Patients with Type 1 diabetes (T1D) have more fractures than non-diabetic controls[1-2]. As no difference in BMD was observed between T1D and controls, it was hypothesized that abnormalities in bone material properties occurred in T1D patients[3]. The aim of present study was to analyze such modifications in intrinsic material properties in bone of T1D patients versus corresponding controls. Five iliac bone samples from fractured patients (35+/-12 year-old) with T1D (treated with insulin) and 5 iliac samples from non-diabetic controls (CTR, age and sex matched) were used[3]. Microradiography was performed on 100 µm-thick sections to measure the mean degree of mineralization (DMB, g/cm^3) and the mean heterogeneity index of mineralization (HI, g/cm^3)[4]. Vickers microhardness was calculated on 100 µm-thick sections (20 indents in each cortical and 20 in trabecular bone)[4]. Finally, Fourier Transform Infrared Microspectroscopy[5-6] was performed in the vicinity of indents. Results showed that in T1D versus CTR, DMB increased in both cortical and trabecular bone but HI was not different. Microhardness tended to increase in T1D, but not significantly. Relationships between microhardness and mineral and organic characteristics have then been performed. Significant correlations between micro-hardness and mineralization index was always found, in CTR (r'=0.29, p=0.0018) and T1D (r'=0.180, p=0.0178). Moreover, in T1D, correlations were found close to indents, especially between microhardness and either crystallinity index (r'=0.28, p=0.0002), or collagen maturity (r'=0.16, p=0.037). These correlations were not found in CTR. This preliminary study suggests that alterations in bone materials properties of T1D patients could explain in part their bone fragility.

Bone quality adaptations to running in a murine model of impaired reactive oxygen species (ROS) scavenging. Vanessa Sherk*[1], Lillian Chatham[1], Kathryn Pate[2], Elizabeth Regan[2], Wendy Kohrt[1], Dana Carpenter[1]. [1]University of Colorado Denver, USA, [2]National Jewish Health, USA

A polymorphism (R213G) in the extracellular superoxide dismutase (EcSOD) gene decreases EcSOD protein in tissue extracellular matrix, leaving tissues that normally have high levels of EcSOD (i.e. bone and cartilage) susceptible to oxidative damage. It is unclear whether increased oxidative stress has a negative effect on bone quality. The purpose was to determine whether reduced ROS scavenging ability alters the skeletal adaptations to exercise training. Methods: Heterozygous EcSOD-deficient (Het; n=12) and C57BL/6 wild-type (WT; n=12) adult mice were randomized to treadmill running (Run: 5 d/wk, 45 min/d, 15 m/min) or sedentary (Sed) controls for 8 weeks. Tibias were harvested after sacrifice. Cross-sectional area (CSA) and estimates of bone strength (I_{max}, Z_{max}) were determined with microcomputed tomography. Stress at a standard (100N) compressive load ($Stress_{Std}$) was estimated by finite element analysis. Failure load (F_{max}) was measured in compression. Results: Increased protein nitration and DNA oxidation in knee articular cartilage of Het runners suggested increased oxidative stress. Exercise increased ($p<0.05$) CSA, I_{max}, and Z_{max} in Het mice only. $Stress_{Std}$ was reduced by exercise ($p<0.05$) and was lower in WT than Het ($p<0.001$) (Table 1). F_{max} did not differ among groups. Conclusion: EcSOD-deficient mice had more favorable bone architectural (CSA, I_{max}, Z_{max}) adaptations to running at the tibial mid-diaphysis than WT mice, but the 3D structures of the tibia resulted in lower estimated stress levels at the tibial mid-diaphysis in WT than in Het mice. Oxidative stress may be detrimental to skeletal health when sedentary, but may trigger more robust skeletal adaptations to exercise.

Bone Regeneration Varies in Four Different Mouse Strains after Marrow Ablation. Meghan Moran*[1], Amarjit S Virdi[1], Kotaro Sena[2], Margaret A McNulty[3], D.R. Sumner[1]. [1]Rush Medical College, USA, [2]Kagoshima University, Japan, [3]Louisiana State University, USA

It is well-established that mouse strains exhibit different bone phenotypes, including bone mass, bone mineral density and mechanical properties. Various mouse strains and genetic models also exhibit different responses to injury challenges such as ear punches and fracture healing. One such fracture healing study showed more bone was present in the femoral fracture callus and healing proceeded more quickly in C57Bl/6 mice than C3H/He mice, supporting the idea that genetic variability contributes to bone repair (Manigrasso and O'Connor, 2008). There is very limited data on intramembranous bone regeneration, which is a part of fracture healing, after an injury challenge in different mouse strains. We sought to determine if intramembranous bone regeneration differs in four wild-type inbred mouse strains (BALB/C, C3H/He, C57Bl/6, FVB/N) in response marrow ablation.

Mechanical ablation of the marrow space was performed in 27 to 33 week old females of the four selected strains. Animals were euthanized 3 weeks post-surgery. All bone within the medullary canal of the operated and contra-lateral femurs was analyzed in the region between 30% and 60% of the total femur length by microCT (6 μm voxels). This region is normally lacking bone in intact animals. The sample size was 4 animals per strain.

Mean BV/TV varied between 4.3% and 19.5% in the operated femurs (Table 1, one-way ANOVA p=.004). Specifically, compared to BALB/C mice, FVB/N mice had approximately 4.5-fold more BV/TV (p=.007) and C3H/He mice had 4.1-fold more BV/TV (p=.017). C57Bl/6 mice were not different than any of the other three strains. The differences in BV/TV were due to various combinations of differences in trabecular number, trabecular thickness and trabecular spacing. As expected, the non-operated contra-lateral femurs had much lower mean BV/TVs (0-1.8%).These findings show that there was a large variation in the response to the marrow ablation challenge in these strains. These differences may be due to direct genetic effects on bone healing or possibly to indirect effects because these mouse strains also have inherent differences in bone geometry.

Compressive Loading Reveals Local Changes in Bone Maturation Levels. Ingrid Bergstrom*[1], Jemma kerns[2], Allen Goodship[2], Sara Windahl[3]. [1]Karolinska Institutet, Sweden, [2]UCL Institute of Orthopaedics & Musculoskeletal Science, Royal National Orthopaedic Hospital, United Kingdom, [3]Center for Bone & Arthritis Research, Sahlgrenska Academy, Sweden

Introduction: Bone maturation and metabolism are optimised to accommodate specific physical activity. The role of increased mineral content is to stiffen the material and structure. The strength of bone, however, is dependent on both the mineral and the organic collagen matrix.

Aim: To explore the hypothesis that structural and material properties (bone matrix chemistry) change in adaptation to a specific loading regimen.

Methods: At three months of age, the right tibia of 7 mice were subjected to short periods of cyclic compressive loading three times a week for two weeks (40 cycles, peak strain 3097με). Following dissection, Raman spectra (830nm laser, Renishaw, UK) were acquired directly from 4 positions (cranial, medial [tensile area], caudal/medial and caudal/lateral [compression area]) at the mid-diaphysis of each bone. Raman spectra were analysed to determine mineralisation levels, crystallinity and collagen characteristics. Further, multivariate analysis was employed to determine the variance across each position for loaded vs. non-loaded data, at each position. Reference point indentation (RPI) measurements were acquired along the medial side of each bone, from proximal to distal, at 2N for 10 cycles (Active Life Scientific, USA).

Results: Analysing the spectra by anatomical position revealed that there was a significant difference between the non-loaded and loaded bones. Specifically the medial position showed that non-loaded bones had a significantly higher proportion ($p=0.01$) of mineral to collagen. Compared with the non-loaded bone, the loaded bone crystal maturity was lower for the caudal/lateral, but elevated for the medial position. Indentation results along the medial position of the bones revealed that both the non-loaded and loaded bones were more resistant to indentation in the mid-diaphysis than at either metaphysis.

Conclusions: Overall the loaded bones are less mineralised than the non-loaded bones, indicating new bone that is not fully mineralised. This supports the hypothesis that the bone matrix chemistry changes in response to loading. The pattern of bone matrix chemistry at different anatomical positions of the non-loaded and loaded bone is also different, suggesting that as bone remodels it responds locally to the loading conditions of the prevailing environment. Our data support the hypothesis that local and specific changes occur in both material and structural adaptation of bone to new loading conditions.

Cortical bone Adaptation is greater at the Metaphysis than Diaphysis. Annette Birkhold*[1], Hajar Razi[1], Georg Duda[1], Sara Checa[1], Bettina Willie[2]. [1]Julius Wolff Institute, Charité Universitätsmedizin Berlin, Germany, [2]Charité- Universitätsmedizin Berlin, Germany

Age-related bone loss is a major clinical problem that occurs already during adulthood, at which time it mainly affects trabecular bone. It is unclear whether cortical bone at the metaphysis compensates for the loss of trabecular bone to maintain the bone's ability to withstand external loading. We hypothesized that metaphyseal cortical bone has a greater adaptive capacity than diaphyseal cortical bone, load-induced bone formation would be higher and resorption lower.

Six female 26wk old C57Bl/6J mice underwent 2 weeks of in vivo cyclic tibia loading (*216 cycles/day; f = 4 Hz; Fmax = -11 N; εmax = 1200 μstrain*, right tibia internal control). In vivo microCT (10.5μm) was performed at day 0, 5, 10, and 15. The metaphyseal region began below the growth plate and the diaphyseal region was centered at the midshaft, both extended 5% of tibia length. Images were aligned using rigid registration, binarized and separated into trabecular and cortical regions. Static measure included: cortical volume (ctBV) and mean cortical thickness (ctTh). Dynamic measures of bone formation/resorption included: volume (fBV/tBV, rBV/tBV), surface area (fSA/tSA, rSA/tSA) and thickness/depth (fTh, rTh). Local strains were determined using a FE model, validated by strain gauge data (day 0, n=7 mice). An ANOVA assessed effects of loading, region, and interactions.

In the nonloaded control tibia, (re)modeling at all time points (fBV/tBV, fSA/tSA, rBV/tBV, rSA/tSA) was greater at the metaphysis than at diaphysis. Loading increased metaphyseal cortical bone formation (ctBV, all time points, fBV/tBV and fSA/tSA at 5, 10d) and fTh at 10, 15d), but did not alter resorption. Loading increased diaphyseal cortical bone formation (ctTh and ctBV at 10, 15d, fBV/tBV and fSA/tSA at 5, 10, 15d) and reduced resorption (rBV/tBV at 10, 15d).The cortical bone location affected the response to loading: formation increased more with loading in metaphysis compared to diaphysis (fBV/tBV, fSA/tSA, fTh); rSA/tSA decreased more in diaphysis. Local maximal strain was similar in both regions: 1400 ± 950 με at diaphysis and 1100 ± 740 με at metaphysis.

These data indicate that metaphyseal cortical bone has a greater mechano-reponsiveness than diaphyseal cortical bone. The resulting increased formation in metaphysis may compensate for the loss of trabecular bone and maintain the ability of the metaphyseal region to withstand external loading with diminishing trabeculae with increasing age.

Distinguished Density and Structure Analysis of the Distal Radius under the Aspects of Trauma Surgery. Volker Kuhn*[1], Gerald Degenhart[1], Thomas Müller[2], Felix Eckstein[3], Martin Lutz[1]. [1]Medical University Innsbruck, Austria, [2]ETH Zürich, Switzerland, [3]PMU Salzburg, Austria

Knowledge of the mechanical competence of osteoporotic bone is a big challenge in the surgical treatment of fragility fractures in the distal radius. Due to the thin cortical bone fracture fixation occurs predominantly in the trabecular compartment.

Purpose of this study was to compare DXA, HR-pQCT and loads from a biomechanical fall simulation upon the outstrechted forearm.

156 forearm specimens were harvested from formalin-fixed cadavers (mean age: 79.5+/-10.3; ranging 52-100; 82 male; 44 female). 21 were excluded due to former fractures.

DXA scans (pDEXA; Norland/Stratec) were analyzed within the clinically typical ROIs, and trabecular analyses from HR-pQCT data (Scanco) were performed for different distal and ultradistal slices. Under the aspect of usual surgical approaches, there was an additional division in dorso-palmar aligned halves and thirds for the slices, respectively.

According T-score 33% of the specimens presented normal bone quality, 37% were osteopenic, and 30% osteoporotic. Failure loads ranged from 250N to 5038N and were 43% higher in males (2645+/-1097N) compared with females (1512+/-711N). Fractures were comparable with types seen clinically.

DXA vs. failure loads provided the highest correlations (BMC: r = 0.806; BMD: r = 0.781). Structure parameters (Tb.N., Th.Th., Tb.Sp.) of the variably placed trabecular slices correlated only slightly smaller (r = 0.65 to 0.70) with the failure loads, especially for the density related parameters (BV/TV and app. density) (r = 0.75 to 0.77). Highest values were found close-by the subchondral plate. A central placed cylindric ROI presented only moderate correlations (r = 0.54 to 0.66).

Comparing palmar and dorsal subregions of the trabecular bone in the distal radius, the palmar compartment provided 6 to 10% higher values for density based parameters. Under this aspect it might make sense to favour the palmar side in the case of surgical treatment of fragility fractures. On the other hand, the surgeon has always to consider the individual fracture type concerning his approach.

Evaluation of Bone Mineral Density and Bone Strength in Autochthonous Transgenic Mice for Diabetes Mellitus (Akita mice). Kentaro Ohuchi*, Naohisa Miyakoshi, Yuji Kasukawa, Koji Nozaka, Toyohito Segawa, Hayato Kinoshita, Yoichi Shimada. Akita University Graduate School of Medicine, Japan

Introduction: It is widely known that diabetes mellitus (DM) causes osteoporosis or bone fragility. However, detailed analyses of bone mineral density (BMD) or bone strength changes in type II DM have not been done to date. Akita mice (AM) spontaneously present severe diabetes and are a model of non-obese type II DM in humans. These mice are used to investigate mechanisms of type II DM complications, and to evaluate the effects of medication. However, the evaluation of bone in Akita mice has yet to be performed. The objective of this study was to evaluate the effects of type II DM on BMD and bone strength in Akita mice.

Materials and Methods: Akita mice and control mice (C57/BL/6NCrSlc: CM) were used in this study. Left tibias and right femurs were harvested from both genders (AM-male: n=7, AM-female: n=10, CM-male: n=7, CM-female: n=10) at the age of 14 weeks. BMD with dual energy X-ray absorptiometry was measured in the left tibia, and the right femur was evaluated for bone strength by three-point bending tests at the midshaft.

Results: The BMD of the AM-group was significantly lower than that of the CM-group (male: p=0.0088, female: p=0.0006). Moreover, in the AM-group, the BMD of the female mice was significantly lower than that of the male mice (p=0.0226). The breaking force of the AM-group for the three-point bending tests was significantly lower than that of the CM-group (p=0.041) in females, but not in males. On the other hand, the maximum load of the AM-group was significantly lower than that of the CM-group (p=0.0168), but only in males. Breaking deformation and breaking time in the AM-group were higher than in the CM-group, but the differences were not statistically significant (p=0.0719-0.0789).

Conclusion: BMD and bone strength in the AM-group were significantly lower than in the CM-group in the present study. Thus, prolonged hyperglycemia in type II DM might lower BMD and bone strength. Akita mice may be a useful model to evaluate bone metabolism in type II DM.

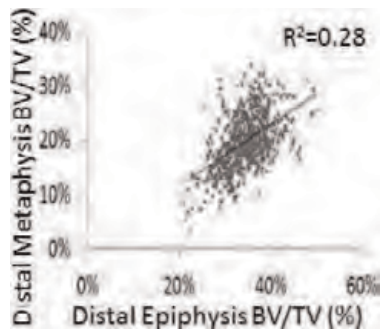
Genetic Regulation of Bone Morphology is Strongly Non-Uniform within a Single Bone. Jeyantt Srinivas Sankaran*[1], Svetlana Lublinsky[1], Weidong Zhang[2], Leah Rae Donahue[2], Stefan Judex[1]. [1]Stony Brook University, USA, [2]Jackson Laboratory, USA

Genetic variations are the primary determinant of differences in bone morphology across individuals. These relationships have typically been established for a specific skeletal site. While the genetic influence on one bone can, at least in part, transfer to other sites within the skeleton, little is known about the uniformity of the genetic influence within a single bone. To this end, we tested whether the degree of the genetic contribution is similar across functionally similar, as well as contiguous regions within the mouse femur. Two inbred strains with distinct bone morphology, BALB/cByJ and C3H/HeJ, were double-crossed to produce genetically heterogeneous offspring. Six different anatomical sites within the femur of each of the F2 male mice were analyzed via μCT and variables indicative of bone quantity, architecture, and tissue density were correlated across six regions containing trabecular and cortical bone (head, neck, proximal and distal metaphysis, diaphysis, distal epiphysis). When limiting correlations across all mice to the two regions that are functionally the most similar, the proximal and distal metaphysis, R2 values for trabecular indices ranged from 0.06 for Tb.N to 0.32 for BV/TV. Reflecting these low correlations, mice that were at the 95th and the 90th percentile for trabecular number and connectivity density in the proximal metaphysis were as low as the 50th and 25th percentile in the distal metaphysis for the same variables. Correlations of cortical indices between these two regions were similarly low (R2=0.06-0.37 for Ct.Th-Ct.Ar). Mice at the 95th percentile for cortical area and cortical thickness at the distal metaphysis were as low as the 5th percentile at the proximal metaphysis. Focusing the correlations on two regions that are spatially separated by less than 1mm, the distal metaphysis and epiphysis, R2 values remained low for both trabecular (0.11-0.28) and cortical (0.06-0.28) variables. Expanding the correlations across all anatomical sites considered here did not significantly improve the coefficients of determination for either trabecular or cortical bone. Correlations between trabecular BV/TV and cortical area at any given site were low, indicating a low level of co-regulation. Even when considering environment-gene interactions, these data suggest a strongly non-uniform genetic regulation of trabecular and cortical bone morphology with potential implications for the detection and treatment of osteoporosis.



Correlation of BV/TV between the distal epiphysis and metaphysis

In silico simulations of bone remodeling with improved parameter estimation from local strains and dynamic morphometry in vivo. Alina Levchuk*[1], Remo Sommer[2], Sandro D. Badilatti[2], Friederike A. Schulte[2], Davide Ruffoni[2], Claudia Weigt[3], Gisela Kuhn[2], Ralph Müller[2]. [1]ETH Zurich, Switzerland, [2]ETH Zurich, Insitute for Biomechanics, Switzerland, [3]ETH Zurich, ETH Phenomics Center, Switzerland

Today, in silico simulations allow prediction of bone remodeling over time. A recent study on the algorithm validation using a mouse model of bone adaptation showed good agreement between in vivo and in silico outcomes. Yet, such simulations typically have a number of input parameters that must be defined, and thus cannot account for physiological differences in animals. We hypothesized that estimation of these parameters directly from in vivo measurements at the onset of the study would improve the simulations. For the study, C57Bl/6 mice were ovariectomized or sham operated at week 15 (OVX, SHM). At week 26, the 6th caudal vertebra was loaded (8N, 3000 cycles, 10 Hz, 3/wk, 4 wks). In vivo micro-CT scans were taken at weeks 26, 28 and 30. Formed, quiescent, and resorbed areas of bone were identified from in vivo scans. In silico parameters for formation and resorption set points were derived from strain energy density (SED) distributions calculated using micro-finite element analysis. Maximum remodeling rates were set directly from the in vivo dynamic morphometry. Finally, parameters controlling remodeling sensitivities to SED were selected iteratively within the algorithm. Condition-specific mechanostat curves were based on the selected parameters. Simulations were compared to in vivo data using local surface evaluation as well as static and dynamic morphometry, followed by repeated measures ANOVA. Results showed that cyclic loading decreased remodeling sensitivity more than twofold, while increasing remodeling set points. This led to the emergence of an SED range at which bone remained quiescent, corresponding to a "lazy zone". Ovariectomy also lowered remodeling sensitivity and increased thresholds. Deriving in silico input parameters directly from these calculations reduced prediction errors in the simulations. Static morphometry was not significantly different between experiment and simulations, except for trabecular thickness in the loaded OVX group. For dynamic morphometry, only bone resorption rate showed significant differences ($p<0.05$). Neighborhood comparison of local remodeling sites produced matches greater than 50%. These results indicate that accurate simulation of bone remodeling can be achieved through incorporation of in vivo derived parameters measured at the onset of the study. Modified mechanostat curves translate physiological differences in animals into computational terms, thus allowing improved prediction of biological processes.

Inequivalence in Functional Morphology among Individuals: An Intraskeletal Investigation into Covarying Traits. Stephen Schlecht*, Karl Jepsen. University of Michigan, USA

Previous investigations found tibial robustness (i.e. total bone area relative to length) to significantly covary with cortical tissue mineral density (Ct.TMD) and cortical area (Ct.Ar). Moreover, varying tibial robustness and strength was found to be inadequately compensated for via the adjustment of Ct.TMD and Ct.Ar, resulting in a variable degree of functional inequivalence. How these traits covary across bones and whether the degree of functional inequivalence in these traits is consistent throughout the appendicular skeleton is unknown.

Using pQCT, the level of covariance among robustness, Ct.Ar, and Ct.TMD was assessed in the femoral, tibial, humeral, radial, and 2nd and 3rd metacarpal diaphyses of 115 male and female young adult cadavers. Significant covariance between traits within all bones was observed, finding that slender bones are predictably 5-8% higher in Ct.TMD and 25-50% lower in Ct.Ar compared to robust bones. The attainment of similar trait sets was consistent throughout the skeleton irrespective of body size and the weight-bearing status of the bone (Fig 1A). Thus, individuals with more/less Ct.Ar or higher/lower Ct.TMD in one long bone, relative to robustness and body size, demonstrated the same impairment throughout their skeleton, except within the metacarpi. Additionally, Ct.TMD ($r = 0.79$-0.66, $p < 0.0001$) and Ct.Ar ($r = 0.71$-0.29, $p < 0.05$), in all bones except the metacarpi, significantly varied in a predictable manner across skeletal elements, regardless of body size and robustness (Fig 1B and C). Bones that were slender were as much as 2x less stiff for body size compared to those that were more robust ($R^2 = 0.52$-0.79, $p < 0.0001$). This functional inequivalence was relatively consistent and significantly predictable throughout the skeleton, suggesting that there are intrinsic (biological) limitations to the functional adaptation process that are responsible for naturally varying strength among individuals. How this limitation can be dealt with clinically remains unknown.

These findings indicate that robustness trait sets naturally vary among individuals in a systemic fashion. This variation is of a significant magnitude, warranting consideration of functional inequivalence between traits when clinically assessing an individual's susceptibility to fracture. Better understanding of how these traits covary will help to identify genetic and environmental perturbations contributing to diminished bone accrual.

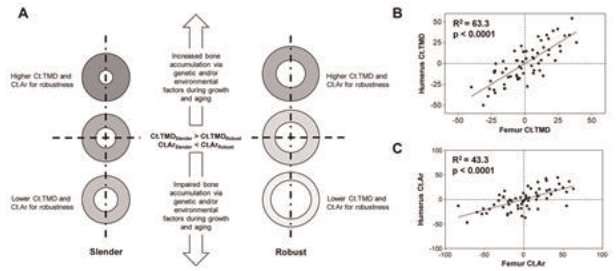

Figure 1. Trait covariance of slender and robust phenotypes. A) schematic diagram demonstrating the variation in robustness, Ct.TMD, and Ct.Ar between males and females within the study population; B) linear regression of Ct.TMD values adjusted for body size and robustness between male femora and humeri; C) linear regression of Ct.Ar values adjusted for body size and robustness between male femora and humeri.

Measuring Bone Heterogeneity with Raman Spectroscopy to Explain Aging Differences in Human Fracture Toughness. Alexander Makowski*[1], Sasidhar Uppuganti[2], Ahbid Zein-Sabatto[2], Jack Whitehead[2], Mathilde Granke[3], Anita Mahadevan-Jansen[2], Jeffry Nyman[3]. [1]Department of Veterans Affairs, Vanderbilt University, USA, [2]Vanderbilt University, USA, [3]Vanderbilt University Medical Center, USA

Heterogeneity is thought to be an important determinant of bone quality, but how compositional or organizational heterogeneity influences the age-related decrease in fracture resistance is unclear. Because Raman spectroscopy (RS) is sensitive to the orientation and composition of both mineral and collagen, it was used to assess these relationships between tissue heterogeneity and age-related decreases in fracture resistance.

Bone samples were cut from the distal lateral midshaft of 9 cadaveric femurs (males age 24yo to 91yo) and polished to create 3pt bend notched beam specimens. Following ASTM standards for fracture toughness testing, stress intensity factor K_{Ic} and J-integral were calculated from force-displacement curves where the crack was propagated against the osteonal axis.

For each sample, RS maps (32x32 samples) were obtained on the polished surface normal to crack propagation at an osteonal-interstitial border for 0 and 90° rotations. RS peak ratio intensity was analyzed for mineralization, crystallinity, and carbonate substitution. Peak ratio heterogeneity was quantified as image contrast (histograms), mean intensity value, and the coefficient of variation (COV). Linear regressions of ratio intensity mean and COV were used to explain fracture toughness.

RS peak ratio maps of composition (polarization insensitive) –mineralization (v1 Phosphate/Proline, v2 Phosphate/AmideIII), carbonate substitution (Carbonate/ v1 Phosphate) and crystallinity ($FWHM^{-1}$ v1Phosphate)– illustrate contrast between the osteon and interstitial space only at high J-integral values. This suggests that compositional heterogeneity between osteonal and interstitial space fades with the age-related decrease in fracture toughness. Mapping a peak ratio that is influenced by tissue organization (v1 Phosphate/Amide I) further reveals lamellar contrast, but only in specimens with high fracture toughness.

High J and high K_{Ic} correspond to bivariate and platykurtic histograms, respectively; regardless of histogram shape, lack of heterogeneity corresponds to low fracture toughness. Multivariate regressions using the mean and COV of mineralization or carbonate substitution each significantly (F test; $p<0.05$) explain K_{Ic}. Regressions of COV only for v1 Phosphate/Amide I or crystallinity ($FWHM^{-1}$ v1 Phosphate) each significantly explain J integral. Increases in both compositional and organizational heterogeneity of bone separately correspond to increases in fracture toughness.

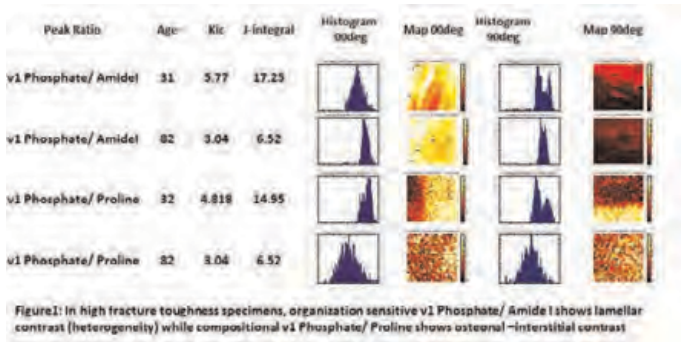

Figure1: RS Maps Explain Fracture Toughness

Non-Collagenous Proteins in Genetically Modified Mice Exercise a Control on Bone Size and Shape. Stacyann Morgan*[1], Atharva Poundarik[2], Caren Gundberg[3], Deepak Vashishth[1]. [1]Rensselaer Polytechnic Institute, USA, [2]Rensselaer Polytechnic University, USA, [3]Yale University School of Medicine, USA

Osteocalcin (OC) is the most abundant non-collagenous protein (NCP) in bone. It is produced during bone formation, late after mineralization by osteoblasts and forms a complex with Osteopontin (OPN) and other molecules in the extra-cellular matrix. Both OC and OPN controls mineral size and orientation. Recent studies in our laboratory showed that the OC-OPN complex regulates bone toughness through its control over matrix quality. Such control may also help in determining bone size. Therefore, we investigated whether these proteins play a role in regulating bone size and shape.

Radii from male 6 month old $OC^{-/-}$, $OPN^{-/-}$, $OC\text{-}OPN^{-/-;-/-}$ and Wild Type mice (n=12 per group) were separated from the ulna and stored in saline soaked gauze at -80 C until use. Samples were scanned using μCT with a 10.5 μm voxel size (μCT 40; Scanco Medical) in saline eppendorf tubes. Bone geometry was determined from the mid-shaft of each sample and the parameters measured were: length, moment of inertia, cross-sectional area (CSA), cortical thickness and bone mineral density (BMD). Differences between the groups were tested for significance using one-way ANOVA ($p<0.05$) with post-hoc Tukey multiple comparison test (SigmaPlot11.0).

The ANOVA results showed that double knockouts were shorter (10.08 mm, $p=0.005$) with thicker cortices (0.160 mm, $p=0.017$) and larger CSA(0.270 mm^2, $p=0.005$) compared to WTs. There was no statistically significant difference between single and double knockouts or single knockouts and WTs for the above traits. ANOVA showed lack of significant difference between the groups ($p=0.095$) for BMD. Individual groups were therefore compared using t-tests. BMD values of double knockouts (1185.20 mgHA/ccm) and $OC^{-/-}$ (1177.80 mgHA/ccm) were both significantly higher than WT (1160.30 mgHA/ccm) with $p<0.05$, but there were no differences between the other groups.

Taken together, this study demonstrates for the first time that Osteocalcin and Osteopontin play a redundant role in regulating bone size (length, cortical thickness and cross-section area) where the absence of OC is compensated by OPN and vice versa. BMD, in contrast, is regulated only by Osteocalcin.Acknowledgements: NIH RO1 AR38460 and AR 49635

Physical Activity Producing Loads from Diverse Orientations Enhances Growing Bones. Ian Wallace*[1], Brigitte Demes[1], Stefan Judex[1], Andrea Kwaczala[1], Kristian Carlson[2]. [1]Stony Brook University, USA, [2]University of the Witwatersrand, South Africa

Objective: An experiment was conducted to determine if emphasizing habitual activities that produce loads from diverse directions can augment the growing skeleton. Methods: At 4 weeks postnatal, female C57BL/6J mice were housed individually for 3 months in custom-built cages with tunnel apparatuses that accentuated either non-linear locomotion (diverse-orientation loading) or linear locomotion (stereotypic-orientation loading) (n=10 animals per cage type). Daily behavioral assessments were performed throughout the experimental period to quantify home-cage activity level and profile. At the end of the experiment, trabecular bone morphology in the humeral head and distal femoral metaphysis were assessed with micro-CT. Results: Throughout the experiment, groups did not differ in cage activity level or profile. Yet, at the end of the experiment, animals that experienced more diverse-orientation loading had 12% greater bone volume fraction in the proximal humerus (p=0.004) and 24% greater bone volume fraction in the distal femur (p=0.04). In both skeletal regions, group differences in bone volume fraction were primarily the result of differences in trabecular thickness. Conclusions: Diverting habitual physical activities to involve loading from more diverse directions can enhance the growing mouse skeleton. This study suggests that low-intensity physical activities that engender loads from diverse directions may be a viable alternative to vigorous, high-impact activities as a way to improve skeletal health during the growing years. Our results may also be pertinent to the designs of physical activity regimens aimed at stemming bone loss in adults, particularly frail individuals for whom intense exercise imposes a high risk of injury.

RANKL and OPG Administration Influence the Pattern and Location of Fractures Created During Biomechanical Testing of Intact and Fatigued Mouse Tibia. Nicolas Bonnet*[1], Paul Kostenuik[2], Mike Ominsky[3], Serge Ferrari[4]. [1]University Geneva Hospital-Department of Internal Medecine Specialities, Switzerland, [2]Amgen Inc., USA, [3]Metabolic disorders, Amgen Inc., USA, [4]Geneva University Hospital & Faculty of Medicine, Switzerland

The pattern and anatomical location of long bone fractures can depend on the loading type, bone mass, structure, and potentially accumulation of prior damage. We sought to discern how these factors might influence fracture patterns by inducing fatigue damage in low- and high bone mass states caused by osteoclast activation or inhibition, respectively.

Adult male mice were treated with RANKL (2mg/kg/day), OPG-Fc (5mg/kg 2x/week) or PBS (Veh) for 28 days prior to fatigue loading of one tibia for 20 minutes by in vivo axial compression (14N, 4 Hz). Treatments continued for 1 week, and fatigued and non-fatigued (NF) tibiae were collected for microCT and destructive axial compression testing. The resulting test-induced fracture was evaluated by caliper measures of the greatest (Dmax) and lowest (Dmin) distances from the proximal tibial plateau to the fracture site. Fracture location was assessed by Dmean (average of Dmax and Dmin), and fracture pattern (obliqueness) by Dmax-Dmin (Delta). Crack number per cortical bone area (CrN/BA) was investigated by fuchsin staining of proximal and distal transverse sections located 2 and 8mm from the plateau, respectively.

In the NF tibia, RANKL decreased Tb.BV/TV, CtTh and Dmean (-94.9%, -32.3%, -47.5%, $p<0.001$) and increased Delta (+152%, $p<0.01$) compared to Veh, indicating that with high bone remodelling and low bone volume the fracture was more proximal and oblique. OPG-Fc treatment of NF tibia increased BV/TV and CtTh vs Veh (+58.5% and +3.4%, $p<0.01$) without modifying Dmean or Delta. Fatigue increased CrN/BA, with RANKL>Veh>OPG in the proximal section and RANKL>Veh=OPG distally. In Veh controls, fatigued tibiae exhibited test-induced fractures that were more proximal (Dmean -18%, $p<0.05$) and oblique (Delta +376%, $p<0.05$) compared to NF tibia. In contrast, with OPG-Fc, Dmean and Delta did not differ between fatigued and NF tibia, with fractures in both states occurring more distally and more transversely vs Veh controls. Similar to their NF tibia, fatigued tibia from RANKL animals fractured more proximally (Dmean -31.9%, $p<0.05$) and obliquely compared to the fatigued Veh. Across groups, linear regression analysis demonstrated that fracture location was better associated with proximal aBMD($R=0.75$) than with diaphyseal damage (CrN/BA, $R=0.55$).

These observations suggest that the location and obliqueness of a test-induced fracture can be modulated by fatigue damage, and by changes in bone remodelling rate and/or bone mass.

The involvement of tumor necrosis factor-α in osteoclast differentiation induced by mechanical stress in a murine maxilla loading model. Kengo Fujiki*[1], Noriyuki Wakabayashi[2], Natsuki Suzuki[2], Libor Borák[3], Keiichi Ohya[1], Kazuhiro Aoki[1]. [1]Tokyo medical & dental university, Japan, [2]Department of Removable Partial Prosthodontics, Graduate School, Tokyo Medical & Dental University, Tokyo, Japan, [3]Institute of Solid Mechanics, Mechatronics & Biomechanics, Brno University of Technology, Czech Republic

Introduction: Mechanical loading at the residual ridge by denture is known to induce bone resorption in the jaw bone of edentulous patients. Although animal studies show that inflammatory cell infiltration appears near the site of mechanical loading in the jaw bone, it is not still clear whether the denture-bearing-bone-resorption promotes by loading-induced inflammation or not. The aim of this study is to clarify the involvement of tumor necrosis factor-α in osteoclast differentiation appeared at the site of mechanical loading.

Materials and Methods: The thirteen-week-old male TNF-α-deficient mice (n=8) and C57BL/6 mice as a wild type (WT) mice (n=8) were used in this study. Both kinds of mice were divided into two experimental groups, 1) mice with loading stimulation (n=4) and 2) without loading stimulation (n=4) to the maxilla. Each mouse was fixed on the loading device and was subjected to continuous pressure on the hard palate region of 2kPa or 0 kPa for 30min/day for 7 consecutive days (See figure). Mice were sacrificed on 16 hours after the last loading and bone histomorphometric analyses were performed by using the cross sections of maxilla.Two measuring regions for bone histomorphometry were set as ROI1 and ROI2 (See figure). ROI1 was set close to the loading site and ROI2 was set far from the loading site. Both ROI1 and ROI2 were proven to bear a similar mechanical stress by using finite element analyses.

Results: A significant increase of inflammatory cell infiltration was appeared in the ROI1 of WT mice, whereas ROI2 of WT mice and ROI1 and 2 of TNF-α-deficient mice showed no significant increase of those cells. Bone histomorphometric analyses revealed that the number of osteoclasts(N.Oc/BS) was increased 6.8 times higher by the mechanical loading than that of no loaded group in ROI1 of WT mice, whereas it was just 2-3times increase by the same loading schedule in ROI2 of WT mice and in ROI1 and ROI2 of TNF-α-deficient mice. The increasing rate of eroded surface (ES/BS) by the mechanical loading also showed the same tendency as that of N.Oc/BS.

Discussion and conclusion: These results suggest that the bone resorption in jaw bone induced by mechanical loading could be accelerated by inflammation, possibly via the TNF-α-related mechanism, hopefully leading to the future development of therapeutic interventions against unexpected bone resorption of jaw bone induced by mechanical loading by use of denture in edentulous patients.

The Relationship Between Microscopic Damage Accumulation and Impaired Biomechanical Performance in Cancellous Bone Under Fatigue Loading. Floor Lambers*[1], Amanda Bouman[1], Kristin Regan[1], Clare Rimnac[2], Christopher Hernandez[1]. [1]Cornell University, USA, [2]Case Western Reserve University, USA

Stress fractures associated with osteoporosis are believed to develop over time as a result of the accumulation of microscopic tissue damage during cyclic loading. While an increase in the number of microcracks has been associated with stiffness loss in cortical bone, few studies have investigated the effects of microscopically observed microdamage on biomechanical performance in cancellous bone. The aim of the current study was to determine the relationship between the amount of fatigue loading, the accumulation of microdamage, and reductions in specimen stiffness during cyclic loading of human cancellous bone.

Cancellous bone cores (n=34, 8 mm diameter) from the third lumbar vertebra of 16 donors (10 m, 6 f, age 76±8.8) were subjected to compressive fatigue loading, using a sinusoidal waveform between 0 N and a normalized load (σ/E_0 of 0.0035 mm/mm, where E_0 is the initial Young's modulus determined from preconditioning). Fatigue loading was stopped before failure based on the slope of the fatigue curve at 1 of 7 different predetermined regions (Fig. 1). The relation between mechanical parameters and fatigue life was estimated from the average fatigue curve to failure. After cyclic loading, specimens were stained for microdamage using lead-uranyl acetate and scanned with μCT at a voxel size of 10 μm to determine damage volume per bone volume fraction (DV/BV).

DV/BV varied from 0.9±0.5% (mean±SD) in the group with no loading to 3.4±2.1% in the group loaded to complete failure. DV/BV waslinearly related to the reductions in Young's modulus caused by fatigue loading (Fig. 2). Creep strain, cyclic strain, and energy dissipation increased almost linearly in the secondary phase and exponentially in the tertiary phase.

Our data express the biomechanical meaning of previously reported measures of naturally occurring microscopic damage in human cancellous bone. Our results suggest that an observed DV/BV of 2% caused by fatigue loading is on average associated with a 40% reduction in Young's modulus and a 10-fold reduction in fatigue life. In addition to impairing fatigue life and contributing to stress fractures, microdamage accumulation may reduce the ability to resist overloads due to falls or heavy lifting.

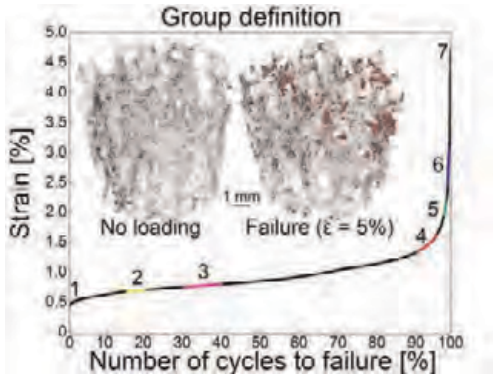

Fig1: Fatigue curve with regions where loading was stopped for the 7 groups. Damage (red) in bone

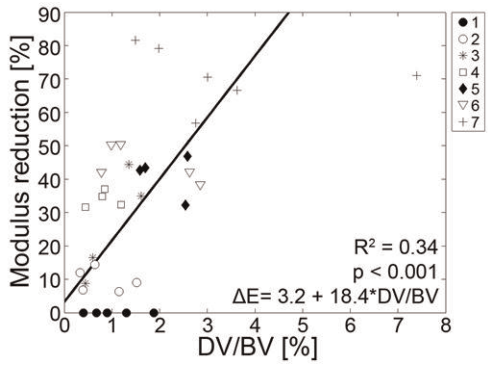

Fig2: Linear association between DV/BV and reduction in Young's modulus. Symbols indicate groups.

Tissue-scale Bone Mechanical Behavior Varies between Measurement Sites and Mouse Strains. Pinaki Bhattacharya*[1], An-Katrien Braeken[1], Michael Laurent[2], Dirk Vanderschueren[3], Steven Boonen[4], Harry Van Lenthe[5]. [1]Biomechanics Section, KU Leuven, Belgium, [2]Laboratory of Molecular Endocrinology & Gerontology & Geriatrics, KU Leuven, Belgium, [3]Catholic University of Leuven, Belgium, [4]Center for Metabolic Bone Disease & Division of Geriatric Medicine, Bel, [5]Katholieke Universiteit Leuven, Belgium

Reference-point indentation (RPI) is a novel technique for in vivo assessment of bone tissue mechanical properties. Similar to nanoindentation, the elastic response of bone tissue is related to the average unloading slope (US) of an RPI measurement, while the total indentation distance (TID) is a measure of the tissue inelastic behavior combining elasticity, plasticity, viscoelasticity and damage. Yet, the significance of RPI parameters in determining fracture risk is unclear; furthermore, potential site-specific variations have not received attention. Therefore, the aim of this study was to quantify US and TID at multiple locations within a specific bone in two inbred mouse strains with known bone morphological differences.

Left tibiae from 7 C57BL/6 (B6) mice and left and right tibiae from 7 C3H/He (C3H) mice were excised. All mice were male and 12 weeks of age. RPI tests were performed at three anatomical regions labeled R1, R2 and R3 (Fig. 1) using the BioDent (Active Life Scientific, Santa Barbara, CA) using a maximum force of 2 N and 10 indentation cycles/measurement. Three measurements were made at R1, two at R2, and two at R3. The measurements were calibrated against those on PMMA. Wilcoxon rank-sum test was used to test for significant differences in US and TID between strains and between anatomical sites.

Site-specific variation in US and TID was found in B6 and C3H (Fig. 2). For left tibiae in each strain, US at R2 was lower than US at R1 and R3 ($p < 0.05$). In left tibiae of B6, TID at R1 was lower than TID at R2; in right tibiae of C3H, TID at R1 was lower than TID at both R2 and R3. Furthermore, inbred strain-specific variation in US was found comparing only the left tibiae; for each of the three sites, US in C3H was higher than US in B6 ($p < 0.01$). In C3H, no left–right differences in US were found ($p > 0.40$). However, TID at sites R2 and R3 were higher on the right tibiae than TID at R2 and R3 respectively on the left tibiae ($p < 0.05$).

We conclude that RPI could detect differences in US between B6 and C3H mice. The higher US in C3H agrees with the higher modulus in C3H as measured in tensile testing tests[1]. The different response of the left and right tibiae needs confirmation. The site-specific variation may relate to growth patterns in these bones and could be helpful in evaluating fracture behavior of these bones.

Trabecular Bone Matrix Composition in Cynomolgus Monkeys Treated with Sclerostin Antibody. Ryan Ross*[1], Michael Ominsky[2], Alvin Acerbo[3], Lisa Miller[3], D. Rick Sumner[1]. [1]Rush University Medical Center, USA, [2]Amgen Inc., USA, [3]Brookhaven National Laboratory, USA

Sclerostin antibody (Scl Ab) leads to increased bone formation, but the effect of Scl Ab treatment on bone matrix mineralization is largely unknown. We sought to determine if Scl Ab treatment affected global mineralization or the rate of matrix maturation in a primate model.

Lumbar vertebrae (L2) from a previous fibular osteotomy study in which 4-5 year old male cynomolgus monkeys were treated with vehicle or 30 mg/kg Scl Ab (romosozumab) once every 2 weeks for 10 weeks (n=10 per group) were used. Global bone mineral density distributions (BMDD) were assessed using backscattered SEM. Mineralization kinetics were assessed by examining tissue between fluorochrome labels which had been given 0.5, 2, 6.5 and 8 weeks prior to sacrifice with Fourier-transform infrared microspectroscopy.

Scl Ab treatment led to 42% more trabecular bone volume (p=0.001). The mean global mineralization was 0.8% lower in the Scl Ab group, although not significant (p=0.097). The standard deviation of the BMDD was 9% lower in the treated animals (p=0.012) without affecting skewness. The number of highly mineralized bone pixels was reduced (p=0.035) with only a marginal increase in low density pixels (p=0.092). Scl Ab caused a 2-fold increase in BFR/BS (p=0.009), and a 46% reduction in the eroded surface (p=0.014). Local analysis of tissue mineralization (mineral-matrix ratio) for tissue of known age showed a significant tissue age effect ($p<0.001$) with no difference between groups. Specifically, the tissue between 0.5 and 2 weeks old was ~80% mineralized, and the tissue between 2 and 8 weeks old was >90% mineralized compared to the oldest tissue (>8 weeks).

BMDD is related to both the average tissue age and the rate of matrix mineralization. Even though a larger fraction of the tissue in the Scl Ab group was young compared to the control group, there was only a small non-significant lowering of mean global mineralization, which would seem to imply that the rate of mineralization must have been accelerated. However, direct examination of tissue of known age showed that Scl Ab treatment did not affect mineralization kinetics despite the elevated bone formation rate. The finding that newly formed bone in the control animals had already reached 80% of its mineralization potential within 0.5 to 2 weeks suggests rapid inherent mineralization within the trabecular bone of cynomolgus monkeys, but ultimately the mineralization process was unaffected by Scl Ab treatment.

Alterations of Gene Expressions of Osteogenic Growth Factors and Transcription Factors in Response to Dynamic Fluid Flow Stimulation. Minyi Hu*[1], Yi-Xian Qin[2]. [1]Stony Brook University, USA, [2]State University of New York at Stony Brook, USA

Non-pharmaceutical interventions with mechanotransduction approaches are promising in promoting bone formation. We have shown that a dynamic hydraulic stimulation (DHS) is capable to induce osteogenic responses. Subsequent research points to the functional process of how DHS-derived mechanical signals act on bone cells to regulate bone metabolism. The objective of this study was to evaluate the alterations of the gene expressions of osteogenic growth factors and transcription factors in response to DHS over time. Using hindlimb suspended (HLS) female SD rats, DHS was applied to the right tibiae with a loading frequency of 2Hz and a magnitude of 30mmHg static pressure+30mmHg (p-p) dynamic pressure. The daily loading regime was "10 min on–5 min off–10 min on" over a time course of 3, 7, 14, and 21 days. Rats in the 3-day group were stimulated for 2 days; and the rats in the other groups were stimulated for 5 days/week. According to the time points, animals were sacrificed and the total RNA was isolated from the tibiae for quantitative real-time PCR analysis of the selected osteogenic genes (RUNX2, β-catenin, osteopontin, VEGF, BMP2, IGF-1, and TGF-β). Interesting data indicated a time-dependent fashion of gradual changes in mRNA levels in response to DHS. Great reductions of the overall mRNA levels of the selected genes were observed in the HLS rats compared to the age-matched. On the other hand, while DHS-driven fold changes of the mRNA levels remained low before day 7, the fold changes started to elevate by day 14 (3.0 (RUNX2), 4.5 (β-catenin), 3.5 (osteopontin), 3.5 (VEGF), 3.7 (BMP2), 4.6 (IGF-1), and 3.2 (TGF-β)) and then became less pronounced by day 21 (Figure 1). This study indicated that the gene expressions of the selected osteogenic growth factors and transcription factors were altered in response to DHS. However, it was highly time-dependent. This study gave insights into the molecular mechanism of DHS-derived mechanical signals. Augmented external biomechanical stimulation, such as DHS in the present study, may trigger the recognition of mechanical signals by osteoblasts. The received signals then ultimately induce secretion of growth factors that act as local regulators for osteogenesis. Potent growth factors, including IGF, TGF-β, BMP and VEGF, strongly modulate the osteoblastic activities as well as other bone growth regulators. These genes play critical roles in the fate of osteoblastogenesis, which is crucial for bone formation.

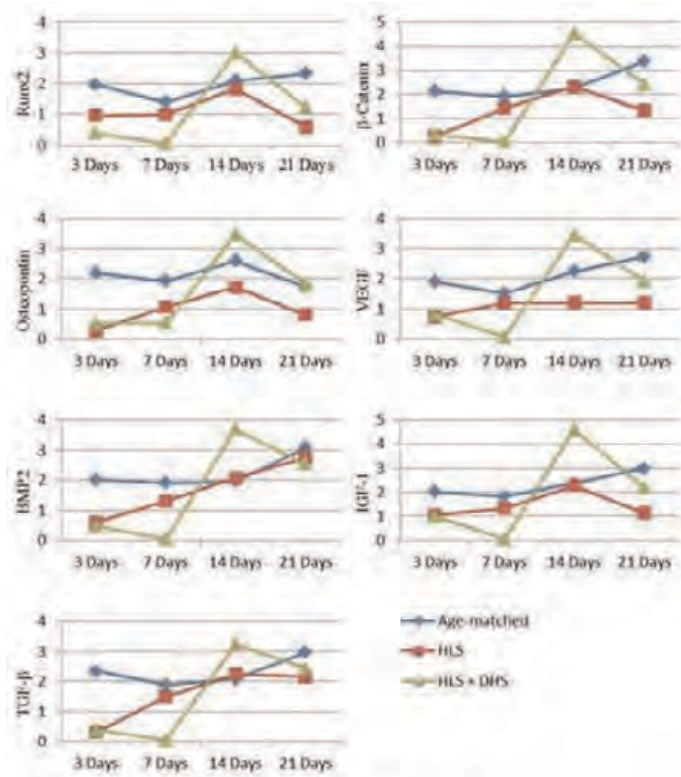

Figure 1. Summary of mRNA fold changes of the selected osteogenesis related genes over the 21-day time course. In general, the mRNA levels of the selected genes in the HLS groups attempted to catch up to the according age-matched levels. However, the mRNA levels of these genes in the HLS+DHS groups did not elevate until day 14.

Enhancement of Nucleo-Cytoskeletal Connectivity by Low Intensity Vibration Augments Mechanosensitivity in Mesenchymal Stem Cells. Gunes Uzer*[1], Buer Sen[2], Zhihui Xie[1], William Thompson[1], Maya Styner[3], Clinton Rubin[4], Stefan Judex[5], Janet Rubin[3]. [1]University of North Carolina, USA, [2]University of North Carolina At Chapel Hill, USA, [3]University of North Carolina, Chapel Hill, School of Medicine, USA, [4]State University of New York at Stony Brook, USA, [5]Stony Brook University, USA

Mechanical loading, including low intensity, high frequency vibration (LIV), improves bone strength through biasing of mesenchymal stem cell (MSC) lineage. *In vitro* application of both LIV (<0.001% substrate strain) and high-magnitude strain (1-2%; HMS) limits MSC adipogenesis via mTORC2/Akt/GSK3β induced increases in β-catenin. This signaling pathway is amplified at a second mechanical treatment; the amplification after HMS is dependent on increased cytoskeletal elements connected at cell attachments. Although virtually absent of strain, LIV is also amplified at a repeated bout. We hypothesized that signal amplification after LIV would be dependent on cytoskeletal changes distinct from those induced by HMS. To test this hypothesis, we applied 90Hz 0.7g LIV to marrow derived MSCs. A single bout of LIV showed insignificant induction of pAkt (Tyr-473) but a 2nd LIV bout increased pAkt to 169 ±37%. To test whether the 2nd LIV response was sensitive to the actin cytoskeleton, we replaced the 1st LIV bout with lysophosphatidic acid (LPA, 62.5 uM) to activate RhoA and actin connectivity. LPA increased both basal (194 ±40%) and LIV induced (383 ±110%) pAKT. Similarly, FAK activation (pFAK, Tyr-397), also induced by LIV, was increased to 266 ±130% after a 2nd LIV tx, and to 671 ±34% when LIV followed an LPA pretreatment, adding evidence for a cytoskeletal role in signal enhancement. As well, disrupting the cytoskeleton with cytochalasin-D reduced basal (10-fold) and LIV-induced (62%) pFAK. In contrast, preventing microtubule polymerization with colchicine did not prevent LIV responses. Importantly, actin and vinculin staining showed that, in contrast to the stress fibers forming following HMS that arc between peripheral focal adhesions (FAs), LIV induced formation of short actin fibers which spanned from the nucleus to peripheral FAs. These results suggest that LIV induces a cytoskeletal reorganization typified by nucleo-cytoskeletal connections, and that this adaptive reorganization serves to amplify a response to a 2nd LIV treatment. As both Akt and FAK are found in FAs, this might indicate that nuclear motion driven by LIV activates signaling molecules at FAs by pulling nuclear-actin tethers, a force distinct from that of substrate strain. As such, LIV induced nuclear motion might represent a novel form of "inside-inside" signaling, in contrast to the "outside-in" signaling generated when HMS pulls on the cytoskeleton via integrins.

Enhancement of Osteogenic Ingrowth and Proliferation in 3-D Scaffolds with Low-Intensity Pulsed Ultrasound. Lin Wu*, Liangjun Lin, Yong Gao, Yi-Xian Qin. State University of New York at Stony Brook, USA

Bone tissue engineering approaches represent a great potential for improved regeneration of damaged bone in comparison with conventional therapies [1]. It is hypothesized that mechanotransduction may enhance cell dynamics and proliferation. The low-intensity pulsed ultrasound in vivo studies have shown to enhance osteoconduction into porous implants made of hydroxyapatite (HA), titanium, tantalum, and bioglass [2]. However, the mechanism of ultrasound on the osteoblast behavior inside the porous scaffold are still unknown. The aim of this study is to evaluate the effects of ultrasound induced mechanotransduction in promoting osteoblastogenic ingrowth and proliferation through 3D porous scaffolds. Porosity of two kinds of ceramic scaffolds, SiC and HA/TCP scaffolds, were measured using μCT. Quantitative ultrasound (QUS) measurement was performed to evaluate the ultrasound attenuation in the scaffolds. Seeded MC3T3-E1 mouse pre-osteoblasts on the scaffolds were cultured for 4 and 7 days with daily 20min ultrasound treatment, and were evaluated for Cell viability, in depth ingrowth, and volumetric proliferation. The porosities of SiC and HA/TCP were observed as 75% and 52%, 0.36mm and 0.19mm of pore size, respectively. The simulated ultrasound attenuation was significantly different (16%, $p<0.05$) between SiC (20.87±1.28dB) and HA/TCP (17.91±3.31dB) ($p<0.05$). After 4 and 7 days of culture and ultrasound exposure, cell density was higher in the ultrasound group compared with the sham group on both SiC and HA/TCP scaffolds. Cell ingrowth depths of SiC scaffolds significantly increased in the scaffolds with ultrasound radiation compared with those with sham radiation after both 4 and 7 days post-seeding. Whereas HA/TCP scaffold was only remarkable at 7 days post-seeding (Fig 1). There were significant differences in the dsDNA content between the ultrasound group and the sham group both on SiC scaffolds and HA/TCP scaffolds. Ultrasound group of SiC construct showed 9% ($p<0.05$) and 27% ($p<0.05$) increase in the average dsDNA content at 4 days and 7 days over the sham control group, And as to HA/TCP construct, 28 % and 24 % increase, respectively (Fig 2). ANOVA test showed significant difference ($p<0.05$) between ultrasound and sham groups and between SiC and HA/TCP scaffolds, at both 4 and 7 days. These results suggested that ultrasound facilitated ingrowth and enhance the proliferation of osteoblast in both SiC and HA/TCP scaffolds, but with different kinematics.

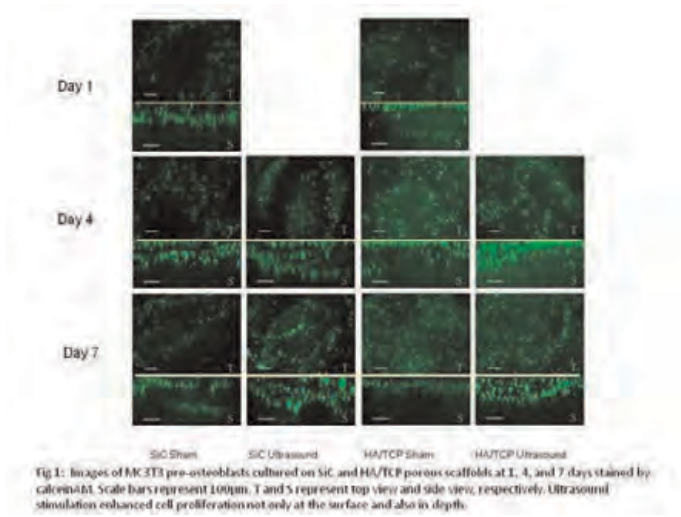

Fig 1: Images of MC3T3 pre-osteoblasts cultured on SiC and HA/TCP porous scaffolds at 1, 4, and 7 days stained by calcein-AM. Scale bars represent 100μm. T and S represent top view and side view, respectively. Ultrasound stimulation enhanced cell proliferation not only at the surface and also in depth.

Mechanically Activated Fyn Modulates Adipogenic Commitment through mTORC2/Akt/RhoA Effects on Mesenchymal Stem Cell Cytoskeleton. William Thompson*[1], Sherwin Yen[2], Buer Sen[3], Zhihui Xie[2], Natasha Case[4], Gunes Uzer[1], Maya Styner[4], Janet Rubin[4]. [1]University of North Carolina, USA, [2]University of North Carolina Department of Medicine, USA, [3]University of North Carolina At Chapel Hill, USA, [4]University of North Carolina, Chapel Hill, School of Medicine, USA

Bone density is dependent on mesenchymal stem cell (MSC) lineage allocation where adipogenic commitment depletes the pool available for osteogenesis. Cell architecture influences lineage decisions, as the cytoskeleton provides critical elements allowing response to the mechanical and physical environment. We have shown that mTORC2 is proximal to activation of Akt and inhibition of GSK3β that leads to downstream β-catenin preservation. We recently demonstrated that the Src-like kinase Fyn is proximate to mechanical activation of mTORC2, a kinase involved in downstream RhoA activation. RhoA is critical for cytoskeletal reorganization, as it directs actin stress fiber formation. As such, we asked if Fyn might modulate cellular architecture and lineage allocation of mdMSCs. First we showed that Fyn was recruited to FA sites following substrate strain. Strain (2%, 100 cycles) enhanced Fyn association with the FA protein vinculin. Further, pharmacological inhibition of Fyn prevented the actin stress fiber formation observed following mechanical strain, and specific disruption of Fyn function, using siRNA, prevented mechanical activation of RhoA. As it is known that inhibition of RhoA suppresses osteogenesis and enhances adipogenesis, our data showing that Fyn played a critical role in actin stress fiber formation and RhoA activation suggested that Fyn might regulate basal MSC cytoskeletal control of mdMSC lineage. Indeed, siRNA knockdown of Fyn led to an enhancement of mdMSC adipogenic lineage commitment. Protein levels of the adipogenic markers adipocyte protein 2 (aP2), adiponectin (APN),

peroxisome proliferator-activated receptor gamma (PPARγ), and perilipin were all significantly increased when Fyn expression was suppressed. Protein quantities for adipogenic markers were normalized to β-actin expression and fold increases over treatment with a control siRNA were 2±0.3, 35±3.4, 6±0.9, and 89±11.3 respectively. Adaptation of the structural framework of the cell reinforces essential mechanical signals that guide lineage decisions, biasing MSC commitment away from adipogenesis and towards osteogenesis. As such, Fyn expression in mdMSCs regulates basal cytoskeletal architecture and, associated with FAs, functions as a proximate mechanical effector transmitting environmental signals that influence MSC lineage allocation.

Novel Silorane Bone Cements Exhibit Similar Mechanical Properties but None of the *in vivo* Inflammatory Effects of Commercial Bone Cement. Lianxiang Bi*[1], David Eick[1], Kathleen Kilway[1], Rachel Weiler[1], Bradley Miller[1], Thomas Schuman[2], Lynda Bonewald[1]. [1]University of Missouri Kansas City, USA, [2]Missouri University of Science & Technology, USA

Bone cement is typically used for the more than 1 million total joint replacements performed annually in United States. However, the typical bone cement can be toxic, have high heat generation and shrinkage and can potentially have negative effects such as cardiopulmonary complications mainly due to a major component, polymethylmethacrylate. We have developed novel bone cements using silorane resin which have no heat generation, low shrinkage, improved biocompatibility and excellent biomechanical properties in dry (DY5-ECHE, 5.853±0.519; DY5-1TOSU, 5.249±0.256; M12-ECHE, 5.327±0.762; M12-1TOSU, 5.327±0.762; Simplex 5.393±0.202 MPa) and wet environment (M12-1TOSU, 2.288±0.466; M12-ECHE, 1.960±0.259; DY5-1TOSU, 1.896±0.396; Simplex P, 3.067±0.193 MPa). Using MLO-A5 osteoblast cells to examine toxicity, not only were the silorane bone cements non-toxic as compared to the toxicity of commercial bone cement, but bone cells plated on silorane bone cement discs showed increased alkaline phosphatase enzyme activity (DY5-U,2.981±0.135; DY5-ECHE, 2.574±0.276; control, 1.352±0.069; Simplex P, 1.082±0.141) and increased mineralization (DY5-U, 0.032±0.003; DY5-ECHE, 0.033±0.001; control, 0.016±0.003; Simplex P, 0.013±0.001, using the alizarin red assay O.D/ug protein) suggesting osteogenic potential. To examine the properties of the silorane bone cement *in vivo*, rat femora were implanted with a titanium rod in the bone cements. Periosteal inflammation was monitored by radiography at week 1, 4 and 8, and the body weight of rats was measured at week 1, 2, 4, 6 and 8 post surgery. The body weight of rats implanted with commercial bone cement were significantly decreased by 8% at week one post surgery compared to the silorane cement groups ($p<0.01$). A periosteal reaction in the commercial bone cement was observed at weeks 4 and 8 post surgery (76% of animals), in contrast to no reaction in the silorane cement groups. Pull-out and histological evaluation are underway. In summary, the silorane-based bone cements enhance bone cell differentiation and mineralization *in vitro* and do not have inflammatory effects *in vivo.* The silorane cements are promising materials for bone repair and joint replacements.

Elevated Serum Sclerostin Levels Point Towards Compromised Mechanotransduction in Type 2 Diabetic Postmenopausal Women with Fragility Fractures and Have Potential as Biomarker for Fracture Risk Assessment in Type 2 Diabetics. Ursula Heilmeier*[1], Janina Patsch[2], Dana Carpenter[3], Roy Harnish[1], Joyce Keyak[4], Thomas Baum[5], Gabby B. Joseph[1], Andrew J Burghardt[6], Ann Schwartz[1], Thomas Lang[1], Thomas Link[1]. [1]University of California San Francisco, USA, [2]Medical University of Vienna, Austria, [3]University of Colorado Denver, USA, [4]Department of Radiological Sciences, University of California, Irvine, USA, [5]Klinikum rechts der Isar, TU Muenchen, Germany, [6]Department of Radiology & Biomedical Imaging, University of California San Francisco, USA

The osteocyte-specific Wnt-inhibitor sclerostin is a key regulator of mechanotransduction and increasingly recognized as a protein of potential clinical relevance. Diabetic bone disease is a complication of type 2 diabetes mellitus (T2DM) with paradoxically increased fracture risk despite relatively high bone mineral density (BMD). The purpose of this study was to assess bone fragility properties (fracture load, BMD) and sclerostin serum levels in diabetic patients with a history of fragility fractures, compared to fracture-free diabetics and normal postmenopausal controls with and without fragility fractures. All subjects (controls [Co] n=20; controls with fragility fractures [Fx] n=20; diabetics without fractures [DM] n=20; diabetics with fractures [DMFx] n=20) were mobile, free of bone affecting diseases or medications and underwent quantitative computed tomography (QCT) of the left proximal femur, DXA (hip, spine), and blood draw for sclerostin, Vitamin D, PTH, HbA1c and eGFR measures. QCT scans were used to compute femoral neck BMD and femoral fracture load for fall and stance loading via finite element modeling. Using multiple linear regressions adjusted for age, race and BMI we found that sclerostin levels were significantly elevated in DMFx women compared to DM (p=0.013), Fx (p=0.033) and controls subjects (p=0.028) (Fig.1) while all groups did not differ significantly in height, weight, BMI, PTH, Vitamin D, eGFR or stance fracture load. DMFx and DM subjects had comparable HbA1c levels (7.9 ± 0.6 vs. 7.9 ± 0.3). All fragility fractures were at least 5 months old. Average fracture age was 3.5 ± 0.6 years for DMFx and 3.7± 0.8 years for Fx subjects. Areal BMD was particularly high in DM subjects, whereas it was normal to osteopenic in all other groups. DM subjects had significantly higher volumetric BMD than controls (p=0.033) or DMFx subjects (p=0.041), but not higher bone strength under fall conditions. In contrast, DMFx subjects showed normal vBMD, similar to controls, but significantly reduced fall failure loads (p=0.042). We conclude that elevated sclerostin levels in DMFx women suggest that mechanotransduction in diabetic patients with fragility fractures could be compromised. Sclerostin might also serve as a novel biomarker to assess fracture risk in diabetics and be a potential therapeutic target for diabetic bone disease. However, the pathophysiology leading to elevated sclerostin levels in diabetics with fractures remains to be elucidated.

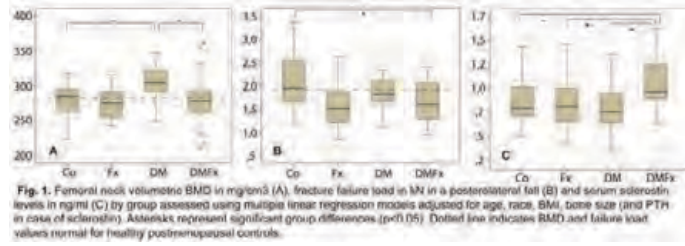

Fig. 1. Femoral neck volumetric BMD in mg/cm3 (A), fracture failure load in kN in a posterolateral fall (B) and serum sclerostin levels in ng/ml (C) by group assessed using multiple linear regression models adjusted for age, race, BMI, bone size (and PTH in case of sclerostin). Asterisks represent significant group differences ($p\leq0.05$). Dotted line indicates BMD and failure load values normal for healthy postmenopausal controls.

Femoral strength computed from QCT-based finite element analyses is not influenced by voxel or smooth mesh type. Dieter Pahr*[1], Michael Kinzl[1], Enrico Dall'Ara[1], Oleg Museyko[2], Klaus Engelke[2], Jarunan Panyasantisuk[3], Philippe Zysset[3]. [1]Vienna University of Technology, Austria, [2]University of Erlangen, Germany, [3]University of Bern, Switzerland

Femoral fractures represent an important endpoint in clinical trials in osteoporosis. Areal bone mineral density (aBMD) measured by DXA is still the current gold standard to evaluate fracture risk in vivo. Although quantitative computed tomography (QCT)-based homogenized finite element (FE) models are more accurate predictors of femoral strength than aBMD. The aim of this study was to evaluate the influence of the model's mesh type – homogenized voxel (hvFE) or smooth (hsFE) finite element meshes - with respect to prediction of strength in vitro.

Thirty-six pairs of femora were scanned with QCT and total femur BMC was evaluated. For each pair, one femur was positioned in one-legged stance configuration (STANCE) and the other in a sideways impact configuration (SIDE). Non-linear hvFE models were directly generated from the QCT images (linear hexahedral elements, 3mm edge length), whereas in case of smooth hsFE models the cortical and trabecular compartments were segmented using MIAF and meshed with quadratic tetrahedral elements (~4.5mm edge length). The same isotropic, density dependent, non-linear material law was used for all elements and bone compartments in order to change only the parameter ''mesh type''. Loading configurations were imposed from the biomechanical tests. All models were generated with MEDTOOL and analysed with ABAQUS. The ultimate loads were computed from the models and compared to those measured in the experiments.

In both configurations, hvFE/hsFE show similar predictability of femoral ultimate load ($adjR^2$=0.794/0.785 for STANCE and $adjR^2$=0.849/0.852 SIDE with $p>0.49$). The relative root mean square errors (RMSE) were comparable (17.9%/17.7% for STANCE and 18.0%/16.3% for SIDE) and slightly lower for smooth models. The hvFE/hsFE slopes (0.649/0.569 for STANCE and 0.902/0.735 SIDE) were different but not significantly ($p>0.08$ for STANCE/SIDE). For both mesh types, FE predicted femoral ultimate load better than BMC ($adjR^2$=0.678 for STANCE or $adjR^2$=0.696 for SIDE).

This study shows that the mesh type (voxel or smooth) has no influence on the quality of the strength predictions. Only the slopes changed, but not significantly. Smooth models included modelling of the cortex but with the same material behaviour as trabecular bone. Thus, smooth models offer space for improvements with respect to the geometrical definition and material behaviour of the cortex, but to the cost of increased complexity and effort for mesh generation.

Highly efficient HRpQCT-based plate and rod (PR) finite element models of whole bone distinguish postmenopausal women with vertebral fractures. Ji Wang*[1], Bin Zhou[1], Emily Stein[2], Elizabeth Shane[2], X Guo[1]. [1]Columbia University, USA, [2]Columbia University College of Physicians & Surgeons, USA

In postmenopausal women, risk of fragility fractures is associated with impaired whole bone strength. *In vivo* assessment of whole bone strength at distal tibia and radius has been possible through micro finite element (μFE) analyses based on high-resolution peripheral quantitative computed tomography (HRpQCT) images, but

demands high computational efforts. We have recently developed a highly efficient HRpQCT-based plate-rod (PR) model that allows fast and accurate prediction of elastic modulus and yield strength of trabecular bone, and found that vertebral fracture is associated with a remarkable decrease in elastic modulus and yield strength of the trabecular bone at both distal radius and tibia. In this study, we extended the PR modeling technique to include the cortical bone and created a patient-specific whole bone PR model, in which cortical bone was modeled with triangular shell elements enclosing the trabecular compartment composed of beam and shell elements, representing rod-and plate-like trabeculae, respectively. To evaluate the technique, we applied a whole bone PR FE model to HRpQCT images at the distal radius in 50 postmenopausal women with (n=25, age 69±1, 86% Caucasian, 28% Hispanic) and without (n=25, age 69±1, 93% Caucasian, 5% Hispanic) a history of vertebral fracture, and compared predictions by PR models with those of voxel models (Fig 1). Both PR and voxel μFE model analyses showed that whole bone stiffness at the radius was 10% lower in fracture patients than controls. Whole bone stiffness estimated by the PR model was significantly correlated with that of the voxel model (r=0.80, Fig 2). Furthermore, the whole bone PR model reduced the number of elements by 76-fold, leading to an over 1,300-fold reduction in μFE computation time (Table 1). PR models of the fracture patients had fewer elements, given the lower bone volume fraction and trabecular number. Overall, we evaluated a HRpQCT-based whole bone PR model with respect to a voxel model in estimating whole bone stiffness of distal radius, demonstrating the interesting potential of this highly efficient PR approach. Both models revealed weakened whole bone stiffness in vertebral fracture patients. However, mechanical properties of whole bone in individual patients can be assessed in about 5 seconds on a laptop PC. Due to its efficacy and efficiency, the HRpQCT whole bone PR model has great promise to assist in biomechanical functionality-based assessment of vertebral fracture risk.

HIV Infected Patients have Deteriorated Bone Material Properties at a Tissue Level Measured by "in vivo" Microindentation. Robert Guerri Fernandez*[1], María Rodríguez Sanz[2], Judit Villar-Garcia[2], Natalia Garcia-Giralt[3], Elisa Torres del Pliego[4], Laia Vilaplana Marz[4], Ana Guelar-Grinberg[2], Xavier Nogues[5], Leonardo Mellibovsky[2], Daniel Prieto-alhambra[6], Hernando Knobel[2], Adolfo Diez-Perez[7]. [1]Fundacio IMIM, Spain, [2]Internal Medicine-Infectious Diseases. Hospital del Mar, Spain, [3]IMIM, Spain, [4]Internal Medicine-Infectious Diseases, Spain, [5]Institut Municipal D'Investigació Mèdica, Spain, [6]University of Oxford, United Kingdom, [7]Autonomous University of Barcelona, Spain

Background: HIV infection and anti-retroviral therapies have detrimental effects on bone metabolism, high prevalence of osteopenia and osteoporosis was described in HIV-infected patients, and there is a growing evidence of the association between HIV infection and fracture risk. The etiology is not well understood, but bone material properties might be deteriorated.

Patients and Methods: In a HIV group of patients, we analyzed the bone material properties at a tissue level by microindentation. Two groups of patients were included: HIV + (with and without Antiretroviral Treatment (ART)), and controls, without HIV infection and no bone disease. A general laboratory workup, bone densitometry by DXA, and bone microindentation were carried out. Bone Material Strength (BMS) was measured with Osteoprobe® applying a 20N force on the anterior mid tibia normalized on a PMMA phantom. Age and gender-adjusted ANOVA was used for comparisons.

Results: 23 HIV patients (9 on ART) and 43 controls were included. Age (42+9.9 vs 69+13.4) and gender (14 men, 9 women vs. 4 men and 39 women) for HIV+ and controls respectively. After adjusting by age and gender, HIV+ patients showed worse (lower) BMS (79.6+12.7) (mean±SD) than controls (84.9±6.2, p=0.013). The BMS is lower in HIV+ treated patients (76±8)) with regard controls (p<0.001) and with regard to HIV+ untreated (BMS 81±14), nevertheless the difference was not significant between HIV-infected patients. T-scores in lumbar spine (-1.5+1.7) and total hip (-1.2+1.7) were, on average, in the range of osteopenia in the HIV+ patients. No differences in BMD were observed between HIV+ and controls. There was no correlation between BMS and lumbar spine BMD (R2=0.002, p=0.80) or total hip BMD (R2=0.002, p=0.81).

Conclusions: HIV-infected patients have deteriorated bone material properties at a tissue level measured by microindentation and this effect seems more pronounced in those receiving ART. BMD values do not reflect this bone deterioration. BMS does not correlate with bone density reinforcing the concept that measures a different bone dimension.

Microstructural and Biomechanical Properties, Bone Mineral Density and Bone Turnover in Patients with Hip Osteoporotic Fracture vs. Osteoarthritis.

Mª José Montoya*[1], Merce Giner[2], Cristina Miranda[3], Mª Angeles Vazquez[1], Ramón Pérez-Temprano[4], David Guede[5], José Ramón Caeiro[6], Ramon Perez-Cano[1]. [1]University of Seville, Spain, [2]Bone Metabolism Unit, "Virgen Macarena" University Hospital, Spain, [3]Bone Metabolism Unit, "Virgen Macarena" University Hospital of Seville, Spain, [4]Bone Metabolism Unit, "Virgen Macarena" University Hospital & University of Seville, Spain, [5]Parque Tecnolóxico de Galicia, Spain, [6]Department of Orthopaedic Surgery, Complexo Hospitalario Universitario de Santiago de Compostela, A Coruña, Spain

Introduction: Osteoporosis (OP) and osteoarthritis (OA) are the most prevalent musculoskeletal disorders in the elderly but the relationship between them is unclear.

Clinical and epidemiological studies have showed an inverse relationship between these diseases. However other studies, from different points of view, have reported the opposite hypothesis.Objectives: The purposes of this study are to analyze the bone turnover markers (BTM), bone mineral density (BMD) and the structural and mechanical properties of trabecular bone in patients with OP and OA, and to explore the level of relation among them.Materials and Methods: We studied 25 patients: 12 patients with hip osteoporotic fracture undergoing prosthetic hip replacement (OP group) and 13 patients with hip osteoarthritis undergoing total hip arthroplasty (OA group) (age range: 65-80). We analyzed bone parameters (PTH, Vitamin D, β-Crosslaps and PINP), BMD (DXA) and microstructural and biomechanical parameters (micro-CT).Statistical analysis of the results was conducted using the T-student test. Correlations between variables were assessed with the Pearson correlation coefficient. Statistical package SPSS 20.0 for Windows (IBM Corp., Armonk, NY, USA) was used and results with a $p<0.05$ were considered statistically significant.Results: OA group has lower levels of β- Crosslaps and higher BMD at femoral neck. Also, OA patients have an increased volume of trabecular bone and trabecular number, with architecture showing prevalence of plate-like trabeculae and with better connectivity than OP patients. The biomechanical parameters were better in OA group.

BMD was correlated with almost structural and biomechanical parameters, the best correlation was with volume of trabecular bone. β-Crosslaps was negatively correlated with hip BMD and with bone surface density and positively with trabecular separation.Conclusions: BTM, BMD and bone microstructural changes in osteoarthritis are opposite to those of OP. These findings mostly justified a more resistant bone with less risk of fragility fractures in OA respect to OP patients, as clinical and epidemiological studies have pointed out for decades.

SU0071

Regional Heterogeneity of Trabecular Bone Microcrack Density in Association with Trabecular Microarchitecture and Bone Resorption in Whole Human Lumbar Vertebrae.

Vincent Carpentier[1], Helen Tsangari[2], Nicola Fazzalari[3], Julia Kuliwaba*[2]. [1]Harvard School of Dental Medicine, USA, [2]SA Pathology, Australia, [3]The University of Adelaide, Australia

Purpose: Vertebral deformity, intervertebral disc disorganisation, and changes to vertebral bone architecture are morphological features associated with degeneration of the spine and with back pain. Vertebral strength is determined by bone size, shape, bone mineral density, microarchitecture, and bone material properties (eg. collagen characteristics, mineralisation, microdamage). Despite its importance to vertebral biomechanics, no studies have reported on the variation of bone microdamage present in the human vertebra. Thus, the purpose of this study was to assess regional changes in trabecular bone microdamage in association with bone microarchitecture and resorption in whole human lumbar vertebrae.

Methods: L2 vertebrae were obtained from twelve human cadaveric spines (six males, aged 53-82 years; six females, aged 56-87 years), with no history of spinal surgery, vertebral fracture, or disease/medication that may have affected bone turnover. Parasagittal slices, low speed diamond wheel saw cut from each vertebral body, were *en bloc*-stained in basic fuchsin, cut into 9 sectors, and resin embedded. Histomorphometric assessment of trabecular bone microarchitecture, *in vivo* bone microdamage, and extent of bone resorption was undertaken.

Results: Data analysis revealed few differences for the 9 sectors and no differences for the antero-posterior axis were observed. For the cranio-caudal axis, the mid-vertebral region had the lowest bone volume fraction ($p<0.03$), trabecular number ($p<0.02$), and highest trabecular separation ($p<0.03$). Microcrack density parameters were highest in the mid-vertebral region ($p<0.04$); with the shortest crack lengths observed in the caudal region ($p<0.04$). Diffuse microdamage was minimal or absent. Bone resorption was highest in the cranial region (eroded bone surface, $p<0.04$).

Conclusions: For the cranio-caudal axis of the L2 human vertebra, the mid-vertebral region may be biomechanically compromised due to reduced bone volume and microarchitectural changes being accompanied by an increased microcrack burden. The increased bone resorption found in the cranial region may be an adaptive response to intervertebral disc degeneration. This is the first study to report on the regional variation of *in vivo* bone microdamage in whole human vertebrae. The implications of these observations are being further investigated with comparison to available biomechanical and intervertebral disc grading data.

SU0072

Substitutability of Cortical Parameters of Bone Strength Assessed by DXA and HR-pQCT in Premenopausal Women at the Distal Tibia.

Albrecht Popp*[1], Helene Buffat[1], Kurt Lippuner[1], Ursula Eberli[2], Manuela Ernst[2], R Geoff Richards[2], Vincent Stadelmann[2], Markus Windolf[2]. [1]Department of Osteoporosis, University Hospital & University of Berne, Switzerland, [2]AO Research Institute Davos, Switzerland

Introduction: With regard to bone strength, structural elements of bone add information to Bone Mineral Density (BMD). A novel index, which combines areal BMD (aBMD) and the polar moment of inertia (pMOI) calculated directly from a single dual X-Ray absorptiometry (DXA) measurement, was shown ex vivo to be a good predictor of bone strength and stiffness assessed by high resolution peripheral quantitative computed tomography (HR-pQCT) at the distal tibia diaphysis (T-DIA), with a high correlation coefficient of $R^2=0.88$ (Popp AW Bone 2012). Whether this also applies in vivo is unknown.

Methods: A random cohort of healthy, community-dwelling, non-pregnant, 20 to 40-year old women living in the region of Davos, Switzerland, was generated by using a commercial nationwide address database. Women were contacted by regular mail (N=485). After given informed consent, 72 participants underwent volumetric BMD (vBMD) measurement at T-DIA by HR-pQCT (XtremeCT™, Scanco Medical AG, Brüttisellen, Switzerland) and aBMD measurement at T-DIA and femoral neck (FN) by DXA (Hologic Discovery C™, Hologic, Bedford, MA, USA). Cortical thickness (CTh) at T-DIA was either directly assessed by HR-pQCT or calculated from T-DIA DXA scans by using DICOM images, analyzed with a Canny threshold-based tool implemented in MATLAB™ (MathWorks™, Natick, MA, USA). Corresponding pMOIs were either directly determined (HR-pQCT) or derived from CTh values (DXA), following a methodology described earlier (Popp AW Bone 2012).

Results: In total, 72 healthy premenopausal women were included. Mean (±SD) age was 33.8 (±5.2) years, with 167.6 (±6.2) cm for height, and 23.2 (±4.1) kg/m^2 for BMI. Mean FN BMD was 0.853 (±0.119) g/cm^2 corresponding to a mean Z-score of 0.0 (±1.1). At T-DIA, a high correlation ($R^2 = 0.74$) was found between the cortical bone strength indexes assessed by DXA (aBMD × pMOI) and HR-pQCT (vBMD × pMOI), indicating that bone strength assessed by DXA and HR-pQCT are predictive of each other.

Conclusion: In a cohort of randomly selected premenopausal women, bone strength assessed by combining structural and densitometric parameters of bone determined by either DXA or HR-pQCT were highly correlated.

The Trabecular Bone Score is Associated with Volumetric Bone Density and Microarchitecture as Assessed by cQCT and HRpQCT in Chinese-American and Caucasian Women.

Alice Abraham*[1], Barbara Silva[2], Marcella Walker[1], Stephanie Boutroy[3], Chiyuan Zhang[1], Donald McMahon[4], George Liu[5], Didier Hans[6], John Bilezikian[4]. [1]Columbia University, USA, [2]Columbia University Medical Center, USA, [3]INSERM U1033 & Université de Lyon, France, [4]Columbia University College of Physicians & Surgeons, USA, [5]New York Downtown Hospital, USA, [6]Lausanne University Hospital, Switzerland

High resolution peripheral quantitative computed tomography (HRpQCT) indicates that Chinese-American (CH) women have smaller bone size but denser and thicker cortices and more plate-like trabeculae at the radius and tibia than Caucasian (CA) women. Central quantitative computed tomography (cQCT) also demonstrates cortical advantages at the hip among CH women but similar trabecular (Tb) volumetric bone mineral density (vBMD) at the central skeleton between races. While high resolution imaging has advanced the assessment of bone microarchitecture, it is not readily available in the clinical setting. The trabecular bone score (TBS) provides an estimate of Tb microarchitecture from DXA spine images and predicts fracture risk independent of areal BMD (aBMD). In this analysis, we assessed if TBS reflects vBMD and microarchitecture measured by cQCT and HRpQCT in pre- (PreM; n=71) and postmenopausal (PostM; n=44) CH and CA women. Age was comparable between races. Height and weight were higher in CA vs. CH women. TBS did not differ by race (PreM: 1.465±0.091 vs. 1.467±0.064, p=0.92; PostM: 1.336±0.097 vs. 1.318±0.089, p=0.52) before or after adjusting for weight. In the entire cohort, TBS correlated with lumbar spine (LS) Tb vBMD ($r=0.664$; $p<0.001$); femoral neck (FN) integral ($r=0.651$, $p<0.001$), Tb ($r=0.641$, $p<0.001$) and cortical (Ct) vBMD ($r=0.346$, $p<0.001$) and Ct thickness (C/I; $r=0.540$, $p<0.001$) by cQCT.

TBS also correlated with integral (r=0.643, p<0.001), Tb (r=0.574, p<0.001) and Ct vBMD (r=0.491, p<0.001) and C/I (r=0.541, p<0.001) at the total hip (TH). LS aBMD correlated with all cQCT indices at all sites except FN cortical vBMD. Together, TBS and LS aBMD explained more of the variance in cQCT measures vs. aBMD alone (LS Tb vBMD R^2 0.605 vs. 0.474, p=0.005; FN: integral vBMD R^2 0.467 vs. 0.258, Tb vBMD R^2 0.540 vs. 0.401, C/I R^2 0.338 vs. 0.210, all p<0.01; TH: integral vBMD R^2 0.510 vs. 0.352, C/I R^2 0.301 vs. 0.126, all p<0.05). TBS was associated with all HRpQCT indices (r=0.20-0.52) except radial cortical thickness and tibial Tb thickness. Similar to our prior LS cQCT results, Tb indices by TBS did not differ by race in this cohort. TBS was associated with most HRpQCT and cQCT indices except for bone size. In conclusion, TBS reflects vBMD and bone microarchitecture derived from higher resolution imaging and may be a useful adjunct to aBMD for assessing central Tb microstructure between races or other groups with differences in bone size.

SU0074

Bone geometry and strength are negatively affected even by low-normal or subclinical thyrotoxic range of TSH level in the elderly. Su Jin Lee*[1], Kyoung Min Kim[2], JO EUN KIM[1], Sung-Kil Lim[3], Yumie Rhee[4]. [1]Yonsei University Health System, South Korea, [2]Seoul National University Bundang Hospitatl, South Korea, [3]Yonsei University College of Medicine, South Korea, [4]Department of Internal Medicine, College of Medicine, Yonsei University, South Korea

Overt hyperthyroidism has been recognized by a secondary cause of osteoporosis. More studies have suggested that subclinical hyperthyroidism may also result in decreased bone mineral density (BMD). We analyzed bone geometry and BMD to investigate whether bone strength properties could be different according to the level of thyrotropin (TSH) in the elderly.

Inclusion criteria were patients older than 65-year-old and who had the level of TSH lower than 5.0 mIU/mL without any histories of functional thyroid diseases. Bone mineral density (BMD) was measured by dual energy X-ray absorptiometry (DXA) and further analyzed for hip geometry properties with APEX program. A total of 286 men and 588 women were included and stratified into 3 groups according to the level of TSH ; lower group with lower than 1.0 mIU/mL, middle group with 1.0 to 3.0 mIU/mL, and upper group with higher than 3.0 mIU/mL.

TSH level showed positive correlations with femur neck cortical thickness in both men and women (r=0.184, p<0.05 for men; r=0.096, p<0.05 for women). The lumbar spine BMD was not different according to the group of TSH levels. However, BMD and cortical thickness of the femur neck vary positively with the TSH groups in both men and women (p for trends <0.05, respectively). In addition, the buckling ratio of the femur neck in the lower TSH group was significantly higher in women (p<0.05) and showed higher tendency in men (p=0.09). These associations were consistently observed even after adjusting for age, BMI and PTH levels.

In conclusion, low-normal or subclinical thyrotoxic range of TSH level negatively affects bone strength in the hip via thinning of the cortex and increased buckling ratio in the older population who have the highest risk of hip fracture.

Changes in Fracture Strength as a Function of Time since Spinal Cord Injury. William Edwards*[1], Thomas Schnitzer[2], Karen Troy[1]. [1]University of Illinois at Chicago, USA, [2]Northwestern University, USA

Spinal cord injury (SCI) is characterized by marked bone loss at regions below the neurological lesion. The clinical consequence of this bone loss is a rate of low-energy fracture similar to that of post-menopausal osteoporotic women. The greatest reductions in bone are observed around regions of the knee. Within the first 2 to 3 years of SCI, some 50% of the bone mineral at the distal femur and proximal tibia is resorbed. Unfortunately, the mechanical consequence of this bone loss remains unclear. Therefore, our purpose was to quantify changes in fracture strength at the proximal tibia as a function of time since SCI. Fifty one adults with SCI and a reference group of 5 able-bodied adults participated in this study. Computed tomography (CT) data were acquired for the proximal most 15cm of the non-dominant tibia. All CT images included a calibration phantom to convert CT attenuation to bone equivalent density. Bone mineral content (BMC) and volumetric bone mineral density (vBMD) were determined. Fracture strength of the proximal tibia loaded in torsion was quantified using validated patient-specific finite element modeling procedures. Exponential decay curves were used to describe changes in bone parameters and fracture strength as a function of time since SCI: y = Aexp(-bt)+C, where A is the loss amplitude; b, the loss rate; C, the new steady state; and t the time in years. Reductions in BMC (r^2 = 0.60), vBMD (r^2=0.71), and fracture strength (r^2=0.63) with time since SCI were well described using exponential relationships. New steady state values in bone mineral and fracture strength were met within 2.0 – 2.4 years after SCI, depending on the parameter (Figure 1). Whereas, new steady state values for bone parameters were approximately 47% lower than the reference group, the new steady state value for fracture strength was approximately 63% lower than the reference group. In summary, fracture strength of the proximal tibia decreased exponentially and reached a new steady state following SCI. Although the time to reach steady state was similar amongst bone parameters and fracture strength, steady state values for fracture strength were considerably lower than bone parameters when expressed relative to an able-bodied reference group. These data provide a more in-depth understanding of the mechanical consequence of bone loss after SCI, which ultimately may help in the prevention of SCI-related fragility fracture.

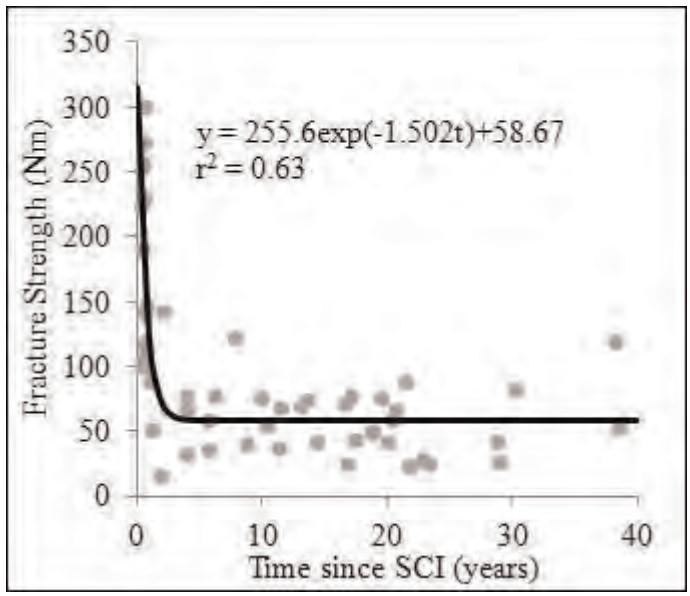

Figure 1. Fracture strength vs. time since SCI

Influence of Physical Activity on the Distribution of Human Cortical Tissue as a Function of its Mass and its Mechanical Quality. Paola Reina[1], Gustavo Roberto Cointry[1], Laura Nocciolino[1], Sara Feldman[1], Jose Ferretti*[2], Joern Rittweger[1], Ricardo Francisco Capozza[1]. [1]Center for Phosphocalcic Metabolism, Argentina, [2]National University of Rosario, Argentina

Increasing evidence shows that bone *mechanostat* would optimize bone structural stiffness as a function of the usage-derived peak strains sensed by osteocytes. One mechanism proposed to achieve this homeostatic control of bone structure is the spatial orientation of modeling drifts as a function of the maximal loads determined by customary mechanical usage of the skeleton.

To test that hypothesis, we analyzed the correlations between pQCT indicators of the mass (BMC), the mechanical "quality" (vDMO, a variable known to vary linearly with bone tissue stiffness), and the efficiency of the spatial distribution of cortical tissue to resist deformation in bending or torsion (cross-sectional moments of inertia, MIs) in slices taken at every 5% of the tibia length, as well as the maximal cross-sectional muscle area (MA) of the calf, in 22 males and 20 females aged 25-35 years who either had sedentary habits or were trained in long-distance running during more than 8 years.

All MIs (y) correlated with cortical CMO following positive, exponential relationships ("distribution/mass" curves, d/m) and with cortical vDMO following negative, hyperbole-like relationships ("distribution/quality" curves, d/c) in all bone sites. The distribution of correlation coefficients of both d/m and d/c curves along the bone were described by bell-shaped curves, with maximum values toward the central region of the diaphyses, reflecting the predominance of the usual bending and torsion stresses over that of compression stress. The residual values of both the d/m and d/c curves correlated linearly with MA (p<0.001) in every group and also in all the individuals analyzed as a whole ("bone/muscle" relationships, b/m).

Results verify no less than 3 correlative hypotheses: 1: That the preferential distribution of the available bone cortical tissue in specific sites across the diaphyseal section results from the directional optimization of local modeling drifts (d/m curves), 2. That that geometrical adaptation is more evident in sites where the bone tissue is less stiff (d/c curves), and 3. That local muscle strength and/or usage is synergic with those two manifestations (b/m curves). In addition, the collected evidence a. supports the proposed role of bone *mechanostat* with inedit arguments for the human skeleton, and b. offers a basis for developing reference graphs suitable for a comparative diagnosis of the *mechanostat* condition in individual cases.

Muscle Force and Bone Strength in Osteogenesis Imperfecta Type I. Louis-Nicolas Veilleux*, Frank Rauch. McGill University/Shriners Hospital for Children, Canada

Context: Osteogenesis imperfecta (OI) type I is a heritable bone fragility disorder that most often is caused by mutations affecting collagen type I. We have recently shown that patients with OI type I often have muscle weakness. In healthy individuals muscle force is closely related to bone strength. If this relationship is maintained in OI, this would suggest that muscle weakness contributes to the disease-related bone fragility.

Objective: The objective of the current study was to investigate the functional muscle-bone unit of the lower leg in patients with OI type I and healthy age- and gender-matched controls.

Patients and Other Participants: Thirty children and adolescents with OI type I (20 females; mean age [SD]: 11.2 years [3.9]) who had never received bisphosphonate treatment were compared to 30 healthy age- and gender-matched controls (mean age [SD]: 11.1 years [4.5]).

Main Outcome Measures: In order to estimate bone strength, tibia bone mineral content (BMC; mg/mm) was measured by peripheral quantitative computed tomography. Lower extremity peak force (kN) was measured by jumping mechanography through the multiple two-legged hopping test.

Results: Compared to age- and gender-matched controls, patients with OI type I had 17% lower peak force (1.3 kN vs. 1.7 kN; $p = 0.002$) as well as a 22% lower BMC (128 mg/mm vs. 165 mg/mm; $p < 0.001$). Multiple regression analysis showed that muscle force and tibia length were positively related to BMC ($r^2 = 0.90$, $p < 0.001$). On the contrary disease status was negatively related to bone strength indicating that patients with OI type I have a 20 mg/mm disadvantage on BMC as compared to age- and gender matched controls.

Conclusions: These results suggest that the muscle-bone relationship differs in OI type I as compared to healthy age- and gender-matched controls. More specifically, the regression analyses indicate that at a specific peak muscle force and tibia length, patients with OI type I will have a 12% lower BMC relative to the average control results. Therefore, our results suggest that both muscle weakness and the disease status effect on the muscle-bone relationship contribute to decreased bone strength in patients with OI type I.

Association Between Lumbar Bone Density (BMD) and Lumbar Disc Degeneration (LDD). Sami Salo*[1], Ville Leinonen[2], Toni Rikkonen[3], Pauli Vainio[2], Risto Honkanen[1], Heikki Kroger[2], Joonas Sirola[4]. [1]University of Eastern Finland, Finland, [2]Kuopio University Hospital, Finland, [3]University of Eastern Finland, Bone & Cartilage research unit, Finland, [4]University of Eastern Finland / Kuopio, Finland

Introduction: Osteoporosis and lumbar disc degeneration (LDD) are common among the elderly. Higher vertebral BMD has been found to be related with LDD. On the other hand in a couple of studies it has been reported that many patients with osteoporosis have severe disc degeneration. The aim of our research was to study relationship between LDD and BMD in lumbar spine.

Materials and methods: The study population consisted of 168 postmenopausal women (aged 63,3 - 75,0 years, mean 68,6 years) belonging in the prospective OSTPRE and OSTPRE-FPS study cohorts. Out of all study subjects with valid lumbar DXA-measurements 168 had a history of lumbar MRI-scan (1,5 T unit). The severity of LDD was graded from T2-weighted images using 5-grade Pfirrmann classification. Four vertebral levels (L1-L4) were studied (altogether 672 discs). The association between lumbar BMD and severity of LDD was studied separately for each vertebra level with UNIANOVA test with controlling for the effect of confounding factors, including age, body mass index (BMI) and the time between DXA-measurements and MRI-scan.

Results: Higher lumbar BMD was associated with more severe LDD in all levels (L1-L4): between L4-L5 disc and L4 BMD ($p=0.044$), between L2-L3 disc and L3 BMD ($p=0.001$), in all other levels ($p<0.001$). All results remained statistically significant after controlling for the confounding factors.

Conclusions: Higher lumbar BMD seems to be associated with more severe LDD. Higher lumbar BMD seems to be associated with more severe LDD. This might be related to dehydration of nucleus and shift of load to the annulus and endplate. However, the causality should be more closely studied in further studies.

keywords: bone mineral density, intervertebral disc degeneration, postmenopausal women, lumbar spine, osteoporosis

Plasma Concentration and Expression of Matrix Gla Protein (MGP) in Ectopic Calcification Model Rats. Naoko Tsugawa*, Haruna Sakurai, Tetsushi Kasuga, Toshio Okano. Kobe Pharmaceutical University, Japan

OBJECTIVE: Matrix Gla protein (MGP) is known as a potent vascular calcification inhibitor. MGP is a vitamin K dependent protein (VKDP) which is activated by gamma-carboxylation of Glu residues (Gla) in the presence of vitamin K. Previous *in vitro* study has shown that MGP expression was induced in vascular smooth muscle cells by stimulation of calcification. However, it is unclear whether gene expression of MGP is stimulated in ectopic calcified tissues *in vivo*. The aim of our study was to investigate the changes of the plasma concentration of inactive form of MGP (uncarboxylated MGP: ucMGP), and the gene expression of MGP in ectopic calcification model rats induced by administration of excess vitamin D or adenine-containing diets.

METHODS: Ectopic calcification model rats were generated by two methods. Wistar male rats (10 weeks of age) were fed 0.75% adenine-containing diet for 3 week (Ad group). In another group, vitamin D_3 (25 mg/kg/d) were administered to Wistar male rats (9 weeks of age) for 7 days (VD group). Calcium and phosphorus concentrations in plasma and soft tissues (aorta, heart, kidney, lung and trachea) were measured. The expression of MGP mRNA in soft tissues was measured by real-time RT-PCR. Plasma concentration of ucMGP was measured by ELISA.

RESULTS: Plasma calcium concentrations in VD group and phosphorus concentration in the Ad group were elevated significantly. Ectopic calcification in soft tissues was observed in the VD and Ad group, and the VD group showed more severe calcification than did the Ad group. Gene expression of MGP was up-regulated in ectopic calcified tissues, but not in cartilage. Plasma ucMGP concentration was remarkably elevated in the Ad group, but its elevation in the VD group was not significantly.

CONCLUSION: The mRNA expression of MGP was prominent in aorta, heart, kidney, lung and trachea of both ectopic calcification model rats. However, the two model rats displayed different profiles in plasma ucMGP concentrations. These results suggest that plasma ucMGP concentration does not necessarily correlate with expression of MGP in ectopic calcified tissues.

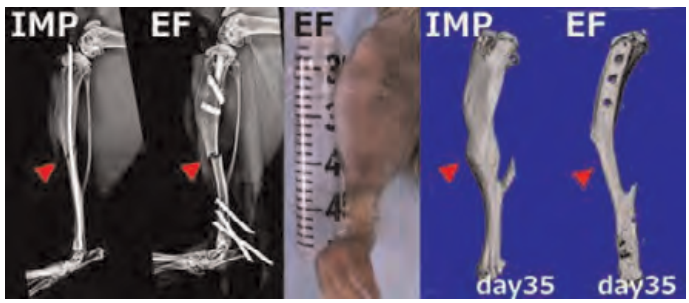
Post-Union Response to External Fixation versus Intramedullary Pinning in Mouse Tibia Fracture Healing. Yusuke Hagiwara*, Douglas Adams, Nathaniel Dyment, Xi Jiang, David Rowe. University of Connecticut Health Center, USA

Progression of long bone fracture healing to union, and subsequent remodeling of callus and original cortex toward restoration of anatomy, are modulated by the stability and compliance afforded by fixation. Our previous work compared intramedullary pinning (IMP) to external fixation (EF) in the mouse tibia fracture model, reporting a larger cartilaginous callus for IMP at 2 weeks. IMP allowed

deformities such as angulation, rotation, or shortening which were greatly reduced with EF. The relatively simple, cost-effective method of EF (3×25G proximal and 3×28G distal percutaneous needles held laterally with a tuberculin syringe barrel) holds the potential for further modulating repair by removing structural components to increase load transfer. This study extended the comparison of IMP vs EF through 5 weeks of healing to elucidate the effects of internal vs external fixation and associated compliances on post-union remodeling at 2 and 5 weeks post-fracture (32 animals, 8/group, 4 mo old). Fixation was placed prior to creating a single, transverse fracture located proximal of the tibia-fibula junction, using a standard drop-weight method. IMP employed the Ender nailing technique, whereby IM pin diameter was maximized to the canal and inserted with slight pre-bent angulations at the tip and midspan, using a twisting motion to navigate tibia curvature. EF was achieved by placing all components, removing the syringe barrel to create the fracture, and replacing it to achieve anatomical reduction. Healing and measurement of deformity were followed longitudinally using digital radiographs, and with μCT imaging of excised specimens. EF achieved union without substantial callus formation (Figure) and maintained rotational alignment ($<10^{\circ}$ deformity). IMP demonstrated persistent callus with a substantial and variable rotational deformity (20-40°) by radiographic and gait analysis (DigiGait). Incidence of spontaneous fibula fracture was higher for IMP (80 & 89% at 2 & 5 wks) than for EF (12 & 40%). Mechanical integrity was measured at 5 wks via torsion tests, suggesting lower strength for EF vs IMP. At 2 weeks, EF specimens (and IMP specimens lacking significant callus) demonstrated a propensity to break at the fracture site during manual manipulation of soft tissue dissection. These findings suggest a trade-off between establishing anatomical reduction and mechanical integrity of repair that might be accomplished by progressively increasing the compliance of EF.



Fixation with IMP resulted in persistent callus that was not present for EF

Tissue-specific Extracellular Matrix Controls the Fate of Bone Marrow-derived Mesenchymal Stem Cell Differentiation. Rubie Rakian[1], Zhi-Liang Zhang[2], Travis Block[1], Qiuxia Dai[1], Zhongding Lu[1], Xiao-Dong Chen*[1]. [1]University of Texas Health Science Center at San Antonio, USA, [2]Ren-Ji Hospital, Shanghai Jiao-Tong University School of Medicine, China

Mesenchymal stem cells (MSCs) differentiate into many distinct cell lineages depending upon the local microenvironment that is mainly constituted by extracellular matrix (ECM) proteins and associated growth factors. However, it has been challenging to dissect the key components that direct the differentiation of MSCs because of the limited availability of in vitro models. Previously, we reported that in both mice and humans, cell-free ECM prepared from marrow stromal cells (BM-ECM) significantly promoted proliferation of MSCs and preserved their stem cell properties. Here, we wanted to investigate whether the BM-ECM was unique in its ability to preserve MSC properties by comparing to ECM made by fibroblasts derived from different tissues such as skin and fat. Cell-free bone marrow-, skin-, and adipose-derived ECMs were prepared by cultured bone marrow cells, skin fibroblasts and adipose stem cells (ASCs), respectively. Human marrow stromal cells (hMSCs, passage 1 to 3) were cultured on the various ECMs, or tissue culture plastic (TCP) in expansion medium until confluence (~7 days), then maintained under conditions known to induce commitment to a specific cell lineage including osteoblasts and adipocytes. The lineage specific transcripts were measured by TaqMan PCR at day 7, 14, 21 and 28 post-confluence. We found that hMSCs maintained on BM-ECM expressed much higher levels of alkaline phosphatases (ALP), type I collagen and bone sialoprotein than cells maintained on adipose-ECM and skin-ECM after treatment with osteoblast differentiation medium. The cells maintained on skin-ECM did not respond to the treatment of osteoblast differentiation medium, showing no increased expression of these osteoblast markers compared to the untreated cells. In contrast, hMSCs maintained on adipose-derived ECM in both the expansion and adipose differentiation media expressed significantly higher levels of PPARγ2, and C/EBPα (a key regulator of adipogenesis) than the cells maintained on TCP, BM-ECM or skin-ECM. Interestingly, only hMSCs cultured on skin-ECM in the expansion medium expressed a considerable high level of keratin 6A (an early differentiation marker of epithelial cells). We conclude that the differentiation of hMSCs can be directed by exposure to tissue-specific ECM. The unique protein profiles for these ECMs will be further determined using proteomic analysis.

An Essential Role of Bmp Receptor1A (ALK3) in Postnatal Skeleton Formation. Junjun Jing*[1], Zhaowen Zhong[2], Chuanju Liu[3], Nobby Kamiya[4], Ying Liu[5], xuedong zhou[6], Jian Feng[7]. [1]Baylor college of dentistry,TA&M Health Science Center, USA, [2]TX A&M Baylor College of Dentistry, USA, [3]New York University, USA, [4]Texas Scottish Rite Hospital for Children, USA, [5]baylor college of dentistry, USA, [6]State Key Laboratory of Oral Diseases, West China Stomatology Hospital, China, [7]Texas A&M Health Science Center, USA

ALK3 plays a critical role in both chondrogenesis and osteogenesis during embryonic development. To test the postnatal role of ALK3 in skeletal tissues, we initially studied the skeletal phenotype in 2-wk, 4-wk and 8-wk in *Alk3 c*onditional knockout (cKO) mice, which were crossed between $Alk3^{fl}$ and aggrecan-Cre^{ER} (specific for cartilage tissues) and induced by tamoxifen at postnatal day 7. The X-ray and mCT images displayed a reduced bone length in null femora and vertebrae, 40% and 30% reduction, respectively. There was no apparent change in the cortical bone quantity as well as other flat bones such as calvarial and alveolar bones as assessed by bone volume/total volume. H&E and Toluidine Blue stains showed no evidence of chondrocytes in the null epiphysis and metaphysis, suggesting a complete block of endochondral bone formation in Alk3-cKO mice. Moreover, sulfated proteoglycan and Sox9 (an essential early transcription factor for chondrogenesis) were undetectable in the cKO epiphyseal and growth plate cartilage. Interestingly, mice lacking Alk3 in the late chondrocyte obtained from the offspring of mice crossing between *Col X-Cre & Alk3fl* showed no apparent change in the cartilage, suggesting an essential early (but not late) role of ALK3 in controlling postnatal chondrogenesis, likely via regulation of SOX9. Of note is that the ribs are composed of true (bonny) and false (cartilage) components, whereas ribs are known to undergo intramembranous ossification. Surprisingly, the inactivation of Alk3 in early cartilage led to a sharp cortical bone volume increase in the boney ribs, indicating that rib ossification is cartilage-dependent and regulated by ALK3. Finally, we showed that inactivation of *Alk3* in cartilage led to a switch from the epiphysial perichondrium to a periosteum-like structures such as the lack of cartilage and great expansions of the bone bark (>10-fold increase) as evidenced by X-rays, uCT, immunostain, Safranin O and Toluidine Blue stains. In summary, our data support the vital role of ALK3 in postnatal endochondrogenesis via regulation of Sox9. The finding that severe defects in rib ossification but not in other flat bones suggest that rib bone formation is chondrocyte-dependent, in which ALK3 plays an essential role.

C-raf is Required for Normal Postnatal Growth Plate Maturation. Eva Liu*[1], Adalbert Raimann[2], Eric Zhu[3], Marie Demay[4]. [1]Brigham & Women's Hospital & Massachusetts General Hospital, USA, [2]Medical University Vienna & Massachusetts General Hospital, Austria, [3]Massachusetts General Hospital, USA, [4]Massachusetts General Hospital & Harvard Medical School, USA

Growth plate maturation is dependent upon differentiation of proliferative chondrocytes expressing type II collagen into type X collagen(Col X)-expressing hypertrophic chondrocytes. Hypertrophic chondrocyte apoptosis and signaling of vascular invasion are critical for replacement of cartilage by bone during endochondral bone development. Hypophosphatemia leads to rickets by impairing

hypertrophic chondrocyte apoptosis. Inhibiton of MEK1/2 blocks phosphate-induced Erk1/2 phosphorylation and hypertrophic chondrocyte apoptosis. However, it is unclear what signaling molecules upstream of MEK1/2 lead to phosphate-induced hypertrophic chondrocyte apoptosis. Lack of A-Raf and B-Raf in chondrocytes does not lead to a growth plate phenotype. However, C-raf is the predominant Raf isoform in hypertrophic chondrocytes and the role of C-Raf in the postnatal growth plate has not been examined.

Chondrocyte specific C-raf knockout (*C-raf$^{fl/fl}$*/Cre+) mice were generated by mating *Col2a1*- Cre transgenic mice to mice with floxed *C-raf* alleles. *C-raf$^{fl/fl}$*/Cre+ mice are born at normal mendelian ratios and are phenotypically indistinguishable from normal littermates at birth. Studies of the tibial growth plates of day 18 *C-raf$^{fl/fl}$*/Cre+ mice demonstrated a 2.5 fold increase in the number of hypertrophic chondrocytes per column compared to those of the *C-raf$^{fl/fl}$*/Cre- mice. *In situ* hybridization analyses for Col X confirm that the growth plate phenotype is secondary to an expansion of the hypertrophic chondrocyte layer and TUNEL labeling demonstrates a decrease in hypertrophic chondrocyte apoptosis, supporting the important role of C-raf in growth plate maturation. Immunohistochemical analyses show impaired Erk1/2 phosphorylation in hypertrophic chondrocytes on day 18. The growth plate phenotype of the C-*raf$^{fl/fl}$*/Cre+ mice persists but is milder at day 35.

Hypertrophic chondrocytes isolated from C-*raf$^{fl/fl}$*/Cre+ mice exhibit impaired Erk1/2 phosphorylation in response to 3 mM sodium phosphate, but not 7 mM sodium phosphate. These studies place C-raf upstream of MEK1/2 and Erk1/2 phosphorylation in the pathway of phosphate-induced hypertrophic chondrocyte apoptosis. They also suggest that high doses of phosphate may activate alternative signaling pathways that compensate for the lack of C-raf in the postnatal growth plate.

Dullard/Ctdnep1 regulates endochondral bone formation through limiting TGF-ß signaling. Tadayoshi Hayata*[1], Yoichi Ezura[2], Makoto Asashima[3], Ryuichi Nishinakamura[4], Masaki Noda[5]. [1]Medical Reserach Institute, Tokyo Medical & Dental University, Japan, [2]Tokyo Medical & Dental University, Medical Research Insititute, Japan, [3]Research Center of Stem Cell Engineering, National Institute of Advanced Industrial Science & Technology (AIST), Japan, [4]Department of Kidney Development, Institute of Molecular Embryology & Genetics, Kumamoto University, Japan, [5]Tokyo Medical & Dental University, Japan

TGF-ß signaling plays critical roles during skeletal development and homeostasis. Although excessive TGF-ß signaling is involved in pathogenesis of connective tissue genetic disease, little is known about maintenance of TGF-ß signaling at proper level during normal skeletal development. Unexpectedly, we found that Dullard/Ctdnep1, a phosphatase that negatively regulates BMP signaling and is required for kidney maintenance after birth, controls endochondral bone formation by suppressing TGF-ß signaling. Genetic inactivation of Dullard gene in limb bud and sternum by Prx1-Cre displays impairment of growth and ossification of skeletal elements and sternum leading to postnatal lethality. Ossification of sternum was severely impaired. There was no bone marrow space in sternebra, which was occupied with hypertrophic chondrocytes. To investigate how endochondral bone formation is affected by Dullard deficiency, we performed micromass culture experiment using early limb bud mesenchymal cells. Dullard-deficient limb bud mesenchymal cells show enhanced condensation and cartilage differentiation, which resembles TGF-ß-treated cells rather than those with treated with BMP. Moreover, LY-364947, a TGF-ß receptor I inhibitor, partially restored this phenotype in a dose-dependent fashion. Immunostaining experiment showed that levels of phospho-Smad2 are increased in Dullard-deficient micromass culture, while levels of phospho-Smad1/5/8 are comparable. When cultured in mineralizing condition, Dullard-deficient cartilage nodules did not show mineralization even without treatment with TGF-ß that can suppress mineralization. Although expression of hypertrophic chondrocyte marker genes including Col10a1, CTGF, Vegfa was upregulated, expression of genes related to mineralization including Alpl was suppressed, suggesting that terminal differentiation of hypertrophic chondrocyte was impaired by Dullard deficiency. Thus, we identified Dullard as a novel suppressor of TGF-ß signaling to regulate endochondral bone formation during skeletal development.

SU0085

Endogenous BMP7 activity maintains articular cartilage integrity by modulating inflammatory and catabolic factors. Kahaer Abula*[1], Takeshi Muneta[1], Kazumasa Miyatake[1], Jun Yamada[1], Yu Matsukura[1], Makiko Inoue[1], Ichiro Sekiya[1], Daniel Graf[2], Aris Economides[3], Vicki Rosen[4], Kunikazu Tsuji[1]. [1]Tokyo Medical & Dental University, Japan, [2]University of Zurich, Switzerland, [3]Regeneron Pharmaceuticals, Inc., USA, [4]Harvard School of Dental Medicine, USA

While the chondro-inductive activities of recombinant bone morphogenetic protein 7 (BMP7) are well established, evaluation of the role of endogenous BMP7 in articular cartilage homeostasis has been hampered by perinatal lethality in BMP7 knockout mice. To overcome these problems, we employed conditional deletion of BMP7 from the embryonic limb prior to the onset of skeletogenesis to create limb skeletons lacking BMP7. We have reported that the absence of locally produced BMP7 reduced proteoglycan contents in articular cartilage in the adult mice (at 8 and 24 weeks of age) and this was not due to the defect in cartilage formation since there was no significant alteration in both articular structure and proteoglycan contents in the juvenile BMP7 knockout mice (at 4 weeks of age).

To further analyze the physiological roles of BMP7 in the maintenance of articular cartilage, we investigated the chondrocyte survival, severity of synovial inflammation, and expression of matrix-degrading enzymes, such as hyaluronidase and MMP-13, in the BMP7 knockout mice. TUNEL staining of articular cartilage revealed that BMP7 did not affect chondrocyte survival at 8 weeks of age. Histological evaluation revealed that extensive synovial hyperplasia was observed in 8-week old BMP7 knockout mice. It seemed that severe synovitis occurred in the knockout mice since significant numbers of the cells in synovial membrane were positive for F4/80, a surface marker for mice macrophages. In contrast, appearance of synovial membrane was quite similar between control and BMP7 knockout mice at 4 weeks of age. Gene expression analysis of joint tissue from BMP7 knockout mice revealed that the expression of MMP-13 but not hyaluronidase was increased at 24 weeks of age. These data suggest that BMP7 maintains articular cartilage by negatively regulating synovial inflammation and MMP expression in the adult mice.

Essential roles of Cdc42 during endochondralossification. Wataru Suzuki*[1], Atsushi Yamada[1], Ryo Aizawa[2], Dai Suzuki[2], Mutsuko Nakayama[2], Shu Takeda[3], Koutaro Maki[2], Matsuo Yamamoto[4], Atsu Aiba[5], Kazuyoshi Baba[2], Ryutaro Kamijo[4]. [1]Showa University School of Dentistry, Japan, [2]Showa University, Japan, [3]Keio University, Dept. of Nephrology, Endocrinology & Metabolism, Japan, [4]Showa University School of Dentistry, Japan, [5]Tokyo University, Japan

Rho GTPases are regulators of multiple cellular functions, including cytoskeletal organization, cell migration, proliferation, and apoptosis. We previously reported that Cdc42, one of a Rho GTPases, is essential for limb development and limb bud interdigital programmed cell death using limb bud mesenchyme-specific inactivated Cdc42 mice (*Cdc42$^{fl/fl}$; Prx1-Cre*) (Aizawa R. *et al.* 2012 ASBMR Annual Meeting; Aizawa R. *et al. Mech. Dev.* 129; 38-50, 2012). In the present study, to investigate the physiological functions of Cdc42 during cartilage development, we generated chondrocyte-specific inactivated Cdc42 mutant mice (*Cdc42$^{fl/fl}$*; *Col2-Cre*), since conventional *Cdc42* null-embryos (*Cdc42$^{-/-}$*) die before embryonic day 7.5. The gross morphology of mutant neonates showed shorter limbs and body as compared to the control mice (*Cdc42$^{fl/fl}$*). Skeletal preparations stained with alcian blue and alizarin red also revealed that the body and long bone length of the mutants were shorter. Furthermore, severe defects were found in growth plate chondrocytes of the femur sections of mutant mice, characterized by a reduced height of proliferating zone, wider hypertrophic zone, and loss of columnar organization in proliferating chondrocytes. We speculated that this growth plate disorganization in the mutant mice was caused by abnormal differentiation of chondrocytes. *In situ* hybridization analyses were performed to investigate the expressions of cartilage differentiation marker genes, such as *type II collagen*, *type X collagen* and *Matrix metalloproteinase 13*, in growth plates of femur sections. The expression levels of those marker genes in mutant mice were decreased as compared to the control mice. Finally, Villanueva bone staining performed to detect mineralization of trabecular bones in femur sections showed it is decreased in mutants as compared to control mice, whereas osteoid volume was increased. Together, these results suggested that chondrocyte proliferation and differentiation in growth plates of the present mutant mice were not normally organized, which contributed to abnormal bone formation. We concluded that Cdc42 is essential for cartilage development during endochondral ossification.

Estrogen Via Estrogen Recptor Beta Inhibits Growth Of The Mandibular Condylar Cartilage. Sunil Wadhwa*[1], Manshan Xu[2], Jing Chen[1], Yoskue Kamiya[1]. [1]Columbia University, USA, [2]University of Connecticut Health Center, USA

Objective- Approximately 10 % of the United State population has suffered from temporomandibular joint disorders (TMD). 70% of the patients who present for TMD treatment are women of childbearing ages (16-35 years of age), suggesting that estrogen plays a role in TMD. However, the biological mechanism is largely unknown. It has been previously shown that ovariectomized female Willdtype (WT) mice have increased thickness and number of cells in their mandibular condylar cartilage compared to sham operated controls. In this study, we wanted to examine the role of estrogen receptor beta (ER Beta) in mediating the response.

Material and Methods- 21 day-old female WT and ER Beta Knock Out (KO) were divided into 3 groups- 1) Sham, 2) ovariectomy + vehicle and 3) ovariectomy + estrogen (0.01 mg/60 days), with an n=6-8 for each of the groups. The mice were sacrificed when they were 49 days of age. Histomorphometry of the mandibular condyle was performed. Measurements included cartilage thickness and cell counts for

the total mandibular condylar cartilage and for each of its 4 zones (articular, polymorphic, flattened and hypertrophic)

Results- *Intragroup*-We found that ovariectomy in female WT mice caused a significant increase in cell counts and thickness for the whole mandibular condylar cartilage and in the articular, polymorphic and flattened zone compared to sham operated WT mice. Further, this effect was reversed by exogenous estrogen treatment. In contrast, ovariectomy in female ER beta KO mice caused only a significant increase in cell counts and thickness in the hypertrophic zone compared to sham operated ER Beta KO controls. *Intergroup*- There was a significant increase in mandibular condylar cartilage thickness between Ovariectomized WT, Sham operated ER beta KO and Ovariectomized ER beta KO compared to sham operated WT controls and ovariectomized WT mice treated with estrogen supplementation.

Conclusion-The increase in mandibular condylar cartilage thickness by ovariectomy is mainly due to decreased estrogen - estrogen receptor beta signaling.

Expression of PPARα, β, γ, and H- and L-PGDS During Osteoarthritis in the Spontaneous Hartley Guinea Pig and the Experimental Dog Models. Sarah Salwa Nebbaki*, Fatim Ezzahra El Mansouri, Hassan Fahmi. Osteoarthritis Research Unit, Research Center- Hospital Center of Montreal University, Canada

Purpose: To investigate the expression of peroxisome proliferator-activated receptor (PPAR) α, β, γ, and hematopoietic and lipocaline-type prostaglandin D synthase (H- and L-PGDS) over the course of osteoarthritis (OA) in the spontaneous Hartely guinea pig and the anterior cruciate ligament transection dog models.

Methods: Guinea pigs were sacrificed at 2 (control group), 4, 8, and 12 (n = 5 per group) months of age. Non-operated (control) and operated dogs were sacrified at 4, 8 and 12 weeks post-surgery. Cartilage was evaluated histologically using the Osteoarthritis Research Society International (OARSI) guidelines. The expression of PPARα, β, γ, and H- and L-PGDS were evaluated by real-time PCR and immunohistochemistry. The non-parametric Spearman test was used for correlation analysis.

Results: PPARα, β and γ were detected in medial tibial plateau from control animals in both the spontaneous and surgical models. The levels of PPARα and β did not change over the course of OA, whereas PPARγ levels decreased during the progression of the disease. We also showed that the expression of H-PGDS remained unchanged, whereas that of L-PGDS increased over the course of OA. PPARγ levels correlated negatively, whereas L-PGDS levels correlated positively, with the histological score of OA.

Conclusion: The level of PPARγ decreased, whereas that of L-PGDS increased during the progression of OA. These data suggest that reduced expression of PPARγ may contribute to the pathogenesis of OA, whereas enhanced expression of L-PGDS may be part of a reparative process.

H3K9 Demethylation by LSD1 Contributes to IL-1-Induced mPGES-1 Expression in OA Chondrocytes. Fatima Ezzahra El Mansouri*[1], Hassan Fahmi[2]. [1]Research Center-CHUM, Canada, [2]Osteoarthritis research Unit, Research Center- Hospital Center of Montreal University, Canada

Introduction: Microsomal prostaglandin E synthase-1 catalyzes the terminal step in the biosynthesis of PGE_2, which plays a critical role in the pathophysiology of osteoarthritis.

Purpose: To investigate the role of histone H3 (H3K9) methylation in interleukin-1b (IL-1)-induced microsomal prostaglandin E synthase-1 (mPGES-1) expression in human osteoarthritic (OA) chondrocytes.

Methods: Chondrocytes were stimulated with IL-1 and the expression of mPGES-1mRNA was analyzed using real-time reverse transcriptase-polymerase chain reaction. H3K9 methylation and the recruitment of the histone demethylase LSD1 to the mPGES-1 promoter were evaluated using chromatin immunoprecipitation assays. The role of LSD1 was further evaluated using the the amino oxidase inhibitor tranylcypromine (a potent inhibitor of LSD1 activity).

Results: Treatment with IL-1 induced mPGES-1 expression in a time dependent manner. The induction of mPGES-1 expression by IL-1 was associated with H3K9 demethylation at the mPGES-1 promoter. These changes were concomitant with the recruitment of the histone demethylase LSD1. Treatment with tranylcypromine inhibited IL-1-induced H3K9 demethylation as well as IL-1-induced mPGES-1 expression.

Conclusion: These results indicate that H3K9 demethylation by LSD1 contributes to IL-1-induced mPGES-1 expression and suggest that this pathway could be a potential target for pharmacological intervention in the treatment of OA and possibly other arthritic diseases.

Hdac3 Promotes Chondrocyte Proliferation and β-Catenin Stability. Elizabeth Bradley*, Lomeli R. Carpio, Jennifer Westendorf. Mayo Clinic, USA

Histone deacetylases (Hdacs) modify histones and other proteins posttranslationally to influence gene expression and other cellular processes. We recently reported that conditional deletion of Hdac3 in osterix-expressing osteo-chondroprogenitor cells disrupts the maturation of growth plate chondrocytes and causes severe osteopenia and decreased bone length. Hdac3-deficient chondrocytes are smaller, have decreased expression of matrix genes and Vegf, and secrete less extracellular matrix. The decrease in matrix production is due to increased expression of the protein phosphatase Phlpp1, which dephosphorylates and inactivates the intracellular kinase, Akt. Here we report that β-catenin levels are also repressed by Hdac3 deficiency, as well as by Hdac inhibitors. Since β-catenin promotes chondrocyte division, we measured chondrocyte proliferation in Hdac3-deficient animals. Conditional deletion of Hdac3 decreased the number of proliferating, Ki67-positive chondrocytes in newborn mice. Wnt3a, an activator of β-catenin, did not alleviate the effects of Hdac3-deficiency on matrix production, suggesting that the effects of Hdac3 deficiency are due to defects in downstream signaling. Gsk3β, a kinase that triggers β-catenin degradation and is subject to negative regulation by Akt, is more active in Hdac3-deficient and Hdac-inhibitor treated cells. Inhibiting Gsk3β activity with lithium chloride partially rescued β-catenin levels, matrix deposition, and expression of Vegf. Constitutively active Akt also partially restored matrix production, Gsk3β inactivation and β-catenin levels caused by Hdac inhibition. However, proteasome inhibition completely restored β-catenin levels. Thus, Hdac3-deficiency reduces chondrocyte proliferation by promoting β-catenin phosphorylation and ubiquitination. These data demonstrate that Hdac3 represses both Gsk3β-dependent and -independent mechanisms to control β-catenin levels in chondrocytes.

Hif-2α inhibits chondrocyte differentiation through Runx2 degradation. Xiangguo Che*[1], Na-Rae Park[1], Gyoung-Ho Cho[1], Min-Su Han[1], Kyung-Eun Lim[1], Eui Kyun Park[1], Seungwoo Han[2], Youn-Kwan Jung[2], Gun-Woo Kim[2], Jae-Hwan Jeong[3], Je-Yong Choi[3]. [1]Kyungpook National University, South Korea, [2]Daegu Fatima Hospital, South Korea, [3]Kyungpook National University, School of Medicine, South Korea

Skeletogenesis is controlled by the cooperative activity of transcription factors. Runx2 is a critical regulator for both osteogenesis and chondrogenesis. Hypoxia inducible factor-2α (Hif-2α) has been known as an upstream regulator of Runx2 in osteoblasts. However, Hif-2α regulation of Runx2 in chondrocytes has not been determined. We found that forced expression of Hif-2α degraded Runx2 with no change of Runx2 mRNA expression in chondrocytes. Hif-2α-mediated Runx2 degradation was dependent on polyubiquitination-proteosome pathway. Interestingly, Hif-2α-mediated Runx2 degradation was blocked by overexpression of Cbfβ, suggesting the protective role of Cbfβ in Runx2 degradation. With respect to the effects of Hif-2α on Cbfβ function, Hif-2α inhibited nuclear localization of Cbfβ while its expression was not changed in chondrocytes. Diminished nuclear localization of Cbfβ by Hif-2α was due partly to the upregulation of Hdac4. Indeed, Hif-2α increased Hdac4 expression, and Hif-2α shRNA decreased Hdac4 expression in chondrocytes. Overexpression of Hdac4 decreased Runx2 and Runx2/Cbfβ complex formation in

chondrocytes. Both knockdown of Hif-2α in chondrocytes and micromass culture of mesenchymal cells derived from Hif-2α heterozygous mice accelerated chondrocyte differentiation. Collectively, these findings indicate that Hif-2α accelerates Runx2 degradation through upregulation of Hdac4, which inhibits chondrocyte differentiation.

NELL-1 Exerts Stage Specific Chondrogenic Effects During Chondrogenesis. Chenshuang Li*[1], Jie Jiang[1], Varsha Gupta[1], Michelle Ruano[1], Steven Shen[1], Chelsea Fan[1], Xinli Zhang[1], Chia Soo[1], Yanheng Zhou[2], Kang Ting[1]. [1]University of California, Los Angeles, USA, [2]Peking University, School & Hospital of Stomatology, China

Chondrogenesis is a complex process that leads to the establishment of cartilage and bone. Recently, our lab and others have shown NELL-1, a secreted growth factor, plays a significant role in this process. We found NELL-1 to be normally expressed in resting chondrocytes in the developing limb (P1) and in adult articular cartilage. Previous reports have shown Nell-1 deficiency results in abnormal skeletal development. Here we show that lack of Nell-1 results in the reduction of cartilaginous matrix deposition in both the vertebral body and the rib cage. In addition, we observed dis-regulation of the hypertrophic region in the vertebra and developing limbs. To further examine the role of NELL-1 during chondrogenesis we tested its chondrogenic effect on embryonic mesenchyme cell line, C3H10T1/2, as well as primary murine limb bud mesenchymal stem cells (E11.5). C3H10T1/2 cells were seeded in high density micromass culture. NELL-1 alone suppressed chondrogenic differentiation while combination of NELL-1 and BMP-2 enhanced the chondrogenic effect of BMP2 treatment after 6 days. Primary embryonic mesenchymal progenitor cells underwent chondrogenesis in pellet culture. NELL-1 treatment suppressed the expression of several chondrogenic differentiation markers including Sox9, Col2a1 and Agg. By Day 21, extensive cellular hypertrophy was seen histologically and a significant increase in hypertrophic markers was evident through qPCR. NELL-1 treated groups showed significant suppression of both hypertrophic (Adamts4, Mmp13, Col10, Ihh) and calcification markers (Alp, Ocn). Unlike Day 7, NELL-1 treatment also resulted in the up-regulation of anabolic cartilage markers (Col2a1, Agg) at Day 21.Our data demonstrates that NELL-1 plays an important role in skeletal development and chondrogenesis. We show here that NELL-1 exerts stage specific chondrogenic effect during chondrogenesis. It inhibits initial chondrogenic differentiation of progenitor cells, but promotes cartilage matrix deposition and inhibits hypertrophy and calcification in differentiated chondrocytes.

SU0093

Neutral Sphingomyelinase 2 Is Increased During BMP-induced Differentiation of ATDC5 Chondrocytes to Suppress the Maturation as a Negative Feedback Mechanism. Shingo Maeda*[1], Hironori Kakoi[2], Kanehiro Matsuyama[2], Katsuyuki Imamura[2], Ichiro Kawamura[2], Naohiro Shinohara[2], Masahiro Yokouchi[2], Yasuhiro Ishidou[2], Setsuro Komiya[2]. [1]Graduate School of Medical & Dental Sciences, Kagoshima University, Japan, [2]Department of Orthopaedic Surgery, Graduate School of Medical & Dental Sciences, Kagoshima University, Japan

Neutral sphingomyelinase 2 (nSMase2) is encoded by Sphingomyelin phosphodiesterase 3 gene (*Smpd3*). nSMase2 generates a lipid second messenger ceramide from a cell membrane component sphingomyelin. *Smpd3* knockout mice, or mice with a chemically induced loss-of-function genetic mutation called *fragilias ossium* (*fro*), show adult bone loss accompanied by impaired bone matrix mineralization. Interestingly, these mice displayed chondrodysplasia with increased chondrocyte maturation and decreased apoptosis of hypertrophic chondrocytes in developing bone growth plates. In fibroblasts, *Smpd3*/nSMase2-ceramide axis was shown to block Akt signaling and subsequent expression of hyaluronan synthase 2 (*Has2*), which enzyme is known to be crucial for hyaluronan synthesis in chondrocytes. However, the cell-autonomous roles of *Smpd3*/nSMase2 in chondrocytes remain largely unclear. Here, in ATDC5 chondrocytes, *Smpd3* was gradually up-regulated upon BMP-2 treatment. siRNA-mediated loss of *Smpd3*, or application of nSMase inhibitor GW4869, enhanced the expression of BMP-2-induced *Col2a1*, whereas overexpression of *Smpd3* by adenovirus, or addition of membrane permeable C2-ceramide, suppressed it. Knockdown of *Smpd3* specifically enhanced the phosphorylation of Akt and down stream ribosomal protein S6, assessed by examinations of receptor tyrosine kinase antibody arrays and immunoblotting. Expression of *Has2* was suppressed or elevated by gain or loss of function of nSMase2, respectively. By immunofluorescence of E17.5 mouse humerus growth plate, nSMase2 protein was detected not only in bone matrix, but also in maturating proliferating chondrocytes, prehypertrophic and hypertrophic chondrocytes. In contrast, Has2, as well as hyaluronan-binding protein (HABP), was detected in proliferating and prehypertrophic chondrocytes, but excluded from hypertrophic chondrocytes. Importantly, siSmpd3-mediated up-regulation of *Col2a1* and *Has2* in ATDC5 cells was cancelled by application of inhibitors for PI3K, Akt, or mTOR. Finally, by TUNEL staining, we found that knockdown of *Smpd3* decreased the rate of apoptosis in BMP-induced maturating ATDC5 chondrocytes. In conclusion, Smpd3/nSMase2-ceramide pathway is activated during BMP-induced chondrocyte maturation to inhibit PI3K-Akt-mTOR pathway, thereby keeping chondrocyte in immature state producing hyaluronate, as a negative feedback. In addition, nSMase2-produced ceramide seemed to prevent ATDC5 chondorcytes from apoptosis.

SU0094

The distinct role of the infrapatellar fat pad in a murine high-fat diet-induced osteoarthritis model. Munetaka Iwata*[1], Hiroki Ochi[2], Yasushi Hara[3], Masahiro Tagawa[3], Daisuke Koga[4], Atsushi Okawa[4], Yoshinori Asou[5]. [1]Nippon Veterinary & Life Science University, Japan, [2]Laboratory of Veterinary Microbiology, Nippon Veterinary & Life Science University, Japan, [3]Division of Veterinary Surgery, Department of Veterinary Science, Faculty of Veterinary Medicine, Nippon Veterinary & Life Science University, Japan, [4]Department of Orthopaedic Surgery, Tokyo Medical & Dental University, Japan, [5]Tokyo Medical & Dental University, Japan

Obesity and high body mass index are associated with a higher incidence of osteoarthritis (OA). As the infrapatellar fat pad (IPFP) from OA patients contains inflammatory cytokines, the IPFP could play an important role in the initiation and progression of knee-OA. However, the precise roles of the IPFP at the initiation of OA have not been elucidated. The aim of this study is to investigate the involvement of the IPFP in the sub-acute effect of a high fat diet (HFD) on the development of knee-OA. C57BL/6J male mice were fed either a HFD or a normal diet beginning at seven weeks of age. As excess weight caused by obesity introduces increased weight bearing on the knee joints, a tail suspension model (HFD+TS) was employed for HFD mice to clarify the involvement of mechanical stress in the histological alteration in the knee joints of the HFD mice. Tissue sections were evaluated with immunohistological analysis. The IPFP tissue was excised using a surgical microscope and microsurgical technique at sacrifice, and mRNA expression profiles were compared using real-time RT-PCR analysis. As results, osteoarthritic changes were initiated in the HFD and the HFD+TS group after 8 weeks of diet. Increased synovial cell number and angiogenesis at the anterior edge of the tibial plateau were exhibited prior to osteophyte formation. Quantitative histological analysis indicated that osteophyte volume was significantly increased both in the HFD and the HFD+TS group after 8 weeks, along with an increase in the IPFP volume, the size of individual adipocytes and the number of vessels in the IPFP. Histomorphometrical analysis revealed osteophyte area was significantly associated with IPFP area, individual adipocyte area and vascular area. Real-time RT-PCR analysis demonstrated elevated mRNA expression of inflammatory cytokines, growth factors, and adipokines, such as Nampt, Leptin, Chemerin and Lipocalin2, in the IPFP after eight weeks of the HFD regardless of TS. These findings were in parallel with increased expression of the CD68 in the IPFP. Moreover, expression levels of the adipokines were significantly correlated with the expression of TNF-α, VEGF and TGF-β. TUNEL-positive cells were abundantly observed in the superficial layer of the articular cartilage and at the site of osteophyte formation in the HFD and the HFD+TS mice. These observations suggest the IPFP plays a pivotal role in the formation of osteophytes and functions as a secretory organ in response to a HFD.

A ChIP-seq Defined Genome-wide Map of MEF2C Binding Reveals Pathways Associated with Bone Disease. Matthew Johnson*[1], Sandra Deliard[1], Fengchang Zhu[2], Andrew Wells[1], Kurt Hankenson[2], Struan Grant[1]. [1]Children's Hospital of Philadelphia, USA, [2]University of Pennsylvania, USA

Genome-wide association studies (GWAS) have demonstrated that genetic variation at the *MEF2C* (MADS box transcription enhancer factor 2, polypeptide C) locus is robustly associated with bone mineral density (BMD), primarily at the femoral neck (Estrada *et al*, Nat Genet 2012). MEF2C is a transcription factor known to operate via the Wnt signaling pathway. Our hypothesis is that MEF2C regulates the expression of a set of molecular pathways critical to skeletal function. Drawing on our laboratory and bioinformatic experience with ChIP-seq with another GWAS-implicated member of the Wnt signaling family, namely TCF7L2 [the most strongly associated locus for type 2 diabetes reported to date (Grant *et al*, Nat Genet 2006)], we analyzed ChIP-seq data for MEF2C available via the ENCODE project to similarly gain insight in to its global genomic binding pattern.

We aligned the ChIP-seq data generated for GM12878 (an established lymphoblastoid cell line). A total of 17,611 binding sites were observed using HOMER set at a false discovery rate of 1%, corresponding to 8,118 known genes.

We then performed a pathway analysis of the gene list using Ingenuity. Interestingly, the category entitled 'Cell Morphology, Skeletal & Muscular Disorders, Skeletal & Muscular System Development and Function' was ranked the most significantly enriched for 'Associated Network Functions'. Furthermore, when considering 'Ingenuity Canonical Pathways', ''RANK Signaling in Osteoclasts'' was among the top 10 most significant categories (P=9.3x10^{-10}; corrected P=6.85x10^{-8}), while ''Increased activation of Alkaline Phosphatase'' was significantly enriched in 'Top Tox Functions'. We also observed that MEF2C binding sites were significantly enriched near both inflammation and cardiovascular associated genes identified from GWAS; indeed, a similar enrichment for inflammation genes has been reported

previously using a similar approach for the vitamin D receptor, an established key regulator of bone turnover (Ramagopalan *et al*, Genome Res 2010).

These results represent the first ever reported ChIP-seq derived genome wide map of MEF2C binding. Our analyses point to known connective tissue and skeletal processes but also provide novel insights in to networks involved in skeletal regulation. The fact that specific GWAS categories are significantly enriched among genes bound by MEF2C not only speaks to its known cardiac role but also points to a possible role of inflammation through which it impacts BMD.

Altered collagen pro-peptide endopeptidases, bone morphogenetic protein-1 and a disintegrin and metalloproteinase with thrombospondin motifs-2, in thrombospondin-2 deficient osteoblasts. Eugene Manley, Jr.*, Andrea Alford. University of Michigan, USA

Our recent data suggest that thrombospondin-2 (TSP2) deficiency is associated with decreased collagen levels in the extracellular matrix (ECM) assembled by mesenchymal stem cells (MSC) undergoing osteoblastic differentiation in culture. Western blot analysis implicates deficient type I collagen pro-peptide removal. Here, our objective was to investigate factors associated with collagen processing and matrix stabilization in the context of TSP-2 deficiency.

Bone marrow-derived MSC were obtained from 6-week old male wild-type and TSP-2 null C57/B6 mice. Adherent cells were passaged and cultured in osteoblastic medium. After 4 days, RNA was harvested and reverse transcribed to cDNA, which was then used in quantitative RT-PCR reactions. Relative expression values, normalized to β-actin, were determined using the ΔΔCt method. Gene expression data are from MSC pooled from 2 animals per genotype and are presented as mean fold change. In two additional cell harvests, conditioned medium was collected for ELISA after day 4 and day 10. Protein data are mean and SD from two independent cell harvests totaling 6-9 wells per genotype.

At day 4, relative expression of the C-terminal pro-peptidase, bone morphogenic protein -1 (BMP-1) was decreased 1.75 fold in TSP2-null vs. wild-type cells. Conversely, at this time point, total BMP-1 protein levels were significantly increased in TSP2-null MSC-conditioned medium (153.9 $\pm$ 17.3 vs. 100.6 $\pm$ 30.5 ng/mL in TSP2-null and wild-type cultures, respectively, $p<0.001$). BMP-1 protein levels were similar after 10 days (147 $\pm$ 23.3 vs. 149.4 $\pm$ 12.3 ng/mL in TSP2-null and wild-type cultures, respectively). Compared to wild-type cells, expression of the N-terminal pro-peptidase, ADAMTS-2 was decreased 2.27 fold in TSP2-null cultures. We observed no differences in gene expression levels for procollagen C-endopeptidase enhancer 1 (PCPE1). We were unable to detect PCPE2. Lysyl oxidase (LOX), as well as lysyl oxidase-like 1-4 (LOXL1-4) catalyze intermolecular lysine-lysine bonds in the collagen ECM and these genes were not affected by TSP2-deficiency. Our preliminary data suggest that alterations in expression, bioavailability at the cell surface or activity of collagen pro-peptide endopeptidases may be responsible for impaired collagen matrix formation observed in TSP2-null osteoblasts.

Differentiation Potential and Molecular Characterization of Mesenchymal Stem Cells During Long-Term Monolayer Culture. Ali Mirsaidi[1], Reto Luginbuehl[2], Willy Hofstetter[3], Rainer Egli*[2]. [1]Bone & Stem Cell Research Group, CABMM, University of Zürich, Switzerland, [2]RMS Foundation, Switzerland, [3]University of Bern, Switzerland

Mesenchymal stem cells (MSC) are promising for regenerative approaches of musculoskeletal tissues. Due to their scarce occurrence, an *in vitro* culture expansion phase is necessary where the MSC lose their differentiation potential, which limits their clinical application. In this study we characterized the molecular changes in monolayer cultures of MSC and correlated those with the cells' differentiation potential. Human bone marrow derived MSC were obtained from a commercial supplier at passage 2 (P2) and were further expanded to P11 (= 16 population doublings (PD) from P2 - P11). Cells from all passages could be differentiated towards the adipogenic and osteogenic lineages in monolayer cultures with appropriate supplements. Chondrogenic differentiation and formation of a cartilaginous matrix in the presence of $TGF\beta_1$ was successful until P8 (= 13 PD) in micromass cultures. However, from P6 - P8 a gradual decrease was observed in levels of transcripts encoding collagen type II and aggrecan and in the staining intensity for glycosaminoglycans within the micromasses. The expression of MSC specific markers (CD44, CD105, CD166, CD271) did not change in monolayer cultures from P4 - P11, as assessed by flow cytometry. Transcript levels of 182 genes (MSC markers and molecules governing lineage specific differentiation) were measured in monolayers from P5 - P11. 48 genes were found with higher (up to 11-fold compared to P5) or lower (up to 4-fold) transcript levels with increasing passage numbers. We further selected for genes whose transcript levels are altered in parallel with the reduction of the chondrogenic potential to identify factors regulating chondrogenesis. Interestingly, whereas levels of transcripts encoding 2 TGFβ signaling inhibitors (BAMBI and BMPER) were found to be elevated (2-3-fold) in cells which lost their chondrogenic potential, no changes were observed in the transcript levels of TGFβ receptors. Thus, increased expression of these inhibitors may reduce the efficiency of exogenously added $TGF\beta_1$ to induce a signal cascade and as a consequence inhibit chondrogenic differentiation. Other genes that exhibit a change of transcript levels at least by a factor of 2 at P11 as compared to P5 and paralleling the loss of chondrogenic potential were ICAM1, PDE1A, SLC40A1, CREB3, IGFBP1 and IGF1. How the different transcript levels translate into protein levels and whether these are relevant in chondrogenesis of MSC requires further elucidation.

Second Generation Sequencing Reveals the micro-RNA Expression Patterns in Primary Human Bone Cells treated with Parathyroid Hormone or Dexamethasone. Navya Laxman*[1], Carl-Johan Rubin[1], Hans Mallmin[2], Olle Nilsson[1], Christian Tellgren-Roth[1], Andreas Kindmark[2]. [1]uppsala University, Sweden, [2]Uppsala University Hospital, Sweden

Objective: Parathyroid hormone (PTH) has a positive effect and Dexamethasone (DEXA) has a negative effect on bone formation. In the present project, we have investigated the impact of treatment of parathyroid hormone (PTH) and dexamethasone (DEXA) on global miRNA expression in primary human bone (HOB) cells by second generation sequencing of small RNA. Micro-RNAs (miRNAs), small non-coding RNAs, identified as regulators in various biological processes, have been shown to be involved in human development and disease. By binding to complementary RNA strands, they efficiently affect mRNA levels and/or mRNA translation.

Method: HOB cells were isolated from human trabecular bone collected from donors undergoing total hip replacement, and treated with either PTH or DEXA or left untreated for 2 and 24 hours. Small RNA was isolated from these cells and cDNA synthesized using SOLiD library reagents. Second generation sequencing was performed using SOLiD4 on barcoded library constructs of small RNA 50bp plus barcode, at the Uppsala Genome Center. Sequence reads were aligned to a scaffold consisting of all known miRNA sequences, and number of sequence reads mapping uniquely to each miRNA were counted. The value used for each miRNA was the number of reads per miRNA normalized to per million total reads.

Results: A total of 207 million reads from the small RNA library constructs was obtained, and normalized absolute expression was retrieved for the 500 most abundant miRNAs. The 75 miRNAs that exhibited the highest mean expression across the four experiments per individual were taken forward for downstream analyses. Expression levels were set to percent of each samples respective untreated control, and results show a significant effect of treatment with PTH vs treatment with DEXA at 2 hours and even more pronounced at 24 hours on miRNA expression. Interestingly, several miRNAs exhibiting significant differences in expression have predicted mRNA targets involved in bone metabolism, e.g. miR-197 targeting IGF and Wnt pathway members. Also, miR-31 showed differential expression, and we have previously shown that miR-31 expression in bone cells is correlated with mRNA expression for WNT, WNT3A, b-Catenin and GSK3b.

Conclusion: miRNA absolute expression data from second generation sequencing show that PTH and DEXA affect miRNA expression in primary human bone cells, and that these miRNAs in turn are correlated to expression levels of mRNAs known to affect bone metabolism.

SU0099

Comparison of a Novel Osteogenic Oxysterol Molecule and rhBMP2 Fusion Rates in a Rabbit Posterolateral Lumbar Spine Model. Trevor Scott*[1], Kevin Phan[1], Scott Montgomery[1], Akinobuh Suzuki[1], Haijun Tian[1], Michael Daubs[1], Sotirios Tetradis[2], Elisa Atti[1], Theodore Hahn[3], Jeffrey Wang[1], Farhad Parhami[2]. [1]UCLA, USA, [2]University of California, Los Angeles, USA, [3]VA Greater Los Angeles/ UCLA Medical Center, USA

The non-union rate following lumbar spinal fusion is potentially as high as 35%. This can be a significant clinical problem. Traditionally iliac crest autograft was used as a fusion adjunct, but its use is limited by donor site morbidity and lack of available graft volume required for large fusion surgeries. Over the past 10 years recombinant human bone morphogenic protein 2 (rhBMP2) has been used as a biological adjunct to promote bony fusion. However, recently there have been increasing concerns about rhBMP2 relating to increased inflammatory response, and potential problems with bone fusion quality. The small molecule osteogenic oxysterol 133 (Oxy133) has been shown to promote excellent fusion rates in rodent lumbar spine models and offers a potential alternative to rhBMP2. The purpose of this study, a randomized control trial in an animal model, was to compare the fusion rate of rhBMP2 and Oxy133 in a posterolateral lumbar rabbit spinal fusion model.

24 male adult white New Zealand rabbits (3-3.5kg) underwent bilateral posterolateral lumbar spinal fusion at L4-L5. Rabbits were divided into 4 groups: control (A), 30 ug rhBMP2 (B), 20 ug oxy (C), and 60 ug oxy (D). A mineral collagen matrix infused with saline for control or one of the above compounds was implanted at the

fusion site. At 4 weeks fusion was evaluated by fluoroscopy. At 8 weeks the rabbits were sacrificed and fusion was evaluated radiographically and by manual palpation of excised spines. At 4 weeks fusion rates were as follows: group A 25%, group B 67.7%, group C 91.7%, group D 90.0%. At 8 weeks fusion rates by radiographic analysis were: group A 40.0%, group B 91.7%, group C 91.7%, and group D 100%. Groups C and D had a significantly higher fusion rate than group A at 4 weeks (P= 0.003 A vs. C, P=0.004 A vs. D). At 8 weeks group D had a significantly higher fusion rate than group A (P= 0.011). When the fusion masses were evaluated by manual palpation group A was 40% fused, group B was 67.7% fused, group C was 67.7% fused, and group D was 100% fused. Based on these results, in a rabbit model low dose Oxy133 appears to promote earlier fusion than rhBMP2 and our high dose oxysterol group seemed to have both earlier fusion and a greater ultimate fusion rate than rhBMP2 (100% vs. 67.7%, respectively). Given its osteogenic potency, anticipated lack of immunogenicity, and low cost of production, Oxy133 may be an excellent alternative to rhBMP2 for spinal fusion procedures.

Dose dependent effect of low intensity pulsed ultrasound on the condylar growth during functional appliance treatment. Harmanpreet Kaur*, Hasan uludag, Douglas Dederich, Tarek El-Bialy. University of Alberta, Canada

Objective: One of the common anomalies of oro-facial region is underdeveloped lower jaw, also known as Class ll malocclusion. Underdeveloped lower jaw can compromise airway and may lead to sleep apnea. Treating malocclusions in growing patients by using functional appliance is believed to produce satisfactory improvement in esthetics and minimize the need for the surgical intervention. However, the effectiveness of these functional appliances is controversial. Previous studies have found that therapeutic ultrasound (low intensity pulsed ultrasound LIPUS)can stimulate cartilage and bone growth, but optimum LIPUS treatment to maximize lower jaw growth is not known. The objective of this study is to evaluate the synergetic effect of functional appliance combined with daily 20 min or 40 min LIPUS on the mandibular condyle growth.

Materials & Method: 54 Sprague Dawley rats were divided into 6 groups (n=9) namely; 1 conrol- no functional appliance or LIPUS application, 2 Functional Appliance group, 3 LIPUS 20 min application, 4 LIPUS 40 min application, 5 Functional Appliance + LIPUS 20 min, 6 Functional Appliance + LIPUS 40 min. The appliance was custom made for each rat and was placed on upper anterior teeth when the rats were 28 days old. LIPUS was applied for 20 min or 40 min per day for 4 weeks. After euthanasia, mandibles were dissected and were fixed in 10% formalin for the anthropometric measurements and the condyles were decalcified and processed for histological examination.

Results: Anthropometric measurements showed increase in mandible length, height and condyle length which was statistically significant in both LIPUS treated functional appliance groups ($p<0.05$). Similarly, histological studies showed increase in proliferative and hypertrophic cell counts in both LIPUS treated functional appliance groups ($p<0.05$). LIPUS treated functional appliance groups showed increase in the thickness of proliferative and hypertrophic cell layers. However, no significant difference was found between 20 min and 40 min LIPUS application in functional appliance groups.

Conclusion: LIPUS enhances the condylar growth when combined with the functional appliance. The effect of LIPUS and functional appliance on the growing condyle is expressed through the increase in anthropometric measurements (length, height of mandible and condyle length) and increase in the cell numbers. However no significant difference was found between 20 min and 40 min LIPUS appcation.

Effects of Selective Serotonin Reuptake Inhibitor Exposure on Markers of Osteogenesis. James Cray*[1], Kameron Khaksarfard[1], Seth Weinberg[2], Mohammed Elsalanty[3], Jack Yu[1]. [1]Georgia Regents University, USA, [2]University of Pittsburgh, USA, [3]Georgia Health Science University, USA

Recently, serotonin has been shown to have an effect on the development and maintenance of bone. Selective Serotonin Reuptake Inhibitor (SSRI) drugs have been implicated in both birth defects of the craniofacial skeleton, e.g. craniosynostosis, and long term disruption of bone health, e.g. osteoporosis. Here we provide a preliminary report of the effects of exogenous SSRI exposure on cells derived from murine calvaria. Murine derived calvaria cells were exposed to the SSRI, escitalopram oxalate at critical doses for 3 or 7 days in culture. Endpoint assays were designed to determine the effects of the drug exposure on markers of osteogenesis and included, MTS proliferation, quantitative ALP activity, quantitative PCR (qPCR) for osteogenic markers (*Runx2, Alp, Ocn*), and target receptors of the drug (*Slc6a2, Slc6a3, Slc6a4*), and genome-wide arrays with qPCR confirmation of dysregulated targets. There appeared to be little effect on proliferation after drug treatment. However, exogenous exposure to SSRI appears to stimulate cells to express ALP in a dose dependent manner. *Alp* and *Ocn* were confirmed to be significantly upregulated (>2 fold) after 7 days in culture treated with SSRI. In addition, *Slc6a4*, the serotonin transporter, was the only monoamine transporter target that was significantly downregulated after treatment. The genome wide microarray identified 35 genes that were significantly dysregulated (>2 or <-2 fold change in regulation of mRNA). 17 targets were chosen due to identification in bone or craniofacial development pathways. 3 genes were confirmed as upregulated (*Msx1,Notch1, Fgf2*) and 6 genes (*Aspn, Col2a1, Fgfr2, Gdf6,Igf1, Tgfβ2*) were confirmed as downregulated after treatment. These data appear to suggest multiple influences of SSRI drugs on bone likely through its effects on serotonin. The dysregulation of *Aspn* and the *Fgf*s are likely candidates for mechanism of action in craniosynostosis, while the downregulation of *Igf1, Gdf6*, and *Tgfβ* after drug treatment make likely candidates in the cascade of events influencing osteoporosis.

Human Dental Pulp Cells as Sources for iPS Cell Banking. Ken-Ichi Tezuka*[1], Tomoko Kawaguchi[2], Naritaka Tamaoki[2], Kazuki Iida[2]. [1]Gifu University Graduate School of Medicine, Japan, [2]Gifu University, Japan

Human dental pulp cells (DPCs) are present in the cell population isolated from dental pulp tissues. We reported that viral introduction of four transcription factors (*OCT3/4*, *SOX2*, *KLF4*, and *c-MYC*) can reprogram DPCs into induced pluripotent stem (iPS) cells. However, we also found that establishing validated iPS cell lines from a number of patients require considerable time and cost. Human leukocyte antigen (HLA) plays a major role in rejection of tissues and cells transplanted from allogenic donors. Because of shortage of the donors, immnosuppressants are frequently used to suppress rejection; however, when the immune system function is suppressed, there is an increased susceptibility to infectious diseases and cancers.

To solve this problem, usage of HLA haplotype-homo donors has been considered in iPS cell therapy. HLA haplotype-homo donors have a couple of identical HLA gene sets. Therefore, iPS cells derived from HLA haplotype-homo donors are expected to be successfully transplanted to many patients with less possibility of rejection. We screened 171 DPC lines to find three patients having only one genotype in each of three HLA loci, A, B, DRB1. If iPS cells will be established from these three patients, they are expected to show complete match with approximately 20% of the Japanese population.DPCs are medical wastes collected from a large number of healthy donors without large ethical problems. Therefore, DPCs will be considered as one of the somatic cell sources for future iPS cell banking and regenerative medicine.

IDG-SW3 osteocyte-like cell line expresses insulin receptor as well as GLUT1 and GLUT3. Donna Pacicca*[1], Tammy Brown[1], Karen Kover[1], Lynda Bonewald[2]. [1]Children's Mercy Hospital, USA, [2]University of Missouri - Kansas City, USA

As diabetes can affect bone quality and the osteocyte product sclerostin has been shown to be elevated in diabetes, we sought to determine if high or low concentrations of glucose will have an effect on osteocyte products. The IDG-SW3 cell line was used as this cell differentiates in culture from a late osteoblast to early osteocyte to late osteocyte. IDG-SW3 cells were cultured under four different glucose concentrations: low (2.5 mM), normal (10mM), high (25mM) and mannitol control for high osmolarity (glucose 10mM with mannitol 15mM). Media was changed daily and cells were harvested at 7, 14 and 21 days. Assays were performed for LDH, lactate, glucose and gene expression. PCR array was performed to evaluate for gene expression versus normal mouse tissues, and qPCR was performed on samples from the four groups. Glucose utilization and lactate production increased over time, with similar rates across. PCR demonstrated expression of insulin receptor, and glucose transport proteins 1 and 3 at levels similar to those previously reported. GLUT1 was significantly decreased in high glucose, with no significant changes in osteocalcin, E11/gp38, sclerostin and FGF23. IDG-SW3 cells demonstrate primarily glycolytic use of glucose, similar to findings using whole bone. They also express GLUT1, responsible for basal cell uptake of glucose, as well as GLUT3 similar to neurons. Hypo- and hyperglycemic conditions did not appear to have an adverse effect on osteocyte gene expression, however the osteoblast marker keratocan was elevated with high and decreased with low glucose. We also show that osteocytes express InsR which has not previously been seen in vivo in osteocytes. Our data suggest that osteocytic cells may be able to tolerate changes in glucose concentration without affecting their function in bone.

MLB13 Cells Recapitulate In Vitro Endochondral Bone Formation with Distinct Responses to Various Skeletal Growth Factors. Valerie Salazar*, Vicki Rosen. Harvard School of Dental Medicine, USA

Immortalized mouse limb bud cells from E13 embryos, or MLB13 cells, were originally used to demonstrate sequential induction of chondrocyte and osteoblast markers by bone morphogenetic protein 2 (BMP2). To understand how these clonal endochondral progenitors respond to other growth factors that regulate bone mass, we conducted a timecourse study to monitor the effects of Noggin, BMP2, TGF-β, Wnt3a, or PTH_{1-34} on osteoblast and chondrocyte lineage markers, and performed endpoint biochemical stains to identify the type of mature matrix produced. Consistent with our previous study, MLB13 cells (clone 14) respond vigorously to exogenous BMP2, exhibiting robust collagen deposition and alkaline phosphatase (ALP) activity coupled with matrix calcification and cartilage formation. Osteogenic markers such as *Alp1*, *Osx*, *Ocn*, and *Opn* are induced at the mRNA level, in addition to the chondrocyte markers *Ihh* and *Col10*. Noggin has reciprocal effects, with dramatically diminished collagen deposition and ALP activity, and undetectable amounts of mineralized or cartilage matrix, thus revealing that endogenously produced BMPs drive basal levels of osteochondral activity in these cells. Wnt3a mildly increases collagen production but has little impact on expression of osteoblast markers, ALP activity or matrix calcification. Consistent however with reports that Wnts antagonize chondrogenesis, MLB13s downregulate *Ihh* and *Col10* mRNAs and do not deposit cartilage in the presence of Wnt3a. PTH_{1-34} has similar effects, resulting in a strong suppression chondrogenesis without a compensatory increase in osteoblast formation. In fact, ALP activity was mildly diminished by PTH_{1-34} relative to control cultures. TGF-β has a striking inhibitory effect, completely blocking ALP activity, matrix calcification, and cartilage deposition, in correlation with strong downregulation of *Osx*, *Alp1*, *Ocn*, and *Ihh*. TGF-β has minimal effects on *Col1α1*, *Col2* and *Col10*. Meanwhile, *Col2* and *Col10*, but not *Col1α1*, are reciprocally regulated by Noggin and BMP2. Interestingly, total collagen deposition is not predicted by collagen mRNA expression alone, suggesting additional mechanisms contribute to collagen biosynthesis. Furthermore, collagen deposition plus ALP activity does not predict production of mineralized or cartilage matrix. In summary, our study presents MLB13 cells as a robust *in vitro* model of osteochondrogenesis, with particular suitabililty for studies on BMP/TGF-β signaling.

Nutritionally Induced Delayed Union Model of Femur Fractures In Mice. Anthony De Giacomo*[1], Joshua Teich[1], Marie Demay[2], Elise Morgan[3], Louis Gerstenfeld[1], Thomas Einhorn[4]. [1]Boston University School of Medicine, USA, [2]Massachusetts General Hospital & Harvard Medical School, USA, [3]Boston University, USA, [4]Boston Medical Center, USA

Introduction: Fracture healing, a complex biologic process, requires the synchronization of several cell types to regain mechanical competence and allow weight bearing. Failure in coordinating, or completing, this biologic process results in a non-union of the fractured bone. Inorganic phosphate, an essential mineral for maintaining healthy bones, is believed to be a critical component for bone healing. The goal of this study was to generate a nutritionally induced murine non-union model of fracture healing.

Methods: A standard diet and one deficient in phosphate, was administered to C57/B6 mice two days prior to closed fracture of the femur. Mice were maintained on the phosphate deficient diet for 5, 10, 15, and 20 days prior to being returned to the normal diet. RNA was isolated from the callus at various time points (3-35days). Plain film and MicroCT radiography was used to assess the progression of fracture healing. The biologic process of bone healing was assessed by histology and qRT-PCR was used to evaluate mRNA expression for multiple marker genes of chondrogenesis (Aggrecan, Collagen 2a1, Collagen10a1) and osteogenesis (Osterix, RUNX2, ID1).

Results: Delayed bone healing was induced by a phosphate restricted diet. The phosphate restricted diet led to a time dependent impairment of healing where mice maintained on longer periods of phosphate restriction (i.e. 15 & 20 days) showed a more prolonged period of impaired healing. Phosphate restriction did not inhibit chondrogenesis, but rather led to a delayed and enhanced expression of chondrogenic markers, indicating that the callus remained primarily cartilage. Conversely, compared to controls, osteogenic gene expression was blunted and a progressive delay in initiation of osteogenic gene expression was observed with progressively longer periods of dietary phosphate restriction. When phosphate was re-introduced to the diet, the process of fracture healing reinitiated; however, progressively longer periods of time were required to achieve union based on the initial period of phosphate restriction.

Discussion: Phosphate restriction demonstrated an inhibitory affect on bone healing by impairing osteogenesis, but not necessarily chondrogenesis. The data suggest that dietary restriction of phosphate can be used as a model of nutritionally induced delayed union of femur fracture, while allowing identification of, the molecular events that promote cartilage mineralization and initiation of osteogenesis.

PLGA/TCP Scaffolds Incorporating Phytoestrogenic Molecule Icaritin Developed for Bone Defect Repair. Shihui Chen*[1], Lizhen Zheng[2], Xinhui Xie[2], Xinluan Wang[2], Ling Qin[3]. [1]Prince of Wales Hospital, Hong Kong, [2]The Chinese University of Hong Kong, Hong Kong, [3]Chinese University of Hong Kong, Hong Kong

Introduction: The concept of bone loss therapy focuses on the conductive scaffold for tissue regeneration. In this project, growth factor BMP2 or phytoestrogenic small molecule icaritin (ICT) was combined respectively with PLGA/TCP scaffolds served as a delivery system for bone regeneration, namely PLGA/TCP/icaritin with three different doses and PLGA/TCP/BMP2 by low temperature pro-typing technology. The hypothesis is that the technology can maintain the original bioactivity of BMP2 and icaritin, which will lead to ready to use production for efficient orthopaedics application.

Methods: Fabricated scaffolds: P/T (A), P/T/LICT (B), P/T/MICT (C), P/T/HICT (D), P/T/BMP2 (E). Our previous *in vitro* results demonstrated the increasing ALP activity and calcium deposition of BMSCs onto scaffolds of group B, C, D compared to group A and E, we further detected the mRNA expression of osteogenic genes. We established an ulnar bone defect model in rabbits and measured X-ray, Xtreme CT and histology at weeks 2, 4 and 8. One-way ANOVA was used for statistical analysis.

Results: The scaffolds were fabricated with $78 \pm 3.63\%$ porosity and 300-450 μm pore diameter (Figure 1). mRNA expression of Collagen type I and Osteopontin were up-regulated in P/T/ICT compared with P/T and P/T/BMP2 scaffolds. At weeks 2, 4 and 8, the radiographic results showed that there were more bone regeneration in the pores of scaffolds in group B, C, D compared with group A and E (Figure 2). CT analysis showed the better bone formation in group B, C, D in comparison with those in group A and E (Figure 3). H&E staining in decalcified histology of the rabbit ulna segmental bone defect at week 2, 4 and 8 post surgery also indicated the same results.

Discussion: *In vitro* study, the results demonstrated that P/T/ICT could enhance significantly osteogenic differentiation of cultured BMSCs, as ICT was able to keep its normal activity during fabrication procedure. However, P/T/BMP2 did not show initially osteogenic effects, which might be explained by that BMP-2 exerted unstable bioactivity during preparation of scaffolds, which however did not occur using immersion protocol. In bone defect model, P/T/ICT treatment showed enhanced bone regeneration than P/T and P/T/BMP2 treatments. However, the osteogenesis mechanism of composite scaffolds still need to be deteced in the next step. P/T/ICT as innovative composite scaffolds possess osteogenic differentiation potential *in vitro* or *in vivo* data.

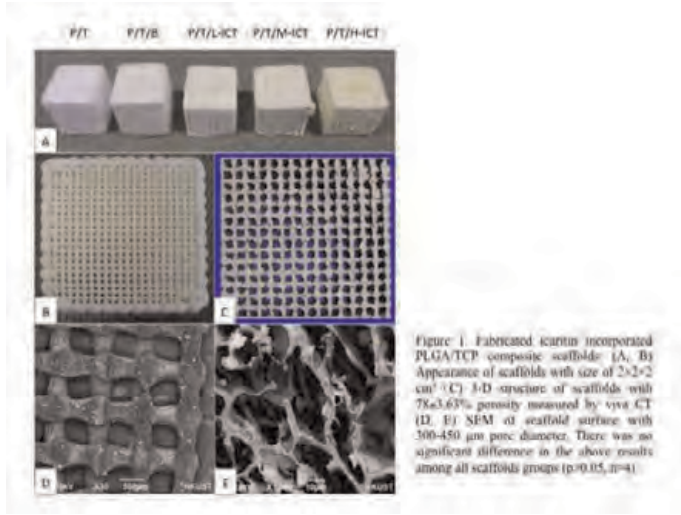

Figure 1. Fabricated icaritin incorporated PLGA/TCP composite scaffolds (A, B) Appearance of scaffolds with size of 2×2×2 cm^3 (C) 3-D structure of scaffolds with 78±3.63% porosity measured by vivo CT (D, E) SEM of scaffold surface with 300-450 μm pore diameter. There was no significant difference in the above results among all scaffolds groups (p>0.05, n=4)

Figure 1

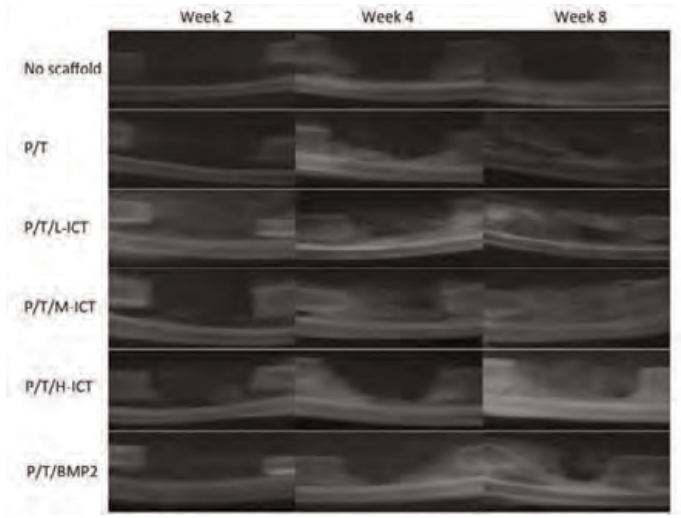

Figure 2a

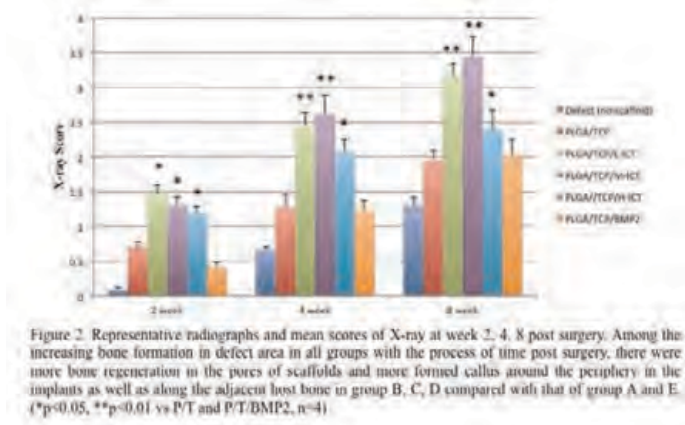

Figure 2. Representative radiographs and mean scores of X-ray at week 2, 4, 8 post surgery. Among the increasing bone formation in defect area in all groups with the process of time post surgery, there were more bone regeneration in the pores of scaffolds and more formed callus around the periphery in the implants as well as along the adjacent host bone in group B, C, D compared with that of group A and E. (*p<0.05, **p<0.01 vs P/T and P/T/BMP2, n=4)

Figure 2b

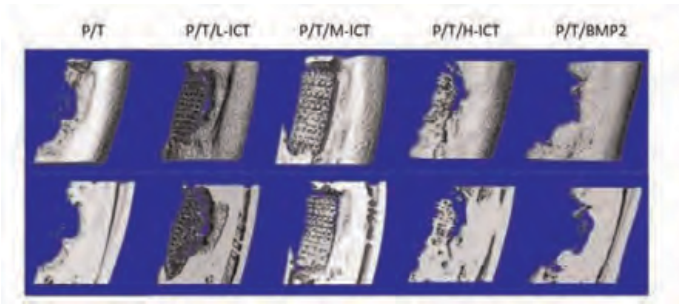

Figure 3a

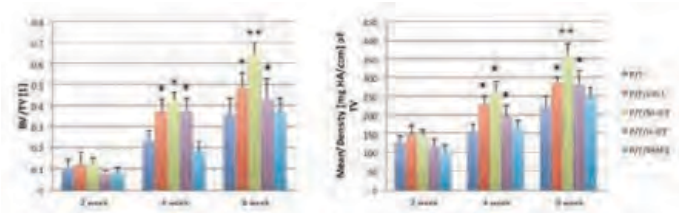

Figure 3 Representative XtremeCT analysis images and evaluated data at week 4,8 post surgery. Images showed the better bone formation in defects of group B, C and D compared to that in group A and E, and bone density and relative bone volume in defect area demonstrated the significant increasing in group B, C, D in comparison with those in group A and E. (*p<0.05, ** p<0.01 vs P/T and P/T/BMP2, n=4)

Serum Undercarboxylated Osteocalcin correlates with aging related hearing loss. SANG HYEON JE[1], Duck Joo Lee*[2]. [1]Ajou University Hospital, Department of Family Medicine, South Korea, [2]Ajou University School of Medicine, South Korea

Background: Recent studies have revealed that elevated levels of serum UCOC (undercarboxylated osteocalcin) are associated with low bone mineral density. Further studies have proved bone mineral density in lumbar vertebra increases after taking vitamin K, which is a strong factor in decreasing serum UCOC. Because bone metabolism also affects ear bones, the serum UCOC may affect ear bone mineral density. The aim of this study is to understand the relationship between levels of serum UCOC and hearing loss.

Materials and methods: The study comprised of 2,316 patients who had visited Geoje Health Promotion center, Daewoo Hospital for general health checkups. The levels of serum UCOC, PTA, Fasting blood glucose, GOT, GPT, Uric acid, insulin, ESR, CRP were measured. PTA (pure tone audiogram) was used to measure hearing loss. We used statistical software SPSS 11.0 for data analysis.

Results:The serum UCOC levels were significantly correlated with decibels in all frequency levels of PTA (0.280 in 1000 Hz and 0.184 in 4000 Hz, $P<0.05$). The higher the decibels in PTA are, the lower the hearing ability is. Both men and women groups showed a similar result in hearing ability by each PTA frequency and in UCOC levels.The 30s age group showed a significant decrease in serum UCOC levels (1.27 ± 0.81ng/mL) as compared with 40s or 50s age group. The decibel in PTA was significantly higher in the high serum UCOC group (15.21 ± 13.39 DB in 1000 Hz) than in the low serum UCOC group (13.74 ± 11.50 in 1000 Hz, $P < 0.05$) and nonsignificantly higher in other frequency groups.

Conclusion: Serum UCOC's effects on hearing bones may point toward their possible application of vitamin K supplements in improving hearing, especially for the aging related hearing loss. However, as we used PTA, we don't know whether the loss is caused by a sensory problem or a mechanical problem. Further studies should be followed.

Characterization of an Fkbp10$^{-/-}$ mouse model of recessive Osteogenesis Imperfecta. Caressa Lietman*[1], Erica Homan[1], Tao Yang[2], Elda Munivez[1], Ming-Ming Jiang[1], Terry Bertin[1], Yuqing Chen[1], Deborah Krakow[3], Brendan Lee[4]. [1]Baylor College of Medicine, USA, [2]Van Andel Research Institute, USA, [3]UCLA, USA, [4]Baylor College of Medicine & Howard Hughes Medical Institute, USA

Osteogenesis Imperfecta (OI) is the most commonly inherited form of brittle bone disease and displays a spectrum of severity from mild phenotypes to severe early lethality. Key clinical features of OI are bone fragility and low bone mass, whereas patients may also display blue sclera, dentinogenesis imperfecta, joint and skin laxity, hearing impairment and/or wormian bones on the skull. Mutations in FK506 Binding Protein 10 (*FKBP10*) that encode the FKBP65 protein result in recessive OI as well as Bruck Syndrome. FKBP65 is thought to act as a collagen chaperone and possesses PPIase activity for proper trimer formation. Currently, we do not understand the consequences of *FKBP10* loss and its role in collagen and ECM formation. Therefore our goal is to elucidate the role of *FKBP10* in the skeleton and how null mutations lead to progressively deforming OI and Bruck syndrome. We generated a mouse model using the EUCOMM allele to further elucidate the effects of FKBP65 in bone development. We have utilized the LacZ knockin allele to assess expression during development as well as the knockout first allele to discern the phenotypic outcomes of FKBP65 loss in the mouse. Furthermore, mouse embryonic fibroblasts (MEFs) have been used for comparison to human cells and for collagen studies and analysis. We found that *Fkbp10* is expressed at low levels at E13.5 particularly in skeletal tissues and increasing through E17.5 with expression in not only skeletal tissues, but also other mesothelial lined tissues, vessels and villi of intestine. Postnatally, expression is limited to developing bone and ligaments, suggesting a more restricted role at this timepoint. Null mice display neonatal lethality with viable embryos isolated up to E18.5 but not after birth, growth delay and generalized tissue fragility. *Fkbp10*$^{-/-}$ mouse embryonic fibroblasts show retention of procollagen in the cell layer after ascorbic acid stimulation, similar to what is seen in patient fibroblasts. These data suggest a requirement for *Fkbp10* function during embryonic connective tissue development in mice but restricted expression postnatally in bone, ligaments, and tendons correlating with the bone fragility and contracture phenotype in humans.

Expression of both Bone Sialoprotein and Osteopontin Is Necessary to the Anabolic Action of PTH on Mouse Calvaria Bone. Wafa Bouleftour*[1], Guénaëlle Bouët[2], Renata Neves Granito[1], Mireille Thomas[1], Marie-Thérèse Linossier[1], Arnaud Vanden Bossche[1], Jane Aubin[3], Marie-Helene Lafage-Proust[4], Laurence Vico[5], Luc Malaval[6]. [1]LBTO/INSERM U1059 - Université de Lyon, France, [2]LBTO/INSERM U1059 - F42023 Université de Lyon, France, [3]University of Toronto Faculty of Medicine, Canada, [4]INSERM Unit 890, France, [5]University of St-Etienne, France, [6]INSERM U1059-Université de Lyon-Université Jean Monnet, Saint-Etienne, France

Bone remodeling is tightly regulated by central, systemic, and local factors, including extra-cellular matrix proteins. Among these, osteopontin (OPN) and bone sialoprotein (BSP), both members of the "small integrin-binding ligand, N-linked glycoprotein" (SIBLING) family, are coexpressed in both osteoblasts and osteoclasts and involved in primary and secondary ossification. Previous work suggested that some functions of BSP and OPN are redundant while others are not. Here, we investigated their degree of specificity and redundancy in a local (calvaria) model of PTH-induced remodeling.

Comparison of calvaria cell cultures from BSP+/+ and BSP-/- mice revealed few osteoblast colonies (bone nodules) and no mineralization in mutant dishes, along with little/no expression of osteocalcin (OCN) nor SIBLING proteins MEPE or DMP1. In contrast, OPN levels showed a 5x increased in BSP-/- vs BSP+/+ cultures. Treatment of the cultures with 50 ng/ml hPTH1-34 induced an increase in alkaline phosphatase (ALP) activity at day 6 in BSP +/+ and BSP-/- cultures, with the appearance of OCN expression in BSP-/- dishes, and their mineralization (at day 17). In a model of intermittent injection of hPTH1-84 (8µg daily, 14 days, 5 mice/group) over the periosteum of the right mouse hemicalvaria, µCT and histomorphometry analysis showed that PTH stimulates bone formation in the injected side in both genotypes, increasing to the same degree the thickness and vascularity of the periosteum, osteoid thickness, total bone volume (BV, BSP+/+:427 ± 65 vs $254 \pm 48 \mu m^3$ in NaCl injected controls, BSP-/-: 420 ± 64 vs $270 \pm 34 \mu m^3$, $p<0.001$ for both genotypes, N=5, MWU), bone thickness and porosity, BFR/BS as well as the expression of bone formation and mineralization markers (OPN, osterix, OCN, DMP1 and the endopeptidase PHEX). SiRNA blocking of OPN expression concomitant to PTH treatment did not affect the anabolic action of PTH in BSP+/+ calvaria (BV:450 ± 84 vs $432 \pm 73 \mu m^3$ in PTH+scrambled RNA controls, NS). In contrast, the reduction in OPN production blunted the increase in bone thickness and volume induced by PTH in the BSP-/- (BV: 344 ± 24 vs $482 \pm 31 \mu m^3$, $p<0.01$).

In conclusion, full expression of both OPN and BSP is necessary for the anabolic effect of PTH at least in the calvaria injection model. This suggests that OPN may functionally compensate the lack of BSP in the response to this hormonal challenge, and provides evidence of functional overlap between these two cognate proteins.

Two Fibronectin Isoforms Exert Opposite Effects on Osteoblast Differentiation and Affect the Interaction of the Integrin–Wnt Signaling Cascades. Carla Sens, Carina Wuerfel, Anja von Au, Inaam Nakchbandi*. Max-Planck Institute of Biochemistry & University of Heidelberg, Germany

Fibronectin is an extracellular matrix protein involved in cell differentiation. It is secreted in various isoforms, the role of which remains to be clarified. In earlier work we have shown that the oncofetal isoform of fibronectin (oFN) inhibited osteoblast

differentiation *in vitro* and *in vivo* (>80%). The aim of this study was to evaluate how this isoform inhibits osteoblast differentiation and whether other isoforms exert any effects on osteoblasts.

oFN is defined by an O-glycosylation at threonine 33 in the variable region. Enzymatic O-deglycosylation and site-directed mutagenesis revealed that the O-glycosylation was responsible for inhibiting osteoblast differentiation in vitro. Another isoform containing the extra-domain-A (EDA) is produced by osteoblasts during differentiation. Indeed, osteoblast transfections with EDA showed a significant increase in their differentiation *in vitro* (2-fold). Since both the variable region and EDA bind to α4β1 and α4β7 integrins, and EDA to α9β1 we evaluated their expression during differentiation. α4 protein expression increased 4-fold, α9 3-fold, while β1 decreased 10% and β7 protein was not expressed. In line with this, oFN addition resulted in significant decrease in α4 protein (50%), while EDA transfection was associated with a significant increase in α4 mRNA (40%). α9 did not change. To test this further, β1 integrin deletion in osteoblasts using the collagen-α1(I) promoter in floxed β1 integrin mice results in significant delay in mineralization (37%). Normal osteoblasts were then cultured onto a VCAM-matrix which binds α4. This resulted in increased a4 expression and differentiation (1.5-2 Fold). These data suggest that α4β1 integrin, at least in part, mediates fibronectin effects on osteoblast differentiation.

Because of the possibility of interaction between α4 integrin and wnt signaling, we asked whether fibronectin affected wnt signaling. EDA significantly increased rac1 expression, which is downstream of integrin signaling (2-fold). In addition, b-catenin protein increased 2-fold and wisp-1 mRNA 30%, suggesting increased wnt signaling. Thus, the pro differentiation effects of fibronectin seem to be mediated by an interaction between α4β1 integrin and the wnt signaling pathway.

In summary, we identified a new mechanism for fibronectin-mediated osteoblast differentiation mediated by EDA and α4β1 integrin, and some of this effect is mediated by potentiation of wnt signaling in the osteoblasts.

WISP3 Affects Cell Survival in Human Chondrocytes and Mesenchymal Stem Cells. Sylvia Hondke*[1], Viola Zehe[2], Katrin Schlegelmilch[2], Susanne Wiesner[2], Alexander Keller[3], Norbert Schütze[2]. [1]University of Wuerzburg, Germany, [2]University of Wuerzburg - Orthopedic Center for Musculoskeletal Research, Germany, [3]University of Wuerzburg - Biocenter - DNA Analytics, Germany

Introduction: WISP3 (wnt1 inducible signaling pathway protein3) is known as an important signal modulator connected to the extra cellular matrix. It is essential for musculoskeletal development, induces the expression of chondrogenic markers and regulates chondrocyte homeostasis. Mutations in WISP3 are associated with progressive pseudorheumatoid dysplasia (PPD), a disease characterized by joint swelling and stiffness leading to cartilage degeneration. In this study, we examined consequences of WISP3 signaling through an enforced loss or treatment of the protein in human mesenchymal stem cells (hMSC) and chondrocytes.

Materials&Methods: Gene silencing was performed with specific lentiviral shRNA constructs affecting endogenous WISP3 expression in different cell types in vitro. Microarray analysis of WISP3 deficient hMSC (n=3, knock down vs. scrambled) was performed and validated by RT-PCRs of selected differentially expressed genes. WISP3 treatment of chondrocytes was performed with recombinant WISP3-Fc produced in Sf21 cells using a baculovirus expression system.

Results: Successful down-regulation of WISP3 considerably affected viability of several cell types of the musculoskeletal system. Apoptosis was shown by annexin V staining. Array analysis confirmed this observation by uncovering distinct clusters of differentially expressed genes connected to apoptosis or cell survival. For example, loss of WISP3 significantly influences pathways like TGFβ and p53. Results of the array analysis could be validated by RT-PCR. Treatment of WISP3 deficient chondrocytes with rWISP3 could not rescue the phenotype, but led to a positive feedback loop with the up-regulation of endogenous WISP3.

Discussion: Hereby, we present for the first time that a loss of WISP3 leads to cell death in distinct cell types. Global gene expression patterns provide new insights into gene expression changes, which indicate signaling of different apoptotic pathways. Thus, these findings generated an essential fundament for further examinations to clarify the role of WISP proteins on cell survival.

Visualization of Chondrocyte Mechanotransduction in 3D. Qiaoqiao Wan*[1], Eunhye Cho[2], Seungman Park[1], Bumsoo Han[1], Hiroki Yokota[2], Sungsoo Na[2]. [1]Purdue University, USA, [2]Indiana University-Purdue University Indianapolis, USA

Articular cartilage is subjected to dynamic mechanical loading during normal daily activities. This complex mechanical loading, including cell compression and interstitial fluid flow, affects chondrocyte mechano-chemical signaling and subsequent cartilage homeostasis and remodeling. FAK and Src are known to be main mechanotransduction proteins, but little is known about the effect of mechanical loading on FAK and Src under its varying magnitudes and types.

In this study, C28/I2 chondrocytes were used for this study. Type II collagen-conjugated 3D agarose gels were used to mimic the physiologically relevant cell environment. During imaging, pulsed (0.2 Hz) fluid flow (2, 5, 10, 20 μl/min) was applied to the cells/gel construct in the chamber. Two different types of mechanical loading were subjected to the cells: interstitial fluid flow (IFF) only and combined cell compression/IFF. Cell compression was measured by computing the ratio of changes in cell diameter to the original cell diameter in the direction of fluid flow. FRET-based biosensors for monitoring FAK and Src activities were used. The DNA plasmids were transfected into the cells using a Neon transfection system. A Nikon Ti-E inverted microscope was used for imaging experiments. FRET images for FAK and Src activity was generated by computing the emission ratio of CFP/YFP for individual cells using NIS Elements software.

Results show that the cell compression was negligible under IFF only (Fig. 1A), whereas under combined loading (i.e. cell compression + IFF), it was dependent on the magnitude of the loading (Fig. 1B). Under 10 μl/min IFF, we observed a transient increase in Src activity, followed by a decrease at 20 min (Fig. 2A). However, under combined loading (4.4% cell compression + 10 μl/min IFF), Src activity decreased rapidly within 2 min and gradually increased until 60 min (Fig. 2B). These results suggest that Src activity is loading type dependent. In contrast, FAK activity is not dependent on the types of loading (data not shown). Both FAK and Src were similarly increased or decreased depending on the fluid flow magnitude under IFF (Fig. 3A). However, they behaved differently under combined loading (Fig. 3B), possibly due to the additive effects of the two different types of loading on Src activity (Fig. 2). Collectively, the data suggest that the intensities and types of mechanical loading are critical in regulating FAK and Src activities in chondrocytes.

Association of 25-hydroxyvitamin D, Parathyroid Hormone Levels with Blood Pressure in Elderly Populations. HyeonMok Kim*[1], Beom Kim[2], Jung-Min Koh[3]. [1]South Korea, [2]Departments of Internal medicine, Seoul Veterans Health service medical center, Seoul, Korea, South Korea, [3]Asan Medical Center, South Korea

Background: Although lower vitamin D status or higher parathyroid hormone(PTH) status have been associated with higher blood pressure(BP), there are few studies in the general population.

Objective: The purpose of this study is to investigate the association between serum vitamin D, PTH level and blood pressure, in population with or without antihypertensive medication.

Methods: A population-based, cross-sectional study from the Korea National Health and Nutrition Examination Surveys. Participants included 2,019 men and 2,494 women aged over 50yrs or older. Serum 25-hydroxyvitaminD3 and PTH were measured by radioimmunoassay and BP was determined with a sphygmomanometer. We performed univariate linear regression analysis and analysis of covariance(ANCOVA) to examine the influence of serum 25(OH)D3 and PTH on blood pressure with adjustments for age, weight, height, antihypertensive medication, waist circumference, estimated glomerular filtration rate, Diabetes mellitus prevalence, smoking status, exercise status.

Results: In general population, serum 25(OH)D3 showed negative correlation with BP in women, but not in men. Serum PTH was positively associated with BP in both genders. In the group without antihypertensive medication, both 25(OH)D3 and PTH showed significant correlation with blood pressure. Also consider the interaction between 25(OH)D3 and PTH to Blood pressure, adjustment for PTH resulted in an inverse correlation of serum 25(OH)D3 with blood pressure in non BP med users, and PTH is independently positive correlation with blood pressure, when adjusted for 25(OH)D3

Conclusion: Participants who did not take BP medication, 25(OH)D3 can be a negative predictor of BP, independent of PTH and other confounders. Also PTH can be a positive predictor of BP.

Gain-of-Function Mutations in Gα11 Cause a Novel Form of Autosomal-Dominant Hypoparathyroidism. Michael Mannstadt*[1], M. Andrew Nesbit[2], Sarah Howles[2], Angela Rogers[2], Rajesh Thakker[2], Harald Jueppner[3]. [1]Massachusetts General Hospital Harvard Medical School, USA, [2]Nuffield Department of Clinical Medicine, University of Oxford, United Kingdom, [3]Massachusetts General Hospital, USA

Purpose: Heterotrimeric G-proteins play pivotal roles in the transmission of signals from ligand-activated seven transmembrane receptors such as the PTH/PTHrP receptor or the calcium-sensing receptor (CASR) to intracellular effector molecules such as cAMP and intracellular free calcium ($[Ca^{2+}]_i$), respectively. Post-zygotic or somatic mutations in G proteins resulting in gain-of-function contribute to the development fibrous dysplasia or tumors such as uveal melanoma. By contrast, germline gain-of-function mutations are extremely rare. Here, we provide initial functional characterization of two heterozygous mutations in *GNA11,* encoding the a-subunit of G11 (Gα11), recently identified in patients with autosomal dominant isolated hypoparathyroidism (AD-IHP).

