Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia, ³Department of Andrology, ANZAC Research Institute, Sydney, Australia, ⁴Institute of Social and Preventive Medicine, University of Basel, Switzerland, ⁵ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, UT, USA, ⁶Department of Medicine and Pathology, University of Utah, Salt Lake City, UT, USA, ⁷Bone Research Program, ANZAC Research Institute, Sydney, Australia.

One third of osteoporotic fractures occur in men. Data on the influence of gonadal hormones on incident fracture risk in elderly men are limited. The present study examined the prospective relationship between serum levels of testosterone (T) and estradiol (E2) and future fracture risk in elderly men as part of the long-term observational Dubbo Osteoporosis Epidemiology Study of community-dwelling men over 60 years followed prospectively since 1989. This analysis included men who had serum samples for baseline measurements (n=609, 70.6%) with follow-up of 5.8 years (up to 13 yrs) closing in 2005. Clinical risk factors, including bone mineral density (BMD) and lifestyle factors were assessed at baseline. Serum T and E2 were measured by tandem mass spectrometry (LC-MS/MS). The incidence of low-trauma symptomatic fracture was ascertained by X-ray record.

During follow-up, 113 men suffered at least one low-trauma fracture. Fracture risk was increased in men with reduced T levels (hazard ratio [HR] 1.33; 95%CI: 1.09, 1.62). After adjustment for SHBG, both low serum T (HR 1.48; 95%CI: 1.22, 1.78) and serum E2 (HR 1.21; 95%CI: 1.00, 1.47) were associated with increased overall fracture risk. After further adjustment for major fracture risk factors (age, weight or BMD, fracture history, smoking status, calcium intake and SHBG), lower T was still associated with increased risk of hip (HR 1.88; 95%CI: 1.24, 2.82) and non-vertebral (HR 1.32; 95%CI: 1.03, 1.68) fracture. By contrast, lower E2 was only associated with increased fracture risk in the presence of body weight (HR 1.25; 95%CI: 1.02, 1.54), but not at any site after adjustment for BMD (HR 1.19; 95%CI: 0.69, 1.03).

In community-dwelling men over 60 years of age, serum T, but not E2, is an independent predictor of osteoporotic fracture and its measurement may provide additional clinical information for the assessment of fracture risk in elderly men.

Disclosures: C. Meier, None.

Respiratory Function Is Associated with Bone Ultrasound Measures and Hip Fracture: European Prospective Investigation Into Cancer-Norfolk Population Cohort Study. A. Moayyeri¹, R. N. Luben¹, S. Bingham², A. Welch¹, N. J. Wareham³, S. Kaptoge¹, J. Reeve¹, K. T. Khaw¹. ¹Department of Public Health and Primary Care, Institute of Public Health, School of Clinical Medicine, The University of Cambridge, Cambridge, United Kingdom, ²MRC Dunn Human Nutrition Unit, The University of Cambridge, Cambridge, United Kingdom, ³MRC Epidemiology Unit, The University of Cambridge, Cambridge, United Kingdom.

Forced expiratory volume in 1 second (FEV1), an easily obtainable measure of respiratory function in clinics, has been shown to be associated with physical activity. We hypothesized that FEV1 is linked with bone health. In the context of the European Prospective Investigation into Cancer-Norfolk study, 14,800 participants aged 42-81 in 1997-2000 were evaluated by spirometry and heel ultrasound and were followed for fracture outcomes up to July 2007. After excluding participants with history of pulmonary diseases, among 5,555 men and 6,935 women (mean age 62.1±9.0), FEV1 significantly correlated with heel broadband ultrasound attenuation (BUA; Pearson r=0.403; p<0.001) and velocity of sound (VOS; r=0.269; p<0.001). The association remained significant in sex-stratified linear regression models after adjustment for age, history of fracture, height, body mass index, smoking status and alcohol consumption (standardized Beta coefficient=-0.057 and p<0.001 in men; Beta=0.075 and p<0.001 in women). Mean adjusted FEV1 among 109 hip fracture patients (2.00±0.60 liter) was significantly lower than that of other participants (2.49±0.71 liter; t-test p<0.001). In a Cox proportional hazards regression model, FEV1 was a significant predictor of hip fracture after adjustment for age, sex, history of fracture, height, body mass index, smoking and alcohol consumption (hazard ratio for 1 standard deviation [700 ml in 1 second] decrease in FEV1=1.39, 95%CI 1.03-1.88, p=0.029). Among 6197 current and former smoker participants, hazard ratio for 1 standard deviation decrease in FEV1 was 1.67 (95%CI 1.11-2.57, p=0.014). Middle aged and older men and women with lower respiratory function appear to be at increased risk of osteoporosis and hip fracture. The observed association might be related to the level of physical activity or deformities in thoracic spine related to osteoporosis. Given the feasibility and affordability of spirometry in general practices, it can be used to improve the identification of high risk groups at the first point of care.

Disclosures: A. Moayyeri, None.

Competing Risk of Subsequent Fracture and Death After Hip Fracture in Nursing Home (NH) Residents. S. Berry, K. Broe, D. Kiel. IFAR, Hebrew SeniorLife, Boston, MA, USA.

Prior studies have demonstrated an increased risk of subsequent fracture among community dwellers with hip fracture. It is unclear whether this is also true in NH residents given the high burden of co-morbidities and associated competing risk of mortality. Therefore, we described the incidence of second fractures and the competing risk of death following a hip fracture in a large NH.

Participants were 218 consecutive residents (49 men, 169 women) of Hebrew Rehabilitation Center, a 725 bed long term care facility in Boston, MA, with a hip fracture between 1/1/1999 and 12/31/2006. Fractures were identified from a review of mandated injury files (excluding fractures associated with malignancy, Paget's disease, or prosthesis; n=3). Second fractures included any fracture occurring after the initial fracture, excluding toe and hand fractures. Baseline characteristics were obtained from administrative databases in the three months preceding the initial hip fracture. Subjects were followed from initial hip fracture until second fracture, death, discharge, or 12/31/2006. A Wilcoxon rank sum compared baseline age among subjects with second fracture and subjects who died without second fracture. Cumulative incidence estimates, taking into account the competing risk of death, described the incidence of second fractures.

At baseline, 82% of subjects had 0-1 major co-morbidities, and 35% were functionally intact or had mild impairment. Over a median follow-up of 11 months (range, 2 d- 8 yrs), 17% of subjects (7 men, 31 women) experienced a second fracture (17 hip, 5 leg, 2 ankle, 5 arm, 5 pelvic, 2 clinical vertebral, 1 skull, 1 clavicle), and 55% of subjects (30 men, 90 women) died. Subjects with second fracture were younger than subjects who died without second fracture (median 88 yrs vs. 91 yrs, p=0.02). Five percent of subjects experienced a second fracture within six months, and 10% experienced a second fracture within 1 yr of the initial hip fracture. In contrast, 27% of subjects died within 6 months, and 37% died within 1 yr of the initial hip fracture (Kaplan-Meier estimates). In conclusion, the striking mortality among NH residents with minimal co-morbidities and hip fracture highlights the importance of hip fractures as a sentinel event in the NH. Among NH residents who survive a hip fracture, second fractures are common. Future studies should focus on identifying likely survivors with sufficient quality of life to target secondary fracture prevention.

Survival after a hip fracture among NH residents

Factors Influencing the Diagnosis and the Treatment of Osteoporosis Following a Fragility Fracture. L. Bessette¹, J. P. Brown¹, S. Jean^{*2}, K. S. Davison¹, M. Beaulieu^{*3}, M. Baranci^{*4}, J. Bessant^{*5}, L. Ste-Marie^{*6}. ¹Laval University, Quebec, PQ, Canada, ²INSPQ, Quebec, PQ, Canada, ³Merck Frosst, Montreal, PQ, Canada, ⁴sanofi aventis, Montreal, PQ, Canada, ⁵P&G Pharma, Montreal, PQ, Canada, ⁶U. of Montreal, Montreal, PQ, Canada.

ROCQ (Recognizing Osteoporosis and Its Consequences in Québec) revealed that 73% of women 50y and over are not provided anti-fracture therapy following fragility fracture. This study's objectives were to determine predictors of osteoporosis (OP) diagnosis (DX) and treatment (TX) 6 to 8 months after fragility fracture.

At phase 1, women were recruited at cast or outpatient clinics in 17 hospitals 0 to 16 weeks following fracture. Consenting patients were contacted by phone to answer a short questionnaire to classify them as having either experienced a fragility or traumatic fracture. During the first phone contact, there was no reference to the possible association between the fracture and OP and no investigation or intervention was proposed. At phase 2, 6-8 months following fracture, women were contacted again by phone to complete a questionnaire on demographic features, clinical characteristics and risk factors for OP. The DX (informed of OP and/or BMD measurement with diagnosis of OP) and TX (bisphosphonates, raloxifene, nasal calcitonin or teriparatide) rates of OP were determined

via this questionnaire. This analysis included only women with a fragility fracture who were not receiving OP TX at phase 1.

Of the 1273 women who completed phase 1, 1001 (79%) sustained a fragility fracture; 818 were not on treatment at phase 1 and completed the phase 2 questionnaire. Overall, 79% of these participants had not received a DX of osteoporosis or were without OP TX at phase 2. The highest rate of DX and TX of OP was observed between 0-5 months following fracture and decreased considerably thereafter. In multivariate analyses, the results of BMD tests before or after the fracture event (p<0.0001) and mobility problems (p=0.03) were the only variables that influenced the DX of OP. The BMD test result was the strongest predictor (p<0.0001) of TX followed by the fracture site (hip, femur and pelvis; p=0.015) and vitamin D supplements at the time of fracture (p=0.035). All other risk factors for OP such as age, fracture history after age 40, family history of OP, and comorbidities did not influence the DX or TX rate. No demographic and clinical features or OP risk factors were significantly associated with the decision to send women for a BMD testing following fracture.

Despite the evidence clearly showing that the occurrence of a fragility fracture represents a greater risk of future fragility fracture than a low BMD measurement, physicians based their decision to treat on BMD results and not on the clinical event (fragility fracture).

A Comparison of the Effects of Thiazide Diuretics and Angiotensin Converting Enzyme Inhibitors on Fracture Risk - A Randomised Controlled Trial. T. Winzenberg¹, K. Willson^{*2}, P. Ryan^{*2}, M. Nelson^{*1}, G. Jones¹. ¹Menzies Research Institute, Hobart, Australia, ²Adelaide University, Adelaide, Australia.

Observational evidence suggests that antihypertensives, particularly thiazide diuretics may affect bone and fracture risk. However head-to-head comparisons of the effects of different antihypertensives on fracture risk to inform choice of antihypertensive are lacking. We aimed to prospectively compare the effects of thiazide diuretics and angiotensin converting enzyme (ACE) inhibitors on fracture risk.

The second Australian National Blood Pressure trial is a prospective, randomized, open-label study which was conducted in 6083 hypertensive Australian family practice patients aged 65-84 years. Subjects were followed for a median of 4.1 years. Family practitioners (FPs) were responsible for the stepwise management of antihypertensive treatment, guided by study protocols for drug choices and the study's blood pressure treatment goals. Management was to conform to the randomized treatment assignment. Patients were randomised to initially receive either diuretic (hydrochlorothiazide recommended first-line) or ACE inhibitor (enalapril recommended first-line), but the choice of the specific agent and dose was made by the FP. Fractures were a secondary outcome, and were ascertained from FPs' records. Relative risks (RR) were calculated using log-binomial Generalized Estimating Equations, using both intention-to-treat and per-protocol analyses. In the diuretic group, 251 subjects had a fracture (8.3%), compared to 236 (7.8%) in the ACE group. There was no evidence of a difference in fracture rates between those patients randomised to diuretic and those to ACE with the age- and sex-adjusted RR for fracture in the diuretic compared to ACE groups being 1.06 (95% CI 0.90-1.25) for all fractures and 1.16 (95% CI 0.72-1.86), 1.02 (95% CI 0.66-1.57) and 1.15 (95% CI 0.82-1.62) for hip, vertebral and upper limb fractures respectively, in intention-to-treat analyses. Per protocol analysis examining treatments received and comparing use of thiazides, indapamide or either of these diuretics with use of neither of these agents demonstrated similar results, again with no differences in fracture rates.

There is no evidence to suggest that either thiazide diuretics or ACE inhibitors are superior to each other for reducing fracture risk in elderly hypertensive patients, or that choice of hypertensive therapy should be influenced by concerns about effects on fracture risk. Treatment of hypertension should still be guided by current best practice recommendations taking into account other significant co-morbidities.

Disclosures: T. Winzenberg, None.

Vasomotor Symptoms Are Related to Lower Bone Mineral Density (BMD): A Longitudinal Analysis. C. J. Crandall¹, S. Crawford^{*2}, R. Thurston^{*3}, E. Gold^{*4}, J. Johnston^{*3}, G. Greendale¹. ¹University of California, Los Angeles, CA, USA, ²University of Massachusetts, Worcester, MA, USA, ³University of Pittsburgh, Pittsburgh, PA, USA, ⁴University of California, Davis, CA, USA.

Vasomotor symptoms (hot flashes or night sweats, VMS) are common in perimenopausal and postmenopausal women. We determined within each menopause transition stage whether women with vasomotor symptoms had lower BMD than women without VMS.

We analyzed longitudinal data from 2136 participants of the Study of Women's Health Across the Nation, a cohort study of Caucasian, African American, Japanese, and Chinese women. At baseline, women were aged 42 to 52 years, had intact uterus and ≥1 ovary, and were pre- or early peri-menopausal. Menopausal stage and VMS were assessed by annual questionnaire. We defined frequent VMS as reporting VMS for >5 days in the past 2 weeks. Menopause stages were premenopausal (no change in menstrual regularity), early perimenopausal (decreased regularity in past 3 months), late perimenopausal (no menses in past 3-11 months), or postmenopausal (no menses for ≥12 months). Using data from

baseline to annual follow-up visit 5 in repeated measures mixed models, we determined the association between VMS (any vs. none, frequent vs. infrequent) and BMD (by DXA) within each menopause status category.

After controlling for age, menopausal stage, cumulative time in each menopausal stage, ethnicity, study site, and baseline menopause stage, postmenopausal women with any VMS had lower lumbar (0.007g/cm² lower, P=0.002) and lower total hip (0.004 g/cm² lower, P=0.04) BMD than postmenopausal women without VMS. Compared to early perimenopausal women without VMS, early perimenopausal women with any VMS had lower femoral neck BMD (0.003g/cm² lower, P<0.0001). Premenopausal women with any VMS had lower femoral neck BMD (0.003g/cm² lower, P=0.02), compared to premenopausal women without VMS. Results from analyses of women with frequent vs. infrequent VMS were similar. Lumbar and total hip BMD were not different among premenopausal women with any VMS compared to premenopausal without VMS, or among early perimenopausal women with any VMS compared to early perimenopausal women without VMS. Results from analyses additionally controlled for baseline weight, height, and weight change were similar for any vs. no VMS, and frequent vs. infrequent VMS.

Within each menopause transition stage, women with VMS had lower BMD than women without VMS. Effects varied by anatomical site, being most evident in postmenopausal women at the lumbar spine and total hip, and among premenopausal and early perimenopausal women at the femoral neck. Even at the earliest menopause transition stages, women with VMS are at risk for greater bone loss than women without VMS.

Comparison of Sex Steroid Measurements in Men by Mass Spectrometry vs. Immunoassay: Relationships with Cortical and Trabecular Volumetric BMD. S. Khosla, R. J. Singh*, L. J. Melton, S. Achenbach*, J. Peterson*, B. L. Riggs. Mayo Clinic, Rochester, MN, USA.

While immunoassays (IA) have been used extensively for measurement of serum testosterone (T) and estradiol (E₂) levels, there is concern about their specificity, particularly at low E₂ levels as present in men. Thus, we developed and validated mass spectroscopic (MS) measurements of T and E₂ and used this method to measure T and E₂ levels in a population-based sample of men (n = 313), age 22 to 91 yrs. We compared the MS levels with values previously obtained using IAs and, to test the biological relevance of E₂ measured by the two techniques, related bioavailable (bio, or non-SHBG bound) E₂ to cortical and trabecular volumetric BMD (vBMD) at various skeletal sites using QCT. Panels A and B show the relationships between the bio T and bio E₂ levels determined using either the MS or IA for the T and E₂ measurements. Bio T measurements using the two methods were highly correlated, but the correlation was weaker for bio E₂.

Since, based on IAs, we previously postulated the existence of a "threshold" bio E₂ level for E effects on cortical, but not trabecular, bone we reanalyzed these relationships for values below vs. above the median levels for bio E₂ in men > 60 yrs (8.6 pg/ml and 8.1 pg/ml for the MS and IA, respectively); the Table shows the respective correlation coefficients. As is evident, for both assays, vertebral trabecular vBMD showed similar correlations with bio E₂ in subjects with low or high bio E₂ levels, whereas femur neck cortical vBMD was correlated with bio E₂ at low, but not high bio E₂ levels. In summary, although E₂ measurements with IAs correlate less well with the MS measurements than do the T measurements in men, these data indicate that the fundamental relationships with BMD for E₂ observed with the IAs are also present with the MS measurements. Thus, while MS is considered the "gold standard", the lower cost and greater accessibility of IAs justifies their ongoing use to assess sex steroid levels, at least in men.

		Vertebral vBMD	trabecular vBMD	Femur vBMD	neck vBMD	cortical vBMD
Bio E ₂ below the median	MS-derived bio E ₂	R = 0.25, P = 0.021		R = 0.22, P = 0.044		
	IA-derived bio E ₂	R = 0.27, P = 0.012		R = 0.29, P = 0.009		
Bio E ₂ above the median	MS-derived bio E ₂	R = 0.26, P < 0.001		R = 0.06, P = 0.398		
	IA-derived bio E ₂	R = 0.23, P < 0.001		R = 0.01, P = 0.888

Morphometric Vertebral Fracture Status and WHO Predictors of Fracture Risk. P. Chen^{*1}, J. H. Krege^{*1}, D. Goltzman^{*2}, J. C. Prior^{*3}, A. Tenenhouse^{*2}, J. P. Brown^{*4}, M. Papadimitropoulos^{*1}, N. Kreiger^{*5}, W. P. Olszynski^{*6}, R. G. Josse^{*5}, J. D. Adachi^{*7}. ¹Eli Lilly and Company, Indianapolis, IN, USA, ²McGill Univ, Montreal, PQ, Canada, ³Univ of British Columbia, Vancouver, BC, Canada, ⁴Laval University, Ste-Foy, PQ, Canada, ⁵Univ of Toronto, Toronto, ON, Canada, ⁶Univ of Saskatchewan, Saskatoon, SK, Canada, ⁷McMaster Univ, Hamilton, ON, Canada.

The WHO tool considers BMD, age, prior clinical fragility fracture, current smoking, alcohol use, family history of osteoporosis, and glucocorticoid use to assign a 10-year absolute fracture risk [Kanis et al. Osteopor Int 2002; 13:527-36]. We assessed the information gained from consideration of baseline morphometric vertebral fracture (MVF) status and some of the likely WHO risk factors. Data were from 4744 subjects aged >50yr (3452 women, 1292 men) with baseline and 5-yr radiographs from the Canadian Multicentre Osteoporosis Study (CaMos), a prospective, randomly-selected, population-based cohort. Using the CaMos method [Jackson et al. Osteopor Int 2000; 11:680-87], MVF status was defined as: a) present or absent; b) number; c) maximum severity (normal=0, mild=1, moderate or severe=2); and d) spinal deformity index (SDI, sum of severity scores of T4 to L4). Incident vertebral fractures were identified via baseline and 5-year lateral spine radiographs and non-vertebral fractures by an annual questionnaire with medical confirmation. Logistic regression analyses were performed to assess the prediction of 5-yr risk of any fragility fractures (vertebral or non-vertebral) using individual WHO risk factors and MVF status. In univariate analyses, age, BMD, family history, glucocorticoid use, prior clinical fragility fracture and MVF status were statistically significant predictors. As the results were similar, multivariate analyses were performed in men and women together. This analysis of the statistically significant factors showed MVF status, especially greater number or severity of vertebral deformities or higher SDI, provided the greatest discrimination of risk (Table). MVF was the most important predictor of 5-yr fracture risk in this population-based cohort.

Odds ratios (95% CI) for baseline significant risk factors. Analyses were repeated with MVF status defined as yes/no, maximum severity, number, and SDI.

	Yes/No	Severity	Number	SDI
Age (per year)	1.03 (1.02, 1.04)	1.03 (1.02, 1.04)	1.03 (1.02, 1.04)	1.03 (1.02, 1.04)

Changes in Hip Geometric Structures with Aging--Longitudinal Data Analysis from the Women's Health Initiative Observational Study. T. Bassford^{*1}, T. J. Beck², G. Wu^{*1}, J. A. Cauley³, A. Z. LaCroix^{*4}, C. E. Lewis⁵, Z. Chen¹. ¹University of Arizona, Tucson, AZ, USA, ²Johns Hopkins University, Baltimore, MD, USA, ³University of Pittsburgh, Pittsburgh, PA, USA, ⁴Fred Hutchinson Cancer Research Center, Seattle, WA, USA, ⁵University of Alabama-Birmingham, Birmingham, AL, USA.

Fracture risk increases with age. In addition to bone loss, change in the distribution of bone mass is another significant factor associated with bone fragility. The objective of this study was to investigate the relationship between aging and changes in hip geometry derived from hip structure analysis (HSA). A prospective study in an ethnically diverse subcohort of 5,856 postmenopausal women enrolled in the Observational Study of the Women's Health Initiative was conducted. Eligible subjects were between 50 and 79 years of age and had completed bone scans using Dual-energy X-ray Absorptiometry (DXA). The Beck HSA software was used to estimate bone mineral density (BMD), cross-sectional area (CSA), outer diameter (OD), section modulus index (SM), average cortical thickness (CT) and buckling ratio (BR) for the femoral narrow neck (FNN), intertrochanter (IT) and proximal femoral shaft regions (FS). Analyses showed that BMD, CSA, SM and CT were all significantly lower and the OD and BR measures were significantly higher in the older age group in comparison to the younger age group at baseline ($p < 0.01$). Results from paired t-test indicated significant changes in all HSA measures from baseline to year 6 (Table). Interestingly, both the bone bending strength (SM) and the likelihood of cortical failure under compression (BR) increased significantly over this same time frame, suggesting a complex process with changes in the hip geometry associated with aging. The rates of changes in HSA measures varied by age group and by femoral site. For example, OD expansion in all regions was significantly larger in the 60-69 or 70-79 years age group in comparison to the 50-59 years age group. While significant age differences in the change of other HSA measures were only observed in the FNN region. In conclusion, hip geometric structures change significantly with aging and the rate of changes varies by age and femoral site. The impacts of these changes on hip bone strength are complicated and remained to be investigated.

FNN	Baseline	Year 6	Change	*P-value
BMD (g/cm ³)	0.719 ± 0.130	0.713 ± 0.136	-0.006 ± 0.070	<0.001
CSA (cm ²)	0.204 ± 0.365	0.205 ± 0.391	0.007 ± 0.208	0.037
Outer diameter (cm)	2.997 ± 0.209	3.033 ± 0.228	0.035 ± 0.139	<0.001
SM (cm ³)	0.910 ± 0.190	0.935 ± 0.220	0.025 ± 0.133	<0.001
CT (cm)	0.137 ± 0.026	0.136 ± 0.028	-0.001 ± 0.014	<0.001
BR	12.3 ± 2.84	12.6 ± 3.04	0.344 ± 1.647	<0.001

Relationships Between Lower-Limb Physical Function and Bone Mineral Density in Community-Dwelling Older People. T. Komatsu^{*1}, H. Park¹, D. Nozaki^{*1}, S. Kashiwaguchi^{*2}, T. Kamitani^{*2}, C. Okada^{*3}, Y. Mutoh^{*1}.

¹Department of Physical and Health Education Graduate School of Education, The University of Tokyo, Tokyo, Japan, ²Department of Orthopedic Surgery, Tokyo Koseinenkin Hospital, Tokyo, Japan, ³Department of Rehabilitation, Tokyo Koseinenkin Hospital, Tokyo, Japan.

The Fall Prevention Program was established in 1997 to decrease falls and fall-related fractures in community-dwelling older people. We investigated the relationship between lower-limb physical function, such as gait function and single-leg stance, and osteoporosis (Komatsu, 2006). Four hundred and eighty-four older adults (average age 71.0±3, 52.5±8.9kg, BMI 22.3±3.3) participated in the Fall Prevention Program between December, 1997 and January, 2007. The bone mineral density (BMD) of the femoral neck was measured by dual-energy X-ray absorptiometry using the Hologic co. QDR2000. The subjects were classified into four groups according to BMD by the WHO criteria: normal, osteopenia, osteoporosis and severe osteoporosis. For the linear relationship, that calculated the partial correlation coefficients. Analyses of covariance (ANCOVA) assessed independent associations between the BMD and the lower-limb physical function after controlling the effect of the age. Moreover the logistic regression analysis was used to determine odds ratios and their 95% confidence intervals adjusted by age for the BMI in order to assess association between the osteoporosis and the lower-limb physical function. The probability less than 5% significance was assumed to be significant by using the Statistical Package for Social Science (Ver.15.0). A significant correlation was observed between the BMD and the lower-limb physical function ($r = -0.567$, $p = 0.013$). Subjects who are in the lowest quartile of the maximum gait speed were 1.96 folds more at risk of osteoporosis than the highest quartile (Table1). Therefore, we concluded that gait speed is an important factor in determining fall and fracture risk (Kanis, 2005). In this study of community-dwelling older people who participated in the Fall Prevention Program, the relationship between gait speed and osteoporosis was explained.

Table 1 Age and sex adjusted odds ratio (95% confidence interval) for the estimated risk of osteoporosis in quartiles (Q1-Q4) of rapid gait speed

	Gait speed	Odds ratio (95% CI)
Q1	≤ 1.59	1.96 (1.20-2.96)
Q2	1.5-1.82	1.18 (0.64-2.14)

Disclosures: T. Komatsu, None.

Associations Between Body Composition and Hip Geometry in Postmenopausal Women in the Women's Health Initiative. S. Going^{*1}, T. Beck^{*2}, L. Arendell^{*1}, J. Cauley^{*3}, B. Lewis^{*4}, T. Bassford^{*1}, Z. Wang^{*5}, A. LaCroix^{*6}, T. Lohman¹, Z. Chen^{*1}. ¹Univ of AZ, Tucson, AZ, USA, ²Johns Hopkins Univ, Baltimore, MD, USA, ³Univ of Pittsburgh, Pittsburgh, PA, USA, ⁴Univ of Alabama, Birmingham, AL, USA, ⁵Columbia Univ, New York, NY, USA, ⁶Fred Hutchinson Cancer Research Center, Seattle, WA, USA.

Body weight (wt) and composition are associated with bone mass and bone mineral density (BMD) and likely also affect bone strength through associations with other structural features. While ethnic differences in mass and BMD have been described, differences in structural parameters and their association with soft tissue composition are not well studied. The aim of this study was to assess the associations among measures of body composition and hip geometry (HG) in non-Hispanic White, African American, Hispanic and Native American postmenopausal women (n=5,761) aged 50 to 79 y, in the observational arm of the WHI. Participants' mean age, wt and height (ht) at baseline was 63.7 ± 7.5 y, 72.7 ± 17.1 kg, and 161.4 ± 6.5 cm respectively. Whole-body fat (FM) and lean soft tissue (LSTM) masses and BMD were measured by dual energy x-ray absorptiometry. HG measures, estimated with Hip Structural Analysis (HSA), included femur narrow neck, inter-trochanter, and shaft cross-sectional area (CSA), outer diameter (OD), section modulus (SM), cortical thickness (CT) and buckling ratio (BR). The means and standard deviations of HG measures in the femoral narrow neck region by the quartile of baseline LSTM (table) suggest increased bone strength with higher LSTM.

	Baseline Lean Soft Tissue Mass			
	Quartile 1 mean (st. dev)	Quartile 2 mean (st. dev)	Quartile 3 mean (st. dev)	Quartile 4 mean (st. dev)
Narrow Neck Cross-sectional area (cm ²)	1.81 (0.28)	1.92 (0.30)	2.10 (0.33)	2.30 (0.39)
Narrow Neck Out diameter (cm)	2.93 (0.19)	3.00 (0.20)	3.03 (0.21)	3.08 (0.23)
Narrow Neck Section modulus (cm ³)	0.78 (0.14)	0.86 (0.15)	0.94 (0.18)	1.06 (0.23)
Narrow Neck Cortical thickness (cm)	0.12 (0.02)	0.13 (0.02)	0.14 (0.03)	0.15 (0.03)
Narrow Neck Buckling ratio	13.3 (2.9)	13.1 (3.1)	12.3 (2.7)	11.5 (2.7)

*Quartiles, Q2-Q4 (except for Q2& 3 of OD) were sig. different from Q1 after adjusted for age, ethnicity, HT, WT ($p < 0.05$).

Linear regression was used to assess the association of baseline LSTM and FM with baseline, year 3 and year 6 HG, with baseline wt, ht, physical activity (PA), age and ethnicity as covariates. Body wt and composition, age and ethnicity were significantly correlated with HG LSTM and FM were related positively to BMD, CSA, OD, SM and CT, and negatively to BR at all sites at all years. LSTM explained more variance in HG (adj R²=0.4 to .41) than FM (adj R²=0.01-.03). The associations were not confounded by age, ethnicity, PA or baseline ht and wt. In conclusion, HSA measurements are significantly related to soft tissue composition, especially LSTM in postmenopausal women.

Recognition of Postmenopausal Women at Risk of Fracture Using BMD and Clinical Risk Factors: Results from a Northern Italian Multicenter Study. A. Giusti¹, A. Barone^{*1}, G. Pioli², G. Girasole³, G. Bianchi³, E. Palummeri^{*1}, M. Pedrazzoni⁴. ¹Gerontology, Galliera Hospital, Genova, Italy, ²Gerontology, ASMN, Reggio Emilia, Italy, ³Rheumatology, La Colletta Hospital, Arenzano, Italy, ⁴Internal Medicine, University of Parma, Parma, Italy.

Objectives: To estimate the prevalence of 4 internationally validated independent clinical risk factors (CRFs) (low body mass index (BMI), prior history of fragility fracture, family history of fracture, current smoking) for fragility fractures in a cohort of Italian postmenopausal women and evaluate the impact of the combined assessment of CRFs with bone mineral density (BMD) measurement on risk stratification.

Subjects: Postmenopausal women examined in 3 osteoporosis centers from Northern Italy (Arenzano, Genoa, Parma) over a period of 2 years.

Methods: All women answered a standardized questionnaire to assess smoking habits,

history of prior fragility fractures at any site and fractures of the spine, ribs, distal forearm, humerus and hip in first-degree relatives. Each subject underwent anthropometric assessment to calculate BMI. BMD measurements of lumbar spine (L1-L4) and total hip were obtained by dual-energy x-ray absorptiometry. The relative risk (RR) of fracture versus the general population was modeled as a function of BMD only and BMD plus CRFs, using published data from Kanis et al. (Bone, 2004; Osteoporos Int, 2005).

Results: 10068 post-menopausal women were included in the study (mean age \pm standard deviation, 63.3 \pm 8.7 years; range 45-97). The overall population was divided in subgroups according to the number of prevalent CRFs: the proportion of women with 0, 1, 2 and ≥ 3 prevalent CRFs was 53.1%, 36.1%, 9.8% and 1%, respectively. Overall 4702 women (46.9%) presented at least one risk factor. The most frequent risk factor was a prior history of fragility fracture (21.8%), followed by a parental history of fracture (16.7%), current smoking (14.7%) and BMI < 20 kg/m² (5.6%). As expected, the relative prevalence of some risk factor varied with age. In particular, the proportion of women with a prior fragility fracture increased progressively with age; whereas the percentage of current smokers decreased.

The addition of CRFs to BMD improved risk stratification as compared to BMD alone. The effect was modest in women with only one CRF (RR based on BMD: 1.2; RR based on BMD plus CRFs: 1.7), but more marked in women with 2 CRFs (a 2-fold increase in RR from 1.4 to 2.9) and in women with ≥ 3 prevalent CRFs (a 3-fold increase from 1.7 to 5.4).

Conclusion: The prevalence of risk factors in this cohort of postmenopausal Italian women is similar to that observed in international population-based studies. The addition of CRFs to BMD resulted in a clinically significant increase in the gradient of risk in about 10% of subjects.

Hip Geometric Structure Is Weaker in Anemic Women--Results from the Women's Health Initiative Observational Study. G. Wu^{*1}, T. J. Beck², T. Bassford^{*1}, J. A. Cauley³, A. Z. LaCroix^{*4}, C. E. Lewis⁵, Z. Chen¹. ¹University of Arizona, Tucson, AZ, USA, ²Johns Hopkins University, Baltimore, MD, USA, ³University of Pittsburgh, Pittsburgh, PA, USA, ⁴Fred Hutchinson Cancer Research Center, Seattle, WA, USA, ⁵University of Alabama-Birmingham, Birmingham, AL, USA.

Anemia is a common health problem in the U.S. older population and it is associated with increased hip fracture risk. The influence of anemia to bone geometric structures is unknown. This study used baseline data from participants of the Women's Health Initiative Observational Study to examine the association between hip geometric structure and anemia. Participants were age 50-79 years and postmenopausal women who came from different ethnic backgrounds. Only participants who had hemoglobin measurements (Hb) and hip bone density scans on dual-energy x-ray absorptiometry at one of the three WHI bone mineral density (BMD) centers were included in this study (n = 5,617). The Beck's hip structure analysis (HSA) method was used to measure BMD, cross-sectional area (CSA), outer diameter (OD), section modulus (SM), cortical thickness (CT) and buckling ratio (BR) in the femoral narrow neck (FNN), intertrochanter (IT) and femoral shaft (FS) region. Anemia was defined as Hb concentrations less than 12 gm/dl based on the definition by the World Health Organization (WHO). Overall, 6.8% of the participants were anemic and the rate of anemia varied by age and ethnicity. The results from multiple regression analyses showed that, after adjustment for age, height, weight, ethnicity, hormone use, physical activity and total body percent lean mass, women with anemia tend to have lower BMD, CSA, SM, CT, and higher BR in all the three femoral regions compared to women with a normal Hb level. However, statistically significant differences by anemic status were only observed for the SM and BR measure in the IT region (Table 1). Compared to the FNN and FS region, the differences in HSA measures were more obvious at the FN. In conclusion, hip geometric structure differs by anemic status and the differences seem bigger in the IT region than in the FNN and FS region.

Table 1. Baseline hip geometric measurement by anemia status

	Normal (N=5237)	Anemia (N=380)	p
	Mean \pm SE	Mean \pm SE	
Intertrochanter			
BMD (g/cm ³)	0.714 \pm 0.002	0.703 \pm 0.006	0.104
Cross-sectional area (cm ²)	3.451 \pm 0.008	3.395 \pm 0.030	0.072
Outer diameter (cm)	5.088 \pm 0.004	5.079 \pm 0.016	0.582
Section modulus (cm ³)	2.856 \pm 0.007	2.790 \pm 0.027	0.020
Cortical thickness (cm)	0.289 \pm 0.001	0.283 \pm 0.003	0.072
Buckling ratio	10.394 \pm 0.032	10.646 \pm 0.122	0.047

How Should Hypercalciuria Be Defined? N. M. Maalouf, M. A. Cameron*, K. Sakhaee, Charles and Jane Pak Center for Mineral Metabolism, University of Texas Southwestern Medical Center, Dallas, TX, USA.

Background: Although hypercalciuria is a well-established risk factor for nephrolithiasis and is frequently considered in the differential of secondary osteoporosis, its definition has been debated and the "normal range" for urinary calcium excretion is not clearly defined. The most commonly used definitions for hypercalciuria are based on

absolute calcium excretion and weight-based calcium excretion. We examined whether the prevalence of hypercalciuria differs according to the definition used in a cohort of healthy individuals.

Methods: 24-hour urinary calcium excretion was measured in 149 healthy individuals with no history of kidney stones, while on an unrestricted diet. Absolute hypercalciuria (AHC) was defined as urinary calcium excretion exceeding 250 mg or 300 mg of calcium per day for women and men respectively. Weight-based hypercalciuria (WBHC) was defined as calcium excretion greater than 4 mg/kg of body weight per day. The prevalence of hypercalciuria was evaluated using both definitions, and was examined within the following body mass index (BMI) categories: normal, BMI < 24.9 Kg/m², overweight, BMI 25-29.9 Kg/m², and obese, BMI > 30 Kg/m².

Results: The cohort was composed of 46 individuals with normal BMI, while 52 were overweight and 51 were obese. For the entire cohort, mean BMI was 28.3 \pm 6.6 Kg/m², mean 24-hr urine calcium was 163.0 \pm 94 mg/day, or 2.09 \pm 1.10 mg/Kg/day. The prevalence of AHC was 15.4% while the prevalence of WBHC was 6.7% (p=0.016). Weight based urine calcium excretion did not vary significantly between the 3 groups of BMI (2.10 \pm 1.12 mg/Kg/day for normal BMI, 2.06 \pm 1.10 mg/Kg/day for overweight, and 2.10 \pm 1.11 mg/Kg/day for obese). On the other hand, absolute urine calcium excretion increased significantly with increasing BMI (125.5 \pm 66.0 mg/day for normal BMI, 157.7 \pm 73.3 mg/day for overweight, and 202.0 \pm 117.9 mg/day for obese). Accordingly, the prevalence of hypercalciuria varied significantly between BMI categories using the AHC but not the WBHC definition.

Urinary Calcium Excretion and Prevalence of Hypercalciuria According to BMI

	Urine Calcium mg/d	mg/kg	Prevalence of Hypercalciuria	
			AHC (%)	BWCH (%)
BMI<25	125.5 \pm 66.0†	2.10 \pm 1.12	2.2	4.3
BMI 25-29.9	157.7 \pm 73.3*	2.06 \pm 1.10	11.5*	5.7
BMI>30	202.0 \pm 117.9*,†	2.10 \pm 1.11	31.4*,†,‡	9.8

Conclusions: The prevalence of hypercalciuria depends on the definition used, particularly in obese patients. These results should be considered in the evaluation of calcium excretion in patients with nephrolithiasis and osteoporosis. Further studies are needed to establish the optimal definition of hypercalciuria.

Oral Treatment with the Calcium Receptor Antagonist SB-423557 Causes PTH Release in Multiple Species and Positive Bone Forming Effects in the Rat. S. Kumar¹, X. Liang¹, J. A. Vasko^{*1}, G. B. Stroup², S. J. Hoffman¹, V. R. Vaden^{*2}, H. Haley^{*2}, J. Fox³, E. F. Nemeth³, A. M. Lago^{*2}, J. F. Callahan^{*2}, P. Bhatnagar^{*1}, W. F. Huffman^{*1}, M. Gowen². ¹GlaxoSmithKline, Collegeville, PA, USA, ²GlaxoSmithKline, King of Prussia, PA, USA, ³NPS, Salt Lake City, UT, USA.

Antagonists of the parathyroid calcium receptor (calcilytics) stimulate the secretion of PTH. Previously, we demonstrated the ability of an orally active calcilytic compound to cause sustained increases in circulating levels of endogenous PTH and to stimulate bone formation and resorption (without a net increase in bone formation) in the ovariectomized (OVX) rat. In the present study, a prodrug approach has been used to preserve oral bioavailability and yield a calcilytic with a shorter half-life in vivo. SB-423557 is the ethyl ester prodrug of SB-423562 that, when administered orally to rats, dogs or monkeys, caused a dose-dependent, transient increase in circulating levels of endogenous PTH. In order to examine the bone forming effect of SB-423557, six-month-old female rats received OVX or sham surgery and were untreated for 6 weeks to allow osteopenia to develop and then treated orally daily with either vehicle, SB-423557 (50 mg/kg), or with rat PTH(1-34) (5 µg/kg SC) for 12 weeks. Plasma levels of PTH peaked at 10-60 min following oral administration of 50 mg/kg SB-423557 (3-fold, C_{max} of 40-60 pM) and returned to baseline by 2-3 hours. SC administration of rat PTH(1-34) resulted in a systemic C_{max} of 127-240 pM at 10 minutes post-injection.

SB-423557 significantly and completely prevented additional OVX-induced loss of BMD in the lumbar spine and partially prevented trabecular BMD loss in the proximal tibia by 39% (ns) compared to OVX controls. Histomorphometric analysis indicated greater trabecular bone area (36%, ns) in the spine and increased cortical area (72%) and endocortical bone formation rate (220%) with no effect on the eroded perimeter of the distal tibia in the SB-423557 treated rats compared to vehicle-treated OVX animals. Serum osteocalcin increased (ns) with SB-423557 treatment with no effect on urinary deoxypyridinoline levels. In addition, treatment with SB-423557 resulted in greater ultimate strength (ns), toughness, and elastic modulus of a lumbar vertebral body and at the femoral diaphysis compared to OVX controls. Treatment with PTH(1-34) also completely prevented the OVX-induced loss in bone mass, BMD, and strength.

These data provide a proof of principle for stimulation of bone formation following daily brief antagonism of the calcium receptor in the OVX rat and support the potential use of these agents to treat disorders of bone metabolism such as osteoporosis.

Prior Alendronate Treatment Does Not Inhibit the Early Stimulation of Osteoblast Activity in Response to Teriparatide. R. Lindsay¹, F. Cosman¹, H. Zhou², J. W. Nieves¹, M. Boström³, N. Barbuto^{*1}, D. W. Dempster². ¹Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, USA, ²Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, ³Department of Orthopaedics, Hospital for Special Surgery, New York, NY, USA.

Several studies suggest that the bone density response to PTH treatment is blunted in subjects previously treated with alendronate. The present study evaluates the effects of teriparatide (TPTD) on bone formation variables from iliac crest biopsies in subjects who were either treatment naïve or pretreated with alendronate (ALN). We recruited 25 postmenopausal women with osteoporosis (12 treatment naïve; 13 pretreated with alendronate for at least 1 yr (mean age 63)). The two groups were randomized to control or TPTD (20mcg/day). All underwent iliac crest bone biopsy 7.5 weeks after randomization. We used quadruple tetracycline labeling as previously described (JBMR 2006) to provide longitudinal data on bone formation in each subject. Biopsies were read with the observer blinded to treatment group. Groups were well matched for demographics and indices of cancellous and cortical bone structure. In ALN- treated patients, mineral apposition rate (MAR), mineralized perimeter (Md.Pm) and bone formation rate (BFR) were lower at baseline than in naïve patients.

	MAR		BFR		MdPm	
	Pre	Post	Pre	Post	Pre	Post
Cancellous						
Naïve	0.73 0.06	± 0.88 0.06	± 0.016 0.004	± 0.054 0.015	± 2.16 0.41	± 5.78 ± 1.32
ALN	0.38 0.14	± 0.84 0.05	± 0.005 0.003	± 0.035 0.013	± 0.78 0.39	± 4.25 ± 1.63
Endocortical						
Naïve	0.69 0.05	± 0.86 0.07	± 0.049 0.014	± 0.141 0.034	± 6.69 1.69	± 15.73 ± 3.50
ALN	0.32 0.11	± 0.58 0.13	± 0.006 0.003	± 0.049 0.015	± 1.21 0.39	± 6.36 ± 1.70

After TPTD, the absolute increment in MAR was dramatic in the ALN group, increasing approximately 80-120% above baseline in cancellous bone and on the endocortical surface (Table). MAR also increased significantly with TPTD in the naïve group (21-25%), but the increments were not as marked as in ALN subjects. The absolute increases in BFR and Md.Pm were similar in ALN and naïve groups in cancellous bone but were larger in the naïve group on the endocortical surface due to the higher baseline Md.Pm. However, the percentage increments in all bone formation variables were greater on both envelopes in the ALN compared to the naïve group. We conclude that the increments in the work rate of osteoblast teams (MAR) in response to early treatment with TPTD are greater following ALN pretreatment than in naïve subjects. However, the extent of bone forming surface is overall larger in naïve subjects, perhaps providing an explanation for the possible blunting of the BMD effect in ALN treated women given TPTD.

β2 Adrenergic Receptor Deficiency Enhances Bone Mass in by Antagonizing Against Aging-induced Bone Loss and Blunts Anabolic Effects of PTH on Osteoblasts. R. Hanyu^{*1}, Y. Saita^{*1}, J. Nagata^{*1}, Y. Izu^{*1}, T. Hayata^{*1}, H. Hemmi^{*2}, S. Takeda^{*3}, Y. Ezura^{*1}, K. Nakashima^{*1}, H. Kurosawa^{*4}, M. Noda^{*1}. ¹Department of Molecular Pharmacology, 21st Century COE Program, MRI, Tokyo Medical and Dental University, Chiyoda-ku, Tokyo, Japan, ²MTT Program, MRI, Tokyo Medical and Dental University, Chiyoda-ku, Tokyo, Japan, ³Department of Orthopedics, 21st Century COE Program, Tokyo Medical and Dental University, Chiyoda-ku, Tokyo, Japan, ⁴Department of Orthopedics, Juntendo University School of Medicine, Bunkyo-ku Tokyo, Japan.

Soaring of the aged population in modern world increases the fraction of aged population with diseases and thus in bone field, leads to increase in osteoporosis incidence. Loss of bone mass is accelerated with age regardless of gender. Osteoporotic patients with their bone mass levels at their nadir require treatment to increase bone mass through the activation of bone formation. PTH has been proven to be efficacious in increasing bone mass. However, its efficacy in the highly aged population such as those over 80 years of age in human have not yet been fully elucidated. In mice, aged models of over one year old, indicate lower bone mass than younger adult animals regardless of the gender. Recently, sympathetic nervous system was reported to regulate bone mass in mice. However, these reports always indicate the effects of adrenergic system on young adult mice. Therefore, the purpose of this paper is examine the effects of β2 adrenergic system and PTH on the bone mass in aged mice. Aged (54 weeks old) female mice null for β2 adrenergic receptor (Adrb2^{-/-}) and wild type (WT) were used. Mice were treated with vehicle or PTH (80µg/kg/day sc) for 4 weeks (5 days/week). The base line bone mass levels in these aged mice were significantly reduced compared to young adult mice. Aged Adrb2^{-/-} mice exhibited higher total body BMD, trabecular bone volume fraction(BV/TV), cortical bone volume compared with aged WT mice. In WT, PTH treatment significantly increased the levels of total body BMD, 3D- BV/TV, mineral apposition rate (MAR) and bone formation rate (BFR). In contrast, in aged Adrb2^{-/-} mice, PTH failed to

increase the levels of BMD and BV/TV. Analyses on aged Adrb2^{-/-} mice also revealed that PTH failed to enhance BFR and MAR. Importantly, Adrb2 deficiency increased cortical bone volume compared to WT while this parameter was no longer enhanced by PTH in the mutant mice. Regarding bone resorption side, Oc.S/BS, N.Oc/BS were similar regardless of the genotype or PTH treatment. In conclusion, we found that in one year old aged female mice, β2 adrenergic receptor signal operates to reduce bone mass, while β2 adrenergic signaling is required for the anabolic actions of PTH on bone formation.

PTH Improves Bone Strength in an Osteoporosis Model Through Increasing Mineralized Matrix Yet the Elastic Modulus of the Trabecular Surface Is More Heterogeneous than Observed with Anti-Resorptive Agents. Z. Cheng¹, W. Yao¹, K. J. Koester^{*2}, M. Balooch^{*2}, R. O. Ritchie^{*2}, N. E. Lane¹. ¹Center for Healthy Aging, UC Davis Medical Center, Sacramento, CA, USA, ²Materials Science and Engineering, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, USA.

Current approved medical treatments for osteoporosis reduce fracture risk to a greater degree than predicted from changes in bone mineral density (BMD). Based on these observations, we hypothesize that these bone active agents improve bone strength by altering material properties of the bone.

Methods. 18-month-old female Fischer rats were ovariectomized (OVX) or sham-operated and were untreated for 60 days to induce osteopenia before they were treated with single doses of risenedronate (iv., 500µg/kg), zoledronic acid (iv., 100µg/kg), continuous raloxifene (2mg/kg, po., 3x/wk), hPTH (1-34) (25µg/kg, sc., 3x/wk) or vehicle. Groups of animals were sacrificed after d60 and d180 of treatment. Measurements of bone quality from the proximal tibial metaphyses (PTM) included µCT, the degree of bone mineralization (DBM), mineral heterogeneity index (MHI); localized elastic modulus (EM) mapping of select trabecular surface by scanning probe microscopy, and bone compression testing from a lumbar vertebral body (LVB).

Results. The bone volume (BV/TV), DBM, EM and compressive bone strength were significantly lowered at d60 post-OVX (pretreatment, day 0 study) than at baseline. At d60 all treatments restored bone material measurements (BV/TV, DBM, EM and compressive bone strength) and no differences between OVX + anti-resorptives and OVX + PTH were observed. However, at d180 OVX + PTH further increased BV/TV (+30% from d 60), DBM, MHI and bone strength to baseline levels. EM mapping of PTM from the OVX + vehicle and OVX + PTH at d180 had significant heterogeneity with higher percentage of high and low EM areas than sham. Moreover, at d180 there was a higher percentage of high EM in OVX + PTH compared to other OVX + anti-resorptives and whole bone strength was higher. Therefore, these data suggest that localized changes in the material properties of bone after PTH, differs from anti-resorptive agents, and while the EM of the matrix is more heterogeneous, the overall result in greater bone strength. Additional studies are needed to correlate these preclinical findings with the clinical efficacy of these agents in osteoporosis.

The Use of RAP-011, a Novel Bone Anabolic Agent, in Combination with Parathyroid Hormone or Zoledronic Acid Using a Mouse Model of Established Bone Loss. M. Cornwall-Brady^{*}, M. Mangini^{*}, D. Barbosa^{*}, L. Mazzola^{*}, T. Marvell^{*}, J. Milling^{*}, B. Haigis^{*}, R. Kumar^{*}, K. Underwood^{*}, R. S. Pearsall. Acceleron Pharma, Cambridge, MA, USA.

RAP-011, a novel soluble receptor fusion protein based on the activin receptor type IIA was previously reported to increase bone density in vivo (Pearsall et al, J Bone Min. Res. 21(S1) 2006). Here, we investigate the efficacy of RAP-011 compared with parathyroid hormone (PTH) or zoledronic acid (ZOL).

Eight week old C57BL/6 mice were ovariectomized (OVX) or sham operated (SHAM). 8 weeks after surgery all mice were analyzed by dual-energy x-ray absorptiometry (DEXA) prior to treatment. Mice were administered either RAP-011 (IP, 10 mg/kg, biw), PTH (SC, 80 µg/kg/day) or a single dose of ZOL (IP, 20 µg/kg).

Study 1 included 48 OVX (16 each treated with PBS, RAP-011, PTH) and 8 SHAM mice. After six weeks of treatment, half of each group received a single IP dose of the ZOL. The bone mineral density (BMD) of each animal was measured 0, 6, 10, 14 and 18 weeks after treatment initiation. This study demonstrated an increase in total body BMD of 3.6%, 4.2%, 7.6%, and 10.0% in SHAM VEH, OVX VEH, OVX-RAP-011 and OVX PTH respectively after 6 weeks of treatment. Four weeks after ZOL dosing DEXA results showed an additional increase (relative to week 6 results) of 4.7%, 4.6%, and 1.3% in OVX groups treated with PBS, RAP, and PTH respectively. In groups that did not receive ZOL

treatment the BMD changes were 2.4%, 1.9%, 2.0% and -3.6% for SHAM VEH, OVX VEH, OVX RAP-011 and OVX PTH mice respectively.

Study 2 included 32 OVX (8 each treated with PBS, RAP, PTH, and a combination of both RAP-011 and PTH), 24 Sham (8 each PBS, RAP-011 and PTH). DEXA was performed at weeks 0 and 6. In this study we show an increase in total body BMD of 2.8%, 4.6%, 9.8% and 13.3% for OVX groups treated with PBS, RAP-011, PTH and the combination of both RAP-011 and PTH, respectively. SHAM groups had total body BMD changes of -0.1%, 8.0% and 6.9% for PBS, RAP-011 and PTH respectively.

Consistent with our previously reported results, these data show that total body BMD increased significantly after 6 weeks of treatment with either RAP-011 or PTH. Subsequent treatment with ZOL resulted in equivalent increases in BMD in groups that were previously treated with RAP-011 or PBS. These results indicate that RAP-011 does not alter the bone microenvironment in such a way as to preclude the use of antiresorptive therapy. DEXA results also indicate that the total body BMD increase as a result of a combination treatment with both RAP-011 and PTH was larger than either the RAP-011 or PTH treatment alone in both SHAM and OVX mice. The results of these two studies provide evidence that RAP-011 can be used in combination with other currently approved therapies.

Endogenously Produced n-3 Fatty Acids (Fat-1 transgene) Protects Bone after Ovariectomy in Mice. J. Banu¹, A. Bhattacharya², G. Halade¹, M. Rahman¹, G. Fernandes¹. ¹Med/Clinical Immunology & Rheumatology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, ²Department of Cellular and Structural Biology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Aging is associated with bone loss leading to escalating the risk of fractures. Recently, there is growing interest in identifying nutritional supplements that can be more effective in preventing age-related as well as postmenopausal bone loss with minimum side-effects. There is increasing evidence on the beneficial effects of n-3 fatty acids in the prevention of postmenopausal bone loss. In 2004, a novel transgenic mouse model (fat-1) that could convert n-6 fatty acids to n-3 fatty acids was produced. We studied bone loss after ovariectomy in this mouse model and their wild type counterparts (C57BL/6).

Fat-1 transgenic and wild type C57BL/6 mice were used in this study. Female mice were 8 weeks old when they were either ovariectomized or sham operated. They were maintained in the laboratory for 6 months and then sacrificed. Serum alkaline phosphatase and osteocalcin were measured. The femur, tibia and lumbar were analyzed using peripheral quantitative computed tomography (PQCT) densitometry.

Serum alkaline phosphatase (ALP) was decreased significantly in the wild type mice after ovariectomy. The fat-1 mice had lower ALP when compared to the wild type mice, but after ovariectomy there was no further decrease in the enzyme levels. Osteocalcin levels were not significantly altered after ovariectomy in the wild type mice and fat-1 mice.

In wild type mice, there was significant loss of bone after ovariectomy in the neck of the femur and proximal tibial metaphysis. However, in the fat-1 transgenic mice there was significantly less bone loss after ovariectomy in the neck of the femur and proximal tibial metaphysis. In the femoral diaphysis, fat-1 transgenic mice had significantly higher bone mass when compared to that of the wild type mice. The tibia fibular junction did not show any differences between the wild type and transgenic mice. Similarly, ovariectomy did not affect the pure cortical bone in both wild type and transgenic mice.

We conclude that endogenously produced n-3 fatty acids can attenuate postmenopausal bone loss significantly in the femur followed by the tibia and this bone loss is mainly due to decreased endocortical resorption.

Vitamin K Supplementation in Postmenopausal Women with Osteopenia: The ECKO Trial. A. M. Cheung¹, L. E. Tile¹, Y. Lee², G. Tomlinson³, G. Hawker⁴, J. Scher¹, H. Hu¹, R. Vieth⁵, L. Thompson⁶, S. A. Jamal², R. Josse². ¹Osteoporosis, University Health Network, Toronto, ON, Canada, ²Osteoporosis, St. Michael's Hospital, Toronto, ON, Canada, ³Medicine, University Health Network, Toronto, ON, Canada, ⁴Osteoporosis, Women's College Hospital, Toronto, ON, Canada, ⁵Pathobiology and Laboratory Medicine, Mt. Sinai Hospital, Toronto, ON, Canada, ⁶Nutrition, University of Toronto, Toronto, ON, Canada.

BACKGROUND: Vitamin K has been widely promoted as a supplement for decreasing bone loss in postmenopausal women, but the long-term benefits and potential harm are unknown.

METHODS: We performed a 2-year single-centre placebo-controlled double-blind randomized trial involving 440 postmenopausal women with osteopenia: 217 received 5mg of vitamin K1 daily and 223 received placebo daily. Outcome measures included bone mineral density (BMD), bone turnover markers, fragility and non-fragility fractures, long-term adverse effects and health-related quality of life. The study was extended for earlier participants for a maximum duration of up to 4 years because of interest in long-term safety and fractures.

RESULTS: Bone mineral densities decreased by -1.28% and -1.22% (p=0.84) at the lumbar spine and -0.69% and -0.88% (p=0.51) at the total hip in the vitamin K and placebo groups over two years, respectively. There were no significant differences in changes in

BMDs at any site between the vitamin K and the placebo groups over the 2 to 4-year duration of the trial. Vitamin K supplementation did increase serum vitamin K levels (22.6% versus 2.0%, p<0.0001) and carboxylation of osteocalcin (-21.4% versus -2.0%, p<0.0001) and lowered total osteocalcin levels (bone formation marker) (-13.2% versus -0.1%, p<0.0001); however, it did not change C-telopeptide (6.2% versus -1.2%, p=0.10). There were fewer cancers (3 versus 12, p=0.02) and fewer clinical fractures in the vitamin K group (9 versus 20, p=0.04). Health-related quality of life was not significantly different between the two groups.

CONCLUSIONS: Daily vitamin K supplementation for 2 to 4 years did not protect against age-related decline in BMD in postmenopausal women with osteopenia. There were lower incidences of fractures and cancer

with vitamin K supplementation. Further studies are required to confirm these findings. (ClinicalTrials.gov number, NCT00150969)

Bisphosphonate Treatment During Long-Term Disuse Blunts the Recovery Response of Bone to Restored Weight-Bearing. J. C. Fritton¹, C. Y. Li¹, X. Zhang¹, D. Laudier¹, R. Mann², M. B. Schaffler¹. ¹Leni & Peter W. May Department of Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA, ²Bronx VA Medical Center, New York, NY, USA.

Bone retention with bisphosphonates (BIS) may set the stage for improved recovery from disuse osteoporosis. We previously found that risedronate (RIS) treatment attenuates approximately half of cortical bone loss associated with long-term immobilization. The purpose of this study was to test whether bone that remains after RIS-treatment during long-term immobilization better recovers its architecture after restoration of mechanical usage. Right forelimbs of 5-7 year-old retired breeder female Beagles (N=27) were immobilized (IM) with splints as in our previous studies. Dogs were treated daily with either RIS (0.5 mg/kg, p.o., provided by P&G Pharmaceuticals) or sterile-water vehicle for 6 months, after which tissues were obtained. In remaining animals, RIS treatment was stopped and splints removed. Remobilized (RM) dogs were allowed 12 months of unrestricted weight-bearing. Age-matched dogs served as controls. Cortical bone structure was assessed by μ CT scanning of third metacarpals at 20- μ m resolution. Calibrations determined bone mineral density (BMD) values; structural analyses used a global BMD threshold of 600 mg/cc. Cross-sectional properties obtained at the mid-shaft included cortical bone, marrow cavity and total areas, and polar moments of inertia. Effects were tested by ANOVA with post-hoc PLSD comparisons (p<0.05, data shown as Means \pm SD). RIS treatment prevented approximately 60% of the bone loss due to IM. RM of vehicle-treated dogs restored significant amounts of cortical bone lost during disuse. Surprisingly, despite discontinuation of RIS, a similar remobilization response was absent in the animals drug-treated during IM.

BIS have long half-lives (on the order of years) and thus have effects after active dosing has stopped. This may underlie the impaired response of RIS-treated bone to restored loading. The decision to use BIS in prevention of bone loss during long-term immobilization (e.g., bed rest or space flight) must include consideration of side effects. Our results indicate that these side effects include an impairment of the ability of cortical bone to respond appropriately to the reintroduction of mechanical loading.

Combination Treatment with a Selective Androgen Receptor Modulator (SARM) and a Bisphosphonate has Additive Effects in Osteopenic Female Rats. E. G. Vajda, A. Hogue*, K. N. Griffiths*, W. Y. Chang*, K. Burnett*, K. Marschke*, D. E. Mais*, B. Pedram*, Y. Shen*, A. van Oeveren*, F. J. López*. Ligand Pharmaceuticals, San Diego, CA, USA.

Recent clinical trials with bisphosphonates and PTH have not supported the hypothesis that combination treatments with antiresorptive and anabolic agents would lead to synergistic activity. We hypothesized that combination treatment with a SARM, LGD3303, and a bisphosphonate would be beneficial. In vitro, LGD3303 is a potent androgen that shows little or no cross-reactivity with related nuclear receptors. In male rats, LGD3303 has tissue selective properties, increasing the levator ani muscle weights above eugonadal levels at high doses, but having greatly reduced activity on the prostate, never increasing the ventral prostate weight above eugonadal levels. To assess bone effects, three month-old female SD rats were ovariectomized (OVX) and allowed to develop osteopenia for 8 weeks. Rats were orally dosed with vehicle, LGD3303, alendronate sodium, or the combination from week 8 to 20 post-OVX (all dosed at 3 mg/kg/day). LGD3303 and combination treatment significantly increased gastrocnemius muscle weight, unlike alendronate. All three treatments increased whole femur BMD and BMC measured by DEXA. BMC was significantly higher with LGD3303 and combination treatment (19.0% and 19.9% increase, respectively) compared to alendronate (8.3% increase). At the lumbar spine, LGD3303 and alendronate increased BMD (10.8% and 7.6% increase, respectively), but combination treatment restored it to near sham levels (18.0% increase). Similarly, elevations in bone strength at the femur and lumbar spine were also observed with all treatments; however the combination had the largest increase, particularly at the lumbar spine. Histomorphometry confirmed that LGD3303 and combination treatment significantly increased mid-femur periosteal bone formation (75.9% and 74.2%, respectively), whereas alendronate (6.3%) was nearly inactive. In contrast, all three treatments suppressed cancellous bone remodeling at the lumbar spine and increased trabecular bone volume. Collectively, these results indicate that LGD3303 and alendronate have positive effects on cancellous bone, but the combination treatment is the most effective at suppressing bone turnover and improving spinal strength and bone density. Muscle and cortical bone were unaffected by alendronate, whereas LGD3303 has anabolic activity which is unaltered by combination treatment with alendronate. At every measured site, combination treatment was as effective as either single agent and in some cases showed significant added benefit.

Decreased Bone Turnover and Porosity Are Associated with Improved Bone Strength in Ovariectomized (OVX) Cynomolgus Monkeys Treated with Denosumab, a Fully Human RANKL Antibody. M. S. Ominsky¹, J. Schroeder^{*1}, J. Jolette^{*2}, S. Y. Smith², D. J. Farrell^{*2}, J. E. Atkinson¹, P. J. Kostenuik¹. ¹Amgen Inc., Thousand Oaks, CA, USA, ²Charles River Laboratories Preclinical Services Montreal, Inc., Montreal, PQ, Canada.

Denosumab (DMab), a fully human monoclonal antibody against RANKL, was previously shown to decrease biochemical markers of bone turnover and increase bone mineral density in adult OVX cynomolgus monkeys. We now report from that study the effects of DMab on bone turnover at the histologic level, and their relationships with bone strength.

One month after surgery, OVX cynos (9-16 years old) were treated with either vehicle (OVX-Veh) or DMab (25 or 50 mg/kg, SC, once/month) for 16 months (n=14-20/group). Sham controls were treated with vehicle (n=17). Double fluorochrome labels were injected prior to iliac and rib biopsies (at month 6 and 12), and prior to sacrifice. Histomorphometry was performed on these biopsies, the tibial diaphysis, and cancellous bone in L2 vertebra and the proximal femur.

Cancellous bone turnover was increased in OVX-Veh animals, based on significantly greater mineralizing surface (MS/BS), bone formation rate (BFR), and activation frequency at the lumbar spine, iliac crest, and femur neck (P<0.05 vs Sham). Both doses of DMab fully prevented these OVX-related changes while reducing values significantly below those of sham controls (P<0.05). Osteoclast and osteoblast surfaces were 78-100% lower in the lumbar spine, iliac crest, and femur neck of DMab groups, while eroded surface was decreased by 45-93% (P<0.05 vs OVX-Veh).

Cortical bone turnover was also increased in OVX-Veh cynos, as shown by significantly greater cortical porosity, labeled perimeter, and BFR at the endocortical and haversian surfaces of the tibial diaphysis and rib (P<0.05 vs Sham). Both doses of DMab fully prevented these OVX-related changes, while reducing labeled perimeter and BFR significantly below sham control levels (P<0.05).

Prolonged DMab-related turnover suppression was associated with significant increases in strength parameters at the lumbar vertebrae, femur neck, and femur diaphysis (P<0.05 vs OVX-Veh). Regression analysis of all groups combined demonstrated significant inverse relationships between the strength of L5-L6 cores (yield load) and mineralizing surface (r²=0.44) or eroded surface in L2 (r²=0.37; P<0.001). Cortical porosity in the tibia was negatively correlated with peak load at the femur diaphysis (r²=0.21; P<0.001).

In summary, denosumab treatment of OVX cynos was associated with significant decreases in histomorphometric indices of bone turnover. These changes were accompanied by significant improvements in bone strength at cortical and cancellous sites.

Bone Effects of Cathepsin K Inhibitor in Ovariectomized Rhesus Monkeys. P. Masarachia, S. Pun*, D. Kimmel. Molecular Endocrinology and Bone Biology, Merck Research Laboratories, West Point, PA, USA.

Cathepsin K (CatK), a cysteine protease highly expressed in osteoclasts, degrades type I collagen. CatK inhibitors, by slowing bone matrix degradation that follows the demineralization phase of bone resorption, may be useful as anti-resorptive agents for treating osteoporosis. The objective of this study was to evaluate bone mineral density (BMD) and bone turnover in newly-ovariectomized (OVX) non-human primates treated with CatK inhibitor MK-0822. Rhesus monkeys (age 12-19 yrs) were assigned to four groups (N=10-11): (1) vehicle-treated intact; and OVX treated with (2) vehicle, (3) 6mg/kg/d or (4) 30 mg/kg/d MK-0822. Daily oral dosing started on ~day 11 following OVX. BMD of spine and hip were measured (DXA, Hologic DiscoveryA) at baseline and 11 months. Calcein (12 mg/kg, SC) was given on the 18th and third days before obtaining right transilial (TIBx) and ninth rib (RBx) biopsies. Specimens were embedded undecalcified and sectioned at 6µm or 100µm. Both trabecular (TB) and endocortical surfaces (EC) were used for standard histomorphometric endpoints. BMD declined significantly at the spine and femoral neck after OVX. This BMD decline was prevented by 30mg/kg/d MK-0822. In both TIBx and RBx, double-labeled surface (DLS/BS) was elevated by OVX and reduced vs. OVX by ~80-90% (P<0.01) by both 6 and 30 mg/kg/d MK-0822. In RBx, Haversian turnover tended to be elevated by OVX and reduced by 30 mg/kg/d MK-0822. In TIBx, mineralizing surface (MS/BS, %) and mineral apposition rate (MAR) decreased vs. OVX for both doses in both TB and EC compartments (P<0.01). All treatment effects were significant except MAR in the TB compartment. Bone formation rate (BFR) tended to increase with OVX, and was decreased relative to OVX by MK-0822; differences were significant for both doses in the TB compartment but only for 6 mg/kg in EC compartment. Osteoid thickness (Os.Th, µm) and surface (OS/BS, %) were increased ≥50% (P<0.05) by OVX and decreased vs. OVX for both MK-0822 doses (P<0.05) in both compartments. The distribution of osteoid thicknesses was shifted to thicker seams by OVX, but was similar to intact animals with MK-0822. In RBx, both osteoclast covered (OcS/BS) and non-osteoclast covered eroded surface (ES/BS) were significantly lower with MK-0822 treatment. In animals with higher amounts of osteoid surface, osteoclasts were seen adjacent to osteoid surfaces with the same low frequency in all groups. MK-0822 reverses the OVX-induced rise in bone turnover in the TB and EC bone of the rib and ilium at 6 and 30mg/kg/d, but reduces rib cortical bone turnover only at 30mg/kg/d, the only dose that preserved spine and hip BMD. We conclude that both doses of MK-0822 reduced TB turnover in biopsy sites and the higher dose tested prevented OVX-induced loss of BMD at osteoporosis fracture sites.

A Comparison of Three High Dose Oral Vitamin D₃ Supplementation Regimens. C. J. Bacon*, G. D. Gamble*, A. M. Horne*, I. R. Reid. Faculty of Medical and Health Sciences, University of Auckland, Auckland, New Zealand.

Vitamin D insufficiency is recognized as a major clinical problem in the elderly. Most previous supplementation studies have provided daily calciferol doses of 400-800 IU/day. It may take considerable time on these doses for many elderly people to attain recommended levels of 25-hydroxyvitamin D [25(OH)D]. The purpose of this study was to compare the magnitude and time-course of 25(OH)D response to three high dose vitamin D₃ regimens. Sixty-three elderly people, aged 81.6±6.7 years (mean±sd), were recruited on discharge from general medical wards. They were randomly assigned to supplementation with either a single dose of 500 000 IU (Stat), 500 000 IU stat plus 50 000 IU monthly (Stat+Monthly), or 50 000 IU monthly alone (Monthly), in a double-blind trial. The figure shows 25(OH)D levels throughout the study. Baseline 25(OH)D was 58±32 nmol/L and was not different between groups. Mixed-model analysis of variance showed significant Month, Group, and Month x Group interaction effects (p<0.001). At one month, 25(OH)D in the Stat and Stat+Monthly groups rose to 120±33 nmol/L compared to 67±24 nmol/L in the Monthly group. The maximum 25(OH)D level reached at one month was 220 nmol/L, from a baseline level of 136 nmol/L. Three other individuals attained levels >150 nmol/L. The Monthly group reached a plateau of approximately 80±20 nmol/L after five months. At the end of the study only the Stat+Monthly and Monthly groups maintained mean levels >80 nmol/L. In order to rapidly increase 25(OH)D to recommended levels and sustain these levels in frail elderly, a loading dose followed by regular supplementation is preferable to regular supplementation alone.

Teriparatide Administration Following Antiresorptive Therapy (BBB-Study): Changes in 3D Microarchitecture, Mineralization and Remodeling at the Iliac Crest After 6 Months. B. Jobke¹, B. Muche², A. J. Burghardt¹, J. Semler², G. Delling³, T. M. Link¹, S. Majumdar¹. ¹MQIR - Dept. of Radiology, University of California, San Francisco, CA, USA, ²Dept. of Osteology, Immanuel-Hospital, Berlin, Germany, ³Inst. for Pathology, Hannover, Germany.

The purpose of this investigation is to obtain more information regarding the onset and duration of new bone formation that result in architectural changes under recombinant human parathyroid hormone 1-34 (rhPTH = teriparatide) following inadequate response to long-term bisphosphonate (BP) therapy for osteoporosis.

Materials and Methods: 25 female osteoporotic patients (age 69 ± 9 years) self-administered teriparatide (20 µg/d), for an ongoing treatment period of 18 months, after long-term BP use (mean duration 40 ± 22 months). In this single center clinical trial, to date, 13 paired iliac crest biopsies (Jamshidi technique) were obtained at baseline (M0) and 6 months (M6) at alternating sides. Tetracycline double-labeled and PMMA embedded biopsies were analyzed semi-quantitatively using light microscopy. Bone volume fraction (BV/TV), structural parameters (Conn.D, SMI, Tb.N, Tb.Th, Tb.S, TBPf) and tissue mineralization (mgHA/ccm) were assessed using µCT (MicroCT 40).

Results: Teriparatide application led to a significant increase in bone remodeling units at M6 compared to M0: in 10/13 (77%) patients an increase was found, in 2/13 there was no change and in 1/13 a decrease in bone turnover was documented. 4 patients showed minor forms of local endosteal fibrosis and 3 had a moderate surface osteoidosis at M6. Pairwise changes in the degree of tissue mineralization did not differ from M0 (p=0.945; mean change: -1.5% to 1087 mgHA/ccm ± 30), independent of bone turnover status. Pairwise changes in BV/TV and 'structure model index' (SMI) improved significantly (p=0.014 and p=0.046, respectively). The average increase in bone volume fraction was +1.8%. Increases in bone volume fraction >2% compared to M0 were observed in 62% (8/13). **Discussion:** Despite previous long-term suppression of bone turnover with BP, rhPTH considerably stimulated or balanced bone turnover after 6 months of treatment. In contrast to previous reports there was no detectable decrease in tissue mineralization under osteoanabolic rhPTH treatment. This observation may be due to a relatively small gain in new mineralized bone at M6. It appears that an early gain in bone volume at M6 was best represented by BV/TV whereas most changes in structural parameters were not significant yet. Our results from the iliac crest are consistent with findings from previous clinical trials which found high levels of bone formation markers at M6 with a subsequent improvement in bone stability.

Pulmonary Delivery of the Parathyroid Hormone Analogue Ostabolin-C™ Stimulates Markers of Bone Formation in Postmenopausal Women. P. Morley¹, J. Bishop¹, R. Anderson¹, C. L. Barclay¹, D. Krause¹, G. Morelli², M. Newhouse³, N. Sadrzadeh⁴, M. Eldon⁴. ¹Zelos Therapeutics Inc., Ottawa, ON, Canada, ²MDS Pharma Services, Montreal, PQ, Canada, ³McMaster University, Hamilton, ON, Canada, ⁴Nektar Therapeutics, San Carlos, CA, USA.

Ostabolin-C is a cyclic analogue of human parathyroid hormone (PTH) (1-31) that has demonstrated marked increases in bone mineral density of the lumbar spine and hip in a 1-year subcutaneous (SC) injection Phase II clinical trial. Pulmonary delivery will improve compliance with PTH therapy, especially in patients averse to self-injection. In the present

study, the pharmacokinetic (PK), safety and efficacy profile of Ostabolin-C inhalation powder (OCIP) was evaluated in healthy postmenopausal female volunteers using a randomized, double-blind, placebo-controlled single and 28-day repeat escalating dose study design. Seventy two subjects (49-105 kg; 47-74 years of age) in 9 cohorts of 6 OCIP and 2 placebo treated subjects received a single inhalation of OCIP (dose range 0.1-1.6 mg/day) or placebo powder followed by 28-days of daily inhalation of OCIP or placebo for 7 of the 9 cohorts. Pre- and post-dose urinary cAMP, PINP, osteocalcin, CTx, NTx, ECG vital signs, spirometry, adverse events (AEs) and plasma Ostabolin-C levels were recorded. Following administration of OCIP using the Nektar T326 inhaler, C_{max} and AUC increased proportionally with dose while T_{max} and t_{1/2} were dose independent. There was no accumulation with repeat dosing and PK profiles of OCIP and SC Ostabolin-C were similar. Biological activity, measured by urinary cAMP, showed significant dose-dependent increases from pre- to post-dose on Day 1 that were maintained with repeat dosing. Significant dose-dependent increases in PINP and osteocalcin were observed on Day 28. There was no change in the markers of bone resorption CTx or NTx. The safety profile was consistent with PTH class effects, i.e., headache and nausea were the most commonly reported AEs and a dose-dependent increase in heart rate was recorded. There were no treatment-emergent pulmonary or cardiovascular AEs, no effect on pulmonary function and no clinically relevant laboratory abnormalities. Tolerability was poor in subjects receiving 1.2 mg or greater due to PTH class AEs. Serial total serum calcium (0.25-24 hours post-dose) in subjects dosed with 0.8 or 1.2 mg demonstrated a pharmacological effect on serum calcium only at the 1.2 mg dose. This first-in-human trial of inhaled Ostabolin-C demonstrates that it is well tolerated and stimulates cAMP and markers of bone formation to the same extent as SC Ostabolin-C. Inhaled Ostabolin-C represents a convenient alternative to daily injections for patients who require PTH therapy.

Efficacy of Adding Teriparatide Versus Switching to Teriparatide in Postmenopausal Women with Osteoporosis Previously Treated with Raloxifene or Alendronate. F. Cosman¹, R. A. Wermers², C. Recknor³, K. F. Mauck⁴, L. Xie⁴, E. V. Glass⁴, J. H. Krege⁴. ¹Helen Hayes Hospital, West Haverstraw, NY, USA, ²Mayo Clinic, Rochester, MN, USA, ³United Osteoporosis Centers, Gainesville, GA, USA, ⁴Eli Lilly and Company, Indianapolis, IN, USA.

In patients previously treated long term with antiresorptive drugs, information regarding the relative efficacy of adding teriparatide (TPTD, 20 mcg/d) versus switching to TPTD is not available. Postmenopausal women with osteoporosis previously treated for at least 18 months with alendronate (ALN, 70 total mg/week, median treatment duration 37.3 months) or raloxifene (RLX, 60 mg/d, median treatment duration 36.9 months) were randomized to either add TPTD or switch to TPTD for 6 months. A preplanned 12-month extension of this study is currently ongoing. Efficacy results included markers of bone turnover and DXA BMD. Baseline BMD and other characteristics were well matched with the exception that previous ALN patients had lower baseline bone turnover than previous RLX patients (Table). Adding TPTD conferred smaller increases in bone turnover versus switching to TPTD; these differences were more marked between the groups previously treated with ALN. However, adding TPTD conferred greater increases in BMD versus switching to TPTD; these differences were again more marked between the groups previously treated with ALN. All regimens were well tolerated. In conclusion, an anabolic response to TPTD was observed in patients previously treated with ALN or RLX regardless of whether the previous antiresorptive drug was continued or discontinued. In general, greater bone turnover was achieved by switching from antiresorptive to TPTD, while greater BMD increase was achieved by continuing antiresorptive during TPTD treatment.

Table: Baseline and change from baseline after 6 Months of TPTD Treatment.

Variable	Alendronate Pretreated				Raloxifene Pretreated			
	TPTD (N=50)	6-Mo Δ	TPTD+ALN (N=52)	6-Mo Δ	TPTD (N=49)	6-Mo Δ	TPTD+RLX (N=47)	6-Mo Δ
PINP (µg/L)	27.5	101.5 (400.9%*)	30.0	21.5 (69.1%*†)	43.0	103.0 (245.7%*)	42.0	62.5 (125.4%*†)
BSAP (U/L)	20.1	11.9 (73.3%*)	20.3	3.1 (16.1%*†)	25.1	9.7 (38.6%*)	27.1	8.1 (30.6%*)
CTx (ng/ml)	0.16	0.40 (231.0%*)	0.18	0.05 (28.6%*†)	0.31	0.37 (136.1%*)	0.28	0.14 (64.6%*†)
LS DXA BMD (g/cm ²)	0.86	0.012 (1.9%**)	0.82	0.033 (4.5%*†)	0.84	0.034 (4.2%*)	0.84	0.037 (4.6%*)
FN DXA BMD (g/cm ²)	0.66	0.0001 (0.1%)	0.66	0.004 (0.7%)	0.66	0.002 (0.3%)	0.67	0.012 (1.9%**)
TH DXA BMD (g/cm ²)	0.72	-0.007 (-0.8%)	0.73	0.009 (1.4%*†)	0.72	0.003 (0.5%)	0.73	0.013 (1.8%*†)

For bone markers, values are median baseline, median absolute change from baseline (% change). For BMD, values are mean baseline, mean absolute change from baseline (% change). BL, baseline; PINP, amino-terminal propeptide of type I collagen; BSAP, bone specific alkaline phosphatase; CTx, C-terminal telopeptide of type I collagen; LS, lumbar spine; FN, femoral neck; TH, total hip. P-values are based on percent changes. *P<0.001 and **P<0.05 within group from baseline; †P<0.001 and ‡P<0.05 between groups within a stratum.

Correlations between Bone Turnover Markers and BMD in Patients treated with Teriparatide or Alendronate for Glucocorticoid-induced Osteoporosis. A. L. Burshell¹, R. Möricke², R. Correa-Rotter³, P. Chen^{*4}, M. R. Warner^{*4}, J. H. Kregge⁴. ¹Endocrinology, Ochsner Clinic Foundation, New Orleans, LA, USA, ²Clinical Research Laboratory, Magdeburg, Germany, ³Nephrology and Mineral Metabolism, National Medical Science and Nutrition Institute, Mexico City, Mexico, ⁴Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN, USA.

Correlations between bone turnover markers and BMD were assessed in a double-blind, active-comparator study of anabolic versus antiresorptive treatment for glucocorticoid-induced osteoporosis (GIOP). Men and women taking ≥ 5 mg/d prednisone equivalent for ≥ 3 months prior to screening were randomized to teriparatide (TPTD) 20 mcg/d (N=214) or alendronate (ALN) 10 mg/day (N=214) for 18 months. Markers of bone formation included N-terminal and C-terminal propeptide of type I procollagen (PINP and PICP) and bone-specific alkaline phosphatase (BSAP), and a resorption marker, carboxy-terminal telopeptide of type I collagen (CTX). Morning fasting blood specimens were measured at baseline and at 1 and 6 months. Lumbar spine (LS) and femoral neck (FN) BMD were measured by DXA at baseline and 18 months. Spearman correlation coefficients were calculated for baseline and changes from baseline in biomarkers at 1 and 6 months with changes from baseline in BMD at 18 months (Table). Baseline median glucocorticoid dose was 7.8 and 7.5 mg/d in the ALN and TPTD group, respectively; mean (\pm SD) LS BMD T-score was -2.5 ± 1.0 and -2.4 ± 1.0 in the ALN and TPTD group, respectively. In the ALN group, baseline markers were correlated with change in FN BMD, 1 and 6 month change in PINP and CTX were negatively correlated with increases in FN BMD, and 1 month change in CTX was negatively correlated with increased LS BMD. In the TPTD group, increases in PINP were correlated with gains in LS and FN BMD. In conclusion, bone turnover at baseline was correlated with FN BMD response to ALN but not to TPTD. In the ALN group, decreases in markers were correlated with gains in FN BMD. In the TPTD group, increased PINP was correlated with increased LS and FN BMD. These results demonstrate the opposite mechanism of action of TPTD and ALN in patients treated for GIOP.

Table: Correlation coefficients: baseline markers and the change in markers versus the change in lumbar spine (LS) or femoral neck (FN) BMD

Marker	Time (month)	Alendronate		Teriparatide	
		Lumbar spine	Femoral neck	Lumbar spine	Femoral neck

Antagonism of Calcium Sensing Receptor Stimulates Dose-related Release of Endogenous Parathyroid Hormone in Normal Volunteers: A Proof of Concept Study. D. Ethgen¹, T. Danoff^{*1}, M. Schultz^{*1}, D. Tenero^{*1}, A. Anderson^{*1}, G. B. Stroup², S. Kumar¹, A. M. Lago^{*2}, J. F. Callahan^{*2}, P. Bhatnagar^{*1}, W. F. Huffman^{*1}, M. Gowen², L. A. Fitzpatrick¹. ¹GlaxoSmithKline, Collegeville, PA, USA, ²GlaxoSmithKline, King of Prussia, PA, USA.

Calcium sensing receptor antagonists (calcilytics) are a new class of drugs that stimulate bone formation through a PTH-mediated mechanism. Preclinical investigation has shown that briefly antagonizing the calcium receptor (CaR) on the parathyroid gland results in a transient secretion of endogenous PTH, a profile that stimulates bone formation.

SB-423562 is a small molecule with potent short-lived CaR antagonist activity. This was the first clinical study administering this compound to healthy male volunteers. Safety and tolerability, as well as preliminary pharmacokinetics and pharmacodynamics of a single IV administered rising doses were investigated.

A single 10-minutes IV infusion of SB-423562 (dose range 0.02 to 5.0 mg) in 28 healthy adult male humans resulted in a strong dose-related transient PTH release at varying dose levels.

Pharmacokinetic measurements showed that SB-423562 was quantifiable for 0.25 h post-dose (155 μ g dose) up to 3 h post-dose (5.0 mg dose). SB-423562 area under the concentration-time curve (AUC) and maximal observed plasma concentration (C_{max}) increased in an approximately dose-proportional manner. The elimination half-life, where estimated, was <1 h. Total clearance was moderate (approximately 500 mL/min). Volume of distribution was approximately 20 L.

SB-423562 produced a strong endogenous PTH release profile, particularly at 1.25 mg, 2.5

mg and 5.0 mg. Mean T_{max} was 15 minutes or less. Duration of effect was typically less than 1 h. A 3- to 5.5-fold increase in PTH levels relative to baseline was observed with the 1.25, 2.5 and 5.0 mg doses at 10-15 minutes post infusion. At the higher doses (0.625 to 5 mg), a PTH profile was produced that is consistent with bone forming effects observed with previous experience with SC administered PTH (1-34). A dose related effect was observed on total and ionized serum calcium levels.

SB-423562 was generally safe and well tolerated in healthy male volunteers, no deaths, serious adverse events or withdrawals due to adverse events were reported during the study. There were no apparent differences observed across regimen for safety laboratories values, blood pressure and heart rate.

These data provide a proof of principle that a small molecule with CaR antagonizing properties delivered to healthy male subjects can generate endogenous PTH release in a profile compatible with a long term bone forming effect. Further work is ongoing to develop a formulation allowing the oral delivery of this class of drugs to osteoporotic patients.

Low Energy Femoral Diaphyseal Fractures Associated with Alendronate Use. B. Lenart^{*}, A. Neviasser^{*}, M. G. Peterson^{*}, F. Edobor-Osula^{*}, B. Schreck^{*}, C. Chang^{*}, D. G. Lorich^{*}, J. M. Lane. Orthopedic Surgery, Hospital for Special Surgery, New York, NY, USA.

The purpose of this study was to elucidate a correlation between prolonged alendronate use and low energy subtrochanteric and shaft fractures in postmenopausal women.

We performed a retrospective case-control study to investigate our hypothesis. Cases were defined as postmenopausal women with low energy subtrochanteric/shaft fractures verified by xray who presented from 2000-2007 at a university hospital. Controls were postmenopausal women matched by age, race and body mass index with low energy intertrochanteric or femoral neck fractures. Forty one cases were identified and matched to 82 controls, one intertrochanteric and femoral neck fracture each. Patients with diseases or drugs known to affect bone metabolism were excluded.

Alendronate use occurred at a rate of 36.6% in the cases, significantly higher than the 11% observed in controls (p<.001) with an odds ratio of 4.68 for subtrochanteric/shaft fractures with alendronate use (95% CI, 1.83-11.98). Furthermore, alendronate was the bisphosphonate prescribed in each of the cases, which was significantly different than that expected based on 2003 estimates of proportion of bisphosphonates prescribed (p=.042). Logistic regression analysis showed that calcium and alendronate were most significantly associated with cases (p=.09 and p=.003 respectively). Baseline characteristics of cases and controls were similar except serum calcium, which was significantly lower in the cases (p=.02). Patients with subtrochanteric/shaft fractures taking alendronate also shared a common xray fracture pattern, defined as a simple or oblique fracture with cortical thickening and beaking of the cortex on one side. This xray pattern was highly associated with alendronate use (p<.001) with an odds ratio of 15.33 (95% CI, 3.06-76.90). Patients with the xray pattern had an average duration of alendronate use of 7.3 years, while that for those on alendronate without the xray pattern was 2.8 years (p<.001). Wilcoxon survival analysis yielded significantly different cumulative survival without fracture between these two groups (p=.003). By Spearman's rank correlation, duration of alendronate use was significantly correlated to the ratio of the cortical thickness to diameter (p<.001).

Alendronate treatment historically reduces the rate of hip fracture by 50%. Our study demonstrates that alendronate may actually increase the risk of low energy subtrochanteric and shaft fractures with prolonged use. While this data does not prove a causal relationship, it provides strong evidence that a correlation exists between prolonged alendronate use and femoral diaphyseal fractures.

The Effect of Risedronate on Risk of Clinical Fracture Among Patients with Prior Hip Fracture. M. R. McClung^{*1}, A. Grauer², X. Zhou^{*2}, P. D. Miller^{*3}, S. Boonen^{*4}. ¹Oregon Osteoporosis Center, Portland, OR, USA, ²Procter & Gamble Pharmaceuticals, Mason, OH, USA, ³Denver Osteoporosis Center, Denver, CO, USA, ⁴University Hospital Leuven, Leuven, Belgium.

Previous hip fracture is a risk factor for subsequent fractures. In this analysis, the anti-fracture efficacy of risedronate was examined among patients with previous hip fracture at baseline.

A total of 339 postmenopausal women between ages 70-79 years with low BMD in HIP trials (McClung, MR et al. 2001 NEJM) had a history of at least one hip fracture prior to study entry. These subjects were treated with either placebo (PLC) or risedronate (RIS) 2.5mg or 5 mg daily. The incidence of osteoporosis-related clinical fracture, defined by the occurrence of the radiographically confirmed clinical vertebral fracture or radiographically confirmed non-traumatic non-vertebral fracture was calculated using Kaplan-Meier survival estimates over a 3 year period and was compared between placebo- and risedronate-treated subjects. Treatments were compared using log rank test, and the risk ratio and its 95% confidence interval were obtained using a Cox regression model stratified for study.

Subjects' mean age was 75 years, and their mean femoral neck (FN) and lumbar spine (LS) T-scores were -3.1 and -3.2 SD, respectively. Baseline characteristics were well balanced between the 3 treatment groups. Over the 0-3 year period, the clinical fracture incidences were 28.4%, 14.9% and 13% for the PLC, RIS 2.5mg and RIS 5mg groups, respectively. Relative to the placebo group, RIS 5mg and 2.5 mg statistically significantly reduced the risk for clinical fracture over 0-3 year period (p<0.05). The risk ratio of clinical fracture was 0.5 for both the risedronate 5mg and 2.5 daily groups relative to the placebo group.

Risedronate treatment was well tolerated in HIP trial.

Risedronate significantly reduced the risk of clinical fracture among women with postmenopausal osteoporosis with prior hip fracture.

Table: Incidence of Clinical Fracture (According to Kaplan-Meier Survival Estimates) among Patients with Prevalent Hip Fracture

Placebo	Ris 2.5mg	Ris 5 mg	Ris 2.5 or 5 mg
27/111 (28.4%)	15/122 (14.9%)	12/106 (13.0%)	27/228 (14.1%)
	0.50 (0.26, 0.95)	0.50 (0.25, 1.00)	0.50 (0.29, 0.86)

In the pivotal fracture trial establishing the antifracture efficacy of once-yearly infusions of zoledronic acid (ZOL) 5 mg in women with postmenopausal osteoporosis aged 64-89, we tested whether tissue level responses to ZOL differed with age by analyzing changes in bone remodeling and bone structure between treatment and placebo (PLB) in 3 age groups: < 70, 71-74 and ≥ 75 yrs. Bone remodeling indices were assessed in tetracycline labeled biopsies obtained from 43 patients on ZOL and 49 on PLB (Table 1). Prior to histomorphometric analysis, trabecular bone structure and cortical thickness were assessed on intact biopsy cores by µCT in 50 patients on ZOL and 49 on PLB.

Table 1. Differences (Δ%) in key remodeling and structural indices between ZOL and PLB groups across 3 age groups after 3 yrs.

In the PLB group bone turnover, reflected in activation frequency (Ac.f) and mineralizing surface (MS/BS) decreased with increasing age. Despite this, ZOL induced consistent reductions by 71%, 69%, and 76% across the 3 age groups. Differences between other histomorphometric indices: osteoid surface (OS/BS), mineral appositional rate (MAR), and volume referent bone formation rate (BFR/BV), were stable across age groups. Structural parameters (bone volume (BV/TV), trabecular number (Tb.N), trabecular spacing (Tb.Sp), trabecular thickness (Tb.Th) and cortical thickness (Ct.Th)) indicated preservation of bone structure in patients on ZOL in all age groups, albeit the numerical differences were lower in the oldest age group.

In conclusion, changes in bone remodeling and preservation of bone structure after 3 yrs of treatment with once-yearly doses of ZOL 5 mg iv are similar across all age groups in postmenopausal women aged 64-89 yrs.

Mechanistic Bases of Bone Mineral Density Increase During Alendronate Therapy. D. Vashishth¹, P. Chavassieux², G. Boivin², P. D. Delmas². ¹INSERM Unite 831 Université de Lyon France & Rensselaer Polytechnic Institute, Troy, NY, USA, ²INSERM Unite 831 Université de Lyon, Lyon, France.

An increase in the mean degree of tissue mineralization (DMB) occurring through secondary mineralization has been proposed to increase bone mineral density (BMD) during bisphosphonate (BP) therapy [1]. In this study we conducted additional analyses on human iliac crest biopsies obtained as part of alendronate (ALN) clinical trials [2] to identify the mechanistic bases of BMD increase.

Out of a group of 16 patients on a three-year ALN-therapy [1], we identified two groups of 5 patients each showing lower (8.5 %) and higher (13.3%) bounds of BMD increase but no difference in baseline BMD. For all 10 patients, previously prepared microradiographs were reanalyzed to measure the mean degree of tissue mineralization (DMB) at the osteonal and interstitial compartments in both cortical and cancellous bone tissues. Based on a moving average analysis, six fields each of cortical and cancellous bone tissues were randomly selected for measurement from each biopsy. The average values for patients in each group within osteonal and interstitial compartments were compared between and across cortical and cancellous bone tissues. All DMB measurements were also tested for correlation with standard histomorphometric measures of bone structure (BV/TV, Tb.Th, Tb. Separation, Tb.N), osteoclast activity (EV/BV, E-Depth, Oc#/BS), osteoid (OS/BS, OV/BV, OTh), and bone formation (MAR, BFR/BS, FP) reported previously [2]. The low-BMD-gain group demonstrated no difference between the osteonal and interstitial bone compartments within cortical or cancellous bone tissues but demonstrated a higher DMB in cancellous than in cortical tissue (p<0.05). In contrast, the high-BMD-gain group showed higher DMB in interstitial than in osteonal compartment for both cortical and cancellous tissues as well as a higher DMB in cancellous than in cortical tissue (p<0.05). Out of all the DMB measures in cortical and cancellous tissues, only cortical bone interstitial level DMB correlated to bone formation rate (BFR/BS) (r = -0.86; p = 0.006) and formation period (FP) (r = -0.75; p = 0.04).

In conclusion, this study demonstrates that the effects of ALN-therapy are more evident in cancellous than in cortical bone. Moreover since the interstitial level DMB is at least partially dependent on the duration of secondary mineralization, and negatively correlated to formation parameters, slow bone formation rate and longer bone formation period produce conditions conducive to complete secondary mineralization and consequently larger BMD gain.

Mineralization Status of Bone Matrix in Postmenopausal Women During a 10-year Alendronate Treatment Period. P. Roschger¹, G. Mair², N. Fratzl-Zelman¹, P. Fratzl², D. Kimmel³, K. Klaushofer¹, A. LaMotta³, A. Lombardi³.

¹Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK and AUVA Trauma Centre Meidling, 4th Med. Dept., Hanusch Hospital, Vienna, Austria, ²Max Planck Institute of Colloids and Interfaces, Dept Biomaterials, Potsdam, Germany, ³Merck Research Laboratories, Rahway, NJ, USA.

Knowledge of the effects of long-term antiresorptive treatment on bone material quality is an important issue for the safety and optimal duration of treatment. Mineralization density distribution (BMDD) as well as mineral particle thickness, both important composite parameters of bone material, were studied by quantitative backscattered electron imaging (qBEI) and small angle x-ray scattering (SAXS). Previously published data of biopsies from Phase III alendronate studies of 2 or 3 years treatment duration (placebo, n=12, alendronate (ALN), n=12) were compared to data obtained from the FLEX study (fracture intervention trial long-term extension) (5 yrs ALN + 5yrs placebo, n=14 and 10 yrs ALN, n=16). The mean (CaMean) and the most frequent calcium (CaPeak) concentration, the heterogeneity in mineralization (CaWidth) and the amount of low mineralized bone area (primary mineralization) (CaLow) were determined. ALN treatment for 5 yrs, followed by 5 yrs of placebo treatment resulted in an increase of CaMean (+3.5%) and CaPeak (+2.4%) compared to the group treated with placebo for 2 or 3 yrs. Continuous treatment with ALN for 10 years did not further increase CaMean and CaPeak. Remarkably, the decrease in CaWidth (-14.5 %) observed with 2 or 3 yrs ALN treatment was reversed after 5 yrs and 10yrs ALN treatment, respectively. This transient narrowing of the BMDD around 3 yrs is consistent with computer modeling of BMDD and indicates the effect on BMDD by the sudden decrease in bone turnover during ALN treatment. In none of the investigated cases CaMean and CaPeak values did exceed those of normal adult trabecular bone, nor did the mean mineral particle thickness parameter get out of the normal range (3.5 to 4.2 nm). Our data support the hypothesis that antiresorptive treatment with ALN should be maintained for 3 to 5 years and that there are no negative effects on bone matrix mineralization even with longer treatment.

Bisphosphonates Adherence and Fracture Risk: Time-Dependent Relationships from 103,038 Bisphosphonate Users in the U.S. J. R. Curtis¹, A. Westfall^{*1}, H. Cheng¹, E. Delzell^{*1}, K. Lyles², K. G. Saag¹. ¹University of Alabama at Birmingham, Birmingham, AL, USA, ²Duke University, Durham, NC, USA.

Background: There is high interest in determining if there is a 'threshold' level of real-world adherence to bisphosphonate (BP) therapy, after which additional fracture (fx) risk reduction is minimal.

Methods: Using the claims and pharmacy databases of a large consolidated health plans database, we identified persons initiating alendronate or risedronate (no use in prior 6 months) and calculated adherence as a Medication Possession Ratio (MPR: number of days of BPs dispensed divided by the calendar time since BP initiation (the index date)). Claims data identified non-vertebral fx's occurring after the index date. Survival analyses compared fx rates of persons with MPR $\geq 80\%$ (adherent) vs. those with MPR $\leq 50\%$ (non-adherent) at 90 days, stratifying by history of fx in the 6 months prior to the index date. We then examined fx rate by 10% increments of MPR and characterized MPR in a time-dependent fashion in sequential 3 month intervals. This analysis was repeated excluding those who did not have BPs dispensed for at least 90 days with the expectation that these 'very non-adherent' individuals might confound the adherence-fx relationship.

Results: We identified 103,038 new BP users, mean age 62.2 ± 8.2 (SD) years. Overall, there was a significant relationship between adherence and fx risk ($p < 0.0001$ between adherence groups); survival curves stratified by prior fx (yes/no) are shown (Figure). At 3 years, the absolute fx rate of the adherent vs. the non-adherent was 4.6% vs. 5.6% (number needed to treat = 103). Among those with prior fx, the rate was 35.8 vs. 38.9% (number needed to treat = 32).

The relation between adherence (in 10% increments) and fx was linear with no inflection point observed. After excluding patients who did not have BPs dispensed for at least 90 days, the relation between adherence and fx was curvilinear with an inflection point at MPR = 40-50%.

Conclusions: Adherence with BPs is an important determinant of fx rates, although the number of adherent patients needed to treat to prevent one fx is strongly determined by additional risk factors such as prior fx. The overall relation between adherence and fx is monotonic; although, likely subject to unmeasured confounding. However, even after partially accounting for this confounding, the incremental benefit in fx risk reduction with increasing adherence remained.

Modeling the Contribution of Long-term Persistence with Weekly or Yearly Bisphosphonate Treatment to Fracture Outcomes. S. Rietbroek^{*1}, M. Olson², T. van Staa^{*1}. ¹General Practice Research Database, London, United Kingdom, ²Novartis Pharmaceuticals, Basel, Switzerland.

Purpose: The objective of this study was to evaluate the impact of improving long-term persistence on fracture outcomes.

Methods: The study population included patients prescribed alendronate or risedronate in the UK General Practice Research Database (GPRD). Individualised probabilities of fracture and death during bisphosphonate therapy and of treatment persistence were estimated by age, gender, dosage regimen, calendar year and clinical risk factors using Cox-regression. Persistence was calculated by measuring repeat prescribing. A unique patient-based pharmacoeconomic model was then developed using these probabilities. By varying the persistence probabilities in a simulation, the fracture outcomes with different scenarios of persistence were then evaluated. The model included seven different fracture types, with weighting of different types by post-fracture mortality. The outcomes were simulated over a 4-year period (maximum of 3 years of bisphosphonate use followed by 1 year of offset). It was assumed that the bisphosphonate users had experienced similar fracture reductions as observed in clinical trials and that weekly and yearly bisphosphonates had similar relative rates of fracture risk reduction.

Results: The study population included 43,525 patients. The 1-year persistence for weekly bisphosphonate in the model was 56.7% and 3-year persistence 35.3%. Modeling showed that improvement of the 3-year persistence by 20% (over current persistence in GPRD) would prevent an additional 41.3 hip fractures per 10,000 patients with weekly treatment. If weekly treatment (with refill at 4 week periods) was substituted with yearly treatment (refill once a year), an additional 28.7 hip fractures (per 10,000 patients) would be prevented. If 3-year persistence improved by 20% with yearly treatment, an additional 75.7 hip fractures would be prevented compared to monthly bisphosphonates. The effects of this substitution were largest in elderly patients and in women. Yearly bisphosphonates would prevent an additional 64.8 hip fractures in women aged 80+ compared to weekly bisphosphonates (with equal 3-year persistence), while this number was 3.5 in men aged 40 to 49. **Conclusion:** This study found that the switch of weekly to yearly bisphosphonates may prevent additional fractures due to the longer treatment.

Bone Material Characteristics in Osteoporotic Postmenopausal Women after 3-year Treatment with Strontium Ranelate. C. Li^{*1}, P. Roschger², R. Zoehrer^{*2}, I. Manjubala^{*1}, E. P. Paschalis², N. Fratzl-Zelman², P. Fratzl^{*1}, K. Klaushofer². ¹Max Planck Institute of Colloids and Interfaces, Department of Biomaterials, 14424 Potsdam, Germany, ²Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK and AUVA Trauma Centre Meidling, 4th Medical Department, Hanusch Hospital, Vienna, Austria.

Three-year treatment of postmenopausal osteoporotic women with strontium ranelate is reported to reduce the risk of vertebral and hip fractures by 41% and 36%, respectively. The underlying mechanism of strontium may involve an effect on bone material properties. Biopsies (kindly provided by Servier) from osteoporotic women treated for 3 years with strontium ranelate (n=6) or placebo (n=6) were investigated using complementary nondestructive scanning methods like quantitative backscattered electron imaging (qBEI), x-ray microanalysis (EDX), scanning small- and wide-angle x-ray scattering (sSAXS/sWAXS), and Fourier transform microspectroscopy (FTIRM). qBEI gray level histograms of strontium ranelate-treated subjects showed a distinct shift to bone material with higher average atomic number compared with placebo-treated subjects, which is consistent with the incorporation of Sr (Z=38), which has a higher atomic number than calcium (Z=20). EDX analysis of small selected areas (10x10 μm) within individual bone packet areas revealed that Sr was present in a molar fraction up to 6 %, exclusively in bone packets newly formed during strontium ranelate treatment, while the old bone packets (most likely generated before strontium ranelate treatment was started) had only marginal amounts of Sr (close to the detection limit of the method). As previously shown by others, global mean bone Sr content obtained by destructive chemical analysis was $1.56\% \pm 0.30\%$ (Sr/Sr+Ca %mol/mol). WAXS line scans across the bone packets detected an increase in the hydroxyapatite crystal lattice spacing (c-axis) consistent with the number of Ca atoms replaced by Sr atoms (up to 0.5 of the 10 calcium ions composing each unit cell replaced by 0.5 Sr ions), indicating that Sr is incorporated into the bone mineral. Area scans by sSAXS failed to reveal any Sr-dependent changes in mean mineral particle thickness (3.1 to 3.6 nm). FTIRM analysis of trabecular bone did not detect any differences in collagen cross-link ratio (pyr/deH-DHLNL) between placebo and strontium ranelate treatment. In conclusion, after 3 years of treatment with strontium ranelate, strontium was only found in newly formed bone, with preservation of examined bone material characteristics.

Vitamin-D 800 IU/Day + Calcium 1000 mg Supplementation Decreases the Risk of Falling Among Postmenopausal Ambulatory Women - A Population-based, Randomized, 3-Year Study (OSTPRE-FPS). M. Kärkkäinen^{*1}, M. Tuppurainen¹, T. Rikkonen^{*1}, K. Salovaara², J. Sirola^{*2}, R. Honkanen¹, E. Alhava^{*3}, H. Kröger². ¹Bone and Cartilage Research Unit, University of Kuopio, Kuopio, Finland, ²Department of Orthopaedics and Traumatology, Kuopio University Hospital, Kuopio, Finland, ³Department of Surgery, Kuopio University Hospital, Kuopio, Finland.

Vitamin D insufficiency and subsequent secondary hyperparathyroidism are common especially in Northern latitude. Vitamin D insufficiency has been related to low bone mass, falls and fractures. In this 3-year population-based randomized trial (OSTPRE-FPS) we hypothesized that Vitamin-D and Calcium supplementation improves muscle strength, functional capacity and decreases falls in ambulatory postmenopausal women.

The present study population consisted of 606 ambulatory women age varied from 66 to 71 years (mean (SD) 68.5 (1.7)) who belong to the OSTPRE-FPS cohort (n=3432). The intervention group (n=292) obtained Cholecalciferol 800 IU/d + Calcium 1000 mg/d supplementation (Calcichew-D3 Forte, Leiras-Nycomed Ltd) for 3 years and the control group (n=314) received no supplementation.

Falls (ICD10 W00-W19) were recorded based on phone inquiry done at 4 months intervals. The functional capacity tests included: standing-on-one-foot, squat down, chair rising, standing eyes closed 10s, fast regular walk 10m, tandem walk 6m, grip and leg extension strength measurements.

A total of 873 falls in 364 subjects were recorded during the 3-year follow up. There were 381 falls in 165 women in Vitamin D-supplementation group and 492 falls in 199 women in the control-group. Thus, the vitamin-D and calcium supplementation decreased the incidence of falls by 23 % (p=0.039). Results in chair rising test and leg extension strength improved in the supplementation group (p=0.002 and p<0.001, respectively) but the difference between the groups did not reach statistical significance.

In conclusion, Cholecalciferol 800 IU + Calcium 1000 mg supplementation is effective in fall prevention among ambulatory postmenopausal women. The positive effect may be mediated through improvements in lower extremity muscle strength and balance.

Antiinflammatory Role of Osteoprotegerin (OPG) in the Pathophysiology of Osteoporosis and Arteriosclerosis. C. Kasperk¹, U. Liegibel^{*1}, U. Sommer^{*1}, U. Wolf^{*1}, I. Grafe^{*1}, L. Basler^{*2}, P. Nawroth^{*1}, P. J. Meeder^{*2}. ¹Internal Medicine I, Endocrinology, University of Heidelberg, Heidelberg, Germany, ²Orthopedic Surgery, University of Heidelberg, Heidelberg, Germany.

Osteoporosis and arteriosclerosis are associated diseases which have numerous genetic, cellular and epidemiological characteristics in common, e.g. OPG^{-/-} mice develop osteoporosis and arteriosclerosis (Bucay et al. Genes Develop 12:1260, 1998). Previously, we demonstrated that mechanical stress by cellular elongation exerts a stimulatory effect on OPG production of osteoblastic cells Liegibel et al. J Exp Med 196:1387, 2002). We hypothesized that there is a biphasic response of the OPG gene to mechanical stress in osteoblastic (OC) and endothelial cells (EC) and that OPG exerts an antiinflammatory action on bone and endothelial cell metabolism implicating a direct effect of OPG on OC and EC. We exposed primary human OC and EC (HUVEC) to elongation stress (ES) using a Flexer cell device. ES up to 2.5 % of initial cell length stimulated OPG production in OC (200 % of control) and had no effect on OPG in EC. ES > 10 % inhibited OPG production in OC down to 50 % and in EC to 15 % of control. OPG increased ERK-1 and -2 phosphorylation and α v β 3 integrin production in OC and EC, effects which could be inhibited by antiRANKL antibodies and the MAP kinase inhibitor PD98059, respectively. The proinflammatory cytokine TNF α stimulated IL-6 production in OC and EC which could be inhibited by an OPG co-treatment in both cell types. Interestingly, TNF α and IL-1 β decreased alkaline phosphatase activity (AP) in OC but increased AP in EC. However, a combined treatment of OC and EC with the proinflammatory cytokines TNF α or IL-1 β together with OPG converted the cytokines' effects on AP and thus exerted a stimulation of AP in OC whereas in EC the AP activity was significantly decreased by the cytokine-OPG co-treatment. In order to clarify antiinflammatory OPG effects we examined a possible action of OPG on I κ B and observed a stimulatory action of OPG on I κ B production in OC and EC. In summary, in both OC and EC (1) ES exerts a biphasic effect on OPG production, (2) OPG directly activates MAP kinases and stimulates α v β 3 integrin and I κ B production, (3) TNF α and IL-1 β stimulate IL-6 production which can be inhibited by OPG co-treatment, and (4) TNF α and IL-1 β decreased AP in OC but increased AP activity in EC; OPG-co-treatment converted the inhibitory action of TNF α and IL-1 β and thus resulted in a stimulation of AP in OC and decreased AP activity in EC. In conclusion, OPG is an antiinflammatory cytokine which exerts direct effects on OC and EC metabolism. Locally decreased OPG production may contribute to localized osteoporosis in bone and to mineralization processes closed to branching blood vessels.

Alpha/Beta-T Cells Do Not Modulate Androgen Withdrawal-induced Bone Loss in Aged Rats. R. G. Erben, K. Mildner^{*}, C. Schüller^{*}, M. Skalicky^{*}. Dept. of Natural Sciences, University of Veterinary Medicine, Vienna, Austria.

T lymphocytes are thought to play an important role in the regulation of bone turnover. To explore further the role of T lymphocytes in sex steroid deficiency-induced bone loss, we developed a T cell depletion model in aged Fischer rats. Twelve-month-old male Fischer 344 rats were either thymectomized (TX) or sham-operated (SHAM-TX). Beginning 2 weeks postsurgery, TX rats received 3 intraperitoneal injections (every 3 days) of 20 mg/kg of a monoclonal mouse anti-rat antibody directed against the rat α / β -T cell receptor. SHAM-TX animals received 20 mg/kg of a non-immune monoclonal mouse isotype control antibody. T cell depletion was monitored by FACS analysis of peripheral blood. Three weeks after T cell depletion, TX and SHAM-TX rats were orchietomized (ORX) or sham-operated (SHAM). All animals were killed 2 months post-ORX after fluorochrome double labeling. The data were analyzed by two-way analysis of variance (ANOVA), determining the influence of the factors TX and ORX and their mutual interaction.

FACS analysis revealed that intraperitoneal injection of TX rats with high dose anti-rat α / β -T cell receptor antibody resulted in a lasting depletion of circulating α / β -T cells. As expected, 2-way ANOVA showed that ORX induced pronounced loss of total and trabecular bone mineral density (BMD) of the proximal tibial metaphysis and of the fourth lumbar vertebral body measured by peripheral quantitative computed tomography (pQCT), 2 months post-ORX. TX by itself had no influence on tibial or vertebral BMD, and significant two-way interactions between the factors TX and ORX were lacking. The ORX-induced bone loss and the increase in bone resorption as measured by urinary collagen crosslink excretion were identical in T cell-depleted TX and in T cell replete SHAM-TX rats. Thus, our study provides evidence that circulating α / β -T cells are not involved in the up-regulation of bone turnover and the subsequent bone loss induced by androgen withdrawal in aged male rats.

High Cardiovascular Risk in Men with Increased Bone Resorption or Low Bone Mass. P. Szulc, P. D. Delmas. INSERM 831, Hôpital E. Herriot, Lyon, France.

Recent studies suggest the existence of an association between bone mineral density (BMD) and cardiovascular disease. We studied the predictive value of BMD and biochemical bone turnover markers (BTM) for major cardiovascular events (myocardial infarction, stroke) in 628 men aged 50 years and over in whom 61 such events occurred during an 8-year follow-up. At baseline, BMD was measured at the lumbar spine, hip, whole body and distal forearm. After adjustment for age and co-morbidities, lower BMD at all sites of measurement was associated with an increased risk of cardiovascular event (O.R. = 1.25 to 1.55 per 1 standard deviation decrease, p<0.04-0.002). Low BMD, defined by T-score<-1, was associated with a twofold increase in the cardiovascular risk, e.g. whole body BMD - O.R. = 2.63, 95% C.I.: 1.49-4.65, p<0.001). Elevated levels of the urinary markers of bone resorption were defined by 1 standard deviation above the mean in men aged 50 to 60 years. After adjustment for age, co-morbidities, serum creatinine concentration and season, elevated levels of urinary markers of bone resorption were associated with a higher risk of the cardiovascular event (total deoxypyridinoline - O.R. = 2.90, 95% C.I.: 1.41-5.98, p<0.005; free deoxypyridinoline - O.R. = 2.24, 95% C.I.: 1.13-4.44, p<0.03; β -CTX-I - O.R. = 2.37, 95% C.I.: 1.09-5.16, p<0.03). Bone formation markers did not predict the cardiovascular event.

To the best of our knowledge, this is the first study showing that the increased bone resorption is associated with an increased risk of myocardial infarction and stroke in elderly men. We also confirm that low BMD is associated with an increased cardiovascular risk in elderly men.

Homocysteine Levels and Risk of Hip Fracture in Postmenopausal Women with Poor Renal Function: The Women's Health Initiative Observational Study. M. S. LeBoff¹, R. Narweker^{*1}, A. LaCroix^{*2}, L. Wu^{*2}, R. Jackson^{*3}, J. Lee^{*4}, D. C. Bauer^{*5}, C. Kooperberg^{*2}, J. Cauley^{*6}, S. Cummings^{*7}.

¹Endocrine-Hypertension, Brigham and Women's Hospital, Boston, MA, USA, ²Fred Hutchinson Cancer Research Center, Seattle, WA, USA, ³Ohio State University, College of Medicine and Public Health, Columbus, OH, USA, ⁴University of California, Davis, CA, USA, ⁵San Francisco Coordinating Center, CPMC Research Institute, San Francisco, CA, USA, ⁶University of Pittsburgh, Pittsburgh, PA, USA, ⁷University of California, San Francisco, CA, USA.

Hip fractures are the most serious osteoporotic fractures leading to disability and increased mortality. Recent studies suggest that high homocysteine levels are associated with an increased risk of fractures, although the mechanisms are not fully understood. Women with decreased renal function, as measured by cystatin-C, have elevated homocysteine levels and an increased risk of hip fractures. To assess the relationship between homocysteine levels and renal function on hip fracture risk, we conducted a nested case-control study in the Women's Health Initiative Observational Study (WHI-OS). The WHI-OS, is a multiethnic study among American women (n=93,676) aged 50-79 years at study entry. We selected 400 incident cases of hip fracture and 400 controls matched on age, ethnicity, and blood draw date among women not on treatment for osteoporosis including hormone use at baseline. These analyses were adjusted for body mass index, parental hip fracture history, treated diabetes, alcohol use, smoking, history of stroke, and calcium intake. Serum homocysteine levels were measured using a high-performance liquid chromatography assay. Serum cystatin-C was measured using the Dade Behring BN-II nephelometer with a particle-enhanced immunonephelometric assay (interassay co-efficient of variation=5.7%, sensitivity=0.02 mg/L). The risk of hip fracture increased 1.36-fold (1.13, 1.63) for each SD increase in serum homocysteine level. In multivariate models adjusted for potential confounders, women in the highest quartiles of both homocysteine and cystatin-C (n=111) had a 2.77-fold higher risk of hip fracture (1.60, 4.81) as compared to women in the lowest three quartiles of both homocysteine and cystatin-C (p=0.025 for the interaction). However, women in the highest quartile of homocysteine but lower three quartiles of cystatin-C had an OR= 0.85 (0.53, 1.37) of hip fracture. In summary, high homocysteine levels confer a substantial increased risk of subsequent hip fracture mainly among women with poor renal function.

Mutations in p62 Linked to Paget's Disease Make the Bone Microenvironment Highly Osteoclastogenic. Y. Hiruma¹, N. Kurihara¹, M. A. Subler^{*2}, H. Zhou³, D. W. Dempster³, S. Ishizuka⁴, G. D. Roodman⁵, J. J. Winkler^{*2}. ¹Medicine/Hem-Onc, University of Pittsburgh, Pittsburgh, PA, USA, ²Human Genetics, Virginia Commonwealth University, Richmond, VA, USA, ³Regional Bone Center, Helen Hayes Hospital, New York, NY, USA, ⁴Teijin Biomedical Research, Tokyo, Japan, ⁵Medicine/Hem-Onc, VA Pittsburgh Healthcare System and University of Pittsburgh, Pittsburgh, PA, USA.

Bone lesions in Paget's Disease (PD) are characterized by abnormal osteoclasts (OCL), markedly increased bone resorption and formation and increased RANKL expression in the bone microenvironment. Genetic factors contribute to the pathogenesis of PD, with mutations in the p62 gene being the most frequently linked to PD. p62 plays a critical role in NF- κ B and p38 MAPK activation induced by TNF- α and RANKL, but the contributions that mutations in p62 make to the abnormalities in OCL and the marrow microenvironment in PD are unclear. To address this question, we generated p62^{P394L/P394L} knock-in (KI) mice that express the most frequent p62 mutation in PD and compared these animals to wild-type (WT) mice. KI mice did not develop PD-like lesions in vivo. However, OCL formation in unfractionated marrow cultures from KI mice was increased and OCL formed at much lower concentrations of RANKL, TNF- α and 1,25-(OH)₂D₃, similar to marrow cultures from PD patients. Since the p62^{P394L} mutation in KI mice was expressed in both OCL precursors and marrow stromal cells, we then cultured highly purified OCL precursors (CFU-GM) and marrow stromal cells from KI mice separately to determine their respective contribution to the enhanced OCL formation. Purified KI OCL precursors were hyper-responsive to RANKL and TNF- α and formed increased numbers of OCL compared to WT. However, unlike PD patients, KI OCL precursors were not hyper-responsive to 1 α ,25-(OH)₂D₃. We then treated stromal cells from WT and KI mice with 1 α ,25-(OH)₂D₃ and determined the levels of RANKL expression. KI marrow stromal cells expressed high levels of RANKL and RANKL mRNA compared to WT. To determine the mechanism responsible for increased RANKL expression, we then examined the effects of the p62^{P394L} on activation of downstream signaling pathways induced by 1 α ,25-(OH)₂D₃ in stromal cells. 1 α ,25-(OH)₂D₃ increased p38 MAPK activity in KI stromal cells, and p38 inhibitors as well as a VDR genomic antagonist decreased RANKL expression. 1 β ,25-(OH)₂D₃, which blocks nongenomic actions of 1 α ,25-(OH)₂D₃, also decreased RANKL expression. These results show that expression of p62^{P394L} in marrow stromal cells markedly increases RANKL production via p38 MAPK and genomic and nongenomic actions of VDR. They also suggest that p62^{P394L} enhances RANKL production by the marrow microenvironment in PD and predisposes but is not sufficient to induce PD.

Mast Cell Migration to Bone Surfaces Precedes and Appears Essential for PTH-induced Peritrabecular Fibrosis. K. Marley¹, M. B. Lowry^{*2}, S. Lotinun^{*1}, U. T. Iwaniec¹, R. T. Turner¹. ¹Oregon State University, Corvallis, OR, USA, ²Microbiology, Oregon State University, Corvallis, OR, USA.

Increased mast cell number is associated with osteoporosis, osteopetrosis and marrow fibrosis. However, no cause and effect relationship has been established between the mast cell and any of these metabolic bone diseases. The presence of mast cells at sites of bone turnover and degranulating mast cells in the immediate vicinity of osteoclasts in rats led to investigation of the mast cell's role in the skeletal response to parathyroid hormone (PTH). Intermittent increases in PTH (iPTH) are anabolic to bone whereas chronic increases in PTH (cPTH) result in multiple skeletal abnormalities (parathyroid bone disease), including focal bone resorption, impaired mineralization and peritrabecular marrow fibrosis. We now report compelling evidence that the mast cell mediates many of the actions of PTH on bone: 1) cPTH induced severe bone disease in rats but not in 3 mouse strains (C57BL6, DBA2, WBB6F1) lacking mature bone marrow mast cells. In addition, the effects of iPTH and cPTH on osteoblasts (OB) and osteoclasts (OC) were greatly attenuated in mice compared to rats. 2) Both iPTH and cPTH resulted in rapid migration of mast cells to bone surfaces in rats with the mast cells adhering to OB in response to iPTH, and to fibroblasts in response to cPTH. In a time-course study, cPTH induced rapid mast cell migration to bone surfaces. By day 3, mast cells at the bone surface were increased 3-fold but peritrabecular fibrosis was not detected until day 5. This suggests that mast cell signaling stimulates fibroblast proliferation and facilitates migration of fibroblasts to bone surfaces. In support of this hypothesis, mast cells produce PDGF, a profibrotic cytokine. Administration of Trapidil, a PDGF receptor antagonist, did not impede mast cell migration to bone surfaces but suppressed cPTH-induced fibrosis, suggesting a critical chemotactic role for this mast cell-derived factor on fibroblasts. 3) Kit signaling mediates mast cell migration. OB lineage cells produce kit ligand (stem cell factor) which is chemotactic to mast cells. The Kit antagonist Gleevec prevented mast cell migration to bone surfaces and inhibited fibrosis. 4) Kit signals through phosphatidylinositol 3-kinase (PI3K) to initiate mast cell degranulation. The PI3K inhibitor wortmannin dramatically reduced fibrosis in rats treated with cPTH, suggesting a critical role for this pathway in cPTH-induced fibrosis. Taken together, these findings indicate that mast cell migration to bone surfaces precedes and is obligatory for cPTH-induced peritrabecular fibrosis and suggest that mast cells potentiate the bone anabolic effects of iPTH as well as the catabolic effects of cPTH.

Marked Improvement of Cortical Bone Geometry After Parathyroidectomy in Postmenopausal Women with Primary Hyperparathyroidism. M. Yamauchi¹, R. Nomura^{*2}, H. Kaji², S. Yano¹, T. Yamaguchi¹, T. Sugimoto¹. ¹Internal Medicine 1, Shimane University Faculty of Medicine, Izumo, Japan, ²Division of Endocrinology/Metabolism, Neurology and Hematology/Oncology, Kobe University Graduate School of Medicine, Kobe, Japan.

Cortical bone geometry is one of the most important factors of bone quality. It has been reported that recombinant human PTH(1-34) treatment induced beneficial changes in cortical geometry and our cross-sectional study from women with primary hyperparathyroidism (pHPT) revealed that endogenous PTH excess markedly affected cortical bone geometry (JCEM 2003). On the other hand, our six-year longitudinal study in postmenopausal women with pHPT revealed that parathyroidectomy (PTX) led to marked and sustained increase in bone mineral density (BMD) (Clin Endocrinol 2004). However, no data have been available about geometric changes of cortical bone after PTX in pHPT. In the present study, we assessed the longitudinal effects of removal of endogenous PTH excess on cortical bone geometry in pHPT postmenopausal patients with PTX and compared them with age-, body height and weight-, postmenopausal period-matched normal women. Twenty pHPT postmenopausal women (mean: age 63.6yr, Ca 12.0mg/dl, iPTH 267pg/ml) and thirty control women (age 64.6yr) participated in this study. We assessed volumetric BMD, architectural parameters of cortical bone and SSIP (polar strength strain index) by pQCT at the site of radius. Measurements of pQCT were performed at the time of enrollments and were repeated 1 year after PTX in pHPT group, and 1 year thereafter in control group. During 1-year period, total BMD and cortical BMD significantly decreased in control group (-2.1%, -1.3%), but increased in pHPT group (+2.9%, +1.6%), respectively. Significant decreases in cortical thickness and area were also observed in control group (-3.0%, -2.5%). In contrast, pHPT group showed significant increases in cortical thickness and area (+8.5%, +7.6%) as well as SSIP (+6.2%) during the follow-up period. In conclusion, the present longitudinal study showed that there were significant beneficial changes in vBMD, cortical bone geometry and bone strength in pHPT postmenopausal women, whereas age-related thinning of cortical bone as well as decrease of vBMD were observed in control group. The present findings suggest that the removal of sustained PTH excess markedly affects cortical bone geometry and that PTX in pHPT improve the bone strength by amelioration of cortical bone geometry as well as increase in BMD.

Long-Term Propranolol Improves Bone Mineral Content and Lean Body Mass in Pediatric Burn Patients. L. K. Branski^{*1}, D. N. Herndon^{*1}, W. B. Norbury^{*1}, M. G. Jeschke^{*1}, R. P. Mlcak^{*1}, G. L. Klein². ¹Surgery, University of Texas Medical Branch and Shriners Burns Hospital, Galveston, TX, USA, ²Pediatrics, University of Texas Medical Branch and Shriners Burns Hospital, Galveston, TX, USA.

Burn injury over 40% total body surface area (TBSA) causes marked hypermetabolism and episodic increases in catecholamine production as part of the stress response. The aim of our study was to evaluate the effects of propranolol (Prop) given over the first 12 months post-burn on total body bone mineral content (TBMC) and lean body mass (LBM). Forty-nine (49) children, ages 2-18 yr with burns $\geq 40\%$ TBSA were enrolled and randomized to receive Prop (n=24) or placebo (Cont, n=25). Prop was titrated to achieve a reduction in heart rate by 15%. TBMC and LBM were measured by dual energy x-ray absorptiometry (DXA) using a 4500A absorptiometer (Hologic, Waltham MA) at hospital discharge, 6, 9, and 12 months post-burn. Results were calculated as % discharge (baseline) values. Statistical analysis used two-way ANOVA with post-hoc Tukey's test for inter-group comparisons and one-way repeated measures ANOVA with post-hoc Bonferroni's t-test for intra-group comparisons to baseline values. Prop increased LBM and TBMC and body weight ($p < 0.02$) vs Cont at 12 months post-burn. Within the Prop group, LBM and body weight increased vs baseline at 9 months, while TBMC increased at 12 months compared to baseline ($p < 0.02$). Within the Cont group, patients showed an increase in LBM and body weight at 12 months ($p < 0.05$) compared to baseline. We conclude that long-term use of propranolol has a beneficial effect on bone acquisition due to its effects on increased lean body mass and secondary skeletal loading and/or an inhibition of the episodic increase in endogenous catecholamine production that may promote bone resorption and inhibit bone formation.

Bone Morbidity at Diagnosis among Children with Acute Lymphoblastic Leukemia. L. M. Ward¹, N. Shenouda^{*1}, N. Alos², S. Atkinson³, C. Clarkson^{*4}, R. Couch^{*5}, E. Cummings^{*6}, R. Grant^{*7}, C. Rodd⁸, D. Stephure^{*9}, S. Taback^{*10}, M. Matzinger^{*1}, F. Rauch⁸, and the STOPP Consortium^{*11}. ¹University of Ottawa, Ottawa, ON, Canada, ²Université de Montréal, Montréal, PQ, Canada, ³McMaster University, Hamilton, ON, Canada, ⁴University of Western Ontario, London, ON, Canada, ⁵University of Alberta, Edmonton, AB, Canada, ⁶Dalhousie University, Halifax, NS, Canada, ⁷University of Toronto, Toronto, ON, Canada, ⁸McGill University, Montréal, PQ, Canada, ⁹University of Calgary, Calgary, AB, Canada, ¹⁰University of Manitoba, Winnipeg, MB, Canada, ¹¹Canadian Pediatric Bone Health Working Group, Ottawa, ON, Canada.

Children with acute lymphoblastic leukemia (ALL) can manifest vertebral compression at diagnosis; however, the frequency and pattern of vertebral fractures, as well as their relationship to bone mineral density (BMD), has not been systematically studied. We therefore evaluated bone morbidity in 116 newly diagnosed children (age (mean \pm SD) 6.6 \pm 4.1 years; 62 boys) with ALL (pre-B cell ALL: N=102; T-cell ALL: N=14), who were enrolled in the STeroid-induced Osteoporosis in the Pediatric Population (STOPP) study, a prospective research program comprising 11 Canadian pediatric tertiary care centers. All patients underwent lateral thoracolumbar spine x-rays and BMD studies within 30 days of diagnosis. Forty-one patients (35%) had a total of 113 vertebral compression fractures (90 thoracic, 23 lumbar), as independently assessed by two radiologists at the coordinating site. Twenty-eight patients (68%) had one or two vertebral fractures, 10 patients (25%) had three to seven fractures and 3 patients (7%) had between nine and twelve fractures. Vertebrae T6 and T7 were most commonly affected and accounted for 41 of the 113 fracture events (36%). Ninety-two of the fractures (81%) were graded as mild, 17 (15%) as moderate and 4 (4%) as severe. Eighty-six of the compressed vertebrae (76%) had an anterior wedge configuration. Children with vertebral compression fractures had lower mean lumbar spine areal BMD z scores than those without fractures (-1.5 \pm 1.4 versus -0.67 \pm 1.3; $P < 0.05$). Mean height z scores did not differ between the two groups (0.3 \pm 1.19 for those with fractures; 0.31 \pm 1.25 for those without; $P = 0.9$). Only 14 of the 41 patients with vertebral compressions (34%) reported back pain. Thus, significant overt skeletal morbidity is common in newly diagnosed children with ALL, but is asymptomatic in the majority of cases.

Structural Implications of Low-Magnitude Mechanical Stimulation in a Pilot Study of Patients with Renal Osteodystrophy Evaluated with the MRI-based Virtual Bone Biopsy. C. E. Jones^{*1}, F. W. Wehrli¹, J. E. Magland^{*1}, C. T. Rubin², S. A. Nihtianova^{*3}, M. B. Leonard³. ¹University of Pennsylvania, Philadelphia, PA, USA, ²State University of New York, Stony Brook, NY, USA, ³Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Renal osteodystrophy (ROD) is a pervasive disorder of bone metabolism that results in impaired trabecular architecture, loss of cortical bone, and increased fracture rates. In this

double blind, placebo-controlled pilot study we examined the hypothesis that low magnitude mechanical stimulation (LMMS) increases bone volume fraction and improves the structural integrity of the trabecular bone in ROD. A total of 30 dialysis patients were randomized to daily (20 min/day) LMMS treatment with an active device (0.3g, 30 Hz), or a placebo device. Micro-MRI scans were performed in the distal tibial metaphysis at a voxel size of 137x137x410 μm^3 using a custom designed 3-D spin echo pulse sequence at baseline and after 6 months of treatment. The images subsequently underwent a cascade of processing steps, comprising the virtual bone biopsy, resulting in a final voxel size of 45x45x135 μm^3 and BV/TV was computed. After skeletonization of the images was performed (so that trabecular plates were converted to surfaces and rods to curves), the data were subjected to digital topological analysis. This algorithm establishes the topological identity of each voxel as belonging to a curve, surface or junction between the two fundamental types. To date, repeat MRI scans have been obtained on 10 LMMS and 11 placebo-treated subjects. Fig. 1 illustrates the wide range of structural abnormalities in some of the study subjects at baseline. In patients treated with the active LMMS device, TB/TV was increased 2.8% ($p = 0.02$) while the surface-to-curve ratio (S/C, ratio of all surface-type divided by all curve-type voxels) was increased 8.0 percent ($p = 0.03$), indicating a relative increase in plates over rods. Similarly, the erosion index (a measure of loss of connectivity) was decreased 6.9% ($p = 0.03$) suggesting improved trabecular connectivity. No significant changes were noted in the placebo group. The observed changes are commensurate with the treatment's anabolic effect resulting in improved bone quality and hence potentially reduced risk of fracture. These data are the first showing structural implications of LMMS treatment in patients with renal disease assessed with in vivo structural imaging.

Fig. 1. Transverse μMR images through the distal tibia in three patients: relatively normal bone (a), severely disconnected network (b); presence of marrow fibrosis (c).

Thioredoxin-1 Overexpression Attenuates Streptozotocin-induced Diabetic Osteopenia in Mice: A Novel Role of Oxidative Stress and Therapeutic Implications. Y. Hamada^{*1}, H. Fujii^{*1}, R. Kitazawa², S. Kitazawa², M. Fukagawa¹. ¹Division of Nephrology and Kidney Center, Kobe University School of Medicine, Kobe, Japan, ²Division of Molecular Pathology, Department of Biomedical Informatics, Kobe University School of Medicine, Kobe, Japan.

Diabetes mellitus is associated with increased risk of osteopenia and bone fracture. However, the mechanisms accounting for diabetic bone disorder still remain to be clarified. Moreover, there are few effective treatments for this disease. We have previously reported that streptozotocin-induced diabetic mice develop low turnover osteopenia associated with increased oxidative stress in diabetic condition (BONE 2007). Therefore, in order to determine the role of oxidative stress in the development of diabetic osteopenia, we investigated the effect of thioredoxin-1 (TRX) overexpression, a major intracellular antioxidant, on the development of diabetic osteopenia using TRX transgenic mice (TRX-Tg). TRX-Tg was C57BL/6 mice that carry the human TRX transgene under the control of β -actin promoter.

Eight-week-old male TRX-Tg and wild type littermates (WT) were intraperitoneally injected with either streptozotocin or vehicle alone. Mice were classified into four groups: 1) non-diabetic WT, 2) Non-diabetic TRX-Tg, 3) diabetic WT, and 4) diabetic TRX-Tg. After 12 weeks of streptozotocin treatment, the physical properties of femora, and the parameters of bone histomorphometry of tibiae were assessed. Oxidative stress in the whole body as well as in the bone was evaluated.

TRX overexpression did not affect either body weights or hemoglobin A1c levels both in the diabetic mice and in the non-diabetic mice. There were no significant differences in renal function, and serum levels of calcium, phosphate, and intact parathyroid hormone among four groups. Urinary excretion of 8-hydroxydeoxyguanosine (8-OHdG), a marker of oxidative DNA damage, was significantly elevated in diabetic WT, which was attenuated in diabetic TRX-Tg. Immunohistochemical staining for 8-OHdG was clearly intensified in the bone tissue of diabetic WT compared with non-diabetic WT. In contrast, staining was attenuated in diabetic TRX-Tg. TRX overexpression partially restored reduced bone mineral density and prevented the suppression of bone formation (OV/BV, OS/BS, Ob.S/BS, O.Th, MAR, and BFR/BS) observed in diabetic WT. These results suggest that increased oxidative stress in diabetic condition contributes to the development of diabetic osteopenia. Furthermore, our findings indicate that suppression of increased oxidative stress by TRX induction can be a therapeutic approach for treatment of diabetic osteopenia.

Time Sequence of Secondary Mineralization and Microhardness of Bone in an Ewe Model. Y. Bala*, D. Farlay*, C. Simi*, P. J. Meunier, P. D. Delmas, G. Boivin. INSERM Unité 831, Université de Lyon, Lyon, France.

The degree of mineralization is a major determinant of the mechanical resistance of bone (Follet et al. 2004, Bone 34:783-9). Mineralization begins by a rapid primary mineralization followed, after the full completion of the Basic Structural Units (BSUs), by a secondary mineralization phase, i.e., a slow and gradual maturation of the mineral component leading to complete mineralization of newly formed BSUs (Meunier & Boivin 1997, Bone 21:373-7). The duration of primary mineralization has been evaluated by several authors but the time sequence of secondary mineralization is still poorly investigated [Fuchs et al. 2005, J Bone Miner Res 20(Suppl.1):325]. Our aim was to determine the time course of secondary bone mineralization in ewe, an animal model having an Haversian bone tissue with a remodeling activity close to the Human one (Chavassieux et al. 1997, Bone 20:451-5). 18 ewes (4.5±0.4 years, INRA, Theix, France) received every six months for 30 months fluorescent labelings following the schedule: T0 double tetracycline, T6 single fluorescein, T12 triple tetracycline, T18 double fluorescein, T24 single tetracycline, T30 double alizarin labeling in order to date the age of the BSUs. Transiliac bone samples have been taken on each ewe after T18 and T30 labelings, then embedded in methyl methacrylate. Microradiography (Boivin & Meunier 2002, Calcif Tissue Int 70:503-11) performed on 100±1 µm-thick sections allowed the measurement of the focal Degree of Mineralization of Bone (DMB g/cm³) on 505 different BSUs in which the duration of the mineralization was precisely determined by labeling. Microhardness using a Vickers indenter under a load of 25g for 10s (Hv kg/mm²) was measured on 367 among the 505 BSUs [Bala et al. 2006, J Bone Miner Res 21(suppl.1):S332]. DMB measured at primary mineralization (0.76±0.10 g/cm³) significantly increased during the first 6 months (+26%, p<0.0001). Then, DMB increased more slowly until 30 months to reach a mean of 1.20±0.12 g/cm³. DMB measured at the end of the primary mineralization corresponded to 64% of the final mineralization. DMB after 6 and 12 months were 85% and 91% of the final DMB, respectively. Secondary mineralization is thus the fastest during the first year. Hv followed a similar trend, with a rapid increase during the first six months (+32%, p<0.0008), then a slow increase until 30 months. Hv and DMB are strongly and positively correlated (r²=0.52, p<0.0001). The time course of secondary mineralization can be divided into two parts having separated trends, a rapid increase during the first year then a slowdown of mineralization until 30 months. Mineralization explains a great part of the hardness of bone at BSU level.

Risedronate Reduces Osteonal Cortical Porosity in Osteoporotic Women. B. Borah*, T. Dufresne*, J. Nurte*, P. Chmielewski*, R. Phipps*, M. Lundy*, X. Zhou*, M. Bouxsein*, E. Seeman*. ¹Procter & Gamble Pharmaceuticals, Mason, OH, USA, ²Ortho Biomechanics Lab, Harvard Medical School, Boston, MA, USA, ³Austin Health, University of Melbourne, Melbourne, Australia.

Measurements of cortical porosity include 1) Haversian canals (diam. <50 µm), 2) the remodeling spaces of the osteons (diam. ~100 to 300 µm) in the intra-cortical envelope, and 3) larger cavities (diam. >380 µm) primarily in the endocortical envelope. In this study, we evaluated the effect of risedronate on cortical porosity in transiliac biopsies from osteoporotic women. Paired biopsies taken at baseline and after 5 years risedronate treatment (5 mg/day, n=28) or placebo (n=21) were imaged by micro-CT at 8 µm isotropic resolution. The cavities were then stratified by size, as determined by the minor axis length of the holes in the 2D slices. Porosity was averaged over 10 to 14 slices ~300 µm apart and was calculated as the area of cavities expressed as a percentage of the total cortical bone area. The porosity at baseline was not statistically different between placebo and risedronate for any pore size. Compared to baseline, 5 years treatment with risedronate caused a significant 15% reduction in porosity for cavities of ≤320 µm diameter (p<0.05, Figure), an effect likely to be the result of reduced osteonal remodeling. In the placebo group, porosity from cavities in this same size range increased by ~20% compared to baseline (not significant). The between group difference was significant or approached significance for cavities ≤320 µm diameter (p=0.01 - 0.06). The reduction of porosity by risedronate was not significant when cavities >400 µm were included. These larger cavities produce trabecularization of the inner cortex and cortical thinning. It appears that due to the variability of the age-related changes in the endocortical trabecularization, treatment-related reduction of porosity cannot be reliably assessed from measurements made throughout the cortex. These findings indicate that risedronate reduces cortical porosity by reducing the birth rate of new osteons or by filling in the remodeling spaces in osteons that existed prior to treatment.

LRP5 G171V Mutation Protects Against Disuse-Related Trabecular Bone Fragility. M. P. Akhter, D. M. Cullen, R. R. Recker. Medicine, Creighton University, Omaha, NE, USA.