Methods: The underlying genetic defect in two large unrelated families with AD-IHP had been identified through genome-wide linkage analysis and exome sequencing. Functional consequences of the mutations were now studied using HEK293 cells stably expressing the CASR (HEK-CASR). $[Ca^{2+}]_i$ responses to different extracellular calcium concentrations $[Ca^{2+}]_o$ were measured after transfecting HEK-CASR cells with wildtype or mutant Gα11, and the EC_{50} values determined.

Results: Genome-wide linkage analysis combined with exome sequencing had revealed two distinct heterozygous missense Gα11 mutations, leading to the alterations R60C and S211W. Both affect highly conserved residues, are present in all affected family members, and absent in available unaffected members and databases. *In silico* modeling based on the crystal structure of the closely related Gαq had suggested that both mutations lead to a gain-of-function. Consistent with this prediction, functional *in vitro* assays revealed a leftward shift in the calcium concentration-response curves with significantly lower EC_{50} values when the HEK-CASR cells were transfected with the R60C or S211W mutant, compared to transfection with the wildtype Gα11.

Conclusions: In two different families, heterozygous germline Gα11 mutations were identified as a novel cause of AD-IHP. *In vitro* studies using HEK293-CASR cells transiently transfected with wildtype or mutant Gα11 suggest that both mutations lead to a gain-of-function.

Chronically Elevated Circulating Fgf23 Modulates Renal Sodium Handling in *Hyp* Mice. OLENA ANDRUKHOVA*[1], Ute Zeitz[2], Sathish Kumar Murali[2], Reinhold Erben[3]. [1]INST. OF PHYSIOLOGY, PATHOPHYSIOLOGY & BIOPHYSICS, Austria, [2]Department of Biomedical Research University of Veterinary Medicine, Austria, [3]University of Veterinary Medicine, Austria

Patients with X-linked hypophosphatemia (XLH) and hypophosphatemic (*Hyp*) mice, a mouse model of XLH, show profoundly increased serum concentrations of fibroblast growth factor 23 (FGF23). FGF23 is a hormone originating from bone, regulating renal phosphate reabsorption and vitamin D synthesis. We previously reported that FGF23 also directly regulates the sodium (Na)-chloride cotransporter NCC in distal renal tubules through a pathway involving extracellular signal-regulated kinase 1/2 (ERK1/2), serum/glucocorticoid-regulated kinase 1 (SGK1), and with-no lysine kinase-4 (WNK4). NCC and the epithelial Na channel (ENaC) are the principal ion channels regulating Na reabsorption in the distal nephron. To determine the role of chronically elevated Fgf23 levels in renal Na reabsorption we examined 3-month-old male *Hyp* mice. Analysis of Na homeostasis in *Hyp* mice revealed unchanged urinary but increased serum Na levels as compared to wild-type controls. Serum aldosterone as well as heart-to-body weight ratio were increased in *Hyp* mice. Immunoblotting of renal membrane preparations revealed increased expression of NCC and increased NCC phosphorylation at Thr53, Thr58 and Ser71 in *Hyp* mice. In addition, phosphorylated ERK1/2 and SGK1 as well as total WNK4 protein expression were markedly elevated in kidney homogenates of *Hyp* mice. Interestingly, *Hyp* mice showed 2.2-fold increased renal membrane expression of the alpha ENaC subunit essential for the channel activity, but 5-fold increased expression of beta and gamma ENaC subunits involved in ERK1/2-induced channel internalization and degradation. This finding may imply that the aldosterone-driven upregulation of alpha ENaC is possibly counteracted in *Hyp* mice by an Fgf23-ERK1/2-mediated upregulation of beta and gamma ENaC subunits. Therefore, increased renal membrane expression and phosphorylation of NCC, mediated through the Fgf23/ERK1/2/SGK1/WNK4 signaling axis, may partially be counterbalanced by increased ENaC degradation in *Hyp* mice. Taken together, our study showed that chronically elevated serum Fgf23 results in hypernatremia, increased serum aldosterone, and heart hypertrophic changes under steady state conditions in *Hyp* mice. Thus, our findings may have important implications for the pathophysiological mechanisms underlying the association between serum FGF23 levels and cardiovascular risk in chronic kidney disease patients.

Deletion of *Fgf23* does not Perturb Fetal Mineral Homeostasis, Skeletal Mineral Content, Placental Phosphorus Transport, or Placental Expression of FGF23 Target Genes. M. Manoharee Samaraweera*[1], Yue Ma[1], Beth J. Kirby[1], S. Teja Vatturi[1], Beate Lanske[2], Christopher Kovacs[1]. [1]Memorial University of Newfoundland, Canada, [2]Harvard School of Dental Medicine, USA

FGF23 is a key regulator of phosphorus (P) homeostasis in the adult; its absence causes severe hyperphosphatemia and early mortality. Its role during fetal development is unknown.

We mated $Fgf23^{+/-}$ males and females together and studied their WT, $Fgf23^{+/-}$, and *Fgf23* null fetuses. On embryonic day (ED) 17.5, amniotic fluid (largely urine) was collected, while placental ^{32}P transport was determined by administering ^{32}P and ^{51}Cr-EDTA by intracardiac injection to the mother, and measuring isotopes in the fetuses after 5 min. Serum was collected from ED17.5 and 18.5 fetuses. Whole bodies at ED17.5 and 18.5 were reduced to ash and the mineral content was assayed. qPCR was done on ED18.5 placentas and kidneys. Intact FGF23 was measured by EIA (Kainos).

Serum FGF23 was undetectable (<3.0 pg/ml) in *Fgf23* nulls as compared to 23.8 ± 2.9 in $Fgf23^{+/-}$ and 53.8 ± 4.9 in WT ($p<0.001$), and much lower than the maternal value (236 ± 32.9) ($p<<0.001$). Serum P did not differ between genotypes (3.93 ± 0.24 mM in null vs. 3.91 ± 0.15 mM in WT), and there was also no difference in excretion of P or Ca into amniotic fluid. Fetal ash weight, and P, Ca, or Mg ash content did not differ between genotypes at ED 17.5 or 18.5. Placental ^{32}P transport, normalized to the value of $Fgf23^{+/-}$ fetuses, also did not differ ($97.5 \pm 3.3\%$ in null, $100.5 \pm 1.7\%$ in $Fgf23^{+/-}$, and $103.3 \pm 5.5\%$ in WT).

qPCR revealed low level expression of *Fgf23* in WT placentas which was absent in the *Fgf23* null ($p<0.02$). Placentas of *Fgf23* null and WT expressed all three sodium-phosphate cotransporters (*NaPi2abc*), all four FGF23 receptors (*Fgfr1-4*), FGF23's co-receptor *Klotho,* and *Cyp27b1* and *Cyp24a1*. However, there were no differences in relative expression of these target genes between WT and *Fgf23* null placentas. *Fgf23* null kidneys showed ~1.5 to 2-fold increased expression of *Klotho* and *NaPi2abc*, but no change in *Fgfr1-4*.

In summary, intact FGF23 does not cross the placenta from mother to fetus. Deletion of *Fgf23* did not disturb any measured parameter of fetal mineral homeostasis, including serum and amniotic fluid P, skeletal mineral content, and placental ^{32}P transport. Placentas and kidneys abundantly express FGF23 target genes but only kidneys showed altered gene expression in *Fgf23* null.

In conclusion, despite FGF23's presence in the fetal circulation and expression of its target genes in placenta and kidneys, FGF23 is not an important regulator of fetal P. Placental P delivery may override effects of FGF23's absence.

Metabolic Acidosis Stimulates Fibroblast Growth Factor 23 in Osteoblasts by a Calcium- and Prostaglandin-Mediated Mechanism. Nancy Krieger*[1], Christopher Culbertson[2], Kelly Kyker-Snowman[2], David Bushinsky[1]. [1]University of Rochester, USA, [2]University of Rochester School of Medicine, USA

Serum fibroblast growth factor 23 (FGF23) increases significantly with progressive chronic kidney disease (CKD), leading to reduced renal tubular phosphate (Pi) reabsorption, decreased serum $1,25(OH)_2D_3$ and is associated with increased mortality. FGF23 is synthesized in osteoblasts and osteocytes; however, the primary factors regulating its production are not clear. Patients with CKD have decreased renal net acid excretion leading to metabolic acidosis (MET). During MET, acid is buffered by bone with release of mineral calcium (Ca) and Pi. MET increases intracellular Ca signaling and cyclooxygenase 2 (COX2)-induced prostaglandin production in the osteoblast leading to decreased osteoblastic bone formation and increased osteoclastic bone resorption. We recently found that MET directly stimulates FGF23 in mouse bone and primary osteoblastic cells. We hypothesized that MET would increase FGF23 through similar pathways that lead to bone resorption. Neonatal mouse calvariae were incubated in neutral (NTL, pH=7.44, Pco_2=38 mmHg, $[HCO_3^-]$=27 mM) or acid (MET, pH=7.18, Pco_2=37 mmHg, $[HCO_3^-]$=13 mM) medium in the absence or presence of 2-APB (50 μM), a pharmacologic inhibitor of intracellular Ca signaling. 2-APB significantly inhibited the MET-induced increased medium FGF23 protein and calvarial FGF23 RNA as well as bone resorption at 48h (Table 1). To exclude the potential contribution of MET induced bone Pi release to the increase in FGF23, we utilized primary osteoblastic cells isolated from mouse calvariae. In these cells 2-APB inhibited the MET-induced increase in FGF23 RNA expression at 6h. Similarly, NS398 (1 μM), which is a specific inhibitor of COX2, also inhibited the MET-induced increase in FGF23 RNA at 6h. Thus, the stimulation of FGF23 by MET in mouse osteoblasts appears to utilize the same initial signaling pathways as MET-induced bone resorption. Therapeutic interventions directed toward correction of MET, especially in CKD, have the potential to not only prevent bone resorption but also lower FGF23 and perhaps decrease mortality.

Calvariae at 48h:	NTL	MET	NTL+2-APB	MET+2-APB
FGF23 protein (pg/ml)	156±36	295±50*	26±9*#	50±6*#

Disruption of LRP6 in Osteoblasts Blunts the Bone Anabolic Activity of PTH. Changjun Li*[1], Qiujuan Xing[1], Bing Yu[2], Hui Xie[1], Janet Crane[3], Xu Cao[3], Mei Wan[1]. [1]Johns Hopkins University School of Medicine, USA, [2]Johns Hopkins School of Medicine, USA, [3]Johns Hopkins University, USA

Mutations in Low-density lipoprotein receptor-related protein 6 (LRP6) are associated with human bone disorders. We previously revealed that LRP6 is a key element in PTH-activated both β-catenin and cAMP/PKA signaling in osteoblasts. Here we investigated whether LRP6 directly regulates bone remodeling and mediates PTH bone anabolic effects by analysis of the bone phenotype in mice lacking *Lrp6* specifically in mature osteoblasts (Oc-Cre; *Lrp6$^{f/f}$*, named "KO" hereafter).

Three month-old LRP6 KO mice had a significant reduction in bone mass in the femura secondary spongiosa relative to their WT littermates, whereas marginal changes were seen in femura of 1 month-old KO mice, indicating that LRP6 deficiency in osteoblasts primarily affected trabecular bone remodeling in adults. The remodeling area of the 3 month-old LRP6 KO mice showed a decreased bone formation rate as detected by Goldner's Trichrome staining and calcein double labeling. Bone histomorphometric and immumohistochemical analysis revealed a reduction in bone surface osteoblasts but little change in the numbers of osteoclasts in LRP6 KO mice. Consistently, mRNA levels of bone matrix proteins produced by osteoblasts and osteocytes were decreased in bone tissue from 3 month-old KO mice. In addition, the percentage of the apoptotic osteoblasts on bone surface was higher in KO mice as detected by TUNEL assays. Thus, LRP6 deficiency increased the apoptosis and decreased the differentiation of osteoblasts, leading to the reduction in the number of bone surface osteoblasts and bone formation.

We then examined whether LRP6 in osteoblasts is required for PTH anabolic effects on bone. Two month-old KO mice and WT littermates were injected with PTH1-34 daily for 4 weeks. PTH had no effect on bone mass nor osteoblastic bone formation in either trabecular and cortical bone in KO mice, whereas all were enhanced in WT littermates. Consistently, serum osteocalcin level was not stimulated in PTH-treated KO mice as significantly as in PTH-treated WT mice, whereas the PTH-stimulated increase in serum CTX-I level was similar in KO and WT mice. The anti-apoptotic effect of PTH on osteoblasts in LRP6 KO mice was less significant compared to WT mice, indicating that LRP6 is required for osteoblast survival in PTH-stimulated bone remodeling. Collectively, our findings demonstrate that LRP6 in osteoblasts is essential for osteoblastic differentiation during bone remodeling and the anabolic effects of PTH.

Hospital Care for Primary Hyperparathyroidism in Italy: a Six-Year Register-Based Study. Cristiana Cipriani*[1], Vincenzo Carnevale[2], Elisabetta Romagnoli[1], Rina Fratelloreto[1], Jessica Pepe[1], Sara Piemonte[1], Alfredo Scillitani[3], Salvatore Minisola[1]. [1]"Sapienza", University of Rome, Italy, [2]IRCCS "Casa Sollievo della Sofferenza" Hospital, Italy, [3]Casa Sollievo Della Sofferenza Scientific Institute, Italy

Purpose: Primary hyperparathyroidism (PHPT) is one of the most frequently diagnosed endocrine disorders, but few studies focused on hospital management of the disease in Europe. We investigated the frequency of hospital admission for the diagnosis and surgical treatment for PHPT in Italy.

Methods: We performed a retrospective study on data from the Archive of the forms of Hospital Discharge (SDO) of the Italian Health Ministry, from the year 2006 to 2011, when the Italian version of the ICD-9 CM classification system with two decimals was utilized. We analyzed the codes corresponding to the following medical diagnoses: "PHPT", "not specified hyperparathyroidism", "multiple endocrine neoplasia", "benign parathyroid neoplasia", "malignant parathyroid neoplasia", non tumor-related "hypercalcemia", as well as the following surgical diagnoses: "complete parathyroidectomy", "other parathyroidectomy", "other parathyroid procedures".

Results: Overall, 46,275 hospitalization episodes for PHPT were identified during the entire period, among which 69% in women and 31% in men, (female/male ratio 2.23:1; mean age 63.3 ± 39.8 years). The total admissions were 7,715 in the year 2006, 7,454 in 2007, 7,809 in 2008, 7,876 in 2009, 7,899 in 2010, and 7522 in 2011. Patients' mean age significantly increased during the six years (from 62.7 ± 37.5 in 2006 to 65.8 ± 18.6 in 2011; $p<0.001$). The mean length of stay was 8.2 ± 10.5 days (28% of the episodes requiring less than 3 days of stay). The overall number of admissions for surgical procedures was 11,196, that is the 24.4% of the total hospitalization rate over the six investigated years. There was a trend to a significant increase in the percentage of surgery during the entire period (25.7% in 2006, 26.6% in 2007, 26.8% in 2008, 27.8% in 2009, 26.9% in 2010 and 27.6% in 2011; $p<0.05$). In the year 2011 only, the overall hospitalization rate was 11,426/100,000 for any disease, 11.9/100,000 for PHPT and 19.8/100,000 for uncontrolled diabetes, the most prevalent endocrine disorder.

Conclusions: PHPT considerably impacts the Italian Hospital healthcare system. We observed a tendency to a decrease in the frequency of hospitalization during the period 2006-2011, most probably because of economic issues. Furthermore, there was a concomitant increased age of the patients hospitalized for the disease, and, interestingly, also a progressive increase in the percentage of surgical treatment among patients admitted for PHPT.

SILAC-Based Quantitative Analysis of Phosphorylation Dynamics in Osteoblasts Simulated with Parathyroid Hormone (PTH 1-34). Lauren Ball, Grace Williams*, Louis Luttrell, Mary Berkaw. The Medical University of South Carolina, USA

Recombinant human PTH, residues 1-34, is used for treatment of osteoporosis. In an unbiased approach to identify proteins that undergo a change in phosphorylation status with acute stimulation of the PTH receptor with PTH 1-34, a quantitative phosphoproteomic strategy was applied to differentiating osteoblasts. MC3T3-E1 pre-osteoblasts were grown in the presence of stable, isotopically labeled "light", "medium", or "heavy" lysine and arginine (SILAC) for 6 passages. Cells grown to confluence were induced to differentiate in osteogenic media supplemented with ascorbic acid, beta glycerol phosphate, 10% dialyzed FCS, and isotopically labeled amino acids for 9 days. On day 9, FCS was reduced to 1% for 18 hr prior to receptor stimulation with rhPTH 1-34 for 0, 1, or 5 min. Cells were lysed in urea and 5 mg protein from each treatment condition was combined and digested with trypsin. Peptides were fractionated by SCX chromatography and phosphopeptides were enriched from each fraction by TiO2. Resulting peptides were separated by C18RP-nLC and analyzed by tandem mass spectrometry (Orbitrap Elite) using CID MS/MS

and ETD MS/MS with a decision tree approach. Phosphopeptides were identified, the sites of phosphorylation localized, and changes in the extent of phosphorylation quantified using Proteome Discoverer (Thermo) and Maxquant software packages. Initial analyses yielded 357 peptides that changed in the extent of phosphorylation by 2 fold or greater following stimulation with PTH 1-34. Elevated phosphorylation was observed within the C-terminus of PTH R1 at sites known to be responsive to receptor stimulation indicating effective stimulation. Motif analysis of peptides that were phosphorylated in response to PTH 1-34 suggests activation of cAMP-dependent PKA and CamKII as anticipated based on canonical PTHR signaling via Gs and Gq/11 coupling. Changes in phosphorylation were also observed in regulatory subunits of phosphatases PP1 and PP2a. Interestingly, changes in IRS1 phosphorylation were observed which may represent a node of interaction between PTHR and IGF1/insulin receptor signaling. The goals of these studies are to provide novel information regarding PTH receptor signaling in osteoblasts and to serve as a control for future studies aimed at identifying signaling components employed by functionally selective (biased) agonists of the PTH receptor. This work is supported by RO1 DE020925 (LEB), S10 D010731(LEB), and R01 DK055524 (LML).

SU0122

Three Dimentional Structure of Human PTH (1-84). Abdulhafez Selim*. Center for Chronic Disorders of Aging, PCOM, USA

Parathyroid hormone (PTH), is secreted by the chief cells of the parathyroid glands as a polypeptide containing 84 amino acids. It acts to increase the concentration of calcium (Ca2+) in the blood. PTH is acting upon the parathyroid hormone 1 receptor (high levels in bone and kidney) and the parathyroid hormone 2 receptor (high levels in the central nervous system, pancreas, testis, and placenta).

Parathyroid hormone plays a very important role in calcium phosphate homeostasis and in regulating bone metabolism. It has been reported that full length PTH (1-84) and the C-terminal fragments play distinct biological roles when compared to the N-terminus PTH (1-34).The N-terminal fragment 1-34 of parathyroid hormone (PTH) has been successfully crystallized and the structure has been refined to 0.9 Å resolutions. Due to technical difficulties, no previous studies succeeded in crystallizing the full length PTH (1-84) or its carboxyl-terminal fragments.

It is of great importance to identify the secondary and tertiary structures of PTH (1-84) as well as the C-terminal fragments (34-84, and 53 to 84).

To achieve this object, we used validated bioinformatics tools to create three dimensional models and to screen the models for potential targets (matrix proteins or cell surface receptors). Validated bioinformatics tools can produce high quality models that could be comparable to actual crystallization. It is important to mention that our methods were not based on homology modeling that could be misleading if there is no enough homology with database models. Instead, we used a validated Monte Carlo simulation tools. We used PTH (1-34) three dimensional models (based on crystallization data; PDB ID# 1ET1) as a positive control and we used scrambled peptide as a negative control. Positive control (PTH 1-34) modeling demonstrated valid modeling outcomes that were 100% comparable to the crystallized model of PTH (1-34) [1ET1].

PTH (1-84) model was formed of two alpha helices and one loop; one helix was toward the N-terminus (1-37) and the other helix toward the C-terminus (71-84). The two helices were connected by a large loop (38-70). The three dimensional model of the C-terminal fragment (39-84) was similar not identical to the same region in the full length model (1-84); alpha helix (71-84) was maintained, but the region between 30 and 69 changed from loop (in the 1-84 model) to form a smaller loop (63-89) and two small beta sheets (49-62). The alpha helix domain (71-84) was also maintained in the three dimensional model of PTH (53-84).

The generated PDB files (three dimensional models) were used to identify interacting residues, determine accessibility, search for potential cell surface receptors and interacting extracellular matrix proteins. The data presented in this study will be of great value determining the active sites of the full length (1-84) and designing of agonists and antagonists to modulate the functions of CPTH receptor(s).

Figure 1: Three dimensional structure of Human PTH 1-84

Figure 2: Three dimensional structure of CPTH 39-84

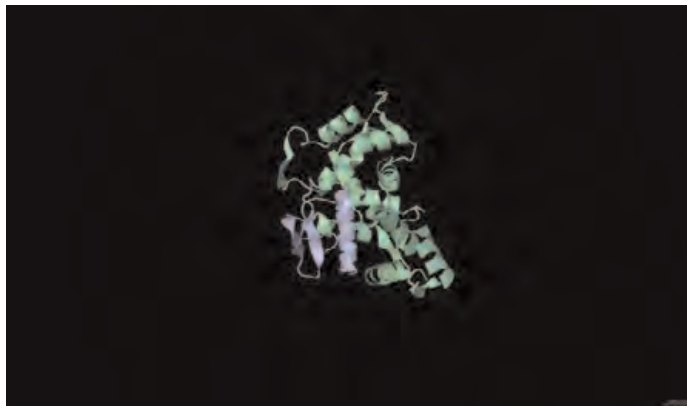

Figure 3: Ligand receptor complex of CPTH 39-84 (blue) and one of the potential CPTHRs (green).

Vitamin D Supplementation Increases Calcium Absorption without a Threshold Effect. Mageda Mikhail*[1], John Aloia[1], Steven Abrams[2], ruban dhaliwal[1], Albert Shieh[3], melissa fazzari[1], louis ragolia[1]. [1]Winthrop University Hospital, USA, [2]Baylor College of Medicine, USA, [3]University of California, Los Angeles, USA

BACKGROUND: The maximal calcium absorption in response to vitamin D has been proposed as a biomarker for vitamin D sufficiency.

OBJECTIVES: To determine if there is a threshold beyond which increasing doses of vitamin D (or level of serum 25OHD) no longer increase calcium absorption.

DESIGN: This was a placebo-controlled, dose-response, randomized double blinded study of the effect of vitamin D on calcium absorption in healthy, postmenopausal women. The gold standard technique of dual isotopes of stable calcium was used with physiologic calcium carrier.

RESULTS: 76 healthy, postmenopausal women were randomly assigned to placebo, 20 mcg, 50 mcg, or 100 mcg of vitamin D3 for 8 weeks. Mean age was 58.8 years. Mean calcium intake was 1142 + 509 mg/day and mean serum 25OHD level was 63 + 14 nmol/L. There was a statistically significant linear trend of increase in calcium absorption adjusted for age and BMI with increasing vitamin D3 dose or serum 25OHD concentration (ANOVA). The absolute increase in the highest vitamin D group (100 mcg) was 6.7%. There was no evidence for non-linearity in the dose-response curve. As serum 25OHD level increased by 10 nmol/L, calcium absorption increased by 1.3%.

CONCLUSION: There is no evidence for a threshold of calcium absorption with a serum 25OHD level range from 40 - 130 nmol/L. Calcium absorption in this range is not a useful biomarker to determine nutritional recommendations for vitamin D.

MAGI-3 Regulates PTH Receptor Signaling in Osteoblasts. Bin Wang*, Harry Blair. University of Pittsburgh, USA

Parathyroid hormone receptor (PTHR), a G-protein coupled receptor (GPCR), mediates PTH actions to maintain mineral homeostasis and bone remodeling. However, the regulation of PTHR signaling has not been fully elucidated. Postsynaptic density 95/discs large/zona occludens (PDZ) scaffolding proteins comprise a key class of GPCR-interacting proteins and influence the signaling of GPCRs like the PTHR that possess a PDZ ligand. In the present study, a GST-tagged carboxyl-terminal 22 amino acid fragment of the wild-type PTHR (PTHR-ctM) and a construct harboring a mutation of the terminal methionine residue to alanine (PTHR-ctA) were generated. PTH1R-ctM and PTH1R-ctA were screened against a newly developed proteomic array of 96 PDZ domains. One novel PTH1R-interacting protein, membrane-associated guanylate kinase with inverted orientation 3 (MAGI-3), was identified. The coimmunoprecipitation data demonstrated that full-length PTHR interacts with MAGI-3, and this association is abolished by mutation of the PTHR terminal methionine residue to alanine, consistent with the overlay results. PTH(1-34)-induced receptor desensitization was measured after 48 hours transfection with vector or MAGI-3 by determining adenylyl cyclase activity following a second exposure to PTH. The results show that MAGI-3 significantly inhibited PTHR desensitization. MC3T3-E1 cells and ROS17/2.8 cells endogenously express MAGI-3. Finally, we examined whether MAGI-3 affected PTHR signaling in osteoblasts. Our data show that overexpression of MAGI-3 in ROS17/2.8 cells does not affect adenylate cyclase activity. However, cAMP formation induced by PTH(1-34) in osteoblasts significantly increased. We conclude that MAGI-3 is a novel PTHR-interacting protein that regulates PTH receptor signaling in osteoblasts.

Osteocytic PTH Receptor is Required for Bone Anabolism Induced by Intermittent PTH Administration, but is Dispensable for Bone Resorption and the Loss of Bone Induced by Chronic PTH Elevation. Xiaolin Tu*[1], Kevin McAndrews[1], Jesus Delgado-Calle[1], Naomie Olivos[2], Abdulah Ben-Awadh[1], Wonjin Kim[3], Rafael Pacheco da Costa[1], Danielle Richardson[1], Munro Peacock[4], Lilian Plotkin[1], Teresita Bellido[1]. [1]Indiana University School of Medicine, USA, [2]IUPUI, USA, [3]Department of Internal Medicine, College of Medicine, Yonsei University, Korea, democratic people's republic of, [4]Indiana University Medical Center, USA

Some skeletal actions of PTH might be mediated by direct effects of the hormone on osteocytes. To explore the role of the osteocytic PTH receptor (PTHR1) in the skeletal response to PTH, we used conditional knockout mice (cKO) generated by mating $PTHR1^{flox/flox}$ mice with DMP1-8kb-Cre mice. 4-month old cKO and $PTHR1^{flox/flox}$ littermate controls received daily injections of human PTH (1-34, 100 ng/g/day) or vehicle, for 28 days (iPTH); and 1 month old cKO and $PTHR1^{flox/flox}$ littermate controls were fed low (0.01%) or normal (0.4%) Ca diets for 14 days to increase continuously endogenous PTH (cPTH). Eight to 10 female and 8 to 10 male mice per group were used. PTHR1 mRNA expression was decreased approximately 70% or 60% in long bone diaphyses enriched in osteocytes of 4 month old or 1 month old cKO mice, respectively. We found that iPTH increased total, spinal and femoral BMD in control male mice (7.9, 11.6, and 8.7% change compared to initial BMD); whereas vehicle induced minimal changes in BMD (0.5, 2.6, and -1.8%). iPTH induced similar increases in BMD in female control mice. In contrast, male and female cKO mice failed to respond to iPTH. Thus, iPTH induced only 1, 2.7, and 0.6% change in total, spinal, and femoral BMD in male mice. In addition, female mice treated with iPTH lost bone in the spine (-7.9% change). uCT analyses revealed a 2-fold increase in cancellous bone volume (BV/TV) of the distal femur in iPTH-treated control mice; whereas no increase was found in cKO mice. Further, whereas iPTH increased circulating AP activity in control mice, it failed to do so in cKO mice. iPTH did not change CTX levels in either group. Sost expression was not changed by iPTH in either group. In contrast, cKO mice responded similarly to controls to endogenous cPTH elevation. Thus, control or cKO mice fed a normal calcium diet gained ~ 30% BMD; whereas control or cKO mice fed the calcium deficient diet exhibited a similar loss of BMD (~ -2 to -3%). Moreover, cPTH increased circulating levels of CTX and AP similarly in control and cKO mice. Further, the expression of Sost was decreased in both control and cKO mice. We conclude that osteocytic PTH receptor is required for bone anabolism induced by intermittent PTH administration, but is dispensable for bone resorption and the loss of bone induced by chronic PTH elevation.

Lentiviral transduction of TCIRG1 into CD34+ IMO cells rescues osteoclast function in a cell stage dependent but promoter independent manner. Christian Thudium*[1], Ilana Moscatelli[2], Carmen Flores[2], Karoline Natasja Stæhr Gudmann[1], Morten Karsdal[1], Johan Richter[2], Kim Henriksen[1]. [1]Nordic Bioscience A/S, Denmark, [2]Lund University, Sweden

The a3 subunit of the V-ATPase is almost exclusively expressed in osteoclasts, and its function is indispensable for osteoclast functionality, as illustrated by the lethal phenotype observed in infantile malignant osteopetrosis caused by mutations in *TCIRG1*, the gene encoding the a3 subunit. Treatments of malignant osteopetrosis are limited to bone marrow transplantations, and hence approaches to rescue the dysfunctional osteoclasts as well as insight into the molecular regulation of TCIRG1 are of great interest. With these things in mind we aimed at developing a lentiviral rescue system for expression of TCIRG1, both as a proof-of-concept and as a means to investigating the threshold of TCIRG1 expression needed for functionality in osteoclasts.

$CD34^+$ cells from peripheral blood of 5 IMO patients and from normal cord blood were transduced with SIN lentiviral vectors expressing endogenous *TCIRG1* and *GFP* under a SFFV promoter. The cells were expanded for 2 weeks, During which they were transduced. Cells were then differentiated for 10 days on bone slices with M-CSF and RANKL to mature osteoclasts, and osteoclastogenesis, activity and expression of TCIRG1 investigated.

qPCR analysis and western blot revealed increased mRNA and protein levels of TCIRG1 compared to GFP transduced controls. TCIRG1 protein was, however, only expressed at late stages of osteoclast differentiation, but not late stages of macrophages not incubated with RANKL, whereas GFP was seen throughout both the expansion and osteoclast differentiation period. Furthermore, this regulation seemed isolated to the hematopoietic lineage as TCIRG1 was readily expressed in HT1080, a non-hematopoietic control cell line. Vector corrected IMO osteoclasts generated increased Ca^{2+} release and CTX-1 into the media and showed clearly visible resorption pits, while non-corrected IMO osteoclasts developed normally but failed to resorb bone. Osteoclast functionality largely relied on TCIRG1 expression in a dose dependent manner, partly restoring bone resorption at rescue percentages as low as 5%.In conclusion, we show that lentiviral-mediated correction of osteoclasts can restore resorptive function, in a TCIRG1 dose dependent manner. In addition, we observed a differentiation dependent regulation of TCIRG1 using a viral promoter, a phenomenon which will is clearly beneficial for future studies working on the rescue of TCIRG1 functionality in vivo.

Adipose Tissues are Reduced in Transgenic Mice with Induced $G_s\alpha$ Signaling in Osteoblasts. Corey Cain*, Edward Hsiao. University of California, San Francisco, USA

Purpose: Osteoporosis and obesity are significant medical conditions that contribute to morbidity and mortality. Although these diseases are often considered separate entities, studies suggest that obese people may be protected from osteoporosis and weight loss can result in bone loss. This clinical link is controversial since other studies show bone mass is inversely correlated with bone marrow adiposity. Bone and adipose tissue have distinct developmental pathways; however, disease states that increase bone tissue may occur because of direct conversion of adipose tissue to bone tissue and lead to systemic metabolic effects.

Methods: In this study, we used the ColI(2.3)+/Rs1+ transgenic mouse model which uses the engineered G-protein coupled receptor Rs1 to activate Gsα G-protein coupled receptor signaling in osteoblastic cells. These mice showed dramatically increased trabecular bone formation resembling fibrous dysplasia of the bone. Mice were subjected to Comprehensive Lab Animal Monitoring System (CLAMS) studies for 48 hours to measure O2 consumption, CO2 production, movement, food, and water consumption. Additionally, Echo MRI was used to determine total and bone marrow fat content in the mice. Blood and sera were collected from control and mutant mice and analyzed for glucose levels after fasting.

Results: EchoMRI showed whole body adipose tissue (Control: 13.85% +/- 2.01%, Transgenic: 7.71% +/- 1.42%) and bone marrow fat content (Control: 3.59%, Transgenic: 0.47%) were both reduced in the mutant mice. ColI(2.3)+/Rs1+ mice showed increased food, water, O2 consumption, and CO2 production despite reduced activity. Preliminary data indicate a sex specific differences in glucose levels, with males having reduced blood glucose and females having increased blood glucose levels (Male: Control: 124 mg/dl Transgenic: 44 mg/dl, Female: Control: 107.3 mg/dl +/- 22.3 mg/dl, Transgenic: 156.3 mg/dl +/- 9.5 mg/dl).

Conclusions: ColI(2.3)+/Rs1+ mice showed significant changes in whole-animal metabolic parameters consistent with recently described endocrine functions of bone. In addition, the ColI(2.3)+/Rs1+ mice showed significant local decreases in the bone marrow fat content, suggesting that activation of Gs-GPCR signaling in osteoblasts may also have a direct effect on local adipocytes. Our findings suggest that adipocytes contribute not only to metabolic homeostasis but may have important roles in the pathophysiology of bone overgrowth diseases.

Alveolar Bone-Associated Dental Anomalies in Craniometaphyseal Dysplasia Patients and Mouse Model. I-Ping Chen*, Aditya Tadinada, Eliane Dutra, Achint Utreja, Flavio Uribe, Ernst Reichenberger. University of Connecticut Health Center, USA

Craniometaphyseal Dysplasia is a rare genetic bone disorder involving hyperostosis of craniofacial bones, metaphyseal widening of tubular bones and dental abnormalities. A knock-in (KI) mouse model ($Ank^{KI/KI}$) carrying a Phe377del in ANK develops many skeletal features of CMD including dental anomalies such as excessive cementum. We examined CMD patients by cone beam computed tomography (CBCT) and by orthodontic indices. We also applied orthodontic force in mice to further evaluate consequences of tooth movement in $Ank^{KI/KI}$ mice.

All work involving human subjects was approved by the UCHC Institutional Review Board. We recruited 7 CMD patients carrying Phe377del or Ser375del mutations in ANKH. Each patient was subjected to dental examination, intraoral photographs and 12-inch field of view CBCT images. 10-week-old male $Ank^{+/+}$ and $Ank^{KI/KI}$ mice received orthodontic tooth movement using a NiTi closed-coil spring between the upper incisors and the left first molars for 14 days. The teeth and maxillae were fixed, subjected to micro-CT analyses, decalcified, embedded in paraffin, sectioned and stained with TRAP.

All patients had a history of delayed eruption of permanent teeth. Intraoral examination revealed normal soft tissue. CBCT data showed significant bucco-lingual expansion of jawbones, with expansion in maxillae more pronounced than in mandibles, however, there was no measurable increase in bone density. The majority of CMD patients had narrowed foramina and multiple impacted teeth. Orthodontic analyses showed all CMD patients had short anterior cranial base, short upper facial height and short maxillary length whereas the relationship between maxillae and mandibles in the anterior-posterior axis was inconsistent. Micro-CT analyses after orthodontic tooth movement in mice showed that $Ank^{KI/KI}$ molars can be moved without ankylosis but at a slower rate. As a result the spacing between first and second molars in $Ank^{+/+}$ mice was wider compared to $Ank^{KI/KI}$ mice ($p<0.05$). Qualitative histologic analyses showed TRAP staining on bone surfaces of the compression sites in both $Ank^{+/+}$ and $Ank^{KI/KI}$ molars, however, the size and numbers of $TRAP^+$ cells were decreased in $Ank^{KI/KI}$ mice. Root resorption was only observed in the $Ank^{KI/KI}$ molars suggesting that excessive cementum formation is more susceptible to OC resorption. Alveolar bone and dental anomalies should be considered when treating CMD patients orthodontically.

Bone Deficits Resulting from MeCP2 Deficiency in a Mouse Model of Rett Syndrome are Partially Restored by Treatment with Teriparatide or Zoledronic Acid. Jay Shapiro*. Kennedy Krieger Institute, Johns Hopkins, USA

Introduction: While 50% of children and young adults with Rett Syndrome (RTT) have osteoporosis, the effect of MECP2 mutations on bone cell function is unknown, and there is no recognized treatment for osteoporosis in RTT. Purpose: To determine the effects of MeCP2 deficiency on osteoblast, osteoclast and osteocyte function in vitro and in vivo and to assess the effectiveness of treatment with teriparatide (anabolic, TPH) or zoledronic acid (antiresorptive, ZA). Methods: We conducted bone micro-CT, histomorphometry analyses and established osteoblast cell cultures from WT male and female Mecp2-null and Mecp2-HET mice using the Bird model of MeCP2 deficiency. For baseline data, untreated mice were sacrificed at 5 weeks (Mecp2-null and WT males) or 8 weeks of age (HET and WT females) and their tibias and femurs were retrieved. Starting at 3 (WT and Mecp2-null M mice) or 8 weeks (WT and HET F mice), teriparatide (TP, 40 mg/kg/day) zoledronic acid (ZA, 20 mg/kg/week) or vehicle (saline), was injected for 6 weeks. Results: On MicroCT, trabecular and cortical bone parameters were significantly decreased in Mecp2-null mice, while trabecular bone thickness was increased in HET compared to WT mice. Osteoblast cells from Mecp2-null mice did not express MeCP2 and had accelerated logrithmic growth rates and increased cell density compared to WT osteoblasts. Alkaline phosphatase activity (by immunostaining) in femur metaphysis showed that the secondary trabeculae (further from the growth plate) and along the endosteal surface, the Mecp2-null osteoblasts appear very thin and small, similar in shape to ''resting cells''. Trabecular bone from HET mice had less alkaline phosphatase activity than in WT, suggestive of deficient osteoblast activity and reduced bone formation in HET mice. Tartrate resistance acid phosphatase (TRAP) staining of osteoclasts showed that Mecp2-null mice had less bone and fewer osteoclasts than WT or HET mice. In WT and Mecp2-null male mice, ZA treatment increased bone volume fraction and tissue mineral density in trabecular and cortical bone, increased trabecular number and decreased trabecular bone separation to a greater amount than did TP. For cortical bone, polar moment of inertia was not significantly different in vehicle, ZA or TP treated null mice. Conclusions: Our preliminary results indicate a defect in osteoblast morphology and function, that osteoblast growth is altered by MeCP2 deficiency, and suggest that ZA may be more effective than TP in promoting increased bone growth and preventing bone loss in this RTT mouse model. Support: International Rett Syndrome Foundation and Rett Research Trust.

Calcific periarthritis as the only complication of adult hypophosphatasia in three middle-aged sisters. Nuria Guanabens*[1], Steven Mumm[2], Ingrid Möller[3], Eva Gonzalez-Roca[4], Pilar Peris[5], Jennifer Demertzis[6], Michael Whyte[7]. [1]Universitat De Barcelona, Spain, [2]Washington University School of Medicine, USA, [3]Institute Poal of Rheumatology, Spain, [4]Immunology Department, Hospital Clinic, Spain, [5]Hospital Clínic of Barcelona, Spain, [6]Musculoskeletal Disease Section, Mallinckrodt Institute of Radiology at Barnes-Jewish Hospital, USA, [7]Shriners Hospital for Children-Saint Louis, USA

Hypophosphatasia (HPP) is the inborn-error-of-metabolism characterized by low serum alkaline phosphatase (ALP) activity due to loss-of-function mutation(s) within the gene that encodes the tissue nonspecific isoenzyme of ALP (TNSALP). In HPP, extracellular accumulation of inorganic pyrophosphate (PPi), a TNSALP substrate and inhibitor of mineralization, leads frequently to premature tooth loss and often to rickets or osteomalacia. In affected adults, the PPi accumulation sometimes also manifests as calcium pyrophosphate dihydrate (CPPD) deposition, PPi arthropathy, or as seemingly paradoxical deposition of hydroxyapatite crystals in ligaments and around joints called calcific periarthritis (CP).

We report three middle-aged sisters with CP as the only clinical complication of HPP. Each presented during early adult life with recurrent episodes of pain principally around the shoulders, elbows, wrists, hips, or Achilles tendon. They were otherwise in good health including no history of unusual dental disease, fractures, or pseudofractures. Calcific deposits were identified in symptomatic areas (Figure) of each sister principally by ultrasonographic assessment compared to radiographic studies. All three sisters had low serum levels of total and bone-specific ALP, hyperphosphatemia, and increased serum concentrations of the TNSALP substrate pyridoxal 5′-phosphate together characteristic of HPP. Mutation analysis revealed a single unique 18-bp duplication within *TNSALP* (c.188_205dup18, p.Gly63_Thr68dup) carried by the sisters, their mother with knee osteoarthritis and no CP or CPPD deposition, and two healthy sons. CP has been reported in a few adult patients with HPP. We find that CP can be the only manifestation of the adult form of HPP. Thus, CP with multiple juxta-articular deposits of hydroxyapatite may be a useful sign of HPP, especially when CP is familial.

Cyclophilin B KO Mouse Model of Type IX OI has Diminished Hydroxylation of Specific Collagen Helical Lysines Causing Altered Bone Crosslink Patterns. Wayne Cabral*[1], Irina Perdivara[2], MaryAnn Weis[3], Masahiko Terajima[4], Angela Blissett[1], Weizhong Chang[1], Elena Makareeva[5], Edward Mertz[5], Sergey Leikin[5], Kenneth Tomer[2], David Eyre[3], Mitsuo Yamauchi[4], Joan Marini[1]. [1]Bone & Extracellular Matrix Branch, NICHD, NIH, USA, [2]Laboratory of Structural Biology, NIEHS, NIH, USA, [3]Orthopaedic Research Laboratories, University of Washington, USA, [4]North Carolina Oral Health Institute, University of North Carolina, USA, [5]Section on Physical Biochemistry, NICHD, NIH, USA

Osteogenesis Imperfecta (OI) is a collagen-related bone dysplasia with bone fragility and short stature. Absence of proteins involved in collagen post-translational interactions results in recessive forms of OI, most of which involve components of the collagen prolyl 3-hydroxylation complex, CRTAP, P3H1 and PPIB/CyPB (OI types VII-IX, respectively). To investigate the role of CyPB in collagen folding and modification, *Ppib* knockout (KO) mice were generated using a gene-trap ES cell clone. KO mice are small, with reduced femoral aBMD, Tb & Ct BV/TV, and MOI. KO mice completely lack *Ppib* transcripts in skin, fibroblasts (FB), femora and calvarial osteoblasts (OB). CyPB was absent on immunoblots of KO cultured FB and OB lysates. The α1(I)P986 3-hydroxylation of cell culture- and tissue-derived collagen was severely reduced (2-11% of WT). Delayed intracellular folding and reduced electrophoretic migration of steady-state collagen from KO cells support the rate-limiting role of CyPB in collagen folding. In contrast, total hydroxylysine and 4-hydroxyproline content was normal in KO cell collagen, suggesting increased glycosylation caused the electrophoretic delay. In skin tissue collagen, total Hyl is reduced, consistent with more rapid gel migration of collagen alpha chains. However, total collagen Hyl is normal in KO bone, with near-normal gel migration and glycosylation. Detailed analysis of bone and OB type I collagen by mass spectrometry revealed site-specific alterations in post-translational modifications. There is dramatic underhydroxylation of helical crosslink residue Lys87 in both α1 (↓20% in OB, ↓40% in bone) and α2 (↓15% in OB, ↓20% in bone) chains, with consequent underglycosylation. The altered Lys modification changes the type and quantity of collagen crosslinks in KO bone. There is a 4-fold increase in trivalent LP crosslinks ($p=0.001$) and a corresponding decrease in the HP/LP ratio detected in bone tissue. Although total bone collagen crosslinks (HP+LP) in KO were double WT ($p=0.003$), abnormal collagen modification and crosslinking is associated with a 70-80% reduction of collagen deposited into KO matrix in culture. These findings suggest a novel role for CyPB in supporting the activity of tissue-specific collagen lysyl hydroxylase(s), thus indirectly regulating collagen glycosylation, crosslinking and fibrillogenesis, and promoting normal bone mineralization and strength. Abnormal crosslinks may be a common pathological feature of OI bone.

Genetic Variation In The Obesity Related GeneMC4R Is Associated With Bone Quality In Elderly Women. Gaurav Garg*[1], Jitender Kumar[2], Fiona McGuigan[3], Mattias Callréus[4], Paul Gerdhem[5], Kristina Akesson[6]. [1]Clinical Research Center, Lund University, Sweden, [2]Upsala University, Sweden, [3]University of Lund, Malmö, Skane University Hospital, Malmö, Sweden, [4]Skåne University Hospital, Sweden, [5]Karolinska Institutet, Sweden, [6]Skåne University Hospital, Malmö, Sweden

Introduction: Osteoporosis is characterized by reduced bone mineral density (BMD) and increased fracture risk. Fat and lean mass are established determinants of bone strength with a strong genetic component. The relationship between obesity and BMD or bone quality are still unclear. In this study we examined the association between three obesity related genes with bone properties and fracture.

Methodology: We studied 2 cohorts of Swedish women at different ages: PEAK25 (all 25 years, n=1061) and OPRA (all 75 years, n=1044). Five common variants from 3 genes identified through GWAS were analysed to determine age related effects on body composition and bone phenotypes: rs17782313 and rs1770633 (MC4R: Melanocortin 4 receptor); rs7566605 (INSIG2: Insulin induced gene 2) and rs9939609 and rs1121980 (FTO- Fat mass and obesity associated).

Results: BMI, total body fat and lean mass were strongly and positively correlated with total body BMD, femoral neck BMD and ultrasound parameters in both cohorts ($r^2=0.2$-0.6). MC4R gene polymorphism rs17782313 was significantly associated with ultrasound, but only in the elderly cohort. Individuals with the rare CC genotype had higher values for all QUS parameters (BUA: $p=0.007$; 0.002); (SoS: 0.02; 0.007); (Stiffness: 0.001; <0.0001) under co-dominant and dominant models respectively. Interestingly, rs17782313 'C' carriers also had lower folate and vitamin D levels ($p=0.03$) and high homocysteine levels ($p=0.06$). MC4R SNPs rs17782313 and rs1770633 were not significantly associated with BMD or body composition in either OPRA or PEAK25. Fracture incidence in the elderly women did not differ with MC4R genotype. The FTO gene was associated with body composition in the young women ($p<0.006$) but FTO and INSIG2 polymorphisms were not associated with bone parameters in either cohort. However vertebral fracture incidence between baseline and 5-year follow-up was lower in elderly women with the rare INSIG2 rs7566605 genotype ($p=0.01$).

Conclusion: Body composition is one of the strongest determinants of bone strength. Genetic variation in theobesityassociatedgeneMC4R contributes to improved bone quality directly and through a trend towards increased BMI among carriers of the rare rs17782313 'C' allele. Our results are supported by other studies in an animal model showing decreased bone resorption with this polymorphism. Further studies are warranted to reveal the mechanism underlying the role of these genes on bone metabolism.

IFITM5 c.−14C>T Mutation Causing Type V Osteogenesis Imperfecta Decreases COL1A1 Expression and Increases Mineralization by Cultured Proband Osteoblasts. ADI REICH*[1], Alison S Bae[2], Aileen M Barnes[2], Wayne A Cabral[2], David Chitayat[3], Joan Marini[1]. [1]National Institute of Child Health & Human Development, USA, [2]NIH/NICHD/BEMB, USA, [3]The Hospital for Sick Children, & the Department of Obstetrics & Gynecology, The Prenatal Diagnosis & Medical Genetics Program, Canada

Osteogenesis imperfecta (OI) is a genetically heterogeneous disorder characterized by bone fragility. Most cases have dominant mutations of type I collagen, while recessive OI is caused by defects in genes whose products interact with type I collagen. Type V OI probands have dominant inheritance; characteristic skeletal findings include ossification of the forearm interosseus membrane, radiodense metaphyseal bands, propensity for hyperplastic callus formation, and mesh-like lamellation on bone histology. Type V OI probands are reported to have white sclerae. The cause of type V OI was recently shown to be a unique heterozygous mutation in *IFITM5* (c.-14C>T), which encodes Bril, a transmembrane protein expressed in osteoblasts. The mutation generates a start codon in the 5'-UTR, adding five residues to the Bril N-terminus. However, the mechanism that leads to the type V OI phenotype and its relationship with type I collagen is unknown. We identified 5 patients with the *IFITM5* (c.-14C>T) mutation : 3 patients with typical type V OI histology and radiographic findings, and 2 patients not previously classified as type V OI. The latter two patients have an atypical phenotype, including a child with strongly blue sclerae and no dense metaphyseal bands and an adult with progressive deforming OI. Using cultured osteoblasts (OB) from patients with characteristic type V OI, we verified expression of mutant *IFITM5* transcripts. Next, type V OI and control OB were cultured in osteogenic differentiation media. During D10-15 of the differentiation timecourse, type V OI OB had less than half the *COL1A1* expression of control, while osteocalcin (*BGLAP)* expression was increased during this timeframe, ranging from 2-8x control. Type V OI differentiated OB also had increased mineralization by alizarin-red assay. Comparison of type V OI and control OB transcripts on osteogenic arrays revealed other significantly altered transcripts, currently being validated. Electrophoretic migration of steady-state type I collagen was normal from proband OB with typical type V OI. We conclude that OI patients without the well-described type V OI phenotype may also have the same *IFITM5* mutation. The collagen-related defect and increased mineralization demonstrated in type V OI OB during differentiation may underlie the overactive tissue calcification and hypertrophic callus formation seen in affected individuals.

Sclerostin antibody treatment improves bone mass and microarchitectural parameters in young Crtap-/- mice, a model of pediatric recessive Osteogenesis Imperfecta. Ingo Grafe*[1], Tao Yang[2], Caressa Lietman[3], Erica Homan[3], Elda Munivez[3], Yuqing Chen[3], Ming-Ming Jiang[3], Terry Bertin[3], Brian Dawson[3], Franklin Asuncion[4], Hua Zhu (David) Ke[4], Michael Ominsky[4], Brendan Lee[5]. [1]Department of Molecular & Human Genetics, Baylor College of Medicine, USA, [2]Van Andel Research Institute, USA, [3]Baylor College of Medicine, USA, [4]Amgen Inc., USA, [5]Baylor College of Medicine & Howard Hughes Medical Institute, USA

Recently, we demonstrated efficacy of sclerostin antibody (Scl-Ab) treatment in adult Crtap-/- mice, a model of recessive Osteogenesis Imperfecta (OI) with defects in posttranslational modifications of type I collagen (Grafe et al ASBMR 2012). Scl-Ab treatment resulted in improved bone mass, bone microarchitecture and increased bone strength. However, whether Scl-Ab treatment is also effective on the growing skeleton in young Crtap-/- mice is still unknown. Consequently, in this study we tested the effects of Scl-Ab treatment in growing Crtap-/- mice as a potential model of pediatric treatment.

One week old female Crtap-/- mice were treated with Scl-Ab for 6 weeks (Scl-AbVI, 25 mg/kg, s.c., twice per week), PBS treated Crtap-/- and wildtype (WT) mice served as controls (n=6/group). After treatment, spines and femurs were analyzed by MicroCT.

At vertebral body L4, Scl-Ab treatment of Crtap-/- mice significantly improved BV/TV (+141%), Tb.N (+61%) and Tb.Sp (-45%) compared to PBS-treated Crtap-/- mice. Tb.Th was increased by 49% and not statistically different from WT mice. Cortical thickness at the femur midshaft was significantly increased by 14%, and at the femur metaphysis, Scl-Ab significantly increased Tb.N (+53%) and BV/TV (+63%), while Tb.Th remained unchanged. Interestingly, the findings in the trabecular bone of femurs differed from a previous report of the effects of the same Scl-Ab in young Brtl/+ mice (a model of dominant OI due to a mutation in the Col1a1 gene), where treatment resulted in improved Tb.Th, but had no significant effects on BV/TV and Tb.N (Sinder et al

ASBMR 2012). These distinctions in treatment outcomes may be due to different genders, treatment duration or genetic background of the mice in these studies. However, it is also possible that the beneficial effects of stimulating the Wnt signaling pathway with Scl-Ab on trabecular bone in the growing skeleton may be different in OI due to mutations in genes involved in post-translational collagen modifications compared to those with OI caused by mutations in the genes encoding type I collagen.

In summary, our results indicate that Scl-Ab treatment improves bone mass and bone microarchitecture in young Crtap-/- mice. These findings suggest that Scl-Ab treatment may be beneficial in pediatric patients with OI, in particular with recessive forms of the disease.

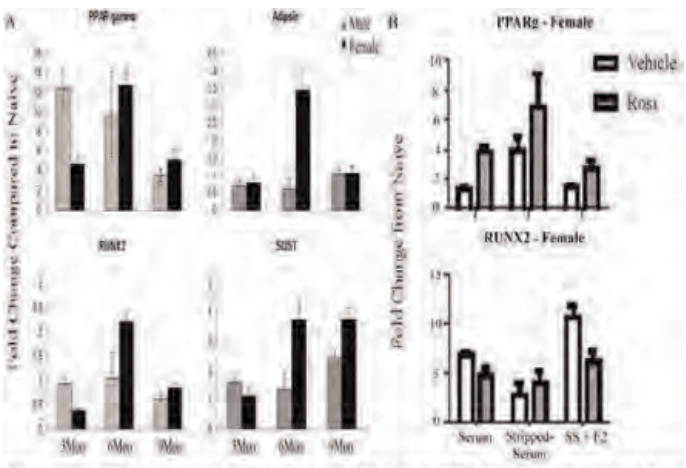
Sexual Dimorphism of Trabecular Bone Is Epigenetically Imprinted. Beth Bragdon*[1], Robert Burns[2], Amelia Baker[2], Anna Belkina[2], Gerald Denis[2], Elise Morgan[3], Louis Gerstenfeld[2], Jennifer Schlezinger[4]. [1]Boston University School of Medicine Department of Orthopaedics, USA, [2]Boston University School of Medicine, USA, [3]Boston University, USA, [4]Boston University, School of Public Health, USA

Introduction: It is well established that females have reduced bone mineral density compared to males and that levels of marrow fat affect bone health. A study of sex linked differences in the anabolic potential of osteoblast and adipocyte differentiation was carried out in mice.

Methods: Male and female C57BL6 (B6) mice (N=4-7) were assessed at 3, 6, and 9 months. Micro-computed tomography (MicroCT) was used to asses the structure of the right tibia. Immunohistological analysis for perilipin was used to assess marrow adipocyte content. RNA was isolated from the whole humeri, and expression of cassettes of mRNAs for osteoblasts/osteocytes (RUNX2, osteocalcin, DMP1, SOST) and adipocytes (PPARγ, FABP4, adipsin, perilipin) was assessed by qRT-PCR. Primary bone marrow stromal cells (BMSC) were cultured from the remaining hind limb long bones to assess their osteogenic and adipogenic potential. Osteogenesis was stimulated with ascrobate and β-glycerolphosphate. Adipogenic potential was based on responsiveness to rosiglitazone (ROSI). Estrogen effects were assessed by comparing BMSCs from mice ovariectomized (OVX) at 4 weeks of age to those from intact females or by culturing female BMSCs in estrogen-stripped or estrogen-supplemented media.

Results: MicroCT showed female mice at all ages had lower trabecular bone compared to age matched males. Immunohistology showed that females always had greater adipocyte content in their marrow than males. Similar expression of bone- and adipocyte-related genes was seen in males and females at 3 and 9 months, while at 6 months, females exhibited ~2X greater expression of both bone- and adipocyte-related genes than males. BMSC cultures retained these sex-linked differences. Female BMSC cultures consistently showed 1.5-2.0X higher expression of bone-associated genes, and female cultures were ~2-3X more responsive to ROSI-induced adipogenesis. BMSCs prepared from OXV mice showed similar results compared to BMSC from intact females. Estrogen-stripped media increased the adipogenic response to ROSI while decreasing the response to osteogenic signals.Conclusions: Even though females have decreased BV/TV compared to males, their bone metabolism is increased. These results suggest that the increased metabolic activity in females renders them more susceptible to adipogenesis resulting in greater adipocyte accumulation. Together, these results suggest an epigenetic component to the sexual dimorphic differences in skeletal tissue.



Messenger RNA expression for whole bone (A) and BMSCs (B). A. RNA isolated from humuri of male (gray bars) and female (black bars) B6 mice. B. BMSCs from B6 females cultured in media containing unmodified serum, charcoal-stripped serum, or estradiol (10^{-8}M) supplemented stripped serum (SS+E2) were stimulated to undergo osteogenesis and treated with vehicle (white bars) or ROSI (gray bars).

Gja1^{Jrt}/+ mice carry a mutation in the gap junction protein, alpha 1 gene (*Gja1*), encoding for a dominant G60S Connexin 43 (Cx43) mutant protein, resulting in production of less than 50% wild type (WT) levels of Cx43 protein and significantly reduced gap junction formation and function in Cx43-expressing cells. Similarly to other Cx43 mutants with loss or reduction in Cx43 gap junction formation and or function, including a global Cx43 deletion, four skeletal cell conditional-deletion mutants and a Cx43 missense mutant (G138R/+), the *Gja1*^{Jrt}/+ mice exhibit early onset osteopenia and changes in the structural (reduced cortical thickness, increased marrow space) and biomechanical properties (reduced material and structural properties) of femoral bones. In contrast to other Cx43 mutants, however, we found that the early osteopenic phenotype results from increased appendicular skeleton osteoblast activity leading to cell autonomous upregulation of both matrix bone sialoprotein (BSP) and membrane-bound receptor activator of nuclear factor kappa-B ligand (mbRANKL). In younger *Gja1*^{Jrt}/+ mice, these contribute to increased osteoclast number and activity on trabecular and endosteal bone surfaces, resulting in early onset high turnover osteopenia. Additionally, *Gja1*^{Jrt}/+ is the only Cx43 mutant mouse model reported to display a protection from old-age related diminution in BMD and exhibit age-related improvement in femoral bone structural and material properties. This is manifested by elimination or abrogation of the reduced trabecular BV/TV, cortical thickness, increased marrow space and reduced material properties in older compared to younger *Gja1*^{Jrt}/+ mice versus WT mice. The age-related protection and improvement in *Gja1*^{Jrt}/+ bone parameters appears to result from increased serum alkaline phosphatase (ALP), osteoprogenitor numbers, and serum osteoprotegerin (OPG) levels, which increase mineral deposition, contribute to the generation of active osteoblasts, and reduce bone resorption, respectively, allowing cortical and trabecular bone thickness to increase over time. Our study is the first to describe a Cx43 mutation in which osteopenia is caused by increased rather than decreased osteoblast function, where production of an abnormal bone matrix activates osteoclastogenesis and bone resorption, and where mice are protected from old-age related bone loss with improvement in structural and material parameters over time.

The Osteogenesis Imperfecta Adult Natural History Initiative: a web-based survey. Laura Tosi*[1], Matthew Oetgen[1], Melanie Rak[2], Marianne Floor[1], Carole Tucker[3], Tracy Hart[4], Mary Beth Huber[4], Fergus McKiernan[5]. [1]Children's National Medical Center, USA, [2]Rehabilitation Institute of Chicago, USA, [3]Temple University, USA, [4]Osteogenisis Imperfecta Foundation, USA, [5]Marshfield Clinic, USA

Introduction: Osteogenesis imperfecta (OI), is a heterogeneous, rare disorder most commonly affecting Type I collagen. Patients with OI face the possibility of complications in nearly every organ system in the body. There is little information about the natural history of OI beyond childhood.The OI Adult Natural History Initiative (OI ANHI) was developed in collaboration with adults with OI, the Osteogenesis Imperfecta Foundation (OIF), and members of the medical community in order to address this data and care gap. The team established a web-based portal within the existing OIF website to create a cost-effective outreach and data management clearinghouse with which to survey the OI community and capture a first-ever ''snapshot'' of the health status, needs, and priorities of adults with OI.

Methods: The ANHI web-based survey was created using the National Institutes of Health (NIH)-sponsored tool PROMIS® (Patient-Reported Outcomes Measurement Information System) and was conducted over 3-months. The survey included questions on general health concerns and health behaviors plus a review of systems, with scale-based rankings of respondents' priorities, concerns, and the impact of common impairments and conditions within each medical system. Respondents were recruited through letters to individuals on the OIF mailing list, as well as through social networking sites.

Results: A total of 959 surveys were fully completed. Over 93% of respondents completed the survey on the web. 70% of respondents were women and 89% were white. 31% of respondents reported they did not know their OI type. Survey analyses suggest that adults with OI have more pulmonary and cardiovascular issues than the general US population. There was limited correlation with respondents' description of themselves as having mild, moderate or severe disease (or OI type) and patient-reported measures of health status

Conclusions: The OI ANHI survey underscored numerous health concerns faced by the adult OI community and identified numerous opportunities for future research. The marked heterogeneity of OI also demands a clearer methodology for stratifying patients; therefore we plan to use survey measures to explore the development of a

new classification/stratification system for OI that might allow both patients and clinicians to assign risk for both skeletal and non-skeletal complications with greater confidence. It will be essential to recruit more men and minorities in future surveys.

Yunis-Varón syndrome (YVS) is an autosomal recessive disorder with cleidocranial dysplasia, digital anomalies and severe neurological involvement. Enlarged vacuoles are found in neurons, muscle, and cartilage. By whole exome sequencing, we identified frameshift and missense mutations of *FIG4* in affected individuals from three unrelated families. *FIG4* encodes a phosphoinositide phosphatase required for regulation of $PI(3,5)P_2$ levels, and thus endosomal trafficking and autophagy. In a functional assay, both missense substitutions failed to correct the vacuolar phenotype of *Fig4* null mouse fibroblasts. Homozygous *Fig4* null mice exhibit features of YVS, including neurodegeneration and enlarged vacuoles in neurons. We demonstrate that *Fig4* null mice also have small skeletons with reduced trabecular bone volume and cortical thickness, and that cultured osteoblasts accumulate large vacuoles. Our findings demonstrate that homozygosity or compound heterozygosity for null mutations of *FIG4* is responsible for YVS, the most severe known human phenotype caused by defective phosphoinositide metabolism. In contrast, in Charcot-Marie-Tooth disease type 4J also caused by *FIG4* mutations, one of the *FIG4* alleles is hypomorphic and disease is limited to the peripheral nervous system. This genotype-phenotype correlation demonstrates that absence of FIG4 activity leads to central nervous system dysfunction and extensive skeletal anomalies. Our results describe a previously unrecognized role for $PI(3,5)P_2$ signaling in skeletal development and maintenance.

Association between Polymorphisms in Leptin, its Receptor and Beta Adrenergic Receptor Genes and Bone Response to Hormone Therapy in Postmenopausal Korean Women. Jung-Gu Kim*[1], Hoon Kim[2], Seung-Yup Ku[2], Seok Hyun Kim[2], Young Min Choi[2], Jong Hak Kim[3]. [1]Seoul National University Hospital, South Korea, [2]Department of Obstetrics & Gynecology, Seoul National University College of Medicine, South Korea, [3]Ewha Womans University Mokdong Hospital, South Korea

Objective: The purpose of this study was to investigate the association between polymorphisms in leptin (LEP), its receptor (LEPR) and beta adrenergic receptor (ADRB) genes and bone response to hormone therapy (HT) in postmenopausal Korean women.

Methods: The LEP c.280G>A, LEPR c.326A>G, c.668A>G, c.1968G>C, c.2096C>T, ADRB2 c.46A>G, c.79C>G, c.718T>C, c.741G>T, c.769G>A, and ADRB3 c.190T>C polymorphisms were analyzed by polymerase chain reaction-restriction fragment length polymorphsim (PCR-REFLP), Taqman assay or direct DNA sequencing in 512 postmenopausal Korean women receiving sequential HT for 1 year. BMD at the lumbar spine (LS) and femoral neck (FN) was determined by dual energy X-ray absorptiometry.

Results: Among SNPs measured, ADRB2 c.46A>G polymorphism only was associated with annual percent changes in BMD at the femoral neck after 1 year of HT (P=0.01), and BMD at the femoral neck in the AA genotype of ADRB2 c.46A>G polymorphism decreased significantly compared to those in other genotypes. When a non-responder was defined as a woman who had lost more than 3% of BMD per year after HT, ADRB2 c.46A>G and ADRB3 c.190T>C polymorphisms among genetic polymorphisms studied were associated with the risk of non-response of HT. The AA genotype of ADRB2 c.46A>G showed a 1.82-times higher risk of non-response at FN (P=0.01) and 1.63-times higher risk of non-response at LS and/or FN (P=0.02), as compared with non-AA genotype. In the analysis of ADRB3 c.190T>C polymorphism, women with the TT genotype demonstrated a 1.51-times higher risk of non-response at LS and/or FN (P=0.03) compared with non-TT genotype.

Conclusions: The ADRB2 c.46A>G and ADRB3 c.190T>C polymorphisms may be associated with risk of non-response to HT in postmenopausal Korean women.

Funding Support: This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology (2011-0022334).

Identification and characterization of novel FGFR2 mutation causing craniosynostosis. Han-sol Bae*[1], Hyun-Mo Ryoo[2], Ye-jin Seo[1], Seung-Hak Baek[3]. [1]Seoul National University, South Korea, [2]Seoul National University School of Dentistry, South Korea, [3]A professor responsible for management, South Korea

Craniosynostosis(CS) is characterized by the premature obliteration of cranial sutures. Fibroblast growth factor receptor2 (FGFR2) mutations have been reported as the most common genetic cause of CS. Our previous studies indicate that activated FGFR2 stimulates an osteogenic master transcription factor, Runx2, through the MAP kinase. Here we identified novel mutation of FGFR2 gene obtained from sequence analyses of 30 Korean CS patients, FGFR2L617F. Features of this newly identified clinical disorder exhibited exorbitism and midface hypoplasia. This mutation occurs in the 2nd tyrosine kinase domain in the C-terminal cytoplasmic region of the molecule. It was verified by Restriction Fragment Length Polymorphism (RFLP). The amino acid sequence alignment revealed that eight species of vertebrates showed high homology around the position of the novel mutation. The high conservation of that domain in many kinds of organism means, the relevant position of L617 is functionally important and the mutation on that site is pathogenic. The mutation displayed high expression of several bone marker genes and enhanced Runx2 transacting activity. Moreover, it also showed strong activation of the ERK-MAPK signaling pathway and FGF signaling through increased phosphorylation of signaling factors and FGFR. These findings would support that L617F mutation may induce aberrant gain of function such as constitutive activation which is leading to early closure of cranial suture. This work identifies FGFR2L617F as a unique mutation causing CS and provides a pathway-based phenotypic link of FGFR2 mutation with the human disease.

On Genome-wide Association Studies and their Meta-analyses – Lessons Learned from Osteoporosis Studies. Yongjun Liu*[1], Lei Zhang[1], Yufang Pei[2], Christopher Papasian[3], Hong-Wen Deng[1]. [1]Tulane University, USA, [2]Tulane, USA, [3]UMKC, USA

Osteoporosis, the most common metabolic skeletal disorder in humans, has strong genetic determination; however, the majority of genetic variants contributing to risk of osteoporosis remain undiscovered. In the past 4 years, the bone field has witnessed great advances in genome-wide association studies (GWASs) of osteoporosis, with a number of promising genes identified. In particular, meta-analysis of GWASs, aimed at increasing the power of studies by combining the results from different study populations, have led to the identification of novel associations that would not otherwise have been identified in individual GWASs. However, it is important to note that inconsistent findings are seen among and between GWASs and meta-analyses, and inconsistencies have even been observed between meta-analyses whose samples overlapped to a large extent. Consequently, the limitations of GWASs and their meta-analyses must be carefully evaluated, with an emphasis on understanding the reasons for inconsistent results between different meta-analyses, before we can correctly interpret the extensive results generated from these meta-analyses. Here we reviewed prominent empirical findings and problems in GWASs and meta-analysis of GWASs on osteoporosis, and then performed computer simulation analyses to help understand these findings and problems. We show that discordant findings in GWASs and meta-analyses are not unexpected, even for true susceptible genes. Importantly, contrary to the general belief, meta-analyses should not be used as a gold standard to evaluate the results of individual GWASs. In particular, individual GWASs in homogeneous populations can detect true disease genes that meta-analyses may have low power to replicate.

SIBLING Family Genes and Bone Mineral Density: Association and Allele-specific Expression in Human. Imranul Alam*[1], Leah Padgett[2], Shoji Ichikawa[1], Mohammed Alkhouli[2], Daniel Koller[1], Dongbing Lai[3], Munro Peacock[4], Xiaoling Xuei[5], Tatiana Foroud[3], Howard Edenberg[6], Michael Econs[1]. [1]Indiana University School of Medicine, USA, [2]Medicine, IUPUI, USA, [3]Medical & Molecular Genetics, IUPUI, USA, [4]Indiana University Medical Center, USA, [5]Biochemistry & Molecular Biology, USA, [6]Biochemistry & Molecular Biology, Medicine, IUPUI, USA

Osteoporosis is a common complex disorder with reduced bone mineral density (BMD) and increased susceptibility to fracture at multiple skeletal sites. Peak BMD is one of the primary skeletal determinants of osteoporotic fracture risk and is under substantial genetic control. Extracellular matrix (ECM), a major component of bone and a highly dynamic structure, influences BMD as it regulates mineral deposition and maintains cellular activity. ECM of bone contains several SIBLING family proteins, null mutations of which cause mineralization defects in humans. In this study, we tested 9 single-nucleotide polymorphisms (SNPs) located in the 5 SIBLING family genes (*DSPP*, *IBSP*, *DMP1*, *SPP1* and *MEPE*) for association with normal variation in peak BMD in healthy men and women. We measured femoral neck (FN) and lumbar spine (LS) aBMD by DXA in 1,692 premenopausal white women, 512 premenopausal black women and 715 white men. SNPs genotyping determined using the Sequenom MassARRAY system was tested for association with the 2 key BMD phenotypes in the 3 study subsamples. In the white women, we observed association ($p<0.005$) with FN-BMD for SNPs in *IBSP* and *DMP1*, and for LS-BMD with SNPs in *DSPP*, *IBSP* and *MEPE*. One SNP in *SPP1* was associated ($p<0.05$) in black women for FN-BMD. Three SNPs, one in each of *DSPP*, *DMP1* and *SPP1* were associated ($p<0.05$) with FN-BMD and one SNP in *DMP1* was associated ($p<0.05$) with LS-BMD in white men. To identify whether there was preferential allelic expression of these genes at these SNPs we measured the allele-specific expression (ASE) by the MassARRAY system using 52 human bone samples obtained from femoral neck during surgical hip replacement (27 female, 25 male, 44 Caucasian and 8 African-American). This approach tests for differences in expression between 2 alleles within the same heterozygous individual. We observed an allelic imbalance in mRNA expression (higher or lower expression of one allele compared to the other) for the SIBLING genes: higher expression of G allele for SNP rs2615497 in *DMP1*, A for SNP rs6812524 in *SPP1* and T for SNP rs1054629 in *IBSP*; lower expression of A for SNP rs2736982 in *DSPP*, G for SNP rs17013182 in *IBSP*, G for SNP rs17013285 in *MEPE* and T for SNP rs1126616 in *SPP1*. Our data shows that SIBLING genes are associated with BMD in healthy subjects and SNPs within the mRNA are associated with variation in allelic specific mRNA expression. ASE of SIBLING genes may contribute to normal variation of peak BMD.

BMP-2 Delivery using Electrospun PLLA/Collagen I Scaffolds with Surface Adsorbed plasmid DNA/Transfection Complexes. Xia Zhao[1], David Komatsu[2], Michael Hadjiargyrou*[3]. [1]Stony Brook University, USA, [2]Stony Brook University, Dept. of Orthopaedics, USA, [3]New York Institute of Technology, USA

Delivery of BMP-2 protein is a wildly used strategy to engineer new bone. However, BMP-2 protein has a very short half-life in vivo which necessitates the delivery of doses ranging from hundreds of micrograms to low milligram levels to ensure significant bioactivity. As an alternative, we hypothesized that BMP-2 plasmid DNA delivery can serve as a lower cost and biologically effective approach. Our laboratory previously fabricated PLLA/Collagen I electrospun scaffolds which supported robust osteoblast cell attachment, proliferation, migration and differentiation. As such, we utilized these scaffolds to test whether the delivery of surface adsorbed BMP-2 plasmid DNA complexed with commercial transfection reagents is able to induce ectopic bone formation. We initially prepared scaffolds with surface adsorbed β-gal plasmid DNA complexes and evaluated their ability to transfect Hela cells *in vitro.* Visual analysis of the treated cells showed the scaffolds to have a ~40% transfection efficiency. Similar studies conducted using MC3T3 preosteoblastic cells revealed that exposure to the scaffolds with adsorbed BMP-2 plasmid DNA/transfection complexes resulted in a robust increase in BMP-2 mRNA levels, verifying the successful delivery and expression of the BMP-2 gene. An *in vivo* study was then performed using the mouse quadriceps muscle pouch model of ectopic bone formation. PLLA/Collagen I scaffold discs (5mm in diameter) with or without surface adsorbed BMP-2 plasmid DNA/transfection complexes were implanted into each muscle pouch. Gene expression analyses of day 7 samples showed a 3-fold increase in BMP-2 mRNA. Similarly, immunohistochemistry of day 7 samples revealed strong expression of BMP-2 protein. Further, ongoing microCT analyses of day 14 and day 28 samples show evidence of ectopic bone formation. Overall, these data demonstrate that electrospun PLLA/Collagen scaffolds with surface adsorbed BMP-2 plasmid DNA/transfection complexes can safely and effectively drive transgene expression both *in vitro* and *in vivo* and suggest that these scaffolds have the potential to advance skeletal tissue engineering.

PERK-ATF4-CHOP Signaling Contributes to TNFα-induced Vascular Calcification. MASASHI MASUDA*, Shinobu Miyazaki, Makoto Miyazaki. University of Colorado-Denver, USA

Purpose: TNFα is a critical regulator of vascular calcification. The purpose of the present study was to investigate whether the PERK-ATF4-CHOP axis of the endoplasmic stress contributes to TNFα induced vascular calcification in chronic kidney disease (CKD).

Methods and Results: We examined the effects of TNFα in the endoplasmic reticulum stress of vascular smooth muscle cells (VSMCs). TNFα treatment drastically induced the PERK-eIF2α-ATF4-CHOP axis of the endoplasmic reticulum (ER) stress response in VSMCs. PERK, ATF4 and CHOP shRNA knockdowns inhibited mineralization and osteogenesis of VSMCs induced by TNFα. CKD induced by 5/6 nephrectomies induced PERK-eIF2α-ATF4-CHOP axis of the ER stress response in the aortas of ApoE-/- mice with increased aortic TNFα expression and vascular calcification. Treatment 5/6 nx ApoE-/- mice with the TNFα neutralizing antibody reduced aortic PERK-eIF2α-ATF4-CHOP signaling increased by CKD, resulting in the inhibition of CKD-dependent vascular calcification.

Conclusions: These results suggest that the PERK-eIF2α-ATF4-CHOP axis of the ER stress mediates TNFα-induced vascular calcification.

Key words: vascular calcification, TNFα, endoplasmic reticulum stress, ATF4, CHOP

Rescuing Impaired Bone Healing in Type 1 Diabetes BBDP/Wor Rats. Tera Filion*[1], David Ayers[2], Jie Song[3]. [1]UMASS Medical School, USA, [2]UMass Memorial Medical Center, USA, [3]University of Massachusetts Medical School, USA

Bone healing in diabetic patients following orthopedic trauma is a significant clinical challenge. We developed an osteoconductive hydrogel-mineral composite containing 50% nanocrystalline HA (nHA) as a synthetic bone graft substitute. When pre-absorbed with a single dose of 400-ng rhBMP-2/7 and press-fit in 5-mm rat femoral segmental defects, the functional repair of the defect in normal rats was enabled by 12 weeks[1]. In this study, the same treatment failed to repair the critical-size defect in BBDP/Wor rats exhibiting diabetes. Delivery of a higher dose of rhBMP-2/7 (3-μg) or rhBMP-2 (6-μg) via the synthetic scaffold was required to induce the formation of a bony callus fully bridging the defect. Taking advantage of the ability of the nHA component of the synthetic scaffold to absorb endogenous proteins, we addressed the mechanism by which diabetic bone microenvironment prevents bone healing. The hydrogel-nHA scaffold alone was fit in the femoral defects in diabetic vs. normal rats and retrieved at 1, 2, 4, and 7 days for immunohistochemical detection of TGFβ, IL-1β, TNFα, VEGF, RANKL, BMP-2, -7, IGF-1 and SDF-1 retained on the scaffold. Absorption of these endogenous factors associated with the initiation of the inflammation/graft healing cascade or stem cell recruitment by the synthetic scaffold was significantly delayed/mitigated in diabetic rats, revealing an impaired biochemical microenvironment underlying the retarded healing. Meanwhile, bone marrow derived stromal cells (MSCs) and periosteal derived cells (PDCs) isolated from the long bones of diabetic rats (n=4) exhibited significant functional impairment in culture compared to normal skeletal progenitor cells. The diabetic MSCs and PDCs contained a significant senescent population, proliferated much slower and underwent highly impaired osteogenic differentiation upon culture induction compared to the normal controls. These findings suggest that co-delivery of multiple therapeutic agents that more effectively rescue the function of impaired skeletal progenitor cells in diabetic rats may be necessary for effective bone healing. Indeed, when IGF-1 and BMP-2 was co-delivered via the synthetic scaffold, a more robust bony callus bridged over the defect by 12 weeks. On-going investigations aim to identify more effective synergistic combinations of therapeutic agents and delivery scaffolds to reduce minimal loading doses of exogenous factors.

Robust and Distinct Patterns of Transcriptional Activity of *Bmp2*, *Bmp4*, and *Noggin* in the Postnatal Skeleton. Steven Pregizer*, Douglas Mortlock. Vanderbilt University Medical Center, USA

BMP signaling plays an important role in the development, maintenance, and repair of skeletal tissues, including bone and cartilage. Nevertheless, the precise etiology of BMP signaling in the skeleton beyond embryogenesis is unclear. In this study, we used a collection of transgenic reporters to highlight the transcriptional activity of two BMP ligands (*Bmp2* and *Bmp4*) and their antagonist (*Noggin*) in the postnatal skeleton during normal development and aging. All three genes are robustly transcribed in distinct patterns one month after birth, a point of peak skeletal growth. Transcription of *Noggin* and *Bmp4* is lineage-dependent, with *Noggin* transcribed

exclusively in cells of the chondrogenic lineage, and *Bmp4* transcribed exclusively in cells of the osteogenic lineage. In contrast, *Bmp2* transcription is tightly linked to maturational status, with cells of both lineages exhibiting robust reporter activity as they progress towards terminal differentiation. At one year of age, when skeletal growth has ceased and the tissues are in a state of maintenance, only *Bmp2* retains transcriptional activity in the skeleton. Interestingly, it is restricted to chondrocytes found at the articular cartilage surface, with no appreciable activity in osteogenic cells. Taken together, these results illuminate the dynamics and cellular localization of *Bmp2*, *Bmp4*, and *Noggin* transcriptional activity in the postnatal skeleton. A fuller appreciation of these nuances will facilitate a better understanding of how BMP signaling orchestrates the development and maintenance of skeletal tissues.

FGF2 Primes Periosteal Cells for Endochondral Ossification via Maintenance of Skeletal Precursors and Modulation of BMP Signaling. Nick Van Gastel*[1], Steve Stegen[1], Riet Van Looveren[1], Ingrid Stockmans[1], Jan Schrooten[2], Daniel Graf[3], Frank Luyten[4], Geert Carmeliet[5]. [1]Laboratory of Clinical & Experimental Endocrinology, KU Leuven, Belgium, [2]Department of Metallurgy & Materials Engineering, KU Leuven, Belgium, [3]Orofacial Development & Regeneration, Institute of Oral Biology, Center for Dental Medicine, University of Zurich, Switzerland, [4]University Hospitals KU Leuven, Belgium, [5]Katholieke Universiteit Leuven, Belgium

Cell-based tissue engineering may be a promising approach for the repair of large bone defects. The bone marrow has traditionally been the preferred cell source, but evidence suggests that periosteum represents a valuable alternative. Given the beneficial effects of fibroblast growth factor 2 (FGF2) on bone formation by bone marrow stromal cells and the potential of this factor to promote fracture healing, a periosteum-driven process, we hypothesized that FGF2 addition during culture expansion could enhance the bone-forming potential of murine periosteum-derived cells (mPDC).

The addition of FGF2 promoted mPDC proliferation and inhibited culture-induced senescence, confirming known effects of FGF2 on mesenchymal stem cells (MSC). When FGF2-pretreated mPDC ($mPDC^{FGF2}$) were implanted on a calcium phosphate-collagen carrier at an ectopic or orthotopic site in mice, a remarkable increase in newly formed bone, associated with large amounts of bone marrow, was observed after 8 weeks compared to control cells. Unexpectedly, $mPDC^{FGF2}$ also formed small islands of mature cartilage at both locations. To further investigate this aspect, we subcutaneously injected cells in collagen gels, which already after 1 week resulted in robust cartilage formation by $mPDC^{FGF2}$, but not by control mPDC. By 2 weeks this cartilage template underwent endochondral ossification, evidenced by the presence of invading blood vessels, chondroclasts and osteoblasts as well as mineralized matrix.

To elucidate the underlying mechanisms we assessed the number of skeletal precursors in the cultures. The $mPDC^{FGF2}$ populations contain significantly more $Nestin^{+}$ mesenchymal stem cells (MSC) as well as osteoprogenitor cells, shown by increased *Runx2* expression and a higher number of osteogenic colony-forming units. Surprisingly, the expression of chondrogenic lineage markers was reduced, indicating that the enhanced *in vivo* chondrogenesis of $mPDC^{FGF2}$ is associated with the higher number of MSC. As we also detected a striking increase in *Bmp2* expression in $mPDC^{FGF2}$, a factor with known osteochondrogenic potential, we genetically knocked down *Bmp2* levels, which resulted in a reduction of the endochondral bone-forming potential of the $mPDC^{FGF2}$.Taken together, our results show that FGF2 markedly enhances the *in vivo* bone-forming potential of PDC, providing new insights in the regulation of periosteal cells and an attractive therapeutic approach for non-healing bone defects.

Molecular Characterization of FGF-18 and FGF Receptors 1, 2 and 3. Abdulhafez Selim[1], Sherry Wang*[2]. [1]Center for Chronic Disorders of Aging, PCOM, USA, [2]Medical Device & Biomedical Technologies Labratory, Industrial Technology Research Institute, Taiwan

Osteoarthritis (OA) and degenerative disc disease (DDD) are prevalent diseases in the United States with staggering socioeconomic effects on today's society and together OA and DDD constitute a major source of health care costs. One particular family of growth factors, the fibroblast growth factor (FGF) family, has been implicated in the regulation of both articular cartilage and intervertebral disc (IVD) homeostasis. This large family of structurally-related proteins binds heparin and heparan sulfate modulates the growth, differentiation, migration and survival of a wide variety of cell types. Specifically, two particular members of the FGF family, basic fibroblast growth factor (bFGF; also known as FGF-2) and fibroblast growth factor-18 (FGF-18), have been found to play prominent regulatory roles in cartilage matrix homeostasis.

There are no previous studies that describe the three dimensional structure of FGF 18 or its interaction with FGF Receptors 1, 2, or 3. Our study is the first one that approaches the molecular characterization FGF18/FGFR complexes. For this purpose, we used validated bioinformatics tools to build three dimensional models for FGF 18, FGF 18/FGFR1 complex, FGF 18/FGFR2 complex and FGF 18/FGFR3 complex. We further analyzed the interface between FGF 18 and FGF receptors (1, 2 and 3).

Study results demonstrated high similarity between FGF 18 and FGF family members. FGF 18 has ten blades of beta sheets and one alpha helix domain. Study results demonstrated that FGF 18 has high affinity to interact with FGFR 3 and least affinity to interact with FGFR 2. FGF 18 has the same interfacing regions to interact with FGFR 1, 2 and 3. There was medium affinity to interact with FGFR 1. FGF 18 interaction with FGFR 3 was mediated by 9 hydrogen bonds and one salt bridge bond. Fewer bonds were involved in FGF 18 interaction with FGFR 1(7 hydrogen bonds and zero salt bridges) and FGF 18 interaction with FGFR 2 (Three hydrogen bonds and zero salt bridges).This affinity profile is very unique to FGF 18 and might explain its unique biological functions compared to other FGFs.

This study will help design therapeutic agonists and antagonists to modulate the functions of FGF 18. The resultant molecules may be of great role in treating cartilage and bone diseases.

Adiponectin Modulates Bone Metabolism Via a Hypothalamic Relay Through the Epigenetic Regulation of CB1 Signaling Pathway. Hua Jiang*[1], Yuwei Wu[2], Qisheng Tu[1], Dana Murray[1], Jin Tang[1], Qianqian Han[1], Jake Jinkun Chen[1]. [1]Tufts University School of Dental Medicine, USA, [2]Tufts University, USA

Objective: Adiponectin is an adipose tissue derived hormone. Our previous studies have shown that adiponectin inhibits osteoclastogenesis and bone resorption. Adiponectin increases bone mass via a hypothalamic relay and exerts its effect through the APPL1 (Adaptor protein containing pleckstrin homology domain, phosphotyrosine domain, and leucine zipper motif) signaling pathway. The cannabinoid system is known for its involvement in regulating bone mass *in vivo*. The cannabinoid type 1 (CB1) receptor is expressed in the hypothalamus and regulates bone metabolism via the hypothalamus. However, whether adiponectin mediates bone metabolism through CB1 receptor remains to be determined. We explored the signaling pathways in which adiponectin modulates bone metabolism via a hypothalamic relay through epigenetic regulation of CB1 receptor.

Methods: Embryonic Mouse Hypothalamic Cell Line N-1 (mHypoE-N1, CELLutions Biosystems INC., Canada) were maintained in DMEM culture medium containing 10% fetal bovine serum (FBS) at 37°C in 5% CO_2/95% air. mHypoE-N1 cells were subjected to serum starvation overnight with or without 10^{-10} M globular adiponectin. Specific APPL1 small hairpin RNA (shRNA) and scramble control non-specific lentiviral-shRNA were transduced into N1 cells to generate stable cell lines.

Cell extracts were used for western blot, real-time PCR and chromatin immunoprecipitation (ChIP) assays.

Results: Real-time PCR and western blot analyses showed that adiponectin stimulation dramatically decreased CB1 expression ($p < 0.01$) and significantly enhanced histone deacetylase 5 (HDAC5) expression ($p < 0.01$) in mHypoE-N1 cells. However, specific APPL1 shRNA pretreatment showed no effects on CB1 and HDAC5 expression. In the mHypoE-N1 cells, the ChIP assay demonstrated HDAC5 occupancy in the CB1 promoter region upon adiponectin stimulation.Conclusions: Adiponectin decreased CB1 expression by regulating HDAC5, which was independent of APPL1 signaling pathway. These results indicate a novel signaling pathway for adiponectin modulating bone metabolism via a hypothalamic relay through epigenetic regulation of CB1.

Disulfide Bond Requirements for Active Wnt Morphogens. Bryan MacDonald*[1], Annie Hien[2], Xinjun Zhang[2], Xi He[2]. [1]Children's Hospital Harvard Medical School, USA, [2]The F. M. Kirby Neurobiology Center, Boston Children's Hospital, Harvard Medical School, USA

Secreted Wnt glycoproteins are cysteine-rich, lipid modified morphogens that bind to the Frizzled (FZD) receptor to initiate Wnt signaling. The structure of Wnt proteins proved elusive until recently with the reported co-crystallization of Xwnt8 with a FZD extracellular cysteine rich domain (CRD). Wnt engages FZD through two protruding finger like domains, each assembled from paired beta strands secured by several disulfide bonds, which grasp both ends of the CRD. However with this new structural information, questions remain regarding the importance of each disulfide bond for Wnt function and their impact on Wnt solubility and receptor binding.

To address these questions we have performed a thorough analysis of the Wnt3a disulfide bonds by cysteine mutagenesis and examined their effect on Wnt biogenesis and activity. Our data show that removal of any one cysteine of Wnt3a results in large aggregations via ectopic, and presumably intermolecular, disulfide bonds which prevent receptor binding. Residual activity from the cysteine mutants shows a tolerance for alterations in the amino saposin-like domain of Wnt while mutations in the cysteine-knot of the cytokine-like domain are not compatible with monomeric solubility.

With solubility and activity affected in most of the single cysteine Wnt3a mutants, we examined a few select double cysteine mutants based on the normal disulfide bond pattern in an attempt to restore Wnt solubility and analyze binding to the FZD CRD. We find that paired mutation of the distal index finger cysteines results in a secreted monomeric ligand with greatly diminished FZD binding and dominant negative signaling properties. Additionally our studies of the amino terminal cysteines of Wnt3a, which are not represented in the shorter crystallized Xwnt8 protein, support a disulfide bond between the first two cysteines found in most Wnt ligands.

Recently loss of function WNT1 mutations have been reported in patients with osteogenesis imperfecta. Of the five reported missense mutations (C143F, G177C, R235W, F298C and V355F) several result in the addition or subtraction of cysteine residues. We have independently tested the five published OI missense mutations and compared their signaling ability with our Wnt3a study and find correlations based on the location of the cysteine mutants. The results of our study will provide a predictive level of severity for future WNT1 cysteine mutations.

EGFR Signaling Promotes Proliferation and Survival in Osteoprogenitors by Increasing Egr2 Expression. Abhishek Chandra*[1], Shenghui Lan[1], Ji Zhu[2], Valerie Siclari[1], Ling Qin[1]. [1]University of Pennsylvania, USA, [2]University of Pennsylvania, School of Medicine, USA

Deficiency in mesenchymal stem cells and osteoprogenitors leads to insufficient number of osteoblasts and low bone formation. Mice with conditional inactivation of epidermal growth factor receptor (EGFR) in osteoprogenitor/osteoblasts (3.6kb collagen1a1-Cre $Egfr^{Wa5/flox}$, Col-CKO) displayed an osteopenia bone phenotype caused by a decreased bone formation and reduced number of bone marrow mesenchymal progenitors, indicating a critical role of EGFR signaling in maintaining the osteoprogenitor pool. EGFR ligands, such as EGF, are known mitogens for osteoprogenitors but the underlying transcriptional machinery remains elusive. Moreover, whether activation of EGFR in these cells stimulates cell survival has not been investigated. EGF treatment significantly increased the proliferation of MC3T3, an osteoprogenitor cell line, and primary calvarial osteoprogenitors through both MAPK/Erk and PI3K/Akt-dependent pathways, and it potently suppressed the serum depletion- and TNFalpha-induced apoptosis of these cells by MAPK/Erk pathway. Furthermore, mouse calvarial organ culture revealed that EGF elevated the number of proliferative cells and decreased the number of apoptotic cells, which led to an increase in calvarial osteoblasts. Microarray analysis revealed that EGFR signaling stimulates the expression of Mcl1, an anti-apoptotic protein, and a family of early growth response protein (Egr) transcription factors (Egr1, 2, and 3) in MC3T3 cells. This up-regulation, mainly through MAPK/Erk pathway, was further confirmed in MC3T3 cells at both RNA and protein levels and in wild-type calvarial osteoprogenitors but not in those from Col-CKO mice. Overexpression of Nab2, a co-repressor for Egrs, abrogated the EGF-induced increase in osteoprogenitor number. Interestingly, knocking down the expression of Egr2, but not Egr1 or 3, not only attenuated the EGF-induced increase of Mcl1 protein expression but also abolished the EGF-induced survival and proliferation. In contrast, overexpression of Egr2 protein resulted in an increased expression of Mcl1 protein, a decrease in apoptosis, and an increase in cell proliferation of MC3T3 cells. Taken together, our data demonstrate that EGFR signaling activates MAPK/Erk pathway to stimulate the expression of Egr2, which in turn leads to cell growth and Mcl1-mediated cell survival. This study reveals a critical role of Egr2 transcription factor in regulating osteoprogenitor population and new bone formation by EGFR signaling.

Erythropoietin (EPO) excess results in Bone Loss in a Transgenic mouse model that overexpresses EPO. Paraskevi-Rea Oikonomidou*[1], Stefano Rivella[2], Jae Hyuck Shim[2], Stephen Doty[3], Sara Gardenghi[2], Zhiwei Yang[2], Carla Casu[2], Maria Vogiatzi[4]. [1]Cornell University, USA, [2]Weill Cornell Medical College, USA, [3]Hospital for Special Surgery, USA, [4]New York Presbyterian Hospital, Weill Cornell Medical College, USA

Erythropoietin (EPO) is a member of the type I cytokine superfamily known for its function to stimulate and support erythropoiesis. However, recent studies suggest that EPO exhibits additional diverse cellular functions in non-hematopoietic tissues such as tissue protection against injury, immune response and cancer. The effect of EPO on bone metabolism has been debatable. EPO administration in wild type (wt) mice resulted in changes in bone mass, albeit the results were contradictory. The tg6 transgenic mice (tg6) that overexpress human EPO driven by the human platelet-derived growth factor B-chain promoter show a 12-fold elevation of serum EPO concentrations and polycythemia vera (hematocrit levels at 80-90%). To gain further insight on the role of EPO on bone remodeling in vivo, we analyzed bone mass in these tg6 mice and wild type littermate controls using micro-CT (n=6/group, age 3mo, all males; Table). Our preliminary findings showed cortical and trabecular bone loss in tg6 mice, suggesting that EPO has an effect on bone mass. Histology, dynamic histomorphometry and measurement of markers of bone turnover are under way to help us determine the specific changes in bone remodeling that are induced by EPO.

Induction of CXC Chemokines in Human Mesenchymal Stem Cells (hMSCs) by Stimulation with Secreted Frizzled-Related Proteins (sFRPs). David Bischoff*, Jian-hua Zhu, Nalini Makhijani, Dean Yamaguchi. VA Greater Los Angeles Healthcare System, USA

CXC chemokines such as CXCL1 and CXCL8 are elaborated from hMSCs during osteogenesis and may be involved in angiogenic stimulation during bone repair. Differentiation of hMSCs with osteogenic differentiation medium (OGM) and dexamethasone (DEX), an OGM component, stimulated the production of the CXC chemokine CXCL5, with an 8- and 5-fold increase in mRNA expression, respectively, compared to control, non-differentiation growth medium (HMSCGM). In addition, non-canonical Wnt signaling is involved in the stimulation of CXCL5 by OGM. Conditioned medium (CM) from L-cells expressing non-canonical Wnt5a, stimulated an increase in CXCL5 mRNA expression and protein secretion in comparison to control L-cell CM. Dikkopf-1 (Dkk-1), an inhibitor of canonical Wnt signaling inhibited basal levels of CXC5 expression at 7 days of culture of hMSCs in OGM but not at 10 days of culture. RoR2, a co-receptor for non-canonical Wnt signaling was also significantly up-regulated by OGM and DEX by approximately 12-fold

compared to control HMSCGM medium. Ru486, a glucocorticoid receptor (GR) antagonist inhibited the OGM- and DEX-stimulated increases in RoR2. Secreted frizzled-related protein1 (sFRP1), which should inhibit both canonical and non-canonical Wnt signaling, enhanced the expression of CXCL5 in hMSCs at 7 and 10 days in culture. We have now tested all four sFRPs and show that all sFRPs induce CXCL8 expression in a dose- and time-dependent manner with maximum expression at 150 nM at 7 days post-treatment. Previously, we demonstrated that sFRP1 stimulated phosphorylation of the extracellular signal regulated kinase (ERK) in hMSCs with maximum stimulation at 5 minutes after sFRP1 addition. We have extended our analysis using specific inhibitors of ERK (PD98059, U0126), p38 mitogen-activated protein kinase (MAPK) (p38 inhibitors SB203589, SB202190), and c-Jun NH2-terminal kinase (JNKII inhibitor) to test for the inhibition of sFRP1-stimulated CXCL8 expression. Initial results indicate that these ERK and p38 inhibitors prevent sFRP1-stimulated CXCL8 up-regulation whereas JNK inhibition had no effect on CXCL8 stimulation. Conclusions: 1) expression of CXC chemokines, CXCL8 and CXCL5, is enhanced in hMSCs undergoing osteoblastogenesis; 2) the non-canonical Wnt pathway appears to be invovled in CXC chemokine expression during osteogenic differentiation; 3) sFRPs which further stimulated CXCL5 and CXCL8 expression in OGM may do so in part via ERK and p38 MAPK signaling pathways.

Myeloid-derived suppressor cells as key immune regulators of nonunion fractures. Seth Levy*[1], Anandi sawant[2], Shawn Gilbert[1], Selvarangan Ponnazhagan[2]. [1]The University of Alabama At Birmingham, USA, [2]UAB, USA

Every year there are more than 6 million fractures in the United States alone and approximately 10% of them result in delayed healing or develop into nonunion fractures. Normally, fractures heal with overlapping phases of inflammation, cell proliferation, and bone remodeling. Osteogenesis and angiogenesis are known to work in concert to control many stages of this process, and when one is impaired it leads to failure of bone healing, termed a nonunion fracture. During fracture, there is an abundant infiltration of immune cells at the fracture site that not only mediate the inflammatory responses but also exert influence on neovasculature. Thus, further understanding the effects of immune cell participation at the fracture site throughout fracture healing may not only lead to additional knowledge as to why some fractures heal while others remain nonunions, but also to the development of novel therapeutics modulating immune cells to increase fracture healing and prevent nonunions. The present study demonstrates the impact of immune cells on angiogenesis in the early stages of fracture healing suggesting key immune modulatory mechanisms may exert an effect on angiogenesis required for proper bone healing.

Results indicate that among infiltrating immune cells, there was a significant increase only in myeloid-derived suppressor cells (MDSC). MDSC, a heterogeneous population of progenitor cells, suppress lymphocytes through cytokines or the release of nitric oxide. MDSC are not only pro-angiogenic through molecules independent of VEGF, but we have demonstrated that MDSC in the presence of breast cancer can differentiate into osteoclasts and aid in bone degradation (Sawant et al. 2013). Thus, in order to further understand the role of immune cells on angiogenesis and osteogenesis we plan to elucidate if MDSC act as immune regulators throughout fracture healing.

During the initial phase of fracture healing there is a dramatic increase in the number and percentage of MDSC in the fracture area followed by a decrease in the number and percentage of MDSC as the fracture heals. Using gemcitabine to specifically decrease the levels of MDSC, we observe delayed healing in the absence of MDSC, further signifying the role of MDSC in fracture healing. Based on this data we predict that MDSC may play a significant role in nonunion fractures and therapeutic targeting of MDSCs after fracture would minimize the chances of eventual nonunion pathology.

The Metabolic Nature of Marrow Fat: insulin signaling, CREB phosphorylation and the 'adiponectin paradox'. Erica Scheller*[1], William Cawthorn[2], Brian Learman[2], Hiroyuki Mori[2], Becky Simon[2], Sebastian Parlee[2], Xiaomin Ning[2], Joshua Miller[3], Katherine Gallagher[4], Pouneh Fazeli[5], Clifford Rosen[6], Mark Horowitz[7], Anne Klibanski[8], Ormond MacDougald[2]. [1]University of Michigan, USA, [2]Department of Molecular & Integrative Physiology, University of Michigan, USA, [3]Department of Orthopedics, University of Michigan, USA, [4]Medical School, University of Michigan, USA, [5]Massachusetts General Hospital & Harvard Medical School, USA, [6]Maine Medical Center, USA, [7]Yale University School of Medicine, USA, [8]Massachusetts General HospitalHarvard Medical School, USA

Marrow adipose tissue (MAT) fills 70% of the skeleton, weighs ~2.6 kg in an average adult and contains ~23,000 kcal of stored energy. Unlike peripheral white adipose tissue, MAT increases in rodents and humans during states of calorie restriction. This implies that MAT is differentially regulated by nutritional status. It also suggests that preservation of MAT may be advantageous to metabolic function. However, the ability of MAT to both contribute to and respond to systemic change is poorly understood.

To address this we profiled adipose tissue mRNAs and observed >300 adipocyte-related gene expression differences in MAT compared to white adipose tissues. Ingenuity pathway analysis predicted that MAT has impaired fatty acid metabolism and insulin sensitivity. *In vivo* injections of insulin and isoproterenol pinpointed differences in signaling intermediates, including altered phosphorylation of Akt in response to insulin and a lack of CREB phosphorylation in response to lipolytic β-adrenergic stimulation. These findings begin to explain fundamental differences in the metabolic response of the bone marrow adipocyte.

MAT also has the potential to secrete regulators of systemic metabolism such as adiponectin. Despite being predominantly an adipocyte-derived protein, the circulating concentration of adiponectin is inversely correlated with % body fat. Although first reported in 1999, this 'adiponectin paradox' remains only partially explained. Like adiponectin, MAT is increased in states of low body fat including anorexia and type I diabetes. Thus, we hypothesized that increases in MAT are the source of elevated serum adiponectin. We found that expression of adiponectin protein is disproportionately conserved in MAT when compared to white adipose tissues. We then examined whether inhibition of MAT accumulation reduces circulating adiponectin. Ocn-Wnt10b transgenic mice overexpress Wnt10b, a secreted inhibitor of adipogenesis, under control of the osteoblast-specific osteocalcin promoter. Calorie restricted Ocn-Wnt10b mice resisted increases in both marrow fat and serum adiponectin (Fig.1). This supports the concept that expansion of MAT is necessary to increase serum adiponectin in states of calorie restriction and explains, at least in part, the 'adiponectin paradox'. Though there is much left to discover, these findings solidify the notion that MAT is a unique adipose depot that can both respond to and contribute to systemic metabolic change.

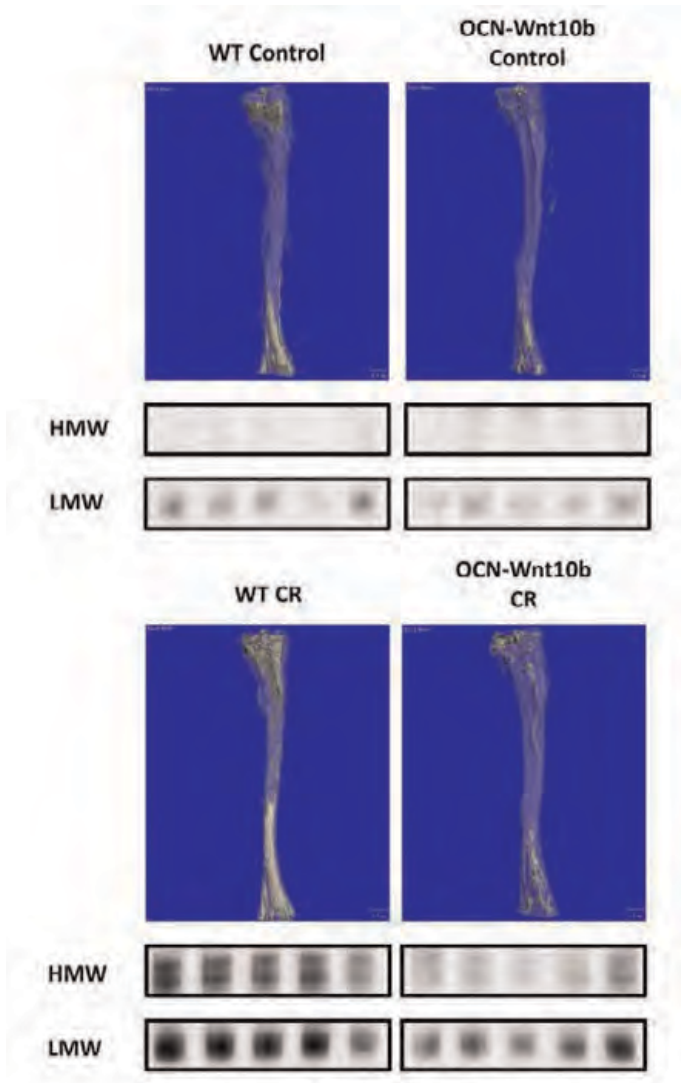

Figure 1. Ocn-Wnt10b mice resist increases in MAT and serum adiponectin with calorie restriction

TLR-2 Serum Level is Higher in Prosthetic Joint Infection Patients: A New Potential Diagnostic Marker of Implant Infection?. Lorenzo Drago[1], Christian Vassena[2], Monica Gioia Marazzi[3], Lucia Salcito[3], Massimiliano Marco Corsi Romanelli[4], Emanuela Galliera*[5]. [1]Department of Bioemdical Science for health, Università degli Studi di Milano, Milan , Italyand IRCCS Galeazzi Orthopaedic Institute, Milan, Italy, [2]IRCCS Galeazzi Orthopaedic Institute, Italy, [3]Department of Biomedical Science for health, Università degli Studi di Milano, Milan, Italy, [4]Department of Biomedical Science for health, Università degli Studi di Milano, Milan , Italy & IRCCS Policlinico San Donato, San Donato, Italy, [5]Department of biomedical, Surgical & Oral Science , Università degli Studi di Milano, Milan , Italy & IRCCS Galeazzi Orthopaedic Institute, Milan, Italy

The interplay between the immune system and bone metabolism has been recognized as important for both of these systems. Toll-like receptors (TLRs) sense pathogen-derived molecules and initiate the inflammatory reactions of innate immune cells.TLR2 and TLR4 are also expressed in bone cells, and their activation affects osteoclasts differentiation and activity: TLRs block the differentiation of early osteoclasts precursors, while they stimulate differentiation survival of differentiating, mature osteoclasts. Moreover, in osteoblasts TLRs induce the production of osteoclastogenic cytokines, thereby contributing to TLR ligand-induced osteoclastogenesis. These processes are the reason for the bone loss observed in variety of infectious diseases. Various factors produced and released during immune responses markedly affect bone cells and bone metabolism, for example in bone osteolysis, the local bone loss due to inflammation in response to pathogen infection. In particular implant infection is a severe complication requiring implant replacement. Prosthetic joint infection (PJI) is a major problem in patients undergoing athroplasty, but since the clinical presentations and the efficacy of diagnostic approaches are different; there is still a continuous need to improve diagnostic methods. PJI is mainly due to Staphylococcus Aureus, a Gram positive bacterium recognized by TLR2, and more rarely by Gram negative bacteria such as Pseudomonas, recognized by TLR4.

In this study TLR2 and TLR4 serum levels, as well as inflammatory marker (IL-6, TNF alpha ,IL-1 , C-Reactive Protein) were evaluated in 30 post-operative PJI patients and in 27 not septic patient, in order to evaluate the potential diagnostic role of TLR2 and TLR4 in PJI. While TLR4 displayed no significative differences, TLR2 level was higher in septic patients , in accordance with IL-6 and C-Reactive Protein increased levels. Accordingly, IL-1, the main TLR2 co-player of the inflammatory response to S.Aureus, resulted higher in septic patients.

These results indicated that TLR2 plays an important role in the inflammatory response to prosthetic join infection. Therefore, the measure of TLR2 serum level could be considered a potential diagnostic tool that could be used in association with canonical inflammatory parameters for the early detection and diagnosis of prosthetic join infection.

Crosstalk of IGF-1 Signaling with the Mechanosensing Machinery of Osteogenic Cells. Candice GT Tahimic*[1], Roger Long[2], Takuo Kubota[3], Alicia T Menendez[1], Chak Fong[1], Jean-Pierre Vilardaga[4], Yongmei Wang[5], Daniel Bikle[1]. [1]Endocrine Research Unit, Division of Endocrinology UCSF & VAMC, USA, [2]University of California, San Francisco, USA, [3]Osaka University Graduate School of Medicine & Dentistry, Japan, [4]University of Pittsburgh, School of Medicine, USA, [5]Endocrine Unit, University of California, San Francisco/VA Medical Center, USA

Physical activity promotes bone formation as observed in long-term tennis players whose playing arms have a higher bone mass compared to their contralateral arms. On the other hand, skeletal unloading in rodents results in bone loss. Our long-term research interest is to determine how the skeleton senses mechanical forces and translates these stimuli into signals regulating osteogenic proliferation and differentiation to ultimately result in bone formation. We have found that one mechanism by which this occurs is via crosstalk between IGF-1 and Integrin signaling. Integrins are membrane-bound proteins that bind to ECM molecules and function in cell adhesion and mechanosensing. In this study, we aim to determine the mechanisms of this crosstalk as examined at three levels: (a) membrane protein-protein interactions between IGF-1R and Integrins, (b) adaptor molecules such as FAK and filamins, and (c) effectors represented by Akt, Erk1/2 and non-receptor tyrosine kinase Src. Our methods for studying protein-protein interactions between IGF-1R and Integrin signaling pathways include a combination of biochemical and pharmacologic approaches and bimolecular fluorescence complementation (BiFC). Our findings indicate that this crosstalk occurs firstly, at the level of the membrane receptors, as indicated by co-imunoprecipitation (co-IP) of Integrin β3 and IGF-1R. The interaction between these two proteins is enhanced by IGF-1 treatment, as determined through BiFC. Moreover, inhibition studies using small molecules show that IGF-1-induced activation of its downstream effectors Akt and Erk1/2 is dependent on FAK and Src, both members of the Integrin signaling pathway. FAK inhibition also abrogates ligand-induced phosphorylation of IGF-1R, suggesting that modulation of IGF-1R activity can be achieved not only through ligand binding but also through internal signals, reminiscient of the outside-in and inside-out components of Integrin signaling. On the other hand in HOS cells subjected to shear stress by pulsatile fluid flow, inhibition of IGF-1 signaling via neutralizing antibodies against its receptor or ligand blunts Akt and Erk1/2 activation, suggesting the role of IGF-1 signaling in modulating the response to mechanical stimulation in osteogenic cells. Taken together, these results highlight the role of integrin signaling in modulating the response of osteogenic cells to IGF-1, and IGF-1 signaling in modulating the response of osteogenic cells to mechanical load.

GH induced linear bone growth in SOCS2 knockout mice is IGF-1 independent. Ross Dobie*[1], S. Faisal Ahmed[2], Katherine Staines[3], Chloe Pass[4], Seema Jasim[4], Vicky MacRae[4], Colin Farquharson[5]. [1]Edinburgh University, United Kingdom, [2]Royal Hospital for Sick Children, United Kingdom, [3]Royal Veterinary College, United Kingdom, [4]University of Edinburgh, United Kingdom, [5]Roslin Institute, University of Edinburgh, United Kingdom

Growth hormone (GH) signalling is essential for post-natal linear bone growth. However, determining the contribution of systemic versus local mechanisms responsible for GH action has proven difficult. The importance of systemic insulin like growth factor-1 (IGF-1) has recently been called into question. To unravel the mechanisms of local GH action we exploited the Suppressor of Cytokine Signalling (SOCS2) -2 KO mice which have enhanced growth despite normal systemic IGF-1 and GH levels.

To determine the mechanisms involved in local GH action embryonic day 17 metatarsals were cultured from wild-type (WT) and SOCS2 KO mice in the presence of GH for a 12 day period to assess downstream signalling and gene expression.

In response to GH, WT bones showed a 17-fold increase in *Socs2* expression ($p<0.01$) with no increase in linear growth. Expression of *Socs1* and *Socs3* were not altered. Conversely, SOCS2 KO metatarsals showed increased linear growth and increased STAT5 phosphorylation in response to GH compared to untreated (Ut) bones ($p<0.01$). Transcript (RT-qPCR) and conditioned medium analysis (ELISA) of SOCS2 KO metatarsals revealed no increase in *Igf1* mRNA (1.01 fold; p=0.9) or protein levels (Ut 3.31 ± 0.39ng/ml, GH 2.76 ± 0.27ng/ml; p=0.29). These data confirm in vivo transcript analysis of micro-dissected growth plates from 7 week-old WT and SOCS2 KO mice, which disclosed similar *Igf1* mRNA levels. Analysis of IGFBP3 levels revealed a modest 1.62-fold increase in transcript expression (p=0.08) and protein levels (Ut 24.99 ± 5.09ng/ml, GH 39.81 ± 3.69; $p<0.05$) in GH treated WT metatarsals. Conversely, in response to GH, SOCS2 KO metatarsals showed a 3.47-fold increase in *Igfbp3* transcript levels ($p<0.01$) and a 124% increase in protein levels within the conditioned medium ($p<0.001$). To further assess the potential of an IGF-1 independent action of GH on linear bone growth we next cultured SOCS2 KO metatarsals in the presence of an IGF-1R inhibitor (NVP-AEW541). Inhibition of endogenous IGF-1 signalling caused, as expected, a decrease in metatarsal growth, however GH was still able to stimulate linear growth (inhibitor 43.92 ± 1.69%, inhibitor + GH 52.06 ± 1.27%; $p<0.01$) .

These studies emphasise the critical importance of SOCS2 in the regulation of GH stimulation of linear bone growth and indicate that GH can enhance linear growth by initiating molecular pathways intrinsic to the growth plate that are independent of local IGF-I production.

IGF-1 Signaling Is Essential for Differentiation of Mesenchymal Stem Cells for Peak Bone Mass. Janet Crane*[1], Luo Zhao[2], Joseph Frye[3], Lingling Xian[4], Tao Qiu[4], Xu Cao[1]. [1]Johns Hopkins University, USA, [2]Peking Union Medical College, China, [3]University of Missouri School of Medicine, USA, [4]Johns Hopkins University School of Medicine, USA

Survival of children with chronic medical illnesses is leading to an increase in secondary osteoporosis due to impaired peak bone mass (PBM). Insulin-like growth factor type 1 (IGF-1) levels correlate with the pattern of bone mass accrual and many chronic illnesses are associated with low IGF-1 levels. Reduced serum levels of IGF-1 minimally affect the integrity of the skeleton, whereas recent studies suggest that skeletal IGF-I regulates PBM. To determine the role of local IGF-1 in postnatal bone mass accrual, we established an inducible type 1 Igf receptor *Crellox* knockout mouse model, in which the type 1 Igf receptor was deleted inducibely in the mesenchymal stem cells (MSCs) from 3-7 weeks of age. The size of the mouse was not affected as knockout and wild type mice had similar body weights and nasoanal and femoral lengths. However, bone volume and trabecular bone thickness were decreased in the secondary spongiosa of female knockout mice relative to wild type controls, indicating that local IGF-1 is critical for maintenance of bone mass. IGF-1 signaling in MSCs in vitro has been implicated to be involved in both migration to the bone surface and differentiation into bone forming osteoblasts. To clarify the exact role of IGF-1 in bone, we found by immunohistochemical analysis that a similar number of Osterix–positive osteoprogenitors were on the bone perimeter, indicating migration of MSCs was not affected. Most importantly, 56% fewer osteocalcin-positive mature osteoblasts were present on the bone perimeter in the secondary spongiosa in knockout mice versus wild type controls. These in vivo data demonstrate that the primary role of skeletal IGF-1 is for the terminal

differentiation of osteoprogenitors, but refute the role of IGF-1 in MSC migration in vivo. Additionally, these findings confirm that impaired IGF-1 signaling in bone MSCs is sufficient to impair bone mass acquisition.

Depletion of TLR4 in Macrophage Involved in Accelerated Bone Healing. Dan Wang*, James R. Gilbert, Melissa A. Shaw, Adam A. Kubala, Sameer Shakir, Joseph E. Losee, Timothy R. Billiar, Gregory Cooper. University of Pittsburgh, USA

OBJECTIVE: Macrophage-mediated inflammation is an essential component during musculoskeletal repair and reconstruction following injury. Expression of the toll-like receptors (TLRs) is found within macrophage, neutrophil, dendritic cell, and bone cell lineages. In previous studies, TLR4-mutant mice ($TLR4^{-/-}$) showed accelerated calvarial bone healing with earlier and higher expression of genes associated with osteoclast differentiation. Here we tested the hypothesis that specific depletion of TLR4 expression in macrophages would demonstrate accelerated bone healing, similar to that seen in global $TLR4^{-/-}$ mice.

METHODS: Circular bone defects were made in the parietal bones using a 1.8mm outer diameter trephine in wild-type (WT) mice, $TLR4^{-/-}$ mice and Lyz cre $TLR4^{-/-}$ (specific depletion of TLR4 in macrophages) mice. Calvarial healing was assessed at different time points using live μCT and histological analyses.

RESULTS: μCT analyses demonstrated accelerated calvarial healing in $TLR4^{-/-}$ and Lyz cre $TLR4^{-/-}$ mice compared to WT mice on postoperative day7, while a similar amount of bone formation was observed by day 28 among all groups. On day7, histomorphometric measurement showed significantly larger new bone area and more surface lining osteoclasts in $TLR4^{-/-}$ and Lyz cre $TLR4^{-/-}$ mice compared to WT. No significant difference was shown on day28. More intense and prolonged macrophage infiltration was also observed in $TLR4^{-/-}$ and Lyz cre $TLR4^{-/-}$ mice compared to WT mice.

CONCLUSIONS: These data suggest that depletion of TLR4 signaling in macrophages cells is responsible for the accelerated healing in global $TLR4^{-/-}$ mice. Further work is required to determine the effect of TLR4 signaling on the inflammatory phenotype of macrophages and how that, in turn, alters calvarial bone healing.

HMGB1 is Essential for Autologous Bone Graft Induced Calvarial Bone Healing. Dan Wang*, James R Gilbert, Adam A Kubala, Melissa A. Shaw, Sameer Shakir, Joseph E Losee, Timothy R Billiar, Gregory Cooper. University of Pittsburgh, USA

Background and Purpose: The synthesis and deposition of extracellular bone matrix and the osteogenic potential of cellular components have been observed to play a role in bone repair. It has only been appreciated recently that extracellular matrix (ECM) and necrotic cells can induce an inflammatory response, which is also involved in tissue regeneration. Previous studies revealed that the release of High-mobility group protein B1 (HMGB1) is important for the survival of ECM scaffolds in vitro. Here we tested the hypothesis that inhibition of HMGB1 signaling released from autologous bone graft will decrease the calvarial healing.

Methods: Suspensions of grounded bone grafts were obtained from femurs and tibias of wild-type (WT) mice. Bone graft suspension was mixed with and without anti-HMGB1 peptide (anti-HMGB1 group and "Bone graft" group). 1 ml PBS was prepared as "control group". All suspension was mixed with fibrinogen and thrombin before surgery. Circular bone defects were made in the parietal bones using a 1.8mm outer diameter trephine in WT mice (n=20). All three groups (Control, anti-HMGB1, bone graft) were implanted into the calvarial defects during the surgeries. Calvarial bone healing was assessed at designed time points using μCT and histologic analyses.

Results: μCT analysis showed that significantly less bone healing was observed in "anti-HMGB1 group" than "bone graft group" on postoperative day28. No significant difference was obtained between "anti-HMGB1 group" and control group. Similar histological healing patterns were shown in all groups on postoperative day28.

Conclusions: These data are consistent with our hypothesis that HMGB1 signaling from implanted autologous bone graft is essential for the calvarial bone healing result. Further work is required to determine if the decreased bone healing is a result of affected host local inflammation due to the inhibition of HMGB1 signaling.

Multiplex Magnetic Bead Assay Panels for Human, Rat and Mouse Bone Metabolism Related Biomarkers Using Luminex xMAP Technology. Munmun Banerjee*[1], Wen-rong Lie[1], Jehangir Mistry[2], Qiang Xiao[1]. [1]EMD Millipore, USA, [2]EMD Millipore.com, USA

Bone metabolism is the dynamic process of ongoing bone deposition and resorption, controlled by osteoblasts, osteocytes, and osteoclasts. The disruption of bone metabolism results in various diseases such as osteoporosis, osteoarthritis, rheumatoid arthritis, chronic kidney disease, and cancer bone metastases. To facilitate basic researches and clinical studies in bone metabolism, we have developed multiplex immunoassay magnetic bead panels using the Luminex® xMAP® technology to measure bone related biomarkers in human, rat and mouse samples including serum/plasma and cell culture media. The Human Bone Panel includes 13 analytes (ACTH, DKK1, IL-6, Insulin, Leptin, TNFa, OPG, OC, OPN, SOST, IL-1b, PTH and FGF23), while both Rat Bone Panel and Mouse Bone Panel include 10 analytes (Rat : ACTH, OPG, Insulin, Leptin, PTH, DKK1, SOST, OPN, FGF23, and OC; Mouse: ACTH, IL-6, OPG, OC, Insulin, Leptin, DKK1, SOST, TNFa and FGF23). The human, rat, and mouse bone multiplex immunoassay panels were fully validated and the validation data demonstrated the robustness of these assays in assay specificity (no cross-reactivity among analytes within each panel), accuracy (recovery within 80-120%), low intra-/inter- assay variability (intra CV <10%, inter CV <15%), and good dynamic range. These human and rodent multiplex magnetic bead assays are useful tools for studying bone metabolism and biomarker analysis in bone-related diseases.

Chronic kidney disease differentially influences bone across two mouse strains. Andrew Cureton[1], Alicia Ortega*[2], Ryan Clark[3], Laura Shum[3], Eric Livingston[4], Xiaoxin Wang[3], Ted Bateman[4], Moshe Levi[3], Karen King[5], Virginia Ferguson[2]. [1]Mechanical Engineering, University of Colorado, USA, [2]University of Colorado, USA, [3]University of Colorado Denver, USA, [4]University of North Carolina, USA, [5]University of Colorado School of Medicine, USA

How bone quality is affected by 5/6 nephrectomy (5/6Nx), an established model of moderate chronic kidney disease (CKD), was examined in two strains of mice previously noted to possess low bone mass. 5/6Nx or sham surgery was performed on 10-week old male FVB and C57Bl/6 mice (n=12/group). Ten weeks post-surgery, mice were euthanized. Serum was collected and bone tissues harvested for: tibia gene expression (SYBR green real time RT-PCR method), femur three-point bending, and proximal tibia and femur diaphysis μCT assessment. All animal work was approved by the institutional IACUC. Data were analyzed using two-way ANOVA with Tukey's HSD post-hoc analysis (α=0.05). Results: Among the sham groups, the FVB strain showed impaired trabecular microstructure as compared to the C57 strain, via metrics including significantly lower BV/TV (-38.1%), Tb.N (-23.8%), Conn.D (-48.6%), and higher Tb.Sp (+37.3%) and SMI (+18.1%). The FVB femur yield strength was also -26.1% less than in C57 mice, possibly due in part to a -22.0% lower polar moment of inertia; however, the TMD at the FVB femur diaphysis was +2.5% greater than in C57 mice. 10 weeks after 5/6Nx, impaired kidney function was indicated in both FVB and C57 strains by significantly increased serum blood urea nitrogen (BUN; +690% and +502%, respectively) and creatinine (+57.5%, +35.3%) levels. Bone quality is noted to diminish with CKD. While proximal tibia trabecular microarchitecture was not significantly altered by 5/6Nx, femur diaphysis cortical bone showed reduced Ct.Th (-10.4%, -4.0% NS) and TMD (-1.9%, -1.9%). Also with 5/6Nx, gene expression profiles in the two strains were opposite. In the FVB mice, RANKL and OPG showed 2.13 and 3.22 fold decreases in expression, respectively, after 5/6Nx, while the C57 mice showed a 1.39 and 1.52 fold increase in expression. Both strains showed a decrease in FGF23 expression with the FVB expression (4.51 fold) and the C57 expression (2.10 fold) after 5/6Nx. Discussion: The trabecular microstructure in sham FVB mice was of lower quality than the C57 mice. However, 5/6Nx may have exerted a greater influence on cortical bone than trabecular bone. While kidney disease was clearly detected in both strains, its etiology and influence on bone and mineral metabolism differed across strains. Moreover, the varied changes observed with 5/6Nx suggest that mineral regulation is complex in CKD. In this study, moderate CKD exists where extensive metabolic changes have yet to occur.

Nutritional Status and Bone Turnover Markers in Adult Post-kidney Transplantation Recipients. Atsushi Suzuki*[1], Hitomi Sasaki[2], Midori Hasegawa[3], Hiroyuki Hirai[1], Yoshiteru Maeda[4], Sahoko Sekiguchi-Ueda[1], Megumi Shibata[1], Yukio Yuzawa[3], Kiyotaka Hoshinaga[2], Kazuhiro Uenishi[5], Mitsuyasu Itoh[4]. [1]Fujita Health University, Division of Endocrinology, Japan, [2]Department of Urology, Fujita Health University, Japan, [3]Division of Nephrology, Fujita Health University, Japan, [4]Division of Endocrinology & Metabolism, Fujita Health University, Japan, [5]Kagawa Nutrition University, Japan

Background: Despite Kidney transplantation (KTx) could restore many disorders in end-stage renal diseases (ESRD) patients, pre-existing chronic kidney disease-mineral and bone disease (CKD-MBD) and other clinical risk factors such as hyperparathyroidism and glucocorticoid therapy would make osteoporosis as a serious problem in post-KTx patients. Because of glucocorticoid therapy and co-existence of diabetes mellitus, KTx recipients often need to restrict their calorie intake. We have previously reported that post-KTx patients in Japan seemed to restrict their calorie intake for the prevention of their overweight and metabolic disorder. The aim of this study is to estimate the association of nutritional status of Ca and other nutrients and bone turn over markers in post-KTx recipients.

Subjects and Methods: Post-KTx recipients in outpatient clinic of Fujita Health University Hospital were recruited (n=81, M/F=48/33, age, 52.8 ± 12.6 years old, mean duration from KTx, 108 ± 77months). Methylprednisolone was prescribed to 78 cases out of 81 patients, and more than a half of them (42/82) took oral bisphosphonate (BP). Median serum albumin and creatinine levels were 4.3 g/dL(3.4-5.0) and 1.14 mg/dL (0.54-3.17). We estimate intake of nutrients including Ca, vitamin D (VD) and other nutrients by simple food frequency questionnaire by Uenishi et al (J Nutr Sci Vitaminol 2008; 54:25-29). Data are median (25^{th}–75^{th}) and 95% cut-off index (CI).

Results: Median body mass index of KTx recipients was 20.4 kg/m^2(15.9-32.5). Median total energy in KTx recipients was 1544 kcal/day (7769-2383). Their daily intake of Ca, VD and vitamin K were 380 mg (139-766), 10 mg (6.5-16.0), and 140 mg (35-553), respectively. Median intact parathyroid hormone (iPTH), Bone ALP (BAP), osteocalcin (OC) and TRAP5b were 129 pg/mL (54-956), 12.5 mg/L(6.1-31.4), 4.8 ng/mL (1.5-22.0) and 287 mU/dL (79-767) respectively.In non-BP user, total calorie intake, Ca intake, VD or VK did not affect bone turnover markers. However, in BP users, VD intake was positively associated with BAP level.

Conclusion: Our findings suggest that sufficient VD intake might contribute to maintain bone formation in BP users after KTx.

Parathyroidectomy and Heart Rate Variability in Patients with Stage 5 Chronic Kidney Disease. Ningning Wang*[1], Jing Zhang[2], Bin Sun[2], Jianling Bai[3], Yongyue Wei[3], Xiaoming Zha[2], Yiyao Cui[2], Ming Zeng[2], Jingjing Zhang[2], Jia Liu[2], Huijuan Mao[2], Bo Zhang[2], Haibin Ren[2], Yifei Ge[2], Xueqiang Xu[2], Zhixiang Shen[4], Changying Xing[2], Kejiang Cao[2], Xiangbao Yu[2]. [1]Nanjing Medical University, Peoples Republic of China, [2]First Affiliated Hospital of Nanjing Medical University, China, [3]Nanjing Medical University, China, [4]Jiangsu Province Geriatric Hospital, China

Objective: Lower heart rate variability (HRV) implies increased risk of cardiovascular disease (CVD). This study aimed to evaluate the relationship between mineral metabolism and HRV and longitudinal changes of HRV after parathyroidectomy (PTX) in stage 5 chronic kidney disease (CKD) patients.

Methods: We conducted a cross-sectional study including 118 stage 5 CKD patients, 87 controls and a prospective study in two subgroups classified as successful (n=17), unsuccessful (n=4) PTX follow-up enrolled from March 2011 through December 2012. Blood examination and 24 hour Holter for HRV were measured.

Results: Clinical characteristics and laboratory results of all participants were shown in Table 1. Prevalent disorders in mineral metabolism, especially serum P, alkaline phosphatase (ALP) and intact parathyroid hormone (iPTH) abnormality was observed in stage 5 CKD patients. Baseline HRV indices were lower in stage 5 CKD patients than controls except for high-frequency (HF) (Table 2). In multivariate stepwise regression models (Table 3), serum iPTH was correlated with mean normal-to-normal R-R intervals (mean NN) (P=0.007), mean HR (P=0.004) and very-low frequency (VLF) (P=0.04), serum calcium was correlated with standard deviation of 5-min average of normal R-R intervals (SDANN) (P=0.004) and serum phosphorus was correlated with VLF (P=0.02) and LF/HF (P=0.002). Serum indices of mineral metabolism were corrected in successful PTX group (Figure 1). Serum iPTH levels were lower from 1717.8(1350.8-3209.7)pg/ml to 72.4(42.7-242.5)pg/ml (P<0.001) and serum P levels were decreased from 6.9 ± 1.8mg/dl to 2.9 ± 1.5mg/dl (P<0.001). There was also significant downregulation of serum Ca levels (10.5 ± 0.6mg/dl vs 8.9 ± 1.0mg/dl, P<0.001) and serum ALP levels {527.3(228.3-1006.8)μ/l vs 169.9(111.0-244.8)μ/l, P<0.001}. A significant increase in serum albumin levels (38.8 ± 4.8g/l vs 41.9 ± 3.7g/l, P<0.05) was also observed. Compared with baseline, successful PTX subgroup had significant improvements (Table 4) in mean NN, mean HR, SDNN, SDANN, VLF, HF and LF/HF. There were no significant changes of HRV in patients after unsuccessful PTX (Table 4).

Conclusions: Disorders of mineral metabolism are associated with decreased HRV in stage 5 CKD. Successful PTX may contribute to reverse this CVD risk in severe secondary hyperparathyroidism patients.

Sclerostin Levels Increase as Kidney Function Declines and Associate Directly with FGF23 Levels in Chronic Kidney Disease (CKD). Tamara Isakova*[1], Katherine Wesseling-Perry[2], Ina Kramer[3], Michaela Kneissel[3]. [1]University of Miami, USA, [2]UCLA Medical Center, USA, [3]Novartis Institutes for Biomedical Research, Switzerland

Sclerostin encoded by the *Sost* gene is secreted by osteocytes and inhibits the canonical Wnt/beta-catenin pathway, which is critical for normal bone homeostasis. *Sost*/sclerostin expression is suppressed by parathyroid hormone (PTH) signaling. A recent study reported that early in the course of CKD in mice *Sost*/sclerostin expression is increased in a PTH-independent manner, suggesting that primary osteocyte dysfunction in CKD may initiate progressive mineral metabolism abnormalities, including excess production of fibroblast growth factor 23 (FGF23).

To examine the association of sclerostin levels with kidney function and FGF23 levels in CKD, we measured sclerostin levels in 37 human subjects (control, n=15; CKD stage 3-4, n=12; and dialysis, n=10, Figure) using the Biomedica ELISA assay. We found that sclerostin levels rise with declining kidney function, and that there is a direct correlation between FGF23 and sclerostin levels (Figure). Further support for a link between sclerostin and FGF23 emanates from the observation that *Sost*/sclerostin deficient mice show decreased FGF23 expression. In 6-month-old *Sost* deficient female mice, *Fgf23* expression was strongly and significantly decreased by 63% relative to wild-type. Concurrently, intact serum FGF23 levels, as determined by ELISA (Kainos Laboratories), were also significantly reduced by 24% in aged *Sost* KO females, and by 37% in aged *Sost* KO male mice.

Taken together, these data suggest that sclerostin may be an important factor in the pathogenesis of disordered mineral metabolism in CKD.

Fibrous Dysplasia with Normal Bone Resorption Markers: An Unexplained Phenomenon. Ruban Dhaliwal*[1], Arnold Moses[2]. [1]SUNY Upstate Medical University, USA, [2]State University of New York Upstate Medical University, USA

Background: Fibrous dysplasia (FD) is a rare skeletal disease characterized by enhanced osteoclastogenesis, marrow fibrosis and osteomalacia. Postzygotic missense mutations of Gsα are correlated with the disease. Bone turnover markers (BTMs) are elevated in parallel, relative to disease activity. We describe a unique case of FD with an isolated elevation of bone specific alkaline phosphatase (BSAP).

Case: A 21-year-old Caucasian female with a history of transient hepatitis following an episode of mononucleosis had persistently elevated alkaline phosphatase 680 IU/L (nl:25-150). Physical examination revealed a protuberance over the left parietal bone. No associated dysmorphic facial features or skeletal deformities were noted. She had no family history of metabolic bone disease.

Further investigation showed markedly elevated serum BSAP 262 ug/L (nl:<21.3) and normal urine NTx 43 nM BCE/mM Cr (nl:5-65). Radiograph of skull showed increased bone formation at left skull base, but not particularly exuberant. Radiographs of extremities were normal. Bone scintigraphy was in keeping with FD, and showed a large area of intensely increased uptake in the left skull base. Computed tomography of head showed pagetoid type lesion of FD (5.6x4.5x4.5cm) involving the left temporal and occipital bones, displacing the left cerebellar hemisphere. Magnetic resonance imaging confirmed the lesion representative of FD with mass effect on the left cerebellum and minimal effacement of the 4th ventricle. Gsα mutation was undetectable in blood. Notably, despite this clinical presentation and persistent elevation of BSAP, all other BTMs were unremarkable (Table 1).

Conclusion: FD is usually an incidental finding. Mosaic nature of the Gsα mutation presents a diagnostic challenge as demonstrated in this case. Clinical sensitivity of mutational analysis is 50% in blood and 90% in the affected tissue. Location of the lesion may render biopsy less feasible. Nevertheless, bone formation and resorption markers have always been reported to be elevated in parallel and indeed a decline in BTMs is considered an indicator of effectiveness of treatment. In this case, an elevation of BSAP in the presence of normal resorption markers is inconsistent with the known pathophysiology of FD. Normal osteocalcin and P1NP further add to the complexity. Therefore, yet unknown mechanisms may contribute to the pathogenesis of FD and further studies are needed to explain this observation.

Table 1: Serum Laboratory Parameters					
Variable (normal range)	Oct. 2011	July 2012	Nov 2012	Jan 2013	Feb 2013

Mutation in the Ligand-Binding Domain of the Vitamin D Receptor (VDR) in a Patient with Spontaneous Recovery of Hereditary Vitamin D-Resistant Rickets (HVDRR). Flavia M Damiani*[1], Regina M Martin[1], Ana Claudia Latronico[1], Pedro Henrique Correa[2], Bruno Ferraz-de-Souza[1]. [1]Univ of Sao Paulo School of Medicine (FMUSP), Brazil, [2]University of Sao Paulo School of Medicine, Brazil

Introduction: Mutations in the vitamin D receptor (VDR) cause hereditary vitamin D-resistant rickets (HVDRR), an autosomal recessive disorder characterized by resistance to calcitriol, severe hypocalcemia and early-onset rickets. Approximately 50 inactivating VDR mutations have been described in HVDRR so far, but relatively little is known about the long-term evolution of these patients.

Objective: To establish the molecular diagnosis in an adult female patient with HVDRR.

Methods: Peripheral blood leukocyte DNA samples were obtained from patient, relatives and controls after informed consent, with IRB approval. The full coding region of VDR was PCR-amplified and directly sequenced. RFLP was used to confirm sequence variants and to screen controls.

Results: A 35 yo female patient with HVDRR has been followed in our institution since infancy. Born to distantly consanguineous parents, she developed diffuse alopecia at 6 mo of life accompanied by progressive muscle weakness and inability to walk. She was first evaluated at 2 y 5 mo, showing low serum calcium and high alkaline phosphatase levels. Treatment was initiated with calcitriol and 200,000 IU of oral ergocalciferol per day, with improvement of symptoms. From 3 yrs of age, she maintained normocalcemia with 600,000 IU ergocalciferol monthly, but evolved to total alopecia. Around puberty, hypercalciuria and nephrolithiasis were detected, resulting in full suspension of treatment by the age of 20. At 32 yrs, she got pregnant and did not have hypocalcemia during gestation or lactation, without any supplementation. Mutational analysis reveals a homozygous p.Gly319Val mutation in the ligand-binding domain of VDR, confirmed by RFLP. Her asymptomatic parents and child are heterozygous for this change, which was not found in 380 Brazilian control alleles. This mutation has been previously reported in association with HVDRR and *in silico* analysis indicates high-probability of disease causation.

Conclusion: We report the long-term follow-up of a female HVDRR patient harboring a homozygous p.Gly319Val mutation in VDR. In accordance with previous reports, mutations in the ligand-binding domain of VDR tend to result in milder forms of rickets with better response to treatment, as seen here. Importantly, despite the permanent molecular defect and maintenance of alopecia, she spontaneously recovered from rickets and hypocalcemia around puberty, as observed by ourselves and others in patients with HVDRR.

Pharmacokinetics and Pharmacodynamics of a Human Monoclonal Anti-FGF23 Antibody (KRN23) after Single-Dose Administration to Patients with X-linked Hypophosphatemia. Xiaoping Zhang*[1], Thomas Carpenter[2], Erik Imel[3], Mary Ruppe[4], Thomas Weber[5], Mark Klausner[1], Tetsuyoshi Kawakami[1], Takahiro Ito[1], Jeffery Humphrey[1], Karl Insogna[2], Munro Peacock[6]. [1]Kyowa Hakko Kirin Pharma Inc, USA, [2]Yale University School of Medicine, USA, [3]Indiana University School of Medicine, USA, [4]The Methodist Hospital, USA, [5]Duke University Medical Center, USA, [6]Indiana University Medical Center, USA

Purpose: In X-linked hypophosphatemia (XLH), elevated serum FGF23 causes low serum phosphorus (P) and inappropriately normal 1,25-dihydroxyvitamin D ($1,25(OH)_2D$) levels. KRN23, a human monoclonal antibody blocking FGF23 activity, is a promising novel treatment for XLH. We report pharmacokinetics (PK) and pharmacodynamics (PD) of KRN23 following single ascending dose administration in adults with XLH.

Methods: 38 subjects were randomized to receive a single dose of KRN23 or placebo either intravenously (IV) (0.003-0.3 mg/kg) or subcutaneously (SC) (0.1-1.0 mg/kg). PK and PD samples were obtained from baseline through Day 50. PD samples were analyzed using commercial assay kits. PK samples were assayed using a validated ELISA method. PK and PD parameters were estimated using non-compartmental analysis method with WinNonlin software (Versions 5 and 6, Pharsight Co. CA).

Results: 22 subjects participated in the IV treatment arm (17 KRN23, 5 placebo), and 16 in the SC treatment arm (12 KRN23, 4 placebo). Age, sex, weight, and height of all groups were comparable. Serum P and intact FGF23 levels at baseline were not correlated (Spearman's correlation coefficient = -0.029). Mean KRN23 terminal half-life was shorter for IV (11-12 days) than for SC (13-19 days) administration. Absolute bioavailability was approximately 100% with SC dosing. There was a dose-proportional increase in circulating KRN23 levels in both IV and SC groups. With SC administration peak serum KRN23 concentration and peak serum P occurred at the same time. Area under the curve (AUC_{last}) for changes from baseline in serum P, $1,25(OH)_2D$, and TmP/GFR were linearly correlated with AUC_{inf} for serum KRN23 concentration. At the same dose level, AUC_{last} for P appears to be similar for IV vs. SC treatment. However, SC dosing exhibited a slow absorption profile (peak time: 8-11 days) and a more sustained effect than IV dosing as indicated by the delayed time to reach maximum mean serum P level (peak time: 8 -15 vs 4 days) and longer time to return to baseline (50 vs 29 days). Dose-normalized serum P AUC_{last} was independent of baseline intact FGF23 levels (r = 0.011).

Conclusions: KRN23 is a promising treatment for XLH patients. Complete absorption, sustained effect on serum P beyond 4 weeks, and a direct linear relationship between PK and PD effects support an SC treatment regimen of once every 4 weeks for KRN23 in XLH patients.

Spondyloepimetaphyseal Dysplasia: A Distinctive Phenotype In A Three-Generation Family. Gary S Gottesman*[1], William McAlister[2], Michael P Whyte[1]. [1]Shriners Hospital for Children-Saint Louis, USA, [2]Washington University School of Medicine, USA

Skeletal dysplasias are developmental disorders of chondroosseous tissue. Over 450 distinct entities have been identified. Most are classified based on the location of abnormal skeletal features on radiographs. Spondyloepimetaphyseal dysplasia (SEMD) refers to developmental shaping abnormalities of the spine together with distortions at long bone ends (epiphyses and metaphyses). Current nosology lists approximately 15 SEMDs. Only 6 are autosomal dominant disorders and the genetic basis is known for each [Missouri type (MMP-13 mutation), 4 entities resulting from mutations in TRPV4, and short limb-abnormal calcification type (DDR2 mutation)].

We report a 3-generation kindred with SEMD that mimics the findings reported in a single unclassified family identified with a new autosomal dominant SEMD.[(1)] A 16-year-old woman with normal facial features presented for a skeletal disorder, previously considered Morquio syndrome versus spondyloepiphyseal dysplasia. She was short (-4.0 SD) with chronic knee pain. Her mother, maternal grandmother, and older brother had similar findings. Each had been evaluated during childhood at Shriners Hospital for Children-St. Louis. Radiographs for each individual permitted assessment of epiphyseal, physeal, metaphyseal, and vertebral development. Remarkable delay in the appearance of mal-shaped epiphyses occurred at the proximal femur. Epiphyseal contours were flattened and irregular along with mild widening and beaking of metaphyses (Figure). In the spine, each had mild-moderate platyspondyly with endplate irregularities (Figure) with prominent lordosis. Family members underwent physeal stapling and osteotomies for genu valgum during childhood, and hip replacements as adults. Notably, male-to-male transmission was absent in this kindred and in the previous family report. Thus, X-linked dominant or autosomal dominant inheritance remains possible.

Whole Body Muscle Mass Is Low and Fat Mass Is High in Osteoporosis Pseudoglioma Syndrome. Sarada Jaimungal*[1], Jin Long[2], Mary Leonard[2], Elizabeth Streeten[3]. [1]University of Maryland Medical Center, USA, [2]Children's Hospital of Philadelphia, USA, [3]University of Maryland School of Medicine, USA

Introduction: Osteoporosis - pseudoglioma syndrome (OPPG) is a rare, autosomal recessive disorder characterized by severe juvenile osteoporosis and congenital blindness due to inactivating mutations in the LDL receptor-related protein 5 (LRP5). We previously found by pQCT low muscle mass and high fat mass in OPPG at the tibia. We hypothesized that similarly abnormal body composition would be present in the whole body in OPPG and would be associated with adverse metabolic consequences.

Methods: Four patients with OPPG underwent whole body DXA at the UM Amish Research Clinic. Sex and race specific Z scores were generated for whole body minus head for lean body mass and fat mass using reference data from the Children's Hospital of Philadelphia in over 900 healthy children and adolescents. Fasting serum lipids and HbA1c were measured.

Results: In spite of normal BMI, fat mass was high and muscle mass low in the 4 patients with OPPG- See Table 1. Lipid profiles and hemoglobin A1c levels were normal in all.

Discussion: To our knowledge, this is the first report of body composition by whole body DXA in patients with OPPG. The 4 patients studied had dramatic lean body mass deficits and fat mass excess which were too severe to attribute to their low levels of activity. In high bone mass due to activating mutations of LRP5, adipogenesis was inhibited both in vivo and in vitro. The opposite effect was found in inactivating LRP5 mutations in vitro in human mesenchymal stem cells. The WNT/LRP5 pathway appears to be important for adipocyte differentiation of marrow stromal cells.

The LRP5 -/- mouse develops hypercholesterolemia when fed a high fat diet and has impaired glucose tolerance on a normal diet. Impaired glucose metabolism was also found in seven adult patients with either homozygous or heterozygous LRP5 mutations. Our patients had no demonstrable abnormalities in glucose or lipid metabolism despite having high fat and low muscle mass. We speculate that metabolic consequences of the abnormal body composition in OPPG may become apparent with age.

In conclusion, we found reduced muscle and high fat mass on whole body DXA in 4 children with OPPG with normal lipids and HbA1c. These body composition abnormalities appear to be intrinsic to the OPPG phenotype.

Table 1 - Body composition in 4 OPPG patients

Occult Hyperosteoidosis in Subjects Undergoing Orthopedic Surgery. Julie Glowacki*, Sherwin Erfani, Laurence Higgins, Shuanhu Zhou, Thomas Thornhill, Lisa Gao, Meryl LeBoff. Brigham & Women's Hospital, USA

Although there is growing awareness of vitamin D-deficiency in the USA, there is little information about prevalence of bone mineralization defects. Bone that is discarded during orthopedic surgery provides an opportunity to assess the prevalence of hyperosteoidosis. Subjects were eligible if they required a joint prosthesis for non-inflammatory disorders; we excluded subjects taking medications or with co-morbid conditions that could affect skeletal metabolism. Bone specimens were obtained with IRB approval either from enrolled subjects consenting for additional research tests or as de-identified material. There were 38 subjects with hip osteoarthritis (OA), 73 with shoulder OA, and 48 with rotator cuff arthropathy (RCA), a disorder associated with rotator cuff tear, "soft" quality of the humeral bone noted at the time of arthroplasty, fatty infiltration of shoulder muscles, and radiographic osteopenia. We tested the hypothesis that osteoid is increased in subjects with RCA, compared with shoulder OA. Portions of trabecular bone from the discarded femoral or humeral head were prepared for non-decalcified histology; they were graded for osteoid relative to bone surfaces on an Osteoid Index (OI) scale of 0-3, without knowledge of diagnoses. For subjects with available serum levels, there was the expected inverse correlation between 25(OH)D and PTH ($p=0.0036$). For hip OA subjects, there was a significant inverse correlation between OI and serum 25(OH)D (Spearman $r=-0.35$, $p=0.033$). The hip OI was 2.6-fold higher in vitamin D-deficient (<20 ng/ml 25OHD) subjects (1.3 ± 0.2) than in non-deficient subjects (0.5 ± 0.1, $p=0.007$). With the shoulder cohorts, there was a significant 1.6-fold higher OI for subjects with RCA (1.1 ± 0.1, $n=48$) than for subjects with shoulder OA (0.7 ± 0.1, $p=0.007$, $n=73$). Likewise, for a subgroup of shoulder subjects for whom serum 25(OH)D levels were available, there was a significant 2.2-fold higher OI for RCA (1.1 ± 0.2, $n=19$) than for shoulder OA (0.5 ± 0.1, $n=21$, $p=0.029$), despite no difference in current serum 25(OH)D levels or other evidence of vitamin D-deficiency. In sum, hyperosteoidosis was evident in RCA and in hip OA subjects with vitamin D-deficiency. Although current D-deficiency can account for hyperosteoidosis in hip OA subjects, it does not explain RCA.

Preadipocyte Cell Lines to Evaluate the Role of PHEX on Osteoblast Differentation and Mineralization *in Vitro*. Cecilia Romagnoli*, Roberto Zonefrati, Gianna Galli, Caterina Fossi, Valeria Nardone, Gaia Palmini, Alessia Gozzini, Luisella Cianferotti, Laura Masi, Annalisa Tanini, Maria Luisa Brandi. University of Florence, Italy

Purpose: X-linked hypophosphatemia (XLH), the most common inherited form of rickets, is a dominant disorder characterized by defective calcification of cartilage and bone, growth retardation, impaired renal tubular resorption of inorganic phosphate (Pi) and abnormal vitamin D metabolism. The PHEX gene (locus Xp22.11), a phosphate regulating gene with homologies to endopeptidases in the X chromosome, was identified as the candidate gene for XLH. It codifies a 749 amino acid protein and it is expressed in particular in cartilage, bone and teeth. PHEX is a member of the M13 family of type II cell-surface membrane zinc-dependent peptidases and, although its precise physiological role is still unknown, it might have a role in regulating the activity of extracellular peptides that act controlling the renal Pi resorption and the skeletal mineralization.

The aim of the present study was to elucidate the effect of this mutation on osteogenic differentiation of human adipose tissue derived mesenchymal stem cells (hADSCs), or preadipocytes, obtained from the patient.

Methods: Two primary culture of hADSCs, PA4 e PA9, were obtained from a patient of three years old and from a healthy child of the same age, respectively, and induced into the osteoblastic phenotype using the osteogenic medium (OM) composed by Ham's F12 Coon's modification medium supplemented with 10% FBS, dexamethasone 10nM, β-glycerophosphate 10mM, L-ascorbic acid 2-phosphate 50 µg/ml and 1% antibiotics. The role of PHEX was evaluated from 4 to 35 days of osteinduction, monitoring the alkaline phosphatase (ALP) activity and the hydroxyapatite production by quantitative analysis with fluorometric methods and by microscopic observations (brightfield, epifluorescence, confocal laser scanning microscopy (LSCM)).

Results: During the PA4 and PA9 induction with OM, we observed significant increments in ALP activity and hydroxyapatite production, respect to the control groups cultivated in GM. In particular, both ALP activity and mineralization analysis of PA4 have shown a trend similar to PA9, although the ALP activity decreases faster in PA4 (after 21 days) respect to PA9 (after 35 days) and the beginning of the mineralization process is delayed in PA4 (after 21 days) respect to PA9 (after 14 days).

Conclusions: The data presented suggest that PHEX activity is required for proper bone formation and controls bone matrix mineralization both through regulation of ALP activation and hydroxyapatite deposition.

Tenofovir-Induced Osteomalacia. Catherine Anastasopoulou[1], Patamaporn Lekprasert*[2], Nissa Blocher[2]. [1]Albert Einstein Medical Center Endocrine Associates, USA, [2]Albert Einstein Medical Center, USA

Tenofovir is widely used as an effective treatment for HIV and HBV infection. Tenofovir-induced osteomalacia is rare and mainly caused by renal phosphate wasting from proximal tubular dysfunction. We report a case of tenofovir toxicity with severe osteomalacia due to complete Fanconi syndrome.

A 54 year-old Caucasian male with HIV/AIDS infection presented with bone pain and multiple fractures: legs, pelvis, scapula and ribs after a simple fall. He had been on tenofovir-based antiretroviral regimen for 10 years. His HIV was controlled with recent CD4 counts of 510 cells/ml3, and undetectable viral load.

In addition to severe diffused osteopenia and multiple fractures on radiographs, further evaluations are shown in table 1. All findings indicated severe proximal tubular dysfunction or Fanconi syndrome. Intact parathyroid hormone was normal (79 pg/ml), with 25-hydroxy vitamin D of 28.1 (30-100) ng/mL, and 1,25-hydroxy vitamin D of 17.5 (10-75) pg/mL.

The patient was given high-dose phosphate and potassium replacement, calcitriol, and sodium citrate for metabolic acidosis. Antiretroviral regimen was switched to zidovudine, lamivudine, and raltegravir. After 10 weeks, the patient still had persistent hypophosphatemia with hyperphosphaturia, reflecting incomplete recovery of tubular function.

Long-term exposure to tenofovir may lead to severe proximal tubular dysfunction and osteomalacia. Incomplete recovery has been reported after discontinuing tenovofir for 6-20 months. Screening and close monitoring of tubular function is required in those patients.

Laboratory data	Baseline	10 weeks after admission
Phosphorus (mg/dL)	0.7	2.5
Fraction excretion of phosphorus (%)	82%	74%
Creatinine (mg/dL)	0.5	0.5
Potassium (mmol/L)	3.3	3.4
Corrected calcium (mg/dL)	9.5	8.54
Alkaline phosphatase (U/L)	355	488
Hyperchloremic metabolic acidosis	present	present
Normoglycemic glucosuria (mg/dL)	>1,000 mg/dL	Not available

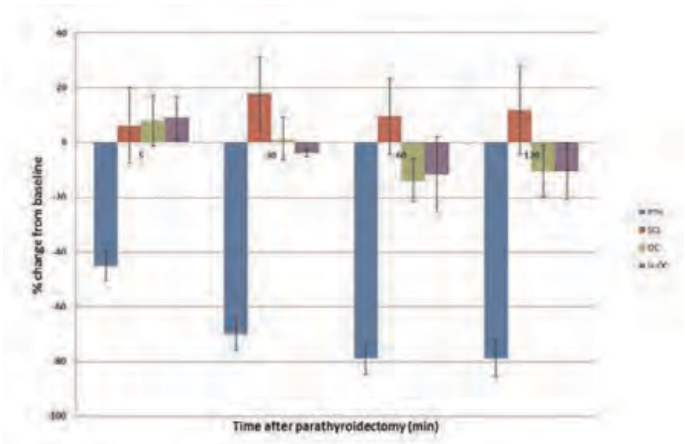
After parathyroidectomy in primary hyperparathyroidism, sclerostin, osteocalcin, and undercarboxylated osteocalcin change rapidly. Aline Costa*[1], Zachary Lenane[1], Chiyuan Zhang[1], Elzbieta Dworakowski[1], Serge Cremers[1], James Lee[1], John Bilezikian[2]. [1]Columbia University, USA, [2]Columbia University College of Physicians & Surgeons, USA

Primary hyperparathyroidism (PHPT) can be cured by surgical removal of the abnormal parathyroid gland(s). With removal of the offending abnormal parathyroid tissue by parathyroidectomy (PTX), parathyroid hormone (PTH) levels fall immediately with slower changes in standard bone turnover markers. No studies have yet been conducted to track rapid changes in newer markers of bone metabolism such as sclerostin and undercarboxylated osteocalcin after PTX. To this end, we conducted a proof-of-concept study to investigate the rapidity and extent to which rapid reductions in sclerostin, osteocalcin and undercarboxylated-osteocalcin follow PTX. We studied four subjects (1 man, 3 postmenopausal women) with PHPT (mean age 59.5$\pm$16yrs) who underwent successful minimally invasive PTX. Acute changes in PTH [RIA(Scantibodies)], sclerostin [ELISA (TECOmedical)], osteocalcin [ELISA (IDS)], and undercarboxylated osteocalcin [ELISA (Takara)] were measured in serum samples obtained at the time of surgery immediately before parathyroid gland(s) removal (baseline) and thereafter at 5, 30, 60 and 120 minutes. After PTX, PTH levels fell quickly (-45% at 5 min, $p<0.0001$) and reached a nadir of 80% reduction ($p<0.0001$) by 60 min. Sclerostin levels tended to increase quickly ($p=0.07$) while osteocalcin and undercaboxylated osteocalcin levels showed a tendency to decline (Fig. 1). These results indicate that PTX is associated with acute changes in markers of bone metabolism that could signify rapid correction of abnormal bone metabolism in PHPT. This is the first study to access acute perturbations on newer markers of bone metabolism after PTX. Additional prospective studies with larger numbers are likely to identify further the utility of these markers in the context of PTX and as forecasters of improvements in bone mineral density and microarchitecture.



Changes in sclerostin, osteocalcin and undercarboxilated osteocalcin after parathyroidectomy in PHPT

Long-term Outcome of Bisphosphonate Therapy in Patients with Mild Primary Hyperparathyroidism. D Segula[1], V Mishra*[2], E MARKS[2], LR RANGANATHAN[2], S NIKOLOVA[2]. [1]University of liverpool, United Kingdom, [2]Royal Liverpool & Broadgreen University Hospital NHS Trust, United Kingdom

Background: Bisphosphonates therapy has been used in patients with primary hyperparathyroidism (PHPT) with the aim of increasing bone mineral density and reducing fragility fractures. We evaluated the effect of bisphosphonate treatment on bone mineral density, rate of fragility fracture and biochemical markers in 50 patients with PHPT who were not suitable for parathyroidectomy.

Results: The mean age of PHPT patients was 74 years, 94% females. Baseline mean serum adjusted calcium (2.74mmol/L, reference range 2.20-2.60mmol/L), mean serum creatinine 99.5µmol/L (reference range, 25-125µmol/L), bone mineral density for lumbar spine (L2-L4, mean T-score -2.5), and left femoral neck (mean T-score -2.1). 14 patients (28%) had bone fragility fractures at baseline. The duration of bisphosphonate therapy was 4.8$\pm$3(mean$\pm$ standard deviation)years.50% patients received either intravenous pamidronate or oral alendronic acid. 36% were treated with more than one bisphosphonate therapy. After a mean 4.8 years of bisphosphonate treatment, there was a significant decrease in serum adjusted calcium to 2.60mmol/L ($p<0.001$), urine calcium to creatinine ratio (0.70 and 0.55 before and after treatment, respectively, $p<0.0001$, reference range 0.3-0.7) and no significant change in renal functions (mean serum creatinine 96.4µmol/L) were seen. There was a significant increase in lumbar spinal bone density (T score L2-L4, -2.1) ($p=0.013$) with no significant change in left femoral neck bone density (T score -2.2). There was no change in rate of bone fragility fracture ($p= 0.167$). Out of the 14 patients who had fragility fractures at baseline, only one patient had a recurrent fracture after 4 years of therapy. A total of 7 patients (including the recurrent fracture) had new fragility fractures after duration of 6$\pm$2.5(mean $\pm$ standard deviation) years of bisphosphonate treatment. 21 PHPT patients received vitamin D supplementation while they were on bisphosphonate therapy. This group showed a significant reduction in serum adjusted calcium ($p<0.0001$) but had no effect on bone mineral density or fragility fractures.

Conclusion: Bisphosphonate therapy in PHPT patients significantly improved the lumbar spine bone mineral density and prevented further increase in rate of fragility fracture. Additionally, the therapy significantly reduced serum adjusted calcium, urinary calcium excretion and prevented deterioration in renal functions.

Table 1: Comparison of Pre- and Post-Bisphosphonate treatment on biochemical markers

Characteristic	Baseline	Post-treatment	p-value
Serum adjusted calcium (mmol/L)			
Mean (SD)	2.74 (0.13)	2.60 (0.12)	<0.0001
Urine calcium (mmol/ 24hours)			
Median (IQR)	4.2 (1.9 – 6.6)	3.8 (1.4-5.5)	0.064
Serum calcium: creatinine ratio			
Median (IQR)	0.70 (0.40 – 0.93)	0.55 (0.30– 1.0)	<0.0001
Serum creatinine (µmol/L)			
Mean (SD)	99.5 (36.9)	96.4 (31.7)	0.930
Serum PTH (pmol/L)			
Mean (SD)	10.6 (5.7)	10.3 (5.1)	0.862
Serum CTx (ug/L)			
Median (IQR)	0.3 (0.14-0.45)	0.28 (0.14 – 0.39)	0.140

Low Vitamin D Levels in Primary Hyperparathyroidism Are Associated with Low Cortical Bone Density at the Radius Independent of PTH. Marcella Walker*[1], Elaine Cong[2], Polly Young[1], Nicole Weber[1], Anna Kepley[3], Chiyuan Zhang[1], Donald McMahon[4], James Lee[1], Shonni Silverberg[1]. [1]Columbia University, USA, [2]Columbia Presbyterian Medical Center, USA, [3]Columbia University Medical Center, USA, [4]Columbia University College of Physicians & Surgeons, USA

Low levels of vitamin D (25OHD) are common in primary hyperparathyroidism (PHPT) but data regarding the skeletal effects of low vitamin D in PHPT are limited. Patients with mild PHPT (n=79; 80% female, age±SEM 62±1yrs, calcium 10.7±0.1mg/dl, PTH 84±5pg/ml; 25OHD 29±1ng/ml) were studied with bone markers, dual x-ray absorptiometry (DXA) and high-resolution peripheral quantitative computed tomography (HRpQCT). 25OHD levels in the deficient and insufficient range were common (21%≤20ng/ml, mean 13±1ng/ml; 53%<30ng/ml, mean 21±1ng/ml). 25OHD correlated positively with age (r=0.35, p=0.002), serum phosphate (PO_4; r=0.31, p=0.006) and FGF-23 (r=0.27, p=0.02), and inversely with GFR (r=-0.35, p=0.001) and BMI (r=-0.29, p=0.01). With regard to PHPT disease activity, 25OHD levels were associated with PTH (r=-0.43, p<0.0001), but not serum calcium, CTX or BSAP, DXA BMD or HRpQCT indices. Those with 25OHD<30 vs. ⩾30ng/ml (mean 38±1ng/ml) did not differ by PHPT duration, nephrolithiasis, fractures, meeting surgical guidelines or race, but they were younger (57±2 vs. 67 ± 2yrs, p=0.0005), more likely to be male (31% vs. 8%; p=0.01) and had higher BMI (29.4±0.9 vs. 26.4±1.0kg/m^2, p=0.03). Before and after adjusting for age and BMI, those with 25OHD<30ng/ml had higher PTH (97±7 vs. 69±7pg/ml; p=0.008), and lower PO_4 (2.9±0.1 vs. 3.3±0.1mg/dl, p=0.003) and FGF-23 (86±20 vs. 143±20 RU/ml, p=0.056) levels but did not differ in serum calcium, CTX or BSAP. They also had lower BMD by DXA at the 1/3 rad (0.633±0.01 vs. 0.669±0.01g/cm^2, p=0.07; T-Score -1.6±0.2 vs. -0.7±0.2; p=0.005) and lower radial cortical density on HRpQCT. Cortical differences by DXA (1/3 rad) and HRpQCT (rDcort 794±14 vs. 842±14 mgHA/cm^3; p=0.03) persisted after adjusting for PTH. Radial trabecular indices and tibial measures did not differ. The small group with 25OHD≤20ng/ml had higher PTH levels (≤ 20 vs. ⩾30ng/ml: 120±9 vs. 72±7pg/ml, p=0.0001; vs. >20ng/ml: 75±5pg/ml, p=0.001), but did not differ by DXA or HRpQCT. Similar findings were seen in women only. In summary, in mild PHPT as in non-PHPT subjects, 25OHD is associated with age, BMI, GFR and FGF23. 25OHD < 30ng/ml is common and associated with higher PTH levels and modestly lower cortical BMD (1/3 radius by DXA and rDcort by HRpQCT) that is not solely mediated by the higher PTH. Although we had few patients with 25OHD < 20ng/ml, these findings suggest that current cut-points for low vitamin D do not have a major impact on the skeleton in mild PHPT.

SU0178

Major changes in the clinical phenotypes of primary hyperparathyroidism in the United States and China over the past 20 years: a tale of two countries. Jian-min Liu*[1], Barbara C Silver[2], Lin Zhao[3], Xiao-yan He[3], Bei Tao[3], Li-hao Sun[3], Hong-yan Zhao[3], Natalie Cusano[4], Wen-wei Fan[2], Megan E. Romano[2], Guang Ning[3], John Bilezikian[4]. [1]Rui-jin Hospital, Shanghai Jiao-tong University School of Medicine, Peoples Republic of China, [2]Department of Medicine, Division of Endocrinology, College of Physicians & Surgeons, Columbia University, USA, [3]Department of Endocrine & Metabolic Diseases, Rui-jin Hospital, Shanghai Jiao-tong University School of Medicine, China, [4]Columbia University College of Physicians & Surgeons, USA

Twenty years ago, primary hyperparathyroidism (PHPT) presented with two distinctly different clinical profiles: in the United States as primarily an asymptomatic disease and in China as primarily a symptomatic disease. With changing clinical standards of care, greater routine availability of serum calcium determinations in China and PTH assays in the United States, we hypothesized that the clinical evolution of PHPT over the past 20 yrs will reflect further major changes in recognition patterns in these two countries. To this end, we compared subjects with PHPT in Shanghai, China (n=249) and in New York, USA (n=77), encompassing a recent experience over the past 10 yrs.

In contrast to virtually 100% symptomatic PHPT in China 20 yrs ago, about 40% of PHPT seen in China is of the asymptomatic variant in the past 10 yrs with the percentage rising even further to 50% in the past 5 yrs. In the USA, asymptomatic PHPT still predominates with over 80% in this category. Normocalcemic PHPT, not seen in Shangeai cohort, has become evident in USA, but constituting a small percentage of subjects (<10%).

Compared to American PHPT, subjects in China were younger (51.3±16 vs 66.4±12 yr, p<0.001), and less likely to be women (68% vs 82%, p=0.015). Chinese had a shorter duration of the disease than American subjects [1 (0-15) vs 5 (1-11) yr, (p<0.001)].

PHPT was more advanced in Shanghai than in New York with higher serum calcium (11.7±1.4 vs 10.6±0.6 mg/dL, p<0.001), PTH [402 (103-2700) vs 67.5 (47.9-94.9) pg/mL, p<0.001], alkaline phosphatase [112 (50-1419) vs 75 (62-92) IU/L, p<0.001], creatinine [1.03(0.55-2.75) vs 0.79 (0.59-1.23) mg/dL, p<0.001] levels, and lower serum 25(OH)D [13.0 (5.2-30) vs 35.3 (24.8-43.0) ng/mL, p<0.001] levels. Nephrolithiasis was more prevalent in Shanghai (48.2%) than in New York (14.3%), p<0.001. While not detected in New York, parathyroid cancer was present in 6% of the subjects in Shanghai (p=0.028). BMD at lumbar-spine was significantly reduced in Shanghai cohort as compared with New York cohort (T-score,-1.905±1.71 vs -1.118±1.68, p=0.002) . The two cohorts did not differ in BMD at femoral neck (T-score: -1.608±1.41 vs -1.705±1.09, p=0.613), fracture rate (17.2 % vs 14.3%, p= 0.596), or eGFR (76.8±42 vs 80.0±19 ml/min, p=0.662).

Although the phenotypes of PHPT in both countries are evolving, towards less evident disease, sharp clinical and biochemical differences are still apparent in PHPT as expressed in China and the United States.

Major Differences in Trabecular Bone Score Between Primary Hyperparathyroidism and Hypoparathyroidism Remain 1 Year After Reversal of the Abnormal Parathyroid State. Barbara Silva*[1], Natalie Cusano[2], Wen-Wei Fan[1], Megan Romano[1], Jim Sliney Jr[1], Zachary Lenane[3], Laura Beth Anderson[3], Didier Hans[4], Mishaela Rubin[3], John Bilezikian[2]. [1]Columbia University Medical Center, USA, [2]Columbia University College of Physicians & Surgeons, USA, [3]Columbia University, USA, [4]Lausanne University Hospital, Switzerland

We have shown that bone microstructure assessed by HRpQCT is markedly different in primary hyperparathyroidism (PHPT) and hypoparathyroidism (HypoPT). Compared to PHPT, HypoPT subjects have denser and thicker cortices, along with denser, thicker, more numerous, and less widely distributed trabeculae. Yet, it is not known if the return of PTH to normal by parathyroidectomy (PTX) in PHPT, or replacement of PTH in HypoPT can reverse the differences in bone structure observed between them. Trabecular bone score (TBS) is a quantitative estimate of trabecular microarchitecture that correlates with measures of bone microstructure by μCT and HRpQCT. In this study, we examined the differences in TBS between PHPT and HypoPT at baseline, and 1yr after PTX in PHPT and PTH(1-84) replacement in HypoPT.

The study group consisted of 12 subjects with PHPT followed for 1yr after successful PTX, and 12 sex-, age-, and BMI-matched HypoPT individuals treated with PTH(1-84) for 1 year. Site-matched spine TBS data were extracted from the DXA image (Hologic) using TBS iNsight software. Differences in continuous variables between PHPT and HypoPT were assessed by Student's t-test.

Each group constituted 8 postmenopausal women and 4 men. PHPT and HypoPT subjects were well matched in age (64±4 vs 57±3 yrs; p=0.2) and BMI (28.8±2.0 vs 27.2±1.2 kg/m2; p=0.5). Serum calcium was higher in PHPT than in HypoPT subjects (10.8±0.2 vs 8.8±0.2 mg/dl; p<0.001). Compared to PHPT, mean duration of disease was longer in HypoPT (23±3 vs 7±5 yrs; p=0.02). At baseline, mean TBS

was lower in PHPT than in HypoPT individuals (1.216±0.054 vs 1.388±0.034; p=0.01). TBS improved by +3.3±2.4% at 12 months post PTX in PHPT, and remained unchanged after 1 yr of PTH treatment in HypoPT (0.8±0.9%). At 1 yr, TBS was still lower in PHPT than in HypoPT subjects (1.247±0.042 vs 1.398±0.029; p=0.01).

We have shown, in agreement with previous studies by HRpQCT, that trabecular microarchitectural texture by TBS is greater in HypoPT than in PHPT subjects. TBS measures remain higher in HypoPT as compared to PHPT at 1 year after reversal of the abnormal parathyroid state. Further follow-up in both groups is required to determine if the correction of PTH excess or deficiency will eventually eliminate the differences in TBS that are evident before therapeutic intervention in PHPT and HypoPT.

PTH(1-84) Administration Improves Three Dimensional Cancellous Bone Structure in Hypoparathyroidism Early in Treatment. Mishaela Rubin*[1], Alexander Zwahlen[2], David Dempster[1], Hua Zhou[3], Natalie Cusano[4], James Sliney[1], maryann dellabadia[1], Donald McMahon[4], Ralph Muller[2], John Bilezikian[4]. [1]Columbia University, USA, [2]Institute for Biomechanics ETH Zurich, Switzerland, [3]Regional Bone Center, Helen Hayes Hospital, USA, [4]Columbia University College of Physicians & Surgeons, USA

Hypoparathyroidism (HypoPT) is characterized by altered trabecular microarchitecture, with increased trabecular bone volume (BV/TV) and thickness (Tb.Th). We previously found, using conventional 2-D histomorphometric analysis of the iliac crest bone biopsy, that PTH(1-84) treatment in HypoPT was associated with an increase in trabecular number (Tb.N) at 1 and 2 yrs and a decrease in Tb.Th at 1 yr. We now investigated whether such changes are also detectable by direct 3-D analysis and how they may relate to bone strength. Fifty-seven HypoPT (26 premenopausal, 15 postmenopausal, 16 men; age, 18-72 years) were treated with PTH(1-84) for 2 yrs. All underwent iliac crest bone biopsies which were analyzed by high-resolution μCT with assessment of bone strength by μFE. Biopsies were performed at baseline (n=44) and at 1 (n=13) or 2 (n=16) yrs; 13 other subjects had one biopsy at 3 months. When compared to the untreated HypoPT biopsies (n=44), the 13 biopsies obtained after only 3 months of PTH had decreased bone surface density (15.69 ± 4.2 vs. 14.28 ± 2.1 mm^2/mm^3; p=0.01), trabecular separation (0.64 ± 0.1 vs 0.56 ± 0.1 mm; p=0.01) and trabecular heterogeneity (0.19 ± 0.03 vs 0.17 ± 0.03 mm; p=0.03), but increased Tb.N (1.84 ± 0.54 vs 2.36 ± 1.31 mm^{-1}; p=0.02). After 1 yr of PTH (n=13), the comparison within only 13 pairs from baseline to 1 yr showed that Tb.Th decreased (0.205 ± 0.04 vs 0.182 ± 0.03 mm; p=0.07) while connectivity density increased (14.10 ± 15 vs 30.70 ± 40 /mm^3; p=0.05). When using the same baseline biopsies as comparators (n=44), treated subjects at 1 yr tended to have an increase in apparent Young's modulus (649.4 ± 460 vs 1050.8 ± 824 N/m^2, p=0.09). The biopsies obtained after 2 yrs of PTH (n=16) showed that within the corresponding baseline 16 pairs, there was a decrease in Tb.Th, although it was not significant (0.194 ± 0.04 vs 0.184 ± 0.03 mm; p=0.3), while there was no difference from the overall baseline group (n=44). These data suggest that administration of PTH(1-84) in HypoPT is associated with early changes in microstructure as determined by direct 3-D histomorphometric analysis. Structural changes at 1 yr are consistent with trabecular tunneling, as indicated by thinner trabeculae and improved trabecular connectivity. The changes at 2 years were not as pronounced, which is similar to our previous observations by 2D analysis. We conclude that PTH(1-84) improves abnormal skeletal quality in hypoparathyroidism early in treatment.

Skeletal Microstructure Improves Markedly After Parathyroidectomy in Primary Hyperparathyroidism: Site- and Gender-specific Differences. Natalie Cusano*[1], Barbara Silva[2], Chiyuan Zhang[3], Kyle Nishiyama[3], Wen-Wei Fan[1], Megan Romano[1], John Bilezikian[1]. [1]Columbia University College of Physicians & Surgeons, USA, [2]Columbia University Medical Center, USA, [3]Columbia University, USA

It is well known that BMD improves after parathyroidectomy (PTX) in primary hyperparathyroidism (PHPT) but little is known about post-PTX changes in skeletal microstructure. Sex-specific differences after PTX have also not been explored. We report post-PTX results in 17 subjects (Age: 65 ± 13 yrs, 96% Caucasian) studied at baseline and at 6 months. Of these participants, 11 were also assessed at 1 yr and 6 at 1.5 yrs. We scanned 12 women (11 postmenopausal) and 5 men at the distal radius and tibia using high resolution peripheral quantitative computed tomography (HRpQCT, Scanco Medical AG) to assess volumetric BMD and bone microstructure. To evaluate changes 18 months after PTX, we used a linear mixed model for repeated measures. At the radius, there were significant increases in cortical area (Ct.Ar; p=0.04) and thickness (Ct.Th; p=0.02) (Table). At the tibia, there were significant changes in total (p=0.002), cortical (p=0.001), and trabecular area (Tb.Ar; p=0.001), total volumetric density (vBMD; p=0.02), Ct.Th (p=0.001), and trabecular thickness (p=0.02).

We investigated sex-specific differences using sex as a covariate in the model. Age was similar (Men: 61 ± 21 vs Women: 67 ± 10 yrs; p=0.6). Men demonstrated shorter duration of disease (0.8 ± 0.3 vs 11 ± 10 yrs; p=0.006) and higher alkaline phosphatase activity (86 ± 11 vs 70 ± 16 U/L; p=0.04). There were no differences in height, weight, BMI, or serum calcium at baseline. We found gender-specific differences at the radius between baseline and 12 months in cortical vBMD (p=0.047) and at the tibia for the following parameters: Tb.Ar (p=0.001), total vBMD (p=0.004), trabecular vBMD (p<0.0001), inner (p=0.001) and outer trabecular density (p=0.001), and bone volume fraction (p<0.0001).

In one of the first reports to describe PTX-associated changes in skeletal microstructural indices by HRpQCT, we also report site-specific, and for the first time, gender-specific differences in cortical and trabecular geometry and microstructure. The changes are mostly present at the weight-bearing site of the tibia. The etiology for sex-specific differences in response to PTX is unclear; others have shown sex-specific differences in HRpQCT parameters with aging. This report also provides the longest post-PTX results for HRpQCT to date. The results help to establish that bone quality improves after PTX and that there are striking differences between men and women.

Table. Percentage change in cortical (Ct) and trabecular (Tb) HRpQCT parameters 18 months after PTX in all subjects with PHPT. Men and postmenopausal women analyzed separately 12 months after PTX.

Radius	**All (%)**	**Men (%)**	**Women (%)**
Ct Area	5.2 ± 16[a]	5.1 ± 19	-0.1 ± 13

Vitamin D Treatment in Primary Hyperparathyroidism: a Randomized Placebo Controlled Trial. Lars Rolighed*[1], Lars Rejnmark[1], Tanja Sikjaer[2], Lene Heickendorff[3], Peter Vestergaard[4], Leif Mosekilde[1], Peer Christiansen[5]. [1]Aarhus University Hospital, Denmark, [2]Department of Medicine & Endocrinology, MEA Aarhus University Hospital, Denmark, [3]Dept. of Clinical Biochemistry, Denmark, [4]Aalborg University Hospital, Denmark, [5]Dept. of Surgery P, Denmark

Low levels of 25-hydroxy vitamin D (25OHD) are common in patients with primary hyperparathyroidism (PHPT) and associated with higher PTH levels and hungry bone syndrome following surgery. However, concerns have been raised on the safety of vitamin D supplementation in terms of aggravated hypercalcemia and hypercalciuria and subsequent impairment of renal function.

We aimed to assess effects of supplementation with high doses of vitamin D in patients with PHPT.

Using a double-blinded design, we randomized 46 patients with PHPT and 25OHD-levels < 80 nmol/l to a daily supplement with 70 microgram (2800 IU) of cholecalciferol or identical placebo for 52 weeks. Accordingly, treatment was administered for 26 weeks prior to parathyroidectomy and continued for 26 weeks following surgical cure.

Patients had a mean age of 58 (range 29-77) years and 76% were women. Preoperatively, 25OHD increased from 50 to 94 nmol/l in the treatment group, whereas levels decreased slightly by 9% in the placebo group (p<0.001 for between group difference). Compared with placebo, cholecalciferol treatment decreased PTH significantly by 17% prior to parathyroidectomy (p=0.01). Postoperatively, PTH levels remained lower in the cholecalciferol- compared with the placebo group (p=0.04). Creatinine, plasma and urinary calcium did not change in response to treatment. Compared with placebo, BMD at the lumbar spine increased in the cholecalciferol group by 2.4% prior to surgery (p=0.01). There were no differences

between groups in the pre- and post-operative BMD changes in the hip or forearm.In conclusion, optimization of vitamin D status in patients with PHPT by supplementation with a daily dose of 70 microgram of cholecalciferol does not seem to possess safety concerns, but may lower plasma PTH and improve BMD.

Bone micro-architectural anomalies and vascular calcification in uremic rats. Fabrice Mac-Way*[1], Alexandra Gauthier-Bastien[2], Ioan-Andrei Iliuta[2], Roth-Visal Ung[2], Richard Lariviere[2], Mohsen Agharazii[2]. [1]L'Hôtel-Dieu de Québec, Canada, [2]CHU de Quebec Research Center, Canada

Background: The relationships between development of vascular calcification and bone micro-architectural disorders, in chronic kidney disease (CKD), are poorly understood. We aimed to evaluate the anomalies of bone micro-architecture and mineralisation in uremic rats with vascular calcification as compared to non CKD rats.

Methods: CKD was induced by 5/6 nephrectomy in male Wistar rats. Vascular calcification was induced by high Ca/P diet and 1.25 $(OH)_2D$ (Ca/P/Vit D). Four groups were studied: (1) CTL + standard diet; 2) CTL + Ca/P/Vit D; 3) CKD + standard diet; 4) CKD + Ca/P/Vit D. After 4-6 weeks, the animals were sacrificed for blood biochemistry, bone specimens and thoracic aorta analysis. Von Kossa quantification was used for aorta calcification and left tibiae of each rats were imaged with high resolution Micro-CT for architectural analysis and further bone histomorphometry analysis.

Results: Von Kossa analysis showed a significantly higher thoracic aorta calcification in CKD + Ca/P/Vit D as compared to CKD + standard diet and CTL group (Figure 1). Bone micro-architectural analysis by Micro-CT showed a significantly lower cortical BMD in CKD vs CTL and a lower cortical thickness in CKD + Ca/P/Vit D vs CTL due to a decreased outer perimeter. Cortical thickness is also significantly lower in CKD + Ca/P/Vit D vs CKD + standard diet (Figure 2) while trabecular bone volume fraction was higher, although non significantly. The thoracic calcification was inversely correlated to the cortical bone thickness (Figure 3).

Conclusions: CKD has a negative effect on bone micro-architecture as shown by decreasing bone cortical thickness and mineral density. Vascular calcification is linked to bone micro-architectural disturbance as bone cortical thickness is even lower in CKD rats with vascular calcification, and that the extent of aortic calcification is negatively correlated to cortical bone thickness of tibiae. This study underlines the interrelationship between vascular calcification and bone micro-architecture in uremic state.

Reduced Nedd4 Function Promotes Vascular Calcification through Stabilizing a Smad1. Ji-Hyun Lee*[1], Michiko Takeda[2], Jae-Jin Cho[3], Je-Yong Choi[4], Hiroshi Kawabe[2], Nils Brose[2], Je-Yoel Cho[5]. [1]Veterinary Medicine, Seoul National University, South Korea, [2]Max Planck Institute of Experimental Medicine, Germany, [3]Seoul National University, South Korea, [4]Kyungpook National University, School of Medicine, South Korea, [5]College of Veterinary Medicine, Seoul National University, South Korea

Vascular calcification is associated with atherosclerosis, diabetes and chronic kidney disease, and it has been suggested that this process is similar to bone mineralization. However, the mechanisms underlying vascular calcification are poorly understood. Neural precursor cell-expressed, developmentally down-regulated protein 4 (NEDD4) is an ubiquitin-protein ligase that contains a calcium/lipid-binding domain, multiple WW domains and a C-terminal HECT domain. We previously reported that Nedd4 may be a modulator of Smad1 in BMP2/TGFβ1 signaling. In the current study, we assessed the effect of Nedd4 in vascular calcification using in vivo and in vitro. The in vivo model of vitamin D_3-induced vascular calcification was significantly promoted in the *Nedd4$^{fl/fl}$;SM22α-cre* mice in compare with their control littermates. In a calcified aortas region associated with increased expression of not only p-Smad1 but also bone related markers. Nedd4 protein level was prominently reduced in both calcified VSMCs and aortas. Moreover, the knockdown of Nedd4 increased bone-related gene expression levels and the formation of mineralized nodules by VSMCs in presence of calcifying medium. These results demonstrated that Nedd4 knockdown repressed its inhibitory effect on osteoblastic differentiation, thereby leading to the calcification of aortas through a process that is mediated by the Nedd4/Smad1 signaling pathway. These results provide evidence for the hypothesis that Nedd4 plays a protective role against vascular calcification.

Delayed Bone Regeneration Is Linked To Chronic Inflammation In Murine Muscular Dystrophy. Rana Abou-Khalil*[1], Frank Yang[2], Marie Mortreux[2], Shirley Lieu[2], Yan Yiu Yu[3], Maud Wurmser[2], Catia Pereira[1], Frederic Relaix[4], Theodore Miclau[2], Ralph Marcucio[3], Celine Colnot[1]. [1]INSERM U781, Université Paris Descartes-Sorbonne Paris Cité, Institut Imagine, Hôpital Necker Enfants Malades, France, [2]Department of Orthopaedic Surgery, University of California at San Francisco, USA, [3]University of California, San Francisco, USA, [4]INSERM, UMR-S 787, UPMC Paris VI, Institut de Myologie, Faculté de Médecine Pitié-Salpétrière, France

Duchenne muscular dystrophy (DMD) patients exhibit skeletal muscle weakness with continuous cycles of muscle fiber degeneration/regeneration, chronic inflammation, as well as low bone mineral density and increased risks of fracture. Fragility fractures and associated complications are thus considered as a consequence of the osteoporotic condition in these patients. Here, we aimed to establish the relationship between muscular dystrophy and fracture healing by assessing bone regeneration in mdx mice, a model of DMD with absence of osteoporosis. Our results illustrate that muscle defects in mdx mice impact the process of bone regeneration at various levels in a non-stabilized tibial fracture model. In mdx fracture callus, histomorphometric analyses showed that both cartilage and bone deposition were delayed followed by a delay in cartilage and bone remodeling. As indicated by PECAM staining and quantification of blood vessels via stereology, vascularization of mdx fracture calluses

was also compromised during the early stages of repair. Dystrophic muscles are known to contain elevated numbers of macrophages contributing to muscle degeneration. Accordingly, using stereological quantification of F4/80 staining, we observed increased macrophage recruitment in the mdx fracture calluses and abnormal accumulation of macrophages throughout the process of bone regeneration. These changes in the inflammatory environment subsequently had an impact on the recruitment of TRAP-positive osteoclasts and the remodeling phase of repair. Further damage to the mdx muscle, using a novel model of muscle trauma, amplified both the chronic inflammatory response and the delay in bone regeneration. In addition, PLX3397 treatment of mdx mice, a cFMS inhibitor in monocytes, partially rescued the bone repair defect through increasing cartilage deposition and decreasing macrophage number. In conclusion, impaired inflammatory response in mdx mice is responsible for the fracture healing delay and is associated with defects in angiogenesis and osteoclastogenesis. By revealing the role of dystrophic muscle in regulating the inflammatory response during bone repair, our results emphasize the implication of muscle in the normal bone repair process and may lead to improved treatment of fragility fractures in DMD patients.

Muscle-derived Cytokines and Chemokines Inhibit Osteoblast Function. Rachelle Johnson*[1], Jason White[2], Emma Walker[1], T John Martin[1], Natalie Sims[1]. [1]St. Vincent's Institute of Medical Research, Australia, [2]Murdoch Childrens Research Institute, Royal Childrens Hospital; School of Veterinary Medicine, University of Melbourne, Australia

The proximity of muscle to the periosteum suggests an inter-tissue pathway of communication controlling cortical bone's response to mechanical and adjacent paracrine stimuli, but the key muscle-secreted factors that might regulate periosteal osteoblast activity are not yet known. Since osteocyte-specific deletion of the glycoprotein130 (gp130) co-receptor and global deletion of the gp130-binding cytokine CNTF both increase periosteal circumference, we hypothesized that 1) muscle-derived cytokines (myokines) inhibit cortical bone formation, and 2) this is dependent on CNTF/gp130 signalling.

To assess whether myokines inhibit osteoblast function, calvarial osteoblasts were harvested from C57BL/6 neonates and cultured for 24 hours in conditioned media (CM) from differentiated myogenic C2C12 myotubes grown for 1, 2 and 3 days in fusion media. These osteoblasts produced dramatically less alkaline phosphatase (ALP) mRNA and protein in the presence of C2C12 CM compared to osteoblasts in non-conditioned media ($p<0.0001$). This inhibition increased with myotube culture length (1day=58-70%, 2days=69-76%, 3days=80-87% mRNA inhibition). Similar effects were observed in primary osteoblasts differentiated in osteogenic media for 23 days until osteocytic genes were expressed, where C2C12 CM treatment dramatically reduced OSX, ALP, PTHR1, osteocalcin and sclerostin mRNA (>7-50-fold, $p<0.01$), and increased RANKL expression >8-fold ($p<0.01$).

To determine whether the inhibitory effect of muscle on periosteal osteoblasts may be gp130-dependent, skeletal muscle was collected from wildtype C57BL/6 mice ($n\geqslant6$) and analysed for gp130 cytokine mRNAs by qPCR. CNTF mRNA levels were 10-fold greater than levels of OSM, IL-11, LIF and IL-6, suggesting it as a candidate inhibitory myokine; however, neutralising antibodies to CNTF or CNTF receptor (10μg/ml) did not block the reduction in ALP mRNA when added to C57BL/6 osteoblasts+C2C12 CM cultures, indicating that a myokine other than CNTF inhibits osteoblasts. Cytokine array analysis of the C2C12 CM revealed TIMP-1, MCP-1, and CXCL10 were the most abundantly secreted proteins, followed by CXCL1, M-CSF, and CCL5. Many of these factors stimulate monocyte migration, but the abundance of these chemokines in the muscle CM suggests that TIMP-1 and MCP-1 are myokines that directly stimulate osteoclastogenesis by promoting osteoblastic RANKL expression, and inhibit osteoblast differentiation on the periosteal surface via paracrine signalling.