Fragility fracture risk is greater in people with low bone mass or osteoporosis. In addition, a sedentary (disuse or lack of exercise) lifestyle choice may further deteriorate low bone mass associated with osteoporosis. We have shown (#F171 ASBMR-06) that disuse causes far greater loss in bone volume fraction (BV/TV) in the KO mice (67%) than in the HBM mice (14%). In this study, we characterized trabecular bone strength properties to determine if the LRP5 G171V mutation will protect against bone loss associated with disuse. Forty eight adult (4 mo.) male mice representing three genotypes (all bred to C57BL/6 mice): WT (Lrp5^{+/+}, wild type), KO (Lrp5^{-/-} knockout), HBM (High bone mass with LRP5 G171V mutation) were randomly divided between control and Disuse groups. The mice in the disuse group were hind limb suspended in individual cages for 4 weeks. All mice were inspected daily to assure compliance, adequate food intake, and general health. Femurs were collected and frozen in saline for biomechanical strength testing. A 1.26 mm diameter indenter was used to measure trabecular bone strength at the distal femur site (testing rate of 3mm/min, Instron 5543). We analyzed the data using the General Linear Model for univariate analysis to test for differences (P<0.05) due to disuse within each genotype. Trabecular bone strength declined in all the three genotypes (Table). Bone strength variables (ultimate load [ULT], yield load [YLD], stiffness [STIF]) were lower in the disuse group as compared to their controls within each genotype (HBM, WT, and KO). Disuse-related loss in strength (ULT) was 48%, 51% and 74% in HBM, WT and KO mice respectively. In addition, trabecular bone strength (ULT, YLD, STIF) in HBM mice remained elevated as compared to both WT and KO within each treatment group (Control & Disuse). Similar to trabecular bone structure data (reported previously), the already fragile KO has a large decrease in trabecular bone strength (74%), and the HBM losses were moderate with final bone strength remaining well above normal for the wild type mice. The mice with the LRP5 G171V mutation (HBM) did show a significant response to disuse demonstrating mechanosensitivity. However, the relative advantage in trabecular bone strength (ULT, YLD) between HBM and KO went from 10 fold in the control mice to 20 fold after disuse (Table). These data suggest that the HBM genotype (LRP5 G171V mutation) is relatively protected against disuse-related bone fragility.

(Mean ± SD)	Control			Disuse		
Indent test (distal femur)	HBM	WT	KO	HBM	WT	KO
ULT (N)	34.3 ± 7.5	5.1 ± 1.3 ^b	3.5 ± 0.7 ^b	17.7 ± 1.6 ^a	2.5 ± 0.7 ^{ab}	0.9 ± 0.3 ^{ab}
YLD (N)	24.3 ± 2.4	2.9 ± 0.9 ^b	2.3 ± 0.4 ^b	12.4 ± 1.8 ^a	1.8 ± 0.6 ^{ab}	0.6 ± 0.4 ^{ab}

Beta-Adrenergic Receptor Agonist Administration During Hindlimb Unloading Attenuates Losses in Bone Geometry, Structure, and Mechanical Properties. J. M. Swift*, J. T. Ali*, J. L. Stallone*, H. A. Hogan*, S. A. Bloomfield*. ¹Health and Kinesiology, Texas A&M University, College Station, TX, USA, ²Mechanical Engineering, Texas A&M University, College Station, TX, USA.

A major challenge to long-duration spaceflight is the significant bone loss that occurs in weightbearing limbs. The rodent hindlimb unloading (HU) model effectively simulates the deleterious effects of microgravity on the skeleton. In addition, HU results in significant declines in blood flow and increases in vascular resistance in unweighted hindlimb bone. Previously, we demonstrated that dobutamine (DOB), a beta-adrenergic receptor agonist (ADRB), given during simulated microgravity significantly blunts decreases in femoral

midshaft cortical bone area and polar moment of inertia (CSMI). The purpose of this study was to assess the effectiveness of DOB in attenuating HU-associated losses in tibiae and femora bone content, density, area, and strength during 28 days of unloading. Male Sprague-Dawley rats, aged 6-mo, were assigned to either a normal cage activity (CC) or HU group (n=24/group). Animals were given one daily bolus dose (4 mg/kg BW/d) of DOB (n=12) or an equal volume of saline (VEH; n=12). In vivo peripheral quantitative computed tomography (pQCT) scans were taken at the proximal tibia metaphysis (PTM) and tibial mid-diaphysis on anaesthetized animals on days 0 and 28 to reveal geometric and structural changes. Post-sacrifice, hindlimb bones were excised for determination of mechanical properties using an Instron 1125 device; ex vivo pQCT scans were performed at the femoral neck (FN) and mid-diaphysis. At the PTM, HU resulted in similar reductions in total bone mineral content (BMC) in animals treated with VEH (-17%) and DOB (-15%); however, reductions in total volumetric bone mineral density (vBMD) were only evident in HU+VEH (-9%). Total BMC, total area, and CSMI were significantly higher at FN in HU+DOB vs. HU+VEH (+18%, +23%, and +52%, respectively). Mechanical testing of FN revealed that HU+DOB exhibited a significantly higher ultimate load (+25%) as compared to HU+VEH. No significant changes in mid-diaphyseal tibia bone structure or area during HU were evidenced by in vivo pQCT scans, but 3-point bending to failure revealed a significantly higher ultimate load (+46%) in HU+DOB vs. HU+VEH. Ex vivo pQCT scans of mid-diaphyseal femora revealed significantly higher total BMC (+7%), total area (+5%), and CSMI (+10%) in DOB-treated rats subjected to 28-day HU vs. HU alone. These results suggest that DOB administration during HU prevents significant declines in total vBMD at PTM and produces a higher midshaft tibia ultimate load. We speculate that these positive effects may be attributed to ADRB-mediated vasodilation, improving blood flow to bone during unloading.

Attenuated Response to Skeletal Load in Connexin43 Deficient Mice. S. K. Grimston, M. D. Brodt*, M. J. Silva, R. Civitelli. Bone and Mineral Diseases, Washington University in St. Louis, St. Louis, MO, USA.

In vitro data suggest that connexin43 (Cx43) plays an important role in mechanotransduction. We reported that the anabolic response to parathyroid hormone is attenuated in mice with conditional ablation of the Cx43 gene (Gja1) in osteoblasts, obtained using a Cx43^{fllox}/LacZ gene replacement model and a 2.1 kb fragment of the $\alpha_1(I)$ collagen promoter to drive Cre (ColCre;Cx43^{fllox}). We tested the hypothesis that the anabolic response of the skeleton to mechanical loading is also dependent on Cx43. Four-month-old female mice were anesthetized and subjected to an in vivo 3-point bending protocol on the tibia, 5 days a week for 2 weeks. ColCre;Gja1^{fllox} mice had significantly greater marrow area, total tissue area, and thinner cortices than wild type equivalent Gja1^{fllox} mice. However, area moment of inertia was similar (0.130±0.059 versus 0.128±0.054 mm⁴, respectively), suggestive of adaptive responses similar to aging bone in Gja1 deficient mice. In Gja1^{fllox} mice, the loading regimen produced abundant new bone formation at the endocortical surface, as evidenced by double calcein labeling (injected ip on days 5 and 12), proportional to the estimated strain applied (1600 $\mu\epsilon$), with maximal effects at the apex (tension) and on the lateral aspect (compression) (arrows and arrowhead in Fig. 1, respectively). Conversely, there were predominantly single labels in ColCre;Gja1^{fllox} mice (Fig. 2). Accordingly, mineral apposition rate (MAR) and bone formation rate were significantly lower (p<0.05) in ColCre;Gja1^{fllox} (1.02±0.97 $\mu\text{m}/\text{day}$; 83.5±84.12 $\mu\text{m}^3/\mu\text{m}^2/\text{yr}$) relative to Gja1^{fllox} mice (1.86±0.65 $\mu\text{m}/\text{day}$; 192.23±89.5 $\mu\text{m}^3/\mu\text{m}^2/\text{yr}$), with heterozygous Gja1^{fllox} mice showing intermediate values (1.86±0.94 $\mu\text{m}/\text{day}$; 150.54±120.89 $\mu\text{m}^3/\mu\text{m}^2/\text{yr}$). Relative to the unloaded contralateral leg, MAR increased in the loaded leg by 67±16% (p<0.01) in Gja1^{fllox} mice, and 19±22% (n.s.) in ColCre;Gja1^{fllox} mice. Loading also stimulated the formation of periosteal woven bone on the surface subject to pressure, and this was also less evident in the conditionally ablated ColCre;Gja1^{fllox} (22.7±4.4%) relative to Gja1^{fllox} mice (31.3±13.1%; p<0.05). Thus, deletion of Gja1 prevents full anabolic response to in vivo skeletal physical loading. Cx43 is critical for bone's rapid adaptive response to mechanical stimuli.

The Lrp5 Gain of Function Mutation Is Associated with an Increased Osteogenic Response to Loading in Trabecular as well as Cortical Bone in Female but not Male Mice. L. K. Saxon, T. Sugiyama, J. Price, L. E. Lanyon. Veterinary Basic Sciences, Royal Veterinary College, London, United Kingdom.

The Lrp5 gain of function G171V mutation (Lrp5⁺) is associated with increased sensitivity to mechanical loading in cortical bone [1], however it is not known if the same occurs in trabecular bone. We therefore used our mouse tibial loading model [2] to investigate the effect of loading on trabecular and cortical bone in male and female Lrp5⁺ mice.

The right tibiae of 17-week-old male (n=6) and female (n=7) Lrp5⁺ and WT mice were subjected to a short period of dynamic axial loading for 40 cycles/day, 10 Hz, 3 days a week for 2 weeks. Strain gauges bonded to the medial mid-shaft were used to determine the magnitude of the load required to apply similar strains within each group. Differences in trabecular bone volume (BV/TV), number (Tb.N), thickness (Tb.Th), total bone area (TA), cortical area (CA), periosteal perimeter (Pp), endocortical perimeter (Ep), moment of inertia (MMI), and cortical thickness (C.Th) in the loaded (right) versus non-loaded (left) tibia were measured using microCT.

In male Lrp5⁺ mice all measured parameters in control bones were higher than in WT except C.Th (p<0.001). To engender 850 $\mu\epsilon$ a 19.8N load was applied to Lrp5⁺ and 10.5N to WT. In WT males loading increased Pp, CA, MMI, Tb.Th (p<0.05) whilst in Lrp5⁺ mice loading only increased C.Th (p<0.05); all other measures showed no loading-related difference. The magnitude of loading-related change between Lrp5⁺ and WT mice was only different for periosteal perimeter (3.9 vs -1.3%, p<0.001).

In female Lrp5⁺ mice all measured parameters were also higher than in WT (p<0.001). A load of 19.8N applied to the tibia of Lrp5⁺ mice and 9N to WT mice induced 1100 $\mu\epsilon$. All loaded WT tibiae showed gains in Pp, CA, MMI (p<0.05), and all parameters increased except Tb.N in Lrp5⁺ mice (p<0.05). In cortical bone the magnitude of the loading response was higher in the Lrp5⁺ mice compared with WT (TA 10.1 vs 1.2%, CA 17.7 vs 1.2%; Pp 5.5 vs -3.1%; Ep 10.4 vs -2.4%; MMI 21.7 vs -3.0%; C.Th 9.1 vs 4.1%, p<0.05). The gains in BV/TV were also greater in Lrp5⁺ mice. This was due to increased trabecular thickness not number (BV/TV 16.8 vs 5.6%; Tb.Th 17.5 vs 2.7%, p<0.05; Tb.N -0.5 vs 3.1%).

In conclusion, the G171V mutation results in a more robust bone phenotype in male mice. However, at the strain levels we used there was no difference from WT in their osteogenic response to loading in trabecular bone, and only a small difference in cortical bone. By contrast, in females the G171V mutation results in both a more robust bone phenotype and increased sensitivity to loading in trabecular and cortical bone.

Bone Adaptation to Impact Loading - Significance of Loading Intensity. A. Vainionpää*, R. Korpelainen*, J. Leppälou*, T. Jämsä*. ¹Department of Medical Technology, University of Oulu, Oulu, Finland, ²Department of Sports Medicine, Oulu Deaconess Institute, Oulu, Finland, ³Department of Physiology, University of Oulu, Oulu, Finland.

It is important to find efficient strategies for prevention of osteoporosis and fragility fractures as the prevention with medication is impossible at the population level. Exercise is one of the major prevention strategies even though the optimal loading patterns of bone have not yet been clearly defined in terms of bone loading forces in clinical settings. Our aim was to study the effects of impact loading on bone and assess the intensity and amount of efficient impact loading.

We conducted a 12 month population-based exercise intervention in 120 premenopausal women aged 35 to 40 years. The women were randomized equally to exercise (EG) and control groups (CG). The exercise regimen consisted of supervised, progressive high-impact exercises three times per week and an additional home program. Bone mineral density (BMD) in the proximal femur was measured by dual x-ray absorptiometry and bone geometry in the mid-femur was quantified by computed tomography (QCT). Also bone turnover was examined by using biochemical markers (TRACP-5b, PINP and Uncoupling Index). Daily impact loading was continuously recorded with a novel accelerometer-based measurement device and analyzed as the daily number of impacts within five acceleration ranges between 0.3 g to 9.2 g (g=acceleration of gravity, 9.81 m/s²).

Regular impact exercise increased the femoral neck BMD by 1.5 % (p=0.003) and led to geometric adaptations by increasing the mid-femur periosteal circumference by 0.2 % (p=0.03) when compared to controls. It also altered bone turnover balance in favour of bone formation. The women with the highest number of impacts at the intensity level above 4 g had the greatest increment in proximal femur BMD. The number of impacts needed exceeding this level was 60 impacts per day. Impacts exceeding 2.5 g were associated with increased periosteal circumference and enhanced bone turnover favouring bone formation.

According to our results, impact loading has significant dose- and intensity dependent effect on weight-bearing bones. The threshold for improving BMD in the hip is 60 impacts per day exceeding 4 g, while geometric adaptation and bone turnover activation can be achieved with lower intensity levels. Impacts required for osteogenic effects can be obtained during habitual exercise training. These thresholds for osteogenic exercise give tools to promote efficient exercise patterns to be included in everyday routines and personal activities, thus increasing the potential to affect in community level.

Gene Polymorphisms, Bone Mineral Density and Bone Mineral Content in Children: The Iowa Bone Development Study. M. C. Willing¹, T. L. Burns², J. C. Torner², E. Letuchy², S. Santiago-Parton¹, K. F. Janz³, T. Marshall⁴, J. M. E. Gilmore⁴, J. J. Warren⁴, S. M. Levy⁴. ¹Pediatrics, University of Iowa Carver College of Medicine, Iowa City, IA, USA, ²Epidemiology, College of Public Health, Iowa City, IA, USA, ³Health and Sports Studies, College of Liberal Arts, Iowa City, IA, USA, ⁴Preventive and Community Dentistry, College of Dentistry, Iowa City, IA, USA.

We examined associations of candidate gene polymorphisms with bone mineral density (BMD) and content (BMC) in a cohort of 412 healthy non-Hispanic white children participating in the Iowa Bone Development Study. Whole body (WB), hip and spine BMD and BMC were determined using a Hologic QDR 4500a densitometer for 213 girls and 199 boys age ~11 years. Candidate genes included the type I collagen genes (COL1A1 and COL1A2), osteocalcin, osteonectin (SPARC), osteopontin, vitamin D receptor (VDR), estrogen receptor (ER), androgen receptor (AR), IGF-1, IGF-2, PTR, PTHR and LRP5. Gender-combined and gender-specific prediction models for bone measures that included age, weight, height, dichotomous Tanner stage (and gender) were developed using multiple linear regression analysis and residuals were calculated. COL1A2 genotype (identified by one or more of the following: RsaI, Intron 12 VNTR, 5'(CA)_n-CGCACA(CG)_m(CA)_nGT_x3') was found to have the strongest and most consistent association with adjusted BMD/BMC measures. When stratified by gender, COL1A2 genotype was associated with WB BMC, spine BMC, and hip BMD in both boys and girls, as well as with hip BMC in girls. IGF-2 (6815 A/T), osteocalcin (C/T promoter), PTHRT3 (AAAG) and VDR (Bsm-I) genotypes were also associated with some bone measures in the combined analyses, but the associations differed by gender. In girls, osteocalcin and IGF-2 genotypes were associated with hip BMC and BMD and with WB BMC and hip BMD, respectively. PTHR genotype was associated with all bone measures except spine BMC in the combined analyses, but results only reached significance in girls. In contrast, VDR (Bsm-I) genotype was associated with hip BMD only in boys, and COL1A1 (RsaI) genotype was associated with spine BMD, hip BMC and BMD only in boys. Gender-specific quartiles of the BMD/BMC residuals were determined and an association analysis using the recursive partitioning technique represented by the nonparametric classification tree approach was used to identify candidate genotypes associated with high vs. low quartile status. Significant gene x gene interaction effects involving PTHR and each of the following: IGF-1, IGF-2, COL1A2, and osteonectin were identified for spine BMD, particularly in girls. Our data suggest that genetic variation at multiple genetic loci is important in bone accrual in children. Combinations of individual genotypes may also impact BMD and BMC.

Jump Starting Skeletal Health: Bone Increases from Jumping Exercise Persist Seven Years Post Intervention. K. B. Gunter¹, A. Baxter-Jones², R. Mirwald², H. C. Almstedt³, S. Durski¹, A. A. Fuller-Hayes¹, C. M. Snow¹. ¹Department of Nutrition and Exercise Sciences, Oregon State University, Corvallis, OR, USA, ²College of Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada, ³Department of Natural Science, Loyola Marymount University, Los Angeles, CA, USA.

Evidence suggests that bone mineral increases attributable to exercise training prior to puberty may confer a significant advantage into adulthood. However, there is a dearth of supportive prospective longitudinal data. We assessed the change in bone mineral content (BMC) at the left proximal femur over eight years in children who participated in a seven-month jumping intervention and who were pre-pubertal at study onset. We hypothesized that jumpers would accrue and retain more BMC compared to controls and therefore be at a considerable advantage in optimizing peak bone mass accrual. Subjects were drawn from the BUGSY study (Building Growing Skeletons in Youth), an ongoing mixed longitudinal study of bone mineral accretion in growing children initiated in the fall of 1997. Participants were recruited from local elementary schools in Corvallis, Oregon and were randomly assigned within classrooms to either an intervention (jumping) or control (stretching) group. Subjects were assessed at baseline, at the end of the intervention (7 months) and at approximately 19 months. Participants were reassessed at 31, 43, 55, 67, 79 and 91 months from study entry for a total of nine measurement occasions over approximately 8 years. Bone mineral content was assessed by dual-energy X-ray absorptiometry. Multi-level random effects models were constructed and used to predict change from study entry in BMC at each measurement occasion. We were able to utilize data from a total of 421 DXA scans on 57 individuals who were measured on 3 or more occasions. At 7 months, the intervention group had 3.6% more total hip bone accrual than the non-intervention group ($p < 0.05$), once the effects of change in age, height and weight were accounted for. The effects of the intervention, in terms of percentage contribution to A total hip BMC, decreased at each measurement occasion thereafter. After an average of 7.6 years, the intervention group had 1.4% more total hip bone accrual than the non-intervention group, once the effects of change in age, height and weight were accounted for ($p < 0.05$). This provides the first evidence that changes in BMC attributable to short-term exercise undertaken prior to puberty persist more than 7 years following exercise cessation in growing children. If the benefits are sustained into adulthood, effectively increasing peak bone mass, this could have substantial effects on fracture risk.

Regular Physical Activity Has Only Temporary Effect on Bone Gain in Pubertal Girls: A 6.5 Year Follow-up Study. E. Völgyi¹, F. A. Tylavsky², H. Suominen¹, S. M. Cheng¹, A. Lyytikäinen¹, M. Alén¹, U. M. Kujala¹, H. Kröger³, S. Cheng¹. ¹Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland, ²Health Science Center; Preventive Medicine, University of Tennessee, Memphis, TN, USA, ³Department of Surgery, Kuopio University Hospital, Kuopio, Finland.

The effects of exercise on bone gain in early puberty have been proven in many different short intervention studies. Whether effects found in early puberty can be sustained until early adulthood in children who are not in athletic training is still debatable. The purpose of this study is to evaluate the relationship between physical activity and bone gain in girls and the relationship with their mothers' physical activity level and bone characteristics. The study subjects consisted of 258 10-13-year old girls with maturation status of I-III at the baseline. They were followed on average of 6.5 years and their results reflect the entire follow-up period. In addition, a group of these girls' mothers ($n=108$, mean age 44yrs) had measurement twice within a 3.5 year interval. Bone area (BA), mineral content (BMC) and density (BMD) of the total femur (TF), femoral neck (FN), and lumbar spine (L2-L4) were assessed by DXA (Prodigy, GE Lunar). The level of leisure time physical activity (PA) was assessed by questionnaire. We only compared those with consistently low (LPA, < 2 times & hours/wk, $n=92$ 0mo, $n=65$ 12mo, $n=92$ 24mo, $n=25$ 36mo, $n=26$ 84mo), to those consistently high (HPA, > 4 times & hours/wk, $n=101$ 0mo, $n=71$ 12mo, $n=71$ 24mo, $n=22$ 36mo, $n=26$ 84mo) PA groups at each measurement point. No differences were found in age, relative weight and height, and in Tanner stage between the HPA and LPA groups in girls through-out the follow-up. Those girls in the HPA group had higher BMC ($p=0.017$, t-test) of the FN at 24mo, and BMD of the FN at 0mo ($p=0.033$), 12mo ($p=0.01$) and 24mo ($p=0.029$) than that of the LPA group. There were no differences in BA from any of the bone sites between PA groups at any follow-up time point. By age 17.9 years the differences in BMC and BMD of FN, TF or L2-4 between the HPA and LPA had vanished. When we compared the girl's PA with the mother's PA (paired), we found PA levels were associated only at baseline but not in other time points. The agreement between mothers and daughters for LPA was 71% and for HPA was 56% ($p=0.043$, χ^2 analysis). They reached the mean value of the mothers ($n=108$ at 36mo) only in FN BMD ($p>0.05$). There were no differences in FN BMC, TF BMD, L2-4 BMD, FN BA and L2-4 BA ($p>0.05$). Daughters had lower TF BMC ($p=0.001$), TF BA ($p<0.001$) and L2-4 BMC ($p<0.001$) compared to mothers. Our results indicate that the higher BMC and BMD value due to HPA during puberty may be temporary or participating physical activity more than 4 times and 4 hours a week was not sufficient to impact on bone gain.

Bone Density at Age of Peak Bone Mass in Women Is Not Associated with History of Childhood Fractures. S. M. Ott¹, A. Z. LaCroix², L. E. Ichikawa³, L. Spangler¹, D. Scholes⁴. ¹U of WA, Seattle, WA, USA, ²U of WA and Fred Hutchinson, Seattle, WA, USA, ³Group Health, Seattle, WA, USA, ⁴U of WA and Group Health, Seattle, WA, USA.

A recent large study of ten-year-old children found that low bone mineral density (BMD) predicted fracture incidence. Peak bone mass is attained during late teenage years at the hip and in the mid-twenties at the spine. Whether childhood fractures are related to the bone density during adolescence or young adulthood has not been as well studied. We therefore examined this in a cross-sectional study of 606 adolescents and young women aged 14-30 years. Members of Group Health, a Washington State HMO, were selected from the health plan computerized databases based on prescriptions for oral contraceptive use and age. We mailed letters of invitation to participate in a study of bone health. BMD (DEXA) was measured at the hip, spine, and whole body. Data on previous fractures and other factors related to bone health were collected via interview and a written questionnaire. Potential subjects with severe health problems, known metabolic bone disease, recent pregnancy, or use of prednisone or progesterone-only birth control methods were excluded. Overall, 51% of the cohort was 14-18 years of age. 206 of 606 subjects (34%) reported at least one fracture; there were a total of 336 fractures. Most common sites were ankle, wrist and toe. Fractures were most common at age 11 when 4.2% of the subjects experiences their first fracture. Ninety percent of the fractures occurred before age 17. The fracture history differed by racial background: 9% of Black subjects, 11% of Asian and 39% of Whites and other races reported history of fracture. Previous fractures occurred in 32% of subjects who were currently underweight and 40% of those who were currently obese; 41% who had weight loss greater than ten pounds in the past; in 46% of subjects with asthma, in 33% of those with menarche older than age 13, and in 43% of those who had a relative with a history of fractures.

The BMD was not lower at the hip, spine, or whole body in the adolescents or young women who had a history of fracture: total hip BMD was .993 g/cm² in those with a fracture history vs .986 in those without; at the spine the results were 1.023 vs 1.019 and at the whole body 1.103 vs 1.096, respectively. Similar findings were seen in teens as in young adults, with slightly higher bone density in the fracture cases at all three measurement sites. Adjusting for age, race, BMI, calcium intake, physical activity, and current smoking status did not alter the findings. Our data show that history of fracture is common, reported in about a third of otherwise healthy young women. At the age of peak bone mass women in this study with childhood fractures did not have lower bone density than those without fractures.

PTHrP Induces Mitogen-Activated Protein Kinase Phosphatase-1 in Differentiated Bone Marrow Stromal Cells, Mouse Osteoblast and Cementoblast Cell Lines. N. S. Datta, R. Kolailat*, G. Pettway*, J. Berry*, L. K. McCauley. Periodontics and Oral Medicine, University of Michigan, Ann Arbor, MI, USA.

This study investigated the signaling mechanisms of Parathyroid hormone (PTH) and PTH related protein (PTHrP) during osteogenic cell proliferation and differentiation. Mitogen-activated protein kinases (MAPKs) play a critical role in this process. In order to understand the up-stream signaling pathways, the role of MAP kinase phosphatase-1 (MKP-1) in regulating MAPKs, cyclin D1 and osteoblast cell growth arrest were studied. Analysis of MAPK activity revealed down-regulation of cyclin D1 (5-10 fold), p38 and ERK1/2 phosphorylation after PTHrP stimulation in differentiated mouse MC3T3-E1 osteoblasts. Interestingly, MKP-1 was induced concurrently with the attenuation of p38 and ERK1/2 phosphorylation. Real-time PCR and western blot analysis revealed 4-8 fold increase in MKP-1 expression following PTHrP stimulation (15 min to 4h) compared to vehicle controls in differentiated osteoblasts. Using different pharmacological inhibitors and activators of cAMP/PKA and PKC pathways both cAMP and PKC were implicated in the PTHrP regulation of MKP-1. MKP-1 expression was also induced in differentiated primary bone marrow stromal cells (BMSCs) and OCCM cementoblast cells (tooth root lining cells phenotypically similar to osteoblasts). Microarray analysis of ectopic ossicles (implanted BMSCs) generated in mice, demonstrated down-regulation of MKP-1 in less differentiated ossicles following acute injection of PTH. In contrast, there was an increase in MKP-1 expression by real-time PCR following three weeks of anabolic PTH treatment in more differentiated ossicles. These findings highlight MKP-1 as a potential regulator of the PTH and PTHrP response in osteoblasts and may be an important target gene in the anabolic action of PTH in bone.

Odd-Skipped Related 2 Functions in Cell Proliferation. S. Kawai, M. Yamauchi*, A. Amano*. Department of Oral Frontier Biology, Osaka University Graduate School of Dentistry, Suita-Osaka, Japan.

The drosophila pair-rule gene Odd-skipped encodes a zinc finger transcription factor required for accurate segment formation in the drosophila embryonic development. Mammalian homologues, Odd-skipped related 1 (Osr1) and Osr2, were expressed in limb, branchial arches, kidney, eye, and dermis. Osr2 is known to play a critical role in the secondary palate development. We previously reported the function of Osr2 in the bone using transgenic mice. In this study, we analyzed more detailed functional role of Osr2. Osr2 was found to be highly expressed in multipotent mesenchymal C3H10T1/2 cells. The expression level of Osr2 by C3H10T1/2 cells was examined under various culture condition. Osr2 expression remarkably increased by the serum starvation along the growth arrest, whereas, the expression decreased promptly by the serum re-addition. Next, the DNA methylation of Osr2 promoter was analyzed with the sodium bisulfite sequencing method, and histone acetylation on Osr2 promoter was also analyzed with the chromatin immunoprecipitation. The expression of Osr2 in the serum starvation, the confluent growth arrest, and the serum re-addition was found to be regulated by DNA methylation in the Osr2 promoter as well as by the histone acetylation. Moreover, Osr2 was observed to be localized in the cellular nuclear euchromatin with the confocal laser scanning microscope. Osr2 was participated in the maintenance at the G0 state that corresponded in the quiescent state at the cell cycle by the flow cytometry. These findings indicate that Osr2 play an important role in cell proliferation, especially in G0 regulation which is thought the entrance of the osteoblastic cell differentiation.

Grx5 Regulates Osteoblast Cell Functions by Protecting Against Oxidative Stress. G. R. Linares, W. Xing, K. E. Govoni, T. T. Nguyen*, S. Chen*, S. Mohan. JLP VAMC and LLU, Loma Linda, CA, USA.

There is now increasing evidence which suggest an important role for reactive oxygen species (ROS) in a variety of pathological situations including osteoporosis. However, little is known on the molecular components of the oxidative stress pathway or their functions in bone. Based on our recent findings that the newly identified member of glutaredoxin (Grx) family, Grx5, is highly expressed in bone and induced by growth hormone and the published findings that Grx5 protects yeast against oxidative stress, we proposed the hypothesis that Grx5 protects osteoblasts (Obs) from oxidative stress. We

found that treatment of MC3T3-E1 Obs with CdCl₂, an inhibitor of Grx activity, increased apoptosis in a dose dependent manner with a 2.5 fold increase ($P < 0.001$) at 1 μ M dose. To verify that the CdCl₂ effects on Ob apoptosis is caused by inhibition of Grx5 activity, we treated MC3T3-E1 Obs with Grx5 siRNA or control siRNA and evaluated effects on apoptosis. Grx5 expression decreased ($P < 0.01$) 80 and 40% at 24 & 72 hrs, respectively, after treatment with Grx5 siRNA. In contrast, neither Grx1 nor Grx2 expression was altered by Grx5 siRNA treatment. Grx5 siRNA treatment decreased osteocalcin expression by 50% ($P < 0.01$) and increased apoptosis by 40% ($P < 0.01$) as determined by DNA fragmentation assay. To identify the molecular pathway by which Grx5 regulates Ob functions, we tested based on findings in yeast that Grx5 deficiency results in impaired biogenesis of Fe-S cluster, a critical co-factor for a large number of regulatory proteins. Accordingly, mitochondrial aconitase activity, which is dependent on Fe-S cluster, was decreased by 37% ($P < 0.01$) in Grx5 siRNA treated cells. Since reduced formation of Fe-S cluster would lead to increased level of free iron, a competitive inhibitor of Mn-SOD (a key mitochondrial enzyme that scavenges ROS) we measured MnSOD activity in Grx5 deficient Obs. Mn-SOD activity was significantly reduced in Grx5 siRNA treated cells (0.89 ± 0.11 vs. 2.04 ± 0.05 U/mg protein; $P < 0.001$). Because estradiol treatment has been shown to protect Obs against oxidative stress and increase Grx5 expression (1.5 fold, $P < 0.05$), we evaluated the consequence of Grx5 overexpression on Obs. We found that Grx5 overexpression using retroviral vectors protected MC3T3-E1 cells against H₂O₂-induced apoptosis and formation of ROS (50 & 40% reduction; $P < 0.01$). Furthermore, Grx5 overexpression increased mineralized nodule formation in MC3T3-E1 cells (23% increase; $P < 0.01$). Our findings are consistent with the hypothesis that Grx5 is an important determinant of Ob cell functions and acts via a molecular pathway that involves regulation of Fe-S cluster formation, Mn-SOD activity, and ROS generation.

ROS Expression in Osteoblasts of NOS1, 2 and 3 Knock Out Mice. H. Watanabe, Y. Sugawara, T. Yanagisawa*. Ultrastructural Science, Tokyo Dental College, Chibacity, CHIBA, Japan.

Oxygen is converted to reactive oxygen species (ROS) and nitric oxide (NO) with high reactivity, and reacted with proteins and genes, affecting cell metabolism and intracellular transport. Bone tissues are readily affected by the gas environment, but reports on the effects of the gas environment on osteoblasts have been rare. In this study, we examined the protein levels of various NO and ROS synthetases (NOX) in normal mice and NOS1 (n-NOS), NOS2 (i-NOS), and NOS3 (e-NOS) knock-out (KO) mice, and evaluated the interrelationships among various NO and ROS synthetases. After 5-week-old normal mice and NOS1, 2, and 3 KO mice were anesthetized, immunohistochemical evaluations were performed using NOXO, NOXA, NOX4, and NQO antibodies. In osteoblasts of the control mice, the NOXO, NOXA, and NQO expression was negative, but NOX4 expression was weakly positive. Both NOXO and NOXA were expressed in NOS2 and NOS3 KO mice, also suggesting the expression of NOX1. Furthermore, since the expression of NOX4 and NQO were strongly positive in NOS2 and NOS3 KO mice, the presence or absence of i-NOS and e-NOS is considered to be involved in the generation of ROS in osteoblasts.

Rapamycin Inhibits Osteoblast Proliferation and Differentiation in MC3T3-E1 Cells and Primary Mouse Bone Marrow Stromal Cells. U. K. Singha*¹, Y. Jiang*², S. Yu*¹, M. Luo*¹, Y. Lu*¹, J. Zhang*¹, G. D. Roodman*¹, G. Xiao*¹. ¹Medicine, University of Pittsburgh, Pittsburgh, PA, USA, ²Pharmacology, University of Pittsburgh, Pittsburgh, PA, USA.

While the roles of the mammalian target of rapamycin (mTOR) signaling in regulation of cell growth, proliferation, and survival have been well documented in various cell types, its actions in osteoblasts are poorly understood. In this study, we determined the effects of rapamycin, a specific inhibitor of mTOR, on osteoblast proliferation and differentiation using MC3T3-E1 preosteoblastic cells (MC-4) and primary mouse bone marrow stromal cells (BMSCs). Rapamycin significantly inhibited proliferation in both MC-4 cells and BMSCs at a concentration as low as 0.1 nM. Western blot analysis shows that rapamycin treatment markedly reduced levels of cyclin A and D1 protein in both cell types. In differentiating osteoblasts, rapamycin dramatically reduced osteoblast-specific osteocalcin (Ocn), bone sialoprotein (Bsp), and osterix (Osx) mRNA expression, ALP activity, and mineralization capacity. However, the drug treatment had no effect on these parameters when the cells were completely differentiated. Importantly, rapamycin markedly reduced levels of Runx2 protein in both proliferating and differentiating but not differentiated osteoblasts. Finally, overexpression of S6K in COS-7 cells significantly increased levels of Runx2 protein and Runx2 activity. Taken together, our studies demonstrate that mTOR signaling affects osteoblast functions by targeting osteoblast proliferation and the early stage of osteoblast differentiation.

Effects of Traumatic Brain Injury on Bone Formation/Remodeling During Fracture Healing in a Rat Model. I. Arango-Hisijara¹, E. R. Kulick^{*2}, S. Rehman^{*3}, M. B. Elliott^{*4}, M. F. Barbe⁴, R. F. Tuma^{*2}, F. F. Safadi¹, S. N. Popoff¹, W. G. DeLong³. ¹Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA, ²Physiology, Temple University School of Medicine, Philadelphia, PA, USA, ³Orthopaedic Surgery and Sports Medicine, Temple University Hospital, Philadelphia, PA, USA, ⁴Physical Therapy, Temple University, Philadelphia, PA, USA.

Previous studies have established that traumatic brain injury can enhance the process of fracture healing. In this study, we examined the effects of traumatic brain injury on bone formation in the fracture callus and on circulating factors that can influence bone remodeling and/or angiogenesis. Ten week old Male Sprague-Dawley rats were separated into four groups: 1) Control; 2) Standard closed femoral fracture (Fx); 3) Low impact traumatic brain injury combined with Fx (LiHtx/Fx); 4) High impact traumatic brain injury combined with Fx (HiHtx/Fx). Rats were injected with calcein at 5 and 2 days prior to being euthanized at 2 weeks post-treatment. Histological analysis of the brains stained with cresyl violet confirmed diffuse axonal injury in both Htx groups; The HiHtx group displayed more axonal injury and neuronal apoptosis compared to the LiHtx group. Radiographic examination of the fracture callus demonstrated greater bony consolidation in the brain injured LiHtx/Fx and HiHtx/Fx compared to Fx rats. Histological analysis of the fracture callus demonstrated greater amounts of periosteal (intramembranous) and endochondral bone formation occurring in the brain injured LiHtx/Fx and HiHtx/Fx compared to Fx rats. Calcein labeling demonstrated a significant increase in bone formation rates in the brain injured rats, providing direct evidence that brain injury can increase bone formation at the fracture site. Serum osteocalcin was also measured with a significant increase in the LiHtx/Fx and HiHtx/Fx groups compared to the Fx group. Analysis of other circulating factors revealed significant increases in TGFβ1, MCP-1, TNFα, IL-1β, IL-6, and leptin levels in the LiHtx/Fx and HiHtx/Fx groups compared to the Fx group. TNFα, IL-1β and IL-6 are osteoclastogenic factors suggesting that remodeling of the fracture callus occurs earlier in the brain injured LiHtx/Fx and HiHtx/Fx compared to Fx rats. High levels of TGFβ1 and MCP-1 could stimulate proliferation of osteoprogenitor cells, and high levels of leptin have been shown to increase VEGF expression resulting in enhanced angiogenesis that is a requirement for accelerated fracture healing. In conclusion, traumatic brain injury accelerates bone formation and remodeling during fracture healing and changes in circulating levels of factors known to influence bone cell development/function may mediate, in part, the acceleration of fracture repair.

TWEAK Is a Regulator of Human Osteoblast Function. G. J. Atkins¹, C. Vincent^{*1}, K. J. Weldon^{*1}, D. R. Haynes^{*2}, C. Holding^{*2}, T. S. Zheng^{*3}, A. Evdokiou^{*1}, D. M. Findlay¹. ¹Discipline of Orthopaedics and Trauma, University of Adelaide, Adelaide, Australia, ²Discipline of Pathology, University of Adelaide, Adelaide, Australia, ³Biogen Idec Inc., Boston, MA, USA.

TNF-like weak inducer of apoptosis (TWEAK), a member of the TNF superfamily is pro-angiogenic, pro-inflammatory and proliferative for endothelial and other cell types. We recently showed that TWEAK is a novel mediator of mouse collagen-induced arthritis and have identified TWEAK expressing cells in human rheumatoid arthritis (RA) tissues. The aim of this work was to investigate a potential role for TWEAK in human bone remodeling.

Human primary osteoblasts (OB) were found, by flow cytometry, to express high levels of the TWEAK receptor, Fn14. OB also expressed abundant TWEAK mRNA. Treatment of OB with exogenous TWEAK was highly proliferative. TWEAK dose-dependently suppressed OCN mRNA expression and increased both the RANKL:GAPDH and the RANKL:OPG mRNA ratios. Time-course studies under mineralising conditions showed that TWEAK suppressed the osteogenesis-related genes OCN and BSP-1 early in cultures, corresponding with the period in which RANKL expression was increased. Whereas RANKL induction was transient (up to day 9), OCN, BSP-1 and type I collagen mRNA expression were inhibited throughout the mineralisation period (up to day 21). Consistent with this, continuous TWEAK exposure inhibited *in vitro* mineralisation by OB and induced the expression of sclerostin, which has been shown to inhibit bone formation via BMP/Wnt signalling. TWEAK stimulated mitogen-activated protein kinase (MAPK) activity in primary osteoblasts, inducing phosphorylation of ERK-1/2 and JNK, but not p38 MAPK. TWEAK had only a slight effect on NFκB signalling and did not invoke the Akt survival pathway. We also found that TWEAK significantly modifies the osteoblast response to TNFα, suggesting that in an inflammatory situation the outcome may vary, dependent on the relative amounts of these cytokines present. Our results suggest that TWEAK is a novel regulator of bone turnover and are consistent with a role for TWEAK in inflammatory bone loss pathologies, such as RA, where its persistent presence may be anti-anabolic.

Lysyl Oxidase Regulates Collagen Quality and Quantity in MC3T3-E1 Cell Culture System. P. Atsawasuwan^{*}, Y. Mochida, M. Yamauchi. Dental Research Center, University Of North Carolina at Chapel Hill, Chapel Hill, NC, USA.

Lysyl oxidase (LOX) is an amine oxidase critical in stabilizing collagen fibrils in tissues including bone. To obtain further insights into the function of this enzyme in osteoblastic cells, we established and characterized the MC3T3-E1 (MC) derived clones stably overexpressing LOX. MC cells were transfected with pcDNA3.1-V5/His containing coding sequence of mouse LOX and several stable clones expressing higher levels of LOX (S clones) were generated. The overexpression of LOX was verified by Western blot analysis with anti-V5 antibody and anti-LOX antibody. Five S clones and two control groups (MC cells and those transfected with an empty vector) were selected and analyzed. Based on MTS assay at day 1, 3 and 5 of culture, all S clones showed the proliferation rate comparable to that of controls. In another set of experiment, the clones and control cells were cultured in α-MEM in the presence of 10% fetal bovine serum, 2mM β-glycerophosphate and 50 μg/ml ascorbic acid for up to 4 weeks. At appropriate time points of culture, cell-matrices were analyzed for collagen content (week 0, 1) and cross-links (wk 2 and 4) by high performance liquid chromatography, fibrillogenesis (wk 3) by transmission electron microscopy and *in vitro* mineralization (wk 0, 1, 2, 3 and 4) by Alizarin-red S staining. The quantitative cross-link analysis revealed that two major cross-links (dihydroxylysinonorleucine and pyridinoline), the major aldehyde (hydroxyllysine aldehyde) and a total number of aldehydes (free + cross-linked) were significantly increased in S clones in comparison to controls demonstrating higher LOX activities in these clones. However, the collagen content in all S clones was significantly decreased. Consistent with this, the number and diameter of collagen fibrils in S clones were significantly fewer and smaller than those of controls. Furthermore, the onset of mineralization was markedly delayed in S clones. These findings indicate that LOX plays crucial roles not only in collagen stability but also in collagen synthesis. The latter function could be due in part to the ability of LOX to bind and modulate transforming growth factor β1 (TGF-β1) function as we have recently reported. These dual functions of LOX may have significant impact on matrix organization and mineralization in bone.

Calcitonin and Teriparatide for Vertebral Fracture Pain. A. Bazarra-Fernandez^{*}. ObGyn, Juan Canalejo University Hospital, La Corunna, Spain.

Background: Fractures, especially vertebral fractures, are a common complication of osteoporosis, leading to significant pain.

Aim: To compare the pain release induced by osteoporotic vertebral fracture, through teriparatide and teriparatide plus calcitonine.

Methods: We performed a study to compare the analgesic effect of 20 mcg teriparatide versus 20 mcg teriparatide plus metered dose intranasal spray 200IU/activation calcitonin in two groups between postmenopausal women undergoing osteoporosis with vertebral fracture. A 10-point visual analog pain scale (1 = least to 10 = most painful) and a four-point pain grade (grade 1 = least to grade 4 = most painful) were used to measure the pain perception.

Results: The mean pain scores for the teriparatide and teriparatide plus calcitonin were 2.3 ± 1.1 and 8.5 ± 1.1 , respectively ($P < 0.05$), while the pain grades for teriparatide and teriparatide plus calcitonin were 1.5 ± 0.3 and 3.5 ± 0.4 , respectively ($P < 0.05$). In teriparatide group, analgesics were requested, but in teriparatide plus calcitonin group no analgesics were requested ($P < 0.001$).

Conclusion: Using teriparatide is more expensive than other osteoporosis treatment. Studies show that taking a bisphosphonate with hormone replacement therapy (HRT), results in increased bone mass when compared to taking either a bisphosphonate or estrogen alone. Besides, calcitonin is better for osteoporotic vertebral fracture pain release than HRT. However, a larger investigation will be needed to achieve more significant case number.

Osteoblasts from Serotonin Transporter Knockout Mice Display Reduced Growth and Mineralization Capacity. M. M. Bliziotis, K. M. Wiren. Medicine, Oregon Health and Science University/pvanc, Portland, OR, USA.

Recent studies in bone have demonstrated the presence of functional pathways for both responding to and regulating the uptake of serotonin (5-HT). This is of high clinical importance given the role of the serotonergic system in affective disorders, and the wide use of pharmacologic agents that target the 5-HT system to manage these disorders. In addition to the presence of 5-HT receptors, osteoblasts, osteoclasts and osteocytes all possess the serotonin transporter (5-HTT). Binding and uptake studies have demonstrated the 5-HTT in osteoblastic and osteocytic cells to be functional and highly specific for 5-HT uptake. Immunohistochemistry of sections of whole bone from rat tibia demonstrated the

in situ expression of 5-HT receptors and the 5-HTT in osteoblasts and osteocytes. Additional evidence for a role of 5-HT signaling in the growing skeleton was more recently provided by animal studies. Using two differing animal models, Warden et al. (Endocrinology 2005) found that mice with a life-long null mutation of the gene encoding for the 5-HTT displayed a consistent skeletal phenotype of reduced mass, altered architecture, and inferior mechanical properties. This finding was confirmed in a second model wherein inhibition of the 5-HTT using a SSRI resulted in reduced bone mineral accrual during growth. In both models, the skeletal phenotype resulted from a reduction in bone formation indicating an osteoblastic defect.

We have investigated the phenotype of osteoblastic cells from 5-HTT knockout mice in vitro. Calvaria from wild type and 5-HTT^{-/-} neonatal mice were isolated and osteoblast populations derived with serial collagenase digestion. Cell growth curves, alkaline phosphatase expression and mineralization capacity (as assessed by alizarin red staining of osteoblast cultures) were assessed.

Cells from 5-HTT^{-/-} mice demonstrated reduced growth capacity in the first week of culture, with approximately 30-60% reduction in growth as assessed by cell counts. Alkaline phosphatase activity was also reduced by 20% in the 5-HTT^{-/-} cells at day 14 of culture. Finally, mineralization capacity was reduced by 20% at day 23 in culture in the 5-HTT^{-/-} cells.

We conclude that the reduced bone formation rates and osteopenia observed in young 5-HTT^{-/-} mice is due, at least in part, to a cell autonomous defect in osteoblasts which results in reduced cell growth, alkaline phosphatase activity and mineralization capacity. The mechanism whereby this defect is expressed is unknown. Given the widespread use of drugs that target the 5-HTT, elucidation of the effects of disruption of this transporter on bone is of major clinical significance.

Strontium Ranelate Effects in Human Osteoblasts Support its Uncoupling Effect on Bone Formation and Bone Resorption. T. C. Brennan^{*1}, M. S. Rybchyn^{*1}, P. Halbout^{*2}, A. D. Conigrave^{*3}, R. Mason^{*1}. ¹School of Medical Sciences (Physiology) and Bosch Institute, University of Sydney, Sydney, Australia, ²Rheumatology, Institut de Recherches Internationales Servier, Courbevoie, France, ³School of Molecular and Microbial Biosciences, University of Sydney, Sydney, Australia.

Strontium ranelate reduces the risk of vertebral and hip fractures in post-menopausal women. Previous studies have shown that strontium ranelate increases bone formation and decreases bone resorption. In the current study, we investigated the uncoupling effect of strontium ranelate in primary human osteoblasts (HOB). For this, we assessed the strontium ranelate effects on indirect markers of bone formation (HOB proliferation, alkaline phosphatase (ALP) activity), on the regulation of osteoclastogenic signals by osteoblasts (OPG mRNA level and RANKL mRNA and protein level) and on HOB lifespan. HOB were cultured in Dulbecco's modified Eagles medium with 10% fetal bovine serum, adapted to serum-free and calcium-free medium for 24h, and then treated with strontium ranelate in physiological Ca²⁺ (1mM). After a 48h-treatment, strontium ranelate increased HOB proliferation, assessed by thymidine incorporation, in a dose-dependent manner, up to 3.8-fold with 2 mM Sr²⁺ (p<0.01). ALP activity was increased after 72 h with strontium ranelate by almost 2 fold (1 and 2 mM, p<0.01). After only 24 h, strontium ranelate dose-dependently increased OPG mRNA expression, by qRT-PCR, up to 1.9-fold with 2 mM Sr²⁺ (p<0.001). Under the same conditions, RANKL mRNA expression was dramatically decreased compared with RANKL expression observed in vehicle: remaining expression was below 25% with strontium ranelate concentrations ≥ 0.1mM (p<0.001). These results were confirmed at the protein level by RANKL-specific western blotting. Finally, strontium ranelate increased HOB survival under oxidative stress conditions induced by peroxide (0.1 mM, p<0.05, 1 and 2 mM, p<0.01), and decreased serum deprivation-induced apoptosis as measured by caspase 3 and caspase 7 activities (0.1 and 1.0 mM, p<0.05). In conclusion, strontium ranelate, at strontium concentrations close to those observed in patients treated with the therapeutic dose of 2g/day, increases human osteoblast replication, differentiation and the ability to withstand stress, parameters associated with promotion of bone formation. In parallel, human osteoblasts stimulated by strontium ranelate express more OPG and less RANKL, thereby decreasing their capability to stimulate osteoclastogenesis. Overall, these results strongly support the dissociation effect of strontium ranelate on bone formation and bone resorption in human osteoblasts.

Primary Murine Osteoblast Cultures Contain Macrophages that Enhance Osteoblast Mineralisation. M. Chang^{*}, A. R. Pettit^{*}, K. Schroder^{*}, V. M. Ripoll^{*}, D. A. Hume^{*}, L. Raggatt^{*}. Institute for Molecular Bioscience, University of Queensland, St. Lucia, QLD, Australia.

Delineation of the phenotype and functional capacity of osteoblasts (OBs) has been widely studied using primary OBs harvested via enzymatic digestion of neonatal rodent calvaria (calvarial OBs). Previous studies have suggested heterogeneity within this cell preparation and reported immune functions that are not traditionally performed by mesenchymal cells. These immune functions have been attributed to the OB, however, the heterogeneous nature of the culture has not been considered. We have demonstrated that macrophages are a significant population in standard calvarial OBs using cells isolated from MacGreen mice (macrophages express an eGFP transgene driven by a myeloid restricted promoter). Microarray analysis of differentiating calvarial OB cultures (day 5, 14 and 21) confirmed a large number of macrophage-associated genes at all time points.

Clustering analysis using microarray datasets representing nearly all tissues and cell lineages (symatlas.gnf.org) linked the gene expression profiles of calvarial OBs to macrophages and osteoclasts. Immunocytochemistry and flow cytometry confirmed that calvarial OB preparations co-isolated a population of F4/80⁺ macrophages that persist and expand during OB differentiation in vitro. Multiple passaging did not eliminate macrophages from these cultures. Bone explant cultures were also examined as an alternative approach to generating primary OBs and were similarly shown to contain F4/80⁺ macrophages. Given these observations, and our recent data demonstrating that macrophages are intercalated within bone lining tissues, we hypothesised that macrophages and OBs cooperate in the control of bone metabolism. To delineate the cooperative and distinct functional roles of macrophages and OBs, we used magnetic-assisted cell sorting to generate a population of highly enriched calvarial OBs by removing haematopoietic cells. The majority of cells removed via this method expressed the F4/80 macrophage marker. Strikingly, macrophage removal significantly decreased both osteocalcin mRNA expression levels and in vitro mineralisation (von Kossa staining) in enriched OB differentiation cultures. The presence of a persistent population of macrophages within primary OB cultures raises the possibility that our existing understanding of in vitro OB biology has been influenced by the contribution of this cell population. Our data provide evidence that macrophages regulate OB function and specifically enhance mineralisation in vitro.

Atm Regulates Osteoblast Differentiation Through the BMP-Smad1/5/8 Pathway. J. F. Chau^{*}, N. Rasheed^{*}, S. Wang^{*}, B. Li^{*}. Institute of Molecular and Cell Biology, Singapore, Singapore.

Ataxia telangiectasia mutated (Atm) is a tumor suppressor that plays a critical role in DNA damage response and is required for genome integrity. In addition, Atm deficient mice have been shown to suffer from osteoporosis (Hishiya et al. Bone 37:497, 2005; Rasheed et al. Hum. Mol. Genet 15:1938, 2006). It was found that Atm deficient osteoblast showed decreased expression of osterix, an essential transcription factor for osteoblast differentiation, leading to the defective osteoblast differentiation in the Atm deficient mice. It is known that osterix is induced by BMPs through the canonical Smad1/5/8 and non-canonical MAPK signaling pathways. As Atm deficiency diminished the BMP induced up-regulation of osterix, we propose that Atm participates in the BMP activated signaling pathways. We found that BMP2 treatment can activate Atm and the activation of Smad1/5/8 was compromised in Atm deficient osteoblast and MEF as detected by Western blotting. This phenomenon was also observed in normal cells treated with wortmannin or caffeine, inhibitors to phosphatidylinositol 3-kinase related kinases (PIKKs), a family of proteins that Atm belongs to. Treatment of wortmannin or caffeine also decreased the protein level of Id1, a known target of BMP-Smad1/5/8 signaling pathway. The results strongly suggest that Atm controls osteoblast differentiation through the BMP signaling pathway.

The Effect of Calcium Channel Antagonists on Bone Metabolism in Aged Male and Female Brown Norway Rats. D. L. DeMoss^{*}, B. D. Kidd^{*}, M. J. Harmon^{*}, L. A. Ashley^{*}, G. C. Howard^{*}, A. J. Auxier^{*}, E. D. Nickel^{*}. Biological Sciences, Morehead State University, Morehead, KY, USA.

Bone metabolism is invariably correlated with calcium transport indicating that calcium channels are a potential point of regulation for skeletal remodeling. Calcium channel antagonists are utilized therapeutically and experimentally to decrease the influx of calcium into cells by blocking voltage-regulated L-type calcium channels. Previous experimental evidence has suggested that calcium channel antagonists decrease osteoblastic activity, thus decreasing the activity of the bone forming cells at a time when bone formation is already exceeded by bone resorption, exacerbating the situation. Therefore, the established principle that bone formation decreases following the attainment of peak bone mass, illustrates the need for a more comprehensive understanding of the action calcium channel antagonists have on bone turnover. Experimentation utilized male and female Brown Norway Rats six months of age to compare the effects of estrogen and the antagonists on blood pressure and bone turnover from skeletal compartments. In order to evaluate the positive or negative impact of various calcium channel antagonists on bone loss, bone resorption parameters were compared between normal males and females, and those receiving calcium channel antagonists (diltiazem, nifedipine, verapamil). The models utilized to study bone turnover were the pharmacokinetic loss of the tracer ³H-tetracycline, a compound deposited in the active mineralization front and freely released in urine, the measurement of various bone degradation markers in urine collected throughout the experimental period and organ isotope extraction. The data suggest significant differences between sexes and antagonist impact on the turnover of calcium from multiple calcium pools.

Protein Kinase D Is an Essential Mediator During Osteoblast Differentiation. D. N. Y. Fan, W. M. W. Cheung, A. W. C. Kung. Department of Medicine, The University of Hong Kong, Hong Kong, China.

Protein kinase D, also known as PKC μ , is a serine/threonine protein kinase that responds to phorbol esters and diacylglycerol. Using MC3T3-E1 cells, we demonstrated that PKD is activated during DMSO-induced osteoblast differentiation. We further demonstrated that prolonged activation of protein kinase C pathways alone, i.e. in the absence of osteogenic inducers such as BMP-2 and/or DMSO, is sufficient to induce bone formation in preosteoblast cells in vitro. In this study, we examined the functional roles of PKD in osteoblastogenesis. Phorbol 12-myristate 13-acetate (PMA) activates most PKCs including PKD. Treatment of MC cells with PMA enhances osteoblast differentiation as indicated by increased ALP activity and bone nodules formation. Treatment with Gö6976, a specific inhibitor for PKD, at 0.02 and 0.2 μ M resulted in a significant dose-dependent decrease in alkaline phosphatase (ALP) activity during osteoblast differentiation of MC cells mediated by DMSO, BMP2 or PMA. Bone nodule formation was attenuated simultaneously. Semi-quantitative RT-PCR analyses demonstrated that Gö6976 treatment resulted in reduced Runx2, Osterix and ALP transcript expression in MC cells. However, a general PKC inhibitor Gö6983 that does not inhibit PKD showed little effect on osteoblast differentiation, suggesting that PKD is crucial in the process. To confirm the functional roles of PKD, we overexpressed wild-type (PKD-WT), constitutively active (PKD-CA) and dominant negative (PKD-DN) PKD in MC cells and examine the effect of PKD modulation on osteoblast differentiation. In the absence of osteogenic inducers, MC cells transfected with PKD-CA resulted in enhanced bone nodules formation as compared to the PKD-DN transfectants. These findings are in good concordance to our previous observations that PKD activation alone is sufficient for inducing osteoblast differentiation. Using both pharmacological and PKD overexpression studies, our findings suggested that PKD plays essential roles in osteoblast differentiation and that osteoblast differentiation can be modulated via the activation of PKD.

Tumor Necrosis Factor- α Stimulated Msx2 Expression in C2C12 Cells. H. Lee*, H. Ryoo, K. Woo, G. Kim*, J. Baek. Department of Cell and Developmental Biology, Seoul National University School of Dentistry, Seoul, Republic of Korea.

Tumor necrosis factor- α (TNF- α) is a pro-inflammatory cytokine that is involved in local and systemic bone loss through both stimulation of osteoclastic bone resorption and inhibition of osteoblastic bone formation. Although previous reports have shown that TNF- α inhibit osteoblast differentiation via enhanced Runx2 degradation, we could observe TNF- α -mediated inhibition of alkaline phosphatase (ALP) activity in Runx2-nulled calvarial cells. Msx2 has been shown to suppress ALP activity via counteracting the ability of Dlx5 to activate ALP promoter. Therefore we examined the effect of TNF- α on Msx2 expression in C2C12 cells. As previously reported, either Msx2 overexpression or TNF- α treatment suppressed BMP2-induced ALP activity in C2C12 cells. TNF- α enhanced the mRNA and protein level of Msx2. TNF- α -mediated Msx2 induction was not suppressed by cycloheximide treatment. BAY-11-7082, an NF- κ B inhibitor, suppressed TNF- α -mediated Msx2 induction but SP600125, a JNK inhibitor, did not. BAY-11-7082 partially reversed TNF- α -mediated inhibition of ALP activity. These results suggest that stimulation of Msx2 expression may be involved in TNF- α -mediated inhibition of osteoblast differentiation, at least in part.

A Novel R131G RUNX2 Mutation Causing Cleidocranial Dysplasia Disrupts Heterodimerization with Core Binding Factor- β . H. Kim*, M. Han*, K. Lim*, A. J. van Wijnen², J. L. Stein², J. B. Lian², G. S. Stein², J. Choi¹. ¹Biochemistry & Cell Biology, Kyungpook Natl. Univ. School of Medicine, Skeletal Diseases Genome Research Center, Daegu, Republic of Korea, ²Cell Biology, UMASS Medical School, Worcester, MA, USA.

Cleidocranial dysplasia (CCD) is caused by haploinsufficiency of the RUNX2 gene. In previous study (Kim HJ et al, J Cell Physiol 207:114-122, 06), we found a novel R131G RUNX2 mutation from CCD patient. Here, we showed functional analysis of this RUNX2 R131G mutation with respect to molecular mechanism. RUNX2 R131G mutation is located in RUNT DNA binding domain and it also located within putative nuclear localization signal. Therefore, we determined mutant RUNX2 with regard to nuclear localization, DNA binding, heterodimerization with partner protein core binding factor- β (CBF- β) and transactivation function against downstream target gene osteocalcin promoters. In nuclear localization function, RUNX2 R131G mutation had normal nuclear localization function, which was confirmed by transient transfection of HA-tagged mutant

RUNX2 into CHO and HeLa cells by in situ immunofluorescent staining. With regard to DNA binding activity, RUNX2 R131G mutant had normal DNA binding activity, which was shown by electrophoresis mobility shift assay. Third, heterodimerization function of mutant RUNX2 with CBF- β was disrupted in cotransfection assays. Finally, RUNX2 R131G mutant showed loss of transactivation function on osteocalcin promoter reporter assay while RUNX2 wild type showed high transactivation function. Collectively, R131G mutation of RUNX2 causes CCD phenotype through the loss of heterodimerization with the partner protein CBF- β without abnormalities of nuclear localization, and DNA binding.

Estrogen Suppression of Adipogenesis Is Mediated by TGF- β . K. B. Clifton, S. Khosla, M. J. Oursler. Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

Osteoblasts and bone marrow adipocytes originate from a common mesenchymal precursor. Investigators have hypothesized that a shunting of the common precursor cell away from the osteoblast and towards the adipocyte may be partly responsible for bone loss with aging, and we have hypothesized that estrogen deficiency with age may be responsible for this shift. While estrogen and transforming growth factor- β (TGF- β) have been shown to enhance osteoblast and inhibit adipocyte differentiation, the exact mechanism(s) by which estrogen may regulate these processes is not yet clear. Peroxisome proliferator-activated receptor- γ (PPAR γ) is a member of the nuclear receptor super-family; it is known to be the master regulator of adipocyte differentiation. We tested the hypothesis that estrogen may play a role in regulating adipogenesis by suppressing expression of PPAR γ , and that its effects are mediated, at least in part, by TGF- β . The bipotential mouse bone marrow stromal cell line, ST2, was used to address this hypothesis. In time course experiments, ST2 cells were treated with estrogen, TGF- β , or the corresponding vehicle from 1 hour up to 12 days. Expression of PPAR γ was significantly reduced ($p < 0.05$) by TGF- β treated ST2 cells compared to the vehicle treatment at the 24 hour time point and each time point thereafter. Similarly, estrogen suppressed PPAR γ expression compared to both the vehicle treated and untreated cells after 48 hours of treatment. ST2 cells were cultured in adipogenic medium for 6 days. Treatment with estrogen or TGF- β reduced PPAR γ expression. Moreover, co-treatment with estrogen and a chemical TGF- β signaling inhibitor partially restored expression of PPAR γ . To examine possible molecular mechanisms by which estrogen and TGF- β regulate PPAR γ expression, cells were infected with dominant negative (dn) Smads 2 and 3, dn MEK, and dn PAK2 to block Smad-dependent and Smad-independent pathways. Both estrogen- and TGF- β -regulated repression of PPAR γ were partially disrupted by blocking the Smad 3 and the Smad-independent PAK2 pathways. These results are consistent with the hypothesis that estrogen may play a role in regulating adipogenesis, and that its effects are mediated, at least in part, by TGF- β through both Smad dependent and Smad-independent signaling pathways.

Regulation of RUNX2 Translation by 5'- and 3'-UTR Binding Proteins. N. Elango*, S. Sudhakar*, M. S. Katz. GRECC, VA Medical Center, San Antonio, TX, USA.

RUNX2, the major regulator of osteoblast differentiation, is expressed as two isoforms (RUNX2-I and RUNX2-II) encoded by two mRNAs differing only in their 5'-UTRs and initial coding regions. Recent studies show that RUNX2 gene expression is regulated at the translational level, and RUNX2-I is translated earlier during osteoblast differentiation than RUNX2-II. Since a 3961 nucleotide-long 3'-UTR is common to both mRNAs and the two 5'-UTRs are distinct, we hypothesize that the 3'-UTR contains a common translational regulatory motif and the two 5'-UTRs contain isoform-specific motifs. We have found by deletion analysis that the region between 2000 and 3000 nucleotides of the 3'-UTR contains a negative regulatory motif. Gel retardation assays reveal a 75 kDa protein, expressed in osteoblastic cells (UMR-106, ROS 17/2.8) but not precursors (ST2), binding to a pyrimidine-rich sequence within the 2000-3000 nucleotide region. Using RNA affinity chromatography we have purified six proteins from UMR-106 cells, including a 75 kDa protein, that bind to the pyrimidine-rich sequence. A high level of luciferase expression by RUNX2-I reporter plasmid but not RUNX2-II reporter mRNA in transfected osteoblasts (Elango et al, J Cell Biochem 99:1108, 2006) suggests that nuclear factor(s) bound to the 5'-UTR of RUNX2-I mRNA during transcription (but absent from in vitro transcribed reporter mRNA) are essential for translation. We have purified from UMR-106 cells by RNA affinity chromatography three proteins that bind to the RUNX2-I 5'-UTR. Translation of RUNX2-I but not RUNX2-II in early osteoblastic cells (UMR-106) expressing both RUNX2 mRNAs suggests that RUNX2-II translation is suppressed until later stages of differentiation. Gel retardation assays show that stem-loop structures of RUNX2-II mRNA 5'-UTR bind proteins expressed in early osteoblasts (UMR-106) but not precursors (ST2) or mature osteoblastic cells (ROS 17/2.8); these proteins may

function as suppressors of RUNX2-II translation in early osteoblasts. Based on these findings, we postulate: 1) translation of both RUNX2 mRNAs is suppressed in precursors by 3'-UTR binding protein(s); 2) RUNX2-I is translated early in osteoblastogenesis upon expression of a 75 kDa pyrimidine-rich region binding protein and removal of suppression. RUNX2-I translation is also enhanced by RUNX2-I 5'-UTR binding proteins; 3) translation of RUNX2-II is suppressed during early osteoblast differentiation by the transient expression of proteins binding to the RUNX2-II 5'-UTR. Our studies provide a model by which 3'- and 5'-UTR binding proteins control sequential translation of the two RUNX2 isoforms and thereby regulate the course of osteoblast differentiation.

Dlx5 Overexpression Promotes Early Odontoblast Maturation. V. L. S. Ferrer^{*1}, Y. Kawano², H. T. Li¹, H. Chin^{*1}, L. Wang^{*3}, A. C. Lichtler¹.

¹Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, ²Division of Oral Anatomy, Niigata University, Niigata, Japan, ³Institute of Molecular Biology, Academia Sinica, Taipei, Taiwan.

Dlx5 is a member of the Dlx gene family of transcription factors, which have been shown to be important for the differentiation of osteoblasts and chondrocytes and the development of craniofacial structures including teeth. To further understand the role of Dlx5 in vivo, our laboratory generated transgenic mice overexpressing Dlx5 driven by the osteoblast- and odontoblast-directed 3.6 kb fragment of the type I Collagen promoter (3.6Col1a1). We have previously reported that 3.6Col1a1-driven Dlx5 overexpression results in accelerated mandibular enamel and dentin mineralization in 7-week-old mouse incisor. Enamel highlighting of micro-CT 3D reconstruction of the mandible showed initiation of enamel mineralization at the level of the 3rd molar in transgenics in contrast to the wildtype enamel, which begins at the level of the 1st molar. Light micrographs showed that transgenic odontoblasts exhibited advanced maturation, displaying the distinct lack of polarity seen in wild-type early, functional odontoblasts.

To further analyze the phenotype, we examined transgenic mice at earlier time points (1, 3, and 5 weeks) to determine the onset of the phenotype. MicroCT revealed no significant differences in enamel and dentin mineralization at these time points. However, light micrographs showed that the odontoblast phenotype is apparent as early as 1 week.

Further histological analysis of 7-week-old transgenic incisors revealed that as odontoblast differentiation progresses towards the incisal end, the odontoblasts become highly disorganized and eventually are indistinguishable from the pulp. The corresponding dentin lacks the parallel arrangement of the dentinal tubules. Predentin in the incisal area is diminished or absent, leading to jagged and thinner dentin and, ultimately, exposed pulp. Trichrome staining revealed ectopic collagen formation in the pulp adjacent to the dentin. Undecalcified sections of calcein and xylenol orange labeled incisors showed that the formations are ectopic mineralizations. The wavy pattern of labeling, which appears at the incisal tip in the wild-type incisor, begins at the middle third of the transgenic incisor.

These observations suggest that 3.6Col1a1-driven Dlx5 overexpression promotes early odontoblast maturation. However, this early maturation results in the eventual loss of recognizable odontoblast morphology and irregularity and depletion of dentin matrix formation, leading to exposed pulp chamber.

Positive and Negative Regulation of Osteoblast Differentiation by the SWI/SNF Chromatin Remodeling Complex. S. Flowers^{*1}, N. G. Nagl^{*1}, H. Guo^{*1}, G. R. Beck², E. Moran¹.

¹Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, PA, USA, ²Division of Endocrinology, Metabolism and Lipids, Emory University School of Medicine, Atlanta, GA, USA.

Osteoblast differentiation requires reprogramming of gene expression to activate tissue specific gene expression and to effect coordinated withdrawal from the cell cycle. Chromatin remodeling is an important part of this process, in which the SWI/SNF complex uses the energy of ATP hydrolysis to disrupt nucleosome architecture, thereby altering the accessibility of gene promoters to transcription factors. The SWI/SNF complex is essential for both positive and negative gene regulation events, which has complicated analysis of its molecular mechanisms of action. A manner by which the complex might distinguish functions is suggested by the occurrence of two subunits as pairs of related alternatives. To test this concept, we used siRNA technology to deplete MC3T3-E1 pre-osteoblast cells of each subunit. The alternative pairs include the largest subunits of the complex, p270/ARID1A and its close relative ARID1B, which are members of the ARID family of DNA

binding proteins. The other subunit that occurs as a mutually exclusive pair is the ATPase itself, which can be either BRM, or the BRM-related protein BRG1.

This approach successfully distinguished complexes with distinct roles in osteoblast differentiation. The p270/ARID1A subunit was revealed as diagnostic of a complex with a repressor role during cell cycle withdrawal. In contrast, complexes containing the ARID1B subunit play an important positive role in cell cycle activity. The high level of c-myc expression seen in MC3T3-E1 pre-osteoblasts is dependent on the integrity of ARID1B-containing complexes, while differentiation-associated repression of c-myc depends on complexes containing the p270/ARID1A subunit. Chromatin immunoprecipitation (ChIP) assays indicate the c-myc promoter is a direct target of the SWI/SNF complexes, and that depletion of either ARID subunit impairs the association of other important regulators with the c-myc promoter. Likewise, depletion of the ATPase subunits reveals separation of key functions. Both ATPases contribute to cell cycle withdrawal, but they have very distinct functions in tissue specific gene expression and the onset of mineralization. The osteocalcin promoter is a direct target of SWI/SNF complexes, and the ATPases distinguish complexes with different roles in its regulation. These analyses give insight into the molecular mechanisms that underlie lineage determination, and the timing and coordination of the differentiation process.

Regulation of RUNX2 at the Nuclear Lamina. P. M. Fonseca¹, G. Zhou^{*1}, Q. Zheng^{*1}, H. Kingston^{*2}, M. Tassabehji^{*2}, B. Lee¹. ¹Molecular Human Genetics, Baylor College of Medicine, Houston, TX, USA, ²St. Mary's Hospital, Manchester, United Kingdom.

RUNX2 is a member of the RUNT family of transcription factors. It is essential for osteoblast formation and chondrocyte maturation. Loss of function mutations in RUNX2 result in the human skeletal disorder cleidocranial dysplasia (CCD). RIP (CBFA1/RUNX2-Interacting Protein) was isolated in a screening of a human osteosarcoma cDNA library using a yeast two-hybrid approach. Two families with rearrangements involving chromosome 8q - where RIP maps - have been reported to have a CCD-like phenotype. In transient transfection experiments, RIP down-regulated the transactivation by RUNX2 in a dose-dependent manner in both 10T1/2 cells and ROS17/2 cells. RIP is mainly localized in the nucleus and it was identified as a component of the nuclear envelope in proteomic screens. The major components of the nuclear envelope are lamins, which are intermediate filaments with an important role in nuclear organization, cell division, apoptosis and transcriptional regulation. Interestingly, mutations in A-type lamins and lamin-associated proteins result in several laminopathies such as mandibuloacral dysplasia (MAD). MAD presents clinical features such as acroosteolysis, dental crowding, hypoplastic clavicles and delayed closure of the fontanels, partially phenocopying CCD. We hypothesize that the skeletal defects observed in these patients are due to the disruption of lamin interactions with transcriptional regulators relevant in bone formation such as RIP and RUNX2. GST pull-down experiments showed an interaction between LaminA/C and RIP, as well as the RUNT domain of RUNX2. The tail domain, which is mutated in MAD patients, is responsible for the interaction. Moreover, LaminA/C could repress RUNX2 transactivation of reporter genes in COS7 cells in a dosage-sensitive way. Mutant versions of lamin carrying MAD mutations seem to lose their repressive action. These mutants had altered binding properties. These data suggest a novel mechanism for transcription regulation of skeletogenesis involving sequestration of a RUNX2 complex at the nuclear lamina. In order to study the effects of A-type lamins on osteoblast differentiation, we are currently generating a C2C12 stable cell line overexpressing laminA/C and we will also knock-down the gene in pre-osteoblastic cells.

Metnrl: A New Secreted Protein Inhibit Differentiation of MG-63. W. Y. Gong^{*1}, Y. Liu^{*2}, R. M. Zheng^{*1}, G. X. Qiu^{*2}, S. Q. Lin¹. ¹Obstetric and Gynecology, Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Science, Beijing, China, ²Orthopaedic Surgery, Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Science, Beijing, China.

It has been reported that AP-1 transcription factor complex modulates the function of osteoblasts and osteoclasts which participate in bone formation and bone resorption respectively. So in our previous study, we constructed a high-throughput assay method based on the AP-1 signaling pathway dual-luciferase reporter system to screen new function gene expressing in fetal osteoblasts. We found one gene (GMSS555) without reporting function in PUBMED inhibited the activation of AP-1 (<50% compare to empty vector). After analysis with basic local alignment tool (BLAST), this gene is noted "Meteorin, glial cell differentiation regulator-like (METRNL)". Now in this experiment, we cloned this gene and studied whether it could influence the differentiation of MG63. The full-length cDNA of METRNL contains an open reading frame encoding 312 amino acids with a putative signal peptide of 45 aa. Northern blotting revealed that a 1.5kb mRNA was constitutively but lowly expressed in most normal adult tissues. The recombinant METRNL was isolated from BL21 codon plus and used to immunize rabbits to raise polyclonal antibodies. Western blot detected an about 34 kDa protein in culture supernatant of CHO cells stably transfected with ORF of METRNL. Immunohistochemistry analysis demonstrated that METRNL was mainly expressed by the undifferentiated osteoblasts and chondrocytes. To study the function of METRNL in osteoblasts, we established stable MG63 cells that express the METRNL tagged with EGFP at its COOH-terminus. After cultured in osteogenic supplement (containing b-Glycerolphosphate/dexamethasone/ascorbic acid-2-phosphate) for 14 days, the METRNL transfected MG63 produces lower matrix than mock-transfected and parent MG63. Real time PCR assays showed METRNL inhibited the ALP and osteocalcin mRNA expression ($p < 0.05$). Our study indicated that METRNL expressed mainly in undifferentiated cells and can inhibited transcription activity of AP-1, and reduced the differentiation of human osteoblastic MG63.

TIEG Suppresses Osteoblast Cell Proliferation Through Modulation of the TGF β /Smad Signaling Pathway and Repression of E2F1 Gene Expression. J. R. Hawse¹, M. Subramaniam¹, J. Pirngruber^{*2}, N. M. Rajamannan³, M. J. Oursler¹, S. A. Johnsen^{*2}, T. C. Spelsberg¹. ¹Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, ²Department of Molecular Oncology, Gottingen Center for Molecular Biosciences, Gottingen, Germany, ³Department of Cardiology, Northwestern University Medical School, Chicago, IL, USA.

TGF β Inducible Early Gene-1 (TIEG) is a member of the Kruppel-like family of transcription factors that was originally identified in osteoblasts. This transcription factor regulates the expression of many genes and plays a critical role in bone formation and maintenance. We have demonstrated that TIEG suppresses the expression of Smad7 following TGF β treatment of osteoblasts and that this suppression does not occur in the absence of TIEG. Further, transient transfection of osteoblasts with a TIEG expression construct results in suppression of Smad7 promoter activity. Through the use of yeast-2-hybrid and co-immunoprecipitation assays, we have shown that TIEG directly interacts with mSin3a, a well characterized co-repressor. In order to determine if TIEG recruits mSin3a to the Smad7 promoter, we performed time course ChIP assays. These studies revealed that TIEG and mSin3a are recruited to the Smad7 promoter within 60 minutes of TGF β treatment, and that phosphorylated polymerase II is displaced from the Smad7 promoter within 30 minutes of treatment. Interestingly, the HDAC proteins do not appear to be involved in this process since they are not recruited to this promoter region and since TSA, an inhibitor of HDAC activity, does not relieve the repression of Smad7 by TIEG. Since we have demonstrated a central role for TIEG in the TGF β /Smad signaling pathway, and since this pathway is known to be an important regulator of cell proliferation, we sought to determine TIEG's role in the proliferation of osteoblast cells. Overexpression of TIEG in osteoblasts results in a significant decrease in cell proliferation by approximately 50%. Additionally, calvarial osteoblasts isolated from TIEG^{-/-} mice proliferate more rapidly relative to osteoblasts isolated from wild-type littermates. To further characterize this proliferative response, we examined the role of TIEG in regulating the activity of the E2F1 promoter, a well known pro-proliferative gene. Transient transfection assays demonstrate that TIEG drastically decreases the activity of this promoter in osteoblasts. Taken together, these data demonstrate a central role for TIEG in suppressing the expression of Smad7 leading to enhancement of the Smad signaling pathway. TIEG is also shown to play a critical role in regulating osteoblast cell proliferation, and potentially osteoblast differentiation, possibly as a result of TGF β /Smad signaling and E2F1 expression.

TFIIA, ATF4, and Runx2 Synergistically Activate Osteoblast-specific Osteocalcin Gene Expression. S. Yu¹, Y. Jiang^{*2}, M. Luo^{*1}, Y. Lu¹, J. Zhang¹, G. D. Roodman¹, G. Xiao¹. ¹Department of Medicine, University of Pittsburgh Medical Center (UPMC), Pittsburgh, PA, USA, ²Department of Pharmacology, University of Pittsburgh Medical Center (UPMC), Pittsburgh, PA, USA.

Runx2, a member of the runt homology domain family of transcription factors, is a master regulator of osteoblast function and bone formation. Mice lacking Runx2 have no mineralized skeleton due to a complete lack of mature osteoblasts. The expression level of Runx2 protein is regulated by a number of factors including BMPs, FGF-2, IGF-1, TNF- α , TGF- β , and PTH, all of which play important roles in osteoblasts and bone both in vitro and in vivo. In addition, the activity of Runx2 protein is positively or negatively modulated through protein-protein interactions. Activating transcription factor 4 (ATF4) is an osteoblast-enriched factor which regulates the terminal differentiation and function of osteoblasts. ATF4 knock-out mice have reduced bone mass and bone mineral density (severe osteoporosis) throughout their life. To identify proteins interacting with Runx2, we used a yeast two-hybrid system and identified TFIIA, a general transcriptional factor, as a Runx2-interacting factor. While pull-down assays confirmed that TFIIA physically interacted with Runx2 when both factors were coexpressed in COS-7 cells, surprisingly, it did not activate or inhibit Runx2-dependent transcriptional activity. In contrast, TFIIA unexpectedly activated ATF4, which we recently identified as a Runx2-interacting protein, in a dose-dependent manner. Deletion analysis found that this activation required the presence of the C-terminal 15 amino acid residues of ATF4 molecule. Finally, TFIIA, ATF4, and Runx2 synergistically stimulated the 0.657-kb mOG2 (mouse osteocalcin gene 2) promoter activity and endogenous osteocalcin mRNA expression. In summary, this study demonstrates a novel mechanism through which bone-specific transcription factors and general transcription factors cooperate in regulating osteoblast-specific gene expression.

siRNA Specific Knockdown of Lamin A/C Inhibits Osteogenic Differentiation of Human Mesenchymal Stem Cells. R. Akter¹, D. Rivas¹, Y. Dong², H. Drissi², G. Duque³. ¹Lady Davis Institute for Medical Research, Montreal, PQ, Canada, ²Orthopaedics, University of Rochester, Rochester, NY, USA, ³Medicine/Geriatrics, McGill University, Montreal, PQ, Canada.

Recent studies have indicated the role of lamin A/C, a component of nuclear lamina, in premature ageing with severe bone loss. Mutations in the gene encoding lamin A/C have shown a deficit in the number of both osteoblasts and osteocytes. We have previously shown that lamin A/C expression levels are reduced in the aging osteoblasts in vivo. However, no study has evaluated the direct role of lamin A/C in osteogenic differentiation of mesenchymal stem cells (MSC). In this study, we hypothesize that reduced expression of lamin A/C has a negative impact on osteogenic differentiation of human MSC. We inhibited lamin A/C using different doses of lamin A/C siRNA (200-800 nM) in MSC committed to differentiate into osteoblasts. Cells treated with vehicle but without the siRNA/oligo were used as a control. The level of siRNA was determined by western blot and RT-PCR. We found that up to 400nM did not have any inhibitory effect, but 600 and 800nM successfully inhibited lamin A/C without affecting cell survival. After 10 days of lamin A/C knockdown, cells were stained with alizarin red (mineralization) and alkaline phosphatase. Additionally, expression of osteocalcin, cbfa1 and lamin A/C were determined by RT-PCR and western blot. Finally, nuclear blebbing, a typical finding of lamin A/C inhibition, was quantified by propidium iodine staining. We found that lamin A/C knockdown induces higher level of nuclear blebbing and significantly reduces alizarin red staining ($p < 0.01$) and alkaline phosphatase activity ($p < 0.01$) in osteogenic differentiating MSC. Additionally, expression of cbfa1 and osteocalcin was reduced in lamin A/C knockdown cells. Overall, to identify the potential mechanism, gel-shift assay analyses were pursued. We found that lamin A/C knockdown affects the DNA/protein interaction of the binding sites in the cbfa1 promoter. In conclusion, our results suggest that lamin A/C is a new factor required for the osteogenic differentiation of MSC and that lamin A/C directly interacts with the cbfa1 transcription pathway.

Osteofornin Enhances Gap Junction Communication of Human Preosteoblastic Cells in Culture. L. X. Bi, E. Mainous, Y. Zeng^{*}, W. J. Buford^{*}. Dpts. of Surgery & Orthopaedics, UTMB, Galveston, TX, USA.

Gap junctions provide a cell-to-cell low resistance conduction pathway for coordination of tissue function. Composed of nonselective channels they allow passage of ions, nucleotides, and other small molecules. Our previous study has shown that marrow sac cells (preosteoblasts) which separate the bone from marrow display intercellular gap junctions (Bi LX JBMR 17: SA219 Suppl. 1, 2002). To investigate activities of gap

junction affected by osteoformin (polyaspartate), we examined the levels of fluorescence recovery after photobleaching (FRAP) using a laser scanning confocal microscope. Human preosteoblast cells were cultured in a minimum essential medium [a-MEM] and 10% fetal bovine serum with or without osteoformin (5ug/ml) for 3 days. The cells were loaded with 5,6-carboxyfluorescein diacetate,acetoxymethyl ester (5,6-CFDA/AM, 5 µg/ml) for FRAP at 37°C for 30 minutes and then de-esterified by washing with phosphate buffered saline before photobleaching. The FRAP was examined using a laser scanning confocal microscope with a 488-nm wavelength light from an argon laser (LSM microscope) and recorded every 5 seconds in 60 seconds after photobleaching. Osteoformin enhanced levels of intercellular gap junction communication by 68-72% ($P<0.01$) compared to that of the control group. To confirm that the fluorescein crosses the gap junction channel, a gap junctional blocker (carbenoxolone, 150 µg/ml) was used. Carbenoxolone blocked the effect of osteoformin on human preosteoblasts. We conclude that osteoformin significantly enhances intercellular gap junction communication which is associated with exchange of regulatory ions and osteoblast differentiation in vitro. It might be an important regulator of bone formation by accelerating fracture and bone defect healing, and controlling bone diseases.

Osteogenic Differentiation of Circulating Endothelial Progenitor Cells. T. Bick^{*1}, N. Rozen^{*2}, E. Dreyfuss^{*1}, M. Soudry^{*1}, D. Lewinson¹. ¹Research Institute for Bone Repair, Orthopaedic Surgery A, Rambam-Health Care Campus, Haifa, Israel, ²Research Institute for Bone Repair, Rambam-Health Care Campus, Haifa, Israel.

The dramatic potential of circulating endothelial progenitor cells (EPC) to heal a large bone defect (critical-sized gap in sheep tibiae, see abstract: Healing of Critical-sized Bone Defects by Endothelial Progenitor Cells. By D. Lewinson et al) led us to investigate whether EPC might be induced to transform into osteogenic cells. Peripheral mononuclear fraction of circulating sheep and human mononuclear cells were isolated using LymphoprepTM (Axis-Shield, Oslo, Norway), seeded on fibronectin-coated plates (Sigma-Aldrich, MS, USA), and cultured in EBM-2 media supplemented with EGM-2MV SingleQuote (Clonetics, Cambrex Bio Science, MD, USA). The endothelial nature of adherent colonies was identified by incorporation of Dil-acetylated LDL (Molecular Probes, Oregon, USA), tube formation on Matrigel (BD Labware, MA, USA) and immunostaining for von Willebrand factor (Dako, Glostrup, Denmark). EPC were expanded and cultured in plastic dishes or seeded into polyethylene glycol/fibrinogen hydrogel scaffolds. Cultures were incubated either in DMEM/F12 (1:1) containing 10% FCS or in an osteogenic differentiation media - DMEM/F12 (1:1) containing 10% FCS, Dexamethasone 10^{-7} M/L, ascorbic acid 5×10^{-3} M/L and β -glycerophosphate 10^{-2} M/L. Changes in cell morphology, nodule formation, von Kossa (vK) and alizarin red (AR) staining as well as osteocalcin (OC) immunohistochemistry served to identify osteoblastic differentiation. Nodular aggregates formation was evident in osteogenic media-incubated sheep EPC already by 1 week. These nodular aggregates stained positively by vK, AR and OC. However, human EPC, when cultured in the same conditions showed very intensive staining of equal intensity over all the confluent culture by AR with many more intensively-stained small noduli. vK staining showed many granular deposits dispersed all over the culture plate. In contrast to sheep EPC, not only the nodular aggregates but most of human EPC stained by both vK and AR. Control cultures of both human and sheep EPC showed minimal background staining. Phase contrast microscopy of sheep EPC-seeded scaffolds demonstrated that the cells were distributed homogeneously throughout the scaffold and formed tube-like structures by 1 week in both media. However the cell-seeded scaffolds cultured in osteogenic media showed prominent nodular aggregates. vK and AR staining were not informative because the scaffold itself retained the stain. Our results support a possible mechanism that explains the potential of blood derived EPC in tissue engineering for bone regeneration.

Differential Effects of Secreted Frizzled-related Proteins (sFRPs) and Wnt Inhibitory Factor (WIF)-1 on Osteoblastic Differentiation of Mouse Pluripotent Mesenchymal Cell Line. S. W. Cho, S. J. Heo, H. J. Sun, O. K. Choi, J. Y. Yang, H. Y. Cho, S. W. Kim, C. S. Shin. Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.

Secreted Frizzled-related proteins (sFRPs) are modulators of Wnt signaling which plays a role in development, apoptosis and tumorigenesis. sFRPs bind directly to the wnts proteins and appear to antagonize the effects of wnts by sequestering them from their receptor. Although overexpression of sFRP-1 in human osteoblasts has been shown to antagonize Wnt-signaling and accelerates apoptosis, a recent report demonstrated that sFRP-3 is a potent stimulator of osteoblast differentiation. This study was undertaken for

definitive assessment of contribution of different sFRPs and WIF-1 in osteoblast differentiation and function. Treatment of C3H10T1/2 cells with sFRP1, -2, -3, and -4 in the presence of Wnt-3A conditioned medium did not show significant difference in alkaline phosphatase (ALP) activity compared to vehicle treated cells. However, WIF-1 strongly inhibited the ALP activity in a dose-dependent manner [5nM, 10nM, 50nM, 100nM; 0.141 ± 0.002 , 0.105 ± 0.026 , 0.041 ± 0.003 , 0.022 ± 0.003 mU/mg protein, $p < 0.05$]. To further investigate the role of cell-associated sFRPs, we have transduced C3H10T1/2 cells with retroviral vector for sFRPs and WIF-1. Consistent with the previous data, sFRP-1, -2, -3, and -4 did not result in significant difference in ALP activity compared to empty virus transduced cells during osteoblastic differentiation using β -glycerophosphate and ascorbic acid. In contrast, overexpression of WIF-1 significantly inhibited the ALP activity compared to control cells at day 14 of culture [10.078 ± 1.835 vs 18.368 ± 3.848 mU/mg protein, $p < 0.05$]. BrdU uptake assay and caspase-3 assay showed that treatment of sFRPs and WIF-1 did not affect cell proliferation or apoptosis. In conclusion, we were not able to demonstrate that sFRP1-4 inhibit osteoblastic differentiation of mesenchymal cells. On the other hand, WIF-1 has consistently exhibited negative effects on osteoblastic differentiations of mouse pluripotent mesenchymal cells.

Mesenchymal Stem Cell Concentration and Bone Repair: Pitfalls from Bench to Bedside. A. V. Cuomo^{*1}, M. Virk², F. Petrigliano^{*1}, E. Morgan^{*3}, C. Kang^{*4}, J. R. Lieberman². ¹UCLA, Los Angeles, CA, USA, ²University of Connecticut, Hartford, CT, USA, ³Orthopaedic Surgery, Boston University, Boston, MA, USA, ⁴Orthopaedic Surgery, UCLA, Los Angeles, CA, USA.

PURPOSE: This is a preclinical trial comparing the osteogenic potential of mesenchymal stem cell enriched bone marrow aspirate (enrBMA) versus unprocessed BMA mixed with demineralized bone matrix (DBM) in a critical-sized athymic rat femoral defect model.

METHODS: The buffy coat was extracted from 8 human BMA donors to obtain the enrBMA. The MSCs concentration was estimated by counting fibroblast colony forming units (f-CFU). Lyophilized DBM allograft (Osteofil-RTTM) was mixed with saline, BMA, enrBMA, or recombinant human bone morphogenetic protein-2 (rhBMP-2) (10ug) and was used to treat a 6mm critical-sized femoral defect in athymic rats. A total of 59 rats were divided into 6 groups (Table 1). Radiographs at 4, 6, 8, and 12 weeks were graded for bone healing by 3 independent observers. All animals were sacrificed at 12 weeks for microCT and histomorphometry.

RESULTS: The BMA and enrBMA from all 8 donors averaged 1072 ± 991 f-CFUs/mL and 6503 ± 6953 f-CFU/mL, respectively. All 10 defects healed in the positive control groups (II, VI) with rhBMP-2 (Table 1). One defect healed in each experimental group (III-V). The radiographic scores did not differ between time-points (data not shown) and the bone volume (BV) and mineral density (MD) did not differ between groups IV and V. The wide radiographic variability of defect healing in Groups IV and V did not correlate with the concentration of f-CFU's, the lot number of the DBM, or the age or sex of the BMA donor. Histomorphometry showed more dense trabecular and cortical bone in groups III-V than in group II.

CONCLUSION: Although enrBMA may demonstrate superior bone healing in certain clinical situations, this pre-clinical study cannot support the use of enrBMA when mixed with DBM to reliably heal critical-sized bone defects. The results of this study introduces one or more possibilities: (1) a higher number of MSC may be required for healing critical-sized defects; (2) an enhanced osteoinductive signal is required in the setting of critical-sized defects that cannot be overcome by enrBMA and DBM alone, and (3) the carrier used did not provide the optimal environment to promote cell growth and signaling. Importantly, this study identifies potential pitfalls when adapting the use of MSC to treat humans in a clinical setting.

Table 1. Radiographic (XR), MicroCT Bone Volume (BV), and Mineral Density (MD) Scores

Group	Healed defect/ group*	12 week XR**	BV (mm ³)	MD (mg HA/ccm)
I Defect only	0/5	2.2(±0.9)	-	-
II ACS+rhBMP-2	5/5	5.0(±0.0)	-	-

The Effect of Caloric Restriction on Bone of Aging Rats Is Exerted Through the Stimulation of Sirtuins. G. Duque¹, D. Rivas², F. Picard^{*3}, S. Miard^{*3}, M. Lafontaine-Lacasse^{*3}, G. Ferland^{*4}, P. Gaudreau^{*4}. ¹Medicine/Geriatics, McGill University, Montreal, PQ, Canada, ²Lady Davis Institute for Medical Research, Montreal, PQ, Canada, ³University of Laval, Quebec, PQ, Canada, ⁴University of Montreal, Montreal, PQ, Canada.

Caloric restriction (CR) in combination with soy protein is reported to inhibit adipose genes in peripheral fat and to increase bone mass in mice and rats. The mechanisms that explain these effects remain unknown. After the recent finding that Sirt1, a member of the Sirtuins family, acts as a repressor of PPAR γ 2 in peripheral fat, we hypothesize that CR combined with soy protein diet reduce adipogenesis in bone through the upregulation of Sirt1 and its co-factors. In this study, male Sprague Dawley rats (8 month-old) were fed for 12 months with either casein or soy protein and exposed to a CR of 40% in comparison to the rats fed to satiety. A control group was fed ad libitum. Changes in body mass index (BMI), weight, length and serum leptin were quantified. At 20 months of age, animals (n=20 per group) were sacrificed and tibiae were obtained for immunohistochemistry, immunofluorescence and in-situ hybridization for Sirt1 and its co-factor AEBP1. Additionally, bone marrow expression of PPAR γ 2 and CEBP α was also quantified. Our results showed that CR induced a significant reduction in weight, body mass index and serum leptin levels in both casein and soy protein fed groups as compared with the ad libitum groups (p<0.001). We found that in the CR rats fed with soy protein there is a significantly higher expression of both Sirt1 and AEBP1 detected by both in-situ hybridization and immunohistochemistry as compared with casein and ad libitum fed rats (p<0.01). Additionally, levels of both PPAR γ 2 and CEBP α expression were significantly reduced in the soy protein group (p<0.01). Our results indicate that the combination of CR and soy protein has an inhibitory effect on bone marrow adipogenesis through the stimulation of Sirtuins (Sirt1 and co-factor AEBP1) thus suppressing the expression of PPAR γ 2. These findings provide the basis for further investigation on the role of Sirtuins in age-related bone marrow adipogenesis.

Bespoke Bioceramic Scaffolds Support Mesenchymal Stem Cell Growth and Osteogenic Differentiation. J. Dyson^{*1}, P. Genever^{*2}, K. Dalgarno^{*3}, D. Wood^{*1}. ¹Leeds Dental Institute, University of Leeds, Leeds, United Kingdom, ²Department of Biology, University of York, York, United Kingdom, ³School of Mechanical and Systems Engineering, University of Newcastle, Newcastle, United Kingdom.

There is a clinical need for new bone replacement materials which combine long implant life with complete integration and appropriate mechanical properties. Apatite-wollastonite (A-W) is a bioactive glass-ceramic that shows excellent biocompatibility in vivo and similar mechanical properties to bone. Selective laser sintering (SLS) is a rapid prototyping technology used to produce intricate porous three-dimensional scaffolds to match the exact geometry of a patient's graft site, and can be applied to A-W powder. Mesenchymal stem cells (MSCs) can be induced to undergo osteogenic differentiation to mature bone-forming osteoblasts making MSCs attractive candidates for orthopaedic tissue engineering applications. We have used human MSCs to populate porous A-W scaffolds produced by SLS to create bespoke bone replacements.

MSCs were cultured on A-W scaffolds for up to 21 days. Confocal and scanning electron microscopy (SEM) were used to determine optimal seeding densities, to demonstrate that MSCs adhered and retained viability on the surface and penetrated into the pores of A-W scaffolds over 21 days culture. We identified a significant increase (p<0.01) in the number of MSCs growing on the scaffolds over 7 days. Using BrdU incorporation we demonstrated that $28.4\% \pm 2.6$ of MSCs proliferated over a period of 24 hours. Using real-time PCR we analyzed the expression of osteogenic markers by MSCs cultured in the absence of osteogenic supplements on A-W scaffolds compared to tissue culture plastic. We identified up to a 3-fold increase in cbfa1, 4-fold increase in alkaline phosphatase, 8-fold increase in type-I collagen, 170-fold increase in osteopontin, 1-fold increase in osteocalcin and a 14-fold increase in osteonectin expression on A-W compared to plastic at different time points over 21 days (p<0.05). At all time points the expression of osteogenic markers was equivalent to or significantly greater on A-W than plastic. We also identified significantly higher (p<0.01) alkaline phosphatase activity at days 7 and 14 compared to a calcium phosphate scaffold. Bespoke A-W scaffolds were engineered with a central channel to increase cell penetration in dynamic culture. Confocal microscopy and SEM were used to demonstrate that MSCs adhered to the scaffolds and retained viability for 21 days culture and cell in-growth was facilitated. These results indicate for the first time the biocompatibility and osteo-supportive capacity of SLS-generated A-W scaffolds and their potential as a bone replacement material.

Enhanced Mesenchymal Stem Cell Properties in Dynamic Three-Dimensional Cultures. J. E. Frith^{*1}, B. Thompson^{*2}, P. G. Genever^{*1}.

¹Department of Biology, University of York, York, United Kingdom, ²Smith and Nephew Research Centre, York, United Kingdom.

Mesenchymal stem cells (MSCs) are multipotent progenitor cells with the ability to self renew and differentiate along the osteogenic, adipogenic and chondrogenic lineages. This makes them good candidates for a range of therapeutic applications. MSCs are routinely cultured as monolayers attached to tissue culture plastic but there are indications that they lose their capacity for proliferation and differentiation after prolonged culture periods. We have grown MSCs as three-dimensional (3D) spheroids under dynamic conditions in both spinner flasks and a NASA rotating wall vessel (RWV). We hypothesised that increased cell-cell interactions, potential for communication and conditions of shear-stress and mass transfer may more closely mimic the in vivo environment to improve retention of stem cell properties.

We have shown that human MSCs spontaneously aggregate when prevented from adhering to culture plastic. These aggregates compact over a period of seven days into dense spheroids with decreased cell size and altered cell surface antigen expression compared to parallel monolayer MSCs, as shown by SEM and flow cytometric analysis. Live/dead staining confirmed that the cells remained viable in both spinner flasks and RWV culture after 7 days of dynamic culture. MSCs were cultured as monolayers and as spheroids in spinner flasks and the RWV in osteogenic medium for a period of 21 days. Staining showed the presence of alkaline phosphatase in all cultures from 7 days onwards with von Kossa-positive discrete staining for mineralised deposits in both dynamic 3D cultures, but not monolayers, at 14 and 21 days. RNA was extracted at 7, 14 and 21 days for analysis of osteogenic marker expression by qRT-PCR. As compared to monolayers, expression of Cbfa1 and osteocalcin was increased in 3D culture across all time points and expression of osteonectin and osteopontin was increased after 21 days. Increases in alkaline phosphatase and type-I collagen were also present in RWV cultures after 14 and 21 days. A comparison of adipogenic differentiation showed lipid droplet accumulation, by Oil red O staining, in dynamic 3D cultures after just seven days with accumulation in monolayers not occurring until 21 days. qRT-PCR analysis of adipogenic marker expression showed increased expression of C/EBP α and FABP4 in spinner flasks and of PPAR γ , LPL, C/EBP α and FABP4 in RWV cultures. Together these results show that dynamic 3D methods are viable for MSC culture and that both osteogenic and adipogenic differentiation potential are enhanced as compared to standard monolayer cultures.

Increasing Osteoblast Number Is Not Sufficient to Enhance the Function of the Hematopoietic Stem Cell Niche. S. Lymperti, A. Cope^{*}, F. Dazzi^{*}, N. Horwood. Kennedy Institute of Rheumatology, London, United Kingdom.

The regulation of haemopoietic stem cell (HSC) fate requires a specialized microenvironment in the bone marrow (BM) cavity called the HSC niche. Accumulating evidence indicates that osteoblasts (OB) are a key component of this niche, regulating HSC number and differentiation state. In this study the role of OB in the niche was further investigated by manipulating their activity with strontium (Sr). Since Sr increases osteoblast activity whilst inhibiting osteoclast differentiation and function, we hypothesized that Sr would improve the HSC supporting capacity of the niche.

Sr, like PTH, promoted bone nodule formation (alizarin red S and Von Kossa staining) and increased production of runx2 mRNA by RT-PCR in primary OB cultures. Administration of Sr to mice resulted in elevated levels of serum osteocalcin as measured by ELISA. Sr-treated mice showed increased bone volume and trabecular thickness defined by micro-CT analysis. In terms of haemopoiesis, Sr-treated mice exhibited increased numbers of haemopoietic progenitor cells compared to untreated control mice as assessed by colony forming unit-cells assay. However, no difference in primitive HSC numbers was detected between the two groups as evaluated by long term culture-initiating cells assay and FACS analysis for lin⁻, sca1⁺, c-kit⁺ cells. When Sr-treated mice were used as donors in HSC transplantation experiments, no difference in HSC engraftment ability was observed. However, when treated mice were used as recipients a delayed recovery was observed. Therefore despite an augmenting effect on OB function, the administration of Sr had no influence on primitive HSC, although the number of haemopoietic progenitors was higher than untreated controls.

It was recently shown that osteoclasts are important in stress-induced mobilization of haemopoietic stem and progenitors cells. The impaired engraftment of HSC observed in Sr-treated recipients, together with the fact that strontium inhibits osteoclastic resorption, implies that BM space could be intimately linked to the effect of bone remodeling whereby factors released from the bone matrix or produced by the osteoclasts themselves are required to provide signals that maintain the stem cell niche. In conclusion, we have shown that, although osteoblasts are indeed key functional component of the niche, an increase in their activity is not enough to expand the stem cell pool size. Therefore, we propose that active osteoclasts and balanced bone remodeling are required for the generation of the optimal HSC niche.

Alteration of Endothelin-1 Effects on Calvarial Osteoblastic Cells from Connexin-43-deficient Mice. G. Geneau^{*1}, C. Niger^{*2}, N. Defamie^{*1}, S. Rodriguez^{*1}, M. Mesnil^{*1}, L. Cronier^{*1}. ¹UMR 6187, Institute of Physiology and Cellular Biology, CNRS, University of Poitiers, Poitiers, France, ²Department of Orthopaedics, University of Maryland School of Medicine, Baltimore, MD, USA.

Gap junctional intercellular communication (GJIC) is known to permit coordinated cellular activities during development and differentiation processes. Accordingly GJIC dysfunction or mutations of gap junction protein (connexin, Cx) genes have been implicated in human pathologies. In bone, in vitro and in vivo studies have demonstrated the implication of Cx43 expression and GJIC in osteoblastic differentiation and in the mineralization process (i.e. Schiller et al., 2001; Chung et al., 2006). Cumulated data support the fact that Cx43 expression is very important for normal bone formation and regulation of cellular responses to hormones/growth factors stimulation and to mechanical load. In this context, since Endothelin-1 (ET1) has been also implicated in the control of osteoblast proliferation/differentiation and in some bone pathologies like prostatic metastasis, the possible cross talk between Cx43 and ET1 was investigated in cultured calvarial osteoblastic cells (OB) isolated from Cx43^{-/-} and Cx43^{+/+} mice.

Interestingly, microcomputed tomographic analysis of 3days-old Cx43^{-/-} mice confirmed the hypomineralization observed in Cx43^{-/-} embryos by Civitelli's group. However, this delayed ossification was restricted to calvaria and in vitro characterization demonstrated that Cx43 protein expression, GJIC, alkaline phosphatase (ALP) activity, osteocalcin mRNA level and mineral deposits were significantly reduced in Cx43^{-/-} OB compared to Cx43^{+/+} OB. Pharmacological approaches using specific antagonists and agonist and quantitative RT-PCR using specific primers for ET1 receptor subtypes (ETA and ETB) revealed that the partial deletion of Cx43 gene was not related to a decrease or a modification in the expression of both receptor subtypes in OB. ET1 (10⁻⁸M) induced an inhibitory effect on OB differentiation in both genotypes whereas this peptide has a mitogenic effect only in Cx43^{+/+} OB. Moreover, the ET1 inhibitory effect on cell differentiation was correlated to a reduced Cx43 expression (-22%) and GJIC (-46%) in Cx43^{+/+} OB. Surprisingly, this correlation was not demonstrated in Cx43^{-/-} OB, suggesting an alternative regulatory pathway. The link between ET1 effect and GJIC was confirmed in the presence of a well-known uncoupler (18-AGA; 30 µM) in the culture medium of Cx43^{+/+} OB cells. In conclusion, these data strongly suggest that the level of Cx43 expression influences the osteoblastic response to ET1.

Modulation of P2X₇ Receptors in Human Osteoblasts by Oestrogen and Corticosteroids. M. Al-qallaf^{*1}, E. J. Kidd^{*1}, B. A. J. Evans². ¹Welsh School of Pharmacy, Cardiff University, Cardiff, United Kingdom, ²Child Health, Cardiff University, Cardiff, United Kingdom.

The P2X₇ receptor (P2X₇R) is usually identified by the greater affinity of dibenzoyl ATP (DBzATP) compared to ATP. Prolonged activation of the P2X₇R results in the formation of a non-selective pore in the cell membrane permeable to molecules as large as 900 Da. Oestrogen has been shown to inhibit osteoblast apoptosis, and hence increase their activity and lifespan. Additionally, oestrogen has been shown to inhibit osteoblast proliferation, an action believed to be through the oestrogen receptor-α. Interestingly, oestradiol has been found to exert non-genomic inhibition of the human P2X₇R in transfected CV-1 monkey kidney cells. The aims of this project were to investigate the modulation of P2X₇R expression and function by oestrogen and dexamethasone in human osteoblasts.

We have studied the effects of pre-incubating (30 minutes or 2 days) human osteoblasts with oestradiol or dexamethasone on P2X₇R expression and function using a cell line representing a late stage of osteoblast differentiation (SaOS2). To investigate the effect of oestradiol and dexamethasone on P2X₇R expression, Western blotting was performed. P2X₇R function was studied by measuring pore formation upon activation with ATP using the YO-PRO 1 (a dye that fluoresces on binding to nucleic acids) uptake method.

Dexamethasone (5 µM) and oestradiol (10 µM) were found to have no effect on P2X₇R protein expression. Concentration-effect curves (CEC) for ATP using the YO-PRO 1 assay gave EC₅₀ values of 0.36 mM ± 0.12. Oestradiol and dexamethasone were found to have no effect on the ATP EC₅₀ values, but they decreased the maximum YO-PRO 1 uptake induced by the agonist. Oestradiol significantly decreased maximum YO-PRO 1 uptake after pre-incubation for 30 minutes and 2 days by 22 and 38%, respectively. Dexamethasone significantly decreased maximum YO-PRO 1 uptake after 30 minutes incubation by 19%, but had no effect following a 2 day pre-incubation.

The results show that the P2X₇R expression at the protein level is not modulated by oestradiol or dexamethasone. However, oestradiol was found to have an inhibitory action on P2X₇R function after 30 minutes and 2 days pre-incubation. A non-classical, non-genomic mechanism must be responsible for the action of dexamethasone and oestradiol after 30 minutes incubation. The effect of the 2 day incubation with oestradiol could be genomic or non-genomic. These effects of oestradiol and dexamethasone on the P2X₇R might be important mechanisms for their modulation of osteoblast function. Further experiments are required to elucidate the function of the P2X₇R in these cells.

Silencing Dkk1 Expression Rescues Dexamethasone-induced Bone Loss In Vitro. J. S. Butler¹, C. J. Hurson^{*1}, R. T. Moon^{*2}, J. M. O'Byrne^{*3}, P. P. Doran^{*1}. ¹UCD School of Medicine & Medical Science, Mater Misericordiae University Hospital, Dublin, Ireland, ²Howard Hughes Medical Institute, University of Washington School of Medicine, Seattle, WA, USA, ³Dept of Trauma & Orthopaedic Surgery, Royal College of Surgeons in Ireland, Dublin, Ireland.

Osteoporosis is a common skeletal disorder characterised by a reduced bone mass and a progressive micro-architectural deterioration in bone tissue leading to bone fragility and susceptibility to fracture. The Wnt/β-catenin pathway is a major signaling cascade in bone biology, playing a key role in regulating bone development and remodeling, with aberrations in signalling resulting in disturbances in bone mass.

Our objectives were to assess the gene expression profile of primary human osteoblasts (HOBs) exposed to dexamethasone with a view to identifying key genes driving bone mass regulation and to assess the effects of the Wnt antagonist Dickkopf-1 (Dkk1) on the bone profile of primary human osteoblasts exposed in vitro to dexamethasone.

HOBs were cultured in vitro and exposed to 10⁻⁸M dexamethasone over a time course of 4hr, 12hr and 24hr. RNA isolation, cDNA synthesis, in vitro transcription and microarray analysis were performed. Microarray data was validated by quantitative real time RT-PCR. Dkk1 expression was silenced using small interfering RNA (siRNA). Quantitative RT-PCR was performed to confirm gene knockdown. Control and Dex-treated HOBs were compared with respect to bone turnover. Markers of bone turnover analyzed included alkaline phosphatase activity, calcium deposition, osteocalcin expression, along with cell proliferation and cellular apoptosis.

Global changes in HOB gene expression were elicited by dexamethasone. Development associated gene pathways were co-ordinately dysregulated with the expression profile of key genes of the Wnt Pathway significantly altered. Dkk1 expression in HOBs was increased in response to dexamethasone exposure with an associated reduction in alkaline phosphatase activity, calcium deposition and osteocalcin expression. Silencing of Dkk1 expression, as confirmed by quantitative RT-PCR, was associated with an increase in alkaline phosphatase activity and calcium deposition, along with increased cell proliferation and reduced cellular apoptosis.

Dkk1 is an antagonist of Wnt/β-catenin signalling and plays a key role in regulating bone development and remodeling. Silencing the expression of Dkk1 in primary human osteoblasts has been shown to rescue the effects of dexamethasone-induced bone loss in vitro. The pharmacological targeting of the Wnt/β-catenin signaling pathway offers an exciting opportunity for the development of novel anabolic bone agents to treat osteoporosis and disorders of bone mass.

Glucocorticoid Suppresses the Differentiation of Osteoblasts by Enhancing the Expressions of BMP Antagonists, Follistatin and Dan, and Pretreatments with Alendronate and PTH Abolish this Process. K. Hayashi^{*}, T. Yamaguchi, S. Yano, M. Yamauchi, M. Yamamoto, T. Sugimoto. Internal Medicine 1, Shimane University Faculty of Medicine, Izumo, Japan.

Glucocorticoid-induced osteoporosis (GIO) is known to be caused by the suppression of osteoblast-mediated osteogenesis, and to be effectively treated by bisphosphonate and parathyroid hormone (PTH). However, the exact mechanisms by which glucocorticoid(GC) suppresses osteoblast functions, or alendronate and PTH cure GIO are still unclear. The impaired BMP-Runx2 signal is known to be one of candidates for the suppression of osteogenesis by GC. The present study was performed by using osteoblastic MC3T3-E1 cells in order to clarify the mechanisms by which GC modulated this signal pathway and whether or not bisphosphonate as well as PTH antagonized GC-induced effect on this process. Dex (10⁻⁷M) significantly inhibited the proliferation of the cells through Day 7 by cell counting and BrdU incorporation. Dex (10⁻⁹ - 10⁻⁷ M) also strongly and dose-dependently suppressed the mineralization of the cells at Days 21 and 28 by Alizarin red stain and von Kossa stain. Real-time PCR revealed that Dex (10⁻⁷ M) reduced the mRNA expressions of type I collagen, osteocalcin, and Runx2. In contrast, mRNA expressions of BMP antagonists, Follistatin and Dan, were increased by Dex (10⁻⁷ M). Western blotting also revealed that protein expressions of Dan and follistatin were increased by Dex (10⁻⁷ M). The addition of a neutralizing antibody for Dan partially reversed the Dex-induced suppression of mineralization of the cells. Moreover, pretreatments of the cells with alendronate (10⁻⁸ M) or human PTH-(1-34) (10⁻⁸ M) also reversed the Dex-induced enhancement in mRNA expression of follistatin and Dan. The present findings suggest that Dex may inhibit the differentiation of osteoblasts by suppressing the BMP signal pathway through enhanced expressions of its antagonists, follistatin and Dan, and that the effectiveness of bisphosphonate and PTH in treating GIO may be partly explained by the abolishment of this process.

ChIP-on-chip Analysis Reveals Novel Glucocorticoid Response Genes Adjacent to Genomic Binding Sites for Steroid Hormone Receptor in Osteoblastic Cells. K. Horie-Inoue^{*1}, K. Takayama^{*2}, S. Inoue². ¹Division of Gene Regulation and Signal Transduction, Research Center for Genomic Medicine, Saitama Medical University, Saitama, Japan, ²Department of Geriatric Medicine, Graduate School of Medicine, University of Tokyo, Tokyo, Japan.

Glucocorticoid causes secondary osteoporosis by increasing bone resorption and impairing bone formation. Investigation of the glucocorticoid-dependent gene regulatory network in osteoblasts will provide useful information to elucidate the pathophysiology of glucocorticoid-induced osteoporosis. Glucocorticoid receptor (GR) belongs to the nuclear receptor superfamily, and functions as a ligand-induced transcriptional factor that regulates the expression of its target genes by recognizing and binding to the steroid hormone response elements (SHREs) in the gene regulatory regions. The prototypic consensus SHRE is a palindromic sequence that consists of two hexameric half-sites arranged as inverted repeats with a 3-bp spacer. Besides GR, other steroid hormone receptors for androgen, mineralocorticoid, and progesterone can also recognize and bind to the identical consensus SHREs. In the present study, we investigate whether novel glucocorticoid response genes can be identified in the vicinity of SHREs that have been previously validated as androgen response elements. Using chromatin immunoprecipitation (ChIP) assay combined with DNA microarray technique (ChIP-on-chip), we identified 10 bona-fide androgen-dependent SHREs in human prostate cancer LNCaP cells in the genomic regions that are being investigated by the ENCYCLOPEDIA OF DNA ELEMENTS (ENCODE) project. We examined whether these SHREs in the ENCODE regions could also recruit GR ligand-dependently and the expression of their adjacent genes could be modulated by glucocorticoid in osteoblastic Saos2 cells. Among the genes in the vicinity of the SHREs, pepsinogen C (PGC) and UDP glucuronosyltransferase 1A1 (UGT1A1) mRNAs were up-regulated by >2-fold in Saos2 cells (4.6-fold and 2.9-fold, respectively) in response to dexamethasone (10 nM) treatment for 6 h. The SHREs in the proximal upstream region of PGC and the 17-kb upstream region of UGT1A1 were shown to recruit GR ligand-dependently by ~2-fold in response to dexamethasone treatment for 1 h. The present data suggest that the systemic investigation of functional SHREs by ChIP-on-chip analysis is useful to identify novel glucocorticoid response genes in osteoblastic cells, which may play roles in the pathogenesis of glucocorticoid-induced osteoporosis as well as in the physiological hormone regulation.

Acid-induced Stimulation of COX-2 and RANKL in Osteoblasts Is Mediated by IP₃. N. S. Krieger, A. C. Michalenka*, K. LaPlante Strutz*, D. A. Bushinsky. Medicine, University of Rochester, Rochester, NY, USA.

Chronic metabolic acidosis stimulates net calcium (Ca) efflux from bone by regulation of osteoblastic activity leading to stimulation of osteoclastic resorption. This acid-induced bone resorption is mediated primarily by stimulation of osteoblastic cyclooxygenase 2 (COX2) mRNA and subsequent prostaglandin E₂-mediated increase in RANKL. We hypothesize that extracellular [H⁺] transduces its intracellular signal through a G protein-coupled proton sensing receptor, OGR1, recently identified in osteoblasts and coupled to inositol trisphosphate (IP₃)-mediated Ca release. We have shown previously that acid-induced bone Ca efflux from neonatal mouse calvariae is inhibited by TMB-8 and 2-APB, both of which inhibit IP₃ mediated Ca signaling. To further define the signaling pathway that responds to H⁺, we now demonstrate that these inhibitors also block osteoblastic COX2 and RANKL production. Neonatal mouse calvariae were incubated for 48h in Met (pH ~7.11) or neutral (Ntl, pH ~7.40) medium in the absence or presence of 100 μM TMB-8 or 50 μM 2-APB. Medium was changed at 24 h. As before, incubation in Met induced a marked increase in net Ca efflux and this bone resorption was significantly blocked by each inhibitor. In parallel, immunoblot analysis shows a significant increase in COX2 protein at 48h in calvariae in response to Met compared with Ntl (Ntl=0.37±0.04, Met=1.18±0.16, normalized to actin, p<0.05). This increase in COX2 protein was also significantly inhibited by treatment with TMB-8 (Met + TMB-8 = 0.13±0.05) or 2-APB (Met + 2-APB=0.20±0.10). Our previous studies have shown that the increase in COX2 in response to Met occurs within 6h in primary osteoblastic cells isolated from the calvariae. We now demonstrate that incubation of cells for 6h in the presence of TMB-8 also significantly inhibits the acid-induced increase in COX2 mRNA, as measured by realtime PCR (Ntl=2.49±0.47, Met=5.70±1.19, Met + TMB-8=1.54±0.27 normalized to actin). Acid stimulation of osteoblastic COX2 protein, measured by immunoblot analysis, was also inhibited by TMB-8 and 2-APB (Ntl=0.84±0.11, Met=1.18±0.11, Met + TMB-8=0.43±0.05, Met + APB= 0.61±0.08, normalized to actin). Increases in RANKL in response to Met occur downstream of stimulation of COX2. In primary cells Met increased RANKL mRNA compared to Ntl after 48h and this stimulation of RANKL mRNA was significantly inhibited in the presence of TMB-8 (Ntl=3.27±0.59, Met=7.81±2.02, Met + TMB-8=1.87±0.56, normalized to actin). Thus, our results are consistent with a requirement for a H⁺-induced increase in osteoblastic IP₃-stimulated Ca release from intracellular stores which would stimulate production of COX2 and then RANKL, leading to the subsequent increase in osteoclastic bone resorption.

ATP Is Released From Human Osteoblasts By Multiple Mechanisms. J. A. Gallagher¹, J. P. Dillon^{*1}, P. M. Wilson^{*1}, H. E. Burrell^{*1}, M. J. Hayton^{*1}, W. D. Fraser², A. Gartland³. ¹Human Anatomy and Cell Biology, University of Liverpool, Liverpool, United Kingdom, ²Clinical Chemistry, University of Liverpool, Liverpool, United Kingdom, ³Bone Biology, University of Sheffield, Sheffield, United Kingdom.

There is a growing recognition that extracellular ATP is one of the most important regulators of bone cell function. Multiple P2 receptor subtypes are expressed by bone cells and these regulate many functions including osteoblast proliferation and gene expression, osteoclast formation and resorptive capacity, and apoptosis of both osteoblasts and osteoclasts. Recent evidence indicates that extracellular ATP plays a pivotal role in mechanotransduction in bone, signalling in part through the P2X7 receptor. Less is known about how ATP is released into the bone microenvironment. We used a combination of end-point and real-time assays, utilising luciferin/luciferase bioluminescence, to monitor release of ATP into the extracellular environment from osteoblast cell lines, SaOS-2, MG63 and Te85, as well as primary human osteoblasts. Real-time assays revealed that ATP is released into the medium constitutively and that this release is exquisitely sensitive to changes in fluid flow. In response to increased flow, there was a rapid rise in ATP concentration in medium bathing the cells, followed by a slower decline back to resting levels. At steady state, the concentration of ATP in the medium of cultures of osteosarcoma cells lines was usually less than 5 nM ATP. In contrast, the ATP concentration in the medium of cultures of primary osteoblasts was up to six fold higher, depending on the donor. The concentration of ATP in medium is a function of ATP release from cells and degradation by ectonucleotidases. End-point assays revealed that fluid flow in the form of medium displacement resulted in a rise in the concentration of ATP which correlated with the number of displacements. After six displacements there was an approximate 10-fold increase in control cultures and 16-fold in cultures treated with ionomycin. Treatment with N-ethylmaleimide inhibited constitutive and fluid displacement-stimulated release, probably by blocking N-ethylmaleimide sensitive factor, a protein that regulates membrane fusion events in exocytosis. Addition of a monoclonal antibody that blocks the action of the P2X7 receptor had variable effects on extracellular concentration of ATP, both in control and fluid displacement cultures, but it was never completely effective in blocking ATP release. These data demonstrate that ATP release varies between osteoblastic cell lines, can be stimulated by fluid flow and is mediated by more than one mechanism. The effect of fluid flow on ATP release could be a key factor in mechanotransduction in bone.

Microstructural Variation in the Bone Matrix and Cell Attachments Modify Strain Amplification on the Osteocyte. A. R. Bonivitch¹, L. E. Bonewald², D. P. Nicoletta¹. ¹Mechanical and Materials Engineering, Southwest Research Institute, San Antonio, TX, USA, ²School of Dentistry, University of Missouri-Kansas City, Kansas City, MO, USA.

Osteocytes make up over 90% of all bone cells and are hypothesized to be the mechanosensors in bone that mediate the effects of loading. Measurements of bone strain in humans using strain gages have been used for strain applications in *in vitro* bone cell experiments. The limitation of applying this strain magnitude to cells *in vitro* is that the *in vivo* strain gage measurements represent continuum measures of bone deformation. Clearly, bone is not a continuum, but heterogeneous, especially at the spatial level of bone cells. Microstructural inhomogeneities result in inhomogeneous strain fields in which local tissue strains are magnified. The objective of this study was to investigate how microstructural bone tissue strains may be transmitted to an embedded osteocyte and its cell processes and to determine how changes in the perilacunar bone tissue structure and properties affect osteocyte strain and deformation. Previously we had created a parametric finite element model composed of an osteocyte lacuna, canaliculi, perilacunar tissue, and surrounding bone tissue. This model showed that a decrease in perilacunar tissue elastic modulus amplifies the perilacunar tissue strain and canalicular deformation. As the perilacunar elastic modulus decreases with glucocorticoid treatment, this may change the level of strain perceived by the osteocyte. In the present model, an osteocyte, cell processes, and glycoalyx attachments to the cell and cell processes were added. A displacement was applied to the model resulting in a global strain of 2000 microstrain and 27 simulations were performed with varying osteocyte and cell process moduli, perilacunar tissue moduli, and glycoalyx and cell process attachment stiffness. Maximum strain levels in the osteocyte reached over 10,000 microstrain, 5 times the applied macroscopic strain of 2000 microstrain. Similar strain levels had been observed in lacunae in bone slices previously. Maximum strain within the osteocyte was found to occur on the cell membrane, parallel to the plane of applied strain. Maximum osteocyte strain was found to increase with a decrease in perilacunar tissue modulus and decrease with an increase in perilacunar tissue modulus consistent with perilacunar tissue strains in the earlier model. A decrease in the osteocyte, glycoalyx, and cell process stiffness led to a decrease in the maximum strain transmitted to the osteocyte. In summary, this model can predict the influence of each component of the osteocyte structure and microenvironment on location and magnitude of cellular and dendrite deformation.

Bone Microarchitecture of Irradiated and Bone Marrow Transplanted Mice. A. Dumas^{*1}, M. Brigitte^{*2}, M. F. Moreau^{*1}, M. F. Baslé^{*1}, R. K. Ghérandi^{*2}, D. Chappard¹. ¹Faculté de Médecine, INSERM, EMI 0335, Angers, France, ²Faculté de Médecine, Université Paris XII, INSERM, EMI 0011, Créteil, France.

Osteopenia and osteoporosis are complications of renal, hepatic, cardiac and bone marrow transplants. Bone loss is attributed to transplant-related treatments (ciclosporine, glucocorticoids...) whether they act directly on bone cells or they deregulate the hormonal system. Total body irradiation provokes hypogonadism and increases osteoclast number and activity without increase in bone formation.

We investigated the effects of total body irradiation and bone marrow transplantation (BMT), without additional treatment, on bone mass and microarchitecture in a murine model. C57Bl/6 (B6) mice were lethally irradiated and within 1 day received syngeneic bone marrow cells expressing the green fluorescent protein. Transplanted mice (T-B6) and age-control B6 mice were euthanized 1, 3 and 6 months after BMT. Bone mass (BV/TV), mean cortical thickness (Ct.Th), trabecular characteristics (Tb.Th, Tb.N, Tb.Sp, Tb.Pf and SMI) were analyzed by microCT at the distal femur.

One month after irradiation and BMT, T-B6 presented a 56.9% bone loss compared to B6 at the same age. T-B6 did not restore their bone mass with time whereas BV/TV of B6 increased. The difference in bone mass between both groups reached 80.8% six months after BMT. Bone microarchitecture was altered in T-B6 mice: Tb.N dramatically decreased 1 month after BMT, Tb.Sp increased whereas Tb.Th was reduced after 6 months. The trabecular bone was less connected with fewer plates. Ct.Th increased significantly with time and, 6 months after BMT, T-B6 had cortical bone of the femoral diaphysis significantly thicker than age-matched B6 (+16%).

Our findings suggest that transplanted bone cells do not restore of the irradiation-induced trabecular bone loss despite an increase in cortical thickness. Effects of irradiation on cortical or cancellous bone remodeling can be considered in the different envelopes.

Lacunocanalicular Fluid Flow and Regulation of Basic Multicellular Unit Activity. G. C. Goulet^{*1}, D. M. L. Cooper^{*2}, D. Coombe^{*3}, D. L. Thomas^{*4}, J. G. Clement^{*4}, R. F. Zernicke^{*5}. ¹Schulich School of Engineering, University of Calgary, Calgary, AB, Canada, ²Department of Orthopaedics, University of British Columbia, Vancouver, BC, Canada, ³Computer Modelling Group, Ltd., Calgary, AB, Canada, ⁴School of Dental Science, University of Melbourne, Melbourne, Australia, ⁵Schulich School of Engineering; Departments of Kinesiology and Medicine, University of Calgary, Calgary, AB, Canada.

Human bone is continuously regenerated through remodeling. This process is carried out by a complex mediator mechanism called the Basic Multicellular Unit (BMUs). Cortical BMUs proceed by osteoclastic excavation of a resorption space (cutting cone) followed by new bone formation by osteoblasts (closing cone). Current theories suggest that the BMU is strain and/or fluid-flow regulated [1,2,3]. While these regulatory models have focused on idealized forms, BMU morphology is variable, including unidirectional, bidirectional, and branched forms. The purpose of this study was to examine strain and fluid flow in relation to realistic BMU forms directly observed in human cortical bone by 3D micro-CT imaging. Computational models were developed in STARS, a coupled finite difference fluid flow and finite element mechanics simulator (Computer Modelling Group, Ltd., Calgary, AB, Canada). Models of a unidirectional and branched BMU were generated. These were subjected to compressive loads, which induced fluid flow through

the simulated lacunocanalicular porosity. Upon loading, fluid flowed from the high-pressure bone matrix into the low-pressure porosity of the BMU. Consistent with previous models, the unidirectional canal model displayed decreased strain in front of the cutting cone, and increased strain behind it. Similarly, the branched model demonstrated strain reduction in front of both cutting cones and increased strain behind them. However, the branched morphology also displayed a similar reduction in strain at the fork where it divided. Fluid stasis has been implicated as a regulating mechanism in BMU activity, whereby decreased osteocytic stimulation results in reduced production of nitric oxide, inducing apoptosis, which subsequently signals the recruitment of osteoclasts. The inter-branch strain shielding and related reduction in fluid flow observed in the branched BMU poses a challenge to this regulatory model since the region between resorption spaces would also be prone to osteocyte apoptosis and osteoclastic activity, effectively eliminating the branched structure. Therefore, strain and related fluid flow alone may not be sufficient to explain BMU regulation.

Increased Expression of Anti-adhesive PODXL in TIEG Knock-Out Osteoclast Precursors Delays Osteoclast Formation and Reduces Osteoclast Size. M. Cicek¹, A. Vrabel^{*1}, M. Subramaniam², T. C. Spelsberg², M. J. Oursler¹. ¹Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA, ²Department of Molecular Biology and Biochemistry, Mayo Clinic, Rochester, MN, USA.

TIEG is a Krüppel-like transcription factor gene which was originally cloned from human osteoblasts as an early response gene to TGF- β treatment. As reported previously, TIEG^{-/-} mice have decreased cortical bone thickness and lower vertebral volume, increased spacing between the trabeculae in the femoral head, and a lower breaking strength compared to wild-type mice. Therefore we investigated the role of TIEG in the osteoclasts that may be responsible for bone phenotype in TIEG^{-/-} mice. In vitro cultures of mouse marrow treated with RANKL and M-CSF, we found that osteoclasts differentiated more slowly and formed reduced numbers of osteoclasts compared to wild type precursors. Moreover, TIEG^{-/-} osteoclasts were significantly smaller than wildtype osteoclasts. Flow cytometry analyses showed that there was no difference in CD11b+ and/or RANK+ and/or c-fms+ in osteoclast precursors in freshly harvested marrow cells between the genotypes. These data led us to hypothesize that loss of TIEG reduced the capacity of TIEG^{-/-} precursors to differentiate into mature osteoclasts. We therefore investigated the role of the anti-adhesive glycosylated cell-membrane protein podocalyxin (PODXL) in osteoclastogenesis in vitro in TIEG^{-/-} and wildtype precursor differentiation. We found that TIEG^{-/-} precursors have increased expression of PODXL relative to the wildtype. Adding RANKL and M-CSF to the in vitro model significantly reduced the expression of PODXL in TIEG^{-/-} precursors, suppressing expression relative to that of wildtype cells. Parallel treatment of wildtype precursors did not reveal any effect on PODXL expression in these cells. These data suggest that the reduced ability of TIEG^{-/-} osteoclast differentiation may be due to an increased expression of anti-adhesive PODXL in these cells. We conclude that TIEG expression may be critical in controlling the rate of osteoclast differentiation and that increased PODXL expression in TIEG^{-/-} may be a key factor in the reduced differentiation and/or the size of TIEG^{-/-} osteoclasts.

Regulation of Integrin Expression by NFATc1 and PU.1 in Osteoclasts. T. N. Crotti¹, M. R. Flannery^{*1}, J. D. Fleming^{*1}, S. R. Goldring², K. P. McHugh¹. ¹Rheumatology and Orthopaedics, Beth Israel Deaconess Medical Center, Boston, MA, USA, ²Hospital for Special Surgery, New York, NY, USA.

Beta-3 and beta-5 integrins play important and contrasting roles in osteoclast (Oc) differentiation and are accordingly reciprocally regulated. The integrin beta-5 is expressed by pre-Ocs and has an inhibitory role in Oc differentiation, as beta-5 knockout mice display enhanced Oc formation. The beta-3 integrin is expressed by mature Ocs and is required for normal Oc function.

NFATc1 is a RANKL-induced and Ca⁺⁺-regulated transcription factor critical for Oc differentiation. NFATc1 with PU.1, an ETS family transcription factor, regulate expression of distinct target genes in Oc differentiation. We provide here direct evidence that NFATc1 and PU.1 are involved in the reciprocal regulation of integrin expression during Oc differentiation.

To test the involvement of NFATc1 in beta-3 integrin expression, we generated mouse beta-3 promoter/reporter constructs (-1350 to +34bp; mB3-1350) which include a composite NFAT and PU.1 binding site conserved from mouse and man. The mB3-1350 construct was trans-activated >60X by co-transfected NFATc1 in RAW264.7 cells, consistent with our previous report on regulation of the human beta-3 promoter. Trans-activation was abolished by deletion to -1084, and further deletions were similarly unresponsive. Direct binding of NFATc1 and PU.1 to the mouse beta-3 promoter was demonstrated by EMSA. Consensus NFAT and PU.1 oligos competed, while oligos with mutant NFAT or ETS sites failed to compete. The identity of the protein moieties was verified by supershift with anti-NFATc1 and PU.1 antibodies. Mutation of either the NFAT or PU.1 binding site, in the context of mB3-1350, abrogated NFATc1 trans-activation. The specificity of PU.1, among ETS family members, to induce mB3-1350 was demonstrated by co-transfection in HEK293 cells. NFATc1 trans-activation of the mB3-1350 promoter was specifically facilitated by PU.1. NFATc1 had no effect when co-transfected with Ets-1, ESE1, or Elf, however Ets-1 and Elf mediated the highest basal expression.

We previously reported that TAT-mediated transduction with a dominant-negative (dn)NFATc1 construct dose-dependently blocked spreading of mouse osteoclasts and inhibited expression of the endogenous beta-3 integrin gene. In addition to this, we find reciprocal dose-dependent induction of the endogenous beta-5 integrin by TAT-dnNFATc1. The mouse beta-3 integrin gene is therefore a specific target of NFATc1 during RANKL-induced Oc differentiation through direct binding of NFATc1 and PU.1 to specific sites in the beta-3 promoter. Furthermore, NFATc1 function is coupled with, and required for, down-regulation of the beta-5 integrin gene Oc cells.

The Decisive Moment of Osteoclast Fusion and Apoptosis Captured Under a Microscope Connected with Time-Lapse Motion Video Picture. A. Itabashi¹, T. Ohnuma^{*2}, Y. Takada^{*1}. ¹Saitama Center for Bone Research, Kumagaya, Japan, ²Yone Production, Tokyo, Japan.

Osteoclasts are multinucleated bone cells that are formed by multiple cell fusions. Mature osteoclasts undergo several cycles of activation and inactivation, where bone is resorbed in the active state and osteoclasts migrate in the resting state, eventually, the cells die apoptotically. However, there are few pictures or videos that captured the moment of osteoclast fusion or apoptosis. In this study, we tried to capture those pictures in collaboration with a science movie company.

We first observed mouse calvarial bone cells under a microscope connected with time-lapse motion video picture in organ culture conditions continuously for more than 96 hours. We could observe osteoblast division and bone matrix formation. We could also capture the decisive moment of osteoclast fusion using isolated rabbit osteoclasts with stromal cells. Osteoclasts had many cell processes folding in and sticking out from their cell surfaces, and moved around in a culture dish actively. When the cell process made contact with that of the other osteoclast, rapid movements between those processes were observed. Often they separated again after some conversation between them. But some cells started to make continuous contact with each other, with busy communication through cell membranes. And then one part of cell membrane overlapped with other cell membrane, and cell contents started to mingle and multiple nuclei from each osteoclast assembled to form a giant multinucleated osteoclast. The huge osteoclast moved around actively as one cell and it could be maintained in the plastic dish under culture conditions for several hours, then rapidly decreased movement. After that, spontaneous apoptosis occurred in that cell with cell shrinkage and fragmentation of nuclei.

Using time-lapse video picture system under regular culture conditions for certain amount of time, we can observe the way the osteoclasts fuse and die. This can contribute to understand the mechanism of osteoclast fusion and apoptosis.

Tropomyosin-2/3 Regulate the Intracellular Scaffold of Osteoclasts. P. Kotadiya^{*}, B. K. McMichael, T. Singh^{*}, B. S. Lee. Physiology and Cell Biology, The Ohio State University, Columbus, OH, USA.

Tropomyosins (Tms) are actin-binding proteins that stabilize microfilaments and inhibit or recruit binding of other actin-associated proteins. In nonmuscle cells, over twenty alternately spliced isoforms are expressed from four distinct genes, namely the alpha gene (Tm-2, -3, -5a/b, -6), the beta gene (Tm-1), the gamma/5NM gene (Tms NM-1 to NM-11), and the delta/Tm-4 gene (Tm-4). Recent studies have indicated that individual Tm isoforms are distributed to different intracellular locations where they regulate specific actin pools. Therefore, the goal of this work is to determine the roles of tropomyosin isoforms in mature osteoclast activity.

Our previous studies showed that at least eight Tm isoforms are expressed in osteoclasts and that some of these, including Tm-2 and 3, are not present in monocyte-macrophage precursors but are upregulated during osteoclastogenesis. These isoforms differ by only a few amino acids; therefore, reagents that distinguish between them are limited. However, Tm-2 is present in osteoclasts at levels about four-fold higher than Tm-3. Immunocytochemical analysis showed that they are dispersed throughout the interior of osteoclasts and are only loosely intercalated in the podosomes and actin rings. To analyze the role of Tm-2/3 in osteoclasts, the effects of both Tm-2/3 suppression and overexpression have been studied in these cells. It was found that cells treated with Tm-2/3-specific siRNAs covered a greater surface area, but contained the same number of nuclei, as control cells. These results suggest that loss of Tm-2/3 results in increased cell spreading. This hypothesis is supported by data showing that the siRNA-treated cells are flattened relative to controls. These cells also are greatly diminished in their motility in Transwell assays. Additionally, resorption assays illustrated that the total resorption area was similar in Tm-2/3-suppressed cells and controls, but the siRNA-treated cells generated fewer, but larger, resorbed areas. On the other hand, increasing Tm-2 levels by overexpression also distorted cell shape. On glass, these cells were distinctly more spherical than controls and lacked podosomes. Instead, these overexpressing cells contained patches of actin and sometimes stress fibers at their base. This in turn led to decreased motility by these cells. In summary, these findings indicate that Tm-2/3 are involved in regulating cell shape and motility, likely due to stabilization of actin microfilaments that create a cellular scaffold.

Effect of Pore Size and Surface Modification of the Circular Poly-Ethylene Glycol(PEG) Polymer Scaffold on Adhesion of Cultured Human Ligamentum Flavum Cells. C. Lee^{*1}, H. Kim^{*1}, J. Lee^{*1}, M. Nan^{*1}, J. Park^{*2}, E. Moon^{*2}, S. Park^{*3}, H. Kim^{*2}, J. Jahng^{*2}, S. Moon^{*2}, H. Lee^{*2}, H. Chun^{*4}, H. Kim^{*2}. ¹Orthopaedic Surgery, Brain Korea 21 Medical Science Graduate School of Yonsei University, Seoul, Republic of Korea, ²Orthopaedic Surgery, Yonsei University College of Medicine, Seoul, Republic of Korea, ³Orthopaedic Surgery, Korea University College of Medicine, Seoul, Republic of Korea, ⁴Mechanical Engineering, School of Mechanical Engineering of Yonsei University, Seoul, Republic of Korea.

Tissue engineering requires viable cells and cellular-compatible scaffold. Poly-Ethylene Glycol(PEG) polymer is a probable option of scaffold with its unique advantages. Nevertheless, it is still needed to be characterized that the effect of surface modification with making pore with various size and coating with collagen. Hence, we report the effect of surface modification by circular pore and type I collagen coated to cellular attachment and viability of ligamentum flavum (LF) cells. Human LF tissue was harvested, digested, and cultured. Poly-Ethylene Glycol(PEG) hydrogel micropatterns were fabricated from PEG by using a photomask illuminated with UV light. Collagen-coated PEGs were made by immersion in type I collagen solution. Then LF cells (1×10^5) were seeded on PEG with various pore size (50, 100, 200 μ m) with or without collagen coating. After 2 days' incubation, adherent cells were imaged in SEM. Cellular viability was assessed by live/dead cell viability kit. Most LF cells were found at the base of pore, however, some patches of cells were found on the surface of PEG and inner surface of the PEG pore. No visible cellular adhesion was noted in PEG with the pore size of 50 μ m. However, in PEG with the pore size of 100 and 200 μ m there is marked cellular adhesion to the surface of PEG and even inner surface of the PEG pore. Surface modification of PEG with type I collagen renders more efficient adhesion of LF cells on the modified surface of PEG. Even with collagen coating, PEG with pore size of 50 μ m failed to show any significant cellular adhesion. Adhered cells on the surface of PEG were all viable in all experiment group. In summary, PEG scaffold with the pore size of 100 and 200 μ m was non-toxic to the LF cell and provided suitable surface for LF cell adhesion. Surface modification with type I collagen facilitated process of cellular adhesion to PEG surface. New modification such as one sided sealing of the pore is need for more efficient cellular containment within PEG pore.

Myosin X Regulates Osteoclast Adhesion Through Linkage of Podosomes and Microtubules. B. K. McMichael¹, R. E. Cheney^{*2}, B. S. Lee¹. ¹Physiology and Cell Biology, The Ohio State University, Columbus, OH, USA, ²Cell and Molecular Physiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA.