Role of the osteoinductive factors, Tmem119, BMP-2 and the ER stress response PERK-eIF2α-ATF4 pathway in the commitment of myoblastic into osteoblastic cells. Ken-ichiro Tanaka*[1], Hiroshi Kaji[2], Ippei Kanazawa[3], Lucie Canaff[4], Geoffrey Hendy[5], Toshitsugu Sugimoto[1]. [1]Shimane University School of Medicine, Japan, [2]Kinki University Faculty of Medicine, Japan, [3]Shimane University Faculty of Medicine, Japan, [4]McGill University, Canada, [5]McGill University, Royal Victoria Hospital, Canada

The endoplasmic reticulum (ER) is crucial for biosynthesis, folding and modification of secreted proteins. Differentiating osteoblasts synthesize and secrete large amounts of bone matrix proteins and ER stress response pathways monitor this process. Fibrodysplasia ossificans progressiva (FOP) is a genetic disease in which heterotopic ossification occurs in muscle. Constitutively activating BMP type 1 receptor mutations underlie the molecular pathogenesis of FOP. We demonstrated that Tmem119, a PTH-responsive Smad3-related osteoinductive factor, is increased by overexpressing an FOP mutant BMP type 1 receptor and promotes the differentiation of myoblasts into osteoblasts by the induction of BMP-2 and the interaction with the BMP signaling pathway (J Biol Chem 2011, BONE 2012). Although both BMP-2 and Tmem119 promote the differentiation of myoblasts into osteoblasts and each increase the levels of the other, the relative contributions of BMP-2 and Tmem119 to the osteogenic differentiation and the mechanisms involved are incompletely understood. In this study, we examined the relationships among BMP-2, Tmem119 and the PERK-eIF2α-ATF4 ER stress response pathway in the osteoblastic differentiation of myoblastic C2C12 cells. Both BMP-2 and Tmem119 induced levels of Runx2, Osterix, Col1a1, ALP and osteocalcin, as well as mineralization. BMP-2 activation of the ER stress sensor PERK stimulated phosphorylation of eIF2α and led to increased biosynthesis of the osteoblast differentiation factor ATF4. When dephosphorylation of eIF2α was blocked by the selective inhibitor salubrinal, the osteogenic effects of BMP-2 and Tmem119 were enhanced further. While BMP-2 stimulated both P-eIF2α and ATF4 levels, Tmem119 had no effect on P-eIF2α but stimulated ATF4 only. Tmem119 siRNA reduced both baseline and BMP-2-stimulated levels of the ATF4 protein. In conclusion, BMP-2 stimulates differentiation of myoblasts into osteoblasts via the PERK-eIF2α-ATF4 pathway but in addition stimulates Tmem119 that itself increases ATF4. Hence, BMP-2 stimulates ATF4 both dependently and independently of the PERK-eIF2α ER stress response pathway. Abbreviations: PERK, protein kinase RNA-like endoplasmic reticulum kinase; eIF2α, eukaryotic translation initiation factor 2 subunit alpha; ATF, activating transcription factor.

Imaging and Quantifying Muscle-Bone Crosstalk via Intact Periosteum. Xiaohan Lai*, Christopher Price, Liyun Wang. University of Delaware, USA

During skeletal growth, strong functional relationships exist between muscle and bone. Recent evidence suggests that soluble factors produced by the muscle could regulate bone cell activity. The periosteum, a fibrous membrane that tightly covers bone's outer surface, lies adjacent to muscle, and contains osteoprogenitor cells crucial for bone modeling, may be a target of these muscle-derived factors. Furthermore, as an interface, the periosteum may act as a molecular sieve, controlling the penetration and transport rates of these factors into the bone tissue. However, few data are available on the permeability of the periosteum.

In this study we aimed to image and quantify the permeability of intact periosteum. Confocal xz imaging was first used to identify the periosteum on the mouse tibial mid-shaft. Using the reflected-light imaging, periosteum's dense irregular connective tissue allowed identification of the periosteum, which was further confirmed by staining the bone using Texas red C2-dichlorotriazine, an amine reactive dye (red channel, Fig. 1). For a 5-month old C57BL/6J mouse the thickness of periosteum was found to be ~ 40 μm. After the periosteum was identified, the PBS solution in the imaging chamber was replaced with a well-mixed solution of sodium fluorescein (376 Da). A time series of x-z line scan was then collected to track tracer penetration into the periosteum. Sodium fluorescein could penetrate into the periosteum within 30 seconds (Fig 2).

To obtain the dynamic transport characteristics, the time series were analyzed using MatLab. From the reflected light intensity profile, the periosteum's boundaries were defined at the half maximal intensity in the profile (Fig. 3). The spatiotemporal profiles agreed qualitatively with the predicted diffusion profiles, where the concentration increased inside the periosteum with time (Fig. 4). The time lag between two adjacent profiles was 6 sec and sodium fluorescein could penetrate (reaching 50% of bath concentration) into the mid-plane of the periosteum within 12 sec. The effective tracer diffusivity can thus be derived. The dependency of the diffusivity on tracer size, animal age and bone site is currently under investigation. The results are expected to identify the rate-limiting factors during this muscle-bone interaction process.

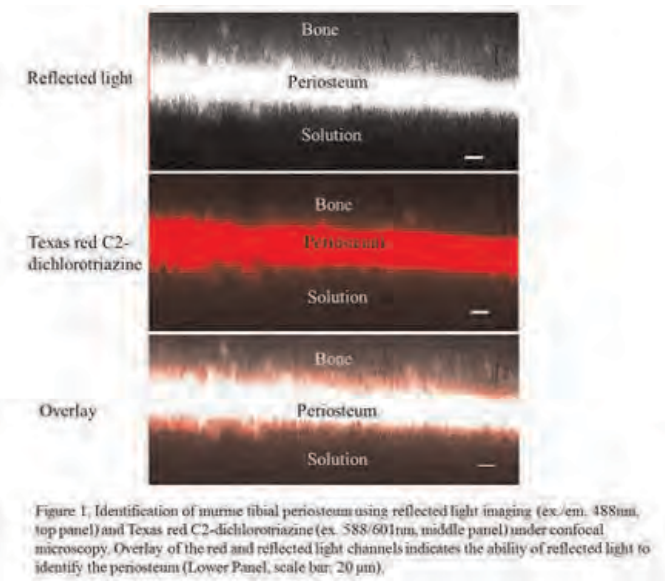

Figure 1. Identification of murine tibial periosteum

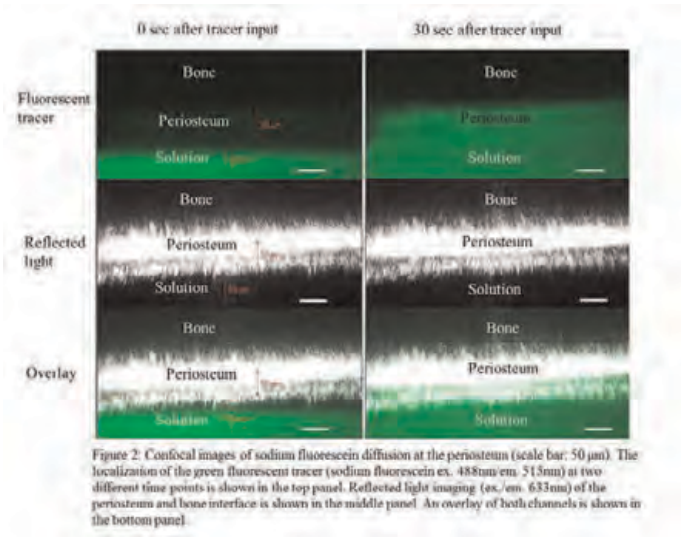

Figure 2: Confocal images of sodium fluorescein diffusion at the periosteum (scale bar: 50 μm). The localization of the green fluorescent tracer (sodium fluorescein ex. 488nm/em. 515nm) at two different time points is shown in the top panel. Reflected light imaging (ex./em. 633nm) of the periosteum and bone interface is shown in the middle panel. An overlay of both channels is shown in the bottom panel.

Figure 2: Confocal images of sodium fluorescein diffusion at the periosteum

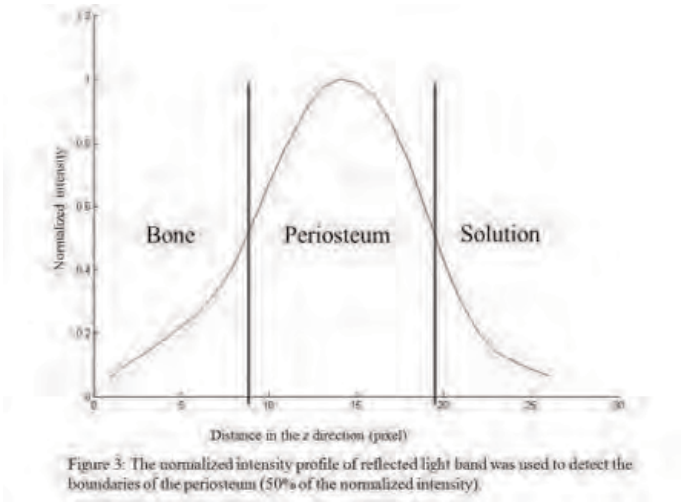

Figure 3: The normalized intensity profile of reflected light band was used to detect the boundaries of the periosteum (50% of the normalized intensity).

Figure 3: The normalized intensity profile of reflected light

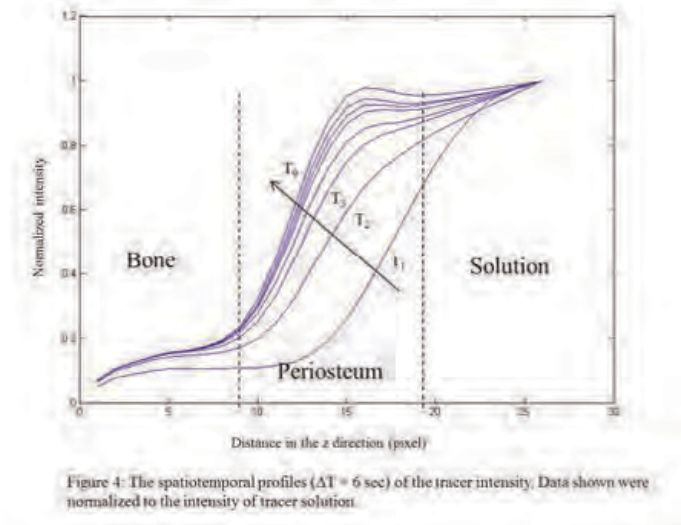

Figure 4: The spatiotemporal profiles (ΔT = 6 sec) of the tracer intensity. Data shown were normalized to the intensity of tracer solution.

Recombinant Osteocalcin Improves Insulin-stimulated Glucose Uptake Following Muscle Contraction. Itamar Levinger*[1], xuzhu lin[1], Xinmei Zhang[1], Alan Hayes[1], George Jerums[2], Mathieu Ferron[3], Gerard Karsenty[3], Ego Seeman[4], Glenn McConell[1]. [1]Victoria University, Australia, [2]University of Melbourne & the Department of Endocrinology, Austin Health, Australia, [3]Columbia University, USA, [4]Austin Health, University of Melbourne, Australia

Background: Studies in mice suggest that osteocalcin (OC), an osteoblast-specific secreted hormone, in its undercarboxylated form (ucOC), increases insulin secretion and insulin sensitivity. Acute exercise increases skeletal muscle insulin sensitivity as well as circulating levels of ucOC post- exercise by mechanisms that are incompletely understood. We tested the hypothesis that OC plays a direct role in the increase in muscle glucose uptake post contraction in C57BL/6J wild-type mice.

Methods: We used an *ex-vivo* muscle contraction model to assess whether recombinant OC can improve insulin-stimulated glucose uptake post contraction. We have compared the differences in EDL muscle glucose uptake from C57BL/6J mice between rest and 3 treatments including (a) contraction alone, (b) contraction plus insulin and (c) contraction plus insulin plus recombinant OC. Data reported as mean ± SEM.

Results: There was a linear increase in muscle glucose uptake across treatments (rest: 1.4 ± 0.2, contraction alone: 1.7 ± 0.2, contraction plus insulin: 2.3 ± 0.1 and contraction plus insulin plus OC: 2.6 ± 0.1 μmol/g/h, p=0.006). Muscle glucose uptake with OC treatment (contraction plus OC plus insulin) post ex-vivo muscle contraction was higher by ~ 14% (p=0.04) compared to contraction plus insulin alone.Conclusion: Our data suggest the OC treatment improves insulin-stimulated muscle glucose uptake following an *ex vivo* muscle contraction. In addition, exercise increases circulating ucOC (from our previous study) and this elevation may account, at least in part, for the insulin sensitizing effect of exercise.

Wnt3a Potentiates Myogenesis in C2C12 Myoblasts by Orchestrated Changes in IP3-mediated Calcium Signaling and β-catenin Activation. Jian Huang*, Chenglin Mo, Sandra Romero-Suarez, Lynda Bonewald, Marco Brotto. University of missouri kansas city, USA

Wnts have a significant potential to directly influence muscle function. We previously found the expression of Wnts, especially Wnt3a significantly increased in MLO-Y4 osteocytes exposed to fluid flow shear stress. To test Wnt3a roles in skeletal muscle myogenesis, C2C12 myoblasts were exposed to 10ng/ml Wnt3a which led to increased number and size of myotubes (4,319 ± 642 μm^2 untreated, vs. 9,833 ± 1,013 μm^2 for Wnt3a treated C2C12, $p < 0.001$). Considering that the concentration of 10ng/ml Wnt3a might be supra-physiological, we have conducted pilot studies with concentrations of Wnt3a ranging from 0.1 to 10ng/ml. A concentration as low as 0.5ng can consistently increase both the number and the size of myotubes during differentiation, a finding that was confirmed morphologically (4,299 ± 594 μm^2 untreated, vs.7,957 ± 1,269 μm^2 for Wnt3a treated myotubes, $p < 0.001$) and also with the concomitant double staining of myosin heavy chain (MHC) and nuclei. Furthermore, when Wnt3a was added to differentiation media, translocation of β-catenin to the nucleus increased by 2-fold compared to control suggesting that Wnt3a might stimulate β-catenin translocation leading to the downstream activation of muscle regulatory factors. Intriguingly, the potent effect of Wnt3a on stimulating the activation of the β-catenin signaling pathway in C2C12 cells strongly correlated with the appearance of intracellular calcium oscillations (ranging from 150-500nM free calcium) in myotubes measured with Fura-2. In a search for the molecular machinery responsible for this enhanced calcium oscillation activity we used several pharmacological agents to specifically block calcium regulatory mechanisms related to store-operated calcium entry, ryanodine receptor mediated calcium release, and IP3 receptor mediated calcium. Only by treating the cells with both gentamycin and 2-APB, which effectively blocks the production of IP3 and inhibits the IP3R, were calcium oscillations abolished, suggesting that the IP3-calcium signaling pathway is involved in this enhanced calcium oscillation activity induced by Wnt3a. In agreement, focused qRT-PCR arrays revealed a 6-fold increase in IP3-R1, and IP3R3, and a 2-fold increase in MyoD expression. We propose that Wnt3a acts through the modulation of intracellular calcium homeostasis, resulting in translocation of β-catenin that enhances expression of MyoD, IP3-1 and IP3-3, which together act in concert to enhance myogenesis.

Effects of Sex Steroid Deprivation on Skeletal Muscle Function and Ryanodine Receptor (RyR1) Modulation. Laura Wright*[1], Dennis Joseph[1], Ahmed Harhash[1], David Waning[2], Sutha John[1], Khalid Mohammad[1], Andrew Marks[3], Theresa Guise[1]. [1]Indiana University, USA, [2]Indiana University School of Medicine, USA, [3]Columbia University, USA

Adjuvant androgen- or estrogen (E_2)-deprivation therapy commonly causes musculoskeletal complications in cancer patients. The mechanism(s) of androgen- and E_2-deprivation-induced muscle dysfunction has not been identified, although both have been associated with increased oxidative stress. The ryanodine receptor (RyR1)/calcium release channel on the sarcoplasmic reticulum (SR) is required for muscle excitation-contraction coupling where the force of contraction is determined by the amount of calcium released via RyR1. Pathological oxidation-dependent depletion of the stabilizing subunit calstabin from RyR1 results in leaky channels and impaired muscle function in other diseases. To determine the role of sex steroid deficiency in skeletal muscle function, young male and female C57BL/6 mice underwent orchiectomy (ORX; n=10) or ovariectomy (OVX; n=5) and were assessed for changes in body composition and bone by dual energy X-ray absorptiometry (DXA) and μCT (SCANCO vivaCT40). Skeletal muscle function was assessed by measurement of maximum contractile force, corrected for muscle size, of the extensor digitorum longus (EDL). The amount of calstabin bound to RyR1 was determined by immunoprecipitation of RyR1 followed by immunoblotting for RyR1 and calstabin. In male ORX mice, percent fat mass increased ($p<0.0001$), bone mineral density (BMD) decreased ($p<0.0001$) and grip strength declined ($p=0.006$) 20 weeks after surgery. Muscle mass was reduced ($p<0.0001$) yet muscle-specific force production of the EDL was greater in ORX mice relative to controls. Expression of calstabin:RyR1 was not different. Female OVX mice similarly had increased percent fat mass ($p=0.037$), decreased BMD and bone volume fraction ($p<0.05$), with associated reduction in grip strength relative to controls. EDL mass was increased ($p<0.05$) yet muscle-specific force production of the EDL was lower in OVX mice and fatiguability was increased ($p<0.0001$). Consistent with the observed muscle dysfunction in OVX mice there was remodeling of RyR1 (i.e. decreased bound calstabin) indicating leaky channels. Thus, sex-steroid deficiency results in muscle weakness, but the mechanisms may differ between androgen and E_2-deprivation, with the former resulting in decreased muscle mass and the latter decreased function. Further studies are needed to determine the mechanism by which E_2-deprivation causes remodeling of RyR1 and whether pharmacological stabilization of RyR1-calstabin might ameliorate muscle weakness.

Uniaxial Cyclic Stretch Enhance Adipose-Derived Stem Cell Myogenesis. Pinar Yilgor Huri*[1], Colin Cook[1], Daphne Hutton[1], Brian Goh[2], Douglas Digirolamo[1], Warren Grayson[1]. [1]Johns Hopkins University, USA, [2]Johns Hopkins University School of Medicine, USA

Purpose: The regeneration capacity of skeletal muscle is limited in cases of large volumetric loss and autograft therapies are limited by the availability of suitable donor tissues [1]. Adipose-derived stem cell (ASC)-based tissue engineered muscle grafts could provide an effective alternative therapy. However, their therapeutic potential is limited by their low differentiation efficiency into myoblasts (0.5-5%) [2]. The aim of this study was to increase the efficiency of ASC myogenesis through the application of uniaxial cyclic stretch which mimics the native biophysical cues.

Methods: Human ASCs were seeded in specialized well plates with flexible membrane substrates. After 24 h, myogenic induction medium (MIM) was added to the *Induced* group for one day (biochemical induction) then replaced with expansion medium. *Un-induced* cells were retained in expansion medium. ASCs in these groups were grown in *Static* or *Dynamic* conditions. From Days 3 – 14 of culture, *Dynamic* cultures were exposed to uniaxial cyclic (11% strain, 0.5 Hz, 1h/day) stretch (biophysical induction). *Static* cells were not subjected to strain. We assessed cell morphology via phase contrast microscopy and actin filament staining and myogenesis was evaluated using immunocytochemistry and RT-PCR for muscle-specific markers. Images were quantified with Image J software.

Results: ASCs align and fuse upon induction where uninduced controls proliferated randomly on Static (Fig.1; day 14 (40x), red: Phalloidin-TRITC, blue: DAPI, FI: Fusion index and quantification of alignment). Although uninduced cells have a tendency to align on Dynamic, they do not specifically fuse in the absence of biochemical induction. Alignment and multinucleation became most pronounced with the application of both biochemical and biophysical induction; the fusion index increased almost 3 times in Induced-Dynamic compared to Induced-Static (2.6 ± 1.3 vs. 7.6 ± 4.8). ASCs in Dynamic conditions exhibited significantly higher Desmin and MyoD protein expression compared to Static (Fig.2) on days 3, 7 and 14. mRNA levels of Desmin, MYF5, Myog and Myosin heavy chain were significantly enhanced under Dynamic conditions (not shown).

Conclusion: ASC differentiation along the myogenic lineage could be significantly enhanced by mimicking the biophysical cues present within the native muscle microenvironment.

Muscle Strength and the Functional Muscle-Bone Unit in Children and Adolescents with Chronic Disease. Dale Lee*, Rachel Wetzsteon, Babette Zemel, Justine Shults, Mary Leonard. Children's Hospital of Philadelphia, USA

Measures of muscle size are often used as surrogates of muscle forces acting on bone. However, chronic diseases may be associated with low muscle strength relative to muscle size, further contributing to bone deficits in these disorders. The relations between muscle and bone were examined in 54 children with chronic kidney disease (CKD), and in 64 children at the time of Crohn disease (CD) diagnosis, and compared with 264 healthy controls. Muscle torque was assessed by isometric dynamometry in ankle dorsiflexion, and lower leg muscle cross-sectional area and tibia cortical section modulus by quantitative CT. Log linear regression was used to determine relations between muscle and bone parameters, adjusted for tibia length, age, Tanner stage, sex, and race.

Compared to controls, muscle area was significantly lower in severe CKD (Stage 4-5) and in mild to severe CD (Table). Muscle Torque relative to muscle area was markedly reduced in all stages of CKD and marginally reduced in severe CD. Cortical section modulus was significantly reduced in CKD, but preserved in CD. In multivariate models in CKD and in CD, greater muscle area and muscle force were

independently associated with greater section modulus (all $p<0.01$; model $R^2 = 0.92$ in CD and CKD). In severe CKD, adjustment for muscle area attenuated the section modulus deficit from 11.5 to 6.7% (p=0.05 compared with controls). With further adjustment for muscle torque, section modulus was no longer significantly lower in CKD (-4.5%;,p=0.19). Section modulus in severe CD was 7.4% greater than predicted (p=0.01) given the muscle area and force deficits, compared with controls.

In conclusion, advanced CKD was associated with significant deficits in muscle area, muscle strength relative to muscle area, and cortical structure. The lower muscle strength may be due to edema or abnormal protein catabolism. These data suggest that muscle area is not an adequate surrogate for muscle loading in CKD and studies should consider the independent effects of muscle strength. In contrast, CD was associated with significant deficits in muscle area due to malnutrition and inflammation, but muscle strength relative to muscle area was largely preserved. The greater section modulus in newly diagnosed CD, relative to the substantial muscle area deficits, may have been due to acute muscle loss preceding diagnosis. It is possible that bone loss from decreased mechanical loading lags behind rapid loss of muscle.

Percent Deficits in Chronic Disease compared with Healthy Controls

	Muscle Area	Muscle Torque Relative to Muscle Area	Cortical Section Modulus
Chronic Kidney Disease			
Mild to Moderate	-2.9 (p=0.35)	-14.3 (p<0.001)	-7.0 (p<0.05)
Severe	-6.7 (p=0.01)	-22.9 (p<0.001)	-11.5 (p=0.005)
Crohn's Disease			
Mild	-9.5 (p=0.002)	-1.7 (p=0.72)	-2.7 (p=0.47)
Moderate to Severe	-14.1 (p<0.001)	-7.6 (p=0.05)	-4.7 (p=0.15)

Models adjusted for age, sex, race, tibia length and sex-Tanner interactions if significant.

Magnetic Resonance Imaging (MRI)-Based Measures of Muscle Structure and Fat Infiltration in the Lower Leg of Postmenopausal Women with Osteopenia and Osteoporosis. Amanda Lorbergs*, Mike Noseworthy, Norma MacIntyre. McMaster University, Canada

Background: Age-related muscle loss and increased fat content between and within skeletal muscles may contribute to bone loss if the critical threshold for bone strain is not achieved. Advanced MRI techniques like diffusion tensor (DT)-MRI and proton MR spectroscopy (^{1}H-MRS) have been recently applied to assess skeletal muscle. While DT-MRI evaluates the shape and orientation of skeletal muscle fibres,^{1}H-MRS can noninvasively discriminate fat deposits within the muscle fibre (intramyocellular lipid, IMCL) from fat deposits external to the muscle fibre (extramyocellular lipid, EMCL).

Purpose: To compare muscle structure and fat deposits in the lower leg of postmenopausal women with osteopenia (OPN) or osteoporosis (OP) using axial MRI, DT-MRI, and ^{1}H-MRS.

Methods: Lower leg images were acquired (GE Signa750 3T MRI scanner) in 8 postmenopausal women (mean age$\pm$SD=71.6$\pm$3.9y; 4 OPN, 4 OP matched for physical activity level). Using custom and commercial software, total muscle cross-sectional area (MCSA) and intermuscular adipose tissue (IMAT), and DT-MRI derived eigenvalues (λ_1, λ_2, λ_3), fractional anisotropy (FA) and apparent diffusion coefficient (ADC) were quantified for medial and lateral gastrocnemius heads, soleus, tibialis posterior, and tibialis anterior (TA) muscles. TA IMCL and EMCL content were measured using ^{1}H-MRS spectra. One-way ANOVAs were performed to compare group means for each muscle outcome.

Results: OPN and OP groups were similar in age, height, and weight ($p>0.05$). No group differences were observed in MCSA ($p=0.68$) or IMAT ($p=0.83$). Compared to the OPN group, TA in the OP group had significantly greater λ_1 (OPN: 2.07 ± 0.03 x10^{-3}mm^2/s, OP: 2.25 ± 0.12 x10^{-3}mm^2/s, $p<0.05$), λ_2 (OPN: 1.42 ± 0.05 x10^{-3}mm^2/s, OP: 1.72 ± 0.08 x10^{-3}mm^2/s, $p<0.01$) and λ_3 (OPN: 1.32 ± 0.04 x10^{-3}mm^2/s, OP: 1.50 ± 0.10 x10^{-3}mm^2/s, $p<0.05$), and reduced FA (OPN: 0.25 ± 0.02, OP: 0.21 ± 0.01, $p<0.05$) and ADC (OPN: 1.61 ± 0.04 x10^{-3}mm^2/s, OP: 1.82 ± 0.10 x10^{-3}mm^2/s, $p<0.01$). No other DT-MRI metrics differed between groups. Similarly, groups did not differ in IMCL ($p=0.73$) or EMCL ($p=0.41$).

Conclusion: Muscle size and IMAT content are similar in OPN and OP women; however, differences in DT-MRI metrics suggest that OP is associated with structural changes in the predominantly slow twitch TA muscle. Future studies should evaluate whether this difference in TA muscle structure is observed in men, other predominantly slow twitch muscles, and is predictive of physical function and fracture risk.

Thigh muscle attenuation measured by computed tomography was associated with the risk of low bone density in community-dwelling elderly population. Jung Hee Kim*[1], Sung Hee Choi[2], Soo Lim[2], Jae Young Lim[3], Ki Woong Kim[2], Hak Chul Jang[2], Chan Soo Shin[1]. [1]Seoul National University College of Medicine, South Korea, [2]Department of Internal Medicine, Seoul National University Bundang Hospital, South Korea, [3]Department of Rehabilitation Medicine, Seoul National University Bundang Hospital, South Korea

Although muscle mass has been shown to be positively related with bone mineral density (BMD), there are only a few studies that investigated the association between muscle strength or muscle quality and BMD. We investigated the effects of muscle strength and muscle fat infiltration, as a measure of muscle quality, adjusted for muscle mass on femoral neck BMD in Korean elderly cohort.

We recruited 242 men and 231 women aged over 65 years who participated in the Korean Longitudinal Study on Health and Aging (KLoSHA). Leg muscle mass and femoral neck BMD were measured by dual-energy X-ray absorptiometry (DXA). Isokinetic strength of knee extensors was measured as a peak torque value by an isokinetic device. Computed tomography scan of the mid-thigh measured the mean Hounsfield unit (HU) of the lean tissue. Low bone density was defined as femoral neck T-score $\leq$ -2.0.

Leg muscle mass, knee extensor strength and thigh muscle HU values were significantly positively correlated with femoral neck BMD in both men and women. However, muscle strength was not a significant determinant for the presence of low bone mass after adjusting for muscle mass in multiple logistic regression analyses. Notably thigh muscle HU values were strong and independent determinant for the risk of low bone density.

Decreased thigh muscle HU values, a measure of fatty infiltration of muscle, were independently associated with increased risk of low bone density in the elderly population.

Prevention of Palmitate-induced Lipotoxicity in Human Osteoblasts. Krishanthi Gunaratnam*[1], Christopher Vidal[2], Chris Brooks[3], Ross Boadle[4], Gustavo Duque[5]. [1]Sydney Medical School-NepeanLevel 5 South Block, Australia, [2]University of Sydney, Australia, [3]Ageing Bone Research Program, Sydney Medical School Nepean, The University of Sydney, Australia, [4]Electron Microscope Laboratory, ICPMR, Westmead, Australia, [5]Ageing Bone Research Program, University of Sydney, Australia

Lipotoxicity is an overload of lipids in non-adipose tissues that affects function and induces cell death. Fatty acids, predominantly palmitic acid (PA), exert a lipotoxic effect on human osteoblasts (Ob) by inducing apoptosis (known as lipoapoptosis) and autophagy. We have previously reported that lipoapoptosis in Ob has a mitochondrial mechanism that could be prevented by inhibiting JNK phosphorylation. However, the role of autophagy in lipotoxicity and the therapeutic approach to prevent lipotoxicity in Ob remain unexplored. Autophagy was identified in PA-treated Ob (Lonza, Switzerland) using western blot (WB), immunofluorescence and electron microscopy (EM). PA induced early autophagy in cultured Ob, which was preceded by the activation of autophagosomes surrounding PA droplets. WB showed an increase in LC3-II/LC3-I protein ratio in PA-treated Ob, indicative of autophagy, in a dose and time dependent manner ($p<0.01$). These observations were confirmed by immunofluorescence of LC3-II punctate expression, which was significantly increased in a dose- and time-dependent manner ($p<0.01$). EM showed increased number of double-membrane and larger diameter autophagosomes at higher concentrations of PA. To evaluate whether autophagic activity could be inhibited, we treated Ob with PA in the presence or absence of 5mM 3-methyladenine (3MA), which has been reported to have a strong inhibitory effect on autophagy. We found a significant reduction in autophagosome formation in 3MA-treated Ob with a concomitant reduction in PA-induced apoptosis ($p<0.01$). Furthermore, to test the potential effect of vitamin D on lipotoxicity, we treated Ob with vitamin D using a well-known anti-apoptotic dose (10^{-8} M). WB showed a significant decrease in the pro-apoptotic proteins cytochrome C and Bax with an increase in BCl-2 in PA+vitamin D-treated Ob as compared with vehicle-treated controls. No changes in LC3 II/LC3-I ratio were observed in PA+vitamin D-treated Ob, thus suggesting that vitamin D has an effect on lipoapoptosis but not on PA-induced autophagy. In summary, we have identified that lipoapoptosis in Ob is induced through the activation of early autophagy followed by activation of mitochondrial apoptotic pathways. Vitamin D prevented lipoapoptosis whereas both autophagy and lipoapoptosis were inhibited by 3MA. The inhibition of lipoapoptosis and autophagy would protect Ob against marrow fat and could become a potential therapeutic target for osteoporosis in the future.

***In Vitro* Cultures of Human Adipose Tissue Mesenchymal Stem Cells and Human Bone Marrow Mesenchymal Stem Cells: Effects of Strontium on Proliferation and Osteoinduction.** Valeria Nardone*, Roberto Zonefrati, Carmelo Mavilia, Gaia Palmini, Cecilia Romagnoli, Gianna Galli, Annamaria Carossino, Laura Masi, Annalisa Tanini, Maria Luisa Brandi. University of Florence, Italy

Introduction: Human adipose tissue mesenchymal stem cells (hAMSCs) are able to differentiate into osteoblasts with analogous characteristics to human bone marrow mesenchymal stem cells (hBMMSCs) producing alkaline phosphatase (ALP) and calcified nodules composed by hydroxyapatite (HA). These characteristics make hAMSCs a good cellular model for *in vitro* studies on the pharmacological responses to the treatment of metabolic bone diseases, such as osteoporosis. Strontium ranelate (SR) is an approved drug for the treatment of postmenopausal osteoporosis. Unlike other drugs, it has a dual effect on bone remodelling. The aim of our study is to evaluate the effects of Strontium (Sr^{2+}) on proliferation and osteoinduction in both hAMSCs and hBMMSCs.

Materials and Methods: Cell cultures of hAMSCs and hBMMSCs were isolated respectively from subcutaneous adipose tissue biopsy and bone marrow aspirate from healthy donors. The cells were cultured in growth medium (GM) and characterizated, to verify their multi-potency, by studying both the adipogenic (AM) and the osteogenic differentiation (OM), utilizing specific media. The cells were cultured in OM in presence of scalar concentrations of Sr^{2+} from 0,5 to 100 μg/ml. Osteoinduction was evaluated quantitatively by fluorometric assays for ALP and HA production during 4-35 days of induction. Cell proliferation was evaluated in presence of scalar concentrations of Sr^{2+} from 1 to 1000 μg/ml in GM containing 1.5% FBS each 3 days from 0 at 12^{th} day.

Results: The highest concentrations of Sr^{2+} tested significantly stimulated the ALP production, with increase in the time of the enzymatic activity; while the lower concentrations of Sr^{2+} tested significantly stimulated the HA deposits formation after 21 days of induction. Cell proliferation analysis has shown that concentrations of Sr^{2+} from 50 to 1000 μg/ml enhance proliferation activity of both hAMSCs and hBMMSCs compared to control, with a maximum response at concentration of Sr^{2+} 500 μg/ml.

Conclusions: Our data confirm that the adipose tissue is an abundant reserve of mesenchymal stem cells and that these cells can be used as a cell model for *in vitro* studies in the field of cell therapies. Finally, these preliminary results suggest that SR has the capacity to stimulate cell growth and to enhance osteoinduction of both hAMSCs and hBMMSCs opening future applications in the bone repair.

Acute Cold-Induced Thermogenesis Uncouples Bone Remodeling by Activation of TRPM8 in a Non-Cell Autonomous Manner. Katherine Motyl*[1], Casey Doucette[1], Daniel Brooks[2], Mary Bouxsein[2], Clifford Rosen[3]. [1]Maine Medical Center Research Institute, USA, [2]Beth Israel Deaconess Medical Center, USA, [3]Maine Medical Center, USA

Recent clinical evidence has uncovered a role for brown-like adipose tissue in cold-induced thermogenesis (CIT) and has led to the development of new pharmacologic approaches to treat obesity. Thermogenesis is controlled by the sympathetic nervous system (SNS), which uncouples bone remodeling by suppressing formation and increasing resorption. We recently demonstrated that SNS activation to compensate for impaired preformed brown adipose tissue function caused accelerated trabecular bone loss in *Misty* mice. To understand the mechanism of thermogenic regulation of bone turnover, we exposed 8-wk-old female C57BL/6 mice to 4℃ for 6 hrs. Although changes in bone microarchitecture are not detectable during this short period, we found that cold suppressed *Runx2* mRNA expression in whole bone. Furthermore, cold significantly increased *Rankl* and suppressed *Opg* expression, resulting in a *Rankl/Opg* ratio that was 1.8-fold higher in 4℃-treated vs 22℃-treated mice (p=0.006). To test whether effects of cold were mediated in a non-bone cell autonomous manner through the SNS, we performed the same experiment in B6 mice with a deletion in the cold-sensing receptor TRPM8, which have suppressed sensitivity to cold. In contrast to wildtype, *Rankl/Opg* ratio was unchanged in *Trpm8*$^{-/-}$ mice at 4℃ compared to mice at 22℃. Furthermore, *Runx2* expression was not suppressed in response to cold in -/- mice. Two-way ANOVA demonstrated a significant genotypeXtemperature effect with both *Rankl/Opg* ratio ($p<0.01$) and *Runx2* expression (p=0.04). Next, to determine if deletion of TRPM8 had an effect on bone mass in mice maintained at 22℃ (below thermoneutrality), we examined total BMD by DXA and trabecular microarchitecture by mCT. Although no changes were visible by DXA, femoral trabecular thickness was significantly higher in -/- mice at 16 wks, but not at 8 wks, suggesting age-related trabecular bone loss was attenuated (ageXgenotype p=0.01). Consistent with a neuron-specific role of TRPM8, primary osteoblast and osteoclast differentiation *in vitro* were not affected by deletion of TRPM8. In conclusion, TRPM8 mediates acute cold-induced changes in osteoblastic gene expression in a non-cell autonomous manner. Studies on the effects of long-term cold exposure on BMD and bone cell function are underway to understand how CIT affects bone remodeling. Our findings suggest that pharmacologic agents that enhance brown-like thermogenesis for weight loss may have deleterious effects on bone.

Biglycan Modulates Angiogenesis and Bone Formation During Fracture Healing. Aaron Brown, Emily Pinnow, Agnes Berendsen, Nancy McCartney-Francis, Vardit Kram, Azusa Maeda, Tina Kilts, Marian Young*. National Institutes of Health, USA

Fracture healing involves a sequence of physiological events, including hematoma formation, inflammation, callus formation, neovascularization, osteoblastic callus mineralization, and osteoclastic remodeling of bone. This process results in the formation of new lamellar bone in the fracture area. Biglycan (Bgn) is a member of the small leucine-rich proteoglycan (SLRP) family that is highly present in bone. Bgn-deficient mice have a reduced growth rate and decreased bone mass due to lower levels of bone formation. To further understand the role Bgn plays in bone formation we created fractures in femurs of 6-week-old male wild type (WT) and Bgn-deficient mice using a custom-made standardized fracture device and analyzed the process of healing over time. The formation of a callus around the fracture site was observed at both 7 and 14 days post-fracture in WT and Bgn-deficient mice and immunohistochemistry revealed that Bgn was expressed in the fracture callus of WT mice localizing around woven bone and cartilage. Micro computed tomography (Micro-CT) analysis of the region surrounding the fracture line showed that the Bgn-deficient mice had a smaller callus with a bone volume and total mineral density (TMD) almost half of that of the WT mice. Histology of the same region also showed the presence of less cartilage and woven bone in the Bgn-deficient mice compared to WT mice. Picrosirus staining of the callus visualized under polarized light showed there was less fibrillar collagen in the Bgn-deficient mice, a finding confirmed by immunohistochemistry using antibodies to type I collagen. The reduction in collagen content could be one basis for the reduced TMD observed in the Bgn-deficient mice. Micro-CT imaging of vessel casting using the radiopaque silicon injection compound Microfil suggested decreased vessel formation in the callus of Bgn-deficient mice. In addition, real time RT-PCR at 7 days post-fracture showed a significant decrease in relative vascular endothelial growth factor (VEGF) gene expression by Bgn-deficient mice as compared to WT. Moreover, VEGF was shown to bind directly to Bgn through a solid-phase binding assay. These results suggest that Bgn plays an important role in the process of bone formation during fracture healing, and further that reduced angiogenesis could be the molecular basis for this deficiency.

Inhibition of GSK3-β Rescues the Impairments in Bone Formation and Mechanical Properties Associated with Fracture Healing in Osteoblast/Osteocyte-Selective Connexin 43 Deficient Mice. Alayna Loiselle*[1], Shane Lloyd[2], Emmanuel Paul[2], Gregory Lewis[2], Henry Donahue[2]. [1]Penn State Hershey, USA, [2]The Pennsylvania State University College of Medicine, USA

Connexin 43 (Cx43) is the main gap junction protein in bone and is required for osteoblastic differentiation and bone homeostasis. We generated mice with osteoblast/osteocyte-selective deficiency of Cx43 using Col1-Cre (2.3Kb) to test the hypothesis that Cx43 deficiency results in impaired bone formation during fracture healing as a result in increased GSK3-β activity and decreased β-catenin expression. Peak expression of Cx43, as measured by qPCR of tissue from the fracture callus, occurred at 28 days in wild type (WT) fractures, and was significantly decreased in Cx43 deficient (cK0) fractures relative to WT during healing. Callus bone volume/ total volume (BV/TV) was significantly decreased in cKO fractures relative to WT at 28 days (WT: 0.3 ± 0.01; cKO: 0.24 ± 0.02, p=0.03). Functionally, cKO fractures displayed a significant decrease in ultimate torque at failure (T_{ult}) at 28 days relative to WT (WT: 21.6 ± 4.9N*mm; cKO: 12.7 ± 1.5, p=0.009). Expression of β-catenin, which plays an important role in bone formation during fracture healing, was significantly attenuated in cKO fractures at 14 (-60%, $p<0.001$) and 21 days (-30%, $p<0.05$) relative to WT. Additionally, expression of GSK3-β, a key component of the β-catenin proteasomal degradation complex was significantly increased at 21 days post-fracture in cKO mice (+45 %, $p<0.001$) relative to WT. To determine if Cx43 may regulate bone formation during fracture healing by modulating GSK3-β levels and thus β-catenin, GSK3-β activity was inhibited during fracture healing with Lithium Chloride (LiCl). LiCl increased BV/TV in WT and cKO fractures relative to untreated genotype controls at 21 and 28 days. Indicative of restoration of normal bone volume fraction in cKO fractures, BV/TV was not significantly different between WT and cKO fractures treated with LiCl at 21 (p=0.69) and 28 days (p=0.72). Biomechanically, LiCl resulted in a significant increase in T_{ult} in both genotypes relative to their respective untreated controls at 28 days, while T_{ult} was no longer significantly decreased in cKO fractures (36.41 ± 5.11N*mm) relative to WT (31.34 ± 4.87N*mm, p=0.61) following LiCl treatment at 28 days (Figure 1). Taken together these data identify a previously unknown role for Cx43 in modulating bone formation during fracture healing through the regulation of β-catenin via GSK3-β, and suggest Cx43 as a potential therapeutic target to enhance fracture healing.

MiR-142-5p Promotes Osteoblast Activity and Bone Repair by Targeting WWP1. Chao Chen*[1], Peng Chen[2], Jiaji Gong[2], Eryuan Liao[2], Xianghang Luo[2]. [1]The Second Xiangya Hospital of Central South University, Peoples Republic of China, [2]Institute of Endocrinology & Metabolism, China

MicroRNAs (miRNAs) play important roles in regulating bone regeneration and remodeling. However, no study has established the pathophysiological role for miRNAs in bone repair. Here we identify a significant up-regulation of miR-142-5p during the bone healing process. Mice with osteoblast-specific over-expression of miR-142-5p showed increased bone formation and accelerated fracture healing than wild-type mice. Mice with osteoblast-specific deficiency of miR-142-5p by miRNA sponge revealed delayed fracture repair, decreased bone formation and age-related bone loss. In vitro miR-142-5p promoted osteoblast activity and matrix mineralization by targeting WWP1 (WW domain containing E3 ubiquitin protein ligase 1). We also found that the expression of miR-142-5p in the callus of aged mice were lower than in those of young mice and directly correlated with the age-related delay in bone healing. Furthermore, in patients with age-related delayed healing of bone fracture, we found that miR-142-5p expression in callus was markedly lower. Notably, osteoblast-specific delivery of miR-142-5p in mice using our aptamer delivery system stimulated osteoblast activity and fracture repair in aged mice. Thus, our study revealed that miR-142-5p play a crucial role in maintaining osteoblast activity, and providing a new molecular target therapeutic strategy for bone healing.

P2X7 Receptor Polymorphisms Modulate Osteoblast Cell Functions. Qi Guang Wang*[1], Elena Adinolfi[2], Alison Gartland[3]. [1]Mellanby Centre for Bone Research, United Kingdom, [2]University of Ferrara, Italy, [3]The Mellanby Centre for Bone Research, The University of Sheffield, United Kingdom

The P2X7 receptor (P2X7R) gene is highly polymorphic with at least six non-synonymous single-nucleotide polymorphisms (SNPs) being previously described as having either loss-of-function (LOF) or gain-of-function (GOF) effects. We have previously demonstrated expression of functional P2X7R on both osteoblasts and osteoclasts and found an association of LOF *P2RX7* polymorphisms and LS-BMD. The exact mechanism behind this observed association is currently unknown. We provide evidence here that it is the effects of *P2XR7* SNPs on osteoblast cells that may be driving the observed association with lower BMD in individuals with *P2XR7* SNPs.

To determine the effect of *P2XR7* SNPs on osteoblast cell function, Te85 cells were transfected with P2XR7 wild type (WT) or SNPs cDNA. P2X7R activation, intracellular calcium levels, cell proliferation, alkaline phosphatase (ALP) activity and in-vitro mineralisation were measured.

Transfected WT or *P2XR7* SNPs did not function in Te85 cells unless co-transfected with a naturally occurring truncated isoform, splice variant B (P2X7B). Upon ATP stimulation, pore formation was observed in the WT and GOF SNP, 155Y; but not in any of the three LOF SNPs; 496A, 568N, or 307Q. Increased intracellular calcium levels were found in all co-transfected Te85 cells, compared to the naïve or single P2X7B transfected cells. As expected, cell proliferation increased in Te85 cells transfected with the trophic P2X7B isoform, but co-transfection of WT or *P2XR7* SNPs reduced cell proliferation. Transfection of P2X7B alone significantly decreased ALP activity by 23% compared to naïve cells, whilst co-transfection of P2X7B and WT significantly increased ALP activity by 36%. Co-transfection with the LOF 496A and 568N *P2XR7* SNPs gave significant decreases in ALP of 15% and 13% respectively. In-vitro mineralisation was also significantly increased with co-transfection of P2X7B and WT or 307Q SNP compared to naïve cells, but this increased mineralisation was not detected with other *P2XR7* SNPs.

The results of this study demonstrate that the P2X7B isoform is necessary for P2X7R-mediated osteogenesis in Te85 osteoblasts cells and that *P2XR7* SNPs significantly alter osteoblast cell function which may account for the reduced BMD previously observed in women with P2X7R polymorphisms. The results of this study extend our knowledge into the role of the P2X7R in maintaining bone homeostasis, and may help identify people at risk of developing osteoporosis.

Real time monitoring for differentiation of primary osteoblast culture by using Raman microscopy. Yusuke Oshima*[1], Atsuhiko Hikita[1], Takeshi Imamura[2]. [1]Ehime University, Japan, [2]Ehime University Graduate School of Medicine, Japan

Osteoblasts are derived from mesenchymal stem cells that play a pivotal role during bone growth and mineralization. Understanding the molecular and cellular details of the mechanism that control bone formation and remodeling is essential for the drug discovery of bone metabolic diseases. Osteogenic differentiation of mesenchymal stem cells is induced by osteoblast-specific transcription factors such as Runx2 and Osterix, and numerous secreted factors of paracrine, autocrine, and endocrine origin. However, the mechanisms of osteoblast-specific gene expression and bone matrix formation are still poorly understood.

Raman spectroscopy is a label-free analytical tool for live cells and provides us detailed information of intracellular molecular composition based on the molecular vibrational mode. Raman spectroscopic studies for osteogenic differentiation have been reported in the last decade. The sensitivity of vibrational spectroscopy to both the mineral and organic elements of bone facilitates the study of both components and their interactions with each other.

To clarify the molecular mechanisms of the differentiation of osteoblasts, we performed Raman spectroscopic observation of mouse primary osteoblasts that were induced osteogenesis by bone morphogenetic protein 2 (BMP2). The primary osteoblasts were isolated from calvaria of neofetal mice (P0-P3, C57BL6) by collagenase digestion. Raman spectra were obtained by focusing a laser beam onto osteoblasts cultured with and without BMP2 treatment, respectively. The degree of osteogenesis was assessed by alizarin red staining.In the result, the Raman band at 960 cm^{-1} assigned to phosphate moiety (PO_4^{3-}) of osteoblasts with BMP2 treatment was significantly larger than that without BMP2 treatment. Increase of the phosphate Raman band may reflect accumulation of mineral component such as hydroxyapatite. The results suggest that the Raman spectrum captures the process of extracellular matrix formation. We will perform further study to reveal the function of vesicular secretion by using the high-sensitive custom-made Raman microscopy system.

Supplementation of Bone Substitutes with Prolyl Hydroxylase Inhibitors: Insights in the Cellular Responses and the Effect on Craniofacial Bone Regeneration. Hermann Agis*[1], Heinz-Dieter Müller[2], Ulrike Kuchler[2], Barbara Cvikl[3], Reinhard Gruber[4]. [1]Medical University of Vienna, Austria, [2]Department of Oral Surgery, Medical University of Vienna & Austrian Cluster for Tissue Regeneration, Austria, [3]Department of Conservative Dentistry & Periodontology, Medical University of Vienna & Austrian Cluster for Tissue Regeneration, Austria, [4]Laboratory of Oral Cell Biology, School of Dental Medicine, University of Bern, Switzerland

Prolyl hydroxylase (PHD) inhibitors stimulate regeneration of hard and soft tissue by stabilizing the labile hypoxia-inducible factor (HIF)-1alpha, a central mediator of angiogenesis. Whether PHD inhibitors can also support craniofacial tissue regeneration is unclear. Here, we followed an innovative approach where bone substitutes and collagen barrier membranes were supplemented with the PHD inhibitors. We assessed

the release kinetic of PHD inhibitors by functional assays and tested the effect on bone regeneration in a calvaria defect model in diabetic rats.

PHD inhibitors released from bone substitutes and collagen barrier membranes maintained their capacity to stimulate HIF-1alpha levels and the production of vascular endothelial growth factor in periodontal fibroblasts. Moreover, PHD inhibitors reduced plasminogen activation in fibroblasts, and decreased osteoclastogenesis and resorption in murine bone marrow cultures. However, supplementation of bone substitutes with PHD inhibitors did not support bone regeneration.

In summary, our results suggest that even though the PHD inhibitors provoke a strong cellular response in vitro, further research is required to optimize the release kinetic of PHD inhibitors to support craniofacial tissue regeneration.

Acknowledgment: This study was supported by the International Team for Implantology (Grant RCL 653), the Osteology Foundation (Grant 10-063), and the Austrian Science Fund (Erwin Schrödinger Fellowship J 3379-B19).

The Phosphorylation and GTPase activity of Dynamin are Critical for Osteoblast Function. Pierre Eleniste*, Su Huang, Heather Largura, Kornchanok Wayakanon, Angela Bruzzaniti. Indiana University School of Dentistry, USA

Osteoblasts (OB) migrate to eroded bone surfaces to form new bone. Dynamin has been shown to be important for cytoskeletal remodeling, focal adhesion turnover and endocytosis, but its function in bone cells is largely unknown. Dynamin GTPase activity is stimulated in part by tyrosine phosphorylation, but the mechanism that leads to its dephosphorylation by phosphatases and subsequent GTPase inactivation remains to be determined. We previously reported that inhibition of dynamin inhibits osteoclast bone resorbing activity and migration. In the current study, we examined the novel role of dynamin in OBs. We found that chemical inhibition of dynamin or over-expression of a dynK44A, a GTPase-defective mutant, increased alkaline phosphatase (ALP) activity in calvarial OBs, but led to inhibition of OB migration (-45%, $p<0.05$) in vitro. Next, to examine the mechanism of dynamin activation, we examined whether tyrosine dephosphorylation of dynamin by the protein tyrosine phosphatase PTP-PEST affected dynamin GTPase activity and OB function. For these studies dynamin was co-expressed with or without PTP-PEST, and dynamin phosphorylation and GTP-hydrolyzing activity were then quantified by immunoprecipitation and chemical GTPase activity assays, respectively. PTP-PEST decreased dynamin phosphorylation and activity in a dose-dependent manner. Further, we found that the dynamin tyrosine mutants Y231F, Y597F and Y231F/Y597F exhibited reduced tyrosine phosphorylation (~70% reduction for all mutants) and were resistant to dephosphorylation by PTP-PEST, suggesting they were PTP-PEST target sites. In addition, these mutants exhibited reduced dynamin GTPase activity (~70% reduction for all mutants). In contrast to dynK44A, we found that dynY231F/Y597F had no effect on ALP expression in MC3T3-E1 cells, but inhibited OB migration by 80%. These studies suggest that PTP-PEST regulates dynamin phosphorylation and consequently its GTPase activity. Furthermore, dynamin phosphorylation and GTPase activity have distinct, but overlapping effects in OBs, which are mechanistically linked with OB differentiation and migration. Finally, our findings suggest that inhibitors that target dynamin GTPase activity may be useful for the treatment of bone loss through their ability to inhibit osteoclast activity and promote osteoblast differentiation.

The Role of Donor and Host Age on Human Muscle Derived Stem Cells Mediated Bone Regeneration. Xueqin Gao*[1], Johannes Schneppendahl[1], Ying Tang[1], Aiping Lu[1], Bing Wang[1], Johnny Huard[2]. [1]University of Pittsburgh, USA, [2]Orthopaedic Surgery, USA

Introduction: Human muscle derived stem cells (hMDSCs) have been shown to efficiently repair a critical sized bone defect when transduced with lenti-BMP2; however, the role that the age of the donor hMDSCs and host have on the cells capacity to regenerate bone have not been evaluated. In order to address this question, we tested the bone repair capacity of young and old donor hMDSCs in both young and old host ICRSCID mice using a critical size calvarial bone defect model. Material and Methods: hMDSCs were isolated from young (23yo) and old (76yo) muscle biopsies. hMDSCs were transduced with lenti-BMP2/GFP and sorted for GFP. BMP2 secretion was measured with ELISA. Ten 1 year old and 10 six weeks old male ICRSCID mice were divided into 4 groups(N=5):(1)Young cells+young mice;(2)young cells+old mice;(3)old cells+young mice;(4) old cells+old mice. After creating a 5mm defect in the right parietal bone, 1.5 million hMDSCs were implanted into the defect using fibrin sealant as a scaffold. Bone formation was monitored using microCT biweekly. At 6 weeks, mice were sacrificed and skull tissues were harvested, fixed and decalcified. GFP immunostaining was performed to identify the donor cells. Herovici's staining was used to determine collagen I formation. TRAP staining was used to identify osteoclasts.

Results: At 2 weeks, microCT scanning showed that there were no differences in new bone volume between the young and old host using either young or old donor cells; however, bone density was significantly higher in the old host animals with both cell types. At 4 and 6 weeks, there was significantly less new bone volume in the defect area of the old mice than in the young mice using either the young or old cells. By 6 weeks there was no difference in the bone density between the young and the old host mice. A higher bone volume was generated by the old donor cells in both the young and old host mice and also covered the defect area significantly greater than the young cells in the old host mice. The young host mice had a greater number of GFP+ donor cells, both young and old, than the old host mice. TRAP staining indicated more osteoclasts in the new bone area of old mice than that in young mice. Herovici's staining identified collagen I matrix in all the groups. Conclusion: Our study revealed that old donor hMDSCs are as efficient as young donor hMDSCs for regenerating bone in young and old mice; however, the new bone in the old hosts was resorbed more quickly.

The role of intracellular calcium phosphate in monoosteophil-mediated bone apatite formation. Zhifang Zhang*[1], Keith Le[2], Frances Chang[2], John Shively[2]. [1]City of hope, USA, [2]Department of Immunology, City of Hope, USA

ABSTRACT

BACKGROUND: Monoosteophils, derived from LL-37-treated monocytes, are a novel type of calcifying/bone forming cells. We have shown that monoosteophils have the ability to form bone-like nodules in vitro and ectopic bone in vivo and accelerate bone repair in a drilled bone model. Since monoosteophils do not express alkaline phosphatase, it suggests that monoosteophils may use a different mechanism to form bone nodules in comparison with well-known osteoblasts which predominantly express alkaline phosphatase.RESULTS: Here we show that monoosteophils release 1-2 μm bone-like nodules on osteologic disc in low Ca^{2+} concentration 10% FBS RPMI1640 medium after 3 weeks by using scanning electronic microscopy. Furthermore, transmission electron microscopy showed that monoosteophils, harvested from osteologic discs, express intracellular vesicles of calcium phosphate. Even in the absence of osteologic discs, our results from transmission electronic microscopy showed that monoosteophils still form intracellular bone-like nodule granule in RPMI1640 medium after cultured for 6 weeks. When monoostophils were cultured in the 10% FBS αMEM medium with 2.5mM $CaCl_2$ for 3 weeks, significant intracellular calcium phosphate formations were observed by phase contrast microscopy and scanning electron microscopy and monoosteophils were positive using alizarin Red S staining in comparison with control monocytes.CONCLUDION: Our observations highlight the unique mechanism of bone formation of monoosteophils. These observations may have important implications in deciphering both how normal bone forms and in understanding pathological mineralization.

Thrombin receptor deficiency leads to osteopetrosis by decreasing the RANKL/OPG ratio. Bram Van Der Eerden*[1], Kukiat Tudpor[2], Prapaporn Jongwattapapisan[2], Marijke Schreuders-Koedam[3], Cindy van der Leije[3], Titia E Woudenberg-Vrenken[2], Rene JM Bindels[2], Joost GJ Hoenderop[2], Johannes PTM van Leeuwen[3]. [1]Erasmus MC, The Netherlands, [2]Cell Physiology, Radboud University Nijmegen Medical Centre, Netherlands, [3]Internal Medicine, Erasmus MC, Netherlands

Communication between osteoblasts and osteoclasts is crucial for bone remodeling. Thrombin and its thrombin receptor (TR; PAR-1) are expressed in osteoclasts and osteoblasts, respectively. However, the physiological roles of thrombin and TR in bone metabolism have been poorly studied. Therefore, we characterized the bone phenotype of mice lacking the thrombin receptor.

We performed bone microarchitectural analyses of the femurs of 10-12 week old wild type (WT) and TR knockout (TRKO) mice, using micro-computed tomography (μCT) and histomorphometry. We found an increased trabecular bone volume fraction (20.9 ± 1.2 vs 15.1 ± 0.2 %; $p=0.002$) and cortical bone volume (0.42 ± 0.004 vs 0.35 ± 0.004 mm^3; $p<0.001$) in TRKO mouse femurs compared to WT littermates. Trabecular bone thickness (8%) and connectivity (33%) were also significantly enhanced. In addition, the TRKO mice showed increased bone mineral density (BMD; 1.25 ± 0.006 vs 1.21 ± 0.004 g/cm^3; $p=0.003$) and decreased urinary deoxypyridinoline crosslinks (DPD) concentration (114 ± 9 vs 79 ± 4 nM; $p=0.007$), indicating reduced bone resorption. TRKO cortical bones had a larger diaphyseal perimeter (12.9 ± 0.23 vs 10.4 ± 0.02 mm; $p<0.001$) and a higher moment of inertia (0.60 ± 0.01 vs 0.42 ± 0.01 mm^4; $p<0.001$), implying stronger bones. Besides thicker trabeculae, histological examination did not reveal any abnormalities in the morphology of the TRKO femurs. Osteoblast and osteoclast surface and number corrected for bone surface were all similar between WT and TRKO mice. Compared to WT, the serum RANKL/OPG ratio in the TRKO mice was 80% reduced, which was primarily explained by inhibition of RANKL. In line with this, conditioned medium from thrombin-treated MC-3T3 osteoblasts contained a higher RANKL/OPG ratio (+135%) compared to non-treated cells, predominantly by stimulation of RANKL production. The thrombin-induced RANKL/OPG ratio was completely normalized to non-treated cells both by a TR antagonist (SCH79797) and by the p42/p44-ERK inhibitor U0126.

We conclude that the thrombin/TR system maintains normal bone remodeling through activating RANKL and limiting OPG synthesis by osteoblasts through the p42/44-ERK signaling pathway. Although the precise mechanism behind the thrombin effect on osteoclasts remains to be determined, TR deficiency leads to reduced osteoclast activity and osteopetrosis, making this receptor an interesting drug target candidate.

Wnt5a Enhances Wnt/β-catenin Signaling Through the Up-regulation of Lrp5/6 During Osteogenesis. Masanori Okamoto*[1], Nobuyuki Udagawa[2], Teruhito Yamashita[2], Shunsuke Uehara[2], Hiroyuki Kato[1], Naoto Saito[3], Yasuhiro Minami[4], Naoyuki Takahashi[2], Yasuhiro Kobayashi[2]. [1]Department of Orthopaedic Surgery, Shinshu University School of Medicine, Japan, [2]Matsumoto Dental University, Japan, [3]Department of Applied Physical Therapy, Shinshu University School of Health Sciences, Japan, [4]Department of Physiology & Cell Biology, Kobe University Graduate School of Medicine, Japan

Wnt proteins regulate bone formation through β-catenin-dependent canonical and –independent noncanonical Wnt pathways. Human and mouse genetic studies have revealed that LRP5/6, co-receptors for the canonical Wnt pathway, are critical for osteogenesis. Canonical Wnt10b suppresses Ppar-γ expression and inhibits adipogenesis. Noncanonical Wnt5a also suppresses adipogenesis and promotes osteogenesis. We and others have reported that *Wnt5a*$^{+/-}$ mice exhibit impaired bone formation. These findings indicate that the canonical and non-canonical Wnt pathways cooperate with each other during osteogenesis and adipogenesis, although Wnt5a antagonizes the canonical Wnt pathway in various types of cells. Here, we show that Wnt5a up-regulates *Lrp5/6* expression, thereby enhancing osteogenesis and suppressing adipogenesis. 1) The expression of *Wnt5a, Wnt10b* and *Lrp5/6* but not *Ror2*, a co-receptor of Wnt5a, was increased in calvaria-derived osteoblastic cells (calvarial cells) under osteogenic culture conditions. 2) Treatment of calvarial cells with Dkk-1, which disrupts Lrp5/Wnt interactions, failed to suppress the up-regulation of *Lrp5/6*, suggesting that the canonical pathway is not involved in the up-regulation of *Lrp5/6*. 3) Short hairpin RNA-mediated knockdown of Wnt5a in calvarial cells reduced expressions of *Lrp5/6*. 4) Calvarial cells obtained from *Wnt5a*$^{-/-}$ mice exhibited impaired mineralization in culture. The expression level of *Lrp5/6* in *Wnt5a*$^{-/-}$ calvarial cells was lower than that in wild-type cells. This finding was further confirmed by reduced expression of *Axin2*, a target gene of the canonical Wnt pathway, in *Wnt5a*$^{-/-}$ cells. 5) Treatment with recombinant Wnt5a up-regulated *Lrp5/6* expression, which in turn rescued the impaired mineralization in *Wnt5a*$^{-/-}$ calvarial cells. 6) Adenovirus-mediated gene transfer of *Lrp5* to *Wnt5a*$^{-/-}$ calvarial cells rescued impaired mineralization, and suppressed adipogenesis. 7) μCT analysis showed that osteoblast-lineage-specific *Wnt5a*-deficient mice (*Osterix*-Cre: *Wnt5a*-floxed mice) exhibited low bone mass, but osteoblast-lineage-specific *Ror2*-deficient mice (*Osterix*-Cre: *Ror2*-floxed mice) did not. These results suggest that Wnt5a-induced noncanonical signals enhance the canonical Wnt pathway through up-regulation of Lrp5/6 to achieve proper bone formation, and that the stimulatory effect of Wnt5a on the canonical Wnt pathway is independent of Ror2-mediated signals.

Both the Connexin43-specific Channel and C-terminus Are Required for the Regulation of Runx2 Activity and Osteoblast Gene Expression. Carla Hebert*[1], Joseph Stains[2]. [1]University of Maryland, USA, [2]University of Maryland School of Medicine, USA

Connexin43 (Cx43) plays an important role in regulating osteoblastogenesis, bone formation and turnover and the acquisition of peak bone mass. In this study, we examined the structure-function relationship between Cx43 and the regulation of Runx2 activity, downstream signaling and the expression of osteoblast genes. We hypothesized that the function of Cx43 in osteoblasts requires not only the ability to exchange small molecules (channel function), but also the ability to locally recruit signaling complexes (signal docking function) to the C-terminus of Cx43. Accordingly, we show in MC3T3 cells that overexpression of a truncated Cx43 construct lacking the C-terminus (Cx43 S244Stop) is less effective than full length Cx43 at activating Runx2 activity when stimulated with fibroblast growth factor 2. Similarly, we show that overexpression of Cx43, but not Cx43 S244Stop, stimulates the expression of *Bglap* (osteocalcin), *Col1a1*, *Sp7* (osterix) and *Tnfrsf11b* (osteoprotegerin) in cultured MC3T3 cells. In contrast to full length Cx43, overexpression of just the Cx43 C-terminus (amino acids 236 to 382) inhibited both transcription from a Runx2 reporter and signaling via PKCδ and ERK, indicating that the C-terminus is necessary but not sufficient to effect osteoblast function. To further explore the mechanism of Cx43 regulation of osteoblasts, we examined the ability of chimeric connexin constructs to affect Runx2 activity. In contrast to Cx43, overexpression of Cx45, a connexin that forms a channel with reduced permeability and an unconserved C-terminus, inhibited Runx2 activity. Similarly, a construct that possess the Cx43 channel but the Cx45 C-terminus (Cx43/45) and a construct that possess the Cx45 channel but the Cx43 C-terminus (Cx45/43) were unable to stimulate Runx2 activity. Using a series of pathway specific luciferase reporters, we demonstrate that the full-length Cx43 construct is most effective among the chimeras and truncation mutants to stimulate, not only Runx2 activity, but also signal transduction via the PKA, MAPK, β-catenin and NFκB pathways. In total, the data support our hypothesis in which an intact Cx43 is required for both signal propagation/permeability (channel function) and local recruitment of signaling complexes to the C-terminus (signal docking function) in order to mediate its cellular effects and highlights potential new modes of activation of osteoblast function.

Decipering the Role of Parafibromin in Wnt Transcription During Osteoblast Differentiation. Casey Droscha*[1], Cassandra R. Zylstra-Diegel[2], Travis Burgers[1], Jake Baker[3], Bart Williams[2]. [1]Van Andel Institute, USA, [2]Van Andel Research Institute, USA, [3]VAI, USA

Hyper-parathyroidism-jaw tumor (HPT-JT) syndrome is an autosomal dominant disorder in which patients present with fibro-osseous tumors of the maxilla or mandible. HPT-JT is caused by loss of heterozygosity or inactivating mutations within the hyperparathyroidism 2, (*HRPT2*) gene that encodes the protein product parafibromin. As a core member of the Polymerase Associated Factors (PAF complex), parafibromin binds to nuclear β-catenin and is known to associate with RNA Polymerase II to facilitate transcriptional initiation and elongation. Recently, the ability of parafibromin to associate with β-catenin and drive Wnt target gene transcription was found to be dependent on dephosphorylation by protein tyrosine phosphatase 2 (Shp2). Additionally, Bruton's Tyrosine Kinase (BTK) has been identified as a negative regulator of Wnt target gene transcription through interaction with parafibromin. Together, these findings suggest that the phosphorylation status of parafibromin may define its role as a transcriptional repressor or activator. It is our objective to determine how the phosphorylation status of parafibromin regulates Wnt target gene transcription. As Wnt is well known as a positive regulator of osteogenesis, it is also important to decipher the role parafibromin plays within osteoblast differentiation. Conditional deletion of *Hrpt2* within mature osteoblasts using osteocalcin (OC) Cre results in increased bone mineral density, cortical thickness, and overall stiffness of 3- and 6-month-old murine femurs. In addition, loss of *Hrpt2* within mesenchymal progenitors using Dermo1-Cre results in embryonic lethality at approximately E12.5. However, initial *in vitro* investigations assessing rates of mineralization and calcium deposition within Hrpt2-null osteoblasts show no significant changes as compared to wildtype controls. From these results, it is clear that parafibromin is essential for embryonic development and is a potential inhibitor of bone mass accrual, yet further investigation as to what genes are being occupied and regulated by parafibromin is needed. These findings will help to further elucidate the genetic mechanisms that govern bone development and homeostasis.

DICER is Specifically Regulated by RUNX2 During Osteogenesis and Enhances Osteogenic MicroRNA Expressions. Leilei Zheng*, Shu Meng, Liming Yu, Lan Zhang, Qisheng Tu, Jake Jinkun Chen. Tufts University School of Dental Medicine, USA

DICER, an RNase III endonuclease, is the central enzyme that cleaves precursor microRNAs (miRNAs) into 21-25 nucleotide duplex in cell lineage differentiation, identity, and survival. However, the mechanism regulating DICER expression in bone development or disease is unknown. In this study, we demonstrated that DICER played an important role in osteogenesis by enhancing "osteogenic" miRNAs expression, and was specifically regulated by the osteogenic master gene, runt-related transcription factor 2 (RUNX2), which specifically binds DICER promoter.

Cultured C3H10T-1/2, MC3T3-E1, MLO-Y4, and MLO-A5 cells were induced with 50 mg/mL of ascorbic acid for 1, 4, 7, and 10 days. Expression of bone metabolism genes and osteogenic-related miRNAs was determined by real-time PCR and western blot analyses. MC3T3-E1 cells were cotransfected with the DICER luciferase promoter reporter, pMIR-beta-gal and transcriptional factor cDNA plasmids to detect luciferase level. C3H10T1/2 and MC3T3 cells were transiently transfected with a RUNX2 overexpression or empty vector. Furthermore, calvarial cells from RUNX2-/- mice embryos were cultured *in vitro*, and were transiently transfected with a DICER overexpression or empty vector. Expression of bone metabolism genes and osteogenic-related miRNAs were determined.

miR-335-5p mRNA levels initially decreased when osteogenic differentiation was initiated, and the target gene DKK1 expression increased. miR-17~92 cluster increased during osteogenesis while the target gene, BIM expression decreased. DICER and RUNX2 mRNA and protein expressions increased simultaneously, while DKK1 expression was down-regulated. The DICER luciferase activity dramatically increased after co-transfection with RUNX2 when compared with the empty vector control. DICER expression increased 3-5 folds in C3H10T-1/2 and MC3T3-E1 cells overexpressed with RUNX2. Dicer overexpression in RUNX2-/- embryo calvarial cells increased 4-5 folds in miR-17~92 and decreased 2-3 folds in BIM.

These results suggest that DICER is specifically regulated by the osteogenic master gene RUNX2, which can bind the DICER promoter. Consequently, DICER cleaves pre-miR-335-5p and miR-17~92 cluster to form mature miRNAs, which target and decrease the DKK1 and BIM levels, and therefore promote bone formation. These observations first reveal a central mechanism underlying lineage-specific regulation by miRNAs during osteogenic differentiation and bone development.

Ebf1 Promotes Early But Suppresses Late Osteoblast Differentiation. Vappu Nieminen-Pihala[1], Kati Tarkkonen[2], Julius Laine[2], Kei Yamana[3], James R. Hagman[4], Roland Baron[5], Riku Kiviranta*[2]. [1]Department of Medical Biochemistry & Genetics & Department of Medicine, Finland, [2]Department of Medical Biochemistry & Genetics & Department of Medicine, University of Turku, Finland, [3]Teijin Institute for Biomedical Research, Japan, [4]University of Colorado, National Jewish Medical Research Center, USA, [5]Harvard School of Medicine & of Dental Medicine, USA

Early B cell factor 1 (Ebf1) is a zincknuckle containing transcription factor that regulates differentiation of multiple cell types including B- and neuronal cells. We and others have shown that Ebf1 is expressed in osteoblasts (OBs) and that deletion of Ebf1 results in increased bone formation. Conversely, overexpression of Ebf1 in osteoblasts with type I collagen 2.3 kb promoter resulted in impaired bone formation implicating Ebf1 as a negative regulator of osteoblast function. Despite these data, it has remained unclear which of the effects of Ebf1 are autonomous for bone cells. We aimed to determine, whether Ebf1 had a cell autonomous role in OBs to regulate their differentiation and function.

We first overexpressed Ebf1 in mesenchymal cell line C3H10T1/2 cells. Elevated levels of Ebf1 led to enhanced OB differentiation showed by increased alkaline phosphatase (ALP) activity and expression of Osterix (Osx) mRNA. Conversely, $Ebf1^{-/-}$ calvarial cells had severely impaired differentiation capacity seen as low ALP activity and impaired formation of mineralized bone nodules. To reconcile these data with our previous in vivo findings, we hypothesized that Ebf1 could have a dual role in OB differentiation promoting early but inhibiting late stages, as has been suggested for Runx2. To allow for some Ebf1 activity to overcome the early defect in differentiation we used haploinsufficient $Ebf1^{+/-}$ calvarial cells. $Ebf1^{+/-}$ cells showed reduced expression of Osx and ALP at early stages of the culture (days 0-14), although the phenotype was milder than in $Ebf1^{-/-}$ cells. Interestingly, on day 21 $Ebf1^{+/-}$ cells had caught up or even passed the control cells showing significantly higher expression of Osx and ALP compared to controls suggesting indeed a dual function for Ebf1 in OBs.

To test whether these findings would be true in vivo, we generated conditional Ebf1 knockout mice in which Ebf1 deletion was targeted to early or late OBs by crossing with Osx- or hOC-Cre mouse lines, respectively. Deletion of Ebf1 in early OBs with Osx-Cre resulted in significantly increased bone volume (BV/TV) and trabecular number (Tb.N) in the tibia at the age of 12 weeks by mCT analysis. However, $Ebf1_{hOC}^{-/-}$ mice tibia had no changes compared to controls. These data are being confirmed by histomorphometry.

Taken together our data suggests that Ebf1 has a cell autonomous role in OBs promoting mesenchymal stem cell commitment to the OB lineage but suppressing the function of mature cells.

Epigenetic control of osteoblast differentiation by Osterix and NO66 histone demethylase. Krishna Sinha*[1], Xin Zhou[2], Hideyo Yasuda[1], Benoit DeCrombrugghe[1]. [1]U.T.M.D. Anderson Cancer Center, USA, [2]MD Anderson Cancer Center, USA

Osterix (Osx) triggers the *Runx2*-expressing precursor osteoblasts to differentiate into functional osteoblasts and then osteocytes, through activation of a large repertoire of genes essential for bone formation. In *Osx*-null embryos, *Runx2*-positive *Osx*-null cells are arrested in their differentiation and expression of Osx-target osteoblast genes is absent. It is not yet known whether Osx has a role in remodeling the chromatin architecture of its target genes during transition of preosteoblast to osteoblast. In testing the hypothesis that Osx is indispensible for active chromatin architecture, we first showed that in *Osx*-null calvarial cells, occupancy of the transcriptional activators Runx2, c-Myc and Wdr5 at the Osx target gene *Bsp* was very markedly decreased. The levels of methylation of lysine 4 and 36 and acetylation of histone H3, markers for active chromatin, were also reduced at the *Bsp* gene in these cells. In contrast, occupancy of the transcriptional repressors HP1 and the NO66 histone demethylase previously identified as an Osx-interacting protein was increased at the *Bsp* gene in *Osx*-null calvarial cells. Further, the *Bsp* promoter was hypermethylated in ES cells and in E9.5 embryos, but was markedly hypomethylated in calvaria of E18.5 embryos, coinciding with robust *Bsp* expression. In contrast, CpG methylation in the *Bsp* promoter remained high in *Osx*-null calvaria compared to *Osx*-wt calvaria. Our data also revealed that NO66 interacted with DNMT1A and HDAC1A as well as HP1 which are known to control the histone and DNA methylation. In addition, HP1 stimulated the demethylase activity of NO66 for its substrates H3K4me3 and H3K36me3, suggesting that the interaction of NO66 with the chromatin of the *Bsp* and *Oc* genes during repression of these genes in *Osx*-null cells might regulate histone methylation levels at the chromatin through its demethylase activity. Our findings strongly suggest that in the absence of Osx, the chromatin of Osx target genes is transcriptionally inactive. We propose that Osx is a molecular switch for the formation of an active chromatin state during osteoblast differentiation, whereas NO66 helps gene repression through histone demethylation and/or by participating in formation of a repressor-complex resulting in a multi-layer control of the chromatin architecture of specific osteoblast genes.

Hepatic Lipase Is Expressed by Osteoblast and Affects Bone Mass in Diet-induced Obesity in Mice. Alexander Bartelt[1], Timo Beil[1], Brigitte Müller[1], Till Koehne[1], Markus Heine[1], Tayfun Yilmaz[1], Jörg Heeren[1], Thorsten Schinke[2], Andreas Niemeier*[1]. [1]University Medical Center Hamburg-Eppendorf, Germany, [2]Department of Osteology & Biomechanics, University Medical Center Hamburg Eppe, Germany

Purpose: A number of unexpected molecules were recently identified that link bone homeostasis to systemic energy metabolism. Here we identify the lipolytic enzyme hepatic lipase (HL, encoded by *Lipc*) as a novel cell-autonomous regulator of osteoblast function.Methods and Results: In an unbiased genome-wide expression analysis, *Lipc* was found to be highly induced upon osteoblast differentiation, as verified by quantitative Taqman analyses of primary osteoblasts *in vitro* and of bone samples *in vivo*. Functionally, loss of HL in vitro led to increased expression and secretion of osteoprotegerin (OPG), while osteoblast differentiation was mildly impaired. Challenged with diet-induced obesity (DIO), lack of HL led to a significant increase in bone formation markers and a decrease in bone resorption markers. Accordingly, in the DIO setting, we observed in *Lipc*-/- animals but not in wild-type controls a significant increase in lumbar vertebral trabecular bone mass and an increase in bone formation rate as determiend by histomorphometry. Taken together, here we demonstrate that HL expressed by osteoblasts has an impact on osteoblast OPG expression and that lack of HL leads to increased bone formation in DIO. Conclusions: These data represent a novel and completely unexpected molecular link between osteoblasts and systemic lipid metabolism. HL may ultimately evolve as a drug target for disorders associated with low bone mass in obese individuals.

Identification of Slc9a9 as a candidate gene for a bone mineral density locus on mouse Chromosome 9. Kwangbom Choi[1], Kathryn Shultz[1], Dana Godfrey[1], Rong Yuan[2], Matthew Hibbs[3], Daniel Gatti[1], Gary Churchill[1], Beverly Paigen[1], Wesley Beamer[1], Cheryl Ackert-Bicknell*[1]. [1]The Jackson Laboratory, USA, [2]Southern Illinois University School of Medicine, USA, [3]Department of Computer Science, Trinity University, USA

Over 80% of the variance in peak bone mass is due to heritable factors. We have previously published a vertebral bone mineral density (BMD) locus on mouse Chromosome (Chr) 9 at 44.24 cM. We have since confirmed that this locus affects both vertebral BMD and whole body areal BMD by generating and phenotyping congenic mice wherein c3h alleles were introgressed onto an otherwise C57BL/6J genetic background. Specifically, c3h/c3h congenic female mice have lower whole body areal BMD (b6/b6 = 0.0533 vs. c3h/c3h = 0.0507 mg/cm2, P = 0.008) and lower lumbar spine BMD (b6/b6 = 0.0894 vs. c3h/c3h = 0.0727 mg/cm2, P = 0.004), however no difference was observed in males. This BMD locus has previously been identified in other genetic crosses: MRLxSJL (42.3 cM), NZBxSM (46.08 cM) and in a new cross of: PL/J x KK/HIJ(45.3 cM). The confidence intervals for these overlapping loci, along with the known boundaries of the c3h-like interval for our congenic were used to define the genomic interval most likely to contain the underlying gene(s). The single nucleotide polymorphisms (SNP) allele pattern in this interval was examined to identify genes wherein all strains contributing the high BMD allele for the locus shared the same SNP allele and vice versa. Only three SNP within the interval possessed this allele distribution pattern and all were found within the Slc9a9 gene. This gene codes for one of the many solute transporter transmembrane proteins, but little is known about the function of this gene in particular. Using next generation RNA-seq we examined the expression profile of genes during osteoblastogenesis in primary calvarial osteoblasts. From this data, we determined that expression of Slc9a9 is low early in osteoblastogenesis, but expression increased with maturation. We identified 537 genes with expression profiles that were highly positively correlated (R2 $>$ 0.9) with that of Slc9a9 by using co-expression network analysis. These genes included Bmpr1a, Lrp6 and Mmp2. Gene-annotation enrichment analysis showed that this list of 537 genes is highly enriched for proteinaceous extracellular matrix genes (fold enrichment = 4.4, Bonferroni corrected P = 9 x 10-12). This list was also enriched for genes annotated as being involved with ossification (fold enrichment = 5.1, Bonferroni corrected P = 6 x 10-3). In summary, Slc9a9 is a strong candidate for a BMD locus on mouse Chr 9 and may be associated with osteoblast function.

Novel Compounds Mimic Hedgehog Activity and Promote Osteoblast Differentiation in C3H10T1/2 Cells and Osteoblastic Cells from Runx2-Deficient Mice. Takashi Nakamura*[1], Masahiro Naruse[1], Tomoko Ikeuchi[1], Toshihisa Komori[2], Aya Yamada[1], Masahiro Iwamoto[3], Satoshi Fukumoto[1]. [1]Tohoku University Graduate School of Dentistry, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Japan, [3]Children's Hospital of Philadelphia, USA

Hedgehog proteins are involved in multiple cellular actions including cell proliferation, migration, differentiation, and cell fate determination. Recently, HH-Ag 1.3 and HH-Ag 1.7 have been discovered by the high throughout screening of small molecule compounds that activate the expression of Gli1, a target gene of hedgehog signaling. Hedgehog signaling exerts important roles in hard tissue development such as bone, cartilage, and tooth. In this study, we demonstrate that HH-Ag 1.3 and HH-Ag 1.7 strongly activated the expression of endogenous Gli1 and promoted osteoblastic differentiation in pluripotent mesenchymal cell line C3H10T1/2.

Both HH-Ag compounds stimulate alkaline phosphatase (ALP) activities in dose dependent manners and were induced osteoblast marker expressions in C3H10T1/2 cells. These results suggest that both those compounds promote osteoblast differentiation in C3H10T1/2 cells. Interestingly HH-Ag 1.7 exerts synergistic promotion on ALP activities in C3H10T1/2 cells with BMP-2. We hypothesize that those compounds induced an intra-cellular signaling crosstalk between hedgehog and BMP. Because both compounds promotes osteoblastic differentiation in C3H10T1/2 cells, we screened several osteoblastic marker genes including Runx2 and Sp7. HH-Ag 1.7 strong induced Sp7 expression, while no significant upregulation was observed for Runx2 expression in C3H10T1/2 cells. This result suggests that HH-Ag 1.7 activates the downstream target molecules of Runx2 in osteoblast differentiation. To confirm this result, we used osteoblastic cells derived from Runx2 KO mice. Interestingly, Runx2 KO cells gain the ALP activity by HH-Ag 1.7, while no ALP activity was observed in control. It has been reported that the SNP alleles of Runx2 gene are associated with the reduction of bone mineral density as well as femoral neck fracture in osteoporosis patients. Thus, our research will contribute to develop novel therapies for fracture and bone defect, and especially osteoporosis patients.

Odd-skipped related 2 regulates Wnt signaling pathway through Dkk1. Shinji Kawai*[1], Atsuo Amano[2]. [1]Osaka University Graduate School of Dentistry, Japan, [2]Osaka University, Japan

Zinc finger transcription factor Odd-skipped related 2 (Osr2) is one of the factors which functions in bone formation. We previously used the transgenic mice of dominant negative type Osr2, and reported the function as a factor which controls proliferation of osteoblast cells and bone formation. Moreover, joint fusion, supernumerary teeth, and cleft palate have been reported on the Osr2 knockout mice. On another front, Wnt family is secreted protein and related with embryogenesis and oncogenesis, and also plays the important role in bone formation and cartilage formation. In this study, we aim to clarify the relationship between Osr2 and Wnt signal pathway. We reported last year that the expression profile of signal pathway genes was analyzed on Osr2 over-expressed cells by DNA microarray. As a result of clustering analysis, Wnt signal pathway was most controlled among various kinds of signal pathways. Osr2 regulated TopFlash activity. In this study, we found that Osr2 negatively regulated the expression of Wnt target genes (cyclin D and Ror2), Wnt signaling factors (beta-catenin, LEF, and TCF), and several Wnt genes. Conversely, Osr2 positively regulated the expression of Wnt signaling inhibitors (Dkk1 and Sost). From reporter assay of Dkk1 promoter and luciferase, Dkk1 promoter contained Osr2 binding site between -500 and -120 region. Consequently, it is suggested that Osr2 negatively regulates Wnt signal pathway and participates in bone formation or joint formation.

Persistent low level of Osterix accelerates interleukin-6 production and impairs regeneration after tissue injury. Wook-Young Baek*[1], Seung-Yoon Park[2], Yeo Hyang Kim[3], Yeon-Ju Lee[1], Tae-Hwan Kwon[1], Kwon-Moo Park[1], Benoit de Crombrugghe[4], Jung-Eun Kim[1]. [1]Kyungpook National University School of Medicine, South Korea, [2]Department of Biochemistry, School of Medicine, Dongguk University, South Korea, [3]Department of Pediatrics, Keimyung University School of Medicine, South Korea, [4]University of Texas M. D. Anderson Cancer Center, USA

Osterix (Osx) is an essential transcription factor for osteoblast differentiation and bone formation. Osx knockout show a complete absence of bone formation, whereas Osx conditional knockout in osteoblasts produce an osteopenic phenotype after birth. Here, we questioned whether Osx has a potential role in regulating physiological homeostasis. In Osx heterozygotes expressing low levels of Osx in bones, the expression levels of pro-inflammatory cytokines were significantly elevated, indicating that reduced Osx expression may reflect an inflammatory-prone state. In particular, the expression of interleukin-6, a key mediator of chronic inflammation, was increased in Osx heterozygotes and decreased in Osx overexpressing osteoblasts, and transcriptionally down-regulated by Osx. Although no significant differences were revealed in renal morphology and function between Osx heterozygotes and wild-type under normoxic conditions, recovery of kidneys after ischemic damage was remarkably delayed in Osx heterozygotes, as indicated by elevated blood urea nitrogen and creatinine levels, and by morphological alterations consistent with acute tubular necrosis. Eventually, protracted low Osx expression level caused an inflammatory-prone state in the body, resulting in the enhanced susceptibility to renal injury and the delayed renal repair after ischemia/reperfusion. This study suggests that the maintenance of Osx expression in bone is important in terms of preventing the onset of an inflammatory-prone state.

Primary osteoblasts from CKD patients retain abnormal gene expression ex vivo. Renata Pereira*[1], Barbara Gales[1], Navdeep Tumber[1], Harald Jueppner[2], Isidro Salusky[3], Katherine Wesseling-Perry[4]. [1]UCLA, USA, [2]Massachusetts General Hospital, USA, [3]University of California, Los Angeles School of Medicine, USA, [4]UCLA Medical Center, USA

Over the past decade, osteocytes have been identified as key regulators of mineral metabolism and skeletal mineralization and expression of osteocytic proteins are markedly altered by CKD. Evaluation of human osteocytes is limited by the lack of stable human osteocyte cells lines; morever, whether abnormalities in cells of osteoblast/osteocyte lineage are intrinsic to bone or are mediated solely by changes in circulating mineral metabolism is unknown. Thus, primary osteoblasts were cultured from bone biopsies from 24 pediatric PD patients (14M, 10F), age 17.1 + 0.7 years who had varying types of renal osteodystrophy. 8 subjects received active vitamin D sterols at the time of biopsy; 16 subjects were not on vitamin D sterols for at least 4 weeks prior to the biopsy. Biochemical values were: Ca: 8.9+0.2 mg/dl, P: 6.5+0.4 mg/dl, PTH: 589+79 pg/ml, FGF23: 1826(425, 4825) RU/ml. Histomorphometric analysis was performed on all biopsies and RNA was isolated in TRIzol from bone cores. Trabecular bone fragments were washed in DMEM with antibiotics, minced into small pieces, and incubated in fetal bovine serum for 2 hours in 5% CO_2 at 37°C until adherent to plates. 7 cc of DMEM supplemented with 20% FBS and ascorbic acid was added to each plate and incubated at 37°C. Media was changed twice weekly until formation of 7-20 cell colonies per plate (1 to 4 weeks). Colonies were split and grown until semi confluent. Cells were collected and frozen for later experiments; one plate was kept at confluence for RNA extraction. Expression of osteoblastic and osteocytic gene expression was evaluated at passage 0 by qPCR and normalized by GAPDH expression in each sample. Expression in dialysis patients was then normalized by RNA from normal control primary osteoblasts. RNA was of high quality and was non-degraded. (Table 1)

As evidenced by the increased expression of multiple markers of osteoblast maturation and function and by correlations with osteoblastic genes involved in cell-signaling from bone cores, osteoblast function is dysregulated in CKD and primary osteoblasts retain these characteristics ex vivo. Whether these factors differ in different subtypes of ROD and whether they translate into alterations apparent in mature osteocytes remain to be evaluated.

Reciprocal Control of Adipogenesis and Osteogensis by ERK/MAP Kinase Phosphorylation of PPARg In Vitro and In Vivo. Chunxi Ge*[1], Guisheng Zhao[2], Hui Li[2], Binbin Li[2], Renny Franceschi[3]. [1]Pom Univ of Michigan School of Dentistry, USA, [2]University of Michigan School of Dentistry, USA, [3]University of Michigan, USA

Osteoblasts and adipocytes differentiate from a common mesenchymal stem cell (MSC). Accumulating evidence suggests a reciprocal relationship between osteogenesis and adipogenesis mediated by the relative activity of PPARg and RUNX2. Increased PPARg activity stimulates adipogenesis and suppresses osteogenesis while excess RUNX2 has the opposite effect. The ERK/MAPK pathway stimulates MSC commitment to osteoblasts and inhibits adipogenesis. This effect is explained by phosphorylation of RUNX2 and PPARg at specific serine residues (S301/S319 for RUNX2, S112 for PPARg) leading to stimulation of RUNX2 transcriptional activity and inhibition of PPARg (Ge et al. JBMR 27:S23, 2012).

To examine the importance of PPARg phosphorylation in the reciprocal control of MSCs, knock-in mice harboring a S112A mutation in PPARg rendering it resistant to ERK/MAPK inhibition (Ragwala et al, Dev Cell 5:657,2003) were examined for in vitro and in vivo adipogenesis and osteogenesis. Calvarial osteoblasts, marrow stromal cells (MSCs) or ear mesenchymal stem cells (EMSCs) isolated from wild type, heterozygous and homozygous PPARg S112A mice were grown under osteogenic or adipogenic conditions and differentiation was assessed by Alizarin Red or Oil Red O staining and measurement of marker gene expression. Bone density from new born and 3 month old mice was assessed by microCT.

Overall BMD of new-born mice was dramatically decreased in homozygous PPARg S112A mice compared to wild type litter mates. Wider calvarial sutures and delayed maturation of multiple bones was also observed. Analysis of 3 month old S112A mice revealed a decrease in BV/TV in tibia accompanied by decreased trabecular thickness and increased trabecular spacing with no apparent change in cortical bone. Cell culture studies using primary calvarial osteoblasts, MSCs and EMSCs from wild type and mutant mice revealed that the PPARg S112A mutation increased adipocyte differentiation (increased Oil Red O staining and induction of PPARg, C/EBP, Adiponectin and AP2 mRNA) and suppressed osteoblast differentiation (decreased Alizarin Red staining and Runx2, OCN and BSP mRNA). Interestingly, even under osteogenic conditions, calvaria osteoblasts from homozygous S112A mice spontaneously differentiated to adipocytes.

These studies indicate that ERK/MAP dependent phosphorylation of PPARg affects bone as well as fat development.

Small Interfering RNA Targeting Smad1 suppresses osteoclast differentiation. Yoshihiro Yoshikawa*, Eisuke Domae, Seiji Goda, Isao Tamura, Aiko Kamada, Takashi Ikeo. Osaka Dental University, Japan

Bone morphogenetic protein 2 (BMP-2) plays a critical function in the differentiation of bone cells. It has also been suggested that BMP-2 promotes osteoclast differentiation. BMP-2 phosphorylates Smads (R-Smads), including Smad1. Smads play central roles in the downstream signaling effectors of BMP receptors. However, it is unclear whether Smad1 is involved in osteoclast differentiation.

To examine the effects of Smad1 on osteoclast differentiation, we cocultured bone marrow (BM) cells isolated from mouse tibia and primary osteoblasts (POB) isolated from calvaria of newborn mice and performed tartrate-resistant acid phosphatase (TRAP) staining. We evaluated expression of genes by real-time PCR and proteins by Western Blot and immunofluorescence in the presence of 10^{-8} M $1,25(OH)_2D_3$ and 100 ng/ml BMP-2 in POB. In addition, mouse osteoblast-like cells (MC3T3-E1) were transfected with vitamin D receptor element (VDRE)-Luc reporter construct and POB were transfected with siRNA (Smad1) using siRNA transfection reagents. Subcellular localization of Smad1 and vitamin D receptor (VDR) was detected by a fluorescence-based assay in MC3T3-E1.

Results showed that BMP-2 alone had no effect, but BMP-2 upregulated numerous TRAP-positive multinucleated osteoclasts formation when combined with $1,25(OH)_2D_3$. The differentiation of BM cells into osteoclasts was significantly suppressed by Smad1 siRNA. In addition, BMP-2 upregulated the mRNA expression of the VDR target gene receptor activator of nuclear factor-κB ligand (RANKL) in POB. It also upregulated transcription of a reporter gene in a VDRE-dependent manner in MC3T3-E1.Similarly, mRNA expression of RANKL was significantly suppressed by Smad1 siRNA. Next, we examined whether BMP-2 affected nuclear translocation of VDR. VDR acts as a transcription factor, which requires nuclear translocation. BMP-2 increased the expression of VDR protein and promoted nuclear translocation of VDR in MC3T3-E1.

We suggest that Smad1 not only promotes osteoblast differentiation, but also promotes osteoclast differentiation by interacting with VDR.

The Osteoblast Negative Regulator, BRM-SWI/SNF, is a Positive Regulator of Adipocyte Differentiation. KEVIN HONG NGUYEN*[1], FUHUA XU[2], Stephen Flowers[3], Shruti Goel[1], Elizabeth Moran[4]. [1]Department of Orthopaedics & NJMS-UH Cancer Center, UMDNJ, USA, [2]New Jersey Medical School, UMDNJ, USA, [3]NJMS-UH Cancer Center, University of Medicine of Dentistry of New Jersey, USA, [4]University of Medicine & Dentistry of New Jersey, Cancer Center, USA

The chromatin remodeling complex SWI/SNF, with its core ATPase BRG1, is required for tissue-specific gene expression. A subset of SWI/SNF, powered by the alternative ATPase BRM, generally has auxiliary effects. In osteoblast precursors, BRM-SWI/SNF represses tissue-specific gene expression, preventing premature induction of osteogenic genes whose activation is BRG1-dependent and BRM-independent. The role of BRM in other lineages derived from bone marrow stromal cells (BMSCs) is largely unknown, but its role in adipocyte differentiation is of particular interest because an improper balance of adipocyte *versus* osteoblast differentiation underlies certain skeletal pathologies. To address this question, stable knockdown lines targeting BRM or BRG1 were generated in 3T3-L1 preadipocytes. In contrast to their opposing roles in osteoblasts, BRM and BRG1 are both required for adipogenesis. Depletion of either BRM or BRG1 has a similar effect in inhibiting adipogenesis and expression of key early and late adipocyte markers, whose promoters they co-target. The finding of opposing roles for BRM in osteoblast *versus* adipocyte differentiation suggests a future possibility of targeting BRM to perturb the fate of BMSCs so as to increase bone formation and reduce bone marrow adiposity *in vivo*.

Accumulation of Menaqunone-4 in the Bones of Mice Orally Given K Vitamers and Its Biological Activity in Osteoblasts. Kimie Nakagawa*[1], Yoshitomo Suhara[2], Toshio Okano[1]. [1]Kobe Pharmaceutical University, Japan, [2]Shibaura Institute of Technology, Japan

Aims: Vitamin K serves as a cofactor for gamma-glutamyl carboxylase (GGCX) that converts glutamate residues to gamma-carboxyglutamate residues in vitamin K-dependent proteins. Thus, vitamin K may exert beneficial effects on bone formation and remodeling. There are two forms of naturally occurring vitamin K, phylloquinone (PK) and menaquinones (MK-n). Moreover, menadione (MD) is a synthetic compound lacking a side chain. Clinically, menaquinone-4 (MK-4) has been shown to prevent bone fractures in osteoporotic patients although the mechanism underlying the suppression of bone fractures by MK-4 remains unclear. Recently, we identified a novel enzyme, UbiA prenyltransferase domain containing 1 (UBIAD1) that is responsible for the conversion of PK to MK-4 in mammals [*Nature* (2010), 468:117]. In the present study, we examined whether orally given K vitamers are converted to MK-4 and accumulate in the bones of mice. We also examined the biological activities of K vitamers in terms of the steroid and xenobiotic receptor (SXR)-mediated transcriptional activity and GGCX activity in human osteoblast like MG-63 cells.

Methods: Female mice, 8 weeks of age, were given orally deuterium (D)-labeled–K vitamers at the single dose of 10 μmol/kg body weight. After 24 h, the mice were sacrificed, and femur were collected and the concentrations of MK-4-d_7 were measured by LC-APCI-MS/MS. MG-63 cells were treated with PK-d_7 and MD-d_8 at the concentration of 10^{-6} M for 24 h, and the concentrations of MK-4-d_7 were measured by LC-APCI-MS/MS. SXR-mediated transcriptional activity and GGCX activity were measured by a SXR-GAL4 hybrid luciferase assay and an enzyme assay using mouse liver microsomes, respectively. Regulatory activities of K vitamers on proliferation and differentiation of MG-63 cells were examined by WST-1 assay and von Kossa staining, respectively. Results and Discussion: Accumulation of MK-4-d_7 in the bones of mice orally given D-labeled K vitamers was consistently observed in all mice tested and the amounts of MK-4-d_7 were almost similar among the animals. This finding suggest that MK-4 is a common metabolite of K vitamers in mice. Among the K vitamers, MK-4 exhibited the highest biological activity not only in the transcriptional activity and GGCX activity but also regulation of proliferation and differentiation of MG-63 cells. This finding strongly suggests that MK-4 may be an active metabolite of vitamin K and play an important role in osteoblast function.

Both SOST and SOSTDC1 Bind to E1 Domain of LRP5 and Inhibit Wnt/b-catenin Signaling in MC3T3E1 Cells and INS-1 Cells. Mi Jeong Lee*[1], Sung Kil Lim[2], Eun Jin Kim[2], Myung Jin Lee[2], Han Seok Choi[3], Si Hoon Lee[4]. [1]Yonsei University Health System, South Korea, [2]Yonsei University, South Korea, [3]Dongguk university, South Korea, [4]Gachon university, South Korea

Wnt/ b-catenin signaling is important for bone development and osteoblast differentiation and it is also involved in pancreas development, islet function, and insulin production and secretion. SOSTDC1 is expressed in pancreas as well as bone during early embryonic period. SOSTDC1 has moderate homology with Sclerostin, and both SOSTDC1 and Sclerostin inhibit Wnt/b-cateninsignaling in in-vitro assays by binding to YWTD propeller 1 and 2 of LRP5 or LRP6. Recently, Sclerostin-neutralizing monoclonal antibodies have been developed to inhibit binding of Sclerostin to bind the LRP5,6 receptors, resulting in activation of Wnt/b-catenin signaling pathway. To study the inhibitory potency of SOSTDC1 and abrogation capacity of Sclerostin inhibitors on Wnt//b-cateninsignaling and insulin secretion, we expressed Sclerostin and SOSTDC1 in E-coli as a fusion protein and insect cells, and E1 domain of LRP5 was also expressed as a fusion protein in E-coli, and tested the effects of known oligopeptide-DKK1 or SOST inhibitors in MC3T3E1-Top flash reporter cells and INS-1 cells transfected with LEF-TCF reporter DNA. In XPR-36 analysis, Sclerostin and SOSTDC1 revealed a comparable binding activity to E1 domain of LRP5. Wnt3a and Wnt7a stimulate Wnt/b-catenin signaling in both MC3T3E1 and INS1 cells. Furthermore both Sclerostin and SOSTDC1 could inhibit Wnt3a induced Wnt//b-catenin signaling in MC3T3E1-Top flash reporter cells and INS-1 cells with comparable potency. Interestingly, a lineal oligopeptide did not show any abrogating activity at all, meanwhile a cyclized oligopeptide abrogated Wnt/ b-cateninsignaling inhibited by Sclerostin but not by SOSTDC1, which indicated that the binding site of SOSTDC1 on E1 domain of LRP5 might be little different from that of Sclerostin. We are now studying the effects of Sclerostin, SOSTDC1, and Dkk1 or SOST inhibitors on insulin secretion in INS-1 cells.Key words: Sclerostin, SOSTDC1, Wnt signaling, insulin

Dock7 plays an Integral role in the Adhesion, Migration and Morphology of Osteoblasts. Kathleen Bishop*[1], David Maridas[1], Katherine Motyl[1], Clifford Rosen[2]. [1]Maine Medical Center Research Institute, USA, [2]Maine Medical Center, USA

Dock7 is a guanine nucleotide exchange factor (GEF) important in neuronal cell function and axon tracking; however, little is known about the role of Dock 7 in bone remodeling. Mice with an insertion in the Dock7 locus, the Misty mouse, have undetectable Dock7 protein levels. Loss of Dock7 expression in the Misty model resulted in a low bone mass phenotype and accelerated age related bone loss, possibly related to both non-cell autonomous factors (i.e. increased sympathetic tone) and cell autonomous defects. In support of the latter, Misty mice have decreased osteoblast and bone lining cell numbers, but increased osteoclast and marrow adipocyte numbers by histomorphometry. In order to further elucidate the role of Dock7 in bone, primary bone marrow stromal cells (BMSCs) were isolated from 6-8 wk old mice and expanded *ex vivo* in culture. Osteogenic differentiation was impaired in cells from the Misty mouse as shown by decreased Von Kossa and alkaline phosphatase staining while osteoclast differentiation was accelerated. Cell migration was evaluated using Collagen I coated Boyden chambers in serum free media. Misty BMSCs showed decreased cell migration onto the Collagen I matrix compared to cells isolated from control mice. As cell mobility is heavily dependent on the strength of cell attachment, cell adhesion was assessed. Both control and Misty BMSCs were incubated on Collagen I or Fibronectin coated plates and non-adherent cells were removed once cells began to attach and adherent cells counted. BMSCs from Misty mice had increased adhesion on both matrices when compared to cells from control mice suggesting a differential expression and/or function of adhesion complex proteins and likely an increased expression of both Collagen- and Fibronectin-binding integrins. In support of these data, analysis of the F-actin cytoskeleton in Misty BMSCs by immunocytochemistry suggests decreased cell spreading and a more cuboidal morphology. The delay in cell migration associated with increased cell adhesion and changes in cell morphology in Misty BMSCs points to a novel cell autonomous role for Dock7 in mesenchymally derived bone cells and may contribute to the skeletal changes observed in the Misty mouse. Alterations in cell adhesion may be the principal mechanism of decreased migration observed with Dock7 deficiency and could play a role in the osteoclastic recruitment of osteoblasts to sites of bone remodeling within the bone microenvironment.

Macrophage Stimulating Protein Stimulates Osteoblast Differentiation via ERK Signaling Pathway. Byung-Chul Jeong*[1], Hyuck Choi[2], Jeong-Tae Koh[3]. [1]Chonnam National University School of Dentistry, South Korea, [2]Post-doctoal fellowship, South Korea, [3]Chonnam National University, South Korea

Macrophage-stimulating protein (MSP) plasys an important role in calcium homeostasis and skeletal mineralization in zebrafish. However, the precise role of MSP in osteoblast differentiation is not fully understood. In this study, we examined the effects of MSP on osteoblast differentiation using mesenchymal C3H10T1/2 and pre-osteoblast MC3T3-E1 cells. Expression of Ron receptor for MSP is significantly increased during osteoblast differentiation. Introduction MSP peptide increases the gene exprssion of osteogenic markers including alkaline phosphatase (ALP), osteocalcin (Ocn), Type I collagen (Col 1a), osterix (Osx) and Runx2, and ALP staining was enhanced as well. Consequently, mineralized nodules formations were remarkably stimulated by MSP in a dose-dependent manner. Furthermore, treatment of MSP significantly enhanced ERK1/2 phosphorylation, and pre-treatment of ERK inhibitor PD98059 attenuated the osteoblast differentiation by MSP. Taken together, these data demonstrate that MSP is an regulator for promoting osteoblast differentiation via ERK1/2 MAPK signaling pathway.

Mechanism of Action for Cell Cycle and Apoptosis Regulatory Protein (CARP)-1 expression and Cytoplasmic Translocation by PTH in Differentiated Osteoblasts. Sonali Sharma, Varsha Das, Chandrika Mahalingam, Nabanita Datta*. Wayne State University School of Medicine, USA

The mechanisms underlying the actions of Parathyroid hormone (PTH) in osteoblast proliferation, differentiation, apoptosis and bone mass are complex and incompletely understood. PTH controls osteoblast cell cycle regulatory proteins and suppresses mature osteoblasts apoptosis. Cell Cycle and Apoptosis Regulatory Protein (CARP)-1 (aka CCAR1) is a novel regulator of apoptosis signaling by diverse agents including cell growth and differentiation factors. Our previous report identified significant presence of CARP-1 protein for the first time in osteocytes, osteoblasts (mice femora and calvariae), and MC-4 (MC3T3-E1 clone-4) osteoblastic cells. In this study Western blot analysis with anti-CARP-1 polyclonal antibody reveals that PTH down-regulates CARP-1 protein 2-3 fold in 7-day differentiated MC-4 cells or primary calvarial osteoblasts in a dose- and time-dependent manner compared to vehicle treated control cells. PMA, a protein kinase C (PKC) agonist, mimics PTH action, and the PKC inhibitor, GF109203X, partially blocks down-regulation of CARP-1, implying involvement of PKC. H-89, a protein kinase A (PKA) inhibitor, partially antagonizes PTH action suggesting PKA pathway to be a mediator of PTH inhibition of CARP-1 protein expression in differentiated osteoblasts. U0126, a MEK inhibitor, does not alter the effect of PTH, and SB208530, P-p38 inhibitor, attenuates PTH down-regulation of CARP-1 protein expression implying a P-p38 dependent and P-ERK independent mechanism. Immunofluorescence staining reveals nuclear to cytoplasmic translocation of CARP-1 protein in differentiated osteoblasts following PTH induction. The significance of CARP-1 protein translocation and its role in PTH regulation of apoptosis and bone anabolic action remains to be investigated. These findings highlight CARP-1 protein as a potential candidate in PTH signal transduction pathways in osteoblasts.

Osteoblast Differentiating Activities of Thyroxine (T4), 3,5,3'-triiodo-L-thyronine (T3) and Their Metabolites. Shaohong Cheng*[1], Weirong Xing[2], Sheila Pourteymoor[3], Subburaman Mohan[4]. [1]VA Loma Linda Health Care Systems, USA, [2]Musculoskeletal Disease Center, Jerry L. Pettis Memorial Veteran's Admin., USA, [3]Jerry L Pettis VA Medical Center, USA, [4]Jerry L. Pettis Memorial VA Medical Center, USA

Studies involving human genetic mutations and mutant mouse models involving production and actions of thyroid hormone (TH) have provided irrevocable evidence for a key role for TH in the regulation of skeletal growth. Thyroid glands predominantly secrete the pro-hormone, T4, which is deiodinated by iodothyronine deiodinase enzymes to generate active T3 and their inactive metabolites, 3,3',5'-T3 (reverse T3) and 3,3'-diodothyronine (T2). While T3 binds to TH receptors with higher affinity than T4, T4 occupied TH receptors has also been reported in the nucleus under euthyroid conditions raising the possibility that T4 bound nuclear receptors may be biologically relevant in thyroid syndromes with elevated free T4 and reduced T3 levels. We, therefore, evaluated the direct effects of T4, T3 and their metabolites (rT3 and T2) in stimulating osteoblast differentiation using MC3T3-E1 osteoblasts which do not produce detectable levels of deiodinases, thereby eliminating

the confounding effects caused by local conversion of T4 to T3. Under serum-free conditions, 24 hour treatment of MC3T3-E1 cells with TH caused a dose-dependent increase in osteocalcin (OC) mRNA levels with 1125 and 1050-fold increases at 100 and 1000 ng/ml T3 and T4, respectively. T2 and rT3 were less active with the potency of T3>T4>T2 >rT3. At circulating concentrations, T3 and T4 caused a similar increase in OC expression (approximately 100-fold) while T2 and rT3 had no significant effect. Treatment with T4, T3 and its metabolites also increased osterix expression (12-fold maximum, $P<0.01$) with dose effects comparable to that of OC expression. Besides the classical genomic mechanism of action of TH, there is evidence for non-genomic action of T4 involving integrin, $\alpha v\beta 3$. To determine if T4 and T3 effects on OC expression is mediated via activation of integrin signaling, we pretreated MC3T3-E1 cultures with inhibitors of integrin signaling, cycloRGDfv peptide (5 μM) or echistatin (20nM) prior to TH treatment. Surprisingly, inhibition of integrin signaling with both cycloRGDfv and echistatin increased the T3 and T4 effect on OC expression by 50-200% ($P<0.01$). Based on these data, we conclude that elevated T4 levels in the absence of T3 may exert stimulatory effects on osteoblast differentiation. The establishment of cell-specific effects of T4 on osteoblasts may provide a strategy to generate T4 mimics that exert skeletal specific effects without the confounding T3 effects on other tissues.

Utilizing hTERT-immortalized Primary Mouse Osteoblasts to Assess the Role of Cx43 in Osteoblast Signaling Pathways. Atum Buo*, Joseph Stains. University of Maryland, School of Medicine, USA

The coupling of osteoblasts by connexin43 (Cx43)-comprised gap junctions is critical for osteoblastogenesis and optimal bone formation. We have begun to define the molecular details that enable Cx43 to regulate osteoblast differentiation and function. Previously, using MC3T3-E1 osteoblast-like cells, we identified several signaling cascades that are affected by overexpression or knockdown of Cx43. Further, alterations of these signaling cascades modulate the activity of the essential osteogenic transcription factors Runx2 and Osterix. In this preliminary study, we used a recently reported human telomerase reverse transcriptase (hTERT)-immortalized primary mouse osteoblast cell line isolated from Cx43-null mice (MOB-Cx43KO) and a paired wild type control cell line (MOB-WT) (M. Thi *et al.*, *Am J Phys Cell Phys.* 2010) to determine if the effects observed in MC3T3-E1 cells translated into this more sophisticated cell system. We examined the hypothesis that the osteogenic defects characterized in Cx43-deficient cells are due to reduced signaling resulting in impaired Runx2 and Osterix activation. Confluent cultures of MOB-Cx43KO and MOB-WT cells were examined by western blotting for levels of Cx43, Runx2, Osterix, and key signaling molecules. To test the effects of growth factor signaling, cells were serum starved overnight and then treated with FGF2 for 0, 5, or 30 minutes and analyzed for phospho-extracellular signal-regulated kinase (pERK) and phospho-protein kinase C delta (pPKCδ) levels. Under standard culture conditions, we found that MOB-Cx43KO cells had reduced pERK and pPKCδ levels compared to MOB-WT cells. Runx2 abundance was unaffected by loss of Cx43. Conversely, Osterix expression was diminished in MOB-Cx43KO compared to MOB-WT cells. Additionally, MOB-Cx43KO cells displayed reduced pERK and pPKCδ levels relative to MOB-WT cells when treated with FGF2. These findings are consistent with our results in mouse MC3T3-E1 osteoblasts that implicate ERK and PKCδ as downstream mediators of the Cx43-dependent effects on Runx2 and Osterix activity. Future studies will examine Runx2 and Osterix recruitment to target osteoblast promoters by chromatin immunoprecipitation assays. In summary, our data support the hypothesis that the presence of Cx43 is needed for efficient basal and growth factor induced activation of ERK and PKCδ and highlight that this model (MOB-Cx43KO cells) is appropriate for more detailed mechanistic studies of Cx43 function in osteoblasts.

Active DNA demethylation controls osteoblastic and adipocytic differentiation. Roman Thaler*[1], Monika Rumpler[1], Ines Sturmlechner[1], Silvia Spitzer[1], Klaus Klaushofer[2], Franz Varga[1]. [1]Ludwig Boltzmann Institute of Osteology, Austria, [2]Hanusch HospitalLudwig Boftzmann Institute of Osteology, Austria

Osteoporosis is associated with reduced bone mass and increased bone marrow fat. Osteoblasts (OBs) and adipocytes differentiate both from mesenchymal stem cells and aberrantly increased adipocyte differentiation may trigger osteoporosis development.

Expression of several osteoblastic genes like osteocalcin (*Bglap2*), Msh homeobox 2 (*Msx2*), distal-less homeobox 5 (*Dlx5*) or alkaline phosphatase (*Alpl*) can be silenced by epigenetic DNA methylation of their promoters by DNA (cytosine-5-)-methyltransferases (DNMTs). The inverse process, namely active DNA demethylation by proteins of the Tet-methylcytosine-dioxygenase (TET) gene family emerges as a new and essential molecular mechanism controlling tissue development and cellular differentiation. We have recently demonstrated that activation of *Dlx5* expression via active DNA demethylation stimulates osteoblastic differentiation. Here we tested if active DNA demethylation modulates osteoblastic and adipocytic differentiation.

Pre- and differentiated OBs form calvaria of newborn mice were transfected with *Tet1* or *Tet2* siRNA and cultured in osteogenic medium for 2-3 weeks for mRNA and protein expression analysis and for mineralization assessment. 3T3-L1 pre-adipocytes were transfected with *Tet1* and *Tet2* siRNA and induced to adipocytic differentiation for 10 days. Thereafter, mRNA isolation and red oil O staining (fat droplet formation) were performed. Expression patterns of genes involved in DNA methylation and of genes implicated in active DNA demethylation were very similar between OBs and adipocytes during differentiation. Thus, expression of *Dnmt1* and TET1 was down regulated whereby *Dnmt3a* and *Tet2* were up-regulated during differentiation. Although cultured in osteogenic medium, knock down of both, *Tet1* and *Tet2* strongly induced fat droplet formation in pre- and in differentiated OBs. Moreover, *Tet2* knockdown significantly decreased expression of *Runx2*, *Lox*, *Col1a2* or *Bglap2* and strongly enhanced *Plin1* expression, a marker for mature adipocytes. In adipocytes, although cultured in adipocytic medium, knock down of both *Tet1* and *Tet2* dramatically decreased fat droplet formation and *Plin1* gene expression. Furthermore, expression of osteoblastic genes like *Runx2*, *Lox*, *Col1a2* or *Bglap2* was significantly increased. In summary, we found that expression of *Tet1* and *Tet2* maintains the osteoblastic and adipocytic phenotype, while knocking down these gene results in inversion of their differentiation status.

The involvement of genes responsible for active DNA demethylation in maintenance of the osteoblastic and adipocytic phenotype suggests active DNA demethylation as a central regulator for OB and adipocytic differentiation.

Constitutive Activation of NF-κB Impairs Osteogenesis and Skeletal Development. Yousef Abu-Amer[1], Gaurav Swarnkar*[2], Kaihua Zhang[3], Fanxin Long[4]. [1]Washington University in St. Louis School of Medicine, USA, [2]Washington University SOM, USA, [3]Washington University, USA, [4]Washington University School of Medicine, USA

Pathologic conditions impair bone homeostasis. The transcription factor NF-κB regulates bone homeostasis and is central to bone pathologies. Whereas contribution of NF-κB to heightened osteoclast activity is well-documented, the mechanisms underlying NF-κB impact on chondrocytes and osteoblasts are not well defined. In this study, we examined the effect of constitutively active IKK2 (IKK2ca) on chondrogenic and osteogenic differentiation. We show that retroviral IKK2ca but not GFP, IKK2WT, or the inactive IKK2 forms IKK2KM and IKK2SSAA, strongly suppressed differentiation of ST2 and ATDC5 cells. In order to explore the effect of constitutive NF-κB activation on bone formation in vivo, we activated this pathway in a conditional fashion. We crossed the R26StopIKK2ca mice with mice carrying the Col2-cre in order to express IKK2ca in osteoblasts (OB) and chondrocytes (CHC). Both CHCs and OBs derived from Col2Cre/IKK2ca expressed Flag-tagged IKK2ca as detected by western blot. Mice were born alive yet died shortly thereafter. Histologically, newborn Col2Cre+/RosaIKK2ca hets (Cre+/fw) and homozygotes (Cre+/ff) showed smaller skeleton, deformed vertebrate and reduced or missing digit ossification. The width of neural arches as well as ossification in vertebral bodies of Cre+/fw and Cre+/ff were reduced or diminished. H&E staining of proximal tibia from new born pups showed that Cre+/fw displayed disorganized hypertrophic zones within the smaller epiphysis. X-ray analysis of 4-wk old Cre+/fw and WT littermate showed that Cre+/fw mice have deformed and thinner vertebrate compared to WT littermates. Micro-CT analysis showed that 4-wk old Cre+/fw has abnormal trabecular bone in proximal tibia compared to WT littermate. Mechanistically, ex-vivo experiments show that expression of the differentiation marker alk phos in calvaria derived from newborn IKK2ca knock-in mice cultured in vitro under osteogenic conditions was diminished compared to WT-derived cells. Further, IKK2ca, but not GFP, inhibited cellular levels of b-catenin concomitantly with increased expression of RBPjk (mediator of Notch signaling). ISH studies showed that the hypertrophic chondrocyte marker type-X collagen (Col X), the pre-hypertrophic chondrocyte markers IHH and AP, and the early markers Aggrecan and type-II collagen (Col II) were reduced in Cre+/fw mice. Altogether, the in-vitro, in vivo and ex-vivo evidence suggest that IKK2ca perturbs osteoblast and chondrocyte maturation and impairs skeletal development.

Human Serine Protease HTRA1 is A Novel Mediator of Human Bone Marrow-Derived Stromal Cell Osteogenesis. Andre Tiaden*[1], Maike Breiden[2], Ali Mirsaidi[1], Fabienne Weber[1], Gregor Bahrenberg[1], Stephan Glanz[1], Paolo Cinelli[1], Michael Ehrmann[2], Peter Richards[3]. [1]University of Zürich, Switzerland, [2]University Duisburg-Essen, Germany, [3]CABMM, Zurich University, Switzerland

Human high-temperature requirement serine protease A (HTRA1) is a secreted member of the broadly conserved HTRA family of trypsin-like serine proteases. A prominent feature of this protein is its ability to degrade and modify a variety of extracellular matrix (ECM) proteins. As such, HTRA1 is now regarded as being an important mediator of musculoskeletal development and disease. In the current study, we aimed to establish a role for HTRA1 in bone formation by examining the effects of HTRA1 loss- or gain-of-function on human bone marrow-derived stromal cell (hBMSC) osteogenesis and subsequent mineral formation. Extracellular addition of recombinant HTRA1 enhanced osteogenesis of hBMSCs as evidenced by significant alterations in several osteogenic markers including integrin-binding sialoprotein (IBSP), bone morphogenetic protein 5 and sclerostin. HTRA1 also enhanced mineral formation in differentiating osteoblasts as shown by increased Alizarin red staining

and was dependent on its proteolytic activity. Conversely, matrix mineralization was completely abolished in these cultures following treatment with small interfering RNA (siRNA) specific for HTRA1. Immunofluorescence studies identified high levels of HTRA1 protein in association with IBSP at sites of newly formed bone mineral both in vitro and in vivo. Indeed, proteolytic enzyme assays confirmed IBSP as being a novel HTRA1 substrate. In contrast to its positive role in osteogenesis, HTRA1 imparted a negative effect on adipogenesis as demonstrated by its ability to significantly reduce lipid droplet formation in BMSCs undergoing adipogenic differentiation. This was confirmed by loss-of-function studies, where HTRA1 silencing resulted in a significant increase in the adipogenic potential of hBMSCs as demonstrated by increases in the expression levels of specific adipogenic markers including peroxisome proliferator-activated receptor gamma and fatty acid binding protein 4. This differential effect of HTRA1 on BMSC differentiation was further emphasized by its secretion profile, where increases in the levels of endogenous HTRA1 protein were observed during osteogenic differentiation only. In summary, our data reveals HTRA1 as being an essential requirement for osteogenesis. Its dual role as both an osteogenic promoter and an adipogenic inhibitor may have significant implications in terms of its functional involvement in diseases such as osteoporosis, where deficiencies in BMSC lineage commitment are evident.

LIF: A Mediator of Reciprocal Regulation by *Pkig* of Osteoblast and Adipocyte Differentiation. Xin Chen*[1], Bryan Hausman[1], Guangbin Luo[1], Guang Zhou[1], Shunichi Murakami[1], Janet Rubin[2], Edward Greenfield[1]. [1]Case Western Reserve University, USA, [2]University of North Carolina, Chapel Hill, School of Medicine, USA

The Protein Kinase Inhibitor (*Pki*) gene family inactivates nuclear PKA and thereby terminates PKA-induced gene expression. We previously showed that *Pkig* is the primary *Pki* expressed in osteoblasts. We also showed that *Pkig* knockdown significantly increases the effects of parathyroid hormone on PKA activation, rapid gene expression, and inhibition of apoptosis. More recently, we showed that PKA activation by *Pkig* knockout (KO) or knockdown reciprocally increases osteogenesis and inhibits adipogenesis. Leukemia Inhibitory Factor (LIF) is a PKA-regulated cytokine that can stimulate osteogenesis and inhibit adipogenesis. The goal of this study was therefore to determine whether LIF mediates the reciprocal regulation of osteogenesis and adipogenesis by *Pkig*. Murine Embryonic Fibroblasts (MEFs) from *Pkig* KO mice generated in our lab were compared with wild type MEFs. *Pkig* KO significantly increases nuclear PKA activation induced by forskolin and thereby significantly increases expression of *Lif* mRNA and LIF protein. An antibody that neutralizes mouse LIF significantly reduces the effects of *Pkig* KO on osteogenesis as determined by Alkaline Phosphatase (ALP) activity and staining, and Alizarin Red S staining of mineralization. The LIF antibody also significantly reduces the effects of *Pkig* KO on adipogenesis as determined by Oil Red O staining of lipid accumulation. Similar results were also obtained in mesenchymal stem cells (MSCs) following siRNA-mediated *Pkig* knockdown. Thus, real time RT-PCR for mRNA markers of osteogenesis (ALP and osteocalcin) and adipogenesis (PPARγ, C/EBPα, Adiponectin, and Leptin) showed that the LIF antibody significantly reduces the effects of *Pkig* knockdown on both osteogenesis and adipogenesis in murine marrow-derived MSCs. Moreover, an antibody that neutralizes human LIF significantly reduces the effects of *PKIG* knockdown on expression of ALP and osteocalcin mRNAs by human MSCs. In conclusion, our results show that the reciprocal regulation of osteogenesis and adipogenesis by *Pkig* is mediated, at least partially, by LIF.

Metformin stimulates compact bone mesenchymal stem cells and accelerates wound healing in a Type 2 Diabetes mouse model. Xin Li*[1], Satoko Matsumura[2], Yuqi Guo[2], Huawei Yuan[2], Wenbo Yan[3]. [1]New York University, USA, [2]New York University College of Dentistry, USA, [3]Nyack College, USA

Background: Type 2 diabetes (T2D) is associated with increased fracture in spite of having a normal or even higher bone mineral density. Multipotent mesenchymal stem cells (MSCs) in bone are critical in bone health and regeneration. It is possible that MSCs are impaired in T2D patients which leads to bone fracture. However, it is unclear whether and how hyperglycemia affect MSCs. Metformin, an anti-T2D medicine stimulates osteoblasts while inhibites osteoclasts. It has been suggested that metformin stimulates MSCs in bone marrow. Compact bone MSCs are more abundant and metabolically more active compared to bone marrow MSCs. However, effects of metformin on compact bone MSCs are unknown. We hypothesize that metformin helps to enhance population and function of MSCs residing in compact bone and improve bone metabolism and regeneration under T2D condition.

Methods: We evaluate the effects of metformin on compact bone MSCs *in vivo* and *in vitro* using male T2D MKR mice. MSCs derived from bone marrow flush or compact bone digestion were analyzed by flow cytometry with markers: $CD45^{low}$-$Ter119^{low}Sca1^{+}CD105^{+}CD29^{+}$. MSCs digested from compact bones were cultured with and without metformin *in vitro* for CFU-F, osteogenesis and adipogenesis assays. To study the effects of metformin on MSCs in T2D MKR mice *in vivo,* ten-weeks-old MKR mice were daily treated with vehicle or metformin for 14 days. The percentages of compact bone MSCs were determined and CFU-F, osteogenesis and adipogenesis were analyzed. To evaluate metformin effects on bone regeneration in 10-week-old MKR mice, we applied a drill-hole model in which an 8-μm hole was drilled in the left femur mid-diaphysis. After surgery, mice were randomly divided into two groups for a 14-day vehicle or metformin treatment. Femurs were analyzed by microCT and histomorphometry. Body weight and length, fat tissue weight, blood glucose, insulin levels in metformin treated mice were determined and compared with vehicle group. RNAs were isolated from MSC cultures, bone marrow flush and cortical bones for gene expression.

Results: In male MKR mice: (1) Compact bone digestion method yielded 10-fold higher MSCs population compare to bone marrow flush; (2) direct treated MSCs culture with metformin in vitro stimulates ALP and Runx2 expression; (3) Compact bone MSCs were stimulated in metformin treated mice: the population increased by 20%, proliferation increased by 3-fold and osteogenesis increased by 35% compare to vehicle treated mice; (4) Metformin facilitated wound healing process in hyperglycemic mice (Attached Fig); (5) Metformin regulated a panel of bone metabolism related genes including DMP-1, Runx2, PPARγ and ALP *in vivo*.

Conclusion: Our study suggests that by promoting compact bone MSCs proliferation and differentiation, metformin is a promising agent to maintain bone health and facilitate bone regeneration under T2D condition.

NF-κB RelB-/- Mice Have Enhanced Mesenchymal Progenitor Cell Differentiation and Fracture Repair. Zhenqiang Yao*[1], Yanyun Li[2], Lianping Xing[1], Brendan Boyce[2]. [1]University of Rochester, USA, [2]University of Rochester Medical Center, USA

Fracture repair recapitulates aspects of endochondral ossification with mesenchymal progenitor cell (MPC) differentiation into chondroblasts and osteoblasts (OBs) to bridge fracture gaps followed by callus remodeling by osteoclasts (OCs) to complete fracture repair. NF-κB RelA promotes MPC proliferation and inhibits differentiation of mature OBs, but the role of RelB in MPC differentiation or bone repair is unknown. We derived CD45-Sca-1+ MPCs from WT and RelB-/- mouse long bones (bMPCs). WT and -/- bMPCs express MPC marker, CD105 (51% and 61%, respectively). RelB-/- bMPCs have enhanced differentiation into ALP+ OBs (32 ± 4 vs 15 ± 1/mm2, $p<0.05$) and chondrocytes (42 ± 5 vs 9 ± 3 cells per pellet), the latter associated with early increased Sox9 mRNA expression and larger chondrocyte pellets than WT cells. We performed closed femoral fractures in 2-month-old WT and RelB-/- mice and found significantly increased bone volume in the callus evaluated by μ-CT in RelB-/- mice at day 14 (BV/TV 12 ± 3 vs 8 ± 3% vs WT, $p<0.05$), but not at day 21. Histomorphometry showed that the area of total callus, cartilage and woven bone were also significantly increased in RelB-/- mice at day 14 (2.7 ± 0.8 vs 1.5 ± 0.7 mm2, 0.9 ± 0.4 vs 0.3 ± 0.2 mm2 and 0.8 ± 0.1 vs 0.56 ± 0.14 mm2 vs WT mice, respectively). By 21 day, cartilage had been resorbed in both mice, but there was more woven bone in sections from RelB-/- than WT mice. Fracture callus in RelB-/- mice had significantly more OCs at day 21 (170 ± 54 vs 79 ± 49/mm2,$p<0.05$) when the woven bone is being actively remodeled, and spleen cells from RelB-/- formed more OCs and resorption pits in vitro. Quantitative RT-PCR mRNA expression levels of Sox9, Osx and Runx2 were significantly higher in fracture callus at day12 in RelB-/- than in WT mice. RelA directly targets Sox9 to stimulate chondrocyte proliferation and differentiation and also promotes Osx activation. We found that RelA protein levels and nuclear translocation were significantly increased in RelB-/- MPCs. Importantly, RelB formed a complex with RelA in WT MPCs and dose-dependently inhibited RelA-induced Sox9 and Osx luciferase activity in ADTC and C2C12 cells. In

summary, RelB-/- MPCs have enhanced chondro- and osteoblast differentiation and RelB-/- mice have accelerated fracture callus formation and remodeling. Inhibition of RelB in MPCs could be novel strategy to enhance fracture repair.

No correlation between in vitro osteogenic differentiation of MSCs and hip implant healing. Jessica Alm*, Niko Moritz, Hannu Aro. University of Turku, Finland

Mesenchymal stem cells (MSCs) are involved in the osseointegration of cementless total hip arthroplasty (THA). A recent study showed that aging, low BMD and geometric changes of the proximal femur are risk factors for early migration and delayed osseointegration of femoral stems in postmenopausal female THA patients. Individual variations in MSCs reservoirs and functional capacity may also influence the speed of osseointegration. We asked how the in vitro proliferative and osteogenic capacities of MSCs reflect in the magnitude of initial stem migration and time point for osseointegration.

A cohort of 19 women with primary hip osteoarthritis (mean age 64 years, range 41-78) underwent successful preoperative analysis of bone marrow-derived plastic adherent MSCs as well as a two-year radiostereometric analysis (RSA) of stem migration after cementless THA. Stem migration was defined as micromotions exceeding the precision values of RSA measurements (0.40 mm for translation vector and 1.32 degrees for rotation vector). The growth kinetics of MSCs was evaluated by calculating population doublings (PD). Osteogenic capacity was evaluated by analyses of alkaline phosphatase (ALP) expression and mineralization after culturing in osteogenic medium. Associations between MSC parameters and the magnitude of RSA stem migration were analyzed with linear correlations and with partial correlation controlling for confounding factors (age and canal flare index). MSCs of younger fracture patients (F/M 8/5, mean age 37 years, range 19-60) served as the reference for the MSC capacities of the THA patients and the comparisons were made using Student's t-test and ANCOVA with adjustment for age.

As an indicator of age-related decline in MSC capacities of THA patients, PD-rate, average ALP and von Kossa stained areas were around 50% of the reference values. There were no significant correlations between the in vitro assayed osteogenic or proliferative capacity of the patients' MSCs and the magnitude of stem migration or time point for osseointegration.

This study represents a first attempt of comparing in vitro osteogenic properties of MSCs with clinical implant healing in vivo. Against our hypothesis, decreased osteogenic capacity of MSCs did not reflect in stem migration or delayed osseointegration in this female cohort. These findings support the concept that non-biological factors such as physiological loading predominate in dictating the progress of femoral stem osseointegration.

Novel Potent Lactam Acetylene EP_4 Agonists Stimulate Alkaline Phosphatase Production and Differentiation in Bone Marrow Cells. Stephen Barrett*[1], Gregory Endres[1], Thomas Owen[2], Adam Uzieblo[1], Bradlee Germain[1], Andrei Kornilov[1], Joseph Colombo[1], James Kramer[1], Liyue Huang[1], Jeffrey Johnson[1], Jim O'Malley[2]. [1]Cayman Chemical Company, Inc., USA, [2]Myometrics, LLC, USA

The prostaglandin E G-protein coupled receptors (GPCR) subtypes 2 and 4 (EP_2 and EP_4 receptors, respectively) are stimulated by interaction with two eicosanoid products of the cyclooxygenase-catalyzed pathway, prostaglandin E_1 (PGE_1) and prostaglandin E_2 (PGE_2), and signal by increasing intracellular cAMP levels. Expression of EP_2 and EP_4 receptors in human bone and their roles in differentiation, growth, and remodeling have been previously investigated. Although the presence and function of the EP_2 receptor remains ambiguous, the clear significance of the EP_4 receptor in bone anabolism has been demonstrated through the extensive drug discovery work prosecuted on the target in the form of both systemic and locally-administered selective EP_4 agonists. Most initial osteoporosis programs focused on generating agonists with high systemic exposure and selectivity for EP_2/EP_4 versus EP_1 and EP_3. Substituted g-lactam (pyrrolidinone) derivatives that structurally mimic the carbocyclic prostaglandin scaffold were found to possess notable selectivity for EP_4 over the other EP receptor subtypes, especially EP_1. As the osteoporosis development programs were failing for safety reasons associated with their systemic exposures, attention shifted to localized delivery of anabolic agents to bone, resulting in the approval of the costly recombinant human bone morphogenetic protein 2 (BMP-2) for orthopedic indications. We have prepared and screened a novel potent series of g-lactam derivatives designed to maximize selectivity for EP_4 versus EP_1, EP_3, and other prostanoid receptors and to minimize systemic exposure through localized administration to bone in suitable delivery matrices and rapid metabolic elimination. These compounds were first tested for cellular activity by measuring cAMP formation following treatment of EP_4 transfected cells and by measuring SEAP formation following treatment of EP_2 transfected cells. Compounds of interest were then tested for their ability to stimulate osteoblastic differentiation of primary rat bone marrow cells.

Osteoanabolic Effect of Alendronate and Zoledronate on Bone Marrow Stromal Cells (BMSCs) Isolated from Senile Osteoporotic Patients and its Implications for their Mode of Action in the Treatment of Age-related Bone Loss. Richard Lindtner[1], André Tiaden[2], Konstantin Genelin[1], Hannes Ebner[1], Claudia Manzl[1], Marina Klawitter[2], Ingrid Sitte[1], Brigitte von Rechenberg[2], Michael Blauth[1], Peter Richards*[3]. [1]Innsbruck Medical University, Austria, [2]Zurich University, Switzerland, [3]CABMM, Zurich University, Switzerland

The primary purpose of this study was to evaluate the osteogenic potential of human bone marrow stromal cells (hBMSCs) isolated from aged osteoporotic patients following *in vitro* and/or *in vivo* exposure to aminobisphosphonates.

The influence of aminobisphosphonate treatment on hBMSC osteogenesis was assessed by the quantitative measurement of alkaline phosphatase (ALP) activity and qRT-PCR analysis of known osteogenic markers. Mineralized matrix formation by hBMSC-derived osteoblasts was visualized and quantified using Alizarin red staining.

No significant changes in cell viability or proliferation were observed in hBMSC cultures treated for up to 72 hours with zoledronate (10 and 100 nM) as assessed by the Annexin V and WST-1 assays respectively. Human BMSC cultures treated with osteogenic medium supplemented with zoledronate demonstrated a significant increase in Alizarin red staining after 3 weeks as compared to cells cultured in osteogenic medium alone. Similarly, cultures of differentiating hBMSCs isolated from patients receiving alendronate treatment also demonstrated an increased propensity for osteoblastogenesis, even in the absence of further *in vitro* stimulation by zoledronate. The stimulatory effects of aminobisphosphonate treatment on hBMSC osteogenic potential were independent of any alterations in ALP activity, although significant changes in the mRNA expression levels of osteocalcin and osteopontin were evident in hBMSCs following either *in vitro* or *in vivo* exposure to aminobisphosphonates.

The results presented here demonstrate for the first time that aminobisphosphonate treatment of osteoporotic hBMSCs *in vitro* or *in vivo* enhances their capacity for osteoblast formation and subsequent mineral deposition, thus supporting the concept of aminobisphosphonates as having an osteoanabolic effect in senile osteoporosis.

P2X7 receptors – do they have a role in commitment of mesenchymal stem cells?. Solveig Petersen*[1], Susanne Syberg[2], Peter Schwarz[2], Niklas Jorgensen[3]. [1]Research Center for Ageing & Osteoporosis, Departments of Diagnostics & Medicine, Glostrup Hospital, Denmark, [2]Glostrup Hospital, Denmark, [3]Copenhagen University Hospital Glostrup, Denmark

The purinergic P2X7 receptor is an ATP-gated ion-channel that is primarily expressed in cells of hematopoietic origin such as osteoclasts and macrophages. It is also expressed in mature osteoblasts and is involved in the regulation of bone metabolism. We have previously reported that P2X7 null mice have increased body weight and that expression of markers of bone- and fat metabolism are altered in bone marrow isolated from P2X7-null mice compared to wild type mice. However, no reports have demonstrated the role of the P2X7 receptor in the determination of phenotype of adult mesenchymal stem cells, nor the role of the receptor in regulation of fat metabolism. The aim of this study was therefore to demonstrate the expression of P2X7 receptors in fat cells and to determine the role of the receptor in the differentiation of adipocytes versus osteoblasts.

White and brown fat tissue was isolated from wild type BALB/cJ mice. Expression of RNA coding for the P2X7 receptor was determined using reverse-transcriptase polymerase chain reaction (RT-PCR). P2X7 receptor protein expression was determined by Western Blotting and immune-staining. Mesenchymal stem cell differentiation into osteoblasts and adipocytes was determined using real-time PCR determination of expression of RUNX-2 and PPAR-gamma genes and by staining with and Oil-Red O and Alizarin Red , respectively.

RT-PCR made on RNA isolated from white and brown fat tissue from the mice showed expression of P2X7 receptors in white fat tissue from both intestinal and subcutaneous fat, while brown fat only expressed low levels of P2X7 receptors. When determining expression of the P2X7 receptor protein a similar picture was found. – white fat from both the intestinal and subsutaneous compartments expressed high levels of P2X7 receptor protein while brown fat only expressed very small amounts of receptor protein. Experiments determining the role of P2X7 receptors in commitment of bone marrow-derived mesenchymal cells into either adipoctyes or osteoblasts are currently ongoing.

In conclusion, P2X7 receptors are expressed in high amounts in white fat tissue while only small amounts are expressed in brown fat. P2X7 receptors might play an important role in determining the fate of mesenchymal stem cells and in the regulation of fat and energy metabolism.

Pulsed Electromagnetic Field Stimulates Human Osteoblastic Cells and Inhibits Human Osteoclastic Cells. Nicola Partridge*, Zhiming He. New York University College of Dentistry, USA

The beneficial therapeutic effects of low energy, time varying pulsed electromagnetic fields (PEMFs) have been widely documented to treat therapeutically resistant problems of the musculoskeletal system, though its mechanisms remain unclear. Our previous work has shown the PEMF (by Orthofix, Inc.) effects on stimulating both cell proliferation and early differentiation in rat calvarial osteoblastic (OB) cells. Here we have studied the effects of PEMF (by Orthofix, Inc.) on human bone marrow stromal cells (hBMSCs) differentiated to OB cells and human bone marrow monocytic cells (hBMMs) differentiated to osteoclasts (OCs) as well as some of the mechanisms of action of PEMF. Fresh hBM samples were obtained from the iliac crest of females (27-65 years old). Purified mononuclear cells were used to acquire stromal and non-adherent monocytic cells. Both types of cells were treated with/without 4h daily PEMF exposure. PEMF significantly stimulated proliferation of pre-OBs from young women. ERK/MAPK activation was seen after 30-60 min of PEMF exposure on day 5 of culture (paralleled by stimulation of cyclin A). PEMF stimulated early gene expression and mineralization of BMSCs from young women, but less so for a postmenopausal woman. Gene expression analysis of PEMF vs. control with hBMSCs of the 27 year old woman using Affymetrix GeneChip Arrays (HG-U133 P2) showed 37 and 173 known genes with at least 1.5 fold changes were regulated by PEMF in the differentiation and mineralization stages, respectively. Gene ontology analysis showed that differentially expressed genes were mainly involved in transcription, cell cycle, transport, signal transduction, metabolic processes, growth factors, etc. In contrast, PEMF had striking inhibitory effects on OCs from cells of older women (50-65%) which were greater than the inhibitory effects seen with cells from a younger woman (22%). In all cases, there was a significant inhibition of OCs formed. This was paralleled by OC gene marker results. In conclusion, PEMF stimulates proliferation, ERK activation and early gene expression and mineralization of human pre-OBs from BMSCs of young women and microarray analysis shows a pattern of PEMF-regulated gene expression. PEMF inhibits human female OC formation at all ages, with greatest effects on cells from older subjects. Thus, PEMF may be very effective for bone mass maintenance for potential reduction in adjacent vertebral compression fractures in spinal fusions.

The Nuclear Envelope Protein Emerin Regulates Mesenchymal Stem Cell Differentiation. Sandra Bermeo*[1], Christopher Vidal[1], Wei Li[2], Gustavo Duque[3]. [1]University of Sydney, Australia, [2]University of Sydney, Nepean Clinical School, Australia, [3]Ageing Bone Research Program, University of Sydney, Australia

Emerin is a nuclear envelope protein required for the regulation of diverse nuclear functions including cell differentiation and protein translocation. We have previously reported that other proteins of the nuclear envelope, such as lamin A and MAN1, play an essential role in mesenchymal stem cell (MSC) differentiation and thus in the pathophysiology of age-related bone loss and osteoporosis. However, the role of emerin in MSC differentiation remains unknown. Since the proteins of the nuclear envelope are in constant interaction, and since emerin has shown to be an important regulator of β-catenin trafficking in other cell models, we therefore hypothesized that emerin is also required in MSC differentiation. Human MSC (Lonza, Switzerland) were induced to differentiate into either osteoblasts or adipocytes. Emerin gene was knocked down using 20nM of siRNA Emerin (Santacruz), with transfections performed at day 1, 3 and 6 of differentiation. Transfection efficiency showed an emerin gene expression of 20% at days 3, 6 and 9 of differentiation. Osteogenesis was decreased as demonstrated by significantly reduced alkaline phosphatase and alizarin red staining and quantification when compared with control siRNA-transfected cells ($p<0.01$). Additionally, osteogenic markers evaluated by RT-PCR showed down regulation of alkaline phosphatase and osteoprotegerin gene expression. In addition, confocal microscopy identified alterations in the expression and localization of lamin A, MAN1 and β-catenin together with changes in the nuclear shape and actin fibers disposition in emerin siRNA-transfected MSC. On the other hand, adipogenesis was significantly increased as a result of the lack of emerin expression as demonstrated by a significantly higher number of adipocytes ($p<0.01$), oil red O staining ($p<0.01$), and significantly lower expression of adipogenic genes ($p<0.01$) in emerin siRNA-treated cells. In summary, emerin is essential in MSC differentiation. Low levels of emerin expression affect the proper differentiation of MSC towards the osteogenic lineage, alter the interaction between the proteins of the nuclear envelope involved in osteogenesis, block osteogenic signals, and favor adipogenesis. We therefore conclude that emerin plays an important role in the pathophysiology of age-related bone loss and osteoporosis that deserves further investigation.

Transcriptional control of bone and fat lineage determination by Zinc finger protein 521 (Zfp521). William Addison*[1], Martin Fu[1], Helen Yang[1], Zhao Lin[1], Francesca Gori[2], Roland Baron[3]. [1]Harvard Medical School & Harvard School of Dental Medicine, USA, [2]Harvard School of Dental Medicine, Massachusetts General Hospital, USA, [3]Harvard School of Medicine & of Dental Medicine, USA

Osteoblasts and adipocytes arise from a common mesenchymal precursor cell. The cell-fate decision of a mesenchymal precursor cell is under the influence of multiple molecular cues and signaling pathways that are integrated into the activation or repression of lineage-specific transcription factor expression and/or activity. Epigenetic events, characterized by histone modifications on chromatin, determine the transcriptional status of these lineage-specific master transcription factors. Little is known about the epigenetic regulatory mechanisms that repress transcription factors of alternate lineages during differentiation. In this study, we examined the role of Zfp521, a regulator of lineage progression in multiple immature cell populations and a key promoter of osteoblastogenesis (Hesse et al., 2010; Kiviranta et al., 2013), on lineage specification in mesenchymal progenitor cells during BMP-induced differentiation. Knockdown of Zfp521 in stromal cells resulted in increased expression of the master adipocyte commitment and transcription factors, Zfp423 and PPARγ. This was associated with reduced Histone H3K9 methylation and increased H3K9 acetylation at their promoter regions, an epigenetic signature typical of transcriptionally active chromatin. This demonstrates that Zfp521 deletion led to derepression of transcriptional activity of these factors. Indeed, we found that Zfp521 occupies the promoter regions of both Zfp423 and PPARγ. Accordingly, conditional deletion of Zfp521 in mesenchymal precursors inhibited heterotopic bone formation in response to calvarial injection of BMP2 *in vivo*. Interestingly, marrow adiposity, Zfp423 and PPARγ expression within BMP2-induced bone was markedly increased in Zfp521 deficient mice suggesting that precursor cells lacking Zfp521 differentiate preferentially into adipocytes instead of osteoblasts. Consistent with a cell-autonomous role of Zfp521 in mesenchymal precursors, deletion of Zfp521 in stromal cells prevented BMP2-induced osteoblast-marker expression and simultaneously enhanced the expression of adipocyte-related genes and lipid droplet accumulation. Taken together, the data suggests that Zfp521 is a critical cell-fate switch that favors osteoblast differentiation and inhibits adipocyte commitment. We propose that Zfp521 is important for the epigenetic maintenance of transcriptional silencing of adipocyte lineage factors in mesenchymal precursors in an undifferentiated state or during osteoblastogenesis.

Up-regulation of Inhibitors of DNA Binding/differentiation Gene During Alendronate-Induced Osteoblast Differentiation. Min Hyung Jung[1], Hoon Choi*[2], Heung Yeol Kim[3]. [1]School of Medicine, Kyung Hee University, Kyung Hee Medical Center, South Korea, [2]Inje University Sanggyepaik Hospital, South Korea, [3]Department of Obstetrics & Gynecology, College of Medicine, Kosin University, South Korea

Purpose: To investigate the effect of alendronate on the expression of Id genes in osteoblast differentiation.

Methods: C2C12 cells were treated with alendronate for various concentrations and time periods. For evaluation of alendronate-induced osteoblast differentiation in C2C12 cells, alkaline phosphatase (ALP) activity was measured. The expression of osteoblast differentiation markers such as ALP, type-1 collagen (Col 1), and osteocalcin (OCN), and the expression of Id-1 and Id-2 were measured by RT-PCR. In order to understand the mechanism underlying the regulation of Id genes, the promoter region of the Id-1 gene was identified. Database analysis of the promoter region for Id-1 using known consensus sequences identified several putative response elements, including CCAAT/enhancer-binding protein beta (C/EBPβ).

Results: Alendronate treatment significantly increased not only ALP activity but also the expression of ALP, Col 1, and OCN, Id-1 and Id-2. C/EBPβ and alendronate cooperatively increased the promoter activity and expression of Id-1.

CONCLUSIONS: These results suggest that C/EBPβ-mediated Id-1 transcriptional activation may regulate alendronate-induced osteoblast differentiation of C2C12 cells.

Using mouse embryonic and human induced pluripotent cells, differentiated into osteoblasts, to identify genes critical for osteoblastogenesis to pave ways for future genetic engineering. Pablo Roman-Garcia*, Linda Raphel, Vijay Yadav. Systems Biology of Bone, Wellcome Trust Sanger Institute, United Kingdom

With the advancements in gene targeting in mouse embryonic and human induced pluripotent stem cells (ES and HiPS), gene-deficient cells can be generated and the potential of stem cells lacking a specific gene to form osteoblasts can be investigated. However, protocols for differentiation of ES and HiPS cells into osteoblasts and the

underlying mechanisms remain unclear. The aim of this study was to set up a reliable osteogenic differentiation protocol and investigate gene expression changes through RNA sequencing during the differentiation of pluripotent stem cells into mature osteoblasts. It is well established that retinoic acid reduces mesodermal differentiation but enhances expression of markers of neural crest. Substitution, in the differentiation protocol, of the adipogenic factors with BMP4 results in the development of a mature osteogenic phenotype.

To achieve differentiation of ES or HiPS into osteoblasts cells were cultured in a non-differentiating medium to form embryoid bodies (EBs) and treated with retinoic acid for 48hrs and then plated on to gelatin and supplemented with BMP4 and TGFβ to form osteogenic media. The EBs were harvested at different days post addition of osteogenic media and qRT-PCR, alkaline phosphatase (ALP) activity and alizarin red staining were used to test their differentiation status compared to primary osteoblasts

Gene expression analysis of osteoblastic markers such as *Runx2 and Osteocalcin*, showed that the stem cells were successfully differentiated into mature osteoblasts, and were able to mineralize the matrix; on the other hand the stem cell markers were undetectable. In addition, ALP activity assay showed a 3.5-fold increase during differentiation from day 0 to day 20. Analysis of transcriptome trough Illumina RNA-sequencing revealed 765 differentially expressed genes; of them, 520 were up-regulated, and 245 were down-regulated. Gene interaction network analysis and gene set enrichment analysis on the differentiated cells' transcriptome showed that the secretory pathway(s) were amongst the most highly perturbed pathways.

Together, we have established a reproducible protocol to differentiate ES and HiPS cells into mature osteoblasts, and identified genome wide expression changes that define mouse and human osteoblasts. Currently efforts are underway to genetically target HiPS cells to pave a way in future for patient-specific generation of osteoblasts to investigate the underlying pathophysiological changes.

Consequences of calcification, ageing and deglycosylation on collagen fiber degradation by cathepsin cysteine proteases. PREETY PANWAR*. University of British Columbia, Canada

Introduction: Collagens are the crucial elements of the extra cellular matrix and provide anchorage, support, and structure to tissues. Abnormal degradation of collagens by proteolytic enzymes contributes to a variety of processes, including osteoporosis and atherosclerosis. Cathepsin K (catK), a cysteine protease is of particular interest as this enzyme is critically involved in bone degradation and at the same time responsible for weakening of arteries. Interestingly, there is a strong correlation between osteoporosis, the loss of bone, and the formation of mineral deposits in arteries. The present study is aimed to explore the effect of calcification, ageing and deglycosylation of collagen fibers and their degradation by cathepsin cysteine proteases.

Methods: Different categories of collagen fibers (calcified, uncalcified, age-modified and deglycosylated) were incubated with cathepsins and the consequences on their structural integrity and mechanical functionality were analyzed by different biochemical methods, scanning electron microscopy and tensile strength measurements.Results: Our data revealed that calcification and deglycosylation of collagen fibers decrease their hydrolysis by catK as indicated by reduced levels of collagen a-chain fragments. However, age modification elevated collagen degradation. Deglycosylated fibers showed minimum degradation as GAGs are required for the generation of collagenolytically active catK/GAG complexes for the complete degradation of collagen fibers. Structural analysis showed that the shape of calcified collagen fibers remains intact for longer time during degradation. However, non-calcified and age-modified fibers were completely destroyed by cathepsin K before calcified and deglycosylated fibers. Besides their structural disintegration, a strong reduction in the tensile properties of calcified, deglycosylated and age-modified fibers was observed when compared with control fibers before and after catK treatment. In contrast to catK, other cysteine proteases such as cathepsins S, B, L, and V had little or no effect on non-calcified, calcified, deglycosylated and age-modified collagen fibers.

Conclusion: Calcification leads to a partial protection against catK activity but leads to an overall loss of mechanical stability. Age-associated modifications of collagen fibers result into an increased susceptibility towards catK mediated hydrolysis. Our data provide new insights in matrix degradation which participate in various (patho) physiological processes.

Exosite inhibitors targeting the collagenase activity of cathepsin K . Dieter Bromme*. The University of British Columbia, Canada

Introduction: Cathepsin K (catK) is the major collagen-degrading protease in osteoclasts. Several catK inhibitors are presently in clinical trials for osteoporosis. However, some drug candidates failed due to adverse effects. This may be caused less by off-target effects but rather by the inhibition of non-skeletal functions of the protease. Thus, the selective inhibition of the collagenolytic activity of catK without blocking its non-collagenolytic activities would be a desirable feature of novel inhibitors. The collagenase activity of cathepsin K depends on the formation of oligomeric complexes with glycosaminoglycans and the inhibition of this complex formation by exosite inhibitors would lead to the selective inhibition of the collagenase activity. Using specific assays discriminating between the inhibition of catK complex formation and the inhibition of its active site allowed us to identify selective anti-collagenase inhibitors of catK.

*Methods:*A flurorometric polarization assay was developed to screen for anti-complex formation inhibitors of catK. Fluorogenic peptide substrate assays were used to exclude inhibitors affecting the active site of the protease and a collagen-degradation assay to demonstrate the anti-collagenase activities of these inhibitors. AFM and SEM were used to demonstrate the interference of these inhibitors with complex formation and the selective inhibition of collagen fiber degradation.

Results: We have screened a 1700-member drug library and have identified several selective anti-collagenolytic compounds. Of particular interest are polyaromatic compounds, which included flavonoid, terpenoid, and SERM-like molecules. IC50 values for complex formation inhibitors were between 0.7-80 μM in the collagenase assay. For comparison, the active site inhibitor, odanacatib, revealed an IC50 of 0.4μM. Molecular docking suggests the binding of these inhibitors either at protein-protein or protein-glycosaminoglycan interaction sites. AFM studies revealed the prevention of ring-like catK complexes associated with its collagenase activity by these inhibitors and the inhibition of fibrillar collagen fiber degradation. These compounds were also effective in bone resorption assays.

Conclusion: We identified a novel class of catK inhibitors that specifically targets the collagenase activity of the protease. These inhibitors may overcome intrinsic off-substrate effects of active site-directed inhibitors presently in development.

Subcellular calcium-calpain signaling regulates uropod retraction, but not lamellipod outgrowth in migrating osteoclasts. Benjamin Wheal*[1], Natsuko Tanabe[2], S. Jeffrey Dixon[1], Stephen Sims[1]. [1]The University of Western Ontario, Canada, [2]Nihon University School of Dentistry, Japan

Osteoclasts are large multinucleated cells responsible for the resorption of bone and other mineralized tissues during development, physiological remodeling and pathological bone loss. Osteoclasts have the unique ability to resorb substrate while concurrently migrating. However the subcellular processes underlying osteoclast migration are not well understood. It has been proposed that, in other cell types, cytosolic free Ca^{2+} concentration ($[Ca^{2+}]_i$) regulates cell protrusion as well as retraction. Integration of these distinct events would require precise spatiotemporal patterning of subcellular Ca^{2+}. The large size of osteoclasts offers a unique opportunity to monitor patterns of Ca^{2+} during migration. Our purpose was to characterize spatiotemporal changes in cytosolic calcium of osteoclasts and examine the role for calcium in regulating cell motility. We used ratiometric imaging to map $[Ca^{2+}]_i$ within authentic rat osteoclasts. Migration was characterized by lamellipodial outgrowth at the leading edge along with intermittent retraction of the uropod at the rear. Migrating osteoclasts displayed elevation of $[Ca^{2+}]_i$ in the uropod, preceding retraction. Dissipation of this $[Ca^{2+}]_i$ gradient by loading osteoclasts with the Ca^{2+} chelator BAPTA abolished uropod retraction. In contrast, elevation of $[Ca^{2+}]_i$ using the Ca^{2+} ionophore, ionomycin, initiated prompt uropod retraction. To investigate downstream effectors, we treated cells with calpain inhibitor-1, which impaired uropod retraction. Furthermore, direct application of ionomycin to calpain inhibitor-1-treated cells failed to induce prompt uropod retraction, implicating calpain acts downstream of Ca^{2+}. However, lamellipodial outgrowth at the leading edge of osteoclasts was unaffected by any of these interventions, indicating that the signals regulating outgrowth are distinct from those triggering retraction. The large size of mature, multinucleated osteoclasts allowed us to discern a novel spatiotemporal pattern of Ca^{2+} involved in cell migration. Whereas localized elevation of Ca^{2+} is necessary for uropod retraction, lamellipod outgrowth is independent of Ca^{2+} – a heretofore unrecognized degree of specificity underlying the regulation of osteoclast migration.

Downstream Effects of BMP Signaling in Osteoclasts: BMPs Induce MKP1 Activity and NFATc1 Nuclear Localization. Broege Aaron*, Raphael Huntley, Zainah Shaker, Eric Jensen, Kim Mansky, Raj Gopalakrishnan. University of Minnesota, USA

Osteoclasts are multinucleated cells responsible for resorbing damaged bone during the process of bone remodeling. Receptor activator of NF-kB ligand (RANKL) is the primary cytokine responsible for differentiating cells of the monocyte-macrophage lineage into mature, multinucleated osteoclasts. Numerous other factors can also modulate osteoclast differentiation. Our lab has previously shown BMPs to enhance RANKL-mediated osteoclast differentiation. Furthermore, we have shown that the intracellular signaling events during osteoclastogenesis in response to BMPs are complex – BMPs signal through MAPKs in pre-fusion osteoclasts and switch to canonical signaling around fusion. Our focus is now to elucidate the mechanism by which BMPs direct osteoclast differentiation as well as how BMP signaling shifts from non-canonical to canonical signaling during differentiation. In this study we explore two downstream intracellular effects of BMPs: 1) modulation of MAPK signaling; and 2) regulation of NFATc1 localization. By quantitative RT-PCR analysis we show that BMP2 represses the expression of MAPK Phosphatase-1 (MKP1) early in differentiation. In addition, we have found that in osteoclasts that have been starved for 4 hours, stimulation with BMP2 induces phosphorylation of MKP-1, suggesting that BMPs are also able to affect activation of MKP-1 in osteoclasts. Regulating MKP expression at the transcriptional and protein activity level are two ways through which BMP may modulate MAPK signaling within the cell. We also explored regulation of NFATc1, a transcription factor required for osteoclast differentiation, by BMP2 treatment in osteoclasts. Treatment with BMP2 throughout differentiation leads to an increase in nuclear localization of NFATc1 as assessed by western blot. We are currently investigating the mechanism by which BMP signaling affects NFATc1 localization in osteoclasts. This study expands our understanding of how BMP signals affect osteoclast differentiation.

Leptin increases polyethylene particle-induced osteolysis in *oblob* mice. Kenneth Philbrick*, Carmen Wong, Russell Turner, Urszula Iwaniec. Oregon State University, USA

Particles generated from wear of prosthesis joint bearing surfaces induce inflammation and promote pathological periprosthetic osteoclast-mediated bone resorption (osteolysis). Obesity increases the risk of prosthesis failure. However, despite being morbidly obese, leptin-deficient *oblob* mice are resistant to osteolysis. We therefore investigated if leptin treatment increases osteolysis in *oblob* mice. 6-week-old *oblob* mice were randomized into 3 treatment groups: 1) no-treatment (N=8), 2) particles (N=8), and 3) particles+leptin (N=6). 2.5 mg of polyethylene particles were suspended in 95% ethanol and implanted over the calvarial periosteum to induce osteolysis. An additional control consisted of wild type (WT) mice treated with particles (N=8). Osmotic pumps delivering leptin (6 µg/d) were implanted subcutaneously in the leptin-treated mice. All mice were sacrificed 2 weeks after surgery. Body composition was assessed by DXA. Calvarial bone volume was quantified by µCT and osteolysis scored blinded from 0 (no osteolysis) to 4 (severe osteolysis). Leptin-treated *oblob* mice weighted slightly less at sacrifice than particle-treated *oblob* mice (P=0.011, Table). Blood leptin at sacrifice in leptin-treated *oblob* mice was only slightly less than in particle-treated WT mice (P=0.032, Table). As expected, calvaria from WT mice treated with particles had a greater osteolytic score (P=0.044) and lower bone volume (P=0.004) than *oblob* mice treated with particles (Table & Figure). Calvaria from *oblob* mice treated with particles+leptin exhibited a greater osteolytic score (P=0.033) and lower bone volume (P=0.035) than particle-treated *oblob* mice (Table & Figure). These findings provide evidence that leptin acts to increase particle-induced osteolysis in *oblob* mice. Ongoing studies are directed toward determining the respective role of leptin in promoting osteoclast recruitment, differentiation, and function during particle-induced osteolysis.

Table: Body weight, blood leptin, osteolysis score, and calvarial bone volume (BV) from ob/ob mice, particle-treated ob/ob mice, particle+leptin treated ob/ob mice, and particle-treated WT mice. Data ± SE.

	ob/ob	ob/ob (particles)	ob/ob (particles+leptin)	WT (particles)
N	8	8	6	8
Body Weight (g)	28 ± 1	27 ± 1	25 ± 0	18 ± 1
Blood Leptin (ng/mL)	0.0 ± 0.0	0.0 ± 0.0	10.0 ± 1.5	14.5 ± 1.0
Osteolysis Score (0 – 4)	0.0 ± 0.0	1.2 ± 0.2	2.2 ± 0.4	2.0 ± 0.5
Calvarial BV (mm³)	2.9 ± 0.1	2.9 ± 0.1	2.8 ± 0.1	2.4 ± 0.2

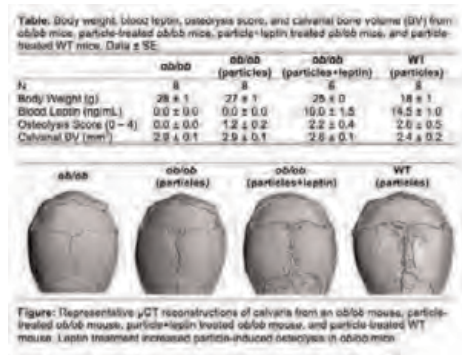

Figure: Representative µCT reconstructions of calvaria from an ob/ob mouse, particle-treated ob/ob mouse, particle+leptin treated ob/ob mouse, and particle treated WT mouse. Leptin treatment increased particle-induced osteolysis in ob/ob mice.

BMP-Binding is Essential for Inhibitory Effect of Twisted Gastrulation on Osteoclast Differentiation. Raphael Huntley*, Raj Gopalakrishnan, Charles Billington, Lan Pham, Eric Jensen, Aaron Broege, Anna Petryk, Kim Mansky. University of Minnesota, USA

Twisted gastrulation (TWSG1), a secreted glycoprotein, is an extracellular regulator of bone morphogenetic protein (BMP) signaling. We have previously shown that *Twsg1-/-* mice are osteopenic because of enhanced osteoclastogenesis and bone resorption mediated through increased BMP signaling. We also showed that BMP2 can directly enhance RANKL-mediated differentiation and increase phosphorylated Smad1/5/8 (P-SMAD) levels in wildtype osteoclast cultures. In this study we investigated the functional significance of three previously identified sites that mediate BMP binding (two glycosylation sites within exon 4 [QQ], and a conserved tryptophan residue in the N-terminus [W66]) in the inhibition of BMP signaling and osteoclastogenesis. Adenoviral vectors overexpressing wildtype or mutant TWSG1 ($TWSG1^{QQ}$ and $TWSG^{W66}$) were generated. Overexpressing WT TWSG1 in bone marrow derived osteoclasts decreased their size and number compared to cultures infected with control adenoviral vector. On the other hand, differentiation of cultures overexpressing either $TWSG1^{QQ}$ or $TWSG1^{W66}$ mutants was not inhibited. WT TWSG1 decreased the level of P-SMAD whereas $TWSG1^{QQ}$ and $TWSG1^{W66}$ mutants did not. Interestingly, unlike WT TWSG1, which reversed the enlarged osteoclast phenotype of *Twsg1*$^{-/-}$ osteoclasts, *Twsg1*$^{-/-}$ cultures expressing $TWSG1^{QQ}$ and $TWSG1^{W66}$ mutants were further increased in size compared to control adenovirus-infected cultures. In conclusion, our studies demonstrate that the ability of TWSG1 mutant proteins to inhibit osteoclast differentiation correlates with their ability to bind BMPs.

Caspase-2 as a Mediator of Osteoclast Apoptosis and Differentiation. Danielle Victor*[1], Brian Herman[2], Jean Jiang[3]. [1]University of Texas, USA, [2]UT HSC San Antonio, USA, [3]University of Texas Health Science Center at San Antonio, USA

Caspase-2 is a cysteine protease that is well known for its role as an upstream initiator of apoptosis. Loss of caspase-2 has been shown to have deleterious effects on bone of old mice (>24 mos). Namely, mice lacking caspase-2 (*Casp2*$^{-/-}$) exhibit decreased trabecular bone volume, increased levels of urinary deoxypyridinoline (a clinical marker for bone resorption), and, interestingly, increased numbers of osteoclasts compared to wild-type (WT) animals. Evidence points towards an osteoclast-based defect underlying the decreased bone density in *Casp2*$^{-/-}$ animals; however, the role of caspase-2 in osteoclasts has not yet been described. Here, we

show that caspase-2 is involved in both osteoclast apoptosis and differentiation. An immunoblot for osteoclasts treated with H_2O_2 (≥300 μM) for 6 hours shows an increase in cleaved caspase-2 relative to total caspase-2, indicating apoptosis initiation. Additionally, osteoclasts derived from *Casp2*$^{-/-}$ mice exhibit protection from apoptosis compared to cells from WT mice when treated with rotenone (≥1μM) and H_2O_2 (≥700μM). Furthermore, primary osteoclasts treated with the chemical inhibitor of caspase-2, zVDVAD, showed a decrease in spontaneous apoptosis after 24 hours compared to untreated controls, suggesting that loss of caspase-2 confers protection against apoptosis not only under conditions of oxidative stress, but also in natural cell death.Osteoclast differentiation is reliant on reactive oxygen species (ROS) in order to activate signaling pathways to promote osteoclast gene transcription. Because caspase-2, also, has a close relationship with ROS, it is possible that caspase-2 may be involved in osteoclast differentiation. In both RAW 264.7 and primary macrophages induced to differentiate into osteoclasts with sRANKL, caspase-2 protein levels decreased steadily during the differentiation process. Strikingly, caspase-2 levels were reduced more than 10-fold during late stage differentiation when mature osteoclasts appear in culture. Furthermore, primary cultures from *Casp2*$^{-/-}$ animals yielded more TRAP^{+} multi-nuclear cells then that of the WT, suggesting that loss of caspase-2 promotes increased osteoclastogenesis in accordance to what was seen in the bone phenotype of these animals. Together, these data suggest the involvement of caspase-2 in osteoclast apoptosis and a novel role as a mediator of osteoclastogenesis.

Epigenetic regulation of osteoclastogenesis. Naohiro Izawa*[1], Takanori Fujita[2], Seitaro Nomura[2], Hiroyuki Aburatani[2], Sakae Tanaka[1]. [1]The University of Tokyo, Japan, [2]Genome Science Division, Research Center for Advanced Science & Technology, The University of Tokyo, Japan

Recent studies have uncovered that the epigenetic regulation, such as histone methylation and acetylation, plays a critical role in determining cell fate. Osteoclasts are terminally differentiated cells derived from monocyte/macrophage-lineage precursor cells, and receptor activator of nuclear factor kappa B ligand (RANKL) plays an essential role. Although several genes essential for osteoclast differentiation have been identified, its epigenetic regulatory process is barely understood. Using chromatin immunoprecipitation sequencing (ChIP-seq) analysis, we generated a genome-wide map of acetylated histone H3 Lysine 27 (H3K27ac) marks, which distinguish active enhancer regions, in murine bone marrow-derived macrophages treated with RANKL. We also performed formaldehyde-assisted isolation of regulatory elements sequencing (FAIRE-seq) analysis, which detects open chromatin conformations. In the enhancer regions of many osteoclast-specific genes, such as Acp5 (expressing TRAP) and Calcr (Calcitonin receptor), RANKL treatment markedly increased H3K27ac marks as the differentiation proceeded. On the other hand, H3K27ac marks were abundantly found in many genes associated with inflammatory/immune responses such as Cd28, Tlr8 (Toll-like receptor 8) and Ccr2 (C-C chemokine receptor type 2) before RANKL treatment, which rapidly decreased in response to RANKL. Peaks of H3K27ac and FAIRE were largely overlapped, confirming that enhancer binding regions exhibited an open chromatin conformation. Motif analysis of these regions identified some transcription factors such as PU.1, STAT and FOX, which are considered to play important roles in osteoclastogenesis. These results suggest that RANKL treatment dramatically changed the epigenetic landscapes in osteoclast precursors, particularly in genes implicated in inflammatory/immune responses and osteoclast differentiation.

Metabolic Adaptation during Osteoclastogenesis. Yoriko Indo[1], Sunao Takeshita*[1], Hiroyuki Aburatani[2], Kyoji Ikeda[1]. [1]National Center for Geriatrics & Gerontology, Japan, [2]RCAST, Univ of Tokyo, Japan

The osteoclast is a giant cell that resorbs calcified matrix by secreting acids and collagenolytic enzymes. The molecular mechanisms underlying metabolic adaptation to the increased biomass and energetic demands of osteoclastic bone resorption remain elusive. In the present study we show that during osteoclastogenesis the expression of both Glut1 and glycolytic genes is increased, along with increases in lactate production and glucose consumption. The knockdown of HIF1α, as well as glucose deprivation, inhibits the bone-resorbing function of osteoclasts, with no inhibition on differentiation, and the suppression of resorbing function was associated with down-regulation of Glut1 and glycolytic gene expression. Furthermore, the expression of the glutamine transporter Slc1a5 and glutaminase 1 was increased early in differentiation, and a depletion of L-glutamine or pharmacological inhibition of the Slc1a5 transporter suppressed osteoclast differentiation and function. Inhibition of c-Myc function with a small molecule inhibitor JQ1 abrogated osteoclast differentiation and function, along with a suppression of Slc1a5 and glutaminase 1 gene expression. Thus, the uptake of glucose and glutamine and utilization of the carbon sources derived from them, coordinated by HIF1α and c-Myc, is essential for osteoclast development and bone-resorbing activity.

The *rankl* knock-out medaka exhibits a defective phenotype of bone resorption following abnormal organogenesis together with a small number of osteoclasts regulated by RANKL-independent osteoclastogenesis. Masahiro Chatani*[1], Tomoko Ishikawa[2], Takeshi Todo[2], Akira Kudo[1]. [1]Tokyo Institute of Technology, Japan, [2]Graduate School of Medicine, Osaka University, Japan

Bones have a variety of shapes in the body for supporting various organs, mainly nerves and blood vessels. The bone shapes are regulated by osteoclasts that are bone resorptive cells. RANKL (Receptor Activator of Nuclear Factor Kappa-B Ligand) binds to RANK, the osteoclast cell-surface receptor, and functions as a key factor for osteoclast differentiation. The *rankl* knock-out mouse exhibits severe osteopetrosis, however, bone resorption may occur during endochondral ossification. Therefore, it is unclear how RANKL is involved in bone resorption in the early bone development.

We previously reported that osteoclasts are important for bone modeling including organogenesis in medaka and zebrafish (Chatani et al., 2011). Here, to study the function of RANKL, we established the *rankl* knock-out medaka by using the Tilling (Targeting Induced Local Lesions In Genomes) method. The mutant survives to adulthood and generates offspring. To study bone phenotypes, we performed the Alizarin Red staining. The pharyngeal bone that forms a spongy structure like trabecular bone to support teeth was disordered, which was caused by abnormal bone remodeling. In the vertebral bone, the diameters of neural and hemal canals became narrower. To investigate the resorptive cells, we generated a hybrid line showing an osteoclast-specific mutant (*TRAP*-GFP/*rankl* -/-). Interestingly, fewer osteoclasts were emerged in the developmental stages of spinal cord and blood vessels, followed by the abnormal organogenesis in the mutant. These results suggested that the disorder of bone resorption in the mutant is associated with osteoclasts generated from the RANKL-independent signaling.

***Nrp2* Deficiency Leads to Trabecular Bone Loss and Is Accompanied by Enhanced Osteoclast and Reduced Osteoblast Numbers.** Lieve Verlinden*[1], Carsten Kriebitzsch[2], Ine Beullens[2], Geert Carmeliet[3], Annemieke Verstuyf[3]. [1]KULeuven, Belgium, [2]KU Leuven, Clinical & Experimental Endocrinology, Belgium, [3]Katholieke Universiteit Leuven, Belgium

Neuropilin 1 (Nrp1) and Nrp2 are transmembrane receptors that can bind class 3 semaphorins (Sema3A-G) in addition to VEGF family members to play important roles in axonal guidance, angiogenesis and immune responses. Moreover, recent evidence implicates Sema3A/Nrp1-mediated signaling in bone metabolism. However, to date the expression of Nrp2 in bone has not been investigated and a possible role for Nrp2 in bone homeostasis *in vivo* remains unexplored. Here we show that *Nrp2*, together with its possible coreceptors (Plexin A family members and Plexin D1) and class 3 semaphorin ligands, were expressed during *in vitro* osteogenic differentiation of bone marrow stromal cells. Moreover, Nrp2 transcript and protein levels were highly induced in hematopoietic bone marrow cell-derived osteoclast cultures. Osteoblastic as well as osteoclastic Nrp2 expression was confirmed by immunohistochemistry of the long bones of mice. Interestingly, *Nrp2* knockout mice displayed a low bone mass phenotype which was accompanied by a decreased osteoblast count and an increased number of osteoclasts. In accordance, coculture experiments of calvarial osteoblasts and hematopoietic cells derived from either *Nrp2* wildtype or knockout mice revealed an increased support of osteoclastogenesis by *Nrp2* deficient osteoblasts as well as an improved ability of *Nrp2* deficient hematopoietic cells to differentiate towards osteoclasts. Collectively, these data point to a physiological role for Nrp2 in bone homeostasis.

An antibody targeting Siglec-15 decreases bone loss in OVX rats by reducing osteoclast activity and increasing bone formation. Anna Moraitis*, Émilie Turcotte, Dominique Bédard, Martine Pagé, Elisabeth Viau, Mauricio Lemus, Julie Laurin, Matthew Stuible, Mario Filion, Gilles Tremblay. Alethia Biotherapeutics, Canada

Siglec-15 has recently emerged as an osteoclast-specific receptor that could potentially be targeted therapeutically for treatment of bone loss. Antibodies targeting this receptor impair osteoclast differentiation, reduce secretion of TRAP5b and block osteoclast resorptive activity. The objective of this study was to determine the effect of an antibody targeting Siglec-15 in the rat ovariectomy (OVX) model.

Forty Sprague-Dawley rats were sham operated or ovariectomized and treated 12 weeks later with PBS (q28d), Siglec-15 antibody (25B2, 10 mg/kg, q28d) or zoledronic acid (ZOL, 0.1 mg/kg, single injection). After a twelve-week treatment, bones were analyzed by densitometry, microCT, histomorphometry, 3-point bending (femur) and axial compression (LV4) and serum was analyzed for TRAP5b and ALP levels.

As expected, bone mineral density (BMD) was reduced dramatically in the OVX-PBS group compared to the sham operated animals, while ZOL treatment increased BMD. Administration of 25B2 caused a significant increase in BMD at all sites. These changes were confirmed by microCT analyses, which showed significant increases in bone volume, trabecular (Tb) number and corresponding decreases in Tb separation compared to the control group. Correspondingly, improvements in bone strength in animals treated with the 25B2 antibody were observed by biomechanical analysis: maximum load, stiffness and energy-to-failure parameters were all increased. Examination of tibial sections showed that the number of osteoclasts was significantly increased by 25B2 treatment, but the TRAP-positive cells were smaller and more intensely stained. Serum TRAP5b was decreased in the 25B2 group consistent with a decrease in secretion of this enzyme by osteoclasts. Interestingly, the serum level and the histological staining of ALP were unchanged in the 25B2-treated animals. This contrasts with the effect of ZOL treatment, which caused a significant decrease in ALP staining. Dynamic histomorphometry analysis using dual-calcein labeling indicated that the endosteal mineral apposition rate was greater in the 25B2-treated group compared to both the vehicle and ZOL treated groups, suggesting stimulation of new bone formation by 25B2.

Taken together, our results reveal that targeting Siglec-15 with a monoclonal antibody in a pathologic bone loss model improves bone quality and strength, likely due to combined inhibition of osteoclast function and maintenance of osteoblast activity.

Dual functions the role of Pax6 in the regulation of bone and glucose metabolism. Masahito Matsumoto*[1], Masakazu Kogawa[2], Koji Hisatake[3], Gerald Atkins[4], David Findlay[4], YUICHIRO ENOKI[5], Tsuyoshi Sato[5], Seiki Wada[6], Aya Fukuda[3], Shigehiro Katayama[7], Tetsuya Yoda[8], Tatsuo Suda[9], Yasushi Okazaki[10]. [1]Saitama Medical University, Japan, [2]Discipline of Orthopaedics & Trauma, The University of Adelaide, Australia, [3]Laboratory of Gene Regulation, Faculty of Medicine, University of Tsukuba, Japan, [4]University of Adelaide, Australia, [5]Saitama Medical University, Japan, [6]Musashifujisawa Central Clinic, Japan, [7]Department of Endocrinology & Diabetic Internal Medicine, Saitama Medical University, Japan, [8]Department of Oral & Maxillofacial Surgery, Saitama Medical University, Japan, [9]Research Center for Genomic Medicine Saitama Medical School, Japan, [10]Division of Functional Genomics & Systems Medicine, Research Center for Genomic Medicine, Saitama Medical University, Japan

Paired-box homeodomain transcription factor Pax6 is essential for normal development of eye and pancreatic endocrine cells producing hormones that affect muscle and liver, resulting in the maintenance of glucose homeostasis. However, little is known about the role of Pax6 in bone metabolism. Herein we show the Pax6 acts as an intrinsic negative regulator of RANKL-mediated osteoclast differentiation. Electrophoretic mobility shift and reporter assays found that Pax6 binds endogenously the proximal region of the *tartrate-acid phosphatase (TRAP)* gene promoter and suppresses NFATc1-induced *TRAP* gene expression. Introduction of Pax6 retrovirally into bone marrow macrophages (BMM) attenuates RANKL-induced osteoclast formation. Moreover, we found that the Groucho family member co-repressor Grg6 contributes to Pax6-mediated suppression of the *TRAP* gene expression induced by NFATc1. These results suggest that Pax6 interferes with RANKL-mediated osteoclast differentiation together with Grg6. Our results demonstrate that the Pax6 pathway constitutes a new aspect of the negative regulatory circuit of RANKL-RANK signaling in osteoclastogenesis and that the augmentation of Pax6 might therefore represent not only for a novel target to block pathological bone resorption but also for glucose metabolism by appropriate cell fate specification (Kanzawa Medical Research, the Kowa Life Science Foundation, the Life Science Foundations, Saitama Medical University internal research grant and Kawano Masanori Memorial Foundation for promotion of Pediatrics.)

Ectopic Expression of Human Leucine Rich Repeat Kinase 1 (hLRRK1) in *Lrrk1* Knockout Osteoclast Precursors Rescues the Bone Resorption Defect *in vitro* by Modulating C-Terminal Src Kinase (Csk) Activity. Weirong Xing*[1], Shaohong Cheng[2], Subburaman Mohan[3]. [1]Musculoskeletal Disease Center, Jerry L. Pettis Memorial Veteran's Admin., USA, [2]VA Loma Linda Health Care Systems, USA, [3]Jerry L. Pettis Memorial VA Medical Center, USA

We have recently shown knockout (KO) of *Lrrk1* in mice resulted in the highest observed body aBMD by DXA high-throughput screening (Z-score of 9.0 above the mean) of 3629 distinct gene KO lines. The osteopetrosis phenotype is much more severe in the *Lrrk1* KO mice than *Sost* or *c-Src* KO mice. Precursors derived from *Lrrk1* KO mice differentiate into multinucleated osteoclasts (OCs) in response to M-CSF/RANKL treatment, but fail to resorb bone due to defects in the formation of peripheral sealing zones and ruffled borders. The phosphorylation of c-Src at Tyr-527 is significantly elevated whereas at Tyr-416 is decreased in LRRK1 deficient OCs in response to MCSF/RANKL treatment. To determine if *hLrrk1* functions similar to mouse *Lrrk1* (*mLrrk1*), precursors-derived from *Lrrk1* KO mice were transduced with lentivirus containing either *hLrrk1* or GFP control and the transduced cells were then differentiated in the presence of MCSF/RANKL. Ectopic expression of full length hLRRK1 in *Lrrk1* null cells completely rescued OC resorptive functions *in vitro*. Although *Lrrk2*, a structural homolog of *Lrrk1*, is also expressed in macrophage lineage cells, there was no obvious skeletal phenotype in *Lrrk2* KO mice, suggesting that *Lrrk1* has a unique function in bone, and the distinguishing ankyrin (ANK) structure present in *Lrrk1* but not *Lrrk2* may determine its specific function. Sequence analyses found that hLRRK1 and mLRRK1 contain ANK repeats that are 34% identical to the ANK repeat consensus sequence. Because the predicted 3-D structure of hLRRK1 ANK contains functional motifs that have been implicated in protein-protein interactions and overexpression of ANK repeats containing protein ASPP2 in choriocarcinoma cells decreased pY416 c-Src activation, and this c-Src inactivation can be abolished by knocking down Csk expression, we hypothesize that the hLRRK1 ANK repeats may mediate hLRRK1 specific function through interacting with Csk in OCs. Accordingly, our computer-based analyses predict the residues of the inner helices andturns of ANK repeats 1-3 of hLRRK1 contact the SH2 domain (93-116) and the N-terminal of the Csk kinase domain (268-279). Immunoprecipitation studies using RANKL treated RAW264.7 cells that were transfected with pcDNA-Flag/hLrrk1 revealed that hLRRK1 interacted with Csk in OCs. In conclusion, our data indicate that hLRRK1 plays a critical role in regulating OC activity by suppressing Csk kinase activity, and could be a novel anti-resorptive drug target.

Inhibition of osteoclastogenesis and inflammatory bone resorption by targeting bromodomain-containing chromatin regulators. Kyung-Hyun Park-Min*[1], Elisha Lim[1], Rab Prinjha[2], Lionel Ivashkiv[1]. [1]Hospital for Special Surgery, USA, [2]GlaxoSmithKline, United Kingdom

Although it was recently appreciated that RANKL-induced changes in the chromatin state of osteoclast precursor cells (OCPs) are important for osteoclast differentiation, the epigenetic mechanisms that regulate osteoclast function are not clear. In addition to enzymes that deposit and remove chromatin modifications, so-called "readers" directly bind to modified histones and recruit regulatory complexes to control gene expression. Among such readers, bromodomain (BRD)-containing proteins recognize acetylated lysine residues. Recently, small molecule inhibitors, named I-BET and JQ1, that suppress binding of the BET subfamily of BRD proteins to acetylated histones were described. BET inhibitors effectively suppress cancer growth in mouse models, but their effects on osteoclastogenesis and bone resorption have not been described. Here, we investigated the effects of the BET inhibitor I-BET on osteoclastogenesis, and on pathological bone resorption in vivo. Treatment of human blood-derived OCPs or mouse bone marrow-derived OCPs with I-BET strongly inhibited RANKL-induced osteoclastogenesis in a dose-dependent manner. These suppressive effects were mediated by inhibition of RANKL-induced expression of NFATc1, a master regulator of osteoclastogenesis. Furthermore, I-BET administration suppressed inflammatory arthritis and TNF-induced inflammatory osteoclastogenesis and bone resorption in vivo, demonstrating for the first time therapeutic efficacy of epigenetic drugs in suppressing pathological bone resorption. The mechanism of I-BET action was suppression of the expression and binding of MYC to the NFATc1 promoter, which resulted in decreased histone acetylation and expression of *NFATC1*. Experiments targeting MYC using pharmacological inhibitors or RNA interference (RNAi) established a role for RANKL-induced MYC in osteoclast differentiation. These data implicate MYC as an important factor in osteoclastogenesis and suggest targeting MYC as another therapeutic strategy to control bone resorption. Taken together, our findings provide insights into new transcriptional and epigenetic mechanisms that control osteoclastogenesis, and suggest that targeting of chromatin regulators such as BET proteins represents a promising new approach to treat pathological bone resorption.

Jaw Bone Marrow-Derived Osteoclast Precursors Internalize More Bisphosphonate than Long-Bone Marrow Precursors. Jenny Vermeer*[1], Ineke Jansen[2], Matangi Marthi[1], Fraser Coxon[3], Charles McKenna[4], Shuting Sun[4], Teun De Vries[5], Vincent Everts[6]. [1]Department of Oral Cell Biology & Functional Anatomy, Academic Centre for Dentistry Amsterdam (ACTA), University of Amsterdam & VU University Amsterdam, MOVE Research Institute Amsterdam, Netherlands, [2]Department of Periodontology, Academic Centre for Dentistry Amsterdam (ACTA), University of Amsterdam & VU University Amsterdam, MOVE Research Institute Amsterdam, Netherlands, [3]Musculoskeletal Programme, Division of Applied Medicine, Institute of Medical Sciences, University of Aberdeen, Foresterhill, Aberdeen, United Kingdom, [4]Department of Chemistry, University of Southern California, Los Angeles, CA, USA, [5]ACTA, University of Amsterdam & VU University, The Netherlands, [6]Department of Oral Cell BiologyAcademic Centre of Dentistry Amsterdam (ACTA), The Netherlands

Bisphosphonates (BPs) are widely used to treat several bone diseases, such as osteoporosis and cancers that have metastasized to bone. Due to their ability to potently inhibit osteoclastic bone resorption, they improve bone quality and reduce fracture risk. Osteonecrosis of the jaw (ONJ) has been reported in some patients receiving a high intravenous dose of certain BPs, but it is not clear why in particular jaw bone is affected. We hypothesized that BPs could have distinct effects on jaw and long-bone-marrow-derived osteoclasts and their precursors, for example as a result of differences in the ability to endocytose the drugs. To investigate this, jaw and long-bone marrow cells were isolated from mice and the cells were primed to differentiate into osteoclasts with the cytokines M-CSF and RANKL. Before fusion occurred, cells were incubated with fluorescein-risedronate (FAM-RIS) for 4 or 24 hours and uptake was determined by flow cytometry. We found that cultures obtained from the jaw internalized 1.7 to 2.5 times more FAM-RIS than long-bone cultures, both after 4 and 24 hours. Accordingly, more unprenylated Rap1a accumulated in jaw osteoclasts after treatment with BPs for 24 hours. Surprisingly, differences in BP uptake did not differentially affect osteoclastogenesis on plastic. On bone, however, 1 μM of BP significantly stimulated osteoclastogenesis of long-bone marrow precursors, but not of jaw bone marrow precursors. In conclusion, our findings are the first to demonstrate different responses of bone-site-specific osteoclast precursors to bisphosphonates. This study may help to improve the understanding of the association between BPs and osteonecrosis of the jaw.

Long-chain Fatty Acid Analogues Inhibit Osteoclastogenesis. Jillian Cornish*, Jian-ming Lin, Karen Callon, Andrew Marshall, William Denny, Ian Reid, Andrew Grey. University of Auckland, New Zealand

Body weight, particularly fat mass, is positively correlated to bone mass. The relationship between fat and bone is mediated through skeletal loading, hormonal and neuronal pathways. Experiments showing that feeding acutely influences bone turnover, raising the possibility that ingested nutrients have direct bone effects and could function as an additional link between fat and bone. We recently reported long-chain, saturated fatty acids such as. palmitic acid (C18) inhibit osteoclastogenesis *in vitro* and G-protein coupled receptors (GPR) for fatty acids are expressed in bone cells.. It is likely this effect is mediated by binding of fatty acids to the cell surface receptor GPR120, with known GPR120 receptor agonist GW9508 also inhibiting osteoclastogenesis. We have also shown that the marrow stromal cell (Kusa4b 10) is a novel target of palmitic acid, possibly by signalling through GPR120 and GPR40/41. Therapeutic exploitation of these observations is complicated by the modest potency, rapid metabolism and relative insolubility of the natural long-chain fatty acids, which likely limit them reaching the bone environment in sufficient concentration for long enough to exert a substantial therapeutic effect *in vivo*. Thus in this study we explored two new classes of analogues and evaluated their activity in an *in vitro* osteoclastogenesis assay.

Two novel classes of palmitic acid analogues: 8 compounds modified by ether or 6 compounds by triazole units were constructed. They were prepared by condensation of alkyl halides and diols, followed by Jones oxidation; triazolyl acids by copper-catalysed click chemistry between the appropriately-protected azides and alkynes, followed by deprotection and oxidation. The analogue activity was assessed in primary murine bone marrow cultures and the most potent were compared in efficacy to palmitic acid, the GPR120 agonist GW9508, and OPG.

The findings of this study indicate the anti-osteoclastogenic activity of natural long-chain saturated fatty acids is changed very little by introduction of an ether moiety anywhere in the chain, but is improved markedly by the introduction of a more rigid triazole group, placed distant from the acid unit (most potent reduced osteoclastogenesis by 88% at 10 ug/mL).

In clinical practice, agents that decrease bone resorption by 50-80% are effective in reducing the risk of fragility fractures. Further characterization of the skeletal effects of these compounds is therefore justified.

Novel Human RANKL Inhibitors Targeting Its Trimerization. Vagelis Rinotas[1], Fotini Violitzi[1], Polyxeni Alexiou[2], Fotini Liepouri[3], Anna Maranti[3], Katerina Tsiliouka[3], Alexandros Strongilos[3], Thanos Papakyriakou[2], Christos Papaneophytou[4], George Kontopidis[4], Elias Couladouros[2], Elias Eliopoulos[2], Eleni Douni*[5]. [1]BSRC Alexander Fleming, Greece, [2]Agricultural University of Athens, Greece, [3]pro-ACTINA SA, Koropi Attikis, Greece, [4]Centre for Research & Technology-Thessaly, Greece, [5]Agricultural University of Athens/ BSRC Al. Fleming, Greece

Receptor activator of nuclear factor-κB ligand (RANKL), a trimeric tumor necrosis factor (TNF) superfamily member, is the central mediator of osteoclast formation and bone resorption. Functional mutations in RANKL lead to human autosomal recessive osteopetrosis (ARO), whereas RANKL overexpression has been implicated in the pathogenesis of bone degenerative diseases such as osteoporosis. Following a forward genetics approach using chemical random mutagenesis, we have recently shown that a novel loss-of-function allele of Rankl with a glycine-to-arginine mutation at codon 278 (G278R) at the extracellular inner hydrophobic F beta-strand of RANKL, causes severe recessive osteopetrosis in mice. RANKLG278R monomers fail to assemble into homotrimers, are unable to bind and activate the RANK receptor but interact with wild-type RANKL exerting a dominant-negative effect on its trimerization and function in vitro. Furthermore, as G278 is highly conserved within the TNF superfamily, we identified that similar substitutions in TNF and B-cell activating factor (BAFF) also impaired trimerization and binding to cognate receptors, resulting in loss of biological activity. Notably, SPD304, a small molecule inhibitor of TNF trimerization, also binds and inhibits RANKL, suggesting similar inhibitory mechanisms. Based on the trimeric structure of RANKL and its interaction with SPD304, novel small molecules were designed to abrogate trimer formation and biological function displaying higher specificity and less toxicity compared to SDP304. Of the 72 SPD304-like derivatives synthesized and tested, 13 displayed complete inhibition of human RANKL function in osteoclastogenesis assays with less cytotoxicity compared to SPD304 using MTT assays. Our results identified potent small molecule inhibitors of human RANKL designed to target and block its trimerization. The more effective inhibitors will be further evaluated in vivo using our unique human RANKL-expressing transgenic mouse models of osteoporosis.

S1P-mediated Osteoclast Precursor Monocyte Migration Is a Critical Point of Control in Antibone-resorptive Action of Active Vitamin D. Junichi Kikuta*[1], Fumie Okiji[1], Mai Shirazaki[1], Sadaoki Sakai[2], Hitoshi Saito[2], Masaru Ishii[1]. [1]Department of Immunology & Cell Biology, Graduate School of Medicine & Frontier Biosciences, Osaka University, Japan, [2]Medical Affairs Division, Chugai Pharmaceutical Co., Ltd., Japan

Osteoclasts are bone-resorbing giant polykaryons that differentiate from mononuclear macrophage/monocyte-lineage hematopoietic precursors. The migratory mechanisms of osteoclast precursor monocytes in systemic circulation and homing into bone spaces are controlled by the blood-enriched lipid mediator sphingosine-1-phosphate (S1P) and have recently been shown to be critical points of control in osteoclastogenesis and bone homeostasis.

Active vitamin D analogs have been clinically used for bone and mineral disorders, although the actual pharmacological action in bone has remained elusive. Here, we showed the potential role of vitamin D signaling in the control of osteoclast precursor migration.

First, we examined the effects of the active form of vitamin D, calcitriol (1,25-D), and its clinically used active vitamin D analog,eldecalcitol (ELD), on the expression of several chemokine receptors in a monocytoid cell line, RAW264.7. Both 1,25-D and ELD significantly suppressed the expression of S1PR2, a chemo-repulsive receptor for blood S1P, in a dose-dependent manner, whereas the expression levels of other chemokine receptors were essentially unaltered. By using an *in vitro* chemotaxis assay, we also found that active vitamin D-treated RAW264.7 cells could more readily migrate to a high concentration of S1P, such as in the blood.

Next, we examined the *in vivo* effects of active vitamin D on mice. Oral treatment both with 1,25-D and ELD prevented ovariectomy-induced bone loss. Under this condition, the $CD11b^+$-circulating osteoclast precursor monocytes in mice treated with active vitamin D expressed lower levels of S1PR2 than cells that were subjected to the control conditions.

Finally, we examined the *in vivo* mobility of $CX_3CR1\text{-}EGFP^+$ osteoclast precursor monocytes in living bone tissues by using an intravital multiphoton microscopy. The mobility of the $CX_3CR1\text{-}EGFP^+$ monocytoid cells was significantly increased in mice treated with active vitamin D drugs such as 1,25-D and ELD, suggesting that *in vivo* treatment with active vitamin D action suppresses S1PR2 expression and the mobilization of osteoclast precursor monocytes from the bone to the blood circulation.

These findings demonstrate a novel mechanism of active vitamin D for controlling the migratory behavior of circulating osteoclast precursors, and this action should be conducive to limiting osteoclastic bone resorption in vivo, which is the main therapeutic effect of active vitamin D.

An Osteoclast Transmembrane Protein-tyrosine Phosphatase, PTP-oc, Enhances Osteoclast Activity In Part Through Dephosphorylation of the EphA4 Receptor in Osteoclasts. Kin-Hing William Lau*[1], Virginia Stiffel[1], Matilda Sheng[2], Shin-Tai Chen[1], Mehran Amoui[1]. [1]Jerry L. Pettis Memorial VA Medical Center, USA, [2]Loma Linda University, USA

We have previously shown that an osteoclast (OCL)-specific protein-tyrosine phosphatase (PTP-oc) is a positive regulator of OCL activity, and its action is in part mediated via dephosphorylation of phosphotyrosine (pY)527 of Src and Src-dependent activation of several downstream pathways. However, our PTP-oc trapping mutant pull-down assay showed that EphA4 may also be a potential cellular substrate of PTP-oc. We have previously presented preliminary evidence that EphA4 is a negative regulator of OCL activity. In this study, we also showed that reintroduction of EphA4 in EphA4 KO OCLs with lenti-Epha4 led to formation of ~40% smaller resorption pits than those of control OCLs (0.29 ± 0.01 vs. 0.49 ± 0.1 cm^2, $p<0.05$). Thus, we sought to test the hypothesis that PTP-oc enhances OCL activity also through PTP-oc-mediated dephosphorylation and inactivation of EphA4. OCLs derived from PTP-oc transgenic mice reduced the overall pY-EphA4 level in OCL to <5% ($p<0.05$) compared with WT OCLs. There are 4 important pY residues (pY596, pY602, pY779, and pY928) in EphA4. Overexpression of PTP-oc in OCLs also reduced the pY602-EphA4 and the pY779-EphA4 level (normalized against total EphA4) to <5% ($p<0.05$ for each) of that in WT OCLs. Transduction of EphA4 KO OCLs with lenti-Y779F-Epha4 led to $318 \pm 14\%$ ($p<0.01$) increase in pY174-Vav3 (normalized against Vav3) (used as a surrogate indicator of OCL activity), whereas transduction with lenti-WT-Epha4 reduced the pY173-Vav3 by $48 \pm 11\%$ ($p<0.05$). Transduction with lenti-Y602F-Epha4 resulted in only a marginal increase ($158.1 \pm 10\%$, p=N.S.). Epha4 expression in OCLs yielded contrasting effects on the activation status of Rho vs. Rac, as deficient EphA4 expression in OCLs increased GTP-Rac (by ~2.5-fold, $p<0.05$) but reduced GTP-Rho (by~60%, $p<0.05$) without affecting total Rho or Rac levels. Overexpression of PTP-oc also resulted in higher levels of GTP-Rac (~300% of WT, $p<0.05$) but reduced levels of GTP-Rho (~50% of WT, $p<0.05$). The total Rho and Rac levels were also not different. The similarity between EphA4 KO and PTP-oc overexpression on the differential actions on Rho vs. Rac provides further support for the premise that PTP-oc enhances OCL activity may in part involve the relief of the suppressive action of EphA4 on OCL activity. In conclusion, PTP-oc acts not only through Src-dependent activation of the various stimulatory pathways of OCL activity but also via Src-independent mechanism to reduce the suppression action of EphA4.

DOK3 negatively regulates RANKL-induced osteoclastogenesis. Mary Beth Humphrey*, Courtney Long. University of Oklahoma Health Sciences Center, USA

Osteoclasts are giant, multinucleated cells of myeloid lineage activated to resorb bone. Receptor activator of NF-kB ligand (RANKL) promotes osteoclast differentiation and function but requires costimulation of immunoreceptor tyrosine-based activation motif (ITAM)-coupled immunoreceptors. One such receptor is triggering receptor expressed on myeloid cells (TREM)-2 which is coupled to ITAM-adaptor protein DAP12 and mediates PI3K production and intracellular calcium release during osteoclastogenesis. We have recently shown that downstream of kinase-3 (DOK3) negatively regulates TREM2-DAP12 signaling and inflammatory cytokine production in response to TLR stimulation of macrophages. To test the hypothesis that DOK3 negatively regulates TREM2-DAP12 ITAM signaling in osteoclasts, we evaluated bone micro-architecture and histology of sex matched 16 week old control and DOK3-deficient (DOK3ko) mice. DOK3ko mice have significantly reduced trabecular bone mass at the tibia and femur whereas cortical bone is unchanged. Bone formation rates are similar between the groups. Pre-osteoclasts derived from DOK3ko mice exhibit increased sensitivity to 5-35ng/ml RANKL with significantly increased osteoclast numbers compared to control. DOK3ko osteoclasts have significantly increased resorption compared to controls. In response to TREM2 crosslinking but not RANKL stimulation, DOK3 becomes phosphorylated and associates with SHIP1. Further studies are underway to determine the effect of DOK3 on ITAM signaling in osteoclasts. In conclusion, our data supports an important role for DOK3 in the regulation of osteoclastogenesis in vivo and in vitro.

Mice deficient in CD44 display reduced pro-MMP9 activation and membrane localization of MT1-MMP in osteoclasts. Meenakshi Chellaiah*. University of MarylandDental School, USA

CD44, MT1-MMP and MMP9 are implicated in osteoclast migration and bone resorption. This study was designed to determine the functional relationship between CD44 and MT1-MMP in the activation of pro-MMP9. We used osteoclasts isolated from wild-type and CD44-null mice. Results showed that MT1-MMP is present in multiple forms with a relative molecular mass of 63, 55, and 45kDa in the membrane of wild-type osteoclasts. CD44-null osteoclasts demonstrated a 55kDa-active MT1-MMP form in the membrane and conditioned medium. It failed to activate pro-MMP9 because TIMP2 binds and inhibits this MT1-MMP (~55kDa) in CD44-null osteoclasts. The role of MT1-MMP in the activation of pro-MMP9, CD44 expression and migration was confirmed in wild-type osteoclasts knockdown of MT1-MMP. Although, MMP9 knockdown suppressed osteoclast migration, it had no effects on MT1-MMP activity or CD44 expression. These results suggest that CD44 and MT1-MMP are directly or indirectly involved in the regulation of pro-MMP9 activation. Surface expression of CD44, membrane localization of MT1-MMP and activation of pro-MMP9 are the necessary sequence of events in osteoclast migration.

Myo9B, a Rho-GAP Protein Associated with Inflammatory Bowel Disease, is Critical for Osteoclast Function. Beth Lee*[1], Brooke McMichael[2]. [1]Department of Physiology & Cell Biology, Ohio State University, USA, [2]Ohio State University, USA

Inflammatory disorders of the gut, including the inflammatory bowel diseases (Crohn's disease and ulcerative colitis) and celiac disease are associated with high rates of osteoporosis and with growth retardation in juvenile patients. Nutritional deficit and inflammation, especially as mediated by TNFα, contribute to these conditions. Here we demonstrate that a recently described gene associated with these diseases, Myo9b, is highly expressed in osteoclasts and may contribute directly to intrinsic bone defects associated with these intestinal diseases. Myo9b is a myosin that contains a Rho inhibitory (Rho-GAP) domain and is highly expressed in hematopoietic cells of the monocyte lineage and in gut epithelia. Loss of Myo9b function in gut epithelia results in loss of tight junction integrity, a known contributor to inflammatory bowel disorders. In this study, the consequences of loss of Myo9b on osteoclast function were examined. Because of the well-established importance of Rho signaling to osteoclast cytoskeletal organization, it was predicted that loss of Myo9b, a Rho inhibitor, would enhance osteoclast function. Unexpectedly, knockdown of Myo9b resulted in a loss of osteoclast activity, including cell spreading, motility, and bone resorptive capacity. A dramatic loss of bone resorptive capacity was noted even though sealing zones appeared normal. These losses in function were reversible with addition of a Rho inhibitor. Further experimentation demonstrated that lack of resorptive function in cells with diminished Myo9b levels might be explained by poor stabilization of microtubules or by mislocalization of c-Src, a tyrosine kinase with critical effects on osteoclast actin cytoskeletal rearrangement and function. Importantly, treatment of Myo9b-suppressed osteoclasts with TNFα strongly reversed the osteoclast dysfunction, demonstrating the potential of this factor to activate what are otherwise defective osteoclasts. These results indicate that the RhoGAP activity of Myo9b plays a key role in regulating the actin-based structures necessary for osteoclast motility and resorption, and is suggestive that variants of Myo9b associated with inflammatory gut diseases may also play key roles in bone metabolism.

PDK1/Akt pathway in osteoclast signaling in Paget's disease of bone. Stephen McManus*, Gino Laberge, Martine Bisson, Sophie Roux. University of Sherbrooke, Canada

Introduction: In Paget's Disease of Bone (PDB), osteoclasts (Ocs) are increased in size and number, overactive, and resistant to apoptosis. All of the mutations identified to date in PDB are clustered either within or near the UBA domain of the signaling protein p62, indicating a critical importance of p62 in bone pathophysiology. In rodent and human osteoclasts, p62 is a major scaffold involved in the RANKL-induced signaling complex that includes TRAF6 and atypical PKCζ. We have previously shown that PDK1 also associates to p62 in response to RANKL, and may play an important role in p62-driven Oc activation. The PI3K/Akt pathway, a major target of PDK1, is involved in osteoclast formation and survival, and through mTORC1 activation, inhibits autophagy. Our aim was to investigate the activation of the Akt pathway in Pagetic osteoclasts.

Methods: We used an *in vitro* human osteoclast model from peripheral blood monocytes (PBMCs) obtained from patients with PDB (n=8) and healthy donors (n=8), and HEK293T cells transfected to express RANK. Akt is known to be activated/phosphorylated at two unique sites, stimulated by RANKL-induced signals at Ser473, and at Thr308 through PDK1. We used Western blot analysis to study the phosphorylation of Akt at both sites, and LC3 expression.

Results: In HEK293T cultures, the presence of an inhibitor specific to PDK1 (3-hydroxy-anthranilic acid) inhibited the RANKL-induced Thr308 phosphorylation, but Ser473 activation appeared unimpaired, consistent with expectations. In Oc cultures, p-Akt/Akt significantly increased after RANKL stimulation at Ser473, and the basal phosphorylation of Akt was significantly increased in the PDB cohort compared to controls, at both phosphorylation sites, particularly Thr308, suggesting that PDK1 may have a role in the overactivation of Akt in Pagetic Ocs. The autophagy flux was assessed in Oc cultures. We found that the basal LC3-II/LC3-I ratio, a reliable marker for autophagy, was higher in Pagetic osteoclasts than in controls.Conclusion: Our results show that PDK1 and Akt pathway are involved in RANKL-induced Oc signaling, and provide an additional potential contributor to the

pathology of PDB. These new insights to the events following RANKL stimulation may help further explain the increased signaling as well as the potential autophagy impairment in Pagetic osteoclasts.

SU0273

Regulator of Calcineurin 1 (Rcan1) is Highly Induced in Mouse Osteoclasts Generated on Bone and Regulates RANKL-induced Calcineurin Activity and Osteoclast Formation. Diana Metz-Estrella*[1], Kofi Mensah[1], Bryant Darnay[2], Betty Lamothe[3], Ed Purdue[1], Allison Shaber[1], Song Xue[4], Steven Goldring[1], Kevin McHugh[4], F. Patrick Ross[1]. [1]Hospital for Special Surgery, USA, [2]University of Texas M.D. Anderson Cancer Center, USA, [3]MD Anderson Cancer Center, USA, [4]University of Florida, USA

Microarray profiling of mouse osteoclast (OC) precursors differentiated on bone or plastic identified molecules involved in OC terminal differentiation. We focused on regulator of calcineurin *(Rcan)1,* a gene highly enriched on bone and expressed as two isoforms, 1.1 and 1.4. Human *RCAN1* was identified as Down syndrome (DS) critical region 1 gene (DSCR1) based on its presence within the locus duplicated in the partial trisomy 21 associated with DS. In cardiomyocytes Rcan1.4 controls calcineurin (CN) phosphatase function and thus NFATc1 nuclear translocation by a mechanism involving phosphorylation by TGFβ activated kinase (TAK1), leading to its dissociation from CN and and augmented activity of the phosphatase. We find that Rcan1.4, but not Rcan1.1 mRNA increases markedly during osteoclastogenesis (OCg). This result, combined with its cardiac role, suggests Rcan1.4 regulates OCg and may contribute to DS bone disease. Relevantly, TAK1 and NFATc1 are key regulators of OC formation. Given all these facts we focused on the role of Rcan1 in bone homeostasis, using WT mice or those lacking the gene. OCg is induced more rapidly and robustly in Rcan1 null versus WT BMMs suggesting Rcan1 is inhibiting the canonical calcium ion flux pathway. CN levels are unchanged during OCg of Rcan1 bone marrow macrophages (BMMs), but its phosphatase activity increases significantly in Rcan1$^{-/-}$ OCs but not BMMs; thus, Rcan1 mediates RANKL-induced CN function. Consistent with this hypothesis, NFATc1 nuclear translocation is much higher in OCs lacking Rcan1 and mRNA levels of NFATc1, TRAP, cath K and beta3 integrin subunit increase more rapidly and to higher levels during OCg of Rcan1 null BMMs versus WT cells. Turning to mechanism, both M-CSF and RANKL stimulate phosphorylation of TAK1 in WT BMMs. Pharmacological inhibition of TAK1 activity decreases significantly OCg of WT BMMs, while affecting Rcan1 null precursors to a lesser degree, suggesting that TAK1 and Rcan1 have an epistatic relationship. Since Rcan2 null mice have only an osteoblastic phenotype it is not surprising that the high expression of Rcan2.4 in Rcan1 null OCs, fails to suppress the enhanced OCg of Rcan1 null BMMs. In summary, we find that Rcan1 is an inhibitor of CN activity, and hence its deletion results in increased osteoclastogenesis.

The Transcription Factor Sox4 Regulates TRAF6 Activity and Subcellular Localization. Philip Auron[1], Deborah Galson[2], Juraj Adamik[2], An-Jey Su*[1]. [1]Duquesne University, USA, [2]University of Pittsburgh School of Medicine, USA

Pathologies associated with the skeletal diseases osteoporosis, multiple myeloma and rheumatoid arthritis result from misregulated osteoclast differentiation and activity. The E3 ubiquitin ligase, Tumor necrosis factor receptor-associated factor 6 (TRAF6) is an indispensible cytoplasmic signal transducer for the RANKL/RANK/NF-kB axis of osteoclastogenesis. Understanding the molecular and mechanistic details of TRAF6 and its interacting proteins is necessary to develop effective skeletal disease therapies. Many studies use overexpression of TRAF6 as a dominant positive for NF-kB activity in HEK293. We report that overexpression of TRAF6 in two distinct murine osteoclast precursor cell lines (calvaria derived 4B12 and monocyte/macrophage RAW246.7) cannot activate NF-kB. 4B12 cells only differentiate into functional osteoclasts in the presence of both M-CSF and RANKL, physiologically akin to primary cell differentiation. TRAF6 interacts with signaling partners bearing TIMs: TRAF Interaction Motif(s). We report novel TIM sequences within the linker region (194-200) between the two scaffolding PDZ domains of Syntenin (Syn-1) and two TIMs in the GRR: lysine rich region of Sox4 (151-155; 193-197). Our experiments using both endogenous and various ectopically expressed muteins and tagged proteins indicate both Syn-1 and Sox4 can attenuate TRAF6 dependent signaling but Syn-1 interacts with TRAF6 in a Ubiquitin dependent manner. Further we observed intranuclear translocation of all three molecules (TRAF6, Syn-1, Sox4) of the protein-complex upon stimulation. The endogenous proteins of the triad were observed to rapidly translocate to the nucleus when the murine cells were stimulated with RANKL or LPS. These results provide a direct mechanism for the normally cytoplasmic TRAF6 to enter the nucleus as well as novel targets for treating bone disease.

Functional Interplay between Connexin Hemichannels, Integrins, and PI3K-AKt Signaling in Mechanotransduction of Osteocytes. Jean Jiang*. University of Texas Health Science Center at San Antonio, USA

Mechanical loading induces the release of small factors, such as prostaglandins, from osteocytes and this release is mediated by opening of connexin 43 (Cx43) hemichannels at the cell surface. However, the mechanism for mechanotransduction that leads to the opening of these hemichannels is unknown. Integrinsexpressed on the cell surface are thought to be mechanical sensors in the osteocytes. Our recent study showed that activation of PI3K/AKT induced the conformational activation of integrin α5 upon mechanical stimulation in the form of fluid flow shear stress (FFSS), and led to the opening of Cx43 hemichannels in osteocytic MLO-Y4 cells. Here, we show that integrin αvβ3 located in the dendritic processes is the primary mechanosensor that activates PI3K/AKT signaling. Activated AKT further phosphorylates both Cx43 and integrin α5, enhances their interaction and increases Cx43 hemichannel activity in the cell body. Integrin αv colocalized with integrin β3 but not Cx43 on the dendritic side of the cells. Inhibition of integrin αv activation upon FFSS attenuated the activation of PI3K/AKT and blocked hemichannel opening on the cell body. Interestingly, integrin αvβ3 present on the dendritic processes activated PI3K, which was required for the activation of integrin α5β1 and opening of Cx43 hemichannels on the cell body. FFSS activated AKT and facilitated hemichannel opening. Cx43 and integrin α5 were both directly phosphorylated by AKT and FFSS increased their phosphorylation due to activation of AKT. AKTi, an inhibitor specific to AKT, disrupted the interaction between Cx43 and integrin α5, preventing the hemichannel from opening. These results show that the interaction is essential for Cx43 hemichannels to open. Taken together, these results suggest that integrin αvβ3 is the mechanical sensor that activates PI3K/AKT leading to the increased phosphorylation of integrin α5 and Cx43, and enhanced their interaction, thereby inducing the Cx43 hemichannels to open and release important bone modulating factors.

SU0276

Integrin αv in the Mechanical Response of Osteoblast Lineage Cells. Keiko Kaneko*[1], Masako Ito[2], Adam Lacy-Hulbert[3], Kyoji Ikeda[4]. [1]NCGG, Japan, [2]Nagasaki University Hospital, Japan, [3]MGH, USA, [4]National Center for Geriatrics & Gerontology, Japan

Osteocytes, terminally differentiated from osteoblasts, are thought to be a primary mechanosensory cell in bone; however the identity of the mechanosensing machinery and downstream signaling pathways remain largely unknown. To investigate the role of integrin αv in mechanotransduction in bone, we first generated mice lacking αv in osteoblast lineage using Osx-Cre (ΔOB). The ΔOB mice exhibited a lower BV/TV at baseline by microCT, along with reductions in serum CTX and OCN concentrations, compared with control, pointing to a lower turnover osteopenic state. When we subjected the ΔOB mice to tail suspension, a decrease in hindlimb BV/TV was attenuated. Histomorphometric analysis at the proximal tibia revealed that OS/BS, Ob.S/BS and BFR/BS were suppressed during tail suspension in the control group, whereas a significant suppression was not observed in the ΔOB mice.

We also generated mice lacking αv in osteocytes using Dmp1-Cre (ΔOCy). Similar to the ΔOB mice, the ΔOCy mice displayed a tendency of lower bone mass with lower turnover at baseline than the control group. Again, bone loss during tail suspension of the ΔOCy mice was less than that of control, suggesting the role of osteocytic αv integrin in mechanotransduction.

Finally, we examined a signaling pathway downstream of αv integrin in vitro using αv flox/flox primary osteoblastic cells, with or without adeno-Cre infection, mechanically stimulated with fluid shear stress (FSS). FSS increased phosphorylation of a Src substrate p130Cas and JNK, along with nuclear translocation of YAP/TAZ and subsequent transcriptional activation of target genes, ANKRD1 and CTGF. In the absence of αv integrin, phosphorylation of p130Cas and JNK in response to FSS was impaired, along with attenuation of YAP/TAZ nuclear translocation and ANKRD1 and CTGF gene expression. Thus, αv integrin may constitute the mechanosensing machinery in osteoblasts/osteocytes and transduce a mechanical signal through a Src-JNK-YAP/TAZ pathway.

Lower Bone Volume Fraction and Bone Formation Rate in Premenopausal Women with Abdominal Obesity Are Associated with Less Physical Activity and Higher Serum Sclerostin. Adi Cohen*[1], Aline Costa[2], Robert Recker[3], Joan Lappe[4], Serge Cremers[2], David Dempster[2], Hua Zhou[5], Alexander Zwahlen[6], Ralph Müller[7], Emily Stein[8], Thomas Nickolas[8], Clifford Rosen[9], Elizabeth Shane[8]. [1]Columbia University Medical Center, USA, [2]Columbia University, USA, [3]Creighton University, USA, [4]Creighton University Osteoporosis Research Center, USA, [5]Helen Hayes Hospital, USA, [6]ETH Zurich, Switzerland, [7]ETH Zurich, Institute for Biomechanics, Switzerland, [8]Columbia University College of Physicians & Surgeons, USA, [9]Maine Medical Center, USA

Recent studies have linked abdominal obesity to low bone mass and decreased bone formation. Additionally, abdominal obesity is associated with a sedentary lifestyle that may lead to less mechanical stimulation of bone. Sclerostin is an inhibitor of Wnt signaling, secreted by osteocytes, and mechanical stimulation has been shown to down-regulate sclerostin levels. Because sclerostin is a negative regulator of bone formation, we hypothesized that young women with more abdominal fat would have higher circulating sclerostin levels, and that sclerostin would be inversely associated with bone volume fraction and bone formation at the tissue level. We divided 40 healthy premenopausal women (age 37 ± 8 yrs; BMI 25.8 ± 4.7 kg/m^2) into tertiles based on DXA % trunk fat, a surrogate for visceral adiposity (Table). All were normally menstruating, had normal areal BMD by DXA, no history of fragility fracture and no known cause of bone loss. As previously reported, those with the most abdominal fat had substantially lower bone formation rates and lower bone volume fraction in iliac crest biopsies compared to those with the least abdominal fat. In addition, those with more abdominal fat reported significantly less physical activity (modified Baecke questionnaire), suggesting a state of low mechanical stimulation. Circulating sclerostin concentrations (ELISA, Tecomedical, Sissach, Switzerland) were highest in those with the most abdominal fat. Circulating sclerostin was significantly and directly related to age and abdominal adiposity and was inversely related to bone volume fraction, mineralizing perimeter, bone formation rate, exercise level, serum PINP and IGF-1. We conclude that lower mechanical stimulation and higher sclerostin levels may contribute to the lower bone formation and inferior microarchitecture seen among healthy premenopausal women with abdominal obesity.

Post-Natal Deletion of the Connexin43 Gene (*Gja1*) in Osteoblasts/Osteocytes: Model Development. Susan Grimston*[1], Marcus Watkins[1], Michael Brodt[2], Matthew Silva[1], Roberto Civitelli[1]. [1]Washington University in St. Louis School of Medicine, USA, [2]Washington University in St. Louis, USA

Mice with a conditional *Gja1* deletion develop a cortical (Ct) phenotype reminiscent of bone subject to disuse, and have reduced resistance to bending despite an increased moment of inertia (MOI). Earlier gene deletion reduces BMD and results in collagen matrix disorganization. Cx43 deficient bones require greater force to generate similar periosteal (Ps) strains compared to WT, while the Ps bone formation response to in vivo mechanical loading is enhanced. To gain insights regarding development of the structural abnormalities in Cx43 deficient bones, we used two approaches to achieve post-natal *Gja1* ablation. First, we treated *Osx-Cre;Gja1^{flxl}*-(*Osx-Cre;*cKO) mice with doxycycline (Doxy), to suppress the tetracycline repressible *Osx* promoter. Although Doxy dose-dependently attenuated the development of the Ct phenotype, even at the highest dose (200 mg/ml) we found expansion of Ma.Ar (+50.1±18.1%*) and Tt.Ar (+34.4±22.8%*), with Ct thinning (-12.7±7.9%*) and increased pMOI (+25.2±13.9%*) in *Osx-Cre*;cKO mice vs WT. Since *Gja1$^{+/-}$* are normal, development of Ct expansion despite Doxy suppression in *Osx-Cre;*cKO mice may reflect submaximal Cre repression by Doxy, resulting in >50% reduction in Cx43 relative to WT leading to the Ct phenotype. Secondly, we utilized the Tamoxifen (Tmx) inducible *Osx-CreER^{T2}* system were Cre expression is induced by 5 daily Tmx injections (100 mg/kg). In vivo µCT scanning revealed no differences in Ct parameters pre vs post Tmx treatment. Accordingly, and in contrast to other *Gja1* deletion models, strain gauge testing revealed similar force-strain relationships in Tmx-treated WT and *Osx-CreER^{T2};*cKO mice, suggesting that acute loss of Cx43 does not alter this relationship. In whole bone extracts, Cre mRNA was strongly induced by Tmx. However, total *Gja1* mRNA was only slightly reduced vs WT (0.7±0.4 vs 1.1±0.3), probably reflecting persistent *Gja1* expression in osteocytes (OCY). Indeed, immunohistochemistry revealed decreased but not complete loss of punctate Cx43-specific staining within the Ct OCY network of *Osx-CreER^{T2};*cKO 1 wk after Tmx treatment. Conversely, Cx43-specific stain was completely absent in Ps cells of Tmx-treated mutant mice. These data support the notion that Ct expansion and bone matrix abnormalities in Cx43 deficient bones are the result of a post-natal modeling defect. Tmx inducible *Gja1* deletion represents a good strategy for defining the role of Cx43 in mechanotransduction in adult animals.*p<0.05

New Tool to Study Human Sclerostin Gene Expression In Vitro. Jesus Delgado-Calle*[1], Carolina Sañudo[2], Marta Morante[3], Jose Riancho[4]. [1]Indiana University School of Medicine, USA, [2]IFIMAV, Spain, [3]Univ Francisco de Vitoria, Spain, [4]University of Cantabria, Spain

The osteocyte product sclerostin is emerging as a critical factor in bone remodeling and, consequently, in determining bone mass. However, the study of the factors involved in the regulation of sclerostin expression and activity is compromised by the absence of human osteocytic cell lines and protocols suitable to isolate human osteocytes. In an attempt to circumvent these problems, we aimed to establish a cell line that expressed high levels of sclerostin in vitro.

The human osteoblast-like cell line SaOs was cultured under standard conditions and the expression of SOST (the gene encoding sclerostin) and other genes was determined by real time PCR with Taqman assays and normalized to the housekeeping gene TBP. The methylation level of CpG islands located in gene promoters was determined by methylation-specific quantitative real time PCR (qMSP).

We confirmed that SaOs expressed low levels of sclerostin (SOST:TBP, 0.01 relative units). Then, they were subjected to limiting dilution in 96-well plates attempting to seed one cell per well and several clones were tested for sclerostin expression. Four clones with opposite expression levels were eventually selected and grown in culture.

In cultures of the two negative clones, sclerostin expression was very low (0.0006-0.06 r.u.), whereas the two positive clones expressed high levels of sclerostin (0.7-8.5 r.u.), similar to the level found in whole bone tissue and about 300-fold higher than the expression level in the original SaOs cultures. Those differences persisted through cell passages for several months, but sclerostin decreased in cultures reaching confluence. Sequencing the 5' region (1400 bp) of the SOST gene that includes its promoter revealed no differences across the clones. However, the differences in gene expression were inversely correlated with the methylation level of a CpG island in the sclerostin gene promoter, which was >90% methylated in the negative clones and only 27±11% in the positive clones. However, there were no consistent differences across sclerostin-positive and sclerostin-negative clones regarding the expression or the methylation of other genes, such as alkaline phosphatase and RANKL. In line with these results, the demethylating agent AzadC induced a 6-fold increase in SOST expression by the parental cell line.

In conclusion, these SaOs-derived clones may be a useful tool to study the mechanisms and factors regulating sclerostin expression. Additionally, these results confirm the influence of DNA methylation on sclerostin expression.

Novel immortalized cell lines expressing a membrane targeted GFP variant in osteocytes – identification of a "mini-bone" forming clone. Lisa Le*, Patricia Veno, Sarah Dallas. University of Missouri - Kansas City, USA

We have previously shown that osteocytes show dynamic properties by the extension and retraction of dendrites and that they shed membrane-bound microvesicles which may provide a novel mechanism for intercellular communication. To facilitate further studies of osteocyte dynamic properties and the function of osteocyte-derived microvesicles, immortalized cell lines were generated from transgenic mice expressing a membrane-targeted green fluorescent protein(GFP) variant driven by the 10kb dentin-matrix-protein-1 promoter (Dmp1-memGFP-mouse). Calvarial cells from these mice were transfected with SV40T antigen using the pSV3neo immortalizing vector and stable clones were generated. Two clones, OmGFP-10 and OmGFP-66, were selected for further characterization of their osteocytic properties over a 4 week culture period. Both cell lines initially showed strong alkaline phosphatase activity, a marker of the late osteoblast. Expression of the early osteocyte marker, Dmp1-memGFP, was induced in the presence of ascorbate and β-glycerophosphate. Mineralized foci were formed in association with GFP+ve cells that had a stellate osteocyte-like morphology. Western blotting in OmGFP-10 showed that the early osteocyte marker, E11/gp38 was expressed by day 3, with

expression peaking on days 14-21. Sclerostin was faintly detectable by day 21, with robust expression by day 28, consistent with progression from an early to a late osteocyte-like phenotype. Clone OmGFP-66 had the unique property of producing highly structured trabecular bone-like spicules, which we have termed "mini-bones". These mini-bones formed well organized lacunae containing embedded GFP-positive cells with an interconnected dendritic morphology and an inter-cell spacing closely mimicking osteocytes in bone tissues. Both cell lines released microvesicle-like structures into the matrix and culture media. Culturing OmGFP-66 on a collagen gel containing hydroxyapatite strongly induced expression of Dmp1-mem-GFP, suggesting that collagen-HA gels may provide a culture system in which acquisition of the osteocyte-like phenotype can be accelerated. These two new osteocyte-like cell lines will provide novel tools with which to study osteocytes and their dynamic properties and the composition and function of microvesicles

Osteocyte-derived Notch is a Determinant of Bone Mass and has Sexually Dimorphic Effects on Skeletal Remodeling. Ernesto Canalis, Stefano Zanotti*. St. Francis Hospital & Medical Center, USA

Notch are transmembrane receptors that play a critical role in cell fate decisions. Notch regulates skeletal development, chondrogenesis and osteoblastic cell differentiation, but its function in osteocytes remains poorly understood. In the present study, we define the function of Notch in osteocytes by studying the dual conditional *Notch1* and *2* inactivation in these cells. Mice where the *Notch1* and *2* alleles were targeted with *loxP* sequences were crossed with transgenics expressing the Cre recombinase under the control of the Dentin matrix protein 1 promoter (*Dmp1-Cre*) to create *Dmp1-Cre;Notch1/2$^{\Delta/\Delta}$* conditional null mice. Since Osterix (Osx)-expressing cells differentiate into osteocytes, *Notch1* and *2* conditional mice also were crossed with *Osx-Cre* transgenics to create *Osx-Cre;Notch1/2$^{\Delta/\Delta}$* null mice. Microcomputed tomography and histomorphometry demonstrated that male and female *Dmp1-Cre;Notch1/2$^{\Delta/\Delta}$* conditional null mice had increased trabecular bone volume and connectivity at 3 months of age due to an increase in trabecular number. The phenotype was transient in male and sustained and more pronounced in female *Notch1/2* null mice, which exhibited a sustained increase in cancellous bone for up to 6 months of life. Cortical bone was not affected in either sex. Male and female *Dmp1-Cre;Notch1/2$^{\Delta/\Delta}$* null mice displayed an early increase in osteoblast and a decrease in osteoclast number, explaining the increase in trabecular bone. The cellular phenotype evolved, and male, but not female, mice exhibited a 1.5 fold increase in osteoclast number and eroded surface at 3 months of age, explaining why the sustained increase in bone volume was observed in female, but not in male, *Notch1/2$^{\Delta/\Delta}$* conditional null mice. The skeletal phenotype of *Osx-Cre;Notch1/2$^{\Delta/\Delta}$* mice was similar, and male mice exhibited a transient increase in trabecular bone volume at 3 months of age due to an increase in trabecular number caused by an increase in osteoblast and a decrease in osteoclast number and bone resorption. Female *Osx-Cre;Notch1/2$^{\Delta/\Delta}$* mice exhibited a pronounced (2.5 – 2.75 fold) and sustained increase in cancellous bone for up to 6 months of life. In contrast, cortical bone was thinner and porous in *Osx-Cre;Notch1/2$^{\Delta/\Delta}$* mice, suggesting sex and compartment specific effects of Notch in the skeleton. In conclusion, osteocyte-derived Notch regulates the osteoblast and osteoclast cell pool and as a consequence it is a determinant of bone mass.

Rapid, Automated Counting of Osteocytes from Histological Sections Using Matlab Based Software. Ganesh Thiagarajan[1], Nuria Lara[1], Bhavani Ramneedi[2], Mark Johnson*[3]. [1]University of Missouri - Kansas City, USA, [2]UMKC School of Computing & Engineering, USA, [3]University of Missouri, Kansas City Dental School, USA

We have previously shown using the TOPGAL mouse that there is a rapid activation of the β-catenin signaling pathway in osteocytes and eventually to cells on the bone surfaces following in vivo forearm loading. These data were quantitated using a manual counting method that has proven to be labor intensive, time consuming and subject to potential bias. Therefore we have developed an automated counting program using the Matlab software platform that greatly expedites and improves data quantitation. Following in vivo loading of the right forearm, both forearms were harvested and stained for β-galactosidase activity, followed by sectioning and immunostaining using fluorescent antibodies against proteins of interest and finally bright field and fluorescence photography. Manual counting of these images for β–gal positive, immuno-positive and total osteocytes requires ~30 minutes/section and does not take into consideration color intensity. To reduce potential bias and insure accuracy, data generated by two individuals blinded to each other's results were compared. The advantages of the automated software are a significant reduction in time required for analysis, a reduction in individual bias and greater accuracy with regards to quantitative staining intensity. The automated method first quantitates a nonimmune IgG image to set a lower threshold for the immunostained images, counts the DAPI image to obtain the total number of osteocytes in the section, then obtains stained areas, various distance and size information, and finally analyzes the β-galactosidase and immunostained images. The program operator has the ability to select any area of the image to be analyzed at multiple points while the program is being executed, guided by user interface prompts. Specific sized areas can be excluded to remove blood vessels and filter out sectioning artifacts. The entire image capture and analysis is ~2 minutes/section. We have performed a number of correlation studies to compare manual versus automated counting and obtained correlation coefficient (r^2) values of 0.98 for total and β–galactosidase positive cells, 0.92 for DAPI counts and 0.97 for sclerostin positive cells. This automated method is a major advance in terms of manual counting of osteocytes from histological sections and the procedure is easily adaptable to any staining method and color combinations. Further development of this program is underway to enable counting of bone surface cells.

Altered Osteocyte Mechanosensitivity in Response to Elevated Extracellular Glucose Levels. Chao Liu*[1], Hashem Al-Dujaili[2], Christian Fischer[3], Liyun Wang[4], Lidan You[5]. [1]University of Toronto, Canada, [2]University of Western Ontario, Canada, [3]University of Würzburg, Germany, [4]University of Delaware, USA, [5]Mechanical & Industrial Engineering, University of Toronto, Canada

Introduction: Hyperglycemia contributes to resulting in bone loss, and an elevated risk of bone fracture in diabetic patients. The effects of hyperglycemia on osteocyte mechanosensitivity are unknown. Osteocytes are bone cells that detect mechanical stimulation, and regulate osteoblasts and osteoclasts via paracrine pathways. This study tests the hypothesis that hyperglycaemia suppress the effects of mechanical loading (fluid shear) on osteocytes. We will examine secretion of anabolic cytokine, PGE2, catabolic cytokine RANKL and osteocyte apoptosis, which play a role in initiation of bone remodeling.

Methods: MLO-Y4 cells were seeded on rat tail type I collagen coated slides at a density of 3000 cells/cm2 and incubated for 72 hours in one of three media: i) Normglycemic control medium, ii) osmotic control medium with 20 mM of D-mannitol; and iii) hyperglycaemic medium with 20 mM D-glucose.

Parallel plate flow chambers were used to apply 10 dynes/cm2 of oscillating shear stress at 1Hz for 2 hours. Then, they are incubated at 37C with fresh media. Media were collected after 24 hours of incubation.

Protein Quantification: ELISA was used to quantify RANKL in media. PGE2 levels were quantified using EIA assay. Total protein was determined using a colorimetric kit and lysis buffer

Apoptosis Measurement: Caspase 3/7 level was measured with fluorescent kit.

Results: Osteocytes in the normglycemic or mannitol-supplemented media showed decreased apoptosis induced by fluid flow (Fig 1), which was abolished in hyperglycaemic medium. In normglycemic and osmotic control media, fluid flow resulted in decreased secretion of RANKL by osteocytes, which was inhibited in hyperglycaemic medium (Fig 2). PGE2 production increased in fluid flow conditions in normglycemic and osmotic control media was suppressed in hyperglycemia media (Fig 3).

Discussion: This study investigated how hyperglycaemia affected protein expression of markers involved in bone remodeling in osteocytes under mechanical loading. Hyperglycemia abolished mechanical loading induced changes in RANKL and PGE2 levels released by MLO-Y4 cells. Osmotic controls did not exhibit the same effect on osteocytes, suggesting hyperglycaemic condition may have direct effects on osteocytes, adversely influencing osteocyte's ability to respond to mechanical loading. This effect may be responsible for the impaired bone structure and properties seen in diabetic patients.

Osteocyte Specific Deletion of Superoxide Dismutase2 Induces Osteocyte Loss Resulting in Bone Loss Associated with Impairment of Bone Remodeling. Keiji Kobayashi*[1], Hidetoshi Nojiri[2], Yoshitomo Saita[3], Daichi Morikawa[4], Masato Koike[5], Yusuke Ozawa[6], Yoshinori Asou[7], Kazuo Kaneko[8], Takahiko Shimizu[9]. [1]Chiba university, Graduate school of medicine, Japan, [2]Juntendo University, School of Medicine, Japan, [3]Department of Orthopaedics, Juntendo University School of Medicine, Japan, [4]Juntendo Univerisity, Japan, [5]Juntendo University, Japan, [6]Chiba university, Graduate school of medicine, Japan, [7]Tokyo Medical & Dental University, Japan, [8]Juntendo university, Japan, [9]Chiba University Graduate School of Medicine, Japan

Superoxide dismutase 2 (*Sod2*) is a mitochondrial antioxidant enzyme that plays a pivotal role in the maintenance of mitochondrial redox balance. However, the physiological function of *Sod2* in bone metabolism has not been fully elucidated. To address this question, mice lacking *Sod2* in osteocytes were generated by cross-breeding mice harboring a *Sod2* conditional allele with *Dmp1*-Cre transgenic mice (*Sod2* cKO). pQCT and micro-CT analyses revealed that BMD (-20%), BV/TV (-29%), Tb.N (-25%), and cortical thickness (-12%) were significantly reduced in *Sod2* cKO femora, while Tb.Sp was increased (+63%) in *Sod2* cKO. In the three-point bending test, bone stiffness was significantly weakened in *Sod2* cKO (-23%). Furthermore, *Sod2* deficiency significantly suppressed bone formation parameters such as MS/BS (-24%), MAR (-32%), and BFR/BS (-41%) in *Sod2* cKO. *Sod2* loss also significantly increased osteoclast number (+35%) and osteoclast surface (+37%) in *Sod2* cKO. These data indicated that *Sod2* deficiency in *Dmp-1* positive cells exhibited bone loss and fragility due to impaired bone remodeling. In addition, histomorphometric analyses revealed that *Sod2* loss significantly increased number of empty lacunae and markedly disorganized bone canaliculi in the cortical bones, indicating osteocyte loss and dysfunction. Since osteocyte dysfunction up-regulates *Rankl* expression in osteocytes, we investigated the expression levels of *Rankl* and *Opg* in bone. Quantitative PCR analysis revealed that *Rankl*/*Opg* ratio was significantly increased by four-fold in bones of *Sod2* cKO, supporting the increase of osteoclast number and activity. In culture experiments, mineralized nodule formation was markedly suppressed in both calvaria- and bone marrow-derived cells in *Sod2* cKO mice, suggesting the impairment of bone forming ability. These findings demonstrated that *Sod2* deficiency in osteocytes induced osteocyte cell death resulting in bone loss associated with *Rankl*-mediated bone resorption and impaired bone forming ability.

Osteocytes Reveal NADH Fluorescence Heterogeneity *in Situ* in Response to Ischemia. Dorra Frikha-Benayed*[1], Jelena Basta-Plajkic[2], Robert Majeska[3], Mitchell Schaffler[4]. [1]The City University of New York, USA, [2]City college of NY, USA, [3]City College of New York, USA, [4]City College of New York, USA

Osteocyte apoptosis (OtAp) is a key signaling step in bone remodeling. Hypoxia is thought to be a major cause of OtAp and subsequent signaling. NADH levels rise in hypoxia as mitochondria stop producing ATP by oxidative phosphorylation. Since NADH autofluorescence can be monitored in situ, we therefore tested if this could serve to assess Ot cell stress in intact bones subjected to ischemia. To image osteocytes, dorsal surfaces of adult C57BL/6J mouse metatarsals were exposed under anesthesia, preserving periosteum and blood supply (IACUC approved). In situ Ot NADH was visualized by multiphoton microscopy (40X Obj; Ex: 833 nm, Em: 460 nm) at baseline, and following euthanasia to induce ischemia. Ots were imaged over time at depths to 100μm below the periosteum and fluorescence intensity values for individual cells were measured. NADH fluorescence was not detected in Ot at baseline in vivo, but began to accumulate within 20 min after onset of ischemia (Fig 1). NADH accumulation in osteocytes was not uniform throughout the cortex. In cells < 40 μm below periosteum, NADH accumulation peaked at 84 ± 10 min after ischemia (Fig 2). Ot deeper in bone reached peak NADH levels at 145 ± 10 min after ischemia (Fig 2). In both regions, NADH fluorescence declined thereafter (not shown). These results show that NADH autofluorescence can be used to monitor changes in Ot redox state in situ. Changes in Ot NADH fluorescence after ischemia resembled those seen in other aerobic tissues. Absence of NADH signal under basal conditions indicates that Ot reside in a normoxic environment, while increases in NADH levels following hypoxic stress indicate mitochondrial dysfunction from lack of O2. Later declines in NADH levels likely reflect ATP depletion and onset of cell death. Most interesting were the spatial differences in Ot NADH accumulation with cortical depth. These may result from differing proximity to blood supply, but could also indicate intrinsic differences in Ot metabolism at different cortical depths. Regardless of the cause, our results are the first to show that Ot in situ are clearly a heterogeneous cell population with regard to metabolic state. Since metabolic stress is considered an essential step for initiation of Ot signaling in response to many stimuli, we posit that NADH monitoring in vivo will be an important new approach for identifying Ot that are ''at risk'' to undergo apoptosis following mechanical or metabolic insult.

Osteocytic Osteolysis Induced by Immobilization in Rats. Fiona Bach-Gansmo*[1], Jesper Thomsen[1], Annemarie Brüel[2], Henrik Birkedal[1]. [1]Aarhus University, Denmark, [2]University of Aarhus, Denmark

We measured osteocyte lacunar volumes to show that disuse osteoporosis induces osteocytic osteolysis. The ability of osteocytes to demineralize the perilacunar matrix, osteocytic osteolysis, has been heavily debated for more than a century [1]. Osteocytes are housed in lacunae, and form a vast interconnected 3D lacuno-canalicular network (LCN) with a large surface area. Osteocytic osteolysis is expected to manifest itself through increased lacunar (and/or canalicular) volumes, as the LCN is the negative imprint of the cellular/dendritic network and its activities. The mechanism for such a resorptive capability remains unclear. Much effort is currently being put into characterizing and understanding the activity of the LCN. Previous studies have reported that while lactation induces osteocytic osteolysis, immobilization does not [2], or even result in reduced lacunar volumes [3]. Here we show that osteocytic osteolysis does occur upon immobilization.

The right hind limbs of female 3-months-old Wistar rats (N=5) were immobilized using injections of botolinum toxin A (Botox), with the contralateral leg serving as a biologically matched control [4]. A second group of animals (N=5) were injected with saline, and their right hind limbs used as an external control. Samples of mid-femoral cortical bone were obtained from animals put down 4 weeks post treatment. The lacunar volumes of more than 530000 osteocytes were determined using high resolution (0.37 μm voxel size) synchrotron radiation nano-tomography.

Osteocyte lacunar volumes were signifcantly larger in immobilized (median 226 μm^3) than contralateral (199 μm^3) and control samples (202 μm^3), see the figure. A model was developed to obtain quantitative understanding of the change in lacunar volume distributions between the Botox treated and contralateral legs (orange curve in figure).

The present results reveal that osteocytic osteolysis can be induced by immobilization in rat cortical bone in contrast to previous reports [2,3]. These prior studies were based on measurements of fewer lacunae and/or with poorer spatial resolution than in the present work.

TNF-α upregulates sclerostin expression through NF-κB signaling pathway in high fat diet fed obese mice. Kyunghwa Baek*[1], Hyo Rin Hwang[2], Hyun-Jung Park[2], Arang Kwon[2], Abdul Qadir[2], Seong-Hee Ko[3], Jeong-Hwa Baek[4]. [1]Gangneung-Wonju national university, School of dentistry, South Korea, [2]Seoul National University, South Korea, [3]Gangneung-Wonju National University, South Korea, [4]Seoul National University, School of Dentistry, South Korea

Sclerostin, the osteocyte-specific glycoprotein, is known to lower bone mass by antagonizing Wnt signaling pathway. We examined whether obesity-induced bone loss is associated with Sclerostin expression and whether obesity-related inflammatory cytokine tumor necrosis factor-α (TNF-α) directly upregulates Sclerostin expression. Five weeks old male mice were assigned into two groups (n=10 each): control diet (10% kcal from fat) fed mice (CON) and high fat diet (60% kcal from fat) fed mice (HF) during 12 weeks. After the 12-week experimental period, final body weight and whole body fat mass of HF mice were higher than those of CON mice. Distal femur cancellous bone mineral density and bone formation rate was lower in HF mice *vs* CON mice (by 17% and by 73%, respectively). Percent resorbing surface was higher by 7-fold in HF *vs* CON mice. The expression level of Osteocalcin in femur was lower in HF mice *vs* CON mice while the ratio of receptor activator of NF-kB and Osteoprotegerin was higher in HF mice *vs* CON mice. Serum level and femoral osteocytic protein expression level of TNF- α was significantly higher in HF mice *vs* CON mice. Sclerostin expression in mRNA level and osteocytic protein level in femoral cortex was also higher in HF mice *vs* CON mice. Sclerostin expression in

MLO-Y4 osteocytes increased with TNF-α treatment and TNF-α-induced Sclerostin expression was blocked by the inhibition of NF-kB activation. Chromatin immunoprecipitation and luciferase reporter assay demonstrated that NF-kB directly binds to the NF-kB binding elements on the mouse *sost* promoter, stimulating Sclerostin expression. These results support an idea that, in the context of obesity or other inflammatory diseases increasing production of TNF-α, TNF-α upregulates the expression of Sclerostin through NF-kB signaling pathway, contributing to bone loss.

This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korean government (MEST) (2011-0016548 and 2010-0005836).

Imaging Mass Spectrometry-based Molecular Histology of Bone Shows the Implication of MEPE-ASARM for the Klotho-Deficient Phenotype. Yoko Fujino*[1], Tomoko Minamizaki[2], Kaoru Sakurai[1], Yasumasa Irie[3], Hirotaka Yoshioka[2], Yuichiro Takei[2], Katsuyuki Kozai[2], Mitsugi Okada[2], Yuji Yoshiko[2]. [1]Hiroshima University Graduate School of Biomedical & Health Sciences, Japan, [2]Hiroshima University Institute of Biomedical & Health Sciences, Japan, [3]Hiroshima University Faculty of Dentistry, Japan

Recent growing evidence suggests that osteocytes play a significant role in bone, while their functions remain largely unknown. We searched biomolecules linked to osteocyte functions not only in normal mice but also in Klotho-deficient (*kl/kl*) mice. Klotho, originally identified as a putative aging-suppressor, exhibits diverse functions in mice depending on its binding partners, causing a limited understanding of skeletal anomalies in Klotho deficiency. We initially analyzed bone samples by using a combination of two-dimensional-liquid chromatography-tandem mass spectrometry (2DLC-MS/MS) and plant proteomic techniques (Proteomics, 12: 1870, 2012). Moreover, osteocytes were fractionated and subjected to microarray analysis. To define osteocyte origin, we focused on small proteins/peptides detectable by high-resolution matrix-associated laser desorption ionization (MALDI)-imaging mass spectrometry (IMS) which provide label-free localization of molecules in tissue samples. To do this, we prepared fresh frozen bone sections with or without decalcification. 2DLC-MS/MS and microarray revealed a variety of proteins/genes including multiple cell origins. MALDI-IMS could identify molecules less than 20-kD including proteins/peptides localized in osteocytes. Amongst these molecules, we concluded that one of peaks corresponding to Klotho-deficient mouse osteocytes was matched to that of matrix extracellular phosphoglycoprotein-derived acidic serine and aspartic acid-rich motif peptide (MEPE-ASARM). To confirm whether MEPE-ASARM accumulation in *kl/kl* osteocytes is dependent on *Mepe* gene expression, we examined mRNA and/or protein levels of MEPE, together with other SIBLING family members such as osteopontin, bone sialoprotein and dentin matrix protein 1. Cathepsin B involved in MEPE degradation was also examined. In comparison to wild-type mice, expression levels of these molecules were not apparently changed in *kl/kl* mice. However, in parallel with MALDI-IMS, immunohistochemistry revealed that MEPE-ASARM was abundantly accumulated in *kl/kl* osteocytes. Because MEPE-ASARM was detectable in circulation and inhibited mineralization not only in osteoblast cultures but also in vascular smooth muscle cell cultures, MEPE-ASARM from osteocytes may be involved in biological mineralization processes. Thus, molecular histology using MALDI-IMS may provide new insight into osteocyte and bone biology.

Selective Deletion of c-fms in Osteocytes Increases Cortical and Trabecular Tissue Mineral Density. Meiling Zhu*[1], Benhua Sun[2], Joshua VanHouten[2], Christine Simpson[2], Karl Insogna[2]. [1]Yale University, USA, [2]Yale University School of Medicine, USA

Background: How osteocytes remodel their lacunae is poorly understood. Recent evidence suggests that this process is dynamic and may contribute to systemic mineral homeostasis. Osteocytes also express biochemical features of mature osteoclasts in certain physiologic states such as lactation. Since osteocytes express the CSF1 receptor, c-fms and since CSF1 plays a key role in osteoclast differentiation and survival as well as in mature osteoclast function, the role of c-fms in osteocytes was examined.

Methods: Mice with two floxed c-fms alleles were crossed with transgenic animals expressing cre recombinase under the control of an 8 kb DMP1 promoter and then appropriately backcrossed to yield animals with either a $cre^{+/}$ -c-$fms^{flox/flox}$ genotype (k/o) or a $cre^{-/}$ -c-$fms^{flox/flox}$ genotype (control). Bone density was analyzed by DXA and by microCT using a Scanco 35 instrument at 6 micron nominal resolution. Serum CTX, FGF23 and sclerostin were measured using commercially available kits. Serum phosphorus was measured with a Roche autoanalyzer. .

Results: The k/o mice exhibited normal growth. BMD measured by DXA adjusted for body weight was not different in these animals compared to controls (28.9 ± 1.2 vs. 28.0 ± 1.2, 33.8 ± 1.2 vs. 32.7 ± 0.9 and 24.0 ± 0.8 vs. 23.8 ± 1.0, gms/cm2x10,000/g-bw; spine, femur and total body; knock out vs. controls respectively). However, when analyzed by microCT, cortical BV/TV was significantly higher in the k/o animals(0.915 ± 0.003 vs. 0.907 ± 0.002 g/cm3, p=0.02). Tissue mineral density (TMD) was also significantly higher in cortical bone (1045.5 ± 5.3 vs.973.1 ± 7.9 g/cm3, p<0.0001). In addition there was a significant increase in TMD in trabecular bone (885.1 ± 4.1 vs. 834.6 ± 6.9 g/cm3, p<0.001). Mean serum CTX was 19.6 ± 2.3 ng/ml in k/o animals and 18.9 ± 2.6 pg/ml in controls. Serum sclerostin values were slightly higher in the k/o animals but the difference was not significant (538 ± 50 vs. 509 ± 48 pg/ml). Serum FGF23 levels were also slightly higher in the k/o animals (313.3 ± 23.6 vs. 300.0 ± 28.8 pg/ml) but again the difference was not significant. Mean serum phosphorus was 8.1 ± 0.9 mg/dl in k/o animals and 7.2 ± 0.8 mg/dl in controls.

Conclusions: TMD is influenced by the composition of the extracellular matrix and by osteocyte lacunar frequency and size. Deleting c-fms in these cells changes one or both of these parameters.

Distributions of serum total osteocalcin, undercarboxylated osteocalcin, N-propeptide of Type 1 collagen and C-telopeptide of Type 1 collagen in older men. The Health In Men Study. Peter Ebeling*[1], SA Paul Chubb[2], Elizabeth Byrnes[2], John Beilby[2], Kieran A McCaul[3], Samuel Vasikaran[2], Paul E Norman[4], Leon Flicker[5], Bu B Yeap[6]. [1]The University of Melbourne, Australia, [2]PathWest Laboratory Medicine, Australia, [3]Western Australian Centre for Health & Ageing, Centre for Medical Research, University of Western Australia, Australia, [4]School of Surgery, University of Western Australia, Australia, [5]University of Western Australia, Australia, [6]School of Medicine & Pharmacology, University of Western Australia, 6Department of Endocrinology & Diabetes, Fremantle Hospital, Australia

Bone turnover markers (BTMS) have been advocated as a means of stratifying fracture risk in conjunction with assessment of bone mineral density, and for monitoring responses to anti-osteoporosis therapy. We aimed to characterise the distribution of bone turnover markers in older men, and to describe analyte reference ranges based on levels found in healthy older men.

We assayed early morning serum aliquots from 4,020 community-dwelling men aged 70-89 years resident in Perth, Western Australia. Total osteocalcin (TOC), N-propeptide of Type 1 collagen (P1NP) and C-terminal cross-linking telopeptides of Type 1 collagen (CTX) were assayed using an automated analyser (Roche E170, Roche Diagnostics, Australia). Undercarboxylated osteocalcin (ucOC) was assayed before and after hydroxyapatite binding (Roche E170, Roche Diagnostics, Australia).

Distributions of TOC, ucOC, P1NP and CTX were skewed to the right. Correlations between bone turnover markers (Spearman's rho) were: TOC and ucOC 0.87, TOC and P1NP 0.77, TOC and CTX 0.75, P1NP and CTX 0.75. After excluding men with Paget's disease, osteoporosis, recent bone fracture, or receiving warfarin, glucocorticoids or bisphosphonates, median (interquartile range) for bone turnover markers in 3,442 men were: TOC 18.7 (14.7-24.1) ng/ml, ucOC 10.1 (8.0-12.9) ng/ml, P1NP 36.8 (28.1-49.2) ng/ml and CTX 0.282 (0.201-0.390) ng/ml/. All BTMs were positively correlated (Spearman's rho) with age TOC 0.22, ucOC 0.17, CTX 0.14, and P1NP 0.09 - all p<0.0001.

In a reference group of 366 very healthy older men, the 2.5^{th} to 97.5^{th} percentiles were: TOC 10.0-40.8 ng/ml, ucOC 5.1-20.1 ng/ml, P1NP 17.8-117.0 ng/ml and CTX 0.105-0.683 ng/ml.

In older men, BTMs are distributed in similar fashion with moderately strong correlations between markers of bone formation and resorption and all show age-related increases. This supports prior data showing that bone remodeling increases with age in elderly men. However, additional research is needed to clarify the value of individual bone turnover markers to predict fracture risk, and to ascertain the value of biochemical reference ranges for BTMs in the assessment of responses to anti-osteoporotic therapy in older men.

Serum Levels of Sclerostin and dickkopf-1 in Geriatric Patients with Osteoporotic Hip Fractures. Sonja Dorfer[1], Andrea Kapfenberger[1], Ursula Föger-Samwald[1], Stefan Kudlacek[2], Peter Dovjak[3], Peter Pietschmann*[1]. [1]Department of Pathophysiology & Allergy Research, Medical University Vienna, Austria, [2]Department of Medicine, Hospital Barmherzige Brüder, Austria, [3]Department of Geriatric Acute Care, Hospital Gmunden, Austria

Sclerostin and dickkopf-1 are inhibitors of the canonical wnt signaling pathway and consequently decrease bone formation. Since osteoblast dysfunction is an important aspect of age related osteoporosis, we studied serum levels of the afore mentioned wnt inhibitors in 164 patients with osteoporotic hip fractures (mean age: 81 ± 8 years), 119 geriatric control subjects and in 68 young control subjects (mean age: 23 ± 5 years). Serum concentrations of sclerostin and dickkopf-1 were measured by ELISA (Biomedica Medizinprodukte GmbH & Co KG, Vienna, Austria).

In men (but not in women) a significant increase of serum sclerostin levels with age was seen. Sclerostin levels were consistently higher in men than in women. In women with hip fractures, serum sclerostin was significantly lower than in young control women. Serum dickkopf-1 levels increased significantly with age in women and in

men. Dickkopf-1 levels were significantly higher in hip fracture patients than in geriatric or young controls.

We conclude that the determination of sclerostin and dickkopf-1 is useful for the study of age related bone fragility. Nevertheless, sclerostin and dickkopf-1 levels in the peripheral circulation appear to reflect different biologic events.

SU0292

A novel image analysis method for longitudinal assessment of trabecular volumetric bone mineral density (vBMD) in rabbit lumbar vertebrae using Quantitative Computed Tomography (QCT). Randolph Crawford*[1], Sangeetha Somayajula[1], Brenda Pennypacker[2], Dahai Xue[1], Christopher Winkelmann[3]. [1]Merck & Co., USA, [2]Merck Research Laboratories, USA, [3]Merck, USA

Ovariectomized (OVX) rabbits are a model for post-menopausal osteoporosis. We employed longitudinal QCT imaging to evaluate the impact of novel therapies on trabecular vBMD (Tb.vBMD) of the rabbit vertebrae. An automated tool was developed to provide efficient evaluation of Tb.vBMD. This novel tool was applied to an efficacy study where OVX rabbits (n=12-19/group) were treated with vehicle, alendronate (ALN), and/or parathyroid hormone (PTH) over the course of 10 months. Rabbits were scanned on the GMI eXplore Locus Ultra at baseline, 3, 6, and 10 mo. The caudal $5^{th}/6^{th}$ region of the 6^{th} lumbar vertebra was chosen as the region of interest (ROI) because it contains the largest amount of trabecular bone and avoids both the caudal physis and the region of absent trabecular bone in the middle of the vertebra. We developed custom programs that performed the following steps: (1) convert the CT images from Hounsfield units (HU) to mg/cc of hydroxyapatite (HA) using a density phantom, (2) isolate the 6^{th} lumbar (L6) vertebra from the QCT images, (3) rigidly co-register (no scaling) all later time point L6 images of each rabbit to its own baseline , (4) create a mask of trabecular bone from the caudal $5^{th}/6^{th}$ region of the L6 baseline image (average volume of 94.9 mm^3), (5) apply this mask to the registered longitudinal images for each rabbit, and (6) output the average Tb.vBMD (mg/cc HA) of this region. The co-registration of the later time points to baseline of each rabbit ensures longitudinal consistency of measurement ROI . Total automated image processing run time for ~500 image data sets was ~8 hours. The manual component was reduced to visual inspection and/or correction as needed for <10% of the images. The manual correction rate could be further reduced by standardization of animal positioning and imaging field of view. Longitudinal analysis of QCT images showed robust increases in Tb.vBMD in the ALN (9.0%) and PTH (13.3%) treated groups at 10 months compared to vehicle. QCT analysis resulted in significance between groups at 3 mo. compared to 6 mo. for DXA results. With slight modification of the tool, additional analyses could be performed including evaluating L6 cortical and sub-cortical bone regions, and voxel by voxel analysis of BMD changes to evaluate longitudinal BMD difference "maps" of L6. In summary, this tool allowed for robust, efficient evaluation of Tb.vBMD of large, longitudinal rabbit L6 QCT data sets.

Agreement Between Forearm Measurements Performed on the Norland pDEXA and the Norland XR-800 Table Scanner. Jingmei Wang*[1], Felix Rajan[2], Chad Dudzek[3], Terry Schwalenberg[3], Tom Sanchez[4]. [1]Norland–a CooperSurgical Company, China, [2]Siemens Healthcare, USA, [3]Norland–a CooperSurgical Company, USA, [4]Norland - A Cooper Surgical Company, USA

Differences have often been reported between measurements made using different models of DXA equipment. These differences result from differences in beam geometry, calibration and analysis routines. While the Norland pDEXA and table scanners are calibrated against the same chemical standards and have similar analysis routines we wanted to directly examine the relationship between forearm measurements performed on these two significantly different Norland DXA systems to establish if studies done on the two systems may be comparable.

Five repeated scans of seventeen forearm phantoms were performed, using standard scan settings, on the Norland pDEXA System (scan speed of 16mm/s and resolution of 1.0 mm x 1.0 mm) and Norland XR-800 System (scan speed of 8mm/s and resolution of 1.0mm x 1.0mm). Agreement between the two systems for the Distal Radius + Ulna, Proximal Radius + Ulna and Proximal Radius Bone Mineral Density, Bone Mineral Content and Bone Area measurements was evaluated by Regression Analysis and a Bland-Altman Analysis.

Regression analysis and a Bland-Altman Analysis showed a very strong positive agreement between measurements of Bone Mineral Density for the Distal Radius + Ulna (difference 0.2%, r=0.9977), Proximal Radius + Ulna (difference 0.9%, r=0.9863) and Proximal Radius (difference 0.9%, r=0.9801). Measurements of Bone Mineral Content—where calibration differences might cause a greater effect—showed the XR-800 had a slightly higher value but a very positive relationship in regression analysis for the Distal Radius + Ulna (0.6% difference, r=0.9983), Proximal Radius + Ulna (1.8% difference, r=0.9944) and Proximal Radius (1.9% difference, r=0.9943). Finally, measurements of Bone Area—where differences in beam geometry might cause an effect—also showed the XR-800 had a slightly larger area with a very strong positive relationship in regression analysis for the Distal Radius + Ulna (0.5% difference, r=0.9701), Proximal Radius + Ulna (1.0% difference, r=0.9831) and Proximal Radius (1.0% difference, r=0.9866).

In conclusion, evaluation of forearm phantom studies done on the Norland Table Scanner and the pDEXA showed equality in results for Bone Density, Bone Mineral Content and Bone Area for the three regions of interest evaluated by the systems in default settings. This supports a conclusion that results on the two systems are directly comparable.

Bone Micro-Architecture Assessed by Spine TBS Predicts Osteoporotic Fractures in Men: The Manitoba Study. William Leslie*[1], Berengere Aubry-rozier[2], Didier Hans[2]. [1]University of Manitoba, Canada, [2]Lausanne University Hospital, Switzerland

One quarter of hip fractures and a similar proportion of other osteoporotic fractures occur in men. TBS, a novel gray-level measurement derived from lumbar spine DXA image texture, is related to microarchitecture and fracture risk independently of BMD. Previous studies have reported the ability of spine TBS to discriminate and predict osteoporotic fracture in women. Our aim was to evaluate the ability of lumbar spine TBS to predict clinical osteoporotic fractures in men.

3,620 men age ⩾50 years at the time of baseline hip (femoral neck) and spine (L1-4) DXA were identified from a database containing all clinical results for the Province of Manitoba, Canada. Health service records were assessed for the presence of non-traumatic osteoporotic fracture codes after BMD testing. Lumbar spine TBS (TBS iNsight®) was derived from each spine DXA examination blinded to clinical parameters and outcomes. We used Cox proportional hazard regression to analyze time to first fracture with adjustment for clinical risk factors (FRAX score derived without BMD), recent osteoporosis treatment (OTX) and BMD (hip and spine).

Mean age of the men was 67.6 ± 9.8 y. During mean 4.5 y of follow up there were 183 (5.1%) men with major osteoporotic fractures (MOF), 91 (2.5%) clinical vertebral fractures (CVF), and 46 (1.3%) with hip fractures (HF). Correlation between spine BMD and spine TBS (adjusted for BMI) was modest (r=.31) and less than the correlation between spine and hip BMD (r=.63), consistent with a skeletal parameter largely unrelated to BMD. Significantly lower spine TBS parameters were found in fracture versus non-fracture men for MOF (p<.001), HF (p<.001) and CVF (p=.003). ROC analysis for incident fracture discrimination was significantly better than chance (MOF AUC=0.59, p<.001; HF AUC=0.67, p<.001; CVF AUC=0.57, p=.032). TBS predicted MOF and HF (but not CVF) in models adjusted for cliniucal risk factors (FRAX without BMD) and OTX. TBS remained a predictor of HF (but not MOF) after further adjustment for hip BMD or spine BMD.

In conclusion, despite the relatively small number of incident fractures, we observed that spine TBS predicted MOF and HF independently of the clinical FRAX score. Furthermore, TBS predicted HF independent of FRAX and BMD. TBS may be able to improve fracture risk assessment in men, but studies with larger numbers of incident fractures are needed to confirm these findings.

	HR per SD decrease in spine TBS (95% CI)		
Covariate adjustments	MOF	HF	CVF
FRAX, OTX*	1.22 (1.06 – 1.41)	1.60 (1.21 – 2.11)	1.12 (0.91 – 1.38)
FRAX, hip BMD, OTX*	1.12 (0.96 – 1.30)	1.36 (1.01 – 1.83)	1.14 (0.97 – 1.34)
FRAX, spine BMD, OTX*	1.08 (0.93 – 1.26)	1.57 (1.19 – 2.07)	1.02 (0.81 – 1.27)

Bone Strength Differences in Older Women With and Without a Recent Distal Radius Fracture. Katie Crockett*, Cathy Arnold, Jonathan Farthing, Phil Chilibeck, Adam Baxter-Jones, Saija Kontulainen. University of Saskatchewan, Canada

Introduction: Distal radius fracture (DRF) in women over age 50 is one of the first signs of bone fragility and a strong predictor of fracture risk. Dual-energy X-ray absorptiometry (DXA) measured areal bone mineral density (aBMD) derived t-score of the femoral neck is the primary clinical tool to diagnose osteoporosis and assess fracture risk; however, most fractures occur in women who are not diagnosed as osteoporotic possibly due to the deterioration in bone structure and strength, which planar DXA measures cannot detect. The aim of this study was to compare bone properties at the forearm measured with peripheral quantitative computed tomography (pQCT) and DXA in postmenopausal women with and without a recent DRF. Methods: 77 postmenopausal women age 50-78 with (Fx) and without (Ctl) a recent DRF (6-24 months post-fracture) were recruited from local clinics and through advertisement. Participants (N=35) were excluded for: corticosteroid, bisphosphonates or hormone replacement therapy in the past year, medical conditions that

severely affected daily living or the upper extremity. We compared bone properties between age matched Fx (n=21) and Ctl (n=21). All bone measures were from the non-dominant (Ctl) or non-fractured limb (Fx). We used pQCT to measure total (To), trabecular (Tr), and cortical (Co) density (D), area (A), content (C) and estimate bone strength in compression (BSIc) at the distal radius and stress strain index in torsion (SSIp) at the shaft. DXA was used to measure aBMD and BMC at the ultradistal forearm, spine and femoral neck. Differences in aBMD at the hip and spine were assessed using independent t-tests and differences for TrD and BSIc at the distal radius, SSIp at the radial shaft, and aBMD and BMC at the ultradistal forearm with MANCOVA using $p < 0.05$. Results: There were no significant differences in aBMD at the femoral neck or lumbar spine. After controlling for forearm muscle cross sectional area and height, there was a significant MANCOVA group difference Pillai's Trace, $p < 0.001$, with the Fx group demonstrating lower TrD, TrC, ToC, BSIc at the distal radius, lower CoD and CoC at the radius shaft, and lower aBMD and BMC of the ultradistal forearm (Table 1). Conclusions: Women with a recent DRF have lower pQCT derived TrD, estimated bone strength, DXA derived aBMD and BMC at the distal radius/forearm. Site specific measurement of bone may improve the assessment of distal radius fracture risk in postmenopausal women.

Table 1. DXA: Derived t-score classification and MANCOVA results

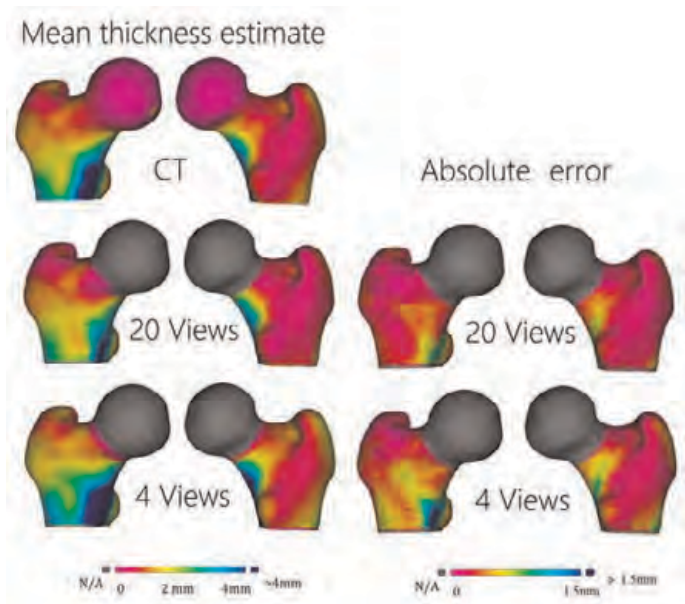
Cortical Thickness Mapping from Multi-view DXA. Nikolaos Tsaousis*[1], Andrew Gee[2], Graham Treece[3], Kenneth Poole[3]. [1]Cambridge University, United Kingdom, [2]University of Cambridge Engineering Department, United Kingdom, [3]University of Cambridge, United Kingdom

Cortical thickness maps, which show the precise distribution of cortical bone around the proximal femur, have recently opened up new areas of understanding in fracture mechanisms (Poole et al., 2012) and therapy monitoring (Poole et al, 2011). Currently, localised cortical thickness can be estimated accurately down to 0.3mm from CT data of the hip (Treece et al., 2010, 2012). While CT remains the gold standard for scientific investigation, low dose DXA imaging is the leading tool for clinical fracture risk estimation, so applying cortical mapping technology to the DXA platform is highly desirable. In this study, we constructed a statistical model of the proximal femur, encoding both its shape and the cortical thickness distribution. The model was generated from CT scans of 642 femurs from 642 individuals. Each femur was segmented manually and then the cortical thickness was estimated at all points around the surface. Next, each femur was spatially registered to a canonical femur shape, using a similarity transformation followed by a B-spline free-form deformation. The cortical thicknesses were then projected onto the canonical femur. We thus obtained 642 cortical thickness maps, all expressed on the canonical morphology, and 642 deformation fields describing the femoral shapes. Principal compoment analysis identified the dominant modes of shape and thickness variation. We retained 12 shape and 12 thickness modes, accounting for 69% and 59% of the population variance respectively.The resulting 24-parameter model was subsequently fitted to multi-view DXA scans of 48 test subjects. The DXA images were actually digitally-reconstructed radiographs (DRRs) generated from CT data: in this manner, we could also calculate cortical thickness from the gold-standard CT data, and compare the two sets of results. To fit the model, we synthesised DXA views by ray-casting through the model, and then optimized for the model parameters that caused the synthetic views to best match the DRRs. The results for 20 DRRs in the range 0-171 degrees (validation), and 4 DRRs in the range 0-51 degrees (clinically viable) are shown in Figure 1. Compared with CT, DXA thickness estimation errors are -0.07+/-0.56mm for 20 views, and 0.11+/-0.61mm for 4 views. It remains to be seen whether this performance meets clinical requirements: this will depend on the location and size of fracture-predicting regions of interest that are only now beginning to emerge from cohort studies.



Cortical thickness maps

Interpreting Bone Mineral Density Results: Whose Job Is It, Anyway?. Sonya Allin*, Sarah Munce, Leslie Carlin, Gillian Hawker, Susan Jaglal. University of Toronto, Canada

Background and Purpose: Current Osteoporosis Canada guidelines promote fracture risk assessment as the basis for osteoporosis treatment recommendations. However, risk assessments as they appear on bone mineral density (BMD) reports have a tendency to omit modifying risk factors, like fracture history. In a 2008 sample of BMD reports for Ontarians with verified recent fragility fractures, over 50% did not include fracture history; risk was under-estimated on these reports as a result. The research presented here sought to determine referring physicians' understanding of potential errors on BMD reports, and the tools they use to detect and compensate for these. In addition, the research explored referring physicians' use of treatment recommendations that accompany risk assessments on BMD reports. Methods and Analysis: A descriptive qualitative approach was used and involved telephone interviews with family physicians (FPs), who make the majority of BMD test referrals in the province. Study Sample or Initiative Scope: Twenty-two FPs with practices in Ontario were recruited through an Ontario College of Family Physicians event on osteoporosis and subsequent snowball sampling. The average roster size of each physician was 1280 patients, and the average number of BMD reports they reviewed per week was four. Findings: 18 of the 22 physicians (82%) acknowledged the possibility of error related to risk assessment on BMD reports, including inaccurate patient self-reports, machine error, inconsistencies between competing assessment heuristics and inaccurate definitions of fragility fracture. 10 physicians (45%) reported that they regularly double-checked or re-computed risk assessments themselves; several others indicated desire, but inability to perform such checks due to time constraints. Physicians were divided as to whether treatment recommendations should be included on reports or left to the referring physician to determine. Conclusion: While risk assessments are the basis for treatment decisions, FPs are divided as to the role of the BMD report in determining risk. Referring physicians have assumed at least partial responsibility for risk assessment despite practical constraints and potential duplication of work. Efforts to improve assessments on BMD reports and to expedite assessments made by FPs may ameliorate inefficiencies caused by ambiguity in fracture risk assessment responsibility.

Investigation of the Local Relationship Between Bone Marrow Fat Content and Bone Mineral Density in the Proximal Femur of Subjects With and Without Fragility Fractures. Julio Carballido-Gamio*[1], Dimitrios C. Karampinos[2], Andrew Lai[3], Sonia Lee[3], Roland Krug[3]. [1]University of California, San Francisco, USA, [2]Musculoskeletal & Quantitative Imaging Research Group, Department of Radiology & Biomedical Imaging, University of California, San Francisco, USA; Department of Diagnostic & Interventional Radiology, Technische Universität München, Germany, [3]Musculoskeletal & Quantitative Imaging Research Group, Department of Radiology & Biomedical Imaging, University of California, San Francisco, USA

Marrow fat content partly explains bone strength independently of BMD. Here we assess the local relationship of marrow fat content measured by MRI, and BMD measured by QCT, in the proximal femur of postmenopausal women; and determine the spatial variation of fat content and BMD in postmenopausal women with fragility fractures and healthy controls using Computational Anatomy.

Fifteen postmenopausal women, 6 without fracture (Controls; age=62.4±8years), and 9 with fragility fractures (Cases; age=62.8±9 years) were included in this study. Coronal-oblique images of the proximal femur were acquired at 3 Tesla with a novel fat quantification technique based on chemical shift MRI-—a 3D spoiled gradient echo pulse sequence with 6 echoes and a very accurate multi-frequency model of fat using IDEAL (Reeder 2005)—to generate Fat-Fraction (FF) maps. QCT scans of both hip joints were obtained and calibrated to generate BMD maps. FF and BMD maps were spatially normalized to an atlas (Carballido-Gamio 2011), and FF- and BMD-difference maps (Cases minus Controls), and FF-BMD Pearson correlation coefficient maps (Controls vs Controls, and Cases vs Cases) were generated. Due to the small sample size, and that small BMD and FF differences were expected between Controls and Cases, significance of the difference maps was not evaluated. Significance of the correlation coefficient maps was evaluated based on paired t-tests, and false-discovery rate (FDR) correction was used to correct for multiple comparisons.

Figure 1 summarizes the results of this study. Results showed positive and negative BMD differences between Cases and Controls, and higher FF values in the neck and intertrochanteric regions in Cases. As it was expected based on previous studies, BMD and FF were mostly negatively correlated, however, small regions with positive correlations were also observed. Although regions with significant correlations between BMD and FF were similar between Controls and Cases, Cases showed a distinct pattern.

Unfortunately, the main limitation of this study is the small sample size, which is a potential explanation of the variability of the BMD difference maps, and a reason to avoid any strong conclusions. We are currently recruiting more subjects to investigate if the observed patterns in the correlation map of Cases are due to changes in BMD alone, FF alone, or both, and to apply techniques such as voxel-based morphometry (Carballido-Gamio 2013) for further analysis.

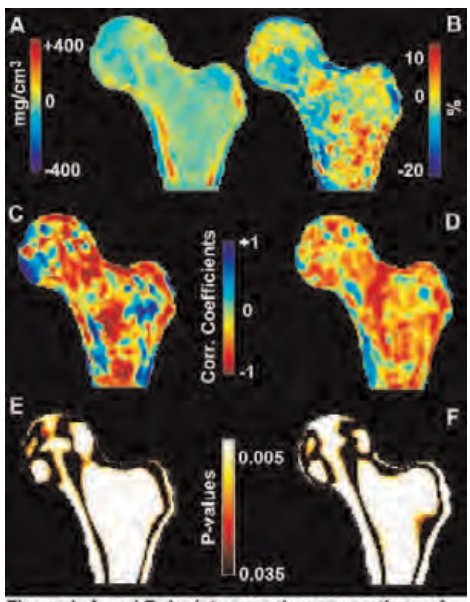

Figure 1. A and B depict coronal cross-sections of the BMD and FF difference maps (Cases minus Controls), respectively. C and D show the correlation coefficient maps of BMD and FF values for Controls and Cases, respectively. E (Controls) and F (Cases) indicate regions where correlations were significant after FDR correction.

No More annual BMD exam in Rheumatoid Arthritis Patients with Osteoporosis. Mie Jin Lim*[1], Won Park[2], Seong Ryul Kwon[2], Kyung Hee Jung[2], Kowoon Joo[2], Hoyeon Joo[3]. [1]Inha University Hospital, Republic of Korea, [2]Inha University Hospital, South Korea

Introduction: There are controversies regarding how often patients with osteoporosis should take bone mineral density (BMD) exam. Rheumatoid arthritis (RA) and glucocorticoid are classified as risk factors for osteoporosis. In order to evaluate the progression of osteoporosis, BMD exams were performed annually in RA patients with osteoporosis.

Goal: We aimed to find out that annual BMD exams in high risk patients such as RA patients with osteoporosis are clinically useful.

Methods: RA patients (n=139, age of 64.6 ± 9, 124 women and 15 men) who visited Inha university hospital in Incheon, Korea during January, 2012 ~ June, 2012 were recruited. All of them were previously diagnosed as osteoporosis and were on anti-osteoporotic medication. BMD results of past 5 years were retrospectively reviewed. We compared results of total L spine, femur neck and total hip at baseline to sequential follow-ups.Results: Nineteen percent of patients (n=26, 66.6 ± 9.7 years old, 22 women and 4 men) quitted anti-osteoporotic medication as follow-up BMD result improved. Over past 5 years, 339 follow-up BMD exams were performed and 26 follow-up BMD (8% of total exams) were shown to be T score > -2.5. As shown in Table 1, BMD results significantly improved after 2 years, except density of femur neck. In case of femur neck, T-score failed to show clinical improved after a year.

Conclusion: Most RA patients (81%) continued on anti-osteoporotic medication over 5 years and only a small fraction of follow-up BMD exams showed recovery from osteoporosis. BMD results of RA patients with osteoporosis did not change much over 2 years. Thus, we recommend performing BMD in RA patients with osteoporosis at intervals of least 2 years.

	Mean of Total L spine		Mean of Femur Neck		Mean of Total Hip	
	T score	Density (g/m²)	T score	Density (g/m²)	T score	Density (g/m²)

Potential Sources of Quantification Error When Retrospectively Assessing Metacarpal Bone Loss from Historical Radiographs by Using Digital X-ray Radiogrammetry. Johan Kälvesten*[1], Torkel Brismar[2], Anders Persson[3]. [1]Linköping UniversitySectra, Sweden, [2]Karolinska Institutet, Sweden, [3]Linköping University, Sweden

Introduction: During the past decade, digital X-ray radiogrammetry (DXR) has been used to measure metacarpal bone mineral density (BMD). DXR is often used to measure BMD in existing cohorts where X-ray images are available but were not acquired in accordance with the DXR imaging protocol (DIP). The purpose of the current study was to investigate how deviations from DIP in historical cohorts may affect the reproducibility of DXR-BMD measurements.

Method: Five anthropomorphic cadaver hand phantoms (The Phantom Laboratory, Salem, NY, USA) were used to perform repeat measurements of deviations from DIP with respect to voltage, exposure, lateral displacement, supination, combination of lateral displacement and supination or rotation, extension of the wrist, and edge enhancement. The phantoms ranged in DXR-BMD from 0.35 to 0.60 g/cm^2, corresponding to T-score values of -4.9 to 0.5. Direct digital radiography (Aristos; Siemens Healthcare, Erlangen, Germany) was used for image acquisition, and dxr-online (Sectra, Linköping, Sweden) for DXR-BMD measurements.

Results: The impact of the tested deviations from DIP ranged from 0 mg/cm^2 to 32.5 mg/cm^2 (0–6.8%). Influence from specific deviations are listed in Table 1. On repetition with the same phantom specimen, none of the deviations resulted in a within-specimen reproducibility error greater than 2 mg/cm^2 (0.4%, equivalent to a T-score of 0.042) (Table 1).

Conclusions: All the tested deviations except tube voltage had a magnitude greater than the normal measurement noise for the technique but moderate relative to absolute BMD. When performing a retrospective study based on absolute BMD, e.g. for fracture risk, impact from the tested deviations is limited. When performing a retrospective study based on change of BMD, e.g. for rheumatoid arthritis, impact from the tested deviations can be significant. When designing and planning a study with DXR-BMD change measurements made on historical radiographs, an analysis should be made on which image deviations are acceptable for the study setup. The data in this current study may be used for such calculations. This study is valid only

for retrospective off-label use of DXR-BMD and does not consider its prospective on-label use.

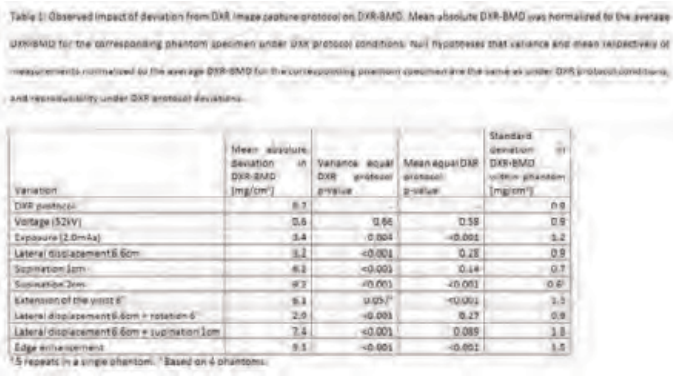

Table 1: Observed impact of deviation from DXR image capture protocol

Prevalent Osteoporotic Fracture and Past Use of Glucocorticoids Induce a Microarchitectural Impairment in Subjects Treated with Glucocorticoids. Edward Leib*[1], Renaud Winzenrieth[2], Didier Hans[3]. [1]University of Vermont, USA, [2]Med-imaps, Hôpital X. Arnozan, PTIB, Pessac, France, France, [3]Lausanne University Hospital, Switzerland

Aim: The aim of the study was to evaluate whether microarchitectural changes as measured by Trabecular Bone Score (TBS) can identify those patients who are more likely to fracture and are on glucocorticoid (GC) therapy either presently or in the past.*Materiel and Methods:* The study group was composed of women aged 40 and older receiving GCs (⩾ 5mg/day for ⩾3months). BMD was assessed at the lumbar spine (L1-L4) using a Prodigy densitometer (GE-Lunar, Madison, USA). TBS was calculated at L1-L4 using the TBS iNsight® (Medimaps, France). Clinical data, presence of osteoporotic fracture (OPF), GC treatment and common clinical risk factors (CRFs) were documented. Logistic regressions (backward) were used to investigate possible relationships between independent variables and the presence of fracture for subjects presently on or with past use (p_GC) of GC. Odds ratio per standard deviation decrease (OR) was calculated.

Results: The cohort consisted of 362 women treated with GCs who had TBS testing. Mean age and BMI were 62.0±11.2 yrs and 25.5±4.1 Kg/m^2. 92% were postmenopausal, 31% had a family history of osteoporosis, 10% had a maternal history of OPF. In addition, 13% had sustained a prevalent OPF (all types) and 9% had p_GC. Correlation between TBS and BMD was, as expected, low (r=0.32) and there was no correlation between TBS and BMI (r = -0.09). There were no differences in terms of age, BMI, weight and height between subjects with or without fracture (p>0.2). GC-treated patients who had sustained an OPF compared to those without OPF were characterized by a lower TBS (p=0.004) while no difference in BMD was observed (p=0.36).TBS was associated with the presence of OPF (OR=1.63[1.22-2.17]). TBS was significantly lower in all subjects with p_GC use than in subjects on GCs only presently (p=0.025) whereas BMD was not significantly different (p=0.19). Finally, in only those subjects without fracture, p_GC users had a lower TBS compared with current GC users (p<0.03) while no difference was observed for subjects with fracture (p=0.76).*Conclusion:* GCs induced a microarchitectural texture impairment whereas no change was observed with BMD measurement. These results are consistent with previous TBS studies on GCs. We have also observed that past use of GCs has a negative effect on microarchitectural texture which is similar to the presence of an OPF. TBS is a reliable tool for management of patients with present or past GC treatment, and outperforms BMD measurement in its ability to identify a population on glucocorticoids at greater risk for fracture.

Relationships Between Age, Sex and Bone Microarchitecture at the Distal Radius and Tibia in Late Adulthood. Mark Edwards*[1], Camille Parsons[1], Jennifer Thompson[2], Ann Prentice[2], Cyrus Cooper[1], Elaine Dennison[1], Kate Ward[2]. [1]MRC Lifecourse Epidemiology Unit, University of Southampton., United Kingdom, [2]MRC Human Nutrition Research, United Kingdom

Bone health is known to deteriorate with age but exact relationships are thought to vary between men and women. The advent of high resolution peripheral quantitative computed tomography (HRpQCT) scanners has permitted the direct and indirect non-invasive assessment of bone macro- and micro-architecture, including detailed delineation of cortical and trabecular structure. We used this new technique to explore differences in bone according to age and sex in a large, well characterised, cohort of older adults. 198 men and 178 women from the Hertfordshire Cohort Study born between 1931 and 1939 were studied. HRpQCT (Xtreme CT, Scanco Medical) images (voxel size 82μm) of the non-dominant distal radius and tibia were acquired. Standard morphological analysis was performed for assessment of macrostructure, density, cortical porosity and trabecular microarchitecture. The mean(SD) age of participants was 76.1(2.5) and 76.5(2.6) years in men and women respectively (range 72.1 to 81.4 years). At both radius and tibia, men had greater bone area (cortical, trabecular, total); trabecular volumetric density; and trabecular number than women (all p<0.001). Trabecular thickness was greater in men than women at the radius (p<0.001) but not the tibia (p=0.2). Conversely, cortical volumetric density was greater in men in the tibia (p<0.001) but did not differ at the radius (p=0.8). Radial cortical porosity was higher in men whereas tibial cortical porosity was greater in women. In the radius and tibia of women, there was a negative association between age and both cortical area and thickness, and a positive association with trabecular area. In this group we also observed an inverse association between age and both cortical and trabecular density at both sites (p<0.05). Furthermore, trabecular number and thickness were lower in older women, particularly in the radius. These relationships were not seen in men. In summary, using HRpQCT techniques to ascertain bone macro- and microarchitecture, we have confirmed consistently greater bone areas in men than women. Conversely, sex differences in trabecular microarchitecture and cortical density and porosity appear to be site specific. In this cross-sectional study, we noted an age-difference in cortical and trabecular density, trabecular microarchitecture, and bone geometry at both sites in the eighth decade among women; no such difference was observed in men.

Screening for Osteoporosis Using Digital X-ray Radiogrammetry (DXR) in Conjunction with a National Mammography Screening Program. Michael Wilczek*[1], Christel Nielsen[2], Johan Kälvesten[3], Jakob Algulin[4], Torkel Brismar[5]. [1]Karolinska Institutet, Sweden, [2]Region Skåne, Sweden, [3]Linköping UniversitySectra, Sweden, [4]Sectra, Sweden, [5]Karolinska Institutet, Sweden

PurposeIn this first report from the Stockholm Osteoporosis Project (STOP) we assess the feasibility of mass screening using digital X-ray radiogrammetry (DXR) in conjunction with the Swedish national mammography screening program (women aged 40-74 years). The association between DXR T-score and clinical risk factors for hip fracture is also studied.Method and Materials

This study was conducted two days per week at a single mammography screening center (Unilabs AB, Tumba, Sweden) between March 2010 and June 2012. The local participation in the mammography screeningprogram was approximately 70%. Women who chose to participate in our study (n =8,810) answered a questionnaire about clinical risk factors and a radiograph of the non-dominant hand was taken. DXR-T-score was obtained by analyzing metacarpals II-IV.

Univariate associations between bone density, analyzed as T-score, and potential risk factors for osteoporosis were examined. A generalized linear regression model was fitted to independent variables with univariate associations at P<0.05. The model was reduced through manual backward elimination, with P>0.1 as the exclusion criterion. Observations with non-missing values for the identified independent variables (n =7,384) were used in the multivariate analysis.Results

76% of the patients chose to participate in our study. The difference in number of daily mammograms performed on days with or without DXR was not significant. All univariate associations between DXR-T-score and potential risk factors were highly significant. In a multivariate setting heredity was no longer significant, and was thus excluded from the multivariate model. Smoking status was not significant as a main effect, but an interaction term between smoking status and age was fitted together and found to be significant (P=0.009). The multivariate model included height, weight, age, right-handedness, menopause, alcohol consumption, cortisone treatment, rheumatic disorder, age × smoking status. The coefficient of determination of the model was 0.37.Conclusion

It is possible to combine DXR with mammography screening. The acceptance rate of patients was high and no impact on clinical workflow was observed. Clinical risk factors partially predicted DXR-T-score, indicating an additive value of combining clinical risk factors and DXR in fracture risk estimation.

Systematic Bias between Results Measured on Cross-calibrated DXA Scanners in Pediatric and Young Adult Females. Jodi Dowthwaite*[1], Paula Rosenbaum[2], Tamara Scerpella[3]. [1]SUNY Upstate Medical University;Syracuse University, USA, [2]SUNY Upstate Medical University, USA, [3]University of Wisconsin, USA

Purpose: Consistency of DXA scan results is critical for data integrity. For pediatric subjects, the extent to which cross-calibration of DXA scanners alleviates model to model scanner differences is unclear. In the current study, DXA bone outcomes were compared for same-day measurements performed using different scanner models that had been cross-calibrated to alleviate discrepancies.

Methods: Differences between results for the two scanners were evaluated in approximately 130 females aged 8 to 24 years. Whole body, forearm, hip and lumbar spine scans were performed in a single session on both a Hologic QDR4500W scanner

(QDR) and a cross-calibrated Discovery A scanner (Disco). Results were compared for standard projected Area, bone mineral content (BMC), and areal bone mineral density (BMD) for Whole body (total and sub-regions), radius (1/3 and ultradistal regions), lumbar spine (Vertebra L3) and femoral neck output. Wilcoxon Signed Rank tests evaluated differences between results for the two scanners.

Results: Although inter-scanner correlations were high for all outcomes (rho> 0.93, p<0.001; except Head Area rho= 0.76 p<0.05), significant differences were found between scanner results. In most cases, QDR values were significantly lower than Discovery values (p< 0.05). Exceptions where QDR results were significantly higher included: Head Area, Head BMC, Head BMD. Significant differences were not detected for Ultradistal Radius BMD, Femoral Neck BMD or Lumbar Spine Area.

Conclusion: In pediatric and young adult subjects, systematic differences were noted between scans obtained on Hologic Discovery A and QDR 4500W model scanners, despite cross-calibration. Values appear to be systematically higher for Discovery A results. These findings have important implications for both clinical and research purposes. In the event that substitution of scanners is required, it would be advisable to repeat measurements on each scanner within the same session to evaluate and address any systematic bias.

SU0305

Trabecular bone score (TBS) marginally improves the prediction of prevalent vertebral fractures with bone densitometry in primary care. Petra Elders*[1], Thomas Merlijn[2], Martin Den Heijer[3], Coen Netelenbos[4]. [1]Free University Medical Centre, The Netherlands, [2]dpt General Practice & Elderly Care, VU Medical Centre, Netherlands, [3]VU Medical CenterPostbus 70571007 MB Amsterdam, The Netherlands, [4]VU Medical Center, The Netherlands

Introduction: The trabecular bone score TBS is a quantification technique of local variations in gray level that can be applied to an existing DEXA exam. In case control studies TBS has been shown to give an incremental increase in the odds ratio for spine fracture when combined with lumbar BMD [1]. Also it has been shown to predict clinical fractures independently from and equally well as spinal BMD [2].

Research question

We studied whether the TBS of the lumbar spine (TBS) improves the prediction of prevalent vertebral fractures with FRAX and bone densitometry measurements in the prediction of vertebral fractures in primary care.

Design: N=3601 women who were referred for bone densitometry in a primary care laboratory by there GP's filled in a fracture risk questionnaire, received bone densitometry and instant vertebral assessment (IVA) and had their height and weight measured. Single component and multiple component prediction models consisting of FRAX (estimated absolute risk of major osteoporotic fractures without BMD, UK reference data), BMD measurements and TBS were compared with both univariate and multivariate regression analysis and receiver operator curve (ROC) analysis.

Results: Mean age ± SD of the women was 64.4 ± 11.4 years. Mean BMI ± SD was 26.5± 4.8 kg/m^2. Of the women 42% had previous fracture(s) and 16% had apparent vertebral fractures on IVA (thoracic spine: ⩾ Genant grade 2, lumbar spine; ⩾ Genant grade 1). Odds ratio's and AUC of the univariate, bivariate and multivariate logistic regression models are shown in table 1.

Condusion: TBS predicted vertebral fractures independently from BMD and FRAX and improved the prediction with both BMD measurements. However, the differences were small. FRAX was the best single predictor of prevalent vertebral fractures and performed equally well as the model in which BMD and TBS were also included.

Trabecular Bone Score: Evaluation of Precision and Comparison of Values Between GE Lunar Prodigy and Lunar iDXA Densitometers. Diane Krueger*, Jessie Libber, Neil Binkley. University of Wisconsin, Madison, USA

Trabecular bone score (TBS), a novel gray-level measurement derived from lumbar L-spine DXA image texture, is related to microarchitecture and fracture risk independently of BMD and clinical risk factors. Widespread clinical TBS use will require stability over time and ideally comparability across scanners. This study explored short-term TBS reproducibility and evaluated whether TBS differs between GE Lunar Prodigy and iDXA densitometers.

Reproducibility was assessed from replicate scans in 30 women participating in a comparative Prodigy/iDXA precision assessment and 180 men and women evaluated to compare BMD precision between sex and technologist on an iDXA. Comparability between instruments was evaluated in 3 groups; 72 participants in a Prodigy/iDXA comparison, 30 women participating in the precision assessment noted above and 30 men and women in a clinical cross calibration exercise using 3 instruments (2 Prodigy, 1 iDXA). All scans were obtained on each instrument the same day, except for the cross-calibration exercise, which was performed over 2 weeks. Prodigy and iDXA TBS values were compared using linear regression and Bland-Altman analyses. Precision was assessed with the ISCD Precision Calculator and compared by F-test or factorial ANOVA. All analyses were performed on raw TBS values without TBS phantom cross-calibration.

Short-term L1-L4 BMD and TBS precision was similar on iDXA and Prodigy; L1-4 BMD %CV = 1.9% and 1.5% respectively. TBS %CV = 1.6% on Prodigy and 1.4% on iDXA. iDXA precision in 3 technologists ranged from a %CV of 0.96 - 1.59 for BMD and 1.46 - 2.72 for TBS. Between technologist differences ($p < 0.05$) of similar magnitude were observed for both BMD and TBS. No sex difference was observed with either method.

Prodigy to Prodigy TBS values were highly correlated; $R^2 = 0.90$ with bias of -0.013 TBS units (~ 0.14 SD). Agreement was less robust comparing multiple Prodigy and iDXA instruments; TBS $R^2 = 0.63 – 0.85$ with biases of -0.008 to -0.035 TBS units (up to ~ 0.3 SD).In conclusion, TBS precision is comparable to that of BMD and does not differ between men and women. Additionally, in these small samples, slight TBS differences were observed between iDXA and Prodigy scans. These data suggest a potential difference between instruments, perhaps due to higher iDXA image resolution. Further study to clarify potential between-instrument TBS differences, and whether such differences have clinical significance, is indicated.

SU0307

A novel method for obtaining bone mineral densities from a dataset of radiology reports and clinic notes: Natural language processing in a national cohort of postmenopausal veterans. Joanne LaFleur*[1], Thomas Ginter[2], Jeffrey Curtis[3], Robert Adler[4], Irene Agodoa[5], Brad Stolshek[5], Richard Nelson[2], Scott DuVall[2]. [1]University of Utah, USA, [2]University of Utah Division of Epidemiology, USA, [3]University of Alabama at Birmingham, USA, [4]McGuire VA Medical Center, USA, [5]Amgen Inc, USA

BACKGROUND Large epidemiology studies of osteoporosis are often limited to structured data such as claims (medical diagnosis, procedure codes, and pharmacy records) and electronic medical records (problem lists, medication lists, and laboratory findings). It is difficult to assess patient bone mineral density (BMD) T-scores in such studies without human chart review because these data are rarely recorded in discrete fields.

OBJECTIVE We developed a natural language processing (NLP) tool that could extract these data from narrative clinic notes and radiology reports.

METHODS We identified female veterans ⩾50 years of age who filled a bisphosphonate (BP) prescription in 2003-11. Of those, incident and prevalent BP users were included if they received care at least 6 months prior to the first BP fill. Narrative records for all patients including radiology reports and clinic notes were mined using NLP techniques for mentions of T-score observations at the femoral neck, total hip, lumbar spine, or 1/3 radius. A random sample of these records was reviewed by trained human annotators to assess the accuracy of the tool for extracting anatomy, T-score, and the relationship between anatomy and T-score. These findings were compared to the proportion of women who had a procedure code for a BMD scan in the structured data.

RESULTS Out of 1.6 million female veterans, 43,543 (2.6%) received a BP during the study period, of which 36,280 (83.3%) had ⩾6 months pre-index observation and were included in the cohort. The mean (SD) age was 65.7 (12.5). The NLP tool identified 22,964 (63.3%) with at least one BMD T-score at within 6 months before and 3 months after the index BP. Validation showed that overall accuracy was 92.6% for anatomic site, 82.8% for T-score value, and 82.8% for the relationship between the two. Accuracy was much higher for radiology reports than for clinic notes: 92.8%, 92.8%, and 90.4% (anatomic site, T-score, and relationship, respectively) in radiology reports versus 94.4%, 72.8%, and 75.2% in clinic notes. The figure shows the proportions with results versus procedure codes. Of those with at least one T-score observation, the mean (SD) was -1.58 (1.75); 11,105 (48.3%) had osteopenia and 7,139 (31.1%) had osteoporosis.CONCLUSIONS NLP was effective at extracting BMD T-score results from narrative records, particularly radiology reports. This new tool makes available clinical data previously unavailable in large secondary datasets.

Bone Mineral Density in Korean Women with Uterine Leiomyoma. Tae-Hee Kim*[1], Hae-Hyeog Lee[2], Junsik Park[2], Soo-Ho Chung[2], Dong-Won Byun[3]. [1]Soonchunhyang University College of Medicine, South Korea, [2]Department of Obstetrics & Gynecology, Soonchunhyang University College of Medicine, South Korea, [3]Internal Medicine, Soonchunhyang University College of Medicine, South Korea

Objective: Uterine leiomyomas, benign pelvic tumors, are prevalent and main cause of hysterectomy. As leiomyomas' growth has been reported to be linked with estrogen hormones, the question of whether there is any association between leiomyomas and bone health arises. The objective of the present study was to examine the relationship between leiomyomas and bone health in Korean women. Design: Retrospective observational study. Material & methods: We collected past data of 426 Korean women who underwent bone densitometry from January, 2010 to December, 2012. BMD and T-score of lumbar spine and femur neck were measured using DXA machine (GE Lunar Prodigy, GE Lunar Corp., Madison, WI, USA). Data are presented as mean ± SEM. Results: For the entire study population, the mean age (years) was 56.66. Uterine leiomyoma group was 158 and control group was 304. There was a significant difference in the mean BMD (g/cm^2) in the uterine leiomyoma group (spine :1.04 ± 0.01, femur neck : 0.85 ± 0.01), compared with control group (spine : 0.98 ± 0.01, p=0.003, femur neck: 0.81 ± 0.01, p=0.001). The T–score of spine for uterine leiomyoma group was significantly higher, compared with the control group (spine: -0.79 ± 0.01 and -1.25 ± 0.08 with p=0.001, femur neck: -0.62 ± 0.08 and -1.01 ± 0.06 with p=0.000). Conclusion: Consistent with previously reported data, our data showed a significantly higher BMD in Korean women with uterine leiomyoma. The implications of these findings need to be confirmed in future longitudinal studies. For comparison not only with BMD, but also with actual fracture risk in both groups, further studies are suggested.

Differences in bone geometry, mass and microarchitecture between Caribbean-Hispanic and Caucasian young men. Anna Kepley*[1], Chiyuan Zhang[2], Donald McMahon[3], Elizabeth Shane[3], Thomas Nickolas[3]. [1]Columbia University Medical Center, USA, [2]Columbia University, USA, [3]Columbia University College of Physicians & Surgeons, USA

United States epidemiologic data on bone mass in Hispanics are currently based upon Mexican-Americans and may not be generalizable to Caribbean-Hispanics who may have more African racial admixture than Mexican-Americans. In addition, it is not known whether bone geometry, mass and microarchitecture differ between Caribbean-Hispanic and Caucasian men at peak bone mass. Therefore, we enrolled 60 healthy young men between the ages of 25 and 35, 22 Caribbean Hispanic and 38 Caucasian (n=38) men in a cross-sectional study. We measured areal bone mineral density (BMD) by dual energy X-ray absorptiometry (DXA) of the lumbar spine (LS), total hip (TH), femoral neck (FN), 1/3- and ultra- distal radius (1/3R and UDR, respectively). High-resolution peripheral quantitative tomography (HRpQCT, Scanco Medical) was used to assess bone geometry, mass and microarchitecture at the distal radius and tibia. Results are expressed as Means ± SD. Univariate comparisons were made with Students T-Test; multivariate comparisons were made with generalized linear models adjusted for age and anthropometric differences. Hispanics were slightly but significantly older and considerably heavier with higher BMI than Caucasians. By DXA, univariate models demonstrated that Hispanics had greater UDR BMD ($p<0.05$). In multivariate models, differences in areal BMD were no longer significant. By HRpQCT at the radius, univariate models demonstrated that Hispanics had smaller trabecular area ($p<0.05$), but greater cortical area ($p<0.01$), thickness ($p<0.01$) and density ($p<0.01$); these relationships persisted in multivariate models, which also revealed that Hispanics had thicker trabeculae than Caucasians ($p<0.05$). At the tibia, Caribbean-Hispanics had greater cortical area ($p<0.001$), thickness ($p<0.001$) and density ($p<0.001$); these relationships persisted in multivariate models, which also revealed greater total density ($p<0.05$) than Caucasians. In conclusion, after adjustment for differences in anthropometric measures, Caribbean-Hispanic men had equivalent areal BMD to Caucasian men. However, by HRpQCT Caribbean-Hispanic men had smaller bones with thicker and denser cortices, differences that could lead to greater bone strength. Further studies are needed to elucidate genetic, biochemical and metabolic factors that could lead to differences in skeletal structure between Caribbean-Hispanics and Caucasians, and to assess skeletal differences between Hispanics of Caribbean and non-Caribbean origin.

Table. Univariate comparisons using Students T-Test. Multivariate comparisons using a generalized linear model adjusted for age, weight, height and height-weight interactions.

	Hispanic (n=22)	Caucasian (n=38)	Univariate p-value	Adjusted p-value
Age (years)	31.3±3.3	28.4±2.6	<0.01	-
Height (cm)	178.3±6.7	181.6±7.4	NS	-
Weight (kg)	95.1±18.2	81.2±10.4	<0.01	-
BMI (kg/m^2)	29.8±5.0	24.6±2.5	<0.0001	-
BMD by DXA				
Lumbar Spine (g/cm^2)	1.112±0.122	1.076±0.106	NS	NS
Total Hip (g/cm^2)	1.152±0.109	1.094±0.117	NS	NS
Femoral Neck (g/cm^2)	1.035±0.132	0.971±0.131	NS	NS
1/3R (g/cm^2)	0.827±0.065	0.816±0.055	NS	NS

Impact of a Patient Self-Referral of DXA Intervention on Patient-Provider Communication about Osteoporosis Testing and Treatment: A Randomized Trial in Two Large Regional Healthcare Systems. Amy Warriner*[1], Ryan Outman[1], Jeffrey Curtis[1], Adrianne Feldstein[2], David Redden[1], Junling Ren[3], Brandi Robinson[3], Douglas Roblin[3], Ana Rosales[4], Monika Safford[1], Kenneth Saag[1]. [1]University of Alabama At Birmingham, USA, [2]Kaiser Permanente Center for Health Research, USA, [3]Kaiser Permanente Georgia, USA, [4]Kaiser Permanente Northwest, USA

Purpose: Patient-provider communication around osteoporosis testing and treatment is suboptimal and methods to improve it are incompletely understood. Using traditional care approaches, treatment is often not initiated following abnormal DXAs due to inadequate provider-patient communication. We hypothesized that a DXA self-referral intervention would lead to greater patient-provider communication about osteoporosis testing and treatment than the usual practice of physician referral.

Methods: We conducted a group randomized controlled trial involving 14 Kaiser Permanente Northwest (KPNW) primary care clinics and 15 Kaiser Permanente Georgia (KPG) primary care clinics. Women 65 years or older with no identifiable

DXA scan in the past 5 years and no osteoporosis treatment in the past year were eligible. Clinics were randomized into 1 of 3 groups: A self-referral intervention (SELF) (invitation by mail to self-schedule a DXA); SELF+DVD (consisting of SELF, plus an educational brochure and DVD promoting patient-provider communication about osteoporosis); and, Usual Care (UC) (No DVD or self-referral). Providers in all groups were directed to web-based CME training on osteoporosis screening and treatment. Nine months after randomization, patients were mailed a survey to assess whether they had talked with a provider about osteoporosis testing and treatment.

Results: In KPNW, 3191 women were randomized to SELF, 3720 to SELF+DVD, and 1889 to UC of which 1659 (52%), 1438 (39%) and 989 (52%), respectively, completed the survey. In KPG, 1064 women were randomized to SELF, 1005 to SELF+DVD, and 1170 to UC of which 327 (31%), 278 (27.7%) and 406 (34.7%), respectively, completed the survey. The table shows the rates and odds of communication with providers about osteoporosis testing and treatment by study arm and region.

Conclusions: In both regions, patients receiving a DXA self-referral intervention reported significantly higher rates of communication with a provider about osteoporosis testing. In KPNW, intervention patients also reported significantly higher rates of communication about osteoporosis treatment. The addition of an educational DVD promoting patient-provider communication did not result in significantly higher rates of communication over the self-referral intervention alone. Allowing eligible women to self-schedule DXA scans may be an effective low cost strategy to increase patient-provider communication about osteoporosis related behaviors.

Table. Rates and odds of patient-provider communication related to osteoporosis testing and treatment by study arm and region.

Region	Study Arm	Total Survey Respondents n	Communication about Osteoporosis Testing n (%)	Odds Ratio (95% CI)	Communication about Osteoporosis Treatment n (%)	Odds Ratio (95% CI)

National osteoporosis risk factor's and BMD measurements study of postmenopausal women population in Latvia. Inese Pavlina*[1], Ingvars Rasa[1], Inara Adamsone[2], Ilze Daukste[3], Sandra Jaundzeikare[1], Dainis Kaneps[4], Ingrida Kaze[1], Agita Medne[5], Signe Zelca[1]. [1]Riga East Clinical University Hospital, Latvia, [2]Pauls Stradins Clinical University Hospital, Latvia, [3]Riga 2nd Hospital, Latvia, [4]Latvian Maritime Medicine Cente, Latvia, [5]Health Centre 4, Latvia

Objective(s): We aimed to assess the prevalence of osteoporosis (OP) risk factors, OP preventive and therapeutic measures among postmenopausal women in Latvia. We also aimed to correlate bone mineral density (BMD) with those OP risk factors in the population.

Material & Methods: 1,598 women took part in a national cross-sectional study conducted during May-October 2012. All women filled out a questionnaire with 25 multiple choice questions regarding to OP risk factors, i.e. fragility fractures, family history of fractures, physical exercises.Previous DXA, calcium, vitamin D usage and antiosteoporosis medication were recorded. BMD was subsequently measured in all participants by DXA in lumbar the spine (L1-L4) and total hip.

Results: The mean age of patients (pts) was 65.6 ±9.0 years. The mean body weight was 71.9 ±13.7 kg. The mean height was 159 ±6.3 cm, the mean time since menopause was 16.3 ± 4.6 years. Progressively reduced height was recorded in 79.2% of the patients. Previous fragility fractures were recorded in 38.6% patients, 26.8% had a family history of fractures. 59.5% had no physical activities. 63% of pts underwent DXA scan before, in 41.9% of them OP was previously diagnosed. 40.3% of pts measured 25 (OH) vitamin D before. 66.1% of them had reduced 25 (OH) vitamin D level. 60.7% of the pts used supplemental calcium and 36.2% - vitamin D. 31.3% received specific osteoporosis treatment. By over all DXA scan 14.3% of pts were identified as having osteoporosis, 56.4% were osteopenic values, and 29.3% had normal BMD. BMD measurements in the lumbar spine revealed that 30.8% of pts had normal BMD, 46.4% - were osteopenic, and 22.8% had osteoporosis. Different situation were in the hip measurments. Left hip measurements showed normal BMD in 27.7% pts, osteopenic values – in 62.7% patients, osteoporosis – in 9.6% pts. Right hip - BMD was found normal in 29.6%, but osteopenic values were found in 62.7% and osteoporosis in 7.8% of pts. BMD measurements in the lumbar spine, left and right hip negatively correlated with age ($p< 0.001$, $p< 0.001$ and $p< 0.001$ respectively), positively correlated with body weight ($p< 0.001$, $p< 0.001$ and $p< 0.001$ respectively).

Conclusion(s): This survey suggests that OP is suboptimally diagnosed, in Latvia, and insufficient attention is paid to OP risk factors. The results of this study also suggest that advancing age and lower weight are significant risk factors for low BMD in postmenopausal women in Latvia.

Reliable Osteoporosis Diagnostics with Pocket Size Ultrasound Instrument. Janne Karjalainen*[1], Ossi Riekkinen[1], Juha Töyräs[2], Jukka Jurvelin[2], Heikki Kroger[3]. [1]Bone Index Finland Ltd., Finland, [2]University of Eastern Finland, Finland, [3]Kuopio University Hospital, Finland

As we lack effective diagnostic devices at primary healthcare, over 75% of osteoporotic patients are not diagnosed nor receive treatment for their pathological condition[1]. In this study, a pocket size ultrasound (US) device was validated by using International Society for Clinical Densitometry (ISCD) and National Osteoporosis Society (NOS) guidelines for osteoporosis (OP) diagnostics[2,5]. The guidelines suggest a triage approach for reliable use of peripheral densitometry techniques. This approach requires determination of 90% sensitivity and specificity thresholds for osteoporosis as measured with axial DXA[2,3].

Elderly Caucasian women (n = 445, age = 68.8 ± 8.5 years) under OP suspicion were examined using pulse-echo US measurements (2.5MHz) of cortical bone thickness in proximal tibia (Bindex® prototype, Bone Index Finland Ltd., Kuopio, Finland). The device provides a diagnostic parameter, Density index, DI[4] (patent pending), based on the US measurements and subject characteristics. Further, bone mineral density of the femoral neck (BMD_{neck}) and total hip (BMD_{total}) was determined by using axial DXA. Osteoporosis was diagnosed in individuals with T-Score lower than -2.5 in total hip or femoral neck. The 90% sensitivity and specificity thresholds for DI were determined according to the ISCD guidelines. In addition, the reproducibility (root mean square coefficient of variation (CV_{rms} %)) of DI measurement was analyzed as average of two operators CV_{rms}, who measured 16 subjects three times.

In total 16.9% of the patients were diagnosed with OP osteoporotic by DXA. By using triage approach for DI, 50.3% of patients were over the healthy threshold , 17.1% was under the osteoporotic threshold and only 32.6% of the patients were found to require additional DXA measurement to verify osteoporosis diagnosis. The mean reproducibility of DI measurement was 2.5%.The results demonstrate that the ultrasound instrument provides a fast (~ 1 minute) and reliable method for osteoporosis diagnostics, feasible at primary healthcare. According to the NOS guidelines, treatment is recommended for patients with peripheral densitometry value under the osteoporotic threshold (90% specificity threshold)[5]. By using the triage approach and the US technology the treatment of osteoporosis would significantly increase.

The relationship between sarcopenia and bone mineral density over the year post hip fracture. Denise Orwig*[1], Marc Hochberg[2], Emma G. Shledon[1], William G. Hawkes[2]. [1]University of Maryland, Baltimore, USA, [2]University of Maryland School of Medicine, USA

The relationship between muscle mass and bone mineral density (BMD) is complex and understanding these interactions is critical among older adults who are at risk for declines in both. There is growing evidence linking low muscle mass (sarcopenia) to functional disability, falls, and decreased BMD. Studies have reported high levels of sarcopenia following hip fracture and hip fracture patients can lose up to 6% additional BMD in the year post fracture. However, little is known about the relationship between sarcopenia and loss of BMD following a hip fracture. We performed a post-hoc analysis of data from the Baltimore Hip Studies (BHS)-4 cohort, a randomized controlled trial of a home-based exercise program in 180 community-dwelling older women (mean [SD] age 82.3 [7.0] years)with surgical repair of an incident non-pathologic hip fracture. Women were recruited and baseline data were acquired within 15 days of fracture. BMD of the whole body and contralateral hip (total hip and subregions) and grip strength were measured at baseline and 2, 6, and 12 months post fracture. Sarcopenia was defined at baseline as appendicular skeletalean muscle mass relative to height ≤ 5.67 kg/m2 and grip strength < 20 kg (n=138). At baseline 42% of the sample were sarcopenic; however, mean (SD) total hip BMD values did not differ significantly between those who were sarcopenic (0.625 (0.10) g/cm2) and those who were not (0.639 (0.11) g/cm2). Less than half the sample had sarcopenia at the time of fracture and just over half had sarcopenia at any time point over the 1 year post fracture. Baseline sarcopenic status was significantly associated with12-month total hip BMD ($p<.04$). A longitudinal analysis using a mixed effect model was performed. There was a trend for the time by sarcopenia interaction ($p<.08$) such that total hip BMD for those who were sarcopenic was lower at 12 months [(0.618 (0.01) vs. 0.628 (0.01)]. The fact that BMD did not differ by sarcopenic status at time of fracture, yet those with sarcopenia had lower BMD at 12 months highlights the possible longitudinal effects of muscle loss on BMD. More research is needed to understand whether interventions to increase muscle mass translate into reduction in BMD declines in such an at-risk group of hip fracture patients.

Associations among Vitamin K Intake, Serum Osteocalcin Concentrations and Bone Traits in 37-to-47-year-old Caucasian Population - The PHOMI Study. Suvi Itkonen*[1], Lotta Juslin[1], Elisa Saarnio[1], Virpi Kemi[1], Merja Kärkkäinen[1], Heini Karp[1], Minna Pekkinen[2], Harri Sievänen[3], Kaisa Ivaska[4], Christel Lamberg-Allardt[1]. [1]University of Helsinki, Finland, [2]Folkhälsan Institute of Genetics, University of Helsinki, Finland, [3]UKK Institute for Health Promotion Research, Finland, [4]University of Turku, Finland

Vitamin K (VitK) is required in the carboxylation reaction of osteocalcin (OC). Low serum concentrations of undercarboxylated OC have been associated with hip fractures and lower bone mineral density (BMD). However, the role of dietary vitK in bone health remains unclear. The aim of the study was to investigate the associations among vitK intake, serum total OC concentrations and tibial BMD and bone mineral content (BMC) and bone strength indices in a cross-sectional Caucasian population in Finland.

A sample of 364 37-to-47-year-old pre-menopausal females who participated in the PHOMI Study was included in the analyses. Fasting blood samples were collected, as well as habitual dietary intake by 3-day food records and background data by a questionnaire. Serum total OC and some other biomarkers related to bone metabolism were analysed. BMD and BMC from distal and proximal sites of tibia were measured with peripheral quantitative computed tomography (pQCT). The data was analysed by correlation analysis and partial correlation analysis as T-scores of bone traits, adjusted for height, weight, physical activity, dietary calcium intake, smoking and serum 25-hydroxy vitamin D concentrations.

Dietary vitK correlated positively with distal tibia total area ($r=0.128$, $p=0.015$) but correlations with other bone traits were non-significant ($p>0.05$). After adjusting for covariates, no correlations among VitK intake and any bone traits existed ($p>0.05$). No correlation was observed between vitK intake and serum OC ($p>0.05$) neither in unadjusted nor adjusted models. Serum total OC correlated negatively with BMC ($r=-0.164$, $p=0.002$), BMD ($r=0.218$, $p<0.001$), bone strength index (BSI) ($r=0.204$, $p<0.001$), and stress-strain index (SSI) ($r=-0.127$, $p=0.016$) in distal tibia and in cortical strength index (CSI) ($r=-0.115$, $p=0.030$) in proximal tibia. After adjustment, statistically significant negative correlations existed between OC and distal tibial BMC ($r=-0.122$, $p=0.023$), BMD ($r=-0.157$, $p=0.003$) and BSI ($r=-0.140$, $p=0.009$), as well as proximal tibial BMD ($r=-0.160$, $p=0.003$). No significant correlations were found between OC and other bone traits ($p>0.05$).

In conclusion, we did not find associations between vitK intake and bone health in the adjusted model in the current study but serum OC was negatively correlating with some bone traits.However, there is a need for analysis of the role of different forms of vitK in the bone metabolism.

Associations of Protein Intake and Protein Source with Bone Biomarkers, Bone Mineral Density and Fracture Risk in a Canadian Population-based Study. Lisa Langsetmo*[1], Claudie Berger[2], Nancy Kreiger[3], David Goltzman[4], Susan Barr[5], Stephanie Kaiser[6], Jerilynn Prior[5], Robert Josse[7], Elham Rahme[8], David Hanley[9], Alexandra Papaioannou[10], Jonathan Adachi[11], Christopher Kovacs[12]. [1]Canandian Multicenter Osteoporosis Study, Canada, [2]CaMos, McGill University, Canada, [3]University of Toronto, Canada, [4]McGill University, Canada, [5]University of British Columbia, Canada, [6]Dalhousie University, Canada, [5]University of British Columbia, Canada, [7]St. Michael's Hospital, University of Toronto, Canada, [8]University of McGill, Canada, [9]University of Calgary, Canada, [10]Hamilton Health Sciences, Canada, [11]St. Joseph's Hospital, Canada, [12]Memorial University of Newfoundland, Canada

Background: High dietary protein has been hypothesized to lead to high dietary acid load causing bone resorption, increased calcium loss, and increased risk of fracture; but not all studies support this hypothesis.

Objective: To determine the association between total protein intake, and protein intake by source (dairy, non-dairy animal, plant-based) with biomarkers of bone/mineral metabolism [25-hydroxy vitamin D (25OHD), parathyroid hormone (PTH), insulin-like growth factor 1 (IGF1)], bone mineral density (BMD), and osteoporotic fracture.

Methods: Canadian Multicentre Osteoporosis Study participants completed a food frequency questionnaire at Year 2 (1997-99). Protein intake was assessed as percent of total energy intake (TEI) for 1919 men and 4591 women. At Year 5 participants had BMD measured and a subset had fasting blood samples taken. Participants were contacted annually up to Year 15 to ascertain incident fracture. Cox proportional hazards and multiple linear regression models were used to assess association between protein and incident main fracture (hip, spine, forearm, humerus), biomarkers and BMD. Hazard ratios (HR) or betas were adjusted for confounders and reported with 95% confidence intervals (CI).

Results: Among women 50+y, higher dietary protein (%TEI) was associated with higher serum 25OHD, lower serum PTH, higher IGF1, and higher total hip BMD (Table 1-2);similar but non-significant (NS) relationships were found in men. Higher dairy protein (%TEI) was associated with increased serum 25OHD in both women and men 50+y. Plant-based protein (%TEI) was associated with lower BMD at all sites in women 50+y, with similar but NS relationships in other groups. In men 50+y, higher dairy protein (%TEI) was associated with higher BMD at all sites, with similar but NS relationships in other groups. In subjects 50+y, moderate protein intake (15%TEI) was associated with lowest risk of main fracture; with HR= 1.76 (95% CI: 1.03-3.02) for 10%TEI vs 15%TEI in women and HR=4.16 (95% CI: 1.29-13.4) for 10%TEI vs 15%TEI in men, while protein intake greater than 15%TEI was associated with a NS trend of increased main fracture risk. There was no heterogeneity by source of protein.Conclusion: In contrast to hypothesized risk of high protein, we found that for adults 50+y, low protein intake (below 15% TEI) may lead to changes in serum biomarkers, low bone mass and increased fracture risk. Source of protein was a determinant of BMD, but not fracture risk.

Development of a Simplified Self-Questionnaire for Evaluation of Calcium Intake in Osteoporosis Prevention: a Study from the Workgroup SOLIDOS.

Florence Levy-Weil*[1], Eric Lespessailles[2], Catherine Beauvais[3], Dominique Aubraye[4], Francoise Debiais[5], Christelle Sordet[6], Corinne Thevenot[7], Didier Poivret[8], Patrice Fardellone[9], Anne-Christine Rat[10]. [1]Centre Hospitalier Victor Dupouy, France, [2]Centre Hospitalier Regional, France, [3]Service de Rhumatologie, CHU Saint-Antoine, France, [4]Service de Rhumatologie, Centre hospitalier Victor Dupouy, France, [5]Hopital Jean Bernard, France, [6]Service de Rhumatologie, CHRU Strasbourg, France, [7]Médecine Interne et Spécialité, CH Laon, France, [8]Service de Rhumatologie, CHR Metz-Thionville, France, [9]Service de rhumatologie, CHU Hôpital Nord, France, [10]Lorraine Universié Ea 4360 Apemac, Cic-Ec Cie6 et Rhumatologie, CHU Nancy-Brabois, France

Background: An adequate supply of calcium and vitamin D is essential for bone health. An assessment of calcium intake is necessary among patients with bone loss for correct adjustment.

Calcium intake measures are usually imperfect because validated questionnaires are few or too complex to be used in daily practice. The aim of the study was to develop a shorter form of the validated calcium intake self-questionnaire (the Fardellone questionnaire (FQ)) currently used in France (1).

Methods: The FQ is based on 20 different types of food with a high calcium content and/or frequently eaten in France (hereafter called items). The first stage was to update the existing FQ to be more suited with the current French diet (mainly by adding new mineral waters). In stage two, based on this updated FQ, we implemented a step-by-step approach in which we progressively reduced the number of answering modalities, the number of items based on their maximal daily calcium intake and we simplified the weight (calcium content) used to calculate the score of calcium intake. Analyses were based on equivalence tests with a limit of equivalence set at 100 mg (table 1).

Results: 717 in or outpatients from 7 hospitals completed the FQ throughout 2012. Mean age was 62 years (±12), 90% were women and 34% had a diagnosis of osteoporosis. All the obtained selected scores were equivalent except for the one including only the dairies (table 2). Finally, the questionnaire with 13 items was retained because it was easily and quickly completed by the patients and it still remained equivalent to the validated FQ. In this new questionnaire, we simplified the answering modalities, the number of items by deleting all foods containing less than 150mg of daily calcium intake and we simplified the weight to calculate the score.

Conclusion: The new 13 items self-questionnaire is equivalent to the French reference FQ. It has the advantage to be easy to use and quick to fill. Thus, it can be accessible to a large majority of patients in clinical practice. The validity of this short form will need further assessment by performing comparison with calcium intake as measured by a detailed diet survey. Thereafter, this new questionnaire can be applicable to other countries provided that food habits are similar.

Early Postmenopausal Dietary Patterns and Markers of Bone Formation, but not Bone Resorption, Predict Bone Mineral Density 10 Years On.

Helen Macdonald*[1], Adrian Wood[2], Ania Gryka[2], Antonia Hardcastle[3], Lorna Aucott[2], Alison Black[4], William Fraser[2], David Reid[5]. [1]University of Aberdeen Musculoskeletal Research, United Kingdom, [2]University of Aberdeen, United Kingdom, [3]University of East Anglia, United Kingdom, [4]Woolmanhill Hospital Aberdeen Osteoporosis Research Unit, United Kingdom, [5]University of Aberdeen, GBR

The role of diet in bone health during adulthood is unclear. There is concern that by focusing on only one or two nutrients (eg calcium) the diet may become unbalanced to the detriment of other important nutrients, as their intake or gastrointestinal absorption may be reduced. As many nutrients have common food sources, associations attributed to a single nutrient may be spurious, as intakes for that nutrient may be a marker for a different nutrient. Investigating dietary patterns may be more appropriate. The aim of this study was to determine what dietary pattern consumed by early postmenopausal women predicted bone mineral density (BMD) ten years on.

We used dietary data collected from food frequency questionnaires from 3239 women (mean age 54y) at visit 2 (1997-2000) of the Aberdeen Prospective Osteoporosis Screening Study (APOSS) to generate dietary patterns using principal components analysis. At that visit, bone markers (urinary pyrridinoline cross-links expressed relative to creatinine, DPD/Cr, PYD/Cr; and serum pro-peptide of type 1 collagen P1NP) were measured. At visit 3 (2009-2012) 2099 women (mean age 66 y) returned for BMD measurements of the hip and spine (Lunar iDXA) of whom 1850 had dietary data at visit 2.

The third principal component at visit 2, reflecting a dietary pattern marked by high intakes of carbohydrates and fat, and low spirits (liquor) consumption, was associated with lower BMD at the hip and spine at visit 3. This remained significant after adjustment for visit 2 age, weight, height, physical activity and menopausal status. No other dietary pattern predicted BMD. Bone formation markers and not bone resorption markers at visit 2 predicted lower BMD at visit 3. There were small incremental changes for some nutrients with increasing quintile of this dietary pattern, but the dominant characteristic was alcohol intake, where the bottom quintile (10.8 g/d) had > twice the mean alcohol intake of the top quintile (4.1 g/d). Further examination of food groups showed that all classes of alcoholic drinks (beer, wine and spirits) decreased with increasing quintile of this diet.

Care needs to be taken when interpreting dietary patterns, but they provide data that are not subjected to the problems of co-linearity as with nutrient intakes. Our data are consistent in indicating that alcoholic drinks are protective for bone health. Early postmenopausal markers of bone formation may predict future bone health better than bone resorption.

Bone Mineral Density (BMD) Loss May Predict Fracture Differently in Older Adults According to Fall History. Sarah Berry*[1], Robert McLean[2], Marian Hannan[3], L. Adrienne Cupples[4], Douglas Kiel[5]. [1]Hebrew SeniorLife/Beth Israel Deaconess Medical Center, USA, [2]Hebrew SeniorLife Institute for Aging Research & Harvard Medical School, USA, [3]HSL Institute for Aging Research & Harvard Medical School, USA, [4]Boston University School of Public Health, USA, [5]Hebrew SeniorLife, USA

Purpose: It is important to identify clinical factors that inform the decision of whether a repeat BMD screening test should be performed. The purpose of our study was to determine whether BMD loss over 4 yrs affects the risk of hip and non-vertebral fracture differently according to an individual's history of falls or recurrent falls.

Methods: Participants included 492 women and 310 men in the Framingham Original Cohort Study with baseline and second BMD measures at the femoral neck (mean interval: 3.7 yrs) and no prior hip fracture. Falls were ascertained by self-report at time of second BMD measure, and categorized as recent fall (any fall during past yr) or recurrent falls (≥ 2 falls in past yr). Hip fractures were confirmed with medical records, whereas other non-vertebral fractures were self-reported. Cox regression models were used to calculate hazard ratios (HR) for the association between annual percent BMD change (per SD loss) and risk of fracture adjusting for baseline BMD, age, sex, BMI, and history of fracture. Separate models were used for history of recent fall and recurrent falls. Interactions were tested by including 'fall history * BMD change' in the models.

Results: Mean age was 79 yrs (± 4 yrs). 28% of participants reported a recent fall, and 11% reported recurrent falls (range: 2-21 falls/yr). Over a median follow-up of 9.6 yrs, 76 hip and 175 non-vertebral fractures occurred. BMD loss was associated with a modest increased risk of hip (HR 1.4, 95% CI 1.2, 1.8) and non-vertebral fractures (HR 1.2, 95% CI 1.0, 1.4). The association between BMD loss and hip fracture was similar regardless of fall history (Table 1: p for interactions ≥ 0.2). For non-vertebral fractures there was a suggestion that BMD loss was associated with fracture among individuals without a recent fall (HR 1.3, 95% CI 1.1, 1.6), but not among individuals with falls (HR 0.9, 95% CI 0.7, 1.3; p for interaction =0.07).

Conclusion: Our results suggest that when predicting non-vertebral fractures, individuals without a history of falls may benefit from repeating a BMD screening test, whereas individuals with a fall may not. These surprising findings could be explained if BMD change contributes less to fracture risk when a strong risk factor for fracture, such as falls, is present and unrelated to bone health. Replication of these findings is needed before recommending that fall status be used to determine whether a repeat BMD screening test should be performed.

Table 1. Effect of BMD loss on risk of hip and non-vertebral fracture over 12-years as characterized by history of falls: the Framingham Osteoporosis Study

	Hip fracture			Non-vertebral fracture		
	Multivariate adjusted HR*	95% confidence intervals	p-value for interaction	Multivariate adjusted HR*	95% confidence intervals	p-value for interaction
Recent fall	1.4	0.9, 2.2	0.6	0.9	0.7, 1.3	0.07
No recent fall	1.5	1.2, 1.9		1.3	1.1, 1.6	
Recurrent falls (≥ 2)	1.1	0.6, 2.2	0.2	0.7	0.4, 1.2	0.2
No recurrent falls	1.5	1.2, 1.9		1.3	1.1, 1.5	

* Models include age, sex, BMI, history of fracture, and baseline BMD

Changes In Femoral Shaft Cortical Thickness In Older Women: the Study of Osteoporotic Fractures. Dennis Black*[1], Katherine Peters[2], Kristine Ensrud[3], Nicola Napoli[4], Jane Cauley[5]. [1]University of California, San Francisco, USA, [2]California Pacific Medical Center, USA, [3]Minneapolis VA Medical Center / University of Minnesota, USA, [4]University Campus Biomedico, Italy, [5]University of Pittsburgh Graduate School of Public Health, USA

Background: The 2010 ASBMR definition of atypical femur fractures (AFF) includes cortical thickness (CT) at the femoral shaft as a "minor" feature. However, there has been little systematic study of femoral shaft CT nor its relationship to AFF. We recently showed that in bisphosphonate naïve women in the Study of Osteoporotic Fractures (SOF), thicker cortices were associated with lower, not higher, risk of subtrochanteric fractures. In this analysis, we analyze changes in CT over 8 years in SOF.

Methods: Using baseline pelvic radiographs obtained at baseline and follow-up (about 8 years later) from women in the SOF study, we measured CT at the top of the femoral shaft in a random sample of 394 women. Women were > age 65 (mean 71) at the start of SOF in 1986. We analyzed two parameters at the femoral shaft: total CT (medial plus lateral) and total bone width (BW) (both averaged across the right and left sides). We looked at changes in these two parameters over time and predictors of these changes.

Results: On average, total CT was 1.34 cm at baseline and decreased by 0.26 (+ SE=0.01) cm (to 1.09 cm) over the 8 yrs. Overall bone width increased by 0.21(+ 0.01) cm from 3.69 to 3.89cm.

Changes in total CT were only weakly related to age: decreases were only somewhat higher in the oldest women (0.23cm in age 65-70 vs 0.29 cm in those >80, p=0.18). The only other risk factor with a trend toward significance was current estrogen use (HT current users had slower decrease in CT with age, p=0.12). Walking for exercise and smoking were not related to changes in CT.

Age was more strongly related to changes in BW. Among younger (65-70 yrs) women, BW increases were larger (0.24 cm) compared to older women (0.1 cm in those over age 80, p=0.03). Those with excellent or good self-reported health also showed larger increases in bone width than those with poorer self-reported health, although this did not reach statistical significance (p=0.12). Other variables did not predict changes in BW.

Conclusions: We found that femoral shaft CT decreased and BW increased over time in women over age 65. Our findings at the femoral shaft confirm other studies showing increased BW and decreased TC with age at other anatomical sites at the hip. The slowing of BW increases after age 80 may help explain the exponential increase in risk of subtrochanteric and diaphyseal fractures with age.

Prevalent Vertebral Fractures Predict Risk of Vertebral and Non-Vertebral Fractures in Older Men: the MrOS Study. Dennis Black*[1], Katherine Peters[2], Peggy Cawthon[3], Jane Cauley[4], Steven Cummings[5], Eric Orwoll[6], Kristine Ensrud[7], Howard Fink[8], Lynn Marshall[6], Neeta Parimi[9], Deborah Kado[10], Marcia Stefanick[11], John Schousboe[12]. [1]University of California, San Francisco, USA, [2]California Pacific Medical Center, USA, [3]California Pacific Medical Center Research Institute, USA, [4]University of Pittsburgh Graduate School of Public Health, USA, [5]San Francisco Coordinating Center, USA, [6]Oregon Health & Science University, USA, [7]Minneapolis VA Medical Center / University of Minnesota, USA, [8]GRECC, Minneapolis VA Medical Center, USA, [9]California Pacific Medical Center, USA, [10]University of California, San Diego, USA, [11]Stanford University School of Medicine, USA, [12]Park Nicollet ClinicUniversity of Minnesota, USA

Background: Prevalent vertebral fractures in women have been shown to be strongly predictive of future vertebral as well as non-vertebral fractures. However the ability of prevalent vertebral fractures to predict future risk of various types of fractures in men has been less well studied.

Methods: Prevalent vertebral fractures were defined from baseline X-rays in men from the MROS study, a longitudinal cohort study in men over age 65. Baseline prevalent vertebral fractures (PVfx) were defined as a semi-quantitative (SQ) grade fracture >=2 and incident vertebral fractures by a change of SQ>=1 between baseline and follow-up radiographs. The analysis included 4389 men with both baseline and follow-up x-rays and was restricted to follow-up time prior to repeat x-ray (mean=4.5 years). We examined presence and number of PVfx to predict incident spine fracture as well as non-spine (any non-spine, hip and wrist) fractures. Adjustments for age, site, BMD and other risk factors used multivariable models (logistic or PH)

Results: Over 4.5 years, there were 197 incident spine and 157 non-spine fracture (including 23 hip and 34 wrist fractures). After age adjustment, men with PVfx (7%) were at more than 5 times risk of incident radiographic vertebral fracture (OR=5.7, p<.0001). Among those with PVfx, risks of non-spine fractures were also significantly increased (any non-spine, RH=2.2, p<.001) as was risk of hip (RH=3.3,p=.02) and

wrist fracture (RH=4.1, p=0.001). Relative risk for each fracture type increased strongly with number of PVfx (see figure). Defining PVfx by SQ>=1 increased prevalence but attenuated the associations. Adjustment for BMD, history of non-vertebral fracture or other factors only slightly attenuated the association for incident spine fracture (OR=3.4,p<0.001). The associations for non-spine fractures were more strongly attenuated: the RH for non-spine and wrist fracture remained marginally significant (p=0.003 and 0.02, respectively) but the relationship to hip fracture was no longer significant (p=0.33).

Conclusion: PVfx were strongly predictive of incident spine as well as non-spine fractures. PVfx in men may reflect some aspect of bone quality not assessed by BMD or other risk factors and therefore may play an important independent role in future fracture risk assessment, particularly for incident vertebral fracture.

SU0321

Concordance and Discordance between Incident Radiographic Vertebral Fractures and Clinical Vertebral Fractures in Older Men. Kristine Ensrud*[1], Terri Blackwell[2], Howard Fink[3], Jie Zhang[4], Jane Cauley[5], Peggy Cawthon[2], Dennis Black[6], Douglas Bauer[6], Jeffrey Curtis[4], Eric Orwoll[7], Elizabeth Barrett-Connor[8], Deborah Kado[8], John Schousboe[9]. [1]Minneapolis VA Medical Center / University of Minnesota, USA, [2]California Pacific Medical Center Research Institute, USA, [3]GRECC, Minneapolis VA Medical Center, USA, [4]University of Alabama at Birmingham, USA, [5]University of Pittsburgh Graduate School of Public Health, USA, [6]University of California, San Francisco, USA, [7]Oregon Health & Science University, USA, [8]University of California, San Diego, USA, [9]Park Nicollet ClinicUniversity of Minnesota, USA

Prior studies in older women have reported that 1/4 to 1/3 of incident vertebral fractures identified on the basis of radiographs alone (radiographic vfxs) are also clinically diagnosed as fracture events (clinical vfxs), but there is a lack of data in men. Among 4398 men aged ⩾65 years enrolled in MrOS, we determined the proportion of incident radiographic vfxs also diagnosed as incident clinical vfxs and vice-versa. Incident radiographic vfxs were identified by comparing baseline and follow-up lateral and thoracic spine study films (average 4.6 years between films) using a semiquantitative (SQ) method and defined as those with a change in SQ reading of ⩾1 at a given vertebral level from baseline to follow-up radiograph (for incident radiographic vfxs with grade 1 severity, endplate depression also required). Men were queried every 4 months after baseline about clinical fracture events (>99% of follow-up contacts completed). Incident clinical vfxs were those reported by participants and confirmed by the study radiologist, who used the SQ method to establish that the community imaging study showed a new deformity of higher grade than was present in the same vertebra on the baseline study film.

197 men (4.5%) had 237 incident radiographic vfxs identified by comparison of study films, whereas 31 men (0.7%) experienced 37 incident clinical vfxs. For men with incident clinical vfxs, back pain was the presenting complaint in 84% of cases. Of the 237 incident radiographic vfxs, 29 (12.2%) were also clinically diagnosed at the same vertebral level, with clinical diagnoses made for 14.4% of incident radiographic vfxs with SQ change ⩾2 compared with 8.3% of incident radiographic vfxs with SQ change = 1. Of the 37 confirmed incident clinical vfxs, 29 (86.5%) were also identified as incident radiographic vfxs at the same vertebral level, most of them (22 of 29) with SQ change ⩾2. Using an alternative definition of concordance (fxs identified at same vertebral level ±1 level) did not substantially alter these results.

In this study of older men, less than 1/7 of incident radiographic vfxs were also clinically diagnosed as new vfxs; the proportion clinically diagnosed was somewhat higher for more severe radiographic vfxs. Most, but not all, incident clinical vfxs were also identified as incident radiographic vfxs. These results in men complement those in women and suggest a complex relationship between clinical and radiographic vfxs in older adults.TBD

Construction validity of the ICECAP-O index amongst people with non-traditional low trauma fractures. Yu Zhang*[1], Mark Kotowicz[2], Julie Pasco[3], Kerrie Sanders[4]. [1]University of Melbourne, Australia, [2]Deakin University School of Medicine, Australia, [3]Deakin University, Australia, [4]NorthWest Academic CentreThe University of MelbourneWestern Health, Australia

Osteoporotic fractures could affect patients' health related and general quality of life (QoL). The IcePop Capability Index (ICECAP-O) is a relatively new tool that measures individuals' general QoL using five attributes [1]: attachment (love and friendship), security (thinking about the future without concern), role (doing things that make you feel valued), enjoyment (enjoyment and pleasure) and control (feeling independent). Each attribute has four levels, allowing four a total of 4^5=1024 possible health states. Our aim was to investigate the construct validity of the ICECAP-O in patients who suffered a minimal trauma fracture at non-traditional/non-classical sites.

Patients with radiologically confirmed fractures, recruited from the Emergency Department and Imaging Department of the Geelong Hospital, were interviewed within two weeks after their first fracture-related healthcare visit. The interview included their demographic information (age, gender, income level, employment, and living conditions, activity level etc.), and measurements of health related QoL (HRQoL, measured using the EuroQol-5D instrument), anxiety and depression levels (measured using the Hospital Anxiety and Depression Scale, HADS) and overall ICECAP-O values. Measurements were repeated after 4 (phase II) and 12 months (phase III). A Kendall Taub's test was used to assess convergent validity. We hypothesized that patients' ICECAP-O values would correlate with their HRQoL and HADS values. Multivariate regression analysis was used to assess discriminant validity; confidence intervals obtained using bias corrected accelerated bootstrap method (10000 reps). We expected those who were inactive to have lower ICECAP-O scores.

Of the 778 fracture cases, 246 participants recruited at baseline, and information was obtained from 210 and 171 participants for phases II and III, respectively. Results for convergent validity are shown in tables 1 and 2. There were significant correlations between capabilities and HRQoL, both at phases II and III respectively. This was shown by the significant correlations between the ICECAP-O and the EQ5D and EQ-VAS scores. However, the correlations are not strong. Capabilities were also significantly correlated with the HADS scales, but again, the correlation was weak. For discriminante validity, regression analysis showed a positive association between ICECAP-O values and activity levels at both phases II (coefficient: 0.1, p<0.01 95%CI: 0.04-0.1) and III (coefficient: 0.1, p=0.01, 95%CI: 0.02-0.2).

The ICECAP-O uses different set of attributes to measure QoL than instruments that assesses HRQoL. Our results showed reasonable convergent and discriminant validity for ICECAP-O. Those with higher activity levels showed significantly higher ICECAP-O values.

Dissecting the Relationship between High-Sensitivity Serum C-Reactive Protein and Increased Fracture Risk: the Rotterdam Study. Ling Oei*[1], Natalia Campos[2], Abbas Dehghan[2], Edwin Oei[2], Lisette Stolk[2], Joyce Van Meurs[1], Albert Hofman[2], Andre Uitterlinden[3], Oscar Franco[2], Carola Zillikens[2], Fernando Rivadeneira[1]. [1]Erasmus University Medical Center, The Netherlands, [2]Erasmus MC, The Netherlands, [3]Rm Ee 575, Genetic Laboratory, The Netherlands

Inflammatory diseases are associated with bone pathology, reflected in a higher fracture risk. Serum high-sensitivity C-reactive protein (CRP) is the most well-described inflammatory biomarker. Our aim was to investigate the relationship between CRP and bone health in the Rotterdam Study, a prospective population-based cohort. At baseline, bone mineral density (BMD) and hip bone geometry parameters were measured with dual-energy X-ray absorptiometry (DXA). For Mendelian randomization purposes, a weighted score for high CRP was computed including single nucleotide polymorphism (SNPs) (Illumina HumanHap550 Beadchip genotyping and HapMap imputation), which have previously been identified as associated with serum CRP levels. Models were adjusted for sex, age, BMI and other potential confounders and effect estimates reported per unit increase in log-transformed CRP. Linear regression was performed for continuous outcomes, logistic regression for radiographic vertebral fractures and Cox proportional hazard regression to estimate the risk of all other types of fracture. Complete data was available for 6,386 participants, of whom 1,561 persons sustained a fracture (mean follow-up: 11.6 years). CRP was significantly associated with all-type fracture risk (HR: 1.06; 95% CI: 1.01-1.12; P=0.03), including hip fractures (HR: 1.15; 1.03-1.27; P=0.009) and vertebral fractures (OR: 1.19; 1.06-1.34; P=0.003). The association seemed strongest in the lowest femoral neck (FN-) BMD tertile (0.39-0.80 g/cm^2: HR: 1.13; 1.04-1.23; P=0.002). The combined genetic risk score of CRP SNPs was significantly associated with serum CRP levels (P=9x10^{-56}), but not with fracture risk (HR: 1.00; 0.99-1.00; P=0.23). In conclusion, serum high-sensitivity CRP is associated with fracture risk, lower femoral neck width and bending strength. Mendelian randomization analyses did not yield evidence for this relationship being causal. Future studies might reveal what factors truly underlie the relationship between CRP and fracture risk.

Frequency of calcaneal insufficiency fracture in elderly patients. Koji Nozaka*, Naohisa Miyakoshi, Michio Hongo, Yuji Kasukawa, Hiroyuki Tsuchie, Kentaro Ohuchi, Hayato Kinoshita. Akita University Graduate School of Medicine, Japan

Background: Although a number of reports have examined insufficiency fracture of the calcaneus in elderly individuals, the frequency of this injury induced by bone fragility remains unclear.

Objective: To examine the frequency of calcaneal insufficiency fractures in the elderly.

Subjects: We investigated 123 patients (46 men, 77 women) ^{3}60 years old who visited the outpatient clinic due to calcaneal and calcaneus region pain without obvious external injuries and underwent calcaneus radiography between 2006 and 2010. Patients who clearly had a malalignment syndrome such as pes cavovarus or pes planovalgus were excluded from the study.

Results: The mean age of patients was 76.2 years (range, 60-100 years). The frequency of calcaneal insufficiency fracture was 8.1% (10 women). Of the 123 patients, 89 patients visited the clinic on their own without assistance of stretchers or wheelchairs. Fracture frequency in these 89 patients was 10.1% (9 of 89). None of the 10 patients with fracture had underlying diseases such as rheumatoid arthritis or diabetes, and none were taking steroidal medications. In addition, none were being treated for osteoporosis. Bone density tests were performed after injury in only 5 patients, and all five had a bone density <70% of the young adult mean (YAM) and subsequently started osteoporosis treatment medications. All 10 patients were successfully treated with conservative therapy on an outpatient basis. Eight patients received external fixation. Mean duration between onset of pain and initial visit was 17.4 days (range, 0-40 days). Osteosclerosis was observed on radiography performed on the initial visit in 2 patients. Definitive diagnosis of the fracture was made on magnetic resonance imaging (MRI) in 6 patients. In 2 patients, MRI was not performed due to various circumstances, but osteosclerosis was determined on radiography conducted during routine follow-up.

Discussion: Frequency of calcaneal insufficiency fracture in elderly individuals who had pain in the calcaneal region was 8.1%. This type of fracture cannot always be diagnosed solely by radiography on the initial visit, and MRI appears valuable for early diagnosis. This type of fracture can be treated using conservative therapy alone.

Bone mineral density (BMD) is the most widely used predictor of fracture risk. Twin studies demonstrate that genetic factors play an important role for BMD and fracture risk. A recent large-scale meta-analysis identified 63 autosomal SNPs to be associated with BMD and 16 BMD-associated SNPs were also associated with fracture risk. Based on these findings two genetic risk scores (GRS63 and GRS16) were developed. The aim of the present study was to determine the clinical usefulness of these GRS for the prediction of BMD, BMD loss and fracture risk in elderly subjects.

Genotype data from two male (MrOS US and MrOS Sweden) and one female (SOF) well-powered cohorts of older subjects were evaluated against BMD (n=8,212), BMD loss (n=5,312), and incident fractures (n=8,067 including 2,185 incident fracture cases).

The GRS63 was significantly associated with BMD at both femoral neck (FN) and lumbar spine (LS) in all cohorts, with similar proportion of the variation in BMD explained (*FN*: MrOS Sweden 3.1%, MrOS US 3.2%, SOF 2.6%; *LS:* MrOS Sweden 3.3%, MrOS US 2.6%, SOF 3.2%). In contrast, the GRS63 was not significantly associated with BMD loss.

Although both the GRS63 and the GRS16 were associated with all fractures, the effect size for GRS63 (HR 1.16, 95% confidence interval (CI): 1.11-1.20, per SD increase) was larger than that for GRS16 (HR 1.06, 95% CI: 1.02-1.11, per SD increase). The GRS63 (HR 1.20, 95% CI: 1.11-1.30, per SD increase), but not the GRS16, was significantly associated with hip fractures. After adjustment for FN-BMD, the effect sizes between GRS63 and all fractures (-50%) and hip fracture (-64%) risk were substantially reduced.

Only minor improvements in C-statistics (AUC) for all fractures were seen when GRS63 was added to a base model including age, weight and height and no significant improvements in C-statistics were seen when GRS63 was added to a base model further adjusted for BMD (Fig). Net reclassification improvement (NRI >0) with the

addition of GRS63 to a base model was modest in all three cohorts and this improvement was substantially attenuated in BMD-adjusted models (Fig).In conclusion, the GRS63 predicts BMD, but not BMD loss, in elderly subjects, suggesting that the genetic determinants of the acquisition of BMD differ from those of BMD loss. As BMD is usually known, the clinical utility of the BMD-associated GRS63 for fracture prediction is limited in elderly subjects.

How well hip fractures can be captured using the postal enquiry?. Reijo Sund[1], Liisa Ollikainen[2], Risto Honkanen[2], Heikki Kroger*[3]. [1]National Institute for Health & Welfare, Finland, [2]University of Eastern Finland, Finland, [3]Kuopio University Hospital, Finland

The purpose of the study was to examine how well follow-up using postal enquiry can capture hip fractures.

Study population in the Kuopio Osteoporosis Risk Factor and Prevention (OSTPRE) study consisted the total population of 14220 women aged 47-56 years resident in the province of Kuopio in January 1989. The baseline postal enquiry was conducted in June-August 1989 and gave a high response of 92.8%. Follow-up enquiries have been sent every fifth year, i.e. in 1994, 1999, 2004 and 2009. Each enquiry contained question on occurred fractures. Self-reported fractures were verified from the medical records.

We used the Finnish Hospital Discharge Register to identify all hospitalizations with hip fracture diagnosis (ICD-9: 820, ICD-10: S72.0, S72.1, S72.2) during 1987-2011 for the OSTPRE population. A total of 1001 records for 384 persons with hip fracture diagnosis were found. After removing obvious follow-up hospitalizations there remained 470 records possibly indicating hip fracture. All these candidates for hip fractures were verified from the medical records.

After verification, the total number of hip fractures (excluding pathologic and periprothetic fractures) for the OSTPRE population during 1987-2011 turned out to be 363. Five hip fractures (1.4%) were not identified from the register with hip fracture diagnosis: one patient with only outpatient treatment for hip fracture was missing and four other had diagnosis of lower part of femur. More strikingly, only 122 hip fractures (33.6%) were captured using the postal enquiries. Obvious reasons for missed fractures were found for 110 (30.4%) cases. Failed reporting of hip fractures in 16 cases (4.4%) was surprising as hip fractures are typically major life events for individuals. Nonresponse was the main reason for missed fractures consisting of 115 cases (31.7%).

In conclusion, nonresponse and drop out have severe consequences for identification of hip fractures in postal inquiries. More than half of the hip fractures would have been missed without register-based data. Probably hip fractures and nonresponse are related to similar risk factors such as long-term care and increased comorbidity. Such major limitation must be kept in mind while utilizing purely self-reported (hip) fracture data.

Keywords: hip fracture, postal enquiry, registers

SU0327

Impact of Vertebral Fractures on Hospitalization for Major Disease and Longterm Care Placement. Jane Cauley*[1], Li-Yung Lui[2], Misti Paudel[3], Lih-Wen Mau[4], Brent Taylor[4], Peggy Cawthon[2], Teresa Hillier[5], John Schousboe[6], Kristine Ensrud[7]. [1]University of Pittsburgh Graduate School of Public Health, USA, [2]California Pacific Medical Center Research Institute, USA, [3]Department of Epidemiology, University of Minnesota, USA, [4]University of Minnesota, USA, [5]Kaiser Center for Health Research, USA, [6]Park Nicollet ClinicUniversity of Minnesota, USA, [7]Minneapolis VA Medical Center / University of Minnesota, USA

Purpose: Vertebral fractures (VFx) are the hallmark of osteoporosis. Women with VFx have a higher risk of death, fracture and impaired function. The purpose of this analysis was to test the hypotheses that the impact of VFx extends to hospitalizations for major disease events and longterm care placement (LTC).

Methods: We studied 3603 Caucasian women enrolled in the Study of Osteoporotic Fractures (SOF) and merged SOF cohort data with Medicare claims. To be included in this analysis, women had to be enrolled in Medicare Fee for Service [(FFS), i.e. parts A and B but not C] as of 1/1/1992 and have radiographic information on VFx status at visit 3 (1990-91). VFx status was assessed using quantitative morphometry on lateral thoracic and lumbar spine radiographs obtained at visit 3 and defined as any height ratio >3 standard deviations below normal. Women were censored if they died or disenrolled in FFS. Hospitalizations with a primary diagnosis of congestive heart failure (CHF), myocardial infarction (MI), stroke, chronic obstructive pulmonary disease (COPD) and hip fracture were identified using ICD-9 hospital discharge diagnoses using Medicare data from inpatient files. Longterm (>100 days)or permanent placement in a LTC facility was also identified using claims data from inpatient and carrier (physician files). We used a Cox proportional hazards model to estimate the multivariable (MV) adjusted relative hazard (RH) [95% confidence interval (CI)] of hospitalization for one of the conditions listed above or LTC placement.

Results: The mean age of the women was 74.4 (68-95 yrs) and 810 (22.5%) had a VFx. Over an average of 10.4 ± 5.0 years of follow-up, 1676 (46.5%) were hospitalized for one of the major disease events and 825 (22.9%) were placed in a LTC facility. The MV adjusted RH (95% CI) for hospitalization for a major disease event among those with a VFx was 1.15 (1.02, 1.30) in comparison to women without a fracture, Table. Because VFx are major risk factors for hip fracture, we redid our analysis removing hip fracture as a hospitalization, MV adjusted RH, 1.12 (0.99, 1.28). VFx were also associated with LTC placement, MV adjusted 1.20 (1.02, 1.42). The association between VFx and hospitalization was especially strong for women with >2 VFx.

Conclusion: Our results extend the potential public health impact of radiographic VFx to include an increased risk of hospitalization for major diseases and placement in a LTC facility.

Table: Multivariate adjusted hazard ratio (HR) (95% confidence interval) for hospitalization or longterm care placement by vertebral fractures status. Referent=no vertebral fracture.

	Hospitalization[1]	Hospitalization[2]	Longterm care placement
Vertebral fracture (any)	1.15 (1.02, 1.30)	1.12 (0.99, 1.28)	1.20 (1.02, 1.42)
Vertebral fracture			
1	1.08 (0.93, 1.25)	1.08 (0.92, 1.26)	1.20 (0.99, 1.47)
>2	1.26 (1.07, 1.49)	1.19 (0.99, 1.43)	1.21 (0.95, 1.53)

Low Bone Mineral Density in Swedish Men with Distal Radius Fracture. Lisa Egund*[1], Fiona McGuigan[2], Kristina Akesson[1]. [1]Skåne University Hospital, Malmoe, Sweden, [2]University of Lund, Malmö, Skane University Hospital, Malmö, Sweden

A distal radius fracture is considered a predictor of future risk for osteoporosis and fragility fractures in women.Although men with this fracture type are known to have lower bone mineral density (BMD) the etiology has not been extensively studied. The purpose of this study was to evaluate on a large scale, the BMD of Swedish adult men of all ages with distal radius fracture and compare them to the background population.*Material* In this cross-sectional study, adult men presenting with a distal radius fracture and living in Malmö, Sweden, were recruited in two ways: All men who fractured during 1999-2000 (n=288) were invited to participate during 2003. Additionally, men who sustained a distal radius fracture from 2003-2007 (n=460) were invited to the prospective study-arm and followed during the first year post-fracture. A total of 233 patients were enrolled. Controls were chosen from a

preexisting database of individuals all randomly selected from the population registry and from the same geographical area. *Methods* BMD was measured using DXA at the femoral neck, total femur and lumbar spine. Medical history and other risk factors for health were obtained through questionnaire. Participants were grouped according to age at fracture: 20-44, 45-64 and >65yrs and in 10-yr age-bands to determine mean BMD levels.

Results The mean age of men with fracture of the distal radius was 52.2 ±16.7 and BMI was 26.5±3.9. The fracture distribution according to age group was 27%, 44% and 29%, respectively. The fracture group had significantly lower BMD ($p<0.001$) compared to controls at the femoral neck (45-64yrs: 0.930 vs 0.989 g/cm^2; >65yrs: 0.839 vs 0.939); Total hip (45-64yrs: 0.985 vs 1.048; >65yrs: 0.898 vs 1.019); Spine (45-64yrs: 1.153 vs 1.225, >65yrs: 1.109 vs 1.277). The corresponding difference in T-score at the femoral neck was 0.4-0.8 and at total hip 0.5-0.9.). At the hip sites, compared to controls, this equates to a 6.0% lower BMD for patients 45-64y and 11.9% for those 65y and above. The 3.1% lower BMD in those below 45 yrs was not significant. The proportions with osteoporosis were: 20-44yrs: 3.6% vs 1.0%; 45-64yrs: 5.5% vs 2.2%; >65yrs: 19.0% vs 5.5%. *Conclusion* In this study, to our knowledge the largest on men with distal radius fracture, those with fracture have significantly lower BMD at all sites. Interestingly, compared to controls the difference in BMD becomes more pronounced with increasing age, but is already evident from middle age.

Outcomes in Patients with Atypical Femur Fractures: the Ontario AFF Cohort. Angela M. Cheung*[1], Aliya Khan[2], Robert Josse[3], Earl Bogoch[4], Lianne Tile[5], Robert Bleakney[6], George Tomlinson[7], Adrian Lau[7], Rowena Ridout[8], Heather McDonald-Blumer[7], Moira Kapral[5], Savannah Cardew[9], Khalid Syed[5], Nicholas Bellamy[10], Jessica Chang[5], Judite Scher[5], Hanxian Hu[5], Alexandra Papaioannou[11], Suzanne Morin[12], Jonathan Adachi[13]. [1]University Health Network-University of Toronto, Canada, [2]McMaster University, Canada, [3]St. Michael's Hospital, University of Toronto, Canada, [4]St. Michael's Hospital, Canada, [5]University Health Network, Canada, [6]Mount Sinai Hospital, Canada, [7]University of Toronto, Canada, [8]Toronto Western Hospital, Canada, [9]Women's College Hospital, Canada, [10]The University of Queensland, Australia, [11]Hamilton Health Sciences, Canada, [12]McGill University, Canada, [13]St. Joseph's Hospital, Canada

Background: Atypical femur fractures (AFFs) are associated with delayed healing and high morbidity. To better understand outcomes in patients with AFFs, we conducted a prospective cohort study to systematically assess health related quality of life (HR-QOL), pain, and functional disability post fracture.

Methods: Patients with AFFs were recruited through specialty clinics and orthopedic practices across Ontario. All AFF patients were assessed by at least one osteoporosis specialist (often two), and their plain radiographs were reviewed by the specialist(s) and a central musculoskeletal radiologist to confirm the diagnosis of AFF based on the ASBMR diagnostic criteria. Patients were asked to complete questionnaires on health related quality of life (HR-QOL,RAND SF-36), visual analogue pain scale (VAS), and the Western Ontario and McMaster Universities Arthritis Index (WOMAC) modified for use in the AFF population. They were asked to complete one set for the present and one set by recalling their experience 1 year prior to their AFF diagnosis.

Results: Of the 105 AFF patients in the Ontario AFF cohort, 100 were postmenopausal women and 5 were men. Mean age at time of fracture was 66.1 years (range18.8-87.0). 59% were Caucasians, 15% South Asians and 26% Oriental. 44% had fractures prior to their AFFs and 67% had bilateral AFFs. Of those with bilateral fractures (n=70), 2 (2.9%) had bilateral subtrochanteric fractures, 56 (80.0%) had bilateral mid-diaphyseal fractures, and 12 (17.1%) had one of each. Of those with unilateral AFFs (n= 35), 6 (17.1%) had subtrochanteric fractures and 29 (82.9%) had mid-diaphyseal fractures. Average duration of bisphosphonate use was 9.4 years (range 0-28 years). Mean serum 25-hydroxyvitamin D level was 97 nmol/L. Areal BMD T-scores ranged from 0.84 to -3.95 for lumbar spine, 0.82 to -3.53 for total hip, and 0.33 to -3.79 for femoral neck. Average time from first AFF to time of first survey was 2.5 years (range 0-10 years). Of the 110 femurs with surgical repair, 18 required surgical re-intervention. AFF patients had a much lower SF-36 physical composite score than their age and sex matched controls (mean physical component summary (PCS)=39.5, SD=11.5; mean mental component summary (MCS)=45.2, SD=12). Pain scores by VAS were 4.4 (2.8) and on the modified WOMAC, the mean (SD) scores were 3.1 (2.4) for pain, 3.7 (2.6) for weakness and 3.4 (2.6) for function.

Conclusions: Patients with AFFs have decreased HR-QOL, persistent disability and pain long after their initial fracture.

Prediction of Fracture and Fracture-associated Outcomes. Tuan Nguyen*[1], Steven Frost[2], Nguyen Nguyen[1], Jacqueline Center[1], John Eisman[1]. [1]Garvan Institute of Medical Research, Australia, [2]University of Western Sydney, Australia

Background and Aim — A fragility fracture signals a series of adverse events, including recurrent fracture and mortality. Existing predictive models in osteoporosis have been developed to predict the risk of an initial fracture only, and do not predict the risk of subsequent fractures. In this study, we sought to examine the inter-relationships between an initial fracture, subsequent fracture, and mortality.

Methods — This study was based on a population-based cohort consisting of 757 men and 1224 women, aged 60 years and older, whose fracture status and health outcomes had been continuously monitored for up to 24 years. Fragility fractures were ascertained using X-ray report and circumstance of fracture. The incidence of mortality was obtained from individual participant during the follow-up period. Femoral neck bone mineral density and risk factors (eg lifestyle factors, physical activity, and concomitant illneses and medications) were also ascertained at the initial visit as well as during the study period. A multistate Markov style of the Cox's proportional hazards model was used to estimate the transition probabilities between three statuses (ie initial fracture, refracture, and mortality) with adjustment for competing risk of death.

Results — The average age of participants was 70 years (range: 60 to 101). Approximately 25% of women and 12% of men had osteoporosis (BMD T-scores <-2.5). Among women without a fracture, approximately 37% would remain fracture-free during the subsequent 10-year follow-up; 24% would suffer a fracture, and 8% went on to refracture, and another 32% would die during this 10-year period. Among women with an initial fracture, 56% died after within 10 years, and 60% died after a recurrent fracture. Among men without a fracture, 38% would remain fracture-free, 14% would sustain a fracture, and 45% would die during the next 10 years. Among men with an initial fracture, the risk of a recurrent fracture was 16%, and the risk of death was 76%. However, in both genders, the risks of subsequent fracture and mortality were increased with advancing age and reduced BMD (Table)

Conclusions — These results show that individuals with an initial fracture have an increased risks of subsequent fracture and mortality, and the risk of fracture-associated mortality in men is greater than in women. The strong effects of advancing age and reduced BMD on the three related events of fracture, refracture, and mortality allow an individualized approach to the risk assessment for a man and woman. Such an assessment can aid patients and doctors to reach an informed decision concerning treatment for individuals with an initial fracture to reduce fracture and mortality in the general population.

Predicted risk of fracture, refracture and mortality for men and women by age and bone density T-score.

Predictors of Re-fracture in Patients Managed within a Fracture Liaison Service: A 7-year Prospective Study. Kirtan Ganda*[1], Markus Seibel[2]. [1]Concord Hospital, Australia, [2]Bone Research Program, ANZAC Research Institute, University of Sydney, Australia

Background: Effective fracture liaison services (FLS) increase treatment initiation rates and adherence amongst patients with incident osteoporotic fracture, and significantly reduce the risk of subsequent fracture. Predictors of re-fracture have been well documented in untreated populations but not in patients managed long-term within the setting of secondary fracture prevention programs. Based on 7 years of continuous follow-up data we identified predictors of re-fracture amongst a specialist-managed population.

Methods: The analysis included 212 subjects who at baseline presented with an incident osteoporotic fracture and were treated for at least 4 years since then. All patients were managed within the well-established Concord FLS (Sydney, Australia). Relevant anthropometric, clinical and technical data were documented at each six-monthly visit. Predictors of re-fracture were identified by logistic regression analysis before and after adjustment for potential confounders.

Results: The mean duration of follow-up was 5.57 years (range: 4.02-7.51). At baseline, mean age (SD) was 72.4 (12.7) years, 79% of subjects were female and 38% had prevalent fractures at the time of the index fracture. The mean (SD) total hip T-score was -1.2 (1.2) SD. Adherence to osteoporosis therapy was high throughout. During the study period, 24% of treated subjects re-fractured. Re-fracture rates in a population of similar composition were reported at 35-46% over 2-6 years. In unadjusted analyses, predictors of re-fracture were female gender, use of oral steroids, significant co-morbidities (>3), gastro-oesophageal reflux, cardiovascular disease, body weight < 66.4kg, total hip T-score <-1.65 SD, previous falls, maternal history of hip fracture, sunlight exposure of <30 min/d, and >2 prevalent fractures. After adjusting for confounders female gender (OR 7.3, 95%CI 1.6-33.8, p=0.01), comorbidity (OR 4.1, 95%CI 1.9-9.1, p<0.01), total hip T-score <-1.65 SD (OR 3.9, 95%CI 1.8-8.3, p<0.01), and ⩾1 fall within the last year (OR 2.2, 95%CI 1.0-4.8, p=0.04) remained significantly associated with re-fracture. Prevalent fracture status and age were not associated with re-fracture.

Conclusion: Female patients with low hip BMD, a history of recent falls and significant comorbidity are at heightened risk of re-fracture even when managed by a dedicated FLS. This sub-group at patients require intensive management including falls reduction strategies.

SU0332

Changes in Frailty-Related Characteristics of the Hip Fracture Population and their Implications for Healthcare Services: Evidence from Quebec, Canada. Mohammad Auais*[1], Suzanne Morin[2], Lyne Nadeau[3], Lois Finch[3], Nancy Mayo[3]. [1]Ivey International Centre for Health Innovation, Can, [2]McGill University, Canada, [3]McGill University Health Centre, Canada

Purpose To estimate secular changes in the prevalence of selected frailty-related characteristics among the hip fracture population in Quebec (2001-2008) and the potential impact of these changes on healthcare services.

Methods The Quebec hospitalization database was used to identify non-traumatic hip fractures for the purposes of calculating age- and sex-specific rates. Also estimated were time trends for selected frailty-related characteristics and discharge destinations.

Results A significant decline in fracture rates was evident for all age groups except for those <65; sex differences were also observed. Almost all frailty-related characteristics increased over time, ranging from 2% to 14% per year, which translates to an estimated increase from 16 to 112%, over the study period. For those whose prior living arrangement was LTC, rates declined significantly (women OR= 0.93; 0.91-0.95; men OR=0.97; 0.94-0.99). In-hospital mortality and discharge to in-patient rehabilitation decreased while discharges back to community and to LTC increased.

Conclusions Although hip fracture rates decreased for older hip fracture patients, the absolute number and prevalence of specific frailty-related characteristics increased. Policy-makers should review care models to ensure adequate resources are provided to the community to offset the expected increase in demand arising from ongoing changes in patients' characteristics.

Serum Pentosidine and its Decoy Receptor, endogenous secretory receptor for Advanced Glycation End Products, Predict Fragility Fractures in Elderly Men: the Fujiwara-kyo Osteoporosis Risk in Men (FORMEN) Study. Junko TAMAKI*[1], Katsuyasu KOUDA[1], Yuki FUJITA[1], Masayuki IKI[1], Akiko YURA[1], Eiko KADOWAKI[1], Masakazu MIURA[2], Yuho SATO[3], Nozomi OKAMOTO[4], Norio KURUMATANI[4]. [1]Department of Public Health, Kinki University Facluty of Medicine, Japan, [2]Hokuriku University Faculty of Pharmaceutical Sciences, Japan, [3]Department of Human Life, Jin-ai University, Japan, [4]Department of Community Health & Epidemiology, Nara Medical University School of Medicine, Japan

Objectives: The aim was to evaluate the ability of serum pentosidine (PEN) and the endogenous secretory receptor for advanced glycation end products (esRAGE) to predict fragility fractures in community-based cohort study of elderly men. Methods: We analyzed 1,290 Japanese men in FORMEN Study which baseline survey was conducted in 2007-2008 as part of Fujiwara-kyo study, and followed during 5-year period. The outcome was the initial fracture event defined as clinical fractures of the hip, vertebra, forearm, proximal humerus, clavicle, rib, proximal and distal cubitus, and pelvis that occurred without strong external force and diagnosed with radiographic reports. Bone mineral density (BMD) at femoral neck (FN) and at lumbar spine (LS) was measured at baseline (QDR4500A, Hologic, USA). The multiple logistic regression analysis was used to estimate the odds ratio (OR) per 1 standard deviation (SD) increase of the log-transformed PEN and esRAGE values at baseline measured using the FSK pentosidine ELISA kit, and the B-Bridge esRAGE ELISA Kit, respectively. Receiver operating characteristics (ROC) curves analysis with expected probabilities for fragility fractures was performed, and cut-off values were determined by Youden's index which gives maximum difference between sensitivity and false-positive rate. Results: The mean age at the baseline was 73.1 $\pm$ 5.1 years. The twenty-six men suffered incident fractures and were significantly older and had significantly lower BMD values and higher proportions of type 1 diabetes mellitus or high glycemic status with fasting glucose ⩾ 160 mg/dl or with HbA1c(NGSP) ⩾ 8.4%, and higher PEN (p=0.019) and lower esRAGE (p=0.128) levels than those without fractures. The age-adjusted ORs per 1SD increase of PEN and esRAGE were 1.50 [95% confidence interval (CI): 1.03-2.17, p=0.033], and 0.70(0.48-1.01, p=0.058), respectively. The ORs per 1SD increase for PEN and esRAGE were 1.54(1.05-2.28), 0.66(0.45-0.97), respectively, adjusted for age, FN BMD, type 1 diabetes mellitus, and high glycemic status. The area under ROC curve (AUC) of the expected probabilities obtained by the model was 0.72(0.61-0.84) with 61.5% sensitivity and 79.0% specificity at a cutoff determined by Youden's index. The adjusted ORs of PEN and esRAGE obtained by the model in which LS BMD substituted for FN BMD were 1.60(1.07-2.37), 0.64(0.43-0.95), respectively, with AUC value of 0.78(0.68-0.87), 61.5% sensitivity, and 85.0% specificity. Conclusions: Higher serum pentosidine and lower serum esRAGE values were associated with an increased risk of fragility fractures independently of BMD among Japanese elderly men over a 5-year follow-up period.

Interaction of a single genotype and body mass index for prediction of hip fracture risk: a prospective cohort study. Joshua Lewis*[1], Karol Estrada[2], Andre Uitterlinden[3], Fernando Rivadeneira[4], Richard Prince[5]. [1]University of Western Australia, Sir Charles Gairdner Hospital, Australia, [2]Analytic & Translational Genetics Unit, Massachusetts General Hospital, USA, [3]Rm Ee 575, Genetic Laboratory, The Netherlands, [4]Erasmus University Medical Center, The Netherlands, [5]Sir Charles Gairdner Hospital, Australia

To date, studies on the genetic determinants of fracture risk adjust for environmental and nutritional influences but have not tested the relationship of these factors with the genetic polymorphisms associated with fracture. To study this further, we undertook a proof of principle study on the interaction between body mass index (BMI) and the six polymorphisms that reached genome wide significance in osteoporotic fracture prediction (Estrada K et al. Nat Genet 2012;44:491-501) in 1,316 women enrolled in the Calcium Intake Fracture Outcome study (CAIFOS) who were genotyped as part of the GEFOS GENOMOS consortium study. The participants were aged 70-85 at baseline and provided complete 10-year hip fracture data from the WA Hospital Morbidity Database and Mortality Registry.

In logistic regression, modifiers of the association of genotype on 10-year hip fracture risk were analysed including age and BMI (PASW, IBM). In the first analysis, the six polymorphisms association with hip fracture was studied. Only the rs4727338 polymorphism (SLC25A13) was associated with an increased the risk of 10-year of hip fracture (GG 17/166, 10.2%; CG 34/575, 5.9% and CC 28/575, 4.9%; OR per copy of the risk allele 1.46 (1.05-2.01), P = 0.022) which remained significant after adjustment. Interaction testing for the rs4727338 genotype and each of these factors was undertaken. For tertiles of BMI but no other covariates an additive interaction between the rs4727338 C→G polymorphism and BMI was identified for 10-year hip fracture, P = 0.005. In women in the lowest tertile of BMI (below 24.9 kg/m^2) per copy of the rs4727338 risk allele (G) there was an increased risk of 10-year of hip fracture in unadjusted analysis; (GG 11/58, 19.0%; CG 16/186, 8.6% and CC 7/191, 3.7%; OR per copy of the risk allele 2.48 (1.51-4.08), P < 0.001. However in the two higher tertiles of BMI (24.9-28.7 and >28.7 kg/m^2) there was no association with the risk allele and hip fracture (P = 0.849 and P = 0.659 respectively). Whilst genes in this locus have been associated with split-hand/foot malformations, the biological mechanism in which these variants are increasing fracture in combination with low/normal BMI is yet to be explored. In conclusion the rs4727338 G allele is associated with an increased hip fracture risk and an additive interaction between this polymorphism and body mass index may be responsible for underestimation of the reported genetic association of this polymorphism.

Testing reported SNPs for cortical and trabecular vBMD for hip and spine in the Age, Gene/Environment Susceptibility-Reykjavik Study. Tamara Harris*[1], Albert Smith[2], Thomas Lang[3], Kristin Siggeirsdottir[1], Gudny Eiriksdottir[2], Vilmundur Gudnason[4]. [1]Intramural Research Program, National Institute on Aging, USA, [2]Icelandic Heart Association, Iceland, [3]University of California, San Francisco, USA, [4]Icelandic Heart Association Research Institute, Iceland

Introduction: As bone exists in two primary compartments, the cortical and trabecular, it might be expected that these might have different genetic associations. Paternoster et al. (PLOS Genetics 9(2):e1003247) reported GWAS results for cortical volumetric BMD (vBMD) and trabecular vBMD based on values from the tibia. As the hip and spine are the main sites of osteoporotic fracture, we extended the published results by examining the association between the identified loci and measures of cortical vBMD in the hip and spine as well as fractures.

Methods: We used volumetric QCT scans of the hip and spine from the Age, Gene/Environment Susceptibility-Reykjavik Study (AGES-Reykjavik). We defined cortical vBMD and trabecular vBMD using standardized analytic protocols for the total femur, neck and trochanteric areas and the average of L1 and L2. From genotype data on 3,200 participants, we created an unweighted cortical BMD genetic risk score using the four loci for cortical vBMD reported by Paternoster et al.: RANLK, rs1021188; LOC285735, rs271170; OPG, rs783959; and ESR1/C6orf97, rs6909279. Paternoster et al. reported only one SNP for trabecular BMD, FMN2/GREM2, rs9287237. We used regression models for vBMD that adjusted for age, gender, the log of weight, and height. For fractures, we used data that has been compiled into a Fracture Registry as well as reports of fracture from recent hospitalizations categorized with specific ICD codes for location of fracture.

Results: The cortical vBMD score was strongly related to trochanteric cortical vBMD (1.37×10^{-10}), neck cortical vBMD (7.691×10^{-4}), and total femoral cortical vBMD (2.947×10^{-10}) and to vertebral cortical vBMD (3.03×10^{-4}). The cortical vBMD score was also associated with trochanteric trabecular vBMD (2.282×10^{-4}), which may be due to a correlation of .51 between the cortical and trabecular measures. There was no association of all fractures with the cortical vBMD score. The trabecular SNP was associated with femoral trabecular bone, but associations were weaker (trochanteric vBMD=.005; neck vBMD=.03; total femoral trabecular vBMD=.025 and that for vertebral trabecular vBMD was not significant (P=.07). There was no significant association with fracture.

Conclusion: SNP's identified for volumetric cortical bone showed a strong association with cortical vBMD at the hip and spine in our cohort while associations for an independent SNP for trabecular bone were much weaker. Further examination and analysis is needed to understand the contribution of these risk alleles to fracture risk.

SU0336

TNSALP Mutation Analysis in Women with Atypical Femoral Fracture and Bisphosphonate Therapy for Osteoporosis. Melissa Sum*[1], Margaret Huskey[1], Kathryn Diemer[1], Roberto Civitelli[1], Michael Gardner[1], Christopher McAndrew[1], William Ricci[1], Michael Whyte[2], Steven Mumm[2]. [1]Washington University, USA, [2]Shriners Hospital for Children-Saint Louis, USA

Hypophosphatasia (HPP) is caused by loss-of-function mutation(s) in the tissue non-specific alkaline phosphatase gene (*TNSALP*), resulting in low serum alkaline phosphatase (ALP) activity and inorganic pyrophosphate (PPi) accumulation extracellularly. PPi is a substrate for TNSALP and inhibits mineralization, thus providing a mechanism for the impaired bone matrix calcification and consequent femoral diaphyseal pseudofractures typical of adult HPP. Bisphosphonates (BPs) are analogs of PPi and can also inhibit mineralization. Since atypical subtrochanteric and diaphyseal femoral fractures (ASFFs) associated with long-term BP use for osteoporosis clinically resemble the pseudofractures seen in adult HPP, we hypothesized that carrying a *TNSALP* mutation, or having a mild form of HPP, predisposes to ASFFs with BP exposure. Indeed, one such case (Sutton et al. 2012) has been published. Here, we report prospective *TNSALP* mutation analysis of 11 patients with ASFFs and BP use. We sequenced all coding exons and adjacent splice sites of *TNSALP* in these individuals, and found a mutation in one patient. This heterozygous single-base change (c.648+1G>A) alters the mRNA splice donor site (GT) at the 3' end of exon 6, likely preventing normal splicing. This mutation has been reported once in a severe perinatal HPP case involving a second *TNSALP* mutation (Mornet et al. 1998). In our 66-year-old patient, serum ALP was 33 and 40 U/L on BPs (Nl: 35-129) compared to 86 IU/L (mean) in the 10 subjects with ASFF but without a *TNSALP* mutation. Low serum ALP levels are consistent with being a carrier of a loss-of-function *TNSALP* mutation, and this patient was never diagnosed with HPP. Based on DXA, she had "osteopenia". She suffered one ASFF while receiving BP therapy. Thus, we have prospectively identified 1 out of 11 women with BP-associated ASFF who is a carrier of a *TNSALP* mutation. Although the precise prevalence of *TNSALP* mutations in the general population is unknown, our results support the hypothesis that *TNSALP* mutation may contribute to ASFFs in some women exposed to BPs. If our hypothesis is validated in studies of larger populations, identification of such carriers before treatment might help to reduce the incidence of ASFFs.

Gastrointestinal Events and Osteoporosis Treatment Initiation among Elderly Women with Medicare Part D Coverage. Ethel Siris[1], Jingbo Yu*[2], Ankita Modi[2], Mitch Dekoven[3], Anshu Shrestha[4]. [1]Columbia University College of Physicians & Surgeons, USA, [2]Merck & Co, Inc., USA, [3]IMS Health, USA, [4]Precision Health Economics, LLC, USA

Objectives: To examine the association of gastrointestinal (GI) events with osteoporosis (OP) treatment initiation among elderly osteoporotic women with Medicare Part D drug coverage.

Methods: This was a retrospective cohort study using the Medicare 20% medical and pharmacy claims (Part D) from 2006-2009. Patients were included if they were female; ⩾66 years old; had a diagnosis for OP (ICD-9-CM 733.0x; 1st diagnosis date as index date); no prior OP treatment; and no Paget's disease, malignant neoplasm diagnosis, or estrogen use in the 12 month pre-index. GI event was defined as having a diagnosis or procedure for a GI condition between OP diagnosis and treatment initiation or end of 12 month follow-up, whichever occurred first. OP treatment initiation was defined as use of any pharmacological OP medication within 1 year post-index, including bisphosphonates (BIS) and non-BIS. Descriptive and multivariate analyses were conducted. Cox proportional hazard regression was used to model association of GI events and treatment initiation and logistic regression was used to model GI events and type of initial therapy (BIS vs. non-BIS) among those treated, adjusting for age, use of glucocorticoid, GPA and NSAID, and comorbidities.

Results: 126,188 women with newly-diagnosed OP were included in the analysis. Of them, 72.1% did not receive any OP medication within 1 year of diagnosis, 41.6% had pre-index and 40.4% had post-index GI events. Compared with those without post-index GI, patients who had post-index GI were less likely to start OP treatment (14.3% vs. 37.1%, $p<0.001$), and were less likely to be on BIS vs. non-BIS upon treatment initiation (10.1% vs. 29.4%). Patients with post-index GI had a 68.8% lower hazard among those with pre-index GI (HR=0.312, $p<0.001$) and a 74.6% lower hazard among those without pre-index GI (HR=0.254, $p<0.001$) to initiate treatment than those without post-index GI, controlling for covariates. Treated patients with a post-index GI event had 12% lower odds ($p<0.001$) of starting with BIS vs. non-BIS, compared with patients without a post-index GI event, controlling for pre-index GI and other covariates.

Conclusions: Among women with Medicare Part D coverage who were newly diagnosed with OP, about 40% of them had GI events between OP diagnosis and treatment initiation within 1 year. The presence of a GI event was associated with a higher likelihood of not being treated and increased likelihood of being treated with a non-BIS vs BIS.

Objectively Measured Physical Activity and Bone Health in Frail Older Adults. Hyuntae Park*, Hiroyuki Shimada, Hyuma Makizako, Daisuke Yoshida, Yuya Anan, Takehiko Doi, Kazuki Uemura, Kota Tsutsumimoto, Sangyoon Lee, Tadashi Ito, Takao Suzuki. National Center for Geriatrics & Gerontology, Japan

Age-related bone loss and decline in physical activity are a serious public health problem, especially in frail populations. Previous study [1] shows significant associations between bone characteristics and yearlong physical activity in healthy older adults, with better health in those taking >7,000 steps/day and/or spending >15 min/day of moderate to vigorous physical activity (MVPA, >3 METs). Despite this finding, it remains unclear the relationship between the habitual physical activity and bone health in frail older adults. The present study examines these relationships. A cross-sectional study of 239 older adults with frailty (mean [SD] age: 73.2 [5.1] y, 105 men) in a sub study of the Obu Study of Health Promotion for the Elderly (OSHPE). Frailty was defined according to the criteria developed by Fried et al. in participants of the OSHPE, a cohort of 5,104 community-dwelling older adults. Daily physical activity was measured using a triaxial accelerometer on 30 consecutive days and duration of MVPA and daily step counts were calculated. Bone mineral density (BMD) in lumbar spine 2-4 and total hip were measured by dual energy X-ray absortiometry. Linear regressions showed that after controlling data for age and/or sex, BMD was associated with physical activity, more closely for the femur values than for the lumbar spine, and for duration of MVPA than for step count. Multivariate logistic models with control for potential confounders (age, BMI, alcohol and drug intake, tobacco, nutritional status) confirmed the risk of osteoporosis was related to both measures of physical activity (step count and MVPA) in both men and women. These relationships, however, were stronger for the duration of MVPA than for step count. After adjusting for confounders, men and women in the lowest quartile of step count and in the two lowest quartiles of moderate-exercise duration showed, respectively, 1.5 and 1.8, and 1.7.–2.2 and 2.1–2.8 times greater risk of osteoporosis than those in the highest quartile. The direction of causation cannot be inferred from a cross-sectional study and further prospective research is required to clarify this. Nevertheless, we suggest that from the viewpoint of the prevention of osteoporosis, frail older adults should be encouraged to engage in low- and moderate-intensity habitual physical activity, taking >5,800 steps/day with a duration >10 min/day at moderate to vigorous intensity. Physical Activity in Midlife Is Associated with Peripheral Bone Density and Microarchitecture in Later Life: The Framingham Osteoporosis Study. Kerry Broe*[1], Marian Hannan[2], Elizabeth Samelson[3], Robert McLean[4], Ching-An Meng[1], Mary Hogan[1], Danette Carroll[1], Xiaochun Zhang[1], L. Adrienne Cupples[6], Mary Bouxsein[7], Douglas Kiel[8]. [1]Institute for Aging Research, Hebrew SeniorLife, USA, [2]HSL Institute for Aging Research & Harvard Medical School, USA, [3]Hebrew SeniorLife, Harvard Medical School, USA, [4]Hebrew SeniorLife Institute for Aging Research & Harvard Medical School, USA, [6]Department of Biostatistics, Boston University School of Public Health, USA, [7]Beth Israel Deaconess Medical Center, USA, [8]Hebrew SeniorLife, USA

The intensity of physical activity (PA) during childhood and adolescence may have lasting effects on bone health. Less is known about the effects of PA in midlife on later bone health. PA has modest associations with traditional measures of areal BMD in older adults but has not been studied with regard to bone microarchitecture. Our objective was to determine the association between PA, assessed in midlife, on subsequent bone density and microarchitecture in a community-based sample of middle-aged adults.