Osteoclasts generate two distinct actin-based adhesion structures--podosomes for migration, and the actin ring of the sealing zone for resorption. Although podosomes are actin-based structures, their patterning is microtubule dependent. In this study, the role of myosin X (myo10) in osteoclast adhesion was assessed. Myo10 is an unconventional myosin that consists of a motor domain, three light chain binding domains, and a unique tail consisting of pleckstrin homology domains (PH), a myosin tail homology 4 domain (MyTH4), and a FERM domain. The multifaceted myo10 has been shown to bind many osteoclast regulatory proteins including microtubules, β 1/ β 3/ β 5 integrins, products of PI3 kinase, and VASP, along with binding actin via the motor domain. Initial immunocytochemical analysis of osteoclasts showed myo10 to be localized immediately adjacent to, but not overlapping, podosome belts and the actin ring, suggesting a potential role in positioning of these structures. To analyze its role, myo10 expression was inhibited in both RAW264.7 and mouse marrow derived osteoclasts via RNA interference. Myo10 suppression resulted in diminished spreading of osteoclasts cultured on glass. Suppression also led to a decrease in the size of the actin ring with an even greater decrease in bone resorption and motility. Further, inhibition of myo10 levels resulted in a microtubule-based podosome patterning defect. When microtubules of osteoclasts were depolymerized by cold treatment, both siRNA-treated and control cells showed redistribution of podosomes away from the cell periphery. However, when allowed to recover, the siRNA-treated cells, unlike the control cells, could not distribute their podosomes back to the periphery even though they reformed the microtubule network. These results suggest that myo10 may act as a link between podosomes and microtubules through its tail domains. Indeed, detailed immunocytochemical analysis of osteoclasts during podosome positioning shows myo10 localized between podosomes and the surrounding microtubule system. Over-expression of sections of the tail, either PH, MyTH4, or FERM alone or in combination, caused formation of aberrant podosomes while over-expression of all three domains had a dominant negative effect similar to the phenotype manifested in the siRNA-treated cells. These results taken together clearly suggest a role for myo10 in linking the microtubule network to podosomes through its tail domain.

Expression and Possible Role of PVR/CD155/ Necl-5 in Osteoclastogenesis. I. Morita, S. Kakehi^{*}, K. Nakahama. Cellular Physiological Chemistry, Tokyo Medical and Dental University, Tokyo, Japan.

Osteoclast, the bone-resorbing cell, is differentiated from hematopoietic precursors via two-step cell-cell interactions; interaction between osteoclast precursor and stromal cell, and interaction among osteoclast precursors. We have previously reported that some adhesion molecules have a crucial role in these interactions. Recently, poliovirus receptor (PVR, CD155, Necl-5) was reported to play important roles in cell adhesion and migration. However, there is no report of PVR in osteoclastogenesis. Here, we examined the expression of PVR and its ligand, DNAX accessory molecule-1 (DNAM-1, CD226) in osteoclast precursor, mature osteoclast and stromal cell. We found that the PVR was constitutively expressed in both osteoclast cells and stromal cells. The expression of PVR was not changed at various stages of osteoclast formation. In contrast, the expression of DNAM-1 was observed in mononuclear cells and was down-regulated during osteoclastogenesis. Moreover, multinucleated osteoclast formation was inhibited by treatment with extracellular domain of DNAM-1 (ED-DNAM-1) as a soluble ligand for PVR, but mononuclear preosteoclast formation was not affected. Especially, during the 7-days cultivation, osteoclast formation was suppressed by the treatment with ED-DNAM-1 on days 6 and 7, when mononuclear preosteoclast fused into multinucleated osteoclasts. This suppression was abrogated partially by small interfering RNA specific for PVR. These results indicated that the binding of PVR with DNAM-1 negatively regulates osteoclast formation via inhibition of cellular fusion caused by PVR mediated signaling. Our report may suggest the possibility of a new therapy for bone loss diseases by activation of PVR signaling.

Spacio-Temporal Analysis of Osteoclastogenesis Using Co-culture System. K. Nakahama¹, S. Ichinose^{*2}, I. Morita¹. ¹Cellular Physiological Chemistry, Tokyo Medical and Dental University, Tokyo, Japan, ²Instrumental Analysis Research Center, Tokyo Medical and Dental University, Tokyo, Japan.

The mechanism of osteoclast differentiation has been well studied in vivo and in vitro. But, in our knowledge, little is known about the spacio-temporal aspects of preosteoclast differentiation into multinuclear osteoclast. To examine the spacio-temporal aspects of osteoclastogenesis, the stromal cells and spleen-derived mononuclear cells were labeled with calcein-AM and CellTracker Orange CMRA respectively. The spleen-derived mononuclear cells were co-cultured on the confluent stromal cells. In this co-culture system, tartrate-resistant acid phosphatase (TRAP)-positive multinuclear osteoclasts were observed under the stromal cells after 5-days culture without stimulation. Confocal microscopic observation revealed that mononuclear cells migrated under stromal cells after 6-hrs co-culture. Surprisingly, in addition to the paracellular migration (migration via cell junction), transcellular migration (migration via stromal cell body) of spleen-derived mononuclear cell was detected. These two types of migrations were confirmed using scanning electron microscopy. Immunocytochemical study showed strong expression of intercellular adhesion molecule-1 (ICAM-1) and its counter receptor macrophage antigen-1 (Mac-1) on spleen-derived mononuclear cell, but not on stromal cells at 24-hrs after co-culture. The polarized localization of ICAM-1 indicated that ICAM-1 plays some roles in the migration of spleen-derived mononuclear cells. Two-days after co-culture, some aggregated mononuclear cells expressed ICAM-1 at cell-cell adhesion sites. After 5-days co-culture of the cells, multinucleated TRAP-positive osteoclasts were formed. Interestingly, we also detected the localization of ICAM-1 at cell-cell association site among osteoclasts. ICAM-1 localization in some osteoclasts was observed at apical surface of the membrane. Collectively, these results suggest that preosteoclasts will migrate under the stromal cells paracellularly and transcellularly, thereafter they will fuse each other. There may be suitable conditions at basolateral side of stromal cells. Polarized localization of ICAM-1 on osteoclast would indicate some important roles in migration and fusion of preosteoclasts.

HMGB1 Regulates Actin Cytoskeleton Organization and RANKL-induced Osteoclastogenesis in a Manner Dependent on RAGE. Z. Zhou¹, D. Ferguson², J. Xie¹, C. Xi¹, D. Stern², L. Mei¹, W. Xiong¹. ¹Institute of Molecular Medicine and Genetics, Medical College of Georgia, Augusta, GA, USA, ²University of Cincinnati, Cincinnati, OH, USA.

High-mobility group box 1 (HMGB1), a non-histone nuclear protein, is released by macrophages into the extracellular milieu consequent to cellular activation. Extracellular HMGB1 has properties of a pro-inflammatory cytokine via its interaction with receptor for advanced glycation endproducts (RAGE) and/or toll-like receptors (TLR2 and TLR4). Although HMGB1 is highly expressed in macrophages and differentiating osteoclasts, its role in osteoclastogenesis remains largely unknown. Here we present evidence for a function of HMGB1 in this event. HMGB1 is released from macrophages in response to RANKL stimulation, and is required for RANKL-induced osteoclastogenesis *in vitro* and *in vivo*. In addition, HMGB1, like other osteoclastogenic cytokines (e.g., TNF α), enhances RANKL-induced osteoclastogenesis *in vivo* and *in vitro* at sub-threshold concentrations of RANKL, which alone would be insufficient. The role of HMGB1 in osteoclastogenesis is mediated largely by its interaction with RAGE, and regulation of α v β 3 integrin signaling and osteoclastic actin ring formation. Together, HMGB1-RAGE signaling appears to be important in regulating osteoclastic actin cytoskeleton reorganization, thereby participating in RANKL-induced osteoclastogenesis. These observations provide a new link between inflammatory mechanisms and bone resorption.

Precursor Analyses of CD11c⁺Dendritic Cells-derived Osteoclasts. M. Alnaeeli^{*}, D. Mahamed^{*}, J. Park^{*}, Y. Teng^{*}. Department of Microbiology & Immunology and Eastman Department of Dentistry, University of Rochester, Rochester, NY, USA.

Inflammation-induced osteoclastogenesis is a well established osteoimmunological phenomenon, whereby osteoclasts (OC) frequency and activity become elevated under inflammatory conditions. Dendritic cells (DC) are professional antigen presenting cells that not only infiltrate bone tissues during inflammation, but are also suggested to share common precursors with OC. Previously we reported and characterized the *in vitro* development of TRAP⁺ CT-R⁺ cathepsin-K⁺ CD11c⁺ MHC-II⁺ multinucleated functional OC from murine CD11c⁺DC (called; DDOC), in response to RANKL and bacterial or protein antigens during immune interactions [J. Immunol. 177(5): 3314-26 & JBM, in press, 06/2007]. Here, we aimed to study the clonal characteristics of DDOC by determining their OC precursor frequency and proliferative capability. We employed colony forming unit assay and limiting dilution analysis, using purified murine bone marrow-derived CD11c⁺DC (purity $\geq 98\%$) in the presence of 100ng/ml RANKL & 10 μ g/ml sonicated antigens of *Aggregatibacter* (*Actinobacillus*) *actinomycetemcomitans*; an anaerobic human pathogen. After 5 days culture and when compared to the controls, the purified CD11c⁺DC: i) did not manifest any proliferative capability ($p=0.003$), and ii) had an estimated precursor frequency of $8.4 \pm 0.06\%$, based on the number of TRAP⁺ multinucleated (≥ 3 nuclei) OC yielded. To investigate the physiological relevance of the DDOC phenomenon, we studied the osteoclastogenic potential of murine CD11c⁺DC *in vivo*. Interestingly, after the injection of carboxyfluorescein succinimidyl ester-labelled freshly purified DC onto mouse calvarias, we found CFSE⁺ TRAP⁺ multinucleated OC-like cells associated with higher local bone loss, compared to the control groups, suggesting that CD11c⁺DC can become TRAP⁺ multinucleated OC under inflammatory conditions *in vivo*. Furthermore, our immunohistochemical analysis detected the presence of CD11c⁺ multinucleated OC-like cells on the subchondral bone surfaces of the arthritic joints in DBA mice but not healthy controls. Collectively, these findings support the possible development of DDOC at the osteo-immune interface, which may be an integral part of the mechanisms underlying inflammation-induced osteoclastogenesis in inflammatory bone disorders such as rheumatoid arthritis and periodontal disease.

In Vivo Activation of Toll-Like Receptor 9 Modulates Osteoclastogenesis. A. Amcheslavsky^{*}, Z. Bar-Shavit. Experimental Medicine and Cancer Research, Hebrew University, Jerusalem, Israel.

Toll-like receptor (TLR) ligands are pathogen-derived molecules that activate the innate immune response. Many studies have shown that activation of these receptors in osteoclast lineage cells accelerates osteoclast formation and activity. In recent years, several groups have shown that pathogen-derived molecules such as peptidoglycan, viral RNA (mimicked by poly-IC), lipopolysaccharides and bacterial DNA (mimicked by CpG-oligodeoxynucleotides [CpG-ODNs]), the ligands of TLR2, 3, 4 and 9, respectively, inhibit RANKL-induced osteoclastogenesis under certain conditions. *In vitro* studies led to the hypothesis that activation of TLRs in early osteoclast precursor cells inhibits their differentiation, while in cells that have been primed with RANKL and have already begun their osteoclastic differentiation, TLR ligands are potent stimulators of osteoclastogenesis. In the present study, we examine how *in vivo* administration of the TLR9 ligand CpG-ODN impacts osteoclastogenesis. Mice were injected, either *i.p.* or *i.v.*, with the TLR9 ligand CpG-ODN. Bone marrow cells were harvested 1-7 days later and an osteoclastogenesis assay was performed. No effect was observed 1 day

after injection, but in all other treatments the injection of CpG-ODN increased the number of osteoclasts formed in response to RANKL. Consistent with previous *in vitro* findings, osteoclast differentiation was greater in cells harvested from BALB/c mice injected with CpG-ODN than in cells from C57BL/6-injected mice. CpG-ODN did not exert any effect when injected to TLR9 knockout mice. The failure to identify conditions under which CpG-ODN inhibits osteoclast differentiation can be explained in two ways. Either, this effect occurs only *in vitro*, or both inhibition and stimulation of osteoclastogenesis take place *in vivo*, but the stimulatory effect is more pronounced and, therefore, a net inhibitory effect is not observed. Since the inhibitory effect of CpG-ODN is exerted on early precursors, we injected mice with 5-fluorouracil (5FU), which is known to enrich the bone marrow with early stem cells. Indeed, a reduction in osteoclast differentiation was observed when CpG-ODN was injected into 5FU-treated mice. Thus, TLR9 activation *in vivo* confirms the effect observed *in vitro*. The inhibition of osteoclast differentiation in early precursor cells may play a role in reducing the excessive bone loss caused by pathogenic infection and shifting the balance between the bone and immune systems during infection to recruit the immune system.

CreatinE Kinase Brain Type (CK-B) Involves in the Bone Resorptive Activity of Osteoclast Activity through by Regulating the V-ATPase and Rho Activity. E. Chang¹, J. Ha¹, F. Oerlemans², H. Kim¹, B. Wieringa², Z. Lee¹, H. Kim¹. ¹Department of Cell and Developmental Biology, College of Dentistry, BK21 and DRI, Seoul National University, Seoul, Republic of Korea, ²Department of Cell Biology, Nijmegen Centre for Molecular Life Sciences, Radboud University Medical Centre, Nijmegen, Netherlands Antilles.

Osteoclasts, responsible for bone resorption, differentiate from the hematopoietic precursor cells of the monocyte/macrophage lineage. Receptor activator of nuclear factor- κ B ligand (RANKL), in the presence of M-CSF, mediates osteoclast formation and activation through binding to its receptor RANK on osteoclast precursor cells. Some proteins highly expressed in osteoclasts have been suggested as molecular targets for development of anti-bone resorptive drugs. Previously, we identified through a proteomics approach that the brain type cytoplasmic creatine kinase (CK-B) is greatly increased in osteoclasts. In this study, we found that inhibition of CK-B blocked V-ATPase and Rho activity, resulting in the decrease of *in vitro* bone-resorbing activity of osteoclasts. *In vivo* experiments with a CK inhibitor also showed a reduced bone resorption in ovariectomized rat model. Using CK-B (-/-) KO and wild-type (WT) mice, we investigated the V-ATPase and Rho activity and *in vitro* bone-resorbing activity on dentine slice. Compared with that in WT mice, both the V-ATPase and Rho activity was decreased in KO osteoclasts. In aged mice, BMD in femur was significantly more increased in KO than in WT mice. These data reveal that CK-B, up-regulated in osteoclasts, plays an important role for bone resorbing activity of osteoclasts. Therefore, CK-B might be a good target for anti-resorptive drug development.

Jagged1-Notch2 Signaling Promotes Osteoclast Differentiation In Vitro. H. Fukushima¹, A. Nakao¹, F. Okamoto¹, H. Kajiya¹, E. Jimi², K. Okabe¹. ¹Physiological Science & Molecular Biology, Fukuoka Dental College, Fukuoka, Japan, ²Molecular Signalling & Biochemistry, Kyusyu Dental College, Fukuoka, Japan.

Notch related genes play a key role in various cell differentiation processes. Expression of Notch receptors in hematopoietic cells and expression of their ligands in bone marrow stromal cells suggests a possible role for Notch signaling in the regulation of osteoclastogenesis. However, the role of this Notch signaling pathway is unclear. Expression of Notch2 is upregulated during osteoclast differentiation, on the other hand, expression of Jagged1 of the Notch ligand family increases in osteoclasts and primary osteoblasts stimulated with osteoclast differentiation factors. To assess the involvement of Notch signaling in osteoclastogenesis, we generated RAW264.7 cells to permit the conditional induction of Notch2 specific shRNA using tetracycline-induced expression. Induction of Notch2 shRNA resulted in suppression of RANKL-induced osteoclast differentiation. Transient transfection of constitutively active intracellular domain of Notch2 in bone marrow macrophages increased NFATc1 activity and osteoclast differentiation. Treatment with Jagged1 activated Notch2 signaling and osteoclastogenesis. The selective γ -secretase inhibitor, L685,458 suppressed Notch signaling activity and RANKL-induced osteoclast differentiation from bone marrow macrophages. Furthermore, the intracellular domain of Notch2 was found to interact with p65 and p50 in NF κ B signaling but not c-Fos. RBPJ κ , a transcription factor in the downstream Notch signaling pathway, possesses a consensus sequence near the NF κ B binding site of NFATc1/P1 promoter. Activation of Notch2

increased the promoter activity of RANKL-induced NFATc1/P1 in RAW264.7 cells. Co-activation of Notch2 and p65 also activated NFATc1/P1 promoter. These data suggest that Notch2 interacts with Jagged1 and promotes osteoclastogenesis via activation of NFATc1 and NFkB signaling in osteoclast precursor cells.

Extracellular Matrix Proteins Affect both Osteoclast Formation and Resorptive Activity. A. Gramoun^{*1}, D. P. Trebec², N. Azizi^{*1}, J. Sodek^{*1}, M. F. Manolagas¹. ¹Faculty of Dentistry, University of Toronto, Toronto, ON, Canada, ²Department of Biochemistry, University of Toronto, Toronto, ON, Canada.

Tissue destruction in arthritis is associated with bone loss and elevated levels of the extracellular matrix (ECM) proteins in affected joints. Osteoclasts (OCs), the bone resorbing multinucleated cells, are formed by fusion of mononuclear precursors. The ECM proteins, vitronectin (VN), fibronectin (FN) and osteopontin (OPN), all implicated in arthritis, interact with OCs through the integrin $\alpha\beta3$. To determine the effects of VN, FN and OPN on OC formation and resorptive activity RAW 264.7 (RAW) cells were plated and differentiated (using 100 ng/ml RANKL) on dishes or OsteologicTM slides precoated with 0.01-20 μ g/ml FN, VN, and OPN; concentrations shown not to affect cell proliferation. After 96 hours of differentiation, dose response experiments showed that OC number on VN and FN remained significantly lower than those on OPN and the uncoated controls. Measuring tartrate-resistant acid phosphatase (TRAP) activity levels revealed that only VN and OPN attenuated differentiation up to 72 hours. Furthermore, counting the number of mononuclear TRAP+ cells (preOCs) at 48 hours and large OCs (> 10 nuclei) at 96 hours showed that while FN did not affect preOC number, it significantly decreased OC formation and multinucleation compared to the uncoated control. OPN on the other hand, had the opposite effect. Resorption studies revealed that both FN and OPN increased the total area of resorption and resorptive activity/OC by 40% compared to VN and the uncoated control groups. Further, FN increased the released TRAP/OC in cultures. Nitric oxide levels (as measured by Griess reagent) were significantly elevated by FN but not in any of the other groups. When cells were differentiated for 3 days then incubated with 1 μ g/ml of the anti-rat $\alpha\beta3$ antibody, VNR149, (or its IgG control) for 24 hours, VNR149 significantly increased the total OC number on FN compared to its control by 37% while VN, OPN and the control groups showed a significant decrease in OC numbers. We also observed that OCs on FN had a 1.5 fold increase in $\alpha\beta3$ cell surface expression compared to uncoated group, as determined by flow cytometry. In conclusion, despite its inhibitory effect on preOC fusion and OC formation, FN significantly enhanced resorption/OC. FN's induction of nitric oxide and the increased $\alpha\beta3$ expression, could both explain the increased OC activity. VN attenuates both differentiation and preOC fusion thus decreasing OC formation. This results in an overall reduction in total resorption and resorption per OC. Early effects of OPN on osteoclastogenesis are similar to VN. Beyond 48 hours, OPN promotes both the formation and fusion of preOCs resulting in an elevation of resorption.

Suppression of Osteoclastogenesis by N,N-dimethyl-D-erythro-sphingosine: A Sphingosine Kinase Inhibition-Independent Action. H. Kim^{*}, Y. Lee^{*}, E. Chang^{*}, H. Kim^{*}, S. Hong^{*}, Z. Lee^{*}, J. Ryu^{*}, J. Ko, H. Kim. Cell and Developmental Biology, College of Dentistry, BK21 and DRI, Seoul National University, Seoul, Republic of Korea.

N,N-dimethyl-D-erythro-sphingosine (DMS) competitively inhibits sphingosine kinase (SPHK) and has been widely used to assess the role of SPHK during cellular events including motility, proliferation, and differentiation. In the present study, the effect of DMS on the differentiation of bone marrow macrophages (BMMs) to osteoclasts was investigated. When the osteoclast precursor cells were treated with DMS, the receptor activator of nuclear factor kappa B ligand (RANKL)-induced osteoclastogenesis was completely blocked. Surprisingly, however, knock-down of SPHK by siRNA in BMMs did not reduce osteoclastogenesis. Furthermore, both overexpression of SPHK and exogenous addition of sphingosine-1-phosphate, the product of SPHK activity, failed to overcome the anti-osteoclastogenic effect of DMS. These results suggest that DMS inhibited osteoclastogenesis independently of SPHK. Subsequent characterization of the DMS-mediated suppression of osteoclastogenesis revealed that DMS did not affect RANKL-induced activation of JNK, p38, NF- κ B, and Ca^{2+} oscillation. On the other hand, DMS strongly inhibited two separate signaling pathways, the RANKL-induced activation of ERK and Akt, which eventually converged on the transcription factors c-Fos and NFATc1. There was significant increase in the osteoclast formation in the presence of DMS when BMMs were overexpressed with c-Fos, suggesting that c-Fos was a critical downstream target of DMS for the inhibition of osteoclastogenesis. Taken together, our data demonstrate that DMS has an anti-osteoclastogenic function independently of its SPHK inhibitory activity. Considering previously reported anti-cancer properties of DMS, our study may also propose that DMS is an ideal drug candidate for bone metastases, for which osteoclastic bone-resorption is crucial.

PIAS3 Negatively Regulates RANKL-induced Osteoclastogenesis. T. Hikata¹, H. Takaishi^{*1}, M. Matsumoto^{*2}, H. Takayanagi^{*3}, A. Yoshimura^{*4}, H. Asahara^{*5}, Y. Toyama^{*1}. ¹Department of Orthopaedic Surgery, School of Medicine, Keio, University, Tokyo, Japan, ²Department of Molecular Biology, Saitama Medical School, Saitama, Japan, ³Department of Cellular Physiological Chemistry, Tokyo Medical Dental University, Tokyo, Japan, ⁴Division of Molecular and Cellular Immunology, Medical Institute of Bioregulation, Kyusyu University, Kyusyu, Japan, ⁵Department of Innovative Surgery, National Center for Child Health and Development, Tokyo, Japan.

It is known that protein inhibitor of activated STAT3 (PIAS3) not only inhibits the DNA binding activity of STAT3 in the JAK/STAT signaling pathway, but also interacts with MITF that is an important transcription factor for the osteoclast differentiation, and to regulate the gene expression in the downstream. We found that PIAS3 was widely expressed in RAW 264.7, bone marrow-derived monocyte/macrophage lineage cells (BMMs) and mouse primary osteoblasts (POB). To clarify the physiological role of PIAS3 in the bone resorption, we examined the biological effect of PIAS3 on RANKL-induced osteoclastogenesis in the culture systems using hematopoietic osteoclast precursors. Retroviral gene transduction of PIAS3 in RAW264.7 and BMMs drastically inhibited the formation of the multinucleated TRAP-positive osteoclasts. PIAS3 also suppressed the expression of osteoclast differentiation markers such as TRAP and Cathepsin K, and attenuated the protein expression of c-Fos and NFATc1 during RANKL-induced osteoclastogenesis. In PIAS3-transduced RAW264.7, the suppression of c-fos and NFATc1 DNA-binding activity was observed using ELISA-based screening system for the several transcription factors regulating osteoclast differentiation. To confirm further the functional roles of PIAS3 in osteoclast-specific gene regulation, we performed reporter gene assays using 293T and Cos7 cells. PIAS3 suppressed NFATc1, PU.1, and MITF-induced promoter activity of the TRAP and CathepsinK in a dose dependent manner. PIAS3 also produced dose-dependent inhibition of MITF-induced c-Fos promoter activity. ChIP assays showed that overexpression of PIAS3 in RAW264.7 inhibited MITF binding to the c-Fos promoter region mediated by RANKL treatment as compared to the mock-transduced control. Furthermore, siRNA knockdown of PIAS3 led to accelerated expression of RANKL in the POB stimulated with IL-6 and sIL-6R. Taken together, our results demonstrate that a possible role of PIAS3 as a negative transcriptional regulator in osteoclastogenesis directly and indirectly. These results may offer molecular approaches for the treatment of inflammatory bone destruction.

Osteoclast Differentiation During Medullary Bone Formation Period in Japanese Quail Bone Marrow Cell Culture. S. Hiyama, E. Yamanishi^{*}, M. Watanabe^{*}, T. Uchida^{*}. Department of Oral Biology, Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan.

Medullary bone is a unique tissue of female birds, that is formed in the long bone marrow cavity to reserve and provide for calcium of egg-shell. This bone is remodeling during the reproductive period. On the other hand, when male birds are once injected estrogen (E2) into male birds, medullary bone is formed by osteoblasts that are derived by bone lining cells and immediately resorbed by osteoclasts. However, it is not clear why osteoclasts can differentiate rapidly, and can resorb to medullary bone. To address this question, we isolated to bone marrow cells (BMC) from femurs of male Japanese quails that injected E2 at 3 (Day3), 2 (Day2), 1 (Day1), and 0 days (Day0) before slaughter, and cultured with or without RANKL & M-CSF for 4 and 8 days. At culture 4 days, in either of the presence or the absence of RANKL & M-CSF, TRAP-positive mononuclear cells were existed. TRAP-positive multinucleated cells were slightly found in RANKL & M-CSF treated BMCs. TRAP-positive multinucleated cells were increased from culture 4 days to 8 days at BMCs of each Day. However, these cells in the absence of RANKL & M-CSF were small compared with these cells in the presence of RANKL & M-CSF. In Day3 RANKL & M-CSF treated BMCs, there was much number of TRAP-positive multinucleated cells in comparison with other Days BMCs, and these cells were very large. To confirm that these BMCs were expressed the transcription factors, NFATc1 and c-Fos, RT-PCR analysis was carried out. Although c-Fos mRNA was expressed all Days BMCs, non-RANKL & M-CSF treated BMCs were very low expressed and RANKL & M-CSF treated BMCs were high expressed. The expression of NFATc1 mRNA was increased in RANKL & M-CSF treated BMCs during culture, but not expressed in non-treated BMCs. Furthermore, to evaluate the ability to resorb of bone in these cells, we cultured with these cells on the calcium-phosphate coated culture dishes. In the absence of RANKL & M-CSF, resorption area was almost observed to neither BMCs of each Day. However, the area of resorption was recognized in RANKL & M-CSF treated BMCs, especially Day3 BMCs. In addition, bone resorption activity was inhibited by osteoprotegerin, as a decoy receptor of RANKL. Our results suggest that osteoclast precursor cells increase in the bone marrow cavity during medullary bone formation. Moreover osteoclast differentiation may be regulated by osteoblasts that formed medullary bone.

Actin Binding Activity in the B Subunit Is Required for Sorting Vacuolar H⁺-ATPase (V-ATPase) in Osteoclasts. L. S. Holliday¹, J. Zuo^{*1}, R. Ricofort^{*1}, E. Serrano^{*1}, A. Cooper^{*1}, S. S. Grieshaber^{*2}, ¹Orthodontics, University of Florida College of Dentistry, Gainesville, FL, USA, ²Oral Biology, University of Florida College of Dentistry, Gainesville, FL, USA.

Actin binding activity is required for transport of virally-expressed B1 subunit of the vacuolar H⁺-ATPase (V-ATPase) to the ruffled membranes of osteoclasts(1). We are seeking the mechanistic basis for this requirement. Gel filtration chromatography, immunoprecipitations, differential detergent extractions, differential centrifugations and Native Blue gel electrophoresis were used to determine the assembly state of V-ATPases that bound actin in osteoclasts. Cholera toxin beta chain, which binds ganglioside GM1 (GM1), lysotracker probes and anti-V-ATPase subunit antibodies were used to probe the pathways responsible for ruffled membrane formation in murine osteoclasts. V-ATPase subunit B1 and B1mut (which does not bind actin) were expressed using adeno-associated virus. LY294002 was used to block phosphatidylinositol-3 kinase activity. Our results were consistent with B subunit interacting with actin only as part of intact, membrane-associated V-ATPases. This suggests that the actin binding activity is required for sorting V-ATPases into a specific vesicular trafficking pathway. GM1 was identified as a "surprising" marker for V-ATPase-rich vesicles in inactive osteoclasts and for ruffled membranes of resorbing osteoclasts. GM1 is normally endocytosed from the plasma membrane and sorted into a retrograde pathway through the golgi to the endoplasmic reticulum. Virally-expressed B1 subunit co-localized extensively with GM1, but B1mut did not. Sorting along this retrograde pathway has been reported to require the activity of vps34p (class III PI 3-kinase) and phosphatidylinositol 3-phosphate 5-kinase (PIKfyve). When PI 3-kinases were blocked using LY294002, large vacuoles that were rich in GM1 and V-ATPases quickly became apparent, a result consistent with disruption of the retrograde pathway. We also found that PIKfyve was upregulated 5-fold during osteoclastogenesis suggesting it plays an important role in osteoclasts. Our data indicate that the actin binding activity of subunit B of V-ATPase enables sorting of V-ATPases away from their default locations in the endocytic pathway into GM1-rich vesicles that then fuse with the plasma membrane as osteoclasts activate to form ruffled membranes. We are testing the hypothesis that this actin-dependent sorting targets V-ATPases into the vps34p/PIKfyve-dependent retrograde pathway, which may have been adapted in osteoclasts for the formation of ruffled membranes.

Alterations in MicroRNAs and GW Bodies Are Associated with Osteoclastogenesis. J. Zuo^{*1}, A. Jakymiw^{*2}, K. M. Pauley^{*2}, E. K. Chan^{*2}, L. S. Holliday¹, ¹Orthodontics, University of Florida College of Dentistry, Gainesville, FL, USA, ²Oral Biology, University of Florida College of Dentistry, Gainesville, FL, USA.

Understanding and manipulating osteoclastogenesis requires knowing the mechanisms that regulate gene expression during this process. MicroRNAs, small endogenous RNAs, about 22 nucleotides in length, are thought to use the elements of the RNA-interference pathway to post-transcriptionally down-regulate the expression of protein-coding genes. Recent reports have identified GW bodies (mammalian P bodies) as sites that are important for microRNA-dependent regulation. We screened for differential expression of microRNAs in RAW 264.7 cells grown with or without treatment with recombinant Receptor Activator of Nuclear Factor Kappa B-ligand (RANKL) using a microRNA microarray. Some results were then confirmed by real time PCR. GW bodies, sites of microRNA-based regulation were identified using specific antibodies. We identified 9 microRNAs that were strongly downregulated (expressed to not expressed) and 6 microRNAs that were strongly upregulated (not expressed to expressed) in response to RANKL during osteoclastogenesis. In addition, the members of the let-7 family were expressed at high levels in both stimulated and unstimulated RAW cells, and all increased from 2-3 fold in response to RANKL. Six of the twelve subunits of vacuolar H⁺-ATPase as well as a number of other proteins known to be upregulated during osteoclast formation are predicted targets (MIRANDA and TargetScan 3.1, Sanger Institute) of one or more of the downregulated microRNAs. MicroRNAs 146 and 155, which have been reported to be upregulated during inflammatory responses in macrophages, were strongly upregulated in response to RANKL. GW bodies increased in number in RAW 264.7 cells as they differentiated into osteoclast-like cells. In summary, our data support the hypothesis that regulation of gene expression by microRNAs plays a role in osteoclastogenesis. Understanding this regulation may identify novel categories of pharmaceuticals for the treatment of osteoclast-mediated diseases.

Molecular Cloning and Characterization of Mouse RANK Gene Promoter Region. J. Ishii^{*1}, R. Kitazawa¹, T. Kondo¹, K. Mori¹, K. P. McHugh², S. Kitazawa¹, ¹Division of Pathology, Kobe University Graduate School of Medicine, Kobe, Japan, ²Beth Israel Deaconess Medical Center, Orthopaedic Research, Boston, MA, USA.

Receptor Activator of NF- κ B (RANK), expressed on osteoclasts and their precursors, is a receptor for RANK ligand (RANKL), a membrane-bound cytokine expressed in stromal/osteoblastic cells; signals transduced by RANK-RANKL interaction are prerequisite for differentiation, activation and maintenance of osteoclasts. To elucidate the mechanism regulating RANK gene expression during osteoclastogenesis, we cloned and characterized the 5'-flanking region of the mouse RANK gene. A 6-kb fragment containing this region was subcloned from a BAC clone and sequenced. The transcription start sites were determined by the 5'-RACE method. A 1-kb fragment upstream of the transcription start sites was ligated to the promoterless and enhancerless pGL3-basis vector (pGL3-RANK) and transfected into the mouse monocyte/macrophage cell line, RAW264.7, by the liposome mediated technique. The transfected cells were subjected to luciferase assay. Transient transfection studies showed significant pGL3-RANK promoter activity in RAW 264.7 cells. The basic promoter region of the mouse RANK gene lacked canonical TATA boxes but contained four Sp-1 binding sites located at -98, -79, -65, and -58, and four transcription start sites located at -54, -41, -27, and -23 upstream of the translation start site. Putative binding sites for PU.1 (-480), CRE/AP-1 (-240), E-box (-510, -260, -100), and NFAT (nuclear factor of activated T cells) (-720, -550, -370) were located within the 1-kb fragment of the transcription start sites. Co-transfection studies with the use of the expression vectors of MTF and PU.1 revealed that MTF and PU.1 increased RANK promoter activity three-fold and two-fold, respectively, and six-fold synergistically. Since lipopolysaccharide (LPS) is one of the factors that influences RANK gene expression in osteoclasts and their precursors, we examined the molecular mechanism whereby LPS affects RANK expression. Quantitative real-time RT-PCR showed that the expression of RANK as well as MTF and PU.1 mRNA was suppressed by treatment with LPS. Mirroring the decrease of MTF and PU.1 mRNA to 70% by LPS treatment, transient transfection studies with pGL3-RANK revealed that short-term treatment with LPS also decreased the promoter activity to 70%. We therefore speculated that RANK gene expression is influenced by two transcription factors, MTF and PU.1, both of which are prerequisite for macrophage and osteoclast differentiation, and that LPS suppresses the RANK gene, at least in part, by downregulating the expression of MTF and PU.1 genes.

Iron Uptake Through the Transferrin Receptor 1 Promotes Osteoclast Differentiation and Function. K. Ishii^{*1}, S. Takeshita¹, N. Shimohata^{*2}, M. Ito³, H. Aburatani^{*4}, S. Taketani^{*5}, K. Iwai^{*2}, K. Ikeda¹, ¹Department of Bone and Joint Disease, National Center for Geriatrics and Gerontology (NCGG), Obu, Japan, ²Department of Molecular Cell Biology, Osaka City University Graduate School of Medicine, Osaka, Japan, ³Department of Radiology, Nagasaki University School of Medicine, Nagasaki, Japan, ⁴Genomescience Division, University of Tokyo School of Medicine, Tokyo, Japan, ⁵Department of Biotechnology, Kyoto Institute of Technology, Kyoto, Japan.

Osteoclasts are acid-secreting polykaryons that are rich in mitochondria. However, how mitochondrial biogenesis is stimulated during osteoclast development remains unknown. Gene expression analysis with mouse genome arrays containing 39,000 transcripts revealed transferrin receptor (TfR) 1 mRNA, which was barely detectable in bone marrow macrophages (BMMs), was markedly induced along with osteoclast differentiation. Electrophoretic mobility shift assays revealed binding of iron regulatory protein (IRP)2 to iron-responsive element (IRE) in the TfR1 mRNA 3'UTR to be markedly increased during osteoclastogenesis. Thus, IRP2 senses a heme/iron deficient state in osteoclasts and, by binding to IRE of TfR1, leads to the upregulation of TfR1 through stabilization of its mRNA. Through the increased TfR1 on the cell surface, the addition of holo-Tf as well as apo-Tf markedly stimulated the formation of TRAP-positive osteoclasts from BMMs dose dependently, which effect was inhibited by iron chelation with desferrioxamine (DFO). The pit area resorbed by mature osteoclasts was also significantly increased by Tf and decreased by DFO, suggesting that TfR1 on osteoclasts is functional, and that iron uptake through TfR1 not only promotes osteoclast formation but also the bone-resorbing function of mature osteoclasts. Gene chip analysis disclosed that almost all of the mRNAs coding for respiratory complexes I-V of mitochondria were concomitantly upregulated during osteoclastogenesis. As many of these heme-containing proteins are involved in electron transport, the mitochondrial membrane potential was increased by RANKL, which was markedly enhanced by Tf. Finally, pre-treatment of OVX mice with DFO significantly inhibited bone loss and the level of a bone resorption marker, CTX, suggesting that iron is an important regulator of osteoclastic bone resorption in vivo. In conclusion, uptake of iron through TfR1 and subsequent incorporation of heme/iron into mitochondrial respiratory proteins are critical for osteoclast development and bone-resorbing function.

Role of P-Rex1 in Osteoclast Differentiation. H. Kang*¹, D. Wu*². ¹Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, ²Pharmacology, Yale University, New Haven, CT, USA.

Guanine nucleotide exchange factors (GEFs) directly activate Rho family GTPases in response to various extracellular stimuli and play a crucial role in actin cytoskeleton rearrangement, an essential part for the differentiation and function of osteoclasts. Despite of presumed implication of GEFs in osteoclast biology, in vivo role of GEFs in osteoclasts has been poorly demonstrated. Here, we test possible involvement of P-Rex1 in osteoclast formation and ultimately in bone remodeling. P-Rex1 was identified as a phosphatidylinositol (3,4,5) trisphosphate- and Gbetagamma-regulated GEF for Rac that is implicated in chemotactic response in neutrophils. In order to examine the role of P-Rex1, P-Rex1 knockout mice were generated by inactivating Dbl homology domain, which is an essential region for GEF function to activate target Rho GTPases. Osteoclast differentiation of bone marrow-derived macrophages (BMMs) was induced by recombinant RANKL (receptor activator of NF- κ B ligand). The osteoclast formation was estimated using tartrate-resistant acid phosphatase (TRAP) staining. BMMs from P-Rex1 knockout mice showed a defect in forming TRAP-positive multinuclear cells (controls were syngenic wild-type mice). This result suggests that P-Rex1 is among the regulators for development of functional multinuclear TRAP-positive osteoclasts. Given the fact that nitrogen-containing bisphosphonates, which target small G proteins in osteoclasts, are used as antiresorptive agents in the treatment of metabolic bone diseases, identification of key GEFs in osteoclasts may contribute to more specific pharmaceutical targeting of small G proteins.

BMP-2-Inducible Osterix Increases Osteoblastic CSF-1 and RANKL/OPG Ratio to Induce Osteoclast Maturation. C. C. Mandal¹, G. Ghosh-Choudhury*², H. Drissi³, N. Ghosh-Choudhury⁴. ¹Pathology, UTHSCSA, San Antonio, TX, USA, ²Medicine, UTHSCSA, GRECC, STVHCS, San Antonio, TX, USA, ³Orthopaedics, University of Rochester Medical Center, Rochester, NY, USA, ⁴Pathology, UTHSCSA, STVHCS, San Antonio, TX, USA.

Bone remodeling results from balanced action of osteoblasts and osteoclasts. BMP-2-inducible master transcription factor osterix (Ox) is essential for osteoblast differentiation and mature bone formation. Through a paracrine cytokine signaling loop, osteoblasts contribute to differentiation and maturation of osteoclasts by producing two critical factors, CSF-1 and RANKL. Expression of Ox in two different mesenchymal progenitor cells, 2T3 and C2C12, resulted in increased expression of CSF-1 and RANKL mRNA. In contrast, Ox reduced mRNA expression of osteoprotegerin (OPG), a RANKL antagonist and negative regulator of osteoclast differentiation. To investigate the mechanism, we tested the effect of Ox on CSF-1, RANKL and OPG transcription using luciferase reporter constructs driven by these promoters. BMP-2 as well as Ox independently increased transcription of CSF-1 and RANKL, while OPG transcription was significantly reduced. However, expression of Ox additively increased CSF-1 and RANKL transcription and prevented transcription of OPG. Thus osteoblast-specific Ox maintains significantly high RANKL-OPG ratio. In an effort to elucidate the mechanism, Genomatix analysis of the CSF-1 promoter revealed the presence of consensus Ox binding site between -287 bp and -246 bp (from transcription start site). Nuclear extracts prepared from BMP-2-stimulated C2C12 cells were tested in electrophoretic mobility shift assay (EMSA) using ³²P-labeled double stranded oligonucleotide representing this Ox site in the CSF-1 promoter. BMP-2 significantly increased protein-DNA complex formation, the specificity of which was determined by cold competition analysis. Use of Ox antibody in EMSA showed the presence of Ox in the DNA-protein complex. To further characterize the role of Ox in osteoclastogenesis, we stably transfected HA-tagged Ox into C2C12 and 2T3 cells respectively. Anti-HA immunoblotting of the cell lysates confirmed expression of Ox in both these cells. These cells were used in coculture assay to examine their osteoclastogenic property. Both C2C12 and 2T3 cells overexpressing Ox significantly increased TRAP positive multinucleated osteoclast formation. Together these data for the first time show a mechanism for the master transcription factor Ox action, which regulates expression of osteoblastic cytokines CSF-1, RANKL and OPG. Furthermore, we provide the first direct evidence confirming the contribution of Ox in osteoclast maturation.

Use of Nanogels as a Drug Delivery System for Tumor Necrosis Factor- α Antagonist in Murine Bone Resorption Model. C. N. R. Alles*¹, M. H. Mian*¹, N. S. Soysa*¹, H. Saito*², K. Aoki², K. Akiyoshi*¹, K. Ohya².

¹Center of Excellence for Frontier Research on Molecular Destruction and Reconstruction of Bone, Tokyo Medical and Dental University, Tokyo, Japan, ²Section of Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan.

Our previous study has shown that a TNF antagonist peptide (WP9QY/W9) inhibits RANKL-induced bone resorption (J Clin Invest 116:1525-1534, 2006). Easy degradation in serum is a major drawback in clinical application of this peptide. On the other hand nanogels have emerged as a promising carrier in delivering proteins and peptides. Hence we hypothesized cholesterol group-bearing pullulan (CHP) nanogel as a candidate in delivering TNF- α antagonist in vivo. We reported previously (C.N.R. Alles et al. ASBMR 2006) using C57BL/6J mice on low Ca diet injected with veh, CHP nanogel, W9 or CHP-W9 complex, that twice a day subcutaneous injections of the CHP-W9 complex prevented the reduction in BMD in mice on low Ca diet. From these BMD data it was not clear whether the formation was increased or the resorption is decreased. To this end histomorphometry was performed at the sites of metaphysis of tibiae. CHP-W9 complex prevented the decrease of bone volume parameters significantly: trabecular volume ($p < 0.001$), trabecular thickness ($p < 0.05$) and trabecular number ($p < 0.001$) and prevented the increase of trabecular separation ($p < 0.001$) compared to low Ca-veh group. CHP-W9 complex prevented the increase of osteoclast surface ($p < 0.05$) and number ($p < 0.05$) to bone surface brought by low Ca as well. Conversely the complex substantially mitigated the increase of osteoblast surface to bone surface ($p < 0.005$) and mineral apposition rate (MAR) ($p < 0.005$). Similarly the bone resorption parameter, urine deoxypyridinoline in low Ca-veh group ($p < 0.05$) was significantly increased compared to the normal Ca-veh and CHP-W9 complex groups. To further confirm the in vivo complexation of W9 with CHP nanogel, in vitro stability test was performed. W9 was easily dissolved in alkali whereas it tends to aggregate in low pH. By using Dynamic Light Scattering (DLS) analysis, we observed the association of peptide with nanogels. When peptide is added with CHP nanogel, even at pH 6.5, W9 could completely dissolve in nanogels. Taken together these results suggested that the twice a day subcutaneous injection of CHP-W9 complex was effective in preventing the bone resorption brought by low Ca feeding as agreeing with previous study which use 8x/day injections. This implied that the complex was stable in serum and achieved a constant release corroborating our in vitro data. Hence our study confirmed that nanogels could be used as an effective carrier to deliver W9 peptide.

Development of Cell-Based Assays for Identifying Antiresorptive Compounds Targeting RANK Signaling through High Throughput Screening. J. Ashley*¹, Z. Shi*¹, E. Mills*¹, D. Clements*¹, T. Chen*², X. Feng¹. ¹Dept. of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, ²Dept. of Chemical Biology & Therapeutics, St. Jude Children's Research Hospital, Memphis, TN, USA.

Current antiresorptive drugs either lack satisfactory efficacy or cause serious side effects. The unraveling of the RANKL/RANK/OPG system has provided an opportunity to develop more effective antiresorptive drugs, but agents currently under development targeting RANK/RANKL interactions are likely to have side effects due to the role of the system in other biological processes. We recently identified three functional TRAF-binding motifs (Motif 1: PFQEP³⁶⁹⁻³⁷³, Motif 2: PVQEET⁵⁵⁹⁻⁵⁶⁴ and Motif 3: PVQEQG⁶⁰⁴⁻⁶⁰⁹) in the RANK cytoplasmic domain. While Motif 2 and Motif 3 are very potent in mediating osteoclast formation and function, Motif 1 plays a minimal role in these processes, instead being the primary actor in RANKL-mediated immune function. Thus, Motifs 2 and 3 can serve as potent and specific antiresorptive targets.

We have developed cell-based high throughput screening (HTS) assays for identifying compounds inhibiting Motifs 2 and 3 signaling. The assays contain three key components: RAW264.7 (RAW) cells, an NF- κ B-responsive luciferase reporter, and a chimeric receptor consisting of human Fas external domain linked to the transmembrane and cytoplasmic domains of normal or mutant RANK. First, we established a RAW cell line stably expressing the luciferase reporter, which showed a 6-fold induction of luciferase activity in response to RANKL treatment. We then prepared and expressed the following chimeric receptors in the stable RAW cell line: M2 (Motifs 1 and 3 in RANK domain are mutated), M3 (Motifs 1 and 2 in RANK domain are mutated). Cells expressing M2 or M3 can be used in HTS for identifying compounds inhibiting Motifs 2 and 3, respectively. For example, treatment of the cells expressing M2 with anti-human Fas antibody (hFas-AB) causes recruitment of TRAF3 to Motif 2, leading to the formation of a signaling complex and activation of NF- κ B, which, in turn, activates the luciferase reporter. If a compound blocks the TRAF3-Motif 2 interaction or the formation of signaling complex, no NF- κ B will be activated by the M2 receptor and subsequent reporter activation will be reduced. Preliminary data indicate that cells expressing M2 and M3 can induce ~1.5-fold reporter activity following hFas-AB treatment. We have also developed additional assays for hit follow up and are now improving assay efficiency by optimizing hFas-AB concentration and treatment time as well as selecting subclones with higher levels of induction. In addition, we are seeking partnerships with groups interested in utilizing our assays.

Cytoplasmic Terminus of a V-ATPase Accessory Subunit Ac45 Is Required for Proper Interaction with V0 Domain Subunits and Efficient Osteoclastic Bone Resorption. T. Cheng^{*1}, H. Feng^{*1}, K. H. M. Yip^{*1}, N. J. Pavlos^{*1}, A. Carrello^{*1}, R. Seeber^{*2}, K. Eidne^{*2}, M. H. Zheng¹, J. Xu¹. ¹Centre for Orthopaedic Research, University of Western Australia, Perth, Australia, ²Western Australia Institute for Medical Research, University of Western Australia, Perth, Australia.

Solubilization of mineralized bone by osteoclasts is largely dependent on the acidification of the extracellular resorption lacuna driven by vacuolar type proton pump (V-ATPases) polarized within the ruffled border membranes. V-ATPases consist of two functionally and structurally distinct domains, V1 and V0. The peripheral cytoplasmically oriented V1 domain drives ATP hydrolysis which necessitates the translocation of protons across the integral membrane bound V0 domain. Here, we demonstrate that an accessory subunit, Ac45, interacts with the V0 domain and contributes to V-ATPase-mediated function in osteoclasts. Consistent with its role in intracellular acidification, Ac45 was found to be localized to the ruffled border region of polarized resorbing osteoclasts and enriched in pH-dependent endosomal compartments which polarized to the ruffled border region of actively resorbing osteoclasts. Interestingly, truncation of the 26aa-residue cytoplasmic tail (aa437-463) of Ac45 (Ac45C-mutant) which encodes an autonomous internalization signal was found to impair bone resorption in vitro. Furthermore, immunoprecipitation and bioluminescence resonance energy transfer (BRET) analysis revealed that although both wild type Ac45 and Ac45C-mutant were capable of associating with V-ATPase subunits a3, c, c', and d, deletion of the cytoplasmic tail altered its binding affinity with a3, c' and d. In all, our data suggest that the cytoplasmic terminus of Ac45 contains essential elements necessary for its proper interaction with V-ATPase and efficient osteoclastic bone resorption.

Modeling Role of ER in Transcellular Calcium Flux in Bone Resorbing Osteoclasts. H. K. Datta. Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom.

It has been shown that Ca^{2+} produced in the osteoclast (OC) hemivacuole by the action of secreted acid is continually transported to the basolateral surface; thus, preventing accumulation of the cation in the resorptive lacuna. Ca^{2+} may be taken up through store-operated Ca^{2+} channels in the basal membrane, the site of the resorptive hemivacuole, and is pumped into the basal endoplasmic reticulum (ER) by Ca^{2+} -ATPases. Ca^{2+} then diffuses through the lumen of the ER from the base to the apical region, where it is released into the cytosol via specific Ca^{2+} channels i.e. inositol 1,4,5-triphosphate (IP_3) and ryanodine receptors. Ca^{2+} is then pumped out of the cell by plasma membrane Ca^{2+} -ATPases which are located in the apical membrane. The route through the lumen of the ER is attractive because of the abundance of calreticulin, a high capacity Ca^{2+} -binding protein which is involved in Ca^{2+} homeostasis. In view of these observations, we attempted to define the role of ER and have modeled the calcium disposal through bone resorbing osteoclast. The modeling was performed using Virtual Cell Software, available from National Resource for Cell Analysis and Modeling (NRCAM), at the website: <http://www.nrcam.uchc.edu>. The model is comprised of four physiological structures, namely hemivacuole, cytosol, ER and extracellular fluid space, giving four respective resolved geometric subdomains. For these resolved structure mixed boundary conditions Neuman and Dirichlet were chosen. The kinetics of calcium pumps and channels are given by linear equation; SERCA pump uptake is modelled by a Hill type equation and channels influx is catalyzed by reaction described by the Michaelis-Menton equation. 2-D geometry involves extensive network, two exact mirror image of the osteoclast-hemivacuole; the line of symmetry of two opposing actively resorbing osteoclast therefore passes through the resorptive hemivacuole. Other relevant parameters, such as constants, functions, and volumes were selected based on published literature. The results of simulations experiments were compared with the experimental observations, and were found to successfully mimic in vivo observations, such as elevated $[\text{Ca}^{2+}]_{\text{ER}}$ and maintenance of $[\text{Ca}^{2+}]_i$ within known physiological range but with high localized $[\text{Ca}^{2+}]_i$ (so-called calcium puffs) near the hemivacuole site. Perturbation experiments performed established a critical role of the ER and its key components in the transcellular Ca^{2+} -transport and buffering. The model has ER which is functionally continuous unit, where Ca^{2+} released from the apical ER is quickly replenished from the base. In conclusion, OC provides an excellent model to test recent suggestion that ER is an important conduit for the transcellular transport of Ca^{2+} in polarized cells.

Tetracyclines [Doxycycline(Dox) and Minocycline(Mino)] Effectively Inhibit Osteoclast Differentiation and Function. S. Kinugawa^{*1}, M. Koide², T. Ninomiya^{*2}, H. Nakamura³, Y. Kobayashi², N. Takahashi², N. Udagawa⁴. ¹Graduate School of Oral Medicine, Matsumoto Dental University, Siojiri, Japan, ²Institute for Oral Science, Matsumoto Dental University, Siojiri, Japan, ³Department of Oral Histology, Matsumoto Dental University, Siojiri, Japan, ⁴Department of Biochemistry, Matsumoto Dental University, Siojiri, Japan.

Tetracyclines (Dox and Mino) are widely used in the treatment of periodontal disease to suppress the growth of bacteria. Tetracyclines also have been shown to prevent bone loss, but the mechanism of action of tetracyclines to inhibit bone resorption is not elucidated. Here, we examined how tetracyclines inhibit bone resorption. We found that both Dox and Mino directly acted on osteoclast (OC) precursors to inhibit their differentiation into OCs, and on mature OCs to inhibit their function.

(1) Increasing concentrations of Dox and Mino were added to co-cultures of mouse bone marrow cells (BMCs) and osteoblasts (OBs) in the presence of PGE_2 and $1\alpha,25(\text{OH})_2\text{D}_3$. Both Dox and Mino dose-dependently inhibited OC formation induced by PGE_2 and $1\alpha,25(\text{OH})_2\text{D}_3$. (2) Effects of Dox and Mino on RANKL and COX-2 mRNA expression in OB cultures were examined by RT-PCR. Treatment of OBs with $1\alpha,25(\text{OH})_2\text{D}_3$ up-regulated RANKL mRNA expression. Dox and Mino added to OB cultures failed to affect $1\alpha,25(\text{OH})_2\text{D}_3$ -induced RANKL mRNA expression. Neither Dox nor Mino induced OB COX-2 mRNA expression. (3) Mouse bone marrow macrophages (BMMs) and human CD14-positive monocytes were cultured as OC precursors in the presence of RANKL and M-CSF with increasing concentrations of Dox and Mino. RANKL and M-CSF stimulated mouse and human OC formation. Dox and Mino dose-dependently inhibited mouse and human OC formation with the complete inhibition at 20 $\mu\text{g}/\text{ml}$ of either compound. (4) When mouse OCs were cultured on dentine slices, they formed many resorption pits on the slices in the presence of OBs. Addition of Dox and Mino at 20 $\mu\text{g}/\text{ml}$ also inhibited the pit-formation activity of OCs. (5) Western blot analysis demonstrated that the treatment of BMMs with lipopolysaccharide stimulated phosphorylation of ERK, a MAP kinase, which was completely inhibited by pretreatment with Dox and Mino. Thus, both Dox and Mino directly inhibited differentiation and function of not only mouse but also human OCs. These inhibitory effects on bone resorption are proposed to be associated with the suppression of MAP kinases. These results suggest that Dox and Mino have great therapeutic potential for the periodontal therapy to suppress alveolar bone loss.

M-CSF Receptor C-fms Antibody Inhibits Mechanical Stress-Induced Root Resorption. H. Kitaura, Y. Fujimura^{*}, M. Yoshimatsu^{*}, T. Eguchi^{*}, H. Kohara^{*}, N. Yoshida^{*}. Division of Orthodontics and Dentofacial Orthopedics, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

Root resorption is occurred during orthodontic treatment, and lead to serious problem. However, because a suitable experimental animal model has been lacking, the biological mechanism is not clearly understood. We established mechanical stress-induced osteoclastogenesis model in mice using orthodontic tooth movement in which an Ni-Ti coil spring was inserted between the upper incisors and the upper first molar. And we found root resorption was occurred in this model during mechanical loading. The formation of osteoclasts depends on macrophage-colony-stimulating factor (M-CSF) and a ligand for the receptor activator of necrosis factor κB (RANKL). It has recently been reported that administration of an antibody of the M-CSF receptor c-fms completely blocked pathological osteoclastogenesis and bone erosion induced by TNF administration or inflammatory arthritis. This study aimed to examine the effect of monoclonal anti-c-fms antibody to a root resorption in mechanical stress-induced osteoclastogenesis model. We injected 10 micro gram anti-c-fms antibody in PBS daily into a local site for 12 days during mechanical loading. We assessed the root resorption of upper first molar after mechanical loading and carried out histological observations. The amount of the root resorption was evaluated by measuring the resorption area at disto-buccal root of the first molar by an electron microscope. Anti-c-fms antibody significantly inhibited root resorption after mechanical loading ($p<.01$). Further, the number of osteoclasts stained for TRAP on the root surface in the anti-c-fms antibody injected group was markedly reduced compared with controls. The results suggested that M-CSF and/or its receptor are potential therapeutic targets in mechanical stress-induced osteoclastogenesis, and that injection of an anti-c-fms antibody might be useful for inhibition of mechanical stress-induced root resorption.

A Possible Suppressive Role of Galectin-3 in Osteoclastic Bone Destruction Accompanying Adjuvant-induced Arthritis in Rats. Y. Li^{*1}, J. Teramachi^{*1}, K. Nagata^{*1}, Z. Wu^{*1}, A. Kukita², A. Akamine¹, T. Kukita¹. ¹Faculty of Dental Science, Kyushu University, Fukuoka, Japan, ²Faculty of Medicine, Saga University, Saga, Japan.

Galectin-3 is a β -galactoside-binding animal lectin having pleiotropic effects on cell growth, differentiation and apoptosis. This lectin has shown to be involved in phagocytosis by macrophages and inflammation. Here we investigated an involvement of galectin-3 in the regulatory process of inflammatory bone resorption in rats with adjuvant-induced arthritis accompanying severe bone destruction in the ankle joints. The protein level of galectin-3 in the ankle-joint-extracts was markedly augmented at week 3 after adjuvant injection, at the time when severe bone destruction was observed. Immunohistochemical

analysis revealed an extremely high expression of galectin-3 in macrophages and granulocytes infiltrated in the area of severe bone destruction in the distal tibia. To estimate a role of galectin-3 in osteoclastogenesis and osteoclastic bone resorption, recombinant galectin-3 was added to *in vitro* systems. Exogenously added recombinant galectin-3 markedly inhibited the formation of osteoclasts in cultures of murine osteoclast precursor cell line (RAW-D cells) as well as in rat bone marrow culture systems for evaluating osteoclastogenesis in a carbohydrate-independent manner. This inhibition was not observed by heat-inactivated galectin-3 and by galectin-7. Although recombinant galectin-3 did not affect signaling through MAP-kinases and NF- κ B, it specifically suppressed the induction of NFATc1, a key transcription factor required for osteoclastogenesis. Furthermore, galectin-3 significantly inhibited dentin resorption by mature osteoclasts. Thus, abundant galectin-3 observed in the area of severe bone destruction could act as a negative regulator for the up-regulated osteoclastogenesis accompanying inflammation, that would contribute to prevention of excess bone destruction.

P2X7 Nucleotide Receptors Couple to Isoform-Specific Activation of PKC in Osteoclasts: Spatio-Temporal Patterning of PKC Translocation Revealed by Live-Cell Imaging. S. Armstrong, A. Pereverzev*, S. M. Sims*, S. J. Dixon. Physiology and Pharmacology, University of Western Ontario, London, ON, Canada.

Nucleotides, released from cells in response to mechanical or inflammatory stimuli, signal through P2 nucleotide receptors in many cell types including osteoclasts. Osteoclasts express functional P2X7 receptors -- calcium-permeable channels that are activated by high concentrations of extracellular ATP. Targeted disruption of the gene encoding the P2X7 receptor leads to increased resorption and reduced skeletal response to mechanical stimuli. However, little is known about the signaling pathways stimulated by P2X7 receptors in osteoclasts. Our purpose was to investigate whether P2X7 receptors couple to activation of protein kinase C (PKC). An early step in activation of PKC involves translocation, with many PKC isoforms moving from the cytosol to the plasma membrane. RAW264.7 mouse monocytic cells were differentiated with RANKL and transiently transfected with plasmids encoding PKC-EGFP fusion proteins or the fluorescent protein EGFP alone. Live-cell confocal imaging was used to monitor changes in the distribution of PKC isoforms in the resulting multinucleated osteoclast-like cells. Within 20-40 s, benzoylbenzoyl-ATP (BzATP, 150 μ M, a relatively potent P2X7 receptor agonist) induced translocation of PKC α to the basolateral membrane. Translocation was transient with duration of 5-10 min. In contrast to BzATP, the PKC activator phorbol myristate acetate (PMA) induced sustained translocation of PKC α . UTP (150 μ M) or ATP (10 μ M), which activate several P2 receptors other than P2X7, failed to induce translocation of PKC α ; whereas, ATP (3 mM, a concentration sufficient to activate P2X7) caused translocation. Translocation was inhibited by the selective P2X7 antagonist Brilliant Blue G. These data are consistent with involvement of P2X7 receptors. To investigate the role of cytosolic calcium, we simultaneously monitored PKC α location and calcium concentration. BzATP induced transient rise in cytosolic calcium that was temporally correlated with translocation of PKC α . Moreover, removal of extracellular calcium prevented translocation induced by BzATP, but not by PMA. BzATP induced translocation of PKC α and PKC β I, which are both calcium-dependent PKC isoforms. In contrast, BzATP did not induce translocation of the calcium-independent isoform PKC δ . These findings establish that activation of P2X7 receptors induces calcium-dependent translocation of PKC to the basolateral membrane domain of osteoclasts, an aspect of spatio-temporal signaling not previously recognized. Thus, ATP -- released in response to inflammatory or mechanical stimuli -- may signal through specific PKC isoforms to regulate osteoclast functions *in vivo*.

Novel Pro-Survival Functions of the Kruppel-Like Transcription Factor Egr2 in Promotion of M-CSF-Mediated Osteoclast Survival Downstream of the MEK/ERK Pathway. E. W. Bradley*¹, M. M. Ruan*², M. J. Oursler². ¹Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, ²Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

M-CSF promotes differentiation and survival of cells within the monocyte/macrophage cell lineage, including bone resorbing multinucleated osteoclasts. As osteoclast survival is in part mediated by M-CSF, determining the molecular mechanisms of M-CSF-promoted osteoclast survival is crucial in treating pathological bone loss. However, the signaling mechanism M-CSF utilizes to support osteoclast survival is poorly characterized. This study addressed activation of MEK/ERK, a signaling pathway implicated in controlling osteoclast survival, in response to M-CSF and identified a novel pro-survival downstream effector of this pathway. M-CSF transiently activated the MEK/ERK pathway, an effect blocked by chemical inhibition of MEK1/2 or adenoviral expression of dnMEK1. M-CSF also induced expression of two Kruppel-like transcription factors, Egr1 and Egr2. Induction of both Egr1 and Egr2 expression was blocked through chemical inhibition of MEK1/2. To determine if one of these Egr transcription factors was a potential downstream mediator of the M-CSF-activated MEK/ERK pathway, the nuclear Egr1 and Egr2 corepressor Nab2 was employed to inhibit the function of

both Egr1 and Egr2. In addition, the difference between Nab2 expression alone or Nab2 expression in combination with MEK inhibition by U0126 was examined. While both Nab2 and MEK inhibition increased osteoclast apoptosis, a concomitant increase in osteoclast apoptosis with Nab2 expression in combination with MEK1/2 inhibition treatment was not evident. These data suggest a role for Egr1 and/or Egr2 in M-CSF-promoted osteoclast survival and demonstrate the necessity of Egr family members in the promotion of MEK-dependant osteoclast survival. Both Egr1 and Egr2 were therefore pursued as downstream effectors of MEK/ERK mediated osteoclast survival downstream of M-CSF. Two forms, a wild-type (wt) and a mutant form (ca) lacking the Nab corepressors binding site, were utilized. Expression of wtEgr2 and caEgr2, not wtEgr1 or caEgr1, reduced the basal rate of osteoclast apoptosis. In addition, expression caEgr2 bypassed the block of M-CSF-promoted osteoclast survival mediated through MEK1/2 inhibition. M-CSF therefore promotes osteoclast survival through activation of the MEK/ERK pathway and induction of Egr2, providing a novel function of Egr2 in the promotion of cell survival.

Disruption of WASP-Associated Signaling Complex Formation Leads to Defects in Sealing Ring Formation and Bone Resorption in Osteoclasts. T. Ma*, M. A. Chelliah. Department of BMS Rm 7207 South Dental School, University of Maryland, Baltimore, MD, USA.

Wiscott-Aldrich Syndrome protein (WASP) has a unique regulatory role in sealing ring formation and bone resorption in osteoclasts. The activities of different kinases have been correlated to the phosphorylation of WASP and osteoclast bone resorption. The purpose of this study was to identify the WASP domain that regulates osteoclast function *in vitro*. TAT-mediated delivery of different WASP domains and full-length WASP into osteoclasts was performed. Transduction of TAT-fused full-length WASP peptide induced Arp2/3 complex formation, F-actin content, sealing ring formation and bone resorption largely as compared with other peptides containing different WASP domains. Transduction of WASP peptides containing basic, verpulin-central, pTyr294, and proline-rich regions exhibited inhibitory effects at various levels on the processes listed above. The ability to resorb bone by WASP peptides containing basic, verpulin-central, and proline-rich regions was reduced and the resorbed area matched the size of the sealing ring. However, osteoclasts transduced with WASP peptide containing pTyr294aa demonstrated total loss of sealing ring-like structures but displayed actin-rich clusters at the peripheral edge that contains filopodia-like projections. Abnormal cytoskeletal changes have been coupled with the reduced capacity for bone resorption *in vitro*. The resorption pits were small, simple, and superficial. Taken together, these findings suggest that modulation of phosphorylation state of Tyr294aa assists in integrating multiple signaling molecule and pathways that partake in the assembly of sealing ring

Regulation of RANKL-induced MAP Kinase Activation by Reactive Oxygen Species. H. Choi¹, H. Yu¹, J. Shin¹, S. Lee². ¹Life and Pharmaceutical Sciences, Ewha Womans University, Seoul, Republic of Korea, ²Division of Life and Pharmaceutical Sciences, Center for Cell Signaling & Drug Discovery Research, Ewha Womans University, Seoul, Republic of Korea.

Osteoclasts (OCs) are multinucleated hematopoietic cells that resorb bone and are essential for bone homeostasis. Signaling between receptor activator of NF- κ B ligand (RANKL) and TNF (tumor necrosis factor) receptor-associated factor (TRAF) 6 is essential for differentiation of bone marrow monocyte/macrophage (BMM) lineage cells into osteoclasts. Here, we show that enhanced intracellular reactive oxygen species (ROS) levels by RANKL in BMM are dependent on the binding strength between RANK and TRAF6. ROS generation was decreased in overexpression of modified RANK (E342/449A and E342/375/449A) in TRAF6-binding sites, but not in reconstitution of wild-type RANK which has normal interaction between RANK and TRAF6. Consistently, MAPKs activation including ERK, JNK and p38 were attenuated by the modified RANK expression. To examine whether MAPK phosphatases (MKPs) play a role in the negative regulation of MAPKs through inactivation by ROS, we first investigated expression of MKPs in BMM through quantitative real-time PCR. The mRNA expression levels of MKP1 and MKP3 were much higher than other MKPs. We found MKP1 regulates JNK activation and MKP3 controls JNK and p38 activation in response to RANKL in 293-TR cells that express Flag epitope-tagged RANK inducibly in 293 cells. Moreover overexpression of catalytic mutant of MKP1 and MKP3 prompted osteoclast differentiation. These results suggest that MKPs including MKP1 and MKP3 might be an intracellular signal modulator for osteoclast differentiation between ROS and MAPKs.

Mice Overexpressing Nucleolar PTHrP Driven by Type II Collagen Promoter Show Disordered Distribution of Chondrocytes in the Epiphyseal Cartilage. N. Amizuka¹, T. Komori², K. Oda³, D. Goltzman⁴, A. Karaplis⁴, M. Li¹. ¹Center for Transdisciplinary Research, Niigata University, Niigata, Japan, ²Division of Cell Biology, Nagasaki University, Nagasaki, Japan, ³Division of Biochemistry, Niigata University, Niigata, Japan, ⁴Faculty of Medicine, McGill University, Montreal, PQ, Canada.

The main pathway for parathyroid hormone-related peptide (PTHrP) action is that of extracellular secretion and subsequent activation of the cell membrane-bound PTH/PTHrP receptor. PTHrP has also been reported to translocate into nucleoli, and modulate cellular functions through its nuclear/nucleolar actions. PTHrP molecule, lacking the signal sequence but encompassing the nucleolar targeting signal, was shown to successfully translocate into nuclei and nucleoli, without following the secretory pathway in transfected chondrocytic cell line, CFK2. When this nuclear form of PTHrP cDNA tagged with the myc epitope was inserted into a type II collagen promoter/enhancer cassette and transfected in primary cultured chondrocytes from mouse epiphyseal cartilage, PTHrP and myc immunoreactivity was observed in their nuclei and nucleoli, but not in the cytoplasmic region. Based on these experiments, we generated mice overexpressing nucleolar PTHrP, which is driven by the type II collagen promoter. Transgenic mice at 18-19 day-old fetal stages were sacrificed, and the transgene was examined by PCR using specific primers recognizing the DNA sequence from the C-terminal region of myc-tagged PTHrP. Immunohistochemistry for PTHrP and myc demonstrated their localization to be restricted to nuclei and nucleoli of resting and proliferative chondrocytes, but not in hypertrophic cells. The width of the resting, proliferative and hypertrophic zones of the tibial and femoral epiphyses, as well as cell proliferation estimated by statistical analysis for PCNA (proliferating cell nuclear antigen)-immunopositive cells were not different between transgenic and wild-type fetuses. In addition, the width of the type X collagen-positive hypertrophic zone in transgenic mice was similar to that of wild type mice. Therefore, unlike PTHrP's receptor-mediated pathway, nucleolar PTHrP appeared not to dynamically affect proliferation or differentiation of chondrocytes. However, chondrocytes of various sizes were present in the lower region of proliferative zone were irregularly distributed. In summary, overexpression of the nuclear form of PTHrP appears to influence the distribution of chondrocytes rather than their proliferation or differentiation in mouse epiphyseal cartilage.

Induction of kinin B₁ Receptor in Osteoarthritis Is Performed by Vasoactive Peptide Endothelin-1. H. L. Attalah¹, D. Debois², C. A. Manacu³, N. Newman⁴, A. Moreau⁵, F. Moldovan⁵. ¹Faculty of Dentistry of Montreal University, Research Center CHU Ste Justine Hospital, Canada, PQ, Canada, ²Pharmacology, University of Montreal, Canada, PQ, Canada, ³Research Center CHU Ste Justine Hospital, Canada, PQ, Canada, ⁴University of Montreal, Canada, PQ, Canada, ⁵Dentistry Faculty of Montreal University, Research Center CHU Ste Justine Hospital, Canada, PQ, Canada.

Endothelin-1 (ET-1) and kinin B₁ receptors are involved in pain. ET-1 and B₁ receptor activate similar signalling pathways, and their expression is under the control of the pro-inflammatory mediators that are key molecules for Osteoarthritis (OA) pathophysiology. Kinins are potent agonists that participate in inflammatory and pain responses to insults by acting through the inducible B₁ receptor. We hypothesize that ET-1 has a specific role in OA pathophysiology in the early phase by promoting cartilage degradation and late phase by inducing B₁R expression leading to thereby exacerbating inflammation and pain induction in late stage OA.

Analysis of B₁R expression in synovial tissues of OA patients by immunohistochemistry and in situ hybridization revealed that its presence locally dependent on the level of tissue inflammation since its expression appears to be directly regulated by inflammatory mediators such as ET-1 and IL1 β . We also observed that B₁R co-localizes with ET-1 in both endothelial cells and type A synoviocytes (macrophage like cells). In OA chondrocytes, western blotting revealed p70S6 and p85S6 kinases and the p70S6 kinase is phosphorylated by ET-1, and that this phosphorylation is inhibited by rapamycin. Both of which act on mitogen-activated signalling pathways downstream of phosphoinositide 3-kinase (PI3K), and are targets of rapamycin FRAPm/TOR. Activation of PI3K-Akt and Ras-Raf MEK-ERK signalling cascades by ET-1 is thought to play an important role in cartilage matrix degradation via the activation of MMP-1 and MMP-13 which specifically cleave OA cartilage collagen.

These results prompted us to propose that ET-1 over expression in OA synovial tissues contributes to B₁R up-regulation, although it remains unclear whether such an effect is solely due to elevated ET-1 levels. These data point toward a possible role of ET-1 in inflammatory pain. Thus, ET-1 is potentially attractive therapeutic target for OA pathology characterised by a chronic pain.

Hydrostatic Loading of Growth Plate Chondrocytes in Vitro. Y. Y. Shao^{*1}, J. Welter², L. Wang^{*3}, R. T. Ballock⁴. ¹Department of Biomedical Engineering, Cleveland Clinic, Cleveland, OH, USA, ²Department of Biology, Case Western Reserve University, Cleveland, OH, USA, ³Department of Biomedical Engineering, Cleveland Clinic, Cleveland, OH, USA, ⁴Departments of Orthopaedics and Biomedical Engineering, Cleveland Clinic, Cleveland, OH, USA.

Objective: It is well-established that mechanical forces can influence the behavior of cartilage chondrocytes, however little is known about the response of growth plate chondrocytes to these mechanical forces. The objective of this study was to examine the effects of hydrostatic compression on the behavior of growth plate chondrocytes by testing the hypothesis that hydrostatic loading would inhibit proliferation and differentiation of these cells through modulation of the Ihh-PTHrP feedback loop.

Methods and Results: Epiphyseal chondrocytes were isolated from the distal femoral growth regions of two day old Sprague-Dawley rats and cultured as three-dimensional cell pellets (3x10⁵ cells/pellet) for five days. The pellets were then either subjected to hydrostatic compression or cultured as unloaded controls. A custom-designed mechanical loading system was used apply an intermittent 1MPa hydrostatic compression force (1 hour on, 1 hour off) for 1 or 2 days at 37°C and 5% CO₂. After the compression period, AQ 96 proliferation assays were carried out immediately for analysis of cell viability, while others were frozen for later testing. The growth plate chondrocytes subjected to hydrostatic compression increased proliferation more than the control cells after one day of loading, but were identical to control samples after two days. Real-time quantitative RT-PCR analysis demonstrated that type X collagen (ColX) expression was increased by 12 fold in the loaded samples after one day of compression, while Ihh mRNA was up-regulated more than 6-fold and expression of patched (Ptc) and runt-related transcription factor (RunX2) were both increased two-fold. In addition, Ihh expression was also examined after shorter periods of compression (0.5, 1, 2, and 4 hours), Ihh expression increased 1.5 fold in response to the compression as early 30 minutes following application of the hydrostatic load. Measurement of caspase 3/7 activity and immunoblotting of Bcl₂ protein failed to reveal any increase in apoptotic activity in the hydrostatically loaded pellets compared to the unloaded controls.

Conclusions: Our results show that in vitro hydrostatic compression can stimulate Ihh expression, chondrocyte proliferation and terminal differentiation in growth plate chondrocytes cultured as three-dimensional cell pellets.

Establishment of a Rat Culture System for Studying the Morphological Diversity of Hypertrophic Chondrocytes. K. Chen^{*}, L. Tatarczuch^{*}, Y. Ahmed^{*}, M. Mirams^{*}, C. N. Pagel^{*}, E. J. Mackie. School of Veterinary Science, The University of Melbourne, Parkville, Australia.

During endochondral ossification, hypertrophic chondrocytes exist in two forms, "dark" and "light" cells. We have recently observed that these cells undergo two different forms of non-apoptotic physiological cell death (PCD) in horse growth cartilage, and have established a culture system for studying hypertrophy and death of equine chondrocytes. The aim of the current study was to develop a culture system using rodent chondrocytes in order to study differences between dark and light cells and their modes of death. Chondrocytes were isolated from femoral epiphyseal cartilage from neonatal rats and cultured as pellets in the presence of triiodothyronine (T3) in 0.1% FCS. After 14 days, the pellets were examined by light and electron microscopy. The proportion of hypertrophic light chondrocytes was double that of hypertrophic dark chondrocytes. Hypertrophic light chondrocytes from the T3-treated pellets could be purified through centrifugation in a gradient concentration of Ficoll-PaqueTM Plus. The microarray technique was performed to compare the difference in gene expression between the purified hypertrophic light chondrocytes and the mixed hypertrophic dark and light cells in the T3-treated pellets. A number of genes of interest have been selected for validation by real-time PCR. These include genes encoding Egr2 and tissue plasminogen activator, which appear to be more highly expressed in light cells than dark cells, and periostin and osteoglycin, which appear to be more highly expressed in dark cells than light cells. Staurosporine induces apoptosis in many cell types, but when staurosporine was added to pellets cultured in 10% FCS, apoptotic chondrocytes were rarely observed. Instead, there was an increase in the proportion of dark cells dying by the process observed for these cells in vivo. Staurosporine significantly down-regulated mRNA expression of type X collagen, type II collagen, runx2 and aggrecan. Fewer dark cells were seen in chondrocyte cultures from rats than in those from horses, which is probably due to the fact that very few dark cells are observed in neonatal growth cartilage from rats. This will be a useful system for studying molecular mechanisms of chondrocyte hypertrophy and death.

Role of the Transcription Factor Lbh in Endochondral Bone Formation. K. L. Conen¹, S. Nishimori^{*1}, S. Provot², H. M. Kronenberg¹. ¹Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA, ²Department of Anatomy, University of California, San Francisco, CA, USA.

In endochondral bone formation, mesenchymal condensations develop into chondrocytes that proliferate and form the fetal growth plate. As round, flat and hypertrophic chondrocytes they undergo progressive, well-ordered stages of differentiation. All differentiation steps are characterized by the synthesis of stage-specific matrix proteins and the expression of different transcription factors (TF). In order to study the transcriptional control of endochondral bone formation we previously analyzed genes expressed in discrete layers of the mouse newborn (NB) growth plate using microarray analyzes. There the TF limb-bud-and-heart (Lbh) appeared to be expressed predominantly in hypertrophic chondrocytes. Lbh is thought to act as a transcriptional co-activator and is highly conserved among species. It has a to date uncharacterized role in endochondral bone formation. In situ hybridization (ISH) of sections of NB mouse tibia confirmed that Lbh is expressed in hypertrophic chondrocytes. We therefore investigated whether Lbh has a key regulating role in the induction of the differentiation steps from flat to hypertrophic chondrocytes in an experimental model, providing advantages for a relatively easy and fast testing: The fetal growth plate of chicken embryos at E10, a time when growth cartilage and bone become visible. Our hypothesis is that Lbh plays a key role in hypertrophic chondrocyte differentiation. We have begun to use the avian Replication-Competent ASLV long terminal repeat with Splice acceptor (RCAS) retroviral vector strategy. Lbh cDNA samples have been cloned into this RCAS virus. We infect chicken limb buds at E3-E3.5 in ovo and then analyze the effect of Lbh by comparing the gross aspect of E10 infected limbs compared to the uninfected contralateral limb using skeletal preparations and ISH. Whole-mount ISH of Lbh in the chicken system revealed an early signal in the entire outgrowing limb buds of E4.5 chickens. This signal subsequently remains visible only in the fetal growth plate area between E6 and E10. These data suggest a possible role of Lbh in chondrogenesis of chicken and mouse endochondral bone formation.

Effect of Removal of Nucleus Pulposus Cells on the Annulus Fibrosis of the Intervertebral Disc. C. Dahia^{*1}, A. Durrani¹, E. Mahoney^{*1}, C. Wylie^{*2}. ¹Orthopaedic Surgery, Cincinnati Children's Hospital and Medical Center, Cincinnati, OH, USA, ²Developmental Biology, Cincinnati Children's Hospital and Medical Center, Cincinnati, OH, USA.

The relationship between the nucleus pulposus and the Annulus fibrosis in normal differentiation and maintenance of the IVD is not clearly understood. We studied the effect of removal of NP cells on the AF.

The NP's were surgically aspirated from L2-L3 and L3-4 discs of 2-week old male mice (during the period of rapid postnatal vertebral growth), using a 27-gauge syringe. L4-5 discs in the same mice were sham-operated (needle insertion without aspiration) as controls. The effects on the IVD were assayed 2-8 weeks after the surgery. 8 µm cryosections were collected in the coronal plane and histological analysis was carried out using H&E staining. Cell proliferation and cell death was determined by phospho Histone H3 (PH3) and active caspase-3 staining respectively.

5-weeks following removal of the NP cells there was significant collapse of the IVDs (Fig-B) from which the NP had been removed, compared with those of sham-operated controls (Fig-A). By 7-weeks, fibrocartilage cells derived from the AF were invading the disc space, which became completely filled by 8 weeks. Growth of the disc was reduced in both cranio-caudal and transverse diameters by 30%, compared to control discs. Mitotic cells were absent in the AF indicating that AF cells stopped proliferating in the absence of NP cells. A large number of activated caspase-3 positive cells were found in AF cells 8 weeks after removal of NP cells (Fig-D), compared to sham controls (Fig-C).

Removal of NP cells leads to invasion of the disc space, and its fibrosis by AF cells, decreased proliferation and increased cell death of the AF cells, and decrease in disc growth. These data suggest a requirement for the NP cells in normal differentiation and growth of the AF cells.

Spatial and Temporal Localization of Components of the TGF-beta, BMP, IHH and FGF Signaling Pathways in the Postnatal Mouse Lumbar Vertebral Growth Plate (LVGP). C. Dahia^{*1}, E. Mahoney^{*1}, A. Durrani¹, C. Wylie^{*2}. ¹Orthopaedic Surgery, Cincinnati Children's Hospital and Medical Center, Cincinnati, OH, USA, ²Developmental Biology, Cincinnati Children's Hospital and Medical Center, Cincinnati, OH, USA.

Little is known about postnatal spine growth. A number of signaling pathways have been shown by gene targeting in the mouse to be important in the growth of fetal long bones. The objective of this study was to find out if these signaling pathways are present in postnatal LVGP, and their expression pattern during growth and aging.

8 µm cryosections in the coronal plane from decalcified LVGP of 1-12 weeks old male FVB mice were analyzed by H&E and alkaline phosphatase (AP) staining. Cell proliferation & cell death was determined by phospho-histone H3 (PH3) & TUNEL assay, respectively. Immunolocalization of components of the TGFβ1&2, BMP2&4, IHH & FGF2 pathways was carried out using confocal microscopy.

PH3 positive staining disappeared from the proliferative zone chondrocytes (PZc) of LVGP at 3-weeks indicating cessation of cell proliferation. Membrane localization of IHH (Fig-A) & its receptor PTC-1 was observed on the PZc of LVGP only until 2-weeks of age. Between 2-12 weeks of age, active TGFβ1&2 signaling was present at the junction of PZc and early hypertrophic zone chondrocytes (HZc) of the LVGP, as shown by staining for its activated downstream intermediate (p)Smad2/3 (Fig-B). BMP2&4 pathways were active only in the HZc (Fig-C) of the LVGP at all ages. Staining for its active downstream molecule, pSmad1/5/8 (Fig-D), decreased from 3-weeks onwards, but did not disappear. FGF2 signaling was observed to be active only in the HZ of the LVGP of 2-week old mice and decreased with age. Intensity of AP staining increased in the HZc from 2-week onwards.

Our data suggests that IHH regulates the proliferation of PZc in the LVGP. TGFβ signaling regulates the transition of PZc to HZc. FGF signaling is seen only in the HZ indicating it may play a role in regulating HZc. Active BMP & AP signaling seen only in the HZc in all ages suggests its role in the maintenance of the extracellular matrix.

Histological and Molecular Analysis of the Growth and Differentiation of the Mouse Lumbar Intervertebral Disc. C. Dahia^{*1}, E. Mahoney^{*1}, A. Durrani¹, C. Wylie^{*2}. ¹Orthopaedic Surgery, Cincinnati Children's Hospital and Medical Center, Cincinnati, OH, USA, ²Developmental Biology, Cincinnati Children's Hospital and Medical Center, Cincinnati, OH, USA.

Intervertebral disc (IVD) degeneration is the most common cause of back pain. We wish to understand the cellular and molecular mechanisms of disc growth and development in mouse.

8µm thick coronal and transverse cryosections, from lumbar vertebrae (LV) of 1-48 weeks old male mice, were analyzed by H&E and alkaline phosphatase (AP) staining. Physical growth of the discs was measured using a 1mm graticule. The number and thickness of the layers of the annulus fibrosus (AF), was measured using DIC optics. Cell proliferation and death was determined by phospho Histone H3 (PH3) and TUNEL staining, respectively. Immunolocalization of components of the TGFβ, BMP and Shh pathways was carried out using confocal microscopy.

Growth of the IVD paralleled that of the vertebral column, being most rapid between birth and 3 weeks, and plateauing off by 9 weeks of age. Proliferating cells were found until 3 weeks of age in both the AF and NP (Fig-A). During the first week, the AF became divided into a mineralized component over the vertebral bodies, which stained positively for AP, and non-mineralized component between the vertebrae (Fig-B). Cells in the mineralized component also became hypertrophied. Apoptosis was only found in the NP. DIC imaging revealed that the number of layers of AF increased from 1-2 weeks of age, after which each layer becomes very thick due to the extracellular matrix secreted by them. The number of AF layers decreased in the IVDs of older mice. TGFβ as well as BMP signaling pathway was active in the NP as well as the AF cells, while Shh was secreted by the NP and fibrous AF cells but acted on the mineralized AF cells.

The IVDs grow coordinately with the vertebrae. Both components of the disc grow, and then involute with age. The AF becomes divided into a mineralized and non-mineralized component during growth. Active cell signaling pathways like BMP, TGFβ and Shh suggests that these cells are actively involved in disc maintenance.

Non-covalent Interaction of MMP13 and LTBP1 in a Unique TGFβ Large Latent Complex Produced by Hypertrophic Chondrocytes. B. N. Dragann^{*1}, V. L. Scheinfeld^{*1}, S. M. Routson^{*1}, B. M. Mentzer^{*1}, P. M. Mattioli^{*1}, A. H. Selim², D. M. Appelt^{*1}, M. D'Angelo¹. ¹Center for Chronic Disorders of Aging, PCOM, Philadelphia, PA, USA, ²Department of Biology and Physics, KFUPM, Dhahran, Saudi Arabia.

Our lab has shown that hypertrophic chondrocytes produce a unique TGFβ2 large latent complex that contains collagenase 3 (MMP13) in non-covalent association with latent TGFβ binding protein (LTBP1). In this study, we investigate hypertrophic chondrocyte production of the elements of this unique TGFβ2 large latent complex. Hypertrophic chondrocytes from the avian sterna were cultured 5 days in serum-free alginate. RNA, conditioned media, cell-associated matrix (isolated after release of the chondrocytes from alginate), and cell extracts were analyzed for TGFβ2, MMP13 and LTBP1. Immunoblot analysis revealed the presence of immunoreactive bands for TGFβ2, MMP13 and LTBP1 in the cellular extracts. Assembly into the extracellular matrix and secretion of the components was indicated by the presence of immunoreactive bands for all three proteins in the cell-associated matrix and conditioned media fraction. Immunocytochemistry demonstrated the presence of TGFβ2, MMP13 and LTBP1 in association with the cells and in a pericellular staining pattern. In order to determine whether MMP13 binds non-covalently to LTBP1 of the TGFβ large latent complex, primary monolayer cultures of hypertrophic chondrocytes were double-labeled with antibodies against MMP13 and LTBP1. Optical serial sections were collected from these cells and the images deconvoluted into three-dimensional micrographs. LTBP1 and MMP13 were present both intracellularly and in association with the extracellular matrix between cells. In addition, the fluorescent signal indicated substantial co-localization of the two proteins within the extracellular matrix of the cultures. For additional confirmation, we produced a biotin-

labeled peptide corresponding to the C-terminal hemopexin domain of MMP13 that bioinformatics indicated could interact non-covalently with the C-terminal EGF-calcium domains of LTBP1. Protein from hypertrophic chondrocyte tissue was extracted from day 17 avian upper sternum and immunoprecipitated with antibody to LTBP1. Dot blot analysis of the immunoprecipitate showed binding of the biotin-labeled MMP13 peptide with proteins in the tissue extracts. These data demonstrate that the components of the unique TGFβ2 large latent complex are produced and secreted by hypertrophic chondrocytes and are present in compartments that are characteristic of extracellular matrix assembly. In addition, these data confirm that MMP13 can interact with LTBP1 and underscores the candidacy of MMP13 in the unique mechanism of activation of TGFβ by hypertrophic chondrocytes.

Twist1 Stage-specifically Regulates Chondrocyte Differentiation Downstream of TGF-β and Wnt Signaling. Y. Dong, Y. Chang^{*}, D. Y. Soung, R. O'Keefe, E. Schwarz, H. Drissi. Orthopaedics, University of Rochester, Rochester, NY, USA.

We investigated the molecular mechanisms underlying the transition between immature and mature chondrocytes downstream of TGF-β and canonical Wnt signals. We used two developmentally distinct chondrocyte models isolated from the caudal portion of embryonic chick sternum or chick growth plates. Lower sternal chondrocytes exhibited immature phenotypic features, while growth plate extracted cells display a hypertrophic phenotype. TGF-β significantly induced β-catenin in immature chondrocytes, while it repressed it in mature chondrocytes. TGF-β further enhanced canonical Wnt-mediated transactivation of the Topflash reporter expression in lower sternal chondrocytes. However, it time-dependently inhibited Topflash activity in growth plate chondrocytes. Our immunoprecipitation experiments showed that TGF-β induced Smad3 interaction with TCF-4 in immature chondrocytes, while it inhibited this interaction in mature chondrocytes. Similar results were observed by chromatin IP showing that TGF-β differentially shifts TCF-4 occupancy on the Runx2 promoter in lower sternal chondrocytes versus growth plate chondrocytes. To further determine the molecular switch between immature and hypertrophic chondrocytes, we assessed the expression and regulation of Twist1 and Runx2 in both cell models upon treatment with TGF-β and Wnt3a. We show that Runx2 and Twist1 are differentially regulated during chondrocyte maturation. Furthermore, while TGF-β induced Twist1 in mature chondrocytes, it inhibits Runx2 expression in these cells. Opposite effects were observed upon Wnt3a treatment which predominates over TGF-β effects on these cells. Finally, over-expression of chick Twist1 in mature chondrocytes dramatically inhibited their hypertrophy. Together, our findings show that Twist1 may be an important regulator of chondrocyte progression towards terminal maturation in response to TGF-β and canonical Wnt signaling.

Role of Fe³⁺ Ion and Ferritin on Differentiation of Chondrocytes at the Stage of Calcification. H. Hagiwara¹, N. Hashimoto^{*2}, T. Ohno^{*2}, K. Yamazaki^{*1}, H. Okumura^{*3}, T. Ito^{*3}. ¹Dept. of Biomedical Engineering, Toin University of Yokohama, Yokohama, Japan, ²Dept. of Bioscience and Biotechnology, Tokyo Institute of Technology, Yokohama, Japan, ³Health Effects Research, Energy and Environment Research, Japan Automobile Research Institute, Tsukuba, Japan.

Fe ions are major contents of metal in our body. However, there is a little information about the effect of Fe ions on bone metabolism. In the present study, we examined the effects of Fe³⁺ ion and ferritin, a storage protein of Fe³⁺ ion in cells, on the differentiation and mineralization of cultured chondrocytes, ATDC5 cells. At first, we monitored the expression pattern of ferritin mRNA with RT-PCR during the culture period of ATDC5 cells. Ferritin mRNA was expressed in ATDC5 cells, from day 21, at the late stage of culture. We used ferric ammonium citrate (FAC) as a donor of Fe³⁺ ion and desferrioxamine (DFO) as a chelator of Fe³⁺ ion. Both chemicals did not affect the production of proteoglycan by ATDC5 cells. By contrast, FAC inhibited the deposition of calcium by ATDC5 cells and DFO accelerated it. Furthermore, FAC inhibited the expression of MMP13 mRNA, a differentiation marker at a late stage of differentiation of chondrocytes. In addition, DNA microarray methods revealed that Fe³⁺ ion regulated the expression of collagen mRNAs in ATDC5 cells. These results suggested that Fe³⁺ ion might play an important role on chondrocyte differentiation and mineralization.

A Novel Tumor Necrosis Factor- α Responsive CCAAT/Enhancer-binding Protein Site Regulates Cartilage Cd-Rap Expression. T. Imamura^{*1}, A. McAlinden^{*2}, K. Terada^{*1}, H. Miyahara^{*1}, Y. Iwamoto^{*3}, L. J. Sandell^{*2}. ¹Orthopaedic Surgery, Kyushu Medical Center, Fukuoka, Japan, ²Orthopaedic Surgery, Washington Univ., St. Louis, MO, USA, ³Orthopaedic Surgery, Kyushu Univ., Fukuoka, Japan.

Objective. Rheumatoid arthritis is characterized by an inflammatory process in the synovium resulting in progressive destruction of the affected joints. Cytokines such as Tumor Necrosis Factor (TNF)- α and Interleukin 1 (IL-1)- β regulate inflammation, causing functional impairment. Previous studies in our laboratory have shown that expression of cartilage characteristic genes, such as cartilage-derived retinoic acid sensitive protein (Cd-rap) and Type II collagen (Col2a1), are repressed by IL-1 β by a process involving a CCAAT/Enhancer binding protein (C/EBP) site. The aim of this study is to investigate the mechanism of TNF- α induced inhibition of cartilage gene expression by studying regulation of the Cd-rap gene.

Methods. Rat chondrosarcoma (RCS) cells were transiently transfected with cDNA constructs encoding Cd-rap in the presence of TNF- α . Expression of C/EBP β , Sox9 and p300 after treatment with TNF- α were examined by RT-PCR and Western blot in RCS cells and primary human articular chondrocytes. The effect of TNF- α on endogenous binding of C/EBP β or Sox9 to the Cd-rap promoter was examined by chromatin immunoprecipitation (ChIP) assays.

Results. We identified a new C/EBP binding site in the Cd-rap promoter (position -1059 to -1046). Binding of C/EBP to this site was regulated by TNF- α , but not IL-1 β , resulting in down-regulation of Cd-rap expression. This effect was reversed by mutational inactivation of the C/EBP motif. In addition, the activation potential of Sox9 and CBP/p300 on the Cd-rap promoter was enhanced after mutation of the new C/EBP binding site, indicating that blockage of this site would increase transcription.

Conclusion. TNF- α regulates the expression and/or DNA binding potential of key positive and negative-acting transcription factors that control the expression of the cartilage matrix gene, Cd-rap.

OPG Inhibits Cartilage Degradation in a Knee Instability Mice Model. A. Kadri^{*}, H. Ea^{*}, B. Uzan^{*}, C. Bazille^{*}, M. Ah Kioon^{*}, F. Liote^{*}, M. E. Cohen-Solal. Hopital Lariboisiere, INSERM U606, Paris, France.

Osteoarthritis (OA) is a focal rheumatic disease characterised by cartilage destruction. Mechanical stress and several other local factors are responsible for cellular and molecular changes that contribute to matrix proteolysis. Proteases as aggrecanases (ADAMTS-4 and ADAMTS-5) participate to chondrolysis in OA. Subchondral bone (SCB) may be involved in the pathogenesis of OA. We used a meniscectomy-induced OA model in mice in order to assess to the changes of SCB and the effects of inhibition of cytokines involved in bone and cartilage remodeling (IL1ra and OPG). Ten week-old C57/BL6 male mice underwent medial meniscectomy of the right knees (Mnx) and the left knees were sham-operated (sham). Mice were separated in 3 groups and received intraperitoneal injections of PBS, OPG (10mg/kg) or IL1ra (100mg/kg) twice a week for 6 weeks. At sacrifice, serial sagittal sections of decalcified knees were performed to assess OA score, ADAMTS expressions and micro-architecture of SCB. At the tibia, OA score was increased in Mnx compared to sham-operated mice in PBS group (0.5 ± 0.27 vs 1.9 ± 0.41 , $p < 0.05$). Compared to PBS-treated mice with Mnx, OA score was not altered with IL1ra (1.9 ± 0.41 vs 2.29 ± 0.84), but was decreased by OPG (1.9 ± 0.41 vs 0.17 ± 0.17 , $p < 0.05$). In PBS-treated mice, the number of ADAMTS-4+ cells was significantly enhanced in Mnx compared to sham (64.6 ± 2.1 vs $35.9 \pm 1.6\%$ of total cells, $p < 0.0001$) as well as ADAMTS-5+ cells (47.3 ± 1.9 vs 78.9 ± 2.7 $p < 0.0001$). The number of positive cells in Mnx was then expressed using sham as referent (Δ ADAMTS). Compared to PBS, Δ ADAMTS-4+ cells were lower with IL1ra and OPG (0.81 ± 0.78 vs 0.51 ± 0.12 , vs 0.46 ± 0.29 respectively). Δ ADAMTS-5+ cells were also lower with IL1ra (0.67 ± 0.08 vs 0.42 ± 0.1) and further decreased with OPG (0.67 ± 0.08 vs 0.26 ± 0.09 , $p < 0.05$). In PBS treated-mice, BV/TV was decreased in Mnx vs sham knees ($39 \pm 0.36\%$ vs $49 \pm 0.48\%$) along with an increased Marrow Star Volume (Ma.Sv: $8.9 \cdot 10^3 \pm 3.4 \cdot 10^3$ vs $3.7 \cdot 10^3 \pm 1.5 \cdot 10^3$) suggesting increased bone resorption. In Mnx knees, IL1ra did not change BV/TV ($39 \pm 0.36\%$ vs $42 \pm 0.46\%$), whereas it was increased with OPG ($39 \pm 0.36\%$ vs $53 \pm 0.59\%$). Only OPG decreased Ma.Sv compared to PBS treated-mice ($1.3 \pm 0.37 \cdot 10^3$ vs $8.9 \pm 3.4 \cdot 10^3$, $p < 0.05$).

In conclusion, meniscectomy induces cartilage degradation and increases aggrecanase expressions. This was associated with an increased bone resorption. Inhibition of bone resorption by OPG prevents matrix cartilage degradation and the increase of protease expressions. These data suggested that increased bone resorption at SCB could be implicated in the pathogenesis of OA at early stage. Targeting specifically the inhibition of bone resorption might lead to the prevention of OA.

Therapeutic Effect of KHB9 on Cartilage Degradation and Inflammation in Collagenase-induced Rabbit Osteoarthritis. D. Kim¹, J. Huh^{*2}, Y. Baek^{*2}, J. Lee^{*2}, D. Choi^{*2}, D. Park^{*2}. ¹Internal Medicine, Kyung Hee University Hospital, Seoul, Republic of Korea, ²Acupuncture & Moxibustion, College of Oriental Medicine, Kyung Hee University, Seoul, Republic of Korea.

The aim of this study was to determine the therapeutic effects of an herb medicine, KHB9 on osteoarthritis. We investigated whether KHB9 could suppress the disease progression of collagenase-induced osteoarthritis (CIA) in rabbits.

The right knees of rabbits were injected intra-articularly with collagenase, and rabbits were orally administrated with distilled water, KHB9 (50, 100, 400 mg/kg) or celecoxib (100 mg/kg) once a day for 28 days after the initiation of the CIA induction. The knee joints were evaluated by gross morphology and histology. Target gene expression was analyzed by RT-PCR such as proteoglycan, MMPs, and cyclooxygenases (COX) in knee joints. Also, we measured glycosaminoglycan (GAG) release, MMPs activity, PGE₂ production by colorimetric analysis. COX-1 and COX-2 protein expression were confirmed by immunohistochemistry.

Histological evaluation showed that KHB9 dose-dependently suppressed damage in cartilage and synovium as compared with the control. The mRNA expression of proteoglycan, MMP-1, MMP-3, and COX-2 was dose-dependently decreased, whereas COX-1 expression not affected. As well, GAG release and matrix degradation enzymes including MMP-1 and MMP-3 activities, and PGE-2 production significantly reduced at a dose-dependent manner.

This study indicates that KHB9 play a protective role against cartilage degradation and anti-inflammatory effect in rabbits with OA. The role may be achieved through the down regulation of the MMP-1, MMP-3, PGE2 and COX-2 activity, and expression in CIA rabbit model.

Disclosures: D. Kim, None.

Gene-Trap Mutagenesis Revealed the Involvement of Vinculin in Chondrogenic Differentiation in ATDC5 Cells. T. Koshimizu^{*1}, M. Kimata^{*1}, K. Tachikawa^{*1}, K. Ozono², T. Michigami¹. ¹Department of Bone and Mineral Research, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan, ²Department of Pediatrics, Osaka University Graduate School of Medicine, Osaka, Japan.

Gene-trap mutagenesis is based on the idea that the random insertion of a trapping vector may disturb the function of inserted genes. In the current study, to identify the genes involved in chondrocytic differentiation, we have applied this method to a chondrogenic mesenchymal cell line, ATDC5. As the trap vector, we used pPT1-geo, which lacks its own promoter and enhancer, but contains a lacZ-neo fusion gene geo as a reporter and selection marker. The reporter activity reflects the expression level of the trapped gene. We screened the isolated clones for high β -galactosidase activity, and the selected clones were subjected to the chondrogenic induction to evaluate the phenotypical changes. 5'-RACE was performed to identify the gene trapped in each clone. In clone #4-17, the trap vector pPT1-geo was integrated in intron 13 in the gene encoding vinculin. Vinculin is a cytoskeletal protein and occurs in multimolecular complexes that are thought to function in adhesion and/or signaling between the extracellular milieu and the cell, via integrins and cadherins. Since vinculin-knockout mice are embryonic lethal, the roles of vinculin in skeletogenesis remain unclear. As the result of integration of pPT1-geo, a truncated vinculin lacking carboxyl-terminal paxillin-binding domain fused to geo product was produced from the trapped allele, and Western blotting confirmed that both wild-type and the truncated vinculin were expressed in #4-17. There was no apparent morphological change in the clone. When cultured in the differentiation medium, #4-17 exhibited impaired nodule formation and less accumulation of cartilaginous matrices. RT-PCR analyses revealed that the expression of chondrocytic marker genes including Col2a1 and PTHrP was reduced in the clone, although that of SOX9 was retained. The expression of wild-type vinculin in the parental ATDC5 and that of lacZ in #4-17 were elevated during the culture in differentiation medium, suggesting the involvement of vinculin in chondrocytic differentiation. Integrin-stimulated FAK autophosphorylation was markedly enhanced in the clone #4-17, demonstrating the aberrant signaling transduction induced by adhesion to extracellular matrix, while the phosphorylation state of paxillin was not obviously changed. Taken together, the phenotypical changes caused by trapping of vinculin gene indicated its critical roles in chondrocytic differentiation, and enhanced the indispensability of the signals from extracellular matrix in the process.

Effect of Vertebroplasty Filler Materials on Viability and Gene Expression of Mouse and Human Nucleus Pulposus Cells. Á. Lazáry¹, P. Varga^{*1}, G. Speer^{*2}, K. Bácsi^{*2}, B. Balla^{*2}, J. Kósa^{*2}, Z. Nagy², I. Takács², P. Lakatos².
¹Center of Spinal Disorders, Buda Health Center, Budapest, Hungary, ²1st Department of Internal Medicine, Semmelweis University, Budapest, Hungary.

Consequences of intradiscal cement leakage - often occur after vertebral cement augmentation for the treatment of vertebral compression fractures - are still unknown. In this study, we have investigated the influences of vertebroplasty filler materials (polymethylmethacrylate-, calcium phosphate- and calcium sulfate based bone cement) on isolated nucleus pulposus cells. Cell viability of cultured human nucleus pulposus cells were measured after treatment with vertebroplasty filler materials. Gene expression profile of selected genes was determined with quantitative real-time PCR. The widely used polymethylmethacrylate and calcium phosphate cement significantly decreased cell number in a dose- and time-dependent manner (e.g. cell number was reduced by 79% in human cultures in case of 2 day treatment of 0.1% v/v polymethylmethacrylate) while calcium sulfate cement affected cell viability less. Expression of genes involved in matrix metabolism of nucleus pulposus - aggrecan, collagens, small proteoglycans -, as well as important transcription factors have also significantly changed due to treatment (e.g. 2.5-fold decrease in aggrecan expression was determined in human cultures due to polymethylmethacrylate treatment). Our results suggest that intradiscally leaked bone cement - depending on the type of applied material - can accelerate the degeneration of nucleus pulposus resulting in a less flexible disc. This process may increase the risk of a subsequent new vertebral fracture, the main complication of vertebral augmentation. In conclusion, avoiding of cement leakage and development of vertebroplasty filler material that does not interfere with vital gene expression and cell viability would be desirable.

Regulation of Matrix Metalloproteinase (MMP)-9 Expression by MMP-12 in Interleukin-1 β -treated Articular Chondrocytes. H. Oh, M. Lee^{*}, J. Chun^{*}. Department of Life Science, Gwangju Institute of Science and Technology, Gwangju, Republic of Korea.

Interleukin (IL)-1 β is a major pro-inflammatory cytokine that causes destruction of articular cartilage via induction of several matrix-metalloproteinases (MMPs). MMPs play an essential role in pathological extracellular matrix (ECM) breakdown in arthritic cartilage. In primary culture articular chondrocytes and cartilage explants, IL-1 β caused induction of several MMPs such as MMP-1, -3, -9, -12, and -13, whereas expression of other MMPs including MMP-2, -14, and -15 was not affected. Because the role of MMP-12 in chondrocytes remains largely unknown, we examined the signaling mechanisms and the role of IL-1 β -induced expression of MMP-12 in primary culture articular chondrocytes. Among the mitogen-activated protein (MAP) kinases, extracellular signal-regulated kinase and p38 kinase mediated expression and activation of MMP-12, whereas c-Jun N-terminal kinase regulated MMP-12 activation without effects on its expression. MMP-12 expression by IL-1 β was also mediated by nuclear factor kappa enhancer binding protein (NFkB). Because ECM fragments produced by MMP action were known to regulate expression of several MMPs, we next examined the role of MMP-12 in expression of other MMPs in chondrocytes. Exogenous MMP-12 in IL-1 β -treated chondrocytes caused both expression and secretion of MMP-9, which is known to degrade proteoglycan and denatured type II collagen. However, MMP-12 did not affect of MMP-9 expression in absence of IL-1 β . Taken together, our results suggest that IL-1 β causes expression and activation of MMP-12 through signaling pathway involving MAP kinases and NFkB, and activated MMP-12 may contribute to cartilage destruction by increasing MMP-9 expression.

BMP4 in Postnatal Alveolar Bone Formation and Tooth Cytodifferentiation: Conditional Deletion of BMP4 with the 3.6 Collagen type 1a-Cre Model. J. Gluhak-Heinrich¹, L. Martineze^{*1}, W. Yang¹, J. Zhang², J. Feng³, D. Guo³, A. Lichtler⁴, B. Cream⁴, M. Harris¹, S. Harris¹. ¹UTHSCSA, San Antonio, TX, USA, ²Univ. of Vanderbilt, Nashville, TN, USA, ³UKMC, Kansas City, MO, USA, ⁴UCONN, Farmington, CT, USA.

Bone morphogenetic protein 4 (BMP4) is essential for early tooth and bone development in the postnatal animal. Smad1/5/8 plays a central role in BMP4 signaling, with other transcription factors like: Runx2, Dlx5 and Osx. BMP4 conditional knockout (Bmp4 cKO) leads to mice with reduced bone and osteopenia, as well as reduction in dentin formation during tooth cytodifferentiation. The mechanisms by which BMP4 deficiency leads to defects during bone and tooth cytodifferentiation have not been explored. The objective of this study was to determine the biologic effect of postnatal BMP4 deficiency on tooth and alveolar bone formation and mineralization. To obtain 3.6collagen1a-Cre/BMP4cKO mice, we crossed 3.6 collagen1a-Cre mice with BMP4 floxed mice. Deletion of BMP4 (by excision of exons 3 and 4) occurs in collagen producing osteoblasts and odontoblasts of progeny cells. BMP4cKO mice and their sibling controls were selected for phenotype characterization using analytical methods including X-ray, histological techniques, in situ hybridization, and immunocytochemistry. Our results show that by day 12, BMP4cKO mice display reduced size of calvarias and osteopenia in alveolar bone of the mandible, a 99% decrease in immunoreactivity of

phospho-Smad1/5/8 and reduced DMP1 mRNA in the odontoblasts. By day 18, BMP4cKO mice show 82% reduction of BMP4 mRNA with changed odontoblast morphology and dental tubule formation and 45% decrease in Dlx5 mRNA. Osterix expression was reduced 84% and DSPP 67% in odontoblasts. Amelogenin was reduced 60-80% in ameloblasts in one month old BMP4cKO mice. Dentin thickness was reduced 40% and enamel formation was delayed, although the 3.6 Colla1-Cre shows no activity in ameloblasts at any stage. In conclusion, our results indicate that the absence of BMP4 in osteoblasts and odontoblasts impairs mineralization of the calvaria and mandible, greatly delays the processes of dentinogenesis and amelogenesis. Delayed enamel formation was associated with BMP4 deficiency in odontoblasts and reduced dentin formation, suggesting that disruption in odontoblast differentiation by lack of BMP4 leads to disruption in amelogenesis or enamel formation. These results support the concept that odontogenesis is tightly linked to amelogenesis and is controlled by BMP4. Elucidation of downstream targets for BMP4 signaling using our BMP4cKO mice may provide novel strategies for enhancing bone and tooth integrity.

Angiotensin II Suppresses Bone Mass via AT1 receptor in Long Bones of Adult Mice. Y. Izu, T. Hayata, H. Hemmi^{*}, J. Nagata, Y. Ezura, K. Nakashima^{*}, M. Noda. Department of Molecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan.

Angiotensin II (Ang II), a major effector peptide of the renin angiotensin system, controls blood pressure and body fluid homeostasis. Ang II, derived from Angiotensin I by angiotensin converting enzyme (ACE), binds to its receptors comprised of two major subtypes, angiotensin II type 1 (AT1) and type 2 (AT2). Ang II induces vasoconstriction and sodium retention through AT1 activation, whereas it induces vasodilation and tissue regeneration through AT2 activation. In rodents, two type 1 receptors (AT1a and AT1b) are encoded by distinct genes, although both receptors are pharmacologically identical. In human, clinical and epidemiologic studies suggested that Ang II might have functions to regulate bone metabolism. Indeed, Ang II inhibits differentiation of osteoblasts and matrix calcification in vitro through AT1 activation. In addition, Ang II stimulates osteoclastic bone resorption in a bone marrow cell culture system. However, physiological roles and actions of Ang II in bone metabolism in vivo remain unclear. In order to examine whether Ang II signaling is involved in bone metabolism in vivo, we first examined if its specific receptors, AT1 and AT2, are expressed in the bone of adult mice (9 weeks old). By immunohistochemical approach, we identified AT1 and AT2 expressions in both osteoblasts and osteoclasts in adult long bones. These observations suggest that Ang II may directly regulate osteoblast and osteoclast function in vivo. Additionally, to distinguish physiological roles of AT1 and AT2 in bone in vivo, specific receptor antagonist for AT1, losartan (peroral administration of 10 mg/kg/day) or for AT2, PD123319 (intraperitoneal injection of 10 mg/kg/day) was administered into adult mice (9 weeks old). 3D-micro-CT analysis further revealed that losartan inhibited of AT1 enhanced the levels of bone mineral density (BMD) and cancellous bone volume (BV/TV) in hind limbs. In contrast, blockade of AT2 by PD123319 tended to reduce the levels of both BMD and cancellous BV/TV. These data suggest that Ang II signalings through AT1 and AT2 exhibit opposite roles in bone metabolism in the adult mice.

Identification of Translationally Controlled Tumor Protein (TCTP) as a Nuclear Matrix Protein in Osteoblasts. Y. Jung^{*1}, J. Jeong^{*1}, N. Park^{*1}, K. Lee^{*1}, A. J. van Wijnen², J. B. Lian², J. L. Stein², G. S. Stein², J. Choi¹. ¹Biochemistry & Cell Biology, Kyungpook Natl. Univ. School of Medicine, Skeletal Diseases Genome Research Center, Daegu, Republic of Korea, ²Cell Biology, UMASS Medical School, Worcester, MA, USA.

The composition of nuclear matrix proteins changes as the osteoblast differentiates. To isolate nuclear matrix proteins unique to the bone phenotype, we analyzed nuclear matrix proteins from the primary cultures of rat calvarial osteoblasts by two-dimensional gel electrophoresis at two different stages: proliferation (day3) and differentiation (day 18). We characterized a protein (20 kDa; pI 4.76) that was detected only in the nuclear matrix of differentiated osteoblasts. By MALDI-TOF mass spectrometry and microsequencing, this protein was identified as the TCTP. Expression of TCTP was detected both in vitro bone cell cultures and in vivo bone tissues. In Northern blot analysis, TCTP mRNA expression was detected from early stage to late differentiation stage with no change of its level during the differentiation of human or rat primary cultured osteoblasts. In Western blot analysis, TCTP expression was not changed during osteoblast or chondrocyte differentiation. However, TCTP was detected only in the nuclear matrix fractions of differentiated osteoblasts. In immunohistochemical staining, TCTP was detected in both osteoblasts and chondrocytes in long bone of 17.5 days mouse embryo. These results suggest that TCTP may play an important role in the nucleus during osteoblast differentiation.

Expression of Splice Variants of Collagen XII in Human Osteoblast-like Cells. A. Kamada¹, T. Ikeo¹, Y. Yoshikawa¹, I. Tamura^{*1}, S. Goda^{*1}, E. Domae^{*1}, Y. Takaishi¹, T. Miki². ¹Biochemistry, Osaka Dental University, Hirakata, Japan, ²Geriatric Medicine, Osaka City University, Osaka, Japan.

Type XII collagen, which is a fibril-associated collagen (FACIT), is characterized by a short triple-helical domain with three extended noncollagenous NC3 domains, and may contribute to the stability of collagen I fibrils. Little is known about the role of this FACIT collagen in bone metabolism. In this study, we demonstrated collagen XII gene expression in human osteoblast-like cells, and the influence of beta-glycerolphosphate (BGP) as a biomineralization-inducing agent on the expression of splice variants, which have a long or short NC3 domain.

Two sets of primers and probe for a large variant specific site and a common site in collagen XII NC3 domain were designed based on cDNA sequences in the Gene Bank database. RNA was extracted from cells cultured with or without BGP for 0, 2, 7 days. The expression levels of mRNA were assessed using real-time quantitative RT-PCR technique. The mRNA expression of alpha1(XII) in intact normal human osteoblasts (NHOB) and human osteoblast-like osteosarcoma cells (SaOS2) was confirmed by RT-PCR and agarose gel electrophoresis. Western blot analysis also showed the protein expression of both the long and short form of alpha1(XII) in osteoblast-like cells. When cells were cultured with BGP, mRNA expression levels of alpha1(I), osteocalcin and ALP increased compared with controls ($p < 0.05$). In contrast, the level for the long variant of alpha1(XII) was significantly lower than that in controls two days after BGP stimulation ($p < 0.05$). It is known that the long form NC3 domain of collagen XII can carry glycosaminoglycans and bind to tenascin, while collagenous domains attach to collagen I. Our results clarify that collagen XII gene is transcribed in human osteoblast-like cells, and indicate that the transcription control of splice variants may be concerned with bone formation.

Murine Bone Loss Following Local Irradiation. E. R. Bandstra¹, S. Judex², M. E. Vazquez^{*3}, T. A. Bateman¹. ¹Bioengineering, Clemson University, Clemson, SC, USA, ²Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, ³Medical Department, Brookhaven National Laboratory, Upton, NY, USA.

Spaceflight presents a complex set of challenges to the skeletal system. Unloading is a well documented stressor that results in bone loss. The impacts of radiation on bone have not been well studied. On long-duration exploratory missions, astronauts will be exposed to higher doses of ionizing radiation from both solar and cosmic sources, ranging from protons to iron ions. We have recently identified that multiple spaceflight-relevant types of radiation, approaching doses astronauts will be exposed to on exploratory missions, cause profound trabecular bone loss. This study aims to investigate the effects of local (head only) irradiation on regional and systemic bone. Male C57BL/6 mice were irradiated with 1GeV/n HZE ⁵⁶Fe at 16 weeks of age at the NASA Space Radiation National Laboratory. The radiation was collimated such that the head received 2.4 Gy and the rest of the body, including humerus and tibia, received 14% (33.6 cGy) of the total dose delivered. The mice were sacrificed 8 weeks after irradiation. MicroCT analysis was performed on the trabecular and cortical bone of the proximal humerus and tibia. Within the humerus, a significant 15.1% decline in trabecular volume fraction was observed compared to the control group. However, no differences were observed within the tibia compared to control (insignificant decline in trabecular volume fraction of 4%). Analysis of the cortical bone revealed a 4.2% decrease in bone volume with a 6.5% increase in cortical porosity in the proximal humerus, with no significant cortical changes in the proximal tibia. The bone loss in the humerus, without corresponding loss in the tibia, indicates either a differential response of these bones or a greater loss in bones anatomically closer to higher doses of radiation. Previous work has not found changes in cortical bone following similar doses of low-LET radiation, possibly indicating cortical bone changes are LET-dependent. In contrast, previous studies of radiation at these doses have not shown an LET-dependent response in trabecular bone. Another important contribution of this study is the demonstration of bone loss in mice that are near peak bone mass. Our previous studies examined mice irradiated at 9 weeks of age when the skeletal system is rapidly growing. Radiation-induced bone loss in the mature skeleton further demonstrates that this challenge represents a potential concern for astronauts on long-duration exploratory missions, and should be studied to further characterize the bone loss following irradiation, identify causal mechanisms, and develop countermeasures.

Fracture Threshold in Breast Cancer Patients Treated with Adjuvant Aromatase Inhibitors. F. Bertoldo^{*}, L. Dalle Carbonare^{*}, S. Zenari^{*}, S. Pancheri^{*}, M. Zanatta^{*}, B. Giovanazzi^{*}, M. T. Valenti^{*}, V. Lo Cascio. Biomedical and Surgical Sciences, Medicina D, University of Verona, Verona, Italy.

Aromatase inhibitors (AI) in the adjuvant treatment of breast cancer patients is notoriously associated with an increased risk of fractures as opposed to tamoxifene therapy (ATAC trial). Prospective studies evaluating the long-term effects of AI treatment on bone mineral density (BMD) showed a relatively modest decrease in BMD after 2 years of treatment and no patients with normal BMD at baseline became osteoporotic at the end of observation. Actually it is not clear which patients should receive preventive measures. The latest ASCO guidelines identified BMD as a valid tool in treatment decision making. As the value of BMD T-score ≤ -2.5 for fracture threshold is applicable only for postmenopausal osteoporosis (PMO), and pathophysiology underlying AI induced bone loss may be different from PMO, we planned a pilot cross-sectional study to assess the BMD fracture threshold in AIs treated women. We compared lumbar and femoral neck BMD (Hologic Discovery A), vertebral fracture (vFX) prevalent number, Spine deformity Index (SDI), bone turnover markers among 21 breast cancer patients treated for one year with AIs (AI group), 96 PMO patients (PMO group) and 42 breast cancer patient not treated with AIs (BC group). The groups were comparable for age (52 ± 5 y.o, 52 ± 6 and 51.8 ± 4 respectively) height and BMI. The three group did not differ for the number of prevalent vFX and SDI. Lumbar spine BMD T-score was -2.21 ± 0.5 in AI group, -2.53 ± 0.3 in PMO group and -2.49 ± 0.5 in BC group ($p = 0.042$ ANOVA). Among marker of bone turnover, CTX was significantly higher in AI group than in PMO and BC groups (0.684 ± 0.123 , 0.427 ± 0.185 and 0.408 ± 0.210 respectively; $p = 0.036$ ANOVA). A weak inverse correlation between CTX and spine BMD T-score was found only in PMO and BC group ($r = 0.48$ and $r = 0.32$ respectively). These preliminary data suggest that independent predictive factors of fracture risk, i.e. high bone turnover, could increase BMD fracture threshold in AIs treated patients compared to PMO patients or BC patients not treated with AI.

Identification of Proteins that Interact with the Collagen Type XI (α 1) Amino Terminal Domain. R. J. Brown^{*}, J. R. T. Oxford. Biomolecular Research Center and Department of Biology, Boise State University, Boise, ID, USA.

The extracellular matrix of articular cartilage is composed of collagens, proteoglycans and a variety of noncollagenous, nonproteoglycan molecules which interact to ultimately contribute to the structural integrity, compressibility and tensile strength of the tissue. The ultimate goal of our investigation was to examine the potential interactions of the amino terminal domain (NTD) of collagen. Utilizing the recombinant aminoproteptide common to each of the collagen α 1(XI) isoforms, proteins extracted from bovine articular cartilage were separated by affinity chromatography. Molecules extracted from the articular cartilage and enriched by their association with the surface of the collagen fibril were identified by tandem mass spectrometry. Proteins enriched by the association with the surface of the α 1(XI) collagen fibril were predominantly: the collagen types IX, XII and XIV; the extracellular matrix proteins, COMP (thrombospondin-5), thrombospondin-1, matrilin-1 (CMP), chondroadherin, PARP, matrilin-3, chondrocalcin and proteoglycans; biglycan and fibromodulin. The results presented here provide evidence that the NTD of collagen α 1(XI) may associate, either directly or indirectly, with a variety of cartilage matrix constituents in the connective tissue and suggest the possibility that this region of collagen α 1(XI) may add structural support bridging the environment between chondrocytes and the surrounding extracellular matrix or play a role in fibrillogenesis.

Bioreactor Design for Osteochondral Tissue. S. Cartmell¹, J. Gittings², I. Turner², J. Chaudhuri³, M. Ellis³, S. Waters⁴, L. Cummings⁴, N. Kuiper¹, V. Michael¹. ¹Institute of Science and Technology in Medicine, University of Keele, Stoke on Trent, United Kingdom, ²Department of Mechanical Engineering, University of Bath, Bath, United Kingdom, ³Department of Chemical Engineering, University of Bath, Bath, United Kingdom, ⁴Division of Applied Mathematics, University of Nottingham, Nottingham, United Kingdom.

Bioreactor design for the culture of tissue-engineered constructs is essential for the production of functional tissue. Co-cultures of cartilage and bone tissue together have been shown to be beneficial compared to monocell cultures. We have developed a bioreactor for culturing osteoblasts/chondrocytes together (A). Two separate bone and cartilage culture chambers are assembled together with the bone/cartilage separated by a silicone membrane. This system allows nutrient administration via two separate methods to allow scale up of larger tissues. Media is perfused to the chambers whilst a PLGA porous fibre runs through the bone scaffold delivering extra nutrients via diffusion. Through this fibre, a temperature/oxygen sensor will be introduced to the samples, allowing monitoring of cellular activity. Non-invasive lactate and glucose culture media analysis also allows further quantification. Porous calcium-phosphate scaffolds (15mm x 10mm) and Chitosan hydrogel substrates (15mm x 6mm) are used to support the bone/cartilage cells. The bone scaffold (B) mimics the arrangement in an articulating joint where the porous trabecular bone is covered with a shell of dense cortical bone which, in turn, interfaces with the cartilage component. It is hypothesised that the cap to the porous scaffold will restrict mixing between the bone and cartilage media. Static experiments have been performed by seeding bone scaffolds with MG-63 cells. Mathematical modelling of the bone chamber and porous scaffold has been performed. Preliminary seeding data reveal 59% and 76% of cells were adherent on the scaffold after 2 hours and 4 days in culture respectively (C). Numerical simulations were able to visualise the fluid distribution through the bone chamber, and determine the optimum chamber size and inlet/outlet configuration to achieve minimal regions of stagnation, while maintaining shear stress below the threshold (5-15 dyne/cm²). This sophisticated co-culture bioreactor has the potential to significantly improve the functionality of tissue-engineered osteochondral plugs.

A Novel Model of Impaired Fracture Healing. T. S. Gross¹, S. L. Poliachik^{*1}, S. E. Nork^{*1}, S. D. Bain². ¹Orthopaedics and Sports Medicine, University of Washington, Seattle, WA, USA, ²MDS Pharma Services, Bothell, WA, USA.

The biological pathways responsible for normal fracture repair are well understood. However, the causal factors leading to unsuccessful fracture healing are ill defined and poorly understood. Based on recent data indicating that transient muscle paralysis rapidly induces bone loss in mice, we hypothesized that a transient loss of muscle function superimposed upon a closed femur fracture in rats would lead to delayed fracture healing. To test this hypothesis, Sprague-Dawley female rats (age: 4 months, n=14) underwent a standard closed femur fracture with a Kirschner wire inserted through the right femur diaphysis prior to blunt guillotine impact. Following radiographic confirmation of the location and disposition of all fractures, 7 rats were given a single injection of Botox in their right quadriceps (2 Units/100g, 1/2 of dose 5 mm proximal, 1/2 dose 5 mm distal to the fracture site). The remaining 7 rats received identical volume Saline injections. All rats were allowed to ambulate freely, with 10 rats killed at 4 wk (n=5/grp) and 4 rats killed at 6 wk (n=2/grp). Following sacrifice, right femurs were radiographed and micro-CT scans were obtained of all right and left femurs (1.6 cm region centered at the mid-diaphysis, 21 µm voxel). For each animal, callus volume and the polar moment of inertia (pMOI) of the callus were determined by contrast with the contralateral intact left femur. Botox induced quadriceps paralysis significantly diminished fracture callus volume compared to Saline treated rats at 4 wk (-42.1%, p=0.003) and 6 wk (-39.9%, p=0.05). Similarly, callus pMOI was profoundly reduced in Botox treated rats compared to Saline treated rats (4 wk: -60.0%, p<0.001; 6 wk: -49.8%, p=0.03). Radiographic examination indicated an absence of bone union in 6 of 7 Botox treated rats, while all Saline treated rats demonstrated clear evidence of bone union across the fracture gap. These data clearly demonstrate that transient muscle paralysis of a single muscle group adjacent to the femur leads to impaired fracture healing. Further, the lack of callus formation in the Botox rats was not spatially confined to the anterior cortex adjacent to the quadriceps. As diminished muscle function following trauma or due to aging have both been associated with poor fracture healing, this novel model holds potential to directly impact clinical care by exploring why normal muscle function is required for successful fracture healing.

Formation of Haversian-Type Bone and Blood Vessels Guided by the Artificial ECM of Vasculature-Inducing Geometry. T. Kaku¹, H. Kobayashi^{*1}, S. Iku^{*2}, K. Nemoto^{*2}, T. Miyata^{*2}, Y. Kuboki^{*3}. ¹Oral Pathology, Health Sciences University of Hokkaido, Hokkaido, Japan, ²Koken Bioscience Institute, Hokkaido, Japan, ³Koken Bioscience Institute & Hokkaido University, Hokkaido, Japan.

We have proposed that geometrical property of the artificial extracellular matrices (ECM) must be taken into consideration for successful development of tissue engineering (JBJS 83A:S1-105-115, 2001). Geometry is defined in this case as the three dimensional (3D) structure of artificial ECM at the order of micrometer, which can direct growth of tissues and organs in vivo and in vitro. Previously we have reported that honeycomb-shaped hydroxyapatite (HC-HAP) with the pores less than 100-µm induced endochondral ossification, while one with 350-µm pores induced direct bone formation. By the fact that a single large blood vessels was always noticed in the center of the 350-µm pores of HC-HAP, we attempted to direct the haversian-type bone formation by an artificial ECM with similar geometry to HC-HAP but with biodegradable property. We chose a honeycomb-shaped collagen product (HC-COL) (Honeycomb sponge, Koken, Japan). HC-COL was cut into block-form, combined with the purified BMP cocktail (500 µg) or rhBMP-2 (5 µg) and implanted into rat skin. HC-COL was calcified with a series of the solutions, which contained calcium and phosphate to obtain the hydroxyapatite-coated honeycomb collagen (HAP-HC-COL), which was also implanted into the skin. Two weeks after implantation, it was found that the concentric layered osteogenesis occurred within the each tunnels of HC-COL/BMP, the centers of which, there was a single large blood vessel. The structure was reminded us the haversian system. More interestingly, HAP-HC-COL itself (without BMP) induced the concentric fibrous tissue formation with a blood vessel in the center of the tunnel. Although bone formation was not observed. It was concluded that the characteristic 3D-structure (vasculature-inducing structure) of HC-COL or HAP-HC-COL induced vasculature first, irrespective of the presence of BMP. Then bone formation will occur if the mesenchymal cells were differentiated into osteoblasts by BMP.

Mineral and Matrix Characteristics in Mice with LRP5 G171V Mutation. N. P. Camacho¹, M. P. Akhter². ¹Imaging & Spectroscopy Lab, The Hospital for Special Surgery, New York, NY, USA, ²Medicine, Creighton University, Omaha, NE, USA.

Greater bone density and strength has been reported in mice with the LRP5 G171V mutation. We characterized femoral cortical bone properties to determine if the LRP5 G171V mutation differences in mineral and matrix properties as compared to wild type (WT). Sixteen female mice (4 mo.) representing two genotypes (WT=wild type, HBM=High bone mass with LRP5 G171V mutation) were used. Femoral mineral and matrix properties were analyzed by Fourier transform infrared imaging spectroscopy (FT-IRIS). This allows information on mineral, collagen, and carbonate content and

distribution to be obtained at ~ 7 μm spatial resolution from PMMA-embedded bone sections. Infrared vibrations of both the mineral (a poorly crystalline carbonated apatite (HA)) and matrix phases (primarily Type I collagen) were monitored simultaneously. The ratio of the area of the HA phosphate ν_1 , ν_2 absorbance from 900 to 1200 cm^{-1} , to the area of the protein amide I absorbance from 1590 to 1720 cm^{-1} was calculated to obtain the relative amounts of mineral and protein present (min:matrix), a parameter previously shown to be correlated to ash weight. The carbonate-to-mineral ratio (carb:min), an indicator of carbonate content of the mineral phase, was calculated as the ratio of the area of the carbonate ν_2 absorbance from 850 to 890 cm^{-1} to the area of the phosphate ν_1 , ν_2 absorbance. Crystallinity of the mineral phase was calculated by ratioing the intensity of the absorbance at 1030 cm^{-1} to that at 1020 cm^{-1} , a parameter previously shown to be related to the apatite crystal length in the c-axis direction. The crosslink (Xlink) parameter, related to the ratio of mature to immature collagen crosslinks, was obtained by ratioing the intensity of the absorbance at 1660 cm^{-1} to that at 1686 cm^{-1} . We analyzed the data using the Student's t test for differences due to genotype. There were no differences in FT-IRIS determined bone parameters, except for the Xlink parameter, which tended to be greater in the HBM mice compared to the WT mice ($p = 0.08$). An increase in this collagen parameter likely reflects increased mature crosslinks, a finding which could be consistent with the greater bone strength previously reported in the HBM mice. Further investigations will focus on how the relatively increased crosslinks in HBM mice influence their bone intrinsic material properties as measured by nano-indentation at ultrastructural level.

FT-IRIS (mid-shaft femur)	HBM	WT
Min:Mat	6.95 \pm 0.63	6.53 \pm 0.82
Car/Pho	0.010 \pm 0.002	0.0093 \pm 0.002

Secreted Phosphoprotein-24 Is Converted from an Inhibitor to a Functional Enhancer During BMP-Directed Osteoblastogenesis. M. J. Beckman¹, S. C. Ramage¹, A. Maiti², O. Korchynski². ¹Biochemistry and Molecular Biology, Virginia Commonwealth University, Richmond, VA, USA, ²Orthopaedic Surgery, Virginia Commonwealth University, Richmond, VA, USA.

Bone morphogenetic proteins (BMPs) are members of the TGF β family and key regulators of osteogenesis. BMPs signal through their cognate receptors to SMAD proteins that transduce the signals to activate genes crucially important to osteogenesis. Secreted phosphoprotein-24 (Spp24) is a 24 kDa bone matrix protein isolated from demineralized bovine bone matrix. Spp24 has known homology domains to both cystatin and TGF β receptor type II (T β RII), and like many bone matrix proteins has numerous sites for glycosylation as well as serine and threonine phosphorylation. The T β RII domain of Spp24 has shown a low affinity binding to BMP-2. A truncated form of Spp24 has been shown to possess osteoinductive character and enhance BMP activity. Overexpression of mouse Spp24 (mSpp24) inhibited various BMPs' signaling at early time points. We hypothesize that Spp24 is converted to a more active factor that can enhance later stages of BMP-mediated osteoblastogenesis. This concept was tested using an adult human bone marrow mesenchymal stem cell model (MSC). A mouse Spp24 adenovirus (Adv5CMV-mSpp24) construct was used to transduce MSCs with 100% efficiency for long duration. MSC differentiation to osteoblasts (OB) was induced and maintained by controlled treatment with BMP-2/7 heterodimer dosed over a 14 day period, resulting in fully differentiated OB cells. The experimental design was a 2 x 2 factorial of Adv5CMV-LacZ control, LacZ plus BMP-2/7, mSpp24, and mSpp24plus BMP-2/7. All groups were also co-transduced with a BMP-specific response element reporter to assay BMP-Smad-induced signaling and β -galactosidase for normalization. Results demonstrated marked repression of BMP signaling by mSpp24 after 3 days in culture. By day 7, the mSpp24 repression of BMP signaling was not evident. However, at the subsequent time points, particularly on day 10, the effect of mSpp24 was to significantly enhance BMP signaling. Western blots were performed with the HA-tagged mSpp24 protein product at 3, 7, 10 and 14 days. The results of this analysis revealed a truncated 18 kDa fragment of mSpp24, representing the putative active form, appearing by day 7 and increased at day 10. In conclusion, these data indicate that Spp24 plays an antagonistic role to osteogenic signaling until it is modified in a yet unspecified manner to create this smaller 18 kDa form that is capable of enhancing BMP activity. Our study confirms earlier work by Wozney that described a slow release factor capable of regulating BMP-mediated osteogenesis and later by Murray that Spp18 is the active fragment.

Cross-Talk Between CTGF and TGF- β 1 in Mesenchymal Stem Cell Condensation. F. Del Carpio-Cano^{*1}, J. Y. Belcher¹, K. B. Buck^{*1}, J. A. Arnot¹, R. A. DeLa Cadena^{*2}, S. N. Popoff¹, F. F. Safadi¹. ¹Anatomy and Cell Biology, Temple University, Philadelphia, PA, USA, ²Physiology, Temple University, Philadelphia, PA, USA.

Condensation or the aggregation of mesenchymal stem cells (MSCs) precedes chondrocyte differentiation and is required for cartilage formation. CTGF is a matricellular protein that has been found to be expressed during MSC condensations in vivo. It has been shown that TGF- β 1 regulates CTGF expression and that CTGF acts as a downstream mediator of TGF- β 1 effects on extracellular matrix production. It has also been reported that CTGF has the ability to bind TGF- β 1 and modulates its effects. Using C3H10T1/2 MSCs as a model for mesenchymal condensation, we have shown previously that TGF- β 1 induces MSC condensation in vitro associated with increased matrix production, proliferation and migration and this induction is mediated by CTGF. In this study, we were interested to examine whether CTGF overexpression can mediate MSC condensation in the absence or presence of TGF- β 1. C3H10T1/2 MSCs were infected with adenovirus over-expressing CTGF tagged with GFP achieving a 6-7 fold increase in CTGF mRNA and protein expression. Adenovirus expressing only GFP was used as control. Cells overexpressing CTGF did not show any MSC condensation. Surprisingly, TGF- β 1 induced MSC condensation was inhibited in cells overexpressing CTGF. These results suggest that a fine equilibrium of CTGF expression is required for TGF- β 1-induced MSC condensation. We next examined the effect of CTGF overexpression on MSC adhesion and spreading associated with vinculin localization at focal adhesion and actin cytoskeletal reorganization. Cells overexpressing CTGF spread more robustly with an increased punctuated signal of vinculin at sites of focal adhesion with the formation of lamellipodia when compared to cells infected with GFP virus. We next examined the signaling pathway associated with MAP Kinase family to evaluate differences between TGF- β 1-induced MSC condensation and the inhibitory effect of CTGF overexpression on MSC condensation. Phosphorylated P38, Jnk and Erk were increased in the GFP-infected MSCs treated with TGF- β 1. However, MSCs infected with GFP-CTGF and treated with TGF- β 1 showed only an increase in phosphorylated Jnk and Erk but not P38. These findings indicate that p38 MAPK may mediate MSC condensation by TGF- β 1. Further studies are warranted to modulate P38 expression to elucidate the interaction between CTGF and TGF- β 1 in regulating MSC condensation.

The Three Dimensional ¹H NMR Structure of Bovine Lead Ion-Bound Osteocalcin and Implications for Lead Toxicity. L. Li^{*1}, C. M. Gundberg², T. L. Dowd^{*3}. ¹National Institute of Environmental Health Science, Research Triangle Park, NC, USA, ²Orthopedics, Yale University School of Medicine, New Haven, CT, USA, ³Chemistry, Brooklyn College of the City University of New York, Brooklyn, NY, USA.

Structural information on the effect of Pb²⁺ on proteins under physiologically relevant conditions is largely unknown. We have solved the three dimensional structure of bovine lead coordinated osteocalcin, a bone protein from a target tissue, using ¹H 2D NMR techniques and suggested a molecular mechanism for lead toxicity. The protons in the 49 amino acid sequence were assigned using 2D homonuclear NMR experiments. Lead, at a stoichiometry of only 1:1, was shown to induce a tertiary structure in the protein similar to that induced by Ca²⁺ at a stoichiometry of 3:1. The structure of Pb²⁺-osteocalcin consists of an unstructured N terminus and a C-terminal hydrophobic core (residues 16-49) formed by long range hydrophobic interactions. Elements of secondary structure within residues 16-49 include a type III turn (residues 27-30) and a α_1 helix (residues 31-34). Residues 21-26 formed loose turns with helical characteristics. The 3 Glu residues project from the same face of the helical turns and are surface exposed. The genetic algorithm -molecular dynamics simulation approach was used to place 1 lead ion on the NMR derived structure. The lead ion was coordinated by side chain oxygen ions of OE3 and OE4 of Glu 24 and the side chain oxygen ions of OE1 and OE2 of Glu 21. The best correlation of the distances between the uncoordinated Glu oxygen ions is with the intercalcium distance of 9.43 Å in hydroxyapatite. This mineral binding is similar to what was proposed from the structure of Ca²⁺-osteocalcin. A comparison of Pb²⁺- and Ca²⁺-osteocalcin indicates Pb²⁺ may induce conformational changes and subsequent molecular processes in proteins prematurely. Lead exposure may alter the amount of mineral bound osteocalcin contributing to abnormal bone remodeling. This may play a role in the increased bone resorption and decreased bone density observed in bones from lead exposed animals.

The Biological Trials of Hyaluronic Acid on Osteoclast Differentiation Induced by IL-1. M. Hirata¹, M. Kobayashi^{1*}, K. Miyazaki^{2*}, C. Miyaaura¹, M. Inada¹. ¹Department of Biotechnology and Life Science, Tokyo University of Agriculture and Technology, Tokyo, Japan, ²Seikagaku Corporation, Tokyo, Japan.

Hyaluronic acid (HA) is a component of extra cellular matrix (ECM) in cartilage, polymer of a glycosaminoglycan organized the network with majority of agrican. In human bone marrow, HA produced in both stromal and hematopoietic lineage of cells, the capacities could be counted on regulating cellular response for bone cells. In bone ECM, HA present as a high molecular size, however, the functional effect of HA on osteoclast differentiation is still unclear. Here we demonstrate that the roles of HA in osteoclast differentiation induced by IL-1. When the co-culture of primary osteoblasts from newborn calvaria and bone marrow cells from tibiae in the presence of IL-1, TRAP (Tartrate Resistant Acid Phosphatase) positive multinucleated cells were formed 7 days of culture. HA single treatment did not alter the proliferation of osteoblast/stromal cells. In the presence of IL-1 (2 ng/ml) and HA (900 KDa, 1 mg/ml), however, the number of TRAP positive cells was decreased. RT-PCR was performed using primer sets of RANKL (as an inducible ligand on osteoblast) and NFATc1 (inducible transcriptional factor on osteoclast differentiation). The result showed RANKL expression induced by IL-1 was suppressed in the presence of HA. NFATc1 expression slightly decreased in the culture. To identify further mechanisms of the HA, ex vivo calvarial organ culture was performed. Calvarial bone from day 4 old mice were dissected into 2 portions (control vs. challenge group) of culture, bone resorbing activity was measured by cultured medium calcium. When the presence of IL-1 (2ng/ml) in culture, bone resorbing activity was increased and the activity was suppressed by the simultaneous treatment with HA (900 KDa, 1 mg/ml). These results suggested HA attenuated IL-1 induced RANKL production in osteoblast, following NFATc1 expression was suppressed in osteoclast precursors sequentially decrease the number of mature osteoclast. The potentials shown in the presented study suggested that HA could apply various inflammatory diseases as an inhibitor of bone loss.

The Inhibitor of Metalloproteinases TIMP-1 Rescues the Strong Bone Loss Induced by Runx2 Overexpression in Mice. C. Schiltz*, C. Prouillet*, C. Marty*, M. De Vernejoul, V. Geoffroy. Hôpital Lariboisière, INSERM U606, Paris Cedex 10, France.