Study participants included 185 Framingham Offspring participants who had PA assessed in 1996-2001 (mean age 57 ± 7 yrs, 57% female) and bone density and microarchitecture of the tibia and radius evaluated in 2012, on average 14 ±1 yrs later. PA was measured using the Physical Activity Scale for the Elderly (PASE), a validated activity summary score. Bone density and microarchitecture parameters were measured using high-resolution peripheral quantitative computed tomography (HR-pQCT, Scanco Medical AG). We focused on six bone parameters: cross sectional area (CSA, mm2), total bone density (Dtot, mg/ccm), trabecular density (Dtrab, mg/ccm), trabecular number (TbN, 1/mm), cortical thickness (CtTh, mm), and cortical porosity (CtPo,%). Linear regression was used to assess the association between PASE and bone density and microarchitecture. PASE was categorized into sex-specific tertiles to assess least squares means of bone density and microarchitecture by PASE category. All analyses were adjusted for sex, age, height, and weight.

Average PASE was 163 ±79 and ranged from 12 to 402. At the tibia, higher PASE was significantly associated with greater adjusted Dtot and CtTh and lower CSA. At the radius, higher PASE was associated with greater adjusted Dtot, Dtrab, and CtTh. PASE was not associated with TbN or CtPo at either site. Similar patterns of higher bone measures with higher PASE were observed with bone microarchitectural parameters by PASE tertiles (Table1). At the tibia, significant positive trends were observed between PASE tertiles and adjusted Dtot, Dtrab, and CtTh. At the radius, positive trends were observed with Dtrab (all p-trend ≤ 0.04).

In conclusion, PA in midlife years had a positive effect on subsequent bone density and microarchitecture parameters at peripheral sites, more so at the weight-bearing tibia than the radius. Thus, PA at midlife may confer protective benefits on bone density and microarchitecture at older ages.

A Randomized Controlled Trial Evaluating Appropriate Osteoporosis Treatment by Family Physicians in Response to FRAX® versus CAROC Reports. Karen Beattie*[1], George Ioannidis[1], Alexandra Papaioannou[2], Joy MacDermid[1], Ruby Grewal[3], Jonathan Adachi[4], Anthony Hodsman[5]. [1]McMaster University, Canada, [2]Hamilton Health Sciences, Canada, [3]University of Western Ontario, Canada, [4]St. Joseph's Hospital, Canada, [5]Western University, Canada

Introduction: Current Canadian clinical practice guidelines recommend the use of either the FRAX® or the Canadian Association of Radiologists and Osteoporosis Canada (CAROC) fracture risk assessment tools to report 10-year fracture risk in an individual. The CAROC tool includes sex, age and femoral neck BMD as risk factors. Prevalent fragility fractures and corticosteroid use are incorporated as step-wise categorical modifiers of baseline fracture risk. While the CAROC tool reports fracture risk as low <10%, moderate 10-20%, or high >20%, FRAX® provides a precise estimate of risk in percent. It is unknown whether one reporting system is more effective in helping family physicians (FPs) identify individuals who should be considered for treatment than the other. Thus, compared to the CAROC-based BMD report (hereafter referred to as the BMD report), we hypothesized that the FRAX® report would result in better identification of patients who should be treated by FPs.

Methods: Individuals ⩾50 years old with a distal radius fracture were included provided they had no previous osteoporosis diagnosis and were not taking any osteoporosis medication. Participants underwent a DXA scan and answered questions about fracture risk factors. Each participant's FP was randomized to receive either a FRAX® or a BMD report. The FRAX® report, which was pilot tested with 8 FPs, included statements regarding treatment recommendations as per clinical guidelines. There were no such treatment recommendations on the BMD report. After 3 months, participants were called and asked if they were contacted by their FP and if they were treated. FPs' treatment decisions were compared to recommendations of a rheumatologist (osteoporosis expert).

Results: Sixty non-consecutive participants were enrolled (n=31 FRAX®; 11 low, 16 mod, 4 high risk; n=30 BMD; 22 mod, 9 high risk). Of clinical significance is that 45.2% of FRAX® group participants were contacted by their FPs to discuss their results compared to 28.2% of BMD report group participants. Kappa statistics of agreement in treatment recommendation between the rheumatologist and FPs were 0.64 for FRAX® and 0.32 for BMD group participants. The FRAX® report was preferred by FPs.

Conclusions: FRAX® reporting resulted in better post-fracture follow-up and treatment recommendations that substantially agree with a specialist in osteoporosis care. Treatment recommendations stated on the FRAX® report may have been an important factor in helping FPs make treatment decisions.

Association of Waist Circumference with Bone Mineral Densities in Middle- and Old-aged Men and Women: The Dong-gu Study. Lian-Hua Cui[1], Sun-Seog Kweon[2], Jin-Su Choi[2], Hae-Sung Nam[2], Jane Cauley[3], Min-Ho Shin*[4]. [1]Department of Preventive Medicine, Qingdao University Medical college, China, [2]Department of Preventive Medicine, Chonnam National University Medical School, South Korea, [3]University of Pittsburgh Graduate School of Public Health, USA, [4]Chonnam National University Medical School, South Korea

Several studies have examined the association between waist circumference as the index of abdominal fat and BMD and inconsistent results have been reported. Our study included a total of 8981 Korean (3592 men and 5389 women) community-dwelling individuals aged 50 years and over enrolled between 2007 and 2010. BMD were measured by dual-energy X-ray absorptiometry at lumbar spine and femoral neck skeletal sites. Multiple linear regression analysis was used to evaluate the relationship between the quartiles of waist circumference and BMD, adjusting for age, height, weight, and body fat percent. After adjusting for age, height and weight, there was a negative linear association between waist circumference and BMD at femoral neck and lumbar spine sites in both men and women. Waist circumference was more strongly associated with BMD in men than in women. These associations were slightly attenuated but remained significant after further adjustment for body fat percent. We found that waist circumference was inversely associated with BMD. Our results suggest that the waist circumference is a likely predictor of osteoporosis in middle- and old-aged Korean men and women.

Table Difference in bone mineral density by quartiles of waist circumference

		Quartile of Waist Circumference					
		1st	2nd	3rd	4th	P for trend	P for interaction
Number (men/women)		912/1322	991/1219	961/1318	728/1530		
Range (cm)		57.0-82.4	82.5-87.9	88.0-93.4	93.5-130.1		
Model 1	Lumbar spine						
	Men	0 (reference)	0.010 (-0.010 to 0.029)	0.042 (0.019 to 0.064)	0.082 (0.052 to 0.112)	<0.001	
	Women	0 (reference)	0.006 (-0.006 to 0.018)	0.021 (0.009 to 0.034)	0.036 (0.021 to 0.052)	<0.001	0.002

Associations of Overweight and Obesity with Incident Major Osteoporotic and Hip Fractures: A Large Clinical Cohort Study of Women and Men. Carrie Nielson*[1], Eric Orwoll[1], Suzanne Morin[2], Sumit Majumdar[3], William Leslie[4]. [1]Oregon Health & Science University, USA, [2]McGill University, Canada, [3]University of Alberta, Canada, [4]University of Manitoba, Canada

Although underweight is a known risk factor for hip fracture, many fractures occur in overweight and obese older adults – a rapidly growing segment of the population. Understanding fracture associations with higher BMI and potential differences according to sex is important.

Methods: 51,313 women and 4689 men age ⩾50 years at the time of baseline DXA testing (Lunar DPX or Prodigy; GE Healthcare) were identified in a clinical database from Manitoba, Canada. Height and weight were used to calculate BMI at the time of DXA testing, and classified according to WHO critera (Figure). Major osteoporotic fractures (MOF), including clinical vertebral, hip, humerus, and wrist fractures, were obtained by linkage to a population-based repository. Multivariable Cox proportional hazards models were used to study the independent contributions of BMI on fracture risk, with and without hip BMD adjustment; normal weight was the reference group for all analyses.

Results: Most women were overweight or obese (60%), as were most men (68%), while only 2% of women and 1% of men were underweight. During a mean follow-up of 5 years, incident MOF occurred in 3721 women and 276 men (1027 female and 75 male hip fractures). Most female (51%) and male (59%) MOF occurred in those who were overweight or obese. Adjusting for age and clinical variables, there was an apparent protective effect of higher BMI on MOF in women (Figure, left panel); however, these associations were attenuated and not significant after BMD adjustment (right panel). Similar but weaker associations were seen in men. While a similar pattern in proportions of hip fractures across BMI categories was observed, protective effects of higher BMI were stronger and persisted in obese categories after BMD adjustment. For example, with age and clinical variable adjustments, the HR for obese I was 0.53 (CI: 0.42-0.66) in women. After BMD adjustment, the HR was attenuated to 0.79 (CI: 0.63-0.99). No statistically significant sex interactions were observed.Discussion: In a clinical cohort of more than 50,000 people, a protective association for MOF with higher BMI was explained by BMD in both men and women. However, a protective association of higher BMI with hip fracture in women was only partially explained by BMD. Our findings suggest a substantial burden of fracture in older adults with high BMI. The factors not related to BMD that conferred lower risk of hip fracture in Manitoba women deserve further study.

Changes in the Prevalence of Osteoporosis in the United States After Inclusion of the Long Term Care Population. Nicole Wright*[1], Bess Dawson-Hughes[2], David Redden[1], Jeffrey Curtis[1], Susan Randall[3], Kenneth Saag[1]. [1]University of Alabama at Birmingham, USA, [2]Tufts University, USA, [3]National Osteoporosis Foundation, USA

Purpose: The National Health and Nutrition Examination Survey (NHANES) is the source used for estimating the prevalence of osteoporosis (OP) and low bone mass (LBM) in the United States (US). However, NHANES requires participants to be community dwelling, thus excluding those living in nursing homes or other long term care (LTC) facilities. There is a larger reported prevalence of OP in LTC than the general population. However, it is not known how the inclusion of the LTC population alters the overall prevalence of OP in the US.

Methods: We conducted a literature search to evaluate the reported prevalence of OP in LTC populations. We used mixed-linear models as a meta-analytical technique to generate an overall OP prevalence estimate in the LTC population. We applied this prevalence to the number of US residents in LTC facilities based on the 2010 American Community Survey (ACS), a yearly census like survey that provides information on factors such as living arrangements to help communities plan investments and services. We estimated how including those in LTC alters the overall NHANES OP prevalence estimate.

Results: We found six North American articles that reported OP prevalence in LTC settings, with prevalence ranging from 12-75%. Based on the meta-analysis results, we estimated an OP prevalence estimate of 42.4% (18.2%, 66.7%). The ACS reports that 1,397,107 US residents 50 years and older are in LTC facilities. Using our meta-analysis OP prevalence, we estimate that 592,793 residents over 50 years of age in LTC have OP, with lower and upper bounds of 254,234 and 931,352 individuals, respectively. NHANES reports the most recent overall prevalence of OP in US adults 50 years and older is 9.0%, resulting in 8.9 million adults over the age of 50 with OP based on the 2010 Census. However, when the meta-analytic estimates of OP in the LTC population are taken into account, the new overall prevalence becomes 9.5% (9.1%, 9.8%), resulting in an estimated 9.5 million adults over the age of 50 with OP.

Conclusions: Although the prevalence of OP ranges significantly in the published literature, the overall meta-analysis prevalence of OP is high in LTC settings. The addition of this population produces a somewhat larger overall OP prevalence estimate than reported by NHANES. Additional work examining the statistical significance of the differences and how the addition of LTC potentially alters age, gender, and race/ethnic specific prevalence is needed.

SU0345

Predicting Osteoporosis Knowledge and Perceived Susceptibility and Seriousness of Osteoporosis. Nicole Wright*[1], Stephanie Edmonds[2], Mollie Giller[2], Peter Cram[2], Kenneth Saag[1]. [1]University of Alabama at Birmingham, USA, [2]University of Iowa, USA

Purpose: Adherence to oral osteoporosis (OP) medications is low. While perceived side effects and costs are well known contributors to poor adherence, the roles of OP knowledge and perceived susceptibility are less certain. We used data from the Patient Activation After DXA Result Notification (PAADRN) study to examine factors associated with OP knowledge, perceived susceptibility and perceived seriousness in a regionally diverse cohort of patients undergoing DXA testing.

Methods: We administered the "Osteoporosis and You" Knowledge Scale, a 10 item scale a 5-point Likert response set to 3,860 patients presenting for DXA in 2012-2013 at three clinical sites (University of Iowa, University of Alabama at Birmingham, and Kaiser Permanente Georgia). Based on the scale scoring system, we recorded "correct" answers for those with "agree or strongly agree" responses and "incorrect" answers to all other response categories. We used the proportion correct as the OP knowledge outcome. For those not reporting OP at baseline, we administered the "Susceptibility" and "Serious" subscale questions of the "Osteoporosis Health Belief" Scale, 10 items with a 5-point Likert response sets. We conducted marginal linear regression analyses with a series of demographic, lifestyle characteristic, and co-morbidity variables. Variables significant at the $p<0.10$ level were included into one model. We used a combination of backward elimination and forward addition techniques to produce the final models for each outcome (final terms with $p < 0.05$).

Results: Our cohort was 83% women, 78% White, 20% Black, and had a mean age of 67 years. The mean (SD) Osteoporosis & You knowledge score was 75% (19%). Of the 2,869 participants without OP, the mean (SD) susceptibility score was 11.8 (17.3) out of a range of 4-20 and seriousness score was 17.3 (3.6) out of a range of 6-30. Factors including location, sex, race, prior fracture history, smoking status, and general health were significantly associated with the outcomes in the marginal analyses. The Table provides selected factors associated with a significant increase or decrease in knowledge, perceived susceptibility and seriousness from the final models.

Conclusions: We identified several demographic and lifestyle factors associated with OP knowledge, perceived susceptibility and seriousness. Increasing OP knowledge and correcting potential misconceptions about OP susceptibility and seriousness may improve adherence to medications.

Increased Risk of Hip Fracture Among Spouses. Effect of Homogamy?. Dan Mellstrom*[1], Valter Sundh[2], Cecilie Hongslo Vala[2], Magnus Karlsson[3], Bjorn Rosengren[3], Claes Ohlsson[4], Mattias Lorentzon[5], John Kanis[6], Boo Johansson[7], Anders Odén[8]. [1]Sahlgrenska University Hospital, Sweden, [2]Geriatric Medicine, Department of Internal Medicine & Clinical Nutrition. Center for Bone & Arthritis Research (CBAR) at Sahlgrenska Academy, Sweden, [3]Skåne University Hospital Malmö, Lund University, Sweden, [4]Center for Bone & Arthritis Research at the Sahlgrenska Academy, Sweden, [5]Geriatric Medicine, Center for Bone Research at the Sahlgrenska Academy, Sweden, [6]University of Sheffield, Belgium, [7]Department of Psychology, University of Gothenburg, Sweden, [8]Department of Biostatics, Chalmers University, Gothenburg., Sweden

Hip fracture among parents is an established risk factor for hip fracture. Genetic factors have importance for variation of bone density and fracture risk. However, also lifestyle factors like physical activity, smoking and nutrition are related to bone density and fracture risk. The aim of this study was to investigate if there is an increased risk for hip fracture among spouses.

We studied all patients with hip fracture n=218.285 in the national inpatient register in Sweden from 1987 to 2002. Each patient included in the register had both ICD codes for hip fracture and ICD codes for surgical procedure related to the hip fracture. Only the first hip fracture was recorded. This register was coordinated with the multi generation register, the register of causes of deaths, the national census register from 1970-1990 and the register of the total population in Sweden. We studied all married couples in Sweden (n=1.281.857) born 1902-1951 and married for at least 5 years. The married population was followed for 17.961.850 person-years. The hip fracture risk was estimated with a Poisson regression model.

During the period 1987-2002 hip fracture occurred among both spouses in 4226 married couples. In 7 couples hip fracture occurred in both spouses within 3 days. The HR for hip fracture in a married woman after a hip fracture in husband was 1.13 (95% CI 1.082-1.176). The corresponding HR for a married man was 1.19 (CI 1.145-1.239). The risk was significant from the age of 60 to 90 years. The HR for hip fracture in married women aged 60-70 was 1.35 (CI 1.058-1.712) after a hip fracture in husbands. The higher risk for hip fracture among spouses was consistent after adjustments for income, education, latitude and urbanisation.

We show for the first time an increased risk for hip fracture among spouses. The reason might be common social and life style factors but also assortative mating.

Low thyrotropin levels as a predictor of major osteoporotic fractures in 260,783 adult men and women - The *OPENTHYRO* register cohort. Bo Abrahamsen*[1], Henrik Jørgensen[2], Anne Sofie Laulund[2], Mads Nybo[3], Thomas Brix[4], Laszlo Hegedüs[4]. [1]University of Southern Denmark, Denmark, [2]Bispebjerg Hospital, Denmark, [3]Odense University Hospital, Dept of Clin Biochemistry, Denmark, [4]Odense University Hospital, Dept of Endocrinology, Denmark

Background: Though previous studies have linked hyperthyroidism to an increased risk of osteoporotic fractures in women, recent work from the MrOs study suggests that fracture risk in men with low TSH levels is not increased. We have conducted a population-based assessment of the association between low TSH and major osteoporotic fractures.

Subjects and Methods: All TSH measurements performed in Funen County, Denmark (pop 484,346), between 1995 and 2010 were extracted for analysis, including tests from primary practice. We identified 260,783 individuals with at least one TSH measurement. All measurements were performed at the same laboratory. Using national health registers, we retrieved information on all hospital contacts, prescriptions filled and date of death/emigration. Individuals taking thyroid medications or having a record of thyroid surgery or radioiodine prior to the first TSH measurement were excluded.

Results: The risk of major osteoporotic fractures (16,874 persons) was significantly increased in subjects with TSH levels below reference (N=13,541), unadjusted Hazard Ratio (HR) 1.96 (1.87-2.07), p<0.0001, adjusted HR 1.18 (1.12-1.24), p<0.0001. The adjusted HR for hip fracture was 1.20 (1.02-1.42), p=0.03, in men and 1.28 (1.18-1.39), p<0.0001, in women. For major osteoporotic fractures, the adjusted HR was 1.20 (1.07-1.36) in men and 1.16 (1.09-1.22) in women.

Conclusions: Low TSH (<0.3 IU/L) was associated with an increased risk of major osteoporotic fractures, including hip fractures, with similar relative effect sizes in both genders.

Incident fracture	HR (unadjusted) and 95% CI	HR (adjusted[1]) and 95% CI
Hip (N=6,166)	2.66 (2.48-2.86), p<0.0001	1.24 (1.15-1.34), p<0.001
Spine (N=1,792)	1.56 (1.32-1.84), p<0.0001	1.03 (0.87-1.22), p=0.72
Forearm (N=7,835)	1.62 (1.50-1.75), p<0.0001	1.15 (1.07-1.25), p<0.001
Humerus (N=3,562)	1.94 (1.74-2.16), p<0.0001	1.16 (1.04-1.29), p<0.01

Mild to Moderate Chronic Kidney Disease is Associatedwith Vertebral Fracture Independent of Albuminuria or Bone Mineral Density in Patients with Type 2 Diabetes Mellitus. Masahiro Yamamoto*[1], Toru Yamaguchi[1], Shozo Yano[1], Mika Yamauchi[1], Toshitsugu Sugimoto[2]. [1]Shimane University Faculty of Medicine, Japan, [2]Shimane University School of Medicine, Japan

Purpose: Patients with type 2 diabetes mellitus (T2DM) have an increased risk of vertebral fractures (VFs) compared to non-T2DM controls independent of bone mineral density (BMD) (JBMR 2009). In non-T2DM, a creatinine clearance rate (Ccr) below 65 ml/min is associated with an increased fracture risk, suggesting that the progressive stage of chronic kidney disease (CKD) is a risk factor for fracture. However, it is unclear whether renal dysfunction and urine albumin (uAlb) are associated with bone fragility in T2DM patients. The aim of this study is to clarify these relationships in T2DM men and women.

Methods: We divided 367 Japanese T2DM men over 50 years old and 326 postmenopausal T2DM women into 3 groups based on their calculated Ccr (using the Cockcroft-Gault equation): ?90 (stage 1: S1), 89–60 (S2), and 59–30 ml/min (S3). All of their creatinine levels were within normal range. Logistic regression analyses were performed to assess the relative VF risk of CKD S2 and S3 to S1.

Results: Men and women who experienced VFs were significantly older than those without VFs (68 *vs*. 64 years old, $P<0.01$; 70 *vs*. 65 years old, $P<0.01$, respectively), and had a lower Ccr (83 *vs*. 92 ml/min, $P<0.01$; 79 *vs*. 87 ml/min, $P<0.05$, respectively). There was no significant difference in the uAlb levels in either sex. As the CKD stage advanced from S1 to S3, prevalence VFs rate were significantly elevated in both men (30, 39, 58%, respectively, $P<0.01$) and women (24, 37, 41%, respectively, $P<0.01$), and BMD values were concomitantly and significantly decreased at femoral neck in men (0.792, 0.757, 0.737 g/cm^2, respectively, $P<0.01$) and women (0.713, 0.621, 0.543 g/cm^2, respectively, $P<0.01$) as well as at spine of women (0.946, 0.851, 0.816 g/cm^2, respectively, $P<0.01$). In contrast, uAlb levels were not significantly different among the three CKD stages. The VF risk relative to S1 was 1.8 (95%CI 1.1–3.0, $P<0.05$) for S2 and 4.8 (2.3–9.8, $P<0.01$) for S3 in men and 2.9 (1.2–6.8, $P<0.01$) for S3 in women, after adjustments for BMI, HbA1c, duration of T2DM, uAlb, and spine BMD Z score. The same relationships were observed in men, when these analyses were performed using the estimate GFR instead of Ccr.

Conclusion: CKD stages 2 and 3 were risk factors for VFs in T2DM patients. These associations were independent of uAlb or BMD, suggesting that the progression of CKD, but not albuminuria, may cause bone fragility and enhance VF risk due to deterioration in bone quality inT2DM.

SU0349

Modified "Osteoporosis Questionnaire" of FRAX is sufficient tool for screening of osteoporosis patients. Shinya Tanaka*[1], Sawako Moriwaki[2], Kiyoshi Tanaka[3], Syunpei Niida[2]. [1]Saitama Medical University, Japan, [2]Biobank-Omics, National center for geriatrics & gerontology, Japan, [3]Kyoto Women's University, Japan

Objective; In Japan, a revised version of diagnosis criteria of primary osteoporosis was published in 2012. Although medication of osteoporosis is effective approach, the knowledge of osteoporosis has not widely spread around the general population. To improve the screening efficiency of osteoporosis patients, we assessed the simple "Osteoporosis Questionnaire" composed of the age and the six factors extracted from the fracture risk assessment tool (FRAX), and compared the results with those of FRAX.

Materials and Methods; Total 99 women, age from 43- to 75-y-o, living in a local governments in Aichi, Japan, were included in this study. They took FRAX examination, were analyzed bone mineral density from the 2nd to the 4th lumbar spine and left femoral neck, and was took X-ray of the thoracic and lumbar spine. Osteoporosis was diagnosed in accordance with a 2012 revised version of primary osteoporosis of Japan. Usefulness of probabilities of major osteoporosis fracture of FRAX or the Osteoporosis Questionnair to discriminate subjects with either osteoporosis or non-osteoporosis was made sure by making receiver operating characteristic (ROC) curve or calculating sensitivity and specificity. The Osteoporosis Questionnair was constituted of age points and 6 CRF points, 1 point was given to every CRF and 1 point was given to person who were 59-y-o or below, 2 points was

given to person 60- to 64-y-o, 3 points was given to person 65- to 74-y-o, and 4-points was given to person 75-y-o or above.

Results: The area under ROC curve of FRAX in distinct osteoporosis patient was 0.760. And, if inhabitants who were 3 point or above in the Osteoporosis Questionnair was diagnosed as osteoporosis, sensitivity was 60.5% and specificity was 63.9%.

Conclusion; Both FRAX and "Osteoporosis Questionnaire" are useful for screening osteoporosis patients in group examinations.

Multiple Gene Polymorphisms can Improve Prediction of Non-vertebral Fracture in Postmenopausal Women. Seung Hun Lee*[1], Seon Woo Lee[2], Seong Hee Ahn[1], Taehyeung Kim[2], Beom-Jun Kim[3], Eun-Hee Cho[4], Sang-Wook Kim[4], Tae-Ho Kim[5], Ghi Su Kim[1], Shin-Yoon Kim[6], Changwon Kang[2], Jung-Min Koh[3]. [1]Asan Medical Center, University of Ulsan College of Medicine, South Korea, [2]Department of Biological Sciences, Korea Advanced Institute of Science & Technology, South Korea, [3]Asan Medical Center, South Korea, [4]Department of Internal Medicine, Kangwon National University College of Medicine, South Korea, [5]Kyungpook National University School of Medicine, South Korea, [6]Kyungpook National University Hospital, South Korea

Clinical risk factors (CRFs), with or without bone mineral density (BMD), are used to determine the risk of osteoporotic fracture (OF), which has a heritable component. This study investigated whether genetic profiling can additionally improve the ability to predict OF. Using 1,229 unrelated Korean postmenopausal women, 39 single-nucleotide polymorphisms (SNPs) in 30 human genomic loci were tested for association with osteoporosis-related traits, such as BMD, osteoporosis, vertebral fracture (VF), non-vertebral fracture (NVF), and any fracture. To estimate the effects of genetic profiling, the genetic risk score (GRS) was calculated using five prediction models: (model I) GRSs only; (model II) BMD only; (model III) CRFs only; (model IV) CRFs and BMD; and (model V) CRFs, BMD and GRS. A total of 21 SNPs within 19 genes associated with one or more osteoporosis-related traits and were included for GRS calculation. GRS associated with BMD before and after adjustment for CRFs ($P = <0.001$ to 0.018). GRS associated with NVF before and after adjustment for CRFs and BMD ($P = 0.017$ to 0.045), and with any fracture after adjustment for CRFs and femur neck BMD ($P = 0.049$). In terms of predicting NVF, the area under the receptor-operator characteristics curve (AUC) for model I was 0.55, which was lower than the AUCs of models II (0.60), III (0.64), and IV (0.65). Adding GRS to model IV (in model V) increased the AUC to 0.67, and improved the accuracy of NVF classification by 11.5% ($P = 0.014$). In terms of predicting any fracture, the AUC of model V (0.68) was similar to that of model IV (0.68), and model V did not significantly improve the accuracy of any fracture classification ($P = 0.39$). Thus, genetic profiling may enhance the accuracy of NVF predictions and help to delineate the intervention threshold.

SU0351

Parathyroid Hormone and Bone Mineral Density as Independent Risk Factors for Mortality in Community-Dwelling Older Adults: the São Paulo Ageing & Health Study (SPAH). Diogo Domiciano*[1], Luana Machado[1], Camille Figueiredo[1], Jaqueline Lopes[2], Valéria Caparbo[1], Liliam Takayama[1], Eloisa Bonfa[1], Rosa Pereira[2]. [1]University of São Paulo, Brazil, [2]Faculdade De Medicina Da Universidade De São Paulo, Brazil

Objectives: Previous studies have shown a relationship between osteoporosis and increased risk of death. Moreover, secondary hyperparathyroidism has been linked to mortality amongst frail older hip fractures patients. However, none of these studies performed a concomitant evaluation of the parathormone (PTH)-calcium-vitamin D-axis and bone mass, and this is essential to determine more accurately the contribution of each of these parameters to survival in community-dwelling older subjects. Thus, the aim of this study was to investigate the association between iPTH, calcium, vitamin D and bone mineral density (BMD), and all-cause mortality in a prospective, population-based study of community-dwelling older adults. Methods: 839 community-dwelling subjects (516 women and 323 men), aged over 65 years, were prospectively studied. Clinical data (including history of osteoporotic fractures and cardiovascular events) were assessed by specific questionnaire. Serum 25(OH)D, iPTH, total calcium, phosphorus, creatinine, and alkaline phosphatase were measured. BMD of the lumbar spine and hip were evaluated by DXA. All analysis was done at baseline (2005-2006). Mortality was recorded during follow-up. Multivariate Cox regression analysis was used to compute hazard ratios for all-cause mortality. Results: After a mean 4.1 ± 1.1 years of follow-up, there were 132(15.7%) deaths. In multivariate Cox proportional model, age (HR:1.06 95% CI:1.03–1.09,$P<0.001$), male sex (HR:1.91 95% CI:1.31–2.77,$P<0.001$), history of falls in the last year (HR:1.45 95% CI:1.02–2.07,$P=0.04$), *diabetes mellitus* (HR:2.17 95% CI:1.49-3.16,$P<0.001$), low score of physical activity (HR:2.77 95% CI:1.15-2.73, $P=0.009$), history of any cardiovascular event (HR:1.70 95% CI:1.14-2.52, $P=0.009$), total hip T-score (HR:1.43 95% CI:1.19–1.74, $P<0.001$, per each 1SD reduction in BMD) and iPTH (HR:1.054 95% CI:1.051-1.056, $P<0.001$, per 10pg/ml iPTH) were independently associated to all-cause mortality. Subjects in the highest quartile of iPTH were at higher risk of death (HR 2.90, 95% CI: 1.29-6.50, $P = 0.009$) compared to subjects in the lowest quartile.

Conclusion: Lower BMD and higher iPTH were significantly associated with mortality in community-dwelling older adults. These findings support the notion that a careful screening of bone parameters may help to improve the outcomes in older individuals.

Parental Divorce or Death Is Associated with Lower Adult Bone Strength: The Midlife in the U.S. Study. Carolyn Crandall*[1], Arun Karlamangla[1], Sharon Stein Merkin[2], Neil Binkley[3], Deborah Carr[4], Gail Greendale[1], Teresa Seeman[2]. [1]University of California, Los Angeles, USA, [2]UCLA, USA, [3]University of Wisconsin, Madison, USA, [4]Rutgers University, USA

Background. Because peak bone mass is acquired during childhood, bone health may be susceptible to environmental adversity in childhood. It is not known whether a childhood experience of separation from a parent due to death or divorce or being raised in a single mother family is associated with lower adult bone strength.

Methods. Using DXA data from 627 participants (ages 37-86 years, mean 56.3 years) in the Midlife in the United States Biomarker Project, we examined the associations of composite indices of femoral neck bone strength relative to load (in three failure modes: compression, bending, and impact) in adulthood with the experience of parental death or divorce in childhood and with being raised in a single mother family, adjusting for gender, race, age, menopausal transition stage (for women), body mass index, childhood and current smoking, pack-years of smoking, physical activity (in high school, during young adulthood, and currently), education, childhood socioeconomic status, adult financial status, and peak alcohol intake level.

Results. 110 participants experienced parental death or divorce during childhood (median age 5 years). After adjustment for covariates, participants who experienced a parental death or divorce before the age of 5 years had lower values for each of the composite indices (Table). Exposure to parental death or divorce between ages 5 and 16 years or being raised by a single mother was not associated with femoral neck strength indices (Table).

Conclusions. When experienced in early childhood, parental death or divorce is associated with lower adult bone strength, and this association is not explained by socioeconomic conditions and life style choices in childhood or adulthood.

Table. Adjusted associations of parental death or divorce, and single mother household, with composite indices of femoral neck bone strength relative to load[1]

	Bending Strength Index, SD units (95% CI) (N=627)	Compression Strength Index, SD units (95% CI) (N=627)	Impact Strength Index, SD units (95% CI) (N=627)
Parental death or divorce under age 5 years (n = 42)	-0.347 (-0.561, -0.133)**	-0.228 (-0.422, -0.035)*	-0.211 (-0.446, 0.025)~

Patients with Rheumatoid Arthritis Receiving High Doses of Prednisolone Tended to Fall More Frequently than Healthy Individuals: the TOMORROW study. Tatsuya Koike*[1], Masahiro Tada[2], Yuko Sugioka[3], Tadashi Okano[3], Kenji Mamoto[3], Kentaro Inui[3]. [1]Search Institute for Bone & Arthritis Disease (SINBAD), USA, [2]Department of Orthopaedic Surgery, Osaka City University Medical School, Japan, [3]Osaka City University Medical School, Japan

Purpose Patients with rheumatoid arthritis (RA) who have muscle weakness and stiff or painful joints might be at increased risk of falling and vertebral fractures. The present study prospectively determines the incidence of falls and associated risk factors in patients with RA in the TOMORROW study (UMIN000003876) that started in 2010.

Methods We evaluated muscle volume, bone density, thoracolumbar spine X-rays and disease activity in 202 consecutive patients with RA (54% using biological agents) and 202 age- and sex-matched healthy individuals as controls and then assessed the incidence of falls for 2 years.

Results The incidence of having at least one fall during the 2-year period did not significantly differ between the patients and controls (29.7% vs. 26.7%, NS). However, the patients fell significantly more often than controls (2.37 vs.1.56 falls; p = 0.03) and had a higher prevalence of vertebral fractures (45.5% vs. 30%) and semiquantitative (SQ) grade ⩾2 (15% vs. 5%) than the controls. After adjusting for risk factors of falls such as age, gender, smoking and BMI, multiple logistic regression analysis identified that a history of falls was the most significant parameter associated with the incidence of falls (odds ratios: all, 2.44, p < 0.001; patients, 2.40, p = 0.014; controls, 2.72, p = 0.015; Table 1). Existing vertebral fractures and SQ grade ⩾2 did not correlate with the incidence of falls (Table1). Multiple regression analysis revealed that the number of falls experienced by patients with RA was associated with doses of prednisolone (PSL; β = 0.188, P = 0.010,) and matrix metalloproteinase-3 (MMP-3; β = 0.156, P = 0.028).Conclusion A history of falls was an independent risk factor for any fall in all participants. Patients with RA receiving high doses of PLS or MMP-3 tended to fall more frequently than healthy individuals.

Evaluation of Patients' Response Toward an Automated Osteoporosis Intervention Program. Matt Varacallo*[1], Edward Fox[2], Emmanuel Paul[3], Susan Hassenbein[3], Pamela Warlow[4]. [1]Penn State Hershey, Canada, [2]Pennsylvania State Hershey Medical Center, USA, [3]Penn State Hershey Department of Orthopaedics, USA, [4]Penn State Hershey, USA

INTRODUCTION: Osteoporosis is overshadowed in an era of chronic illnesses and a care gap exists between physicians and patients. Methods for improving the care gap via various intervention programs have yielded modest success. The aim of this study was to determine the effectiveness of implementing an automated system for identifying and sending a letter to patients at high-risk for developing osteoporosis.

METHODS: Penn State Hershey Medical Center (PSHMC) fracture patients 50 years of age and older were tagged with a diagnostic ICD-9 code upon the ER visit, identifying fractures at osteoporosis risk. Hospital encounter screening identified these codes and subjects were pre-screened to exclude cases involving trauma/MVA, repeats in the database, and individuals already being treated for osteoporosis. 103 subjects comprised the final intervention group.

Computer generated letters were sent out to each subject up to 3 months after the initial visit to the ER indicating that he or she was at risk for osteoporosis, and these individuals were urged to schedule an appointment with their PCP or with the bone health clinic at HMC. The control group was not sent a letter, but were contacted via telephone up to 3 months out after the initial injury to determine whether or not they had any follow-up.

RESULTS: For the control group, 84 individuals out of the total 98 (85.71%) did not have any follow-up evaluation after being treated for their fracture, and 14 out of the 98 (14.29%) had some sort of follow-up. For the intervention group, 62 out of 103 (60.19%) did schedule follow-up, while the remaining 41 out of 103 (39.81%) did not seek follow-up. The data were analyzed using the chi-squared test, yielding a p-value of <0.0001.

DISCUSSION: Current literature has demonstrated the low rate of follow-up care received by patients experiencing fragility fractures (1-25% without intervention). Research has shown the effectiveness of various types of intervention programs for improving the continuum of care for these high-risk patients, but many of these programs are non-automated and can have a multitude of human related system failures in the patient identification process. The results of our study are very similar to the current literature demonstrating the benefits of these osteoporosis intervention programs, and we report the success of our automated system that is able to be applied to any hospital with minimal cost and resources.

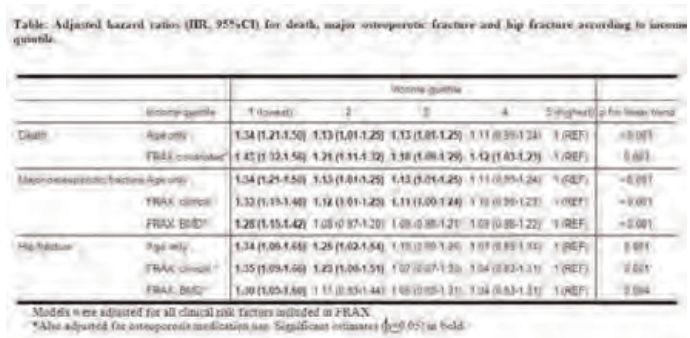
The Performance of FRAX® According to Different Levels of Socioeconomic Status. Sharon Brennan*[1], William Leslie[2], Lisa Lix[2], Helena Johansson[3], Anders Oden[4], Eugene McCloskey[5], John Kanis[6]. [1]The University of Melbourne, Australia, [2]University of Manitoba, Canada, [3]Swedish University of Agricultural Sciences, The Biomedical Center, Sweden, [4]World Health Organization (WHO) Collaborating Centre, University of Sheffield, United Kingdom, [5]University of Sheffield, United Kingdom, [6]University of Sheffield, Belgium

Background: FRAX® was constructed to predict 10-year major osteoporotic fracture (MOF) and hip fracture risk. Social factors may independently affect fracture risk. Therefore, we investigated FRAX calibration and discrimination according to socioeconomic status.

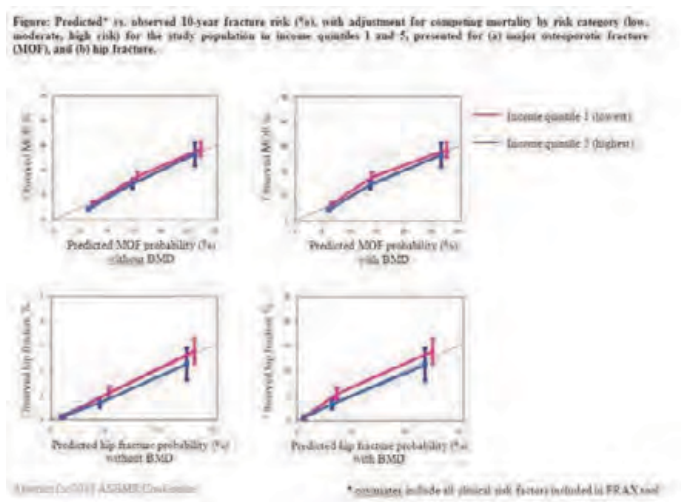
Methods: Women aged ⩾50years with baseline femoral neck BMD measured 1996-2011 were identified from the Manitoba Bone Density Program, Canada (n=51,327). Mean household income was extracted from 2006 census files, and categorized into quintiles. 10-year fracture probabilities were calculated using FRAX Canada. Incident fractures (excluding trauma codes) from population-based administrative data were studied in relation to income quintile in Cox proportional hazards models that adjusted for age and other covariates. To assess calibration, we compared observed *vs.* predicted fractures using a competing mortality framework.

Results: During mean 6.2±3.7 years of follow up there were 6,392 deaths, 3,723 women with ⩾1 MOF and 1,027 with hip fractures. Lower income was associated with higher risk for death, MOF and hip fracture in age and FRAX covariate-adjusted models (all *p* for linear trend <0.005 Table). More women in income quintile 1 (lowest) *vs.* income quintile 5 died (19% *vs.* 8%), or had a MOF (10% *vs.* 6%) or hip fracture (3.0% *vs.* 1.3%) (all $p \leq 0.001$). Adjustment for competing mortality mitigated the effect of socioeconomic status on FRAX calibration such that good calibration was observed for both income quintile 1 (lowest) and income quintile 5 (Figure). FRAX provided significant fracture discrimination for MOF and hip fracture within each income quintile (all $p<0.001$). Area under the curve (AUC) was slightly lower for income quintile 1 *vs.* quintile 5 for FRAX with BMD to predict MOF (0.68, 95%CI 0.66-0.70 *vs.* 0.71, 95%CI 0.69-0.74; $p=0.04$) and hip fracture (0.79, 95%CI 0.76-0.81 *vs*. 0.87, 95%CI 0.84-0.89; $p \leq 0.001$). Similar differences were seen for FRAX without BMD (MOF $p=0.04$, hip fracture $p \leq 0.001$). In contrast, femoral neck BMD performed equally for MOF and hip fracture in income quintiles 1 *vs.* 5 ($p \geqslant 0.4$).

Conclusions: Socioeconomic adversity independently modulates risk for death and fracture. Increased fracture risk in individuals of lower income is offset by increased mortality. Thus, under a competing mortality framework, FRAX provides robust fracture prediction and calibration regardless of socioeconomic adversity.



Adjusted hazard ratios (HR, 95%CI) for death, major osteoporotic fracture and hip fracture according



Predicted* vs. observed 10-year fracture risk (%), with adjustment for competing mortality by risk c

The Risk of Fractures after Initiating Antihypertensive Medications: Results from the National Claim Registry. Hyung Jin Choi*[1], Chanmi Park[2], Young-Kyun Lee[3], Yong-Chan Ha[4], Sunmee Jang[5], Chan Soo Shin[6]. [1]Chungbuk National University Hospital, South Korea, [2]Health Insurance Review & Assessment Service, South Korea, [3]Seoul National University Bundang Hospital, South Korea, [4]Chung-Ang University Hospital, South Korea, [5]College of Pharmacy Inje University, South Korea, [6]Seoul National University College of Medicine, South Korea

Several studies have investigated effects of antihypertensive medications on bone metabolism and fracture. We examined the relative risk of fractures among subjects who initiated antihypertensive medications using the nationwide database of medical and pharmacy claims in South Korea. Among 8,315,709 subjects with antihypertensive prescriptions, 527,500 subjects aged 50 years and older, who initiated single-drug antihypertensive medications from January 2008 to June 2011, were analyzed. Based

on medication possession ratio data, subjects were classified as a non-user, calcium channel blocker (CCB), angiotesin-receptor blocker (CRB), beta blocker (BB), angiotensin converting enzyme (ACE) inhibitor and diuretic users. The outcome measure was the first occurrence for a vertebral fracture or a non-vertebral fracture. The incidence of fracture was analyzed controlling for age, gender, comorbidity score, diagnosis of diabetes, diagnosis of osteoporosis, osteoporosis treatment, and osteoporosis related diseases. Total of 16,765 fractures were observed among 527,500 subjects during the observation period. Fracture rate per 10,000 person-years varied significantly across type of antihypertensive medications, with non-user group having the lowest rate [152.2, 95% confidence interval (CI) 148.7-155.7] and ACE inhibitor group having the highest rate (254.0, 95% CI 225.0-286.7). In models adjusting for all confounding factors, ACEI users (HR=1.68), diuretics users (HR=1.45), CCB users (HR=1.23) and BB users (HR=1.15) showed significantly increased risk of fractures compared with non-users (P<0.05). Only the fracture risk of ARB users (HR=1.00, 95% CI 0.95-1.05) was not significantly different from the non-users. These findings suggest that use of anti-hypertensive agents, except for the ARB, is significantly associated with increased risk of fracture although the relative risk varies depending on the type of medications.

Vertebral and Nonvertebral Fractures Depend on Physical Activity of Osteoporosis Patients. Hans-Christof Schober*[1], Johanna Torner[2], Reimer Andresen[3]. [1]Klinikum Südstadt RostockKlinik Für Innere Medizin I, Germany, [2]Klinikum Südstadt ostock, Germany, [3]Westküstenklinikum, Germany

Introduction: There is a certain relationship between bone health and physical activity level of patients with Osteoporosis. Until now no specific markers were made out that describe the risk of fracture.

Objective:Our aim was to investigate how physical activity in detail influences the number of vertebral and non-vertebral fractures in patients with Osteoporosis.

Patients and Methods:Data of 179 patients with Osteoporosis, aged 32 to 92 years, were retrospectively analyzed. The appearance of peripheral and vertebral fractures, as being the main variable, was documented by questionnaire or medical imaging.Height, weight, body fat percentage, body muscle percentage, abdominal girth and visceral fat were measured during consultation- hour. BMI was calculated.Parameters of physical activity like time in tandem stand, chair rising test and gait speed were measured by stopwatch (manually). Hand grip strength on the right and left side were measured by hand dynamometer.Patient's medication was documented by questionnaire. We divided all mentioned drugs into three groups, concerning their influence on bone health.To examine the influence of age we used the model of medication's relationship to the number of fractures and defined ''age'' as being a co-variable. We once calculated this model with the average age and twice for an age of 50 years.The classification of all patients was realized as follows: group 1(without fractures), group 2(only non-vertebral fractures), group 3(only vertebral fractures) and group 4(both, vertebral and non-vertebral fractures).The statistical calculation was accomplished using Spearman Correlation Coefficients and Glimmix Procedure.

Results:Our calculations showed, that hand grip strength on the left side correlates significantly (p<0,05) negatively with number of non-vertebral fractures.The effects on vertebral fractures were different: Visceral fat correlates positively to this number. Gait speed correlates strongly negatively (p<0,01) to vertebral fractures. Patients who receive drugs with verifiably negative effect on bone health do have significantly more non-vertebral fractures (p<0,05) than patients without any ''negative drugs''. Regarding vertebral fractures, especially patients treated with ''Osteotropica'', do have significantly more fractures (p<0,05) than patients without any osteoporotic treatment.

Conclusion:Gait speed and hand grip strength should be used in order to detect patients at risk for fractures.

Concurrently Lower Chance of Diabetes but Higher Chance of Osteoporosis in Elderly Women with Elevated Osteocalcin. Kyoung Min Kim*[1], Eun Young Lee[2], Ju Mi Lee[3], Young Mi Yun[4], Yoosik Youm[5], Hyeon Chang Kim[3], Chang Oh Kim[2], Yumie Rhee[6]. [1]Seoul National University Bundang Hospitatl, South Korea, [2]Department of Internal Medicine, Yonsei University College of Medicine, South Korea, [3]Department of Preventive Medicine, Yonsei University College of Medicine, South Korea, [4]Medical Research Center, Yonsei University College of Medicine, South Korea, [5]Department of Sociology, Yonsei University, South Korea, [6]Department of Internal Medicine, College of Medicine, Yonsei University, South Korea

Recent animal studies have suggested a new regulatory circuit between bone and energy metabolism via osteocalcin (OCN). Both increased bone remodeling and insulin resistance are major degenerative changes with aging. The aim of this study was to examine the association between serum OCN and metabolic profiles in women aged 64 and over. This is a community-based, cross-sectional study and 616 healthy ambulatory elderly women were enrolled. Serum OCN levels had significant negative correlations with fasting plasma glucose (FPG), HbA1c, insulin and HOMA-IR after adjusting for age and BMI (r=-0.186, -0.162, -0.147 and -0.166. p<0.001 respectively). After dividing the subjects into 3 tertiles by OCN levels, FPG, HbA1c, insulin and HOMA-IR varied inversely with the OCN tertiles (p<0.05, respectively). The prevalence of metabolic syndrome was significantly lower in the women with highest OCN with OCN tertiles (p<0.05 analyzed with linear by linear association). In contrast, those in the higher tertiles of OCN had lower bone mass in the lumbar spine and hip (p<0.05, respectively). In a multiple logistic regression analysis, the OCN level was inversely associated with the development of diabetes, but positively related with risk of osteoporosis after adjusting for the confounding factors (OR, 0.70; 95% CI, 0.54-0.86, p=0.028 for diabetes, OR, 1.28; 95% CI 1.19-1.37, p=0.01 for osteoporosis). Increased OCN level is associated with improved glucose tolerance, but decreased bone strength, which supports a potential link between bone and energy metabolism in elderly Korean women.

Table 1. Stepwise multiple logistic regression of OCN for diabetes and osteoporosis

	Diabetes				Osteoporosis			
	OR per 1SD increase of OCN	95% CI		p-value	OR per 1SD increase of OCN	95% CI		p-value
Crude	0.57	0.44	0.69	<0.001	1.31	1.23	1.40	0.00
Model 1	0.57	0.45	0.70	<0.001	1.33	1.24	1.42	0.00
Model 2	0.58	0.45	0.71	<0.001	1.30	1.21	1.39	0.00

Glycemic Control in Relation to High Bone Mineral Density and Fracture Risk Among Postmenopausal Women: The CEOR Study. Mohammed-Salleh Ardawi*[1], Mohammed Qari[2], Abdulrahim Rouzi[3], Sharifa Al-Sibiani[4], Nawal Al-Senani[4], Bader Mustafa[5]. [1]Center of Excellence for Osteoporosis Research & Faculty of Medicine, Saudi Arabia, [2]Center of Excellence for Osteoporosis Research & Department of Haematology, Faculty of Medicine & KAU Hospital, King Abdulaziz University, Saudi Arabia, [3]Center of Excellence for Osteoporosis Research & Faculty of Medicine, Saudi Arabia, [4]Center of Excellence for Osteoporosis Research & Department of Obstetrics & Gynecology & KAU Hospital,Faculty of Medicine, King Abdulaziz University, Saudi Arabia, [5]Center of Excellence for Osteoporosis Research, King Abdulaziz University, Saudi Arabia

Background: Subjects with type 2 diabetes (T2DM) show increased fracture risk despite higher bone mineral density (BMD). Our objective was to examine the influence of glycemic control on BMD and the risk of fractures among postmenopausal women.

Methods: Data of 3015 postmenopausal women of the Center of Excellence for Osteoporosis Research (CEOR) Study, a prospective population-based cohort, were available (mean follow-up 6.2 $\pm$ 1.3 years). At baseline, 412 women with T2DM were classified by glycemic control (according to HbA1c%), resulting in three comparison groups: well- controlled diabetes (WCD; n=198; HbA1c $<$ 7.5%), poorly-controlled diabetes (PCD; n=214; HbA1c $\geqslant$ 7.5%) and no diabetes (n=2603). Cox proportional hazard regression analysis adjusted for age, BMI, and BMD [neck femur and lumbar spine (L_1-L_4)] were used to test for differences in bone variables and fracture risk (hazard ratio [HR] [95% CI]).

Results: Women in the PCD group had an increased fracture risk compared with WCD group (HR 1.66 [1.26-2.17]) and those without diabetes (1.94 [131-2.87)]; whereas those with WCD had an HR of (0.81 [0.60-1.11]) as compared with women without diabetes. PCD group showed 1.2-5.8% higher BMD, 4.9-6.2% thicker cortices, and -1.3 to 2.1% narrower neck femur than WCD and women without diabetes, respectively.

Conclusions: Poor glycemic control in postmenopausal women with T2DM is associated with fracture risk, high BMD, and thicker femoral cortices in narrower bones. We suggest that osteofragility in apparently ''healthy'' bones in PCD can result from micro-fragility accumulation and/or cortical porosity, reflecting impaired bone repair processes.

SU0360

Bone Turnover Markers and Calcium Metabolism in Young Men With Hyperthyroidism. Ana Paula Barbosa*[1], Mário Rui Mascarenhas[2], Ana Gonçalves[3], Vera Simões[4], António Gouveia de Oliveira[5], Manuel Bicho[6], Isabel do Carmo[3]. [1]Endocrinology, Santa Maria Hospital & Faculty of Medicine, Portugal, [2]Lisbon's Faculty of Medicine, Santa Maria University Hospital, CHLN,EPE, Portugal, [3]Endocrinology, Diabetes & Metabolism Department, Santa Maria Hospital, CHLN-EPE, Portugal, [4]CEDML - Endocrinology, Diabetes & Metabolism Clinic, Lda., Portugal, [5]Biostatistics Department, FCMUNL, Portugal, [6]Metabolism & Endocrinology Center, Genetics Laboratory (FMUL), Portugal

Hyperthyroidism is a known risk factor for reduced bone mineral density (BMD), osteoporosis and fragility fractures, even in young populations. Bone turnover markers can be impaired as well as calcium and the hormones involved in the control of bone metabolism.

Purpose: To evaluate the relationships between the bone turnover markers plasma levels, the hormones affecting calcium metabolism and BMD, in young men with hyperthyroidism.

MATERIAL AND Methods: A group of 48 men aged ≤ 50 years was divided and paired in hyperthyroid (n= 24) and control (n=24) groups. The plasma osteocalcin, CTX, and bone alkaline phosphatase (BAP), as well as the thyroid hormones, TSH, PTH, calcium, and 25(OH)vitamin D blood concentrations were measured.

The BMD (g/cm^2) at the lumbar spine (L_1-L_4), at the proximal femur, at the distal radius and at the whole body and the total body soft tissues composition (lean and fat masses, Kg) were evaluated by dual X-ray absorciometry, using the Hologic QDR Discovery W densitometer.

No patient was previously treated for hyperthyroidism and/or OP.

Descriptive and regression tests were used and statistical significance was considered for P <0.05.

RESULTSThe anthropometric data were similar between the groups; in the hyperthyroidism group, the BMD in all skeletal sites (except at the distal radius), the lean mass and the PTH were decreased, while the bone formation markers were increased (*Table 1*).

In the control group, there were significant relations between PTH and TSH plasma levels and between the BMD at distal radius and the BAP; in the hyperthyroidism group, significant relations were detected between PTH and BMD at the femoral neck.

CONCLUSIONS: The results of this study may suggest that the bone turnover markers and some of the hormones involved in bone metabolism are already modified and associated to an increased bone turnover, even in the youngest hyperthyroid men. Thus, both the diagnosis and therapy of the hyperthyroidism and an increase in calcium intake and sun exposure, should be precociously instituted, in order to minimize the bone mass loss and the possible increase of osteoporotic fractures risk.

GROUPS Variables	CONTROL	HYPERTHYROIDISM	P

SU0361

Influence of vitamin D status on the effect of statins on bone mineral density and bone turnover markers. Jesus Gonzalez-Macias*[1], José L. Hernández[1], Josefina Martínez[1], Sheila Ruiz[1], Jose Olmos[2]. [1]Department of Internal Medicine, Hospital Universitario Marqués de Valdecilla-IFIMAV, Universidad de Cantabria. RETICEF, Spain, [2]Hospital Universitario M. Valdecilla, Spain

Aim: To analyze whether the association between statin use and bone mineral density (BMD) and bone turnover markers (BTM) is influenced by serum 25OHD levels in postmenopausal women.

Methods: Some 1352 postmenopausal women were recruited from the Camargo Cohort after excluding those with any known medical disorder or drug that might affect bone metabolism, apart from statin use and low 25OHD serum levels. Participants were divided into four groups: group 1, women without statin treatment and 25OHD < 20 ng/ml; group 2, women on statin treatment and 25OHD > 20 ng/ml; group 3, women on statin treatment and 25OHD < 20 ng/ml; group 4, women without statin treatment and 25OHD > 20 ng/ml. BMD at lumbar spine (LS), femoral neck (FN) and total hip (TH) was measured by DXA (Hologic, QDR 4500). Bone turnover markers (CTX and P1NP) and 25OHD were determined by automated method (Elecsys, Roche). Multivariate analyses were performed to compare BMD and BTM in groups 2-4 vs. group 1. Adjustement for age, BMI, years since menopause, GFR, dairy calcium intake, exercise, family history of hip fracture, smoking and alcohol intake, diabetes and season was performed.

Results: Results are shown in table 1. Women in groups 3 and 4 did not show significant differences compared to group 1. However, women in group 2 had greater BMD at the FN and TH, and lower CTX, than women in group 1 (p=0.004, 0.035 and 0.05 respectively).

Conclusions: Women on statins and 25OHD above 20 ng/ml have less bone resorption and greater hip BMD than those in which both factors are absent. Differences, however, are not significant in women with only one of them. Vitamin D and statins seem to have a positive interaction in their effects on bone.

Oxytocin, A New Determinant of Bone Mineral Density and Bone Turnover in Post-menopausal Women: Analysis of the OPUS Cohort. Veronique Breuil*[1], Patricia Panaia-ferrari[2], Eric Fontas[3], Christian Roux[4], Sami Kolta[5], Richard Eastell[6], Hedi Ben Yahia[7], Claude Laurent Benhamou[8], Liana Euller-Ziegler[9], Ez Zoubir Amri[10]. [1]Chu De Nice, France, [2]laboratoire d'hormonologie - CHU de Nice, France, [3]statistical department - CHU de Nice, France, [4]Hospital Cochin, France, [5]Centre D'Evaluation, Des Maladies Osseuses, France, [6]University of Sheffield, United Kingdom, [7]Laboratoire d'Hormonologie CHU de Nice, France, [8]CHR ORLEANS, France, [9]Rheumatology Department CHU de Nice, France, [10]CNRS UMR7277, F-06108, University of Nice Sophia Antipolis, France

Introduction: Oxytocin (OT), a neurohypophysial hormone regulated by estrogen, leptin and alcohol, may play a role in bone metabolism in humans as suggested by animal studies. The aim of our study was to assess the relationship between OT and bone status in a large population of post menopausal women.

Subjects and Methods: Subjects were included in the Osteoporosis and Ultrasound study (OPUS), a 6-yr prospective study of osteoporosis related factors, conducted in a population-based cohort from five European cities. Final visit data were used for the present cross-sectional study. OT, leptin and estradiol serum levels were measured in 1097 post-menopausal women and compared with BMD (lumbar, femoral neck and hip), fractures and bone remodeling (PINP, bone ALP and CTX).

Results: The median age of this population was 70.8 years (66 – 76.9), 16% were osteoporotic (OP), 48% osteopenic, 36% had normal BMD and 29% had at least 1 fragility fracture. Univariate analysis showed a positive association between OT serum level and BMD at all sites: femoral neck ($p < 0.0001$), hip ($p < 0.0001$) and spine ($p < 0.0002$). After adjustment for age, estradiol, leptin, BMI, alcohol, tobacco use, parental history of hip fracture and steroid use, the association was no longer significant. However, in women with low estradiol serum levels (≤ 11.79 pg/ml, 89% of the population), after adjustment on all others parameters, OT was positively associated with hip BMD (g/cm^2, p=0.05), and this relation was stronger in women with higher leptin (>19.1 ng/ml) (p=0.001) or higher BMI (> 22 kg/m^2 known to be associated with lower risk of OP)(p=0.01). Univariate analysis showed a negative association between OT serum levels and bone markers: PINP (p<0,0001), bone ALP (p=0.01) and CTX ($p < 0,0001$), and this relation remained significant in women with undetectable estradiol. There was no significant relationship between OT and prior fractures.

Conclusion: High OT levels are associated with high BMD at the spine and hip. The mechanism may be explained by the effect of OT on bone turnover; high OT levels are associated with low bone turnover markers.

Neurorehabilitation Institute Guttmann, Badalona, Spain, [3]CIBERehd. Hospital Clínic of Barcelona, Spain, [4]Rheumatology Department. Metabolic Bone Diseases Unit. Hospital Clinic of Barcelona., Spain, [5]Nuclear Medicine Department. Hospital Clínic of Barcelona, Spain, [6]Hospital Clínic of Barcelona, Spain

Background: Spinal cord injury (SCI) has been associated with a marked increase in bone loss and bone remodelling. The absence of mechanical load seems to be one of the most important factors related to bone loss. However, the pathogenesis and clinical management of this condition remains unclear.

Objectives: To analyze the effect of Wnt signalling antagonists (sclerostin and DKK-1) and their relationship with bone turnover markers and bone mineral density (BMD) evolution in patients with a recent SCI.

Methods: Patients with a recent complete motor SCI (AIS A)(<6 months) were prospectively included.Bone turnover markers (Bone formation: P1NP, bone AP; Bone resorption: sCTx), Wnt antagonists (serum sclerostin and Dkk-1, determined by ELISA, Biomedica Gruppe, Austria) and BMD were assessed in all patients at baseline and at 6 months. The results were compared with 15 healthy individuals of similar age and sex.

Results: 23 men with a mean age of 38±15 years (range18-64) were included at 105±32 days of SCI onset (AIS 23A). 52% had paraplegia. 11 patients were assessed at 6 months of follow-up. Patients with SCI showed a significant increase in bone turnover markers compared to controls (P1NP 191±90 ng/ml vs. 50±9, $p<0.001$; sCTx 1.39±0.49 ng/ml vs. 0.52±0.19, $p<0.001$) and increased levels of sclerostin and Dkk-1 (40.7±15.3 vs. 31.2±17.9 pmol/L, p=0.038; 64.7±32.5 vs. 42.4±16.7 pmol/L, p=0.036). At 6 months, bone turnover markers decreased (P1NP -33%, p=0.008 and sCTx -24%, p=0.021) and BMD decreased about 12% at total femur (p=0.003) compared to baseline. Sclerostin levels increased significantly (40%, p=0.013), whereas Dkk-1 levels significantly decreased (-35%, p=0.041). Changes in Dkk-1 levels were positively correlated with changes in total femur BMD (r=0.6, p=0.05), while changes in sclerostin were negatively correlated with bone AP change (r=-0.668, p=0.025).

Conclusions: Patients with complete SCI have a marked increase in bone turnover markers and early bone loss over 10% at femur. Wnt signalling antagonists seem to be related to bone loss in acute SCI.

The Association between Bone Turnover Markers and Kyphotic Status in Community-dwelling Older Adults. Corinne McDaniels-Davidson*[1], Donna Kritz-Silverstein[2], Mei-Hua Huang[3], Gail Laughlin[2], Elizabeth Barrett-Connor[2], Deborah Kado[2]. [1]SDSU/UCSD Joint Doctoral Program in Public Health (Epidemiology), USA, [2]University of California, San Diego, USA, [3]UCLA School of Medicine, USA

Bone turnover markers reflect the dynamic process of bone formation and resorption, and have been shown to be associated with several bone disorders. Hyperkyphosis, an accentuated curvature of the thoracic spine, is estimated to affect up to 40% of older adults and is associated with negative health outcomes and mortality in the elderly. This study examined the association between serum levels of bone turnover markers and kyphotic status in a large sample of community-dwelling older men and women.

Between 2003 and 2006, 760 participants in the Rancho Bernardo Study age 60 and older (308 men and 452 women) had blood drawn and were assessed for kyphotic status at a research clinic. Serum was assayed for collagen type 1 cross-linked N-telopeptide (NTX), a marker of bone resorption, and procollagen type 1 n-terminal propeptide (PINP), a marker of bone formation. Kyphotic status was assessed as the number of 1.7cm blocks, placed under each participant's head, required to achieve a neutral supine position. Analyses were stratified by sex and estrogen therapy (ET) use. Multivariate logistic regression modeled odds of normal (0-1 block) kyphotic status for each one-SD change in log markers adjusting for age, obesity, and smoking history.

Mean age was 75 years (range=60-100); 49% of non-ET using women, 59% of ET-using women, and 25% of men had normal kyphotic status. Among non-ET using women, higher log PINP and serum NTX were associated with increased odds of normal kyphotic status in fully-adjusted models (PINP OR=1.4, 95% CI=1.1-1.7, p=.007; NTX OR=1.5, 95% CI=1.2-1.8, p=.001). Among ET-using women and men, no significant associations were found between bone turnover markers and kyphotic status ($p>.05$).

Higher bone turnover was associated with normal kyphotic status in non-ET using women, suggesting that increased osteoclast and osteoblast activity may be a compensatory mechanism against developing hyperkyphosis.

Skin Wound Trauma after Low-dose Gamma-ray Exposure Exacerbates Cancellous Bone Loss in Mice. Joshua Swift*[1], Matthew Allen[2], Joan Smith[1], Juliann Kiang[3]. [1]Armed Forces Radiobiology Research Institute, USA, [2]Indiana University School of Medicine, USA, [3]Armed Forces Radiobiology Research Institute, Uniformed Services University of the Health Sciences, USA

Low doses of ionizing radiation result in significant and deleterious effects on numerous physiological systems, including skeletal tissue. However, the effects of a low dose of ionizing radiation combined with another trauma (i.e. non-lethal skin wounding) on bone quantity/quality and biomarkers of bone metabolism have not been elucidated. To determine the timing and extent of damage to skeletal tissue after radiation injury (RI), skin wounding (W), and combined injury (CI; RI +W), 16-week-old B6D2F1/J female mice were exposed to a single dose of 1 Gy gamma rays (Co^{60}, 0.4 Gy/min) immediately followed by skin wound trauma (W and CI groups only; 15-20% total body skin surface area). Distal femur bone properties and serum biomarkers were assessed 3, 7, 30, and 120 days post-irradiation and compared to sham controls. RI significantly lowered cancellous bone volume (BV/TV) and trabecular number (Tb.N), -11% and -12% (vs. SHAM), respectively, by day 7 and recovered to SHAM levels 120 days post-irradiation. Skin wounding (W) resulted in significantly lower BV/TV (-17%) and Tb.N (-14%) compared to SHAM mice. CI demonstrated greater negative effects on BV/TV (-18%), trabecular thickness (Tb.Th; -13%), and Tb.N (-20%) by day 7 (vs. RI), which continued to decline through day 30 and recovered to SHAM levels 120 days post-CI. Femur cortical bone geometry was not affected by RI, W, or CI at any time point. RI increased circulating serum TRAP 5b on day 7 (+34%) and reduced osteocalcin by day 3 (-59%) vs. SHAM. TRAP 5b stabilized by day 30, but osteocalcin remained suppressed through day 30. Wounding increased TRAP 5b on day 3 (+34%) and day 7 (+57%), and reduced osteocalcin by day 3 (-73%) vs. SHAM. CI further increased TRAP 5b (+25 to +39%) from days 3 to 7 as compared to RI. In addition, osteocalcin was reduced on days 3 (-27%), 7 (-53%), and 30 (-49%) vs. RI mice. Altogether, these data indicate that skin wound trauma exacerbates bone loss after radiation exposure as low as 1 Gy and as early as 7 days post-injury. Although the exact mechanisms have not been elucidated, it appears that skeletal tissue damage after radiation and skin wounding may arise from early increases in bone resorption and reductions in formation activity, which persist for at least 30 days post-injury.

Vitamin D supplementation on calcium absorption in young women. Prachi Jindal*[1], J. Christopher Gallagher[1], Lynette Smith[2]. [1]Creighton university medical center, USA, [2]university of nebraska medical center, USA

Background: 1,25 dihydroxyvitamin D ($1,25(OH)_2D$) is the major hormone that controls intestinal calcium absorption. Serum $1,25(OH)_2D$ decreases when serum 25 hydroxyvitamin D (25OHD) falls below <10ng/ml but it is not known at what serum 25OHD level malabsorption of calcium can occur. Based on cross sectional data, one study suggested that a threshold for normal calcium absorption occurred at a serum 25OHD level of 30 ng/ml but in another study it was 5-10ng/ml. We performed a longitudinal study of different doses of vitamin D on absorption to measure the effect on calcium absorption and look for a threshold effect.

Methods: 198 Caucasian and African American women, ages 25-45 years, were randomized to a 12 month double blind study of vitamin D3 - 400, 800, 1600, 2400 IU, or placebo. Calcium intake was increased to 1200-1400mg/day from an average of 655 mg/day. Main inclusion criteria was - serum 25OHD level < 20ng/ml. Exclusion criteria were – medical illness or medications known to affect calcium absorption. Calcium absorption was measured at baseline and after 12 months using a single isotope method with 100 mg calcium and 5 microcuries Ca^{45}, serum Ca^{45} was corrected for weight or BMI. Serum 25OHD and $1,25(OH)_2D$ were measured by immunoassay (Diasorin). Multivariate regression was conducted to predict final calcium absorption with race, age, dietary calcium intake, weight, baseline calcium absorption, serum 1,25OH2D3 and baseline and final serum 25OHD.

Results:128 women completed the study.Mean baseline serum 25OHD was 14.6 ng/ml (39nmol/L) in Caucasians and 11.6 ng/ml in African Americans. In the longitudinal study mean serum 25OHD increased to 40 ng/ml, and there was no difference in final serum 25OHD between groups. There was no increase in 12-month calcium absorption compared to baseline on any dose of vitamin D in either Caucasians or African Americans. In the baseline analysis, serum 25OHD < 20ng/ml was divided into 4 groups of 5ng/ml increments. There was no difference in absorption nor in serum $1,25(OH)_2D$ amongst serum 25OHD groups (ANOVA p 0.86,0.12)

Conclusions:Vitamin D did not increase calcium absorption up to a dose of 2400IU daily or mean serum 25OHD of 41ng/ml. No threshold level of serum 25OHD for calcium absorption was found at baseline or in the longitudinal study suggesting that the threshold for decreased calcium absorption occurs at a very low serum 25OHD level < 5ng/ml.

Key words: Calcium absorption, 25 hydroxy vitamin D

Relationship between Dexamethasone Suppressed Cortisol levels, Bone Mineral Density and Vertebral Fractures in Postmenopausal Women. Miguel Debono*, Selina Simpson, Margaret Paggiosi, Fatima Gossiel, John Newell-Price, Richard Ross, Richard Eastell. University of Sheffield, United Kingdom

Background: Patients with adrenal incidentalomas and cortisol excess are at an increased risk of vertebral fractures. As adrenal incidentalomas are commonly found in the elderly population and up to 50% have dexamethasone cortisol >50nmol/l, we designed a study to assess whether we could commonly find cortisol excess secondary to adrenal incidentalomas in patients with vertebral fractures.

Methods: In a cross-sectional, observational study we recruited 30 postmenopausal women with vertebral fractures and a hip or spine T-score <-1.0 (Group1). In addition two sex-, BMI- and age-matched control groups each consisting of 30 women were studied; one group was BMD matched (Group2) whilst the other had normal BMD (Group3). A 1mg overnight dexamethasone suppression test (ONDST) to assess for excess cortisol, a BMD by DXA scan of the spine and hip with VFA, and high resolution peripheral quantitative computed tomography (HR-pQCT) scans of the tibia and radius were performed. Fractures were confirmed by spinal x-rays using the algorithm-based qualitative method.

Results: By ANOVA there was a significant difference in hip ($p<0.001$) and spine ($p<0.001$) T-scores between the groups. Post-hoc Scheffe tests revealed that Group1 and 2 had similar hip T-scores (mean(SD) Group1: -1.6 (0.9), Group2: -1.1(0.8)) and spine T-scores (Group 1: -2.4(0.8), Group 2: -2.2(0.7)) whilst Group3 T-scores (hip: 0.3(0.8), spine: 0.3(0.9)) differed significantly from both Group 1 and 2 ($p<0.001$). Similarly, measures of bone architecture, as assessed using HR-pQCT, for Group3 were significantly different to those for the other two groups. In Group 1, 2/30 patients (7%) failed the ONDST. Dexamethasone cortisol levels in the rest of the women were similar (Group1: 27 (6) nmol/l, Group2: 28 (7) nmol/l, Group3: 26 (10) nmol/l).

Conclusion: In this analysis we have identified two patients with an ONDST cortisol >50nmol/l and both had a vertebral fracture. This study suggests that hypercortisolism might be identified occasionally in postmenopausal women with vertebral fractures and treatable causes should be investigated and treated; mild elevations in cortisol when screened using a 1mg ONDST are not consistently found among patients with vertebral fracture.

Increased Cortical Porosity in Older Men with Low 25-OH-Vitamin D. Dan Mellstrom[1], Daniel Sundh[2], Magnus Karlsson[3], Anna Nilsson[4], Claes Ohlsson[5], Mattias Lorentzon*[6]. [1]Sahlgrenska University Hospital, Sweden, [2]Geriatric Medicine, Dept. of Internal Medicine & Clinical Nutrition, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden., Sweden, [3]Skåne University Hospital Malmö, Lund University, Sweden, [4]Sahlgrenska University Hospital, Sweden, [5]Center for Bone & Arthritis Research at the Sahlgrenska Academy, Sweden, [6]Geriatric Medicine, Center for Bone Research at the Sahlgrenska Academy, Sweden

The relationship between low serum levels of 25-OH-vitamin D and areal bone mineral density (aBMD) has been established, but whether this relationship is due to affected bone geometry or microstructure of the cortical or trabecular bone has been less studied. Bone loss at peripheral sites after age 65 is mainly cortical and involves an increase in cortical porosity, but the relationship between this bone trait and 25-OH vitamin D has not been previously reported. The aim of the present study was to investigate the association between serum levels of 25-OH-vitamin D and cortical and trabecular microstructure in 445 80-year-old men.

High Resolution Peripheral Computed Tomography (HRpQCT, Scanco) was used to scan the distal tibia and DXA (Hologic) was used to measure aBMD of the spine and hip, while 25-OH-vitamin D was measured with a competitive RIA (Diasorin). Men were divided into quartiles (Q1-Q4) according to 25-OH vitamin D (Q1 41.0 ± 8.2, Q2 55.8 ± 3.3, Q3 67.6 ± 3.7, Q4 85.3 ± 10.5 nmol/l). Men in the lowest vs. the highest quartile of 25-OH-vitamin D were slightly older (80.9 ± 3.2 vs. 79.5 ± 3.5 years) while no differences in height, weight, calcium intake, physical activity, or smoking were found. Cortical porosity at the distal tibia was 13% higher (12.5 ± 4.3 vs. $10.9\pm4.1\%$) while cortical volumetric BMD (4.6%; 757 ± 75 mg/cm^3 vs. 792 ± 74, $p<0.01$), thickness (11.2%; 0.91 ± 0.3 mm vs. 1.02 ± 0.3; $p<0.05$) and femoral neck aBMD (5.2%; 0.74 ± 0.11 mg/cm^2 vs. 0.78 ± 0.13, $p=0.01$) were lower in men in Q1 than in men in Q4. There were no differences between quartiles in spine aBMD or trabecular bone volume fraction. A linear regression model with age, weight, height, daily calcium intake, physical activity (walking distance per day), smoking (yes/no), 25-OH-vitamin D adjusted for season was used to determine the independent predictive role of serum vitamin D on bone variables. In this model, 25-OH-vitamin D independently predicted cortical porosity (standardized β= -0.11, $p=0.02$), thickness (β= 0.15, $p<0.01$), and cortical vBMD (β= 0.16, $p<0.01$) of the tibia as well as aBMD of the femoral neck (β= 0.17, $p<0.01$).

In conclusion, serum 25-OH-vitamin D levels independently predicted cortical porosity, thickness and density as well as aBMD of the femoral neck, a mainly cortical bone site, in older men. Our results suggest that bone fragility due to low vitamin D levels could mainly be due to affected cortical bone, at least partly mediated by increased porosity.

Impact of Traumatic Brain Injury on Bone in a Mouse Model. Hongrun Yu*, Heather Watt, Subburaman Mohan. Jerry L. Pettis Memorial VA Medical Center, USA

The impact of traumatic brain injury (TBI) especially mild TBI on public health is significant. There are 1.7 million cases of TBI reported annually in the United States, and approximately 85% are mild cases. While it is well established that the brain produces hypothalamic hormones and neuropeptides that influence skeletal metabolism, the impact of TBI on bone is not known. Based on the recognition from clinical studies that there is an association between TBI and long-term hypothalamic pituitary dysfunction, we have proposed the hypothesis that TBI including mild TBI exerts a negative impact on skeletal growth and maintenance. To evaluate this hypothesis, we used a recently established mouse model of human repetitive TBI (Kane et al., 2012) which utilized the weight drop method to create a closed head injury. A 72 g weight was dropped at a 1.5 m height onto anesthetized five week old female C57BL/6J mice, once per day for four consecutive days. Control mice underwent anesthesia only. All mice were euthanized two weeks after the first impact. Bone densitometry (DEXA) measurements revealed that total body bone mineral content (BMC), bone area (B area) and bone mineral density (BMD) were reduced 15% ($P < 0.01$), 10% ($P < 0.01$) and 5% ($P < 0.05$), respectively in the impacted mice compared to the controls. Similar reductions were also observed in individual skeletal sites at the femur, tibia and vertebra. Micro-CT analysis of cortical bone at the tibial mid-diaphyseal region indicated 16% and 4% reductions ($P < 0.01$) in total and cortical volumetric BMD (vBMD) of the impacted mice. Accordingly, there was a 33% reduction ($P<0.01$) in breaking strength of the cortical bone as measured by 3-point bending. Micro-CT analysis of trabecular (Tb) bone at the tibial metaphysis revealed a 42% reduction ($P<0.01$) in BV/TV, which was caused by a significant reduction in Tb number (20%, $P < 0.01$) and thickness (8%, $P < 0.01$), and increased Tb separation (26%, $P < 0.01$). Real time RT-PCR analysis showed that mRNA levels of osteocalcin in the femur of the impacted mice was reduced by 37% ($P < 0.05$) while that of osteoclast derived TRAP was unchanged, suggesting that reduced bone formation is the cause for reduced bone mass. In conclusion, repetitive TBI produced a negative impact on both cortical and trabecular bone mass accrual by inhibiting bone formation.

Skin color measurement and serum 25OH Vitamin D level: A comparison in young Caucasian and African American women. SRI HARSHA TELLA*[1], Prachi Jindal[2], J. Christopher Gallagher[2]. [1]Creighton University School of Medicine, USA, [2]Creighton university medical center, USA

Background: Vitamin D is essential for bone health and its level depends on dietary intake and on sunlight which generates vitamin D from 7-dehydrocholeterol in the skin through the effect of ultraviolet-B light (290-315 nm). Dietary intake is usually low, less than 150-200 IU daily, thus, sunlight exposure becomes a major source of vitamin D in most people. Certain groups may be at higher risk for a lower UV-B effect on skin synthesis of vitamin D, such as veiled women or women with darker skin color. The main objective of this analysis is to make quantitative assessments of skin color and its relation to serum 25 OHD.

Design: We recruited 198 young women for a 1-year trial of the effect of vitamin D on serum 25OHD. There were 119 Caucasian and 79 African American women, ages 25-45 years. The main inclusion criterion was vitamin D insufficiency, defined as a serum 25OHD level < 20ng/ml (50nmol/l). Exclusion criteria were sun screen use, medical illness or medications known to affect calcium and vitamin D metabolism. In this study we analyzed the baseline results of skin color measurement with reflectance spectrometry, the dietary intake of vitamin D from 7-day food diaries and the screening serum 25OHD levels. Skin color was measured 3 times on an exposed site – lower forearm and on a clothed area- inside of upper arm.

Results: The mean age for Caucasian women was 37.7 years ($\pm$ 5.58) and for African Americans was 35.1 ($\pm$ 5.94) years. The mean baseline serum 25OHD in African American was 11.6 ng/ml ($\pm$4.19)and 14.4 ng / ml($\pm$4.30) in Caucasians ($p=0.79$). Mean 7 day dietary vitamin D intake was 103 IU/d in Caucasians and 96 IU/d in African Americans ($p=0.53$). The mean forearm skin color in the Caucasian women was 68.28($\pm$ 2.16) and in African American women was 48.09($\pm$6.68) ($p<0.005$). Linear regression analysis showed a significant correlation between serum 25OHD and lower forearm skin color ($r= 0.37$, $p<0.01$) but no correlation with upper arm skin color ($r=0.04$, $p=0.567$). After Vitamin D supplementation for 12 months, there was no correlation between forearm skin color and Vitamin D levels($r=0.05$, $p=0.676$).

Conclusion: The results show that serum 25OHD levels are correlated with skin color only in the exposed skin area. Vitamin D intake was very low in both groups. The results suggest that in women with vitamin D insufficiency serum 25OHD is dependent on exposed skin and is lower in African American women because of darker skin.

Changes in Serum Undercarboxylated/Carboxylated Osteocalcin Ratio in Daily vs. Weekly Teriparatide Therapy for Vertebral Compression Fracture.
Yoichi Kishikawa*. Kishikawa Orthopedics, Japan

Background: At ASBMR 2012, we reported facilitated fracture union and increases in serum bone metabolism markers after 4 months of daily teriparatide (Forteo) injections in 26 vertebral compression fracture patients who were kept at a defined level of rest during early post-fracture stages. Percent changes in tartrate-resistant acid phosphatase (TRACP) 5b, undercarboxylated osteocalcin (ucOC) and carboxylated osteocalcin (OC) levels were 205%, 858% and 313%, respectively, resulting in a significant increase in ucOC/OC ratio by 240%. Meanwhile, a weekly teriparatide product (Teribone) has become available and clinically used in Japan since the end of 2011. Unlike the daily product, it is a chemically synthesized form of parathyroid hormone (PTH) and requires weekly subcutaneous injections of 56.5 μg, approximately 2.8 times the recommended dose of the daily product (20 μg).

Methods: Twenty-two patients with vertebral compression fracture were kept at a defined level of rest during early post-fracture stages and received weekly teriparatide. Changes in serum TRACP 5b, ucOC, OC and ucOC/OC at 4 months were compared to those in patients on daily teriparatide. Alfacalcidol (0.25 μg) was also used in both groups of patients.

Results: After 4 months of weekly doses of teriparatide, TRACP 5b, ucOC, OC and ucOC/OC changed by 96%, 237%, 129% and 145%, respectively.

Discussion: Although the two products are essentially identical in the PTH structures, their differences in dosage and dosing interval resulted in considerably different % changes in bone metabolism markers after only 4 months of treatment. In contrast to the dramatic increases in TRACP 5b, ucOC and OC by daily teriparatide, no change in TRACP 5b and mild increases in OC and ucOC were observed with weekly teriparatide. It is of future interest to examine whether the observed % changes in ucOC/OC would be affected by concurrent administration of vitamin K. An Animal study have shown that daily teriparatide leads to increased cortical porosity; the result of this studies suggest a possible association between ucOC/OC and the effects of the two products on bone quality.

Forteo Voluntary Patient Registry: 3-Year Progress on a Prospective Osteosarcoma Surveillance Study.
Nicole Kellier*[1], Kelly Krohn[2], Alicia Gilsenan[3], David Harris[3], Elizabeth Andrews[3], Daniel Masica[1]. [1]Eli Lilly & Company, USA, [2]Lilly USA, LLC, USA, [3]RTI Health Solutions, USA

Background: In rat toxicology studies, teriparatide, the active ingredient in Forteo, when given for the entire rodent lifespan caused increases in bone mass and a dose-dependent increase in the incidence of osteosarcoma, a rare primary bone cancer. Among adults aged ⩾18 years, the human incidence of osteosarcoma is 2.7 cases per million persons per year. As part of a long-term 12-year surveillance program for a possible signal of osteosarcoma in treated patients, the voluntary Forteo Patient Registry was launched in July 2009 to complement an ongoing retrospective case finding study.

Objective: To describe study progress of the Forteo Patient Registry, designed to estimate the incidence of osteosarcoma in patients treated with Forteo, and to enhance healthcare provider awareness of the progress of the Registry after 3 years.

Methods: Patients who complete a brief pre-enrollment form are sent a registration packet. After completing a one-time registration and consent, patients are considered enrolled. An annual linkage is performed by participating state cancer registries using a standardized linkage algorithm with the Forteo Patient Registry database to identify cases of osteosarcoma potentially associated with Forteo treatment. Linkage variables include name, birth date, sex, address, telephone number, race, ethnicity, and last 4 digits of social security number.

Results: The third annual linkage, performed in September 2012, including a total of 38 state cancer registries covering 86% of the US population linked 26,810 patients from the Forteo Patient Registry with 1,641 adult osteosarcoma cases diagnosed since January 1, 2009. No matches were identified. As of December 2012, of the 30,758 registrants, the distribution by pathway of recruitment was medication packaging (61%), starter kit (26%), study toll-free number (6%), patient brochure (3%), physician tear pad (2%), direct pharmacy mail (2%), and study website (1%).

Conclusion: Evaluation of the first 3 years of data, detected no signals of a possible association between Forteo treatment and osteosarcoma. The most frequent pathway for patient recruitment to date is information about the voluntary patient registry in product packaging. Patient respondent burden is kept to a minimum. Healthcare provider encouragement of Forteo treated patients to consider enrolling in the Registry can contribute to the scientific advancement of this surveillance study.

Monthly Cycles of Teriparatide and Raloxifene Increase BMD Comparable to Continuous Teriparatide: Is it Possible to "Open the Anabolic Window?".
Neil Binkley*, Jessie Libber, Gretta Borchardt, Diane Krueger, Bjoern Buehring. University of Wisconsin, Madison, USA

Osteoporosis therapies reduce fractures by only ~50%; better medications or alternatively, different approaches with current agents are needed. The anabolic window paradigm has been advanced to indicate a period of time during which teriparatide (TPD) produces bone anabolism prior to a coupled increase in resorption. We hypothesized that initial formation stimulation by TPD promptly followed by modest resorption suppression with raloxifene (RLX) then repeated in a cyclic manner may allow ongoing formation without concomitant increased resorption. This 6-month pilot study evaluated the effect of cyclic TPD/RLX compared to continuous TPD on BMD and bone turnover in postmenopausal osteoporotic women.

Community-dwelling postmenopausal women (n = 26) with osteoporosis (T-score ≤ -2.5 and/or prior fragility fracture) were randomly assigned to receive open-label TPD 20 mcg by daily sc injection or to alternating cycles of TPD for 1 mo followed by 1 mo of daily RLX 60 mg/day for 6 mo. All participants received ~1000 mg of calcium from diet and supplements if needed and 1000 IU of vitamin D_3 daily. Fasting serum was obtained at baseline and mo 1, 1.5, 2, 2.5, 3, 4, 5 and 6 to evaluate CTX and P1NP. BMD was measured at the L-spine by QCT (baseline and 6 mo) and at the L-spine, proximal femur and .3 radius by DXA at baseline and after 3 and 6 mo. L-spine trabecular bone score (TBS) was determined from the DXA images. Baseline group comparisons were performed by unpaired T-test with change over time evaluated by repeated measures ANOVA.

Participant mean age, BMI and lowest T-score was 67.0 years, 26.0 kg/m^2 and -2.7; no between group differences in demographics, serum chemistries, 25(OH)D or BMD were observed. No between group differences in BMD change (all $p > 0.10$) were observed (Table).

TBS values were unchanged at 6 months in both groups with no between-group difference. Serum CTX and P1NP increased progressively with TPD; mean increase was 188% and 298% respectively at 6 months. In the TPD/RLX group an undulating pattern in CTX and P1NP was observed with a decrease seen during the RLX treatment months; at 6 months mean CTX was numerically 4% lower and P1NP 21% higher than baseline.

In conclusion, 6 months of cyclic TPD/RLX increases L-spine BMD comparable to daily TPD. Temporal effects on bone turnover markers consistent with an antiresorptive effect of RLX were observed. This pilot work supports feasibility of opening the anabolic window.

BMD mean (SD) % change at 6 months

Group	L-spine (DXA)	L-spine (QCT)	Total proximal femur	.3 radius
TPD	+5.0 (2.8)	13.0 (7.1)	-0.3 (2.5)	-2.5 (3.5)
TPD/RLX	+4.9 (2.3)	9.4 (4.9)	+1.0 (1.3)	-1.4 (2.8)

Anabolic window table

Safety of Concomitant Use of 20 μg Teriparatide Once-Daily Subcutaneous Injection with Active Vitamin D Focusing on Calcium Levels.
Masako Nakano*[1], Mika Tsujimoto[2], Hideaki Sowa[3]. [1]Eli Lilly Japan K.K., Japan, [2]Asia Pacific Statistical Science, LRL DCOE Asia Pacific Eli Lilly Japan K.K, Japan, [3]Lilly Research Laboratories Japan, Eli Lilly Japan K.K., Japan

Objective: Teriparatide once-a-day subcutaneous injection, which stimulates bone formation, is globally approved for treatment of osteoporosis with high risk of fracture. Although it is recommended in Japan package insert of teriparatide to avoid a concomitant use with active vitamin D due to a theoretical risk that serum calcium level may increase, no reports that evaluated the risk in Japanese have been published. Meanwhile, active vitamin D is a common treatment for osteoporosis in Japan. Therefore, we evaluated the safety, including teriparatide's effects on serum and urinary calcium levels, when teriparatide and active vitamin D were coadministered to Japanese patients with osteoporosis. Methods: The trial was conducted at a clinical pharmacology institution under Good Clinical Practice. A total of 30 Japanese female patients (aged 71 years, median) with osteoporosis entered in this post-marketing clinical trial that consisted of 14-day lead-in, 28-day cotreatment, and 7-day follow-up periods (ClinicalTrials.gov identifier: NCT01430104). Patients were orally administered alfacalcidol 1 μg/day and calcium aspartate 600 mg/day during all periods. Teriparatide 20 μg/day was administered during the cotreatment period. Patients self-injected teriparatide after an introductory training. Serum calcium levels were measured at predose and 2, 4, 6, 16, and 24 hours postdose on Days 1, 7, 14, and 28 of the cotreatment period. Daily urinary calcium excretion was also measured by 24-hour urine collection. Adverse events (AEs) were evaluated throughout the trial. Results: No patients had exceeded albumin-corrected serum calcium levels or daily

urinary calcium excretion amounts beyond the predefined maximum limit of 11 mg/dL or 0.30 g/day, respectively (max: 10.3 mg/dL or 0.23 g/day, respectively). No hypercalcaemia or hypercalciuria was reported. Adverse events occurred in 5 patients (17.2%), and no serious AEs occurred during the trial. All AEs were of mild severity, except for one moderate positional vertigo that resulted in her study withdrawal. There were no reports of AEs that were not expected from the safety profile of teriparatide. Conclusion: The results suggest that teriparatide 20 µg/day can be safely coadministered with active vitamin D to the Japanese patients with osteoporosis. However, further experience of coadministration in actual clinical practice will be necessary.

Anti Resorptive Drugs Related Osteonecrosis of the Jaw: Epidemiology, Risk Factors and Evolution. Alice Pham Quang Hai*[1], Bernard Cortet[2], Guillaume Penel[3], Jean Michel Maes[4], Jacques Bonneterre[5], Marie Helene Vieillard[1]. [1]Rheumatology department Lille Hospital, France, [2]Service de Rhumatologie, France, [3]Surgical dental department Lille Hospital, France, [4]Stomatology department Lille Hospital, France, [5]Oncology Oscar Lambret Center Lille, France

Background: Osteonecrosis of the jaw (ONJ) is a rare but serious adverse event. In bisphosphonate (BP) treatment, the incidence is evaluated to 0.6-6.2% in breast cancer, 1.7-15% in multiple myeloma (MM), and 0,028-4,3% in osteoporosis. The aim of our study was to evaluate risk factors, clinical and radiological features and the evolution of ONJ.

Methods: Our study included 83 patients from January 2005 to November 2012. Patients were followed up in multidisciplinary consultation in Lille university hospital. Patients were evaluated regularly every 3 or 6 months according to their clinical symptoms and using our previously published classification. All ONJ completed task force definition.

Results: BP were administrated in 20 cases of osteoporosis, 17 cases of MM and 46 cases of bone metastasis (BM). The average age was 65 years [11]. The follow up median duration was 33 months [1-94]. The average duration between the beginning of BP and the first signs of ONJ was 38 months [35]; 77 months [36] in osteoporosis, 27 months [35] in malignant disease. Tooth extraction was reported in 54%.

In malignant disease, the average duration of treatment was 20 months [14] with zoledronate (ZA) and 21 [19] with pamidronate (Pam).The average cumulative dose of BP was 85mg [63] for ZA and 1600mg [1679] for Pam.

In BM, the average duration of ZA was 28 months [14] and 59 months [19] for Pam.

In MM, the average duration of ZA was 66 months [13] and 33 months [19] for Pam. 94% of patient received chemotherapy, 92% corticotherapy, 60% hormonotherapy and 19 % anti angiogenic treatment.

The time between BP and ONJ seems to be shorter when patients were treated with anti angiogenic (14.5 months [9-84] vs 24 months [1-96] without anti angiogenic treatment ns p=0.09). BP were stopped in 65% of cases.

In osteoporosis, the average duration of alendronate (Al) was 81 months [51]. The average cumulative dose of Al was 24629 mg [15462]. We noted 40% glucocorticoid induced osteoporosis.

According to our clinical classification, 36% of patients were improved (15% of patients were healed), 23% were worsened, and 23% remained in stable stage.

Conclusion: Physicians must be careful in case of association of anti-resorptive drugs, corticotherapy and anti angiogenic treatment. In osteoporosis, ONJ often appears after 6 years of BP treatment, or in case of association with corticotherapy. When ONJ occurred, symptomatic treatment and BP disruption could allow good evolution of ONJ.

Changes in Low Back Pain and Upper Gastrointestinal Symptoms in Japanese Osteoporotic Patients after Switching to Once-monthly Oral Minodronate from Daily or Weekly Bisphosphonates. Nobukazu Okimoto*[1], Akinori Sakai[2], SATOSHI IKEDA[3], Toru Yoshioka[4], Kitau Teshima[5], Shinobu Arita[6], Masato Nagashia[7], Hidehiro Matsumoto[8], Fumio Fukuda[9], Yuichi Okazaki[10], Hiroshi Tsurukami[11]. [1]Okimoto Clinic, Japan, [2]University of Occupational & Environmental Health, Japan, [3]Ken-Ai Memorial Hospital, Japan, [4]Saka Midorii Hospital, Japan, [5]Teshima Orthopaedic Clinic, Japan, [6]Obase Hospital, Japan, [7]Katsuki Neurosurgery & Orthopaedic Clinic, Japan, [8]Sanzai Hospital, Japan, [9]Kitakyushu General Hospital, Japan, [10]Makiyama Central Hospital, Japan, [11]Tsurukami Clinic of Orthopedics & Rheumatology, Japan

Introduction: Minodronate, a new-generation bisphosphonate (BP), is the first BP available as a once-monthly oral regimen in Japan. Aside from being a highly potent inhibitor of bone resorption, minodronate has been shown to possess antagonistic action against the P2X2/3 receptor, which has an important role in nociceptive transmission. The purpose of this study was to investigate the analgesic effects of once-monthly oral minodronate (MIN50mg) on low back pain (LBP) associated with osteoporosis. We also evaluated the changes in upper gastrointestinal (GI) symptoms (common adverse effects with the use of BPs) after switching from daily or weekly BPs to MIN50mg. Methods: We conducted a prospective multicenter study involving 11 institutions in Japan. A total of 397 patients (374 females) using BPs for the treatment of osteoporosis were enrolled. Participants completed a self-administered questionnaire to investigate patient preference for monthly dosing regimens, and were assigned to either the MIN50mg (n=264) or their current BP (n=133) according to their preference. Upper GI symptoms were self-assessed using a six-point symptom severity scale, and LBP was evaluated using a horizontal 100-mm visual analogue scale (VAS), for a period of six months. Results: LBP VAS scores were significantly reduced in the MIN50mg-switched group at one month post-treatment and after ($p<0.001$); however, no significant changes were seen in the previous BP-continued group. Upper GI symptom scores of heartburn, epigastralgia and epigastric fullness in the MIN50mg-switched group were all significantly improved early at one month after switching, and the improvement in epigastralgia was significantly superior compared with the previous BP-continued group ($p<0.05$). Conclusion: MIN50mg significantly improved LBP in patients previously treated with other BPs, and upper GI symptoms were significantly reduced after switching to MIN50mg. These QOL-related benefits of MIN50mg, together with the dosing convenience, may improve treatment adherence, thereby optimizing outcomes.

Comparative Gastrointestinal Safety of Bisphosphonates: A Network Meta-analysis. Mina Tadrous*[1], Lindsay Wong[1], David Juurlink[2], Murray Krahn[3], Linda Lévesque[4], Muhammad Mamdani[5], Suzanne Cadarette[1]. [1]University of Toronto, Canada, [2]Sunnybrook Health Sciences Centre, Canada, [3]Toronto Health Economics & Technology Assessment Collaborative, Canada, [4]Queen's University, Canada, [5]St. Michael's Hospital, Canada

Title: Comparative Gastrointestinal Safety of Bisphosphonates: A Network Meta-analysis

Background: Bisphosphonates are first line treatment for primary osteoporosis. Gastrointestinal (GI) adverse events (AEs) are cited as a primary reason for non-adherence with therapy. Little is known about the comparative GI safety of bisphosphonates.

Objective: To use published clinical trial data to assess the comparative GI safety of bisphosphonates.

Methods: We completed a systematic review of all English language clinical trials that assessed bisphosphonate safety and/or efficacy in primary osteoporosis. Randomized, blinded, and controlled studies were eligible. Extension, open-label, and studies not reporting AEs were excluded. The primary outcome was any GI-related AE. Subanalyses were completed for upper GI, serious GI, nausea, esophageal-related events, and discontinuation due to AEs. A Bayesian based network meta-analysis was completed using WINBUGS and GeMTC to allow for indirect comparisons.

Results: We identified 51 studies eligible for analysis: 33 alendronate, 12 risedronate, 5 etidronate, 7 zoledronic acid, and 44 placebo. Zoledronic acid had the highest probability (91%) of causing the greatest number of any GI AEs and highest probability (70%) of the greatest incidence of nausea. Etidronate (70%) and zoledronic acid (28%) had the highest probability of the greatest attrition due to AEs. Etidronate also had the highest probability (56%) of having the greatest number of upper GI symptoms among oral bisphosphonates. Only risedronate and alendronate had data on both serious GI and esophageal related AEs with no significant difference between drugs or compared to placebo.

Conclusion: Zoledronic acid had the highest probability of having the greatest number of GI AEs. Discontinuation due to AEs may be a more clinically relevant outcome, with the highest probability of greatest occurrence found with etidronate and zoledronic acid. These results question the assumption that annual zoledronic acid will translate into better long-term adherence to bisphosphonate therapy . More research into real-world implications of the comparative safety of bisphosphonates is needed.

Comparison of bone mass in lumbar vertebral segmentation and femoral area after treatment of novel intravenous alendronate in Japanese women with osteoporosis. Keiko Kobayashi, Akio Kanezashi, Serita Ikuro, Norihiko Kato*. otomi orthopedic clinic, Japan

Oral alendronate (ALN) administrations are currently preferred therapy for the treatment of osteoporosis. On the other hand, the efficacy and safety of the new intravenous ALN was reported. However, bone volume of spinal segmentation and femoral area after intravenous ALN administration is uncertain. The aim of this study is to evaluate the changes bone volume in AP lumbar spine from 1, 2, 3, 4 vertebrae and femoral area after treatment of novel intravenous ALN on BMD measurements. In 59 Japanese women (age 52-89 years) with osteoporosis, Intravenous ALN 900

micro-g every 4 weeks for 20 weeks was infused over 30 minutes. The intravenous formulation was a soft bag of 100 ml saline/citrate buffer solution containg 900 micro-g of ALN. The efficacy endpoint was percentage BMD by DXA change from baseline in AP lumbar spine (L1, L2, L3, L4, L1-4) and Ward's triangle (Ward), trochanter (Troch), femoral neck (Neck), total hip after intravenous ALN treatment. Percentage BMD change from baseline in L1, L2, L3, L4, and L1-4 at week 20 were $3.81 \pm 0.076\%$, $3.62 \pm 0.051\%$, $2.87 \pm 0.046\%$, $4.1 \pm 0.08\%$, and $3.7 \pm 0.038\%$. Percentage change in BMD in Ward, Troch, Neck, and total hip at 20 weeks after treatment were $0.33 \pm 0.083\%$, $2.06 \pm 0.05\%$, $0.41 \pm 0.046\%$, and $1.49 \pm 0.035\%$. Thus, Treatment of intravenous ALN in short duration significantly increased bone mass in L4 of vertebrae and trochanter of femur. The present study gives BMD change at anatomical sites in Japanese patients with osteoporosis after new intravenous ALN treatment. Our observation on the treatment of intravenous ALN may provide a clue to develop novel options for the treatment of osteoporosis.

Early Response to Once-monthly Oral Minodronate after Switching from Daily or Weekly Bisphosphonates in Japanese Osteoporotic Patients. Akinori Sakai*[1], SATOSHI IKEDA[2], Nobukazu Okimoto[3], Kitau Teshima[4], Shinobu Arita[5], Hidehiro Matsumoto[6], Hiroshi Tsurukami[7], Yuichi Okazaki[8], Masato Nagashima[9], Fumio Fukuda[10], Toru Yoshioka[11]. [1]University of Occupational & Environmental Health, Japan, [2]Ken-Ai Memorial Hospital, Japan, [3]Okimoto Clinic, Japan, [4]Teshima Orthopaedic Clinic, Japan, [5]Obase Hospital, Japan, [6]Sanzai Hospital, Japan, [7]Tsurukami Clinic of Orthopedics & Rheumatology, Japan, [8]Makiyama Central Hospital, Japan, [9]Katsuki Neurosurgery & Orthopaedic Clinic, Japan, [10]Kitakyushu General Hospital, Japan, [11]Sakamidorii Hospital, Japan

Introduction: Minodronate, a highly potent, new-generation bisphosphonate (BP), is the first BP available as a once-monthly oral regimen in Japan. The aim of the present study was to investigate the effects of once-monthly oral minodronate on bone turnover markers (BTM) and bone mineral density (BMD) in osteoporotic patients previously using daily or weekly BPs in real clinical practice.

Methods: We conducted a prospective multicenter study involving 11 institutions in Japan. A total of 397 patients (374 females) using BPs for the treatment of osteoporosis were enrolled. Participants were divided into two groups depending on their preference for dosing regimens as follows: MIN50mg group (n=264) were switched to once-monthly minodronate (50mg), and d/wBP group (n=133) continued their current daily or weekly BP. Serum TRACP-5b, a bone resorption marker, was measured at baseline and 1, 2 and 6 months post-treatment. Serum P1NP, a bone formation marker, was measured at baseline and 2 and 6 months post-treatment. BMD of lumbar spine, total hip, and/or 1/3 distal radius were measured at baseline and 6 months post-treatment.

Results: In MIN50mg group, significant reductions were seen in TRACP-5b at 1 month post-treatment (-10.2%, $p<0.001$) and onward, and in P1NP at 2 months post-treatment (-8.4%, $p<0.001$) and onward, while remaining within the reference range for a healthy young adult throughout the study period of 6 months. BMD in the MIN50mg group was significantly increased at lumbar spine (+1.5%, $p<0.001$) and 1/3 distal radius (+1.1%, $p<0.01$) at 6 months after therapy; however no significant changes were seen in the d/wBP group.

Conclusion: Once-monthly minodronte after switched from daily or weekly BPs demonstrated prompt BTM suppression within the normal reference range and superior BMD gains compared with continuing previous BPs. Thus, once-monthly minodronate provides an effective and convenient alternative to current BP therapies.

Effect of One Year Alendronate Administration on the Bone Strength, Soft Tissue Mass and Biochemical Markers of Bone Metabolism. Shigeharu Uchiyama*[1], Shota Ikegami[2], Mikio Kamimura[3], Hiroyuki Kato[2]. [1]Shinshu University, School of Medicine, Japan, [2]Department of Orthopaedic Surgery, Shisnhu University School of Medicine, Japan, [3]Kamimura Clinic, Japan

[Hypothesis] It is assumed that alterlation of skeletal conditions by ALN administration can cause secondary effect on the other structures, such as skeletal muscle or adipose tissue in the muscle. We hypothesized that ALN administration would increase not only BMD, but also in the skeletal muscle mass, along with little effect on biochemical markers of bone quality.

[Methods] We enrolled 24 female patients (76 years) without a history of any osteoporotic treatment. At the time of enrollment. QCT analysis of the femoral neck was performed with Mindways QCT-PRO BIT software. Total cross sectional area(CSA), cortical CSA, average cortical thickness were measured as geometrical parameters, and CSMI, section modulus, and buckling ratio, were calculated as measurements of bending strength and risk of buckling. BMD of the proximal femur and lumbar spine derived from DXA was also taken. QCT analysis of soft tissue was also performed using Mindways Tissue Composition Module software. CSA of the skeletal muscle and intramuscular fat at the proximal thigh were calculated. As biochemical markers of bone metabolism, serum BAP, OC, ucOC, serum and urine pentosidine, plasma homocysteine, whole PTH, 1,25(OH)2D, 25(OH)D, TRACP-5b, urinary DPD, and urinary NTX were measured. Oral ALN (35mg/week) was administered and continued for 1 year. Then, the same examinations described above were repeated and each parameter was compared between before and after ALN administration, using a paired t-test.

[Results] DXA-derived BMD of the proximal femur and lumbar spine significantly increased after one year. However, BR, SM and CSMI were not significantly different. Skeletal muscle CSA and fat CSA did not differ. BAP, urine NTX, DPD, and TRACP-5b were significantly decreased. Serum and urinary levels of pentosidine and serum homocysteine did not change significantly. 1,25-(OH)2 vitamin D and 25-(OH)D levels did not significantly differ between before and after ALN administration. (Table).

[Summary points] BMD of the femoral neck increased after one year ALN administration. But this increase was not accompanied by increase in skeletal muscle mass or decrease in fat. This was because such a small increase in BMD may not be large enough to increase bone strength parameters derived from QCT so that its interaction with skeletal muscle may remain the same as before treatment.

Table. Parameters before and after ALN treatment

		Before Treatment	After a year of ALN	P value
DXA	Total Hip BMD g/cm²	0.641 (0.102)	0.655(0.095)	0.0002
	FN BMD g/cm²	0.572 (0.104)	0.587 (0.094)	0.006

MIV-711, a Highly Selective Cathepsin K Inhibitor, First in Man Study – Safety, Pharmacokinetics and Pharmacodynamics of Multiple Ascending Oral Doses in Healthy Subjects. Urszula Grabowska[1], Markus Jerling[2], Disa Böttiger[2], Torbjörn Larsson[2], Kerstin Danielson[2], Erik Lindström[2], Charlotte Edenius*[2]. [1]Medivir, United Kingdom, [2]Medivir, Sweden

Introduction: Excessive resorption associated with bone diseases such as osteoporosis and osteoarthritis, can be regulated by cathepsin K inhibition. Cathepsin K, a cysteine protease expressed in the osteoclast, is necessary for bone matrix resorption. Non-clinical studies have demonstrated that MIV-711, a highly selective cathepsin K inhibitor, successfully attenuates bone resorption. This abstract presents results for multiple dosing over seven days as part of a First in Man study with MIV-711.

Aim: To determine the safety, tolerability, pharmacokinetics and pharmacodynamics of the cathepsin K inhibitor MIV-711 during multiple oral dosing.

Methods: A double-blind, placebo-controlled, randomized study in 27 healthy subjects of both genders. Multiple ascending doses of 50, 100 or 200 mg given in fasting state, once daily for 7 days were investigated for adverse events, clinical chemistry and haematology, vital signs, ECG parameters, pharmacokinetics, and biomarkers both in serum and urine.

Results: MIV-711 was well tolerated with no apparent effect on haematology, clinical chemistry, vital signs, or ECG parameters. Adverse events included skin reactions at ECG electrode sites which appeared both after active drug and placebo, headache, gastrointestinal symptoms and muscle pain. Drug exposure increased linearly with dose. MIV-711 significantly reduced serum CTX-I levels compared to placebo-treated subjects. The reductions in CTX-I compared to baseline levels were consistent after the first dose and after multiple doses for 7 days. At 24 h after dose, 50 mg MIV-711 reduced serum CTX-I levels by 49% and 40% after the first dose and last (seventh) dose, respectively. The corresponding CTX-I reductions in response to 100 mg MIV-711 were 44% (first dose) and 54% (last dose), while for 200 mg MIV-711, CTX-I levels were reduced by 59% (first dose) and 55% (last dose). At 48 h after the seventh (last) dose, serum CTX-I levels were approaching initial baseline levels in most groups indicating reversible efficacy.

Conclusions: Multiple doses of MIV-711 up to 200 mg administered once daily to healthy subjects for 7 days were safe and well tolerated and displayed linear pharmacokinetics over the investigated dose range. Serum CTX-I levels were suppressed by up to 55% at 24 h after last dose.These data suggest that the cathepsin K inhibitor, MIV-711 may be developed as an effective therapeutic agent for diseases characterised by excessive bone resorption.

Patient Preference and Adherence to Once-monthly Oral Minodronate in Japanese Osteoporotic Patients Previously Using Daily or Weekly Bisphosphonates. SATOSHI IKEDA*[1], Akinori Sakai[2], Nobukazu Okimoto[3], Yuichi Okazaki[4], Fumio Fukuda[5], Shinobu Arita[6], Kitau Teshima[7], Masato Nagashima[8], Hidehiro Matsumoto[9], Hiroshi Tsurukami[10], Toru Yoshioka[11]. [1]Ken-Ai Memorial Hospital, Japan, [2]University of Occupational & Environmental Health, Japan, [3]Okimoto Clinic, Japan, [4]Makiyama Central Hospital, Japan, [5]Kitakyushu General Hospital, Japan, [6]Obase Hospital, Japan, [7]Teshima Orthopaedic Clinic, Japan, [8]Katsuki Neurosurgery & Orthopaedic Clinic, Japan, [9]Sanzai Hospital, Japan, [10]Tsurukami Clinic of Orthopedics & Rheumatology, Japan, [11]Saka Midorii Hospital, Japan

Introduction: Bisphosphonates (BPs) are currently the mainstay of treatment in osteoporosis; however, the complex dosing regimens might interfere with long-term adherence, which provided the rationale to develop BPs with less-frequent dosing schedules. Minodronate, a highly potent new-generation BP, is the first BP available as a once-monthly oral regimen in Japan. The aim of the present study was to investigate patient preference for, and adherence to, once-monthly oral minodronate (MIN50mg) in Japanese osteoporotic patients previously using daily or weekly BPs.

Methods: We conducted a prospective multicenter study involving 11 institutions and 397 patients (374 females) in Japan. At enrollment, participants completed a self-administered questionnaire to see whether they were willing to switch to MIN50mg or continue taking their current BP. According to their preference, subjects were assigned to either MIN50mg or their current BP. Treatment adherence was monitored for six months, and patient satisfaction levels with the therapy were assessed at six months.

Results: Of the 397 patients using daily or weekly BPs, 264 patients (66.5%) were willing to switch to MIN50mg, mainly because they expect less-frequent dosing would be more convenient. Significantly more patients, who were dissatisfied with their current BP (e.g., insufficient efficacy) or who have ever missed taking any doses of their current BP, were more willing to switch to MIN50mg than continuing their current BP ($p<0.001$). Treatment adherence at six months was significantly higher in the MIN50mg-switched group compared with the previous BP-continued group (89.8% vs. 79.0%, $p<0.01$). After six months, patients who switched and persisted with MIN50mg all preferred MIN50mg rather than their prior BP.

Conclusion: Once-monthly dosing of MIN50mg was associated with better medication adherence than daily or weekly dosing during a six-month observation period. MIN50mg may provide patients with a more convenient treatment option and enhance compliance and long-term persistence with therapy.

Preliminary results of a randomized head to head study between Denosumab and Zoledronic Acid in severe osteoporotic women. Marco Invernizzi*[1], Stefano Carda[2], Alessio Baricich[3], Carlo Cisari[3]. [1]University of Eastern Piedmont, Novara, Italy, [2]Department of Neurorehabilitation & Neuropsychology, Centre Hospitalier Universitaire Vaudois (CHUV), Switzerland, [3]Physical & Rehabilitation Medicine, Department of Health Sciences, University of Eastern Piedmont "A. Avogadro", Italy

Introduction: Denosumab and Zoledronic Acid (ZOL) are currently used for osteoporosis treatment. The efficacy of these two powerful antiresorptive agents in increasing BMD and reducing fracture risk in osteoporotic postmenopausal women has been demonstrated in numerous clinical trials; however,at present time the effects of these drugs on Bone Turnover Markers (BTM) have not been compared yet.

AIM: to determine the effects on BTM of Denosumab 60mg vs. 5mg intravenous ZOL after multiple administration in severe osteoporotic patients.

Methods: 104 severe osteoporotic post-menopausal woman were enrolled and randomly divided in two groups: 55 were treated with Denosumab 60mg subcutaneously every 6 months and 49 with 5mg of intravenous ZOL once yearly. The inclusion criteria were: age > 70, presence of at least one vertebral or femoral osteoporotic fracture, a T-score at vertebral or hip site <-3. Previous treatment for osteoporosis were recorded. BMT (serum CTX, OC and B-ALP) were assessed at baseline, 1 month after treatment and 1 year after treatment in both groups. Moreover BMT were also assessed in DENOS group at second treatment (6 months) and 1 month after the second treatment. Tolerability was evaluated by adverse experience (AE) reporting.

Results: One month after the first Denosumab treatment were found decreases of OC (-17,1%), serum CTX (-80,3%; $p<0.01$ vs. baseline) and B-ALP (-10,2%) compared to baseline values. Similar trends occured for CTX, OC, and B-ALP after second and third Denosumab treatment. One month after ZOL infusion we observed a decrease in OC (-11%), serum CTX (-41,1%; $p<0.01$ vs. baseline; $p<0.05$ vs. Denosumab group) and B-ALP (-6,4%) compared to baseline values.The percentage of treatment naive patient was 44,1% in Denosumab group an 47,5% in ZOL group respectively. Treatment-Naive patients in both groups showed no significant differences in BTM compared to previously treated patients. 5 patients (9%) experienced moderate self-limiting AE (myalgia) after Denosumab, while 25 patients (51%) experienced a self-limiting acute phase reaction after ZOL.

Conclusions: Denosumab treatment resulted in greater suppression of BTM compared with ZOL. This result is maintained also after the second and third administration. Moreover, Denosumab reported less AE than ZOL. The greater and earlier effect of Denosumab on BTM compared to ZOL may have clinical implications for therapeutic choices in severe osteoporotic patients.

Relationship between Response to Treatment with Risedronate and Baseline TRACP-5b Activity -Subanalysis of Japanese Risedronate 75mg Phase III Trial-. Taro Mawatari*[1], Ryoichi Muraoka[2], Yukihide Iwamoto[3]. [1]Hamanomachi Hospital, Japan, [2]Ajinomoto Pharmaceuticals Co, Ltd., Japan, [3]Department of Orthopaedic Surgery, Kyushu University, Japan

Risedronate increases bone mineral density (BMD) and reduces fracture risk. However, the response to treatment may depend on the baseline state of bone turnover, or more specifically, the degree of bone resorption. We analyzed the results of the Japanese Phase III clinical trial (OMP3) of risedronate 75 mg monthly to examine this question. The subanalysis was performed for 850 subjects whose baseline levels of TRACP-5b activity were measured before risedronate treatment without vitamin D supplementation for 48 weeks in the OMP3 trial. Patients were divided into three groups according to their baseline TRACP-5b level: a low-activity group with TRACP-5b $<$ 379 mU/dL (n = 282), a medium-activity group with TRACP-5b $\geqslant$ 379 mU/dL and $<$ 504 mU/dL (n = 283), and a high-activity group with TRACP-5b $\geqslant$ 504 mU/dL (n = 285). The percentage change and change from baseline in BMD due to treatment with risedronate were evaluated for each group. One-way analysis of variance showed that both the percentage change and change in BMD were greater in the group with high baseline TRACP-5b activity than in the other two groups (One-way ANOVA: $P < 0.0001$). BMD was increased by risedronate treatment in each of the three groups stratified by low, medium, and high baseline TRACP-5b activity, but the response was greater in patients with higher baseline TRACP-5b activity, demonstrating a positive correlation between the increase in BMD and baseline TRACP-5b activity. The degree of BMD increase by the treatment with risedronate may differ according to the state of bone turnover at baseline.

Risk factors for incident vertebral fractures treated with bisphosphonates in glucocorticoid-induced osteoporosis. Mari Ushikubo*[1], Ikuko Tanaka[2], Harumi Kuda[1], Sayaka Kubo[1], Keisuke Izumi[1], Kumiko Akiya[3], Shigenori Tamaki[2], Hisaji Oshima[1]. [1]Tokyo Medical Center, Japan, [2]NAGOYA Rheumatology Clinic, Japan, [3]National Tokyo Medical Center, Japan

Background) Although bisphosphonate (BIs) is one of the most preferred treatments in glucocorticoid-induced osteoporosis (GIO), some patients treated with Bis still have incident fractures. Porpose) To clarify risk factors for incident fracrures in patients with Bis in GIO. Patients and Methods) Patients (n = 137) with connective tissue disease other than rheumatoid arthritis were recruited and observed for 2 years. The means of age, disease duration, total predonisolone (PSL) dosage and daily PSL dosage during the study period were 61 ± 15 (SD), 12 ± 11 years, 34 ± 34g and 8 ± 6 mg/day, respectively. Prevalent vertebral fractures were seen in 44% of the patients. Agents used for prevention and treatments of GIO were Bis (54%), active vitamin D3 (7%) and vitamin K2 (6%). Bone mineral densities (BMD) were measured with DXA at the distal radius. Results) 1) Incident vertebral fractures determined with deterionating grades by the SQ method were seen in 64 patients (47%). 2) Logistic regression analysis showed the age (1.43 (OR)/5yo), total PSL dosage (1.09/5g), daily PSL dosage (2.36/5mg) and BMD (1.25/5% decrease) as independent risk factors, and

treatments with Bis (0.02) and vitamin K2 (0.06) as preventing factors ($p<0.05$). 3) Analysis of 74 patients with Bis, incident fractures, the age was higher and the BMD was lower than those without incident fractures. Multivariable analysis with logistic regression revealed the presence of prevalent fracture (3.6), ther higher daily PSL dosage during the study period (1.7/5mg) and ther lower BMD (1.6/5%) as independent risk factors. Conclusions) Patient treated with Bis in GIO, the presence of prevalent fractures, the higher daily PSL dosage, and the lower BMD were risk factors for incident vertebral fractures. An further treatment may be needed in those patients.

SU0386

Safety and Tolerability of Monthly i.v. Ibandronate Injections: MOVER Study 3-Year Analysis. Toshitaka Nakamura*[1], Tetsuo Nakano[2], Masako Ito[3], Hiroshi Hagino[4], Junko Hashimoto[5], Masato Tobinai[5], Hideki Mizunuma[6]. [1]National Center for Global Health & Medicine, Japan, [2]Tamana Central Hospital, Japan, [3]Nagasaki University Hospital, Japan, [4]Tottori University, Japan, [5]Chugai Pharmaceutical Corporation Limited, Japan, [6]Hirosaki University, Japan

Purpose: The randomized, double-blind MOVER (MOnthly intraVenous ibandronatE versus daily oral Risedronate) study is the first head-to-head comparison of the anti-fracture efficacy and safety of monthly i.v. ibandronate (IBN) with daily oral risedronate (RIS) in female and male Japanese patients (pts) with primary osteoporosis. We present the 3-year safety analysis.

Methods: Ambulatory pts aged ≥60 years, with fragile bone fracture, bone mineral density of the lumbar spine L2–L4 or proximal femur <80% of the young adult mean, and 1–5 vertebral fractures in the thoracic and lumbar spine were randomized to receive i.v. IBN 0.5 or 1 mg/month + oral daily placebo, or oral RIS 2.5 mg/day (licensed Japanese dose) + monthly i.v. placebo. Calcium 305 mg and vitamin D 200 IU/day were also given. Adverse events (AEs) were recorded during the study and for up to 15 days of follow-up.

Results: Of 1265 pts randomized, 37 were not treated, leaving 1228 pts in the safety population (IBN 0.5 mg n=411, IBN 1 mg, n=411, RIS n=406). The groups were balanced with respect to baseline patient characteristics. The study met its primary endpoint, showing non-inferiority for both doses of IBN to RIS with respect to the risk of vertebral fractures (non-inferiority limit 1.55): 0.5 mg, hazard ratio (HR) 1.09 (95% CI 0.77–1.54); 1 mg, HR 0.88 (95% CI 0.61–1.27). The incidence of AEs, serious AEs, and AEs leading to death/withdrawal was similar across the treatment groups. A similar proportion of pts in each group had renal disorder AEs (2.9% IBN 0.5 mg, 2.7% IBN 1 mg, 2.0% RIS) and most of these AEs were mild in all treatment groups. Change from baseline in serum creatinine was similar between the groups. More pts had acute phase reaction (APR) AEs with IBN (9.0%, 0.5 mg; 11.2%, 1 mg) than with RIS (4.9%); most occurred after the first dose of study drug, were mild, transient, and decreased with each subsequent dose. No APR-related AEs led to treatment discontinuation. Gastrointestinal (GI) AEs occurred at a similar incidence in all groups, but there were more GI-related AEs with causality linked to RIS (6.4%) than to IBN (3.4%, 0.5 mg; 1.9%, 1 mg). There were no cases of hypocalcemia, osteonecrosis of the jaw, or atypical fracture of the femur.Conclusions: Monthly i.v. ibandronate injections were well tolerated by Japanese pts with osteoporosis; the safety profile and nature/severity of AEs was similar to studies in Western pts.

SU0387

Short term safety and Acute Phase Reaction assessment of Postmenopausal Osteoporosis patients within 4 weeks after Zoledronic Acid treatment in China. Fuxing Pei*[1], Xun Liu[2]. [1]Department of Orthopaedics, West China Hospital, Sichuan University, China, [2]Novartis Pharmaceuticals (China), Peoples Republic of China

Objectives: The study was aimed to observe the post-infusion safety and APR assessment in clinical practice during the first 4 weeks post Zoledronic Acid (Zol) infusion in PMO patients of mainland China.

Patients and Methods: This was a 4-week, prospective, multicenter, open-label, non-interventional study, enrolling 945 PMO patients (mean age: 67.84±9.97 years). All patients received a single 15' infusion of Zol, and were followed at the infusion day, 1-3 d, 4-7 d, 2 weeks and 4 weeks post infusion. The fever and body pain were primary outcomes. Other adverse events (AE) were secondary outcomes.

Results: Data from 917 patients with complete body temperature were analyzed, 239 (26.06%) patients had a fever (temperature increase 1℃ compared with baseline) within the 1st week (236 and 3 patients at 1-3 d and 4-7d post infusion, respectively). For the 239 patients, the median onset time to fever was one day; the median duration was one day. At the 1st fever day, 19, 113, 103 and 4 patients had temperature ≥39℃, 38.1~39℃, 37.1~38℃ and ≤ 37℃, respectively.

At baseline 513 (54%) patients had body pain. Within the 1st week, 225 (23.8%) patients pain severity aggravated, including 156 patients who had no pain at baseline, (151 and 5 patients at 1-3 d and 4-7 d post infusion respectively), 69 patients with pain at baseline (66 and 3 patients at 1-3 d and 4-7 d post infusion respectively). For the 156 patients the median onset time to pain was one day; the median duration was 3 days. However, 343 more patients felt no pain at the 14th day than at baseline (82.3% vs. 46% respectively). There were 77 patients with pain category information, which were 55 myalgias, 9 arthralgias, 6 headaches, 2 chest pains, 2 stomach aches, 2 backaches and one leg pain.

Except fever and body pain, 50 (5.29%) patients experienced 101 AEs, of which 93 were mild or moderate, 69 AEs resolved without medication. Nausea (1.59%), vomiting (0.95%), dizziness (0.85%), fatigue (0.63%), chest distress (0.53%) were AEs with frequency >0.5%. There was 1 serious AE, not considered drug-related. The patient had pneumonia 9 days post infusion and died of respiratory failure at the 18 days.

Conclusion: APR in Chinese patients was generally mild or moderate. The most frequent symptoms were fever and body pain, which happened mostly within 3 days post infusion, and relieved within the 1st week. Zol treatment is associated with a generally safety profile, with manageable APR symptom.

The Instructive Effects of Minodronate on Prevention of New Vertebral Fractures at the Higher Fracture Risk of Japanese Patients with Osteoporosis. Hiroshi Hagino*[1], Masataka Shiraki[2], Masao Fukunaga[3], Tetsuo Nakano[4], Kunio Takaoka[5], Yasuo Ohashi[6], Toshitaka Nakamura[7], Toshio Matsumoto[8]. [1]Tottori University, Japan, [2]Research Institute & Practice for Involutional Diseases, Japan, [3]Kawasaki Medical School, Japan, [4]Tamana Central Hospital, Japan, [5]Hanwa Joint Reconstruction Center Hospital, Japan, [6]University of Tokyo, Japan, [7]University of Occupational & Environmental Health, Japan, [8]University of Tokushima Graduate School of Medical Sciences, Japan

Minodronate is a potent nitrogen-containing bisphosphonate that was launched in 2009 in Japan for oral daily administration of osteoporosis, and then monthly administration was launched in 2011. Previous in vitro and in vivo preclinical studies demonstrated that minodronate is about ten times as potent as alendronate in inhibiting bone resorption. In clinical study, a randomized placebo-controlled trial was conducted to examine the effect of daily oral 1 mg minodronate on vertebral fractures in 704 postmenopausal women with established osteoporosis for 24 months. Subjects were 55 to 80 years old with 1 to 5 fragility fractures between the T4 and L4 vertebrae, and BMD <80% of the young adult mean. A total of 704 subjects were randomized to take minodronate 1 mg (n = 359) or placebo (n = 345) once a day for 24 months. Daily 1 mg minodronate showed a significant reduction in the risk of new vertebral fractures by 58.9% compared with that in the placebo group. In subgroups analysis of this study, minodronate reduced the risk of new vertebral fractures by 59.1% in patients aged 75 years or older at higher fracture risk population, in the same way as in patients aged less than 75 years. Besides, the relative risk reductions of new vertebral fractures by minodronate treatment were 45.2%, 61.1%, and 64.2%, for patients with one, two, and three or more prevalent vertebral fractures, respectively, and 87.8%, 64.6%, and 50.1%, for patients with mild, moderate, and severe grades of prevalent vertebral fractures, respectively. On the other hand, the results of this study showed that the number and severity of prevalent vertebral fractures had significant relationships with the risk of subsequent vertebral fractures. The number of prevalent vertebral fractures was an independent risk factor for incidence of vertebral fractures in multivariate analysis. In conclusion, minodronate reduced the fracture risk even in Japanese patients with osteoporosis at higher risk of fracture.

The Prevalence of Major Radiographic Features of Atypical Femoral Fractures in Thai Patients. Aasis Unnanuntana[1], Sittichai Luangkittikong*[2]. [1]Hospital for Special Surgery, Siriraj Hospital, Thailand, [2]Siriraj hospital, Mahidol University, Thailand

Introduction: The ASMBR described major radiographic features for diagnosing atypical femoral fracture (AFF) including noncomminuted, transverse or short oblique fracture configurations with medial cortical spike. This study's objectives were to evaluate the prevalence of AFF based on the ASBMR major radiographic criteria and compare clinical characteristics between patients with these criteria who had fractures after low- and high-energy trauma.

Methods: We retrospectively reviewed plain radiographs of 734 patients who were diagnosed with subtrochanteric/femoral shaft fractures from January 2002 to May 2011 at Siriraj Hospital, Bangkok, Thailand. Patients with inadequate radiographs, multiple or pathological or periprosthetic fractures were excluded. From a total of 378 cases, only those who had major radiographic features of AFF according to the ASBMR criteria were included. AFF were then divided into 2 groups based on mechanism of injury: low-energy and high-energy fractures. Low-energy fracture was

defined as fracture after fall from a standing height or less. Comparative analyses were made to compare clinical variables between low- and high-energy AFF.

Results: From a total of 378 patients, 76 (20.1%) had the ASBMR major radiographic criteria of AFF. Of 76 patients, 17 (22.4%) occurred after sustaining a low-energy trauma. Low-energy AFF occurred more at the subtrochanteric region (64.7% VS 3.4% of low- and high-energy AFF, respectively). Patients with low-energy AFF were older, more females, associated with higher scores of Charlson comorbidity index and higher rate of bisphosphonates use ($p<0.01$). Forty seven percent of patients with low-energy AFF had history of bisphosphonates use while none in the high-energy AFF group used bisphosphonates. The odds ratio of bisphosphonates use in low-energy AFF was 106.5 (95%CI, 5.7 to 2000.5).

Conclusions: The prevalence of low-energy AFF in Thai patients at a single institution was 4.5%. The majority of patients with the ASBMR major radiographic features (77.6%) had high-energy trauma. Therefore, these major radiographic criteria are not specific for diagnosing a low-energy AFF. Future refinement of the current ASBMR criteria for AFF should be considered.

Undercarboxylated osteocalcin and vitamin K nutritional status in postmenopausal osteoporotic women during bisphosphonate treatment. Jun Iwamoto*. Keio University School of Medicine, Japan

Bisphosphonates reduce serum undercarboxylated osteocalcin (ucOC) levels as well as bone turnover marker levels in patients with osteoporosis. The high ucOC level (>2.6 ng/mL) is reported to be an independent risk factor for incident fractures in Japanese osteoporotic patients during bisphosphonate treatment. The purpose of this study was to reveal the association between serum ucOC levels and vitamin K nutritional status in postmenopausal osteoporotic Japanese women during bisphosphonate treatment. One hundred and six postmenopausal women with osteoporosis (range: 47–90 years) were initiated bisphosphonate treatment (weekly alendronate, weekly risedronate, or monthly minodronate) in our out-patient clinic. Osteoporosis was diagnosed based on the thoracic and lumbar spine radiographs and speed of sound (SOS) measured using a quantitative ultrasound (QUS) device. The treatment was continued for 6 months and serum calcium, phosphorus, alkaline phosphatase (ALP) levels and urinary cross-linked N-terminal telopeptides of type I collages (NTX) levels were monitored during this period. After 6 months of treatment, serum ucOC levels were measured and vitamin K nutritional status was evaluated using the simple vitamin K intake questionnaire developed by Uenishi (Osteoporosis Japan 2011; 19: 513-518). This questionnaire evaluates vitamin K nutritional status using scores based on *natto* (fermented soy bean) and green vegetable intakes. The patients were divided into two groups according to the serum ucOC level: the high ucOC (>2.6 ng/mL) group and the normal ucOC (≤2.6 ng/mL) group, and all parameters were compared between the two groups. Sixteen patients discontinued bisphosphonate treatment during the 6 months of period due to acute phase reaction (n=1), gastric pain (n=2), drug allergy (n=1), tooth extraction (n=2), and noncompliance (n=10). Eighty-four patients were processed for analyses (n=30 in the high ucOC group and n=60 in the normal ucOC group). There were no significant differences in baseline parameters (age, height, body weight, body mass index, serum calcium, phosphorus, ALP, and urinary NTX) and changes in these parameters during the 6 months of period. However, vitamin K nutritional intake score was significantly lower in the high ucOC group than in the normal ucOC group. These results suggest that one-third of postmenopausal osteoporotic patients treated with bisphosphonates are at a higher risk of incident fractures with higher serum ucOC levels due to inadequate vitamin intake despite the reduction in bone turnover similar to those with normal serum ucOC levels.

***Own the Bone*: A system-based intervention to improve osteoporosis care after fragility fractures.** Andrew Bunta[1], Beatrice Edwards*[2], William Macaulay[3], Kyle Jeray[4], Laura Tosi[5], Clifford Jones[6], Deborah Sietsema[7], John Kaufman[8], Sarah Murphy[9], James Goulet[10], Gary Friedlander[11], Mark Swiontkowski[12], Douglas Dirschl[13]. [1]Northwestern University Feinberg School of Medicine, USA, [2]MD Anderson Cancer Center, USA, [3]Columbia University, USA, [4]Greenville Hospital System, USA, [5]Children's National Medical Center, USA, [6]Orthopaedic Associates of Michigan; Michigan State University, USA, [7]Orthopaedic Association of Michigan, USA, [8]Henry Mayo Newhall Memorial Hospital, USA, [9]American Orthopaedic Association, USA, [10]University of Michigan, USA, [11]Yale University, USA, [12]University of Minnesota, USA, [13]University of Chicago, USA

Objective: Approximately 2 million individuals sustain an osteoporosis-related fracture in the United States each year, at an estimated annual cost of more than $19 billion to the Medicare system. The occurrence of fracture seldom triggers osteoporosis assessment and treatment. Thus, the purpose of this study is to evaluate the success of the American Orthopaedic Association's - Own the Bone program for secondary prevention of recurrent fractures in patients 50 years of age and older.

Design: A retrospective pre-intervention (a pilot study) and postintervention study.

Setting: Sixty-three academic and community hospitals or orthopaedic outpatient centers participating in the program between June 1, 2009, and September 30, 2012. Patients: Patients aged 50 years or older presenting with fragility fractures (n=7065) were enrolled in the Own the Bone web registry.

Interventions: Physicians recommended calcium and vitamin D supplementation, increased exercise, fall prevention, smoking cessation, limited alcohol intake, bone mineral density (BMD) testing, and osteoporosis medications and sent letters to the patient and the patient's primary care physician (PCP) explaining these recommendations

Main Outcomes Measures: The percentage of physicians recommending each quality measure and communicating with PCP as well as patient compliance with BMD testing, compared with pilot study data.

Results:All quality measures improved compared with the pilot study ($p = 0.001$), including calcium and vitamin D intake (95.6%vs. 80%);exercise (95.5% vs. 87%), fall prevention (96.6% vs. 80%), smoking cessation (82.2% vs. 81.8%), osteoporosis medication (85.7% vs. 5%), and BMD testing recommendations (67.6% vs. 11%). BMD testing was completed in 43.5%of patients (compared with 5% in the pilot study), and letters were sent to 86.8% of patients (vs. 77%) and to primary care physicians for 82.8% of patients (vs. 75%). After a 90-day follow up, the percentage of MD's recommending or initiating therapy ranged from 30 - 78%.

Conclusions and Relevance: The Own the Bone intervention has succeeded in improving the behaviors of participating orthopaedic surgeons, medical specialists and PCP's in the areas of bone health and osteoporosis counseling, coordination of care, BMD testing, and recommendations for or initiation of pharmacotherapy for patients who have experienced a fragility fracture.

SU0392

Change in osteoporosis treatment rates after implementation of an electronic consult service for patients with recent fracture. Richard Lee*[1], Kenneth Lyles[2], Megan Pearson[3], Karen Barnard[4], Cathleen Colon-Emeric[2]. [1]Duke University, USA, [2]Duke University Medical Center, USA, [3]Durham VA Medical Center, USA, [4]Duke University Medical Center, Durham VAMC, USA

Background: According to the Office of the Inspector General, less than 9 percent of Veterans received a prescription for an osteoporosis medication within 6 months after an index fracture. An electronic consult (E-consult) service was implemented at 2 Veterans Affairs Medical Centers (VAMCs) and affiliated outpatient clinics to facilitate identification of and to recommend management for patients with recent fracture.

Method: The E-consult service identified Veterans with osteoporotic fractures from inpatient and outpatient encounter data, based on ICD9 diagnosis codes (800-829) from the central data warehouse. Patients were excluded if they were deceased, receiving palliative care, under 50 years, had no primary provider assigned, or if fracture management was already addressed by the primary provider. The medical record of an eligible patient was reviewed by a metabolic bone specialist, and an electronic consult note was sent to the patient's primary provider that specified recommendations for further management. Recommendations were initiated per the provider's discretion.

Results: Prior to implementation of the E-consult service, the rate of osteoporosis treatment at the intervention sites, among patients with recent fractures, was 4.7% for bisphosphonates and 12.3% for vitamin D. After implementation of the program, the treatment rate increased to 5.9% ($P = 0.43$) for bisphosphonates and 17.6% ($P = 0.01$) for vitamin D. The change in treatment rates was not significantly different than the concurrent change among VAMCs without the E-consult service, -1.8% ($P = 0.12$) and +1.5% ($P = 0.10$), respectively.

Conclusion: Implementation of an E-consult service was not able to significantly increase the rate of osteoporosis treatment among patients with a recent fracture. These results suggest an electronic service is feasible, but a program with more direct patient interaction is likely required to significantly improve treatment rates.

SU0393

Management of Fragility Fracture: An Integrated Interdisciplinary Approach. Marie-Claude Beaulieu*[1], Hélène Corriveau[1], Gilles Boire[2], François Cabana[3], Earl Bogoch[4], Pierre Dagenais[5], Suzanne Gosselin[1], Diane Theriault[6], Bernard Burnand[7], Sonia Jean[8], Johanne Filiatrault[9], Sophie Laforest[9], Marie Rochette[10], Alvine Fansi[1], Isabelle Gaboury[1]. [1]Université de Sherbrooke, Canada, [2]Centre Hospitalier Universitaire De Sherbrooke, Canada, [3]CHUS, Canada, [4]St. Michael's Hospital, Canada, [5]INESS, Canada, [6]Dartmouth General Hospital, Canada, [7]CHUV, Switzerland, [8]INSTITUT NATIONAL DE SANTÉ PUBLIQUE DU QUÉBEC, Canada, [9]Université de Montréal, Canada, [10]MSSQ, Canada

In most Canadian provinces, governmental and community organizations provide fall prevention or fragility fracture (FF) prevention programs; however, none fully integrates fall prevention with post-fracture management. It is increasingly accepted that the success of fall prevention and post-fracture screening and treatment programs is mediated by the context in which interventions occur within the local healthcare system and with primary care practitioners.

A secondary FF prevention model is currently under implementation in the province of Québec (Canada). The program is complemented by a research project which aims to 1) compare the performance of these integrated programs to results from conventional care, using a pragmatic study design; 2) identify barriers as well as factors that improve effectiveness across different implementation milieus; and 3) develop and engage in active knowledge transfer activities with clinicians.

The program relies on a collaborative process between secondary healthcare (orthopaedic surgeons and bone specialists), primary care physicians (PCPs), and local and provincial fall prevention programs. This is orchestrated by a program coordinator. The 3192 expected participants are identified for recruitment as outpatients in orthopaedic clinics, inpatients with hip fracture, and from administrative discharge data from the emergency departments and hospital wards. An integrated approach (pharmacological intervention, promotion of healthy habits and fall prevention program) is offered to the intervention group. The research program measures different short-, intermediate-, and long-term outcomes over a 18-month period, including: recurrent fractures, initiation and compliance with osteoporosis treatment, time to first subsequent fall, number of falls, FF-related death, practice of physical activities, participant's quality of life, FF related costs, and perception of care integration.

This novel integrated FF prevention program will help health professionals to improve patient-centered care, and promote chronic disease prevention and management, including interprofessional collaboration and communication between both primary and secondary healthcare practitioners. Lastly, the pragmatic evaluative design of this project will provide estimates of the effectiveness of a FF prevention program in different geopolitical contexts.

A Successful Knowledge Translation Intervention in Long-Term Care: Results from the Vitamin D and Osteoporosis (ViDOS) Cluster Randomized Trial. Alexandra Papaioannou*[1], Courtney Kennedy[2], George Ioannidis[2], Lora Giangregorio[3], Lehana Thabane[2], Suzanne Morin[4], Richard Crilly[5], Sharon Marr[2], Robert Josse[6], Lynne Lohfeld[2], Laura Pickard[2], Mary-Lou van der Horst[7], Jackie Stroud[8], Glenda Campbell[8], Lisa Dolovich[2], Anna Sawka[9], Lynn Nash[2], Ravi Jain[10], Carly Skidmore[2], Jonathan Adachi[11]. [1]Hamilton Health Sciences, Canada, [2]McMaster University, Canada, [3]University of Waterloo, Canada, [4]McGill University, Canada, [5]University of Western Ontario, Canada, [6]St. Michael's Hospital, University of Toronto, Canada, [7]Ontario Osteoporosis Strategy for Long-Term Care, McMaster University, Hamilton Health Sciences, Canada, [8]Medical Pharmacies Group Limited, Canada, [9]Toronto General Hospital, Canada, [10]Osteoporosis Canada, Canada, [11]St. Joseph's Hospital, Canada

Background: Meta-analyses demonstrate that vitamin D reduces falls, and calcium and vitamin D reduce fractures in LTC residents. The objective of the ViDOS trial was to evaluate the feasibility and effectiveness of a knowledge translation (KT) intervention aimed at integrating evidence-based osteoporosis/fracture prevention strategies in Long-term Care (LTC) homes.Methods: We randomized 40 LTC homes in Ontario, Canada to intervention (n=19) or control (n=21) arms. Interdisciplinary teams (physicians, nurses, pharmacists, dietitians) in intervention homes participated in a 12-month multifaceted program. Key components were 3 interactive sessions facilitated by an Expert Opinion Leader (via webinar), audit and feedback, point-of-care tools, and action planning for quality improvement. Control homes received toolkits and optional webinars offered to all Ontario LTC homes. Primary outcomes were the proportion of residents prescribed vitamin D ⩾800 IU/day (primary) and ⩾500 mg/day of elemental calcium at 12-months. We examined differences between intervention arms in the proportion of all residents prescribed vitamin D/calcium using the generalized estimating equations technique assuming an exchangeable correlation structure. Unit of analysis was the resident; unit of inference was the LTC home. Analyses were age-sex adjusted. Prescribing rates and odds ratios (95% CI's) are reported. Results: After randomisation, 7 LTC homes in the intervention group declined to participate (operational issues); they were excluded. 4660 residents [mean 84.5 (SD 10.7) years] resided in the remaining 33 LTC homes [mean size= 180 beds (SD 80)] and at baseline the proportion of residents prescribed vitamin D (⩾800 IU/day) and calcium (⩾500 mg/day), respectively, were: 38.8%, 32.7% of residents in intervention homes and 41.9%, 34.8% in control homes. At 12-months, vitamin D (⩾800 IU/day) was prescribed to 72.4% of residents in the intervention arm versus 49.4% in the control arm (OR 3.14, 95% CI: 2.23, 4.41); and calcium (⩾500 mg/day) was prescribed to 45.5% of residents in the intervention arm versus 37.5% in the control arm (OR 1.59, 95% CI: 1.12, 2.25). Conclusion: This study demonstrated that an interdisciplinary, multifaceted knowledge translation intervention significantly improved prescribing of appropriate vitamin D and calcium in the LTC setting.

Effect of a Mixture of Calcium, Vitamin D, Inulin and Soy Isoflavones on Bone Metabolism in Post-Menopausal Women: A Retrospective Analysis. Giorgio Gandolini[1], Maurizio Bevilacqua*[2], Matteo Alemanni[3]. [1]IRCCS S. Maria Nascente - Don C. Gnocchi Foundation - Milan, Italy, [2]Ospedale L. Sacco - Polo Universitario, Italy, [3]Medical Affairs, Medical Department, Bayer SpA – Pharmaceuticals, Milan, Italy, Italy

Objectives.

Aging might affect the effectiveness of the sole supplementation of calcium and vitamin D in post-menopausal women, due to the development of vitamin D resistance in the gut, which limits calcium absorption. Thus, we wanted to test the efficacy of a mixture of calcium (500 mg), serum 25-hydroxyvitamin D (25(OH)D; 300 UI), inulin (3 g) and soy isoflavones (40 mg), present on the Italian market (Calcidon Menopausa), to improve calcium absorption in this type of population.

Study design.

A retrospective study on otherwise healthy post-menopausal women. Main outcome measures The following parameters were evaluated at baseline and after three months of supplementation: daily calciuria – as an indirect marker of calcium absorption – serum 25(OH)D, parathormone, insulin-like growth factor 1 (IGF-1) as a marker of bone anabolism, collagen telopeptide and osteocalcin as markers of bone resorption.

Results.

Twenty-eight women (median age 67 years) were included in the analysis. The supplementation markedly increased daily calciuria (+60%; $p = 0.00009$), while reducing parathormone levels (-18%; $p = 0.02$) and leaving 25(OH)D unaltered. An increase in IGF-1 (+16%; $p = 0.01$) and a reduction in collagen telopeptide (-17%; $p = 0.04$) were observed, too, as well as a modest trend towards osteocalcin reduction, although not significant. Conclusions.

These results suggest that the considered mixture improved intestinal calcium absorption and bone metabolism in postmenopausal women. Since the amount of supplemented calcium was relatively low and 25(OH)D levels were unchanged, the observed effects are likely due to the combined contributions of inulin and soy isoflavones.

Efficacy of Continuing with Alendronate or Risedronate after Long-term use can be Improved by Adding Alfacalcidol Instead of Plain Vitamin D in Postmenopausal and Male Osteoporosis. Johann D. Ringe*[1], Erich Schacht[2]. [1]West-German Osteoporosis Center, Klinikum Leverkusen (University of Cologne) Leverkusen, Germany, [2]Zurich Osteoporosis Research Group (ZORG), Zollikerberg, Switzerland, Switzerland

Background: Oral once weekly bisphosphonates (BP) are the leading treatment for osteoporosis, but the optimal duration of application has not been defined. A recent publication suggests periodically re-evaluating of such patients and to discontinue in case of low risk and continuation in patients still at high risk (1).

Patients and methods: In our study based on retrospective chart analysis we followed 214 patients (167 female, 47male) still at a significantly increased fracture risk after an average of 4.3 years of oral once weekly BP. 145 had taken alendronate (ALN), 69 risedronate (RIS). We compared continuation of the same BP plus either plain vitamin D as before (group A, n=106) or switching to the active D-hormone analog alfacalcidol (group B, n=108) over 2 more years. Primary endpoint was changes in BMD at the lumbar spine (LS) and femoral neck (FN). Further endpoints were falls, back pain, fractures and adverse events.

Results: The two groups were well matched in terms of age, BMI and severeness of osteoporosis. The respective proportions of males and females and patients with ALN or RIS intake did not differ between the 2 groups. BMD at LS and FN did not change significantly over 2 years in group A, but increased significantly with BP plus alfacalcidol. The average number of falls per patient-year was reduced by 12% in A

(ns) and by 44% in B ($p<0.03$). There was a significant decrease in average back pain score with BP plus alfacalcidol vs. BP plus plain vitamin Vit. D after two years ($p<0.02$). The number of patients with new vert. fractures did not significantly differ between A and B while we found a significantly lower rate of non-vert. fractures with alfacalcidol ($p<0.05$). The pattern of adverse events (AE) did not differ between groups.

By subgroup analysis we could show that men were on the average significantly younger than women (67 vs. 72 years) and had a relatively higher proportion of RIS takers (43% vs. 29%). Nevertheless the overall superiority of the combination BP plus alfacalcidol vs. plain vitamin D in all endpoints was also true for females and males alone and for patients on ALN or RIS once weekly. While the advantage of combining ALN with alfacalcidol had been shown in different previous studies this is the first trial to prove that also RIS plus alfacalcidol is advantageous (2).

Potassium Citrate Supplementation Results in Sustained Improvement in Calcium Balance in Older Men and Women. Kendall Moseley*[1], Connie Weaver[2], Lawrence Appel[3], Anthony Sebastian[4], Deborah Sellmeyer[5]. [1]Division of Endocrinology, Johns Hopkins Bayview Medical Center, USA, [2]Purdue UniversityDept of Nutrition Science, USA, [3]Johns Hopkins University, USA, [4]University of California San Francisco, USA, [5]The Johns Hopkins Bayview Medical Center, USA

The dietary acid load created by the typical Western diet may adversely impact the skeleton by disrupting calcium metabolism. Whether neutralizing dietary acid with alkaline potassium salts results in sustained improvements in calcium balance remains controversial. In this randomized, double blind, placebo controlled study, 52 men and women (mean age 65.2 + 6.2 years) were randomly assigned to potassium citrate 60 mmol, 90 mmol or placebo daily with measurements of bone turnover markers, net acid excretion, and calcium metabolism including intestinal fractional calcium absorption and calcium balance obtained at baseline and six months. At six months, net acid excretion was significantly lower in both treatment groups compared to placebo and negative, meaning subjects' dietary acid was completely neutralized (-11.3 mmol/day, 60 mmol/day; -29.5 mmol/day, 90 mmol/day, $P < 0.001$ compared to placebo). At 6-months, 24-hour urine calcium was significantly reduced in persons taking potassium citrate 60 mmol (-46 $\pm$ 15.9 mg/day) and 90 mmol (-59 $\pm$ 31.6 mg/day) daily compared with placebo ($p<0.01$). Fractional calcium absorption was not changed by potassium citrate supplementation. Net calcium balance was significantly improved in participants taking potassium citrate 90 mmol/day compared to placebo (142 $\pm$ 80, 90 mmol vs. -80 $\pm$ 54, placebo; $p = 0.02$). Calcium balance was also improved on potassium citrate 60 mmol/day, but this did not reach statistical significance ($p=0.18$). Serum C-telopeptide decreased significantly in both potassium citrate groups compared to placebo (-0.03 + 0.04 nmol/L , 90 mmol/d, $p=0.05$; -0.07 + 0.04 nmol/L , 60 mmol/day, $p=0.02$) while bone specific alkaline phosphatase did not change. Intact parathyroid hormone was significantly decreased in the 90 mmol/day group ($p=0.01$). Readily available, safe, and easily administered in an oral form, potassium citrate has the potential to improve skeletal health. Longer term trials with definitive outcomes such as bone density and fracture are needed.

SU0398

Role of Vitamin D Status on Strontium Absorption after a Strontium Ranelate Oral Overload Test and its Influence on Parathyroid Hormone (PTH) Levels. Tatiane Vilaca*[1], Marilia Camargo[1], Olguita Rocha[2], Marise Lazaretti Castro[3]. [1]Unifesp, Brazil, [2]CETEC, Brazil, [3]Escola Paulista de Medicina, Brazil

Strontium ranelate (SrR) is a drug used to treat osteoporosis in many countries. Calcium (Ca) and strontium (Sr) have common features and are absorbed by the same pathways and it is well established that vitamin D is important for Ca intestinal absorption. We aimed to evaluate whether vitamin D status is determinant for Sr absorption and to investigated the PTH behavior after this Sr overload. For this, 25 postmenopausal women with vitamin D deficiency (25OHD<50nmol/L) and 25 women with sufficiency (25OHD>75nmol/L) were submitted to an oral Sr overload test. After that, deficient patients were treated until reaching adequate vitamin D levels (25OHD>75nmol/L) and the Sr test was repeated. Sr absorption was evaluated as the fraction of the absorbed dose and the area under the curve. Blood PTH, $1,25(OH)_2$ D and Sr were measured. One gram of SrR (Protos^{TM}, Servier) was dissolved in 200 mL of deionized water and administered orally. Blood was drawn for Sr and PTH determinations at 30, 60, 120 and 240 minutes. Sr concentrations increased similarly in both groups, no matter the Vitamin D status. No differences were found in any Sr absorption parameters between the vitamin D deficient and sufficient groups. Moreover, no difference in Sr absorption was found in the deficient group before and after treatment. Nevertheless, the correction of vitamin D status in deficients resulted in a significant increase in 1,25(OH)2D (25.0$\pm$4.6 to 34.6$\pm$9.1 pg/mL $p<0,001$) and a reduction in PTH (73.9$\pm$37.5 to 58.2$\pm$20.1 pg/mL $p=0,006$). The Sr increment on blood was followed by a significant decrease in PTH levels. The mean PTH decrement was 27.7% for sufficient, 23.8% for deficient and 26.6% after Vitamin D correction. Interestingly, this decrease was transient, despite crescent concentrations of Sr, with most patients reaching a nadir at 60 min. In conclusion, Vitamin D status seems not to be determinant for strontium ranelate absorption. In fact, all patients had 1,25(OH)2D within the normal range, regardless of their vitamin D status. This finding is in agreement with the idea that, in the absence of kidney failure, vitamin D deficiency must be very severe to cause deficiency in 1,25(OH)2D. Strontium ingestion causes a variation in PTH levels. The anabolic effect on bone of a pulse elevation of PTH is well known but the effects of the acute decrease are not described. More studies need to be performed to evaluate the effects of this PTH oscillation on bone metabolism.

"Is this exercise safe?" - Building consensus around responses to common questions about physical activity posed by people with osteoporosis. Lora Giangregorio*[1], Maureen Ashe[2], Kathy Shipp[3], Angela M. Cheung[4], Ari Heinonen[5], Alexandra Papaioannou[6], Stuart McGill[1], Judi Laprade[7], Ravi Jain[8], Heather Keller[1], Norma MacIntyre[9], John Wark[10]. [1]University of Waterloo, Canada, [2]University of British Columbia, Canada, [3]Duke University Medical Center, USA, [4]University Health Network-University of Toronto, Canada, [5]Department of Health Sciences, University of Jyväskylä, Finland, [6]Hamilton Health Sciences, Canada, [7]University of Toronto, Canada, [8]Osteoporosis Canada, Canada, [9]McMaster University, Canada, [10]University of Melbourne Department of Medicine, Australia

Background: There is little evidence to guide responses to questions commonly asked by individuals with osteoporosis about safe and effective physical activity for health benefits, or safety around activities of daily living.

Objective: The Too Fit To Fracture (2F2F) initiative will create exercise recommendations for people with osteoporosis with or without vertebral fracture, by synthesizing evidence and expert consensus. We report findings from step two in hte Too Fit To Fracture initiative, a consensus process designed to address questions often asked by patients.

Methods: The 2F2F expert panel identified researchers and clinicians with expertise in exercise and osteoporosis, and stakeholder groups (e.g., Osteoporosis Canada, National Osteoporosis Foundation). We used FluidSurveys to deliver a modified RAND/UCLA Delphi survey to 75 invitees. We presented three clinical cases (moderate risk, one vertebral fracture, multiple vertebral fractures/hyperkyphosis/pain) and asked about assessment and exercise prescription; questions included those commonly asked by patients. Descriptive statistics were used to summarize participant characteristics and responses. Content analyses of free text responses were performed by two expert panel members, and merged.

Results: Of 75 invitees, 39 participated (52% response rate). In cases with prevalent vertebral fractures , there was less confidence that existing physical activity guidelines were appropriate (Table 1). There was consensus in the following areas: 1) the importance of resistance and balance training e; 2) spinal extension exercises should be performed; 3) those with vertebral fractures should receive instruction on safe movement and body mechanics, especially in the presence of pain or kyphosis. Regarding activities considered risky, (e.g., golf, yoga), patients with a history of the activity or strong preference may be able to do it with modification, e.g., for yoga controlled twisting in supine, where the spine is least loaded. Other areas of consensus emerged around activities of daily living and safe movement.

Conclusions: Using patient questions to inform the process has generated a number of recommendations that will make the development of exercise recommendations more comprehensive and patient-centred. Further, the process has highlighted a number of gaps that can inform future research.

Table 1: Responses to the question "Do you think that the physical activity guidelines detailed above* (CSEP, ACSM, WHO) are appropriate for this case?" Presented as a % of total respondents (n=39)

	Moderate risk	High risk (1 vertebral fracture)	High risk (1 vertebral fracture, pain, hyperkyphosis)
Yes	54%	31%	25%
No	36%	49%	62%
I don't know	4%	10%	22%
Missing	0	10%	15%

*We provided a summary of the guidelines in the survey. CSEP = Canadian Society for Exercise Physiology, ACSM = American College of Sports Medicine, WHO = World Health Organization

Effect of Denosumab Treatment on Bone Histology and Histomorphometry in Men With Low Bone Mineral Density. David Dempster*[1], David L Kendler[2], Jesse Hall[3], Steven Boonen[4], Michael Bolognese[5], Roland Chapurlat[6], Stefan Goemaere[7], Lars Hyldstrup[8], E Michael Lewiecki[9], Paul Miller[10], Yu-Ching Yang[3], Rachel B Wagman[3], Bente Langdahl[11]. [1]Columbia University, USA, [2]University of British Columbia, Canada, [3]Amgen, Inc., USA, [4]Leuven University, Belgium, [5]Bethesda Health Research Center, USA, [6]Hopital Edouard Herriot, France, [7]Ghent University Hospital, Belgium, [8]Hvidovre Hospital, Denmark, [9]New Mexico Clinical Research & Osteoporosis Center, USA, [10]Colorado Center for Bone Research, USA, [11]Aarhus University Hospital, Denmark

Purpose: In the phase 3 ADAMO trial in men with low bone mineral density (BMD), 1 year of denosumab (DMAb) treatment significantly increased BMD compared with placebo.[1] Consistent with DMAb's mechanism of action, DMAb-treated subjects had reduced bone resorption as measured by serum C-terminal telopeptide. It has been shown that transiliac crest bone biopsies from women with postmenopausal osteoporosis (PMO) treated with DMAb for up to 5 years demonstrated normal bone quality and decreased remodeling at the tissue level.[2,3] Here, we report the effects of DMAb on bone histology and histomorphometry after 1 year of treatment in a subset of ADAMO subjects.

Methods: Following labeling with tetracycline or demeclocycline, transiliac crest bone biopsy was performed as a substudy of the phase 3 ADAMO trial ≤ 30 days before the year-1 visit. For biopsies with only single labels in trabecular bone within the measurable field (20 mm^2), mineral apposition rate was imputed as 0.3 μm/day.

Results: A total of 29 subjects (17 DMAb; 12 placebo) participated in the bone biopsy substudy. Demographics for this subset were comparable with that of the overall ADAMO population. Mean (SD) number of months from the last dose of DMAb to the first dose of label was 5.0 (0.5) months. Qualitative bone histology, assessed in all samples, was unremarkable, showing normally mineralized lamellar bone. Structural indices, including cancellous bone volume and trabecular number and surface, were similar between treatment groups (Table). Consistent with the mechanism of action, bone remodeling was decreased in DMAb-treated subjects. A total of 12/17 (71%) DMAb- and 12/12 (100%) placebo-treated subjects had specimens with double labels in trabecular and/or cortical compartments; 6 DMAb- and 12 placebo-treated subjects were evaluable for dynamic trabecular bone parameters. Static and dynamic remodeling indices were lower in DMAb- than placebo-treated subjects, consistent with reduced bone turnover with DMAb therapy.

Conclusions: Treatment of men with low BMD with DMAb for 1 year resulted in qualitatively normal bone with reduced bone turnover. These findings are consistent with those from women with PMO treated with DMAb for 1, 2, 3, or 5 years.

Effect of TNF inhibitors on BMD in patients with ankylosing spondylitis- a systematic review and meta-analysis. Nisha Nigil Haroon*[1], Jeevitha Srighanthan[2], Angela M. Cheung[3], Robert.D. Inman[4], Nayef Al Ghanim[5]. [1]University of Toronto, Canada, [2]Osteoporosis Program, University Health Network, Canada, [3]University Health Network-University of Toronto, Canada, [4]Rheumatology division, University Health Network, Canada, [5]UHN Toronto Western Hospital, Canada

Background: Patients with ankylosing spondylitis (AS) are susceptible to osteoporosis (OP) and have high fracture risk. Currently, no specific strategies are established to treat OP in these patients. TNF inhibitors are now increasingly used for treating AS. If TNF inhibitors are shown to prevent or reverse bone loss, use of OP medications like bisphosphonates can be avoided. Thus, we did a systematic review and meta-analysis to study the effect of TNF inhibitors on spine and hip BMD in patients with AS.

Methods: 2 authors searched MEDLINE, EMBASE & Cochrane databases (inception to February, 2013), reviewed abstracts,read selected articles in full and extracted data. Discrepancies were resolved by a 3rd author. Studies included had at least 70% of subjects satisfying Modified New York AS criteria and a minimum follow-up of 1 year. Case reports &studies on children and adolescents were excluded. The quality of the studies was assessed by Newcastle–Ottawa Quality Assessment Scale. Primary outcomes (BMD at spine, total hip &femoral neck) were analyzed at 1 and 2 years, to reflect the time points used in our abstracted literature. BMD was expressed as the percent change from baseline. Publication bias was assessed by Funnel plots comparing weight & effect size. Statistical heterogeneity was assessed using Q statistic. The overall summary estimate was determined using the random effects model, which was weighted by the inverse variance of the effect size.

Results:Our search retrieved 5207 articles which were narrowed down to 7 studies (6 observational studies &1 randomized controlled trial; N = 285 at 1 year, 394 at 2 years). 76-92% of subjects were men. Bisphosphonate use was negligible (n=12). Little data was available on intake of calcium /vitamin D. The use of TNF inhibitors led to significant improvement in spine and total hip BMD after 1 and 2 years when compared to baseline (Table).Femoral neck BMD remained stable at 1 year. The BMD gain was also significant in those treated with TNF inhibitors when compared to controls. In a RCT (TNF inhibitors vs. placebo), the gain in BMD was significantly higher in those treated with TNF inhibitors for 2years versus those treated with placebo for the initial 6 months.Conclusions: Treatment with TNF inhibitors is associated with improvement in spine and hip BMD in patients with AS. More studies of longer duration and larger sample sizes are needed to better understand the effect of TNF inhibitors on fracture risk.

Table: Summary estimates of the effect of TNF inhibitors on BMD in patients with AS

Duration of follow up (years)	Lumbar spine Mean difference,% (95% CI)	Total hip Mean difference,% (95% CI)	Femoral neck Mean difference,% (95% CI)
1 year	5.05 (4.01-6.09)	1.77 (1.03-2.52)	0.73 (-0.78-2.23)
2 years	8.71 (6.71-10.72)	2.45 (1.92-2.98)	Insufficient data

A Novel ^{41}Ca Assay to Measure Short and Long-term Mineral Kinetics in Patients Undergoing Cancer Therapy. Susanta Hui*[1], Luke Arentsen[1], Thanasak Sueblinvong[1], Levi Downs[1], David Potter[1], Gary Grammens[1], Rahel Ghebre[1], Sharon Allen[1], Anne Minenko[1], Yang Zhang[2], Chap Le[1], Jerry Froelich[1], George Jackson[3], Maryka Bhattacharyya[4], Douglas Yee[1]. [1]University of Minnesota, USA, [2]Creighton University, USA, [3]Purdue University, USA, [4]Georgia Health Sciences University, USA

Cancer survivors have an increased risk of osteoporotic fractures. *We report here a new isotope* ^{41}Ca *(measured by ultra-sensitive accelerator mass spectrometry) to study bone mineral kinetics in* cancer patients undergoing anti-cancer therapy and prevention of bone loss. *Patients with estrogen positive* breast cancer, ovarian cancer, endometrial cancer receive microdose (below background) of ^{41}Ca during on initial visit to clinic. 4-8 weeks later Patients undergo standard treatment: Aromatase inhibitor for breast cancer, chemotherapy (platinum- and taxane-based regimen) for Ovarian cancer, Chemo and pelvic radiation (45-50 Gy in 25-28 fractions) ± high dose rate brachytherapy (5-18 Gy) for endometrial cancer. 200-400 ml of urine is collected at frequently for 30 days to establish initial excretion rate prior to treatment and later once in two months for one year. For low bone density group, bisphosphonate drug is used as intervention and followed with ^{41}Ca assay. DXA, QCT, were performed. Rapid excretion of ^{41}Ca, following quasi steady state. In breats patients, with 3 patients maintaining and 7 patients increasing their levels of bone remodeling (Figure 1A). The maintenance or loss of bone was confirmed in all patients who are far enough along in the study to have received a follow-up DECT and DXA measurement. The onset of *increased bone remodeling (elevated ^{41}Ca/Ca) is associated with the start of aromatase inhibitor (AI) at day 60.*

Oophorectomy and chemotherapy show elevated excretion of ^{41}Ca/Ca in region II (Figure 1B). This pilot study also helped us perfect our techniques, including timing for ^{41}Ca injection in the hospital, and demonstrates the feasibility of this approach. We observed (Figure 1C) a rapid response to antiresorptive (mainly ZA) treatment intervention using the ^{41}Ca/Ca assay with a) a rapid decrease within 30 days from the start of the BP intervention, b) a slow decrease between 30-60 days and c) a trend to a quasi-steady state. We measured a statistically significant ($p<0.0001$, general linear mixed models) decrease in ^{41}Ca/Ca from the baseline (pre-intervention) at 90 days post BP initiation. The clinical advantage of using ^{41}Ca assay in the intervention is that it may allow us to obtain an early measure of response to BP intervention on bone, thus allowing us to optimize treatment dose or guide alternative drug selection.

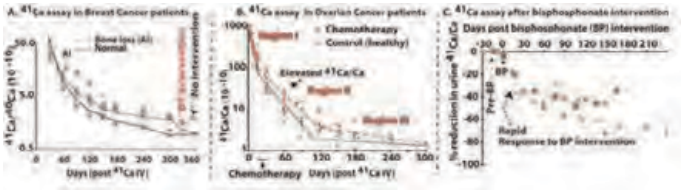

Figure 1. 41Ca detection

Evaluation of QOL and Fracture Probability Using FRAX in Japanese Postmenopausal Women with Osteoporosis Treated with Raloxifene. Kousei Yoh*[1], Etsuro Hamaya[2], Masanori Taketsuna[3], Hisashi Urushihara[4], Kiyoshi Tanaka[5]. [1]Department of Orthopedic Surgery, Hyogo College of Medicine Sasayama Hospital, Japan, [2]Eli Lilly, Japan, [3]Eli Lilly Japan K.K., Japan, [4]Eli Lilly Japan K.K. & Ethics Committee, Graduate School & Faculty of Medicine, Kyoto University, Japan, [5]Kyoto Women's University, Japan

Kanis et al.* analyzed the data from a global large-scale clinical trial and found that raloxifene hydrochloride (RLX) significantly reduced the risks of all clinical and morphometric fractures regardless of the FRAX risk, that is the 10-year probability of major osteoporotic fractures estimated with the fracture risk-assessment tool (FRAX® version 1.3). Previously, we reported on QOL improvement in Japanese patients with postmenopausal osteoporosis treated with RLX. To date, however, no report that assessed QOL with the fracture risk at baseline using FRAX in Japanese patients treated with RLX has been published. In this study, we investigated changes in QOL in Japanese postmenopausal women treated with RLX in relation to the FRAX risk. Patients with postmenopausal osteoporosis (diagnosed based on the diagnostic criteria for primary osteoporosis, 2000 version) participated in this study and were administered RLX for 24 weeks. The FRAX risk was assessed before RLX administration. QOL improvement by 24-week RLX treatment was evaluated by changes from baseline in each score of QOL instruments (SF-8, EQ-5D, VAS and Japanese osteoporosis quality of life questionnaire [JOQOL] 2000). Subgroup analyses based on the FRAX risk $<15\%$ and $\geqslant 15\%$ were conducted with the patient (aged $\geqslant 50$ and <75 years) data for the primary evaluation. Of the 536 enrolled patients, 506 were included in the analysis (mean age: 70.7). The mean FRAX risk level for 411 patients utilized in the subgroup analyses was $15.96 \pm 9.66\%$ at baseline. The baseline scores in EQ-5D, VAS, and JOQOL2000 showed significant differences between the FRAX risk $<15\%$ and $\geqslant 15\%$ groups (p=.006 to .001). At 24 weeks, all QOL instruments at both groups, except for SF-8 mental component of the FRAX risk $\geqslant 15\%$ group (p=.061), significantly improved in scores compared to baseline (p=.001) with the mean changes from baseline in JOQOL2000 of 3.5 ± 9.1 for the FRAX risk $<15\%$ group and 7.4 ± 9.1 for the $\geqslant 15\%$ group. No significant differences in changes from baseline between the groups were shown in physical and mental component summary of SF-8 and EQ-5D (p=.153, .647, and .155, respectively). Meanwhile, in VAS and JOQOL2000, there were significant differences between the groups (p=.001 and .045, respectively). In conclusion, the results suggest that QOL improved in Japanese patients with postmenopausal osteoporosis treated with RLX, regardless of major osteoporotic fracture probability.

Osteoporosis Assessment Questionnaire-Physical Function (OPAQ-PF): a Psychometrically Validated Osteoporosis-Specific Patient Reported Outcome Measure of Daily Activities of Physical Function. April Naegeli[1], Annabel Nixon[2], Helen Doll[3], Sarah Shingler[3], Katie Breheny[3], Russel Burge*[1], Stuart Silverman[4], Deborah Gold[5]. [1]Eli Lilly & Company, USA, [2]Oxford Outcomes, an ICON plc., United Kingdom, [3]Oxford Outcomes, United Kingdom, [4]Cedars-Sinai/UCLA, USA, [5]Duke University Medical Center, USA

This study aimed to evaluate the measurement properties of the Osteoporosis Assessment Questionnaire-Physical Functioning (OPAQ-PF), a new 15-item scale modified from the OPAQ (Silverman, 2000) to measure the impact of osteoporosis on daily activities of physical functioning.

A prospective psychometric validation study of the OPAQ-PF was conducted in a sample of 141 post-menopausal women with moderate to severe osteoporosis (T-score $\leq$-2.5) or a history of a fragility/non-traumatic fracture, 37 of whom had experienced a recent fragility fracture (<6 weeks). Participants completed the SF-36, QUALEFFO-41, WOMAC and four performance based measures (PBMs) at baseline, to assess the construct validity of the OPAQ-PF. Patients without a recent fracture completed the OPAQ-PF and global items 2 weeks after baseline to assess test-retest reliability. Patients with a recent fracture completed the same measures 12 and 24 weeks post-baseline to assess ability to detect change and identify a meaningful change score. Dimensionality of the OPAQ-PF was evaluated by exploratory and confirmatory factor analysis (EFA, CFA).

The OPAQ-PF had a good distribution of scores for recent fracture patients: scores ranged across almost the entire spectrum of the 0-100 scale; median score 58.7. EFA identified a single factor explaining the majority of the variance in the data (75% on principal component extraction). CFA confirmed a total OPAQ-PF score best represents the underlying construct. The OPAQ-PF had good internal consistency (α=0.974) and stability over a two week period amongst patients reporting no global change (ICC range 0.92 - 0.95). The OPAQ-PF differentiated between patients with and without recent fracture, and by severity of osteoarthritis (WOMAC $\geqslant$40). As predicted, the OPAQ-PF correlated strongly with physical and physical function domains of the WOMAC, the SF-36, the QUALEFFO-41 and with performance-based measures ($r>0.3$, $p<0.001$). High correlations were observed between changes in OPAQ-PF score and changes in global concept scores in patients with a recent fracture ($r\geqslant 0.6$, 24-week change). Effect sizes of OPAQ-PF score change increased by level of global change at 12 and 24 weeks ($p<0.001$). Anchor-based methods identified an OPAQ-PF change of >10 at an individual level as meaningful to patients.

The OPAQ-PF has been developed and evaluated following regulatory guidelines for measuring treatment benefit in clinical trials, and has strong psychometric properties.

***In Vivo* Bone Dynamic Imaging Reveals Increased Bone Formation and Inhibited Bone Resorption in Rat Tibia in Response to Combined Alendronate (ALN) and PTH Treatment.** Chantal De Bakker*, Allison Altman, Wei-Ju Tseng, Mary Beth Tribble, Beom Kang Huh, Abhishek Chandra, Ling Qin, Xiaowei Liu. University of Pennsylvania, USA

Anti-resorptive and anabolic agents, such as ALN and PTH, each improve bone quality. However, the effects of combined therapy are controversial, partly due to the inability of standard CT and histology to assess the dynamic process of bone remodeling. We developed a novel *in vivo* bone dynamic imaging technique to evaluate the effects of combination and monotherapy and hypothesized that combined PTH and ALN therapy would increase bone formation while inhibiting resorption.

3-mo-old rats were treated with 60μg/kg PTH (n=6), 50μg/kg ALN (n=6), saline (Veh, n=5), or PTH+ALN (n=7) by daily injection over a 12-day period. Calcein was injected at d3 and d10. The proximal tibia was scanned at 10.5μm (Scanco vivaCT40) at d4 and d12. The two scans were registered and subtracted to identify formation and resorption sites (Fig1). 3D μCT-based bone formation rate: BFR/BS=formation volume/(days*bone surface), mineral apposition rate: MAR=thickness of newly formed bone/days, bone resorption rate: BRR/BS=resorption volume/(days*bone surface), and mineral erosion rate: MER=thickness of resorbed bone/days were quantified. Standard BFR/BS, MAR, osteoblast number (Ob.N), and osteoclast number (Oc.N) were measured by histology, and serum resorption marker TRAP was assessed for a subset of specimens.

In vivo μCT- and histology-based identification of formation sites (Fig 1) as well as BFR/BS ($r=0.8$, $p<.0001$) and MAR ($r=0.6$, $p<.005$) yielded excellent agreement with each other. Compared to d0, PTHALN caused a greater increase in bone volume fraction (BV/TV) than PTH over 12 days (45% *vs.* 33%). μCT-based analysis indicated that PTHALN had 300% greater BFR/BS and 110% greater MAR than both Veh and ALN, while PTH had 300% greater BFR/BS than Veh, which were consistent with increased histology-based BFR/BS, MAR, and Ob.N in both PTH and PTHALN compared to Veh (Table 1). μCT-based resorption measures show that BRR/BS was 50% lower in PTHALN and tended to be lower (35%) in ALN than Veh. PTH resulted in 92% greater MER than ALN. Serum analysis indicated that ALN treatment lowered PTH-induced TRAP activity as compared to PTH monotherapy.*In vivo* bone dynamic imaging provides longitudinal, 3D evaluation of bone formation and resorption. Reduced μCT-based BRR/BS and elevated BFR/BS and MAR in

PTHALN indicate that combined therapy increases bone formation while inhibiting resorption, which partially explains the additive effect of combined PTHALN therapy over monotherapy.

A Closer Look at the Immediate Trabeculae Response to Combined Parathyroid Hormone and Alendronate Treatment. Allison Altman*, Beom Kang Huh, Wei-Ju Tseng, Abhishek Chandra, Ling Qin, Xiaowei Liu. University of Pennsylvania, USA

Combined anti-resorptive and anabolic treatments, such as alendronate (ALN) and parathyroid hormone (PTH), were expected to exert an additive effect compared to PTH monotherapy but conflicting results were found in both clinical and animal studies. A shorter treatment time in rats (<2 wk) may be more clinically relevant to the short PTH treatment window in humans (<2 yr). We hypothesized that combined treatment would result in a greater improvement in trabecular bone structure and strength than PTH monotherapy by immediately enhancing bone formation on the trabecular surface.

Saline (Veh, n=6), PTH (60μg/kg, n=9), ALN (50μg/kg, n=6), or combined PTHALN (n=9) was injected daily to 3-mo rats for 12 days. The right proximal tibia was scanned every 4 days by Scanco vivaCT 40 at 10.5 μm resolution for PTH and PTHALN groups, and days 0 and 12 for VEH and ALN groups. Microstructure and finite element analysis were performed on registered trabecular bone images (Fig. 1). The left tibia was scanned by Scanco MicroCT 35 at 3.5 μm resolution for tissue mineral density (Tb.TMD) analysis.

PTH caused 7%, 19%, and 33% increase in BV/TV at day 4, 8, and 12 compared to baseline, while PTHALN resulted in 9%, 25%, and 45% increase. Similar increases in Tb.Th were observed for both PTH (7-35%) and PTHALN (8-35%) over 12 days. In contrast, little or no change in Tb.Th or BV/TV was detected in the Veh and ALN groups. Tb.N showed no difference between groups or over time. SMI suggests a 15% and 27% increase in plate-like structures in the PTH and PTHALN groups, respectively, compared with a 6% increase in the ALN group and no change in the Veh group. At day 12, the PTHALN group had 9% and 13% greater BV/TV and plate-like structure than the PTH group. Overall, compared to the baseline, treatment by ALN, PTH, and PTHALN achieved 25%, 68%, and 103% increases in stiffness, respectively. On the bone surface, PTH and PTHALN groups had reduced mineralization (4.5% and 3.0%), possibly due to the new bone formation, when compared to VEH and ALN respectively.

We demonstrated an additive effect of combined PTH and ALN therapy over monotherapy on trabecular microstructure and strength in rats over 12 days. The improvement in SMI indicates that PTHALN may further strengthen bone by filling perforated plates. We conclude that rather than blunting the formation stimulated by PTH, the addition of antiresorptive treatment exerts an additive beneficial effect by inhibiting bone resorption.

An Evaluation of Calcilytic Effects on Parathyroid Hormone and Bone Mineral Density Response Using a Physiologically-Based, Multiscale Systems Pharmacology Model. Kyle Baron*[1], Matthew Riggs[1], Ryoko Sawamura[2], Takako Shimizu[2], Fumihiko Okada[2], Jin Zhou[3], Takahiro Shibayama[3], Mendel Jansen[4]. [1]Metrum Research Group LLC, USA, [2]Daiichi Sankyo Co., Ltd., Japan, [3]Daiichi Sankyo Pharma Development, USA, [4]Daiichi Sankyo Development Ltd., United Kingdom

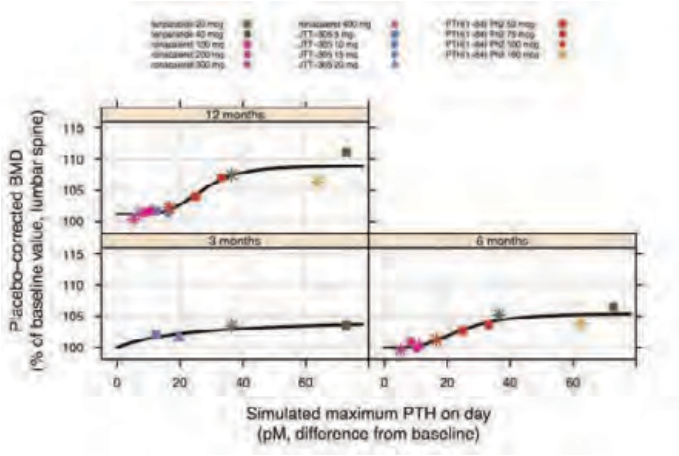
Recent research involving Ca receptor (CaR) antagonists (calcilytics) has focused on assimilating transient spikes in PTH observed with subcutaneous PTH (1-34, 1-84) administration. The goal has been to provide a 'by mouth' osteoporosis treatment comparable to PTH without invasive dosing. Investigations have yet to achieve this target profile, with typical BMD elevations of no more than 2-3% and often notably elevated serum calcium. A model-based approach to quantify the physiologic response to calcilytics was undertaken to support development of DS-9194b, an orally administered investigational calcilytic. An existing physiologically-based, multiscale systems pharmacology mathematical model (MSPM) [Bone2010;46:49–63] was expanded to include a capacity-limited PTH release pool. Pharmacokinetic (PK) and PTH data [ronacaleret (R), JTT-305 (J)] were used for this further MSPM model development. Results indicated a limit to the maximum achievable peak PTH response and described the characteristic persistent PTH elevation.

The MSPM results were coupled with a modeled relationship between peak PTH and BMD (Fig 1); results suggested that mean PTH peak (~20 pM) from the investigated calcilytics equated to a mean BMD increase <3%, as typically observed for these agents; whereas a PTHmax >30pM was considered necessary to provide appreciable BMD increase.

PK, PTH and Ca data were prospectively collected from a single-dose, first-in-human study including DS-9194b administration [0-100 mg]. PTHmax reached an apparent plateau (~30pM) as doses increased above 15mg (Fig 2); this peak was well described by the MSPM as were the prolonged elevations at higher doses. Urine Ca excretion decreased with increased DS-9194b dose (Fig 3); this effect was included in the MSPM through PTH effects on urine Ca excretion. A maximal 12-month 4~5% BMD increase was predicted for DS-9194b based on the prior modeling; only the single-dose clinical data was required to support this prediction and suggests potential for DS-9194b as a future osteoporosis treatment option.

Overall, the modeling indicated that BMD elevation with calcilytic administration routines evaluated is possible but the magnitude of BMD elevation is unlikely to match that seen with exogenous PTH. The MSPM provided a physiologic explanation of maximal PTH response due to capacity-limited PT gland pool of PTH. Results can

guide future considerations for calcilytic-related therapies for osteoporosis or other PTH-related disorders.



Relationship between BMD change and maximum PTH elevation

Ecdysterone, a Main Component from Chinese Herb, Achyranthes Root, Prevents Glucocorticoid-induced Bone Loss by Preserving Osteogenesis and Osteocyte Autophagy. Weiwei Dai*[1], Evan Lay[2], Li Jiang[2], Sarah Amugongo[3], Nancy Lane[4], Wei Yao[4]. [1]Department of Biochemistry, Integrative Medicine Discipline, Shanghai University of Traditional Chinese Medicine, China, [2]UC Davis Medical Center, USA, [3]University of California, Davis, USA, [4]University of California, Davis Medical Center, USA

Introduction. Ecdysterone (Ecd), a main component from Chinese herb, achyranthes root (niu xi), is reported to have some beneficial effects on preserving trabecular bone and cartilage following ovariectomy (OVX) (Kapur et al., 2010). We previously demonstrated that glucocorticoids excess (GC) alters osteocyte cell viability through autophagy or apoptosis and that GC treatment dose-dependently alter gene expression for autophagy, an intracellular degradative mechanism to remove the dysfunctional organelles to keep the cells alive, or apoptosis. Lower GC dose (0.7-2.1mg/kg/d) activating autophagy, while higher dose (5.6mg/kg/d) decreased autophagy but increased apoptosis. The purpose of this study was to evaluate the effects of Ecd on osteogenesis, osteocyte viability (autophagy and apoptosis) and bone loss following GC excess.

Methods. Two-month-old male Swiss-Webster mice received either placebo (PL) or prednisolone (5.6mg/kg/d) and then treated immediately with Ecd (400μg sc 5x/wk) for three weeks. Trabecular bone volume and surface based bone turnover were measured at the distal femurs (DF), lumbar vertebral bodies (LVB) and mid-femoral shafts (FS) by μCT and bone histomorphometry. Osteocyte autophagy and apoptosis were measured at the LVB as well as on FS by western blotting.

Results. We first evaluated the effects of Ecd on osteogenesis in vitro found that Ecd stimulated mesenchymal stem cells towards osteogenesis. Trabecular bone volume (Tb, BV/TV) measured at the DF and LVB were 20% and 30% lower in GC – treated groups as compared to PL, which were accompanied by 30-50% lower mineralizing surface (MS/BS) and bone formation rate (BFR/BS). Cortical bone volume (Ct) was 20% lower in GC-treated mice with almost diminished bone formation at both the periosteal and endocortical surfaces. Ecd completely prevented the decreases in Tb BV/TV, BFR and partially prevented cortical bone loss by maintaining bone formation at the periosteal surface. GC reduced autophagic related protein (ATG-7, ATG-16L and LC3-II) expression by more than 50% and increase expression of caspase 3, corresponding to increased apoptosis. Ecd preserved osteocyte viability by preserving autophagy and preventing apoptosis.

Conclusion. Our data prompt the potential application of Ecd as a treatment option for preventing the detrimental effects of GC on bone via preservations of osteogenesis and osteocyte viability by maintaining the level of autophagy and bone formation.

Effect of Sclerostin Antibody on the Osteocyte in a Glucocorticoid -Induced Osteopenia. Zahra Achiou[1], Stephane Pallu[2], Hechmi Toumi[3], Michael Ominsky[4], Hugues Portier[3], Eric Lespessailles*[5], Claude Laurent Benhamou[6]. [1]EA4708 I3MTO Université d'Orleans, France, [2]EA 4708 - I3MTO Orléans, France, [3]EA4708 I3MTO University of Orleans, France, [4]Amgen Inc., USA, [5]Centre Hospitalier Regional, France, [6]CHR ORLEANS, France

INTRODUCTION: Glucocorticoid-induced bone loss is characterized by decreased bone formation and promotion of osteocyte apoptosis. We have previously demonstrated that modulation of the Wnt signaling pathway using the administration of a sclerostin neutralizing monoclonal antibody (Scl-Ab) prevented deleterious microarchitectural bone changes and limited osteocyte apoptosis in a rodent glucocorticoid-induced osteopenia model (GIO). In the current study, we further investigated the effects of the Scl-Ab on the osteocyte in this animal GIO model to assess possible effects on gene expression, lacunar area and occupancy. METHODS: Thirty male Wistar rats, 4 month-old, were randomly assigned to 3 groups. (C) control group subcutaneously injected 5 days a week with vehicle, (M) group subcutaneously injected 5 days a week with 5 mg/kg methylprednisolone and (M+S) group injected with both methylprednisolone and Scl-Ab (Scl-AbVI, 25 mg/kg/day, 2 days a week) for 9 weeks. Twenty out of the 30 rats (C, n=6; M, n=7; M+S, n=7) were randomly selected for analysis. Decalcified, 1μm thick tibia diaphyseal sections were stained with Toluidine blue, and lacunar density (number per mm^2), lacunar area (area per lacuna in μm^2), and osteocyte lacunar occupancy (% of total lacunae) were calculated. RESULTS: Between the groups, there were no significant differences in mean lacunar area (ranged from 28.5 $\pm$ 2.4 to 34.6 $\pm$ 3.6 μm^2) or mean lacunar density (ranged from 634 $\pm$ 37 to 660 $\pm$ 63 /mm^2). Methylprednisolone caused a significant decrease in osteocyte lacunar occupancy (42% $\pm$ 3.8 vs 53 $\pm$ 4.1 % for C group), that was prevented by coadministration of Scl-Ab (60% $\pm$ 3.2 M+S vs 42 % $\pm$ 3.8 for M group). These changes in lacunar occupancy were inversely correlated with the fractional number of apoptotic osteocytes previously reported ($r = -0.74$; $p=0.001$). CONCLUSION: These data have shown that Scl-Ab prevents the decrease in osteocyte lacunar occupancy and the increase in osteocyte apoptosis caused by methylprednisolone treatment in rats, suggesting an improvement in osteocyte viability.

Parathyroid hormone improves skeletal status of rats with type 2 diabetes mellitus. Christine Hamann*[1], Ann-Kristin Picke[2], Graeme Campbell[3], Martina Rauner[4], Ricardo Bernhardt[5], Claus-C Glueer[3], Gerd Huber[6], Klaus-Peter Günther[1], Michael Morlock[6], Lorenz Hofbauer[2]. [1]Dresden Technical University Medical Center, Germany, [2]Dresden University Medical Center, Germany, [3]Christian-Albrechts Universität zu Kiel, Germany, [4]Medical Faculty of the TU Dresden, Germany, [5]Technische Universität Dresden, Germany, [6]Institute of Biomechanics, Hamburg University of Technology, Germany

The pathogenesis of low bone mass and increased skeletal fragility in diabetes mellitus is unclear, and efficient therapies are limited. ZDF rats with type 2 diabetes mellitus display low bone mass and delayed bone defect healing due to impaired osteoblast function. We tested the hypothesis whether human parathyroid hormone (PTH 1-84) increases bone mass, strength and defect regeneration in diabetic rats. A subcritical femoral defect was created in 11 weeks old diabetic ZDF (fa/fa) and non-diabetic ZDF (+/+) rats. PTH (75 µg/kg) or vehicle was administered subcutaneously five days per week over 12 weeks. The non-operated femur, the lumbar vertebra, and the filling of the femur gap were analyzed by µCT. Three-point bending was performed at the mid-diaphysis of the non-operated femora. In addition, dynamic histomorphometry and serum markers of bone turnover were analyzed. µCT analysis of the femur revealed asignificant reduction in distal metaphyseal BV/TV (-50%) and tBMD (-41%), as well as mid-diaphyseal Ct.Th (-16%) and MOI (-16%) in the untreated diabetic group compared to the control. Treatment with PTH resulted in 59% higher BV/TV and 36% higher tBMD in the diabetic animals, but had no effect on Ct.Th, cBMD or MOI. The diabetic rats showed a significant reduction in extrinsic stiffness (-17%), yield (30%) and ultimate load (-23%), work to yield (-38%), and failure (-23%). PTH treatment improved the work to failure (+28%) and modulus of toughness (+28%) in the wild-type, but not in diabetic rats. While non-diabetic rats filled 63% of the femoral defect, diabetic rats filled only 31%. PTH-treatment increased defect regeneration in the diabetic and non-diabetic groups by 11% and 12%, respectively. Dynamic histomorphometry of the lumbar spine demonstrated an increased BFR by 55% (diabetic rats) to 230% (non-diabetic rats) in response to PTH treatment. Intermittent PTH treatment resulted in increased serum levels of osteocalcin by 33% and 10% in diabetic and non-diabetic animals, respectively, and lower serum levels of CTX (-49% and -19%), consistent with a marked bone-anabolic effect. In conclusion, intermittent PTH therapy is capable of reversing the adverse effects of type 2 diabetes mellitus on bone mass and delayed bone defect regeneration in rats.