The Runx2 gene is essential for osteoblast differentiation and function. Runx2 deficiency results in complete lack bone formation and overexpression of Runx2 in cells of the osteoblastic lineage to severe osteoporosis. Osteoblastic matrix metalloproteinases (MMPs) have been reported to be required for normal bone resorption. Several lines of evidence suggest that osteoblastic MMPs could take part of the increased bone resorption observed in mice after overexpression of Runx2. The goal of our study was to define using transgenic approach whether inhibition of osteoblastic MMPs can reduce the bone loss induced by Runx2.

We examined the rescue of the severe osteopenic phenotype in Runx2 mice by overexpressing the MMPs inhibitor TIMP-1 (tissue inhibitor of metalloproteinase 1) specifically in osteoblasts. 1-, 4- and 8-month-old females with the different genotypes (WT, Runx2, TIMP-1 and TIMP-1/Runx2) were generated. Bone density was measured by DXA and by pQCT for all mice. Microarchitecture and formation and resorption parameters were evaluated in 1- and 4-month-old females by histomorphometry. Primary osteoclasts were differentiated ex vivo from bone marrow or co-cultured with primary osteoblasts isolated from calvaria. Primary osteoblasts were also used to evaluate gene expression by qPCR.

Bone density analysis indicated that TIMP-1 overexpression is efficient at reducing bone loss observed in Runx2 mice but only in 4- and 8-month-old females. The rescue and prevention of bone loss in TIMP-1/Runx2 mice were visible at the long bones and the caudal vertebrae. Histomorphometry analysis on trabecular bone indicated that this rescue in 4-month-old TIMP-1/Runx2 females was due to a decrease of the resorption activity (decreased trabecular separation and osteoclastic surfaces) and a sustained osteoformation (increased trabecular thickness and maintained BFR) compared to Runx2 mice. In addition, we also reported a partial rescue of the cortical bone loss (increased cortical thickness and outer bone diameter) in TIMP-1/Runx2 mice compared to Runx2 mice. Our ex vivo study showed that the ability of osteoclastic cell to differentiated is reduced in TIMP-1/Runx2 mice compared to Runx2 mice due to a reduction in the expression of RANK-L by TIMP-1/Runx2 osteoblastic cells.

In conclusion, we showed that TIMP-1 overexpression in the runx2 background mainly reduces bone resorption (decrease osteoclasts differentiation and activity) and maintains bone formation in trabecular and cortical bone. Our results indicate that osteoblastic MMPs are partly responsible for the bone loss in mice overexpressing Runx2.

Identification of Novel Transcription Factors Necessary for Chondrocyte Hypertrophy. A. M. Ionescu, A. B. Lassar*. BCMP, Harvard Medical School, Boston, MA, USA.

To date, only two families of transcription factors are known to regulate chondrogenesis, Sox and Runx family members. The early steps of chondrogenesis, including mesenchymal condensation and expression of chondrocyte-specific extracellular matrix proteins are critically regulated by Sox9, Sox5, and Sox6. In contrast, the latter steps of chondrogenesis appear to be regulated by Runx2 and/or Runx3. Runx2 is expressed in chondrocytes as they initiate chondrocyte hypertrophy, and loss of this factor in genetically engineered mice severely delays chondrocyte maturation in a number of developing bones.

Interestingly, recent work in the Lassar lab has demonstrated that expression of exogenous Runx2 fails to activate expression of endogenous collagen X in naïve somites, but can activate expression of this gene in somites that have been induced to initiate the chondrocyte differentiation program. Consistent with this result, I have found out that Runx2 and Smad1 (which transduces BMP signals) are only able to induce the expression of a Col X-luciferase reporter in upper sternal chondrocytes (USCs) but not in fibroblasts (CEFs) isolated from chicken embryos, in the presence of exogenous BMP signals. This suggests that hypertrophic chondrocytes express another factor that is required for the expression of Col X.

To identify a chondrocyte-specific DNA binding factor(s), a series of overlapping 40 bp oligomers that cover the Col X enhancer were used in an EMSA to detect DNA binding activities that are specifically present in primary chondrocytes but are absent from fibroblasts. This analysis led to the identification of a Fast Mobility Complex (FMC) that binds to 4 sites in the collagen X regulatory sequences, a Slow Mobility Complex (SMC) that binds to 2 sites and Sox 5 which binds in multiple places along the collagen X regulatory sequences. Mutational analysis of these binding sites indicated that the FMC sites are necessary for efficient induction of a Col X-luciferase reporter by co-transfected Runx2 and Smad1 in chondrocytes. Moreover, 4-fold reiteration of one of the Fast Mobility Complex binding sites (FMC3) placed upstream of Col X-promoter proximal sequences (4x FMC3-Col X-luciferase), led to chondrocyte-specific induction of the downstream luciferase reporter by co-transfected Runx2 and Smad1. Thus, our immediate focus consists in identification and characterization of the proteins that comprise FMC3. The successful identification of FMC3 will lead to the identification of new hypertrophy-specific factors which, if inhibited, could reverse chondrocyte hypertrophy which is pathologically induced during osteoarthritis.

Alpha-2-Macroglobulin Is a Novel Substrate for ADAMTS-7 and ADAMTS-12 and Inhibits Their Degradation of Cartilage Oligomeric Matrix Protein. Y. Luan^{1*}, D. R. Howell^{2*}, L. Kong^{2*}, C. Liu². ¹Orthopaedic Surgery, New York University, New York, NY, USA, ²New York University, New York, NY, USA.

Degradative fragments of cartilage oligomeric matrix protein (COMP) have been observed in both osteoarthritis and rheumatoid arthritis. We previously reported that ADAMTS-7 and ADAMTS-12, two members of ADAMTS (a disintegrin and metalloprotease with thrombospondin motifs) family, sharing the similar domain organization in the family, degraded COMP in vitro and were significantly induced in the cartilage and synovium of arthritic patients (Liu, et al, FASEB J. 2006; 20(7):988 and Liu, et al, J. Biol. Chem. 2006; 281(23):15800). In this study we further demonstrated the importance of COMP degradation by ADAMTS-7 and ADAMTS-12 in vivo, since i) the size of the COMP fragments produced by either ADAMTS-7 or ADAMTS-12 is similar to that of COMP-degradative fragments seen in the patients with osteoarthritis; ii) antibody blocking assay indicated that specific antibodies against ADAMTS-7 or ADAMTS-12 dramatically inhibits TNF- α -induced COMP degradation in the cultured cartilage explants and iii) suppression of ADAMTS-7 or ADAMTS-12 expression using siRNA silencing approach in the human chondrocytes also markedly prevents COMP degradation. Furthermore, we revealed that α_2 -Macroglobulin (α_2 M) is a novel substrate for ADAMTS-7 and ADAMTS-12 based on the observations that both metalloproteinases were able to cleave α_2 M in a dose-dependent manner, which gave rise to the cleavage products with the molecular weights of 180 and 105 kDa respectively. More significantly, α_2 M inhibits both ADAMTS-7- and ADAMTS-12-mediated COMP degradation in a dose-dependent manner; thus α_2 M represents the first endogenous inhibitor of ADAMTS-7 and ADAMTS-12.

MT3-MMP Is a Major Mesenchymal Collagenase Essential for Skeletal Development. J. Shi*, M. Son*, S. Yamada*, L. Szabova*, S. Kahan*, K. Chrysovergis*, L. Wolf*, A. Surmak*, K. Holmbeck*. CSDB/MMPU, NIDCR, Bethesda, MD, USA.

Peri-cellular remodeling of mesenchymal extracellular matrices is considered a prerequisite for mesenchymal cell proliferation, motility and development. Here we explore the molecular mechanisms responsible for collagen remodeling in the skeleton and peri-skeletal tissues of the mouse. We demonstrate that membrane-type 3 MMP, MT3-MMP, is expressed in mesenchymal tissues of the skeleton and in peri-skeletal soft connective tissue. Consistent with these observations MT3-MMP-deficient mice display growth inhibition tied to a decreased viability of mesenchymal cells in skeletal tissues. We document that MT3-MMP works as a major collagenolytic enzyme, enabling cartilage and bone cells to cleave high-density fibrillar collagen and modulate their resident matrix to make it permissive. Collectively, these data uncover a novel extracellular matrix remodeling mechanism required for proper function of mesenchymal cells. The physiological significance of MT3-MMP is highlighted in mice double deficient for MT1-MMP and MT3-MMP. Double deficiency transcends the combined effects of the individual single deficiencies and leads to severe embryonic defects in palatogenesis and bone formation incompatible with life. These defects are directly tied to loss of indispensable collagenase activities required in mesenchymal tissues for extracellular matrix remodeling and cell proliferation during embryogenesis. Based on these observations we conclude that peri-cellular collagen remodeling mediated by the MT1-MMP/MT3-MMP synergizing duo of collagenases is essential for skeletogenesis and palatogenesis in the mouse and demonstrates the requirement for embryonic remodeling of collagen.

BMP-2 Induces Sustained Expression of COX-2 in MC3T3-E1 Osteoblasts. K. A. Blackwell*, P. Hortschansky*, L. G. Raisz*, C. C. Pilbeam*. ¹Endocrine Division and Musculoskeletal Institute, University of Connecticut Health Center, Farmington, CT, USA, ²Leibniz Institute for Natural Product Research and Infection Biology, Hans-Knöll-Institute (HKI), Jena, Germany, ³Endocrine Division and Musculoskeletal Institute, University of Connecticut Health Center, Farmington, CT, USA.

BMP-2 potently stimulates osteoblastic differentiation. We have shown that BMP-2 induces cyclooxygenase-2 (COX-2) expression in murine primary calvarial osteoblasts via a Runx2 binding site at -267/-261 bp in the COX-2 promoter and that the full anabolic response to BMP-2 requires the induction of COX-2 and production of prostaglandin (PG) E₂ in osteoblasts. To study further the mechanisms by which BMP-2 regulates COX-2 mRNA and by which PGE₂ may contribute to effects of BMP-2, we treated MC3T3-E1 osteoblastic cells with vehicle, BMP-2 (300 ng/ml), PGE₂ (1 µM), or BMP-2 + PGE₂ and measured COX-2 mRNA by real time PCR. To prevent effects of endogenous PGE₂ induced by BMP-2, all experiments were performed in the presence of the COX-2 selective inhibitor, NS-398 (0.1 µM). Although the induction of COX-2 is generally transient, BMP-2 induced elevation of COX-2 mRNA was more sustained: 2.9-fold at 4 h, 3.0-fold at 8 h and 2.6-fold at 24 h. PGE₂ alone had no significant effect on COX-2 mRNA levels. However, the addition of PGE₂ to BMP-2 increased the elevation of COX-2 mRNA, relative to BMP-2 treatment alone, by 1.3-fold at 4 h, 1.5-fold at 8 h, and 2.5-fold at 24 h. To assess the role of promoter regulation by BMP-2 in these effects, we used MC3T3-E1 cells stably transfected with 371 bp of the COX-2 promoter fused to the luciferase gene. BMP-2 transiently stimulated luciferase activity by 2.7-fold at 4 h, with levels returning to baseline at 24 h. At 4 h, PGE₂ alone had a small effect on luciferase activity (1.6-fold) and addition of PGE₂ to BMP-2 further amplified luciferase levels by 1.6-fold over BMP-2 alone. Similar to BMP-2 treatment alone, levels returned to baseline by 24 h. Similar results were obtained with MC3T3-E1 cells stably transfected with 3 kb of the COX-2 promoter fused to the luciferase gene. Measurement of mRNA degradation after treatment with inhibitors of transcription indicated that neither BMP-2 or BMP-2 + PGE₂ stabilized COX-2 mRNA compared with controls or PGE₂ alone. These results suggest that BMP-2 may transcriptionally elevate COX-2 expression not only via the proximal promoter region (-300 bp), which stimulates the transient expression of COX-2, but also via distal elements (> -3 kb), which stimulate more sustained expression of COX-2. Additionally, PGE₂ enhances both the transient and sustained induction of COX-2 mRNA by BMP-2.

Craniofacial Reconstruction with Bone Morphogenetic Protein-2. A. Docherty Skogh, C. Arnander*, T. Engstrand*. Plastic and Reconstructive Surgery, Karolinska University Hospital, Stockholm, Sweden.

The purpose of this study is to report the effectiveness and safety of using titanium mesh combined with chitosan-heparin sponge and rhBMP-2(InductOs) for the reconstruction of large through-and-through cranial defects in humans. Previous to this, a study of boneformation in Sprague Dawley rats was performed that showed very good results with the above mentioned carrier system.

Methods: Three patients were operated on and subsequently followed up with CT scans, clinical examination and histological samples. The patients had frontotemporal or parietal defects ranging from 54 to 117 cm(2) resulting from postoperative infection and necrosis of the bone following removal of neoplasms, cerebral aneurysms or haemorrhage. The first patient had received radiation to the operating field. The patients were reconstructed with (1) titanium mesh, chitosan-heparin sponge on the dura mater with 4 mg rhBMP-2, chitosan-heparin sponge with 8 mg rhBMP-2 on the titanium mesh, (2) titanium mesh, chitosan-heparin sponge with 12 mg rhBMP-2 on the dura mater, (3) titanium mesh, chitosan-heparin sponge with 10 mg rhBMP-2 on the titanium mesh. All the patients were followed up by clinical examination and repeated CT scans for a minimum of 8 months. Histological samples were taken from two of the patients.

Results: All the patients had signs of postoperative infection and were given antibiotics. One patient experienced hair loss in the operating field two months postoperatively. The hair grew back uneventfully a month later. Two of the patients had exposure of the titanium mesh and were reoperated once and five times respectively. The latter patient required free flap surgery to get the wound to finally heal. CT scans showed calcification of the dura mater in the operating field, but no signs of boneformation in two of the patients. The third patient showed ongoing boneformation after eight months and CT scans are to be repeated thirteen months postoperatively.

The histological samples taken six and nine months postoperatively showed no sign of boneformation or angiogenesis.

Conclusions: Titanium mesh combined with chitosan-heparin sponge and rhBMP-2 (InductOs) appears to be a potential way to reconstruct significant craniofacial defects. The patients did have quite a lot of complications postoperatively, in particular the patient with the chitosan-heparin sponge and rhBMP-2 directly on the dura mater. The chitosan seems to cause an inflammatory response that impairs the healing of the wound. In one patient local hair loss was seen, most likely due to the effect of BMP-2. This study illustrates the difficulties of translating the results from studies on rodents to humans, and also the need for a more inert carrier system.

Acid Swelling Overcomes Osteogenesis Inhibition of Xenogeneic Collagenous Matrix Delivery System used for Naturally-Derived Bone Morphogenetic Protein Complex. B. Rothman*, E. Olivier*, N. Duneas*. ¹Altis Biologics (Pty) Ltd, Pretoria, South Africa, ²School of Pharmacy, Tshwane University of Technology, Pretoria, South Africa, ³Biomedical Sciences, Tshwane University of Technology, Pretoria, South Africa.

The bone morphogenetic proteins (BMPs) are pleiotropic morphogens belonging to the greater transforming growth factor-β (TGF-β) superfamily of growth factors responsible for embryonic patterning as well as post-natal tissue regeneration.

BMPs require a safe and effective delivery system to bring about osteogenesis in clinical settings. Native porcine bone matrix-derived insoluble collagenous bone matrix (ICBM) was treated with various protocols involving organic acid and proteases (pepsin) to determine whether the chemical swelling of the matrix and telopeptide reduction would reduce the inflammatory response in the xenogeneic host, which has been associated with inhibition of the biologic activity of BMPs.

Native and treated porcine ICBM samples were combined with various doses of naturally derived porcine BMP complex and implanted intra-muscularly and subcutaneously in rodents in order to study bone formation. Histological examination of tissue specimens retrieved 12 days post implantation showed that the degree of inflammation induced by native porcine ICBM is high, and bone induction was inhibited at high doses of up to 50mg porcine BMP complex per gram delivery system. In contrast, acetic acid treated porcine ICBM was found to be an effective delivery system for BMPs, dose dependently stimulating bone formation and alkaline phosphatase activity, a specific enzyme marker for bone formation, at dose ranges of between 0 to 12mg porcine BMP complex per gram delivery system.

Porcine ICBM that was treated successively with acetic acid followed by enzyme digestion using porcine gastric mucosa-derived pepsin showed only a slight improvement in bringing about osteoinduction (not significant p>0.05). A striking observation was that the inflammatory response to chemically and/or enzymatically treated ICBM was dose dependently reduced by increasing concentrations of porcine BMP complex. The data demonstrate that chemical swelling plays a major part in improving xenogeneic ICBM for use as a BMP delivery system. This work will assist in the development of xenogeneic derived collagenous matrices with improved host immuno-compatibility which may function as safe and effective delivery systems for BMPs to be used in the clinical repair and regeneration of bone defects in humans.

Xenogeneic Bone Morphogenetic Protein Complex Enhances Allogeneic Demineralised Bone Matrix Osteoinductivity in Rats. N. Duneas¹, B. Rothman², E. Olivier³, G. U. Mohangi⁴. ¹Biomedical Sciences, Tshwane University of Technology, Pretoria, South Africa, ²Altis Biologics, Pretoria, South Africa, ³School of Pharmacy, Tshwane University of Technology, Pretoria, South Africa, ⁴School of Dentistry, University of Pretoria, Pretoria, South Africa.

Demineralised Bone Matrix (DBM) is a widely used allograft material in a variety of clinical settings, including bone voids, as bulking agent for autogenous bone graft material, and orthopaedic and periodontal defects. DBM promotes osteogenesis due to its content of bone morphogenetic proteins (BMPs), a family of morphogens classified under the larger transforming growth factor- β superfamily of growth and differentiation factors. The BMPs induce and regulate bone formation during embryogenesis and in postnatal life during regeneration and healing of traumatic bone defects. We present data that show in animal models that allogeneic DBM can be fortified with xenogeneically sourced BMP complex to improve DBM performance. Rat DBM was fortified with BMP complex purified from porcine diaphyseal bone. BMP complex contains a number of BMPs, and is standardized with respect to hBMP-2 content determined by commercial ELISA kit. Implantation of 25 mg rat allogeneic DBM fortified with 0, 3, 6 and 12 mg BMP complex per gram of DBM resulted in dose dependant upregulation of bone formation on day 12 as scored histologically and against alkaline phosphatase activity, an enzyme marker specific for bone formation. The data may assist in developing tissue banked DBM that is fortified by the adsorption of xenogeneically sourced BMP complex, thereby improving the performance of human sourced DBM.

Oxidative Stress Suppresses Osteoblastogenesis by Antagonizing Wnt/ β -catenin and BMP Signaling. M. Almeida, E. Ambrogini, L. Han, M. Martin-Millan, V. Lowe*, A. Warren*, R. L. Jilka, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

Increased levels of reactive oxygen species (ROS) in aging female or male C57BL/6 mice are temporally associated with progressive loss of bone strength and mass, decreased osteoblast (Ob) number and bone formation rate and increased Ob and osteocyte apoptosis. Moreover Axin2 and OPG mRNA expression is decreased and GADD45 is increased in the bone of old as compared to young C57BL/6 female mice, consistent with compelling in vitro evidence that ROS attenuate Wnt/ β -catenin signaling by diverting β -catenin from TCF- to FOXO-mediated transcription. To test directly the hypothesis that increased oxidative stress decreases osteoblastogenesis, 5 month-old C57BL/6 mice were injected intraperitoneally twice daily (5 days a week) for a total of 6 weeks with 2 mM / Kg of L-buthionine-(S,R)-sulphoximine (BSO), a specific inhibitor of glutathione synthesis. Additionally, 20 mM of BSO was provided in their drinking water. At the end of the experiment, several markers of oxidative stress were determined along with osteoblastogenesis. ROS levels increased and glutathione reductase activity decreased in the bone marrow, while p66^{bc} phosphorylation increased in vertebral lysates, in mice treated with BSO as compared to saline treated controls. Moreover, BSO treatment promoted a decrease in osteoblastogenesis as measured by the number of colony forming units-osteoblasts in ex vivo bone marrow cultures. In addition, treatment of C2C12 cell with H₂O₂ for 24 h inhibited osteoblastogenesis induced by Wnt3a, as measured by alkaline phosphatase (AP) activity. Furthermore, overexpression of a plasmid encoding FOXO3a abrogated AP activity induced by Wnt3a. Conversely, silencing FOXOs using siRNA for FOXO 1, 3a, and 4, up-regulated the basal levels of AP activity. Activation of osteoblastogenesis induced by BMP-2 was also blocked by exposure of C2C12 cells to H₂O₂ for 24 h. This effect was associated with abrogation of BMP-2 induced Smad1/5/8 phosphorylation by H₂O₂ as determined by Western blotting. Taken together with evidence that the replication of mesenchymal stem cell progenitors of osteoblasts is decreased in old as compared to young mice, presented elsewhere in this meeting, these results strongly support the hypothesis that aging, and specifically oxidative stress, decreases osteoblastogenesis and thereby bone formation by antagonizing Wnt/ β -catenin and BMP-signaling.

Evaluation of Bone Phenotype in Mice Carrying Adenomatous Polyposis Coli (APC^{min}) Gene Mutation. Q. Su¹, S. Pun¹, B. Pennypacker¹, C. Winkelmann², O. A. Flores¹, H. Glantschnig¹, D. B. Kimmel¹, F. Chen¹.

¹Molecular Endocrinology, Merck Research Laboratories, West Point, PA, USA, ²Imaging, Merck Research Laboratories, West Point, PA, USA.

The identification of LRP5 mutations that are associated with high or low bone mass in humans has triggered great interest in studying Wnt signaling in bone formation. Current information clearly demonstrates that the canonical Wnt/ β -catenin pathway plays a crucial role in regulating bone mass. Reducing the inhibitory effects of Wnt-signaling antagonists

like Dkk1, SFRP1 or SOST which indirectly increase β -catenin in the nucleus has been shown to increase bone mineral density (BMD). LiCl inhibition of glycogen synthase kinase-3 β which stabilizes β -catenin was also reported to increase BMD in mice and humans by a mechanism that is likely independent of membrane Wnt signaling. Heterozygous mice with APC loss of function gene mutation (APC^{min/+}) also have high levels of nuclear β -catenin. In this study, we investigated the bone phenotype in APC^{min/+} mice by evaluating bone mass and genes related to bone function in comparison to wild type (wt) controls.

BMD of wt and APC^{min/+} mice femurs at 9 weeks and 16 weeks were measured using PIXIMUS. Tibia RNA samples from the above mice were analyzed for gene expression via Taqman.

At 9 weeks of age, no difference in BMD between wt and APC^{min/+} mice was detectable in the distal or central femur. However, at 16 weeks of age, BMD in the distal femur was significantly increased by 5% in APC^{min/+} mice vs. the wt controls (P-value of 0.0107). Gene expression studies of bone (tibia) samples from 9-week old mice showed that both Dkk1 and SOST expression levels were ~7 folds higher in APC^{min/+} mice compared to wt-control. This could indicate negative regulatory feedback mechanism to counter a constitutively active APC mutation. In addition, markers for osteoblast function COL1A1, ALP, OC and osteoclast function OPG, TRACP5, CatK were all ~2 - 4 folds increased in tibia of APC^{min/+} mice. This effect was transient as at 16 weeks of age differences in the above genes between wt and APC^{min/+} were insignificant, with the exception of SOST transcript levels which remained slightly elevated (~2 folds).

In conclusion, increased β -catenin activity derived from APC^{min} locus results in subtle but measurable change in BMD at discrete skeletal sites. Constitutive cytoplasmic Wnt pathway activation resulted in a transient increase in bone cell activities.

Is Erythropoietin a Regulator of Bone Density and Serum Calcium in Elderly Men? - Mr Os Sweden. M. Ethnérsson¹, U. Lerner², H. Nilsson-Ehle³, H. Wadenvik³, M. Lorentzon¹, M. Karlsson⁴, Ö. Ljunggren⁵, E. Orwall⁶, U. Smith³, C. Ohlsson¹, D. Mellström¹. ¹Center for Bone research at the Sahlgrenska Academy, Göteborg University, Göteborg, Sweden, ²Oral Cell Biology, Umeå University, Umeå, Sweden, ³Medicine, Göteborg University, Göteborg, Sweden, ⁴Orthopedics, Lund-Malmö University, Malmö, Sweden, ⁵Medical Sciences, Uppsala University, Uppsala, Sweden, ⁶Bone and mineral Unit, Oregon Health and Sciences University, Portland, OR, USA.

Erythropoietin (EPO) is the main regulator of the erythropoiesis. Erythrocytes and osteoclasts are derived from the same hematopoietic stem cell. With increasing age there is a decline in haemoglobin resulting in an increasing EPO. The aim of the present study is to investigate if erythropoietin, EPO, is related to bone density and serum calcium in elderly men in the Göteborg part of the Mr Os Sweden cohort (n=1010, age 69-80).

Haemoglobin (Hb), EVF and white blood cell count were analyzed in 1010 men between 69-80 years of age. Blood samples were drawn after 10 hours of fasting and non-smoking in the morning. Serum and plasma were placed in a 80°C freezer. Plasma erythropoietin was analyzed with an ELISA method Quantikine IVD, R & D system, Inc, Minneapolis in 980 men. Bone density was measured with a Hologic 4500A.

Mean plasma EPO was 11,51 (9,1) IU/L. We found that EPO inversely correlated to Hb r = -0,324 (p < 0,0001) and EPO increased with age, r = 0,11 p < 0,001. EPO directly correlated to all bone mineral density (BMD)-sites (p < 0,001) and to PTH r = 0,18 (p = 0,0001) and indirectly to serum calcium r = -0,13 (p < 0,001). EPO correlated indirectly to lung function (FEV1,0) and renal function (cystatin C) but also directly to inflammatory parameters IL-6 and CRP (p < 0,001) but not to vitamin D, phosphate or sex hormones.

Height, weight, age, Hb, kidney function, PTH, vitamin D, phosphate were included in regression models for bone mineral density (BMD). EPO was an independent predictor of Hip total BMD β = 0,123, p < 0,001, trochanter BMD β = 0,108, p < 0,001, femoral neck β = 0,143 p < 0,0001 and lumbar spine BMD β = 0,0701 p < 0,05.

A multiple regression model with EPO, PTH, age, phosphate, albumin and cystatin C showed that EPO was an independent predictor of serum calcium β = -0,08 p < 0,01. A multiple regression model with EPO, serum calcium, albumin, phosphate, age, cystatin C showed that EPO was an independent predictor of PTH β = 0,119 (p < 0,0001).

In conclusion we found an inverse correlation between EPO and Hb and EPO increases with age. EPO correlated directly to bone mineral density at all sites and to PTH and indirectly to serum calcium even after multiple regression models taking in consideration several possible covariates. These novel findings indicate that EPO might be involved in the regulation of BMD and calcium metabolism in elderly men.

Disclosures: M. Ethnérsson, None.

FGF2 and TGFβ1 Have Opposite Effects on the Mural Cell Phenotype of CD146⁺ BMSCs. A. Funari^{*1}, S. Michienzi^{*2}, B. Sacchetti^{*3}, S. Cersosimo^{*3}, M. Riminucci^{*1}, P. Bianco². ¹Experimental Medicine, University of L'Aquila, L'Aquila, Italy, ²Experimental Medicine and Pathology, University of La Sapienza, Rome, Italy, ³Fondazione Parco Biomedico S.Raffaele, Rome, Italy.

CD146⁺ Bone Marrow Stromal Cells (BMSC) include skeletal stem cells and are closely associated with sinusoids either in human bone marrow (hBM) and in heterotopic ossicles. Factors regulating proliferation and differentiation of CD146⁺ BMSC are unknown. In this work, we analyzed the effects of FGF2 and TGFβ1 on CD146⁺ BMSC morphology, proliferation and gene expression. Furthermore, we investigated the pattern of expression of FGF2 and TGFβ1 in the ossicle as compared to human bone. FGF2 stimulated BMSC proliferation and downregulated most mRNAs characteristic of mural cell phenotype, including: α-SMA; caldesmon 1; calponins; desmin; PDGF-R beta; basement membrane proteins such as SMOC1 and COL4A1. Of note, FGF2 treatment upregulated VEGF, that promotes cell migration and inhibits apoptosis and a group of sphingosine-1-phosphate receptors including EDG1 that is involved in endothelial cell differentiation and in the proliferative and migratory response of mural cells. All these genes were oppositely regulated by TGFβ1, which stabilizes mural cells and nascent vessels. In the hBM, FGF2 and TGFβ1 are produced by connective tissue cells, embedded in the matrix and either released upon matrix degradation, or activated by proteases (TGFβ1). To assess the expression of the two factors during ectopic osteogenesis, heterotopic ossicles were generated by BMSC transplantation in SCID mice and harvested at different time points. Immunohistochemistry was performed by using antibodies against FGF2, TGFβ1, activated TGFβ1 and human mitochondria antigen. As in the hBM in vivo, in the ossicle either FGF2 and TGFβ1 were expressed in mesenchymal and osteoblastic cells in the developing marrow space. High levels of immunoreactivity for TGFβ1 were also observed in marrow adipocytes which derive from adventitial reticular cells. Active TGFβ1 was not observed in the cell types immunoreactive for the latent form and was specifically detected in a peri-sinusoidal location and in the nascent bone. This result is consistent with its extracellular activation. In conclusion, we have shown that CD146⁺ BMSCs have a mural phenotype in vivo and in vitro and that is strengthened by TGFβ1 and downregulated by FGF2. Both factors are expressed in the ossicle with the same spatial layout observed in post-natal human trabecular bone. The activation of TGFβ1 is detected at the sites of pericyte-endothelial contact where active TGFβ1 induces the expression of SMC/pericyte markers by mesenchymal cells and inhibits proliferation of ECs.

Demonstration of an Anabolic Effect of Prostaglandin E₂ on Bone in CD-1 Mice. Q. Gao^{*}, M. Xu, P. Zhan^{*}, C. B. Alander^{*}, C. C. Pilbeam, L. G. Raisz. Endocrine Division and Musculoskeletal Institute, University of Connecticut Health Center, Farmington, CT, USA.

Previous studies have shown that treatment with prostaglandin E₂ (PGE₂) can lead to increased bone resorption and bone loss in C57BL/6 mice. However, dynamic histomorphometric analyses in these mice showed that osteoblast function was also stimulated, as indicated by increased mineral apposition rate (MAR) and bone formation rate (BFR/BS). To determine if there can be a true anabolic effect of PGE₂ on bone in mice with an appropriate dose and duration of treatment, 9 week old CD-1 male and female mice were injected intraperitoneally with vehicle or PGE₂ (3 mg/kg, 2 times a week for 4 weeks) and euthanized 5 days after the last injection. Body weight, serum calcium and total protein were not significantly changed between vehicle and treatment groups. By dynamic histomorphometric analysis of distal femurs, PGE₂ treatment in both gender groups showed an increase in MAR compared to vehicle treated animals (1.44 ± 0.01 vs. 1.03 ± 0.07 μ/d in males and 2.04 ± 0.04 vs. 1.31 ± 0.27 μ/d in females, n=5-6, p<0.05). BFR/BS was also increased in both males and females (0.52 ± 0.06 vs. 0.27 ± 0.05 μ³/μ²/d in males and 0.74 ± 0.05 vs. 0.38 ± 0.10 μ³/μ²/d in females, p<0.01). Double labeled surface was similar in vehicle treated males and females, and increased significantly from 13.7 % to 26.6 % with PGE₂ treatment. In contrast to previous experiments, there was no loss of trabecular bone volume (BV/TV) in males treated with PGE₂ and there was a trend for an increase in females (3.4 vs. 6.2 % p=0.06). Tibial mRNA was collected at the end of the experiment. Samples were reverse transcribed and RQ values for mRNA calculated by real time PCR. There was an increase in BMP-2 expression in the PGE₂ treated group compared to vehicle (1.45 ± 0.16 vs. 0.99 ± 0.12, p<0.05, n=11-12, pooled male and female data). RUNX-2 expression was also increased in the PGE₂ treated group (1.19 ± 0.11 vs. 0.91 ± 0.06, p<0.05). These results indicate that an anabolic response to PGE₂ treatment can be obtained in mice. This model can be used to study the effects of PGE₂ or selective agonists, as well as the effects of deletion of COX-2 or prostaglandin receptors, on the murine skeleton.

TNF-alpha/CCL3-5/CCR5 Cascade Mediates RANKL+ Cells Migration in Inflammatory Bone Resorption. G. P. Garlet^{*1}, C. R. B. Cardoso^{*2}, S. B. Ferreira^{*1}, C. E. P. Repeke^{*1}, M. J. Avila-Campos^{*3}, A. P. Campanelli^{*1}, J. S. Silva^{*4}. ¹Department of Biological Sciences, School of Dentistry of Bauru, São Paulo University -FOB/USP, Bauru - SP, Brazil, ²Department of Biochemistry and Immunology, School of Medicine of Ribeirão Preto, São Paulo University - FMRP/USP, Ribeirão Preto - SP, Brazil, ³Department of Biological Sciences, Institute of Biomedical Sciences - São Paulo University - ICB/USP, Bauru - SP, Brazil, ⁴Department of Biochemistry and Immunology, School of Medicine of Ribeirão Preto - FMRP/USP, Ribeirão Preto - SP, Brazil.

Inflammatory immune reactions in response to periodontopathogens are thought to protect the host against infection, but may trigger inflammatory bone resorption in periodontium, in a milieu characterized by high levels of the pro-inflammatory cytokine TNF-α and inflammatory cells expressing the osteoclastogenic factor RANKL. Thus, we examined the mechanisms by which TNF-α drives RANKL+ cells migration to bone resorption focus, and therefore modulates the outcome of A. actinomycetemcomitans-induced periodontal disease in WT and genetically modified C57BL/6 mice. Our results showed that TNF-αp55 deficiency results in significantly decreased levels of chemokines CCL3, 4 and 5, and RANKL (evaluated by ELISA), associated with a lower inflammatory infiltrate and less alveolar bone loss. Flow cytometry analysis demonstrate that majority (72%) of RANKL+ leukocytes in inflammatory infiltrate are T cells (CD3+), and that RANKL+ cells are also highly positive (61%) to CCR5, a receptor whose ligands include CCL3-5. Interestingly, CCL3-knockout mice presented a minor decrease in RANKL+CCR5+ cells and in bone loss. However, CCL3 knockout mice presented similar levels of CCL4-5 in the periodontal tissues than WT mice, suggesting a redundancy of these chemokines in determining CCR5+ cell migration. Conversely, the absence of CCR5 resulted in pronounced reduction in the number of leukocytes and RANKL+ cells, and decreased RANKL levels and bone loss, suggesting an important role for this chemokine receptor in the migration of RANKL+ leukocytes to inflammatory focus surrounding alveolar bone. Our results demonstrate a cytokine-chemokine(s)-chemokine receptor cascade involved in inflammatory bone resorption: TNF-α induces the expression of the chemokines CCR3-5, which mediates the chemoattraction of CCR5+RANKL+ cells to periodontal tissues, and consequently leads to bone resorption. Therefore, chemokines and their receptors are potential targets to therapeutic intervention in inflammatory bone diseases.

Relationship of Serum Cytokines and Monocyte Gene Expression to Bone Mineral Density and Content in Postmenopausal Women. E. R. Gertz^{*1}, N. Silverman^{*1}, C. P. Kirschke^{*2}, J. W. Stewart^{*3}, L. N. Hanson^{*3}, L. Huang^{*2}, D. L. Alekel³, M. D. Van Loan². ¹Dept Nutrition, UC Davis, Davis, CA, USA, ²USDA, ARS, WHNRC, Davis, CA, USA, ³Dept Food Science and Human Nutrition, ISU, Ames, IA, USA.

The dynamic balance of bone formation and resorption can be influenced by cytokine and gene interactions. The purposes of our study were to 1) examine the relationships among inflammatory markers, monocyte gene expression, and bone mineral density (BMD) and content (BMC) and 2) determine the contributions of inflammatory markers and gene expression to BMD and BMC in healthy postmenopausal women not taking hormones. Serum samples were obtained from a subsample of 81 women who were enrolled in a 3-yr clinical trial. BMD and BMC from the lumbar spine, total hip, and femoral neck were assessed by dual energy x-ray absorptiometry. Inflammatory markers were: cortisol, IL-1, IL-4, IL-6, IL-7, IL-8, INF-γ, G-CSF, GM-CSF, and TNF-α. Serum cytokines were measured by a cytokine multiplex immunoassay (LINCplex; Millipore). Quantitative PCR was performed on a PRISM ABI 7900HT Sequence Detection System using TaqMan Assay-on-Demand kits for IFN-β, c-Fos, and β-Actin (Applied Biosystems). Genes were quantitated by an absolute standard curve method and normalized to the expression of β-Actin. Cytokine and gene expression data were transformed for normality. We observed a negative association between femoral neck BMC with TNF-α (p<0.05) and a positive association with cortisol (p<0.05). Total hip and femoral neck BMDs were associated with c-Fos gene expression (p<0.05 and p<0.01, respectively). Gene expression of IFN-β was found to be significantly and negatively associated with femoral neck BMC (p<0.05). The contribution of inflammatory markers and gene expression to BMD and BMC was examined using stepwise multiple regression: Total hip BMC=16.294 + 0.446(weight) - 0.879(BMI) + 1.137(c-Fos) Total hip BMD=0.61 + 0.002(weight) + 0.021(c-Fos) Femoral neck BMC=4.075 + 0.013(weight) - 0.181(IFN-β) - 0.384(TNF-α) Femoral neck BMD=0.312 + 0.002(weight) + 0.027(c-Fos) + 0.006(Cortisol) + 0.007(IL-6) In conclusion, c-Fos, IFN-β, TNF-α, cortisol, and IL-6 were significant contributors to hip and femoral neck BMC and BMD and may be important factors in bone health for postmenopausal women. Supported by funds from NIAMS/NIH (AR046922) and USDA,ARS,WHNRC.

Epigenetic Mechanisms Are Involved in the Cytokine-induced de novo Expression of IL-1 beta in Human Articular Chondrocytes In Vitro. K. Hashimoto^{*1}, S. Kokubun^{*1}, E. Itoi¹, H. I. Roach². ¹Department of Orthopaedics, Tohoku University, Sendai, Japan, ²Bone & Joint Research Group, University of Southampton, Southampton, United Kingdom.

Inflammatory cytokines, such as IL-1 β , TNF- α and oncostatin M (OSM), induce abnormal expression of proteases in articular chondrocytes in vitro, analogous to the cytokine-induced abnormal expression in OA chondrocytes in vivo. Previous studies had shown that the latter was associated with loss of DNA methylation (Arthritis & Rheumatism 52:3110-3124) at specific CpG sites in the relevant promoters. DNA methylation at crucial CpG sites usually silences the gene and is replicated during cell division by the maintenance methyl transferase DNMT1. Since loss of methylation is a pre-requisite for gene induction, we hypothesized that the cytokines-induced IL-1 β expression also included DNA de-methylation. Human chondrocytes, isolated from the femoral articular cartilage of six non-OA patients, did not express proteases, IL-1 β or TNF- α , but did express collagen II, aggrecan and DNMT1. The cells from each patient were divided into 5 groups: non-culture; no additions (cultured control); + IL-1 β (10ng/ml); + 5-aza-deoxycytidine (5-aza-dC, 2 μ M); + TNF- α (10ng/ml) combined with OSM (10ng/ml). 5-aza-dC is a non-specific de-methylation agent, which was used for comparison with the effects of cytokines. After 4-5 weeks of culture, mRNA expression and the % of DNA methylation at -289bp were quantified, after initial studies had identified this CpG site to be of crucial importance.

Before culture, 60-66% of cells were methylated, i.e. only 40% of the cells could theoretically respond to inductive factors. However, complete absence of IL-1 β expression suggested that the right inductive factors were not present in these non-OA chondrocytes. Culture per se induced slight expression (set to 1) and some loss of methylation (30-40% still methylated). As expected, 5-aza-dC caused a further 20% loss of methylation, but this corresponded only to a 4-8 fold induction of expression. Remarkably, IL-1 β induced its own expression with a 15-190 fold increase and only 4-25% of cells remaining methylated. However, the greatest effect was seen with the combined TNF- α /OSM treatment, which increased IL-1 β expression 300-1700 fold and abolished methylation. Expression of DNMT1 was reduced considerably by culture alone, but further by cytokine treatment. This study is the first to correlate quantitatively mRNA expression and loss of DNA methylation. The results suggest that inflammatory cytokines are able to cause de-methylation, which leads to increased transcription. The challenge for the future will be to determine the mechanisms of the cytokine-induced loss of DNA methylation.

Identification of TNF- α Shedding Enzyme in Macrophages. A. Hikita¹, R. Suzuki^{*1}, S. Tohma^{*1}, S. Tanaka^{*1}, N. Fukui^{*1}. ¹Clinical Research Center, National Hospital Organization Sagami Hospital, Kanagawa, Japan, ²Orthopaedic surgery, The University of Tokyo, Tokyo, Japan.

Tumor necrosis factor- α (TNF- α) is a cytokine that plays pivotal roles in the pathologies of various inflammatory diseases such as rheumatoid arthritis and Crohn's disease. TNF- α is first synthesized as a membrane-bound protein, and converted into a soluble form by proteolytic cleavage. These two forms are shown to bind to two TNF receptors with different affinities to exert different biological activities. A disintegrin and metalloproteinase 17 (ADAM17), which is also known as TNF- α converting enzyme (TACE), is considered to be a primary sheddase for TNF- α . However, the significance of this enzyme in macrophages is not fully investigated while macrophages are the primary cells for TNF- α production in rheumatoid arthritis. Considering that the activity of TNF- α differs between the membrane-bound form and the soluble form, it is important to identify the sheddase(s) for TNF- α in macrophages.

In order to identify the sheddase(s), we developed an assay system using a plasmid containing cDNA for secreted placental alkaline phosphatase (SEAP) fused with the cDNA coding the stalk region of mouse TNF- α . The TNF- α -SEAP plasmid was transfected into HEK293 cells together with the expression vectors for various matrix metalloproteinases (MMPs) (MMP-1, 2, 3, 7, 9, 11, 13, 19, 23, 28, MT1, 2, 3, 4, 5, 6-MMP) and ADAMs (ADAM9, 10, 17, 19), and the TNF- α shedding activity of these proteinases was detected as alkaline phosphatase activity in the culture media. In this assay, ADAM9, 10, 17, MMP7, MT1, 2, and 3-MMP showed shedding activities for TNF- α . Among these proteinases, the expression of ADAM9, 10, 17 and MT1-MMP was detected at substantial levels in mouse macrophages by real-time PCR. Then the plasmids for these proteinases were transfected to 293 cells together with a full-length TNF- α expression vector, and the occurrence of shedding was evaluated by the appearance of soluble TNF- α in the culture media, which was detected by Western blotting. As predicted by the TNF- α -SEAP system, the occurrence of shedding was observed with all four proteinases with the full length TNF- α . Among these proteinases, suppression of ADAM10 by siRNA resulted in a significant reduction in the TNF- α shedding.

These results suggest that, besides ADAM17, ADAM10 also works as a dominant sheddase for TNF- α in macrophages. The results also suggest that other proteinases such as ADAM9 and MT1-MMP can be the sheddases for TNF- α , depending on the biological situations. It may be notable that several other proteinases can take the place of ADAM17 as a sheddase for TNF- α .

Lysophosphatidic Acid Promotes Maturation and Survival in Rat Growth Plate Chondrocytes. J. L. Hurst-Kennedy^{*1}, J. Greene^{*2}, Z. Schwartz², B. D. Boyan². ¹School of Biology, Georgia Institute of Technology, Atlanta, GA, USA, ²Department of Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA, USA.

The bioactive phospholipid metabolite lysophosphatidic acid (LPA) has been implicated in a number of cellular processes including wound healing, smooth muscle contraction, cell proliferation, survival, and migration. Recent studies have shown that LPA is a potent stimulator of osteoblast maturation as well. LPA is derived from phosphatidic acid (PA), which is produced by the action of phospholipase D (PLD). One physiological regulator of PLD in growth plate cartilage cells is the vitamin D metabolite 24,25-dihydroxyvitamin D3 [24R,25(OH)₂D₃]. When resting zone chondrocyte cultures are treated with 24R,25(OH)₂D₃, PLD activity is increased, resulting production of diacylglycerol (DAG), as well as increased PKC activity, increased cellular maturation and increased cell survival. DAG is a metabolite of LPA, suggesting that LPA acts as a second messenger during the promotion of chondrocyte differentiation and survival in growth plate cartilage cells. The purpose of this study was to determine if chondrocytes produce LPA and if so, whether LPA signaling mediates chondrocyte maturation and survival and the mechanisms involved. To investigate this, we used resting zone chondrocytes isolated from the rat costochondral cartilage growth plate as a model system. 24R,25(OH)₂D₃ treatment regulated LPA production in a dose-dependent manner. These cells were shown to express the LPA receptors LPA1, LPA3, LPA5, and peroxisome proliferator-activated receptor gamma (PPAR- γ). LPA treatment also promoted an increase in two markers of chondrocyte differentiation: alkaline phosphatase activity and proteoglycan sulfation. Furthermore, apoptosis induced by phosphate and the protein kinase C (PKC) inhibitor chelerythrine was attenuated by LPA. Western Blot analysis indicated that LPA decreased the abundance of the tumor-suppressor protein p53. LPA treatment regulated the expression of the p53-target genes Bcl-2 and Bax to enhance cell survival. Collectively, these data suggest that LPA signaling promotes cellular maturation and survival in resting zone chondrocytes demonstrating a novel function of LPA signaling in 24R,25(OH)₂D₃-mediated chondrogenesis.

Continuous Infusion of Insulin-like Growth Factor-I into the Epiphysis of the Tibia. A. Abbaspour, S. Takata, Y. Matsui, M. Takahashi^{*}, S. Katoh^{*}, N. Yasui^{*}. The Department Of Orthopedics, The University of Tokushima, Tokushima, Japan.

We have developed a method to promote longitudinal bone growth at the level of a specific growth-plate in young rabbits. Twenty-four male young rabbits weighing about 500 grams were divided into three groups, one-week treatment of IGF-I (n=5), two-week treatment of IGF-I (n=5), and four-week treatment of IGF-I (n=14). Insulin-like growth factor-I was continuously infused by means of an osmotic pump into the bone marrow cavity of the proximal epiphysis of the left tibia. In the epiphysis of right tibia, normal saline was infused continuously as a control. Longitudinal growth of the tibia was monitored by weekly-taken soft X-ray. After 4 weeks of treatment, the animals were sacrificed for histological examination and peripheral QCT (pQCT) analysis. Radiological measurement showed a 2-mm overgrowth of the tibia after 4 weeks of treatment, while histological analysis demonstrated a 15% increase in the thickness of the selected growth-plate. The local infusion of IGF-I increased the numbers of both proliferative and hypertrophic chondrocytes and promoted hyperplasia of bony trabeculae within the epiphysis. Bone mineral density (BMD) at the proximal metaphysis of the tibia was also significantly higher in both 2 weeks and 4 weeks treatment of IGF than in control sides. The distribution of material infused locally into the epiphysis was simulated by the infusion of Indian ink using the same methodology (osmotic pump) as that for IGF-I. Most of the dye remained within the bone marrow cavity of the epiphysis, but a portion infiltrated into the growth-plate, reaching the deep layer of the physal chondrocytes and primary spongiosa of the metaphysis. These results suggest that the method reported here is a valid one for delivering cytokines or growth factors to the selected growth-plate and for controlling the growth and differentiation of physal chondrocytes.

Disclosures: A. Abbaspour, None.

IGF-Binding Protein 3, 4 and 5 Triple Knock-out Mice Have Larger Bones. B. M. Boudignon^{*1}, M. Qin^{*2}, J. Pintar^{*2}, B. P. Halloran¹. ¹Endocrine unit, Veteran Affairs Medical Center San Francisco, San Francisco, CA, USA, ²Department of Neuroscience and Cell Biology, University of Medicine and Dentistry of New Jersey, Piscataway, NJ, USA.

IGF-I, the most abundant growth factor in the bone microenvironment, plays an important role in maintaining normal bone structure and mass. The activity of IGF-I is regulated by a family of IGF-binding proteins (IGF-BP 1-6). All 6 BPs have crucial roles in association with IGF-I and in some cases can modulate cell metabolism independent of IGF-I. Animals (C57BL6/129ReJ mixed background) harboring targeted defects in IGF-BP-3,4,5 have been developed and provide a unique opportunity to study the role of these BPs in metabolism and whole animal physiology (Ning et.al, Mol. Endo., 20:2173, 2005).

Triple KO animals are slightly smaller and have reductions in serum total and bioactive IGF-I of 55% and 63%, respectively. To study the role of BP-3,4,5 in bone we examined bone structure and density in wild type and triple KO mice using microCT analysis. Femurs from triple KO animals were longer, and tissue volume of the secondary spongiosa in the distal femoral metaphysis was increased by more than 30%. Fractional bone volume and segmented bone mineral density remained unchanged. Tissue, bone and marrow volumes of the femoral midshaft were all significantly increased by nearly 20% whereas bone fraction remained unchanged. Whereas the endocortical surface of the femoral diaphysis in wild type animals displayed a smooth curvature, the surface in the triple KO mice was irregular and wavy (see fig.) These results suggest that the combined global loss of BP-3,4,5 results in an increase in bone size (length, volume and diaphyseal diameter) but proportionately with normal bone volume despite low serum IGF-I and reduced body weight.

In Vivo Models To Study IGF-1 Receptor Dynamics Of Bone Stem Cells. B. C. Bragdon^{*1}, K. Young^{*1}, L. G. Horton^{*2}, R. Gundersen^{*1}, C. J. Rosen^{*2}, A. Nohe¹. ¹University of Maine, Orono, ME, USA, ²Jackson Laboratory, Bar Harbor, ME, USA.

Insulin-like Growth Factor- I (IGF-I) is a critical peptide in skeletal growth and consolidation. In detail IGF-I is key in the differentiation of bone marrow stromal cells (BMSCs) into osteoblasts. Current research indicates that localization of the IGF-I receptor in specific regions of the membrane does effect the specificity of signaling. However research is lacking the correlation between membrane domain dynamics, osteoblast differentiation and osteoporosis. Using the Family of Image Correlation Spectroscopy (FICS) we showed that membrane domain dynamics are altered in bone marrow stromal cells derived from mice exhibiting an age related osteoporotic phenotype, B6.C3H-6T (6T). 6T contains the wild type C57BL/6J (B6) background with an inversion of a segment of chromosome 6. This inversion includes Ppar gamma. Ppar gamma is a key mediator of adipogenesis. The mouse also has low serum IGF-I and reduced bone density which is characteristic of age related osteoporosis. Using FICS we observed an increase in cluster density (number of clusters per unit area) of both the membrane domains and IGF-I receptors, while the percent of co-localization was unchanged in the BMSCs. Our data indicated that the receptors as well as the membrane domains reshuffle on the membrane. This shuttling is crucial for their function. Especially caveolae flask-shaped invaginations of the plasma membrane are effected. Utilizing reporter gene assays with reporters for major down stream signaling pathways we showed significant differences in IGF-I signaling in 6T mice versus control. Further our data showed that cholesterol content and lipid composition are altered in 6T mice measured by HPLC and cholesterol assays. These results point to the importance of lipid balance and cholesterol in IGF-I signaling. Our data indicated that membrane, receptor dynamics are affected in mice exhibiting an osteoporotic phenotype.

Systemic IGF-I Shows Concerted Anabolic Actions on Bone and Muscle: Evidence from Male Mice with Liver-Specific Overexpression of IGF-I. F. Callewaert^{*1}, K. Venken^{*1}, J. Ophoff^{*1}, L. Liao^{*2}, S. Boonen¹, R. Bouillon¹, J. Xu^{*2}, D. Vanderschueren¹. ¹Katholieke Universiteit Leuven, Leuven, Belgium, ²Department of Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX, USA.

Serum IGF-I is principally derived from the liver and stimulates not only bone but also muscle during growth. We questioned to what extent overexpression of IGF-I by the liver affects bone and muscle mass and how the changes in bone and muscle are interrelated. To answer this question, transthyretin (TTR)-IGF-I transgenic mice and controls were evaluated longitudinally. Tibial bone mineral density and whole-body composition were assessed weekly by in vivo pQCT and DEXA, respectively, until 16 weeks of age. Transgenic mice showed 21% higher serum IGF-I during the entire experiment ($p < 0.01$). The increased serum IGF-I level was accompanied by enhanced lean body mass (+7% vs.

controls, $p < 0.01$) and muscle cross-sectional area (+10% vs. controls, $p < 0.01$). In addition, cortical bone mass (but not trabecular bone mass) and strength strain index were 7% and 12% greater in transgenic mice, respectively ($p < 0.01$). Regression analysis was performed to assess the impact of hepatic IGF-I overexpression on cortical bone mass and bone strength in relation to changes in muscle mass. Cortical bone mass and bone strength were very strongly related to changes in muscle cross-sectional area in both transgenic and control mice ($p=0.0001$), as represented by the figure, which shows the relationship between changes (Δ in figure, week16 - week4) in cortical content and muscle cross-sectional area. Moreover, regression analysis showed that the difference in cortical bone mass and bone strength between transgenic and control mice did not persist after correction for changes in muscle mass so that changes in bone and muscle mass during growth were proportionate in transgenic mice versus control mice. In conclusion, our data indicate that systemic IGF-I shows significant and concerted anabolic actions on both bone and muscle.

Local Application of GH and IGF-I Have a Similar Effect on Intramembranous Bone Healing in a Rat Femur Osteotomy Model - A Comparative Study. M. Huening¹, T. Lindner^{*1}, A. Flyvbjerg^{*2}, W. Weichert^{*3}, M. Raschke^{*1}, H. Bail^{*1}. ¹Dept. of Trauma and Orthopaedic Surgery, Charité, Berlin, Germany, ²Medical Department (Diabetes and Endocrinology), Kommunehospital, University Aarhus, Aarhus, Denmark, ³Dept. of Pathology, Charité, Berlin, Germany.

Previous studies showed that systemic application of growth hormone GH stimulates bone and fracture healing. According to the "somatomedin-hypothesis" liver-derived IGF-I exerts this effect as the main endocrine transmitter of GH on physiological bone formation whilst the "dual-effector-theory" hypothesizes an additional direct effect of GH on longitudinal bone growth. To test these theories we performed an in-vivo study to elucidate the local effects of GH and IGF-I on callus formation.

A monolateral external fixator was mounted to the left femurs of 72 adult SD-rats followed by a standardized osteotomy creating a 0.3 mm gap. Three groups were created that received either GH, IGF-I or vehicle via mini-osmotic pumps with a tube routed to the osteotomy.

group I: phosphate buffer

group II: 100 µg/kg bodyweight/day IGF-I

group III: 100 µg/kg bodyweight/day rh-GH

Femurs of each group (n=8) were harvested after 7, 14 and 21 days and processed for histological and histomorphometrical analysis. Sections were stained and evaluated with a semi-quantitative histological score regarding bone formation and gap bridging at all time-points. In addition histomorphometrical measurement were performed after 21 days with an image analysis system.

While no difference for bone formation and gap bridging between groups was detectable after 7 days, scores appeared to be higher for groups II and III after 14 and 21 days with a significant higher score for group II compared to group I after 21 days.

Histomorphometry displayed a significant increase of callus area and mineralized callus area in groups II and III compared to group I. The cartilage area and the cartilaginous share were nearly doubled in the vehicle group compared to groups II and III. The structure of the callus, represented by the callus bone density and the callus diameter were not different between the three groups after 21 days.

In conclusion our study demonstrates that both, local application of GH and IGF-I increase hard callus formation in the process of bone healing. Moreover both agents change the callus composition towards a lower share of cartilage. The results also strongly suggest that GH exerts a direct, non-liver mediated effect on bone healing which is comparable to the effect induced by IGF-I. Our findings clearly support the hypothesis that the "dual-effector-theory" is not only applicable for longitudinal bone growth but also for intramembranous bone healing.

Cortical Bone Is Positively Associated with Serum IGF-I and Testosterone and Negatively with Fibrinogen in Men and Women. K. L. L. Landin-Wilhelmsen¹, P. Trimpou^{*2}, S. Lindstrand^{*1}, A. G. Nilsson¹, A. Odén^{*2}, L. W. Wilhelmsen^{*2}. ¹Section for Endocrinology, Sahlgrenska University Hospital, Göteborg, Sweden, ²Sahlgrenska University Hospital, Institution of Medicine, Göteborg, Sweden.

Lower calcaneal ultrasound values predict fractures during follow-up. The purpose was to analyse factors of importance for the ultrasound variables in a random population sample of men and women aged 25-64 years, 54% women, from the 1995 World Health Organisation (WHO) MONItoring of trends and determinants in Cardiovascular disease (MONICA) study in Gothenburg, Sweden. The baseline examination in 1995 included history of fractures, physical activity at work and during leisure time, psychological stress, smoking habits, coffee consumption, BMI, blood pressure, total cholesterol, HDL-cholesterol, ApoA, ApoB, triglycerides, fibrinogen, CRP, IGF-I, IGFBP-1, IGFBP-3, osteocalcin, procollagen, estradiol, free estradiol, testosterone, free testosterone, PTH, procollagen, SHBG, and insulin. The calcaneal ultrasound (LUNAR Achilles) variables were: Stiffness, Speed Of Sound (SOS) and Broadband Ultrasound Attenuation (BUA). We have previously shown that leisure time physical activity was positively associated with calcaneal cortical bone. In the present analysis we analysed the additional influence of selected blood variables and hormones. The table shows number of individuals with results available (n), partial correlation coefficients [r] and p-values.

	Stiffness			SOS			BUA		
	n	r	p	n	r	p	n	r	p
Fibrinogen	546	-0.080	0.0618	543	-0.090	0.0360	542	-0.052	0.2269
IGF-I	348	0.170	0.0014	345	0.158	0.0032	344	0.131	0.0150
Testosterone	330	0.139	0.0114	327	0.162	0.0033	326	0.084	0.1302
Free testosterone	328	0.105	0.0575	325	0.128	0.0209	324	0.017	0.7607

All calcaneal ultrasound variables were associated with IGF-I, SOS and stiffness with testosterone, whereas SOS was negatively associated with fibrinogen. A more detailed analysis of relations to gender showed that testosterone was important for the ultrasound variables in both men and women.

In summary, out of a large series of hormones IGF-I and testosterone were positively associated with calcaneal cortical bone. Fibrinogen, indicating chronic inflammation, was negatively associated with cortical bone.

The Role of IGF-I and IGFBP-1 Status and Secondary Hyperparathyroidism in Relation to Osteoporosis in Elderly Swedish Women. H. S. Salminen¹, M. Sää^{*2}, H. Ringertz^{*3}, L. Strenger^{*1}. ¹Centre for Family and Community Medicine, Karolinska Institutet, Huddinge, Sweden, ²Department of Endocrinology, Metabolism and Diabetes, Karolinska Institutet, Stockholm Sweden, Sweden, ³Department of Surgical Sciences, Institution of Diagnostic Radiology, Karolinska Institutet, Stockholm, Sweden.

Our aim was to investigate among elderly women the relationship to osteoporosis of calcium-regulating hormones and anabolic growth factors. A population-based cross-sectional study of 350 elderly women (mean age 73 years). Measurements of bone mineral density (BMD) of the left hip, lumbar spine and heel and risk markers for osteoporosis were studied. The BMD values showed significant inverse relationship with the values of insulin-like growth factor binding protein (IGFBP-1) at all sites of measurement and significant positive relationship with the values of insulin-like growth factor-I (IGF-I) at all sites with the exception of the lumbar spine. There was no significant association between the values of BMD and the values of 25-hydroxy vitamin D (25(OH)D). The use of loop diuretics was strongly and significantly associated with elevated levels of PTH (OR 4.4, P<0.001). The anabolic growth factors IGF-I and IGFBP-1 showed a stronger association with the BMD values than the calcium regulating hormones 25(OH)D and PTH. In this study the use of loop diuretics was a more important cause of secondary hyperparathyroidism than vitamin D status.

Analysis of regression between BMD, vitamin D, PTH and IGF-I and IGFBP-1

Variable	IGF-I slope	p-value	IGFBP-1 slope	p-value
BMI (kg/cm2)	-0.0010	0.79	-0.0505	<0.0001
BMD(g/cm2)				
neck	0.0572	0.001	-0.0557	<0.0001
total hip	0.0706	0.001	-0.0804	<0.0001
lumbar spine	0.0538	0.057	-0.0687	<0.0001
heel	0.0269	0.010	-0.0350	<0.0001
25-OH vitamin D (nmol/L)	0.0534	0.28	0.0392	0.66
PTH (pg/ml)	-0.0532	0.23	0.0015	0.99

Opposing Effects of Growth Hormone and Alcohol on Bone Marrow Adiposity and Cancellous Bone Mass and Turnover Reveal a Critical Role for the Local Action of Growth Hormone in the Reciprocal Relationship between Adipocyte and Osteoblast Differentiation. R. T. Turner, P. J. Menaghy^{*}, G. Maddalozzo^{*}, U. T. Iwaniec. Nutrition and Exercise Sciences, Oregon State University, Corvallis, OR, USA.

Cancellous bone loss is accompanied by an increase in bone marrow adiposity. Adipocytes and osteoblasts are derived from a common progenitor cell, and adipocytes produce cytokines (e.g., IGF-I) and adipokines (e.g., leptin) which affect bone turnover. Thus, it is possible that the formation of fat and reduction in bone are regulated by a common factor. Excessive alcohol consumption is known to result in bone loss and marrow adiposity. We evaluated the effects of alcohol in a rat model in which the caloric intake of the animals fed the alcohol and control diets was the same. Alcohol consumption decreased % body fat and bone mass but increased bone marrow adiposity. Alcohol consumption reduced IGF-I mRNA levels in liver and bone, suggesting that growth hormone (GH) signaling may play a causal role in the observed reciprocal relationship between bone marrow adiposity and bone mass. We further investigated this relationship in hypophysectomized (HYPOX) rats. HYPOX of rapidly growing male rats reduced bone formation and led to cancellous osteopenia in tibiae. Despite a large reduction in body weight, there was a dramatic increase in bone marrow adiposity (from <1% to >50% marrow volume). Similar changes were observed in sexually mature male and female HYPOX rats. GH (0.8 mg/kg/d) normalized bone formation and bone mass, skeletal expression of IGF-I, and bone marrow adiposity in HYPOX rats. In contrast, administration of IGF-I (200 ug/kg/d) to HYPOX rats had no effect on either bone formation or adiposity, and administration of PTH (80 ug/kg/d) to HYPOX rats increased bone formation and increased the skeletal expression of IGF-I but had no effect on adiposity. To rule out estrogen deficiency as a contributing factor, we administered GH to: 1) HYPOX, 2) ovariectomized (OVX) + HYPOX and 3) estrogen-replaced OVX + HYPOX rats. In each case, GH was effective in reversing the effects of HYPOX on bone and adiposity. Taken together, these findings demonstrate that GH, a key hormone in the integration of energy production and expenditure, regulates the balance between bone and adiposity by enhancing bone formation and inhibiting adipocyte differentiation. Furthermore, the absence of a positive response to IGF-I treatment suggest that GH acts directly on osteoblasts and adipocytes.

Transforming Growth Factor β Stimulates New Bone Formation in Neonatal Mouse Calvariae via Suppression of Dickkopf-1. L. M. Bevelock^{*}, K. L. Clines^{*}, J. M. Chirgwin, T. A. Guise, G. A. Clines. Internal Medicine, University of Virginia, Charlottesville, VA, USA.

Wnt signaling is important in normal bone remodeling and the pathogenesis of bone metastases. The secreted Wnt inhibitor dickkopf-1 (DKK1) contributes to the dysregulation of bone formation in cancer metastases. Increased DKK1 in multiple myeloma is associated with osteolytic bone disease and suppressed bone formation, while tumor-produced endothelin-1 (ET-1) suppresses secretion of DKK1 from osteoblasts, contributing to the abnormal new bone formation associated with osteoblastic metastases. However, little is known about the local control of DKK1 expression. We hypothesized that the Dkk1 promoter in osteoblasts is regulated by TGF β , a factor abundant in the bone microenvironment.

We first examined regulation of Dkk1 transcription by TGF β . C3H10T1/2 pre-osteoblastic cells were transfected with a Dkk1 promoter/luciferase construct and treated with 5ng/ml TGF β , which decreased promoter activity threefold (p=0.04). TGF β significantly inhibited DKK1 protein secretion from neonatal mouse calvariae at 2d and 4d, as determined by ELISA. This was associated with an increase in new bone formation, osteoblast number and osteoblast nuclear phosphoSmad2 staining compared to control (p<0.001). Recombinant DKK1 protein (50 ng/ml) blocked TGF β -stimulated new bone formation (p<0.001). TGF β treatment of neonatal calvarial mouse osteoblasts increased β -catenin nuclear staining, indicating activation of canonical Wnt signaling.

TGF β can signal via Smad-dependent and -independent pathways. We mutated two putative Smad-binding elements (SBEs) within the Dkk1 promoter and transfected mutant and wild-type promoters into C3H10T1/2 cells. Mutation of the individual SBEs did not reverse TGF β repression of Dkk1 transcription, suggesting a possible Smad-independent mechanism.

Our data from cells and calvarial organ cultures contrast with previous studies in whole animals, where inhibition of TGF β signaling increases osteoblast activity and bone mass. In solid tumor metastases to bone, TGF β is released from the bone matrix by osteoclastic bone resorption, and promotes metastases by stimulating tumor cell production of pro-metastatic factors. The paradoxical stimulation of calvarial organ cultures suggests that effects of TGF β on bone are context-dependent. In calvariae ex vivo TGF β can stimulate bone formation by suppressing DKK1 and activating Wnt signaling through Smad-dependent and -independent mechanisms. Further studies are needed to elucidate the context-dependent effects of TGF β on osteoblast function and the role of DKK1.

NF- κ B-Regulated Gene Expression and Kinase Phosphorylation Oscillate Rapidly Over Time. J. Iqbal*, L. Sun, M. Zaidi. Mount Sinai Bone Program, Department of Medicine, Mount Sinai School of Medicine, New York, NY, USA.

For the first time, we show that the expression of any eukaryotic gene, in our case NF- κ B regulated genes, and kinase phosphorylation oscillate with time. The closest to this paradigm is gene expression phasicity noted over days, not over hours, as we describe. Our fundamental observation is that TNF α -induced mRNA expression is dynamic, undergoing rapid oscillations over hours. Expression of the "early genes" c-fos and IL-6 was enhanced transiently within 30 minutes of TNF- α application. Expression of "late genes", namely Mn-SOD and RANTES genes was oscillatory beginning 3 hours post-TNF α . A third group, "continual genes", namely IkB α , A-20 and MIP-2 α showed robust induction, but unlike c-fos and IL-6, continued to display oscillations over 8 hours. We also show that, whereas the early oscillatory profiles induced by TNF α and RANK-L can almost be superimposed, "continual genes" failed to oscillate after 4 hours of RANK-L. These results indicate that TNF superfamily members not only trigger a distinct pattern of oscillations for different gene groups, but that oscillatory behavior is ligand-specific. Second, we found that the phosphorylation of signalling molecules was dynamic, with parallel, but distinct, waves of activation. Intracellular phospho-flow cytometry showed that p65, JNK and p38 phosphorylation oscillated for up to 8 hours, while ERK1/2 displayed a single wave. The only period where all four molecules displayed an overlapping phosphorylation was during the first signaling wave. Furthermore, p38 and p65 phosphorylation were in unison. However, their oscillations were slower than JNK1/2 phosphorylation within the first 3 hours, but at 4 hours, the three became aligned. Finally, we showed that a super-repressor of IkB α altered the amplitude and frequency of kinase phosphorylation. The amplitude of JNK phosphorylation was increased and oscillation frequency altered. ERK1/2 phosphorylation was converted from a monophasic to oscillatory frequency in unison with JNK for the first 3 hours. ERK1/2 did not show any appreciable phosphorylation after 4 hours, while JNK1/2 phosphorylation continued to oscillate. These latter results suggest that NF- κ B negatively modulates both the amplitude and frequency of JNK and ERK1/2 phosphorylation. In conclusion, we show that TNF superfamily members induce robust ligand-specific oscillations in NF- κ B regulated genes and phosphorylation of downstream kinases. This constitutes a novel paradigm through which cells can use multiple signaling molecules to coordinate gene expression and so regulate time-resolved physiological processes, such as chemokine and cytokine secretion.

New Insights into the Determination of Smads Signaling by TGF β Superfamily. B. Kim*, J. Lee*, H. Park*, S. Lee*, M. Lee*, H. Koo*, W. Yoon*, J. Kim*, H. Ryoo*, J. Cho*. ¹Biochemistry, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea, ²Department of Cell and Developmental Biology, School of Dentistry, Seoul National University, Seoul, Republic of Korea.

A considerable number of studies have been done on TGF β superfamily / Smad pathway. But, the mechanisms how to specify Smads in response to TGF β and BMP stimuli is still unknown. In this study, we have used a combined method of the enrichment of phosphoproteins with proteomics strategy to discover those mechanisms. In early stage (at 30 min) after stimuli, we purified phosphoproteins from premyoblasts C2C12 cells using antibody-based phosphoaffinity column for the identification of the phosphoproteins regulated by BMP-2 or TGF β 1. We have identified about 1600 potential phosphoproteins using by GeLC-MS/MS. Interestingly, we detected that both Smad1 and Smad2 are temporally phosphorylated by opposite signals (that is, Smad2 by BMP-2, Smad1 by TGF β 1). This phosphorylation level, however, rapidly decreased (from 30 min to 1hr), and dramatically restored by proteasome inhibitor MG132 pretreatment. These data suggest that ubiquitination-proteasomal degradation system would play a key role in the early events of TGF β signal transduction. In the proteome data analysis, several ubiquitination / deubiquitination enzymes were identified. HECT-domain E3 ligases Nedd4 and Nedd4L, deubiquitin enzymes UCHL3/4 and USP4 respectively. Nedd4L was identified as a unique phospho-protein by BMP-2, but Nedd4 was detected commonly in both BMP-2 and TGF β 1 stimulation. The Smads ubiquitination by Nedd4 has not been elucidated yet. So, we hypothesized that temporally phosphorylated-Smads would be polyubiquitinated by Nedd4 family (that is, p-Smad1 by Nedd4, p-Smad2 by Nedd4L) in TGF β signaling pathway and degraded by proteasome. When coexpressed together with Nedd4, wild type Smad1 was polyubiquitinated and constitutive phospho-Smad1 mutant (DVD) is more polyubiquitinated than non-phospho Smad1 mutant (AVA). In addition, ALP (Alkaline phosphatase) staining confirmed that overexpressed Nedd4 suppress transdifferentiation of BMP-2 induced C2C12. Overall, our results suggested that TGF β 1 induced phospho-Smad1 was selectively ubiquitinated by Nedd4 and followed by proteasomal degradation. We argue that Nedd4 ubiquitin E3-ligase family would serve as 'modulators' of the TGF β activated Smad signaling pathway determination by ubiquitination-proteasomal degradation system.

NELL-1 Promotes Bone Formation in a Sheep Spinal Fusion Model. S. S. Lu*, J. Whang*, X. Zhang*, B. Wu*, S. Turner*, H. B. Seim*, K. Ting*, J. C. Wang*, C. Soo*. ¹School of Dentistry and Medicine, University of California-Los Angeles, Los Angeles, CA, USA, ²Veterinary Science, Colorado State University, Fort Collins, CO, USA.

NELL-1 is a Runx2 regulated secretory protein with marked osteochondrogenic cell specificity. NELL-1 exhibited comparable osteoinductivity to bone morphogenetic protein 2 (BMP-2) in a rodent calvarial defect model when placed on poly(lactic-co-glycolic acid) scaffolds. The purpose of this study was to test NELL-1 the osteoinductivity in a sheep interbody fusion model and to establish preliminary dose ranges. Eight sheep divided into four groups underwent interbody fusion at L4-L5 and at L5-L6 with a radiolucent vertebral spacer (2 animals/group; 4 sites/group). The control group was filled with sheep demineralized bone matrix (DBX) and saline within and around each vertebral spacer. The other three groups received sheep DBX mixed with NELL-1 at final concentrations of 0.3, 0.6, and 1.5 mg/ml within and around the vertebral spacers. To assess spine fusion, X-rays (0, 2, and 3 months), CT images (2 and 3 months), and microCTs (explanted 3 month specimens) were obtained. Spinal fusion criteria were either > 50% contiguous bone volume within the spacer or contiguous bone formation within the callus totaling > 1/3 anterior vertebral body circumference. All animals were sacrificed at 3 months after surgery. The results showed significantly increased bone formation in NELL-1 treated animals relative to controls. CT images at three months demonstrated successful spinal fusion in 100% of the 0.6mg/ml NELL-1 dose sites and none of the controls. Representative post-sacrifice microCT images of L5-6 from two controls (right) and two NELL-1 animals (left) also confirmed this finding (Figure 1). MicroCT analysis of central bone within the spacers revealed increased bone density and bone volume in NELL-1 specimens relative to controls. We conclude that all three NELL-1 doses induced significantly more bone formation than controls. 0.6mg/ml NELL-1 appears to induce the most robust bone, and this initial finding will be investigated in a larger follow-on study. Overall, NELL-1/DBX at the 3 month time point may induce comparable sheep interbody fusion to published BMP-2 studies carried out to the 6 month time point.

TGF-beta Suppresses POEM Expression in Osteoblasts. A. Miyazono^{*1}, A. Yamada^{*1}, N. Morimura^{*2}, D. Suzuki^{*1}, M. Kobayashi^{*3}, M. Takami¹, K. Tezuka⁴, M. Yamamoto³, R. Kamijo¹. ¹Department of Biochemistry, Showa University, Tokyo, Japan, ²Laboratory for Comparative Neurogenesis, RIKEN Brain Science Institute, Saitama, Japan, ³Department of Periodontology, Showa University, Tokyo, Japan, ⁴Graduate School of Medicine, Gifu University, Gifu, Japan.

POEM (preosteoblast epidermal growth factor-like repeat protein with MAM domain), also known as nephronectin, is an extracellular matrix protein that is thought to play a critical role in the development and functions of various tissues, such as those of the kidney, bone, muscle, and endocrine organs, through interaction with other extracellular molecules. In the present study, we found that transforming growth factor-beta (TGF-beta) dose-dependently and strongly inhibited POEM expression in mouse osteoblastic cell lines, MC3T3-E1 and UAMS-32. Inhibition of POEM expression by TGF-beta could be seen at concentrations exceeding 10 pg/ml. The time-dependent effects of TGF-beta on the reduction of POEM expression were further examined using 1 ng/ml of TGF-beta. A decrease in POEM mRNA was detected at 3 hours after the addition of TGF-beta and the decrease continued up to 24 hours, demonstrating that the TGF-beta induced decrease of POEM gene expression occurs in both time- and dose-dependent manners. When the cells were pretreated with a selective inhibitor of ALK5 (TGF-beta R1, a TGF-beta type 1 receptor) prior to the addition of 1 ng/ml of TGF-beta, down-regulation of POEM expression was completely blocked. These results suggest that regulation of POEM expression by TGF-beta occurs via TGF-beta R1. Further, bone morphogenetic protein-2 (BMP-2) slightly blocked the effect of TGF-beta toward the reduction of POEM expression. TGF-beta is a key regulator of bone matrix properties and composition, and it inhibits the expression of RUNX2 which is a critical transcriptional regulator of osteoblast differentiation in MC3T3-E1. Therefore to elucidate the relationship between the inhibition of osteoblast differentiation and reduction of POEM expression by TGF-beta, effect of TGF-beta on the expressions of alkaline phosphatase (ALP), osteocalcin, and bone sialoprotein (BSP) were examined. Each of those genes was down-regulated by TGF-beta in a manner consistent with that of POEM mRNA. These results indicate that POEM is a novel marker gene for osteoblast differentiation similar to others, such as ALP, osteocalcin, and BSP. In addition, reduced POEM expression may contribute to the inhibition of osteoblast differentiation by TGF-beta.

A Novel Activin/Nodal-binding Protein, G11, Inhibits Matrix Mineralization in Osteoblasts. Y. Mochida, D. Parisuthiman^{*}, M. Katafuchi^{*}, P. Atsawasuwan^{*}, M. Kaku^{*}, M. Yamauchi. Dental Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA.

Transforming growth factor-beta (TGF-β) superfamily consists of three major sub-families including TGF-β, bone morphogenetic protein (BMP) and activin/nodal, and they are known to be potent effectors in almost all crucial biological/developmental/regenerative events. Currently, however, the presence of activin/nodal and, if present, their roles in osteoblasts are largely unknown. In an effort to identify TGF-β superfamily binding proteins, we have taken a bioinformatics approach and just identified a novel gene, G11. The gene structure of G11 is related to chordin family. To investigate the potential function of G11 in osteoblasts, first, its expression pattern during cell differentiation and matrix mineralization was analyzed by quantitative real time PCR. Second, MC derived clones overexpressing G11 (S clones) were established and characterized by analyzing cell proliferation and in vitro mineralization. The phenotypes of S clones were evaluated by comparing to those of two control groups, i.e. MC and a clone transfected with an empty vector (EV clone). The data demonstrated that G11 was highly expressed in the early differentiation stage, i.e. at day 7 in mineralization medium, and decreased thereafter. The cell proliferation rate in S clones was not affected. However, in vitro mineralization in S clones was significantly delayed in comparison to those of controls. In order to gain mechanistic insights into an inhibitory function of G11, the interaction between G11 and TGF-β superfamily members (TGF-β1, -β2, -β3, BMP-2, -4, -6, -7, inhibin-ba, -bb and nodal; all were expressed in MC) was examined by immunoprecipitation-Western blotting. The data demonstrated that G11 was strongly bound to activin/nodal, and furthermore, G11 enhanced activin/nodal-induced Smad2 phosphorylation in MC cells. These results indicate that G11 is a novel chordin-like extracellular protein expressed in osteoblasts, and that it inhibits in vitro matrix mineralization possibly through its early interaction with activin/nodal.

Collagen Binding Characteristics of Collagen Binding Domain from Clostridium Histolyticum Class I Collagenase. J. Sakon^{*1}, P. S. T. Leena^{*1}, O. Matsushita^{*2}. ¹Biochemistry, University of Arkansas, Fayetteville, AR, USA, ²Molecular Biology, Kitasato University School of Medicine, Kanagawa, Japan.

Weekly intraperitoneal injection of a fusion protein of PTH(1-33) with CBD for 8 weeks in mice showed 15% BMD increase. Clostridium histolyticum ColG collagenase activated by Ca²⁺ is responsible for extensive tissue destruction, and the CBD is a segment of the multi-domain enzyme. Binding of two Ca²⁺ on CBD is co-operative and is both enthalpically and entropically driven ($K_{d1} = 2.13 \mu\text{M}$; $K_{d2} = 4.63 \mu\text{M}$). Structures in the presence and absence of Ca²⁺ have been solved at ultrahigh resolution (<1.2 Å). N-terminus 14 residues of CBD adopt an alpha-helical conformation; however, an addition of Ca²⁺ unwinds the linker into a new beta-strand. To rule out the crystal-packing artifact, NMR titration studies were done and they confirm the conformational changes upon addition of Ca²⁺. The changes in Stokes and hydrodynamic radii as measured by size exclusion chromatography and dynamic light scattering experiments showed drastic transition upon Ca²⁺ addition. With Ca²⁺ CBD becomes thermally stable ($T_m > 90^\circ\text{C}$), less susceptible to proteolysis and stable against chemical denaturants. Collagen binding affinity of CBD was detected only in the presence of Ca²⁺. Mutagenesis experiments identified a cluster of Tyr residues involved in collagen binding. The Tyr-rich surface becomes accessible upon Ca²⁺ binding. Co-crystallization of collagen:CBD have yielded no crystals thus far. Docking experiment of CBD with collagen-like peptide G(POG)₆ resulted in 3 different binding orientations. NMR titration of CBD against G(POG)₁₀ eliminated one of the probable in silico orientations. N¹⁵ enriched CBD and unlabeled (POG)₁₀ were used for the titration experiment. Studies thus far demonstrate the drastic structural changes accompanied upon secretion of the enzyme from a bacteria to infected tissues. They also provide atomic insights into how CBD interacts with extracellular collagen.

Smad4 Has a Direct Apoptogenic Role at the Mitochondria. H. Yuan^{*1}, T. Qiu¹, J. Huang^{*2}, X. Cao¹, M. Wan¹. ¹Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, ²Shihezi University School of Medicine, Shihezi, China.

Smad4, originally isolated from the human chromosome 18q21, is a key factor in transducing the signals of the TGF-β superfamily of growth hormones, which is an important player in regulating bone homeostasis and cancer cell growth and apoptosis. Smad4 plays a pivotal role in mediating antimitogenic and proapoptotic effects of TGF-β, but the mechanisms by which Smad4 induces apoptosis are elusive. Here we report that Smad4 directly translocates to the mitochondria of apoptotic tumor cells.

Smad4 overexpression significantly promotes, whereas Smad4 gene silencing by siRNA inhibits, TGF-β- and UV-induced apoptosis in two pancreatic cancer cell lines. To further clarify the mechanism by which Smad4 induces apoptosis, we found that a fraction of Smad4 translocates to mitochondria upon TGF-β treatment or UV exposure by Western blot analysis of cytosol and mitochondrial Smad4 protein. Smad4 mitochondria translocation was also confirmed by Smad4 colocalization with Mitotracker Red observed by confocal fluorescence microscope.

To examine the functional significance of mitochondrial Smad4 localization in apoptosis, we searched for mitochondria proteins that have physical interactions with Smad4 using yeast two-hybrid screening approach. DNA sequence analysis identified 34 positive clones, five of which encoded subunits in mitochondria complex IV, i.e. one clone encoded cytochrome c oxidase (COX)II, three clones encoded COXIII and one clone encoded COXVb. The data indicate that Smad4 might associate with mitochondria proteins and may have mitochondria-related function. Strong interaction between Smad4 with COXII was verified in yeast by β-gal activity assays and in mammalian cells by immunoprecipitation assays. Importantly, we isolated the mitochondrial portion and confirm the interaction between COXII and Smad4 in mitochondria upon TGF-β treatment or UV exposure. COXII is encoded by mitochondrial DNA, synthesized in the mitochondria, and inserted into the inner membrane by mitochondrion-dependent

pathways. COXII also has been shown to bind directly to cytochrome c and is speculated to regulate apoptosis through this affinity for cytochrome c. The association of Smad4 with COXII in mitochondria demonstrated in the present study implies that Smad4 may regulate cell apoptosis by directly targeting mitochondria.

Arkadia, an E3 ubiquitin Ligase, Represses Skeletal Muscle Differentiation Through Enhancement of Myostatin and TGF-beta Signaling. H. Yuzawa^{*1}, D. Koinuma^{*1}, S. Maeda¹, M. Takahata^{*1}, M. Hayashi^{*1}, K. Miyazawa^{*2}, K. Yamamoto^{*3}, T. Imamura¹. ¹Department of Biochemistry, The Cancer Institute of the Japanese Foundation For Cancer Research, Tokyo, Japan, ²Department of Molecular Pathology, Graduate School of Medicine, University of Tokyo, Tokyo, Japan, ³Department of Orthopaedic Surgery, Tokyo Medical University, Tokyo, Japan.

Myostatin belongs to transforming growth factor (TGF)-beta family, and act as a negative regulator of skeletal muscle differentiation. Myostatin knockout mice cause dramatic and wide spread increase in skeletal muscle, and naturally occurring myostatin mutations in cattle breeds lead to a heavy muscle condition due to hyperplasia and hypertrophy. Regulation of Myostatin signaling is thus a matter of physiological and pathological importance. However, how positive and negative regulators affect myostatin signaling is still not fully understood. Here we investigated the function of Arkadia in Myostatin signaling during myoblast differentiation. Arkadia was originally identified as an intracellular protein that is essential for formation of a mammalian node during mouse development through enhancement of Nodal signaling. In addition, we have previously reported that Arkadia is an E3 ubiquitin ligase that degrades an inhibitory Smad, Smad7, to enhance TGF-beta family signaling. In the present study, we first showed that mouse myoblast C2C12 cells express increased level of Myostatin and TGF-beta3 during myoblast differentiation. Adenoviral-mediated expression of Arkadia effectively enhanced suppression of myoblast differentiation by Myostatin and TGF-beta3, as determined by myotube formation and target gene expression, including myosin heavy chain. We further examined the role of endogenous Arkadia by lentiviral shRNA knockdown system, and showed that loss of endogenous Arkadia enhances myotube formation. Moreover, protein level of endogenous Smad7 was elevated by knockdown of Arkadia suggesting that Arkadia represses skeletal muscle differentiation through modulation of negative feedback mechanisms. In conclusion, we propose a physiological role of Arkadia as an important negative regulator of myoblast differentiation through enhancement of TGF-beta family signaling. Investigation of expression and activity of Arkadia is thus required in the future.

The Duodenum Rapidly Senses and Modulates Renal Phosphate Reabsorption Via Novel PTH- and Phosphatonin-Independent Pathways. T. Berndt^{*}, L. Thomas^{*}, T. Craig^{*}, S. Sommer^{*}, X. Li^{*}, E. Bergstralh^{*}, R. Kumar. Nephrology Research, Mayo Clinic Rochester, Rochester, MN, USA.

The mechanism by which phosphorus homeostasis is preserved during alterations in dietary phosphate intake is not completely understood. Net phosphorus balance in mammals is maintained by the absorption of phosphate in the duodenum and jejunum and by the tubular reabsorption of phosphate by the kidney. We have previously demonstrated that renal phosphate reabsorption is altered by the infusion of phosphate into the duodenum by PTH- and phosphatonin-independent pathways. In order to localize the segments of the gastrointestinal tract responsible for this response, we infused phosphate either into the duodenum or the stomach of anesthetized rats previously fed a normal phosphate diet and measured renal phosphate reabsorption following the infusion. After a control clearance, sodium phosphate was administered into the duodenum (n=7) or the stomach (n=6). Five, ten, twenty, and thirty minutes following the infusion of sodium phosphate, renal phosphate reabsorption was measured. The administration of phosphate into the duodenum resulted in rapid and significant increases in the fractional excretion of phosphate (FEP) at 10, 20, and 30 minutes. Basal FEP (mean±SD) was 28.4±8.6%, 5 min = 28.7±7.9%, 10 min = 31.9±7.6%, 20 min = 41.8±9.9%, 30 min = 44.0±11.4%, resulting in a slope/min of 0.6±0.3, P=0.0037. The administration of sodium chloride did not alter the fraction excretion of phosphate in similarly prepared rats (FEP 23.7±7.2%, 20.2±4.0%, 21.6±6.9%, 24.5±8.5% and 24.6±5.4%, resulting in a slope/min of 0.096±0.09, P=0.066). This effect is independent of PTH and the phosphatonins, FGF-23 and sFRP-4. When sodium phosphate was infused into the stomach, no change in the fraction excretion of phosphate was observed (FEP was 26.3±6.6%, 25.9±8.0%, 27.4±7.8%, 27.8±6.6%, 29.0±5.8%, resulting in a slope/min of 0.083±0.28, P=0.46). Our results show that a phosphate sensing mechanism exists in the duodenum but not in the stomach that rapidly decreases renal phosphate reabsorption following the ingestion of a high phosphate meal.

Transgenic Mice Overexpressing sFRP-4 Have Low Bone Mass but Do Not Exhibit Disturbed Phosphate Homeostasis. H. Y. Cho^{*}, H. J. Sun^{*}, J. Y. Yang^{*}, H. J. Choi^{*}, J. H. Ahn^{*}, S. W. Cho, S. W. Kim, S. Y. Kim^{*}, C. S. Shin. Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.

Secreted frizzled-related protein-4 (sFRP-4) is a member of secreted modulators of wnt signaling pathways that regulate biological processes ranging from developmental cell fate, cell polarity and tumorigenesis. Moreover, sFRP-4 has recently been recognized to play important roles in the pathogenesis of oncogenic osteomalacia as a potential phosphatonin. To investigate the role of sFRP-4 in bone metabolism in postnatal life, we have generated transgenic mice that overexpress sFRP-4 under the control of the serum amyloid P (SAP) promoter, which drives transgene expression postnatally. Transgene expression was identified in various tissues including serum, bone, liver and kidney in transgenic mice. At 10 week of age, the serum phosphorus concentration and urinary phosphorus excretion in transgenic mice were not significantly different from those of wild-type mice in both female and male. However, transgenic female mice exhibited decreased bone mineral density (0.045 ± 0.001 , $P < 0.05$) and bone mineral content (0.407 ± 0.026 , $p < 0.05$) compared to wild type female mice. Body fat contents were not different between wild-type and transgenic mice. On histological examination, transgenic mice showed decreased osteoid mass, thickness, decreased growth plate width and prolonged reversal phase. Histomorphometric analysis revealed that transgenic mice had decreased osteoid volume ($P < 0.05$), osteoid thickness ($P < 0.05$), and mineralization lag time ($P < 0.05$) compared to wild type mice. There was no difference in bone resorption parameters. Whereas difference in the mRNA expression of Na/P cotransporters, Npt2a and Npt2c, were not apparent, the 1- α -hydroxylase expression was increased in transgenic mice. Our data do not support the role of sFRP-4 as a phosphatonin but suggest a direct effects of sFRP-4 on new bone formation without disrupting phosphate homeostasis.

Evaluation of FGF 23 (c-terminal and intact) ELISA Kits in End-stage Renal Disease Patients. W. J. Fassbender¹, M. Hanfland-Schmidt^{*1}, J. Windolf^{*2}, U. C. Stumpf². ¹Department of Internal Medicine, Hospital z. HI. Geist, Kempen, Germany, ²Department of Traumatology and Handsurgery, University Hospital, Duesseldorf, Germany.

Hyperphosphataemia, calcitriol deficiency and secondary hyperparathyroidism (sHPT) are common complications in end-stage chronic kidney disease (CKD). Fibroblast Growth Factor 23 (FGF-23) is a phosphaturic peptide that also inhibits renal 1 α -hydroxylase activity and tubular phosphate reabsorption by inhibition of sodium-dependant renal phosphate transport. Consequences are the decrease of serum 1,25 dihydroxyvitamin D3 and phosphaturia. Therefore FGF 23 plays a role in hyperphosphataemia associated with CKD and may be involved in the pathogenesis of sHPT. Increased FGF 23 may contribute to maintaining normal serum phosphate levels in the face of advancing CKD, but up to a reduction of a creatinine clearance lower than 30 ml/min the capacity of this regulative mechanism ends and hyperphosphataemia results. Within end-stage renal disease we find markedly increased serum FGF 23 associated with hyperphosphataemia, phosphaturia and decreased serum calcitriol and sHPT.

Material and methods: We evaluated the actual in Europe available ELISA kits for FGF 23 (c-terminal and intact, "Human Intact FGF 23 ELISA Kit" and "Human FGF 23 (C-Term) ELISA Kit", Immutopics) for assessment of serum and EDTA-plasma in patients requiring dialysis, as expected with high serum FGF 23 levels compared with values derived from a normal collective of healthy persons with normal renal function. Furthermore preanalytical testing for stability of FGF 23 was performed by comparing samples which were stored at -20° C with samples stored for 6 days at -4° C.

Dialysis patients: 23 patients, 17 male, 6 female, age: 36 - 79 years (mean age: 62,13). Collective of healthy subjects: 17 subjects, 8 male, 9 female, age: 24 - 56 years, (mean age: 33,41).

Results: Dialysis patients: mean values serum FGF 23 15,32 pg/ml (intact) and 2774 U/ml (c-terminal, arithmetic mean). Mean values in EDTA-plasma FGF 23 (intact) 271 pg/ml; FGF 23 (c-terminal) 2606 U/ml; collective of healthy subjects: mean serum values FGF 23 0,64 pg/ml (intact) and 13,67 U/ml (c-terminal, arithmetic mean). Mean values of EDTA-plasma FGF 23 (intact) 13,09 pg/ml; FGF 23 (c-terminal) 19,18 U/ml.

Discussion: The parallel investigation of serum and EDTA-plasma FGF 23 certifies the advantage of EDTA-plasma in subjects with intact renal function. The significantly increased levels of FGF 23 in patients requiring dialysis demand dilution of the samples. Further investigations concerning age-related changes of serum FGF 23 should be performed. The feed-back mechanism of FGF 23 and serum 1,25 dihydroxyvitamin D3 implements possible future therapeutical options within the treatment of sHPT.

Venous Sampling for FGF23 as a Tool for Pre-Operative Localization of Tumors Giving Rise to Hypophosphatemic Osteomalacia. E. Hagström^{*1}, P. A. Westerberg^{*2}, G. Toss^{*3}, T. Lindhe^{*2}, Ö. Ljunggren², T. E. Larsson². ¹Dept. of Surgical Sciences, Uppsala University Hospital, Sweden, ²Dept. of Medical Sciences, Uppsala University Hospital, Sweden, ³Dept. of Medicine, Linköping, Sweden.

Tumor-induced hypophosphatemic osteomalacia (TIO) is a rare paraneoplastic syndrome, characterized by hypophosphatemia, low or inappropriately normal 1,25(OH)2D3 and rickets/osteomalacia. Increased serum level of Fibroblast Growth Factor-23 (FGF23) has been identified as the causative factor for TIO. In this study, we report on the diagnostic difficulties and tumor localization in a 55-year old male with presumable TIO.

Primary imaging studies, including CT/MRI scans and octreotide scintigraphy, failed to localize the tumor, however consistently elevated FGF23 levels were found (180-220 pg/mL). Venous sampling, followed by intact FGF23 analysis, revealed locally increased FGF23 level in the left femoral vein (343 pg/mL). Octreotide scintigraphy of the upper left leg revealed a 20 mm large tumor located at the left lateral condyle of the femur. Surgical resection of the tumor normalized serum phosphate and vitamin D within 5-10 days, however serum FGF23 declined from 292 to 12 pg/mL 24 hours after surgery. Pre-operative bone mineral density (BMD), as determined by DXA analysis, revealed a T-score of -1.6 in lumbar spine and -1.16 in total hip. Lumbar spine BMD was increased by 25% two months after tumor resection. Notably, our patient post-operatively developed a secondary hyperparathyroidism, which may reflect a transient hypocalcemia related to increased bone mineralization. In conclusion, our study demonstrates the diagnostic complexity and difficulties in localizing small TIO tumors. Venous sampling for FGF23 followed by octreotide scintigraphy may constitute a powerful tool for tumor localization in subjects with hypophosphatemic osteomalacia.

Rise in FGF-23 Precedes 1-84PTH and Linear Decline in Calcitriol Precedes Rise in FGF-23 in Non-diabetic Predialysis Patients. T. Hamano^{*}, K. Tomida^{*}, S. Mikami^{*}, N. Fujii^{*}, T. Ito^{*}, E. Imai^{*}. Nephrology, Osaka University Hospital, Suita, Japan.

Today fibroblast growth factor-23 (FGF-23) was found to be another phosphaturic hormone derived from osteocyte and osteoblast. The reduction in calcitriol synthesis by phosphate load can be explained by the increase in FGF-23. Although many study measured FGF-23 using a two-site ELISA that detects carboxyl-terminal portion of FGF-23, full-length FGF-23 (intact FGF-23) at different glomerular filtration rate (GFR) is not well documented in large cohort. Our aim is to know at what level of GFR intact FGF-23 and 1-84PTH increase and serum calcitriol decrease significantly. In this cross-sectional observational study (OVIDS-CKD; Osaka Vitamin D Study in patients with CKD), we enrolled non-diabetic patients in outpatients nephrology clinic at two major hospitals in Osaka. Patients who were or had been receiving glucocorticoid, bisphosphonate, vitamin D, calcium, or hormone replacement therapy were excluded. We measured serum phosphorus, calcium, albumin, intact FGF-23, whole PTH, calcitriol, and 25-hydroxyvitamin D (25OHD). We check the relationship of fold increase of two phosphaturic hormones and change in other parameters with estimated GFR (eGFR). Patients were divided into 9 groups by eGFR.

In this study 574 patients were enrolled. In comparison with patients with eGFR more than 80 mL/min/1.73m², intact FGF-23, 1-84PTH, and serum phosphorus increased significantly in those with eGFR<60, eGFR<50, and eGFR<30 mL/min/1.73m², respectively. In patients with eGFR<50 mL/min/1.73m², steeper rise in 1-84PTH was observed than intact FGF-23. Whereas serum 25OHD had no correlation with eGFR at all, significant decline in serum calcitriol was observed even in patients with eGFR<80 compared to those with eGFR>80 mL/min/1.73m². Multiple linear regression analysis revealed that significant positive contributors to serum calcitriol were eGFR, 1-84PTH, and 25OHD. Negative contributor was intact FGF-23. The significant decline in calcitriol was found even when significant rise in intact FGF-23 was not observed. Therefore the reduction of calcitriol synthesis in earlier stage of CKD seemed not to be explained by the fact that FGF-23 decrease 1 α -hydroxylase in proximal tubules. There might be another mechanism for calcitriol decline in this early CKD stage. The earliest sign for phosphate overload relative to viable nephron numbers was compensative rise in intact FGF-23, not in serum 1-84PTH. Given the origin of this two phosphaturic hormones, this fact might suggest that the bone is more sensitive to minimal phosphate overload than the parathyroid glands. Significant linear decline in calcitriol with CKD progression precedes significant rise in FGF-23.

Comparison of Rapid Intraoperative Parathyroid Hormone to IRMA in Patients with Hyperparathyroidism. M. Al Mukaddam^{*}, C. Albany^{*}, C. Hajj-Shahine^{*}, G. El-Hajj Fuleihan. Calcium Metabolism and Osteoporosis Program, American University of Beirut-Medical Center, Internal Medicine, Beirut, Lebanon.

The use of rapid intact parathyroid hormone (iPTH) assay is central to the success of minimally invasive parathyroidectomy. Comparing information obtained with this assay and the classical immunoradiometric PTH assay (IRMA) is limited.

142 blood samples collected from 71 patients referred to a tertiary care center for parathyroidectomy were analyzed. PTH levels on the intraoperative blood samples (pre- and post- gland excision) were concomitantly measured with the rapid and the classical IRMA kits. The classical IRMA kit utilizes monoclonal antibodies specific for the mid and C terminal part 39-84 and polyclonal antibodies specific to the N terminal moiety of PTH (CIS Bio International, Gif sur Yvette, France). The rapid iPTH was performed with the electrochemoluminescence immunoassay "ECLIA" (Roche Elecsys 2010 analyzer, Roche Diagnostics, Indianapolis, USA). It employs two monoclonal antibodies that react with epitopes in the amino acid regions 26-32 and 37-42 of PTH.

ECLIA assay (y) values strongly correlated with IRMA assay (x) values; y=1.63x -63.86 (r = 0.956, p<0.0001, pre- gland excision) and y=1.31x +4.22 (r=0.938, p<0.0001, 10-15 minutes post gland excision). This correlation was also evident with the percentage drop in PTH level using the above assays y=0.96x+0.51 (r =0.944, p<0.0001). Both assays yielded similar prediction of cure using the 50% drop as cut-off. However, mean pre- and post-gland excision PTH were significantly higher by ECLIA than IRMA, suggesting a systematic difference between the two assays, that is independent of mean PTH levels.

	PTH by ECLIA Median (min-max)	PTH by IRMA Median (min-max)	P value	%CV mean \pm SD
Pre-excision	177 pg/ml (39-3130)	129pg/ml (28-1648)	<0.0001*	22 \pm 16
Post-excision	39 pg/ml (9-452)	27pg/ml (2-265)	<0.0001*	31 \pm 22
% PTH Drop	77% (5-95)	80% (18-98)	NS	5 \pm 1

* paired t-test on log transformed values of PTH, NS: Not Significant

The manufacturers report a normal range for PTH of 15-65 pg/ml with ECLIA, which is very similar to the normal range for IRMA assay of 8-76 pg/ml. However, this study reveals that there is significant difference in the values obtained with the two assays, and underscores the importance of using the same assay when monitoring patients. Further studies should be implemented to elucidate sources of discrepancies between the two assays.

Ability of XL α s to Mimic Gs α in Mediating Parathyroid Hormone Signaling In Vivo. C. Aydin¹, L. F. Fröhlich^{*2}, D. Ozturk^{*1}, M. Bastepe¹.

¹Endocrine Unit, Department of Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA, ²Institute of Pathophysiology, University of Veterinary Medicine, Vienna, Austria.

XL α s, an imprinted, paternally expressed variant of the α -subunit of the stimulatory G protein (Gs α), can mediate parathyroid hormone (PTH)-induced adenylyl cyclase activation and, thus, is able to replace Gs α in transfected cells. However, XL α s knockout mice show phenotypes that are significantly different from those observed in Gs α knockout mice, suggesting that XL α s is unable to mimic Gs α in vivo. To address this question, we generated a transgenic mouse strain in which the rat type-I γ -glutamyltranspeptidase promoter was employed to target XL α s expression to the proximal tubule, a major site of PTH action. Southern blots identified five different founders (rptXL α s mice), and Northern blots showed that the F1 generation from two of the founders (G14 and G28) expressed transgenic rat XL α s mRNA at the age of two months. In G14 rptXL α s mice, but not in wild-type littermates, RT-PCR using whole kidney total RNA and primers common to both mouse and rat XL α s mRNA yielded a specific amplicon, whose sequence matched the cDNA sequence of rat XL α s. Western blots using a polyclonal antibody against the C-terminus of XL α s detected the XL α s protein in membrane extracts from the proximal tubules of the G14 rptXL α s mice but not of wild-type littermates. Endogenous Gs α mRNA levels appeared similar in transgenic and wild-type animals, which was determined by real-time RT-PCR using total RNA isolated from the proximal tubule. In contrast, the level of 1 α -hydroxylase mRNA, a downstream target of Gs α -mediated PTH signaling, was elevated in the G14 rptXL α s mice compared to wild-type littermates. These findings suggest that proximal tubular PTH actions that typically rely on Gs α signaling are enhanced in the G14 rptXL α s mice without changes in Gs α levels, providing strong evidence for the ability of XL α s to function in a manner similar to Gs α in vivo. Since XL α s mRNA is disrupted by most paternal mutations that disrupt Gs α mRNA and is preserved when those mutations are maternal, the Gs α -like activity of XL α s may be important in the pathogenesis of disorders associated with altered Gs α activity, such as pseudohypoparathyroidism, Albright's Hereditary Osteodystrophy, and fibrous dysplasia of bone.

Estrogen Deficiency and PTHrP Infusion Do Not Fully Reproduce the Bone Loss of Lactation. S. Brian*, P. Dann*, J. Wysolmerski. Endocrinology and Metabolism, Yale University, New Haven, CT, USA.

Lactation is associated with increased bone turnover and rapid bone loss. Suckling inhibits GnRH secretion, causing hypogonadotropic hypogonadism and low circulating levels of estradiol. In addition, the lactating mammary gland secretes PTHrP into the circulation. Estrogen replacement in lactating mice reduces bone loss by 60%, while disrupting the PTHrP gene in the lactating mammary gland reduces bone loss by 50%. Therefore, we hypothesized that the combination of estrogen deficiency and PTHrP excess is sufficient to explain bone loss in lactating mothers. To test this hypothesis, we attempted to reproduce lactational bone loss in nulliparous mice by suppressing estrogen and raising PTHrP levels. We administered 100 micrograms of leuprolide acetate twice daily to induce hypogonadotropic hypogonadism and lower estrogen levels. PTHrP(1-36) was infused at a rate of 10 pmol/hr using Alzet miniosmotic pumps. We studied 5 groups of mice: 1) lactating controls, 2) nulliparous controls, 3) PTHrP-treated, 4) leuprolide-treated, and 5) combined PTHrP and leuprolide. All mice were CD-1's between 11 and 14 weeks of age at the beginning of the experiment. BMD was measured by DXA prior to the start of the treatments and again after 11 days, and in lactating mice on day 1 and day 11 postpartum. After 11 days, mice were sacrificed and blood and urine were collected. As expected, lactating mice had lower estradiol levels (4.2pg/ml) than did randomly cycling virgins (13.7 pg/ml). Importantly, leuprolide-treated mice also had suppressed levels of estradiol (3.5 pg/ml) that were equivalent to those of lactating mice. Infusion of PTHrP led to mild hypercalcemia. Urinary C-telopeptide excretion (corrected for creatinine) (CTX) was elevated for all groups as compared to non-lactating controls. However, treatment with leuprolide, PTHrP or the combination did not raise CTX levels as high as those measured in lactating mice. BMD declined by 22% at the spine, 19% at the femur and 16% for the total body in lactating mice. PTHrP treatment caused losses of 8.0% at the spine, 8.7% at the femur and 8.0% at the total body. Interestingly, leuprolide treatment alone caused no bone loss and bone loss in the combined leuprolide and PTHrP group was no worse than with PTHrP treatment alone (5.0% at the spine, 5.1% at the femur and 7.0% for the total body). In conclusion, infusion of PTHrP combined with hypogonadotropic estrogen deficiency does not reproduce the extremely rapid rate of bone loss observed during lactation. These data suggest that either antecedent pregnancy or some other aspect of lactation magnifies bone loss caused by estrogen deficiency and PTHrP.

Activation of the Calcium Sensing Receptor With Cinacalcet Increases Serum Gastrin Levels in Healthy Older Subjects. L. Ceglia, S. S. Harris, H. Rasmussen*, B. Dawson-Hughes. Bone Metabolism Laboratory, Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts University, Boston, MA, USA.

Gastric acidity is postulated to enhance calcium absorption since calcium is better dissolved at low pH. Extracellular calcium stimulates gastrin and gastric acid secretion in humans. Ex vivo studies indicate that the calcium sensing receptor (CaR), which is expressed on the surface of human G cells and parietal cells, may be involved in this regulation. We evaluated whether cinacalcet (C), a CaR agonist, compared to placebo (P) would increase serum gastrin level (G) and basal gastric acid output (BAO) in healthy subjects.

17 subjects age 47-70 were placed on a metabolic diet with fixed protein, calcium, phosphorus, sodium, magnesium, potassium and vitamin D for 18 days. We measured G, BAO, intact parathyroid hormone (PTH), and 24-hr urine calcium-to-creatinine excretion ratio (Ca/Cr) at baseline (day 8, following a run-in period) and post-intervention (day 18). C was titrated to 30 mg daily. G was measured by the Diasorin method. Gastric volume, pH and acid mEq were measured to calculate BAO.

Mean G was similar in the 2 groups at baseline (C = 33.1 ± 13.9 (SD) pg/ml (n=9), P = 38.5 ± 13.9 pg/ml (n=8)). However, mean change in G differed (C = 7.0 ± 7.3 pg/ml, P = -4.6 ± 6.8 pg/ml, p = 0.004). Mean BAO at baseline was similar in the 2 groups (C = 2.14 ± 1.77 mEq/hr, P = 2.43 ± 1.56 mEq/hr), and mean change in BAO did not differ significantly (C = 1.32 ± 2.37 mEq/hr, P = -0.24 ± 1.08 mEq/hr, p = 0.109). In the group as a whole, change in G correlated with change in BAO (r = 0.530, p = 0.029 (n=17)). Baseline mean PTH was similar in the 2 groups (C = 43.9 ± 16 pg/ml, P = 47.8 ± 18.0 pg/ml), and as expected mean change in PTH differed (C = -26.9 ± 11.7 pg/ml, P = 14.3 ± 17.0 pg/ml, p = <0.0001). Ca/Cr did not differ significantly at baseline in the 2 groups (C = 84.9 ± 59.9 mg/g, P = 114.3 ± 80.1 mg/g, p = 0.401), but mean change in Ca/Cr was significantly different (C = 17.9 ± 24.6 mg/g, -12.2 \pm 24.3 mg/g, p = 0.023).

These results show that activation of the CaR with cinacalcet stimulates gastrin secretion, and that an increase in gastrin is associated with a rise in basal gastric acid output in healthy older subjects. The impact of these changes on calcium absorption requires further investigation.

The Discriminative Power of the 24h-Calcium/Creatinine Clearance Ratio (CCCR), the 24h-Calcium/Creatinine Ratio (CR) and the 24h-Calcium Excretion (CE) for the Separation Between Familial Hypocalciuric Hypercalcemia (FHH) and Primary Hyperparathyroidism (PHPT). S. E. Christensen¹, P. H. Nissen^{*2}, P. Vestergaard¹, L. Heickendorff^{ff2}, L. Mosekilde¹. ¹Dept. of Endocrinology, C., Aarhus University Hospital, THG, DK-8000 Aarhus C., Denmark, ²Dept. of Clinical Biochemistry, Aarhus University Hospital, THG, DK-8000 Aarhus C., Denmark.

Introduction: The 24h-urine calcium/creatinine clearance ratio (CCCR) is used clinically to separate familial hypocalciuric hypercalcemia (FHH) from primary hyperparathyroidism (PHPT).

A CCCR < 0.01 is often considered to indicate FHH, whereas a CCCR > 0.02 may be diagnostic for PHPT. Values between 0.01 and 0.02 are probably inconclusive. The simpler 24h-urine calcium/creatinine ratio (CR) and the 24h-urine calcium excretion (CE) have also been used. However, the discriminative powers of the different indices have not been sufficiently evaluated in well-defined subsets of patients.

Objective: To evaluate the diagnostic powers of CCCR, CR and CE in separating FHH from PHPT, using ROC curve analyses and overlap performance analyses.

Materials: We included 59 hypercalcemic FHH-patients characterized by clinically significant mutations in the CaSR gene and 97 hypercalcemic patients with surgically verified PHPT. All patients had a plasma creatinine (P-Cr) level < 150 pmol/l.

Methods: We calculated the CCCR as (P-Ca / 24h-U-Ca) x (24h-U-Cr / P-Cr), the CR as 24h-U-Ca/ 24h-U-Cr (mmol/mmol) and the CE as 24h-U-Ca (mmol/24h).

In FHH, all protein coding exons in the calcium sensing receptor gene (CaSR) were sequenced and aligned to GenBank reference sequence NM_000388.

Results: Highly significant differences between the two groups were found for all three indices (p<0.001). The table reports the ROC curve analyses. CCCR had the largest area under the ROC curve and a slightly higher sensitivity and specificity at the optimal separation point compared to the CR and CE.

ROC analyses	curve	Optimal separation point	Sensitivity	Specificity	Area under ROC curve
CCCR		<0.015	0.78	0.83	0.856
CR (mmol/mmol)		<0.45	0.71	0.86	0.831
CE (mmol/24h)		<5.5	0.76	0.72	0.800

CCCR < 0.01 had a positive predictive value of 0.89 for FHH, whereas CCCR > 0.02 had positive predictive value for PHPT of 0.93. Overlap performance analyses supported a two step diagnostic approach based on CCCR determination in all patients with CaSR gene analyses in those with CCCR < 0.02

Conclusions:

The diagnostic differentiation between PHPT and FHH should be based on CCCR determination with CaSR analyses in all patients with CCCR < 0.02.

The Calcim-Sensing Receptor (CaSR) Dampens the Calcemic Response to Exogenous 1,25 (OH)₂vitamin D In Vivo Independent of Parathyroid Hormone (PTH). O. Egbuna¹, L. Kantham², S. Quinn², J. Pang^{*2}, R. Butters^{*2}, M. Pollak^{*3}, E. Brown². ¹Divisions of Endocrinology and Nephrology, Brigham and Womens's Hospital and Beth Israel Deaconess Med Ctr, Boston, MA, USA, ²Division of Endocrinology, Brigham and Womens's Hospital, Boston, MA, USA, ³Division of Nephrology, Brigham and Womens's Hospital, Boston, MA, USA.

The CaSR has known actions on the parathyroid gland, parafollicular C-cell, and kidney. Our studies of the adaptations of mice with targeted disruption of the PTH gene (CaR^{-/-}PTH^{-/-} aka PTH KO), both the PTH and CaR genes (CaR^{-/-}PTH^{-/-} aka DKO) or wild type mice (CaR^{+/+}PTH^{+/+} aka WT) to exogenous 1,25 (OH)₂ vitamin D₃ have revealed striking phenotypes that provide new insights on the roles of the CaR and PTH in calcium homeostasis. The 3 groups mice were given 0.5 ng/g BW of 1,25 (OH)₂vitamin D₃ by intraperitoneal injection, and the calcemic response over 72 hrs analyzed. Injections were given while the mice were given free access to a calcium replete diet [0.6% calcium (Ca) w/w chow and plain water] and repeated after conditioning the mice for 18-72 hrs on a Ca-deficient diet (0.01% Ca in the chow and plain water) prior to injection. Peak calcemic responses were observed in all genotypes on either diet at 24 hrs post injection. On the Ca replete diet (top figure), there was a 125% increase in serum calcium (SCa) in the DKO mice at 24 hrs. The increase in SCa was substantially less marked in the (PTH KO) (+41%), and less in the WT mice (+25%). On the Ca deplete diet (lower figure), the calcemic response at 24 hrs in the DKO mice was much less robust- +37%, and was similar to that in the PTH KO mice (+39%) but again was greater than that in the WT mice (+13%).

Lack of the CaSR renders mice lacking PTH markedly more sensitive to the calcemic action of vitamin D₃ than mice lacking PTH alone or WT mice. This exaggerated response appears selective for vitamin D-mediated intestinal Ca absorption rather than bone resorption, since it was observed on a Ca replete but not a Ca deplete diet. Additional factors that may contribute to the increased vitamin D sensitivity of the DKO mice are impaired secretion of calcitonin and decreased renal Ca excretion, although the latter could not explain the differences in the responses on the Ca replete and deplete diets.

Testin, a Novel Binding Partner of the Calcium-Sensing Receptor. A. L. Magno^{*1}, B. K. Ward^{*2}, E. Ingley^{*1}, A. D. Conigrave³, T. Ratajczak^{*2}.

¹Western Australian Institute for Medical Research, University of Western Australia, Perth, Australia, ²Endocrinology and Diabetes, Sir Charles Gairdner Hospital, Perth, Australia, ³School of Molecular and Microbial Biosciences, University of Sydney, Sydney, Australia.

The calcium-sensing receptor (CaR) is a G protein-coupled receptor that can respond to a diverse range of stimuli. Besides its integral role in calcium homeostasis, the CaR is involved in a wide variety of cellular processes through its mediation of different intracellular signalling pathways. To elucidate the mechanisms that convert the various extracellular stimuli for the CaR to specific intracellular responses we used the CaR intracellular tail as bait in a yeast two-hybrid screen of a mouse haemopoietic cell line

library. Identified in this library screen was testin, a protein that has been proposed to act as a tumour suppressor and is involved in cell adherence. Testin is a triple LIM domain protein that localises to focal adhesions and actin stress fibres. LIM domains are composed of two zinc fingers that mediate protein interactions important in coordinating specific signalling pathways. Three distinct clones of testin containing a 61 amino acid overlapping region were identified. This overlapping region incorporates the second zinc finger of the first LIM domain. Yeast two-hybrid based deletion mapping studies revealed that testin binds to the membrane-proximal region of the CaR tail, a domain critical for activation of several intracellular signalling pathways. The interaction between the CaR and testin in a mammalian system was confirmed in coimmunoprecipitation studies using lysates from HEK293 cells transiently expressing FLAG-tagged CaR and EGFP-tagged testin. The focus of our current studies is to investigate the possible colocalization of the CaR and testin at focal adhesions and/or actin stress fibres in conjunction with experiments examining testin's potential modulating role in CaR-mediated activation of the mitogen-activated protein kinase, phosphatidylinositol 3-kinase and Rho pathways. In this regard, we have preliminary evidence that overexpression of testin reduces CaR-mediated extracellular signal-regulated kinase phosphorylation in HEK293 cells stably expressing the CaR. In conclusion, we have identified the LIM domain protein, testin, as a novel interaction partner for the CaR that may regulate CaR-mediated signalling linked to the cytoskeleton.

Regulation of Calcium-Sensing Receptor by Glial Cells Missing 2 in Hyperplastic Parathyroid Cells. M. Mizobuchi^{*1}, C. S. Ritter^{*1}, G. Sicard^{*2}, E. Slatopolsky¹, A. J. Brown¹. ¹Renal, Washington University School of Medicine, St Louis, MO, USA, ²Surgery, Washington University School of Medicine, St Louis, MO, USA.

Glial cells missing 2 (Gcm2) is the key regulating transcription factor for parathyroid gland development. The continued expression of high levels of Gcm2 in mature parathyroid glands suggests that it is required for maintenance of parathyroid cell differentiation. The role of Gcm2 in parathyroid cell physiology, however, has not been fully investigated. In preliminary studies, we confirmed that Gcm2 mRNA continued to be expressed in hyperplastic parathyroid cells placed in culture. Western blot analysis of the human parathyroid tissue using a polyclonal antibody for Gcm2 revealed a band of approximately 57 kDa, the predicted size of the Gcm2 protein. We then examined the effects of Gcm2 silencing on cultured human parathyroid cells. Collagenase-dispersed human parathyroid cells from patients with chronic kidney disease were placed in monolayer cultures, and treated with lentivirus expressing shRNA for human Gcm2 for 24 hours. Fresh medium was added and the cells were harvested after 48 hours. RNA was analyzed for Gcm2, PTH, vitamin D receptor (VDR), calcium-sensing receptor (CaR) and proliferating cell nuclear antigen (PCNA) mRNAs by qPCR. Gcm2 mRNA was decreased by 75 ± 4 % (p < 0.01; mean of 3 cultures). Immunoblot analysis confirmed the decrease in Gcm2 as well. VDR, PTH and PCNA were not significantly affected by Gcm2 silencing, but CaR mRNA was consistently reduced by 48 ± 9% (p < 0.01). Further analysis of CaR mRNA indicated that transcripts containing Exon 1B, derived by transcription from CaR promoter 2, were down-regulated by the Gcm2 silencing. These results indicate that one function of Gcm2 is to maintain high levels of CaR expression in parathyroid cells. Further studies are underway to identify other targets of Gcm2 action.

Calcilytics Block the Suppressive Effect of Calcimimetics on PTH mRNA Levels in Bovine Parathyroid Cells. B. T. Brinton^{*1}, M. Chan^{*1}, J. Li^{*1}, T. Le-Capling^{*1}, R. Fantáske^{*1}, E. F. Nemeth². ¹NPS Pharmaceuticals, Toronto, ON, Canada, ²Dept. Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada.

Extracellular calcium is the primary regulator of parathyroid cell function and most, if not all its actions are mediated by the calcium receptor (CaR). Thus, activation of CaR by the calcimimetic compound NPS R-568 decreases PTH secretion, PTH mRNA levels, and parathyroid cell proliferation elicited by hypocalcemic conditions. CaR antagonists (calcilytics) increase PTH secretion but, under normocalcemic conditions, do not appear to increase parathyroid cell proliferation. The effects of the calcilytic compound NPS 89636 on PTH synthesis (mRNA levels) in parathyroid cells is reported here. Dissociated bovine parathyroid (bPT) cells were cultured in media containing 0.9 mM phosphate and various concentrations of extracellular calcium (0.5 to 3 mM) in the presence or absence of NPS R-568 and/or NPS 89636. PTH mRNA levels were determined by real time quantitative PCR. Levels of PTH mRNA were similar following incubation of bPT cells for 24 hrs in media containing 0.5 or 1.8 mM calcium but were reduced by 70% at an extracellular calcium concentration of 3 mM (n=4; p=0.0001). The addition of NPS R-568 to cells cultured for 24 hrs in 1.8 mM calcium reduced PTH mRNA levels by 80%. These inhibitory effects of NPS R-568 were concentration-dependent (IC₅₀ = 42 nM) and stereoselective (no effect with 1 uM NPS S-568) and were essentially the same as our previous results using Northern blots to quantify PTH mRNA. The stability of PTH mRNA, as assessed by comparison to mRNA half-life at 1.8 mM extracellular calcium,

was reduced 2.8-fold by 3 mM extracellular calcium and 4.3-fold by 300 nM NPS R-568. The inhibitory effect of 3 mM extracellular calcium was completely blocked by NPS 89636 in a concentration-dependent manner ($EC_{50} = 21$ nM). The calcilytic similarly blocked the inhibitory effect of 300 nM NPS R-568 on PTH mRNA levels and shifted the NPS R-568 concentration-response curve to the right. By itself, NPS 89636 did not significantly affect PTH mRNA levels at extracellular calcium concentrations of 0.5 or 1.8 mM. Secretion of PTH, however, was stimulated by NPS 89636 (30-300 nM) at extracellular calcium concentrations of 1.25 to 2 mM. The ability of a calcilytic compound to completely block the effects of extracellular calcium on PTH secretion and mRNA levels demonstrates that both these effects are mediated solely through the CaR. In contrast to PTH secretion, levels of PTH mRNA appear to be maximally elevated at extracellular calcium levels of 1.8 mM and can be lowered but not further increased by compounds that act on the CaR.

Role of G-alpha-q in Parathyroid Gland Function Elucidated by Mouse Genetic Approaches. M. Pi, Q. Luo*, L. D. Quarles. The Kidney Institute, KUMC, Kansas City, KS, USA.

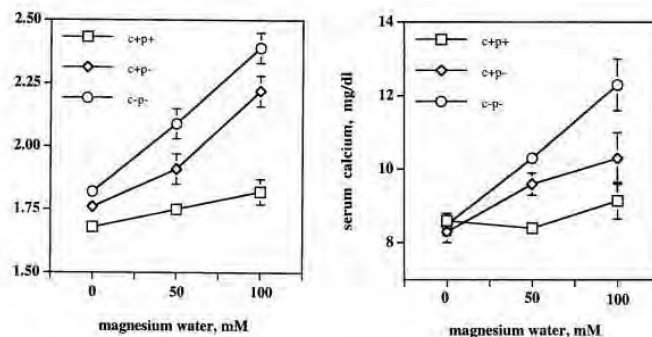

The calcium-sensing receptor (CASR) is a heptahelical receptor coupled to G-alpha-i and G-alpha-q. CASR regulates parathyroid gland (PTG) function, including PTH secretion and production as well as chief cell hypertrophy and hyperplasia. The specific and/or separate functions of G-alpha-q and G-alpha-i in regulating these different aspects of PTG function have not been elucidated. To investigate the role of G-alpha-q in the PTG, we initially assessed serum PTH levels in heterozygous G-alpha-q-deficient mice. We found that G-alpha-q-deficient mice had small but significant elevation of serum PTH levels compared to wild-type littermates. Next, we created transgenic ($Tg^{PTHp-Gqloop}$) mice using the human PTH promoter to drive the overexpression of a dominant negative Gqloop mini-gene to selectively disrupt G-alpha-q function in the PTG. We found that the gross appearance, body weight and survival of the $Tg^{PTHp-Gqloop}$ mice were indistinguishable from that of wild-type littermates. We also found that the Gqloop messenger RNA was expressed in parathyroid gland but not in other tissues of the $Tg^{PTHp-Gqloop}$ mice. Adult $Tg^{PTHp-Gqloop}$ mice exhibited a ~ 2-fold increase in basal serum PTH levels compared to wild-type mice (43 ± 5 pg/ml vs 25 ± 2 pg/ml; $p=0.001$), as well as increased PTH mRNA levels in PTG containing tissue. However, stimulation of PTH secretion by lowering the serum calcium with EGTA (300 microM/kg body weight) resulted in identical maximum levels of serum PTH in $Tg^{PTHp-Gqloop}$ and wild-type mice, but the percentage increment in PTH levels was less in $Tg^{PTHp-Gqloop}$ due to the higher baseline PTH values. Of interest, CASR mRNA expression was increased in the PTG, but decreased in the kidney of $Tg^{PTHp-Gqloop}$ compared to wild-type mice. In conclusion, we have demonstrated that the selective targeting of the PTG to investigate signaling mechanisms downstream of CASR is feasible. Our observations suggest a role for G-alpha-q in the regulation of PTH and CASR expression in the PTG, but fail to identify G-alpha-q-dependent regulation of PTH secretion in response to hypocalcemic stimuli. Studies are ongoing to determine if further reductions of G-alpha-q, achieved by crossing $Tg^{PTHp-Gqloop}$ onto heterozygous G-alpha-q-deficient mice, will uncover additional effects of G-alpha-q in CASR-dependent signaling. In addition, future studies will use the PTH promoter to separately target G-alpha-i to investigate its function in mediating CASR effects on PTG function.

Intact Calcium-Sensing Receptor and PTH Genes Are Required to Regulate the Extracellular Magnesium and Calcium Concentrations Independently. S. Quinn*, O. Egbuna, L. Kantham, R. Butters*, J. Pang*, M. Pollak*, E. M. Brown. Medicine, Brigham and Women's Hospital, Boston, MA, USA.

Although the systems governing Ca^{2+} and Mg^{2+} homeostasis share elements in common, e.g., a common mechanism for paracellular reabsorption in the renal cortical thick ascending limb, the circulating levels of these two divalent cations are generally regulated independently of one another. We have studied the adaptations of mice with targeted disruption of the PTH gene ($CaR^{+/+}PTH^{-/-}$), both the PTH and CaR genes ($CaR^{-/-}PTH^{-/-}$) or wild type mice ($CaR^{+/+}PTH^{+/+}$) to variations in calcium or magnesium intake. The results have revealed striking phenotypes that shed light on the roles of the CaR and PTH in permitting independent regulation of Ca^{2+} and Mg^{2+} . When maintained on sufficient calcium intake to sustain normocalcemia, $CaR^{-/-}PTH^{-/-}$ mice show a dose-dependent, 55% and 33% increases in both blood Ca^{2+} and Mg^{2+} , respectively, when Mg^{2+} in the water is increased to 50 and then 100 mM (Figure 1). $CaR^{+/+}PTH^{-/-}$ mice show similar, but less marked increases of 24 and 26%, respectively, while wild type mice show 6% and 9% changes. Increasing Ca^{2+} in the water from 0% to 1% and then 2%, produces analogous changes in both blood Ca^{2+} and Mg^{2+} , elevating the two divalent cations by 106% and 50%, respectively, in the $CaR^{-/-}PTH^{-/-}$ mice, by 53% and 17% in the $CaR^{+/+}PTH^{-/-}$ mice and by 6% and 3% in the wild type mice (not shown). Thus loss of both PTH and the CaR results in an apparent "default" mode, in which increased intake of either Ca^{2+} or Mg^{2+} elevates the blood levels of both divalent cations. This defect is less severe when only PTH is missing, but the full capacity to maintain constancy of both Ca^{2+} and Mg^{2+} in the face of markedly increased oral loads of one or the other requires both PTH and the CaR.

Deletion of the 25 Hydroxy Vitamin D 1 α Hydroxylase from Mice Expressing the Null Mutation for the Calcium Sensing Receptor Converts a Hypercalcemic to a Hypocalcemic Hyperparathyroid Phenotype. C. Richard*, D. Miao*, R. Samadifam*, Y. Wang*, G. N. Hendy*, D. Goltzman*. ¹Dept of Medicine, Calcium Laboratory, McGill University, Royal Victoria Hospital, Montreal, PQ, Canada, ²Department of Human Anatomy, Nanjing Medical University, Nanjing, China, China.

The calcium sensing receptor (CaSR) is functional mainly in the parathyroid gland and kidney, but likely as well in other tissues such as the gastrointestinal tract and the skeleton. These tissues are also target sites for the action of 1,25-dihydroxyvitamin D [$1,25(OH)_2D$]. Mice which are heterozygous or homozygous for the calcium sensing receptor null mutation ($CaSR^{+/+}$ and $CaSR^{-/-}$ respectively) develop hypercalcemia and hyperparathyroidism to a moderate or severe degree, respectively. Mice which are homozygous for targeted deletion of the 25 hydroxyvitamin-D 1 α -hydroxylase [$1\alpha(OH)ase^{-/-}$] which synthesizes $1,25(OH)_2D$ develop hypocalcemia, hyperparathyroidism and rickets but survive long term. To assess the interactions between the important calcium regulating molecules, CaSR and $1,25(OH)_2D$, we created compound mutants of the CaSR and 1 $\alpha(OH)ase$ mutants and assessed their growth, biochemistry and skeletal morphology. $CaSR^{+/+};1\alpha(OH)ase^{+/+}$ mice grew normally and exhibited normal longevity. $CaSR^{+/+};1\alpha(OH)ase^{-/-}$ mice developed severe rickets and osteomalacia as assessed by faxitron x-ray analysis and von Kossa staining of the skeleton but survived at least 2 months. $CaSR^{+/+};1\alpha(OH)ase^{-/-}$ mice developed even more severe rickets, osteomalacia and growth retardation but also survived long term. BMD, assessed by PIXIMUS, was reduced by 68% in the lumbar spine and by 49% in the femur compared to wild type mice, but only by 58% and 38% in the lumbar spine and femur respectively of the $CaSR^{+/+};1\alpha(OH)ase^{-/-}$ mice. Although $CaSR^{-/-};1\alpha(OH)ase^{+/+}$ mice develop severe hypercalcemia and most die before or shortly after weaning, deletion of the 1 $\alpha(OH)ase$ in $CaSR^{-/-};1\alpha(OH)ase^{-/-}$ mice facilitated survival for at least 2 months although these animals exhibited the most severe growth retardation, rickets and osteomalacia of all mutants. All mutant animals showed evidence of hyperparathyroidism with $CaSR^{+/+};1\alpha(OH)ase^{+/+}$ and $CaSR^{-/-};1\alpha(OH)ase^{+/+}$ mice displaying hypercalcemia. In contrast, $CaSR^{+/+};1\alpha(OH)ase^{-/-}$ mice and $CaSR^{-/-};1\alpha(OH)ase^{-/-}$ mice were severely hypocalcemic (serum calcium 1.28 and 1.27mM respectively). The results indicate that the phenotypic manifestations of hyperparathyroidism may be markedly influenced by the vitamin D status of animals with CaSR mutations, confirm that elimination of hypercalcemia sustains longevity in mice homozygous for the CaSR null mutation, and suggest that mutations in the CaSR contribute to worsening of skeletal mineralization.

Periarticular Bone Loss in Arthritis: Role of Synovial Glucocorticoid Generation. M. S. Cooper¹, R. Hardy^{*1}, E. H. Rabbitt^{*1}, N. J. Gittoes¹, M. Hewison², C. D. Buckley^{*1}, K. Raza^{*1}, P. M. Stewart^{*1}. ¹University of Birmingham, Birmingham, United Kingdom, ²Cedars-Sinai Medical Centre, Los Angeles, CA, USA.

Periarticular osteoporosis is a common feature of inflammatory arthritis. This feature is related to disease activity and is associated with uncoupling of bone resorption from formation. We previously hypothesised that local glucocorticoid generation within osteoblasts in response to inflammation may underlie this bone loss. An alternative possibility is that excess glucocorticoids are generated from other joint tissues. Primary synovial fibroblasts express the 11 β -hydroxysteroid dehydrogenase type 1 (11 β -HSD1) enzyme that generates the active glucocorticoids cortisol and prednisolone from their inactive counterparts cortisone and prednisone suggesting that synovium might generate glucocorticoids. We have now explored this hypothesis by characterizing glucocorticoid metabolism in synovial tissue explants from patients with rheumatoid arthritis (RA) and osteoarthritis (OA).

Glucocorticoid metabolism was examined in synovial tissue taken from subjects with OA (n=8) or RA (n=12) during orthopedic surgery using radiolabelled steroids and TLC. Immunohistochemistry was used to identify the cellular distribution of enzymes. The functional consequences of enzyme activity on IL-6 production were examined by ELISA.

All synovial biopsies had substantial capacity to activate glucocorticoids (cortisone to cortisol and prednisone to prednisolone) which was blocked by a specific 11 β -HSD1 inhibitor confirming 11 β -HSD1 expression. No difference in steroid metabolism was seen between samples from RA and OA subjects. In patients with RA, synovial cortisol generation increased with the ESR of the tissue donor ($R^2=0.4$, $p<0.05$). 11 β -HSD1 activity had functional consequences with cortisone able to decrease synovial IL-6 production in tissue from patients with RA or OA ($31\pm15\%$ for RA, $36\pm9\%$ for OA, both $p<0.05$). Steroid inactivation was also apparent in synovium and was not blocked by inhibition of 11 β -HSD1. Using immunohistochemistry 11 β -HSD2 expressing cells were identified in RA synovium and expression colocalized with the monocyte marker CD68. This pattern was distinct from 11 β -HSD1 which was expressed in fibroblasts.

Synovial tissue metabolises glucocorticoids with the predominant effect being glucocorticoid activation and this increases with inflammation. Endogenous glucocorticoid production in the joint is likely to regulate tissue inflammation but in excess might detrimentally impact on periarticular bone integrity. Additionally, a subset of immune cells expressing 11 β -HSD2 within synovium will be resistant to cortisol/prednisolone through steroid inactivation and this could perpetuate synovial inflammation.

The Effects of Glucocorticoid on BMP-2 and BMP-7 Expressions in Bone and Kidney. L. Cui¹, L. Zhou^{*1}, T. Wu^{*2}. ¹Department of Pharmacology, Guangdong Medical College, Zhanjiang, Guangdong, China, ²Guangdong Key Laboratory for R & D of Natural Drugs, Guangdong Medical College, Zhanjiang, Guangdong, China.

Aims: To determine the effects of long-term over dose of glucocorticoid (GC) on the genes and proteins expressions of bone morphogenetic proteins (BMP)-2 and BMP-7 in the bone tissue and kidneys of rats, to explore the relationships between BMPs changes in kidney-blood-bone and osteoporotic, hence to evaluate the roles of BMP-2 and BMP-7 in GC-induced osteoporotic. **Methods:** Three months-old Sprague-Dawley male rats were divided to control, GC-treated, GC-treated plus Danshen and GC-treated plus epimedium groups. Rats were oral gavages prednisone (3.2mg/kg/d) in the morning and the other treatments in the afternoon for three months. At endpoint, all rats were sacrificed for the collections of blood, bone and kidneys. The bone histomorphometry parameters in proximal tibial metaphyseal (PTM) were measured. The contents of BMP-7 and BMP-2 in blood serum were determined. RT-PCR was applied to test gene expressions of BMP-2 and BMP-7 mRNA and Immunohistochemistry was applied to analyze the expression locations and quantities of BMP-2 and BMP-7 in kidney and femoral bone. **Results:** Glucocorticoid induced bone loss by decreasing 28.96% ($P<0.01$) in trabecular area and 14.53% in trabecular thickness and 17.93% in trabecular number in PTM respectively, the trabecular separation increased 27.97% ($P<0.05$) when compared with control. Simultaneously, glucocorticoid decreased the gene and protein expressions of BMP-2 and BMP-7 in femoral bone ($P<0.05$), however, it decreased BMP-7 expression but increased BMP-2 expression in kidney ($P<0.05$). Glomerulus and collecting duct atrophy and protein cast were seen in kidneys of glucocorticoid treated rats. The contents of BMP-7 and BMP-2 in blood serum were decreased in the glucocorticoid treated rats. There was a positively correlation ($P<0.05$) in expressions of BMP-7 among kidney, blood and bone mass and a negatively correlation ($P<0.05$) in expressions of BMP-2 between kidneys and bone mass. Traditional Chinese medicine Danshen and epimedium can prevented glucocorticoid induced bone loss by regulating BMP-2 and BMP-7 expressions in bone and kidneys. **Conclusions:** Glucocorticoid induce bone loss in rats and down-regulated the expressions of BMP-2 and BMP-7 in bone tissue, down-regulated BMP-7 but up-regulated BMP-2 expression in kidney. BMP-2 and BMP-7 may play an important role in the mechanism of glucocorticoid induced osteoporosis. Some kidneys action Traditional Chinese medicine can prevented glucocorticoid induced osteoporosis by regulating the BMPs expressions in bone and kidneys.

A Vitamin D Deficiency in an Italian Central Town Normal Population (MIMOSA-G project). P. De Remigis^{*1}, P. Ranieri^{*1}, A. De Remigis^{*1}, B. De Laurentiis^{*2}, M. Lattanzio^{*2}, L. Vianale^{*1}. ¹Endocrine Unit, General Hospital, Chieti, Italy, ²Endocrine Laboratory Unit, General Hospital, Chieti, Italy.

In the context of MIMOSA (Mineral Metabolism Osteoporosis in Abruzzo) project, a study was carried out about the correlation between 25-hydroxyvitamin D and PTH levels, in order to unveil vitamin-D deficiency and to schedule a prophylaxis program.

200 healthy subjects were considered; this population, belonged to a town (Guardagrele) of 9970 inhabitants, located in Abruzzo, a Central Italian Region, was selected from a randomized group of 820 subjects, who had ultrasound BMD screening, on the basis of normal t-score at QUS and ruling out other risk factors for osteoporosis, by questionnaire (this project is called MIMOSA-G, because it is restricted to total people of Guardagrele). The population was homogeneous for environmental factors and nutritional intake, of both genders, ranged from 20 to 85 yrs. They were subdivided in four groups of 25 members, for each gender: a) ranged from 20-50 yrs b) 50-60 c) 60-70 d) over 70. The blood samples were taken in winter; 25-hydroxyvitamin D and PTH were assayed by chemiluminescent method.

In our population of healthy individuals, calcidol levels are decreasing very significantly from 12.3 ng/ml (young people group) to 8.31 (the oldest one). There is not differences between male and females at any different age classes we considered. On the other hand, in parallel way, PTH levels are increasing significantly from 39.2 pg/ml in young people to 52.9 pg/ml in older ones, showing that a condition of secondary compensatory hyperparathyroidism is realizing by aging.

25-hydroxyvitamin D and PTH levels are negative correlated (correlation coefficient of 0.18). The threshold of 25-hydroxyvitamin D, above which the correlation becomes not significant, is 30 ng/ml (to be considered our biological reference). 50.2% of subjects show a level of 25-hydroxyvitamin D below 8 ng/ml. The profile of 25-hydroxyvitamin D graphic indicates the level of a vitamin D is sharply declining in general population over 60 yrs (more evident in females, while in man the curve is smoother), putting at risk of femoral fractures people for secondary hyperparathyroidism. Vitamin D deficiency is shown in Abruzzo severe over all in aged population probably due to inadequate exposure in winter and also insufficient dietary compensation.

The Protective Effects of Mechanical Strain on Osteocyte Viability Is Mediated by the Effects of Prostaglandin on the cAMP/PKA and the β -Catenin Pathways. Y. Kitase^{*}, M. L. Johnson, L. F. Bonewald. Oral Biology, School of Dentistry, UMKC, Kansas City, MO, USA.

Mechanical loading has been shown to prevent or reduce osteocyte cell death or apoptosis in vitro and in vivo. Fluid flow shear stress (FFSS) has been shown to reduce osteocyte apoptosis in response to glucocorticoid (GC). As GC induced osteoporosis is the second most common form of osteoporosis, we sought to identify the molecular mechanisms responsible for the protective effect of mechanical loading. Application of FFSS (16 dynes/cm²) significantly inhibited apoptosis of osteocyte-like MLO-Y4 cells induced by dexamethasone (Dex, 10⁻⁶ M). We hypothesized that PGE₂ is a protective factor for osteocytes as osteocytes release PGE₂ within minutes in response to FFSS. The protective effect of FFSS on Dex-induced apoptosis was significantly inhibited by indomethacin (10⁻⁶ M) while exogenous PGE₂ (10⁻⁶ M) significantly prevented apoptosis induced by Dex. The use of PGE₂ receptor agonists (butaprost, PGE, alcohol, sulprostone) and antagonist (AH6809) showed that the EP2 receptor was responsible. Dex was found to inhibit EP2 receptor and COX-2 expression and PGE₂ production as determined by gene array, real-time PCR and ELISA. As the EP2 receptor is known to signal through the classical cAMP/PKA pathway, the cAMP analog, 8Br-cAMP (100 μ M) was tested and found to protect against Dex-induced cell death. However, the PKA inhibitor H89 (5 μ M) only partially abrogated the protective effects of PGE₂. As recent studies suggest that PGE₂