Retreatment With Sclerostin Antibody Increased Bone Formation and Bone Mass in Ovariectomized Rats. Xiaodong Li*, Kelly S Warmington, Qing-Tian Niu, Denise Dwyer, Chun-Ya Han, Marina Stolina, Andreas Grauer, Hua Zhu Ke. Amgen, Inc., USA

Treatment with sclerostin antibody (Scl-Ab) resulted in transient increases in bone formation markers and sustained decreases in bone resorption markers, leading to substantial bone mass gains. Here we explored the effects of Scl-Ab retreatment on bone formation and bone mass in ovariectomized (OVX) rats after an initial treatment and withdrawal phase.

Seven-month-old OVX rats (11 wks post-OVX) were treated with vehicle (Veh) or Scl-Ab (Scl-Ab VI, 5 mg/kg, SC, 2x/wk) for 12 wks (initial treatment), followed by treatment with Veh for 12 wks (withdrawal). Thereafter, 1 group of Scl-Ab-treated OVX rats received Scl-Ab and the other group received Veh for 6 wks (n=8/group, retreatment). All groups were evaluated for serum P1NP and BMD. In addition, bone histomorphometry was evaluated in Veh- and Scl-Ab-treated OVX rats at wks 6, 12, 24, and 30 (n=8/group).

During the initial treatment phase, P1NP increased significantly in the Scl-Ab group at wks 2 and 4 and gradually returned to OVX control levels at wk 10; it then remained at OVX control levels during the withdrawal phase (through wk 24). During the retreatment phase, Scl-Ab treatment resulted in increases in P1NP comparable to those observed after the initial treatment. Lumbar spine BMD increased continuously throughout Scl-Ab treatment and peaked at wk 14, 2 wks after withdrawal, gradually returning to sham control levels at wk 24 (Figure). After 6 wks of retreatment, BMD had significantly increased again to the peak level initially observed at wk 14. Trabecular (Tb), endocortical (Ec), and periosteal (Ps) bone formation rate (BFR/BS) peaked at wk 6 in the Scl-Ab group and then returned to OVX controls at wk 24, but Tb and Ec BFR/BS were significantly greater in the Scl-Ab group than OVX controls at wk 12. During the retreatment phase, the increases in Tb and Ec BFR/BS with Scl-Ab retreatment were similar to those following initial treatment; there were significant increases in Ps BFR/BS. For Tb and Ec eroded surface (ES/BS), similar decreases were observed in the Scl-Ab group compared with Veh during initial and retreatment phases. After treatment withdrawal, Tb ES/BS increased to levels above OVX controls and Ec ES/BS returned to OVX control levels.

In conclusion, Scl-Ab retreatment reproducibly increased bone formation and BMD, and decreased bone resorption, as seen during initial treatment in OVX rats. These results suggest that retreatment with Scl-Ab could be a viable way to increase bone mass.

Romosozumab (Sclerostin Antibody) Improves Bone Mass and Bone Strength in Ovariectomized Rats After 12 Months of Treatment. Michael S Ominsky*[1], Aurore Varela[2], Susan Y Smith[2], Elisabeth Lesage[2], Sabina Buntich[1], Rogely W Boyce[1]. [1]Amgen, Inc, USA, [2]Charles River Laboratories, Canada

Romosozumab, a sclerostin antibody, is a bone-forming agent under clinical investigation for the treatment of osteoporosis. To examine the effects of romosozumab on bone quality over the duration of proposed clinical treatment, bone mass and strength were assessed at cortical and cancellous sites in ovariectomized (OVX) rats treated for 12 months.

Six-month old SD rats were OVX and, beginning at 8 months of age, treated with weekly subcutaneous injections of either vehicle (Veh), or 3, 10, or 50 mg/kg romosozumab (n=10-15/group) for 12 months; a Sham control group treated with Veh was also included. Bone mass was evaluated in vivo by DXA and pQCT, and ex vivo by pQCT and microCT after termination at month 12. Bone strength was assessed at the femur midshaft (in 3pt bending), femur neck (in shear), and L4 and L5 vertebra (in compression).

Bone mass was dose-dependently increased throughout the skeleton, with DXA BMD increases >40% over baseline at the lumbar spine and whole femur at the 50 mg/kg/wk dose. At the tibia diaphysis, cortical thickness was significantly increased by pQCT at all doses compared to OVX controls, due to geometric changes on both periosteal and endocortical surfaces. Romosozumab also resulted in significant increases in ex vivo bone area and bone strength parameters at the femur midshaft, femur neck, and lumbar vertebra at all doses tested. Peak load was significantly dose-dependently increased by romosozumab at the femur midshaft (41-121%), femur neck (33-46%), and lumbar vertebra (150-268%) (all doses/sites $P<0.05$ vs Veh). These improvements correlated positively with the bone mass at these sites, with r^2 values of 0.92, 0.41, and 0.94 at the femur shaft, femur neck, and lumbar vertebra, respectively, across groups. Material properties calculated at the femur shaft suggested that romosozumab improved ultimate strength and toughness while elastic modulus remained unaffected by treatment.

These data demonstrate that 12 months of romosozumab treatment in OVX rats resulted in marked improvements in bone mass, cortical geometry, and bone strength. Bone quality assessment by regression analysis and calculated material properties demonstrated that long-term romosozumab treatment resulted in bone matrix that had normal-to-improved bone strength. These results support the bone efficacy and safety profile of romosozumab and suggest that treatment-related improvements in BMD should yield greater bone strength in patients with osteoporosis.

Sclerostin-Antibody is More Effective Than Dkk1-Antibody for Augmenting Bone Mass in Adult Rice Rats. Carley Trcalek*[1], Jose Aguirre[1], Kathleen Neuville[1], Donald Kimmel[2], Thomas Wronski[1]. [1]University of Florida, USA, [2]Kimmel Consulting Services, USA

Sclerostin (Scl) and Dickkopf-1 (Dkk1) are well known antagonists of Wnt signaling, which results in negative regulation of bone formation. Therefore, treatment with neutralizing antibodies to inhibit Scl (Scl-Ab) and Dkk1 (Dkk1-Ab) is thought to be a promising approach for increasing bone mass in osteoporotic patients. The purpose of this study is to compare the effects of monotherapy with Scl-Ab or Dkk1-Ab on bone mass in adult rats.The experimental animals were rice rats (*Orozomys palustris*), which are more genetically diverse than conventional outbred strains of rats used for biomedical research. At 22 weeks of age, groups of male rice rats (N=10-12) were treated SC twice weekly with vehicle, Scl-Ab, or Dkk1-Ab at a dose of 25 mg/kg for 8 weeks. At 30 weeks of age, the left tibia and femur were collected from each rat for bone histomorphometric and pQCT analyses, respectively. Due to high variability of bone parameters in rice rats, some data were not normally distributed, and the nonparametric Kruskal Wallis test was used for statistical comparisons. Data are expressed as the mean ± SEM.Treatment of rice rats with the Scl-Ab or Dkk1-Ab for 8 weeks did not affect body weight. In comparison to vehicle-treated rats, cancellous bone volume in the proximal tibial metaphysis was significantly increased by nearly 3-fold in Scl-Ab-treated rats (4.2 ± 1.8% vs. 12.1 ± 3.1%, $P<0.05$), but not by treatment with the Dkk1-Ab (4.2 ± 1.2%). This augmentation of cancellous bone mass in rats treated with the Scl-Ab was associated primarily with increased trabecular width (23.4 ± 2.0 μm vs. 42.0 ± 4.0 μm, $P<0.001$) rather than increased trabecular number. Compared to vehicle-treated rats, osteoblast surface was increased by at least 50% in rats treated with Scl-Ab or Dkk1-Ab, but these trends indicative of increased cancellous bone formation did not achieve statistical significance. In the distal femoral metaphysis, pQCT analyses revealed that total BMD was significantly increased in Scl-Ab-treated rats (657.6 ± 32.5 mg/cm^3, $P<0.02$) compared to both vehicle-treated rats (556.5 ± 33.0 mg/cm^3) and Dkk1-Ab-treated rats (541.7 ± 17.0 mg/cm^3). In the femoral diaphysis, cortical thickness was significantly increased in Scl-Ab-treated rats compared to both vehicle-treated rats (0.63 ± 0.01 mm vs. 0.55 ± 0.02 mm, $P<0.001$) and Dkk1-Ab-treated rats (0.59 ± 0.01 mm, $P<0.02$). These findings indicate that, in genetically diverse adult rice rats, the Scl-Ab was more effective than the Dkk1-Ab for augmentation of bone mass.

Combination Therapy with Ibandronate and Eldecalcitol Enhances Bone Strength via Elevation of BMD in Aged Ovariectomized Rats. Sadaoki Sakai*[1], Satoshi Takeda[1], Masanori Sugimoto[2], Masaru Shimizu[3], Koichi Endo[3]. [1]Chugai Pharmaceutical Co., Ltd., Japan, [2]Molecular Function & Pharmacology Laboratories, Taisho Pharmaceutical Co., Ltd, Japan, [3]Chugai Pharmaceutical Co., Ltd., Japan

Ibandronate [IBN; 1-hydroxy-3-(methylpentylamino)-propylidene bisphosphonate] is an intravenously injected anti-osteoporosis medicine. Eldecalcitol [ED-71, ELD; 1α,25-dihydroxy-2β-(3-hydroxypropyloxy) vitamin D_3], an active vitamin D_3 derivative, is superior to alfacalcidol, a prodrug of active vitamin D_3, in preventing bone fractures in postmenopausal osteoporotic patients. However, there are no reports on the effects of combined IBN and ELD treatment for osteoporosis.

In this study, we examined the effects of combination treatment with IBN and ELD on the lumbar vertebrae and femur in aged ovariectomized rats. Eight-month-old Wistar-Imamichi rats were ovariectomized and treated for 12 weeks with either vehicle, IBN (3 μg/kg/month, s.c., monthly), ELD (15 ng/kg/day, p.o., daily), or a combination of IBN and ELD. Serum and urine were collected every 4 weeks. BMD and bone strength of the lumbar vertebrae and femur were measured after 12 weeks of treatment.

Urinary deoxypyridinoline (DPD), a bone resorption marker, was significantly reduced in each monotherapy group. The combination therapy group showed further decreases in DPD compared to each monotherapy group at 4, 8, and 12 weeks of treatment. Osteocalcin, a bone formation marker, in each of the 3 therapy groups was not lower than the level in the sham group throughout the experimental period.

Lumbar (L2–L4) BMD after 12 weeks was significantly higher in the IBN and ELD monotherapy groups than in the vehicle control group, and BMD was higher in the combination group than in either monotherapy group. A compression test showed the mechanical strength of L5 was improved in each monotherapy group and in the combination group compared with the vehicle control group. The maximum load was higher in the combination group than in the IBN monotherapy group. BMD of the proximal, middle, and distal femur was increased in the IBN and ELD monotherapy groups, and was significantly higher in the combination therapy group than in either monotherapy group. In the 3-point bending test, the maximum load of the femur was slightly, but not significantly, higher in each monotherapy group than in the vehicle control group and was significantly higher in the combination therapy group.

5This study demonstrates the additive effect of IBN and ELD combination therapy on the mechanical strength of the lumbar vertebrae and femur. This effect may be induced by increased BMD via reduction of bone resorption without suppression of bone formation.

Effects of Odanacatib on Early and Late Stage Fracture Healing in an Adult Rabbit Radial Osteotomy Model. Tara Cusick*[1], Rana Samadfam[2], Le Thi Duong[3]. [1]Merck & Co., Inc., USA, [2]Charles River Laboratories, Canada, [3]Merck Research Laboratories, USA

Cathepsin K (CatK), a lysosomal cysteine protease highly expressed by osteoclasts, degrades de-mineralized bone matrix proteins. Odanacatib (ODN) is an orally active and reversible CatK inhibitor in development for the treatment of postmenopausal osteoporosis. Fracture (Fx) healing is a complex process that involves both bone resorption and formation. Various preclinical models of skeletal repair have evaluated agents that alter these processes. Here, we characterized effects of ODN on Fx repair in the rabbit radial osteotomy model during the reparative (6wks) and remodeling (25wks) phases. Skeletally-mature female rabbits (n=150, 6 mo-old) were randomized by radii/ulnae DXA-based aBMD into four groups and pretreated for 12wks prior to radial osteotomy with: vehicle (Veh), ODN in food at ~ 1.7-fold (1.5mg/kg/d or 12μM-24hr) and 7-fold clinical exposure (6mg/kg/d or 50μM-24hr), or alendronate (ALN, 0.3mg/kg/wk, sc). The ALN dose was previously shown to fully prevent bone loss in ovariectomized rabbit. Post-surgery, ODN groups were further divided into continued (ODN/ODN) or discontinued (ODN/Veh) groups and maintained on the same treatment for an additional 6 or 25wks. Study endpoints included longitudinal radiography, histopathology, pQCT and biomechanical testing. Rates of radiographic healing among all groups were comparable based on callus initiation (p=0.20), radiographic bridging (p=0.80) and radiographic union (p=0.41). Histopathology of the Fx callus in ODN/ODN, ODN/Veh, ALN groups were not different from that in Veh. ODN/ODN and ALN increased pQCT-based total vBMD at 6wks (9-10%, $p<0.01$) and 25wks (26-33%, $p<0.001$) without altering total callus area vs Veh. Moreover, ODN/ODN enhanced mature (mineralized) callus vBMC by 15-18% ($p<0.05$) at 6 wks and 49-69% ($p<0.01$) at 25wks vs Veh. Mature callus vBMC in the ALN group was unaltered at 6wks and increased 9-18% ($p<0.05$) at 25wks vs Veh. Biomechanical tests of fractured and intact radii in all treatment groups at 6wks were not different from Veh. However, at 25wks, while peak load across the healing sites in ODN/Veh and ALN groups were the same as that in Veh, peak load in ODN/ODN groups increased by 18% (1.5mg/kg, p=0.11) and 25% (6mg/kg, $p<0.05$), reaching intact contralateral levels. Taken together, in the rabbit radial osteotomy model of fracture repair, ODN treatment did not delay fracture union and callus remodeling while at the same time tended to improve callus mineralization and strength.

Introduction of a New Class of Cathepsin K Inhibitor with Peptidomimetic Structure, SI-591. Toshiaki Fujii*, Yoshitaka TANAKA. SEIKAGAKU CORPORATION, Japan

We have synthesized and developed a series of unique peptidomimetic compounds with hydrophilic and neutral properties, which potently inhibit the activity of the lysosomal cysteine protease, cathepsin K. SI-591 is a prototype compound in this chemical class and possesses a superior pharmacological activity *in vitro* and *in vivo* with orally bioavailable characteristics.

In an enzyme inhibition assay, SI-591 inhibited human cathepsin K with an IC_{50} value of 1.4 nM, which was 8- to 320-fold more selective for cathepsin K than other members of the human cathepsins.

In an *in vitro* assay, osteoclast-like cells were cultured with various doses of SI-591 on dentin slices in the presence of RANKL and M-CSF for 6 days. The C-terminal cross-linking telopeptide of Type I collagen (CTX-I) released into the culture medium was measured as a bone resorption marker. Resorption pits formed on the slices were stained with Mayer's hematoxylin. SI-591 (0.01-10 μM) dose-dependently inhibited the release of CTX-I and significantly decreased the formation of the resorption pits.

To study the preventative effects of SI-591 on the ovariectomized (OVX) rat as a model of postmenopausal osteoporosis, adult female F344 rats underwent OVX surgery and were treated with a vehicle or SI-591 (0.26-10 mg/kg p.o., b.i.d.) for 4 weeks from the day following surgery. SI-591 dose-dependently inhibited urinary CTX-I release and prevented bone mineral density (BMD) loss at the lumbar vertebrae and femur. To further investigate the therapeutic effect of SI-591, OVX rats were treated with a vehicle or SI-591 (4-25 mg/kg p.o., b.i.d.) for 12 weeks from 12 weeks following surgery. SI-591 dose-dependently inhibited urinary deoxypyridinoline release and prevented BMD loss in the lumbar vertebrae and femur. In addition, to evaluate the long-term preventive effects of SI-591 on the OVX model, cynomolgus monkeys (aged 9-16 years) underwent OVX surgery and were treated with a vehicle or SI-591 (4-36 mg/kg p.o. b.i.d.) for 6 months from the day following surgery. SI-591 inhibited the urinary N-terminal cross-linking telopeptide of type I collagen (NTX) release and prevented BMD loss in the lumbar vertebrae and the body as a whole.SI-591 remarkably prevented bone resorption in *in vitro* and *in vivo* assays.

In conclusion, our results support that our second generation cathepsin K inhibitor, SI-591, may have a therapeutic potential in the treatment of postmenopausal osteoporosis.

Treatment with Odanacatib Increases Bone Mass and Maintains Normal Biomechanical Properties in Orchidectomized Male Rabbits. Brenda Pennypacker*[1], Charles Chen[2], Tara Cusick[2], Rana Samadfam[3], Le Thi Duong[1]. [1]Merck Research Laboratories, USA, [2]Merck & Co., Inc., USA, [3]Charles River Laboratories, Canada

Odanacatib (ODN) is a selective Cathepsin K (CatK) inhibitor in development for the treatment of postmenopausal osteoporosis. We evaluated the effects of long-term ODN treatment on bone quality in the lumbar vertebrae (LV) and femur of orchidectomized (ORX) male rabbits, a model of male osteoporosis. Adult male rabbits (age 11 mo.) were sham-operated (N=20) or ORX (N=24/group) for 7.5 months prior to the start of treatment. ORX rabbits were randomized by LV BMD into the following treatment groups: vehicle (Veh), ODN (1.5 or 6mg/kg/d, in food), or alendronate (ALN) (300μg/kg/wk, sc) for 14 mo. *Ex vivo* endpoints included DXA- and pQCT-based BMC and BMD and strength testing. ORX resulted in ~9% bone loss in LV3-4 aBMD vs. Sham ($p<0.01$). ODN dose-dependently increased LV aBMD by 21% and 26%, respectively ($p<0.001$), compared to ALN (9.9%, $p<0.01$) vs. Veh. pQCT-based LV5-6 trabecular (Tb) vBMC and vBMD were increased in ODN groups (up to 88%, $p<0.001$) vs. Veh. Similarly, ALN increased Tb.vBMC and BMD by 11% and 8% ($p<0.05$ for both), respectively. ODN at both doses increased Tb thickness (32-51%, $p<0.001$). Significant increases in strength parameters (peak load, apparent strength, yield load, and yield stress, stiffness) of LV5-6 were noted for the comparison between ALN to Veh and ODN to Veh or Sham. From compression testing of LV, peak load from all groups was positively correlated with pQCT-vBMC ($R=0.9383$, $p<0.001$). ODN also dose-dependently increased aBMD of the total hip and distal femur, but did not change central femur (CF) aBMD compared to Veh. However, ODN 6 mg/kg increased cortical thickness and area by ~7% ($p<0.01$), and reduced endocortical perimeter by 4% ($p<0.05$) vs. Veh. ODN-treated CF trended to have higher peak load and significant increases in work-to-failure (25%, $p<0.05$) and toughness (29%, $p<0.01$) vs. Veh. No significant changes in biomechanical parameters of CF were noted in the ALN group. CF peak load vs. pQCT-vBMC was highly correlated ($R=0.7555$, $p<0.001$). Taken together, ODN treatment for 14 months increased bone mass and strength in the lumbar spine to levels above Veh and Sham, as well as maintaining biomechanical properties at femoral sites of ORX male rabbits. These findings support the clinical evaluation of the CatK inhibitor ODN for the treatment of osteoporosis in men.

Effects of Fructus Ligustri Lucidi Extract and Its Fractions on Renal Calcium Reabsorption and Trabecular Bone Structure in Type 1 Diabetic Mice. Yan Zhang*[1], Teng-Yue Diao[2], Man-Sau Wong[1]. [1]The Hong Kong Polytechnic University, Hong Kong, [2]University of Shanghai for Science & Technology, China

Our previous study demonstrated that the alterations of vitamin D metabolic enzymes expression and the increase in urinary Ca excretion as a result of the decrease in renal Ca transporters expression contributed to the deteriorations of bone properties in type 1 diabetic mice. Our previous study indicated that Fructus Ligustri Lucidi (FLL), one of kidney-tonifying herbs, could improve Ca balance in mature and aged rats through its ability to modulate circulating levels of calciotropic hormones as well as intestinal Ca absorption and renal Ca wasting. This study was conducted to determine if FLL exert the beneficial effects on bone health via its actions on calcium homeostasis in type 1 diabetic mice induced by streptozotocin (STZ). The diabetic dba/2J mice after 1 week of STZ injection were divided into 4 groups with 8 mice in each group, and treated with vehicle (DOP, diabetic osteoporosis), ethanol extract of FLL (EF), ethyl acetate-soluble fraction of EF (EA), and water-soluble fraction of EF (WF) for 6 weeks on a medium-Ca diet (0.6% Ca), and one additional group without any treatment was used as non-diabetic control. There was no statistical difference of serum Ca level among groups, while, EA and WF could both increase serum parathyroid hormone level ($P < 0.05$). Compared to normal control, the urinary Ca level climbed up significantly in DOP group ($P < 0.01$), and EF, EA and WF could effectively reversed the high urinary excretion to the normal level. EF and EA could up-regulate renal 25-hydroxyvitamin D-1a-hydroxylase mRNA expression, in contrary, WE could down-regulate the mRNA expression of 25-hydroxyvitamin D-24-hydroxylase (24-OHase) and calcium-sensing receptor (CaSR) in kidney of DOP mice. Micro-CT analysis of trabecular bone parameters at tibial proximal metaphysis showed that WF could markedly inhibit the decrease in trabecular bone number and connectivity density and the increase in trabecular bone separation. However, the improvement of EF and EA on trabecular bone properties was not statistically different as compared to those of DOP mice. Therefore, our present study suggested that the biological targets, including renal 24-OHase and CaSR, might, at least partially, contribute to the improvement of urine Ca excretion and bone loss in WF group, and this underlying mechanism might be different from those of EF and EA on diabetic mice.

Prevention and Restoration of Bone Loss by n-3 fatty acids in an Ovariectomized Mouse Model. Jameela Banu*[1], Gabriel Fernandes[2]. [1]University of Texas-Pan American, USA, [2]University of Texas Health Science Centre, USA

Recently, there have been many reports about the benefits of n-3 fatty acids (n-3 FA) on bone. n-3 FA decrease bone resorption and protect bone from ovariectomized bone loss in preclinical studies. However, there is very little information on the preventive and restorative properties of n-3 FA on bone. We used a mouse model to determine if n-3 FA are more beneficial as preventive agents or can restore bone loss after established bone loss.

Two experiments were conducted. Experiment 1 – Prevention studies. Ten months old, C57BL/6, retired breeder mice were started on a diet regimen containing lab chow (LC) or fish oil (FO) for 3 months before they were either ovariectomized or sham operated. The different groups were: Group 1. LC sham (LC S); Group 2. LC ovariectomized (LC O); Group 3. FO sham (FO S); Group 4. FO ovariectomized (FO O). Mice were fed LC or 10% FO respectively and maintained in the respective diet regimens for another 3 months and sacrificed. The long bones were subjected to micro-architectural analyses. Experiment 2 – Restoration studies. Ten months old, C57BL/6, retired breeder mice were either sham operated or ovariectomized and left for 3 months. The different groups were: Group 1. LC S; Group 2. LC O; Group 3. FO S; Grouop 4. FO O. Mice were fed either LC or FO (10%). The LC and FO fed groups were kept in the respective diet regimens for the next 3 months, at the end of which they were sacrificed. Long bones were subjected to micro-architectural analyses.

Experiment 1: In the DFM, ovariectomy caused significant decreases in the trabecular thickness (Tb Th) and trabecular width (Tb W) and FO prevented this decrease. Trabecular number (Tb N) increased in sham and ovariectomized mice fed FO. Trabecular separation (Tb Sp) increased in the ovariectomized mice (LC and FO) and FO decreased this to a lesser extent. In the PTM, however, FO did not protect trabecular bone.

Experiment 2: In the DFM, there were significant decreases in Tb N and Tb Th of LC O mice, compared to LC S mice. FO O mice had significantly higher Tb N and Tb Th compared to those of LC O. Tb W decreased in the LC O mice by 14% and by 4% in the FO O compared to the respective sham mice. Tb Sp increased only in the LC O, not in the FO O compared to their respective shams. In the PTM, again there was no effect of FO.

In conclusion, FO could prevent and restore trabecular bone in the DFM and did not have any effect on the PTM in a rodent model for bone loss.

Eldecalcitol Increases Bone Mineral Density and Improves Trabecular Structure and Biomechanical Properties of the Lumbar Spine in Streptozotocin-Induced Diabetic Rats. Satoshi Takeda*, Sadaoki Sakai, Koichi Endo. Chugai Pharmaceutical Co., Ltd., Japan

It is well known that type 1 diabetes mellitus (DM) increases the risk of fragility fractures owing to low bone mineral density (BMD) and deteriorated bone quality. Eldecalcitol (ELD), an active vitamin D_3 analog, is reported to reduce the risk of fractures in osteoporotic patients; however the effects of ELD on fragility fractures in DM patients have not been fully examined. In the present study, we evaluated the efficacy of ELD on bone metabolism including biomechanical properties of lumbar spine in type 1 DM rats.

Male Sprague-Dawley rats (12-weeks old) were injected intravenously with streptozotocin (STZ) (35 mg/kg). From 1 week after STZ injection, ELD (10, 20 and 40 ng/kg) was administered orally 5 times a week for 12 weeks. Urinary deoxypyridinolin (DPD) and serum osteocalcin (OC) were measured every 4 weeks after ELD treatment began. After 12 weeks of treatment, lumbar (L2-L4) BMD and biomechanical properties of the L5 vertebra were assessed, and bone histomorphometry was performed using the L3 vertebra.

DM was confirmed by the development of hyperglycemia (blood glucose >250 mg/dL) after 1 week of STZ injection. After 12 weeks of treatment, blood glucose levels in the ELD-treated groups were not significantly different from those in the disease control (DC) group. In the DC group, urinary DPD tended to increase, while serum OC significantly decreased compared with that in the normal control group during the treatment period. ELD decreased urinary DPD in all doses but did not change serum OC. ELD inhibited the decrease in lumbar BMD observed in the DC group. Although DM induced a significant reduction in bone volume at the L3 vertebra, accompanied by a decrease in trabecular thickness and an increase in trabecular separation, ELD improved this deterioration in trabecular architecture. In the compression test of the L5 vertebral body, max load, stiffness and ultimate stress decreased in the DC group, and ELD improved max load and ultimate stress. These results suggested that treatment with ELD increased lumbar BMD and improved trabecular architecture, resulting in an increase in biomechanical strength of lumbar vertebra in type 1 DM rats. ELD may be useful in preventing vertebral fragility fractures in DM patients.

High prevalence of vitamin D insufficiency in older community people: the role of season, diabetes, parathormone, female gender and age. The Sao Paulo Ageing & Healthy Study (SPAH). Camille Figueiredo*[1], Jaqueline Lopes[2], Georgea Fernandes[1], Liliam Takayama[3], Valeria Caparbo[3], Rosa Pereira[4]. [1]Hospital das Clinicas da Faculdade de Medicina da USP, Brazil, [2]Hospital das Clínicas da FMUSP, Brazil, [3]Faculdade de Medicina da USP, Brazil, [4]Faculdade de Medicina da Universidade de São Paulo, Brazil

Purpose: To estimate the prevalence and analyze the risk factors associate to hydroxyvitamin D insufficiency (25OHD< 20ng/mL) in community-dwelling older people.

Methods: This cross sectional study included 750 (506 women and 244 men) older subjects (> 65 years old) living in São Paulo, Brazil. The serum concentration of 25-hydroxyvitamin D was measured using a radioimmunoassay technique. Anthropometrical data and information about lifestyle habits, physical activity and comorbities were obtained. Bone mineral density (BMD) was measured by DXA. Other laboratory tests were also determined. Multiple logistic regression models were designed 25OHD<20ng/mL as the dependent variable and all other parameters as the independent ones.

Results: The prevalence of 25OHD<20ng/mL was of 57.9% (95% CI 54.4 - 61.4). The main factors associated with 25OHD<20ng/mL were age, body mass index, female gender, diabetes, season (winter/spring), alkaline phosphatase, phosphorus, intact parathormone (iPTH), creatinine clearance and Total femur T-score. After adjustment for these variables, the logistic regression analyses revealed that age (OR = 1.04, 95%CI 1.01 - 1.07, p = 0.024), iPTH (OR = 1.01; 95% CI 1.01 – 1.02; p = 0.003), female gender (OR = 1.45; 95% CI 1.06 – 2.0; p = 0.020), diabetes (OR = 1.84; 95%CI 1.23–2.76; p = 0.003), and season (winter/spring) (OR = 3.63, 95% CI 2.65 - 4.97; p<0.001) remains as independent factors for 25OHD<20ng/mL.

Conclusions: Our results suggest that the vitamin D insufficiency is common in Brazilian community-dwelling older and age, iPTH, female gender, diabetes and season (winter/spring) are major risk factors associated. The clinical use of these parameters can be help to design and target appropriate interventions in the public health for vitamin D insufficiency in older population.

12/15-LO But Not 5-LO is Critical For Denervation-Induced Bone Loss In Mice. Md Rahman*, Arunabh Bhattacharya, Sabia Marian, Rasel Mohiuddin, Amanda Jernigan, Holly Van Remmen. University of Texas Health Science Center, USA

Unloading or skeletal immobilization-induced osteoporosis is a critical issue in paralyzed, bed-ridden patients and astronauts. Skeletal immobilization or disuse induces bone loss resulting from increased bone resorption and decreased bone formation. However, a rapid surge in bone resorption due to significant increase in the number of osteoclasts is considered to be the key reason in skeletal immobilization associated bone loss. Unloading bone loss can be induced in animals by denervation of sciatic nerve. This study examines the role of 5- and 12/15-lipoxygenase (LO) lipid metabolic pathways in denervation-induced bone loss. In the left leg, surgical sciatic nerve transection was performed in 6 month old wild-type, *12/15-LO*$^{-/-}$ and *5-LO*$^{-/-}$ male mice. In addition, wild-type mice were injected with either vehicle control or 12/15-LO specific inhibitors, PD146176, and Baicalein or 5-LO specific inhibitor, Zileuton (4 mg/kg, i.p.) in mice subjected to nerve transection. Tibias were collected 7 days post-denervation and analyzed by dual energy x-ray absorptiometry (DXA). Wild-type mice exhibited significant bone loss in the denervated leg as compared to contralateral control leg. While 12/15-LO$^{-/-}$ mice and both 12/15-LO inhibitors treated wild-type mice were protected against denervation-induced bone loss, genetic or pharmacological inhibition of 5-LO did not confer any protection against denervation-induced bone loss. These data indicate a specific role for 12/15-LO and its downstream mediators in denervation-induced bone loss. Our *in vitro* study in RAW264.7 cell and bone marrow cell cultures subjected to osteoclast differentiation (with RANKL and M-CSF) in the presence of 12/15-LO and 5-LO specific inhibitors corroborated our *in vivo* findings. Both PD146176 and Baicalein dose-dependently inhibited osteoclast differentiation, whereas Zileuton had no effect. Our preliminary findings support a role for 12/15-LO in osteoclastogenesis and indicate that 12/15-LO may be an important therapeutic target in diseases associated with excessive osteoclastogenic bone resorption.

Effects of a carbon-containing polyhedral boron-cluster compound BA321 on bone loss due to sex steroid deficiency by AR- and ER-dependent mechanism. Chiho Matsumoto, Masaki Inada, Michiko Hirata, Chisato Miyaura*. Tokyo University of Agriculture & Technology, Japan

Carboranes are a class of carbon-containing polyhedral boron-cluster compounds having exceptional hydrophobicity, and their features may allow a new medical application as a biologically active molecule that interact with steroid hormone receptors. We have reported carborane compound BE360 having carborane structure with two phenols, binds to estrogen receptor and exhibits estrogenic action in bone but not in uterus as selective estrogen receptor modulator (SERM). On the other hand, we have designed carborane compounds having affinity with androgen receptor (AR) and synthesized them to search effective compounds for osteoporosis in the male. Among several carborane compounds, we noticed two compounds, BA321 and BA341, as a putative AR antagonist, in which a benzene ring with electron-withdrawing group (-NO2, -CN) and a hydroxyl group are placed at the opposite vertices of the hydrophobic carborane cage. In the competitive binding assay, BA321 and BA341 exhibited binding affinity to AR, and their affinities are 10-fold higher than that of hydroxyflutamine. In NIH3T3 cells transfected with AR, both BA321 and BA341 exhibited anti-androgenic activity in reporter gene assay. To examine the effects of BA321 and BA341 in bone, male mice were orchidectomized (ORX) and some of the mice were treated with BA321 and BA341 (10, 30, 100 μg/head/day) subcutaneously for 4 weeks using a mini-osmotic pump. Orchidectomized (ORX) mice showed severe bone loss due to androgen deficiency measured by femoral BMD and micro-CT, and the bone loss was completely recovered by the treatment with BA321. BA341 significantly restored the bone loss in ORX mice, but the potency of BA341 was relatively less than that of BA321. The weight of seminal vesicle was reduced in ORX mice, and not influenced by the treatment of BA321, indicating that BA321 does not exhibit androgenic action in sex organ in the male. On the other hand, BA321 bound to ER, and prevented the bone loss due to estrogen deficiency in ovariectomized female mice. BA321 may selectively bind to AR and ER, and act on bone tissues as selective androgen receptor modulator (SARM) or selective estrogen receptor modulator (SERM).

Preclinical Assessment of mesenchymal stromal cell (MSC) transplantation to treat type II (age-related) osteoporosis. Jeffrey Kiernan*[1], John E Davies[1], William Stanford[2]. [1]University of Toronto, Canada, [2]Ottawa Hospital Research Institute, Canada

Osteoporosis and low BMD affects over 52 million people in the United States and Canada, and represents a substantial economic burden. In the USA and Canada approximately 1 in 3 women, and 1 in 5 men, will suffer an osteoporotic fracture in their lifetime with a cost to the system in excess of 22 billion dollars annually. While therapies targeting type I (post-menopausal) osteoporosis are well developed, those targeting type II (age-related) osteoporosis remain underdeveloped. Our lab has generated a Sca-1 null mouse model of human type II osteoporosis. Sca-1 null mice display decreased mesenchymal stromal cell (MSC) self-renewal and expansion capabilities. This model strongly suggests that defects in MSC function can contribute to age-related osteoporosis. Therefore, we wished to increase the MSC pool in Sca-1 null mice, by transplantation of wild-type (WT) bone marrow derived MSC, and assess the putative therapeutic potential of this approach. Donor MSCs were highly clonogenic, devoid of hematopoietic cell contamination, and retained a high osteogenic capacity. Short-term engraftment of 2x10^6 DiR labeled MSCs transplanted via intravenous injection display successful engraftment into hind limbs of Sca-1 null mice for at least 14 days. Flow cytometry of nucleated cells flushed from marrow shows engraftment of between 1:1000 to 1:3000 cells. To assess long-term engraftment, we transplanted 2x10^6 eGFP+ MSCs from male donor mice into 2.5-month-old Sca-1 null females. At approximately 8.5 months of age, mice were sacrificed and engraftment was assessed. Sca-1 null mice that received the eGFP+ MSC transplant display low-level engraftment beyond 8.5 months of age. Bone micro-architecture assessed in 8.5-month-old mice via Micro CT displayed improved trabecular connectivity density in mice transplanted with 2x10^6 WT MSCs vs Sca-1 null controls ($p \leq 0.05$). Further, trabecular number, bone volume/total volume, trabecular spacing, and trabecular degree of anisotropy showed trends towards improvement ($0.1 \geqslant p \geqslant 0.05$). These results show that a single systemic transplanted dose of MSCs is capable of engrafting into the bone marrow of osteoporotic mice and protects against progressive bone loss and reduction in bone quality for at least 6 months. Ongoing experiments including mechanical testing and histological analysis will further investigate the efficacy of MSC transplantation to treat osteoporosis in our preclinical model of type II osteoporosis.

Therapeutic Potential of Adipose-derived Stromal Cells (ASCs) for the Treatment of Osteoporosis. Ali Mirsaidi*[1], Jolanda Vetsch[2], Matthias Arlt[3], Ralph Müller[3], Sandra Hofmann[2], Peter Richards[1]. [1]CABMM, Zurich University, Switzerland, [2]ETH Zurich, Institute for Biomechanics, Switzerland, [3]Balgrist University Hospital, Switzerland

We have previously confirmed that unlike bone marrow-derived stromal cells, adipose-derived stromal cells (ASCs) isolated from osteoporotic senescence-accelerated mouse prone 6 (SAMP6) mice retain their osteogenic potential when cultured under standard two-dimensional (2D) conditions. As such, ASCs may represent an alternative therapeutic approach for enhancing bone quality in patients with osteoporosis. In the present report, we have extended these studies to examine the influence of 3D-culture conditions on the osteogenic potential of ASCs from SAMP6 mice in an attempt to better assess their suitability as a cell-based therapy for treating osteoporosis. ASCs were isolated from subcutaneous inguinal fat pads by collagenase digestion and stem cell purity determined by fluorescence-activated cell sorting (FACS). Cells were grown in 3D-cultures either as scaffold-free microtissues (ASC-MTs) or in silk fibroin scaffolds. Osteogenic differentiation of ASCs was determined at selected time points using molecular, histological and micro-computed tomography (micro-CT) analyses. Bone morphogenetic protein 2 (*Bmp2*) and osteopontin (*Spp1*) expression levels were significantly upregulated in a time dependent manner in ASC-MTs in response to osteogenic stimuli. Mineral deposition was also apparent in osteogenic ASC-MTs as determined by Alizarin Red staining, and could be detected after only 6 days of differentiation. Silk fibroin scaffolds seeded with ASCs were cultured in bioreactors for up to 42 days, and mineral formation monitored by micro-CT. The bone volume fraction (BV/TV) was significantly elevated in silk fibroin scaffolds seeded with ASCs as compared to scaffolds alone. Silk fibroin scaffolds seeded with ASCs also stained positive for Alizarin Red, and expressed high levels of both *Bmp2* and *Spp1*. Preliminary *in vivo* studies confirmed that fluorescent-labeled isogenic ASCs could be injected directly into the tibial bone cavity of SAMP6 mice without any adverse effects and could be identified within the bone marrow after 24 hours. In conclusion, ASCs harvested from osteoporotic mice have the potential to undergo efficient osteogenic differentiation in a 3D-microenvironment resulting in the formation of a mineralized matrix. Adipose tissue may therefore represent a promising autologous cell source in the development of novel stem cell-based therapeutic strategies for the treatment of osteoporosis

Differential effects of calorie restriction on the skeleton implicate marrow adipose tissue as an independent adipose tissue depot. Casey Doucette*[1], Erica Scheller[2], Ormond MacDougald[3], Mark Horowitz[4], Clifford Rosen[5]. [1]Maine Medical Center Research Institute, USA, [2]University of Michigan, USA, [3]Department of Molecular & Integrative Physiology, University of Michigan Medical School, USA, [4]Yale University School of Medicine, USA, [5]Maine Medical Center, USA

The role of marrow adipose tissue (MAT) in the regulation of bone formation and resorption is largely unknown. Many studies have indicated an inverse relationship between bone mass and MAT content; humans with anorexia nervosa show increased levels of MAT and decreased BMD compared to healthy control subjects. Marrow fat content also increases with age along with age-related bone loss. Here, we investigate the role of MAT in the regulation of bone remodeling and energy homeostasis during a period of caloric deprivation in adolescent and aging mice. In cases of reduced energy intake, we hypothesized that MAT volume increases but is protective of bone. We took advantage of the innate differences between the C57BL/6J (B6) and C3H/HeJ (C3H) strains, which have diverse bone phenotypes; male C3H mice display significantly higher bone density and MAT volume than B6. Male B6 and C3H mice were fed a 30% calorie restricted (CR) diet for a period of 12 weeks from either 3-15 weeks of age (adolescent) or 40-52 weeks of age (aging). Littermate controls from each strain were given control (CTRL) diet *ad libitum*. As expected, adolescent CR mice had significantly lower trabecular BV/TV in the distal femur by μCT analysis in both strains ($n=10$, $p<0.001$), due to the detrimental effect of CR on bone formation during peak acquisition. Tibial MAT content, quantified by osmium staining, was significantly increased with CR in B6 ($n=5$, $p<0.01$) but not C3H mice compared to controls, while body composition by DEXA showed that adolescent C3H mice lost a greater percentage of body fat with CR than B6. CR in aging C3H mice led to significantly reduced cortical and trabecular BV/TV in the femur ($n=10$, $p<0.01$) as compared to CTRL-fed mice; remarkably, aging B6 CR mice were resistant to loss of bone mass, suggesting that CR is protective of skeletal mass in aging B6 but not C3H mice. Whole-body DEXA analysis showed that aging B6 mice lost a greater percentage of body fat with CR than C3H, while quantification of tibial MAT content from these mice showed significant increases in MAT volume in both strains with CR ($n=9$, $p<0.03$). Our results demonstrate that CR has strain-dependent effects on bone mass and adipose tissue depots and that MAT is an independent adipose depot that may serve distinct purposes within the skeletal niche depending upon age, energy status, and genotype. The previous tenet that MAT is purely a filler in response to reduced trabecular bone volume is no longer tenable.

Effects of opioid substitution therapy with diacetylmorphine or methadone on bone health: a controlled study. Lisa Strahm*[1], Christoph Senn[1], Robert Haemmig[2], Kurt Lippuner[1]. [1]Department of Osteoporosis, University Hospital & University of Berne, Switzerland, [2]University Psychiatric Departement Addiction Therapy Unit, Switzerland

Introduction: Opioids, and thus opioid substitution treatment (OST), may have deleterious effects on bone mass leading to increased fracture risk. Whether long term OST with either diacetylmorphine (DAM) or methadone (MET) have different effects on bone is unknown.

Methods: Cross-sectional controlled study with 55 men in three groups: former heroin addicts on OST with DAM (n=19) or MET (n=17), and healthy controls (n=19). All patients on OST had been substituted for at least five consecutive years. Patients with known confounders in regard to bone health apart from smoking and non-cirrhotic viral hepatitis were excluded. BMD was assessed at the lumbar spine (LS), total hip (TH), femoral neck (FN), and tibial epiphysis (T-EPI) and diaphysis (T-DIA) using Dual X-ray Absorptiometry (DXA). Fractures history was recorded and prevalent spine fractures were assessed by Vertebral Fracture Assessment (VFA) during DXA acquisition.

Results:Patients substituted with DAM or MET, had a significantly lower Z-score than controls at T-EPI (-0.8 and -0.5 vs. 0.3, with p=0.001 and 0.015, respectively). Patients substituted with DAM, but not MET, had a significantly lower Z-score than controls at LS, -1.6 vs. -0.6 (p=0.016) and TH, -0.5 vs. 0.1 (p=0.049). Prior fractures at any localization were reported by 16 patients on DAM (38 fractures), 10 patients on MET (22 fractures), and 12 controls (24 fractures). Prior fractures during adulthood were detected in 10 patients on DAM (24 fractures), 7 patients on MET (13 fractures) and 6 controls (8 fractures). VFA detected two vertebral fractures (one severe on DAM and one moderate on MET).

*Conclusion:*Former heroin addicted men under long term OST have lower BMD than healthy controls, with numerically worse Z-scores at all measurement sites, and significantly lower Z-scores at the LS (DAM) and T-EPI (DAM and MET). Fractures were also numerically more frequent in these patients.

Abnormal Microarchitecture and Stiffness in Postmenopausal Women Treated with Glucocorticoids. Stephanie Sutter[1], Kyle Nishiyama[2], Anna Kepley[1], Thomas Nickolas[3], Adi Cohen[1], Bin Zhou[2], X Guo[2], Elizabeth Shane[3], Emily Stein*[3]. [1]Columbia University Medical Center, USA, [2]Columbia University, USA, [3]Columbia University College of Physicians & Surgeons, USA

Patients treated with glucocorticoids (GCs) are more likely to fracture than untreated patients with similar areal bone mineral density (aBMD), suggesting that GCs increase fragility via mechanisms distinct from their effects on bone density. This study used high resolution peripheral computed tomography (HRpQCT) and micro finite element (μFE) analyses to characterize bone microarchitecture and stiffness in postmenopausal women on GCs. We hypothesized that women using GCs would have disrupted microarchitecture and lower stiffness compared to controls, and that abnormalities would be more prominent in the trabecular compartment, as GC-related fractures traditionally occur at primarily trabecular sites. 27 postmenopausal women using oral GCs for >3 months were matched 1:2 with 54 controls of the same ethnicity and age. All had aBMD of lumbar spine, total hip, femoral neck, 1/3 and ultradistal radius (UDR) by DXA. Trabecular (Tb) and cortical (Ct) volumetric BMD, and Tb microarchitecture were measured by HRpQCT (voxel size ~82 μm) of the distal radius and tibia. Whole bone stiffness was estimated by μFE. Mean age of subjects was 68 ± 9 years (67% Caucasian). BMI and menopausal age were similar between groups. GC subjects were more likely to be using bisphosphonates (33% vs. 6%;$p<0.01$). Among GC subjects, 74% had rheumatologic diseases. Mean daily dose of prednisone was 7.8 mg and duration of use 3.4 years. Mean T-scores both groups were in the osteopenic range and did not differ significantly at any site. There were substantial microarchitectural differences between groups by HRpQCT (Table). At the radius, GC subjects had lower total and Tb density and Tb thickness. Ct thickness tended to be lower, and Tb separation higher among GC subjects (representative HRpQCT images are shown in Figure). At the tibia, GC subjects had lower total, Ct and Tb density. Tb thickness was lower and network heterogeneity was greater. Ct thickness tended to be lower among GC subjects. Differences remained significant after adjustment for aBMD. Whole bone stiffness was lower in GC subjects at both sites. In summary, postmenopausal women using GCs had microarchitectural and biomechanical deterioration at both radius and tibia compared to controls, despite similar aBMD by DXA. As hypothesized, Tb abnormalities, particularly Tb thinning, were most marked. These abnormalities in microarchitecture and stiffness may be important determinants of skeletal fragility in patients using GCs.

Microarchitecture in GC subjects vs. Controls (% difference)

	RADIUS	p-value	TIBIA	p-value
Total Density	-12	<0.03	-15	<0.003

Altered Cortical Microarchitecture and Bone Metabolism in Patients with Monoclonal Gammopathy of Undetermined Significance. Joshua Farr*[1], Wei Zhang[1], Richard Jacques[2], Alvin Ng[1], Louise McCready[1], Matthew Drake[3]. [1]Mayo Clinic, USA, [2]University of Sheffield, United Kingdom, [3]College of Medicine, Mayo Clinic, USA

Monoclonal gammopathy of undetermined significance (MGUS) is associated with increased fracture risk. Recent evidence shows that MGUS patients have altered trabecular microarchitecture but no differences in bone turnover markers as compared to controls (Blood 118:6529, 2011). However, whether MGUS patients have deficits in cortical microarchitecture or bone strength is unknown. Furthermore, no study in MGUS patients has simultaneously considered the complementary processes of bone balance and turnover, using the ''bone marker plot'' (Eur J Clin Invest 39:220, 2009). Thus, we used HRpQCT and micro-finite element analysis to assess bone microarchitecture and strength of the distal radius in a case-control study of 50 men and women (age 49–88 yrs) with MGUS and 100 age-, sex-, and BMI-matched (1:2 ratio) controls. Serum levels of Dickkopf-related protein 1 (DKK1) and markers of bone formation and resorption were also measured. Compared to controls, MGUS patients had significantly altered cortical microarchitecture at the radius [i.e., higher cortical porosity (+16.8%; $P<0.05$); lower cortical volumetric BMD (–4.5%; $P<0.001$)], while also having greater endocortical and periosteal circumferences (+5.7% and +4.2%, respectively; $P<0.01$). In addition, radial apparent modulus (stiffness corrected for cross-sectional area) was significantly lower (–8.9%; $P<0.05$) in MGUS patients relative to controls. When all MGUS patients were combined, bone balance and turnover were not different between MGUS patients and controls. However, MGUS patients with higher monoclonal protein levels (>2.0 g/dL) showed a significant shift towards a reduced bone turnover rate in bone marker plot analyses (Figure; P=0.022). In addition, these patients tended to have higher DKK1 levels.

In conclusion, despite their larger radial bone size, MGUS patients have compromised cortical microarchitecture and bone strength as compared to controls. Furthermore, MGUS patients with higher monoclonal protein levels have reduced bone turnover. Given the critical role of DKK1 as an inhibitor of Wnt signaling in bone cells, the higher DKK1 levels observed in these patients may reflect suppression of bone formation. Our findings point to the need to further define the factors that regulate bone microarchitecture and metabolism in MGUS in order to better identify patients at risk for skeletal complications and to develop appropriate treatment strategies to reduce the increased fracture risk in these patients.

Bone density and bone material strength measured by microindentation ten years after kidney transplant. Laia Vilaplana[1], Maria José Pérez-Sáez[2], Daniel Prieto-alhambra[3], Elisa Torres-Del-Pliego[4], Leonardo Mellibovsky[5], Marta Crespo[2], Roberto Güerri-Fernández[5], Julio Pascual-Santos[2], Xavier Nogues[6], Adolfo Diez-Perez*[7]. [1]Internal Medicine Department, Parc de Salut Mar, Universitat Autònoma de, Spain, [2]Nefrology Department, Parc de Salut Mar, Universitat Autònoma de Barcelona, Spain, [3]University of Oxford, United Kingdom, [4]Internal Medicine Department, Hospital del Mar, Barcelona, Spain, [5]Internal Medicine Department, Parc de Salut Mar, Universitat Autònoma de Barcelona, Spain, [6]Institut Municipal D'Investigació Mèdica, Spain, [7]Autonomous University of Barcelona, Spain

Background: Kidney transplant recipients (KTR) suffer an increased fracture risk in the months following the procedure that later on comes back to background population rates. However, no data is available on the bone status several years after the transplant. We assessed bone strength related parameters in a cohort of KTR ten years after the procedure.

Methods: Consecutive series of patients with over 10 years of kidney transplant and recovery of kidney function (MDMD 42.6+14.3 ml/min). BMD was measured using DXA. Vertebral fractures were assessed in dorsal and lumbar lateral spine radiography. BMS was measured by microindentation in the anterior midtibia with an Osteoprobe® device (Active Life Scientific, Santa Barbara, CA) applying a 20N force with a test probe, standardized as the ratio to a PMMA phantom. Statistical analyses were performed by ANOVA.

Results: A total of 27 KTR cases and 41 controls have been studied. Average BMD T-score at lumbar spine (-1.3 + 1.33) and total hip (-1.45 + 0.99) in transplant patients where within osteopenia range. BMS values were 81.01 + 7.40 in KTR and 84.62 + 6.17 in controls (p=0.65 after adjusting by age, sex and BMI). In 10 KTR cases vertebral fractures were detected (40% over 25 cases with X-rays). No differences in BMS were seen between KTR cases with (80.70+8.27) and without (81.26+7.33) prevalent fractures (p=0.69 after adjustment by age, gender and BMI). All variables expressed as mean + SD. No significant correlation was observed between BMS and BMD at any location.

Conclusions: Ten years after kidney transplant bone parameters are normal, as assessed by densitometry and microindentation. The high prevalence of vertebral fractures may be related with increased bone fragility in the period after the procedure. In these patients, with recovery of kidney function, there are no detectable long-term skeletal abnormalities and our results suggest a full recovery.

Bone Density Changes after Lower Limb Amputation. Debra Bemben*[1], Vanessa Sherk[2], Michael Bemben[1]. [1]University of Oklahoma, USA, [2]University of Colorado - Denver, USA

Cross-sectional studies have reported that lower limb amputees have compromised bone health. Recently, we found that areal BMD (aBMD) for the hip sites was lower in the amputated side compared to the intact side. The purpose of this longitudinal study was to assess changes in total body, hip and spine areal BMD occurring in the early stages after lower limb amputation. Six participants (1 premenopausal female, 5 males), ages 23 to 53 years were enrolled in the study immediately prior to their amputation surgery. They all were traumatic unilateral amputees (1 above knee, 5 below knee) who had undergone the Ertl procedure. BMD variables (total body, lumbar spine, dual proximal femur) and body composition were assessed by DXA (GE Lunar Prodigy) after amputation prior to prosthesis fitting (pre-ambulatory baseline), at 6 months walking with prosthesis, and at 12 months walking with prosthesis. Participants gained body weight ($p < 0.05$) from baseline to the 6 month time point. There were no significant changes in total body or spine (L1-L4) aBMD at either ambulatory time point compared to pre-ambulatory baseline. One participant had a spine T-score ≤ -1.1 at each time point. There were significant ($p < 0.01$) side, time, and side × time interaction effects for the total hip and femoral neck sites. Total hip aBMD significantly decreased from baseline to 6 months ($p = 0.001$) and 12 months ($p = 0.003$) with prosthesis for the amputated side but not for the intact side (Table 1). Similarly, the femoral neck aBMD for the amputated side significantly decreased, however, the intact side also significantly ($p = 0.008$) decreased from baseline to 6 month time points. The % decreases were -15.8% and -14.9% for the amputated side total hip and femoral neck sites. None of the participants were osteopenic or osteoporotic for the amputated or intact side hip sites at baseline. By 6 months, 2 participants were osteopenic at the total hip for the amputated side and by 12 months, 3 (below knee) participants were osteopenic and 1 (above knee) was osteoporotic for the amputated side total hip. In conclusion, large decrements occurred in the amputated hip aBMD by 6 months walking with prosthesis and was maintained at the 12 month time point. These findings suggest that bone losses resulting from unloading with amputation were not regained with prosthesis use.

Table 1. Total Hip aBMD (n=6)

	Amputated Side	Intact Side
	(g/cm²)	(g/cm²)
Baseline	1.122 ± 0.031	1.145 ± 0.032
6 Months with Prosthesis	0.956 ± 0.031**	1.136 ± 0.036
12 Months with Prosthesis	0.944 ± 0.039**	1.136 ± 0.034

Bone Health in Postmenopausal Women with Breast Cancer Receiving Aromatase Inhibitors. Vit Zikan*[1], Martina Zimovjanova[2], Luboš Petruželka[2], Jana Přibylová[2], Michaela Cabinakova[3], Maria Raskova[1]. [1]3rd Department of Medicine - Department of Endocrinology & Metabolism, First Faculty of Medicine, Charles University in Prague & General University Hospital in Prague, Czech Republic, [2]Department of Oncology, First Faculty of Medicine, Charles University in Prague & General University Hospital in Prague, Czech Republic, [3]Department of Oncology, First Faculty of Medicine, Charles University in Prague & General University Hospital in Prague, Dominican Republic

Aromatase inhibitors (AIs) are the standard of care for the treatment of most postmenopausal women with early stage hormone-receptor-positive breast cancer (EBC). However, one side-effect of AIs on bone is a decrease in bone mineral density (BMD) and an increased risk of fracture. Early identification of women with poor bone health offers opportunities for interventions aimed at reducing fracture risk. In this study we investigated bone health in a prospective cohort of patients recruited prior to adjuvant AIs therapy, with the aim of establishing potential AIs impact on bone loss and fractures. Methods: Eighty-one postmenopausal women (mean age: 61.4 years) who have been considered for adjuvant AIs therapy for EBC were enrolled for the study. BMD was measured by dual-energy X-ray absorptiometry (DXA). Clinical risk factors and FRAX algorithm were evaluated. Bone remodeling was assessed using circulating concentrations of type 1 collagen cross-linked C-telopeptide (CTX) and N-terminal propeptide of type I procollagen (PINP). In addition, we examined the prevalence of vitamin D deficiency. Results: Twelve patients (14.8%) met the criteria for osteoporosis and thirty six patients (44.5%) for osteopenia. The mean 25 (OH) D level was 21.9 ± 11.1 ng/ml (range 4.6-47.3 ng/ml). Of the 53 patients, 7 patients (13.2 %) had vitamin D deficiency (< 10 ng/ml), 34 patients (64.2 %) had an insufficiency (10 to 30 ng/ml) and 12 patients (22.6 %) had normal values (> 30 ng/ml). Conclusion: Low BMD and vitamin D insufficiency were highly prevalent among patients considered to adjuvant AIs for EBC. Therefore, it is important to assess BMD and 25 (OH) D levels before starting AIs therapy. However, factors other than BMD levels alone may influence fracture risk and a combined fracture risk assessment (eg, FRAX algorithm) will probably more accurately identify breast cancer patients who require bone-protective therapy. Longitudinal study is currently underway.

Endosteal Resorption and Worsening Cortical Porosity after Roux-en-Y Gastric Bypass Surgery. Elaine Yu*[1], Melissa Putman[2], Mary Bouxsein[3], Adam Roy[1], Nicolas Derrico[1], Joel Finkelstein[1]. [1]Massachusetts General Hospital, USA, [2]Massachusetts General Hospital, Children's Hospital Boston, USA, [3]Beth Israel Deaconess Medical Center, USA

Purpose: We have previously reported discordance between reported effects of Roux-en-Y gastric bypass (RYGB) on BMD when assessed by DXA versus QCT, likely due to imaging artifact related to large weight loss at central sites. High-resolution peripheral quantitative computed tomography (HR-pQCT) may provide more accurate estimates of skeletal changes after RYGB.

Methods: We assessed cortical and trabecular volumetric BMD (vBMD) and bone microarchitecture at the distal radius and tibia in 50 severely obese adults (30 undergoing RYGB surgery + 20 non-surgical controls) using HR-pQCT (Scanco, Basserdorf, SZ) at 0 and 12 months. Specialized software was used for more detailed assessment of cortical bone, including cortical porosity, and to estimate bone strength by microfinite element analysis (mFEA).

Results: The RYGB and control groups were well matched at baseline. Body weight fell 37 ± 2 kg in the RYGB group versus 3 ± 2 kg in the controls ($p<0.0001$). In the RYGB group, total vBMD declined significantly at the radius and the tibia ($p<0.001$ for both sites, see Table). The decline at the radius was largely due to a fall in trabecular vBMD whereas the decline at the tibia was largely due to a decrease in cortical vBMD (Table). Cortical porosity increased by 27 ± 11% at the radius and by 31 ± 8% at the tibia though only the latter value was significantly different from controls (Table). After RYGB, cortical area and cortical bone volume declined with a parallel increase in trabecular area at both sites ($p<0.03$ for all, Table), consistent with endosteal resorption and "trabecularization" of cortical bone. Changes in trabecular microarchitecture were not significantly different between RYGB and control groups. Estimated failure load declined significantly at the tibia but not at the radius in the RYGB group compared with controls (Table). There were no significant associations between changes in vBMD, microarchitectural or mFEA parameters and changes in weight, PTH, or 25OHD in the RYGB group. Lastly, declines in total vBMD at the radius and tibia after RYGB were not associated with changes in spine or hip BMD by DXA or QCT.

Conclusions: Volumetric BMD at both the distal radius and tibia decreases after RYGB, accompanied by increased endosteal resorption. At the tibia, these changes are primarily due to increased cortical porosity and lead to a decrease in estimated strength. The long-term consequences of the early skeletal changes after RYGB need to be assessed.

Percent change in HR-pQCT parameters from 0 to 12 months

	RADIUS		TIBIA	
	RYGB	Controls	RYGB	Controls
Total vBMD	-3.0 ± 0.7%*	1.7 ± 0.6%	-3.3 ± 0.7%*	-0.4 ± 0.2%
Cortical vBMD	-0.5 ± 0.4%	-0.1 ± 0.5%	-2.4 ± 0.6%*	0.1 ± 0.5%
Trabecular vBMD	-1.7 ± 0.7%*	0.5 ± 0.8%	-0.7 ± 0.9%	-1.6 ± 0.5%
Cortical Porosity	27 ± 11%	6 ± 17%	31 ± 8%*	-8 ± 4%
Cortical Area	-3.3 ± 1.0%*	3.0 ± 1.2%	-2.7 ± 1.1%*	0.3 ± 0.6%
Trabecular Area	1.0 ± 0.4%*	-1.1 ± 0.6%	0.7 ± 0.3%*	-0.1 ± 0.1%
Failure Load	-0.8 ± 1.1%	0.0 ± 0.8%	-1.4 ± 0.8%*	1.4 ± 0.7%

*p-value <0.05 for difference between RYGB vs. controls

Genetic determinants of bone mineral density loss in Aromatase inhibitors treatment. MARIA RODRIGUEZ-SANZ[1], Daniel Prieto-alhambra[2], Sonia Servitja-Tormo[3], Elisa Torres-Del-Pliego[4], Leonardo Mellibovsky[4], Laia Garrigós[3], Natalia Garcia-Giralt[1], Adolfo Diez-Perez[5], Ignacio Tusquets[3], Xavier Nogues*[6]. [1]IMIM, Spain, [2]University of Oxford, United Kingdom, [3]Medical Oncology Department, Parc de Salut Mar, Barcelona, Spain, Spain, [4]URFOA-IMIM, Red Temática de Investigación Cooperativa en Envejecimiento y Fragilidad (RETICEF), Instituto de Salud Carlos III FEDER, Barcelona, Spain, Spain, [5]Autonomous University of Barcelona, Spain, [6]Institut Municipal D'Investigació Mèdica, Spain

Purpose: Therapy with Aromatase inhibitors (AI) for estrogen receptor-positive breast cancer in postmenopausal women results in bone mineral density (BMD) loss and fractures. This study aims to identify genetic variants associated with BMD in the first year of AI treatment.

Methods: Single nucleotide polymorphisms (SNPs) were selected in genes potentially involved in: 1.Vitamin D and estrogen signaling pathways, 2.described association with BMD and fractures in a GWAs study (Estrada K et al, Nature Genetics, 2012), and/or 3.AI CYP450 metabolizer subunits. Selected SNPs were genotyped in 280 Caucasian, postmenopausal women with early breast cancer, starting adjuvant treatment with AI as recommended by ASCO guidance. Outcome was absolute (baseline minus 1-year BMD [in gr/cm2]) BMD loss at 1 one year of therapy as measured using DXA scan at three sites: Lumbar spine (LS), femoral neck (FN) and total hip (TH).

Paired T-tests were used to measure AI-related BMD loss. Multivariate linear regression models were fitted to test the association between the selected SNPs and absolute BMD loss after 1 year of follow-up. All models were adjusted for body mass index, years since menopause and baseline BMD. For the analyses of the SNPs involved in vitamin D signaling, we further adjusted for baseline vitamin D concentrations.

Results: After 1 year of AI therapy, participants experienced a significant 1.42 % [95 % CI 0.93–1.91 %] BMD loss at LS (0.014 g/cm2 [0.009–0.019], $P < 0.0001$), 1.16 % [95 % CI 0.62–1.70 %] at FN (0.009 g/cm2 [0.005–0.013], $P < 0.0001$), and 0.72 % [95 % CI 0.30–1.14 %] at TH (0.007 g/cm2 [0.003–0.010], $P = 0.01$).

Under the hypothesis of Vitamin D and estrogen signaling, rs2544037 in VDR gene and rs6013897 in CYP24A1 reached significant p-values (P=0.04 and P=0.01 respectively) for the association with LS BMD loss. The same SNP in VDR (P=0.02), as well as rs11907350 in CYP24A1 were associated (P=0.02) with FN BMD loss. For the analyses of genes previously associated with BMD, rs7851693 in FUBP3 showed a significant association (P=0.01), and rs163879 in DCDC5 yielded a borderline p-value (P=0.06) for the association with LS BMD loss. Finally, rs4986894 in CYP2C19 gene and rs9332982 in CYP4A11 gene, both involved in AI metabolization, obtained significant results in the association with LS BMD loss (P=0.01 and P=0.004 respectively).

Conclusions: SNPs in VDR, CYP24A1, FUBP3, DCDC5, CYP4A11 and CYP2C19 genes appeared significantly associated with BMD loss in the first year of AI treatment. None of the three postulated hypothesis stood out amongst the others, suggesting that BMD loss during AI therapy is determined by an interaction of genes involved in several metabolic pathways: Vitamin D and estrogens signalling, AI-metabolization by CYP450, genetic determinants of BMD and fracture risk.

HIV+ male patients receiving fluoride, present in an antiretroviral therapy (TRUVADA®), have an improved trabecular bone density and micro-architecture at the tibia. Pierre Sellier[1], Hervé Trout[2], Corinne Collet[3], Amanda Lopes[1], Karine Champion[1], Guy Simoneau[1], Agnès Ostertag[3], Sylvie Fernandez[3], Jean-Dominique Magnier[1], Marie-Christine De Vernejoul*[4], Jean-François Bergmann[1]. [1]Service de Medecine interne A, Hopital Lariboisiere, Assistance Publique-Hopitaux de Paris, France, [2]Pharmacie : medicaments et laboratoires, Hopital Lariboisiere, Assistance Publique-Hopitaux de Paris, France, [3]INSERM U 606 & University Paris Diderot, Service de rhumatologie, Hopital Lariboisiere, Assistance Publique-Hopitaux de Paris, France, [4]Fédération De Rhumatologie Et INSERM U606, France

Background: HIV+ patients are considered at risk for excessive bone fragility. Several factors could contribute: age, low body mass index (BMI), HIV infection *per se* and antiretroviral treatment (particularly tenofovir, a reverse transcriptase inhibitor). Tenofovir is used with [TRUVADA®] or without [VIREAD®] emtricitabine (FTC). FTC is 5-fluorinated to increase bioavailability and half-life of the drug; the daily intake of fluoride in patients treated with TRUVADA® is 15.4 mg. Fluoride induces bone formation by stimulating osteoblasts. The aim of our study was to investigate if this fluoride supplementation impact on bone.

Methods: We have included in this retrospective cross-sectional study 35 HIV+ male patients treated with TRUVADA® for more than 60 months. We compared them to 18 HIV+ male patients treated with VIREAD® who had never received TRUVADA® and were matched to the TRUVADA® group for age, ethnic origin, BMI, total HIV+ duration and tenofovir exposure. Fluoride metabolism was studied by measurement of fluoride in blood, bone formation by measurement of serum P1NP. Dual X-ray absorptiometry was used to determine the areal bone mineral density (aBMD) of the lumbar spine, femoral neck and distal radius. Volumetric BMD (v-BMD) and micro-architecture of distal radius and tibia were studied using a HR-pQCT scan (Xtreme, Scanco).

Results: The age of the patients (50 ± 9 vs. 49 ± 8 yrs, p=0.57), the disease duration (13 ± 6 vs. 15 ± 5 yrs, p=0.27) and the total tenofovir exposure (78 ± 19 vs. 77 ± 11 months, p=0.83) of TRUVADA® and VIREAD® groups were not different. The two groups did not differ significantly regarding the mean fluoride in blood, the mean P1NP (47 ± 15 vs. 41 ± 11 ng/ml, p=0.21), the a-BMD of the lumbar spine, femoral neck and distal radius (assessed by Z-scores, after adjustment on age and ethnic origin). Micro-architectural parameters at the radius were not different between groups. At the tibia, trabecular v-BMD (171 ± 39 vs. 143 ± 41 mg HA/cm^3 $p< 0.05$), BV/TV (0.14 ± 0.03 vs. 0.12 ± 0.03, $p<0.05$), trabecular number (2.0 ± 0.3 vs. 1.7 ± 0.4, $p<0.01$) were significantly higher in the TRUVADA® group, whereas trabecular separation was reduced (0.45 ± 0.08 vs. 0.56 ± 0.14 mm, $p<0.01$). There was no difference in any cortical parameters.Conclusions: The improved trabecular bone parameters observed in HIV+ male patients chronically treated by TRUVADA®, compared to those receiving VIREAD® were compatible with a positive action of small amount of fluoride on trabecular bone.

Longitudinal Change in Bone Mineral Density Among Adult Patients with Malignant Lymphoma Receiving Chemotherapy. Julien Paccou*[1], Isabelle Henry-Desailly[1], Lavinia Merlusca[1], Said Kamel[1], Daciana Ursu[1], Rachel Desailloud[1], Jean-Pierre Marolleau[1], Patrice Fardellone[2], Gandhi Damaj[1]. [1]Université De Picardie Jules Verne, France, [2]Service de rhumatologie, CHU Hôpital Nord, France

The time course of bone mineral density (BMD) loss is poorly characterized in malignant lymphoma patients. The present study was designed to measure the extent of bone loss assessed by BMD in a cohort of adult patients with known malignant lymphoma receiving chemotherapy.

This was a single-center, prospective, longitudinal study. Inclusion criteria: Patients aged ⩾18 years with previously confirmed malignant lymphoma treated by chemotherapy. Exclusion criteria: Patients with low baseline vertebral or hip BMD defined as T-score ≤ -2.5 and/or history of osteoporotic fractures. BMD was measured at baseline before initiating chemotherapy with final BMD testing one year later. BMD in the lumbar spine, total hip and femoral neck using pencil-beam dual energy X-ray absorptiometry, and clinical, biochemical, and anthropomorphic changes were assessed. Predictive factors of BMD loss and factors associated with an unfavourable outcome (death or no remission) were investigated. Osteoporotic fractures were also assessed at baseline and at the end of follow-up.

Forty-one patients with malignant lymphoma receiving chemotherapy were enrolled. No patients were lost to follow-up, but 6 died before one year and 3 required treatments with bisphosphonates during the first month of the study. The characteristics of the remaining 32 patients at baseline and 12 months later are shown in Table. Mean absolute BMD changes were -0.027 g/cm^2 ± 0.042 for lumbar spine (-2.7 $\pm 3.9\%$), -0.021 g/cm^2 ± 0.067 for femoral neck (-2.2 $\pm 7.6\%$) and -0.026 g/cm^2 ± 0.043 for total hip (-2.6 $\pm 4.5\%$). Predictive factors of BMD loss at lumbar spine were female gender (-6.1 $\pm 4.0\%$) versus male (-1.7 $\pm 3.5\%$) (P=0.009), International Prognostic Index (IPI) score=3-4 (-6.2 $\pm 5.3\%$) versus IPI=0-2 (-2.0 $\pm 3.1\%$) (P=0.03) and WHO score=1-2 (-4.7 $\pm 4.9\%$) versus WHO score=0 (-1.7 $\pm 3.1\%$) (P=0.04). No predictive factors of BMD loss at femoral neck or total hip were found. Factors associated with an unfavourable outcome in multivariate analyse were WHO score with OR = 19.8 (95% CI: 11.59 - 247.01; P=0.02) and chemotherapy duration with OR = 16.59 (95% CI: 1.31 - 209.82; P=0.03). Four patients developed osteoporotic fractures during follow-up.

In conclusion, adult patients with known malignant lymphoma receiving chemotherapy experienced significant bone loss as assessed by BMD at the lumbar spine, total hip and femoral neck. Moreover, BMD loss in the lumbar spine was influenced by female gender, IPI and WHO scores.

Pregnancy Associated Osteoporosis with Vertebral Fractures: Report of a Case with 5-Year Follow-Up. Gulseren Akyuz*[1], Ozun Bayindir[2], Beyhan Eren[3]. [1]Marmara University, Turkey, [2]MD, Department of Physical Medicine & Rehabilitation, School of Medicine, Marmara University, Turkey, [3]MD, Physical Medicine & Rehabilitation Clinic, Mersin State Hospital, Turkey

Pregnancy associated osteoporosis (PAO) is a rare clinical condition that may affect women during third trimester of pregnancy or after the delivery. Little is known about the prevalence, reasons, risk factors and prognosis of PAO. It can cause severe or prolonged back pain with one or more vertebral fractures and loss of height. Herein we report a case of PAO in a 32 year-old female who presented with severe back pain with multiple vertebral fractures 1 month after delivery. There were delayed menarche and low dietary calcium intake in history. The radiological examinations have shown compression fracture of 8th thoracic vertebra and wedging of 11th and 12th thoracic vertebrae and lumbar spine. In the bone mineral density (BMD) total lumbar spine T-score and Z-score were -2,8 while femoral neck T-score and Z score were -1,2 and -1,1, respectively. There were no abnormality in laboratory findings except mild alkaline phosphatase elevation and 25-hydroxy vitamin D insufficiency. Three months after delivery for pain reduction T8 kyphoplasty was applied. Along 5-year follow-up vitamin D_3, calcium, calcitonin, bisphosphonate, GABA anologs, analgesics, physical agents, dry needling were used for treatment. Back pain decreased with all kind of treatments significantly (VAS decreased from 10 to 3 point) but localized pain around kyphoplasty area have been continued even if low level pain severity (VAS 3 point) along 5-year follow-up. There were no new fractures and marked recovery of spine BMD was observed during the same period. Her activities of daily living improved permenantly. As a conclusion, when back pain occurs at last trimester of pregnancy or early postpartum period, PAO should be considered in differential diagnosis and long term treatment should be planned for the patient's well being.

Bone Density and Vitamin D Status in Liver Transplant Patients 12 Years After the First Assessment. Elena Segal*[1], Yacov Baruch[1], Rimma Kramsky[1], Marina Nodelman[2], Marina Hefetz-Kustanovich[1], Sophia Ish-Shalom[1]. [1]Rambam Health Care Campus, Israel, [2]Western Galilee Hospital, Israel

Twelve years ago we evaluated 29 liver transplant patients. Nineteen (65.5%) had decreased bone mass, 11 (37.8%) were osteoporotic, 28 (96.5%) had serum level of 25(OH)D<20 ng/ml, mean 12.52±3.19, mean PTH 59.67±29.78 pg/ml. None was treated with calcium or vitamin D supplements, in spite of low calcium intake and low or suboptimal 25OHD serum level. The patients received letters containing the diagnosis and treatment recommendations.

Now we re-evaluated patients' charts. Nineteen patients continued follow-up at the Liver Unit, 9 men, 10 postmenopausal women, aged 58.8±15.8. Ten patients died, none of them had fractures. Twelve fractures were reported following transplantation, 10 (83.3%) within the first year, 2 in the following years, both were traumatic.

Second BMD results were available for 8 (42%) patients, two (25%) were osteoporotic, 6(75%) - osteopenic. 13 patients (68.4%) received 600 mg of elemental calcium, 400-1600 IU of vitamin D daily, 2 (10.5%) received bisphosphonates.

Plasma PTH ranged from 32-71 pg/ml, mean 61.9±26.42 , 25OHD range was 14-22, mean 24.72±9.49 ng/ml; increased form the 12 years ago assessment PTH 59.67±29.78 pg/ml, 25OHD 12.52±3.19 ng/ml; p=0.068 and p=0.003 respectively

Since the first evaluation, 20 new post liver transplant patients joined the Rambam Liver Unit. They were not evaluated in the Bone Metabolism Unit. According to the information retrieved from the patients' charts, 7 of them had BMD evaluation, one woman was in the osteoporotic range, 6 –osteopenic, PTH was 82.83±67.01 pg/ml, 25OHD was 23.95±8.7 ng/ml.

Nine (45%) of them are treated at present with calcium 600 mg/day and vitamin D, 400-2000 IU/day, r two are treated with oral bisphosphonates. No fractures were reported by these patients since the time of transplantation.

In the whole group of post liver transplant patients PTH was 71.82±49.64 pg/ml, 25OHD 25.11±9.31ng/ml.

Conclusions: Osteoporotic fractures in liver transplant patient occurred during the first postransplantation year. No osteoporotic fractures were observed during subsequent long term follow-up. Vitamin D deficiency and low calcium intake were actively treated and secondary hyperparathyroidism was not observed during long term follow-up. BMD follow-up was not routinely performed in all patients. No significant change in BMD was observed during long term follow-up in the tested group.

Case-control Study of the *SQSTM1/P392L* Post-zygotic Mutation in Paget's disease of Bone. Sabrina Guay-Bélanger*[1], Edith Gagnon[2], Jean Morissette[2], Jacques P. Brown[2], Laetitia Michou[4]. [1]Centre de recherche du CHUQ-CHUL, Canada, [2]CHU de Québec Research Centre, Canada, [4]Université Laval, Canada

Purpose: Paget's disease of bone (PDB) is a uni or plurifocal metabolic bone disorder transmitted, in one third of cases, in an autosomal-dominant mode of inheritance with incomplete age-dependent penetrance. The germinal *SQSTM1/P392L* mutation is the most common mutation, present in 40% of patients with a familial form of PDB, and 8% of unrelated patients. Given the focal nature of PDB, some authors have suggested that somatic mutations in *SQSTM1* gene could occur in pagetic lesions in absence of germinal mutation. The objective of this study was to search if *SQSTM1/P392L* post-zygotic mutations can occur in peripheral blood of PDB patients. Methods: Since PCR-clamping method has been reported to be effective to detect post-zygotic mutations in fibrous dysplasia, we optimized this PCR method to detect the *SQSTM1/P392L* post-zygotic mutation in PDB patients. We used a LNA specific for the *SQSTM1/P392L* mutation, which blocks the wild-type allele amplification. We analyzed 217 unrelated PDB patients, and 289 individuals without diagnosis of PDB based on a questionnaire and total alkaline phosphatase measurement, all without any germinal *SQSTM1/P392L* mutation. We then compared PDB patients with post-zygotic mutation (n=11) to unrelated patients with a germinal mutation (n=23) and without any germinal nor post-zygotic mutation (n=207) for age at diagnosis and number of affected bones. Results: Among the PDB patients, eleven (5.1%) were carrier of a *SQSTM1/P392L* post-zygotic mutation and, surprisingly, we identified this post-zygotic mutation in three a priori healthy individuals (1.0%) (p=0.011, OR=5.08 [1.32; 28.71]). PDB patients with a post-zygotic mutation tended to have a lower number of affected bones than patients carrying a germinal mutation (1.91±0.83 vs. 4.45±3.42 respectively, p=0.059). However, we found no association with age at diagnosis in this rather small sample. Conclusion: This study confirms that PCR-clamping increases considerably the sensitivity to detect *SQSTM1/P392L* mutations in the French-Canadian population. The detection of *SQSTM1/P392L* post-zygotic mutation in individuals a priori healthy has possibly led to the identification of individuals with asymptomatic undiagnosed PDB, which we plan to verify with bone imaging. This post-zygotic mutation would less likely act like a polymorphism.

SU0440

Environmental Factors are Associated with Paget's Disease of Bone or with the *SQSTM1/P392L* Mutation Carriage. Marie-Claude Audet*[1], Claudia Beaudoin[2], Jeannette Dumont[2], Jacques P. Brown[3], Laetitia Michou[4]. [1]CHU de Québec, Canada, [2]Centre de recherche du CHU de Québec, Canada, [3]CHU de Québec Research Centre, Canada, [4]Université Laval, Canada

Background: Several publications have demonstrated that the most frequent mutation in Paget's disease of bone (PDB), *SQSTM1/P392L,* leads to some of the phenotypic characteristics of PDB, but this single mutation is seemingly unable to result in the complete pagetic phenotype, suggesting that other mechanisms such as environmental factors may play a role.

Purpose: To identify environmental factors associated with PDB or with the *SQSTM1/P392L* mutation in the French-Canadian population.

Methods: We investigated environmental factors through a questionnaire in 176 French-Canadian patients with PDB and 185 healthy controls. This questionnaire relied on socio-demographic and physical characteristics, tobacco exposure, diet, residency, work, leisure, and contact with animals, during childhood/adolescence and adulthood. We searched for associations with PDB phenotype, or with the *SQSTM1/P392L* mutation (86 individuals carried the mutation and 275 were non carrier), independently of the PDB status. We performed Chi-squared or Fisher exact tests when appropriate for nominal values and t test for continuous variables. Odds ratio (OR) and 95% confidence interval were calculated.

Results: We found an association of PDB with tobacco exposure (p=0.02), which was stronger in individuals who smoked >20 cigarettes per day (p=0.005, OR =2.12 [1.25-3.58]) or for 20 years (p=0.01). PDB was also associated with rural residency in adolescence (p=0.02), residency close to a farm (p=0.02), and wood-fired heating during childhood/adolescence (p=0.001, OR=2.14 [1.37-3.36]). The carriage of the *SQSTM1/P392L* mutation was associated with loss of weight 10kg in 6 months (p=0.04), wood-fired heating during adulthood (p<0.001, OR=3.76 [2.04-6.94]), residency close to a mine (p=0.005, OR=3.21 [1.36-7.58]), work on a farm (p=0.001, OR=2.24 [1.36-3.68]), and contact with dog and bovine during childhood/adolescence (p=0.003, OR=2.22 [1.29-3.81] and p=0.009, OR=1.92 [1.17-3.14], respectively).

Conclusions: The variables most strongly associated with PDB phenotype were smoking 20 cigarettes per day and exposure to wood-fired heating during childhood/adolescence; whereas those most strongly associated with the *SQSTM1/P392L* mutation were exposure to wood-fired heating during adulthood, living close to a mine as well as having worked on a farm and contact with domestic animals during childhood/adolescence. Multivariate analyses should be done to confirm these associations.

Valosin containing protein is a key link between autophagy and osteoclastogenesis in Paget disease of bone (PDB). Milka Budnik-Zawilska*. University of East Anglia, United Kingdom

Dominant mutations in the N-domain of the valosin containing protein (VCP) give rise to the complex disease syndrome known as Inclusion body myopathy with Paget disease of the bone and frontotemporal dementia (IBMPFD). VCP plays a key role in the ubiquitin-proteasome dependent protein degradation although mutations in VCP result in a late stage autophagy defect. There is also an enhanced activation of NFκB pathway involved and osteoclast precursors containing VCP mutations are hyper-responsive to RANKL. This suggests that under normal homeostasis VCP plays an important role in regulating the response of osteoclasts to bone microenvironment. However, the mechanisms by which VCP mutations stimulate osteoclast differentiation in Paget disease of the bone (PDB) are not completely understood. To investigate this further we examined the role of VCP in autophagy and the role of autophagy on osteoclastogenesis. We used immunofluorescence to evaluate whether VCP co-localises to autophagic components such as p62 (sequestosome) and LC3. We also tested any direct interaction of VCP with p62 and LC3 by co-immunoprecipitation. We assessed the effect of initiating autophagy on osteoclastogenesis by treating RAW264.7 cells with either Rapamycin or Torin 1 at different time point during osteoclastogenesis. Expression of VCP mutants in cell culture results in the increased expression of autophagic markers p62 and LC3. By using immunofluorescence we observe that VCP, p62 and LC3 all co-localize to pathogenic polyglutamine (Q79) inclusions which are degraded by autophagy. In cells expressing poly(Q)-79 both VCP and p62 surround large, perinuclear inclusion bodies, suggesting that VCP is directly involved in the aggresome formation. In contrast, in cells expressing non-pathogenic control polyglutamine repeat (Q35), there's no VCP-positive perinuclear inclusion bodies. We show that VCP co-immunoprecipitates with p62 in the autophagy-dependant manner. Initiation of autophagy in RAW264.7 cells in the presence of RANKL results in marked reduction in osteoclast formation, regardless of the time point at which the treatment begun. These data together with the already existing knowledge on VCP, and the link with PDB, suggest that modulation of the autophagy pathway by VCP may represent a major regulator of bone remodelling and maintenance. We show that autophagy has direct effect on the fate of osteoclast progenitor cells and is thus a key process underlying the pathogenesis of PDB.

Glucocorticoids antagonize RUNX2 during osteoblast differentiation in a locus and concentration-dependent manner. Theodora Koromila*[1], Anthony Martin[1], Jian Xiong[2], Yae Sam Song[2], Sanjeev Baniwal[1], Baruch Frenkel[1]. [1]University of Southern California, USA, [2]Department of Biochemistry & Molecular Biology, Institute for Genetic Medicine, Keck School of Medicine of the University of Southern California, USA

A common side effect of glucocorticoids (GC) treatment for autoimmune and inflammatory diseases is GC-induced osteoporosis (GIO). One of the mechanisms contributing to GIO is inhibition of the bone master regulator RUNX2 in osteoblast precursors. To address the hypothesis that GCs inhibit RUNX2-mediated stimulation of gene expression in a locus-dependent manner, we employed ST2/Rx2^{dox} cells, a bone marrow stroma-derived pluripotent cell line, engineered to expresses RUNX2 in response to doxycycline (dox). Cells were treated with 500 μg/ml dox either alone or along with 10 nM or 1 μM dexamethasone (dex). Runx2-induced osteoblast differentiation was confirmed by histological staining for alkaline phosphatase (ALP) activity. Expression of RUNX2-responsive genes was measured by RT-qPCR and cell proliferation was assessed by MTT assays. Each assay was performed in triplicate and repeated at least twice. Differences between groups were considered significant when $p<0.05$ using Student's t-test. Dox-mediated induction of RUNX2 was associated with a 3- to 12-fold increased mRNAs levels of all RUNX2-target genes tested including those related to osteoblast differentiation (Bsp, Bglap, Alp) and those related to osteoblast-driven osteoclastogenesis (Sema7a, Tnc, OPG, Hey1, Cdk5rp, Enfb1). Dex antagonized RUNX2-mediated stimulation of all the genes tested. This antagonism, however, was strongly dependent on the target gene and the dex concentration. Whereas 10 nM dex antagonized RUNX2-mediated stimulation of most genes tested, the RUNX2-mediated stimulation of Alp and Efnb1 was resistant to 10 nM Dex. In contrast, 1 μM Dex antagonized RUNX2-mediated stimulation of all genes tested. Consistent with the Alp mRNA results, histological staining demonstrated inhibition of RUNX2-induced ALP activity by 1 μM, but not 10 nM Dex. MTT assays showed no significant alterations in cell proliferation. The locus-dependent antagonism of RUNX2 by increasing dex concentrations offers an opportunity to discern RUNX2 target genes relevant to GIO. Specifically, the inhibitory effects of GCs at most RUNX2 target genes is likely irrelevant to GIO because these genes are strongly affected at low GC concentrations, which inhibit neither osteoblast differentiation in vitro nor bone formation in vivo. Genome-wide analysis of the concentration-dependent interactions between RUNX2 and GCs in osteoblast progenitor cells will facilitate identification of GIO-relevant RUNX2 target genes.

Glucocorticoids Promote a Greater Decrease of VEGF, RANKL, Bone Turnover, Vasculature, and Material Properties in the Murine Femoral Head as Compared to the Distal Femur or Lumbar Vertebra: New Insights into the Pathogenesis of Osteonecrosis. Robert Weinstein*, Erin A. Hogan, Stuart B Berryhill, Stavros Manolagas. Central Arkansas VA Healthcare System, University of Arkansas for Medical Sciences, USA

Glucocorticoids (GC) are the most common cause of nontraumatic osteonecrosis of the femoral head but the reason for the susceptibility of this site is unexplained, the cellular and molecular mechanisms responsible remain unidentified, and the sequential pathological changes are unknown. We report that in C57Bl/6 mice, expression of both the receptor activator of nuclear factor-κB ligand (RANKL) and vascular endothelial growth factor (VEGF), and the bone formation rate were higher in the cancellous bone of the femoral head than in the distal femur or lumbar vertebra (L5). Fourteen days after prednisolone administration, cancellous bone volume of the femoral head began to decrease and was markedly lower than placebo after 28 days, well before significant changes were detected in the distal femur or L5. Osteocalcin, RANKL, and VEGF expression in the femoral head decreased after GC, but RANKL and VEGF did not change in the distal femur or L5. Surprisingly, the material density of the femoral head increased similar to the radiographic sclerosis typical of clinical osteonecrosis; nonetheless, GC reduced the strength and toughness of the femoral head. In addition, the dendritic pattern of the vasculature of the femoral head, as determined by infusion of lead chromate, was converted to lakes, in distinction to the femoral diaphysis and L5 where vessel volume decreased but dendritic morphology was preserved. The abnormal vascular pattern was verified histologically and was reminiscent of the increased water signal detected by magnetic resonance imaging in patients with osteonecrosis. GC also decreased canalicular fluid as determined by reduced cancellous fluorescence after injection of procion red, perhaps accounting for the decreased strength in spite of increased material density. Finally, in line with clinical evidence that repeated delivery of large doses of GC is associated with a greater risk of osteonecrosis than with steady-state dosage, sequential high GC administration induced a unique and profound increase in femoral head cortical and cancellous porosity and in osteoclast number. These results validate the mouse as a model of glucocorticoid-induced osteonecrosis of the femoral head that replicates the progression of the human disorder. Furthermore, they suggest that the susceptibility of the load-bearing femoral head to osteonecrosis may be due to the high bone turnover of this site and the abrupt remodeling imbalance caused by GC administration.

Treatment of aged rats with methylprednisolone decreases bone mass accrual by suppression of bone formation. Rana Samadfam*, Elisabeth Lesage, Susan Y. Smith. Charles River Laboratories, Canada

The objective of this study was to investigate the effects of methylprednisolone (3 mg/kg/day) on bone when administered to aged rats (19 weeks old female Wistar Hannover) with an inactive growth plate, for a period of 13 weeks. The effects on bone densitometry and bone geometry were evaluated using pQCT at baseline and at Weeks 4 and 13. In addition, body weight, food consumption, selected urine and serum biochemistry, bone turnover markers, PTH and 1, 25 dihydroxyvitaminD were also evaluated to add perspective to mechanisms underlying the effects on bone. A sharp decrease in body weight was noted one week following treatment compared to the baseline with no further loss for the remaining of the treatment period. Steady weight gain for controls over the treatment period along with lack of gain (or loss during the first week) resulted in marked differences between treated and controls. Trends for increases in food consumption were noted compared to controls. At the proximal tibia metaphysis the mean BMC (bone mineral content) and BMD (bone mineral density) were significantly lower compared to vehicle controls. Slightly lower values were also noted for total slice area. At the diaphysis, significantly lower BMC was noted with lower bone diameter indices, indicating smaller bones. Lower bone geometry indices at the diaphysis (total slice area, periosteal circumference) along with shorter bone length were consistent with the lower body weights and slower or lack of growth. Growth suppression was consistent with decreases in bone formation markers (osteocalcin and P1NP) most notably at Week 4/5. No effect was noted on the bone resorption markers. No effect was noted on PTH with a trend for decreases in VD3 at week 4. No effects were noted on serum biochemistry including phosphrous and calcium. Statistically significant increases in urinary calcium were noted over the study period compared to controls. Lack of any significant effects on bone resorption along with increases in urinary calcium suggests an increase in the GI absorption of calcium. Slight increases in food consumption (in spite of lower body weight) are in agreement with this observation. These data collectively indicate that treatment with methylprednisolone is associated with decreases in bone formation resulting in lower values for bone densitometry indices.

Gene Expression Profiling of Avian Osteoclasts Treated with Estrogen for Exploring Unidentified Action(s) of Estrogen in Bone. Shinji Hiyama*[1], Yumiko Kadoyama[2], Mineo Watanabe[1], Takashi Uchida[1]. [1]Hiroshima University Institute of Biomedical & Health Sciences, Japan, [2]Hiroshima University, Faculty of Dentistry, Japan

Medullary bone (MB), a calcium reservoir for egg-shell formation, in the bone marrow cavity of female birds is remodeled under the powerful control of estrogen. A single injection of estrogen causes the formation of MB even in male birds and subsequent activation of bone resorption by osteoclasts with diminished circulating estrogen levels. Estrogen induces osteoclast apoptosis, which may be implicated in postmenopausal bone loss. This hormone, however, does not induce apoptosis in MB osteoclasts, while their activity and morphology were affected. Clarifying the difference between avian and mammalian osteoclast responses to estrogen may be valuable to identify additional roles of estrogen in bone. We, then, provided a comprehensive analysis of the estrogen-dependent gene expression in the avian medullary bone osteoclastogenesis model. Male Japanese quails were given a single injection of 17b-estradiol (E2). After a couple of days, bone marrow cells were collected and cultured with or without E2 in the presence of RANKL/M-CSF for a week. Total RNA was extracted and subjected into DNA microarray analysis (Chicken oligoDNA). In parallel with these cultures, we estimated the effects of E2 on osteoclast formation and activity by TRAP staining and pit assay, respectively. As described before, E2 did not change the number of osteoclasts, while it decreased their resorption activity. Of the genes displaying significant changes (more than 4-fold) in expression levels, 108 genes were up-regulated and 42 genes were down-regulated in response to E2. We found that 13 genes (up, 10 genes; down, 3 genes) were identical to functional genes in mammalian osteoclasts. Amongst these, 11 genes are involved in osteoclastogenesis and 3 genes are associated with bone resorption, e.g., NHA2, CTLA-4 and ATG7. Further, remainders (137 genes) included common genes with unknown functions in bone and avian-specific genes, such as multimerin 1, GAL7 and TICAM1. We are exploring functional genes involved in both avian and mammalian osteoclasts by siRNA-meidated gene silencing.

Oxidative Stress Induced CD4 T Cell Activation Plays A Critical Role in Estrogen Deficiency Induced Bone Loss Mediated via Bmi1. Jinbo Li*[1], Qian Wang[1], Dengshun Miao[2]. [1]Nanjing Medical University, China, [2]Nunjing Medical University, Peoples Republic of China

Role of CD4 T cell activation in estrogen-deficiency induced bone loss has been well studied; however, it is unclear whether oxidative stress mediates such role. To answer this question, we examined the effect of ovariectomy (OVX) on oxidative stress, CD4 T cell activation and RANKL production. Results revealed that ROS levels were raised, whereas expression levels of antioxidant enzyme genes including SOD2, GSR and GPX1 were down-regulated, the percentage of activated T cells and RANKL production were increased significantly in CD4 T cells from OVX mice compared those from sham mice. Moreover, oxidative stress induced by H_2O_2 increased activated CD4 T cells when con-cultured with macrophages. Previous studies have demonstrated that Bmi1 deficiency resulted in increasing oxidative stress and bone loss. To explore whether Bmi1 involves estrogen-deficiency induced bone loss by regulating oxidative stress, we examined the effect of OVX on Bmi1 expression and found that Bmi1 expression at both mRNA and protein levels were down-regulated dramatically in CD4 T cells from OVX mice. Furthermore, we found that alterations of oxidative stress, CD4 T cell activation, RANKL production related parameters in Bmi1 deficient mice were closely resembled those occurred in OVX mice. In contrast, the alterations of those parameters were reversed in Eμ-Bmi1 transgenic (Eμ-Bmi1) mice with overexpression of Bmi1 in lymphocytes. To further determine whether oxidative stress mediates CD4 T cell activation in estrogen-deficiency and Bmi1 deficiency induced bone loss, OVX mice and $Bmi1^{-/-}$ mice were treated with antioxidant N-acetylcysteine (NAC, 1mg/ml) in their drinking water and compared them with untreated OVX and $Bmi1^{-/-}$ mice, respectively. NAC supplementation of OVX mice and $Bmi1^{-/-}$ mice decreased ROS levels, inhibited CD4 T cell activation and reduced RANKL production in CD4 T cells. Consequently, BMD, cortical and trabecular volume were increased significantly, whereas TRAP positive osteoclast surface was reduced significantly in NAC-treated OVX and $Bmi1^{-/-}$ mice compared to untreated ones. To determine whether Bmi1 mediates estrogen deficiency induced bone loss, we created estrogen deficient Eμ-Bmi1 (Eμ-Bmi1+OVX) mice and found that those alterations occurred in OVX mice were rescued in Eμ-Bmi1+OVX mice. These results indicate that oxidative stress induced CD4 T cell activation plays a critical role in estrogen deficiency induced bone loss mediated via Bmi1.

Duodenal Ca Absorption Increases to Compensate for the Loss of Vitamin D Receptor (VDR) from the Large Intestine and Kidney of Mice. Perla Reyes*, James Fleet. Purdue University, USA

Habitual consumption of low dietary Ca increases renal 1,25 dihydroxyvitamin D (1,25D) production to stimulate vitamin D receptor (VDR)-mediated regulation of genes that increase Ca absorption efficiency in intestine, Ca reabsorption in the kidney, and bone resorption. Our previous research suggests that 1,25D-mediated Ca absorption in the lower bowel contributes significantly to whole body Ca homeostasis. Our goal was to determine the impact of large intestinal VDR deletion on Ca/bone metabolism. We used the CDX2P9.5 promoter-Cre transgenic mice to delete floxed VDR alleles throughout the caudal region of the mouse. This was confirmed by detection of Cre recombinase activity in multiple tissues, including kidney, ileum, and colon. Weanling $CDX2\text{-}Cre^{+/-}$,$VDR^{fl/fl}$ (CDX2-VDRKO) and control littermates ($CDX2\text{-}Cre^{-/-}$,$VDR^{fl/fl}$, WT) mice were fed low (0.25%) or normal (0.5%) Ca diets until 10 weeks of age. Serum and urinary Ca, vitamin D metabolites, bone parameters (by μCT), and gene expression in kidney, duodenum, ileum and colon were analyzed. Serum 1,25D was increased by low Ca intake but was not different between genotypes while CDX2-VDRKO mice had serum PTH levels 67% lower than WT mice ($p<0.001$). CDX2-VDRKO mice had renal mRNA levels consistent with those previously seen in global VDR KO mice, i.e. low calbindin D_{9k} (CaBPD9k, -85% WT $p<0.001$), high TRPV5 (+49%, $p<0.005$), and no change in CaBPD28k mRNA levels. In addition, urinary Ca/creatinine ratio was 10-fold higher ($p<0.001$) in CDX2-VDRKO mice. As expected, TRPV6 mRNA levels (a marker of active Ca absorption) were low in the proximal (-92% WT, $p<0.001$) and distal colon (-88% WT, $p<0.001$) where the VDR was deleted in CDX2-VDRKO mice. Despite elevated urinary Ca loss and reduced TRPV6 expression in the lower bowel, CDX2-VDRKO mice had normal femoral cancellous and cortical bone density. However, duodenal TRPV6 mRNA expression was 4-fold higher in CDX2-VDRKO compared to WT mice ($p<0.001$), suggesting that there is up-regulation of duodenal Ca absorption that protects bone and contributes to increased urinary Ca loss. These data support the hypothesis that large intestine VDR significantly contributes to whole body Ca metabolism but suggests that duodenal adaptation can prevent the consequences of VDR deletion from large intestine and kidney.

Effect of Vitamin D Receptor Gene Polymorphism on Associations between Serum 25-hydroxyvitamin D and Biochemical Parameters in Young Adults.
Rieko Tanabe*[1], Yuka Kawamura[1], Naoko Tsugawa[2], Mayu Haraikawa[1], Natsuko Sogabe[3], Toshio Okano[2], Takayuki Hosoi[4], Masae Goseki-Sone[5]. [1]Department of Food & Nutrition, Faculty of Human Sciences & Design, Japan Women's University, Japan, [2]Kobe Pharmaceutical University, Japan, [3]Department of Health & Nutrition Sciences, Faculty of Human HEalth, Komazawa Women's University, Japan, [4]National Center for Geriatrics & Gerontology, Japan, [5]Japan Women's University, Japan

Several genes have been implicated as genetic determinants of osteoporosis. Vitamin D receptor (VDR) is an intracellular hormone receptor that specifically binds to the biologically active form of vitamin D, 1-alpha, 25-dihydroxyvitamin D_3 [1, $25(OH)_2D$], and mediates its effects. One of the most frequently studied single nucleotide polymorphisms is the restriction fragment length polymorphism (RFLP) *Fok-I* (rs2228570). The presence of a *Fok-I* site, designated f, allows protein translation to initiate from the first ATG. An allele lacking the site (ATG>ACG: designated F), initiates from a second ATG site. Thus, translation products from these alleles are predicted to differ by three amino acids with the f variant elongated. In the present study, we explored the effect of the VDR *Fok-I* genotype on associations among serum bone-specific alkaline phosphatase, 25-hydroxyvitamin D_3 [25(OH)D], 1, $25(OH)_2D$, intact parathyroid hormone (PTH), and the dietary nutrient intake in healthy young Japanese subjects (n=193). Dietary nutrient intakes were calculated based on 3-day food records before the day of blood examinations. Quantitative ultrasound (QUS) parameters at the right calcaneus were measured. The study protocol was approved by the Institutional Review Board of Japan Women's University, and written informed consent was obtained from all study subjects. As the results, the mean ($\pm$SD) levels of serum bone-specific alkaline phosphatase, 25(OH)D, 1, $25(OH)_2D$, and intact-PTH were 26.9 ± 7.8 U/l, 20.1 $\pm$ 6.9 ng/ml, 50 ± 17 pg/ml, and 43 ± 13 pg/ml, respectively. The allele frequencies were 0.622 for the F allele and 0.378 for the f allele in all subjects. Grouped by the *VDR* genotype, a significant positive correlation between the levels of serum bone-specific alkaline phosphatase activity and 25(OH)D was observed in the FF-type (38% of the study population) (p=0.005) and Ff-type (48% of the study population) (p=0.004), but not in the ff-type (14% of the study population). In addition, there was a significant positive correlation between the level of serum 25(OH)D and osteo-sonoassessment index (OSI) in the FF-type (p=0.008). There was no such significant positive correlation between the level of serum 25(OH)D and OSI in the ff-type. These results suggest that the level of circulating 25(OH)D is an important factor when assessing the VDR *Fok-I* polymorphism to prevent osteoporosis.

Gender-related differences in the skeletal phenotype of aged Vitamin D Receptor Knockout mice.
Jackson Ryan*[1], Howard Morris[2], Paul Anderson[3]. [1]University of South Australia, Australia, [2]SA Pathology, Australia, [3]Musculoskeletal Biology Research, University of South Australia, Australia

Global VDR deletion in a mouse model (VDR-/-) demonstrates features typical of vitamin D-dependent rickets type II unless weanling mice are fed a 'rescue' diet containing high levels of calcium (2%) and phosphorus (1.25%). This diet prevents the development of hypocalcemia and secondary hyperparathyroidism and is sufficient to normalise mineralization of bone at 10 weeks of age. However, at 17 weeks of age male VDR-/- exhibit marked osteopenia associated with decreased osteoblast number and mineral apposition rate, despite no induction of osteoclast activity (Panda, et. al. 2004). The role for VDR in bone appears to be complex and dependent on the physiological context, with reports of both inhibitory and enhancing roles of VDR in bone in both *in vitro* and *in vivo* studies[1-3]. To clarify the role of VDR in maintaining skeletal health in aged animals, male and female VDR-/- mice were fed a rescue diet containing 2% calcium and 1.25% phosphorus from weaning until 26 weeks of age and compared to VDR+/- litter mate controls fed the same diet. At time of death, femora and tibia were collected for histomorphometric analyses. Consistent with previously reported data[4], in male VDR-/- mice, metaphyseal BV/TV% declined (36%; p=0.06) due to decreased Tb.Th (p=0.03). Cortical bone volume and width were also decreased (23%, p=0.003; 10% p=0.006) when compared to control. However, in female VDR-/- mice metaphyseal BV/TV% increased 2-fold (p=0.04), largely due to increased Tb.N (p=0.009), compared to control mice. No significant differences were seen in cortical bone volume or width of female mice. These data suggest that there exist significant gender-related differences with regards to the role of VDR in maintenance of bone mineral volume in aged animals. Furthermore, quantitation of calcium content of trabecular bone was performed using back-scatter electron microscopy. Male VDR-/- mice display a significant increase in calcium width (24%; p=0.004), with no changes to overall wt% calcium within trabecular bone, suggesting greater heterogeneity of the mineralisation state in male VDR-/- mice compared to control mice. Taken together, these data suggest that VDR is required to maintain both bone quantity and bone quality and these effects are dependent on age and gender.

Mechanism of Hyponatremia-Related Vitamin D Deficiency in Rats.
Julia (Julianna) Barsony*[1], Qin Xu[2], Aifen Wang[2], Joseph Verbalis[2]. [1]Georgetown University Hospital, USA, [2]Georgetown University, USA

Chronic hyponatremia is frequent in the aging population due to medication use and the syndrome of inappropriate antidiuretic hormone secretion (SIADH), and has been associated with increased fall risk and fracture frequency in patients, and with high bone resorption and loss of bone mineral density (BMD) in a rat model of SIADH. Chronically hyponatremic old and young male and female rats all displayed features of vitamin D deficiency, including reduced serum 25OHD and $1,25(OH)_2D$ levels. It is difficult to isolate causes of vitamin D deficiency in elderly patients; therefore we used our rat model to explore how hyponatremia might lead to abnormal vitamin D metabolism. In two experiments, 12-month-old male and female F44BN rats (8 per group) were infused with desmopressin at 5 ng/h and fed a liquid diet to generate hyponatremia (serum $[Na^+]=114 \pm 8$ mmol/L) for 3 months; controls were pair-fed with the same liquid diet but did not receive desmopressin infusions (serum $[Na^+]=147 \pm 1$ mmol/L). All rats received defined vitamin D3 in the liquid diet (75 IU/day) in the first experiment, and received10-fold higher vitamin D3 in the diet (750 IU/day) in the second experiment. In both experiments, urine 25OHD losses were increased in hyponatremic rats, in proportion to the vitamin D intake. Urine vitamin D binding protein (DBP) and albumin were significantly increased in the hyponatremic rats, more so in males than females. Serum albumin was significantly reduced in both male and female hyponatremic rats, and DBP was slightly reduced. Serum $1,25(OH)_2D$ were reduced and PTH and alkaline phosphatase were moderately increased in hyponatremic groups (males more than females), which may have contributed to the bone loss observed by DXA and micro-CT. Analysis of mRNA expression from kidneys revealed that hyponatremia did not significantly influence VDR expression, but it increased 1alpha-hydroxylase (CYP27b1) and reduced 24-hydroxylase (CYP24a1) expression. The increased urinary vitamin D metabolite clearance was associated with 2-fold reduced megalin (LRP2) mRNA expression ($p<0.01$) in the kidneys from hyponatremic rats; this finding was corroborated by reduced kidney megalin protein expression by immunohistochemistry. Our studies demonstrated for the first time that hyponatremia caused vitamin D deficiency in a rat model of SIADH by inhibiting renal megalin expression, thereby causing increased urinary clearance of vitamin D metabolites along with DBP and albumin.

Ratio of 25-OH-D_3:24,25-$(OH)_2D_3$ is a Novel and Sensitive Measure of Predicting Vitamin D Deficiency.
Martin Kaufmann*[1], J. Christopher Gallagher[2], Munro Peacock[3], Glenville Jones[1]. [1]Queen's University, Canada, [2]Cheighton University Medical School, USA, [3]Indiana University Medical Center, USA

Background: Normal healthy women were recruited for a vitamin D supplementation study; the inclusion criteria included serum 25-hydroxyvitamin D (25-OH-D)< 20ng/ml threshold and no condition that affected calcium and vitamin D metabolism. Because serum 25-OH-D plateaued at the 4,000 IU/day dose level, we explored the role of 25-OH-D_3-24 hydroxylase (CYP24A1) in the regulation of serum 25-OH-D.

Methods: Subjects: 273 healthy Caucasian & African American postmenopausal women age 57-90 years, randomized to 6 doses of vitamin D ranging from 400-4800 IU/day or placebo for 1 year; and 190 young Caucasian and African American women (25-45 years). The primary outcomes of the study were serum 25-OH-D & parathyroid hormone (PTH) levels. A secondary outcome was measurement of serum 24,25-$(OH)_2D_3$. Serum 25-OH-D & 24,25-$(OH)_2D_3$ were measured by liquid chromatography-tandem mass spectrometry using a Waters Xevo TQ-S instrument after derivatization.

Results: Serum 25-OH-D ranged between 5-85 ng/mL; serum 24,25-$(OH)_2D_3$ ranged between 0.1-15 ng/mL; the ratio of 25-OH-D_3: 24,25-$(OH)_2D_3$ ranged between 4-75. After vitamin D supplementation, there was a curvilinear increase in serum 25-OH-D best described by a quadratic model and plateauing at 40-45 ng/ml, showing that serum 25-OH-D is more closely regulated than previously expected. Serum 24,25-$(OH)_2D_3$ increased from a mean value of 1.18 ng/ml to 5.35 ng/ml reaching a plateau at about the 4000 IU dose and showed the same curvilinear increase as the serum 25-OH-D curve. Women with baseline values for 25-OH-D in the 5-12 ng/mL range showed the highest serum 25-OH-D_3: 24,25-$(OH)_2D_3$ ratios of 20-75.

Conclusion: In normal subjects treated with increasing doses of vitamin D there is a wide range of serum 25-OH-D_3 values and a similar curvilinear increase in serum 25-OH-D_3 and serum 24,25-$(OH)_2D_3$ that reaches a plateau on vitamin D doses of about 4000 IU/day. Since CYP24A1 is documented to be the most responsive vitamin D-dependent gene in the human genome, we would expect that CYP24A1 expression to be suppressed in vitamin D deficiency and serum 24,25-$(OH)_2D_3$ levels to decline. We

conclude that a 25-OH-D_3:24,25-$(OH)_2D_3$ ratio less than 25 is a sensitive indicator of vitamin D deficiency & insufficiency and may be a more sensitive measure than PTH. In summary, we found the ratio of 25-OH-D_3: 24,25-$(OH)_2D_3$ is a sensitive predictor of vitamin D deficiency and insufficiency.

Redistribution of the hormone binding protein catalase by 24,25-dihydroxyvitamin D_3. Ilka Nemere*, Yang Zhang. Utah State University, USA

The vitamin D metabolite, 24,25-dihydroxyvitamin D_3 (24,25D_3) is made in vitamin D replete animals, and has been shown by our lab to act as an inhibitor of 1,25-dihydroxyvitamin D_3 with regard to abolishing rapid, pre-genomic responses such as enhanced calcium or phosphate uptake in intestinal cells. We subsequently identified catalase as the binding protein for 24,25D_3 in chick intestinal cells. Upon binding the steroid, catalase activity is decreased and the subsequent increase in H_2O_2 levels oxidizes the 1,25D_3-MARRS receptor, thereby inhibiting the action of 1,25D_3. Catalase is classically thought of as a peroxisomal enzyme. A subset of catalase has been reported to be at the cell surface or complexed with the transcription factor STAT 3. In this study we used confocal microscopy to determine catalase localization in the absence and presence of steroid. Intestinal cells isolated by citrate chelation were cultured on coverslips overnight and then treated with vehicle, 300 pM 1,25D_3, 6.5 nM 24R,25D_3, or 200 pM 24S,25D_3 for varying times prior to fixation, permeabilization, and immunostaining. We found that in permeabilized, vehicle-treated cells, punctate staining for catalase was visible, but diminished rapidly after 15 minutes treatment with 1,25D_3 or 25 minutes treatment with 24S,25D_3, but not with 24R,25D_3. Since 1,25D_3 does not compete with 24,25D_3 for binding to catalase, its effects may be due to the 1,25D_3-MARRS receptor causing actin depolymerization (Sterling and Nemere, unpublished observations). 24R,25D_3 treatment also increased nuclear staining of catalase after 15 min. In unpermeabilized cells treated wtih 200 pM 24S,25D_3 or 6.5 nM 24R,25D_3, we observed both a significant decrease in catalase activity compared with vehicle treated cells, with a p-value less than 0.05. Additional studies are on going in unpermeabilized cells to see what effects these steroids have on cell surface catalase.

Studies in Mice with Transgenic Expression of the Vitamin D Receptor (VDR) Exclusively in the Distal Intestine of VDR Knockout Mice Provide Evidence for a Critical Role of Intestinal Epithelial Cells in the Suppression of Inflammatory Bowel Disease by 1,25$(OH)_2D_3$/VDR. Ran Wei*, Puneet Dhawan, Sylvia Christakos. University of Medicine & Dentistry & New Jersey - New Jersey Medical School, USA

Inflammatory bowel disease (IBD) is a chronic disorder of the GI tract that includes ulcerative colitis and Crohn's disease. Although immune dysfunction has been implicated in the development of the disease, its pathogenesis is still poorly understood. Previous studies reported a link between vitamin D deficiency and IBD and VDR knock out (KO) mice develop more severe IBD. The enhanced severity of IBD in VDR KO mice has been associated with increased numbers of IL-17 and IFNγ secreting T cells. However T cell deficient mice develop IBD, suggesting that other pathways may also be involved in the enhanced susceptibility of VDR KO mice to IBD. In this study VDR KO mice with transgenic expression of VDR exclusively in the distal intestine (distal ileum, cecum and colon) provided a unique model to determine whether the enhanced susceptibility of VDR KO mice to IBD can be entirely caused by a lack of VDR in intestinal epithelial cells. We previously reported the generation of mice expressing VDR exclusively in distal intestine [serum PTH and serum calcium are similar to wild type (WT) and VDR dependent rickets is rescued]. WT, VDR KO mice and mice from two KO transgenic lines (KO/TG [1] and KO/TG [2] which express levels of VDR in distal intestine equivalent to WT) were administered 3.5% dextran sodium sulfate (DSS) in the drinking water. VDR KO mice began to die by the 7th day post DSS administration. Diarrhea, rectal bleeding and loss of body weight preceded mortality of the VDR KO mice. WT mice and KO/TG [1] and [2] mice did not die and showed mild diarrhea and bleeding. DSS treatment that caused a mild form of colitis in WT and KO/TG mice resulted in extensive mucosal damage and blood in the colon of VDR KO mice. In one transgenic line (KO/TG3), which showed low VDR expression, DSS treatment resulted in more severe symptoms than those observed in the other transgenic lines but not as severe as in VDR KO mice. 1,25$(OH)_2D_3$ treatment (0.5 ng/g bw/day) significantly improved symptoms of DSS colitis in WT mice as well as in all 3 transgenic lines and was associated with an induction in colonic expression of E-cadherin. These findings indicate for the first time that VDR expressed only in intestinal epithelial cells can control susceptibility to IBD. Since VDR is absent from immune cells in KO/TG mice, our findings suggest a critical role of intestinal epithelial cells and maintenance epithelial cell integrity in the suppression of IBD by 1,25$(OH)_2D_3$/VDR.

Two-step immunoassay for free 25 Hydroxy Vitamin D. Leon Swinkels, Ernst Lindhout*, Niels Donnelly, Gregg Mayer, Mike Martens. Future Diagnostics, The Netherlands

The objective of this study was to assess the characteristics of a two-step immunoassay for free 25 Hydroxy Vitamin D [25(OH)VitD].

Recent studies suggest that the level and genotype of Vitamin D binding protein (DBP) are important factors that determine the bioavailability of 25(OH)VitD in serum. It has been suggested that measurement of free, non-protein bound 25(OH)VitD in serum, may provide more relevant diagnostic information than total 25(OH)VitD, for instance in bladder cancer and pancreatic cancer (1), or in hemodialysis patients (2).

We have developed a two-step enzyme-linked immunosorbent assay (ELISA) for the determination of free 25(OH)VitD assay. In this assay an anti-vitamin D antibody is coated on a microtiterplate. Free 25(OH)VitD is captured by the antibody during a first incubation. After washing, a biotin-labeled 25(OH)VitD analog is allowed to react with the non-occupied antibody binding sites in a second incubation. After washing and incubation with a streptavidin-peroxidase conjugate, the bound enzyme is quantitated using a colorimetric reaction. The intensity of the signal is inversely proportional to the level of free 25(OH)VitD in the sample. The assay was calibrated against a symmetric dialysis method.

The calibrator range was 0.0 – 35.0 pg/ml. The LOB of the assay was 1.1 pg/ml; the LOD was 1.7 pg/ml. Total assay precision was 5.7% at 6.3 pg/ml, 3.8% at 15.9 pg/ml and 4.8% at 24.8 pg/ml. The antibody in this assay cross-reacts with 25(OH)VitD2 for 60%.

A better inverse correlation was found between PTH and free 25(OH)VitD than between PTH and total 25(OH)VitD in a set of random patient samples that were sent in for measurement of total 25(OH)VitD.

We have developed an assay that reproducibly determines the level of free 25(OH)VitD. The assay can be used as a tool in studies to establish the clinical relevance of bioavailable 25(OH)VitD .

Vitamin D Levels in HIV Infected Adults and its Relation with Immunologic and Virologic Status. Exploratory Study. Silvina Mastaglia*[1], Natalia Bello[2], Vanesa Fridman[2], Daniel Stecher[2], Beatriz Oliveri[3]. [1]Laboratorio de Enfermedades Metabólicas Oseas, Instituto de Inmunología, Genética,y Metabolismo (INIGEM), Hospital de Clínicas, CONCET-UBA. * Researcher of the National Council on Scientific & Technical Research (CONICET)., Argentina, [2]División Infectologia, Departamento de Medicina Interna, Hospital de Clínicas, Universidad de Buenos Aires, Argentina, [3]Centro De Osteopatías Médicas, Argentina

Vitamin D has strong immunomodulting properties. The nuclear vitamin D receptor is expressed in various immune cell lines which locally convert vitamin D to its active form 1,25-dihydroxyvitamin D (1,25[OH]2 D). Under infection condition 1,25[OH]2 D stimulate the production in monocytes and macrophages the antimicrobial peptide, cathelicidin. In vitro studies demonstrate cathelicidin's ability to inhibit HIV replication in CD4+ T cell and macrophages. Aim: evaluated the relationship between 25-hidroxyvitamin D (25OHD), CD4 and HIV viral load. Fifty six clinical records from patients with diagnostic HIV/AIDS attending to the Division of Infectology, Department of Internal Medicine, Clinical Hospital, Buenos Aires University. The data of clinical record as predictors of low vitamin D metabolite were the following: age, gender, ethnicity, duration of HIV infection, hepatic and renal diseases, diagnostic of osteopenia or osteoporosis, vitamin D supplementation and season in that 25OHD was measured. The biochemical parameters were: 25OHD [RIA-DIASORIN], CD4 cell count (absolute number and percentage) and HIV viral load. We considered for this study 25OHD levels sufficient that $\geq$30ng/ml, insufficient: 21-29ng/ml, inadequate $\leq$20ng/ml and deficient $\leq$10ng/ml. Results: In the table 1 showed characteristics of the 56 patients according to 25OHD levels. We observed that 76% of the patients with HIV/AIDS showed 25OHD levels below 30ng/ml (insufficient 28%; inadequate: 30% and deficient: 20%). Our results are consistent with others HIV cohorts recent report[1-3]. A weak negative lineal correlation was observed between 25OHD levels deficient and HIV load, log10 ($r=-0.591$; $p<0.05$) but there are no correlations between 25OHD and CD4 (absolute number/%). Conclusion: Vitamin D deficiency was common in this HIV population, as seen in other HIV cohorts. Vitamin D deficit may affect the immune responder to HIV viral load. Future studies are required to understand the vitamin D metabolism in the HIV/AIDS infection.[1]AIDS 2010; 24:1127-1134; [2]Clin Infect Dis.2011; 52:396-405, [3]AIDS 2011; 25:1305-1315.

Table 1: Characteristics of the patients according to 25OHD levels (mean ±SD)

	25OHD (ng/ml) levels

Are BMP4 and Runx2 more prevalent in malignant canine mammary tumors?. Kristi Milley*[1], Barbara Bacci[2], Stewart Ryan[2], Janine Danks[3]. [1]RMIT University, Australia, [2]The University of Melbourne, Faculty of Veterinary Science, Australia, [3]School of Medical Sciences, RMIT University, Australia

Recently in humans, the presence of a group of proteins traditionally associated with bone and cartilage formation have been demonstrated in breast cancers. These genes include bone morphogenetic protein 4 (BMP4) and Runt related transcription factor 2 (Runx2).

There is limited data on the role of BMP4 in breast cancer in humans. It is known that BMP4 is expressed at low levels in normal tissue whilst tumors have significantly increased expression levels. BMP4 positive breast cancers that are positiveare associated with reduced proliferation rates but also associated with increased recurrence (Alarmo et al. Mod Pathol. 26:10, 2013).

Runx2 has been demonstrated to play a role in human breast cancer progression, particularly in hormone receptor negative cancers and is an independent prognostic factor (Onodera et al. Cancer Sci. 101:2670, 2010). Consequently, the presence of this protein in canine mammary tumours (CMT) is important as the majority are hormone receptor negative and could be used as a prognostic marker.

CMTs are similar to human breast cancers in many crucial respects including hormone dependency, onset age and tumour kinetics (Uva et. al. BMC Genomics 10:135, 2009). Genome-wide comparative analysis of the main pathways involved in breast cancer has shown that transcriptional changes are conserved between both dogs and humans.

We have collected more than 250 CMTs that consist of benign, mixed and malignant mammary tumors. They were classified histopathologically and immunohistochemistry with antibodies to Runx2 and BMP4 completed. Preliminary data has demonstrated the presence of BMP4 and Rnux2 in benign mixed mammary tumours (ASBMR 2012). This was the first demonstration of the presence of BMP4 and Runx2 in canine mammary tissue or tumor. We demonstrated BMP4 and Runx2 in the nucleus of normal ducts but they were preferentially localized in the cytoplasm of tumor cells. In addition, both markers were localized in metaplastic cartilage present and the tumor cells within bone.

We have localized of BMP4 and Runx2 in 90 samples of normal mammary tissue and 80 samples of CMT. This has demonstrated that BMP4 and Runx2 are associated with different grades of breast cancer subtypes and may help to predict survival of our canine patients. These results demonstrate that both proteins could be useful prognostic markers for malignant canine mammary tumours.

Beneficial Effects of Combined Therapy of Halofuginone and Zoledronic Acid on Breast Cancer Bone Metastases and Normal Bone Remodeling. Patricia Juarez*[1], Pierrick Fournier[1], Khalid Mohammad[1], Ryan C Mckenna[2], Desiree Lane[1], Sreemala Murthy[1], Maryla Niewolna[1], Alexander Robling[1], Larry Suva[3], John Chirgwin[1], Theresa Guise[1]. [1]Indiana University, USA, [2]University of Virginia, USA, [3]University of Arkansas for Medical Sciences, USA

Breast cancer frequently metastasizes to the skeleton causing bone destruction. Halofuginone (Hfg), a plant alkaloid derivate, reduces osteolytic bone metastases through inhibition of TGFβ and BMP signaling, both regulators of bone remodeling. Thus we seek to determine the effects of Hfg on normal bone unaffected by cancer and whether current therapies could correct Hfg effects.

Female-nude mice (n=15) were treated with Hfg (1-5mg/d) for 4 wks. Hfg (5mg) significantly decreased whole body BMD (20 ± 3 vs $12\pm2 g/cm^2$, $p<0.01$), as well as spine, tibia, and femur BMD. mCT analysis showed that Hfg (5μg) significantly decreased trabecular bone volume. This was associated with increased osteoclast number as well as decreased osteoblast number, mineralizing surface and bone formation rate.

We then tested whether Hfg-induced bone loss can be prevented by the anti-resorptive zoledronic acid (ZA). Hfg (5mg/d) and ZA (5mg/kg/3x per wk) alone or combined were administrated to female-nude mice over 4 wks. Mice treated with Hfg alone had lower BMD, as described earlier, as well as reduced whole bone stiffness measured by femoral 3-pt bending test. Concomitant treatment with ZA completely rescued the osteopenia (40 ± 3 vs $10\pm2 g/cm^2$, $p<0.01$) and bone stiffness deficiencies caused by Hfg.

We next tested the effect of Hfg (5mg/d) and ZA (5mg/kg/3x per wk) alone or combined in nude mice with MDA-MB-231 breast cancer bone metastases in a preventive treatment. Hfg or ZA alone significantly reduced osteolytic area compared with vehicle ($1.9\pm.9$ vs $3.5\pm.2 mm^2$, $p<0.001$ and $1.3\pm.4$ vs $3.5\pm.2 mm^2$, $p<0.001$, respectively). Combined treatment with Hfg and ZA was significantly more efficient at reducing osteolysis area in mice than either treatment alone ($0.4\pm 0.1 mm^2$, $p<0.001$).

In conclusion, Hfg reduces breast cancer bone metastases in mice, and this effect is enhanced when Hfg is combined with ZA. Our data show that Hfg induces bone loss and should be used in combination with anti-resorptive agents such as ZA to prevent this. Hfg completed Phase II trials in sarcoma patients and could rapidly be brought to the clinic for the treatment of bone metastases in breast cancer patients. However, due to its effects increasing osteoclast activity and reducing bone mass, Hfg should be combined with anti-resorptive therapy.

Osteolytic Bone Lesions in Breast Cancer Cause Local and Systemic Alterations in Bone Composition. Xiaohong Bi*[1], Jeffry Nyman[2], Julie Sterling[3], Daniel Perrien[2], Anita mahadevan-jansen[4]. [1]University of Texas Health Science Center at Houst, USA, [2]Vanderbilt University Medical Center, USA, [3]Department of Veterans Affairs (TVHS)/Vanderbilt University Medical Center, USA, [4]Vanderbilt Univ, USA

Pathological fracture is a common and severe complication in breast cancer metastasis to bone, which is thought to be caused by an increase in osteoclast activity as evidenced by the significant architectural disruption in microCT studies. While the material properties of bone are key determinants of bone strength they have not been investigated. To study tumor effects on bone composition, we examined tumor-bearing bones from a mouse model of breast cancer-induced bone disease using Raman spectroscopy (RS) and quantitative microCT, and examined the relationship between tumor-induced changes in material properties and bone architecture.

Five-week-old female nude mice were inoculated intracardically with MDA-MB-231 breast cancer cells (n = 15) or PBS (n = 15), and sacrificed 4 weeks later. Lesion area was calculated from radiographs. Excised tibiae were analyzed by microCT and RS. Raman spectra were acquired every 500 um from the metaphysis to the mid-shaft of tibiae. Spectral measures such as collagen mineralization, carbonate substitution, mineral crystallinity, and hydroxyproline content were calculated.

Radiographs of tumor-bearing bones primarily displayed osteolytic lesions in the metaphysis. Significant decrease in bone volume fraction and trabecular number, and increase in trabecular space from microCT analysis indicated bone loss and architecture disruption caused by tumor. Raman derived measures from pooled spectra showed significantly higher mineralization, carbonation, mineral crystallinity as well as hydroxyproline content in the cortical bone from the tumor-bearing group than the control. When the data were sorted by the collection location, the increases in mineralization and mineral crystallinity were only present at the metaphysis where the osteolytic lesions are dominant. The carbonation and hydroxyproline, however, showed significant increases at all the locations along the tibiae. The carbonation level at the metaphysis was positively correlated with the lesion area in the bone.

Overall, RS is a valuable tool for analyzing compositional changes in bone resulting from tumor burden. Results from our study indicate an increase in mineralization at the metaphyseal cortex, suggesting a possible compensatory

response in the tissue. Furthermore, the universal changes in carbonation and hydroxyproline content suggested a possible systemic effect of tumor on bone microenvironment, which requires further investigation.

Zoledronic Acids Inhibits Epithelial-mesenchymal Transition (EMT) of Breast Cancer Cells in Bone via Ubiquitin/Proteasome System. Toshiyuki Yoneda*[1], Soichi Tanaka[2], Kenji Hata[3], G. David Roodman[4], Riko Nishimura[3]. [1]Indiana University School of Medicine, USA, [2]Osaka University, Japan, [3]Osaka University Graduate School of Dentistry, Japan, [4]Indiana University, USA

Epithelial-mesenchymal transition (EMT) is a program through which epithelial cancer cells transdifferentiate to mesenchymal cancer cells with enhanced aggressiveness that allows colonization in distant organs. Recent accumulating evidence showed EMT is regulated by the microenvironment in which cancer cells colonize. Since breast cancer preferentially spreads to bone, we examined whether bone microenvironment promoted EMT of breast cancer cells. MCF-7 human breast cancer cells expressing GFP (MCF-7/GFP) were inoculated into the mammary fad pad (MFP) and tibial bone marrow (TBM) of female nude mice and examined for the expression of the mesenchymal marker Snail and epithelial marker E-cadherin. Real-Time PCR showed MCF-7/GFP tumors in the MFP expressed high E-cadherin and low Snail mRNA levels. In contrast, MCF-7/GFP tumors in TBM demonstrated increased Snail and decreased E-cadherin expression, suggesting that the bone microenvironment promoted EMT. Of note, zoledronic acid (ZA) down-regulated Snail expression in tumors in TBM, thus ZA inhibited EMT in bone. ZA blocked the TGFβ-induced Snail increase and E-cadherin decrease and reversed TGFβ-induced mesenchymal shape into epithelial. These in vitro results suggest ZA inhibits EMT not only in osteoclast-dependent but also -independent mechanisms. Since Snail is a target of proteasomal degradation, we next examined whether ZA affected proteasomal degradation of Snail. The proteasome inhibitor MG132 restored ZA-decreased Snail expression, suggesting ZA decreases Snail via the ubiquitin/proteasome system. Differential microarray using mammary tumors in TBM isolated from untreated and ZA-treated mice identified the de-ubiquitinating enzyme, ubiquitin-specific enzyme 45 (USP45), as a candidate molecule involved in proteasomal degradation of Snail. ZA significantly inhibited USP-45 expression and activity, which in turn decreased Snail expression. Finally, to determine the biological significance of ZA inhibition of EMT of breast cancer in bone, the effects of ZA on mammary tumors in TBM were determined. ZA inhibited not only tumor progression but also distant metastasis to lung and liver from bone. In conclusion, our results suggest the bone microenvironment promotes EMT in breast cancer. ZA inhibits EMT via stimulation of proteasomal degradation of Snail by suppressing the de-ubiquitinating enzyme USP-45. EMT inhibition by ZA leads to suppression of aggressive behaviors of breast cancer in bone.

Acidic conditions epigenetically repress the TRAIL receptor DR4 in myeloma cells to confer their resistance to TRAIL. Ryota Amachi*[1], Masahiro Abe[2], Masahiro Hiasa[3], Keiichiro Watanabe[4], Shiro Fujii[5], Takeshi Harada[5], Hirokazu Miki[5], Shingen Nakamura[5], Itsuro Endo[6], Eiji Tanaka[7], Toshio Matsumoto[6]. [1]Dept. of Medicine & Bioregulatory Sciences, Tokushima Univ. /) Dept. of Orthodontics & Dentofacial Orthopedics, Tokushima Univ., Japan, [2]University of Tokushima, Japan, [3]University of Tokushima Graduate School, Japan, [4]Tokushima University Hospital, Japan, [5]Dept. of Medicine & Bioregulatory Sciences, Tokushima Univ., Japan, [6]University of Tokushima Graduate School of Medical Sciences, Japan, [7]Dept. of Orthodontics & Dentofacial Orthopedics, Tokushima Univ., Japan

TRAIL-mediated immunotherapy is an attractive anti-tumor maneuver because of its tumor-specific cytotoxic activity. In osteolytic lesions in myeloma (MM), MM cells and osteoclasts (OCs) create an acidic milieu by protons produced by OCs and lactate by MM cells, which confers drug resistance in MM cells. We found that acidic conditions blunted TRAIL-mediated apoptosis in MM cells. In the present study, we explored the mechanisms of MM cell resistance to TRAIL in acidic conditions. DR4 expression was markedly reduced at mRNA and protein levels in MM cells cultured in acidic media or cocultured with acid-producing OCs. Acidic conditions suppressed H3 and H4 acetylation in MM cells, while enhancing the nuclear localization of Sp1, a transcription factor for HDACs, and thereby HDAC1 and HDAC2 expression in MM cells. Furthermore, the acetylation of H3K9 in a DR4 promoter was found to be suppressed in acidic conditions; treatment with the HDAC inhibitor valproate restored the DR4 expression in MM cells in acidic conditions, indicating HDAC-mediated repression of DR4 in an acidic environment. Acidic conditions also induced Akt phosphorylation in MM cells; the inhibition of the PI3K-Akt pathway by LY294002 or the Akt inhibitor Akt-in (Calbiochem) abrogated the suppression of the histone acetylation and restored the DR4 expression in MM cells in acidic conditions. Although the anti-MM effects of the anti-DR4 agonistic antibody R1-B12 were blunted in acidic conditions, the Akt or HDAC inhibition sensitized MM cells to R1-B12. From these results, an acidic milieu in MM bone lesions is suggested to confer the resistance in MM cells against TRAIL-mediated immunotherapy through the PI3K-Akt-mediated epigenetic repression of DR4 expression.

Autoregulation of RANK Ligand Expression in Oral Squamous Cell Carcinoma Tumor Cells. Yuvaraj Sambandam*[1], Kumaran Sundaram[2], William Ries[1], Sakamuri Reddy[2]. [1]Medical University of South Carolina, USA, [2]Charles P. Darby Children's Research Institute, USA

Head and neck squamous cell carcinoma is the most common malignant neoplasms estimated to be 40,000 cases annually in the US. RANK ligand (RANKL) is an essential bone resorbing osteoclastogenic factor in the bone microenvironment. We previously demonstrated high levels of RANKL expression in oral squamous cell carcinoma (OSCC) tumor cells. Also, OSCC cells stably transfected with RANKL-luc reporter construct showed a significant increase in luciferase activity with tumor growth in athymic mice. Therefore, we hypothesize that RANKL promotes OSCC tumor progression and invasion of bone. Immunohistochemical staining demonstrated high levels of RANKL and its receptor, RANK expression in tumor specimens from human subjects compared to normal adjacent tissues. Confocal microscopic analysis further confirmed RANK expression in OSCC cells (SCC1, SCC12 and SCC14a). Western blot analysis of total cell lysates obtained from OSCC cells stimulated with RANKL revealed a dose-dependent (0-125 ng/ml) increase in RANKL expression. Also, real-time PCR analysis of total RNA isolated from OSCC cells stimulated with RANKL in the presence and absence of RANKL inhibitor, OPG suppress RANKL mRNA expression in these cells. These results suggests an autoregulation of RANKL expression in OSCC cells. We next examined the RANKL capacity to increase OSCC cells proliferation. Interestingly, RANKL stimulation dose-dependently increased OSCC tumor cell proliferation in vitro. Also, RANKL stimulated OSCC cells demonstrated an increased levels of proliferating cell nuclear antigen (PCNA) expression. Furthermore, RANKL dose-dependently increased MMP-9 expression in SCC14a cells. Conditioned media obtained from SCC1 and SCC14a cells treated with different concentrations of RANKL (0-50 ng/ml) subjected to gelatin zymogram analysis showed elevated levels of MMP-9 activity suggesting a functional role for RANKL in tumor invasion of bone. Western blot analysis of total cell lysates obtained from OSCC cells treated with RANKL demonstrated a significant increase in the levels of TRAF-6 expression. We further identify that RANKL treatment significantly increased the levels of phospho-IKK and IkB expression in these cells. Thus, our results implicate RANKL autoregulation plays an important role in OSCC tumor progression and bone destruction.

Denosumab an innovative and effective treatment for Giant Cell Reparative Granuloma. Alicia Dean Ferrer[1], Francisco Alamillos[1], Juan José Ruiz Masera[1], Cristina Navarro Valverde[2], Jose Manuel Quesada gómez*[3]. [1]Servicio de Cirugía Maxilofacial. HU Reina Sofía, Spain, [2]Servicio de Endocrinología, Spain, [3]Servicio de Endocrinología.HU Reina Sofía, Spain

Giant Cell Reparative Granuloma (GCRG) is an expansive eand destructive lesion of the jaw, positive for osteoclast markers, which affects children and young adults (female-male ratio 2:1). The fast growing lesions, despite their innocent histological appearance, have a dramatic aggressive behavior, mimicking a malignant lesion. Conventional management consists of surgical enucleation and curettage, with a recurrence rate of 15-20% (treatment may need to be aggressive even with an ''in block'' resection). Medical treatment such as intralesional steroid injections, calcitonin, or alpha interferon sc. injections have shown limited efficacy. Denosumab is a fully human monoclonal antibody that binds and inhibits RANKL, thereby preventing the activation of the RANK pathway. We tested the possibility to counteract osteoclast activation in GCRG and prevent the potential physiopathological role of RANK pathway. Denosumab has demonstrated its therapeutic potential and safety for Giant-cell tumor of bone.

We hereby report the first therapeutic use of denosumab in two young patients with recurrent GCRG of the jaw (aged 20 and 21 yrs.) after failure of tumor resection and intralesional steroid injections. Compassionate use of Denosumab was approved by Reina Sofía Hospital Ethics Committee, and administrated at a dose of 60 mg sc every three months and 1000 mg of calcium & 1000 IU vitamin D every day. Shortly after initiation therapy both patients recovered from severe pain and mandibular swelling disappeared. After a year of treatment no side effects of denosumab were observed, and both orthopantomography and computed tomography showed near-total tumor regression in on case and complete tumor regression in the second case, with adequate recalcification in both patients. Perforation of mandibular cortical disappeared and it was fully covered with new bone.

Denosumab could represent a medical treatment option for patients with GCRG to prevent dramatic disfiguring destruction of the jaw even without surgery.

Immunomodulatory Role of Mechanical Signals in Regulating the Expansion of Hematopoietic Precursors in a Murine Model of Multiple Myeloma. Gabriel Pagnotti*[1], Benjamin Adler[1], M. Ete Chan[1], Clinton Rubin[2]. [1]Stony Brook University, USA, [2]State University of New York at Stony Brook, USA

Cancer progression, often complicated by a decline in bone quantity and quality and an increased risk of fracture, negatively impacts the bone marrow (BM) niche, disrupting hematopoietic stem cell populations that are critical for immune regulation and control of inflammation. Exercise, recognized as a non-pharmacologic strategy for preserving bone strength, also serves to suppress inflammation. We have demonstrated low intensity vibration (LIV) to be anabolic to bone in an ovarian cancer model by forcing mesenchymal stem cells through osteoblastogenesis without compromising longevity. To investigate the modulatory role of mechanical signals during the early onset of a primary blood cancer in the marrow, 2E6 U266β1 Hu-myeloma cells were injected intravenously into an immunocompromised mouse strain (NSG). Mice were divided into 3 groups (n=10) at 5w of age: diseased (MM), diseased mice treated with LIV, and age-matched control (AC). LIV mice were subject to 15m/d, 5d/w on a vertically oscillating vibrating platform (0.3g @ 90Hz). Pathologies indicative of disease, including lung nodules, splenomegaly, and enlarged kidneys, were significantly observed in MM and LIV. At sacrifice and as compared to AC, flow cytometric analysis of BM from the left femur of MM revealed a +30% ($p<0.001$) and a +27% (ns) increase in hematopoietic precursor stem cells (KLS: C-kit+, Lin-, Sca-1+) and T-cells (CD3+, B220-), respectively, in MM as compared to AC. This inflammatory response was significantly reduced in LIV mice, with KLS (-15%; $p<0.01$ relative to MM) and CD3+ cells (-29%; p=0.06 relative to MM). Natural killer cells (NK1.1+, CD3-) from the left femur were +88% higher in MM relative to AC, while these cells decreased by -20% in LIV compared to MM. These data suggest that induction of U266 cells into the circulation significantly affects hematopoietic outcomes, elevating an immune response to the instigation of myeloma cells, manifested by the elevation of early-stage hematopoietic KLS cells as well as immature T-lymphocytes. Though preliminary, this evidence suggests that induction of disease has incited an apparent increase in immune response at multiple levels of the hematopoietic lineage. Interestingly, this immune response appears somewhat mitigated following 8w exposure to mechanical signals, suggesting a potential immunomodulatory effect on the bone marrow microenvironment.

Loss of Parafibromin Immunoreactivity in Sporadic Ossifying Fibroma. Jessica Costa-Guda*[1], Andrew Arnold[2]. [1]University of Connecticut Health Center, USA, [2]University of Connecticut School of Medicine, USA

Hyperparathyroidism jaw-tumor syndrome (HPT-JT) is an autosomal dominant disorder consisting of a predisposition to benign and/or malignant parathyroid tumors, jaw tumors most often characterized as ossifying, cementifying or cemento-ossifying fibromas and a variety of kidney and uterine lesions. Inactivating mutations of the *HRPT2* (also called *CDC73*) tumor suppressor gene, encoding parafibromin, were identified as the genetic cause of HPT-JT in the majority of affected kindreds. Subsequently, examination of sporadic parathyroid carcinomas revealed germline and/or somatic mutations of *HRPT2* and loss of parafibromin protein expression in the majority of patients. Somatic mutations of *HRPT2* have also been reported in a subset of sporadic renal tumors. Germline and somatic mutations of *HRPT2* were identified in a subset of sporadic ossifying fibromas but aberrant protein expression, even in cases with *HRPT2* mutation, could not be demonstrated. In this study, we examined a series of 9 ossifying fibromas, including ossifying, cemento-ossifying and juvenile active variants, for parafibromin protein expression via immunohistochemistry. Four ossifying fibromas showed a complete absence of nuclear parafibromin expression; loss of parafibromin expression was coupled with aberrant cytoplasmic parafibromin expression in one case. These results provide novel evidence at the level of protein expression for the suggestion that loss of *HRPT2*/parafibromin may play an important role in the pathogenesis of ossifying fibroma. Further studies are needed to determine the extent of involvement of *HRPT2*/parafibromin abnormalities in these tumors, and to identify additional molecular contributors to the pathogenesis of ossifying fibroma.

Lung Cancer Stem-Like Cells (CSC) Display a Retarded Osseous Prometastatic Activity. Anne-Marie Bleau*[1], Carolina Zandueta[1], Miriam Redrado[1], Susana Martinez-Canarias[1], Alfonso Calvo[1], Fernando Lecanda[2]. [1]Center for Applied Medical Research, Spain, [2]Foundation for Applied Medical Research, Spain

Current evidence indicates that a fraction of cells within tumors, called Cancer Stem Cells (CSC), display stem cell–like properties and overt chemoresistance. To enrich for CSC, *in vivo* limited dilution and spheres cultures have been widely used as assays for stem cell properties. These structures present a heterogeneous population of cells, containing a mixture of quiescent CSC together with highly proliferative cells. At present, the extent to which CSC also display prometastatic activity remains poorly understood.

Sphere cultures (SC) derived from a mouse lung adenocarcinoma (LACUN3) showed higher levels of CSC markers including a 5-fold increase in ALDH and a 4-fold increase in Sca-1 (Ly-6A/E), as compared to adherent cultures (non-SC). Consistent with their quiescent phenotype, SC displayed a marked cell cycle arrest in G_0/G_1 phase that was translated into a 15-fold reduction in *in vitro* growth kinetics as compared to the other conditions. More importantly, the evaluation of quiescence by fluorescent-dye retention was 80% higher in SC than in non-SC. As expected, SC presented a 6-fold higher colony formation activity in soft agar assay, as well as a 40% increase in resistance to paclitaxel. All these experiments were repeated with the human lung cancer cell line H460, where SC overexpressed ALDH and ABCG2 markers and were also endowed with quiescent properties.

To delineate the metastatic activity of SC, upon intracardiac inoculation into nude mice, bioluminescence imaging (BLI) showed a dramatic delay in the appearance of bone metastatic lesions as compared to non-SC. At day 21 postinoculation, BLI in SC-injected animals showed a striking decrease in osseous metastatic tumor burden as compared to non-SC mice. Analogous delay was observed when SC were disaggregated and cultured as adherent cells before inoculation. Similar results were obtained when *in vivo* experiments were repeated with other cell lines.

Interestingly, using subcutaneous injection, tumor growth was similar (SC vs non-SC). In contrast, assessment of osseous colonization activity by intratibial injection of SC cells showed a six-fold decrease in bone tumor burden as compared to non-SC injected mice.

Taken together, these data suggest that differentiation of CSC in the target organ might be required for the emergence of cell variants with high prometastatic activity. We postulate that microenvironmental factors imposed by each target metastatic organ might be crucial in this process.

Ras Activation Mediates WISP-1 Induced Increases in Cell Motility and Matrix Metalloproteinase Expression in Human Osteosarcoma. Yi-chin Fong*, Chih-Hsin Tang. China Medical University, Taiwan

WISP-1 is a cysteine-rich protein that belongs to the CCN (Cyr61, CTGF, Nov) family of matrix cellular proteins. Osteosarcoma is a type of highly malignant tumor with a potent capacity to invade locally and cause distant metastasis. However, the effect of WISP-1 on migration activity in human osteosarcoma cells is mostly unknown. In this study, we first found that the expression of WISP-1 in osteosarcoma patients was significantly higher than that in normal bone and corrected with tumor stage. Exogenous of osteosarcoma cells with WISP-1 promoted cell motility and matrix metalloproteinase (MMP)-2 and MMP-9 expression. In addition, the Ras and Raf-1 inhibitor or siRNA abolished WISP-1-induced cell migration and MMPs expression. On the other hand, activation of the Ras, Raf-1, MEK, ERK, and NF-κB signaling pathway after WISP-1 treatment was demonstrated, and WISP-1-induced expression of MMPs and migration activity were inhibited by the specific inhibitor, and mutant of MEK, ERK, and NF-κB cascades. Taken together, our results indicated that WISP-1 enhances the migration of osteosarcoma cells by increasing MMP-2 and MMP-9 expression through the integrin receptor, Ras, Raf-1, MEK, ERK, and NF-κB signal transduction pathway.

Transcriptome Signatures of Mesenchymal Stem Cells and their Osteogenic Offspring after Contact with Myeloma Cells. Julia Dotterweich*[1], Beate Geyer[1], Katrin Schlegelmilch[1], Alexander Keller[2], Norbert Schuetze[1], Franz Jakob[1]. [1]University of Wuerzburg, Orthopedic Center for Musculoskeletal Research, Germany, [2]University of Wuerzburg, Biocenter, DNA-Analytics, Germany

Multiple myeloma (MM) is a hematological malignancy with 90% of all patients developing myeloma bone disease characterized by osteolytic lesions. This bone disease is accompanied with an increased mortality and is caused by a disordered bone remodeling with enhanced bone resorption and impaired bone formation. Insufficient osteoblastogenesis is a consequence of humoral and direct cell-cell interaction between mesenchymal stem cells (MSC) and myeloma cells. To elucidate the alterations of bone-forming cells in the tumor microenvironment, global gene expression analysis for MSC and osteogenic precursor cells was performed after myeloma cell contact.

The global gene expression analysis was performed by using Affymetrix gene chip HG-U133 2.0 Plus Array. MSC were co-cultured with the myeloma cell line INA-6 for 24 h. To separate the co-culture by FACS sorting, INA-6 cells were stained with CellTracker® Green CMFDA before culturing. Same procedure was performed for osteogenic precursor cells. Osteogenic precursor cells were generated by incubating MSC with osteogenic differentiation media for 14 days. Osteogenic differentiation was checked with histological staining for alkaline phosphatase and alizarin red for calcified extracellular matrix. RNA of five independent experiments was used for gene expression analysis, whereas the according MSC or osteogenic precursor cells were used as control. The evaluation was performed by software R (normalization: RMA; filter: $-0{,}5 \leq \log \text{Fold change} \geqslant 0{,}5$, AFFX). Target genes were validated by semiquantitative RT-PCR and analysed by densitometry.

The direct co-culture of INA-6 cells with MSC resulted in 991 differential expressed probe sets (718 genes/86 NA) whereas the contact with osteogenic precursor cells led to 552 differential expressed probe sets (397 genes/32 NA). Both conditions share 161 up-regulated (107 genes/5 NA) and 20 down-regulated (15 genes/2 NA) probe sets. The regulation of target genes was confirmed by semiquantitative RT-PCR. Regulated targets include important angiogenic factors like VEGF-A, chemokines like CCL28, and adhesion molecules like ICAM-1.

We further aim to elucidate candidate genes on protein level in *in vitro* culture with primary myeloma cells and in tumor tissues. Altered surface molecules on bone marrow cells in case of disease will preferentially be looked at to provide a tool for novel therapeutic approaches and diagnostic markers.

Anti-dementia glutaminergic NMDA and Acetylcholine esterase inhibitor inhibits osteoclastogenesis. Charles Inderjeeth*[1], Jiake Xu[1], Dian Teguh[2], Bay Sie Lim[2]. [1]University of Western Australia, Australia, [2]University of WA, Australia

Background: Alzheimer's dementia (AD) and osteoporosis (OP) are common and parallel ageing and frequently coexist in an ageing population. Low BMD appears related to increased risk of AD. Various clinical conditions have been shown to alter Acetylcholine (Ach) signalling and affect bone. Ach Receptor (AchR) subunits and Ach Esterase (AchE) are expressed in bone. We demonstrated an in vitro effect of acetylcholine esterase inhibitors (AchEI) on osteoclast (abstract ECTS 2013). We demonstrated at equimolar concentrations Donepezil inhibit, whereas Galantamine enhances osteoclastogenesis. Memantine, uncompetitive antagonist at glutaminergic NMDA receptors, are also effective in treating AD. NMDA receptors have also been identified in bone. We hypothesised that, given the parallels with ageing in AD and OP and effect of AchEI, NMDA may be a useful target as well.

Methods: BMMs are seeded at 6×10^3 cells/well in 96-well plate. Prior to RANKL stimulation, cultures were incubated with the drugs Memantine, Donepezil and Galantamine at equimolar concentrations of 0.1 to 5.0μM. Control plates were incubated with and without RANKL only for comparison.

Results: At equimolar concentrations Memantine and Donepezil inhibit, whereas Galantamine enhances osteoclastogenesis. Memantine and Donepezil inhibited osteoclastogenesis at the lowest concentration of 0.1μM. IC50 for Donepezil is estimated at 0.35 uM and for Memantine, it is estimated to be 0.75 uM..

Conclusion: This data suggests Ach and glutaminergic neurotransmission may both be important in bone biology. This may have important implications for osteoporosis management in older and dementia populations who have both conditions coexist.

Characterization of Age-related Skeletal Muscle Regenerative Function and Gait Performance Recovery in Hindlimb Injured Fibroblast Growth Factor-2 Null Mice. Toru Nishikawa*[1], Collin Homer-Bouthiette[1], Liping Xiao[1], Marja Marie Hurley[2], Morgan Carlson[1]. [1]University of Connecticut Health Center, USA, [2]University of Connecticut Health Center School of Medicine, USA

Recent evidence suggests an age-dependent role for FGF2 in muscle satellite stem cell quiescence and self-renewal. We examined the impact of Fgf2 knockout on muscle regenerative capacity, and in a cross-age comparative analysis of gait performance following acute injury. *Approach*: The numbers of Pax7-expressing satellite cells were determined in uninjured muscle harvested from 2, 10-12 and 18 months WT and Fgf2KO mice. Ventral plan videography was used to assess whether Fgf2KO resulted in enhanced loss of muscle homeostasis and physiological performance.WT and Fgf2KO mice of different ages walked on a transparent treadmill belt at baseline day 0, and 3 and 5-days post-hindlimb muscle injury. At 5-days post-injury, total numbers of newly-generated myofibers were determined in isolated gastrocnemius by hematoxylin and eosin (H&E) and immunohistochemical staining for embryonic myosin heavy chain (eMyHC). *Results*: Analysis of uninjured muscle from WT and Fgf2KO mice revealed a significant and progressive decline in the number of Pax7 and M-cadherin positive satellite cells with age and genotype. Gait analysis showed no difference at base line in hindlimb propulsion duration (an indicator of muscle strength) between WT and Fgf2KO mice. However, at 3days post-injury propulsion was decreased in both genotypes returning to baseline at 5days post-injury in WT (202.6 ± 13.6ms) but remaining significantly shorter in Fgf2KO (122.8 ± 24.5ms; $p<0.05$). Stride length was similar in both genotypes at day 0 and at 3 days post-injury, returning to baseline in WT at day 5 post-injury (4.1 ± 0.1cm), but remained significantly reduced in Fgf2KO (2.6 ± 0.3cm; $p<0.05$). Stride frequency was similar between genotypes at days 0 and 3 post-injury but was significantly increased at day 5 post-injury in Fgf2 KO (4.9 ± 0.7Hz), compared with WT (2.5 ± 0.1Hz $p<0.05$). Since gait dysfunction was observed in Fgf2KO mice at 5 days post-injury, we determined muscle regenerative responses by quantifying production of de novo myofibers. There was a significant reduction in myofiber density in Fgf2KO (55.6 ± 7.2) compared with WT (77.5 ± 8.8 $P<0.05$). Further analysis revealed fewer active-Notch1 positive satellite cells present in 5 days post-injury Fgf2KO mice. These results demonstrate an age-associated negative impact of FGF2KO on skeletal muscle regenerative capacity, suggesting that losses in endogenous FGF2 signaling with age, may contribute to functional impairment of the muscle stem cell compartment.

MO0003

Inducible Conditional Inactivation of FGFR3 in Collagen II Expressing Cells at adult stage Leads to Early-Onset Degeneration of the Intervertebral Disc. Yangli Xie*[1], Siru Zhou[1], Wei Xu[1], Junlan Huang[1], Xiaolan Du[1], Lin Chen[2]. [1]Trauma Center, Daping Hospital, Third Military Medical University, Peoples Republic of China, [2]Daping Hospital, Peoples Republic of China

Although Fibroblast Growth Factor Receptor 3 (FGFR3) signaling plays a critical role in regulating bone development and homeostasis, its roles in the maintenance of intervertebral disc (IVD) remain poorly understood. FGFR3 knockout mice showed skeletal defects including kyphosis, scoliosis, crooked tails and overgrowth of long bones and vertebrae. Mice with conditional deletion of FGFR3 in collagen2-expressing cells using Col2a1-Cre mice also showed kyphosis, scoliosis and bone overgrowth, suggesting the role of FGFR3 in the development and maintenance of IVD. To distinguish the role of FGFR3 in the early development and adult stage maintenance of IVD, we inducibly inactivated FGFR3 in collagen2-expressing cells including inner annulus fibrosus cells and endplate chondrocytes by injecting tamoxifen (TM) into mice with both floxed FGFR3 alleles and Col2a1-CreERT^2 allele (hereafter referred to as $Fgfr3^{Col2ER}$). $Fgfr3^{Col2ER}$ mice and controls ($Fgfr3^{flox/flox}$) were injected with TM at 2-month (1mg/10 g BW, × 5 days, i.p.), and were examined at 3- and 4- month old. Disc tissue specimens were analyzed by micro-computed tomography, histologic analysis, and real-time PCR.

FGFR3 protein was expressed in the cells of annulus fibrosus and endplate cartilage of IVD and growth plates of WT mice, but not in the nucleus pulposus cells. Compared to WT mice, $Fgfr3^{Col2ER}$ mice showed no significant gross phenotype. The vertebral body height and disc space also showed no remarkable changes. Histologically, $Fgfr3^{Col2ER}$ mice developed early-onset of aging related cartilage loss and had bony tissue in the endplates at 3- and 4-month old. The histology of bone-like tissues resembled those found in ectopically formed bone, containing bone marrow, osteoclasts and mineralized osteoblasts. Immunohistochemical analysis demonstrated a notable reduction in Collagen 2 level and a significant increase in Mmp13 and Collagen 10 expression in the IVD of $Fgfr3^{Col2ER}$ mice. Gene expression analysis of IVD demonstrated that inactivation of FGFR3 led to enhanced Collagen10, Mmp13 and Adamts5 expression and depressed Col2, aggrecan expression.

These results indicate that deletion of FGFR3 in chondrocytes leads to early-onset degeneration of endplate regions, which is similar to changes of early stage IVD degenerative in humans. These findings may provide experimental data for further mechanism studies, and for screening of therapeutic approaches for human disc degeneration.

Selective Amino Acid Supplementation Can Exacerbate or Prevent Low Protein-Induced Bone Loss in the Aged Animal. Kehong Ding[1], Qing Zhong[2], Bryce Wyatt[3], Jarrad Rowse[3], Xing-Ming Shi[1], Jianrui Xu[3], Mona El Refaey[3], William Hill[4], Wendy Bollag[3], Mohammed Elsalanty[1], Nicole Howie[3], Karl Insogna[5], Norman Chutkan[3], Monte Hunter[3], Mark Hamrick[1], Carlos Isales*[3]. [1]Georgia Health Sciences University, USA, [2]Medical College of Georgia, USA, [3]Georgia Regents University, USA, [4]Georgia Regents University & Charlie Norwood VAMC, USA, [5]Yale University School of Medicine, USA

Epidemiologically, low protein diets have been shown to be associated with a higher incidence of hip fractures in the elderly. We have previously reported that L-type amino acids bind to extracellular receptors on bone marrow-derived mesenchymal stem cells, osteoblasts and osteoclasts and modulate their activity depending on the amino acid type. In addition we have demonstrated that a low protein (8%), as compared to a normal protein (18%), diets induces bone loss in the aged (24 month) but not the mature (12 month) C57Bl6 mouse. Low protein diet-induced bone loss can be prevented by supplementing the diet with only three aromatic amino acids (tyrosine, tryptophan and phenylalanine or TTP) up to the 18% protein levels. We wished to extend the previous study and examine the effects of other amino acid supplements in order to determine the selectivity of the aromatic amino acid effects. Three amino acid groups were selected in this IACUC approved study: (1) aromatic amino acids, based on previous data demonstrating them to have the most potent anabolic effects on osteoblasts in vitro; (2) the branched-chain amino acids, valine, leucine and isoleucine (VLI), based on previous data demonstrating them to have no anabolic effects on osteoblasts; and (3) serine, threonine and valine (STV), based on data demonstrating them to have the greatest potency in stimulating osteoclastic activity. We divided 24-month old C57Bl6 mice into five dietary groups (n=12/group): (1) standard protein (18%); (2) low protein (8%); (3) low protein + TTP; (4) low protein + VLT; and (5) low protein + STV. Animals were sacrificed at the end of eight weeks, blood obtained by cardiac puncture and bones removed for micro-CT, DXA, biomechanical, histomorphometric, and biochemical studies. We report that the low protein diets resulted in significant bone loss, decreased biomechanical strength and increased biochemical markers of bone breakdown and decreased bone formation rates. In contrast, (1) supplementing the low protein diets with TTP prevented the low protein-induced bone loss; (2) VLI supplements had no impact on the low protein diets; and (3) STV supplements significantly exacerbated the low protein-elicited bone loss. Taken together we conclude that amino acid supplements have specific effects on bone turnover in the aged animal

Association of Sarcopenia with Muscle Strength and Quality of Life in Postmenopausal Women with or without Osteoporosis. Michio Hongo*, Naohisa Miyakoshi, Yuji Kasukawa, Yoichi Shimada. Akita University Graduate School of Medicine, Japan

Introduction: The purpose of this study was to evaluate the association of sarcopenia with muscle strength and quality of life in postmenopausal women. Methods: A total of 167 postmenopausal women with an average age of 68 years were enrolled in this study. Participants underwent dual energy x-ray absorptiometry for whole body, lumbar spine, and total hip. Relative skeletal muscle mass index (RSMI) was calculated by sum of appendicular muscle mass from whole body scan divided by the square of the height. Sarcopenia was defined as RSMI more than 2 standard deviations below the average of normative data. The diagnosis of osteoporosis was defined by bone mineral density at lumbar spine or hip. Back extensor and grip strength, Roland-Morris questionnaire (RDQ), Short-form-36 (SF-36), and Japanese osteoporosis quality of life score (JOQOL) were measured. Participants were categorized into 4 groups according to the presence of osteoporosis (OP) and sarcopenia (SP): (1) OP+/SP+, (2) OP+/SP-, (3) OP-/SP+, and (4) OP-/SP-. Each measurement was compared among the groups. Results: The prevalence of sarcopenia was 34 women (20%) in this study population. There were 22 (13%) women in OP+/SP+ group, 80 (48%) in OP+/SP-, 12 (7%) OP-/SP+, 53 (32%) OP-/SP-. There was no significant difference in age among the groups. JOQOL scores in OP+/SP+ group showed significantly lower in domains for physical activity, social activity/recreation, posture/figure, fall, and total score compared with other groups. JOQOL scores in OP+/SP- also showed significantly lower in domains for posture/figure and fall compared with OP-/SP- and OP-/SP+. Back extensor strength of OP+/SP- and OP+/SP+ was significantly lower than those of OP-/SP-. However, there was no significant difference between sarcopenia and non-sarcopenia. Grip strength, SF-36 except for mental health status, and pain measurements from RDQ and JOQOL showed no significant difference among the groups. Conclusions: Decreased quality of life in individuals with combination of both osteoporosis and sarcopenia were influenced by poorer physical activity, aggravated posture, or fear of fall, suggesting the importance of detecting patients with combination of both. Although grip strength has been widely used for evaluating sarcopenia, there was no association of muscle strength with the presence of sarcopenia. Identifying sarcopenia with measuring muscle strength is limited for diagnosis and combination with other tools will be needed.

MO0006

Choice of Reference Population Radically Affects Sarcopenic Obesity Prevalence. Bjoern Buehring*, Ellen Fidler, Jessie Libber, Diane Krueger, Neil Binkley. University of Wisconsin, Madison, USA

Saracopenic obesity (SO) can be defined as a relative excess of fat mass in comparison to lean mass. SO impairs health more than either sarcopenia (SP) or obesity independently. However, there is no current consensus definition of SO; until such consensus is reached, SO will not receive needed clinical recognition. Multiple potential definitions of SO have been advanced. We hypothesized that SO prevalence will vary among the definitions and cut-offs used. This study examines different definitions that include fat and lean mass as measured by DXA. Cut-offs for these parameters were based on either an ''ideal'' or a ''regular'' population. The main outcome parameter was SO prevalence based on various definitions in a cohort of older adults.SP was defined by ALM/ht^2 (Baumgartner et al). SO parameters included %body fat, total fat/leg lean mass ratio and leg fat/leg lean mass ratio. Two standard deviation (SD) cut-offs were examined based on an ''ideal'' population (college athletes) and a ''regular'' population (20-29 year olds from NHANES 1999-2004 cohorts) and a published cut-off for %body fat (Dufour et al, M>30%, F>40%). Definitions and cut-offs were applied to a cohort of community dwelling older adults. The prevalences of different SO definitions and the prevalence of the combination of SP and SO were compared.

The reference population cohorts included 326 (150F/176M) athletes and >10,000 DXA data points from 2,116 (999F/1,117M) 20-29 year old individuals in NHANES. The cohort of older adults consisted of 97 (49F, 48M) adults age ⩾70. Two SD cut-offs for %body fat, total body fat/leg lean mass ratio, leg fat/lean mass ratio were higher in the NHANES cohort compared to athletes. Prevalence of SP by low ALM/ht^2 was 24%. SO prevalence varied based on comparison population and SO measure selected and ranged from 1 to 77% (66-77% based on athlete parameters versus 1-6% based on NHANES). Prevalence of SO combined with SP varied from 1 to 16.5%. Percentages based on athlete cut-offs were higher compared to NHANES cut-offs ($p<0.5$).

In conclusion, the prevalence of SO and the combination of SP and SO varies widely depending on the choice of fat and lean mass measures and reference population to define ''normal.'' SO prevalence based on an ''ideal'' (athlete) cut-off is several fold higher compared to a ''regular'' (NHANES) cut-off. These results highlight the need to base SP and SO definitions on health outcomes such as falls and fractures rather than reference populations.

MO0007

Defining Osteosarcopenic Obesity and Identifying its Prevalence in Women Across a Wide Age-range. Julia E. Inglis*[1], Lynn B. Panton[2], Michael J. Ormsbee[2], Owen J. Kelly[3], Jasminka Z. Ilich[2]. [1]Florida State University Dept. of Nutrition, Food, & Exercise Science, USA, [2]Florida State University, USA, [3]Abbott Nutrition, USA

Sarcopenia and sarcopenic obesity have been recognized in the last decade, however, a condition to include the loss of muscle and the loss of bone (osteopenia) with coexistence of adiposity (osteopenic obesity), may be prevalent but has not been defined or adequately studied. Here we consolidate *osteopenic obesity* with the already existing and more familiar term, sarcopenic obesity, and delineate the resulting combined condition assigning it the term *osteosarcopenic obesity*. Further, we examine a population of 602 healthy Caucasian women between 18 and 88 (mean ± SD 49.4 ± 16.2) years to determine the prevalence of osteosarcopenic obesity. Body compostition and BMD of the total body, spine, and femur were measured by iDXA. Obesity was determined based on % body fat, taking >30% as a cutoff for obesity. Sarcopenic obesity was identified using a linear regression (as proposed by Newman et al. 2003) to derive the association between appendicular skeltal muscle mass (obtained from iDXA) with height and fat mass. Negative residuals from the linear regression indicated the obese individuals who had lower appendicular skeletal muscle mass than the expected value and therefore were identified as having sarcopenic obesity. Osteopenic obesity was also identified using the linear regression by comparing BMD of total hip and/or spine to height and fat mass in the obese. Similarly, negative residuals identified those individuals whose BMD was less than the expected value in the presence of obesity, indicating osteopenic obesity. Results identified 492 (82%, ages 18-83 y) obese individuals; 250 (42%, ages 20-80 y) with sarcopenic obesity; 251 (42%, ages 22-83 y) osteopenic obesity; and 148 (25%, ages 22-79 y) presenting with osteosarcopenic obesity. These findings suggest that osteosarcopenic obesity is a relevant health condition for women of all ages, where compromised bone and muscle tissues are combined with excess of adiposity, exacerbating each of these conditions and is not limited just to older individuals. However, this combined condition has not been previously identified or recognized. Further research is warranted to identify prevalence of osteosarcopenic obesity, whether in the newly created studies, or by re-examining existing data-bases.

Effects of Age and Caloric Restriction on the Expression of Leptin in Peripheral Tissues. Phonepasong Arounleut[1], Sunil Upadhyay[2], Xing-Ming Shi[3], William Hill[4], Carlos Isales[2], Mark Hamrick*[3]. [1]Georgia Regents University (formally Georgia Health Sciences University), USA, [2]Georgia Regents University, USA, [3]Georgia Health Sciences University, USA, [4]Georgia Regents University & Charlie Norwood VAMC, USA

Leptin, the product of the obese gene (ob), is known to be secreted by fat cells (adipocytes). Leptin then crosses the blood-brain barrier to bind its receptors in the hypothalamus where it regulates food intake and energy balance. Recent data also show that leptin receptors are abundant in peripheral tissues such as bone and skeletal muscle, and these same tissues are also reported to be sources of leptin itself. Leptin-deficiency is associated with decreased hindlimb muscle and bone mass in ob/ob mice and in food-restricted mice, and so we tested the hypothesis that age-related muscle and bone loss may be associated with reductions in leptin secreted from these peripheral tissues. ELISA assays were utilized to quantify leptin levels in the femur, quadriceps femoris muscle, inguinal fat pads, and liver of mice aged 12 months and 20 months fed ad-libitum (AL) and mice aged 20 months on caloric restriction (CR). We also treated mice aged 20 months on caloric restriction with recombinant mouse leptin for 10 days at 10 mg/kg body weight to examine the response of peripheral tissues to exogenous leptin. Data show that in all groups leptin levels are highest in skeletal muscle, both absolutely and relative to total protein. Leptin levels are slightly lower in the liver and in fat, and lowest in bone. Aging does not significantly alter leptin levels in any of these tissues, but caloric restriction (CR) significantly reduced leptin levels in bone (- 20%) and fat (-45%) of aged mice. Exogenous leptin significantly reduces leptin levels in all tissues of aged CR mice, and this effect is most dramatic in the liver where there is a 10-fold decrease in leptin following leptin treatment. These data suggest that the regulation of local and circulating leptin levels is complex and involves multiples tissues and organ systems. Funding for this research was provided by the National Institute on Aging (P01 AG 036675).

Identification of a single nucleotide polymorphism in the 5'-flanking region of *PRDM16* gene as a novel susceptibility marker for low lean body mass. Tomohiko Urano*[1], Masataka Shiraki[2], Yasuyoshi Ouchi[3], Satoshi Inoue[3]. [1]UMIN, Japan, [2]Research Institute & Practice for Involutional Diseases, Japan, [3]The University of Tokyo, Japan

Loss of skeletal muscle mass and function is a common disorder in the elderly. Sarcopenia is a common skeletal muscle disease characterized by low lean body mass of muscle tissue, leading to decreased skeletal strength and increased susceptibility to fracture. Low lean body mass has a strong genetic component, with heritability ranging over 50%. However, specific genes underlying the variation in low lean body mass are largely unknown. Rapid technological advances have made it feasible to pursue genome-wide association studies (GWAS). A number of GWAS have found novel single-nucleotide polymorphisms (SNPs) associated with complex diseases or traits, including bone mineral density, fat content, and body mass index. By performing a GWAS for SNPs associated with lean body mass by using SNP arrays, we have focused on a SNP located in the 5'-flanking region of the PRDM16 (PRD1-BF-1-RIZ1 homologous domain containing protein 16) gene. We demonstrated that PRDM16 gene polymorphism was significantly associated with lean body mass in 1,081 postmenopausal Japanese women. The SNP was located in the 5'-flanking region of the PRDM16 gene. A luciferase assay using the C2C12 myoblast-like cells revealed that the genomic region has differential transcriptional activity depend on the SNP genotype. Thus, human genetic analyses demonstrated the importance of the PRDM16 gene in the regulation of lean body mass in human.

Osteocalcin and Musculoskeletal Health in Older Women. Itamar Levinger*[1], David Scott[2], Geoffrey Nicholson[3], Gustavo Duque[4], Thomas McCorquodale[5], Amanda Stuart[6], Peter Ebeling[2], Markus Herrmann[7], Kerrie Sanders[8]. [1]Victoria University, Australia, [2]The University of Melbourne, Australia, [3]The University of Queensland, Australia, [4]Ageing Bone Research Program, University of Sydney, Australia, [5] Nepean Clinical School, University of Sydney, Australia, [6]Department of Clinical & Biomedical Sciences, The University of Melbourne, Barwon Health, Australia, [7]Royal Prince Alfred Hospital, The University of Sydney, Australia, [8]NorthWest Academic Centre, The University of MelbourneWestern Health, Australia

Exercise increases total osteocalcin (TOC) and undercarboxylated OC (ucOC) and improves glucose control[1]. We investigated associations between TOC, ucOC and ucOC/TOC ratio (ucOC%) and indices of both muscle and bone health. We hypothesized that in N=90 women aged 70+ years (1) ucOC and ucOC% is associated with increased muscle strength of the lower-limbs and (2) TOC, but not ucOC, is associated with other bone turnover markers and the heel ultrasound measures speed of sound (SOS), broadband ultrasound attenuation (BUA) and stiffness index (SI).

A chemiluminescence immunoassay (DiaSorin) was used to quantify TOC, with hydroxyapatite pre-treatment for ucOC. Lower-limb muscle strength was measured using the Manual Muscle Testing System (SI Instruments, Australia). Peak isometric force at the hip flexors, hip abductors and quadriceps were assessed. Regression statistics were used for analysis.

ucOC% was associated with all three strength tests (age-adjusted; $p<0.05$). The association for both quadriceps and hip abduction strength remained significant following further adjustment for BMI and 25(OH)D or PTH. Neither TOC, nor P1NP or CTx were associated with any of the strength tests (p=0.15 to 0.72). The muscle inflammatory marker, alpha-1-antichymotrypsin (α-ACT), was inversely associated with ucOC% (p=0.03) only. PTH was associated with both TOC and ucOC (p=0.001 and 0.017 respectively). TOC was positively associated with both P1NP and CTx ($p<0.001$), while ucOC% tended to be negatively associated with both P1NP and CTx (both p = 0.06). For each per unit increase in TOC (μg/L) there was a corresponding lower BUA, SOS and SI (β-co-efficient -0.28; -0.23 and -0.23; all $p<0.04$). BUA remained associated with TOC after adjustment for age and BMI, however, all three indices were not significant after adjustment for 25(OH)D or PTH (p= 0.15 to 0.9).

An association between ucOC% (but not TOC) and muscle strength is novel and supports a distinct metabolic musculoskeletal role for ucOC in humans. This and the negative correlation between ucOC% and a-ACT is consistent with improved glucose control mediated through a musculoskeletal interaction. The results confirm that TOC is associated with bone health and provide a potential link whereby TOC, ucOC% and ucOC are all related to falls and fracture risk.

Alterations of Bone Quantity and Quality of the Periarticular and Non-Periarticular Bone in Patients with Rheumatoid Arthritis. Roland Kocijan*[1], Stephanie Finzel[2], Matthias Englbrecht[2], Axel Hueber[2], Jürgen Rech[2], Georg Schett[2]. [1]St. Vincent Hospital Vienna, Austria, [2]Friedrich-Alexander University Medical School, Germany

Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory joint disease characterized by local and systemic bone loss. Thus, RA is an independent risk factor for osteoporosis and fracture. The purpose of this study was to investigate bone quantity and bone quality of the appendicular skeleton in RA patients.

Methods: 90 RA patients (60 women, mean age 52.6 ± 13.9 years and 30 men, mean age 55.8 ± 10.1 years) were included into the study and compared to healthy, age matched female (n=40, mean age 50.0 ± 10.9 years) and male (n=30, mean age 55.5 ± 14.2 years) controls, respectively. HR-pQCT measurements (Xtreme-CT, Scanco) were carried out at the distal radius (DR; non-periarticular) and the ultra-distal radius (UDR; periarticular). 110 slices (voxel size 82 μm) were measured in the DR and the UDR to determine volumetric bone mineral density (vBMD) and trabecular and cortical bone microstructure.

Results: Female and male patients with RA did not differ in age and body mass index from female and male controls, respectively. Less than 10% of RA patients used glucocorticoids with doses over 7.5 mg prednisolone equivalent and none of them was treated with doses of more than 10 mg prednisolone equivalent. Total ($p<0.05$), trabecular ($p<0.001$) and cortical ($p<0.001$) vBMD were significantly lower at DR and UDR sites in female and male RA compared to female and male controls, respectively. At the DR, significantly reduced bone volume fraction (BV/TV, p=0.001), trabecular number (Tb.N, $p<0.05$), trabecular thickness (Tb.Th, $p<0.05$) and cortical thickness ($p<0.05$) were found in both sexes of RA patients as compared to controls. Furthermore, trabecular separation (Tb.Sp, p=0.001) and inhomogeneity ($p<0.005$) were significantly increased in female RA patients compared to controls. No differences were found regarding cortical porosity. At the UDR, BV/TV ($p<0.001$) and Tb.N ($p<0.001$) were significantly decreased in female RA, whereas BV/TV (p=0.001) and Tb.Th ($p<0.005$) were decreased in male RA compared to the respective sex-matched controls.

Conclusions: Both, trabecular and cortical bone is severely affected in RA. Trabecular bone loss is mainly caused by a decrease in trabecular number in female RA, and trabecular thinning in male RA patients. Thus, our data suggest that bone quantity and quality are significantly decreased in the appendicular skeleton of RA patients at both, periarticular and non-periarticular sites.

Control of cartilage maintenance and degeneration by Twist1 and Runx1 transcription factors. Rosa Guzzo*[1], Jason Gibson[1], Douglas Spicer[2], Gregory Polkowski[1], Hicham Drissi[1]. [1]University of Connecticut Health Center, USA, [2]University of New England, USA

There remains a critical gap in our understanding of the molecular signals that control articular cartilage maintenance and degeneration. We previously established the chondrogenic effects of the transcription factor Runx1 in vitro and in vivo. Conversely, we and others demonstrated the anti-chondrogenic and anti-hypertrophic effects of the bHLH factor Twist1. The dichotomy between the functions of these two factors during chondrocyte differentiation led us to examine their expression and function in articular chondrocytes. Within the native murine knee joint, we detected abundant Twist1 and Runx1 protein expression in chondrocytes at the articular surface. This pattern of expression was also observed in human articular cartilage where Twist1 and Runx1 proteins were co-expressed in articular chondrocytes at the superficial zone, with little to no expression in deep zone chondrocytes. In vitro studies using human articular chondrocytes isolated from normal cartilage demonstrated that the expressions of Twist1 and Runx1 declined as chondrocytes undergo hypertrophy, suggestive of a mutual function for these factors within immature cartilage. In human osteoarthritic cartilage, the expressions of Twist1 and Runx1 proteins are activated in cartilage cell clusters near fissures or clefts in the upper articular cartilage layer. To gain insight into the functional roles of these factors in modulating the progression of osteoarthritis (OA), we generated chondrocyte-specific Twist1 gain of function (Col2a1-Cre) and Runx1 loss of function mouse models. Using these two models, we performed surgical destabilization of the medial meniscus (DMM) to induce the development of OA. Micro-CT analyses of wild type joints showed the presence of osteophytes at 12 weeks post-surgery, while little to no evidence of osteophyte formation was observed in the surgical joints of Twist1 transgenic mice at 12 weeks post-surgery. Whereas extensive cartilage erosion was detected in the surgical knee joints of wild type mice, the cartilage surface remained well preserved in Twist1 transgenic mice at 12 weeks post-surgery. We observed advanced cartilage erosion within the surgical knee joints of Runx1 haploinsufficient mice at 8 weeks post-surgery. In vitro experiments indicated a lack of transcriptional cross-regulation between Twist1 and Runx1. We speculate that Twist1 and Runx1 synergistically confer protection against cartilage erosion through independent mechanisms.

Degenerative Changes in Knee Joints and Joint Pain in Surgically and Chemically Induced Rat Models of Osteoarthritis. Jukka Morko*, ZhiQi Peng, Jukka Vääräniemi, Katja Fagerlund, Jukka Rissanen, Jenni Bernoulli, Jussi Halleen. Pharmatest Services Ltd, Finland

Several experimental animal models have been developed for osteoarthritis (OA) and used to study the preclinical efficacy of disease and symptom modifying OA drugs. The preclinical efficacy has been determined by various microscopic scoring systems. Recently, the OARSI histopathology initiative presented recommendations for histological OA assessment in order to standardize preclinical efficacy studies. In this study, we performed a systemic characterization of knee joints in rat OA models using OARSI rat scoring system and pain assessments. The study was conducted using male Lewis rats. Unilateral OA was induced in their knee joints at 3 months of age using the following four rat models: 1) intra-articular monoiodoacetate (MIA) at the dose of 1 mg/kg, 2) medial meniscal tear (MMT) + medial collateral ligament transection (MCLT), 3) anterior cruciate ligament transection (ACLT) + partial medial meniscectomy (pMMx), 4) ACLT. Body weight, static weight bearing and static mechanical allodynia were followed during the study. Knee joints were harvested and digital radiographs of the joints were obtained at two time points in each model. Histological OA assessment was performed in medial tibial plateau following the OARSI recommendations. Static weight bearing decreased in operated knee joints during the first week and paw withdrawal threshold decreased in operated and MIA-injected knee joints during the first week and at end of the study. These results indicated operation-related joint discomfort and OA-related joint pain. Histological OA assessment demonstrated degenerative changes in medial tibial plateau in all models. Mild to moderate changes were observed in MIA and ACLT models and moderate to severe changes in MMT+MCLT and ACLT+pMMx models. Degenerative changes included the loss of chondrocytes, proteoglycans and collagen matrix in superficial layer of articular cartilage. These changes exacerbated down to intermediate layer at 4 weeks in MIA model and down to tidemark at 10 weeks in ACLT model, at 4 weeks in ACLT+pMMx model, and at 3 weeks in MMT+MCLT model. These changes in articular cartilage were associated with moderate to large osteophytes and minimal synovial inflammation in ACLT model and with large osteophytes and mild synovial inflammation in MMT+MCLT and ACLT+pMMx models. Results obtained in this study can be used to evaluate and select rat OA models for testing the preclinical efficacy of disease and symptom modifying OA drugs.

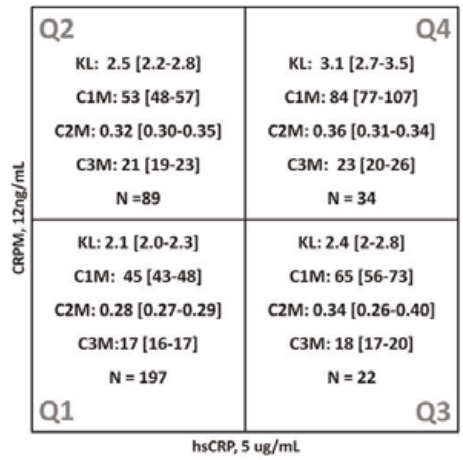
Identification of osteoarthritis patients with chronic tissue inflammation whom may benefit from anti-inflammatory treatment. Anne Sofie Siebuhr*[1], Kristian Kjær Petersen[2], Lars Arendt-Nielsen[2], Line Egsgaard[3], Thomas Eskehave[3], Claus Christiansen[4], Ole Simonsen[5], Hans Christian Hoegh[3], Morten Karsdal[4], Anne-Christine Bay-Jensen[6]. [1]Nordic Bioscience, Herlev, Denmark, Denmark, [2]Center for Sensory-Motor Interaction (SMI), Department of Health Science & Technology, Faculty of Medicine, Aalborg University, Denmark, [3]Center for Clinical & Basic Research, Denmark, [4]Nordic Bioscience A/S, Denmark, [5]Aalborg University Hospital, Orthopaedic Surgery Research Unit, Denmark, [6]Nordic Bioscience, Denmark

Purpose: It is evident that a subset of osteoarthritis (OA) patients has chronic tissue inflammation. These patients may benefit from anti-inflammatory treatment prescribed in inflammatory arthritis. C-reactive protein (CRP) has shown limited use in predicting disease severity, progression or response to anti-inflammatory treatment. The aim was to segregate patients in groups based on the present or absence of systemic and/or chronic tissue inflammation and describe them by serological markers.

Methods: A cross-sectional study of 342 OA patients: 281 patients had symptomatic knee OA and 61 underwent total knee replacement (TKR). Serum biomarkers were measured by ELISA: high sensitive CRP (hsCRP), CRP degradation fragment (CRPM, chronic tissue inflammation), matrix metalloproteinase-mediated degradation fragments of type I, II and III collagen; C1M (connective tissue), C2M (cartilage) and C3M (synovium). Associations between biomarkers and KL were investigated: KL0, Mild, n=12; KL1-2, Moderate, n=202; KL3-4, Severe, n=57; and TKR, KL3-4, n=61. Patients were divided in quartiles (Q) based on cut-off values of CRP and CRPM (mean+2SD of controls). Biomarker reference values were recorded for healthy controls. Data are shown as mean [95%-CI].

Results: hsCRP was elevated in TKRs compared to controls. In contrast, the mean levels of the CRPM were twice as high in all OA groups (10-14ng/mL) compared to controls (5ng/mL). C1M and C2M were elevated in TRKs compared to Moderate and Severe ($P<0.001$), but no difference in C3M. Patients in Q4 (fig) had higher KL compared to patients in Q1 ($P<0.0001$), Q2 ($P=0.017$) and Q3 ($P<0.0001$). C1M, C2M and C3M were lower in Q1 compared to the other quartiles. Comparing Q2 with Q3 showed that C1M was higher ($P=0.0005$) in Q3, but C3M was lower ($P=0.019$). Thus, patients identified by the chronic tissue turnover marker were significantly different compared to that of traditional acute inflammation markers.

Conclusion: OA patients had surprisingly high levels of chronic tissue inflammation. OA patients could be divided in quartiles or 2 groups: i) those who may benefit from anti-inflammatory treatment (Q3, Q4) and ii) those eligible for a tissue centric treatment (Q1, Q2). Patients with high chronic tissue inflammation (Q2 and Q4) had higher levels of tissue degradation (C1M and C2M) suggesting elevated tissue turnover. TKR patients had even higher levels of the tissue turnover markers, suggesting a distinct TKR serological phenotype.



Identification of the patients with systemic and/or chronic tissue inflammation by CRP and CRPM

MO0016

Inhibition of TGF-β Signaling in Articular Chondrocytes Leads to Activation of MMP13 and Adamts5, OA-like Pathological Defects and Pain-Related Behavior Change in Mice. Jia Li*[1], Jie Shen[2], Jeffrey Kroin[1], Guozhi Xiao[3], Hee-Jeong Im[1], Di Chen[3]. [1]Rush University, USA, [2]University of Rochester, USA, [3]Rush University Medical Center, USA

TGF-β signaling plays an important role in chondrocyte differentiation and development of osteoarthritis (OA). However the downstream target genes of TGF-β signaling during OA development remain undefined. In this study, we investigated TGF-β target genes in OA development using mouse genetic approach. *Tgfbr2* conditional knockout ($Tgfbr2^{Col2ER}$) mice were generated by breeding *Tgfbr2-flox* mice with *Col2-CreER* transgenic mice. Deletion of the *Tgfbr2* gene was achieved by administration of tamoxifen into 2-week-old $Tgfbr2^{Col2ER}$ mice. Changes in histology, gene expression and pain-related behavior were analyzed. Deletion of the *Tgfbr2* gene in articular chondrocytes resulted in up-regulation of *Runx2*, *Mmp13*, *Adamts5* and *ColX* expression. Histological analysis showed articular cartilage degradation, increased hypertrophic chondrocyte numbers, early osteophyte formation, and increased subchondral bone mass in 3-month-old $Tgfbr2^{Col2ER}$ mice. Loss of entire articular cartilage, formation of extensive osteophytes, and substantially increased subchondral bone mass were observed in 6-month-old $Tgfbr2^{Col2ER}$ mice. Histomorphometric analysis of changes in articular cartilage volume or evaluation with histological scoring system recommended by Osteoarthritis Research Society International (OARSI) showed a significant decrease in articular cartilage area in $Tgfbr2^{Col2ER}$ mice. Significant reduction in spontaneous rearing activity and ambulation counts were also observed in 4-, 5-, 6-, 7-, and 8-month-old $Tgfbr2^{Col2ER}$ mice. To determine if up-regulation of *Mmp13* and *Adamts5* expression is responsible for $Tgfbr2^{Col2ER}$-induced OA development, we generated *Tgfbr2*/*Mmp13* and *Tgfbr2*/*Adamts5* double KO mice. Deletion of the *Mmp13* gene significantly alleviates OA-like pathological changes observed in 3- and 6-month-old $Tgfbr2^{Col2ER}$ mice. In contrast, deletion of the *Adamts5* gene only reversed OA-like phenotype in 3-month-old $Tgfbr2^{Col2ER}$ mice. These changes were further confirmed by histomorphometric analysis and by evaluation with OARSI scoring system. Treatment of $Tgfbr2^{Col2ER}$ mice with MMP13 inhibitor (CL82198, 10 mg/kg) for 2 months decelerated OA progression in 3-month-old $Tgfbr2^{Col2ER}$ mice. In this study, we demonstrate that inhibition of TGF-β signaling in articular chondrocytes leads to a progressive OA-like phenotype in mice. *Mmp13* and *Adamts5 are* critical downstream target genes of TGF-β signaling during OA development.

Inhibition of TGFβ signaling in Mesenchymal Stem Cells Prevents Onset of Osteoarthritis. Gehua Zhen*[1], Xu Cao[2]. [1]The Johns Hopkins Hospital, USA, [2]Johns Hopkins University, USA

Osteoarthritis (OA) is a highly prevalent and debilitating joint disorder. Currently there is no effective disease modifying treatment due to limited understanding of its pathogenesis. Clinically, changes in the subchondral bone precede cartilage degeneration. Therefore, we investigated the cell signaling mechanism that results in subchondral bone changes, studying the subchondral bone-articular cartilage as a functional unit. We detected high levels of active TGFβ1 in the subchondral bone of human OA knee joints. Using an anterior cruciate ligament transaction (ACLT) mouse model, we were able to replicate the findings of elevated levels of active TGFβ in subchondral bone. High levels of TGFβ in the subchondral bone marrow led to increased numbers of mesenchymal stem cells (MSCs) and osterix^{+} osteoprogenitors post ACLT. Over time, bone formation became uncoupled, angiogenesis increased, and articular cartilage was damaged. To confirm the pathological role of high levels of active TGFβ in the subchondral bone, we analyzed an osteoblast tissue-specific TGFβ1 transgenic mice. Overexpression of active TGFβ1 in the transgenic mice resulted in a similar phenotype with increased osteoblast progenitors and angiogenesis in the subchondral bone preceding the development of OA. We then examined whether inhibition of TGFβ activity in the subchondral bone could prevent OA development. Systemic injection of TGFβ type I receptor (TβRI) inhibitor improved subchondral bone structure and decreased angiogenesis, but only partially attenuated articular cartilage degeneration as TGFβ signaling directly in articular cartilage has protective effects. Direct administration of TGFβ antibody in the subchondral bone resulted in an even better outcome in preventing articular cartilage degeneration. Moreover, deletion of TGFβ type II receptor (TβRII) specifically in nestin^{+} MSCs using an inducible nestin-CreER mouse model prevented osteoarthritic changes seen post ACLT, demonstrating that MSCs are the target cell population for high levels of TGFβ and contribute to the pathological changes at the onset OA in subchondral bone. Therefore, inhibition of TGFβ in subchondral bone prevented OA progression and could be an effective therapy of OA.

K/BxN Mouse Serum–Induced Arthritis Is Aggravated in Mice with Tamoxifen-Induced Chondrocytic Glucocorticoid Receptor Knockout. Jinwen Tu[1], Yaqing Zhang[1], Shihani Stoner[1], Edgar Wiebe[1], Tazio Maleitzke[1], Ulrike Baschant[2], Di Chen[3], Jan Tuckermann[4], Markus Seibel[1], Hong Zhou*[1]. [1]Bone Research Program, ANZAC Research Institute, University of Sydney, Australia, [2]Institute of General Zoology & Endocrinology, University of Ulm, Germany, [3]Rush University Medical Center, USA, [4]University of Ulm, Germany

Background: Exogenous glucocorticoids (GCs) are widely used in the treatment of rheumatoid arthritis (RA), however, the function of endogenous GCs in RA remains unclear. This study aimed to investigate the impact of cartilage-specific glucocorticoid receptor knockout (GRKO) on joint inflammation, cartilage damage, and bone metabolism in the K/BxN mouse serum transfer model of autoimmune arthritis.

Methods: GRKO mice were generated by breeding GRflox mice with tamoxifen inducible Cre (Col2a1-CreER^{T2}) mice. K/BxN arthritis was induced in 8-week-old male Col2a1-CreER^{T2}, GR$^{fx/fx}$ (KO) mice and their Cre-negative GR$^{fx/fx}$ littermates (WT) by injection of K/BxN serum ("KO-K/BxN" and "WT-K/BxN"). KO and WT mice receiving PBS served as controls (CTR). Paw swelling was assessed daily from induction (day 0) to day 14. Micro-CT and histomorphometry of the tibiae were employed to assess for bone morphological changes. Semiquantitative histological scores were used to determine the degree of joint inflammation, cartilage degradation, and bone erosion.

Results: Both KO-K/BxN and WT-K/BxN mice developed acute arthritis. However, the peak inflammatory response was significantly more pronounced in KO-K/BxN mice (Fig. A). In keeping with this phenoptype, histological analysis revealed significantly increased inflammatory activity and greater bone erosions in KO-K/BxN than WT-K/BxN mice (Fig. B). Micro-CT and histomorphometry showed reduced tibial bone volume (BV/TV) in both groups of arthritic mice compared to CTR, with increased osteoclast activity observed in KO-K/BxN compared to WT-K/BxN mice. In addition, spleen weight was significantly increased in KO-K/BxN mice compared to CTR, while no difference was observed between WT-K/BxN and CTR mice.

Conclusion: Disruption of endogenous glucocorticoid signaling in cartilage aggravates K/BxN serum-induced arthritis. Our data suggests that chondrocytes modulate local inflammation via a GR-dependent pathway.

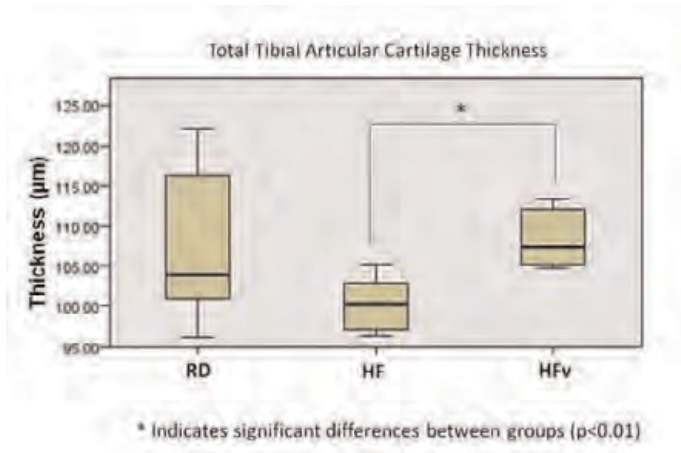
MO0019

The development of articular cartilage thickness, impeded by obesity, is protected by low magnitude mechanical signals. Tee Pamon*[1], M. Ete Chan[1], Denis Nguyen[1], Clinton Rubin[2]. [1]Stony Brook University, USA, [2]State University of New York at Stony Brook, USA

Obesity is a contributing factor to osteoarthritis, a pathology characterized by thinning of uncalcified cartilage (UC) and expansion of the calcified cartilage (CC) zone. This degeneration in the obese is typically attributed to ablation of articular cartilage (AC) by excessive load bearing. Considering the disruption of osteoblastogenesis by obesity, it is possible that chondroblastogenesis is simultaneously interrupted, thus contributing to an inferior bearing surface. Further, in light of recent evidence that low intensity vibration (LIV) has been shown to protect mesenchymal stem cell lineage selection towards the formation of higher order connective tissues, we sought to determine if these mechanical signals could protect the formation of AC in spite of the obese phenotype. C57BL/6 male, 5w mice were separated into 3 groups: Regular diet (RD), High fat diet (HF), and High fat diet + LIV (HFv). Phase I of the protocol consisted of 2w of high fat diet for HF and HFv , and through the 6w of Phase II, HFv were also subject to LIV (90Hz, 0.2g, 30 min/d, 5 d/w). At sacrifice, HF and HFv were 12% and 13% heavier, respectively, than RD mice ($P<0.01$). The left knee joints were sectioned in the sagittal plane and stained with Safranin-O/fast green. Average thickness of the UC and CC regions were measured with IMAGE J across 0.2 mm of the central region of the tibial lateral condyle. Following 8w of a high fat diet, UC thickness in HF mice was 20% lower than RD, while CC thickness was 24% higher in HF compared to RD mice. LIV protected the AC of HFv mice, as evidenced by an 8.4% higher total AC thickness compared to HF mice ($p<0.01$), preserving thickness exhibited in RD mice (nsd). Looking at the individual regions, the HFv displayed a 22.6% higher uncalcified cartilage thickness and a 12.1% reduction in calcified cartilage zone thickness compared to HF. These results suggest that the osteoarthritis that parallels obesity may, to a degree, be a result of a disrupted cartilage formation driven by interrupted chondroblastogenesis rather than excessive loading on the joint surface. Considering that there were no differences in body weight between HF and HFv mice, the protection of the articular surfaces appears to be achieved by the mechanical enhancement of the cartilage development, rather than the mechanical ablation of the tissue.



Total Tibial Articular Cartilage Thickness

TRAF3: A potential biomarker of anti-TNF treatment response in rheumatoid and psoriatic arthritis. Yan Xiu*[1], Christopher Ritchlin[2], Lianping Xing[2], Brendan Boyce[1]. [1]University of Rochester Medical Center, USA, [2]University of Rochester, USA

Rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are characterized by inflammation-induced joint damage mediated in large part by TNF, which also stimulates synovial expression of RANKL, a central mediator of joint destruction. TNF receptor-associated 3 (TRAF3) limits RANKL-induced osteoclast (OC) formation by proteasomally degrading NF-kB-inducing kinase. Thus, TRAF3 could limit resorption in inflammatory bone diseases if its level is increased in OC precursors (OCPs). Anti-TNF treatments (ATTs) have greatly reduced joint inflammation in RA and PsA, but up to 40% of patients are inadequate responders, and we lack biomarkers to predict potential responders from non- responders. We hypothesize that cellular levels of TRAF3 may reflect the responsiveness of peripheral blood monocytes (PBMCs) to extracellular TNF and that RA and PsA patients with high TRAF3 expression in PBMCs will preferentially respond to ATTs. To examine this hypothesis, we compared TRAF2, 3 and 6 protein levels in CD-11b$^+$ OCPs from TNF-Tg and WT mice by Western blotting and found that TRAF3 levels were 5-fold higher than other TRAFs in these cells. In contrast, OCP TRAF3 levels in mice with auto-antibody-induced arthritis were increased far less than in TNF-Tg cells, suggesting that increased TRAF3 elevation is associated with TNF stimulation. Further, FACS analysis revealed higher TRAF3 mean fluorescence intensity (MFI) levels in PBMCs of TNF-Tg mice than in WT littermates. These data support the concept that high TRAF3 levels in PBMCs from RA and possibly PsA patients may serve as a marker of responsiveness to ATTs. To examine this possibility, we stained PBMCs from 5 healthy controls, 10 RA and 10 PsA patients not on ATT with a mixture of labeled cell-specific markers and anti-TRAF3 antibodies and subjected them to FACS to determine their TRAF3 levels. We found that mean/SD TRAF3 MFI levels in CD14$^+$/CD16$^-$ PBMCs were 345/110 (range 224-466) from 5 normal subjects, 520/191 (range 239-740) in 10 RA patients, and 4309/2527 (range 235-7603) in 10 PsA patients. TRAF3 levels were elevated in the PBMCs of ~60% of these patients and low in the remaining 40%, corresponding to the % of RA and PsA patients who respond to ATTs in clinical trials. The relationship between PBMC TRAF3 levels in these patients and their subsequent responses to ATTs are under investigation to determine if TRAF3 is a potential biomarker to predict which RA and PsA patients will respond to ATTs.

Lifestyle therapy preserves bone quality, reduces visceral fat inflammation and bone marrow adipogenic signals in obese old mice. Xavier DeLeon*[1], Lina Aguirre[2], Alexander Proctor[3], Dennis Villareal[4], Reina Armamento-Villareal[4]. [1]Biomedical Research Institute of New Mexico, USA, [2]BRINM, USA, [3]Active Life Scientific, USA, [4]University of New Mexico School of Medicine, USA

Purpose: Weight loss-induced bone loss may exacerbate age-related bone loss and worsen existing osteopenia in the elderly which can be attenuated by exercise. Recent reports of increased fractures in obese patients suggest poor bone quality in these patients. Thus, weight loss in obese elderly may lead to further deterioration in bone quality. In this study, we evaluated the independent and additive effects of weight loss and exercise on bone quality in obese old mice. Secondarily, we evaluated the independent and additive effects of weight loss and exercise on inflammation which may have an important role in bone loss with aging and obesity, in the visceral fat and bone marrow.

Methods: Thirty-two 15-mo old male C57BL6 mice were fed high-fat diet for 12 wks to 18 mo (n=8/grp). Afterwards, mice were assigned to high fat diet (HFD), Diet, Exercise (EX) and Diet+Exercise (Diet-EX). Controls were lean age-matched mice. Diet was by caloric restriction to induce weight loss of 15 to 25% of baseline bw and exercise was treadmill running for 15 min, speed 10cm/sec 3x/wk x 12 wks.

Results: Diet and Diet-EX lost 18% to 24% of bw. Exercise tolerance improved in both EX and Diet-EX (232 $\pm$ 70 and 271 $\pm$ 60 sec) relative to HFD and Diet (-27 $\pm$ 88 and -44 $\pm$ 67 sec), ($p<0.05$). Volumetric BMD by pQCT showed bone loss at the tibial midshaft in HFD and Diet (Fig. 1). BMD on explanted bone showed higher total tibial midshaft BMD in EX (677 $\pm$ 50 mg/cm3) relative to HFD and Diet (545 $\pm$ 40 and 519 $\pm$ 34 mg/cm3) ($p<0.05$), while Diet-EX was lower (565 $\pm$ 30 mg/cm3) but not different from EX. Sclerostin was lowest in EX (327 $\pm$ 11pg/ml), highest in Diet (547 $\pm$ 114pg/ml), and intermediate Diet and EX (422 $\pm$ 181pg/ml) for Diet-EX, p=0.06. Bone biomechanics by Reference Point Indentation showed indentation distance increase and total indentation distance were lower in Diet, EX and Diet-EX compared to HFD (see Fig.2) Visceral fat TNF-α/100gm tissue release was lower in EX relative to Diet and Diet-EX (Fig 3). Bone marrow PPARγ gene expression normalized to GAPDH was suppressed in Diet (0.07 $\pm$ 0.04) compared to EX (1.9 $\pm$ 1.4) and Diet-EX (0.68 $\pm$ 0.4) ($p<0.05$). IL-6 and TNF-α expressions were similar among the groups.

Conclusion: Bone quality is preserved with or without exercise in Diet and Diet-EX, despite bone loss. Exercise is effective in reducing inflammation in the visceral fat. In the bone marrow, lifestyle therapy has no effect on inflammation, but Diet is effective in reducing adipogenic signals.

Healthy Black and White Children Show No Difference in the Relationship between Change in Serum PTH and Change in Serum 25-Hydroxyvitamin D with Oral Vitamin D_3. Kathleen Hill Gallant*[1], George McCabe[2], Linda McCabe[2], Berdine Martin[2], Emma Laing[3], Dorothy Hausman[3], Connie Weaver[4], Richard Lewis[3], Munro Peacock[5]. [1]Indiana University School of Medicine, USA, [2]Purdue University, USA, [3]The University of Georgia, USA, [4]Purdue University, Dept of Nutrition Science, USA, [5]Indiana University Medical Center, USA

Background: The inverse curvilinear relationship between serum PTH and 25 OH vitamin D (25D) found in adult populations is frequently used as an indicator of vitamin D insufficiency with values of serum 25D above maximal suppression of PTH used to determine vitamin D sufficiency. In healthy children, it is unclear if this relationship occurs or whether it differs between whites and blacks who have higher serum PTH and lower 25D than whites. Aim: To examine the relationship between serum PTH and 25D in a sample of white and black healthy children. Methods: Black and white boys and girls (n=318) who participated in randomized placebo-controlled trial of oral vitamin D3 supplementation during winter had fasting serum 25D and PTH measured at baseline and 12 weeks. Results: Blacks (n=162) had higher serum PTH and lower 25D compared with whites (n=156) (PTH mean 29.7 (9.9-70.5) pg/mL [blacks] and 24.9 (10.8-62.0)pg/mL [whites] $p < 0.0001$; 25D mean 24.1 (10.2-42.5) ng/mL [blacks] and 32.0 (17.9-46.0) ng/mL [whites] $p < 0.0001$). Serum PTH was negatively related to serum 25D ($r=-0.37$, $p <0.0001$) and there was no difference in this relationship between blacks and whites. After 12 weeks, serum 25D was higher than baseline in both blacks and whites (mean 33.6 (9.7-92.4) [blacks] and 42.5 (12.7-95.1) ng/mL [whites] $p < 0.0001$). Increasing serum 25D caused minimal change in serum PTH (doubling serum 25D results in a 10% decrease from baseline in serum PTH) and this was not different between races (figure). Conclusion: These results indicate 1) that increasing serum 25D in winter through vitamin D3 supplementation minimally reduces serum PTH in healthy adolescents, and 2) the response does not differ between blacks and whites.

Inclusion of Anthropometric Parameters in the Creation of Reference Curves for Pediatric Bone Mineral Density and Bone Mineral Content: Impact on Classification of Below-Normal Individuals. Thomas Hangartner*[1], David Short[1], Vicente Gilsanz[2], Heidi Kalkwarf[3], Joan Lappe[4], Sharon Oberfield[5], John Shepherd[6], Babette Zemel[7], Karen Winer[8]. [1]Wright State University, USA, [2]Children's Hospital Los Angeles, USA, [3]Cincinnati Children's Hospital Medical Center, USA, [4]Creighton University Osteoporosis Research Center, USA, [5]Columbia University Medical Center, USA, [6]University of California, San Francisco, USA, [7]Children's Hospital of Philadelphia, USA, [8]National Institutes of Health, USA

The goal of this study was to assess the implication of including relevant anthropometric variables in the creation of reference curves for areal bone mineral density (aBMD) and bone mineral content (BMC) in pediatrics.

Analysis of the dual-energy x-ray absorptiometry (DXA) data collected as part of the Bone Mineral Density in Childhood Study[1], including 2012 boys and girls, 5-22 y old, with a total of 10,525 visits, resulting in aBMD and BMC observations at the lumbar spine, hip (neck and total), forearm and whole body (total body and total body less head). Multivariate statistics were used to rank order the influence of the independent variables age, gender, race (black/non–black), height, weight, percent body fat (%fat) and sexual maturity. Two different models were created for each aBMD and BMC parameter, the practical model containing age, gender, race, height and weight as well as the full model, adding %fat. We compared the number of subjects that fell below 2 standard deviations in our models with those below the same limit of the currently standard LMS model[2], which is based on age, sex and race, and of the height adjusted Z-scores[3].

Between 50% and 82% of subjects identified as below normal (<-2 SD) based on the LMS model were not classified as being below normal in our practical model. Using the full model, misclassification increased for all aBMD and BMC parameters, ranging from 49% to 92%. Height-adjusted Z-scores reduced the misclassifications to 33-60% in comparison to the practical model and to 41-73% in comparison to the full model. For both the practical and the full model, misclassifications in comparison to the LMS model were worse for BMC than for BMD at all sites with the exception of the femoral neck. Considering that BMC is more heavily influenced by bone size than BMD, inclusion of body height and weight in the model reclassifies small, underweight subjects away from the lower tail of the distribution, which is not done by the LMS model, as this model takes care of body size only through the surrogate of age.

The traditional comparison of pediatric BMD and BMC data against age-, sex- and race-matched controls can be refined if anthropometric parameters are taken into account.

A Pediatric Bone Mass Scan has Poor Ability to Predict Adult Bone Mass - A 28-Year Prospective Study. Bjorn Rosengren*, Christian Buttazzoni, Magnus Karlsson. Skåne University Hospital Malmö, Lund University, Sweden

Purpose: The correlation between bone mass in childhood and adulthood is not fully understood. This includes the correlation between relative accrual of bone mineral and relative gain in bone size since both these traits independently contribute to bone mineral density (BMD).We conducted a long-term prospective observational study as to determine if a pediatric bone mass scan is useful to predict adult bone mass and evaluate in there are similar relative gain in bone mineral and bone size during growth.

Methods: We measured cortical bone mineral content (BMC; g), bone mineral density (BMD; g/cm^2) and bone width (cm) longitudinally in the distal forearm by single photon absorptiometry in 120 boys and 94 girls with a mean age of 10 years (range 3–17) and mean 28 years (range 25–29) later. We calculated individual bone mass Z-scores, using all participants at each measurement as reference and evaluated correlations between the measurements at baseline and follow-up with Pearson's correlation coefficient. Individual Z-scores were also stratified in quartiles to register movements between quartiles from childhood to adulthood and to calculate sensitivity and specificity.

Results: BMD in childhood and adulthood correlated in both boys ($r=0.35$; $p<0.0001$) and girls ($r=0.50$, $p<0.0001$) and in both children $\geq$10 years at baseline (boys $r=0.43$ and girls $r=0.58$, both $p<0.0001$) and in children <10 years at baseline (boys $r=0.26$ and girls $r=0.40$, both $p<0.05$). 93/211 (44%) of the participants had a proportionally higher accrual of BMC than gain in bone size and 118/211 (56%) a proportionally higher gain in bone size than accrual of BMC.

A pediatric bone scan in the lowest quartile had a sensitivity of 48% (95% CI 27%, 69%) and a specificity of 76% (95% CI 66%, 84%) to predict an adults value in the lowest quartile. Among the children in the lowest quartile of BMD, 58% had left the lowest quartile in adulthood due to a higher than average accrual in bone mineral (Δ BMC Z-score 0.5; 95% CI 0.2, 0.9) and a lower gain in bone size (Δ bone width Z-score -0.3, 95% CI -0.7, 0.0).

Conclusions: Childhood BMD explained in men 12% of the variance in adult BMD and in women 25%. A pediatric distal forearm BMD scan has poor ability to predict adult bone mass since the accrual in bone mineral and the gain in bone size during growth differ between individuals.

MO0026

A Pre-Pubertal Bone Mass Scan has Poor Ability to Predict Peak Bone Mass - A 12-Year Prospective Study in 121 Children. Bjorn Rosengren*[1], Magnus Dencker[2], Jan-Åke Nilsson[2], Magnus Karlsson[1]. [1]Skåne University Hospital Malmö, Lund University, Sweden, [2]Inst of Clinical Sciences, Skane University Hospital, Lund University, Sweden

Purpose: The correlation between bone mineral density (BMD) in childhood and at peak bone mass (PBM) is unclear. Furthermore, among those who have a higher than average gain in BMD during growth, that is leave the lower regions, it is unclear if this is the result of a relative high accrual in bone mineral or a relative low gain in bone size.

We conducted a prospective study to determine if a pre-pubertal bone mass scan is useful to predict bone traits at PBM. In individuals with an initially low BMD but with a favorable gain during puberty we also evaluated if this was the result of a higher than average gain in BMC or a lower than average gain in bone size. We chose femoral neck (FN) as region of interest as data in our cohort shows that PBM is reached there in girls at age 17-18 and in boys at age 18-19.

Methods: We measured BMC (g), BMD (g/cm^2) and bone area (cm^2) longitudinally in FN by DXA in 65 boys and 56 girls, all in Tanner stage I and aged 6-8 years at baseline, and mean 12 years later when they were 18-19 years and all in Tanner stage V. We calculated individual Z-scores, using all participants at each measurement as reference and estimated correlations between the measurements at baseline and follow-up with Pearson's correlation coefficient. Individual Z-scores were also stratified in quartiles in order to visualize movements between quartiles between the pre-pubertal period and PBM.

Results: There was a correlation between pre-pubertal FN BMD and FN BMD at PBM ($r=0.57$; $p<0.001$), but also for BMC ($r=0.65$; $p<0.001$) and bone area ($r=0.37$; $p<0.001$). 47% of the participants had a proportionally higher accrual of BMC than gain in bone size and 53% a proportionally higher gain in bone size than accrual of BMC.

A pre-pubertal FN BMD value in the lowest quartile had a sensitivity of 44.8% and a specificity of 82.8% to predict a FN PBM in the lowest quartile. Among the 29 children in the lowest quartile, 44.8% had left the lowest quartile at PBM (ΔBMD Z-score 0.9 (95% CI 0.6, 1.1). Their gain in BMD was driven by a higher than average accrual in bone mineral (ΔBMC Z-score 0.4; 95% CI 0.1, 0.7) but not from a lower gain in bone size (Δ bone area Z-score -0.1, 95% CI -0.8, 0.4).

Conclusions: A pre-pubertal FN BMD explained 32% of the variance in FN PBM. A pre-pubertal FN BMD scan has poor ability to predict FN PBM since the relative accrual of bone mineral and the gain in bone size vary between subjects.

MO0027

Body Composition and Physical Activity During Childhood and Adolescence: Relations to Biomechanical Bone Strength. Joshua Farr*[1], Shreyasee Amin[1], L. Joseph Melton[1], Salman Kirmani[1], Louise McCready[1], Elizabeth Atkinson[1], Sundeep Khosla[2]. [1]Mayo Clinic, USA, [2]Mayo Clinic College of Medicine, USA

Numerous studies have examined the influences of body composition and physical activity (PA) on bone development, but none have used micro-finite element analysis (μFEA) from HRpQCT scans. Thus, in 150 healthy 8- to 15-yr old boys (n=85) and girls (n=65), we investigated the relations of appendicular skeletal muscle mass (ASM), total body fat mass (TBFM) and PA to distal radius and tibia biomechanical bone strength (failure load), using μFEA. We determined relative ASM and TBFM from whole-body DXA scans. PA strain score (related to mechanical loading) and time spent in vigorous-intensity PA was quantified from a validated questionnaire. Results were similar in analyses stratified by sex; thus, we present analyses from the boys and girls combined. Relative ASM was positively associated with bone strength of the distal radius (r=0.55, P<0.001; Fig. A) and tibia (r=0.61, P<0.001; Fig. B) after adjusting for bone-age, sex, fracture history, relative TBFM and PA. By contrast, after adjustment for the same covariates, substituting relative TBFM for relative ASM, a significant inverse association was observed between relative TBFM and bone strength of the distal radius (r=–0.30, P<0.001), while no correlation was seen at the distal tibia (r=–0.01, P=0.91). In addition, after adjustment for bone-age, sex, fracture history, height and weight, time spent in vigorous-intensity PA was positively associated with bone strength (r=0.28, P<0.01) at the distal tibia only, while PA strain score was significantly associated with greater bone strength of the distal radius (r=0.16, P<0.05) and tibia (r=0.24, P<0.01).

These data thus highlight the importance of skeletal muscle mass and PA for optimizing bone strength during growth. Furthermore, fat mass has differential influences on bone strength at weight-bearing versus non-weight-bearing skeletal sites in children and adolescents. At the distal tibia, fat mass is not associated with bone strength, whereas fat mass is negatively associated with bone strength at the distal radius after adjusting for bone-age, sex, fracture history, skeletal muscle mass and PA. These observations suggest that the strength of the distal radius does not commensurately increase with excess gains in adiposity during growth, which may result in a mismatch between bone strength and the load experienced by the distal forearm during a fall. These findings may, in part, explain why obese children are over-represented in distal forearm fracture cases.

Bone formation markers during growth hormone treatment in short prepubertal children. Diana Swolin-Eide*[1], Björn Andersson[1], Per Magnusson[2], Berit Kriström[3], Kerstin Albertsson-Wikland[4]. [1]The Queen Silvia Children's Hospital, Sweden, [2]Linkoping University,Sweden, Sweden, [3]Institute of Clinical Sciences, Department of Pediatrics, Umeå University, Sweden, [4]Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, The Queen Silvia Children's, Sweden

Purpose: Growth hormone (GH) promotes longitudinal growth and bone remodeling and it is therefore of interest to study bone formation markers during GH treatment.

Method: This study comprised 128 Swedish short prepubertal children (boys=90, girls=38) mean (±SD) age 7.31±2.0 years. The bone formation markers alkaline phosphatase (ALP), bone-specific ALP (BALP), osteocalcin and intact amino-terminal propeptide of type 1 procollagen (PINP) were measured using the IDS-iSYS automated system (Immunodiagnostic Systems). One third received standard GH dose (43 μg/kg/day). The individualized GH dose (mean 49; range 17–100 μg/kg/day) comprised one of six different doses calculated using a prediction model that considers the estimated GH sensitivity for the child corresponding to the same biological dose. The maximum peak GH secretion (GH_{max}) ⩾ 32 mU/L ('old 10 μg/l'), estimated by arginine–insulin tolerance test or by spontaneous GH secretion over a 24 h period, was used to classify the patients as having either idiopathic short-stature (ISS) (n=89) or short stature due to GH deficiency (GHD) (n=39).

Results: All bone markers increased rapidly during the first 3 months of treatment and remained approximately at the same level or decreased slightly after 2 years of treatment, however, still higher than at baseline (Table 1). No significant differences were found between the ISS and GHD subgroups or between individual and fixed dosages of GH at any time point. At start, ALP and BALP correlated with the 2-year growth response to GH treatment (r=0.26, p=0.002; r=0.17, p=0.03, respectively). After 3 months and after 1 year of GH treatment, significant correlations were found with longitudinal growth for ALP (r=0.42, p<0.0001; r=0.41, p<0.0001, respectively), BALP (r=0.37, p<0.0001; r=0.49, p<0.0001), and PINP (r=0.45, p<0.0001; r=0.50, p<0.0001). Multiple regression analysis showed that osteocalcin and BALP, together with PINP at 3 months and BALP and PINP at 1 year, predicted the 2-year growth response with high accuracy (R^2=0.40, p<0.0001). Using only osteocalcin at start and ALP and PINP at 3 months resulted in R^2=0.28, p<0.0001.

Conclusion: Only ALP showed an association with growth at start of GH treatment. However, after 3 months and after 1 year of GH treatment, significant correlations were found for ALP, BALP and PINP with longitudinal growth.

Table 1. Bone markers during 2 years of GH treatment

	Start	3 months	1 year	2 years	P
Osteocalcin	76±30	129±38	131±45	128±44	<.0001[a,b,c]
ALP	3.3±0.9	4.5±1.3	4.2±1.5	4.1±1.2	<.0001[a,b,c]
BALP	70±23	104±37	113±40	105±36	<.0001[a,b,c]
PINP	517±140	900±255	830±248	814±228	<.0001[a,b,c,e]
Vitamin D	69±19	73±22	64±21	63±18	<.001[c,d,e]

Does Bone Resorption Stimulate Periosteal Expansion? A Cross-sectional Analysis of β-C-telopeptides of Type I Collagen (CTX), Genetic Markers of Resorption, and Periosteal Circumference as Measured by pQCT. John P Kemp[1], Adrian Sayers[2], David M Evans[1], Lavinia Paternoster[1], Kevin Deere[1], Mattias Lorentzon[3], Terho Lehtimäki[4], Joel Eriksson[5], Mika Kähönen[6], Olli Raitakari[7], Marika Laaksonen[8], Harri Sievänen[9], Jorma Viikari[10], Leo-Pekka Lyytikäinen[6], William D Fraser[11], Liesbeth Vandenput[5], Claes Ohlsson[5], Jonathan H Tobias*[12]. [1]MRC Centre for Causal Analyses in Translational Epidemiology, School of Social & Community Medicine, University of Bristol, United Kingdom, [2]School of Social & Community Medicine, University of Bristol, United Kingdom, [3]Geriatric Medicine, Dept. of internal medicine & clinical nutrition & The Center for Bone & Arthritis Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Sweden, [4]Department of Clinical Chemistry, Fimlab Laboratories, University of Tampere & Tampere University Hospital, Finland, [5]Centre for Bone & Arthritis Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Sweden, [6]Department of Clinical Physiology, University of Tampere & Tampere University Hospital, Finland, [7]Research Centre of Applied & Preventive Cardiovascular Medicine, University of Turku & the Department of Clinical Physiology & Nuclear Medicine, Turku University Hospital, Finland, [8]Department of Food & Environmental Sciences, University of Helsinki, Finland, [9]The UKK Institute for Health Promotion, Finland, [10]Department of Medicine, University of Turku & Turku University Hospital, Finland, [11]Norwich Medical School, University of East Anglia, UK, United Kingdom, [12]School of Clinical Sciences, University of Bristol, United Kingdom

Aim: Bone size increases across puberty more rapidly in peripubertal males compared to females, in whom bone resorption markers are also higher. Hence in childhood, bone resorption may act to stimulate periosteal expansion and increase bone strength. To address this hypothesis, we examined whether bone resorption, as reflected by serum *β*-C-telopeptides of type I collagen (CTX), is positively associated with periosteal circumference (PC), in contrast to inverse associations with parameters related to bone remodelling such as cortical bone mineral density (BMD_C). To examine the causal nature of this relationship, we analysed whether SNPs within key osteoclast regulatory genes, known to reduce BMD, conversely increase PC.

Methods: CTX and mid-tibial pQCT scans were available in 1130 adolescents (mean age 15.5 years) from the Avon Longitudinal Study of Parents and Children (ALSPAC). Analyses were adjusted for age, gender, tanner stage, lean mass, fat mass and height. Genetic variants were identified within or proximal to *RANK, RANKL* and *OPG*, and previously reported to be associated with areal/cortical BMD in genome wide meta-analyses. To confirm their relationship with bone resorption, we examined associations with CTX (n=2379). Subsequently, we examined associations

between these SNPs and PC, based on a genome-wide meta-analysis involving ALSPAC (n=3382); Gothenburg Osteoporosis and Obesity Determinants (GOOD) (n=938) and the Young Finns Study (YFS) (n=1558).

Results: CTX was positively related to PC [β= 0.19(0.13, 0.24)] (coefficient=SD change per SD increase in CTX, 95% CI)], but inversely associated with BMD_C [–0.46(–0.52,–0.40)] and cortical thickness [β=–0.11(–0.18, –0.03)]. CTX was positively related to bone strength as reflected by SSI [β=0.09(0.03, 0.14)]. 15 *RANKL*/*RANK*/*OPG* SNPs were identified by literature search to be robustly associated with BMD. Supporting the assumption that these associations reflect altered bone resorption, six of these 15 alleles that were previously reported to be inversely related to BMD were positively related to CTX in ALSPAC (P<0.05 cut-off). In our subsequent genome-wide meta-analysis, eight of these 15 alleles were positively related to PC (five based on P<0.05 cut-off, and three P<0.1).

Conclusion: Despite having lower BMD, individuals with a genetic predisposition to higher bone resorption have greater bone size, suggesting that bone resorption represents an important positive stimulus for periosteal expansion.

Estradiol Dependent Accrual of Bone Mass in Young Growing Rats is not Amplitude–Modulated. Ingrid Kantner*[1], Hartmut Blode[2], Kerstin Gude[3], Reinhold Erben[4]. [1]Vetmeduni Vienna, Austria, [2]Bayer Healthcare Global R&D Centre, China, [3]Bayer Healthcare AG, Germany, [4]University of Veterinary Medicine, Austria

There is evidence suggesting that use of low dose monophasic oral contraceptives may impair bone mass accrual in young women. One possible explanation could be that the response of bone to estrogen may be modulated by recurrent episodes of higher estrogen levels found in the preovulatory phase of the natural cycle, i.e., bone may respond to estrogenic amplitude modulation. Constant low doses of estrogen might not be the optimal stimulus for physiological accrual of bone mass in women. It was the aim of the current study to test this hypothesis by comparison of a continuous and a cyclical estradiol dosing regimen administered to growing ovariectomized (OVX) rats over 4 months. Two-month-old female Fischer 344 rats were either OVX or sham-operated. OVX rats allocated to the continuous regimen received 0.15, 0.5, 1.5, or 2.5 µg 17β-estradiol/kg per day subcutaneously (s.c.) 7 times per week throughout the experiment. Using the same mean doses averaged over a 5-day treatment period, cyclical estradiol treatment was achieved by s.c. injection with half of the mean dose over 3 days, followed by 1 day with the 1.5-fold mean dose, and 1 day with the 2-fold mean dose, thus imitating the natural rat 4 - 5-day cycle. This cyclical 5-day administration regimen was repeated over the 4-month treatment period. Controls received vehicle (10% ethanol in saline s.c.) alone. Treatment of OVX rats with estradiol in a continuous or cyclical fashion dose-dependently protected against the development of tibial and vertebral osteopenia as measured by peripheral quantitative computed tomography (pQCT). In addition, bone formation and bone resorption was dose-dependently suppressed by continuous and cyclic estradiol as evidenced by bone histomorphometry in lumbar vertebrae and proximal tibiae, and by measurement of biochemical bone markers at the whole body level. However, regardless of the endpoint the main determinant of the skeletal response to estradiol was the mean dose administered, independent of a continuous or cyclical administration regimen. Thus, the current experiment suggests that estrogen dependent accrual of bone mass is not amplitude-modulated in young growing rats.

MO0031

In Growing Girls, Muscle Functional Indices and Activity Dose Are Robust Predictors of Upper Extremity Bone Outcomes, but Less Consistent as Predictors of 1- Year Growth Velocities. Alex Skwirz[1], Jodi Dowthwaite*[2], Carol Sames[3], Melissa Zajdel[4], Paula Rosenbaum[3], Tamara Scerpella[5]. [1]Syracuse University, USA, [2]SUNY Upstate Medical University; Syracuse University, USA, [3]SUNY Upstate Medical University, USA, [4]Princeton University, USA, [5]University of Wisconsin, USA

Purpose: It is unclear whether muscle force and impact affect bone growth independently. Muscle functional indices (MFI), activity dose and impact exposure were tested as predictors of bone outcomes in young, female gymnasts (GYM) and non-gymnasts (NON).

Methods: Repeated annual measures for 28 GYM & 23 NON yielded 1 year velocities for predictors and bone outcomes (v: T1 to T2 interval= 0.85-1.15yrs). Whole body and forearm DXA yielded non-dominant arm and distal radius data (Arm, UD (ultradistal), 1/3; Hologic Discovery A). For MFI, grip strength (Takei) and elbow/shoulder flexion/extension peak torques were measured (Biodex). Semi-annual questionnaires assessed maturity (pre-puberty, puberty/pre-menarche, post-menarche) and organized non-aquatic activity dose (pre-DXA annual means; OPA, h/wk). Backward linear regression built predictive models. Base models entered maturity, height and all MFI. Activity models added OPA and GYM status to maturity, height and all MFI. For velocities, relative change in maturity level was evaluated; height and MFI velocities were entered (change/time).

Results: Baseline age ranged from 8 to 15 years. NON were taller than GYM (T2); GYM OPA was higher than NON (T1 & 2)(p<0.05). Activity level tracked across time (r=0.85, p<0.05). At Time 1, MFI were positively associated with all bone outcomes (p<0.05), except 1/3 BMD; MFI associations with Arm & 1/3BMC changed after adding activity factors. Time 1 OPA was positively associated with radius BMC & BMD (1/3 & UD, p<0.05 except UDBMD p=0.07). At Time 2, various MFI were associated with bone outcomes (p<0.05), except 1/3BMD. MFI were significant predictors in Time 2 activity models, except 1/3BMD; Time 2 OPA was positively associated with bone outcomes (p<0.05), except 1/3Area. For velocities, vMFI were associated with vArmBMC, v1/3BMC, v1/3BMD (p<0.05). In activity models, vMFI results were similar after adding activity factors. T2 OPA was positively associated with vArmBMC (p<0.10) & vUDBMC (p<0.05). GYM status was associated with higher T1ArmBMC, T1UDBMD and lower vUDBMC (p<0.05).

Conclusion: Muscle peak torque and activity dose varied as predictors of bone outcomes by time, muscle group, skeletal site and bone metric. High physical activity doses were associated with benefits for most bone outcomes at single time points. Tracking of predictors during growth may have limited detection of associations between activity exposure and bone growth velocities.

Leptin Blunts the Starvation-Induced Increase in Bone Marrow Adiposity. Maureen Devlin*[1], Christine Conlon[2], Miranda Van Vliet[2], Leeann Louis[2], Lamya Karim[2], Clifford Rosen[3], Mary Bouxsein[2]. [1]University of Michigan, USA, [2]Beth Israel Deaconess Medical Center, USA, [3]Maine Medical Center, USA

Starvation induces both high bone marrow adiposity and low bone mass in humans, suggesting common mechanisms may underlie these effects. Here we test the role of the adipokine leptin in mediating increased bone marrow adiposity and impaired skeletal acquisition due to caloric restriction. Prior studies have shown leptin increases bone mineral content and decreases bone marrow adiposity in the leptin-deficient ob/ob mouse (Hamrick et al., 2005). Thus we hypothesized that starvation-induced hypoleptinemia may contribute to bone marrow fat accumulation and impaired skeletal acquisition, and that leptin replacement during caloric restriction (CR) would reduce marrow adiposity and improve bone mass. We tested this hypothesis in female C57Bl/6J mice fed a 30% calorie restricted (CR) or normal (N) diet from 5-10 wks of age, with daily injections of vehicle, 1 mg/kg/day leptin, or 2 mg/kg/day leptin (N=6-8/group). Outcomes included daily body mass (BM, g) and food intake, serum leptin, %body fat, whole body bone mineral content (BMC, g) via pDXA, cortical (Ct) and trabecular (Tb) bone architecture at the midshaft and distal femur via µCT, and marrow adiposity via osmium staining. Overall, CR mice had lower body mass, %body fat, and Ct bone area fraction, and higher Tb bone volume fraction and connectivity density vs. N mice (p<0.05 for all). Fasting serum leptin levels (~16h post-injection) were lower in CR vs. N (p<0.05) and did not differ across leptin treatments within either diet. However, within each diet, leptin altered body composition and skeletal acquisition. Leptin-treated CR mice gained less body fat and gained more BMC/BM vs. CR controls, although BMC/BM remained lower vs. N controls (p<0.05 for all). Leptin-treated N mice had lower %body fat (p<0.05) but similar BMC/BM vs. N controls. Importantly, while vehicle-treated CR mice had 354% greater marrow fat in the proximal tibia compared to N, leptin-treated CR mice had only a 113% increase (Figure). Leptin treatment had no effect on bone marrow adiposity in N mice. In conclusion, these data demonstrate that leptin replacement during CR inhibits bone marrow fat formation and increases bone mass acquisition compared to controls, supporting the hypothesis that hypoleptinemia contributes to starvation-induced bone marrow adiposity and low bone mass.

Novel implemental roles of the NF-κB subunit RelB in osteoblastogenesis: intrinsic antagonism of the classical NF-κB pathway by RelB. Masahiro Hiasa*[1], Masahiro Abe[2], Toshio Matsumoto[3], Naozumi Ishimaru[2]. [1]University of Tokushima Graduate School, Japan, [2]University of Tokushima, Japan, [3]University of Tokushima Graduate School of Medical Sciences, Japan

Although the activation of the classical NF-κB pathway suppresses bone formation, the role of the non-classical NF-κB pathway in osteoblastogenesis remains largely unknown. In the present study, we therefore explored the role of the non-classical NF-κB subunit relB in the classical NF-κB signaling activation and osteoblastogenesis. TNF-α suppressed mineralized nodule formation by MC3T3-E1 preosteoblastic cells and bone marrow stromal cells at 100 pg/ml but not at 10 pg/ml. However, TNF-α was able to suppress mineralized nodule formation even at 1 pg/ml by these cells upon treatment with RelB siRNA or by bone marrow stromal cells from $RelB^{-/-}$ mice, suggesting the potentiation of the suppressive effects of TNF-α on bone formation in the absence of RelB. Furthermore, the RelB knockdown facilitated the nuclear localization of the classical NF-κB subunits p65/p50 and their DNA binding in MC3T3-E1 cells in the presence of TNF-α at 10 pg/ml. However, inhibition of the classical NF-κB pathway by IMG-2001 or SN50, inhibitory peptides for the nuclear translocation of p65/p50, restored the mineralized nodule formation under the RelB knockdown in the presence of TNF-α, and was also able to resume fracture healing in $RelB^{-/-}$ mice in which the fractured bones were otherwise not united. Interestingly, the mRNA expression of *RelB* but not other NF-κB subunits, *p50*, *p52*, *p65* and *c-Rel*, was up-regulated in fractured bones in wild-type mice. Similarly, TNF-α enhanced the expression of RelB but not other NF-κB subunits, suggesting the intrinsic mitigation of the classical NF-kB pathway by RelB. Therefore, RelB appears to be indispensable for bone repair, and play an implemental role in osteoblastogenesis at least in part through antagonzing classical NF-κB signaling.

RANKL, OPG, and Exercise Dose in Overweight and Obese Children. Norman Pollock*, Haidong Zhu, De-Huang Guo, Catherine Davis. Georgia Regents University, USA

Our understanding of bone turnover has increased considerably with the discovery of the key molecular drivers of osteoclastogenesis, receptor activator of nuclear factor-κB ligand (RANKL) and osteoprotegerin (OPG). It was demonstrated that binding of RANKL to its receptor, RANK, promotes osteoclast differentiation and bone resorbing activity. OPG, a member of the TNF receptor superfamily, acts as a decoy receptor to RANKL, and therefore inhibits osteoclast activation and bone resorption. The roles of RANKL and OPG in bone have been confirmed by mouse models and by exogenous administration of these molecules. A number of clinical reports on serum RANKL and OPG in musculoskeletal pathology have been published; however, interpretation of these data has been elusive. To increase our understanding of this relationship, it would be desirable to have pediatric data under controlled conditions with no musculoskeletal pathology. Therefore, we investigated the dose-response effect of exercise training on circulating concentrations of RANKL, OPG, and the RANKL/OPG ratio in children. Associations of RANKL, OPG, and RANKL/OPG with bone turnover markers were also determined. Overweight children (n=222, aged 7-11 years, 42% male, 58% black, 85% obese) were randomly assigned to 3 experimental conditions: low-dose (20 min/d, n=71) or high-dose (40 min/d, n=73) aerobic exercise program (13 weeks, 5 d/wk) or a control condition (usual physical activity, n=78). Fasting serum samples were taken at baseline and posttest and concentrations of total RANKL and OPG were quantified together with measures of bone formation [osteocalcin (OC)] and resorption [C-terminal telopeptide of type 1 collagen (CTX)]. A significant linear downward trend indicating dose-response to exercise was observed for OPG (P=.04). A dose-response effect was also observed for RANKL/OPG and OC, as indicated by significant upward trends (both P<.04). There was no effect of exercise on RANKL or CTX. Multiple linear regression adjusting for age, sex, and race revealed that changes in both OPG and RANKL/OPG were associated with changes in OC (both P<.05). Changes in RANKL were not associated with changes in OC or CTX. In overweight children, aerobic exercise training influenced serum OPG, RANKL/OPG, and OC in a dose-dependent manner. The increase in bone formation along with the decrease in OPG might reflect an increase in OPG binding to RANKL, which could explain the beneficial exercise training effect on bone.

Norepinephrine reuptake is required for acquisition of a normal peak bone mass. Yun Ma*[1], Jeffry Nyman[2], Maureen Hahn[1], Florent Elefteriou[1]. [1]Vanderbilt University, USA, [2]Vanderbilt University Medical Center, USA

A large body of evidence supports the role of post-synaptic beta 2 adrenergic receptor (β2AR) signaling in the regulation of bone remodeling. Stimulation and blockade of β2AR signaling indeed cause bone loss and bone gain in mice, respectively, however, the contribution of endogenous norepinephrine released by sympathetic nerves to these processes remains unclear. We show here that differentiated osteoblasts (but not immature osteoblasts), like neurons, express the norepinephrine transporter (NET), whose role is to control duration and intensity of sympathetic signals following action potential. NET expression by osteoblasts was detected at both RNA and protein levels by qPCR, Western blot and immunocytochemistry analyses. Specific NE uptake activity, measured by [^{3}H]NE uptake assays, was observed in differentiated osteoblasts. Moreover, by analyzing the expression of enzymes of the NE synthetic and catabolic pathways, we show that differentiated osteoblasts can catabolize, but cannot generate, NE. Chronic pharmacological blockade of NET by the NET blocker reboxetine for 2 months induced bone loss in growing mice. In addition, lack of extracellular norepinephrine (NE) reuptake in *Norepinephrine transporter* (*Net*)-deficient mice led to reduced bone formation and increased bone resorption, resulting in suboptimal peak bone mass and weakened mechanical properties, in the context of low sympathetic outflow and high plasma NE levels. These findings suggest that the response of differentiated osteoblasts to sympathetic outflow and serum NE levels is controlled by the activity of NET in sympathetic neurons or differentiated osteoblasts and support the notion that the control of endogenous NE release and reuptake is an important component of the complex homeostatic machinery by which the central nervous system control bone remodeling. In addition, they suggest that patients prescribed NET blockers for the treatment of ADHD or depression may be at risk for premature osteoporosis and more susceptible to bone fracture.

***In Vivo* Evaluation of Skeletal Development in Non-Clinical Pediatric Studies in Rabbits.** Rana Samadfam*, Nancy Doyle, Aurore Varela, Susan Y. Smith. Charles River Laboratories, Canada

In recent years there has been an increased emphasis placed on nonclinical pediatric drug testing, with a focus on effects on growth and development of several organ systems including the skeleton (FDA guidance 2006, EMEA guideline 2008). The aim of this study was to establish procedures to evaluate the effects of drugs on skeletal development and bone density in non-clinical pediatric studies in rabbits. A wide variety of techniques are potentially available to assess skeletal development. Feasibility of using some of these techniques including radiography, DXA and pQCT was examined. These imaging techniques were performed repeatedly on the same animals, from juvenile (4 weeks of age) to adulthood (6 months of age).

Animal were anesthetized for in vivo scanning. DXA scans were obtained at the lumbar spine, femur and/or whole body and provided measurements for area, bone mineral content (BMC) and bone mineral density (BMD). Peripheral QCT scans were acquired at the proximal tibia and provided volumetric measurements of area, BMC and BMD of the total slice, trabecular and cortical compartment as well as geometry parameters. Radiographs were used for bone length measurements at the lumbar spine and long bones. In vivo radiograph measurements showed increases in bone length with age. At each time points, the measurements were reproducible with CV lower than 5 %. The results for whole body (area, BMC and BMD), Lumbar spine (L1-L4, area, BMC and BMD) and femur (global and subregional area, BMC and BMD at 24-25 days old and global parameters at 8 weeks old) were reproducible with CV ranging between 1.2-5%. Appropriate positioning and feasibility of tibia for pQCT scanning was also confirmed. The results for total and cortical parameters were reproducible CV lower than 5%. Trabecular parameters were more variable likely due to small amount of trabecular bone at this site. The results of these investigations indicate that in vivo radiography, DXA and pQCT provide safe, reproducible and repeated non-invasive measurements of skeletal growth in skeletally immature rabbits at axial and appendicular sites. These techniques provide a comprehensive set of assessments for the evaluation of the potential effects of drugs on the developing skeleton.

Pamidronate use in Children with Osteogenesis Imperfecta at Boston Children's Hospital: Retrospective Cohort Study. Paulina Ortiz-Rubio*[1], Ingrid Holm[2], Nina Ma[1]. [1]Boston Children's Hospital, USA, [2]Children's Hospital Boston, USA

Osteogenesis imperfecta (OI) is a collagen disorder resulting in bone fragility, progressive deformity and chronic pain. Bisphosphonate therapy, specifically with pamidronate, has been shown to be beneficial in children with severe OI by reducing fracture rate and improving bone mineral density (BMD). Currently, however, there is no standardized approach to treating children with OI using pamidronate, and regimens vary widely in dose and frequency between institutions.

We therefore performed a retrospective cohort study of children with severe OI who were treated with intravenous pamidronate infusions at Boston Children's Hospital during the past fifteen years. Subjects included were those who received a standardized protocol of pamidronate infusions for a single day every four (0.5-0.75mg/kg/dose) or six (1mg/kg/dose) weeks depending on age. Comparisons were made regarding measures of efficacy before and after treatment, and safety data was collected and reported.

Of the 32 children with OI treated with pamidronate, 11 received the 4-6 week standardized regimen and had complete data available. Children ranged from 2 to 15 years old and were treated for 3.73 ±1.89 (mean ±SD) years. Growth data showed

no significant change in height ($p > 0.180$) and weight ($p > 0.267$) z-scores from before to after treatment. Adverse events related to treatment included a mild acute phase reaction after the first pamidronate infusion (45.5%), post-infusion hypocalcemia (9.1%) and delayed fracture healing during treatment (9.1%). Of 11 patients, 8 (72.7%) reported significant improvement in strength and activity, 11 (100%) reported improvement in fracture rate and, of 8 patients complaining of significant pain prior to treatment, 7 (87.5%) reported marked decrease in pain. There was a mean annualized percent change in BMD of +48.24% ± 19.53, and BMD z-scores improved from -3.81 ± 1.93 before to -0.918 ± 1.66 after treatment ($p < 0.001$).

In conclusion, children with severe OI treated with single day pamidronate infusions every 4 to 6 weeks showed significant clinical and radiographic improvement. There was no evidence of a detrimental effect on growth related to pamidronate therapy, which has been a concern raised by clinicians. Lastly, patients should be counseled regarding acute phase reaction symptoms following the first administration of pamidronate and calcium levels should be monitored following infusions as there is risk of hypocalcemia.

Age and Sex Dependence of Baboon Proximal Femur Composite Traits Determined Using Statistical Shape and Density Modeling. Todd Bredbenner*[1], Arthur Nicholls[1], Donald Moravits[1], Jennifer Harris[2], Shayna Levine[2], Lorena Havill[2], Daniel Nicolella[1]. [1]Southwest Research Institute, USA, [2]Texas Biomedical Research Institute, USA

The structural integrity of bone in any mechanical loading environment is an integrative function of a multitude of complex and interrelated characteristics, including microstructural organization, macroscopic bone morphology, and, of course, bone density. In ongoing work utilizing a pedigreed baboon model, we hypothesize that bone traits functionally co-vary in a complex multivariate manner to produce sufficient structural integrity for routine daily loading; however, some bone structures will perform poorly under non-habitual loading conditions, such as those encountered in a fall.Using microCT, we imaged 74 baboon left proximal femurs obtained at routine necropsy, along with a density calibration phantom, in order to investigate the dependency of variation in geometry and bone mineral density distribution on sex and age. To date, volumetric femur models describing geometry and spatial BMD distribution were created for 74 animals (31 males, 43 females; age: 18.8 ± 3.9 years, developmentally equivalent to 56.4 ± 11.8 human years). Each 3D model consisted of 31,874 variables (i.e. spatial location and density at each mesh node located at corresponding anatomic positions for all femurs). Statistical shape and density modeling (SSDM), based on Principal Component Analysis, was used to describe variation in 3D bone geometry and BMD distribution within the set of 74 individual femurs by reducing the ~32,000 highly correlated variables for each model to a set of 73 uncorrelated and independent principal components (e.g. composite geometry and BMD traits) without loss of information. Two-way unbalanced analyses of variance were used to test the principal component weighting factors for dependence on sex and age, where animals were grouped into young (age < 15 years), old (> 22 years), and middle-aged (others). Four of the 74 weighting factors were significantly associated with sex and 2 of the 74 were associated with age grouping. Principal components defined using SSDM identify complex combinations of structural bone traits (e.g. geometric and BMD distribution traits) that vary with sex and age. In ongoing work, we are characterizing these bones with a comprehensive suite of bone traits and we expect that comprehensive description of bone sample variation will allow investigation of important structural differences that differentiate between strong and weak bones under routine loading (i.e. single-leg stance) and abnormal loading (i.e. fall-type loading).

Bone microstructure characteristics in high fat diet induced fatty liver disease mice. Shen Qu[1], Ran Cui*[1], Yunzi Liu[2], Chunlei Jiang[2]. [1]Shanghai Tenth People's Hospital of Tongji University, School of Medicine, China, [2]The Second Military Medical University, China

Purpose: It has been proved that non-alcoholic fatty liver disease (NAFLD) had detrimental effect on bone mineral density (BMD) in both adults and adolescents. However, most of the evidence was from clinical studies, which cannot ensure the adverse effect. Thus, we performed an animal experiment to certify this phenomenon.

Methods: 46 C57 male mice, 8-10 weeks old, average body weight 15-20g at the beginning of the experiment, were enrolled and divided into two groups, feeding for 12 weeks either standard chow (control; N = 21) or high-fat diet (HFD; N = 25). Femur, Tibia and liver samples were collected after sacrifice. The bone samples were scanned using a micro-CT system (mCT-80; Scanco Medical AG) in a high-resolution scanning mode (a voxel size and slice thickness of 20 mm). In HFD group, 20 mice were proved with fatty liver by liver biopsy. Tissue mineral density (TMD), total bone volume fraction (BV/TV), trabecular thickness (Tb.Th), trabecular number (Tb.N), trabecular separation (Tb.Sp), connectivity density (Conn.D) and structure model index (SMI) were compared between control and HFD groups.

Results: Compared to control group, HFD had a lower level of TMD (59.741 ± 23.038 vs. 112.196 ± 54.940, P=0.028), BV/TV (0.017 ± 0.003 vs. 0.068 ± 0.044, P=0.007), and Tb.Th (0.050 ± 0.006 vs. 0.063 ± 0.006, P<0.001) in femur. For tibia, HFD also had a lower level in TMD (25.078 ± 19.822 vs. 85.462 ± 34.011, P=0.021), BV/TV (0.023 ± 0.012 vs. 0.068 ± 0.017, P<0.001), Conn.D (0.359 ± 1.688 vs. 8.522 ± 6.458, P=0.023), Tb.Th (0.048 ± 0.007 vs. 0.061 ± 0.007, P=0.004), while a higher level of SMI (3.428 ± .412 vs. 2.529 ± .454, P=0.002) and Tb.Sp (0.636 ± 0.158 vs. 0.441 ± 0.145, P=0.022).Conclusion: Our results convinced the adverse effect on bone microstructure of high fat diet induced fatty liver mice. However, further study was needed to investigate the mechanism.

Can lost bone be recovered after 12 weeks of reduced energy availability? Corinne Metzger*[1], Kaleigh Camp[1], Sibyl Swift[2], Mary Jane DeSouza[3], Evelyn Yuen[1], Florence Lima[1], Susan Bloomfield[1]. [1]Texas A&M University, USA, [2]Armed Forces Radiobiology Research Institute, USA, [3]The Pennsylvania State University, USA

Reduced energy availability due to restricted caloric intake leads to bone loss; however, less is known about the impact of exercise during reduced energy availability and recovery from a period of reduced energy intake. We hypothesized that bone loss would be minimized, and that recovery of any losses would be enhanced, in animals achieving reduced energy availability (EA=energy intake minus energy expenditure from exercise) with exercise as well as caloric restriction. Virgin female Sprague-Dawley rats (5-mo-old) were acclimated to AIN-93M purified diet for 8 weeks and then randomly assigned into sedentary (Adlib-SED) and exercising (Adlib-EX) adlib-fed controls or sedentary (-25EA-SED) and exercising (-25EA-EX) energy restricted groups. Sedentary -25EA were fed 40% less energy with all other nutrients maintained at 100%. Exercising -25EA received 30% less energy from the diet and achieved another 10% energy reduction by treadmill running 4 days/week for 90-100 min (~60% VO_{2max}). Following 12 weeks of reduced EA, -25EA-SED animals exhibited significantly decreased fat mass ($p<0.0001$) and cancellous volumetric BMD (Canc-vBMD, by pQCT; $p< 0.006$) at the PTM compared to Adlib-SED mice; declines in lean mass did not reach significance. By contrast, 25EA-EX animals' lean mass and PTM Canc-vBMD values were not different from Adlib-EX controls, although fat mass was significantly reduced ($p =0.0014$). Serum leptin concentrations were lower in the -25EA-SED vs. Adlib-EX and AdLib-SED ($p<0.005$), while serum IGF-1 concentrations were lower in -25EA-SED vs. only Adlib-EX ($p=0.005$). Cancellous bone formation rate (BFR) declined in both EA groups relative to their adlib fed controls, but did not reach statistical significance. During recovery from reduced EA, all rats were fed adlib and running exercise volume was halved for 12 weeks. After 12 weeks, lean mass, proximal tibia Canc-vBMD and serum leptin and IGF-1 concentrations recovered to adlib-fed controls' values in both EA groups. Cancellous BFR in both EA groups was recovered to the same values as adlib-fed control values after 12 weeks of recovery. In conclusion, we found decreased EA produces bone loss and a decrease in BFR; however, if the reduced EA is achieved in part by exercise, bone loss and decreases in BFR are minimized. Deficits in bone with reduced EA appear to be reversible by 12 weeks in both exercising and sedentary energy-restricted animals if energy balance is achieved and maintained during recovery.

MO0041

Comparative Experimental Study of the Effect of Osteoprotegerine and Testosterone on the OPG/RANKL System in an Animal Model of Male Castrate Rats. Marta Martín-Fernández*[1], Mónica Sánchez-Sánchez[1], Manuel Díaz-Curiel[2], Concepción De la Piedra[3]. [1]Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Spain, [2]Medicina Interna. Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Spain, [3]Bioquímica Investigación. Instituto de Investigación Sanitaria Fundación Jiménez Díaz, Spain

Lack of androgens leads to a loss of bone mass and bone quality in general. The administration of either Osteoprotegerin (OPG) or testosterone is capable of preventing the negative effects on bone of a lack of androgens. In a previous work we have observed that osteopenia due to ORX was reverted with OPG-Fc administration (totally) and with testosterone administration (partially) to ORX male rats. The aim of this work was to evaluate if OPG-Fc and testosterone treatment act through the OPG/RANKL system.

Sixty 3-month-old male Wistar rats were used and divided into 4 groups: SHAM: n=15, simulated intervention; ORX: n=15, orchidectomized; ORX+TEST: n=15, orchidectomized and treated with testosterone cypionate (1.7 mg/Kg) i.m. every week; ORX+OPG: n=15, orchidectomized and treated with OPG-Fc (a recombinant RANKL inhibitor with rat cross-reactivity) (10 mg/Kg) s.c. twice a week. The treatment was started immediately after orchidectomy, and was maintained for 8 weeks. Total RNA was isolated from the rat femur and reverse-transcribed. Quantitative RT-PCR was performed to evaluate the expression of OPG and RANKL, using GAPDH gene as constitutive control. Results are expressed as the mean ± SEM.

RANKL expression was significantly increased in the ORX group with respect to SHAM group. OPG-Fc and testosterone treatments produced a decrease in RANKL expression although no statistical differences were observed. OPG-Fc treatment produced a significant decrease in OPG expression with respect to all other groups. It

is important to note that testosterone treatment produced a significant increase in OPG/RANKL ratio with respect to ORX group. That could explain the increase observed in femoral BMD when rats were treated with testosterone. Exogenous OPG-Fc (which produced an increase in systemic OPG) but not endogenous femoral expression of OPG could explain the increase in BMD observed in OPG-Fc treated rats.

Correlating FTIRI and Raman Parameters using Iliac Crest Biopsies. Adele Boskey*[1], Lyudmila Spevak[1], Gurjit Mandair[2], Susan P. Bare[3], Robert Recker[3], Michael Morris[4]. [1]Hospital for Special Surgery, USA, [2]University of Michigan, Department of Chemistry, USA, [3]Creighton University, USA, [4]University of Michigan, USA

Fourier transform infrared imaging (FTIRI) and Raman microspectroscopy (RS) have widely been used to probe the physicochemical and microstructural changes in aged or diseased bone for the past decade. Earlier studies in cortical bone have shown that, as expected from theory, parameters measured by FTIRI correlate with those measured by RS. Some parameters, on the other hand, are based on different molecular vibrations in FTIRI and RS, and are not necessarily correlated. In this study, using a small subset (n=20) of a larger study, examines the correlations between select FTIRI and RS parameters of "bone quality" using iliac crest biopsies obtained from age-matched postmenopausal women with and without fractures. Embedded and sectioned biopsies were initially mapped by RS and then by FTIRI using adjacent 1 um-thick sections. The following FTIRI parameters were calculated for cortical and cancellous bone: Mineral/Matrix (Min/Mat), Carbonate/Phosphate (C/P), Collagen maturity (XLR), and Crystallinity (XST). Cortical FTIRI parameters were derived from the thinner side of the iliac crest (cortex b). Each FTIRI parameter was then correlated with a blind set of one of the closest matching RS parameters: Phosphate/Proline, Phosphate/Phenylalanine (Phe), Phosphate/Amide I, 1070/Phosphate, or 1045/ Phosphate. In this correlative FTIRI and RS study, we demonstrate agreement with cancellous bone parameters but not always with cortical bone parameters as measured in the thinner (cortex b) or thicker (cortex a) cortex, or a combination of both (cortex a+b) for FTIRI with RS parameters (Table). Accepting an R^2 value greater than 0.22 as a reportable correlation between FTIRI vs. RS parameters, we report significant correlations (with $p<0.05$) for cancellous Min/Mat vs. Phosphate/Proline, cancellous and cortical Min/Mat vs. Phosphate/Phe, and cancellous C/P vs. 1070/Phosphate. Although the study was not powered to address differences between fracture and control cases, we found that in general that crystallinity and collagen maturity parameters as measured by FTIRI for cancellous and cortical bone tended to be increased in cases relative to controls.

Correlation coefficients (R^2) between FTIRI vs. RS parameters of Bone Quality

Parameter (FTIRI vs. RS)	Cancellous bone	Cortical bone
Min/Mat vs. Phosphate/Proline	0.24	0.054 (cortex b)
Min/Mat vs. Phosphate/Phe	0.28	0.38 (cortex b)
Min/Mat vs. Phosphate/Amide I	0.23	0.28 (cortex b)
C/P vs. 1070/Phosphate	0.55	0.04 (cortex b)
Crystallinity vs. 1045/Phosphate	0.36	0.10 (cortex a+b)

Cx43 Hemichannels Involves in TMJ Cartilage Degradation Induced by Biomechanical Dental Stimulation. Mei-Qing Wang*[1], JIng Zhang[2], Mian Zhang[2], Min Guo[2], Min Guo[2], Ting Yang[2]. [1]School of Stomatology, Fourth Military Medical University, Peoples Republic of China, [2]FMMU, China

Temporomandibular joint (TMJ) is a site that frequently suffers osteoarthritis (OA). It has a biomenchanical association with dental occlusion so that OA like lesions could be induced in TMJ when tdental occlusion is disorderedly altered. Connexin 43 (Cx43) hemichannels and P2 receptors is a putative mechanoreceptor complex that expressed on the surface of articular chondrocytes and involves in the primary cilium. In recent, we developed a rat TMJ OA model by installing a pair of metal tubes onto the left pair of incisors. In present work we used this rat TMJ OA model to explore the role of Cx43 hemichannels in TMJ cartilage degradation. Cartilage from TMJs of Sprague-Dawley rats were sampled for *in vivo*, *ex vivo* and *in vitro* studies. Histomorphometric and micro-CT analysis, real time PCR and immunohistochemistry were used to test the histomorphological changes in cartilage and subchondral bone of TMJs, and also in the expression of Cx43 and molecules related to cartilage degenerative changes, and also to the osteoblastogenetic and osteoclastogenetic activities. In vitro methods like cell shear stress, dye uptake, siRNA, ELISA and western blot were performed on the rat primary chondrocytes and ATDC-5 cell line. Cartilage degradation and condylar subchondral bone loss were observed which changes were more serious with growing of the experimental time. Micro-CT analysis revealed the significant decreased BMD and BV/TV ($P<0.05$). The mRNA expression of RANKL, RANKL/OPG, RANK, TRAP and cathepsin K were significantly increased while the expression of osterix?RUNX2?ALP?osteocalcin?DMP-1 and VEGF decreased initially followed by an significantly increase ($P<0.05$). Aberrant calcification was found at the osteochondral interface. The expression of Cx43 and the synthesis and secretion of PGE_2 increased ($P<0.05$). In vitro data showed that fluid flow shear stress promoted the expression of Cx43 and the synthesis of PGE_2 in primary chondrocytes of rat TMJ cartilage. Mechanical strain could open Cx43 hemichannels, then the release of intracellular PGE_2 increased, and the increased release of PGE_2 could be blocked by the hemichannel inhibitor ($P<0.05$). The similarly changes could be found in ATDC-5 cell line with the shear stress stimulation. In addition, the secretion of PGE_2 decreased due to the effect of siRNA on Cx43 expression ($P<0.05$). All these data indicates that the biomechanical dental stimulation, as well as the stimulation of shear stress, increased the expression of Cx43 and intracellular PGE_2, and opened Cx43 hemichannels in chondrocytes. Then the increased release of PGE_2 through Cx43 hemichannels led to cartilage degradation. Conclusively, Cx43 play a key role in TMJ OA cartilage degradation induced by biomechanical dental stimulation.

Does Reference Point Indentation Assess the Fracture Toughness of Human Cortical Bone?. Mathilde Granke*[1], Sasidhar Uppuganti[1], Alexander Makowski[2], Ahbid Zein-Sabatto[1], Andrew J Schultze[1], Jack M Whitehead[1], Jeffry Nyman[1]. [1]Vanderbilt University Medical Center, USA, [2]Department of Veterans AffairsVanderbilt University, USA

There is a need for diagnostic tools that accurately assess age- and disease-related changes in fracture risk. Reference point indentation (RPI) is one promising tool capable of measuring material properties directly from the patient's tibia. However, this site is not a typical site of fragility fracture nor do RPI measures encompass all contributions of bone's hierarchy to fracture resistance. Therefore, to help establish clinical utility, we assessed the relative contribution of RPI measures and intracortical porosity to fracture toughness.

Cadaveric femurs were acquired from an extensive dataset of 51 human donors (22 female, age = 61±20 [29-101]; 29 male, age = 64±24 [21-98]). We cut single-edge notched beam specimens from the lateral quadrant of each mid-diaphysis, obtained its porosity by μCT, and its initiation toughness K_{Ic} by propagating a crack normal to osteon direction. In order to mimic clinical measurements, we performed RPI (Biodent, Active Life Scientific) on the medial quadrant of the midshaft, below the periosteum.The average value of 10 indents (20 cycles at 2 Hz, 10N maximal force) was recorded to ensure an acceptable confidence interval on the mean values of RPI parameters despite their inherent intra-specimen variablity.

Age-adjusted analysis of covariance showed a significant influence of gender (r^2 = 0.17, $p<0.01$) on K_{Ic}. Including gender as a covariate, regressions on K_{Ic} identified parameters that explain the variance in fracture toughness better than age: porosity (r^2 = 0.43, $p<10^{-5}$), total indentation distance (TID) (r^2 = 0.20, $p<0.01$), average creep indentation distance (avgCID) (r^2 = 0.22, $p<0.001$), average energy dissipation (avgED) (r^2 = 0.20, $p<0.01$), and first indentation distance (ID1) (r^2 = 0.21, $p<0.01$). Of multivariate regressions in which gender and porosity were significant covariates, TID, avgCID, and ID1 significantly improved the explanation of variance in K_{Ic} (table 1). Porosity, TID, avgCID and ID1 contributed negatively to K_{Ic} but did not account for gender difference.

Since microcracking below the indenter tip could dictate RPI parameters, RPI may be a local measure of tissue fracture toughness. Indeed, total, initial and creep indentation at the bone surface explain age-related changes in the fracture toughness at the millimeter scale even when microscopic porosity is a co-determinant.

Table 1. Coefficients (and standard error) from the final mutivariate regression models on K_{Ic} after removing the non-significant interactions

RPI variable / covariate	TID	avgCID	ID1
porosity	-0.082** (0.014)	-0.081** (0.017)	-0.081** (0.017)
sex.women	0.55** (0.19)	0.64** (0.19)	0.55** (0.19)
RPI variable	-0.028* (0.014)	-1.42* (0.60)	-0.033* (0.017)
constant	8.35** (1.19)	8.21** (0.96)	8.47** (1.25)
adjusted-r^2	0.46	0.48	0.47

DPP4 Inhibition Attenuates Bone Loss in Diabetic Rats. Lorenzo Glorie*[1], Geert Behets[2], Lesley Baerts[3], Ingrid De Meester[3], Patrick D'Haese[2], Anja Verhulst[2]. [1]Universiteit Antwerpen, Belgium, [2]Laboratory of Pathophysiology, Belgium, [3]Laboratory of Medical Biochemistry, Belgium

Dipeptidyl peptidase 4 (DPP4) modulates activity of proteins by removing two aminoterminal amino acids. DPP4 inhibitors are currently being used to improve glucose tolerance in type 2 diabetes patients by increasing the halflife of DPP4 substrates. It has been shown that these substrates do not only increase pancreatic insulin secretion, but also influence the activity of bone cells. The potential therapeutic effect of DPP4 inhibition on bone metabolism is thus worth being investigated. In the present study, we evaluated the effect of the DPP4 inhibitor sitagliptin (SG) on bone structure in the streptozotocin (STZ)-induced diabetic rat.

This study included 64 male Wistar rats (age 10 weeks), divided into 4 groups (n=16): 2 diabetic and 2 control groups. One diabetic and one control group received SG through drinking water (2g/L). Rats were scanned every 3 weeks using an in vivo micro-CT scanner. After 6 & 12 weeks, rats were sacrificed after tetracyclin labeling for bone histomorphometric analysis of static and dynamic bone parameters. Mechanical properties of femora were assessed using a three-point bending test.

STZ-treated (diabetic) rats had significantly increased blood glucose and reduced body weight compared to controls, which was not influenced by SG. SG however significantly decreased diuresis and food consumption in diabetic rats. In vivo DPP4 inhibition of 89% was achieved in both SG-treated groups. Trabecular bone volume & bone over tissue volume ratio in the tibia was significantly lower in STZ-treated rats compared to untreated rats, but was normalized through SG treatment (significant at week 9 & 12). Trabecular thickness was decreased and trabecular spacing was increased in diabetic rats. SG treatment also in resulted in partial but significant recovery of these trabecular parameters in diabetic rats. Cortical bone volume stabilized after 3 weeks in diabetic rats, but kept increasing steadily in SG-treated diabetic rats. Although nonsignificant, the SG-treatment resulted in increased presence of osteoid in diabetics. In a three-point bending test performed on femora of rats sacrificed after 12 weeks, applied ultimate load in SG-treated diabetic rats was significantly higher than in non-treated diabetic rats.

Results show an attenuation of diabetic bone loss through DPP4 inhibition. Exact effect of DPP4-inhibitors on the activity of bone cells remains to be elucidated through histomorphometric and biochemical analyses of acquired samples.

Evaluating the Precision of Compressive Failure Tests of the Murine Tibia Using 3D Printing. Lillian Chatham*, Vanessa Sherk, Dana Carpenter. University of Colorado, Denver, USA

Compressive axial loading of the murine tibia has proven to be a valuable model for investigating the effects of mechanical loading on bone functional adaptation [1,2]. One possible endpoint of studies using this model is the experimentally measured strength of the tibia. Three- and 4-point bending tests provide useful measurements of tibial strength, but the loading in these tests is quite different from the axial compressive loading to which the bone adapts in vivo. To determine the precision of tibial strength measurements in a load direction similar to that applied in vivo, we performed a set of compressive failure tests of the murine tibia using 3D printed models. A model of a murine tibia was developed from micro computed tomography data (voxel size=0.02 mm^3). Twenty replicate models were printed on the 3D printer. Two trays with 0.5 $in.^3$ cubic wells were used for potting the model tibiae. To hold the samples upright during potting, holes were drilled into an acrylic plate and aligned with each cube in the trays. The holes were 0.125 in. in diameter, which was sufficient for the tibiae to pass through, but small enough to provide support during potting. Urethane was used to pot each end of the tibia. After curing, samples were removed from the trays and loaded to failure in compression at a speed of 6 mm/min, and the fracture force was recorded. Finite element (FE) models were developed to recreate the mechanical tests. The experimentally measured failure force for each FE model was applied in the axial direction. The average von Mises stress was computed at a mid-diaphyseal cross-section, just proximal to the junction of the tibia and fibula. Due to slipping during testing, three samples were discarded. Therefore, 17 samples were taken into account for calculating the mean, standard deviation, and coefficient of variation (standard deviation/mean) of the measurements. The average experimentally-measured fracture force was 48.01 $\pm$ 3.57 N, and the average FE-based von Mises stress was 43.64 $\pm$ 3.24 MPa. The coefficients of variation of the failure force and the von Mises stress values were both calculated to be 7.43%. The results of these tests suggest that the precision of our mechanical testing method and FE analysis technique will be sufficient for measuring changes in tibial strength and stress magnitudes that occur due to applied mechanical loading.

MO0047

Exercise During Recovery Between Two Hindlimb Unloading Exposures Enhances Cancellous Bone Microarchitecture and Mechanical Properties. Yasaman Shirazi-Fard*[1], Andrea Kwaczala[2], Stefan Judex[2], Susan Bloomfield[1], Harry Hogan[1]. [1]Texas A&M University, USA, [2]Stony Brook University, USA

Bone response to repeated disuse exposures has been a concern for astronauts and clinical patients experiencing periods of non-weightbearing. The goal of the current experiment was to assess effects of resistance exercise during recovery between two bouts of disuse at the proximal tibia metaphysis (PTM) in the adult hindlimb unloaded rat model. We hypothesized that exercise would not only enhance recovery but would also mitigate impact of the 2nd disuse.

Adult male Sprague-Dawley rats (6 mo.) were assigned to age-matched control (AC) and hindlimb unloaded (HU) groups by body weight and total (integral) vBMD. HU animals were exposed to 4 wk of hindlimb unloading (HU), followed by 8 wk of recovery (HU+R), and then a 2nd HU exposure (2HU). Subsets of HU animals performed progressive resistance exercise during recovery for 7 wk (3d/wk) (HU+EX), and were exposed to a second HU exposure (2HU+EX). Bones were analyzed by in vivo pQCT at baseline and every 4 wk. Animals (n=15/group) were euthanized at baseline, after initial HU, after recovery/exercise, and after 2nd HU. Changes in bone mechanical properties were estimated through FEM on ex vivo μCT scans and measured by mechanical testing of cancellous bone.With exercise added following the 1st HU, both Total BMC and vBMD increased significantly (17% & 11.6%, resp.) and even exceeded AC levels, but losses for the 2nd HU were not significant pre-to-post whether exercise was included or not. After the 1st HU exposure, BV/TV and Tb.Th were significantly lower (-31% and -13%, resp.) than AC, but they recovered to AC after 4 wk of reloading without exercise. Exercise had no additional effect on BV/TV, but it was strongly anabolic for Tb.Th, which was significantly higher (25%) than AC and non-exercise levels at the end of recovery and after 2nd HU. Unloading had no effect on Tb.N, but HU+EX and 2HU+EX were significantly lower (-23%) than HU+R and 2HU. With exercise added, PTM cancellous bone ultimate stress and elastic modulus for HU+EX increased significantly (74% & 127%, resp.) but HU+R were not different from post-HU values. When loaded to 1N in a constrained compression test in axial direction using FEM, metaphyseal bone failure load for HU+EX was significantly higher (9%) than HU+R.In summary, exercise benefits were more potent in the cancellous bone of the PTM (compared to integral cortico-cancellous) and were most prominent in mechanical properties and Tb.Th despite no appreciable effect on BV/TV.

Human Ossicles Adapt their Tissular Bone Quality to their Biomechanical Function. François Duboeuf*[1], Brigitte Burt-Pichat[1], Delphine Farlay[1], Paul Suy[2], Eric Truy[3], Georges Boivin[1]. [1]INSERM UMR 1033; Université de Lyon, France, [2]Hôpital Edouard Herriot, Département d'ORL, Lyon, France, [3]Hôpital Edouard Herriot, Département d'ORL, Université de Lyon, France

Bone quality of the middle ear bones was never studied. These tiny bones are subjected to vibrations transmitted from the tympanic membrane through the cavity of the middle ear up to the oval window of the internal ear. We have characterized bone quality and mechanical properties of ossicles (malleus and incus) using a pluri-methodological approach. Ten malleus and 9 incus were obtained from 11 patients [9 cholesteatoma (54$\pm$20 yrs), 1 chronic otitis (30 yrs), 1 external ear cancer (66 yrs)]. Two malleus and 2 incus from a control (80 yrs) were taken at necropsy. Results were also compared to human cortical bone from 1 femoral and 9 iliac samples. Ossicles were analyzed by μCT then embedded in methyl methacrylate for histological study. Microhardness Vickers (Newton/mm^2) was calculated on blocks (10 indentations in lamellar tissue and 10 in woven tissue)[1]. FTIRM was done in 4 pathological ossicles of various ages and in control ossicles to assess mineral maturity, index of crystallinity and mineralization, carbonation and collagen maturity[2-3]. μCT showed that half of the ossicles were morphologically degraded. Mean density of pathological and control ossicles was higher than in human cortical bone. Significant correlation was found between incus density and age (p=0.001,r=0.82). The mean porosity of pathological ossicles was higher than in both control ossicles and human cortical bone. Histology showed a vascularized compact bone, well calcified with mainly a lamellar texture; area of woven tissue persisted. Osteoclasts and osteoblasts were not observable; some areas were rich in periosteocytic lacuna sometimes empty. The calcified tissue was lined with a thick fibrous organic tissue, rarely with a true osteoid tissue. Microhardness of all ossicles was higher than in human cortical bones, and identical in both woven and lamellar tissues. In ossicles compared to human cortical bone, index of mineralization was higher, mineral maturity was lower, and crystallinity,

carbonation and maturity of the collagen were similar. Finally, pathological ossicles showed important bone destruction compared to the control ossicles. Density, microhardness, and index of mineralization were higher than in human cortical bones. These variables reflect a bone quality well adapted to the specific function of the ossicles, i.e., transmission of vibrations.[1]*Boivin et al. 2008, Bone, 43:532 ;* [2]*Farlay et al. 2011, PLoS ONE 6(12):e287;* [3]*Farlay et al. 2010, J Bone Miner Metab 28:433*

Intensive Treadmill Running Induces Microstructural Deterioration in Mouse Femoral Trabecular Bone. Allison Altman*[1], Klyde Breitton[1], Guangyi Zhao[2], Beom Kang Huh[1], Wei-Ju Tseng[1], James H-C Wang[2], Xiaowei Liu[1]. [1]University of Pennsylvania, USA, [2]University of Pittsburgh, USA

Weight-bearing exercise has been shown to strengthen bone in both clinical and experimental settings in human and rodent models. However, intensive endurance running is associated with a reduced bone mineral density (BMD) and a high risk of stress fractures. We hypothesized that in addition to stimulating bone formation, intensive exercise may induce excessive resorption beyond the stimulated formation in mouse femoral bone resulting in a net bone loss.

Twenty-eight 3-month old female C57BL/6 mice were divided into three groups: control (CTL, n=9), moderate treadmill running (MTR, n=9), or intensive treadmill running ITR: n=10). Both MTR and ITR groups ran on the treadmill 5 days/week for 3 weeks at a speed of 13 m/min, after one week of acclimatization to treadmill running. The MTR group ran 50 min/day for 3 weeks and the ITR group ran 3 hr/day, 4 hr/day and 5 hr/day on the 1st, 2nd, and 3rd weeks respectively. Following treadmill running the femurs were scanned at 6 μm using a Scanco MicroCT 35. A 1.2 mm section from the distal femur and a 0.6 mm section from the femur midshaft were analyzed using standard microstructural analysis. Kruskall-Wallis non-parametric ANOVA were performed on all variables of interest.

As shown in Table 1 there were no differences in trabecular bone volume fraction (BV/TV), trabecular number (Tb.N*), trabecular spacing (Tb.Sp*) or polar moment of inertia (pMOI) of the cortex. Structural measures indicated a 21% reduction ($p = 0.02$) in connectivity density (Conn.D) and a 12% increase ($p = 0.07$) in structure model-index (SMI) in the ITR group when compared to the MTR group. There was a 6% increase ($p = 0.04$) in trabecular thickness (Tb.Th*) in the ITR group compared to the MTR group, and a trend towards reduced cortical thickness (Ct.Th) by 4% ($p = 0.09$) in the MTR group compared to the CTL group.

These results demonstrate that intensive treadmill running exercise results in a less connected trabecular network and more rod-like trabecular structure in mouse femoral trabecular bone. The increased Tb.Th* in the ITR group indicates elevated bone formation on the bone surface; however, intensive running may also stimulate resorption, which may have exceed the new formation, leading to lost trabecular structural integrity. This may ultimately lead to injury or reduced BMD with longer training periods. Therefore, we conclude that intensive treadmill running induces microstructural deterioration in mouse femoral bone.

Table 1. Variables of interest shown as mean *(SEM)*. $ indicates significantly different from the MTR group ($p<0.05$), and * indicates statistical trend with respect to MTR group ($p<0.1$).

	CTL (n = 9)	MTR (n = 9)	ITR (n = 10)
BV/TV (%)	10.9 *(0.3)*	11.0 *(0.5)*	10.1 *(0.6)*
Tb.N*	4.07 *(0.05)*	4.10 *(0.07)*	3.90 *(0.08)*
Tb.Sp* (μm)	240 *(2.9)*	238 *(4.4)*	252 *(5.0)*
pMOI (mm^4)	0.33 *(0.01)*	0.32 *(0.01)*	0.32 *(0.01)*

Modeling Reference Point Indention in Equine Cortical Bone with Finite Elements and Mechanical Testing Data. Kevin Hoffseth*, Connor Randall, Paul Hansma, Henry Yang. University of California, Santa Barbara, USA

This study is aimed at investigating cortical bone mechanical properties through minimally invasive in-vivo measurement, which is of value to the community concerned with skeletal health, ranging from the elderly concerned with bone quality degradation, to the equine field concerned with training and diet, to name just two examples. For this purpose, equine cortical bone properties are examined by a recently developed Reference Point Indentation technique (Bridges et al, Rev Sci Instrum 2012), finite element simulation, and mechanical testing data. A broad attempt is made to connect the reference point indentation depth measurement to the cortical bone mechanical properties using the same donor material, with focus on yield strength and inelastic deformation.

Cortical bone tissue from the third metacarpal bone of an equine donor was prepared for testing, and depth was measured by Reference Point Indentation using two different geometry tips. The tips consisted of a sharp 90˚ cone with tip radius less than 15 μm, and a blunt 90˚ cone with tip radius of approximately 35 μm. Material from the same bone was also tested in both axial compression (4 samples) and four-point bending (8 samples) to obtain mechanical property data. Finite element simulations using a Drucker-Prager yield criterion were built to simulate indentation response using mechanical property data as input.

Reference Point Indentation measurement of indentation depth gave values of 159 ± 12 μm for sharp tip and 151 ± 8 μm for blunt tip. Critical mechanical property values from testing were Young's Modulus of 10 GPa, Average Compressive Yield Strength of 89 MPa, and Average Tensile Yield Strength of 48 MPa. Finite element simulations using the mechanical property data were able to replicate indentation depth readings to within 10% for both tip geometries in this study.

These results help show the direct connection in cortical bone between indentation depth, measured through Reference Point Indentation, and important mechanical properties. We also can conclude that, up to a respectable degree, using a Drucker-Prager yield criterion is a reasonably accurate model to study the deformation in cortical bone, acknowledging the certain cracking and microfracture taking place and viewing them as a form of pseudo plasticity.

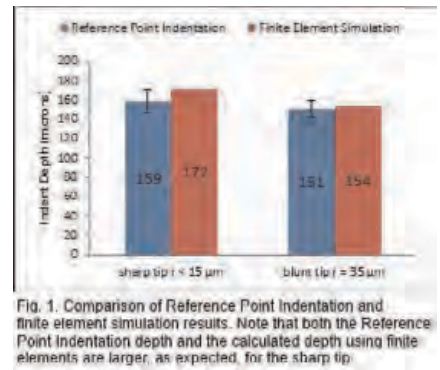

Fig. 1. Comparison of Reference Point Indentation and finite element simulation results. Note that both the Reference Point Indentation depth and the calculated depth using finite elements are larger, as expected, for the sharp tip

Mouse Femoral Neck Architecture Determined by MicroCT Reflects Skeletal Architecture Observed at Other Bone Sites. Robert Brommage*, Sabrina Jeter-Jones, Wendy Xiong, Rose Champ, Jeff Liu. Lexicon Pharmaceuticals, USA

Mouse femoral neck architecture is seldom examined in genetic, physiology and pharmacology studies. Using a Scanco μCT40, we developed a microCT scanning protocol providing reproducible values for total area (diameter), bone area, BV/TV and BS/BV. Careful positioning of the bones in the sample holder to obtain vertical orientation of the neck is critical. The entire neck (~150 slices) is scanned using 6 micrometer voxel dimensions, an X-ray tube voltage of 55 keV, a current of 145 microamperes, an integration time of 200 milliseconds and an analysis threshold of 240. From standard 2-D analysis, the slice having the lowest total area is identified. A 3-D analysis is performed using a total of 20 consecutive slices with the middle slice having the lowest total area in the 2-D analysis. To avoid subjective bias, no attempt is made to distinguish trabecular from cortical bone. Femoral neck architecture consistently reflects results from microCT analyses of LV5 vertebral body trabecular bone and midshaft femur cortical bone. Consistent with findings in femur shaft, femoral neck diameter is higher in male than female C57BL/6J mice and higher in C57BL/6J mice compared to 129SvEv and BALB/c mice. BV/TV declines as mice reach 2 years of age. Femoral neck diameter is elevated in Sost and Sfrp4 knockout (KO) mice but reduced in Lrp5 KO mice. BV/TV is increased, unaffected and reduced with KO of Sost, Lrp5 and Sfrp4, respectively. Reflecting increased trabecular but reduced cortical bone at other sites, femoral necks from Sfrp4 KOs show increased trabecularization, as indicated by a high BS/BV ratio. Bone loss with aging is greater in Sfrp4 KOs. Femoral neck BV/TV is reduced following ovariectomy but increased

with teriparatide treatment. Bones from mice undergoing spontaneous wheel running have increased BV/TV and diameter. Loss of BV/TV occurs during lactation and this loss is greatly increased when lactating rats are fed a low (0.1%) Ca diet. Dramatic gains in bone mass occur during the first 6 weeks post-lactation. These results demonstrate the feasibility of measuring bone mass and architecture in the mouse femoral neck. Several groups successfully determine mouse femoral neck breaking strength. Since this site is particularly important in human osteoporosis, the ability to assess femoral neck architecture in mice may provide insights on the efficacy of potential treatments.

MO0052

Notch1 and Notch2 receptors show opposite patterns of expression and differing effects on osteoblastogenesis in murine and human mesenchymal stem cells. Fengchang Zhu*, Kurt Hankenson, Michael Dishowitz, dereck dopkin, Patricia Mutyaba. University of Pennsylvania, USA

Our previous work has demonstrated that canonical Notch signaling, activated by the Jagged1 ligand, is potently induce osteogenic differentiation in human mesenchymal stem cells (hMSC). However, in stark contrast, canonical Notch signaling in murine MSC (mMSC) inhibits terminal osteoblast differentiation (F Zhu *et al*, *Stem Cells*, 2013 Feb). We hypothesized that this pronounced difference in osteoblastogenic response to canonical signaling could be associated with differing Notch receptor utilization in hMSC compared to mMSC.

We first investigated the expression of Notch1 and Notch 2 in multiple donor-lines of primary hMSC and mMSC using quantitative PCR. The results show that Notch2 expression level is 40-fold greater than Notch1 in undifferentiated hMSC, while in mMSC the expression level of Notch2 is much lower than that of Notch1 (0.15-fold decrease). This elevated Notch1 relative to Notch2 is similar in mouse cortical bone (0.2-fold Notch2 relative to Notch1); however, when bone is injured, during the course of healing, the levels of Notch2 increase relative to Notch1 temporally. Thus, the NICD2/NICD1 ratio is increased to 0.4 at day 5 post-fracture, 2.0 at day 10 post-fracture, and 4.0 at day 20 post-fracture.

Next we evaluated the impact of overexpressing the active intracellular domains of Notch1 (NICD1) and Notch2 (NICD2) in both primary mMSC and hMSC using retrovirus. NICD1 and NICD2 overexpression in either mMSC or hMSC significantly upregulated the canonical Notch target gene Hey1. Both NICD1 and NICD2 are sufficient to induce osteoblast gene expression and mineralization in hMSC. In contrast, overexpression of NICD1 inhibits osteoblast gene expression and mineralization in mMSC, while NICD2 overexpression in mMSC shows no negative effects on osteoblastogenesis.

Collectively, our study shows that Notch1 and Notch2 show opposite patterns of expression in primary mouse and human MSC. Particularly, Notch1 is dominant in mMSC while Notch2 is dominant in hMSC. During fracture healing in mice, Notch1 and Notch2 expression shift during the osteogenic phase of bone regeneration. Intriguingly, when NICD1 is overexpressed in mMSC, it has the same deleterious effect on osteoblastogenesis as we previously observed when mMSC were plated on Jagged1. This suggests that the Notch1 expression dominance in mMSC may limit osteoblastogenesis when cells are exposed to Jagged1.

MO0053

The Effect of Bone Tissue Ductility on Vertebral and Femoral Strength. Shashank Nawathe*[1], Haisheng Yang[1], Aaron Fields[2], Mary Bouxsein[3], Tony Keaveny[1]. [1]University Of California at Berkeley, USA, [2]University of California at San Fracisco, USA, [3]Beth Israel Deaconess Medical Center, USA

While the ability of bone tissue to deform in a ductile manner can decrease with aging and disease, the influence of tissue-level ductility on whole-bone strength, either at the hip or spine, remains poorly understood. Addressing this issue, we performed biomechanical testing and high-resolution micro-CT-based finite element analysis on 12 human thoracic (T9) vertebrae (mean ± SD, age 77 ± 11 years) and 14 human proximal femora (age 76 ± 10 years). The simulations enabled us to directly compare whole-bone strength for two hypothetical situations: fully ductile tissue behavior, in which the trabecular and cortical bone tissue can fail but never fracture (plastic-like behavior); and fully brittle behavior, in which the tissue fractures as soon as it begins to fail (glass-like behavior). Bones were first imaged at ~ 60 micron resolution and then mechanically tested to measure whole-bone strength (compression for the spine; fall loading for the hip). Using massively parallel, non-linear finite element analysis (~ 60 micron element size), we computed the whole-bone strength for compression loading for the spine, and both fall and stance loading for the hip. All analyses were done for two distinct cases of tissue-level post-yield failure behaviors: fully ductile vs. fully brittle. We found that when the assumed tissue-level failure behavior was changed from fully ductile to fully brittle, the whole-bone strength decreased by 40–60% (Figure). This negative effect on strength was relatively uniform across all specimens but at the hip was larger for fall than stance loading. Further, measures of whole-bone strength correlated well between experiment and model — both for the ductile and brittle simulations — despite for each simulation using the same tissue-level ductile or brittle material properties in all specimens (hip: ductile $R^2 = 0.90$, brittle $R^2 = 0.86$; spine: ductile $R^2 = 0.85$, brittle $R^2 = 0.87$). These results suggest that the general ability of bone tissue to deform in a fully ductile manner can substantially influence whole-bone strength. However, the strong correlation between experiment vs. model (brittle or ductile) suggests that typical between-person variations in tissue-level ductility may not be sufficiently large to appreciably alter whole-bone strength. This study therefore highlights the need to better characterize real population variations in tissue-level ductility and to determine the extent to which such variations affect overall strength.

The Optimization and Effect of a Platinum Catalyst on the Mechanical and Handling Properties of Novel Silorane Bone Cements while maintaining Osteogenic Capacity. Kathleen Kilway*[1], Rachel Weiler[1], Lianxiang Bi[1], J. David Eick[1], Bradley Miller[1], Thomas Schuman[2], Lynda Bonewald[1]. [1]University of Missouri – Kansas City, USA, [2]Missouri University of Science & Technology, USA

Commercially available bone cements, however widely used, still have issues, which include toxicity, high polymerization temperatures and shrinkage, all of which can be attributed to polymethylmethacrylate and its polymerization, a major component of bone cements. Our group has developed a novel biomaterial based on a silorane resin filled with modified glasses in order to address the negative attributes of commercialized bone cements previously listed. Our biomaterial also includes a four-component dual initiation system that contains Lamoreaux's catalyst (LMC) and does not require irradiation. We were able to improve the biomechanical properties by optimizing the amount of catalyst needed in the dual initiation system. We hypothesized that the more LMC used for the dual initiation system would result in very fast polymerization leading to a brittle material. On the other hand, a lower amount of LMC would result in a material that polymerized too slowly, if at all, resulting in a low strength material. We used two methods to test the mechanical properties of our material in a dry environment: the 4-pt bend test and a mimic of the traditional pull-out test. We also tested the biocompatibility using the Trypan Blue Assay.

The 4-pt bend was used to test the effect of amount of catalyst (0.46 vs. 0.60 wt%) on flexural strength and modulus on the resulting material. We found that the higher amount of catalyst affected the flexural strength (MPa) (M12-ECHE (0.46% LMC), 19.20±5.86; M12-ECHE (0.60% LMC), 23.27±12.03) but not the modulus (GPa) (M12-ECHE (0.46% LMC), 2.52±0.36; M12-ECHE (0.60% LMC), 2.61±0.54). Using a pull-out mimic test, we measured the strength (MPa) using a LMC range from 0.16 to 0.80 wt% (M12-ECHE (0.16% LMC), 5.71±0.42; M12-ECHE (0.32% LMC), 5.14±0.06; DY5-1TOSU (0.32% LMC), 3.77±0.18; DY5-1TOSU (0.56% LMC), 4.06±0.28; DY5-1TOSU (0.80% LMC), 0.79±0.07). It was found that pull-out strength was not only dependent on the amount of catalyst but also on the type of filler and its modification. These tests revealed that there is an optimal amount of catalyst needed to provide good biomechanical strength, 0.32 wt% of LMC, for the average formulation, independent of filler or filler modification.

The amount of LMC used did not significantly affect the biocompatibility (% dead cells) of our material (DY5-1TOSU (0.46% LMC), 2.9±0.8; DY5-1TOSU (0.80% LMC), 3.2±0.3) thereby maintaining bone cell function while improving mechanical strength.

MO0055

Thoracic vertebral fracture is associated with a localized increase in spine curvature at the fracture site that exceeds the observed increases in global thoracic kyphosis. Alexander Bruno*[1], Dennis Anderson[2], Brett Allaire[2], M. Clara De Paolis Kaluza[2], Douglas Kiel[3], Elizabeth Samelson[4], Mary Bouxsein[2]. [1]Harvard-MIT, USA, [2]Beth Israel Deaconess Medical Center, USA, [3]Hebrew SeniorLife, USA, [4]Hebrew SeniorLife, Harvard Medical School, USA

Prior studies have found an association between vertebral fracture (VF) and increased thoracic kyphosis (T4-T12 Cobb angle (CA)). However, the extent to which the presence of a VF directly increases curvature is unclear, given that hyperkyphosis in the absence of VF is common and likely caused by non-skeletal degeneration. In this study, we sought to determine: i) if the presence of a thoracic VF is associated with a *local* increase in curvature at the fracture site, and ii) whether this *local* increase in curvature accounts for any *global* increase in curvature (T4-T12 CA). We hypothesized that subjects with a single VF in the mid-thoracic region (T6-T8), but not outside this region, would have greater local curvature (T6-T8 CA) as well as greater global thoracic curvature (T4-T12 CA) relative to subjects with no thoracic VF, but that the curvature of the thoracic spine outside the local region would not differ between cases and controls. Subjects were selected from the Framingham Heart Study CT cohort. Cases were 13 men and 19 women with a single VF at T6, T7, or T8 (all VF were grade SQ1), but no other VF between T4 and T12. Controls were 359 men and 397 women with no VF between T4 and T12. The T4-T12 CA and the T6-T8 CA were measured on lateral CT scout views using SpineAnalyzer software (Optasia Medical), and the curvature outside the local VF region was calculated by subtracting the T6-T8 CA from the T4-T12 CA. Multiple regression analysis was used to test for differences between cases and controls in the total sample, and in men and women separately, after adjusting for age, height, and weight. Relative to controls, cases had a significantly higher T4-T12 CA ($36.4^\circ \pm 8.8^\circ$ vs $30.6^\circ \pm 8.9^\circ$, $P<0.05$), and a higher T6-T8 CA ($21.0^\circ \pm 5.0^\circ$ vs $13.7^\circ \pm 4.8^\circ$, $P<0.05$), but similar curvature outside the local region ($15.4^\circ \pm 7.3^\circ$ vs $16.9^\circ \pm 6.8^\circ$, $P=0.15$) (Table 1). The difference in local curvature between cases and controls was numerically greater than the difference in global curvature, indicating that the presence of a VF fully accounts for the greater T4-T12 CA in subjects with VF, and that the increased curvature is localized to the VF site. A trend toward lower curvature outside the local region in cases could indicate compensation for increased local curvature by straightening the remainder of the thoracic spine. In this case, the T4-T12 CA may underestimate the local effects of VF on curvature and mechanical loading of the spine.

Trabecular Plates Have Different Elastic Modulus and Tissue Mineral Density (TMD) from Trabecular Rods in Human Trabecular Bone. Eric Yu*[1], Ji Wang[1], Bin Zhou[1], Zhang Zhendong[2], X Guo[1]. [1]Columbia University, USA, [2]Department of Orthopedic Surgery, First Affiliated Hospital of the Medical College, China

Our previous studies have demonstrated that trabecular (Tb) plates play dominant roles in determining mechanical properties of Tb bone and osteoporosis is hallmarked by a remarkable conversion from Tb plates to rods. We have also observed that Tb plates have significantly higher TMD than Tb rods. However, mechanical properties of individual Tb plates and rods have not yet been measured and co-localized with TMD measurements. In this study, we hypothesized that Tb plates have different tissue elastic modulus than Tb rods and these microscopically determined tissue elastic moduli correlate with co-localized TMD.

Nine cylindrical human Tb bone samples from proximal femurs were imaged with five hydroxyapatite calibration phantoms at 25 μm using μCT (Scanco VivaCT40). Individual Tb plates and rods were segmented using individual trabecula segmentation (ITS) technique (Fig1.A). Samples were embedded and polished for micro-indentations. Microscopic images of the indentation surface were registered with 3D μCT image such that 12 indentation locations were selected for longitudinal plate (LP), transverse plate (TP), longitudinal rod (LR), and transverse rod (TR), respectively (Fig1.C). Microindentations were performed to determine tissue elastic modulus under wet condition. The point-by-point co-localized grayscale values of the μCT image at the indentation site were measured and converted to calculate TMD using calibration phantom (Fig1.D).

The Tb plate tissue modulus was significantly higher than that of Tb rods, which corresponded well with the significantly higher TMD in Tb plates ($p<0.001$, Fig. 2A). No significant differences in either the tissue modulus or TMD were detected between LP and TP. In contrast, modulus and TMD in TR were 28.7% and 19.4% lower than those in LR (*$p<0.001$, Fig.2B*). In addition, both tissue modulus and TMD in TP were significantly higher than those in TR (*$p<0.05$*). Furthermore, Tb tissue moduli determined by microindentation were strongly correlated with μCT measured TMD (*$R^2=0.58$*).

The study reported novel findings in mechanical properties of individual Tb plates and rods. The results suggest that Tb plates are not only distinctly different morphological elements in human Tb, but also have significantly different microscopic mechanical properties. Since Tb plates are the major biomechanical components in human Tb bone, these findings may have significant implications in osteoporosis and its related bone fragility.

Transitional Zones Displacement at the Subchondral Bone Layers in an Experimental Model of Osteoporosis and Osteoarthritis. Santos Castañeda*[1], David Guede[2], Jose R Caeiro[3], Jorge A Roman-Blas[4], Raquel Largo[5], Gabriel Herrero-Beaumont[5]. [1]Rheumatology Department, Hospital de la Princesa, IIS-Princesa, Spain, [2]Coordinator I+D+ i. Trabeculae, Empresa de Base Tecnológica, S.L., Spain, [3]Orthopaedic Surgery Department, Spain, [4]Bone & Joint Research Laboratory, IIS-FJD, Fundación Jiménez Díaz, Spain, [5]Bone & Joint Research Laboratory, IIS-FJD, Spain

INTRODUCTION: Subchondral bone (SB) plays a crucial role in osteoarthritis (OA) pathogenesis. In previous animal experiments, we have confirmed that increased SB remodeling may account for the aggravation of cartilage damage in OA rabbits with previous osteoporosis (OP).

OBJECTIVE: To analyze the microstructural characteristics of the different SB layers and transitional zones (TZ) at the SB in our OP-OA model in the rabbit.

METHODS: Experimental OA was induced in 12 female NZ white rabbits (8 months old; weight 3.5-5 kg) by anterior cruciate ligament transection and partial medial meniscectomy (OA knees) in the left knees. In 6 of them, OP was previously induced by bilateral oophorectomy and subsequent prednisolone administration 1 mg sc/kg/d for 5 wks (OPOA knees). Right knees of OPOA were used as OP knees, while right knees of OA group were used as healthy knees. After sacrifice, cylindrical samples of SB (4 mm in diameter by 9 mm in length) were extracted from femoral condyles. The microarchitectural characteristics of the samples were studied using micro-CT with a SkyScan 1172 (Bruker micro-CT NV). Statistical analysis was performed using the Kruskal-Wallis H test and post-hoc analysis by Dunn's test.

RESULTS: According to the bone area fraction (B.Ar/T.Ar) profile, 3 SB layers were characterized: the SB plate, a dense trabecular bone of mixed characteristics (trabecular SB) and the subarticular trabecular bone. Furthermore, 2 different TZ between these 3 layers could be distinguished. Decreased thickness of SB plate was seen in both OP and OA knees with respect to healthy knees ($p<0.05$ in both cases). OPOA group revealed a deeper reduction of SB plate thickness vs. other groups ($p<0.05$). Other variables analyzed, such as Tb.Th, Tb.Sp, Tb.N, polar moment of inertia and Tb.Pf showed the same behavior. The dispersion curves of these parameters showed a consistent displacement of the TZ toward the joint surface in all experimental groups.

CONCLUSIONS: These data confirm the existence of at least 3 different microstructural layers at SB and 2 different TZ between them. Furthermore, there was a concordant TZ displacement toward more superficial areas, transforming the biomechanic properties of SB, that might partially explain the OA aggravation in rabbits with previous OP. These findings could be of great interest for future therapeutic approach of patients with OA and associated OP.

Effects of Spaceflight and Sclerostin Antibody on Femoral Neck Strength in Estimated by Finite Element Analysis in Mice flown on Space Shuttle Flight STS-135. Lindsay Sullivan*[1], Alicia Ortega[2], Ted Bateman[3], Andrea Hanson[4], Eric Livingston[1], Travis Pruitt[5], Colin Smith[6], Angelica de Rosa[1], Eric Lai[1], Louis Stodieck[7], Laura Bowman[8], Rachel Ellman[9], Jordan Spatz[10], Kelly Warmington[11], HL Tan[11], Dave Hill[11], Rachel Paietta[2], Andrew Cureton[2], Chris Paszty[11], Mary Bouxsein[9], Virginia Ferguson[7], Anthony Lau[8]. [1]University of North Carolina-Chapel Hill-Biomedical Engineering, USA, [2]University of Colorado-Boulder-BioServe/ Department of Mechanical Engineering, USA, [3]Univesity of North Carolina, USA, [4]Wyle Science, Technology & Engineering Group, USA, [5]Clemson Universeity, USA, [6]North Carolina State University-Department of Mechanical & Aerospace Engineering, USA, [7]University of Colorado, USA, [8]University of North Carolina at Chapel Hill, USA, [9]Beth Israel Deaconess Medical Center, USA, [10]Harvard-MIT Division of Health Sciences & Technology (HST), USA, [11]Amgen Inc, USA

Skeletal unloading during spaceflight reduces bone volume and bone mineral density; however, how this loss translates to functional changes in strength and stiffness in the proximal femur is not well understood. This study uses finite element modeling (FEM) that replicates mechanical testing of the femoral neck in mice flown on STS-135 to assess changes in bone stiffness from spaceflight and sclerostin antibody (Scl-Ab).

Thirty mice were flown on Space Shuttle Flight STS-135 for 13-days (FL). Half the mice were treated with vehicle (n=15) and half were treated with a Scl-Ab (n=15). Corresponding ground control (GC) groups were similarly treated. In this study, subject specific FE models were meshed from microCT images from the same mice (down sampled from 10 to 20μm resolution) for a 3.25mm segment of the proximal femur, which was taken from the top of the femoral head. Bone was segmented using the identical threshold previously used in the microCT analysis of the STS-135 femurs. All bone elements were modeled as linear elastic (E=10GPa, ν=0.3). A downward displacement of 50μm was applied to the entire femoral head (Figure) and the femoral neck bending stiffness was calculated from the measured load at 50μm.

FEM of the proximal femur found a 10% decrease in stiffness in the FL mice compared to the GC mice. Scl-Ab treatment resulted in an increased stiffness by 20% in the FL and 23% in the GC. Linear regression found significant correlations ($P<0.01$) between the FEM stiffness and the femoral neck stiffness, fracture load, and force at max load found from mechanical testing. While the FEM correlated well with the mechanical testing, the absolute stiffness values from FEM were greater than those obtained with mechanical testing. These results are expected because the mechanical testing configuration causes large deformations of the femoral head, including a 2 mm tall region directly underlying the greater trochanter, when it loads the femoral neck. This deformation did not occur in the FEM because of the boundary conditions used (Figure).

Conclusion: The unloading environment of microgravity caused a significant loss of femoral neck stiffness in the proximal femur. Scl-Ab prevented the loss of bone strength, and increased femoral neck stiffness in both FL and GC mice. FEM had significant correlation to the previously performed mechanical testing, which makes it a viable alternative to mechanical testing, especially with complex boundary conditions.

Finite Element Analysis of the Dynamically Loaded Mouse Forearm. Ganesh Thiagarajan*[1], Yunkai Lu[1], Mark Dallas[1], Mark Johnson[2]. [1]University of Missouri - Kansas City, USA, [2]University of Missouri, Kansas City Dental School, USA

The mouse forearm compression loading model is widely used to study bone formation in response to mechanical loading. Using standard finite element analysis (FEA) models with uniform strain field distributions, no correlation in magnitude or type of strain and β-catenin signaling in a subpopulation of osteocytes within 1 hour of loading. Therefore, we built models incorporating osteocyte lacuni into the matrix of the ulna and radius and performed simultaneous strain gaging of both the ulna and radius. In addition we have included loading caps that are used in *in vivo* loading for the numerical analysis, and simulated dynamic loading in our computer based numerical studies. Segmented images obtained from microCT of the mouse forearm were imported into GeoMagic Studio 9 and FEA meshes were created using automated tetrahedron mesh creation software (ABAQUS CAE). Mesh convergence was investigated using both 4- and 10-node tetrahedrons. Contact boundary conditions at the wrist and olecranon were included in the model with caps to simulate the experimental loading. Displacement and strain contours resulting from simulated loads of 2 N/3.5 N at 2 Hz/0.2 Hz were calculated using LS-DYNA and compared with experimental values. The maximal compressive strain on the ulna was found to occur at about 3.5 mm from the distal end and on the radius, about 2.5 mm from the proximal end. The magnitude of the maximal compressive strain under dynamic load of 2 N was around 5200 με for the ulna and 1750 με for the radius. These values were much higher than their counterparts (2000 με in the ulna and 1650 με in the radius under 2 N load) using static analysis in which static load with the same magnitude was applied. Under dynamic load of 3.5 N, the corresponding magnitudes increased to 9700 με for the ulna and 3700 με for the radius. In the dynamic models using 4-node tetrahedrons, 72% of the total applied load was sustained by the ulna while only 65% of the load was carried by the ulna in the corresponding static model. These data show that the dynamic ulna/radius FEA model is a superior approach to traditional static models. These models predict a very heterogeneous pattern of strain distributions and are being used to determine the biological strain thresholds required for β-catenin signaling in osteocytes in response to mechanical loading.

FSTL3 Mediates Exercise Driven Bone Formation. Sudha Agarwal[1], Derrick Knapik*[2], Alisa Blazek[2], Beth Lee[3], Lai-Chu Wu[2], JIn Nam[4]. [1]The Ohio State University, USA, [2]Wexner Medical center Ohio State University, USA, [3]Department of Physiology & Cell BiologyOhio State University, USA, [4]University of California at Riverside, USA

Introduction. Exercise promotes bone remodeling, a process involving bone resorption and bone deposition. How exercise drives mechanoresponsive bone remodeling is still elusive. Here, we provide evidence that Follistatin-like3 (*Fstl3*) could be a mechanosensitive protein that takes part in exercise-driven bone formation. Methods: Wild-type rats/mice and FSTL3-/- mice were exercised by treadmill walking (TW) and following 0, 2, 5 or 15 days of exercise, sacrificed and distal femurs analyzed by qrtPCR, Western blots, or immunohistochemistry. Bone mineral apposition rates (MAR) of mice were assessed using Calcein and Alizarin complexones injected on day 3 and 12, respectively. On day 15, femurs were excised, sectioned, and subjected to fluorescence microscopy to examine bone remodeling. Statistical analysis was performed by one-way ANOVA with Tukey's post hoc or T-test. Results: TW dramatically stimulated a ~6 fold increase in *Fstl3* mRNA expression in trabecular bone and bone marrow cells on day 2 and declining by day 5. A robust increase in *Fstl3* was observed in osteocalcin positive cells adjacent to trabecular bone and in osteocytes present in the trabecular bone. *Fstl3*+/+ or *Fstl3*-/- mice subjected to TW for 15 consecutive days and injected with Calcein and Alizarin, revealed significant increase in bone deposition on the endosteal surface of the femur and increase in the total MAR. However, bone deposition in both groups of non-exercised controls was limited. Similar treatment failed to induce exercise-induced bone formation and MAR increase in *Fstl3*-/- mice. *Fstl3*-/- mice also exhibited weaker and brittle femurs and tibias. FSTL3 treatment of osteoblasts induced a rapid and transient induction of BMP-7 and BMP-2 in WT but not in *Fstl3*-/- mice. Conclusions: Our data suggest that *Fstl3* is a novel molecule identified that might be critical for load driven bone formation and strengthening. This is evident by observations that genomic deletion of *Fstl3* abolishes load-dependent bone formation, weakening bones with failure to upregulate genes associated with bone deposition. The identification of *Fstl3* as a mechanoresponsive protein provides a new paradigm for investigating exercise-driven bone formation and to understand bone diseases.

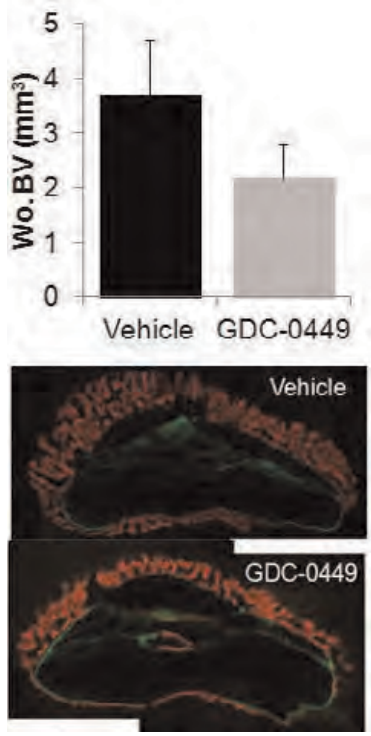
Hedgehog pathway inhibitor GDC-0449 impairs the woven bone healing response to stress fractures in the rat ulna. Jennifer McKenzie*[1], Nikolas Kazmers[1], Fanxin Long[2], Matthew Silva[3]. [1]Washington University in St. Louis, USA, [2]Washington University School of Medicine, USA, [3]Washington University in St. Louis School of Medicine, USA

Hedgehog signaling (Hh) is critical in developmental osteogenesis, and more recent studies suggest it is also involved in regulating osteogenic gene expression in the post-natal setting. However, there is a void of studies directly assessing the effect of Hh inhibition on post-natal osteogenesis. In this study we utilized our previously-described, ulnar stress fracture model (WBF loading) to induce woven bone formation in adult rats. Our objectives were to characterize the temporal profile of Hh signaling after WBF loading and to determine whether Hh signaling contributes to osteogenesis during stress fracture healing. Following creation of a stress fracture by cyclic forelimb compression, rats (F344 males, 5 months age) were given GDC-0449 (Vismodegib, 50mg/kg orally twice daily), a small molecule compound that selectively inhibits the Hh pathway by binding to the smoothened receptor, or vehicle. Based on qPCR assessment of Gli1 and Ptch1 gene expression, upregulation of Hh signaling was noted in vehicle-treated ulnae 72h after WBF loading (Gli1 increased by 31%, Ptch1 increased by 41%), with respect to the contralateral non-loaded ulna. Treatment with Hh inhibitor GDC-0449 significantly decreased Hh signaling 72h after loading; Gli1 and Ptch1 expression decreased to 5.8% and 20.1%, respectively, of vehicle expression levels. Expression of Hh ligands Dhh, Ihh and Shh were unchanged in response to GDC-0449 at 24h, but Shh expression was decreased by 26.4% at 72h ($p<0.05$). Hh inhibition decreased the woven bone callus volume (4.21 vs 2.64 mm^3, $p<0.05$) and density (367 vs 314 mg HA/cm^3, $p<0.05$) as measured by microCT 7 days after WBF loading (Figure). Importantly, stress fracture crack length did not differ between the two groups, indicating equivalent levels of damage. Dynamic histomorphometry revealed that the day 7 callus was composed predominately of woven bone in both the vehicle and inhibition groups (Figure). Furthermore, lamellar bone formation was also inhibited by GDC-0449. Analysis of lamellar bone from the loaded limb (directly adjacent to the woven bone callus) revealed a significant decrease in mineral apposition rate (3.13 vs 2.60 micron/day, $p<0.05$). In the non-loaded limb there was a significant decrease in mineralizing surface (49 vs 37%, $p<0.05$), indicating Hh signaling was required for normal bone modeling. In conclusion, Hh signaling plays an important role in post-natal bone formation in the setting of stress fracture healing.



Hh inhibition with GDC-0449 treatment impairs stress fracture healing.

MO0062

Response and Adaption of Bone Cells to Mechanical Stimulation. Airong Qian*, Hu Lifang, Wang Yang, Shang Peng. Northwestern Polytechnical University, China

Mechanical stimulation is necessary for bone growth and development. Bone loss is a negative balance course especially occurred after long-term space flight for astronauts under weightlessness [1]. Bone remodeling is a dynamic process that requires the coordinated interaction of osteocytes, osteoblasts, and osteoclasts, collaborating in basic multicellular units (BMUs)[2].

In this study, we investigated the effects of different mechanical stimulation, including diamagnetic levitation, random position machine (RPM) or different substrate stiffness on proliferation, morphology, mineralization, cytoskeleton architecture, cell cycle and apoptosis in bone cells (Osteocytes MLO-Y4 and osteoblasts MC3T3-E1) and its mechanism.

The results showed that diamagnetic levitation or RPM condition significantly affected osteoblast proliferation, morphology, mineralization, cytoskeleton and Ca2+/Calmodulin. 24 h treatment of simulated microgravity (SM) significantly inhibited the mineralized nodules formation compared with 1 g condition. In addition, the alkaline phosphatase (ALP) activity was significantly decreased and the expression of OC, Col Iα1 and DMP1 was all down-regulated by 24 h treatment of simulated microgravity. Diamagnetic levitation or RPM condition also influenced osteocyte morphology, cytoskeleton related proteins distribution and expression, and induced cytoskeleton reorganizing and apoptosis. Conditioned medium (CM) of osteocytes cultured in RPM for 48h stimulated proliferation of MC3T3-E1 cells. Cell spread area was inhibited in MC3T3-E1 cells cultured on soft substrate and soft substrate was not conducive to MC3T3-E1 cells proliferation and mineralization.

Our findings indicate that the morphology, cytoskeleton and functions of bone cells are changed under diamagnetic levitation, RPM or different substrate stiffness conditions. It suggests that bone cells are sensitive to alteration of mechanical environment.

The Ability of Human Mesenchymal Stem Cells to Differentiate between Vertical and Horizontal Vibrations in Vitro Depends on the Intensity of the Signals. Suphannee Pongkitwitoon*, Stefan Judex. Stony Brook University, USA

Vibrations can serve as a growth factor to the skeleton but the underlying mechanisms have not been elucidated. In vitro studies have demonstrated that both vertical and horizontal vibrations can be sensed in 2D cell cultures but it is unknown whether cells are preferentially sensitive to one loading direction and whether interactions between the two loading directions may exist. Considering that the mechanical environment of cells in the culture dish is directly dependent on the direction of the applied vibration, data on loading direction sensitivity may provide important cues about a physical transduction mechanism. Here, we exposed human mesenchymal stem cells (hMSCs) to either horizontal, vertical, or a combination of horizontal and vertical vibrations and hypothesized that the efficacy of horizontal and vertical vibrations to enhance mineralization is similar. This hypothesis was tested with two different signal combinations; 30Hz at 1g and 100Hz at 0.15g. These two combinations were selected to produce low shear (0.04Pa at 100Hz/0.15g) and high shear (0.94Pa 30Hz/1g) during horizontal vibrations. During vertical vibrations, shear is at least 10-fold smaller for both mechanical signals due to the restricted motion of the fluid. Osteogenesis was induced in hMSCs and cells were exposed to 30min of either vertical, horizontal, or 15min of vertical followed by 15min of horizontal vibrations. After 16d of 30Hz/1g vibrations, levels of mineralization were 3.7-fold greater in all experimental groups independent of loading direction. In contrast to the 30Hz/1g signal, loading direction played a role in the increase in mineralization in the 100Hz/0.15g group. While vertically vibrated cells experienced a 2.2-fold increase in mineralization, horizontal vibration generated a 3.8-fold increase ($p<0.05$). Interestingly, the combination of horizontal and vertical vibrations further enhanced the levels of mineralization (4.2-fold, $p<0.05$). These data demonstrate that vibration direction can influence ossification at specific signal combinations. Considering the similarity in increased mineralization between groups with greatly different levels of shear, they also emphasize that shear per se did not influence mineralization. The temporal sequence of vertical and horizontal vibrations produced the greatest increase in mineralization under low-intensity (shear) conditions may suggest that mechanotransduction may not be identical between horizontal and vertical vibrations.

Vibrations Increase Osteocyte Gap Junctional Communication Independent of the Level of Fluid Shear. Gunes Uzer*[1], M. Ete Chan[2], Suphannee Pongkitwitoon[2], Stefan Judex[2]. [1]University of North Carolina, USA, [2]Stony Brook University, USA

When applied at high frequencies, bone can sense and respond to mechanical signals of extremely small magnitude. However, the mechanical cues regulating the vibration response are yet to be identified. Computational studies revealed that during the application of vibrations, cell populations within the bone will be subjected not only to acceleratory motions but also to fluid shear as a result of fluid-cell interactions at the bone surface. Mechanosensitive osteocytes can sense local mechanical signals within bone and communicate with other cells, in-part through gap junctions that connect intracellular domains of adjacent cells. Here, we hypothesized that vibrations will increase osteocyte gap junctional intracellular communication (GJIC) and will not require fluid shear as a mechanical input. Applied vibration parameters were selected to vary accelerations between 0.15g to 1g and frequencies between 30Hz to 100Hz, thereby creating fluid shear stresses between 0.04 and 0.94Pa. Osteocyte like MLO-Y4 cells were vibrated at four different vibration frequency/acceleration combinations and the role of fluid shear on GJIC was investigated by parachuting calcein stained donor cells onto unstained osteocytes. All four vibration treatments showed significantly increased GJIC between osteocytes with the largest increase in the 30Hz-1g group ($33.2\% \pm 4.9$, $p<0.001$). Interestingly, increases in GJIC were not different between the four distinct vibration groups despite the large differences in generated fluid shear, suggesting that vibration induced fluid shear does not serve as critical regulatory input. Blocking connexin 43 (Cx43) function with 18α-GA effectively blocked GJIC ($p<0.0001$). In contrast, vibrations did not alter Cx43 mRNA expression levels indicating that vibrations modulate Cx43 function but not its transcription. Spatially enhanced cellular communication was further demonstrated by the greater distance of calcein stained cells from donor cells after vibration treatment. Our data show that vibrations affected GJIC independent of fluid shear stress by directly modulating gap junction function but the specific mechanism by which vibrations can alter Cx43 function is yet to be identified. By not only activating cell mechanotransduction but also providing increased communication between cells, vibrations may have the potential to enhance the efficacy of anabolic signals in bone.

Effect of Body Size on the Quantification of Bone Mineral Density From QCT Images Using a Novel Anthropomorphic Hip Phantom. Serena Bonaretti*[1], Isra Saeed[2], Andrew Burghardt[1], Lifeng Yu[3], Michael Bruesewitz[3], Sundeep Khosla[4], Thomas Lang[1]. [1]University of California, San Francisco, USA, [2]UC San Francisco, USA, [3]Mayo Clinic, USA, [4]Mayo Clinic College of Medicine, USA

Beam hardening associated with variations in body size and skeletal density affect the measurements of bone mineral density (BMD) from quantitative computed tomography (QCT) images. In this study we aimed at evaluating the effect of body size on BMD quantification using a novel anthropomorphic hip phantom, evaluating four CT scanners at two centers.

The hip phantom consists of anthropomorphic hips and pelvis of known amount of hydroxyapatite-equivalent material. The two hips have different neck compositions. One hip contains a *calibration* neck made of three concentric cylinders, with densities spanning typical values of integral, cortical and trabecular compartments. The other hip contains a *test* neck made of an outer ellpise for cortical bone, and an inner cylinder for trabecular bone. Two *test* necks were created, one representing the BMD of a young subject, and the other simulating the BMD of an old subject. Each *test* neck was associated to correspondent pelvis-shaped elements, i.e. with higher density for the young subject and with lower density for the old subject. Hips and pelvis are positioned in a tank filled with water, and which represents the dimensions of a small adult female. Two different girdles can be placed concentrically over the tank, creating a maximum body size that corresponds to a 95% adult male (Figure 1).

We scanned the phantom in four different scanners, two GE VCT 64 systems, one Siemens Biograph and one Siemens Definition. For each machine, the phantom was scanned in 6 different configurations, i.e. combining young/old neck with no/small/large girdle. Each acquisition was performed with a calibration standard underneath the phantoms, used to calibrate the acquired image to units of hydroxyapatite concentration. We measured the cortical BMD of the test neck, and the linear slope relating the nominal BMD of the concentric rings of the calibration neck to the measured values.

For each scanner, we found that the BMD measures in the test femoral neck systematically decreased with increasing phantom size (Table 1), and that the slope measured from the calibration neck systematically increased with increasing phantom size (Figure 2).In conclusion, our phantom simulation shed light on the quantitative effects of beam hardening due to increasing body size. Methodological studies in this area will be important for using QCT to understand the effect of obesity and weight loss on skeletal health.

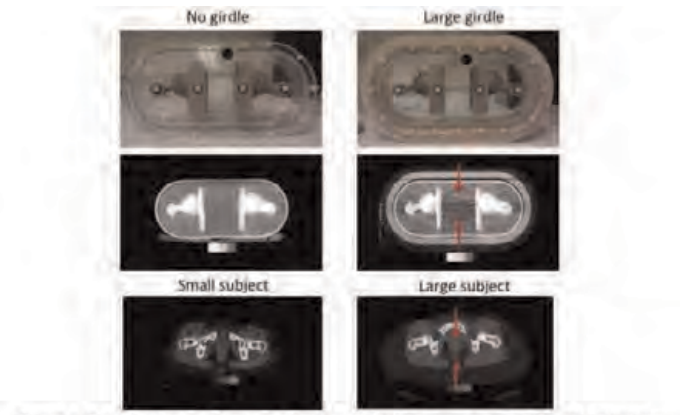

Figure 1. Beam hardening effects on phantom and subject images with different body size. The first row shows the phantom without and with large ring, and the second row shows the corresponding CT images acquired for the two phantom configurations. The final row shows images of larger and smaller subjects. In the CT images of large girdle phantom and fat subject, the beam hardening effect is visible between the two hips.

Figure 1

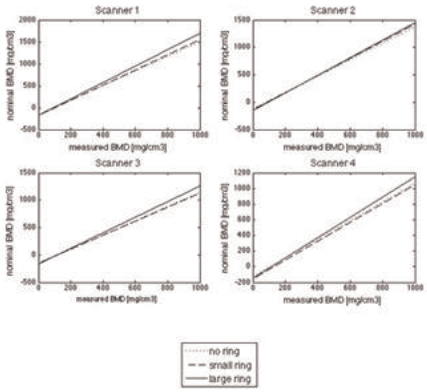

Fig. 2 Calibration line for the *test* neck of the young configuration for the four different scanners. The slope of the calibration line systematically increases with increasing phantom size.

Figure 2

	no ring [mg/cm³]	small ring [mg/cm³]	large ring [mg/cm³]
Scanner 1	430.53	374.60	312.43
Scanner 2	443.61	416.11	405.80
Scanner 3	553.83	528.91	460.22
Scanner 4	579.05	561.97	487.19

Pre- and post-yield mechanical properties are altered in multiple myeloma patients with fractures as assessed by qCT-based finite element models of the vertebral body. Graeme Campbell*[1], Sarah Giravent[2], Christian Graeff[3], Claus-C Glueer[1]. [1]Christian-Albrechts Universität zu Kiel, Germany, [2]Universitätsklinikum Schleswig-Holstein, Germany, [3]University Clinic Schleswig-Holstein, Germany

Multiple myeloma (MM) is associated with bone destruction and high fracture incidence. Surgical necessity is currently determined by the examination of lesion size or number, but this does not consider bone biomechanics. Nonlinear finite element (FE) models simulate mechanical loading and examine both the pre- and post-yield behavior of the bone structure, which may give a more reliable prediction of fracture risk. The purpose of this study was to test the hypothesis that biomechanical properties of the vertebrae, as assessed by non-linear QCT-based FE models, can distinguish between groups of MM patients with and without fracture.

Quantitative computed tomography (QCT) scans of the thoracic vertebrae were evaluated in 48 MM patients, 23 with fracture and 25 without. In-house software was used to generate FE meshes with isotropic tetrahedral elements from the images. The elemental stiffness, yield stress and post-yield behavior were calculated from the local BMD according to relations from Keyak et. al., 1998. Uniaxial compression was simulated (Calculix v.2.5, www.calculix.de) to 1mm and the reaction force-displacement data was determined. The apparent level stiffness, yield and ultimate load and work to yield and failure were calculated. T-tests were used to compare the mechanical parameters between fracture and non-fracture groups. Standardized Odds Ratios (ORs) normalized to standard deviation (SD) and adjusted for age as well as 95% confidence intervals were determined.

Significant reductions in vertebral body stiffness (-23%, p=0.013), yield load (-36%, p=0.003), ultimate load (-35%, p=0.004), work to yield (-48%, p=0.002), and work to failure (-43%, p=0.006) were observed in the fracture compared to non-fracture group. The age-adjusted logistic regression revealed an OR per SD of 2.13 (1.05-4.33) for stiffness, 2.75 (1.24-6.12) for yield load, 2.65 (1.20-5.84) for ultimate load, 3.37 (1.33-8.51) for work to yield, and 2.80 (1.18-6.68) for work to failure.

Reductions in the mechanical properties determined by nonlinear FE were associated with fracture prevalence. These properties had significant Odds Ratios, indicating that FE methods, in particular those that simulate yield and post-yield behavior, may give insight into the susceptibility of fracture in MM patients. Future work will examine prospective datasets to determine the ability of this model to predict fracture.Keyak, J. H., et al. (1998). *J Biomech*, *31*(2), 125–133.

Quantitative 3D microcrack imaging for weak and strong bones assessed by reference point indentation. Philipp Schneider*[1], Paul Hansma[2], Connor Randall[3], Ralph Müller[4]. [1]Institute for Biomechanics, ETH Zurich, Switzerland, [2]University of California, Santa Barbara, USA, [3]Department of Physics, University of California at Santa Barbara, USA, [4]ETH Zurich, Institute for Biomechanics, Switzerland

Recently, reference point indentation (RPI) has been introduced for microindentation of human bone [1], which allows *in vivo* assessment of bone mechanical properties at the tissue level, for instance by the indentation distance increase (IDI). Moreover, RPI can discriminate between patients with and without fractures [2]. It was suggested that this ability of RPI to detect bone fragility differences is due to a negative correlation between IDI and crack growth toughness [2] measuring bone's crack-growth resistance. However, there is a lack of microcrack characterization close to the indentation site for bones of distinct IDI. Therefore, the aim of the study was to assess and quantify microcracks in 3D close to the indentation site for weak and strong bones with high and low IDI, respectively. Cylindrical human bone biopsies (diameter = 1.7 mm) were obtained from the tibial midshaft of two male donors (74 and 23 y/o) with high and low IDI, respectively. Specimens were assessed at the TOMCAT beamline of the Swiss Light Source using synchrotron radiation-based computed tomography (SR CT) at a voxel size of 740 nm for quantitative morphometry of the intracortical bone microstructure [3]. Microcracks, canals, and osteocyte lacunae were quantified by crack volume density (Cr.V/Ct.TV), lacuna volume and number density (Lc.V/Ct.TV and N.Lc/Ct.TV) as well as mean lacuna volume (<Lc.V>) [4]. 3D views of the bone tissue after indentation and morphometric results are provided in Figure 1 and Table 1. Cr.V/Ct.TV was more than five times smaller for high IDI vs. low IDI, where more (N.Lc/Ct.TV) and smaller (<Lc.V>) lacunae were found at comparable Lc.V/Ct.TV. The decreased crack formation for weaker vs. stronger bones (higher vs. lower IDI) is against our expectations to find more microcracks in weaker bones, commonly associated with reduced crack-growth resistance [2]. It may be that the microcracking around the indentation site is actually a way that stronger bone distributes the indentation energy to a greater volume of bone and thus, leaving less energy to deepen the indentation. To clarify the relation between bone fragility, microindentation results, and microcrack behavior, further biomechanical imaging studies are needed, which combine RPI and high-resolution 3D imaging, such as SR CT.

Relationships of Bone Stiffness, Bone Structure, Muscle, and Fat. Edward Colt*[1], Muhammad Akram[2], Xavier Pi Sunyer[2]. [1]Columbia University & St. Luke's-Roosevelt Hospital, USA, [2]Columbia University, USA

This study was done to see how increasing BMI affects bone structure and stiffnes smeasured by high resolution peripheral quantitative computerized tomography (HR-pQCT) of the ankle and wrist. We studied 49 healthy pre-menopausal women aged 18 – 45 - BMI from 18 to 47; they were also studied by whole body DXA. Stiffness of the wrist and ankle was estimated from HR-pQCT by finite element analysis (FEA). The correlation of BMD measured by DXA with BMI was higher than the correlation of bone density parameters measured by HR-pQCT with BMI – which were non-significant. There were high correlations of geometric parameters measured by HR-pQCT with BMI. BMD of the tibia measured by DXA was correlated with fat (r = 0.57) and muscle (r = 0.57) in the legs. BMD of the radius was correlated with fat (r = 0.82) and with muscle (r = 0.83) in the arms. There were correlations of bone cross sectional area with fat and muscle around the tibia (r = 0.49 and r = 0.67) and the radius (0.47 and 0.63). The highest correlations of bone stiffness were with trabecular bone volume fraction in the tibia (r = 0.76) and radius (r = 0.73) . Stiffness of the tibia and radius were correlated ($p < 0.001$) with several parameters in both radius and tibia, including sl area, trabecular thickness, BMD, muscle, fat, average bone density by HR-pQCT, weight (W), and BMI. Geometry changed with increasing obesity – differently in the tibia compared with the radius, suggesting that weight bearing may have effects on bone stiffness independent of obesity.

CONCLUSION: Bone stiffness at the wrist and ankle was correlated with muscle and fat in the extremities. Increasing obesity was associated with increased muscle around both tibia and radius. Bone stiffness of the tibia and radius was more highly correlated with the amount of muscle than with the amount of fat around the bone. It seems likely that in our population there muscle, fat, and bone are inherited together; Livshits et al found that 6 genomic variants were most likely associated with body mass as a composite phenotype. Thus our findings might be one reason that fractures are less common in obese than in lean subjects. We found no correlation between bone density measured by HR-pQCT and BMD measured by DXA. BMD measured by DXA is influenced by the amount of soft tissue (muscle and fat) around and within the bone.

Risedronate Slows or Partly Reverses Microarchitecture Deterioration Depending on Whether Remodelling Is Perturbed or in Steady State. Yohann Bala*[1], Roland Chapurlat[2], Dieter Felsenberg[3], Thierry Thomas[4], Michel Laroche[5], Edward Morris[6], Jose Ruben Zanchetta[7], Angela M. Cheung[8], Ali Ghasem-Zadeh[9], Roger Zebaze[9], Ego Seeman[9], Rene Rizzoli[10]. [1]University of Melbourne, Dept. of Medicine, Australia, [2]E. Herriot Hospital, France, [3]Charité - Campus Benjamin Franklin, Germany, [4]Hôpital Nord - CHU de St-Etienne, France, [5]Centre de Rhumatologie, CHU Purpan, France, [6]Department of Obstetrics & Gynaecology, Norfolk & Norwich University Hospitals, United Kingdom, [7]Instituto de Investigaciones Metabolicas (IDIM), Argentina, [8]University Health Network-University of Toronto, Canada, [9]Austin Health, University of Melbourne, Australia, [10]Geneva University Hospitals & Faculty of Medicine, Switzerland

In young adulthood, remodelling is slow and in steady state; equal numbers of basic multicellular units (BMUs) excavate and refill on the endosteal surface. Remodelling is balanced; equal bone volumes are excavated and replaced by each BMU. In early menopause, steady state is perturbed, remodelling rate increases, the number of resorbing BMUs increases and exceeds the low number now refilling (activated before menopause). BMU balance becomes negative so bone loss accelerates. Later, steady state is restored at a high remodelling rate; the numbers of BMUs resorbing and filling again is equal but the negative BMU balance causes bone loss but more slowly than in early menopause (Figure). We hypothesized that risedronate slows structural deterioration when administered in early menopause and partly reverses it later.

Risedronate (RIS, 35 mg/week) or placebo (PLB) were given to younger (Group 1, n=161: 53 yr, range: 44-55) and older (Group 2, n=163, 61yr, range: 55-76) postmenopausal women, in a double blind placebo controlled study with 2:1 randomization. High resolution-peripheral computed tomography was used to measure distal tibia and radius volumetric bone mineral density (vBMD, g/cm^3) and cortical porosity (%) quantified using StrAx 1.0[1].

At the distal tibia, in group 1, PLB had a $1.1 \pm 0.4\%$ (p=0.007) decrease in cortical vBMD due to a $3.4 \pm 0.9\%$ (p=0.001) increase in compact-appearing cortex porosity. RIS blunted the decrease in cortical vBMD and blunted the increase in porosity by 60%, (p=0.06 vs. PLB). In group 2, there were no changes in PLB. RIS increased cortical vBMD by $0.5 \pm 0.2\%$ (p=0.007 vs. PLB) and trabecular vBMD by $0.4 \pm 0.2\%$ relative to baseline (NS vs. PLB) and decreased cortical porosity by $0.7 \pm 0.3\%$ relative to baseline (p=0.005 vs. PLB). Trends were similar at the distal radius.

Risedronate slows the appearance of porosity in compact cortex following menopause and partly reverses it in older women. These changes likely account for the anti-vertebral and non-vertebral fracture efficacy of risedronate.

Trabecular Plate Deficiencies in Young Men Infected with HIV Early in Life. Bin Zhou*[1], Michael Yin[1], Stephen Arpadi[2], Ji Wang[1], Kyle Nishiyama[1], Emily Broun[2], Jayesh Shah[2], Chiyuan Zhang[1], Marc Foca[2], Natalie Neu[2], John Nelson[2], David Bell[2], Elizabeth Shane[3], X Guo[1]. [1]Columbia University, USA, [2]Columbia University Medical Center, USA, [3]Columbia University College of Physicians & Surgeons, USA

HIV infection and antiretroviral therapy early in life may result in inadequate bone acquisition and abnormal bone microarchitecture, which contributes to bone strength. We conducted a cross-sectional study using high-resolution peripheral quantitative CT (HRpQCT) at the distal radius and tibia in 30 HIV-infected and 15 HIV-uninfected black or Latino Tanner stage 5 men aged 20-25 years. Among HIV-infected men, 15 were perinatally-infected, 15 were infected during adolescence, and all were on stabile antiretroviral regimens. Standard HRpQCT evaluation protocols were used to analyze geometric and microstructural parameters including cortical porosity. Individual trabecula segmentation (ITS) morphological technique was applied to segment trabecular bone network into individual trabecular plates and rods and to examine in-depth the microstructural characteristics. We also estimated bone stiffness using micro finite element analysis. Cross-sectional area and cortical porosity did not differ between the two groups at the radius or tibia. Total vBMD, trabecular vBMD, and cortical thickness were 6-19% lower in the HIV-infected at both sites ($p<0.05$). By ITS analysis, plate bone volume fraction (pBV/TV), plate-rod ratio (PR ratio), plate number (pTb.N), plate thickness (pTb.Th), plate surface (pTb.S), plate-plate junction density (P-P Junc. D) and axial bone volume fraction (aBV/TV) were 29%, 31%, 8%, 5%, 7%, 17% and 23% lower in HIV-infected than controls at the radius ($p<0.05$). Similarly, plate-related parameters pBV/TV, pTb.N, pTb.Th, pTb.S, P-P Junc. D and aBV/TV were 24%, 7%, 4%, 5%, 17% and 20% lower in HIV-infected than controls at the tibia ($p<0.05$). No differences were found in the rod-related parameters at radius or tibia. Differences in microstructure were reflected in the estimated mechanical properties: HIV-infected had 17% and 14% lower whole bone stiffness at the radius and tibia, respectively, and 24% lower trabecular bone stiffness at the radius than controls.

In conclusion, at an age by which young men have typically acquired approximately 95% of peak bone mass, men infected with HIV perinatally or during adolescence who are on stable antiretroviral regimens have profound deficiencies in trabecular plate, (not trabecular rod) microstructure and decreased trabecular bone stiffness. Compromised bone strength due to trabecular plate deficiencies in young adults infected with HIV early in life may place them at higher risk for fractures as they age.

Women With and Without Fragility Fractures: The Bone Quality By TBS. Mário Rui Mascarenhas*[1], Ana Paula Barbosa[2], Ana Gonçalves[3], Vera Simões[4], Didier Hans[5], Isabel do Carmo[3]. [1]Lisbon's Faculty of Medicine, Santa Maria University Hospital, CHLN,EPE, Portugal, [2]Endocrinology, Santa Maria Hospital & Faculty of Medicine, Portugal, [3]Endocrinology, Diabetes & Metabolism Department, Santa Maria University Hospital, CHLN-EPE, Portugal, [4]CEDML - Lisbon's Endocrinology, Diabetes & Metabolism Clinic (Osteoporosis Unit), Portugal, [5]Lausanne University Hospital, Switzerland

Bone strength depends mostly on bone mass (bone mineral density, or aBMD, accessed by DXA) and on bone microarchitecture. The extreme fragility of the bones produced by low mass and deterioration of bone microarchitecture may have, as major consequence, an augmented risk of osteoporotic fractures, mainly at the distal radius, at the spine, at the proximal femur and humerus.

The DXA scan is currently the gold standard to measure BMD, in order to diagnose preciously osteoporosis and estimate fracture risk. The decrease in the BMD is related to an increased risk of osteoporotic fracture.

TBS, a novel gray-level measurement of lumbar spine DXA image texture, is related to microarchitecture and fracture risk independently of BMD. Although some studies were already performed in women, the data about the bone microarchitecture are scarce in women with and without osteoporotic fractures.

Objective: The aim of this study is to compare the lumbar spine bone microarchitecture as estimated by TBS with the spine BMD as well as the correlation between spine TBS and BMD in women with and without fragility fractures.

Material and Methods: The BMD (g/cm^2) at the lumbar spine was measured by DXA (Discovery W, Hologic Inc., USA) in 79 women [mean age 66.0 ($\pm$8.9) years] with osteoporotic fractures (fracture group) and in 76 osteoporotic women [mean age 65.7($\pm$9.2) years] without fractures (no fracture group). Site matched spine TBS was derived for each spine DXA scan (TBS iNsight software, Medimaps, France). Adequate statistical tests were used with the significance level at P<0.05.

ResultsNo significant difference was found between the two groups for all the anthropometric parameters. The mean TBS was lower in the fracture group, as compared with the other group; nevertheless, the mean BMD was not significantly different between these groups of women (Table 1).

There was no significant relationship between spine TBS and BMD, in the fracture group.

Conclusions: The spine TBS was significantly reduced in the osteoporotic fracture group of women, but there was an overlap of the BMD values in both groups, without a clear differentiation of women with and without osteoporotic fractures.These data further suggest that this new diagnostic tool nicely complement the BMD and improve osteoporosis management.

Groups	FRACTURE	NO FRACTURE	P
Spine			
BMD g/cm²	0.860 (±0.1)	0.905 (±0.2)	ns
TBS	1.255 (±0.1)	1.320 (±0.1)	0.0003

MO0072

Characterizing Micro-architectural Changes at the Distal Radius and Tibia in Postmenopausal Women Using HR-pQCT. Chantal Kawalilak*[1], James Johnston[1], Wojciech Olszynski[2], Saija Kontulainen[1]. [1]University of Saskatchewan, Canada, [2]College of Medicine; University of Saskatchewan, Canada

Introduction. There is little longitudinal evidence of bone micro-architectural changes in postmenopausal women; a population highly susceptible to osteoporotic fracture. When interpreting (or designing) longitudinal studies, it is essential to know the monitoring time interval (MTI) required to significantly detect measured changes (Glüer et al. JBMR 1999). MTI has not been defined for HR-pQCT derived bone measures. Our objective was to characterize annual changes in bone density, area, and micro-architecture at the distal radius and distal tibia in postmenopausal women and to define MTI in this population.

Methods. Distal radius and tibia were measured using HR-pQCT at baseline and 1-year follow-up in 51 women (mean age$\pm$SD: 78$\pm$7 years) from the Saskatoon cohort of the Canadian Multicentre Osteoporosis Study (CaMos). We determined the mean and median annual rate of change, and MTI for bone density, area, and micro-architecture. Paired samples *t*-tests or Wilcoxon sign tests were used for to compare bone outcomes between baseline and follow-up; significance was set at $P<0.05$.

Results. At the radius, total and cortical density decreased (-1.5% and -0.7%, respectively), while trabecular area increased (0.4%). Trabecular number decreased (-3.3%). At the tibia, total and cortical density decreased (-1.4% and -1.8%, respectively). Cortical area and thickness decreased (both -3.3%), while trabecular area increased (0.8%). At the radius, change can be measured in approximately 4 years for cortical and trabecular area, total and cortical density, cortical thickness, bone volume fraction, trabecular number, thickness, and heterogeneity (Table 1). At the tibia, change can be measured in less than 3 years for cortical and trabecular area, total and cortical density, cortical thickness and bone volume fraction (Table 1).

Discussion. Observed changes in bone area, density, and micro-architecture suggest trabecularization of the cortex may have occurred at both measured sites and support earlier evidence from cadavers (Zebaze et al. Lancet 2010). Based on the MTIs, 1-year change in HR-pQCT derived bone properties can be monitored reliably for distal tibia cortical area, density and thickness, as well as bone volume fraction at both sites. However, at least 2 years are needed to monitor change for the other skeletal parameters at the distal tibia and at the distal radius.

Table 1. Annual means at baseline and 1-year follow-up scans and significance, the least significant change (LSC), percent median annual change, and the monitoring time interval [LSC/(Median annual change)] for the HR-pQCT derived bone outcomes at the distal radius and tibia.

Atypical Femoral Fractures are Associated with High Cyclic Tensile Strain Regions During Walking. Saulo Martelli*[1], Peter Pivonka[2], Mariana Kersh[1], Peter Ebeling[3], Marcus Pandy[1]. [1]Department of Mechanical Engineering, The University of Melbourne, Australia, [2]Australian Institute for Musculoskeletal Science, The University of Melbourne, Australia, [3]The University of Melbourne, Australia

Atypical femoral fractures (AFF) are rare low-energy stress fractures progressing from the lateral aspect of the subtrochanteric and diaphyseal region to complete and predominantly transverse fractures. AFFs have been associated with bisphosphonate treatment, which may also result in a bone mineralisation increase, narrowed bone mineralisation density distribution, and a reduction in bone remodeling. AFFs may also be associated with abnormal femur geometry, being more common with femur bowing and in Asian populations (J. Bone Miner Res. 25:11, 2010). We examined the physiological loading environment to test the hypothesis that AFF onset in femoral sub-regions is associated with high cyclic tensile strains occurring during daily activities. We computed the femur tensile strain distribution during walking for ten postmenopausal women using the finite-element (FE) method. Ten volunteers underwent a computed-tomography (CT) and gait analysis. The femur FE model was created using the bone geometry and the material properties extracted from the CT images (J Biomech. 40:13, 2007). A generic musculoskeletal model was scaled on the volunteers' anthropometry. The joint net moments driving a selected stance of walking were calculated using the body motion and the ground reaction forces recorded during gait analyses. The muscle and the hip reaction forces were calculated using published algorithms (IEEE Trans Biomed Eng. 54:11, 2007). FE analyses were performed applying the calculated muscle and hip reaction forces and using a full constraint condition distally. Five phases (Fig. 1, phase A, B, C, D, and E) of walking including heel-strike (A), the first (B) and the second (D) peak of the hip reaction force, mid stance (C) and toe-off (E) were studied. Results for one volunteer are shown in Fig. 1. The peak tensile strains corresponded with the two peak values of the hip reaction force magnitude (Fig. 1, B and D). For both peaks, high tensile strains were located on the lateral femur diaphysis across its entire length. The maximum tensile strain value was 0.4%, corresponding with the second peak of the hip reaction force (4.5 body-weight). In conclusion, AFFs may be initiated in a femur sub-region (lateral femur diaphysis) subjected to high cyclic tensile strains where bone micro-cracks may progress to fracture due to a combination of a) high cyclic tensile strain inducing a significant crack opening and b) altered material properties and reduced bone remodeling.

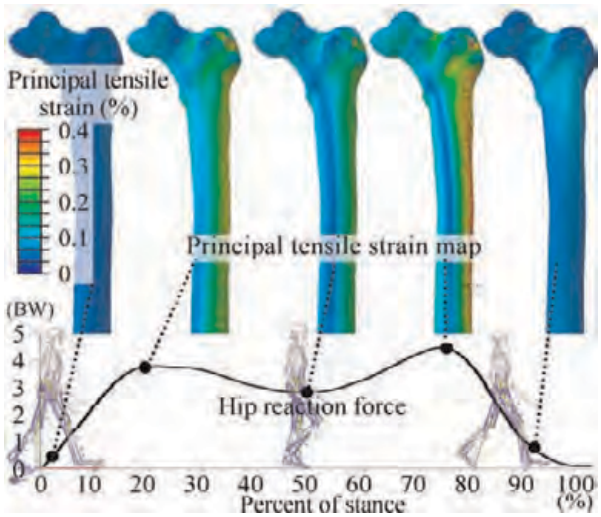

Fig. 1. The tensile strain pattern in the femur during the stance phase of walking

MO0075

Physically Active Women Have Denser Bones and May Be Less Responsive to a Mechanical Loading Intervention. Karen Troy*, Breanna Johnson, Mary Lou Bareither. University of Illinois at Chicago, USA

Physical activity produces mechanical strains within bone that are known to be osteogenic. Several studies have illustrated a positive association between mechanical loading history and bone mass and structure. Loading history is often quantified using one of two bone-specific survey instruments: the Bone Loading History Questionnaire (BLHQ) and Bone Physical Activity Questionnaire (BPAQ). These surveys weight activities based on ground reaction forces, with validations focused on lumbar spine or hip bone mineral density (BMD). The degree to which these survey measures reflect upper extremity loading is not known.

We have developed an *in vivo* upper extremity loading protocol in which women apply a force to their distal radius, resulting in measurable changes to bone. Our purpose was to determine whether physical activity surveys were related to baseline measures of, and changes to, distal radius bone mineral following our loading protocol. We hypothesized that survey scores would be related to baseline measures, and that subjects with high scores would be less responsive to loading, based on the concept that bone adaptation is "error signal" driven.

Twenty-one women age 22 ± 3 years participated in a 6 month loading protocol where a force of 300N was applied to the palm of the hand, 50 cycles/day, 3 days/week. Quantitative computed tomography was performed at baseline and at 6 months to measure bone mineral content (BMC) and density (BMD) of the total and ultra-distal (UD) radius. Subjects completed two physical activity surveys: the BLHQ, and the BPAQ. Upper extremity versions of the surveys were created by scoring the subset of activities that would be expected to produce forces on the hands or arms; e.g., volleyball but not soccer.

Pearson correlations were used to compare survey scores with baseline and 6-month change measures of bone. BPAQ scores were positively correlated with BMD at baseline, but negatively correlated with change in total BMC (Table 1). The positive association at baseline is consistent with previous reports. The upper extremity versions of the surveys were not better predictors of baseline or change values than the full versions. This may be because the surveys used weighting factors for each activity based on ground reaction forces, which are irrelevant to the radius. This research may help us prospectively identify individuals who would most benefit from our mechanical loading intervention targeting the distal radius.

Table 1: Correlations (r) between baseline and change values for bone versus physical activity. *p<0.05

	Baseline values				Change values			
	UD BMC (g)	UD BMD (g/cm^3)	Total BMC (g)	Total BMD (g/cm^3)	UD BMC (g)	UD BMD (g/cm^3)	Total BMC (g)	Total BMD (g/cm^3)
BPAQ - past activities	0.338	0.546*	0.367	0.553*	0.534*	-0.362	-0.614*	-0.512*
BPAQ - current activities	0.168	0.222	0.092	0.233	-0.31	0.097	0.038	0.314

Comparison of Raman spectroscopic mapping and histological characterization of heterotopic ossification. Nicole Crane*[1], Eric Elster[2], Benjamin Potter[3], Jonathan Forsberg[1]. [1]Naval Medical Research Center, USA, [2]Uniformed Services University of Health Sciences, USA, [3]Walter Reed National Military Medical Center, USA

Over 60% of patients with major combat-related extremity injuries develop radiographically apparent heterotopic ossification (HO), the formation of mature lamellar bone in the soft tissues. Nearly a third of patients that develop HO require surgical excision of persistently symptomatic lesions, a procedure that is fraught with complications and delays or regresses functional rehabilitation in many cases. Due to the high prevalence and the morbidity of surgical removal, prophylaxis would be much preferred to treatment. The exact etiology of HO, however, remains unknown. We asked whether Raman spectral changes, also known as Raman spectro-histopathology, mapped across tissue sections correlated with histologic evidence (serial sections of tissue stained with H&E, Alcian blue, Masson's trichrome, S-100, and UCP-1) of the earliest signs of HO formation using tissue biopsies from the wounds of combat casualties. In doing so, we compared tissue biopsies from ten combat-wounded patients, five of whom developed HO after wound closure and five of whom did not. Raman spectroscopic features extracted from mineral and matrix components of tissue biopsies demonstrated strong associations with histologic findings. Raman spectroscopic mapping further demonstrated utility as an adjunct technique by providing information beyond standard histological analysis including evaluation of mineral quality. Raman spectroscopy may therefore prove a useful, non-invasive diagnostic modality to detect and characterize early HO formation, potentially at a time point when primary prophylaxis or selective early excision remains practicable.

High-Precision Analysis of Subchondral Sclerosis as an Early and Progressive Marker of Post-Traumatic Osteoarthritis Using Micro-Computed Tomography. Joseph Temple*[1], Lara Longobardi[2], Tieshi Li[2], Timothy Myers[3], Alessandra Esposito[4], Anna Spagnoli[2]. [1]University of North Carolina at Chapel Hill Department of Biomedical Engineering, USA, [2]University of North Carolina at Chapel Hill, USA, [3]University of North Carolina, USA, [4]University of North Carolina at Chapel Hill Department of Pediatrics, USA

Purpose: It has recently been proposed that subchondral sclerosis (SCS) is an early marker for osteoarthritis (OA). This marker is evident histologically (Fig. 1a-b, dashes), but histological scoring emphasizes cartilage pathology and cannot quantitatively evaluate SCS. The purpose of this study was to localize and evaluate SCS using high-resolution micro-computed tomography (uCT) analysis within rigorously defined volumes of interest (VOIs). This study was aimed at quantifying SCS as an early and progressive marker in a post-traumatic OA mouse model.

Methods: 10-week (W) old male C57BL/6 mice underwent destabilization of the medial meniscus (DMM) or SHAM survival surgery to induce post-traumatic OA. Two, 4, 12, and 20W after surgery, mice were euthanized and tibiae were dissected. Bones were fixed, immersed in Cysto-Conray 2 (24h) to visualize cartilage, and scanned (SCANCO, 55 kVp, 145 μA, 6 μm voxel). Samples were rinsed, decalcified (10% EDTA, 14d), and coronally sectioned for Safranin-O/Fast Green staining.

We developed an algorithm to precisely isolate the VOI where SCS is localized (Fig. 1e, red borders). Axial uCT slices were reconstructed, realigned, and resliced based on the midsagittal plane containing three anatomically invariant landmarks (Fig. 1e, arrows): the tibial tuberosity (blue), the anterior border of the intercondylar notch (AIN, white), and the origin of the posterior cruciate ligament (green). The VOI (Fig. 1e, red dashes) was bordered by this plane (laterally), the coronal plane with the AIN (anteriorly), and the growth plate (inferiorly). The VOI was evaluated for bone morphometric analysis.

Statistics: A two-tailed *t*-test was used to compare DMM and SHAM SCS. Longitudinal comparison was performed with one-way ANOVA. Significance was set at $p < 0.05$.

Results: As early as 4W after DMM surgery, SCS was visible in the medial tibial plateau by both histology (Fig. 1a-b) and uCT (Fig. 1c-d) in the VOI. As shown in Table I, uCT quantified SCS, and DMM VOIs had greater bone density, mineral density, and trabecular thickness than SHAM controls as early as 4W post-surgery. Remarkably, both uCT and histology showed that cartilage was still intact (Fig. 1a-d, arrows), indicating the relevance of SCS as early OA marker. SCS increased longitudinally in DMM mice. These results suggest that SCS is both an early and progressive marker in murine post-traumatic OA and that high-resolution uCT provides a valid means to quantify SCS.

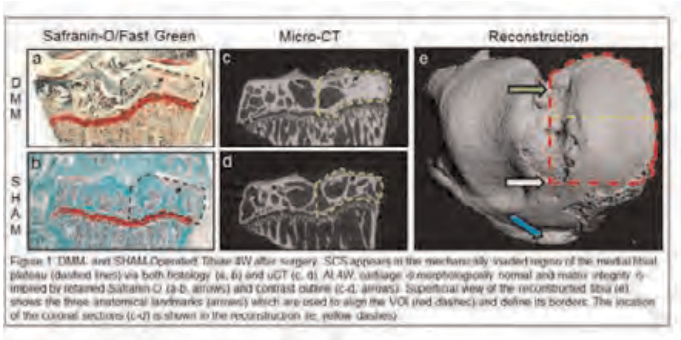

Figure 1. DMM- and SHAM-Operated Tibiae 8W after surgery. SCS appears in the mechanically loaded region of the medial tibial plateau (dashed lines) via both histology (a, b) and uCT (c, d). At 4W, cartilage is morphologically normal and matrix integrity is implied by retained Safranin O (a-b, arrows) and contrast outline (c-d, arrows). Superficial view of the reconstructed tibia (e) shows the three anatomical landmarks (arrows) which are used to align the VOI (red dashes) and define its borders. The location of the coronal sections (c-d) is shown in the reconstruction (e, yellow dashes).

Figure 1

Time	Surgery	BV/TV	mg HA/TV	Tb. Th. (mm)
2W	DMM	0.456 ± 0.058	631.9 ± 50.3	0.120 ± 0.014*
	SHAM	0.373 ± 0.050	564.4± 38.6	0.058 ± 0.009
4W	DMM	0.582 ± 0.023*†	773.8 ± 18.9*	0.119 ± 0.019*
	SHAM	0.394 ± 0.031	575.9 ± 25.6	0.062 ± 0.010
12W	DMM	0.621 ± 0.026*†	776.2 ± 29.6*	0.121 ± 0.006*
	SHAM	0.381 ± 0.023	562.0 ± 33.5	0.065 ± 0.011
20W	DMM	0.680 ± 0.036*†	803.4 ± 37.3*	0.161 ± 0.009*
	SHAM	0.415 ± 0.012	566.4 ± 24.2	0.069 ± 0.004

Table I. Bone morphometric analysis (mean ± standard deviation) of the SCS VOI in DMM- and SHAM-operated mice 2, 4, 12, and 20W after surgery (n = 3 per group). At 4, 12, and 20W, DMM mice had significantly greater bone density (BV/TV), Hydroxylapatite (HA) density, and trabecular thickness (Tb. Th.) than SHAM counterparts (*$p < 0.05$ compared to SHAM). One-way ANOVA of these variables in DMM mice suggested an increase in SCS longitudinally (†$p < 0.05$ compared to DMM 2W).

Joint Bleeding in Factor VIII Deficient Mice Causes an Acute Loss of Trabecular Bone and Calcification of Joint Soft Tissues, Which is Prevented with Aggressive Factor Replacement. Anthony Lau*[1], Junjiang Sun[2], William Hannah[2], Eric Livingston[3], Dominique Heymann[4], Ted Bateman[5], Paul Monahan[6]. [1]University of North Carolina at Chapel Hill, USA, [2]University of North Carolina-Chapel Hill-Gene Therapy Center, USA, [3]University of North Carolina-Chapel Hill-Department of Biomedical Enginering, USA, [4]INSERM U957, University of Nantes, France, [5]Univesity of North Carolina, USA, [6]University of North Carolina-Chapel Hill-Gene Therapy Center & Department of Pediatrics, USA

Adults and children with hemophilia experience both reduced bone density and joint damage from hemarthrosis. The goal of this study is to characterize the acute 1) bone loss and 2) joint damage response from an induced joint bleed in hemophilic mice, and determine the efficacy of aggressive factor replacement treatment. Male 22-week old Factor VIII knock-out mice were used and treated with or without recombinant Factor VIII just prior to and after injury. Mice were subjected to knee joint hemorrhage induction by instilling 5 microliters of saline into the left knee joint space. Thirty minutes prior to inducing joint hemorrhage, mice received an intravenous dose of human recombinant factor VIII 250IU kg^{-1}(n=9) or placebo dose of saline (n=9). This dose was repeated at 4, 24, 48, 72 and 96 hours after bleed induction. Two weeks post-injury, the mice were euthanized and hind limbs were collected and scanned with microCT at 10μm resolution.

For the bone loss goals of the study, microCT analysis was performed on proximal tibia trabecular bone, inferior to the growth plate. Comparing the injured joint against the contralateral un-injured joint found that hemarthrosis resulted in significant reduction of trabecular bone of proximal tibia BV/TV (-25%), trabecular connectivity density (-20%) and thickness (-13%), bone tissue mineral density (-5%), and volumetric bone mineral density (-27%), which was mitigated by aggressive FVIII replacement (Figure 1).

In addition to loss of bone in the proximal tibia, gross degradation of the joint tissues was observed. Analysis of the morphology of this degradation suggests that what the literature has typically described as joint erosion, is actually mineralization of the joint soft tissues. Joint bleeding resulted in mineralization of the articular surface, joint ligaments and tendons, as well as the patella and patellar tendon (Figure 2). Treatment with factor VIII prevented this soft-tissue mineralization. The rapid mineralization of the joint two-weeks post injury alters the joint soft tissue mechanical properties, which could lead to improper joint function, accelerating joint degradation. The finding of rapid mineralization of the joint soft tissues has implications for both the fields of osteoarthritis, and regenerative medicine.

Evidence that Perichondrial Cells are derived from Chondrocytes. Stephan Spath*[1], Michael Chau[2], Ola Nilsson[2]. [1]NIH, USA, [2]NICHD, USA

Background: During early bone formation, mesenchymal stem-cells condense and differentiate into collagen type 2-expressing chondrocytes which form the cartilaginous bone anlagen. This anlage becomes enclosed by the perichondrium. The perichondrium consists of two layers, the inner cambium layer containing chondrocyte- and osteo-precursor cells and the outer fibrous layer important for mechanical and structural support.

Aim: To explore the cellular origins of perichondrium.

Methods: Perichondrium-specific markers were identified by microarray and real-time PCR analysis of microdissected perichondrium. High-density chondrocyte pellets were produced by isolating chondrocytes from rat epiphyseal cartilage and centrifugation. During the dissection, the perichondrium was carefully removed and its absence was confirmed by histological examination and by real-time PCR for perichondrium markers. Differentiation of pellet cultures was studied using real-time PCR and *in situ* hybridization for chondrocyte and perichondrium markers.

Results: Cultured chondrocyte pellets developed a surrounding perichondrium-like tissue. This surrounding tissue did not express chondrocyte markers, collagen 2 or 10, as assessed by *in situ* hybridization. Instead, perichondrium markers Dickkopf 3 (Dkk3), Pleiotrophin (Ptn), Periostin (Postn), Roundabout 2 (Robo2), Protein Tyrosine Phosphatase Receptor Type Z 1 (Ptprz1), Cadherin 2 (Cdh2), L-galectin (Lgals), Thrombospondin 4 (Thsb4) were upregulated during the formation of the perichondrium-like tissue by real-time PCR. Interestingly, molecular markers for the cambium (Dkk3, Lgals and Thsb4) and not the fibrous layer (Collagen 14 and Decorin) were upregulated in cultured chondrocyte pellets.

Conclusions: These results suggest that epiphyseal chondrocytes of postnatal animals are not terminally differentiated, but still retain the potential to transdifferentiate into perichondrial cells, and thus support previous cell-lineage tracing studies suggesting that the perichondrium is formed from collagen 2 expressing chondrocytes in the periphery of the bone anlagen.

Bio-Adhesive for Tissue Integration and Construction of Bone and Cartilage Interface. Hyunji Cho*[1], Changhwan Kim[1], Sung Hyun Kim[2], Seungwoo Nam[1], EunAh Lee[3], Youngsook Son[1]. [1]Lab of Tissue Engineering, Department of Genetic Engineering, College of Life Science, Kyung Hee University, South Korea, [2]Materials Research Center for Information Display, College of Engineering, Kyung Hee University, South Korea, [3]Kyung Hee University, South Korea

Recent advances in tissue engineering made it possible to apply chondrogenic graft to cartilage-defect area. However, successful regeneration of cartilage depends on the integration of transplanted tissue with surrounding natural tissue. In the case of tissue engineering approach for articular cartilage, subchondral bone comprises the surrounding tissue. In the aim of developing bio-adhesive that can acts at the bone-cartilage interface, the surface of hydroxyapatite microcrystals were chemically modified with linker molecules to confer adhesive property. The linker molecules that can participate in chemical reaction to form covalent bonding with the chemical groups on natural tissues were chosen based on the biocompatibility of the reaction. Grafted linker molecules were chemically confirmed and characterized by chromogenic reaction and FTIR analysis. Thereby comprised bioadhesive was names as 'stickyapatite'.

As an *in vitro* attachment test, chondrogenic graft composed of BMSCs or chondrocytes were attached to the surface of rabbit tibia using stickyapatite, and checked for their attachment after 1 hour. While commercial hydroxyapatite showed attachment only in 25%, the stickyapatite showed attachment in 75% of the applied chondrogenic graft. As an in vivo attachment test, chondrogenic grafts composed of chondrocytes were transplanted to full-thickness articular cartilage defect of rabbit autologous chondrocyte implantation (ACI) model with or without stickyapatite. After 6 weeks upon transplantation, coverage of articular cartilage was measured by image analysis, and the attachment interface was subjected to histological analysis. The newly formed cartilage induced by transplanted chondrocytes were covering about 74% of the defect area in stickyapatite treated group, while the control group showed much lower coverage of defect with so much variation in each case indicating that chondrocytes were lost on the transplanted surface.

Being a powder-type bio-adhesive, those 'sticky apatite' exhibited advantageous trait showing no insulation around the interface of attached tissues which was confirmed based on the fact that stickyapatite-induced newly formed cartilage did not show discrete line between the subchondral bone and the transplanted cartilage. This research was supported by a grant from Korean Ministry of Health and Welfare given to Youngsook Son (A040003) and a grant from National Research Foundation of Korea given to EunAh Lee (2011-0009391).

MO0081

Choline Kinase Beta is an Important Regulator of Endochondral Bone Formation. Zhuo Li*[1], Gengshu Wu[1], Roger Sher[2], Kayla Rumack[3], Gregory Cox[4], Michael Doschak[1], Monzur Murshed[5], Frank Beier[3], Dennis Vance[1]. [1]University of Alberta, Canada, [2]University of Maine, USA, [3]University of Western Ontario, Canada, [4]The Jackson Laboratory, USA, [5]McGill University, Canada

Choline kinase converts choline to phosphocholine and is the first enzyme in the choline pathway to generate phosphatidylcholine. Choline kinase has two isoforms encoded by the genes *Chka* and *Chkb*. Inactivation of *Chka* results in embryonic lethality, whereas *Chkb* mutant mice display neonatal forelimb bone deformation. To understand the mechanisms of the bone deformation phenotype, we characterized the major long bones in the forelimb. We found that the deformation is specific to the radius and ulna and the deformation occurs during the late embryonic stage. We also found that the radius and ulna in mutant mice display abnormal chondrocyte cell morphology, unorganized proliferative columns and expanded hypertrophic zones in their growth plates as well as delayed formation of primary ossification centers. We then quantified the choline metabolites by Mass Spectrometry. No change in phosphatidylcholine was observed but the amount of phosphocholine is decreased by approximately 60% in mutant chondrocytes. To further understand these phenotypes, we examined chondrocyte differentiation, proliferation, apoptosis, and cartilage extracellular matrix (ECM) degradation events. We found that mutant chondrocytes have impaired differentiation. They also have a decreased rate of cell proliferation and apoptosis. In addition, the cartilage in mutant mice has diminished ECM degradation by matrix metalloproteinase 9 and 13. Taken together, our data suggests that choline kinase beta plays an important role in endochondral bone formation through regulation of growth plate chondrocyte physiology.

Evaluation of osteoarthritis based on second harmonic generation microscopy. Hiroshi Kiyomatsu*[1], Yusuke Oshima[2], Atsuhiko Hikita[3], Hiromasa Miura[4], Takeshi Imamura[4]. [1]Ehime University Hospital, Japan, [2]Translational Research Center, Ehime University Hospital, Japan, [3]Ehime University, Japan, [4]Ehime University Graduate School of Medicine, Japan

Osteoarthritis restricts daily activities of patients and significantly decreases their quality of life. There is no fundamental treatment other than an invasive surgical treatment at the late stage of the disease, because articular cartilage can't be regenerated and early detection of disease is quite difficult. Quantitative and sensitive methods for diagnosis and evaluation of osteoarthritis must be established to develop new treatments by clarifying the nature of the disease in animal studies and to detect subtle changes from the early phase of the disease. Second harmonic generation (SHG) imaging make it possible to observe non-centrosymmetric molecular assemblies such as collagen fibers without staining. The cartilage matrix consists mainly of type II collagen. The SHG signal reflects the localization and orientation of the fibrous structure of the collagen molecule, and thus enables us to detect its minute changes at the molecular level. Several groups have reported SHG imaging of articular cartilages, but these studies were not done in vivo.To establish a new method for the evaluation of the degenerative articular cartilages in living animal and clinical setting, we performed SHG and two-photon excited fluorescence imaging of articular cartilage matrix and chondrocytes of H2B-GFP mice which express green fluorescence protein in nuclei. Firstly, time-course measurements of drug-induced degeneration of mouse articular cartilage were performed ex vivo. SHG signals was significantly reduced after collagenase treatment, which suggests that SHG signal reduction is associated with the degeneration of the cartilage. Dislocation of chondrocytes from articular cartilage was also observed, which showed the breakdown of the structures of extracellular matrices. Next, hyalronidase treatment of articular cartilage was done in a same manner, but no significant change in the intensity of SHG from articular cartilage was observed.We also developed a cartilage defect model to evaluate the regeneration of cartilage by using MPEM imaging in vivo. We generated this model by removing cartilage of patella groove in mice and observed postoperative change in living mice. We found that SHG signal intensity and distribution were significantly changed.Although further development of this assay and quantitative analysis would be required for establishment of diagnostics and fundamental treatments, SHG imaging of cartilage matrix is promising technique for osteoarthritis study.

Genes significantly highly expressed in synovium derived stromal cells than in bone marrow derived cells are conserved both in mouse and human, and may contribute to higher potential for chondrogenic differentiation. Yoichi Ezura*[1], Tadayoshi Hayata[2], Takuya Notomi[3], Ichiro Sekiya[4], Masaki Noda[4]. [1]Tokyo Medical & Dental University, Medical Research Insititute, Japan, [2]Medical Reserach Institute, Tokyo Medical & Dental University, Japan, [3]GCOE, Tokyo Medical & Dental University, Japan, [4]Tokyo Medical & Dental Univerisyt, Japan

Stromal progenitor cells resident in various adult tissues possess multi-potency to differentiate, and thus are called as mesenchymal stem cells (MSCs). Basic characterization of these cells indicates shared common features. Previously, we have shown that there were consistent differences between the synovium derived human MSCs (SMSCs) and bone marrow (BM) derived MSCs (BM-MSCs) in global gene expression, possibly contributing to their potency for chondrogenic differentiation. To investigate if the differences are conserved among diverse species, we examined expression profiles of mouse synovium derived stromal cells (m-SSCs) and mouse bone marrow derived stromal cells (m-BMSCs). Regression analysis of the relative expression levels of about 10,000 genes that were shared in mouse and human microarray platform indicated that the relative expression of those genes in mouse SSCs v.s. mouse BMSCs were positively correlated with those of human SMSCs vs. human BM-MSCs ($r=0.17$, $p=6.6 \times 10^{-42}$). Importantly, we found that many transcription factors known to be required for chondrogenic differentiation or maturation, including Sox5, Nkx3.2, Zfp521, and Zeb1 were significantly expressed more highly in mouse SSCs or human SMSCs than in mouse BMSCs or human BM-MSCs. In addition, we found many genes encoding extracellular matrix proteins preferentially expressed in cartilage, such as Asporin, Comp, Prg4 were more highly expressed in synovium derived cells than in BM derived cells. A list of 226 genes significantly expressed more highly in synovium derived cells than in bone marrow derived cells both in mouse and human may provide new insight into the differentiation potential of mesenchymal progenitor cells to chondrocytes, and thus would contribute to develop novel diagnostic or therapeutic methods for human osteoarthritis or related diseases.

MO0084

Ihh Directly Regulates ColX Expression by PTHrP-independent Mechanisms via Runx2/Smad Interaction during Limb Development. Katsuhiko Amano*[1], Michael Densmore[1], Riko Nishimura[2], Toshiyuki Yoneda[3], Mikihiko Kogo[2], Beate Lanske[1]. [1]Harvard School of Dental Medicine, USA, [2]Osaka University Graduate School of Dentistry, Japan, [3]Indiana University School of Medicine, USA

Indian hedgehog (Ihh) expressed in pre- and hypertrophic chondrocytes is essential for skeletal bone formation. Ihh has been shown to form a negative feedback loop with parathyroid hormone- related protein (PTHrP) to regulate the rate of chondrocyte differentiation. We and others previously reported that Ihh promotes Collagen type X (ColX) expression, chondrocyte maturation and calcification independently of PTHrP, however, the molecular mechanism for this was still unknown. We hypothesized that Ihh signaling directly regulates ColX expression and transcription and have performed *in vitro* and *in vivo* analyses to address this question. First, we tested the effect of hedgehog-induced transcription factors Gli1/2 on ColX promoter activity and determined that Gli1/2 upregulated the promoter activity. Using ColX promoter deletion constructs and sequence analysis, we identified a Gli1/2 binding site in the basic ColX promoter region (250bp). Further studies with oligo pull-down assays indicated that Gli1/2 physically interacted with this site. We then examined the interaction of Gli1/2 with Runx2/Smads since these are important factors in late chondrocyte differentiation and could show that both interacted with these proteins using binding and ColX Luc promoter assays. To confirm our findings *in vivo*, we generated a *Prx1-Cre;Ihh$^{fl/fl}$* mouse to delete Ihh during development from limb mesenchyme. This model allowed us to analyze the long bone phenotype from embryogenesis to postnatal life. We observed initiation of ColX expression in mutant long bones at E15.5 which then decreased over time, and was completely lost in long bones of *Prx1-Cre;Ihh$^{fl/fl}$* mice at P10. The remaining chondrocytes found close to the distal ends of the mutant bones strongly expressed Collagen type 2 and PTHrP, but ColX expression was completely lost suggesting that Ihh is required to specifically maintain ColX expression. In summary, our data suggest that Ihh directly regulates ColX transcription through Gli1/2 interaction with Runx2/Smads and that Ihh is essential to maintain postnatal ColX expression *in vivo.*

MO0085

Indispensable Role of Thyroid Hormone in Secondary Ossification via a Novel Mechanism Involving Transdifferentiation of Chondrocytes into Osteoblasts. Subburaman Mohan*[1], Shaohong Cheng[2], Weirong Xing[3], Heather Watt[4], Sheila Pourteymour[4], Catrina Alarcon[4], Jon Wergedal[1]. [1]Jerry L. Pettis Memorial VA Medical Center, USA, [2]VA Loma Linda Health Care Systems, USA, [3]Musculoskeletal Disease Center, Jerry L. Pettis Memorial Veteran's Admin., USA, [4]Jerry L Pettis VA Medical Center, USA

Our recent studies using genetic mouse models that are deficient in thyroid hormone (TH) and/or growth hormone (GH) have provided unequivocal evidence that there is an important window of time, prior to puberty, when the effects of GH are surprisingly small and TH plays a critical role in the regulation of skeletal growth. In terms of mechanisms for TH regulation of bone accretion, we focused on the secondary ossification center (SOC), since the time of appearance of SOCs in several species (mice, rats, humans) coincides with the time when peak levels of TH are attained. Accordingly, μCT evaluation of femurs and tibias at day 21 in TH-deficient and control mice revealed that endochondral ossification of SOCs is severely compromised (>75% reduction in BV/TV) due to TH deficiency and that TH treatment for 10 days rescued this phenotype fully. Staining of cartilage and bone in the epiphysis of TH deficient Tshr$^{hyt/hyt}$ and control mice at postnatal day 3, 7, 10, 14, 17 and 21 revealed that while all of the cartilage is converted into bone in the control mice, this conversion failed to occur in the TH-deficient mice. Accordingly, the Col2 mRNA level was increased (30%, $P<0.05$) while Col10, ALP and osteocalcin (OC) mRNA levels were decreased (>70%, $P<0.01$) in the epiphysis of TH deficient mice (day 7). These changes were rescued by TH treatment of Tshr$^{hyt/hyt}$ mice. Immunohistochemistry studies revealed that TH treatment of Tshr$^{hyt/hyt}$ mice induced expression of osterix (Osx) in Col2 expressing chondrocytes (CCs) in the SOC at day 7 which subsequently transdifferentiate into Col10/OC expressing chondro-osteoblasts at day 14. Consistent with these data, treatment of serum-free tibia cultures from 3-day old mice with 10 ng/ml TH for 1, 3 and 10 days increased expression of Osx, Col10, ALP and OC in the epiphysis by 6-60 fold (all $P<0.01$). Furthermore, knockdown of the TH-induced increase in Osx expression using lentiviral Osx shRNA significantly blocked TH-induced ALP and OC expression in CCs, thus suggesting that the TH effect on chondro-osteoblast differentiation is mediated via increased Osx expression. By contrast, knockdown of Runx2 did not block TH-induced OC expression in CCs. Based on our findings, we conclude: 1) TH is indispensable for initiation and progression of the SOC. 2) TH acts via a novel mechanism in which TH acts on Col10 expressing CCs to induce Osx expression to transdifferentiate them into bone matrix producing osteoblasts.

MO0086

Inhibiting calcineurin activity promotes chondrogenic differentiation through induction of Dkk1. Seungwoo Han*[1], Eun-Ju Lee[2], Youn-Kwan Jung[2], Min-su Han[2], Gun-Woo Kim[3], Hye-Ri Park[2], Je-Yong Choi[4]. [1]Daegu Fatima Hospital, South Korea, [2]Laboratory for Arthritis & Bone Biology, Fatima Research Institute, South Korea, [3]Department of Internal Medicine, Daegu Fatima hospital, South Korea, [4]Kyungpook National University, School of Medicine, South Korea

The differentiation of mesenchymal cells into chondrocytes is a multistep process and the precise mechanism is still unclear. In this study, we investigated the role of calcineurin on early chondrogenic differentiation from mesenchymal cells. E11.5 limb bud cells were cultured as high-density 10-μl drops containing 2.5×10^5 cells in chondrogenic media and treated with 100 ng/ml and 1000 ng/ml of FK-506. The inhibition of calcineurin by FK-506 promoted chondrogenesis with increased absorbance of alcian blue staining in dose-dependent manner. Along with alcian blue staining, the m-RNA expression of chondrogenic markers like Sox9, Col2a1 and aggrecan was significantly increased. To investigate the mechanism of FK-506-mediated upregulation of chondrogenesis, Wnt signaling pathways were activated with Wnt3a or Wnt5a (50 ng/ml) together with FK-506. FK-506-mediated chondrogenic differentiation was attenuated by activation of canonical Wnt signaling, but not by non-canonical pathway. With respect to the expression of Wnt pathway components, FK-506 increased Wnt5a, the major ligand of non-canonical Wnt pathway, and Axin2 and Lef1, the major adaptor molecules of canonical Wnt pathway, as well. However, the inhibitory effect in co-treatment experiment suggested that the canonical Wnt pathway may not be involved in FK-506-induced chondrogenic differentiation. Interestingly, FK-506 significantly increased Dkk1, but not Dkk2. When Dkk1 function was blocked by Dkk1-neutralizing antibody in micromass culture, FK-506-mediated upregulation of chondrogenesis was diminished. Collectively, the inhibition of calcineurin/NFAT signaling with FK-506 increases chondrogenic differentiation, which may largely depend on Dkk1 induction resulting in attenuation of canonical Wnt signaling.

IRE1α Dissociates with BiP and Inhibits ER Stress-mediated Apoptosis in Cartilage Development. Fengjin Guo*[1], Xiaofeng han[2], yanna Liu[2]. [1]Chongqing Medical University, Peoples Republic of China, [2]Department of Cell Biology & Genetics, Core Facility of Development Biology, Chongqing Medical University, China

BMP2 (bone morphogenetic protein 2) is known to activate unfolded protein response signaling molecules, including XBP1S, BiP and IRE1α. ER (Endoplasmic Reticulum) stress is induced in chondrogenesis and activates IRE1α signal pathway, which is associated with ER stress-mediated apoptosis. However, the influence on IRE1α and BiP in BMP2-induced chondrocyte differentiation have not yet been elucidated, the molecular mechanism remains unexplored.

In this study, we demonstrate that IRE1α interacts with BiP in unstressed cells and dissociates from BiP in the course of cartilage development. Induction of ER stress-responsive proteins (XBP1S, IRE1α, BiP) was also observed in differentiating cells. IRE1α inhibition ER stress- mediated apoptosis lies in the process of chondrocyte differentiation. Furthermore, knockdown of IRE1α expression by way of the RNAi approach accelerates ER stress-mediated apoptosis in chondrocyte differentiation induced by BMP2, as revealed by enhanced expression of Cleaved Caspase3, CHOP and p-JNK; and this IRE1α inhibition effect on ER stress-mediated apoptosis is required for BiP in chondrogenesis.

Collectively, the ER stress sensors were activated during apoptosis in cartilage development, suggesting that selective activation of ER stress signaling was sufficient for induction of apoptosis. These findings reveal a novel critical role of IRE1α in ER stress-mediated apoptosis and the molecular mechanisms involved. These results suggest that activation of p-JNK, Caspase3 and CHOP were detected in developing chondrocytes and that specific ER stress signaling leads to naturally occurring apoptosis during cartilage development.

MO0088

Runx2 is required for early stages of endochondral ossification but delays final stages of bone repair in Axin2-deficient mice. Meghan McGee-Lawrence*[1], Elizabeth Bradley[1], Wei Hsu[2], Jane Lian[3], Andre Van Wijnen[1], Jennifer Westendorf[1]. [1]Mayo Clinic, USA, [2]University of Rochester Medical Center, USA, [3]University of Vermont, USA

Runx2 and Axin2 are key regulators of skeletal development. We recently reported that Runx2 represses Axin2 transcription to promote osteoblast maturation, and double mutant *Runx2*$^{+/-}$*:Axin2*$^{-/-}$ mice do not have the craniosynostosis phenotype associated with *Axin2*-deficiency, indicating that Runx2 is essential for enhanced calvarial bone formation in *Axin2*$^{-/-}$ mice. Primary osteoblasts from double mutant mice resembled WT cultures, intermediate in phenotype between the extreme low and high osteogenic activity of *Runx2*$^{+/-}$ and *Axin2*$^{-/-}$ cells, respectively. Interestingly, more in depth analyses revealed persistent cartilage in the frontal suture of double mutant animals, exacerbating the cleidocranial dysplasia phenotype found in *Runx2*$^{+/-}$ mice. To better understand this phenomenon, we analyzed chondrocyte development in growth plates and primary cells from wildtype (WT), *Runx2*$^{+/-}$, *Axin2*$^{-/-}$, and *Runx2*$^{+/-}$*:Axin2*$^{-/-}$ mice. Despite relatively normal growth plate morphology, chondrocyte maturation was impaired in the double mutant mice, as chondrocytes arrested at intermediate stages of differentiation and failed to produce a calcified matrix in vitro. We then functionally tested the regulation of bone formation by *Axin2* and *Runx2* using endochondral fracture and intramembranous defect repair models. Pin-stabilized, closed femoral fractures (endochondral repair) or single femoral cortex, 0.7 mm diameter defects (intramembranous repair) were created in mice from each genotype. MicroCT, torsional testing, histology, and molecular analyses were used to quantify healing rates and tissue differentiation patterns. Consistent with the in vitro chondrocyte cultures, both *Runx2*$^{+/-}$ and double mutant mice had larger calluses than WT and *Axin2*$^{-/-}$ mice at early stages of endochondral fracture healing, confirming the dominance of Runx2. However, by day 28 after fracture, double mutant animals diverged from the *Runx2*$^{+/-}$ mice, showing smaller callus size and differences in torsional strength indicative of more rapid healing as seen in the *Axin2*$^{-/-}$ mice. The intramembranous repair model confirmed our earlier osteoblastic results, as double mutant mice showed an intermediate bone volume fraction in the mending defect as compared to *Runx2*$^{+/-}$ or *Axin2*$^{-/-}$ mice after 21 days of healing. Taken together, our data suggest a dominant role for Runx2 in chondrocyte maturation, but implicate Axin2 as an important modulator of the terminal stages of endochondral ossification.

Sclerostin Is Up-regulated In Articular Chondrocytes Exposed To Simulated Microgravity. Liliana Mellor*, Minoti Hiremath, Lindsey Catlin, Travis Baker, Julia Oxford. Boise State University, USA

The skeletal system responds to mechanical changes by remodeling bone tissue, a process orchestrated between osteoblasts and osteoclast activity. During unloading conditions such as the one experienced by astronauts during space missions or prolonged bed rest, osteocytes respond by secreting a protein called sclerostin, which is an inhibitor of the Wnt signaling pathway. Sclerostin has been shown to inhibit bone formation by binding to the LRP5/6 receptors and reducing osteoblast proliferation and differentiation. Clinical trials using a sclerostin antibody have shown promising results in preventing bone loss in unloading conditions. Although bone density loss in space is a growing field of interest, little is know about the possible effects of microgravity on the adjacent articular cartilage. Similar to bone, articular cartilage of the synovial joints are constantly exposed to mechanical forces produced by daily activities here on Earth, and it requires a balance between synthesis and degradation of extracellular matrix components to maintain tissue homeostasis. Our goal is to study the effects of simulated microgravity on articular cartilage using chondrocyte cell lines and articular cartilage explants in a Rotating Wall Vessel (RWV) bioreactor, which models reduced gravity.

Our results show a significant increase in sclerostin expression both at the RNA and protein level. Interestingly, RT-PCR data shows down-regulation of LRP5/6 receptors when sclerostin expression is up-regulated, suggesting that sclerostin may be associated with LRP5/6 turnover. Although cartilage is responding to simulated microgravity in a similar way bone tissue does, little is known about the effects of sclerostin in articular cartilage. A recent study detected sclerostin expression in osteoarthritic cartilage, but believes sclerostin prevents cartilage degradations because it decreases expression of matrix degrading genes such as MMPs and ADAMTSs. This suggests that sclerostin has opposite effects on adjacent bone and articular cartilage tissues, and therapeutic targeting against sclerostin needs to be further investigated.

Our study is the first to detect sclerostin up-regulation in articular cartilage in response to simulated microgravity and to identify Wnt signaling as a potential therapeutic target to prevent cartilage degradation during prolonged bed rest and lack of gravity during spaceflight missions.

Skull growth anomalies in *fgfr3*$^{Y367C/+}$ mice explain craniofacial malformation of achondroplasia. Laurence Legeai-Mallet*[1], Martin Biosse Duplan[2], Catherine Benoist-Lasselin[3], Nabil KACI[3], Arnold Munnich[3], Federico Di Rocco[3]. [1]INSERM U781 - Paris Descartes university, Necker hospital, France, [2]Faculté de Chirurgie DentaireUniversité Paris DescartesAP-HP, France, [3]INSERM U781, France

Activating fibroblast growth factor receptor 3 (FGFR3) mutations in humans are responsible for both the most frequent dwarfism, achondroplasia (ACH) and the most frequent syndromic craniosynostosis, Muenke-Lajeunie (MLS) syndrome. This receptor induces cartilage and bone anomalies in endochondral and membranous ossification. The characteristic features of ACH include an enlarged head with a prominent forehead, midface hypoplasia and severe malocclusion while in MLS the patients exhibit a coronal craniosynostosis. In order to understand how FGFR3 affects membranous ossification (vault) and endochondral ossification (skull base) in FGFR3 related diseases, we studied the skull formation of a mouse model expressing an activating FGFR3 mutation (fgfr3Y367C/+). As expected, the analysis of fgfr3Y367C/+ skull mice shows anomalies of the skull characterized by a domed macrocephalic skull associated to severe brain alteration seen with MRI, a stenotic craniovertebral junction seen with µCT, and an inverted bite. We observed in Fgfr3Y367C/+ mice a loss of the clivo-sphenoid synchondrosis where differentiation of the chondrocytes was disrupted, suggesting a defect in endochondral ossification. The size of the foramen magnum in fgfr3Y367C/+ mice was reduced as in ACH and MLS patients. These data show that endochondral ossfication is modified in both ACH and MLS and that fgfr3Y367C/+ mice mimic these defects. We next focused on areas of the skull that are formed by membranous ossification. Studying the calvaria bones of the vault, we observed a decrease in size in frontal bone, an increase size of the interparietal bone and a wide calvaria frontal defect characterized in fgfr3Y367C/+ mice. Abnormal coronal sutures were also present in mutant mice thus suggesting a possible premature fusion of the suture. Interestingly, when the calvaria were separated from the base, we observed a decrease of the calvaria frontal defect and a modification of the sutures.

In conclusion, anomalies of the skull base and vault were observed in fgfr3Y367C/+mice thus indicating that activating FGFR3 mutations affect both endochondral and membranous ossification.

TGF-β1 inhibits maturation of chondrogenic cell line ATDC5 by impeding canonical hedgehog signaling through direct down-regulation of ciliary component gene Ift88. Makiri Kawasaki*[1], Tetsuya Nakamoto[1], Takuya Notomi[2], Tadayoshi Hayata[3], Yoichi Ezura[4], Masaki Noda[1]. [1]Tokyo Medical & Dental University, Japan, [2]GCOE, Tokyo Medical & Dental University, Japan, [3]Medical Reserach Institute, Tokyo Medical & Dental University, Japan, [4]Tokyo Medical & Dental University, Medical Research Insititute, Japan

Chondrocytes play crucial role in endochondral ossification, and their proliferation and differentiation are tightly regulated by various cytokines such as Indian hedgehog (Ihh). Recent studies have demostrated that Ihh signaling takes place in primary cilium for its signal transduction and thus primary cilium is essential for endochondral ossification. Primary cilia have Intraflagellar transport (IFT) sytem where IFT complex transport proteins bidirectionally between proximal and distal end of cilia. IFT88 is one of the major components of IFT complex and its lack leads

disappearance of primary cilia. It has been reported that conditional knockout mice lacking IFT88 specifically in early limb bud exhibited severe dwarfism and aberrant endochondral ossification accompanied with decreased Ihh signaling.

Preveiously we observed that TGF-β1 dose-dependently decreased Ift88 expression in chondrogenic cell line ATDC5, while TGF-β1 increased type 2 collagen (Col2) expression and decreased type 10 collagen (Col10) expression. To know if TGF-β1 directly down-regulates Ift88 expression, we treated ATDC5 with TGF-β1 in the presence of Cycloheximide (CHX) or D-ribofuranosylbenzimidazole (DRB). The down-regulation of Ift88 expression by TGF-β1 treatment was observed both in the presence of CHX and DRB, suggesting that TGF-β1 directly regulates the transcription and mRNA stability of Ift88. We next treated ATDC5 with TGF-β1 under the attenuated expression level (about 70%) of Ift88 by RNAi and observed that Gli1 expression was enhanced with TGF-β1 treatment under the down-regulation of Ift88 expression. On the other hand, Smoothened Agonist (SAG) treatment markedly down-regulated Gli1 expression when Ift88 was knockdowned in ATDC5 suggesting that Hh signaling through Smoothened is impeded. SAG treatment up-regulated Runx2 expression but its action was ineffective under the attenuated level of Ift88 expression.These data indicate that TGF-β1 inhibits maturation of ATDC5 by suppressing canonical Hh signaling through down-regulation of Ift88 expression.

MO0092

Thyroid Hormone Interacts with Alpha$_{2A}$ Adrenergic Receptor to Regulate Longitudinal Bone Growth. Marcos Silva*[1], Manuela Rodrigues[1], Marilia Teixeira[1], Patrícia Brum[2], Cecilia Gouveia[3]. [1]Department of Anatomy, Institute of Biomedical Sciences, University of Sao Paulo, Brazil, [2]School of Physical Education & Sport, University of Sao Paulo, Brazil, [3]University of Sao Paulo, Institute of Biomedical Sciences, Brazil

It is well known that thyroid hormone (TH) regulates bone development and growth. Hypothyroidism (HYPO) causes a generalized delay in endochondral and intramembranous ossification, in addition to important alterations in the epiphyseal growth plates (EGPs), such as reduced thickness, disorganized columns of chondrocytes, and impaired differentiation of hypertrophic chondrocytes, resulting in reduced growth and skeletal abnormalities. On the other hand, hyperthyroidism (HYPER) results in accelerated skeletal maturation, with premature closure of the EGPs and subsequent decrease in the longitudinal bone growth (LBG). There are evidences that TH has direct actions in the EGPs, acting mainly via its nuclear receptors (TRs), however, the mechanisms through which TH regulates the LBG are still poorly understood. We recently found protein expression of α_{2A} and α_{2C} adrenoceptors (α_{2A}AR and α_{2C}AR) in the EGPs of mice, a decrease in the length of long bones in α_{2A}-AR and α_{2C}-AR single knockout mice and that the double inactivation of these receptors (α_{2A}/α_{2C}-AR$^{-/-}$) leads to resistance to the thyrotoxicosis-induced reduction in the LBG in mice. To investigate if TH interacts with the sympathetic nervous system (SNS), via α_{2C}-AR, to control LBG, we evaluated the effect of 30 days of HYPO (induced by methimazole and sodium perchlorate treatment) and HYPER (induced by daily i.p. injections of 20 times the physiological dose of triiodothyronine = 7μg/100 g body weight / day) on the bone growth of 21-day old female wild-type (WT = C57BL/6J) and α_{2C}-AR$^{-/-}$ mice. As expected, both HYPO and HYPER significantly impaired LBG in the femur, tibia, fourth lumbar vertebra (L4), radius and humerus. Surprisingly, the femur, L4 and humerus of α_{2C}-AR$^{-/-}$ mice were resistant to the negative effects of HYPO and HYPER on bone growth. Only a slight negative effect of HYPO was observed in the LBG of the tibia and radius, while HYPER promoted a slight increase in the length of these two bones. Altogether, these findings suggest that TH interacts with the SNS, via a_{2C}-AR, to control LBG.

Defining Mesenchymal Stem/Stromal Cell Subpopulations With Variable Differentiation and Immunomodulatory Potential. Sally James*, Farinaz Afsari, Jennifer Dyson, James Ashmore, Charlotte Knight, Peter Ashton, Paul Genever. University of York, United Kingdom

Mesenchymal stem/stromal cells (MSCs) can differentiate into bone, cartilage and fat tissues. They have also been shown to have immunomodulatory properties and are prime candidates for cell-based therapy in orthopaedics. However, MSCs lack selective markers and often consist of heterogeneous mixtures of cells that are likely to contain different MSC types of varying potency. To identify functional variance in MSC subpopulations, we isolated >100 clonal MSC lines following immortalisation by human telomerase (hTERT) transduction. From these lines, our interest centred on four clones of hTERT-MSCs (C101, C102, C201 and C202) with different behavioral traits. All lines were positive for typical MSC markers CD29, CD44, CD73, CD90, CD105 and CD166, and CD34/CD45-negative. C101 and C201 were capable of trilineage differentiation and C101 spontaneously differentiated towards osteogenesis with prolonged confluency. C102 and C202 showed no evidence of skeletogenic differentiation. Applying principal component analysis and clustering algorithms to the global gene expression datasets showed grouping of C101 and C201, closest to primary MSCs, whilst C102 and C202 clustered independently. Over 6,000 transcripts were differentially expressed between the four lines and parental MSCs ($P<0.05$, >2-fold) with highly significant differences in gene sets, ontologies and pathways representative of cell-ECM interactions, RTK signalling, adipogenesis and endochondral ossification. Furthermore, C101 and C201 (plus primary MSCs) were enriched in genes representative of typical mesodermal MSCs (PRRX1, PDGFRA, KITLG, GDF5, NGFR) whereas C102/202 were enriched in angiohematopoietic genes (FLT1, KDR, TEK, EDN1, EDN2, VWF, MCAM). Strikingly, immunomodulatory gene sets such as cytokine/inflammatory responses, and interferon/TNF signalling were enriched in the non-differentiating lines. Flow cytometry confirmed >3-fold higher levels of ICAM1 surface expression in C102/C202 versus C101/C201. In samples of primary MSCs, selected only by plastic adherence, we identified a wide range of low to high ICAM1-expressing populations. Finally, expression of nestin, a putative in vivo marker of bone marrow MSCs, was >10-fold higher in C201 compared to the other lines using QPCR. These findings demonstrate the presence of multiple MSC subpopulations in bone marrow, some with typical MSC differentiation ability and others that play a resident immune-regulatory role in bone marrow stroma.

Epigenetic Regulation of Age-Dependent *Sox9* Expression in Mouse Articular Cartilage. Mingcai Zhang*[1], Qinghua Lu[1], James Bernard[1], Andrew Miller[1], Jinxi Wang[2]. [1]Department of Orthopedic Surgery, University of Kansas Medical Center, USA, [2]University of Kansas Medical Center, USA

Purpose: Transcription factor *Sox9* is essential for the differentiation of mesenchymal progenitor cells into chondrocytes during embryonic development. Mice with cartilage-specific inactivation of *Sox9* at the postnatal stages display a loss of proteoglycans in articular cartilage. However, the collagen II protein persists in articular cartilage, with no histopathological signs of osteoarthritis (OA) even at 18 months of age. It remains unclear why deficiency of *Sox9*, the master regulator of cartilage formation, does not cause OA or loss of collagen II in adult mice. This study aimed to test our hypothesis that *Sox9* expression in articular chondrocytes decreases in adult mice and that the age-dependent expression of *Sox9* is mediated by epigenetic mechanisms.

Methods: Joint tissues were harvest from wild-type BALB/c mice at the age of embryonic day 16.5 (E16.5), postnatal day 1 (1-day), and 2, 6, 12, and 18 months for histology and immunohistochemistry (IHC). Total RNA, genomic DNA, and chromatins obtained from femoral and humeral head cartilage at those ages were used for gene expression assay by qPCR, methylated DNA immunoprecipitation (MeDIP), and chromatin immunoprecipitation (ChIP), respectively.

Results: qPCR revealed that *Sox9* mRNA expression in articular cartilage was highest at E16.5 and 1-day, but significantly declined at 2 months and maintained at a lower level until 18 months (Figure 1). IHC showed a similar age-dependent expression pattern of the *Sox9* protein. Epigenetic studies revealed that DNA methylation levels of the 5 islands in the *Sox9* promoter region were low at the developmental stages, elevated at 6 and 12 months, but not significantly changed at 18 months. ChIP assay showed that histone 3 lysine 4 dimethylation (H3K4me2, an epigenetic code for transcriptional activation) was highest at E16.5 and significantly reduced after 2 months (Figure 2); whereas the histone 3 lysine 9 dimethylation (H3K9me2, an epigenetic code for transcriptional repression) was lowest at E16.5 and significantly increased after 2 months of age.

Conclusion: These results indicate that *Sox9* expression in articular chondrocytes decreases after the completion of skeletal development in mice and that the age-dependent expression of *Sox9* is mediated by epigenetic mechanisms. The data suggest that the demand for *Sox9* expression in adult articular cartilage diminishes with possible changes in the regulatory role of *Sox9* in articular chondrocyte function.

Keywords: Epigenetics, *Sox9*, cartilage

Transcriptome Profiling Reveals that Postmenopausal Osteoporosis and Bone Density Correlate with Fat Metabolism but not Adiposity. Sjur Reppe*[1], Ole K. Olstad[2], Simon J. Cockell[3], Paul Sanderson[4], Vigdis T. Gautvik[5], Kaare M. Gautvik[6], Harish Datta[7]. [1]Oslo University Hospital, Ullevaal, Norway, [2]Oslo University Hospital, Norway, [3]Faculty of Medical Sciences, Newcastle University, United Kingdom, [4]The Royal Victoria Infirmary, United Kingdom, [5]Institute of Basic Medical Sciences, University of Oslo, Norway, [6]University of Oslo, Oslo University Hospital, Lovisenberg Deacon Hospital, Norway, [7]Newcastle University, United Kingdom

The negative relationship between adiposity and bone mineral density has been explained in terms of increased rate of mesenchymal stems cells (MSC) differentiation into adipocytes, adversely affecting the osteoblast pool and thereby reducing bone formation capability. Whether marrow adiposity is a cause or consequence of postmenopausal bone loss and ageing, and the underlying molecular mechanisms are unclear. We performed genome-wide gene expression profiling of transiliacal trabecular bone biopsies derived from an unbiased cohort of Caucasian postmenopausal women. The cohort comprised healthy controls, osteoporotics (T-score <-2.5) plus one or more fragility fractures, and a group with intermediate bone mass. The data analysis showed that transcripts associated with fat metabolism were negatively correlated with osteogenic activity (as measured by expression levels of ACSL3, PPARA, FABP3, PHKB, ACADM, ACADSB, LPIN1, PDK4, ABCA1, HADHB, PRKAA2) and areal bone mineral density (aBMD). Furthermore, the transcripts associated with fat metabolism showed higher expression in osteoporotics than controls. However, mRNAs associated with adiposity (PRARG, FAB4, SLC2A4 (GLUT4)) had no correlation with aBMD or elevated expression in an osteoporotic cohort. The importance of metabolic stress playing a critical role in the pathogenesis of postmenopausal osteoporosis was underlined by a strong negative association of BMD of key microRNAs, including miR-378, with an established role in lipid metabolism.

MO0096

Trps1 Regulates Mineralization in a Context-Dependent Fashion. Maria Kuzynski[1], Callie Mobley[2], Tony Winters[2], Manisha Yadav[3], Anne Poliard[4], Odile M.C. Kellerman[5], Jose Luis Millan[6], Dobrawa Napierala*[7]. [1]University of Alabama at Birmingham, USA, [2]Institute of Oral Health Research, Department of Oral & Maxillofacial Surgery, School of Dentistry, University of Alabama at Birmingham, Birmingham, AL, USA, [3]Burnham Institute for Medical Research, USA, [4]Faculté de Chirurgie Dentaire, et UMR-S 747, Université Paris Descartes, France, [5]UMR-S 747 INSERM, France, [6]Sanford-Burnham Medical Research Institute, USA, [7]University of Alabama At Birmingham School of Dentistry, USA

Trps1 is a transcriptional repressor that belongs to the GATA family of transcription factors. A number of *in vitro* and *in vivo* studies demonstrate the involvement of Trps1 in the development of skeletal and dental tissues as well as the mineralization process. The importance of *TRPS1* in tooth formation and mineralization is underscored clinically by dental and skeletal manifestations in two distinctive human disorders caused by different mutations of *TRPS1*: tricho-rhino-phalangeal syndrome (TRPS) and Ambras syndrome. In our previous studies of a mouse model of TRPS ($Trps1^{\Delta GT}$ mice), we uncovered that *Trps1* deficiency leads to premature mineralization of the perichondrium. In turn, overexpression of *Trps1* from the 2.3kb fragment of *Col1a1* promoter results in severe impairment of dentin formation. Interestingly, both $Trps1^{+/\Delta GT}$ and *Col1a1-Trps1* mice present with age-related osteopenia, suggesting that the role of *Trps1* in mineralizing tissues is context-dependent. To understand the molecular consequences of Trps1 deficiency and upregulation in the development and function of cells producing mineralized matrix, we used the 17IIA11 cell line as a cellular model of mineralization. We generated *Trps1*-deficient and *Trps1*-overexpressing cell lines and analyzed their mineralization and expression of osteogenic genes prior to and during the mineralization process. We performed a series of analyses including alizarin red staining and quantification, tissue non-specific alkaline phosphatase activity, qRT-PCR, and western blot analysis. We discovered that downregulation of *Trps1* results in loss of mineralization potential associated with decreased expression of genes critical for the initiation of mineralization. In contrast, upregulation of *Trps1* results in delayed mineralization as well as reduced expression of phosphate homeostasis genes during the propagation phase of mineralization. Based on these data we have concluded that *Trps1* is required for the maturation of cells destined to produce mineralizing matrix and therefore *Trps1* supports the initiation of mineralization. However, in mineralized-matrix producing cells, *Trps1* represses the extent of extracellular matrix mineralization, thus acting as a repressor of mineralization in mature cells.

MO0097

***Sostdc1*, a paralog of *Sost*, is Involved in Bone Maintenance and Fracture Repair.** Nicole Collette*[1], Cristal Yee[2], Salustra Urbin[1], Liqin Xie[3], Aris Economides[4], Gabriela Loots[5]. [1]Lawrence Livermore National Laboratory, USA, [2]University of California, Merced, USA, [3]Regeneron Pharmaceutical company, USA, [4]Regeneron Pharmaceuticals, Inc., USA, [5]Lawrence Livermore National Laboratory, UC Merced, USA

Sostdc1 (Sclerostin domain-containing-1, Sost-Like, Wise, Ectodin, USAG-1) is a paralog of Sclerostin (Sost) that modulates both BMP and WNT signaling. Previously it has been shown that loss of *Sostdc1* causes tooth defects, resistance to kidney disease, and abnormal hair follicles. It is expressed in the developing limb, and we have previously shown that *Sost; Sostdc1* double knockouts display preaxial polydactyly through SHH misregulation and ectopic activation of Sox9 in the digit 1 field. Sostdc1 binds to BMP4 and -7 to antagonize BMP signaling, and to LRP4 and -6 WNT co-receptors to modulate WNT signaling, acting as a WNT activator or antagonist in a context-dependent manner. Recently, a genome-wide linkage analysis identified a quantitative trait locus for femoral neck bone mineral density (BMD) on chromosome 7p21.1. Subsequently, strong association was found between SNPs in *Sostdc1* intron and BMD in Chinese women, suggesting that Sostdc1 may participate in skeletal development or maintenance. Unlike *Sost*, *Sostdc1* is not expressed in osteocytes, trabecular osteoblasts, or osteoclasts; however *Sostdc1* expression is high in the periosteum, vasculature, and connective tissues. Because the periosteum is rich in osteoblasts and osteoprogenitor cells that build and repair bone, we examined whether $Sostdc1^{-/-}$ mice have altered bone mass or fracture repair. Micro-CT analysis revealed that $Sostdc1^{-/-}$ mice have a higher total bone volume (TV) in the femoral cortex ($p<0.01$), distal femur, proximal tibia, and lumbar vertebra ($p<0.005$) compared to C57Bl/6 controls (*WT*). We also found significantly increased BMD in long bones ($p\leq0.05$). In the femoral mid-shaft cortex, the pMOI and BMD was increased ($p<0.05$) suggesting increased biomechanical strength. Despite these improved bone qualities, $Sostdc1^{-/-}$ show a defect in fracture repair, with 1/3 of fractures failing to form unions by 28 days post-injury in a closed Einhorn model, compared to the 100% union rate for control mice. During early fracture repair, *Sostdc1* expression shows a dynamic pattern: in periosteum and surrounding soft tissues (muscle/vasculature) the pool of *Sostdc1* positive cells rapidly expands and migrates into the callus at 3-days post fracture, but the expression diminishes as healing progresses. By 14-days post fracture *Sostdc1* positive cells are no longer visible in the callus. These data suggest that Sostdc1 plays a role in bone maintenance and repair.

This study received funding from NIH DK075730 and LLNL LDRD ER (11-ERD-060). This work was conducted under the auspices of the USDOE by LLNL (DE-AC52-07NA27344) LLNL-ABS-633635.

Application of Silver Nanoparticle-based Materials in Orthopedic Surgery. Zhong Zheng*[1], Ching-Yun Hsu[1], Yulong Zhang[1], Omar Velasco[1], Kevin S. Lee[1], Todd Rackohn[1], Ching Shen[1], Thua Thang Ngo[1], Benjamin Wu[1], Xinli Zhang[2], Kang Ting[2], Chia B Soo[1]. [1]UCLA, USA, [2]University of California, Los Angeles, USA

Purpose: Infection of surgically-implanted materials accounts for nearly 1 million cases of nosocomial infections in the U.S. per year, which exhaust healthcare resources and create an enormous economic burden. This project focuses on engineering multifunctional silver nanoparticle (Ag^{NANO})-based orthopedic devices with sustained antimicrobial and osteoinductive activities. Methods: Ag^{NANO}-based porous PLGA graft was used to induce bone regeneration in a well-documented

grossly contaminated rat femoral segmental defect (FSD) model. Ag^{NANO}/PLGA-coating was used to prevent biofilm formation on orthopedic devices and subsequent implant-related infection. Gram-positive vancomycin-resistant, methicillin-intermediate *Staphylococcus aureus* Mu50 and Gram-negative opportunistic pathogen *Pseudomonas aeruginosa* PAO1 were used as infectious agents. Antimicrobial activity was assessed by bacterial colonization evaluation, microplate proliferation assay, and Taylor-modified Brown and Brenn Gram staining. MC3T3-E1 pre-osteoblasts were used to determine cytotoxicity and osteoinductivity of these Ag^{NANO}-based materials *in vitro*. *In vivo* bone formation was evaluated by radiography, 3D micro-computed tomography, and histological and immunohistological staining. Results: Ag^{NANO}-based materials exhibited strong antibacterial properties *in vitro* and *in vivo* without significant cytotoxicity against osteoblasts. A 6-mm critical-sized FSD (total volume ~ 75 ml) infected with 10^8 CFU bacteria (~10^9 CFU/ml bacteria, which far exceeds the typical 10^5 CFU/ml criteria for invasive tissue infection) and implanted with BMP2-coupled Ag^{NANO}/PLGA graft healed in 8 weeks without evidence of residual bacteria, while the control implanted with non-Ag^{NANO}-containing graft failed to result in new bone formation due to the presence of continued bacterial infection. Additionally, Ag^{NANO}/PLGA-coated stainless steel alloy exhibited strong osteoinductive and antibacterial properties and resulted in bone formation around the alloy without bacterial survival *in vivo*. Moreover, Ag^{NANO}/PLGA-coated titanium also presented antimicrobial properties. Conclusions: Our results indicate that Ag^{NANO} of defined particle size is bactericidal without discernible osteoblast toxicity or negative effects on BMP2 osteoinductivity, making it an ideal antimicrobial and osteoinductive agent for bone regeneration in infected wounds. In addition, Ag^{NANO}/PLGA can be used for coating implants to prevent secondary infection.

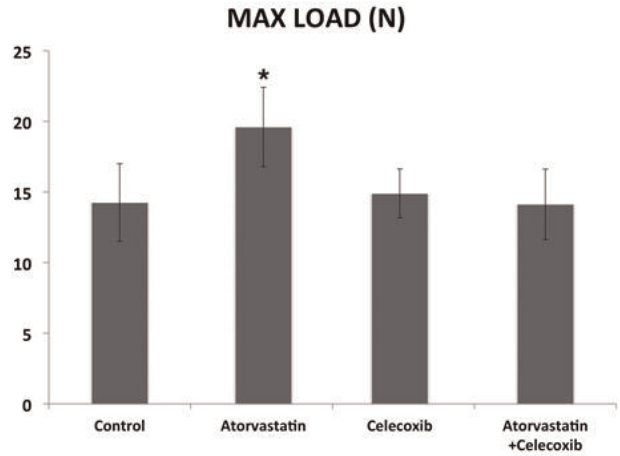
Atorvastatin Increases Biomechanical Strength of Repaired Rotator Cuff Tendon Via a Cyclooxygenase-2 Dependent Mechanism. Oleg Dolkart*[1], Ofir Chechik[2], Tamar Liron[3], Dalia Somjen[2], Tamar Brosh[4], Yankel Gabet[5], Eran Maman[2]. [1]Orthopedic Surgery Division, Tel-Aviv Medical Center & Bone resarch lab. the Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel, [2]Orthopedic Surgery Division, Tel-Aviv Medical Center & the Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel, [3]Bone research laboratory, Department of Anatomy & Anthropology, Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel, [4]Biomechanics Laboratory, School of Dental Medicine, Tel-Aviv University, Tel-Aviv, Israel, [5]Sackler School of Medicine, Tel Aviv University, Israel

Statins are lipid-lowering drugs with many pleiotropic effects, part of which are associated with the stimulation of cyclooxygenase (COX)-2.COX-2 inhibitors of are commonly prescribed in orthopedic patients. Here we investigated whether post-operative Atorvastatin (ATV) administration improves tendon healing by stimulating COX-2 and whether COX-2 inhibitors have a detrimental effect.

Following experimental rotator cuff (RC) tear and suturing, 48 Wistar rats were randomly allocated into four groups: ATV 20 mg/kg, celecoxib (CEL, COX-2 inhibitor) 20 mg/kg, ATV+CEL or saline alone (S). Animals were sacrificed after 3 weeks and evaluated biomechanically by tension testing. Primary tenocytes were obtained from the supraspinatus tendon under sterile conditions. Cells cultures were treated with therapeutic dosage of ATV, CEL, ATV+CEL or prostaglandin E2 (PGE-2). Cell migration (wound healing assay) and proliferation (thymidin incorporation) were evaluated. Expression of the PGE-2 receptors (EP) was determined by qRT-PCR.

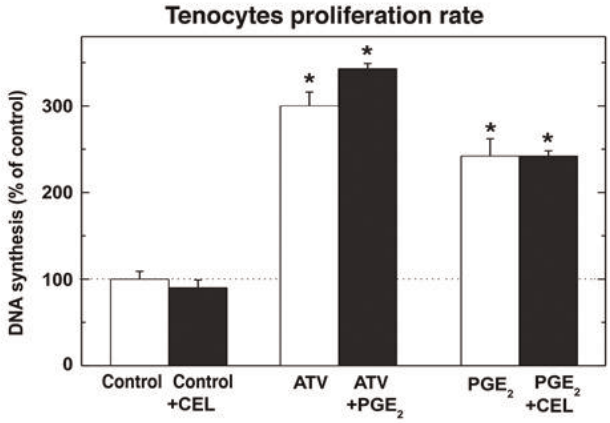
Significantly higher maximal load and stiffness were demonstrated in the ATV group as compared to S (+35% and +74%, respectively; $p<.001$) and CEL group (+34% and +50%, respectively; $p<.005$). Importantly, CEL alone did not affect tendon healing ($p=.88$). Tenocytes treated with ATV demonstrated significantly higher proliferation and migration rates whereas CEL alone had no effect. In line with the in vivo biomechanical results, the mitogenic effect of ATV on tenocytes was abrogated by CEL. However, PGE-2 treatment stimulated tenocyte proliferation even in the presence of CEL. Among the four PGE-2 receptors, tenocytes mainly expressed EP-4, suggesting that this receptor mediates PGE-2 signaling in tenocytes.

These results indicate that statin administration enhances tendon repair in vivo while COX-2 inhibitors have an opposing effect. The statin-induced biomechanical strengthening of the repaired tendon is likely due to the stimulation of tenocyte proliferation and migration via increased COX-2 activity and auto/paracrine PGE-2 signaling. Although chronic inflammation contributes to the development of tendinopathy, our results advocate for a positive role of PGE-2 in tendon healing during the acute inflammatory phase that follows tendon surgical repair. We therefore conclude that the use of post-operative COX-2 inhibitors should be carefully considered while statin administration may improve tendon healing.



Biomechanical testing of rotator cuff, 3 weeks post-surgery showed that Atorvastatin stimulation of tendon repair is blocked by Celecoxib. *, vs. control (saline), p<.005.

Biomechanical testing results



Tenocytes proliferation rate following saline (C), atorvastatin (ATV), celecoxib (CEL) and/or PGE-2 administration. ATV significantly increased tenocyte proliferation rate. This effect was abrogated by CEL addition and was reinstated by PGE-2 treatment even in the presence of CEL. *, vs. control (saline), p<.005.

Tenocyte proliferation results

Epigenetic Transcriptional Silencing of ZIC1 in Human Trabecular Bone Is Associated with Promoter Hypermethylation. Harish Datta*[1], Marianne Kringen[2], Ole K Olstad[2], Sjur Reppe[3], Vigdis T Gautvik[4], Paul Sanderson[5], Kaare M Gautvik[6]. [1]Newcastle University, United Kingdom, [2]Oslo University Hospital, Norway, [3]Oslo University Hospital, Ullevaal, Norway, [4]Institute of Basic Medical Sciences, University of Oslo, Norway, [5]The Royal Victoria Infirmary, United Kingdom, [6]University of Oslo, Oslo University Hospital, Lovisenberg Deacon Hospital, Norway

The zinc finger protein of cerebellum 1 (ZIC1), a neural developmental transcription factor, has a demonstrated role in shear flow mechanotransduction in osteocytes. A transcriptome analysis that compared gene expression in human bone biopsy samples taken from lumbar spine and iliac crest analysis revealed that Zic1 was among the most up-regulated genes in the lumbar spine in comparison with the iliac crest. To determine whether ZIC1 is silenced by promoter hypermethylation, we compared the expression of ZIC1 mRNA in iliac crest (IC) (n=7) and the lumbar spinal vertebrae (LS) (n=25) using Affymetrix expression analysis and validation by qRT-PCR. The methylation pattern of twenty CpG sites in the ZIC1 promoter was measured using pyrosequencing with bisulfite treated genomic DNA as template. To investigate the relationship between ZIC1 expression and promoter hypermethylation, we correlated ZIC1 mRNA expression and degree of CpG site methylation in LS and

IC, respectively. The ZIC1 expression was found to be 47-fold higher in the L5 than IC (P=2.90E-09). The most intensely methylated CpG site had a 55% higher degree of methylation in IC than in the LS (49.2 vs 31.8; p<0.001). All but one of the twenty CpG methylation sites in the ZIC1 promoter region showed strong significant negative correlation between the extent of methylation and ZIC1 expression (Pearson r = -0.43 to -0.79, p= 2.4E-06 to 3.0E-02)). The hypomethylated bone sites, apart from having higher ZIC1 expression, had higher overall bone turnover as reflected by an increased expression of respective genes characteristically associated with osteoblast (Col1a1, BGLAP, SPP1, SPARC, IBSP), osteoclast (CTSK, ACP5) and osteocyte (SOST, DMP1, FGF23). Whilst our findings cannot exclude possible involvement of other mechanisms in silencing of ZIC1, they do however suggest that in human bone promoter CpG methylation is the predominant mechanism for ZIC1 down-regulation at low turnover skeletal sites.

FOXO1 Deletion in Dendritic Cells Leads to Bacteria Induced Osteoclastogenesis and Periodontitis. Wenmei Xiao*[1], Sandra Pacios[1], Maher Alnammary[1], Dana Graves[2]. [1]University of Pennsylvania Dental School, USA, [2]University of Pennsylvania, School of Dental Medicine, USA

Introduction: The host response plays both a protective and destructive role in periodontitis, the most common osteolytic disease in humans. The goal of this study was to establish the contribution of DC to activating a protective lymphocyte response in periodontal disease by limiting DC activation by deletion of the transcription factor FOXO1.

Materials and Method: Conditional deletion of FOXO1 was achieved by breeding FOXO1L/L mice with mice that expressed Cre recombinase under control of CD11c to generate experimental (CD11c.Cre+.FOXOL/L) and the control littermates (CD11c.Cre−.FOXO1L/L). Periodontitis was induced by inoculation of P. gingivalis and F.nucleatum. Mice were euthanized 6 weeks later the periodontium including molar teeth were examined by histomorphometric analysis and three color immunofluorescence and the gingiva adjacent to boneby real-time PCR.

Results: The number of dendritic cells the migrated to the periodontal tissue was ~40% lower in the CD11c.Cre+.FOXOL/Lgroup compared to littermates that did not have FOXO1 deleted (P<0.05).The activation of DC measured by DC produced IL-12 determined by immunofluorescence was reduced by more than 50% by FOXO1 deletion in the experimental mice. CD11c.Cre+.FOXOL/Lmice with FOXO1 deletedin DC had 20-30% more bone loss than the corresponding CD11c.Cre-.FOXOL/Lmice (P<0.05). In addition the experimental micehad 36% increase in osteoclasts and 55% more eroded bone surface (P<0.05). Greater bone loss in the experimental mice was accompanied by 2 fold higher levels of IL-1β and IL-17 (P<0.05).

Conclusion: This study demonstrates that FOXO1 expression in DC is required to generate a protective response to bacteria induced periodontitis. In the absence of FOXO1 there was reduced migration of DC to periodontal tissues and decreased DC activation. This caused an increase in expression of IL-17 and IL-1β along with increased osteoclastogenesis, eroded bone surface and bone loss.

Glycated Osteocalcin. Grazyna Sroga*, Deepak Vashishth. Rensselaer Polytechnic Institute, USA

Non-enzymatic glycatio is a spontaneous biochemical reaction occuring *in vivo* and *in vitro* between reducing sugars and proteins that leads to the formation of crosslinks known as advanced glycation end products (AGEs) [1]. Typically, sugars attach to the functional groups of such amino acids as arginine, lysine, valine and cysteine. Accumulation of AGEs is most pronounced in long-lived proteins such as bone-matrix collagen. In addition to collagen, several non-collagenous bone matrix proteins play an important role in mechanical properties of bone [2, 3]. Osteocalcin (OC) is the second major component of bone matrix accounting for 10-20% of noncollagenous proteins and 2% of total bone proteins. As a matrix protein, OC deposited in the skeleton is only replaced with newly synthesized material during bone remodeling. Among 49 amino acids that compose human OC, there are four arginines and five tyrosines that can undergo glycation. Thus, similarly to collagen, OC in bone could become post-translationally glycated to a variable extent depending upon the age and the local glucose concentration. In the present study, we have quantified the extent of glycation in human OC that was modified *in vitro* using glucose. The extent of OC glycation was measured using the total fluorescent AGE assay as well as ultrahigh liquid pressure chromatography (UPLC) [4].

We established that similarly to other long-lived proteins, OC undergoes glycation, which leads to the production of different AGEs. Interestingly, analysis of acidic hydrolysates of OC using UPLC revealed the presence of pentosidine, a clinically relevant AGE [2], and it has not yet been shown that PEN can form as one of the AGE modifications of OC.

Heterozygous Inactivation of Gnas Induces Heterotopic Ossification and Impairs Normal Skeletal Development. Girish Ramaswamy*[1], Deyu Zhang[1], Frederick Kaplan[2], Robert Pignolo[1], Eileen Shore[1]. [1]University of Pennsylvania, USA, [2]University of Pennsylvania Hospital, USA

Progressive osseous heteroplasia (POH), Albright hereditary osteodystrophy (AHO), osteoma cutis (OC), and pseudohypoparathyroidism 1a/1c (PHP) form a spectrum of disorders that are caused by heterozygous inactivating mutations in *GNAS*, a gene that encodes multiple transcripts including the α-subunit of the stimulatory G-protein ($G_s\alpha$) of adenylyl cyclase. All these disorders exhibit subcutaneous heterotopic ossification (HO); however, POH is the most severe form and is characterized by HO progression into deeper connective tissues including muscle and fascia. The *GNAS* gene shows genomic imprinting and POH is associated with paternal inheritance of the mutation. Mice with paternal inheritance of heterozygous deletion of exon 1 (Gnas $Ex1^{+/-}$) have lower body weight and length, and develop subcutaneous ossifications with age. But whether reduced Gnas expression leads to alterations in the formation or quality of skeletal bone remains undetermined. To investigate the effects of Gnas mutation on skeletal development, we performed μCT and histological analyses to examine the effects of paternal allele inactivation of Gnas on developing bone and cartilage. At postnatal days 1 (P1) and 14 (P14), $Ex1^{+/-}$ mice weighed significantly less than wild-type (wt) littermates. Tibiae from $Ex1^{+/-}$ mice at these ages were significantly shorter in length (15% ± 4). Trabecular bone parameters, analyzed through μCT scans of the distal epiphyseal region in P14 mice, revealed dramatic reductions in bone volume (36% ± 11) and bone volume fraction (20%±12). Microarchitecture of trabeculae was altered with a significant decrease in trabecular thickness and a concomitant increase in the structure model index, suggesting that trabecular bone is more rod-like in these mutants than wt littermates. μCT analyses of the femoral mid-diaphysis region showed reduced cortical thickness (20%±10) and cortical bone volume (35%±8) in P14 mutants. Histology of hindlimb sections from P14 mice showed a marked decrease in the length of the hypertrophic zone of the growth plates of $Ex1^{+/-}$ mice. The calvaria of P1 and P14 heterozygous mutants were reduced in size in both antero-posterior and medial-lateral dimensions. Taken together with our previous findings, heterozygous paternal allele inactivation of Gnas not only alters post-natal progenitor cells to form heterotopic ossification, but also adversely affects normal skeletal development that impacts both endochondral and intramembranous bone formation.

MO0104

The mineral dissolution function of osteoclasts is dispensable for hypertrophic cartilage resorption during the development and growth of long bones. Heiani Touaitahuata*, Gaelle Cres, Virginie Vives, Anne Blangy. CNRS CRBM Montpellier University, France

During long bone growth, the initial cartilaginous model of the skeleton is progressively replaced by bone to allow long bone development and growth. This process is known as endochodral ossification. It involves in particular the resorption of the mineralized cartilage produced by hypertrophic chondrocytes and its replacement by bone. This results in the formation of trabecular bone. Trabecular bone is then remodeled throughout life by alternation of bone resorption and bone formation cycles. Osteoclasts are multinucleated macrophages specialized for mineralized tissue degradation with the combined ability to solubilize hydroxyapatite and to degrade extracellular matrix proteins. We reported previously that osteoclasts lacking Dock5, an activator of the GTPase Rac, are defective for bone resorption due to abnormal podosome organization and absence of sealing zone formation (Vives et al., JBMR. 2011, 26(5):1099-110). As a consequence, $Dock5^{-/-}$ adult mice have increased bone mass. We used $Dock5^{-/-}$ mice to further investigate the implication of osteoclasts resorption function during endochondral bone formation. In $Dock5^{-/-}$ mouse bones, we found normal expression of MMP9 and MMP13 metalloproteases, which are necessary for hypertrophic cartilage formation and resorption. $Dock5^{-/-}$ osteoclasts secrete normal amounts of MMP9, TRAP and CtsK but they are unable to solubilize minerals. Cartilage and primary spongiosa are unaffected in $Dock5^{-/-}$ mouse bones. Conversely, starting from P7 and remaining until adulthood, the secondary spongiosa in $Dock5^{-/-}$ mice showed increased BV/TV as compared to $Dock5^{+/+}$ animals, with normal trabecular numbers but increased trabecular thickness and

reduced trabecular separation. These observations reveal that contrarily to bone resorption, the sealing zone and the ability of osteoclasts to dissolve minerals is dispensable for the removal of hypertrophic mineralized cartilage and the building of the trabecular network geometry during endochondral bone formation.

MO0105

Zfp521 in conjunction with the NuRD complex and Tgm3 regulates mesenchymal stem cell lineage determination and induced pluripotency. Harikiran Nistala*[1], Ken-ichi Takeyama[2], Hsu-Hsin Chen[1], Bernard Boback[2], Francesca Gori[3], Roland Baron[4]. [1]Harvard University, USA, [2]Harvard School of Dental Medicine, USA, [3]Harvard School of Dental Medicine, Massachusetts General Hospital, USA, [4]Harvard School of Medicine & of Dental Medicine, USA

A portfolio of cell fate choices along with the ability for self-renewal is the hallmark of pluripotency in stem cells. Regulatory programs involving master transcription factors and epigenetic regulators mediating chromatin remodeling have been identified in the maintenance of pluripotency. How interactions between transcription factors and chromatin remodeling proteins maintain pluripotency and regulate differentiation remains unclear.

Zinc finger protein 521 (Zfp521) has been implicated in lineage determination of mouse ES cells and in the maintenance of precursor cells within the neuronal, mesenchymal and hematopoietic lineages. Zfp521 regulates chondrocyte and osteoblast maturation and represses adipocyte lineage determination (Hesse et al., 2010;Kang et al., 2013;Kiviranta et al., 2013). In a separate study, proteomic analyses revealed Zfp521 to be part of NuRD complex in a novel configuration that includes nuclear transglutaminases (Tgm1 and 3) in HEK293 cells. The NuRD complex has a dual role, silencing differentiation genes in pluripotent states, as well as pluripotency genes during differentiation, whereas nuclear transglutaminases induce a post-translational modification involving a ε-(γ-glutamyl) lysine cross-link between core histones.

In this study, we validated endogenous interactions between Zfp521, Tgm3 and NuRD components within H3 enriched nuclear fraction in MEFs. These findings led us to hypothesize that Zfp521 along with Tgm3 and NuRD forms an effector complex (Zfp521-Tgm3-NuRD) that regulates transcriptional programs leading to cell-lineage determination. To test this hypothesis in germ layer specification and induced pluripotency we used teratoma formation and the somatic cell reprogramming assay, respectively. Immunocytochemical and gene expression profiling of the explanted teratomas established the inhibitory role of Zfp521 and Tgm3 in mesoderm specification. Despite an increase in $Desmin^+$ mesodermal precursors, loss of Zfp521 or Tgm3 led to impaired osteo-chrondro commitment and increased adipogenesis. In addition, loss of Zfp521 or Tgm3 significantly impaired formation of iPS cells, as evidenced by reduced $SSEA1^+$ or AP^+ colonies. These results underscore the requirement of both Zfp521 and Tgm3 in the maintenance of induced pluripotency. Taken together these results further demonstrate the regulatory role of Zfp521, now in conjunction with NuRD and Tgm3, in mesenchymal cell-fate determination and maintenance of pluripotency.

Development of a WISP2/CCN5-specific immunoassay. Alexander Noll[1], Katrin Schlegelmilch[2], Susanne Duncker*[1], F. Armbruster[1], Norbert Schuetze[3]. [1]Immundiagnostik AG, Germany, [2]Universität Würzburg, Germany, [3]University of Wuerzburg, Orthopedic Center for Musculoskeletal Research, Germany

Introduction: WISP2 (Wnt-inducible signaling pathway protein-2)/CCN5 is a member of the CCN family of matricellular proteins that modify signaling of other molecules, in particular those associated with the extracellular matrix. WISP2/CCN5 is expressed in human bone, muscle, skin, and in the synovium of rheumatoid arthritis patients. Furthermore, WISP2 is differentially regulated during tumor progression. The aim of this study was to develop an immunoassay for the quantification of mature full length WISP2/CCN5 protein in biological fluids.

Material and Methods: Recombinant human WISP2/CCN5-flag protein was expressed in HEK293-EBNA cells and purified from cell culture supernatant by affinity chromatography. The purified protein was used to generate polyclonal antibodies against WISP2/CCN5 in rabbits. A sandwich ELISA for the quantitative detection of WISP2/CCN5 was established and validated. WISP2/CCN5 was measured in serum samples of 192 healthy persons, ages 0-70 years, in order to establish a reference range.

Results: Immunization of rabbits resulted in the generation of a specific antiserum against WISP2/CCN5, with no cross reactivity to related proteins albumin (0.78%), CYR61 (0.01%), CTGF (1.9%), NOV (0.16%), WISP1 (0.01%), and WISP3 (3.2%). The limit of blank was determined to be 0.993 ng/ml. The mean coefficient of variation was < 8 % for intraassay and <9 % for interassay variance. In a healthy population WISP2/CCN5 serum levels increased with age, and there was no significant difference between males and females of each age group. Using this ELISA, it was also possible to determine WISP2/CCN5 in other sample matrices such as EDTA, heparin, and citrate plasma as well as in synovial fluid.

Discussion: We have established a specific and sensitive immunoassay for the detection of WISP2/CCN5 in biological fluids. This ELISA could serve well in future investigations on the function of WISP2/CCN5 in normal and pathological states, maybe even for diagnostics or therapeutic monitoring of arthritic diseases.

Fibrillin-1 is an extracellular component of the Bone Marrow Stem Cell niche. Francesco Ramirez, Silvia Smaldone*. Icahn School of Medicine at Mount Sinia, USA

Fibrillin-1 is a structural component of the bone matrix that also regulates osteoblastogenesis by calibrating the bioavailability of TGFβ and BMP molecules. Mice under-expressing fibrillin-1 ($Fbn1^{mgR/mgR}$ mice) display reduced bone mass (osteopenia) associated with accelerated osteoblast maturation, greater osteoblast-dependent osteoclast activity, and abnormally high TGFβ and BMP signaling. As $Fbn1^{mgR/mgR}$ mice die from ruptured aneurysm at ~3 month of age, osteopenia progression was studied in mice with conditional inactivation of the Fbn1 in the developing limbs ($Fbn1^{Prx-/-}$ mice). Examination of $Fbn1^{Prx-/-}$ femurs by micro-computed tomography (μCT) documented a relatively greater bone loss between 3 and 6 months of age than between 1 and 3 months age. Ex-vivo experiments correlated these in vivo findings with higher and lower than normal clonogenic potential (as evidenced by the CFU-F assay) of marrow aspirates from 3 and 6 month old $Fbn1^{Prx-/-}$ mice, respectively. The additional finding that 3 month-old $Fbn1^{Prx-/-}$ mice have fewer mesenchymal stem cells (MSC) but more osteoprogenitors suggested a premature depletion of the MSC pool. Indeed, the number of osteoprogenitors was dramatically less in 3 month-old $Fbn1^{Prx-/-}$ mice treated with 5-Fluorouracil. As we also found that marrow cultures from $Fbn1^{Prx-/-}$ mice exhibit higher TGFβ activity, 1 month-old mutant mice were systemically treated with pan-TGFβ neutralizing antibodies (1D11) for 8 weeks. The treatment normalized the number of MSCs with the result of preventing bone loss in $Fbn1^{Prx-/-}$mice. Altogether, our data demonstrate that fibrillin-1 is an extracellular component of the bone marrow niche that regulates stem cell lineage commitment by modulating local TGFβ signaling.

Fibronectin Splice Variation in Human Knee Cartilage, Meniscus and Synovial Membrane and Association with Osteoarthritis. Carla Scanzello[1], Dessislava Markova[2], Ana Chee[1], Sherrill Adams[3], D. Greg Anderson[2], Howard An[1], Yejia Zhang*[4]. [1]Rush University Medical Center, USA, [2]Thomas Jefferson University, USA, [3]University of Pennsylvania School of Dental Medicine, USA, [4]Rush University Medical CTR, USA

Purpose: Osteoarthritis (OA) is characterized by extracellular matrix degradation of cartilage and meniscus, and low-grade synovial membrane (SM) inflammation. Fibronectin (FN) is a widely expressed molecule that can participate in these pathological processes. Multiple alternatively spliced isoforms of FN exist which have functional consequences, but splicing in joint tissues other than cartilage has not been well studied. The present study compares FN splice variation in human cartilage, SM and meniscus.

Methods: Joint tissues were collected from a non-arthritic organ donor, and from patients undergoing surgery. Total RNA was amplified by PCR using primers flanking alternatively spliced FN Extra Domain A (EDA), Extra Domain B (EDB) and Variable (V) regions.

Results: The FN EDB+, EDB- and EDA- variants were present in cartilage, SM, and meniscus, while the EDA+ variant was detected in only one SM specimen. V+ variants were present in all three tissues, and synovial expression varied with degree of cartilage degeneration. In addition, two V- isoforms, previously described as specifically expressed in cartilage, were present in SM and meniscus as well.

Conclusions: Fibronectin splice variation in meniscus and SM bears striking resemblance to that of cartilage, including expression of isoforms previously described as "cartilage-specific". While the EDB+, EDB- and EDA- variants are present in all tissues examined, EDA+ variants were largely undetectable. Synovial V+ forms were expressed at higher levels in patients with mild to moderate osteoarthritic changes. V+ FN should be investigated as a potential biomarker of disease stage or progression in larger OA patient populations.

MO0109

Osteopontin as a Novel Substrate for Proprotein Convertase 5/6 (*PCSK5*) in Bone. Betty Hoac[1], Delia Susan-Resiga[2], Rachid Essalmani[2], Edwidge Marcinkiewicz[2], Nilana Barros[3], Nabil Seidah[2], Marc McKee*[1]. [1]McGill University, Canada, [2]Clinical Research Institute of Montreal, Canada, [3]Federal University of Sao Paulo, Brazil

Seven proprotein convertases (PCs) cleave the basic consensus sequence K/R-X_n-K/R ↓ (where n = 0, 2, 4 or 6 variable amino acids) to activate precursor proteins. Despite similarities in substrate specificity, basic amino acid-specific PCs have a distinct tissue distribution allowing for enzymatic actions on tissue-resident substrates. The proprotein convertase PC5/6 (*PCSK5*) exists as soluble PC5/6A or membrane-bound PC5/6B isoforms. *Pcsk5* is highly expressed in mouse bone development, but cellular localization and a substrate for PC5/6 have not been described in this tissue. *Pcsk5*-knockout mice die at birth with a bone phenotype that includes small size, retarded ossification and additional thoracic segments and ribs. Osteopontin (OPN) is an abundant bone extracellular matrix protein with roles in mineralization, cell adhesion and migration, and it has two consensus sequence sites for cleavage by PC5/6A which might modify its functions. We aimed to determine whether OPN is a substrate for PC5/6A. *In situ* hybridization was performed on sections of normal mouse bone using *Pcsk5, Opn*/*Spp1* and *Dmp1* anti-sense and control sense cRNA probes. Quantitative RT-PCR for *Pcsk5* was performed on mouse RNA extracts from the osteoblastic MC3T3-E1 cell line and from primary osteoblast and osteoclast cultures. Enzyme-substrate assays using recombinant human PC5/6A and OPN were performed along with gel electrophoresis to visualize cleavage products. Immunoblotting for OPN was performed after SDS-PAGE of long-bone extracts from *Pcsk5*$^{A1/A1}$ (knockout) E18.5 embryos and wild type (WT) littermates. E18.5 embryos were also analyzed by micro-computed tomography. *In situ* hybridization and quantitative RT-PCR showed expression of *Pcsk5* and *Dmp1* in bone-forming cells (similar to *Opn* expression) but not in osteoclasts. Cell-free *in vitro* digestions showed that PC5/6A efficiently cleaved OPN. Consistent with this finding, immunoblotting of mouse bone extracts confirmed an OPN fragment appearing at ~15 kDa in WT bone that was not present in PC5/6-deficient bone. By micro-computed tomography, PC5/6-knockout embryos had delayed skeletal mineralization. In conclusion, we show that *Pcsk5* is expressed in OPN- and DMP1-producing bone-forming cells, and that OPN is a novel substrate for PC5/6A. Cleavage of OPN by PC5/6A could modify the function of OPN in bone leading to the bone phenotype, and/or it could contribute to downstream sequential processing of OPN by other enzymes. *Supported by CIHR.*

Role of Fibromodulin and Biglycan in Periodontal Development and Homeostasis. Le Wang*[1], Brian Foster[2], Vardit Kram[3], Francisco Nociti[2], Brendan Lopez[4], Anne Tran[2], Kanako Nagatomo[4], Marian Young[5], Martha Somerman[6]. [1]NIAMS/NIH, USA, [2]National Institute of Arthritis & Musculoskeltal & Skin Diseases (NIAMS), USA, [3]National Institute of Dental & Craniofacial Research (NIDCR), USA, [4]University of Washington School of Dentistry, USA, [6]National Institutes of Health, USA, [7]NIDCR, USA

Background: The periodontal apparatus (PA), which includes the periodontal ligament (PDL), and surrounding mineralized tissues, cementum and alveolar bone, is essential for tooth function. A better understanding of key regulators controlling development and homeostasis of the PA is necessary for improved periodontal regenerative therapies. Small-leucine rich proteoglycans (SLRPs) are extracellular matrix (ECM) proteins suggested to regulate collagen organization and cell-cell signaling. Mice with double-deficiency (dKO) in two SLRPs, fibromodulin (Fmod) and biglycan (Bgn), acquire ectopic calcification of tendons, and severe osteoarthritis. However, the role(s) of SLRPs in regulating the PA remain undefined. Results: Radiographic and histologic analyses showed that teeth of dKO mice were fully erupted with normal morphology. Polarized light studies demonstrated abnormal collagen fibrils and defective remodeling of alveolar bone of dKO mice. Immunohistochemistry revealed increased staining of SLRPs, asporin (Asp), lumican (Lum) and decorin (Dcn), in PDL of dKO mice, indicating compensatory mechanisms enhancing expression of alternative SLRPs. Although expression of mature osteoblast/cementoblast markers, bone sialoprotein and osteopontin, remained unchanged, dentin matrix protein-1 (DMP1), a mechanosensory osteocyte marker, was increased markedly in dKO PDL. Disruption of homeostasis of dKO PDL was further supported by increased expression of osteoclast-promoting receptor activator of nuclear factor-kB ligand (RANKL) and elevated numbers of tartrate resistant acid phosphatase (TRAP) positive osteoclasts (~20 fold at 4 wks and ~2 fold at 8 wks). To elucidate the underlying mechanisms, we analyzed PDL tissues by PCR array and found there was hyperactive TGFß/BMP signaling in dKO, further confirmed by dramatically elevated staining of phosphorylated SMAD5 (second messenger for TGFß/BMP) in dKO PDL. Dysregulated TGFß/BMP signaling in the dKO was further confirmed in studies using primary PDL cells, where exogenous BMP2 increased Asp and Dcn gene expression in WT, but decreased both in dKO. Conclusions: We demonstrated the importance of the SLRPs in maintaining homeostasis of PA, identifying Fmod and Bgn as key players in regulating the TGFß/BMP signaling pathway for ECM turnover and collagen organization. These novel findings increased our understanding of PA development and function with application toward designing new periodontal regenerative therapies.

In Vitro Mechanobiological Studies of Tenocyes. David Musson*, JungJoo Kim, Karen Callon, Dorit Naot, Iain Anderson, Vickie Shim, Jillian Cornish. University of Auckland, New Zealand

The musculoskeletal system experiences severe mechanical strain, often causing trauma; this has led to increased studies evaluating mechanical strain on musculoskeletal cells. Most studies use devices where levels of strain applied do not correspond to that experienced by the cell. Furthermore, nearly all studies use fibronectin (FN)-coated culture surfaces to enhance cell attachment. However, recent studies suggest that FN increases cell turnover, DNA damage, while FN fragments cause extracellular matrix degradation - all indicative of musculoskeletal disease. We employed a novel cell stretching device where strain is evenly distributed across the culture surface and to the cell, with two aims: to validate the device and to determine how different substrate coatings affect cell behaviour.

To mimic an experiment looking at collagen synthesis following 1h of knee extension (Miller et al, 2005), primary rat tenocytes were cultured on collagen type I coated silicone and exposed to 4% strain for 1h. Sirius red staining and real-time PCR were performed over 72h to measure collagen gene expression and protein deposition. In addition, primary rat tenocytes cultured on collagen type I or FN-coated silicone were exposed to 2% and 4% strain for 12h. Calcein staining and alamarBlue® assays were used to evaluate cell morphology and viability, while differential gene expression of tenocyte and inflammatory markers was determined using real-time PCR.

Collagen type III gene expression peaked at 48h and collagen type I was highest 72h post-stretching. This differs from that seen by Miller et al, who saw a peak at 24h, although levels were still elevated at 72h, as seen in our study. We also found a marked difference in tenocyte response to strain with different substrate coatings. FN-coated cultures showed greater attachment and growth compared to collagen-coated cultures; and calcein staining suggested cells cultured on FN had a more tenocytic morphology. However, at the gene expression level, cells stretched 2% on collagen had a 2-fold increase in the expression of the matrix protein tenascin-C, and a 3-fold increase in COX-2 expression, a key mechanotransduction mediator. FN coating did not show similar effects on gene expression.

This study suggests that our novel device is a useful tool in mechanobiological studies and is capable of mimicking in vivo studies, while collagen type I coating appears to be a better substrate for studying tenocyte response to strain.

Determination and Modulation of Total and Surface Calcium-sensing Receptor Expression in Monocytes in vivo and in vitro. Julien Paccou*[1], Cédric Boudot[1], Aurélien Mary[1], Said Kamel[1], Tilman Drueke[1], Patrice Fardellone[2], Ziad Massy[1], Michel Brazier[3], Romuald Mentaverri[4]. [1]Université De Picardie Jules Verne, France, [2]Service de rhumatologie, CHU Hôpital Nord, France, [3]University of Picardie, France, [4]INSERM U1088, Fra

Expression of the calcium-sensing receptor (CaSR) has previously been demonstrated in human circulating monocytes (HCM). The present study was designed to measure both total and surface CaSR expression in HCM and to examine its potential modulation by pro-inflammatory cytokines and/or Ca2+ and/or vitamin D sterols in U937 monocytic cell line.

Twenty healthy volunteers underwent blood sampling with subsequent isolation of peripheral blood mononuclear cells (PBMC) at 3 visits. Flow cytometry analysis (FACS) was performed initially (Visit 1=V1) and 19 days later (Visit 2=V2) to examine intra- and intersubject fluctuations of total and surface CaSR expression in HCM and 15 weeks later (Visit=V3) to study the effect of oral vitamin D supplementation. Serum biochemistry parameters were measured at each visit. Moreover, *In vitro* experiments were conducted to assess the effects of pro-inflammatory cytokines (TNFα and IL6), calcidiol, calcitriol and Ca2+ on CaSR expression in U937 monocytic cell line.

By FACS analysis, more than 95% of HCM exhibited cell surface CaSR staining. In contrast, CaSR staining failed to detect surface CaSR expression in other PBMC. After cell permeabilization, total CaSR expression was observed in more than 95% of all types of PBMC. Both total and surface CaSR expression in HCM showed a high degree of intra-assay reproducibility (<3%), an approximately 10% variation from V1 to V2 and a moderate intersubject fluctuation observed at V1, V2 or V3. In response to oral vitamin D supplementation, there was no significant change for both total and surface CaSR expression. In the *in vitro* study, U937 cells showed strong total and surface CaSR expression, and both were moderately increased in response to calcitriol exposure. Neither total nor surface CaSR expression was modified by increasing Ca2+ concentrations. Total CaSR expression was dramatically and concentration-dependently decreased by TNFα exposure. For IL6 stimulation, no clear-cut trend was observed for both total and surface CaSR expression.

In conclusion, CaSR expression can be easily measured in circulating monocytes and could potentially represent an accessible biomarker. It could be of particular interest to follow patients and see how pathological conditions such as osteoporosis modify CaSR expression. In the *in vitro* study, total and surface CaSR expression in U937 monocytic cell line were increased by calcitriol but total CaSR expression was decreased by TNFα stimulation.

MO0113

Effect of adriamycin on mineral metabolism of Pi loaded and vitamin D depleted C57BL/6J mice. Masanori Takaiwa*[1], Kunihiko Aya[2], Kosei Hasegawa[3], Hiroyuki Tanaka[4], Yoichi Kondo[1], Tsuneo Morishima[3], Nobuyuki Kodani[1]. [1]Department of Pediatrics, Matsuyama Red Cross Hospital, Japan, [2]Department of Pediatrics, Kurashiki Chuou Hospital, Okayama, Japan, [3]Department of Pediatrics, Okayama University Graduate School of Medicine, Dentistry & Pharmaceutical Sciences, Japan, [4]Okayama Saiseikai General Hospital, Japan

FGF23 is associated with progression and mortality of CKD. Meanwhile, FGF23 might compensate the aberrant mineral metabolisms in the early CKD. It is also likely that FGF23 potentially prevents the progression of hyperparathyroidism at least in early CKD. However the significance of FGF23 in the parathyroid of early CKD has not been clarified. C57BL/6J mice are relatively resistant against nephrotoxicity of adriamycin (ADR). Hence ADR could be a potent means to create a model of early CKD using C57BL/6J mice. Upon making 3 experimental groups, control group; a group fed a 1.5% Pi diet containing 2200IU/kg of cholecalciferol (VD), VD deficient group; a group fed a VD deficient 1.5% Pi diet, ADR group; a group fed the VD deficient diet, 12-week-old male C57BL/6J mice were weekly administered either serine (the control and VD deficient groups) or ADR (the ADR group, 5mg/kg/dose, ip) for 4 weeks. After the treatment, the ADR group weighed 21.3±0.8g and significantly smaller that the control (28.4±0.1g) and the VD deficent group (28.1±0.3g). Serum creatinine of the ADR group was 5.03±0.69mg/dl and markedly higher than the control (0.90±0.06mg/dl) and VD deficient groups (1.63±0.59mg/dl). ADR group showed significant hyperphosphatemia (10.27±0.25mg/dl) compared with the control (8.12±0.14mg/dl) and the VD deficient group (8.02±0.79mg/dl). Serum intact FGF23 of the control, the VD deficient and the ADR groups were 247.0±19.0, 338.1±19.8 and 368.8±30.9pg/ml, respectively. Serum PTH 1-84 of the control, the VD deficient and the ADR groups were 472.4±64.0, 579.7±202.1 and 598.3±269.2, respectively. Histological studies of kidney showed mild to moderate interstitial and glomerular injuries in the ADR group. The difference in the parathyroid of these 3 groups was not confirmed using the light microscopy. It was indicated that the weekly ADR injection caused chronic renal failure and hyperphosphatemia indicating that ADR treated C57BL/6J could be used as a CKD animal model. Deprivation of cholecalciferol was designed to enhance the aberrant mineral metabolisms of CKD and for further application using animal carries impaired FGF23 signaling. It is suggested that elevations in the FGF23 and PTH 1-84 among these 3 groups were due to dietary Pi and cholecalciferol intake than to the ADR nephropathy. Hence, although further examinations were required, our protocol could be the reasonable platform to examine the significance of FGF23 in the early stage of CKD.

MO0114

FGF23 Reduces Endothelium–Dependent Vasorelaxation and Nitric Oxide Bioavailability. Neerupma Silswal*[1], Dorothy Daniel[1], Chad Touchberry[1], Lynda Bonewald[2], Jason Stubbs[3], Jon Andresen[1], Michael Wacker[1]. [1]University of Missouri-Kansas City School of Medicine, USA, [2]University of Missouri - Kansas City, USA, [3]University of Kansas Medical Center, USA

Fibroblast Growth Factor 23 (FGF23) is a 32-kDa protein that is secreted primarily by osteocytes. Normal serum concentrations of FGF23 are app. 50 pg/ml but can be elevated 1000 fold during chronic kidney disease (CKD). Recent clinical studies have shown that elevated levels of FGF23 are independently associated with endothelial dysfunction and arterial stiffness in CKD patients; however, the direct effects of FGF23 on vascular smooth muscle and endothelial function have not yet been examined. We have detected expression of all four subtypes of FGF receptors in C57BL/6 male mouse aortas (10-12 week old) using real time RT-PCR. FGFR1 was highly expressed while FGFR4 and the co-receptor Klotho were expressed at low levels (n=4). We then examined the vascular effect of different concentrations of exogenous FGF23 (9, 90, 900, 9000 pg/ml) on aortas using isometric tension myography. FGF23 did not induce significant contraction from baseline and did not relax aortic rings precontracted with $PGF_{2\alpha}$ (10^{-5} M) ($P>0.05$; n=5). However, preincubation with FGF23 at 9000 pg/ml caused a 27.6% inhibition of endothelium-dependent relaxation elicited by acetylcholine (Ach) in precontracted aortic rings ($P<0.05$ vs. vehicle; n=5). This inhibition was rescued by preincubation with the FGF receptor antagonist, PD166866 (50nM) ($P<0.05$; n=5). FGF23 pretreatment of vessels did not alter relaxation caused by addition of sodium nitroprusside (SNP) suggesting that the impaired response was endothelium-specific. To further explore this mechanism, total nitrates produced after Ach treatment of aortic rings were measured using a nitrate/nitrite colorimetric assay kit. In FGF23 (9000 pg/ml) pretreated rings, nitrate production was reduced by 53.1% compared to vehicle levels ($P<0.05$; n=5). Therefore, our data suggest that acute exposure of FGF23 can cause endothelial dysfunction by inhibiting nitric oxide bioavailability in mouse arteries. Together, these data provide evidence that high levels of FGF23, as occurs in CKD, may play a role in cardiovascular dysfunction. These data also provide further evidence for crosstalk between kidney, bone, and the cardiovascular system and suggest that therapeutic strategies for treatment of CKD need to take this interplay into consideration.

MO0115

Iron Status Regulates Serum C-terminal FGF23 in Healthy Adult Women. Erik Imel*[1], Siu Lui Hui[1], Amie Gray[1], Dena Acton[1], Anthony Acton[1], Leah Padgett[1], Munro Peacock[2], Michael Econs[1]. [1]Indiana University School of Medicine, USA, [2]Indiana University Medical Center, USA

Purpose: Fibroblast growth factor 23 (FGF23) is secreted as N- and C-terminal fragments and intact protein. Low iron status increases serum FGF23 in the setting of genetic mutations impairing normal FGF23 cleavage. We hypothesized that in healthy women iron status would also influence both C-terminal and intact FGF23 concentrations independently of serum phosphorus (Pi) or 1,25(OH)2D.

Methods: Serum iron, creatinine, Pi, 1,25(OH)2D, and FGF23 were measured in stored fasting samples from healthy white women (n= 974, age 20-55 years). Serum FGF23 was measured with an ELISA specific for intact FGF23 and an ELISA detecting both intact and C-terminal fragments of FGF23. FGF23 was log-transformed. Variables were analyzed with Pearson correlations and multiple regression analyses.

Results: Age correlated negatively with Pi ($p<0.0001$) and positively with C-terminal FGF23 (r= 0.167) and intact FGF23 (r= 0.131)($p<0.001$), but not iron. Creatinine was not related to age, Pi, 1,25(OH)2D or FGF23. Intact and C-terminal FGF23 log-concentrations correlated positively (r= 0.165, $p<0.0001$). Intact FGF23 was negatively related to 1,25(OH)2D (r= -0.111, $p<0.01$), and positively to Pi (r= 0.067, $p<0.05$). C-terminal FGF23 had no relationship with Pi or 1,25(OH)2D.

C-terminal FGF23 was most strongly related to iron (r= -0.254) and iron saturation (r= -0.231, both $p<0.0001$). Thus, subjects with iron <50mcg/dl had higher log-C-terminal FGF23 than those with iron ⩾50 mcg/dl (1.41 ± 0.40 versus 1.13 ± 0.27 RU/ml, $p< 0.0001$). Intact FGF23 was not related to serum iron. Pi did correlate negatively with iron (r= -0.078, P=0.015) and iron saturation (r=-0.128, $p<0.0001$).

Iron status influenced C-terminal FGF23 concentration independently of other variables including age, Pi, and intact FGF23 (R2= 0.112, $p<0.0001$). 1,25(OH)2D did not predict C-terminal FGF23. High Pi decreased the influence of iron on C-terminal FGF23 ($p<0.05$ for interaction of iron and Pi); iron regression slopes became smaller at higher Pi levels.

Conclusion: In healthy women, C-terminal FGF23 was most strongly related to iron status. However, this relationship was blunted at higher Pi level. In contrast, intact FGF23 was not related to iron status, but was related to Pi and 1,25(OH)2D. Thus when low iron status increases FGF23 production, increased cleaving of FGF23 into fragments allows maintenance of normal intact FGF23 and Pi. Further study of the physiologic interaction of iron and FGF23 is needed.

PHEX Substrate Protein Osteopontin and its ASARM Peptide Decrease *NaPT2A* Expression. Gabrielly Chiarantin[1], Raquel Neves[1], Betty Hoac[2], Adriana Carmona[1], Marc McKee[2], Nilana Barros*[1]. [1]Federal University of Sao Paulo, Brazil, [2]McGill University, Canada

X-linked hypophosphatemia (XLH/HYP) is the most prevalent form of inherited rickets in humans, occurring as a consequence of inactivating mutations in the *PHEX* gene (phosphate-regulating gene with homologies to endopeptidases on the X chromosome). XLH is characterized by growth retardation, rickets and osteomalacia leading to hypomineralized bones that deform, and soft tooth dentin prone to infection and abscesses. Associated with XLH and causing hypophosphatemia are defects in renal phosphate reabsorption and vitamin D metabolism. *In vivo* mouse studies have shown that the absence of PHEX leads to the release of a circulating factor(s) that decreases mineralization by inhibiting the sodium/phosphate co-transporter NaPT2A which mediates reabsorption of phosphate in the kidneys. Recently we demonstrated that the mineral-binding bone extracellular matrix protein osteopontin (OPN) is a physiologically relevant substrate for PHEX, whose inactivation by PHEX normally promotes bone mineralization. However, in PHEX-deficient Hyp mouse bone, OPN and its fragments accumulate to inhibit mineralization locally in the extracellular matrix. In the present study, we have extended these observations to show that OPN and a derived OPN fragment

(ASARM peptide; acidic serine- and aspartate-rich motif) affect *Napt2a* expression. Using the supernatant from cultures of a constructed *PHEX*-deficient human osteoblast cell line (MG-63 osteoblasts treated with shRNAi-*PHEX*) we show that, in the absence of PHEX, a secreted factor found in the MG-63 osteoblast supernatant decreased *NaPT2A* mRNA and protein expression in human kidney (HK-2) proximal tubule epithelial cell cultures. Based on this observation and on the fact that OPN is essentially completely degraded by PHEX, we investigated the effects of exogenous OPN and its ASARM peptide on HK-2 cell *NaPT2A* expression. RT-PCR and cell sorting (FACs) analyses revealed that both OPN and its ASARM peptide significantly decreased *NaPT2A* expression. In conclusion, these results provide new insight into circulating humoral factors that might influence phosphate handling in the kidney whose alterations contribute to the osteomalacic XLH phenotype, and they suggest that OPN and its ASARM peptide may be involved in this process. *Supported by FAPESP.*

MO0117

Sympathetic Activation Induces Skeletal *Fgf23* Expression in a Circadian Rhythm Dependent Manner. Masanobu Kawai*[1], Saori Kinoshita[1], Shigeki Shimba[2], Keiichi Ozono[3], Toshimi Michigami[1]. [1]Osaka Medical Center & Research Institute for Maternal & Child Health, Japan, [2]School of Pharmacy, Nihon University, Japan, [3]Osaka University Graduate School of Medicine, Japan

Phosphorus is a pivotal nutritional factor involved in energy and skeletal metabolism, and has been implicated to possess a circadian profile in the circulation; however, the precise mechanisms how phosphate metabolism is regulated by circadian clock network remain largely unknown. In the current study we postulated that skeletal *Fgf23* expression was controlled by sympathetic activity in a circadian rhythm dependent manner. Skeletal *Fgf23* expression exhibited greater levels during dark phase (DP) when food intake was active in mice. To further analyze the association between food intake and *Fgf23* expression, mice were fed exclusively during light phase (LP). Interestingly, *Fgf23* expression pattern showed a peak expression during LP. To determine the mechanisms by which circadian expression of *Fgf23* is regulated by food intake, we analyzed urine epinephrine levels as a marker for sympathetic tone because food ingestion is known to enhance sympathetic activity. As expected, amount of urine epinephrine was greater during DP in mice fed ad lib, whereas it was elevated during LP in mice under LP-restricted feeding conditions. To determine whether sympathetic tone activates *Fgf23* expression, we administered beta-adrenergic agonist, isoproterenol (ISO) into mice at different time points of the day and found it enhanced skeletal *Fgf23* expression only when administered at ZT8 and 12. *In vitro* reporter assays revealed that ISO trans-activates *Fgf23* promoter through a cAMP-response element in osteoblastic UMR-106 cells. To analyze the reason why *Fgf23* induction by ISO is restricted to ZT8 and 12, we tested our hypothesis that Cryptochrome1 (Cry1), a circadian clock gene, suppressed ISO-induced *Fgf23* expression since Cry1 has been shown to inhibit some of G protein-coupled receptor signaling pathways. Cry1 expression was lower at ZT8 and 12, and over-expression of Cry1 in UMR-106 cells inhibited the phophorylation of CREB by ISO. To further understand the role of circadian clock system in ISO-induced *Fgf23* expression, we utilized mice deficient in *Bmal1*, a core clock gene, where Cry1 expression was enhanced. In these mice, ISO-induced *Fgf23* expression was decreased compared to that in WT mice. These lines of evidence indicate that regulation of skeletal *Fgf23* expression by sympathetic activity is dependent on circadian clock system and may shed light on new regulatory networks of FGF23 which could be important for understanding the physiology of phosphate metabolism.

MO0118

Depolarizing Membrane Potential by PTH and VD_3 Regulates RANKL-intracellular Transportation; A Novel Mechanism of PTH- and VD_3-induced Osteoclastogenesis. Takuya Notomi*[1], Miyuki Kuno[2], Yoichi Ezura[3], Masaki Noda[4]. [1]GCOE, Tokyo Medical & Dental University, Japan, [2]Osaka City University, Japan, [3]Tokyo Medical & Dental University, Medical Research Insititute, Japan, [4]Tokyo Medical & Dental University, Japan

The PTH and VD_3 are not only osteogenic reagents but also major regulator for osteoclastogenesis. These molecules transiently increase bone resorption by increment of the expression level of RANKL, whereas their mechanism of RANKL-intracellular transportation (RANKL-iTP) remains unclear. The RANKL-iTP depends on lysosomal vesicles whose fusion is related to increment of intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) following depolarizing membrane potential (MP). Thus, MP could regulate osteoblastic function and RANKL-iTP. So far little is known about the role of MP on bone cells, because it is hard to control temporal patterns of MP. Here, by novel system of light-responsive osteoblastic MP, we show that the transiently increasing $[Ca^{2+}]_i$ following depolarization regulates PTH- and VD_3- induced RANKL-iTP.In membrane fraction of RANKL-GFP expressed MC3T3-E1 cell, PTH and VD_3 increase membrane-bound RANKL (mbRANKL) at 10 min (more than 300% increment compared to control), however those mRNA expression level were unchanged at same time. Confirming by time-lapse imaging, the addition of PTH and VD_3 translocated RANKL-GFP to cell membrane within 10 min. In previous reports, PTH and VD_3 transiently increase $[Ca^{2+}]_i$ following depolarization. The $[Ca^{2+}]_i$ spike was diminished by depolarization-activated Ca^{2+} channel blocker (Diltiazem: Dil) or ER-dependent $[Ca^{2+}]_i$ blocker (Thapsigargin: Tg). The increment of mbRANKL by PTH and VD_3 was also decreased by Dil and Tg. These results showed that depolarization-dependent change of $[Ca^{2+}]_i$ affected PTH- and VD_3-induced RANKL-TPi.To address whether depolarization controls RANKL-TPi, we developed a novel system of light-responsive osteoblastic MP by channel-rhodopsin wide receiver (ChWR). MPs in ChWR stably expressed cell were depolarized immediately (<20 msec) after light-stimulus (ΔMP: 16.3 $\pm$ 1.1 mV) and were returned to the pre-stimulus potential after the off-stimulus. Light induced depolarization increase $[Ca^{2+}]_i$ and mbRANKL at 10 min in similar to addition of PTH and VD_3. In co-culture of RAW267 and RANKL-GFP expressed MC3T3-E1 cell, TRAP activities were increased 4- fold by light stimulus and the development of mature osteoclasts was observed.We showed that depolarizing MP is related to osteoblastic function. Our results indicates that RANKL-iTP is regulated by $[Ca^{2+}]_i$ following depolarization of MP. The mechanism of PTH- and VD_3-induced RANKL-iTP would have benefits for developing PTH- and VD_3-like medicine.

MO0119

Parathyroid hormone (PTH) mediated down-regulation of dentin matrix protein 1 (*Dmp1*) expression. Anne Tran[1], Mudita Patel*[2], Francisco Nociti[2], Kamila Kantovitz[2], Le Wang[2], Brian Foster[3], Martha Somerman[4]. [1]National Institutes of Health, USA, [2]NIAMS/NIH, USA, [3]National Institute of Arthritis & Musculoskeltal & Skin Diseases (NIAMS), USA, [4]NIDCR, USA

Objective: Parathyroid hormone (PTH) plays a critical role in bone remodeling and mineral homeostasis. PTH interacts with PTH1R, a G-protein coupled receptor that activate adenylyl cyclase and phospholipase C, producing cAMP which activates protein kinase A and C pathways. Other key regulators of mineralization 1, 25 dihydroxyvitamin D_3 (Vit. D) and ?broblast growth factor 23 (FGF23), interact with and regulate PTH in a complex feedback loop. FGF23 is, in turn, regulated by dentin matrix protein (DMP1), an extracellular matrix protein, and phosphate regulating endopeptidatse (PHEX). The effect of PTH on DMP1 and the pathway(s) through which they interact has yet to be determined, and was the focus of our *in vitro* studies. Methods: Murine cementoblasts (OCCM.30), expressing DMP1, were exposed to PTH (1-34) in dose-response (10^{-6}M-10^{-8}M) and time--course (1, 3, 12, and 24 hrs) experiments. Activators of the PKA (forskolin, 10^{-6}M) and PKC pathway (phorbol dibutyrate, 20nM), and an antagonist of the PKA pathway (H-89: 2,10, 20 µM), were used to analyze pathways. cAMP was measured in cells treated with 3-isobutyl-1-methylxathine (IBMX, 1mM) and PTH (1-34) using ELISA. Actinomycin D and cycloheximide were used to determine *Dmp1* mRNA stability and protein synthesis requirement, respectively. Gene expression of *Dmp1* and other mineralization markers were analyzed by RT-qPCR. Results: Cells exposed to PTH (1-34) decreased *Dmp1* mRNA expression at all time points, 83% at 10^{-7}M PTH and 90% at 3 hours. The addition of PTH (1-34) to cells pre-treated with actinomycin D showed no acceleration of *Dmp1* mRNA degradation by PTH. There was partial recovery of *Dmp1* mRNA when cycloheximide was added to the cells by 3 fold, suggesting that protein synthesis is required. Treatment with PTH (1-34) increased intracellular cAMP levels by 4-fold. Forskolin decreased *Dmp1* mRNA and H-89 partially recovered the PTH inhibition of *Dmp1*, implicating cAMP/PKA pathway involvement. Conversely, a PKC agonist slightly up-regulated *Dmp1* mRNA, suggesting that PTH (1-34) regulates *Dmp1* mRNA stability through the PKC pathway. Conclusions: For the first time, these data indicate that the cAMP/PKA pathway mediates the PTH (1-34) mediated down-regulation of *Dmp1* mRNA expression in cementoblasts *in vitro*. Elucidating the relationship between PTH and DMP1 provides new insights on phosphate homeostasis and skeletal mineral metabolism.

PTH Alters Cartilage Callus Remodeling in a Model of Delayed Osteotomy Repair. Jiliang Li*[1], Masahiko Sato[2], Yanfei Ma[3], Evan Himes[1], Matthew Hamang[2], Jonathan Lucchesi[2], David Rowe[4]. [1]Indiana University Purdue University Indianapolis, USA, [2]Lilly Research Labs, USA, [3]Eli Lilly & Company, USA, [4]University of Connecticut Health Center, USA

Previously, intermittent hPTH (1-34) enhanced the rodent skeleton in models of osteoporosis and bone healing; however, the mechanistic basis to the latter has not been fully elucidated. To better understand PTH efficacy on formation and remodeling of the cartilage callus and outer cortical shell, we utilized triple-GFP reporter mice expressing a SMA-RFPchry (red), Col3.6-GFPcyan (blue), hOC-GFPtpz (green), which reflect different stages in osteoblastic differentiation. Mice (2 months old) were divided into vehicle and PTH 40 µg/kg/d groups. Bilateral femoral osteotomies were performed, and internally fixed using a sterilized carbon fiber pin (0.8 mm). Animals received EdU (3 mg/kg) and alizarin (30 mg/kg) one day before necropsy. Mice were euthanized at days 7, 14, 21 and 28 day post-surgery, and frozen sections of right femora were obtained for multi-channel fluorescence microscopy. After 4 weeks, µCT (6 mm ROI centered to the fracture plane) showed that PTH induced a 77% larger fracture callus (TV) that contained 57% more bone (BV), 53% higher BMC, 100% more BS, 25% more BS/BV, with 82% greater connectivity, but no increase in overall BMD compared to vehicle. No obvious difference in EdU labeling,

myofibroblast migration into the fracture site, mineralization or expression of Col3.6 or hOC reporters was appreciated at any time point. At day 7, neither group had bridging and had cartilage cores consistent with severe periosteal damage. However by day 14, a cartilage callus was seen in both. A greater proportion of the core had become hypertrophic cartilage with extensive osteoclastic activity in controls than with PTH. More striking was the reduction of osteoclastic activity at the interface between the invading osteogenic front and hypertrophic cells and on the outer cortical shell of the PTH group. By 3 weeks, controls had replaced the cartilage core with bone marrow and a well-formed inward-modeling cortical shell; but the PTH group showed the cartilage was replaced with a highly trabeculated bone undergoing osteoclastic remodeling, with less osteoclastic activity of a trabulated outer cortical surface. These unanticipated results suggest that the larger callus and greater bone volume found by μCT in the PTH treated animals reflects a change in the tempo and intensity of cartilage core removal, and the formation and inward modeling of the outer cortical shell. Analyses are underway to ascertain how these changes ultimately affect the quality of the repaired bone.

Signal Transduction Pathways Associated with PTHrP-induced Proliferation of Colon Adenocarcinoma Cells. Maria Julia Martin, Natalia Calvo, Ana Russo De Boland*, Claudia Gentili. Universidad Nacional del Sur, Argentina

Parathyroid Hormone-related Peptide (PTHrP, also known as its tumoral analog) was initially identified through its role in humoral hypercalcemia of malignancy, one of the most frequent paraneoplastic syndromes. Subsequently, the protein was found to be distributed in most fetal and adult tissues, including intestinal mucosa. It has been observed that its expression correlates with the severity of colon carcinoma and that its overexpression increases cell proliferation in certain intestinal cell lines. However, so far the role of exogenous PTHrP in Caco-2, a cell line derived from human colorectal adenocarcinoma, is not known. This study examined, whether extracellular PTHrP induces proliferation of Caco-2 cells and whether regulates cell proliferation via the MAP kinases and Akt signaling pathways. Using different cell proliferation assays we found that PTHrP (10^{-8} M) increased the number of live Caco-2 cells. Furthermore, Western blot analysis revealed that the PTH analog stimulates the phosphorylation of ERKs as well as the α isoform of p38 MAPK and Akt without affecting their protein expression levels and the phosphorylation/activation of JNK. Fluorescence microscopy studies indicated that extracellular PTHrP induces the translocation of ERK1/2, p38α and Akt into the nucleus of these intestinal cells. PTHrP also stimulates the phosphorylation of ATF-1 and CREB transcription factors in a biphasic manner, the second phase being partially dependent on MAP kinases activation. Moreover, the peptide induces the translocation of β-catenin into the nucleus of Caco-2 cells and increases the amounts of positive cell cycle regulators c-Myc and Cyclin D. In addition, use of specific inhibitors of ERK 1/2, p38 MAPK and Akt signaling pathways indicate that both MAPKs and Akt participate in PTHrP-induced colonic cell proliferation The present work provides, to our knowledge, the first evidence demonstrating that exogenous PTHrP induces the proliferation of Caco-2 cells and identifies, at least in part, the signaling pathways that are involved in the mitogenic effect of PTHrP on these intestinal cells

The Cell Cycle Inhibitor p27 Mediates the Regulation of Dental and Mandibular Development by Parathyroid Hormone-Related Peptide. Wen Sun*[1], Hong Liu[2], Rong Wang[2], David Goltzman[3], Andrew Karaplis[3], Dengshun Miao[4]. [1]Nanjing Medical University, The Research Center for Bone & Stem Cells, Peoples Republic of China, [2]Nanjing Medical University, China, [3]McGill University, Canada, [4]Nunjing Medical University, Peoples Republic of China

Our previous study showed that mice deficient in the nuclear localization sequence (NLS) and C-terminus of parathyroid hormone related protein (PTHrP) (Pthrp KI) displayed severe defects in dental and mandibular development, however underlying mechanisms remain largely unknown. Previous studies have demonstrated that the cell cycle inhibitor p27 serves as a down-stream target to regulate the proliferation of vascular smooth muscle, however, it is unclear whether p27 is involved in the regulation by PTHrP of dental and mandibular development in vivo. To answer this question, we examined the protein expression levels of p27 in mandibles from Pthrp KI and their wild-type (WT) littermates.We found that the expression levels of p27 were up-regulated 5 fold in Pthrp KI mice relative to WT littermates. We then compared mandible and tooth phenotypes of compound mutant mice which are homozygous for both p27 deletion and the Pthrp KI mutation ($p27^{-/-}$Pthrp KI) with $p27^{-/-}$, Pthrp KI, and WT littermates. At 2 weeks of age, the mandible size and mineral density and the alveolar bone formation parameters including alveolar bone volume, osteoblast numbers, ALP and type I collagen positive bone areas, and the dental formation parameters including the dental volume and dentin sialoprotein (DSP) immunopositive areas in the incisor and 1st molar and the percentage of Ki67 positive cells in the nuclei of cells of Hertwig's epithelial root sheath (HERs) were increased significantly in $p27^{-/-}$ mice, and reduced significantly in both Pthrp KI and $p27^{-/-}$Pthrp KI mice compared to WT mice, however these parameters were increased significantly in $p27^{-/-}$Pthrp KI mice compared to Pthrp KI mice. In contrast, the ratio of predentin or biglycan immunopositive dentin areas relative to total dentin area, and the percentage of TUNEL positive cells in HERs were decreased in $p27^{-/-}$ mice, and increased in both Pthrp KI and $p27^{-/-}$Pthrp KI mice compared to WT mice. Nevertheless these parameters were reduced significantly in $p27^{-/-}$Pthrp KI mice compared to Pthrp KI mice. Our results demonstrate that dental and mandibular development were accelerated by the deletion of p27, and were impaired by the deletion of PTHrP NLS and C-tuminus, whereas the deletion of p27 in Pthrp KI mice can partially rescue defects in dental and mandibular development. This study therefore indicates that the p27 pathway may function downstream in the action of PTHrP to regulate dental and mandibular development.

The Remarkable Voyage of the MCL. Meina Wang*[1], Steven Tommasini[2], Ali Nasiri[1], Arthur Broadus[3]. [1]Yale University, USA, [2]Yale School of Medicine, USA, [3]Yale University School of Medicine, USA

One of the most curious examples of modeling of the cortical surface of a long bone during linear growth is the migration of tendon/ligament insertion sites along its periosteal (PO) surface. The tibial insertion of the medial collateral ligament (MCL) is a poster-child of this process, yet the details of how the MCL attaches to and migrates along the tibial PO surface are unknown. We studied this process in CD-1 and PTHrP-lacZ ($PTHrP^{lacZ/+}$) mice during development and linear growth. At birth, MCL fibers are attached to the PO near the epiphyseal end of the tibia. By day 8 (D8), the insertion has migrated to the distal end of the bone bark, and its fibers intermingle with the peripheral osteoblasts (OBs) of the bark and become incorporated into the forming cortical bone in this region (confirmed by calcein labeling at D8). By D12-16, the MCL insertion has migrated into the tibial metaphysis well distal to the bone bark and contains a mixed population of PO osteoclasts (OCs) that excavate and PO OBs that fill in a definable enthesis structure. By D21, the MCL enthesis is fully excavated and contains abundant OCs and OBs in a prototypical pattern of coupled OC/OB activities. At this time (3 weeks), the PO underlying the free-standing MCL immediately above the insertion site contains a ''cutting-cone'' of PO OCs that initiates excavation of the so-called migratory canal. From 3-9 weeks, this PO surface lengthens by 7-to-10 fold and contains an army of OCs and not a single OB, a pattern of completely uncoupled OCic bone resorption. This process forms the migratory canal during growth and doubles as the cortical depression that houses the MCL in adulthood. Both the insertion site and the PO surface overlying the migratory canal express abundant PTHrP/lacZ. This presumably reflects growth-induced loading of the MCL insertion as well as the metaphyseal PO, which is itself anchored to the bone bark above and the MCL insertion below.We conclude that anchoring the MCL insertion to the distal bone bark/proximal metaphysis during the first postnatal week is a key developmental event that enables the MCL insertion to subsequently travel south coincident with linear growth. This anchoring tethers the ligament and also the subjacent PO in such a fashion that growth-driven loading induces PTHrP, RANKL, and OCs that mediate the excavation of the MCL enthesis as well as the migratory canal.

Hypocalcemic myopathy in a 16 -year old boy with pseudohypoparathyroidism. Stepan Kutilek*[1], Pavla Bebova-Mala[2], Kristyna Hasenohorlova[2]. [1]Pardubice Hospital; Faculty of Health Studies; University of Pardubice, Czech Republic, [2]Dept. of Pediatrics, Pardubice Hospital, Czech Republic

Introduction: Calcium plays a key role in muscle contraction and metabolism. Myopathy can be a rare manifestation of hypocalcemia of various origin.

Case Report: A 16-year old previously healthy boy was admitted because of 3 minutes convulsions. Upon admission Glasgow coma scale was 12 points. He had hypocalcemia (total S-Ca<1.0 mmol/L), hyperphosphatemia (S-P 2.8 mmol/L), hypomagnesemia (S-Mg 0.64 mmol/L). Serum creatinkinase (S-CK) activity was 32 μkat/L (normal 0.57-2.45 ukat/L) He immediately received i.v. infusion of 10%calcium gluconate (1.5 ml/kg/hour). His total calcemia improved within 5 hours to 1.25 mmol/L and S-Mg to 0.88 mmol/L, however, S-CK increased to 38 μkat/L. Further he received also oral calcium (3000 mg/day) and oral cholecalciferol (20 000 IU/day) for the following two weeks. There was a gradual improvement in S-Ca (1.6 and 1.7 mmol/L on days 3 and 5, respectively), reaching 1.9 mmol/L on day 14. However, S-CK was initially further on rise (131 μkat/L and 222 μkat/L on days 3 and 4, respectively). Since day 5, S-CK began to drop from 186 μkat/L through 104 μkat/L to 60 μkat/L on days 6, 7 and 9, respectively, to 7.2 μkat/L on day 14. There were no myalgias nor clinical sings of myopathy. Due to hypocalcemia, there was a prolonged QTc interval of 0.47 sec on ECG, with no signs of myocardial damage. Echocardiography was normal, with normal contractility, without calcifications. Serum levels of creatinine and alkaline phosphatase activity (S-ALP) were normal (66 μmol/L and 2.2 μkat/L, respectively). The serum level of parathyroid hormone was repeatedly high (10.3 and 12 pmol/L; normal 0.7-5.5). These findings ruled out vitamin D deficiency and osteomalacia and were compatible with the diagnosis of pseudohypoparathyroidism (PHP). Discussion: In animal experiments hypocalcemia may lead to

cardiac decompensation, but heart failure from hypocalcemia is quite rare in clinical practice. Dilated cardiomyopathy and cardiac failure can occur in children with severe vitamin D deficency and hypocalcemia. Myopathy with extremely elevated S-CK has been very rarely encountered in patients with severe hypocalcemia, due to hypoparathyroidism or PHP. Our patient presented with hypocalcemia due to PHP, manifest tetany, very high S-CK with normal cardiac function and without severe myopathy. Conclusion: Mild myopathy with very high S-CK can occur in hypocalcemic patients with PHP and usualy resolves with normalization of hypocalcemia.

MO0125

Leptin-independent Regulation of Bone Homeostasis by ΔFosB in the Ventral Hypothalamus Contrasts with its Leptin-dependent Effects on Energy and Glucose Metabolism. Kazusa Sato*[1], Anna Idelevich[2], Glenn Rowe[3], Francesca Gori[4], Roland Baron[5]. [1]Harvard School of Dental Medicine, USA, [2]Harvard University, USA, [3]Harvard Medical School, USA, [4]Harvard School of Dental Medicine, Massachusetts General Hospital, USA, [5]Harvard School of Medicine & of Dental Medicine, USA

The hypothalamus plays a pivotal role in bone homeostasis as well as energy balance and glucose metabolism through endocrine and neuronal pathways, but the exact relationship between these three systems is still only partially understood.

Mice in which the expression of ΔFosB, a naturally truncated isoform of FosB that antagonizes AP-1, is driven by the ENO2 promoter in bone, adipose tissues, and the ventral hypothalamus (VHT), develop increased bone mass and energy expenditure and decreased fat mass. ENO2-ΔFosB mice also exhibit increased glucose tolerance and insulin sensitivity despite lower levels of leptin. Moreover, viral-mediated expression of ΔFosB in the VHT phenocopies both the bone and energy phenotypes of ENO2-ΔFosB mice, demonstrating the critical role of the VHT.

The present study was performed to determine whether expression of ΔFosB in the VHT also regulates glucose metabolism, and to evaluate the contribution of leptin to ΔFosB-mediated regulation of these three systems. To this end, C57BL/6 mice were stereotaxically injected in the VHT with AAV encoding ΔFosB (AAV-ΔFosB) or GFP (AAV-GFP) as control. Intraperitoneal glucose (GTT) and insulin (ITT) tolerance tests were performed. ΔFosB transgenic model in leptin deficient ob/ob (ΔFosB-ob/ob) mice were also generated.

AAV-ΔFosB mice had markedly improved glucose tolerance despite lower insulin response to a glucose bolus compared to AAV-GFP mice during GTT, suggesting increased insulin sensitivity. ITT indeed revealed that AAV-ΔFosB mice were more insulin-sensitive and this effect was observed even before their body and fat mass fell behind those of AAV-GFP mice. Elevated insulin signaling was observed in peripheral tissues (muscle and brown fat) but not in bone tissue in AAV-ΔFosB mice, excluding the possibility that the bone phenotype is the result of increased insulin signaling in bone. In contrast, ΔFosB expression in ΔFosB-ob/ob mice did not correct the obesity or decreased energy expenditure yet it made ΔFosB-ob/ob mice glucose tolerant compared to ob/ob mice due to compensatory hyperinsulinemia. Importantly, leptin deletion in ΔFosB-ob/ob mice did not affect the increased bone mass seen in ENO2-ΔFosB mice.Taken together, these results suggest that VHT signaling downstream of ΔFosB affects separately bone homeostasis and energy/glucose metabolism: bone homeostasis is leptin-independent whereas the energy and glucose phenotypes are leptin-dependent.

Altered Behavior of Bone Marrow Mesenchymal Stem Cells in the *Crtap* Murine Model of Osteogenesis Imperfecta. Roberta Besio*, Milena Dimori, Katrin Gruenwald, Roy Morello. University of Arkansas for Medical Sciences, USA

Bone disease is often associated with alterations in extracellular matrix (ECM) composition and/or properties with potential impact on mineralization. Recent evidence suggests that the ECM is an important contributor to the establishment of the mesenchymal stem cell (MSC) niche and the maintenance of MSCs pluripotency in the bone marrow. Collagens are a major component of all ECMs, and our studies have demonstrated that dysregulation of collagen post-translational modifications, including prolyl 3-hydroxylation, cause severe skeletal dysplasia. Mutations in components of the prolyl 3-hydroxylation complex, including Crtap, P3h1 and Cyclophilin B, cause recessive osteogenesis imperfecta (OI) in humans and osteochondrodysplasia with severe osteopenia in mice. Both human and murine *Crtap-KO* osteoblasts/fibroblasts deposit less collagen with fibrils of larger diameter in the ECM, and the bone matrix has altered mineralization kinetics. To determine if such alterations in matrix affect the bone marrow microenvironment and, specifically, the differentiation of osteoblasts from MSCs, we analyzed bone marrow MSCs from *Crtap-KO* and WT mice. MSCs derived from *Crtap-KO* mice and cultured towards osteoblasts showed significantly increased numbers of both alkaline phosphatase (CFU-AP) and alizarin red (CFU-OB) positive colonies compared to controls. This suggests an enhanced capacity of MSCs to be recruited to the osteoblastic lineage and to terminally differentiate into matrix-mineralizing osteoblasts in *Crtap-KO* mice. Moreover, the total number of colony forming unit-fibroblast (CFU-F) was also elevated in *Crtap-KO* mice, suggesting an overall increase in the number and/or proliferation of MSCs in this murine model of OI. Concomitantly, mRNA of the early osteoblastic marker *Sp7* (Osterix) was significantly up-regulated in CFU-F and adult calvaria from *Crtap-KO* compared to control mice. These findings suggest that a MSC adaptation response to abnormal matrix ultimately results in an increased commitment toward the osteoblastic lineage. Because *in vivo* osteoblast numbers are not increased in *Crtap-KO* mice, ongoing studies are addressing the terminal differentiation and mineralization capacity of *Crtap-KO* osteoblasts. Interestingly, the osteoblastic differentiation potential of *Crtap-KO* MCSs is opposite to that described in the BrtlIV mouse model of OI and may reflect different cell adaptation and cell lineage response to distinct and unique bone matrix alterations.

Bone from Low Capacity Running Rats Exhibit Altered Mitochondrial Gene Expression Compared to High Capacity Running Rats after an Exhaustive Bout of Exercise. Anamaria Antolic*[1], Adeel Safdar[2], Steven Britton[3], Mark Tarnopolsky[1], Gregory Wohl[1]. [1]McMaster University, Canada, [2]Harvard Medical School, USA, [3]University of Michigan, USA

BACKGROUND: Aerobic exercise capacity is linked to longevity and decreased disease susceptibility. At the cellular level, increased abundance of mitochondria and higher mitochondrial oxidative enzyme capacity provide the basis for enhanced aerobic capacity. These adaptations have been shown in multiple tissues including, liver, fat depots, heart and brain. The Koch-Britton rat model of low capacity and high capacity runners (LCRs and HCRs respectively) has demonstrated that selection for low and high running capacity led to a divergence in mitochondrial content and function between these two groups. Mechanical strain in the form of exercise has been shown to play a key role in regulating bone health, however underlying mechanisms are still being described. The untrained status and differences in aerobic capacity allow for the elucidations of bone adaptations to exercise.

PURPOSE: To investigate the effect of an acute endurance run to exhaustion on mitochondrial gene expression and enzyme activity in LCR and HCR rats.

METHODS: LCR and HCR rats (30 wk old, n=40; ?=20, ?=20) underwent a graded running exercise. A speed ramped running protocol was used starting at 10m/min (elevation of 15°) and increased 1m/min every 2 min until exhaustion. Upon completion of the test the LCR and HCR rats were randomly assigned for sacrifice three hours (n=20) or three days (n=20) after the exhaustive bout. Femoral, tibial, and lumbar vertebral bones were collected for biomechanical testing, protein content, enzyme activity and gene expression. Acute gene expression at 3 hr was normalized to expression at 3 d after exercise and compared between HCR and LCR groups by MANOVA with Tukey post-hoc.

RESULTS: LCR rats were heavier than HCR rats ($p<0.05$) and ran 75% less than HCR rats ($p<0.05$). LCR rats demonstrated lower citrate synthase activity, an indicator of lower mitochondrial content ($p<0.05$). Exhaustive exercise increased mitochondrial (*Tfam and Cox.iv;* $p<0.05$) and *Vegf* ($p<0.05$) gene expression in the LCR rats compared to HCR at 3 hr. Foxo1 was significantly upregulated in HCR bone at 3 hr, but not in LCR bones ($p<0.05$).CONCLUSION: LCR rat bones exhibited significantly greater mitochondrial and VEGF expression compared to HCR bones following an exhaustive bout of exercise, but changes in osteogenic gene expression were not different between LCR and HCR. These data indicate that the intrinsic aerobic capacity influences bone mitochondrial changes in response to exercise

MO0129

Change of Phenotypic in a Patient with Hypophosphatasia with the Onset of Renal Failure. Tim Cundy*[1], Toshimi Michigami[2], Kanako Tachikawa[3], John Collins[4], Michael Dray[5]. [1]Faculty of Medical & Health Sciences University of Auckland, New Zealand, [2]Osaka Medical Center & Research Institute for Maternal & Child Health, Japan, [3]Department of Bone & Mineral Research, Osaka General Medical Center, Japan, [4]Renal Medicine, Auckland City Hospital, New Zealand, [5]Department of Pathology, Waikato Hospital, New Zealand

Hypophosphatasia is a recessively inherited disorder with a wide phenotypic manifestation ranging from lethality in neonates to asymptomatic in adults. The severity of the phenotype is largely determined by the nature of the *ALPL* mutations. We describe a previously asymptomatic adult whose phenotype dramatically changed after he developed renal failure. A 50 year old man was diagnosed with IgA nephropathy. At age 52 (eGFR 50ml/min) he suffered his first metatarsal fracture. A DXA scan showed osteopenia, and he was prescribed alendronate. His renal failure progressed and he began dialysis (CAPD) at age 55. Prior to and after starting CAPD he suffered multiple non-traumatic fractures affecting metatarsals, vertebrae and ribs. Alendronate treatment was stopped. Further investigation showed low serum PTH levels 1.8-5.2 pmol/L (N 1-7) and discordance between the bone formation markers Alkaline Phosphatase (ALP) 56 U/L (N 40-120) and Procollagen-1 N-peptide 180ug/L (N 20-85). The ALP levels had been low (26-32 U/L) before starting alendronate. A bone biopsy showed osteomalacia, reduced cellular activity and negative staining for aluminium. Genetic analysis showed compound heterozygosity for missense mutations in *ALPL* (T117H and G438S). Expression plasmids for the mutant ALPs fused to green fluorescent protein were transfected into COS7 cells, and the cell lysates were harvested to assay enzymatic activity. The T117H mutant had almost no enzymatic activity, but the G438S mutant retained similar activity to wild-type ALP. Six months treatment with teriparatide produced an increase in ALP activity and histological improvement in bone, but significant side effects. After the restoration of renal function by transplantation there was complete symptomatic resolution. It is probable that as the patient developed renal failure, phosphate retention inhibited his residual ALP enzyme activity, resulting in a marked clinical deterioration – an interesting example of a reversible genotype-environment interaction affecting phenotype

Combination Therapy with Bone Morphogenetic Protein 2 (BMP-2) and Zoledronic Acid (ZA) Improves Posterolateral Spinal Fusion in a Mouse Model of Neurofibromatosis Type 1. Justin Bobyn*[1], Anton Rasch[2], Kathy Mikulec[2], Aaron Schindeler[3], David Little[1]. [1]Sydney University, Australia, [2]Childrens Hospital Westmead, Australia, [3]The Children's Hospital at Westmead, Australia

Introduction: Bone morphogenetic proteins (rhBMPs) are being increasingly utilized to treat the orthopedic complications associated with neurofibromatosis type 1 (NF1). Correction of scoliotic deformities associated with NF1 can be extremely challenging and these individuals exhibit a high rate of spinal pseudarthrosis. As excessive bone resorption is also reported to be problematic in NF1, we hypothesized that BMP-induced fusion could be improved using co-treatment with the bisphosphonate zoledronic acid (ZA).

Materials and Methods: NF1-deficient mice have been reported to show reduced bone healing. A published murine posterolateral lumbar spine fusion technique was applied to 16 wild type (*Nf1*+/+) mice and 16 NF1 deficient (*Nf1*+/-) mice. Fusion surgery involved the delivery of 10μg rhBMP-2 delivered bilaterally via collagen sponge (20μg total). N=8 mice of each genotype received s.c. saline or s.c. 0.02 mg/kg ZA twice weekly for 3 weeks. Mice were culled at 3 weeks and spines harvested for analysis.

Bone volume (BV; mm^3) and total bone mineral content (TMD; mg/mm^3) of the fusion mass were then calculated via CTan software.

Results: μCT images of harvested mouse vertebrae obtained at 3 weeks were reconstructed (Fig 1). Striking increases in bone volume were noted ($p<0.01$) in WT and *Nf1*+/- mice treated with ZA, bone volumes of 131.9 $\pm$15.4 mm^3 and 100.2 $\pm$21.7 mm^3 respectively, compared with WT and *Nf1*+/- mice which did not receive ZA, with volumes of 40.5 $\pm$4.5 mm^3 and 36.6 $\pm$6.9 mm^3. Similarly significant ($p<0.01$) increases in bone mineral density (BMD; mg/mm^3).

Bioquant analysis of TRAP stained sections revealed a significant ($p<0.05$) increase in the osteoclast surface area to bone surface area ratio (OcS/BS) in *Nf1*+/- samples relative to wild type controls. Co-treatment with rhBMP-2 and ZA treatment led to a significant reduction in OcS/BS in both groups.

Discussion: We have described a novel approach for mouse lumbar spine fusion that is safe, efficient, and analogous to contemporary human surgery. This model has shown that dual treatment with BMP and ZA is superior to treatment with BMP alone. ZA increased the fusion mass bone volume by 3-fold with an associated increase in bone density. Even with ZA treatment, *Nf1*+/- mice yielded smaller, less dense fusion masse compared to wild type counterparts. Nevertheless, the ZA-induced increase in bone led to a superior result in *Nf1*+/- mice compared to BMP alone in wild type mice.

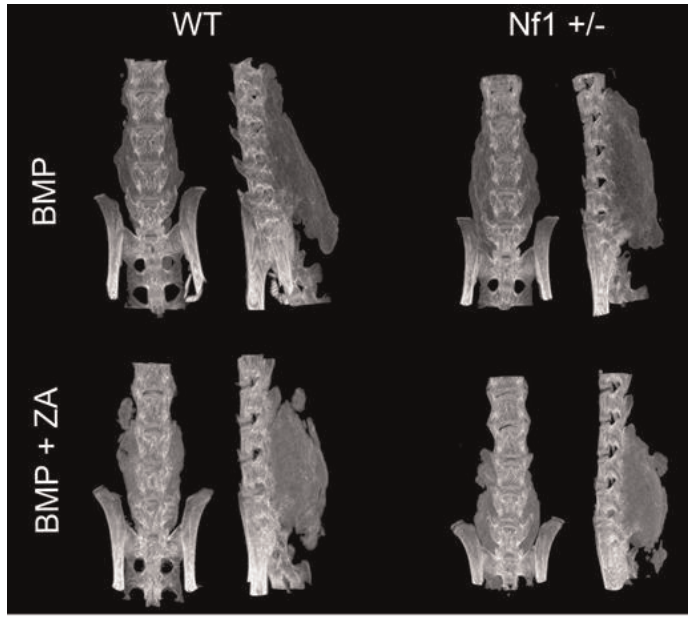

Fig 1. μCT reconstructions of harvested spines demonstrating increased size and mass density in ZA-treated groups over BMP only.

MO0131

Deletion of osteopontin rescues the skeletal deformities observed in *Phospho1*$^{-/-}$ mice. Manisha Yadav*[1], Carmen Huesa[2], Sonoko Narisawa[3], Alain Moreau[4], Colin Farquharson[5], Jose Luis Millan[3]. [1]Burnham Institute for Medical Research, USA, [2]The Roslin Institute & R(D)SVS, University of Edinburgh, Easter Bush, Midlothian EH25 9RG, United Kingdom, [3]Sanford Burnham Medical Research Institute, USA, [4]Sainte-Justine Hospital Research Center, Canada, [5]Roslin Institute, University of Edinburgh, United Kingdom

PHOSPHO1, a phosphatase with specificity for phosphoethanolamine and phosphocholine, plays a functional role in the initiation of calcification. *Phospho1*$^{-/-}$ mice display stunted growth, spontaneous fractures, bowed long bones, osteomalacia, and scoliosis. *Phospho1*$^{-/-}$ mice, as well as their isolated cells and matrix vesicles, display increased output of the mineralization inhibitor PP_i, a situation highly reminiscent of *Alpl*$^{-/-}$ mice, where elevated PP_i levels explain the rickets/osteomalacia characteristic of hypophosphatasia (HPP). Correcting PP_i levels in *Alpl*$^{-/-}$ mice prevents the development of all skeletal and dental abnormalities. Osteopontin (OPN), encoded by the *Spp1* gene, is another potent inhibitor of mineralization whose plasma and tissue levels we have shown changes in parallel to changes in PP_i. *Alpl*$^{-/-}$ mice, not only display elevated plasma PP_i but also elevated OPN levels and we showed that the *Alpl*$^{-/-}$ phenotype is only partially corrected in [*Alpl*$^{-/-}$; *Spp1*$^{-/-}$] double knockout mice while the elevated PP_i concentrations remain unresolved, suggesting that increased OPN contributes in part to the *Alpl*$^{-/-}$ bone phenotype independently of the mineralization inhibitory action of PP_i. *Phospho1*$^{-/-}$ mice display moderately increased levels of plasma PP_i and we have observed particularly high OPN expression in the spine, by immunohistochemistry and qPCR. While the transgenic overexpression of TNAP normalized plasma PP_i, no correction of the skeletal phenotype was observed in *Phospho1*$^{-/-}$ mice. However, here we show that the ablation of *Spp1* leads to the complete rescue of the scoliosis and long bone phenotype characteristic of *Phospho1*$^{-/-}$ mice. Von Kossa/van Gieson staining of vertebral and femoral sections showed decreased unmineralized osteoid in [*Phospho1*$^{-/-}$; *Spp1*$^{-/-}$] mice at 1 month of age and complete absence at 3 months of age. MicroCT analysis also showed improved BV/TV, BMD and trabecular thickness in the double knockout mice. Mineralization assay from chondrocytes harvested from the double KO mice also concur with the histology and μCT results. Thus, while both the *Alpl* and *Phospho1* deficiencies lead phenotypically to skeletal hypomineralization and similar changes in the expression levels of PP_i and OPN, there is a clear dissociation in the hierarchical roles of these potent inhibitors of mineralization, with elevated PP_i being the culprit in HPP while elevated OPN levels appears to be the main determinant of the *Phospho1*$^{-/-}$ skeletal phenotype.

Genetic Analysis of Serum Sclerostin. Allison Kuipers*[1], Yingze Zhang[2], Shibing Yu[3], Candace Kammerer[1], Cara Nestlerode[2], Yanxia Chu[2], Clareann Bunker[2], Alan Patrick[4], Victor Wheeler[4], Iva Miljkovic[2], Joseph Zmuda[1]. [1]University of Pittsburgh Graduate School of Public Health, USA, [2]University of Pittsburgh, USA, [3]University of Pittsburgh Medical Center, USA, [4]Tobago Health Studies Office, Trinidad & tobago

Sclerostin, encoded by the *SOST* gene, is a Wingless (Wnt) inhibitor that regulates bone mineralization and is a potential therapeutic target for bone mineral disorders. Genome-wide association studies have implicated the *SOST* locus as a candidate for osteoporosis. Because little is known about the factors influencing inter-individual variation in serum sclerostin levels, we assessed the genetic and non-genetic factors associated with serum sclerostin in 446 Afro-Caribbean men and women aged 18+ from 7 large, multigenerational families (mean family size: 64; 3840 relative pairs). Thirty-six common single nucleotide polymorphisms (SNP) were genotyped within a 100 KB region encompassing *SOST*. Genetic and non-genetic factors were tested for association with serum sclerostin using variance component linear regression methods. Mean serum sclerostin was 41.3 pmol/l and was greater in men than women ($P<0.05$). Greater serum sclerostin was associated with greater age and body weight, male sex, diabetes and lower glomerular filtration rate, which collectively accounted for 25.4% of its variation. Residual genetic heritability of serum sclerostin was 0.393 ($P<0.0001$). Nine SNPs were significantly associated with sclerostin, of which three (rs851056, rs41455049 and rs9909172) accounted for 7.8% of the total phenotypic variation in serum sclerostin. Thus, in this African ancestry population, known and unknown genetic factors account for more variation in serum sclerostin than do known non-genetic factors. These results highlight the potential importance of genetic evaluation with regard to individual assessment of serum sclerostin in bone mineral disorders.

MO0133

Genotype-Phenotype Correlations and Pharmacogenetic Studies in 152 Swedish Families with Osteogenesis Imperfecta. Katarina Lindahl*[1], Carl-Johan Rubin[2], Eva Åström[3], Barbro Malmgren[4], Andreas Kindmark[5], Osten Ljunggren[5]. [1]Endocrinology, Sweden, [2]Uppsala University, Sweden, [3]Department of Woman & Child Health, Division of Pediatric Neurology, Karolinska Institutet, Sweden, [4]Department of Clinical Science, Intervention & Technology, Division of Paediatrics, Karolinska University Hospital, Sweden, [5]Uppsala University Hospital, Sweden

Objective: Osteogenesis imperfecta (OI) is a rare heterogeneous disease leading to bone fragility, spanning from mild to lethal osteoporosis in severity. Over 1000 mutations causing OI have been described in the genes encoding collagen type I. As *COL1A1* and *COL1A2* are large genes, there are still many codon positions where no mutations have been reported and only a fraction of theoretically possible glycine substitutions have been discovered. Here mutations causing OI in Sweden were investigated with respect to genotype-phenotype correlations and pharmacogenetics.

Method: 152 families (204 individuals) with OI participated; 92 type I, 38 type IV and 23 type III. Extensive clinical data was collected and sequencing of *COL1A1* and *COL1A2* performed.

Results: A total of 119 typical OI mutations were detected, while no mutation was present in 29 families. In *COL1A1* 51 quantitative and 34 qualitative mutations were found and in *COL1A2* 33 qualitative mutations were discovered. 53 of the qualitative mutations had been reported to the collagen database (www.le.ac.uk/ge/collagen/) on average 7.1 times previously. New mutations were found in regions reported to be exclusively lethal, saturating the phenotypic map of *COL1A1* and *COL1A2* mutations. Only 13/66 quantitative mutations were formerly reported. Four families carried two separate mutations, one being a typical OI causing mutation. In two families previously unpublished mutations of unclear significance were discovered.

Delta lumbar BMD Z-score response to bisphosphonate treatment was calculated for the initial two treatment years and for the entire available treatment period. No difference was seen in treatment response in different OI types; in qualitative vs. quantitative collagen defects or *COL1A1* vs. *COL1A2* mutations. A significant increase in delta BMD ($p= 0.03$) for qualitative vs quantitative mutations in *COL1A1* was observed the initial two treatment years, but this effect was not preserved over longer treatment time (mean 5.7 years for quantitative and 6.9 years for qualitative).

Conclusion: The spectrum of mutations causing OI described in this Swedish cohort is of the expected type. It is notable that 79% of qualitative mutations have been reported previously, supporting theories of mutational hotspots or sequencing bias. Pharmacogenetic data does not support a mutation dependent response to bisphosphonate treatment in OI and subsequently all patients may be expected to increase BMD on treatment.

Metabolomics is the quantitative measurement of dynamic metabolic response to pathophysiologic stimuli or genetic modification making metabolome quintessence of biological processes. To identify metabolite signatures for osteoporosis and to understand its underlying biological implication, we measured ~500 metabolites in bone tissue and serum from osteoporosis patients (OP with at least one fragility fracture and low BMD) and age-matched normal-BMD controls. Bone tissues were obtained from trans-iliac biopsies in 84 post-menopausal Caucasian women. Transcriptome profiling of bone biopsies was measured by Affymetrix microchips. Metabolites were measured by LC-MS/MS (+ESI), LC-MS/MS (-ESI) or GC-MS. MS signatures of metabolites were matched to a small-molecule library. Age, BMI, estrogen use, cigarette smoking, menopause age and medication were collected and used in statistical analyses. To find metabolite signature, we applied a support vector machine algorithm with a nonlinear classification and identified 12 endogenous metabolites significantly differed between OP and controls. These 12 metabolites are involved in fatty acid amides; lipid oxidation; bile acid metabolism; tryptophan metabolism and redox homeostasis. Among them, significant accumulation of 5 dicarboxylic fatty acids (2~4 fold higher in OP) suggests potentially suppressed mitochondrial ß-oxidation in OP. Higher levels of the cannabinoid (CB) receptors agonist, oleamide, were observed in OP, indicating a disruption of CB signaling. Serotonin (5HT) was also higher in OP. To further characterize underlying mechanisms, we performed regression analysis between transcriptome and these 12 metabolites, adjusted for covariates described above. The expression of 71 genes was associated with these 12 metabolites at $p < 5x10^{-5}$. *AR*, *FGF2*, *PRKAA2* and several *G-protein coupled receptors* expressions associated with oleamide, providing supportive evidence of the involvement of CB receptors in OP. A pathway enrichment analysis pointed out three distinct cellular functional pathways (synaptic transmission; skeletal development of cortical bone and dystrophy of muscle). In summary, we identified a "signature" of 12 endogenous metabolites associated with osteoporosis in postmenopausal Caucasian women. We used the transcriptome to further characterize their functional implications. A replication study of metabolite signatures in ~1,000 Framingham Study participants is underway to further validate these findings.

MO0135

Mutant ALK2 receptors found in patients with typical and variant fibrodysplasia ossificans progressiva are activated by different BMP type II receptors through phosphorylation at Thr203. Mai Fujimoto*[1], Satoshi Ohte[2], Arei Miyamoto[1], Sho Tsukamoto[3], Kenji Osawa[1], Takato Mizuta[1], Shoichiro Kokabu[1], Naoto Suda[4], Takenobu Katagiri[1]. [1]Saitama Medical University Research Center for Genomic Medicine, Japan, [2]Harvard School of Dental Medicine, USA, [3]Saitama Medical University RCGM, Japan, [4]Division of Orthodontics, Meikai University School of Dentistry, Japan

BMPs are important growth factors for bone formation. BMP signaling is transduced by two types of Ser/Thr kinase receptors, type I and type II receptors. Although type II receptors are constitutively activated Ser/Thr kinases, type I receptors are inducible kinases via phosphorylation by type II receptors in response to BMPs. The ligand-dependent BMP signaling is deregulated in patients with fibrodysplasia ossificans progressiva (FOP), which is a rare hereditary disorder characterized by progressive heterotopic ossification in skeletal muscle. Patients with typical FOP, who show early-onset heterotopic bone formation in childhood, a mutation (R206H) in a BMP type I receptor, ALK2. ALK2(R206H) induces BMP signaling without BMPs and is activated by the presence of BMPR-II, which is one of BMP type II receptors. A substitution mutation at Thr203 in ALK2(R206H) blocked the activation by BMPR-II. Recently, we found that BMPR-II failed to activate a novel mutant ALK2, G325A, which has been identified in a variant of FOP, who showed late-onset heterotopic ossification in adulthood. Thus, we examined molecular mechanisms of the activation of ALK2(G325A). Cellular localization and protein

levels of ALK2 were not distinguishable among WT, G325A and R206H. Overexpression of G325A or R206H in C2C12 cells activated BMP-specific luc reporter, induced ALP activity and, increased phosphorylation levels of FLAG-Smad1. The stimulatory activity of G325A was weaker than that of R206H and was blocked by adding LDN-193189, a specific inhibitor for the Smad phosphorylation by BMP receptors. ActR-IIB, another BMP type II receptor, synergistically increased the ALP activity in cooperation with G325A, although kinase activity-deficient ActR-IIB did not activate G325A, suggesting that ActR-IIB phosphorylates ALK2. ALK2 has nine potential Ser/Thr residues in the intracellular GS domain. In G325A, substitutions of the eight residues except Thr203 by Ala/Val (G325A-8AV) still allowed the activation by ActR-IIB, but, a substitution of Thr203 with Val (G325-T203V) blocked that. These findings suggest that G325A is a novel mutation of ALK2, which is activated by ActR-IIB, but not BMPR-II, through the phosphorylation at Thr203. Interestingly, it has been reported that the patient with G325A did not have heterotopic bone formation even after muscle injury. The sensitivity of mutant ALK2 to BMP type II receptors may change the clinical features of patients with FOP.

We report that hypofunctional alleles of *WNT1* cause autosomal recessive osteogenesis imperfecta, a congenital disorder characterized by reduced bone mass and recurrent fractures. In consanguineous families we identified five homozygous mutations in *WNT1*. In addition, in a family with dominantly inherited early onset osteoporosis, a heterozygous *WNT1* missense mutation was identified in affected individuals. Initial functional analysis revealed that mutant WNT1 proteins failed to activate the canonical LRP5-mediated WNT/β-catenin signaling. Furthermore expression analysis on mRNA and protein level indicates a switch from a neuronal to a skeletal expression pattern during prenatal development and increasing expression levels with advancing osteoblast differentiation. This indicates an unexpected role of the "neuronal" WNT1 in bone development and homeostasis. Our findings might also have relevance for more common forms of age-related osteoporosis.

Primary Cilia are Essential for Determination of Dentin Thickness. Courtney Haycraft*, Michael B. Chavez. Medical University of South Carolina, USA

Primary cilia are solitary organelles found on most eukaryotic cells. Despite their nearly ubiquitous presence, their function on many cell types has yet to be fully investigated, but a growing number of human genetic disorders have been shown to be related to defects in the formation or function of this organelle. Orpk mutant mice have a partial loss of function of the gene Ift88 and homozygous mutants develop pathologies in multiple organs including renal cysts, hydrocephalus, and polydactyly. In addition to these pathologies orpk mutant mice develop supernummary molars due to alterations in signaling pathways essential for tooth patterning including Sonic hedgehog. Despite the known defects in molar patterning, no information regarding the morphogenesis of the molars has been reported. The objective of the current study was to examine the morphology of the first molar in orpk mutant mice to determine the role primary cilia play in the later stages of molar development. We examined molars from orpk mutant and control mice using microCT imaging and analysis. All first molars contained the same number of cusps in control and orpk mutants suggesting that patterning of the cusps is unaffected despite the reduced size of the molars and presence of a supernummary molar in the mutants. Orpk mutant first molars contained significantly less dentin than controls at 30 days of age (P30) through 120 days of age (P120). The volume of dentin relative to the total volume (DV/TV) showed a significant reduction in the oprk mutant molars. Although dentin volume fraction was significantly decreased, we did not observe an increase in predentin thickness at any age examined suggesting that the reduction in mineralized dentin is not due to alterations in the mineralization process. Despite the decreased volume fraction of dentin in orpk mice, enamel volume not altered at P30. Primary cultures of isolated molar mesenchyme from orpk and control mice showed a reduction in the number of mutant cells expressing primary cilia in vitro. Overall our results show that primary cilia are essential for proper molar morphogenesis specifically the volume of dentin. We are currently investigating whether the reduced amount of dentin found in the orpk mutant first molars is due to changes in odontoblast differentiation or matrix secretion.

Role of endothelial cells in heterotopic ossification using FOP iPS cells. Emilie Barruet*[1], Christopher Schlieve[1], Hannah Kim[1], Mark White[2], Christina Theodoris[2], Deepak Srivastava[2], Ashley Urrutia[1], Edward Hsiao[1]. [1]Institute for Human Genetics & the Division of Endocrinology & Metabolism, University of California, San Francisco, USA, [2]Gladstone Institute of Cardiovascular Disease, San Francisco, USA

Musculoskeletal disorders affecting the bones and joints are major health problems for children and adults. Unfortunately, treatments for skeletal diseases are still rudimentary. The recent advent of human induced pluripotent stem cells (hiPSCs) provides an unparalleled opportunity to identify novel therapies for human skeletal diseases. One major regulatory pathway in bone formation involves bone morphogenetic proteins (BMPs). Patients with mutations in the Activin A Type I receptor (ACVR1), a BMP receptor, develop the debilitating disease fibrodysplasia ossificans progressiva (FOP). They show progressive ossification of muscle and tendon. The majority of ACVR1 mutations occur in a single amino acid (R206H) that may increase ACVR1 signaling activity. Recent data suggest that human endothelial cells carrying the ACVR1 R206H mutation may contribute to the formation of FOP lesions. Our overall hypothesis is that activated BMP signaling in endothelial cells increases heterotopic bone formation by increasing osteogenesis. In this study, we use a series of human iPSCs created from normal control and FOP donors. We previously showed that the FOP iPSCs not only demonstrate increased mineralization and enhanced chondrogenesis but also increased levels of gene expressed by endothelial cells (CD31) when cultured in osteogenic conditions. To determine if the ACVR1 R206H mutation leads to increased endothelial cell production, we used a recently-developed protocol to create human iPSC-derived endothelial cells. We successfully derived endothelial cells from our iPS lines. We found a yield of 25% phenotypic endothelial progenitors ($CD31^+/KDR^+$) from control and FOP iPS lines. After sorting they yield more than 95% $PECAM^+/VE\text{-}CAD^+$ cells. Since there was no significant difference in endothelial cell production, we are now testing if the altered BMP signaling in FOP endothelial cells affects their osteogenic properties. These studies use iPSCs created from patients with FOP, a rare and dramatic disease of massive heterotopic ossification, to establish a robust *in vitro* model of human skeletal tissue formation that may be extended to iPSCs created from other skeletal conditions. The cellular mechanistic insights gained from these studies will establish a solid foundation for understanding the roles of non-bone tissues such as endothelial cells in skeletal formation and for identifying new therapies not only for FOP but also other diseases of abnormal skeletal formation.

Introduction: Fracture risk has a multifactorial etiology with a significant heritable component. We estimated how much of the variance in fracture risk could be explained by known genetic variants for phenotypes correlated with fracture risk. Methods: The GEFOS consortium fracture (age >18 years, any bone) GWAS meta-analysis discovery phase included 19,414 cases (total 102,873 participants; 24 GWAS). SNP lists were drawn from published GWAS meta-analyses for correlated phenotypes: 1) bone mineral density (BMD), at femoral neck and lumbar spine measured by DXA); 2) height; 3) type 2 diabetes mellitus (T2DM); 4) C-reactive protein (CRP); 5) vitamin D. Inverse variance fixed-effects logistic regression models were meta-analyzed adjusted for sex, age, height and weight (2,483,202 SNPs). Independent signals for fracture association were clumped by PLINK (distance>250kb; $r^2<0.50$). The variance explained was summed from per-SNP (V_{SNP}) calculations dependent on minor allele frequency (MAF) and the effect estimate for fracture risk from the meta-analysis ($\beta_{fracture}$): $V_{SNP}=2*(\beta_{fracture})^2*MAF*(1-MAF)$. Analyses were performed per trait and as a composite score (independent signals $r^2<0.1$). To determine whether sets of SNPs for the correlated traits explained more phenotypic variance in fracture risk than expected by chance, P-values were derived from random sampling cumulative distributions. Results:The top-associated genome-wide significant signals ($P<5x10^{-8}$, 3 SNPs) explained 1% of variance of fracture risk; a more lenient significance threshold ($P<5x10^{-6}$) resulted in genetic variants (24 SNPs) explaining 5.1%. BMD SNPs explained 3.9% (63 SNPs in 56 loci, $P=2x10^{-4}$), height SNPs 2.5% (180 SNPs in 180 loci, P=0.04), T2DM SNPs 0.7% (68 SNPs in 65 loci, P=0.4); CRP SNPs 0.3% (29 SNPs in 29 loci, P=0.4) and vitamin D SNPs 0.04% (3 SNPs in 3 loci, P=0.26). The composite score explained 6.7% of fracture risk (322 SNPs in 322 loci, P=0.002). Conclusion: Prioritized fracture SNPs explain ~5% of variance in our discovery sample. However, SNPs associated with traits correlated with fracture risk still explain more, validating these traits as important contributors overall. Finding genetic determinants of fracture independently from the known clinically contributing traits is relevant, but will require very large sample sizes for sufficient power. The GEFOS and GENOMOS consortia replication phase is ongoing and our prediction studies should be validated in independent studies.

Transcriptional Induction of ADAMTS5 by an NF-κ Family Member RelA/p65 in Chondrocytes during Osteoarthritis Development. Hiroshi Kobayashi*[1], Makoto Hirata[2], Shozo Itoh[2], Taku Saito[3], Ung-Il Chung[4], Hiroshi Kawaguchi[5]. [1]The University of Tokyo Hospital, Japan, [2]The University of Tokyo, Japan, [3]University of Tokyo, Graduate School of Medicine, Japan, [4]University of Tokyo Schools of Engineering & Medicine, Japan, [5]University of Tokyo, Faculty of Medicine, Japan

ADAMTS5 (aggreacanase-2) is a crucial proteinase that degrades articular cartilage during osteoarthritis (OA) development. To elucidate the molecular network as a therapeutic target of OA, this study attempted to identify transcripion factors to induce ADAMTS5 expression and examined the underlying mechanism. Exhaustive comparison of the genomic sequences of 5'-end flanking regions of human, macaca, and mouse *Adamts5* genes revealed that the 1.4 kb region upstream of the transcriptional start site was highly conserved among the species. The sequence search in this region predicted the consensus binding motifs of NF-κB, C/EBP, GATA, RUNX, AP-1, OCT, SOX, STAT, and HIF. Among the transcription factors that are known to bind to these sites, an NF-κB family member, RelA/p65, most strongly stimulated the luciferase activity containing the 1.4 kb human *ADAMTS5* gene fragment. In the *ADAMTS5* genes, there were three NF-κB binding motifs: −1,196/−1,187, −896/−887, and −424/−415 bp, in which deletion, mutagenesis, and tandem-repeat analyses of the luciferase assay identified the core responsive regions of RelA/p65 to be the two upstream motifs. Electrophoretic mobility shift assay revealed the binding of nuclear extracts of RelA/p65-overexpressed COS-7 cells with the two NF-κB motif oligonucleotide probes. The specificity of the binding was verified by the cold competition with excess amount of the unlabelled wild-type probe and by the supershift with an antibody to RelA/p65. Retroviral overexpression of RelA/p65 markedly increased the *Adamts5* mRNA level in ATDC5 cells. The endogenous *Adamts5* induction by IL-1β, a putative NF-κB inducer, was suppressed by the knockdown of *RelA* through its specific siRNA transfection. The *Adamts5* expression was inhibited by the *Rela* deletion through adenoviral transfection with Cre in primary articular chondrocytes from $Rela^{fl/fl}$ mice. In the *ex vivo* culture of femoral head cartilage from *Prx1*-Cre;$Rela^{fl/fl}$ mice, the aggrecan fragment release induced by IL-1β was significantly lower than that in the culture from $Rela^{fl/fl}$ mice. Finally, in the OA model by surgical induction of instability in the knee joints of 8-week-old mice, Adamts5 and RelA/p65 were co-localized in chondrocytes of the degraded articular cartilage. In conclusion, we identified RelA/p65 as a potent transcriptional activator of ADAMTS5 in chondrocytes. The molecular network related to the RelA/p65-ADAMTS5 axis may thus represent a therapeutic target for OA.

MO0142

Genome-wide association identifies *Wnt4* as a regulator of osteoblast activity. Cheryl Ackert-Bicknell*[1], Gina Calabrese[2], Dana Godfrey[1], Kathryn Shultz[1], Charles Farber[2]. [1]The Jackson Laboratory, USA, [2]University of Virginia, USA

Osteoporotic fracture and fracture-related traits, such as bone mineral density (BMD), are highly heritable. BMD has become the trait of choice for genetic studies of osteoporosis due in part to its high heritability; however, BMD is not an ideal phenotype for genetic studies. Bone mass is the net product of formation and resorption and each of these processes is influenced by a myriad of complex factors. This makes it challenging to translate the discovery of novel BMD genes into a better understanding of bone biology. As an alternative, we have focused on the genetics of osteoblast activity. Osteoblast activity was defined as the ability of osteoblasts to form mineralized modules *in vitro*. Primary calvarial osteoblasts from 22 inbred strains of mice were cultured in differentiation media for 10 days, after which the degree of mineralization was assessed by alizarin red staining. For 16 of these strains, BMD data was also available and we found that mineralized nodule formation was positively correlated with BMD in both females (r=0.35; P=0.17) and males (r=0.54; P=0.03), indicating that this *in vitro* phenotype is physiologically relevant. Using genome-wide association (GWA) analysis we identified three genome-wide significant loci (permutation-derived significance threshold P=2.53 x 10^{-6}) associated with mineralized nodule formation. The most significant (P= 5.25 x 10^{-8}) locus was located on mouse chromosome 4. Mineralized nodule formation was twice as high for strains homozygous for the reference (C57BL/6J) allele (0.89 $\pm$ 0.04 mM, N=16) as compared to strains homozygous for the non-reference allele (0.43 $\pm$ 0.04 mM, N=6). The associated haplotype spanned ~200 Kbp (from 136.65 to 136.88 Mbp) and contained only the *Wnt4* gene, a gene previously implicated in human BMD GWA studies. By examining gene expression across osteoblastogenesis using RNA-seq, we determined that expression of *Wnt4* is highest in pre-osteoblasts, after which expression falls to a low but consistent baseline level. The DBA/2J strain is homozygous for the non-reference allele at this locus and expression of *Wnt4* was 7.3 fold higher in osteoblasts from DBA/2J mice as compared to C57BL/6J (P =0.01). These data suggest that the genetic analysis of physiologically relevant cellular phenotypes is a powerful alternative to complex organismal-level traits and that *Wnt4* is a regulator of osteoblast activity.

MO0143

BMP3 Expression by Osteoblasts Is Regulated by Canonical Wnt Signaling. Shoichiro Kokabu*[1], Laura Gamer[1], Jonathan Lowery[1], Tsuyoshi Sato[2], Tetsuya Yoda[2], Takenobu Katagiri[3], Vicki Rosen[1]. [1]Harvard School of Dental Medicine, USA, [2]Saitama Medical University, Japan, [3]Saitama Medical University Research Center for Genomic Medicine, Japan

Bone morphogenetic protein 3 (BMP3), the most abundant BMP in bone matrix, is produced by osteoblasts and osteocytes in the adult skeleton. Targeted disruption of *Bmp3* in mice results in increased trabecular bone formation and high bone mass, while transgenic overexpression of BMP3 in skeletal progenitors leads to delayed mineral deposition during endochondral ossification and spontaneous fracture. BMP3 suppresses BMP-induced osteoblast differentiation and subsequent maturation through an interaction with the type II BMP/activin receptor, activin receptor 2b (Acvr2b). Thus, BMP3 is regarded as a negative regulator of bone formation.Recently we identified the minimal promoter region of mouse *bmp3* and determined that this region contains several putative canonical Wnt responsive elements. Here we report that canonical Wnt signaling stimulates BMP3 expression in osteoblasts. First, we observed elevated BMP3 expression by calvarial osteoblasts isolated from DKK1 heterozygous knockout mice, a model of increased canonical Wnt signaling. Next we found that when calvarial osteoblasts harvested from wild-type mice were treated with recombinant Wnt3a, BMP3 mRNA levels were strongly increased. Based on these findings, we used primary osteoblasts obtained from mice carrying a LacZ knock-in allele to the *Bmp3* locus as a system to monitor BMP3 production. We find that treatment with Wnt3a and other canonical Wnts greatly increased BMP3 production, as did treatment with LiCl, an inhibitor of GSK3-beta. In contrast, treatment with Wnt5a, an activator of non-canonical Wnt signaling, had no effect on BMP3 expression. Taken together, these data suggest that the BMP and Wnt signaling pathways interact at the level of BMP3. The importance of canonical Wnt signaling in bone is well documented and in general, increasing canonical Wnt signaling correlates with enhanced bone formation through increased differentiation and maturation of osteoblasts. Based on these results, we hypothesize Wnt signaling not only induces bone formation but also regulates osteogenic BMP activity in vivo via induction of BMP3.

Evaluation of muscle derived stem cells combined with a sustained release of BMP2 coacervate for bone regeneration. Hongshuai Li*[1], Noah Johnson[2], Xueqin Gao[1], Yadong Wang[2], Johnny Huard[3]. [1]University of Pittsburgh, USA, [2]Dept. of Bioengineering, University of Pittsburgh, USA, [3]Orthopaedic Surgery, USA

Introduction:Muscle-derived stem cells, (MDSCs) can be isolated from the skeletal muscle via a modified preplate technique [1], which is a promising cell source for bone tissue engineering [2-4]. However, without the transduction of BMPs the cells do not differentiate towards an osteogenic lineage. We report here the efficacy of a unique growth factor delivery platform comprised of native heparin and a polycation, poly(ethylene argininylaspartate diglyceride) (PEAD) incorporated with BMP2 (BMP2 coacervate) that can stimulate mouse and human MDSCs to differentiate into an osteogenic lineage and form viable bone. Methods:Mouse andhuman MDSCs were isolated via a modified pre-plated technique. The BMP2 coacervate was prepared as previously described [5]. The osteogenic effects that the delivered BMP2 had on the MDSCs were evaluated both in vitro and in vivo at an ectopic site and in a critical sized calvarial defect which were compared with MDSCs that were transduced with a lenti-BMP2 viral vector. Results:Prolonged release of loaded BMP2 was observed and BMP2 coacervate significantly stimulated the expression of ALP and mRNA levels of Col-1 and osteocalcin compared to the free BMP2. Micro-CT analysis showed significantly more ectopic bone in the BMP2 coacervate+MDSC group compared with free BMP2+MDSC group. In the calvarial defect model, significantly higher bone volume in the BMP2 coacervate+MDSC group was observed compared to the free BMP2+MDSC group; and there was no significant difference between the BMP2 coacervate+MDSC and BMP2 transduced MDSC groups (Fig. 1). Alizarin red and von Kossa staining revealed calcified osteoid matrix in the transplanted area containing MDSCs with BMP2 coacervate. Immuno-histological staining of GFP and human specific MHC-1 demonstrated the presence of donor cells throughout and at the edge of the osteoid, which suggests that the MDSCs were not only present within the osteoid but were active in the new bone formation. Conclusion:This study demonstrated that a dual muscle cell and growth factor delivery approach may be a viable therapy for bone regeneration. The implantation of non-genetically modified MDSCs to the injury site with an effective BMP delivery system is a practical option for patients in terms of both safety and long term results.

The BMP Type I Receptor Alk2 is a Key Regulator of Chondrogenesis. Andria Culbert*, Salin Chakkalakal, Edwin Theosmy, Linda Wang, Eileen Shore. University of Pennsylvania, USA

Bone morphogenetic protein (BMP) signaling is a critical regulator of cartilage differentiation and endochondral ossification. Suppression or hyper-activation of BMP signaling results in delayed maturation and expansion of cartilage elements respectively. ALK2 (activin receptor-like kinase 2) is a highly conserved bone morphogenetic protein (BMP) type I receptor that responds to exogenous ligand to mediate downstream BMP signaling. Gain-of-function mutations in ACVR1/ALK2 cause the rare genetic disorder fibrodysplasia ossificans progressiva (FOP), characterized by progressive heterotopic (extra-skeletal) endochondral ossification, suggesting that the Alk2 receptor mediates signaling in progenitor cells to regulate chondrogenic cell fate decisions. To test this hypothesis, mouse embryonic fibroblasts (MEFs) were used as a mesenchymal progenitor cell model. MEFs from $Alk2^{R206H/+}$ knock-in and Alk2 knock-out ($Alk2^{KO}$) embryos were used to examine enhanced and absent Alk2 signaling respectively. $Alk2^{R206H/+}$ MEFs showed increased BMP signaling, relative to wild-type cells, as detected by Smad1/5/8 phosphorylation and

increased expression of BMP responsive genes in both the absence and presence of BMP ligand. BMP-induced Smad1/5/8 phosphorylation and BMP-responsive transcripts are reduced in Alk2KO MEFs; the remaining BMP signaling in these cells is mediated by Alk3 and Alk6 BMP type I receptors. BMP-induced chondrogenic differentiation is accelerated in $Alk2^{R206H/+}$ MEFs but suppressed in $Alk2^{KO}$ MEFs, despite BMP signaling through Alk3 and Alk6. We determined that Alk2 mRNA expression is highest in undifferentiated MEFs and decreases rapidly upon differentiation. Depletion of Alk2 at early stages of chondrogenic induction (within 48 hours), but not later stages, impairs chondrogenesis. By contrast, stimulating differentiation of either wild-type or $Alk2^{R206H/+}$ MEFs with BMP for only the initial 48 hours is sufficient to promote differentiation and maintain the enhanced differentiation of $Alk2^{R206H/+}$ MEFs. Our data show that Alk2 in mesenchymal progenitor cells enhances chondrogenic differentiation with specific and key roles during commitment and/or early chondrogenesis.

Determining the role of FGF on osteogenic and adipogenic differentiation and conversion in mesenchymal stem cells. Meike Simann*[1], Solange Le Blanc[2], Franz Jakob[3], Norbert Schuetze[1], Tatjana Schilling[4]. [1]University of Wuerzburg, Orthopedic Center for Musculoskeletal Research, Germany, [2]Universitat Wurzburg, Germany, [3]Orthopedic Center for Musculoskeletal Research, Germany, [4]University of Wuerzburg, Germany

Osteoporosis is commonly accompanied by an accumulation of fat tissue in the bone marrow, referred to as fatty degeneration. Thus, trabecular bone is replaced by adipose tissue. Moreover, adipocytes and osteoblasts emerge from the same origin, the mesenchymal stem cell (MSC), which can differentiate into the adipogenic or the osteogenic lineage. Consequently, there is an inverse relationship between bone and fat. Besides the differentiation of bone marrow MSC (BM-MSC) into adipocytes the conversion of osteoblasts into adipocytes is a major cause of fatty degeneration. To our knowledge, to date common therapeutics do not address this issue. Therefore, our aim is to find and explore factors inhibiting adipogenic differentiation and conversion in order to contribute to a novel approach for osteoporosis therapy and prevention.

So far, we have demonstrated in vitro that human BM-MSC-derived pre-osteoblasts can be converted into adipocytes (adipogenic conversion) and vice versa (osteogenic conversion). Differentiation/conversion status was approved by histological stainings and RT-PCR of adipogenic and osteogenic markers. A global gene expression analysis displayed regulated signaling factors during the onset of adipogenic and osteogenic conversion. Strongly and inversely regulated genes were found in FGF (fibroblast growth factor), IGF (insulin-like growth factor) and G-protein signaling cascades. Members of the FGF family were upregulated in osteogenic conversion and downregulated in adipogenic conversion, hinting at downstream control points favoring osteogenesis while preventing adipogenesis.

Recently, we showed that different promising members of the FGF family strongly inhibit both, the adipogenic differentiation of MSC and the adipogenic conversion of pre-osteoblasts into adipocytes. Furthermore, the addition of a selective FGFR (FGF receptor) inhibitor abolished the inhibitory effect. The relevant FGFR isoform was identified via RNA interference using a stable lentiviral transduction system. Next, we want to address the dose dependency of the inhibitory process. Furthermore, we aim to elucidate the intracellular signaling mechanisms crucial for the onset of conversion and their involvement within either established or so far unknown pathways.

Taken together, our results could aid to prevent the fatty degeneration of bone marrow as well as bone loss in elderly and osteoporotic patients by enhancing osteogenesis and inhibiting adipogenesis at the same time.

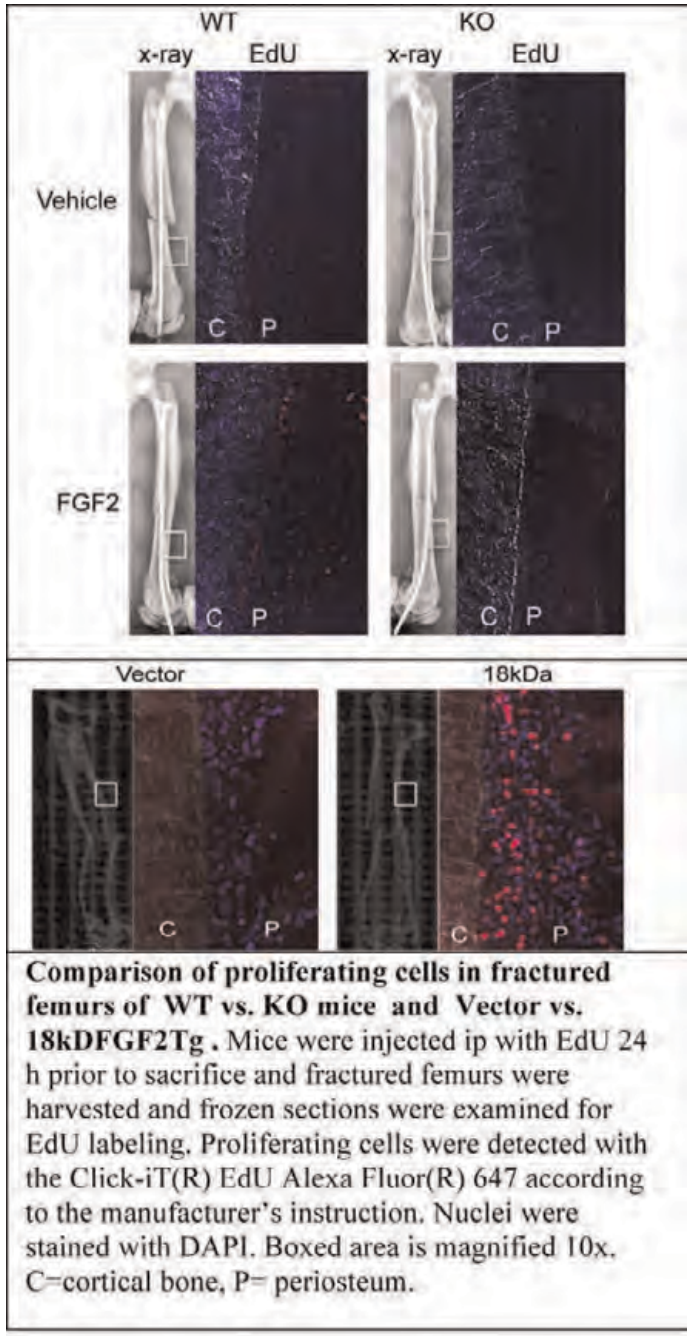
Differential Fracture Healing in FGF2KO and FGF2 Transgenic Mice is Associated with Altered Periosteal Progenitor Proliferation. Collin Homer-Bouthiette*[1], Liping Xiao[1], Marja Marie Hurley[2]. [1]University of Connecticut Health Center, USA, [2]University of Connecticut Health Center School of Medicine, USA

FGF2 is decreased in osteoblasts of aged mice and FGF2 knockout (Fgf2KO) mice have impaired bone formation. In contrast, mice overexpressing low molecular weight FGF2 (18kDaFGF2Tg) in osteoblast progenitors have increased bone mass. We hypothesized that fracture healing would be impaired in Fgf2KO but not 18kDaFGF2Tg mice due to modulation of periosteal progenitor proliferation in the early post fracture period. *Approach:* Femur fracture healing was examined in 2m and 24m WT and Fgf2ko mice, as well as 18kDaFGF2Tg and control mice. To assess periosteal cell proliferation, femur fracture was performed on 6m WT and Fgf2KO mice. Immediately after fracture, mice were S.C injected with 100ug/kg (body weight) FGF2 or Vehicle. Mice were sacrificed on day 2 post fracture. 24 hours prior to sacrificing mice were injected intraperitoneally with EdU (5-ethynyl-2'-deoxyuridine) 3ug/gram (body weight) to assess proliferation. Fractured femurs were harvested and frozen sections were stained for EdU, and counterstained with 4'6-diamidino-2-pheynlindole (DAPI) to identify nuclei. Similar assessment of periosteal cell proliferation was performed in 12m 18kDaFGF2Tg and vector mice, however these mice were not treated with FGF2. *Results:* At day 14 post fracture, x-rays showed that calluses were less mineralized in 24m WT type mice as well as in 2 and 24m Fgf2ko mice compared with 2m WT. Quantitative analysis showed that the ratio of bony/total callus area was decreased in 24m WT compared with 2m WT. In addition bony/total callus area was decreased at all ages in Fgf2KO compared with 2m WT. Decreased labeling with EdU was observed in cells of the periosteal surface of the vehicle treated Fgf2KO femur compared with WT, which was partially rescued by exogenous FGF2 treatment. When compared to Fgf2KO mice, utilizing radiography, micro-CT and histology, 18kDaFGF2Tg mice displayed enhanced femur fracture healing. Micro-CT and histology also showed more complete bridging of the femur fracture callus in 18kDaFGF2Tg mice while remodeling was continuing in femurs of Vector mice. Enhanced fracture healing was associated with increased EdU labeling of cells of the periosteal surface of the cortical bone in 18kDFGF2Tg compared with Vector. Thus enhanced periosteal cell proliferation could contribute to the enhanced fracture healing in these mice. These data suggest that endogenous FGF2 is necessary for normal bone regeneration and the 18kDa isoform displays increased fracture healing.



Comparison of proliferating cells in fractured femurs of WT vs. KO mice and Vector vs. 18kDFGF2Tg . Mice were injected ip with EdU 24 h prior to sacrifice and fractured femurs were harvested and frozen sections were examined for EdU labeling. Proliferating cells were detected with the Click-iT(R) EdU Alexa Fluor(R) 647 according to the manufacturer's instruction. Nuclei were stained with DAPI. Boxed area is magnified 10x. C=cortical bone, P= periosteum.

Bone metastatic melanoma promotes angiogenesis with the production of prostaglandin E2 by host stromal cells. Kenta Watanabe[1], Satoshi Yokoyama[2], Chiho Matsumoto[1], Michiko Hirata[1], Masaki Inada[1], Chisato Miyaura*[1]. [1]Tokyo University of Agriculture & Technology, Japan, [2]Tokyo, Japan

Bone metastasis of malignant melanoma is accompanied by severe bone destruction with increased bone resorption. We reported that sequential pathway of osteoblastic prostaglandin E (PGE) biosynthesis in bone, which is mediated by an inducible PGE synthase, membrane-bound PGE synthase-1 (mPGES-1). *In vivo* mouse cancer injection model, malignant melanoma (B16) proliferation and metastasis were dramatically increased. In the present study, we investigated the mechanisms of PGE associated neo-vascularization with promotion of tumor proliferation and metastasis using mPGES-1-/- mice (mPGES-/-). When B16 cells were injected intravenously into wild-type mice (WT), numerous metastasized locus were found in various tissues including bone, lung, liver, and kidney. In mPGES-/-, however, the number of metastasized locus was markedly suppressed at all. In the laser imaging for *in vivo* detection of neo-vascularization, a red fluorescent labeled polyethyleneglycol particle was used to detect angiogenesis, since the particle was able to incorporate specifically into growing endotherial cells. In WT, the fluorescent signals of neo-vascularization were strongly detected in B16 metastasized foci, but not in mPGES-/-. In the experiments of subcutaneous injection of B16 cells to WT and mPGES-/-, the neo-vascularization was only found in WT. To further elucidate the roles of host-stromal cell derived PGE2 in neo-vascularization for tumor, skin stromal cells from WT and mPGES-/- were co-cultured with fixed-B16 cells. In the co-cultures, stromal cells from WT, but not from mPGES-/-, markedly produced PGE after cell-to-cell interaction with B16 cells. WT derived stromal cells produced vascular endothelial cell growth factor (VEGF)-A and basic fibroblast growth factor (bFGF), and the production of these factors was enhanced by the treatment with PGE. On the other hand, VEGF-A and bFGF production was dramatically decreased in mPGES-/-derived stromal cells. These results suggest that PGE2 produced by host stromal cells promotes VEGF-A and bFGF production, which leads the angiogenesis at the site of melanoma metastasis. The blockage of PGE2 signaling such as PGE receptor antagonist is a candidate for therapy of bone cancer that associate with angiogenesis.

Effect of Foxo1 Deletion in Dendritic Cells on Developing Antibody Levels and Bone Loss in Periodontal Model. Yu Wang*[1], Wenmei Xiao[2], Sandra Pacios[2], Marisa Reason[2], Guangyu Dong[2], Dana Graves[3]. [1]University of Pennsylvania, USA, [2]University of Pennsylvania Dental School, USA, [3]University of Pennsylvania, School of Dental Medicine, USA

Background: Periodontitis is the most common osteolytic disease, is induced by inflammation and characterized by loss of supporting connective tissue and bone. While the host response participates in osteoclastogenesis it also provides essential protection against periodontal pathogens. We determined whether expression of the transcription factor FOXO1 in dendritic cells (DC) played an essential role in protecting alveolar bone from bacteria-stimulated osteolysis or enhanced bone loss.

Methods:FloxedFOXO1 was deleted in dendritic cells *in vivo* by CD11c driven Cre recombinase(CD11c .Cre+.FoxoL/L). Periodontitis was induced in mice by inoculation of P. *gingivalis* and F.*nucleatum* while controls received vehicle alone (2% methylcellulose). Periodontal bone was examined by microCT, antibody level (IgG1) against P. gingivalis was measured by ELISA and migration of dendritic cells was analyzed in vitro in a transwell migration assay. Expression of selected genes that regulate migration was examined by real-time PCR.

Result: Bone loss was observed following infection in both wild type and Foxo1 deletion mice ($P<0.05$). Bone loss in the Foxo1 deletion group compared with wild type was 37% greater in the maxilla and 33% in the mandible. Anti-P. gingivalis IgG1 peaked at 2 weeks after infection was ($P<0.05$) and Foxo1 deletion reduced anti-P. gingivalis IgG1 levels by 51%. Deletion of FOXO1 in dendritic cells decreased CCL21 stimulated migration by 47% ($P<0.05$). FOXO1 deletion reduced mRNA levels of Itgav, Itgb2,Itgb3,CCR7,CXCR4 by 40-60%.

Conclusion: FOXO1 expression in DC is required to protect alveolar bone from periodontal infection that induces bacteria-induced osteolysis. This protection involves regulation of target genes that control DC migration, which is needed to induce an antibody response.

Identification of Novel Small Molecules That Bind to the Loop2 Region of Sclerostin –An *In Silico* Computational Analysis. Karthikeyan Muthusamy*[1], Subburaman Mohan[2], Selvaraman Nagamani[1], Chandrasekhar Kesavan[2]. [1]Dept. of Bioinformatics, Alagappa University, India, [2]Jerry L. Pettis Memorial VA Medical Center, USA

Targeted deletion of sclerostin, a Wnt antagonist, in mice resulted in high bone mass due to a massive increase in the bone formation rate. Furthermore, antibody-based sclerostin inhibition has been used in various studies to reverse bone loss caused by ovariectomy or immobilization and to improve fracture healing. Because of the established importance of sclerostin for the treatment of low bone mass diseases, we screened for novel antagonists against sclerostin using an in *silico* approach. Computational analyses were carried out on a Red hat 5.1 Linux platform. The crystal structure of human sclerostin protein (PDB id -2k8p) was selected as a reference structure (Veverka et al. 2009), in particular loop 2 regions for a molecular docking analysis, as this region is predicted to be involved in binding to Wnts. Screening of a Zinc database containing 99,800 compounds against the active site of sclerostin using virtual workflow revealed 9 potential molecules binding to the loop 2 region of sclerostin. The ADME/T properties predicted by the Qikprop program revealed that the partition coefficient (QPlogPo/w) and water solubility (QPlogS) that provide estimates of absorption and distribution of drugs within the body, ranged between ~ -2.69 to ~ -6.88 and ~ -1.05 to ~ 0.53, respectively, for all nine compounds suggesting that the pharmacokinetic parameters and physicochemical properties are within the acceptable range defined for human use. Compounds 30160056 and 56871042 showed the highest docking score. Density functional theory analysis (an approach that determines the molecular property and biological activity of the compound by using HUMO, LUMO and MESH analysis) showed the best score for compounds 30160056, 56871042 and 72112226 among the 9 molecules. Subsequently, biological activity spectrum analysis (PASS prediction, represents the complex of pharmacological effects, physiological and biochemical mechanism of action results from compound interaction with the biological compound) revealed a best activity score for compounds, 30160056, 56871042 and 72112226 (Table 1). In conclusion, *in silico* analysis revealed nine compounds of which three compounds demonstrated a high binding affinity for sclerostin.

Zinc database Compound[a] ID	DOCKING			ADME		DFT		PASS

miR-125a, a Pro-inflammatory microRNA that Enhances NF-kB Signaling, Is Elevated with Age in Human Bone Marrow Microvesicles. Sunil Upadhyay*[1], Sudharsan Periyasamy-Thandavan[2], William Hill[2], Carlos Isales[1], Randy Ruark[1], Norman Chutkan[1], Jay Hinson[1], Raymond Corpe[1], Mary Anne Park[1], Candelario Laserna[1], Mark Hamrick[3]. [1]Georgia Regents University, USA, [2]Georgia Regents University & Charlie Norwood VAMC, USA, [3]Georgia Health Sciences University, USA

Cell-derived microvesicles are now acknowledged to play important roles in cell-cell communication. These lipid-based carriers are also known to shuttle microRNAs (miRNAs) between cells, delivering their miRNAs to various cell types via endocytosis and membrane fusion. Microvesicle- derived transport of miRNAs therefore represents one cellular and molecular pathway for epigenetic reprogramming of target cells. We therefore tested the hypothesis that microvesicles isolated from the bone marrow microenvironment transport specific miRNAs, and that these miRNAs change with age. To evaluate this hypothesis we obtained bone marrow samples from young (30-50 y.o.) and older (60-70 y.o.) knee and hip arthroplasty patients. Microvesicles were isolated from bone marrow supernatants (interstitial fluid) using a process of sequential ultracentrifugation and filtration. Presence of microvesicles was validated using PKH67 staining and flow cytometry, and western blotting for Alix and TSG101, well-established markers of exosomes derived from multivesicular bodies. MicroRNA arrays were then used to identify miRNAs whose expression was significantly altered with age. Seven miRNAs were identified from the arrays as showing a greater than two-fold change with age, and PCR validation of these

miRNAs showed that expression of miR125a was increased more than three-fold in samples from the older patients. This miRNA is known to enhance NF-kB signaling in macrophages, and is generally regarded as a pro-inflammatory miRNA. These data suggest that miRNAs derived from exosomes and microvesicles may play a key role in age-related bone loss. Funding for this research was provided by the National Institute on Aging (P01 AG 036675).

Oxy133, An Osteogenic Oxysterol, Promotes Healing In A Rat Femoral Defect Model. Scott Montgomery*[1], Michael Daubs[1], Haijun Tian[1], Gil Weintraub[1], Elisa Atti[1], Bayan Aghdasi[1], Akinobu Suzuki[1], Trevor Scott[1], Jeffrey Wang[1], Farhad Parhami[2]. [1]UCLA, USA, [2]University of California, Los Angeles, USA

Proteins and small molecules are commonly used in orthopaedics and neurosurgery to stimulate bone growth, augment fracture healing, and promote spine fusion. We have previously demonstrated the ability of Oxy133, an analogue of naturally occurring oxysterols, to promote bone formation in a rat model of spine fusion. Oxy133 was selected among over one hundred and fifty oxysterol analogues based on its potency in inducing alkaline phosphatase activity and its ability to induce the in vitro expression of osteogenic markers in osteoprogenitor cells. Although Oxy133 has been found to successfully promote spine fusion in rats, efficacy of osteogenic oxysterols has not yet been demonstrated in a femoral defect model, which often demands higher doses of BMP2 to achieve healing compared to that used in spine fusion. The current study further investigated the ability of Oxy133 to heal critical sized rat femoral defects. A 6 mm defect was created in the femurs of twenty-four male Lewis rats and a collagen sponge carrying 40 mg Oxy133, 10 ug BMP2, or buffer solution was implanted at the defect site (n=8 per group). Xrays were performed at 4, 6 and 8 weeks. All animals were killed at 8 weeks and the femurs were dissected out and underwent micro-CT and histological analysis. Callus formation bridging the femoral defect was observed on plain radiographs in 7/8 animals treated with 40 mg Oxy133 and 8/8 in the BMP2 group, compared to 1/8 in the control group. Micro-CT confirmed healing of the defect in 87.5% of femurs treated with Oxy133. Oxy133, which we have previously shown to induce spine fusion in a rat model with equivalent efficacy to BMP2, is also capable of healing a critical sized femoral defect in a rodent model with similar success to BMP2. This pre-clinical data suggests significant promise for the use of Oxy133 in clinical scenarios requiring bone formation, such as spine fusion and fracture healing.

PDGF Induces Development of Vascularized Bone Grafts by Adipose-Derived Stem Cells. Daphne Hutton*[1], Erika Moore[1], Jeffrey Gimble[2], Xiaofeng Jia[1], Warren Grayson[1]. [1]Johns Hopkins University, USA, [2]Pennington Biomedical Research Center, USA

Vasculature is essential to the functional integration of a tissue-engineered bone graft to enable sufficient nutrient delivery and viability after implantation. Native bone and vasculature develop through intimately coupled, tightly regulated spatiotemporal cell-cell signaling. The complexity of these developmental processes has been a challenge for tissue engineers to recapitulate, resulting in poor co-development of both bone and vasculature within a unified graft. To address this, we cultured adipose-derived stromal/stem cells (ASCs), a clinically relevant, single cell source that has been previously investigated for its ability to give rise to vascularized bone grafts, and studied the effects of initial spatial organization of cells, the temporal addition of growth factors, and the presence of exogenous platelet-derived growth factor-BB (PDGF-BB) on the co-development of bone and vascular tissue structures.

Human ASCs were aggregated into multicellular spheroids via the hanging drop method prior to encapsulation and subsequent outgrowth in fibrin gels. Cellular aggregation substantially increased vascular network density, interconnectivity, and pericyte coverage compared to monodispersed cultures. To form robust vessel networks, it was essential to culture ASCs in purely vasculogenic medium for at least 8 days prior to the addition of osteogenic cues. Physiologically relevant concentrations of exogenous PDGF-BB (20 ng/ml) substantially enhanced both vascular network stability and osteogenic differentiation (Fig. 1). Comparisons with bone morphogenetic protein-2 (BMP-2), another pro-osteogenic and pro-angiogenic growth factor, indicated that this potential to couple the formation of both lineages might be unique to PDGF-BB. Furthermore, the resulting tissue structure demonstrated the close association of mineral deposits with pre-existing vascular structures that have been described for developing tissues.This combination of a single cell source with a potent induction factor used at physiological concentrations can provide a clinically relevant approach to engineering robust vascularized bone grafts with greater efficiency and potential for subsequent viability. In on-going studies, we are growing ASCs in 3D-printed PCL scaffolds to engineer vascularized bone grafts and will evaluate their integration and functionality with native tissues *in vivo*.

Progranulin protects against titanium particle induced inflammation and inflammatory osteolysis. Qingyun Tian*[1], Yunpeng Zhao[2], Chuanju Liu[2]. [1]NYU Hospital for Joint Diseases, USA, [2]New York University, USA

It is well known that TNFα play an important role in wear debris induced inflammatory osteolysis, which is a major cause of periprosthetic loosening. We previously reported that Progranulin (PGRN) antagonized TNFα action via binding to TNF receptors and protected against bone erosion in inflammatory arthritis (Tang W, et al, Science, 2011). The goal of this study is to determine whether PGRN plays a protective role in titanium particle induced inflammatory osteolysis. To do so, we took advantage of both in vitro RAW647.3 cells and two in vivo well-accepted mice models. Ti particle dramatically induced expression of endogenous PGRN in RAW647.3 cell and in the mice models. In addition, recombinant PGRN attenuated Ti particle induced inflammation and inflammatory osteolysis in RAW647.3 cell, calvaria explant and mice models, as the elevation of inflammatory biomarkers were significantly impaired, osteoclastogenesis was suppressed and bone erosion of calvaria was protected by PGRN. Furthermore, recombinant PGRN repressed activation of NF-κB signaling pathway by Ti particle. Collectively, PGRN is a novel molecule that inhibits Ti particle induced inflammation, probably through interacting with TNF-α/NF-κB signaling pathways. These findings not only provide novel insights into the role of PGRN in Ti particle induced inflammation reaction, but may also lead to the development of novel therapeutic intervention strategies for periprosthetic loosening.

MO0155

Vasopressin Negatively Regulates Bone Mass. Roberto Tamma*[1], Concetta Cuscito[1], Michelangelo Corcelli[1], Graziana Colaianni[1], Adriana Di Benedetto[1], Maria Grano[1], Silvia Colucci[1], Jianhua Li[2], Tony Yuen[2], Li Sun[2], Mone Zaidi[3], Alberta Zallone[1]. [1]University of Bari Medical School, Italy, [2]Tount Sinai School of Medicine, USA, [3]Mount Sinai Medical Center, USA

Several pituitary hormones, namely TSH, FSH, ACTH, oxytocin (OT) and prolactin, are now known to regulate bone remodeling and bone mass directly. Specifically, a direct anabolic action of the neurohypophseal peptide OT on the skeleton has been demonstrated (Tamma et al., *PNAS,* 2009). Because Arg-vasopressin (AVP) differs from OT by only two amino acids and displays related functions in the brain, we investigated whether AVP directly affects bone and bone cells. We find that the deletion of one of the two AVP receptors, AVPR-1a, in mature mice was sufficient to induce an increase in bone mass, which we documented through micro-CT and by 2D histomorphometry performed at both cortical (femur diaphysis) and trabecular (vertebrae) sites. *Ex vivo* cultures of bone marrow stromal cells obtained from *AVP-1a*$^{-/-}$ mice showed increased expression of osteoblast differentiation genes encoding bone

matrix proteins, and transcription and growth factors (qPCR and Western blotting). *Ex vivo* alkaline phosphatase-positive Cfu-f formation (day 10) and von Kossa-positive Cfu-ob (day 21) formation were also strongly increased in cultures from *AVP-1a*$^{-/-}$ mice. In contrast, TRAP-positive osteoclast formation and resorption of mineralized substrate were both reduced in bone marrow cell cultures from *AVP-1a*$^{-/-}$ mice compared with wild type control cultures, as was the expression (qPCR) of several osteoclast-specific genes. Treatment *in vitro* of both calvarial osteoblasts and bone marrow stromal cells with AVP resulted in reduced mineralized Cfu-ob formation. In contrast, AVP expectedly enhanced the expression of proteins involved in osteoclastogenesis and resorptive activity, namely RANK, c-fms, cathepsin K, TRAP, and the calcitonin receptor. These findings suggest that AVP, through its action on the AVPR-1a, opposes the effect of OT on the skeleton, primarily by decreasing osteoblast differentiation and enhancing osteoclastogenesis and resorption. We also show that both OT and AVP are produced by bone marrow osteoblasts. We believe that mechanisms that control the autocrine production of, and cross-talk between, OT and AVP, as well as those that determine their relationship to the systemic secretion of the two neuropeptides by hypothalamic nuclei, is worthy of further investigation.

Delayed bone fracture healing in mice due to Tamoxifen-induced knockout of IGF1R gene in chondrocyte. Zhiqiang Cheng*[1], Hanson Ho[2], Fuqing Song[3], Nathan Liang[3], Alfred Li[3], Rachel Roston[3], Christian Maria[3], Yongmei Wang[4], michael you[3], Chia-ling Tu[3], Daniel Bikle[5], Wenhan Chang[6]. [1]University of California, San Francisco, USA, [2]VAMC, USA, [3]UCSF, USA, [4]Endocrine Unit, University of California, San Francisco/VA Medical Center, USA, [5]Endocrine Research Unit, Division of Endocrinology UCSF & VAMC, USA, [6]Endocrine Unit, VA Medical Center, University of California, San Francisco, USA

Fracture healing in callus recapitulates all stages of endochondral bone formation that is initiated by chondrocyte differentiation. To investigate the role of IGF1R in chondrocytes in regulating bone fracture healing, we performed unfixed tibial mid-shaft fractures by 3-point bending on Tamoxifen-inducible chondrocyte-specific IGF1R knockout (KO) mice and control (Cont) littermates at 3 months of age. Calluses were analyzed at day 10 and 28 post-fracture by histomorphometry, micro-computed tomography (μCT) and quantitative PCR (qPCR). The ablation of IGF1R gene in the cartilage of KO callus was confirmed by genomic DNA analyses and the lack of protein expression by immunohistochemistry. We previously reported that at day 10 post-facture chondrocyte differentiations in the calluses of KO mice was profoundly delayed and this appeared to block the transition from the chondrogenic phase to the osteogenic phase of fracture healing. In the present study, we investigated whether the delayed chondrocyte differentiation impacts the osteogenic phase of fracture healing. At day 28 post-fracture, the sizes of KO and Cont calluses were comparable. There was no visible cartilage present in the calluses of both KO and WT mice, indicating that the calluses have entered osteogenic phase of differentiation. Histomorphometric analysis showed comparable ratio of trabecular bone volume (Tb.BV) over total callus volume (TV) (Tb.BV/TV) in both groups, but revealed significantly increased ratios of bone surface over BV (BS/BV) and ratios of osteoid volume (OV) over BV (OV/BV) and increased ratio of osteoid surface (OS) over BS (OS/BS) in the KO calluses, indicating delayed matrix mineralization. This concept is confirmed by uCT data that showed increased Tb.BV/TV, Tb.CD, and Tb.N with reduced bone mineral density in the KO vs WT calluses. These histomorphometric and μCT data indicated a delay in progression of osteogenesis in the calluses lacking IGF1R in their chondrocytes. This notion is further supported by the reduced expression of markers of mature osteoblast (osteocalcin; by 30%) and osteocyte (dentin matrix protein 1; by 50%) in the KO callus. Together our data suggest that IGF1R signaling in chondrocytes is essential for chondrocyte differentiation, cartilage development, and timely bone formation during fracture healing.

Skeletal IGF-1 signaling impacts glucose and energy metabolism. Muriel Babey*[1], Chak Fong[2], Monique O'Leary[3], Emmeline Academia[3], Yongmei Wang[4], Candice GT Tahimic[5], Brian Kennedy[3], Pankaj Kapahi[3], Daniel Bikle[5]. [1]UCSF, Division of Endocrinology, USA, [2]UCSF, USA, [3]Buck Institute, USA, [4]Endocrine Unit, University of California, San Francisco/VA Medical Center, USA, [5]Endocrine Research Unit, Division of Endocrinology UCSF & VAMC, USA

Insulin and insulin-like growth factor (IGF), their receptors, and IGF-binding proteins are important in the hormonal control of many metabolic and growth-related processes. Surprisingly, studies from mouse strains lacking the insulin receptor in two classical insulin target tissues, muscle and white fat, failed to demonstrate an impact on whole body glucose homeostasis, whereas deletion of the insulin receptor from osteoblasts did. In osteoblasts the IGF-1 receptor and insulin receptor show reciprocal cross talk interactions, leading us to evaluate whether deletion of the IGF-1 receptor from osteoblasts would also alter whole body glucose homeostasis and energy balance. Our results indicate that it does and in a reciprocal fashion to deletion of the insulin receptor from these cells. With consumption of a regular diet, glucose clearance was significantly increased in mice lacking the IGF-1 receptor in osteoblasts (IGF-1R OBKO, Cre-Recombinase driven by the 2.3 kb Collagen (α)I Type I promoter) compared to control mice. Glucose clearance was faster in the female than in the male group. However, with the ingestion of a high fat diet, the differences in glucose clearance were not significant between IGF-1R OBKO mice and control mice for either gender. Oxygen consumption, CO_2 production and energy expenditure were increased in female IGF-1R OBKO mice compared to control mice ingesting a normal diet. However, the high fat diet increased these parameters in the control females, but not control males or any of the KO mice. These results indicate that osteoblasts have an important role in regulating both glucose and energy metabolism, a role mediated at least in part by IGF-1 signaling. The metabolic effects of IGF-1 signaling in osteoblasts are more pronounced in the female than in the male group in a diet dependent manner. Further ongoing metabolic evaluation will determine whether these effects are due to changes in endocrine factors such as insulin and osteocalcin and/or to alterations in physical activity, food intake or thermogenesis.

MO0159

Bone cells govern T lymphopoiesis by regulating thymic emigrants from bone marrow. Vionnie Yu*[1], Borja Saez[2], Sutada Lotinun[3], Colleen Cook[2], Rushdia Yusuf[2], Marc Raajimakers[2], Joy Wu[4], Henry Kronenberg[2], Roland Baron[5], David Scadden[2]. [1]Massachusetts General Hospital/Harvard University, USA, [2]Massachusetts General Hospital, USA, [3]Harvard School of Dental Medicine, USA, [4]Stanford University School of Medicine, USA, [5]Harvard School of Medicine & of Dental Medicine, USA

Mesenchymal cell direction of parenchymal cell activity is hypothesized to be critical for adult tissue function, but remains poorly defined. We examined how specific subsets of osteolineage mesenchymal cells affect parenchymal hematopoietic cells in the bone marrow by a method of selective cell depletion. Unexpectedly, mature bone cells expressing osteocalcin (Ocn+) were found to be critical for T lymphopoiesis through the modulation of cells destined for thymic emigration. Specific depletion of Ocn+ cells reduced the number of adult bone marrow T-lymphoid biased progenitors by reduced endosteal DLL4 production and hematopoietic progenitor Notch activation. Thymic emigrants were compromised in association with reduced CCR7 expression, yet were capable of normal T lineage differentiation upon adoptive transfer to the thymus. B cell, myeloid progenitor cell and hematopoietic stem cell numbers were unperturbed. Therefore, mature osteolineage cells have a highly constrained hematopoietic cell specific effect, altering T cell production by regulation of thymic emigrants and their ability to translocate to the site of maturation. These data suggest a new role for bone in the homeostasis of the immune system.

IDR-1018: A Synthetic Host Defense Peptide that Decreases Infection of Orthopaedic Implants. Hyonmin Choe*[1], David Corn[1], Ashley Rettew[1], Joscelyn Tatro[1], Steve Marshall[2], Aaron Weinberg[1], Zhenghong Lee[1], Robert Bonomo[2], Edward Greenfield[1]. [1]Case Western Reserve University, USA, [2]Louis Stokes Cleveland VA Medical Center, USA

Orthopaedic implant infection is a serious complication that is becoming more difficult to treat due to the increased prevalence of multiple drug resistant bacteria. IDR-1018 is a 12 amino acid, synthetic host defense peptide that reduces soft tissue infections. IDR-1018 is less likely to induce drug resistance because it acts primarily by recruiting macrophages to the infection site rather than directly killing the bacteria. In the current study, we first confirmed that IDR-1018 is not potently bactericidal in physiological solutions (>30-fold higher minimal inhibitory concentration for *Staphylococcus aureus* in PBS than in bacterial broth, 128 ug/ml vs 4 ug/ml). We therefore determined the effects of IDR-1018 in a novel murine model of orthopaedic implant infection. For this purpose, bioluminescent *S. aureus* (Xen36 strain, Caliper Life Sciences) were adhered to titanium alloy implants (1 mm diameter, 3.2 mm length) before insertion into pilot holes in the mid-diaphysis of the femur of 7-week old mice. IDR-1018 (200ug/injection) was administrated i.p. 4 hours before and 24 and 48 hours after implant insertion. Bioluminescence imaging (Xenogen IVIS 200 system) demonstrated that IDR-1018 decreased the bacteria levels by 2- to 4-fold ($p<0.05$) at 1, 3, and 7 days after implant insertion. The decreased bacterial burden induced by IDR-1018 led to increased implant osseointegration as measured by biomechanical pull-out testing. Thus, ultimate force was increased 12-fold ($p<0.05$) and stiffness was increased 15-fold ($p<0.05$). We hypothesized that IDR-1018 would primarily affect bacteria that had spread into the surrounding bone rather than the bacteria adherent to the implant because bacteria in biofilms are protected from macrophages. Consistent with our hypothesis, IDR-1018 decreased the number of colony forming units in the surrounding bone by 10-fold ($p<0.05$) and the amount of bacterial DNA measured by real-time PCR by 6-fold ($p=0.15$) without affecting the

number of bacteria adherent to the implants. These results suggest that application of IDR-1018 may be especially effective in combination with removal of the implant, which is the standard of care for infected orthopaedic implants in patients.

MO0161

Lectin-like Oxidized Low-density of Lipoprotein Receptor-1 Is Involved in RANKL-production Elevated by Lipopolysaccharide-injection on Mouse Calvaria and thereby Contributes to Inflammatory Bone Destruction. Mai Nakayachi*[1], Junta Ito[1], Mari Okayasu[2], Chiyomi Hayashida[1], Takuya Sato[1], Naoto suda[1], Tatsuya Sawamura[3], Yoshiyuki Hakeda[1]. [1]Meikai University School of Dentistry, Japan, [2]The University of Tokyo Hospital, Japan, [3]National Cerebral & Cardiovascular Center, Japan

We have demonstrated that osteoclastogenesis is associated with the extracellular level of low-density lipoprotein (LDL) and that LDL receptor deficiency causes impaired osteoclastogenesis and increased bone mass in mice because of defect in osteoclastic cell-cell fusion. Here, we used scavenger receptor class A (SRA) and lectin-like oxidized LDL recptor-1 (LOX-1) knockout (KO) mice to elucidate the role of oxidized LDL in regulating osteoclastogenesis and inflammatory bone destruction. Although RANKL-induced osteoclast formation from SRA KO osteoclast precursors was equivalent to that from wild-type (WT) cells, the osteoclastogenesis from LOX-1 KO precursors was increased and the multinucleated cells formed in culture contained more nuclei than WT cells, indicating the increase in cell-cell fusion. These phenotypes were contrast to osteoclastogenesis of LDL receptor KO mice. However, RANKL-induced expression of osteoclastogenesis-related proteins such as c-fos, NFATc1, cathepsin K and TRAP did not alter between LOX-1 KO and WT osteoclasts. Regarding osteoclast differentiation signals, RANKL-induced Erk activation level was also equivalent between the both genotypes. However, Akt phosphorylation evoked by RANKL in LOX-1 KO osteoclast precursors was greater than that in WT cells. When inflammation was induced by subperiosteal injection of lipopolysaccharide (LPS) on calvaria *in vivo*, gene expression of RANKL mRNA in the injected region was elevated equivalently in WT and SRA KO mice. Consistently with the elevation of RANKL mRNA expression, TRAP, cathepsin K and NFATc1 mRNA levels were comparably increased in the both mice. In contrast, the elevation of RANKL gene expression in LOX-1 KO mice was smaller than that of WT and SRA KO mice, whereas level of RANK gene expression did not change among the three genotypes. These *in vivo* results suggest that osteoclast formation following the induction of RANKL production caused by local inflammation depends on LOX-1. Osteoblats and activated T-cells are RANKL-producing cells in inflammation sites. Although mRNA levels of ALP and CD4 were augmented in WT calvariae injected by LPS, the augmentation in LOX-1 KO calvariae was smaller, suggesting an involvement of LOX-1 in RANKL production by osteoblasts and/or activated T-cells. In conclusion, although LOX-1 is potentially a negative regulator in osteoclastogenesis, LOX-1 may contribute to the inflammatory bone destruction.

MO0162

Osteoimmmunology deregulation in the osteopetrotic grey-lethal mouse. Marie Mutabaruka*[1], Monica Pata[1], Nathalie Labrecque[2], Jean Vacher[1]. [1]Institut de Recherches Cliniques de Montréal, Canada, [2]Maisonneuve-Rosemont Hospital Research Center, Montreal, Qc, Canada, Canada

Mutations affecting the *Ostm1* gene are responsible for the most severe form of autosomal recessive osteopetrosis both in humans and in the grey-lethal (*gl/gl*) mouse. This osteopetrotic phenotype is associated with increased population of non-functional osteoclasts, obliteration of marrow space and major lymphopoietic defects leading to death at ~3weeks of age. The *gl/gl* T-lymphoid lineage is characterized by an altered distribution of the double and single positive $CD4^+$ and $CD8^+$ T cells, suggesting a role for Ostm1 in T-cell differentiation program. To investigate whether Ostm1 may have a direct role in the T cell lineage, expression of *Ostm1* was evaluated in the various T-cell differentiation stages from early T cells progenitors (ETPs), double negative (DN) precursors and mature single positive ($CD4^+$, $CD8^+$) T cells. Quantification of the various T-cell populations demonstrated significant reduction in the ratio of early T cells progenitors (ETPs) in *gl/gl* thymus compared to controls. Consistent with Ostm1 expression pattern, *gl/gl* mice display early impaired T-cell differentiation by lower c-kit expression level in the DN1 subpopulation that led to the altered distribution of double negative and double positive ($CD4^+CD8^+$) T-cells. Characterization of the *gl/gl* T-cell populations with mature TCRβ and CD69 markers showed normal expression and indicated that intrathymic mechanisms of selection and production were unaffected. Further, ex-vivo co-culture assays of gl/gl ETPs cells showed a faster differentiation kinetic in comparison to controls. This phenotype suggests that Ostm1 play a role during early T-cell differentiation. To assess whether *Ostm1* has an intrinsic role in thymic homeostasis, transgenic mice were generated by targeting *Ostm1* expression, under the control of the CD2 gene regulatory sequences, from early progenitor to mature T cells. Transgenic CD2-*Ostm1* progenies mice had no lymphoid alteration. Importantly, all CD2-*Ostm1 gl/gl* transgenic mice displayed full rescue of the thymic distribution of ETPs, DN as well as of double and single $CD4^+$ $CD8^+$ positive T cells. Since, these mice still have defective osteoclasts and develop osteopetrosis, the T-cell lineage by itself do not play a role in Ostm1 osteopetrosis. Taken together, our study provides the first evidence of an early cell-autonomous role for the *Ostm1* gene in T-cell lineage and thymus homeostasis independently of the myeloid osteoclast lineage.

MO0163

Inhibition of MCP-5 Signaling Decreases Osteoarthritic Lesions in a Murine Model of Post-traumatic Osteoarthritis. Lara Longobardi*[1], Huseyin Ozkan[2], Joseph Temple[1], Tieshi Li[1], Alessandra Esposito[1], Timothy Myers[3], Anna Spagnoli[1]. [1]University of North Carolina at Chapel Hill, USA, [2]Gulhane Military Academy, Dept. Orthopedics & Traumatology, Turkey, [3]University of North Carolina, USA

In previous studies we found that down-regulation of the chemokine MCP5 by TGF-β Type II receptor (TβRII) signaling is required for joint development. A balance between cytokines and anabolic growth factors is critical to maintain proper tissue homeostasis. MCP-5, its human homologous MCP-1 and their sole common receptor CCR2, are increased in the inflamed joints of patients with arthritis and in rodent models of arthritis. We found that increasing MCP5 expression levels correlate with OA severity in a murine model of osteoarthritis (OA) (destabilization of medial meniscus, DMM). By using a *Tgfbr2-β-Gal-GFP-BAC* mouse, containing β-gal and GFP reporters for TβRII expression, we have recently reported that TβRII expressing cells ($T\beta RII^+$) localize in specific niches that are maintained through development and postnatal life. Our previous studies demonstrated that intra-articular implants of $T\beta RII^+$ cells into DMM knees were able to abolish MCP-5 up-regulation (Longobardi et al., ASBMR 2012). Our *in-vivo* studies are aimed at determining whether blockade of MCP-5 signaling during DMM affected OA progression. For this purpose we followed two approaches: 1) mice subjected to DMM were treated with RS504393 (an antagonist of the MCP5 receptor CCR2) 1, 4 and 8 weeks after DMM; 2) FACS sorted $T\beta RII^+$ cells from *Tgfbr2-β-Gal-GFP-BAC* limb buds were injected in the intra-articular space of DMM knees 1, 4 and 8 weeks after DMM ($25X10^3$ cells/15µl PBS) to inhibit MCP-5 expression in articular cartilage. In both approaches, mice were euthanized 12-weeks after DMM and knees were subjected to Safranin-O/Fast green staining and graded following the OARSI scoring system for mouse. We found that inhibition of MCP5 signaling by both approaches was able to decrease OA lesions when RS504393 treatment or $T\beta RII^+$ cell implants were performed at an early stage of OA development (1 or 4 weeks after DMM), but not at later stages (8 weeks after DMM). In a parallel study conducted in our group we found that micro-CT analysis of DMM posterior medial tibia show an increased mineralization of endochondral bone compared to sham control (Temple et al, abstract submitted). Interestingly, we observed that the endochondral bone mineralization in the posterior medial tibia subjected to DMM was decreased in mice treated with RS504393, compared to untreated. Our findings suggest a potential role for TβRII/MCP-5 axis during early stage of OA development and open new perspective for OA treatment.

MO0164

A Randomized, Double-Blind, Placebo-Controlled study to evaluate the effects of Alendronate (ALN) on bone mineral density (BMD) and bone remodeling in perimenopausal women with low BMD. Aliya Khan*[1], Sacha Dubois[2], Zohair Rahman[3], Christine Derzko[4]. [1]McMaster University, Canada, [2]LakeHead University, Canada, [3]McMaster, Canada, [4]St. Michael's Hospital, Canada

Introduction: Bone loss in association with the menopausal transition begins approximately 2 years before the last menstrual period. This study evaluated the efficacy of alendronate (ALN) in comparison to placebo in preventing bone loss in perimenopausal women with low BMD.

Methods: Women (40-55 years of age; experiencing at least 5 menstrual cycles per year; confirmed FSH level of $>$ 20 iu/L and lower than 40 iu/L ; reduced BMD T $<$ -1.0 at LS, TH or FN) were randomly assigned to treatment (70 mg ALN and 2800 IU cholecalciferol once per week for one year) or control (a placebo tablet, identical in appearance and taste). All patients also received 500 mg of supplemental carbonate daily.

BMD was measured by Dual-energy X-ray absorptiometry at LS,FN, and TH sites. Biochemistry tests at baseline and 12 month follow-up included: bone specific ALP, creatinine, random urine creatinine, and N-telopeptide (NTX) in serum and urine. Analysis of covariance was used to compare 12 month differences on BMD and biochemical markers by group (ALN versus placebo).

Results: At 12 month follow-up, the ALN group mean LS BMD increased by 3.66% (µd= 0.32; ±0.0081 SE) at 12 months versus a reduction of -3.33% (µd= -0.03; ±0.0084 SE) in the control group ($F(1,36) = 25.45$, $p < .001$). The ALN group FN mean BMD increased by 2.07% (µd= 0.014; ±0.0090 SE) at 12 months versus a reduction of -1.87% (µd= -0.014; ±0.0081 SE) in the control group ($F(1,36) = 4.28$, $p = .046$). In the ALN group, bone-specific alkaline phosphates was reduced by 37.79% (µd= -9.90; ±1.92 SE) compared to a 2.46% (µd= 0.56; ±1.79 SE) increase in the control group ($F(1,35) = 13.65$, $p < .001$)). Similarly, N-telopeptide Urine was also reduced in the ALN group (-27.21%; µd= -11.68; ±4.80 SE) compared to an increase of 21.21% (µd= 9.79; ±5.15 SE) in the control group ($F(1,35)=15.44$, $p<.001$).

Discussion: This is the first study conducted in perimenopausal women evaluating the effect of an antiresorptive agent on BMD and bone remodeling. In perimenopausal women treatment with ALN over 12 months lowered bone remodelling and increased BMD. Bone loss was evident in the placebo group. Early intervention with a bisphosphonate for 12 months in the menopausal transition may be effective in maintaining BMD and microarchitectural integrity.

Bone mineral density predicts fractures in men and women with chronic kidney disease. Sarah West*[1], Charmaine Lok[2], Angela M. Cheung[3], Sophie Jamal[1]. [1]The University of Toronto, Canada, [2]Toronto General Hospital, Canada, [3]University Health Network-University of Toronto, Canada

The clinical utility of bone mineral density (BMD) testing by dual energy x-ray absorptiometry to predict fractures in men and women with chronic kidney disease (CKD) is unclear. Indeed, current clinical practice guidelines do not recommend BMD testing to assess fracture risk in CKD. We determined if BMD at the lumbar spine, femoral neck, and ultradistal radius could predict incident fractures (clinical low trauma and morphometric spine fractures) over one year in 161 subjects with stages 3 to 5 CKD. Subjects were recruited from predialysis renal clinics in the greater Toronto area. The mean age was 62.5 $\pm$ 16.3 years, the mean weight 78.1 $\pm$ 18.1 kg, over half the subjects were men (n=94; 58%), and subjects were equally divided between stages 3, 4 and 5 CKD. The most common cause of CKD was diabetes. One third of subjects reported a fall in the past year and one third had a prevalent fracture at study entry. Over the one year follow-up there were 26 new fractures - 6 self-reported clinical low trauma fractures and 20 morphometric spine fractures. We used linear regression models adjusted for age and weight to determine if there were differences in BMD at baseline by incident fractures. We found that those with fractures had a statistically significant lower BMD at the ultradistal radius compared to those without fractures [0.41 g/cm^2 (95% Confidence Intervals: 0.37 to 0.44) vs. 0.44 g/cm^2 (95% CI: 0.43 to 0.46)]. As well, there was a trend towards a lower BMD at the femoral neck in those with fractures than those without [0.68 g/cm^2 (95% CI: 0.63 to 0.74) vs. 0.74 g/cm^2 (95% CI: 0.71 to 0.76)]. There was no significance difference in BMD at the lumbar spine by incident fractures. Our findings, while limited by the small number of incident fractures during follow-up, suggest that BMD testing, particularly at the ultradistal radius may be a useful clinical test to identify men and women with CKD who are at increased fracture risk.

MO0166

Cortical and Trabecular Bone Mass are Severely Compromised in Rats with Renal Failure and Secondary Hyperparathyroidism. Subburaman Mohan[1], Cheryl Sanchez-Kazi*[2]. [1]Jerry L. Pettis Memorial VA Medical Center, USA, [2]JLP VA Medical Center, USA

While chronic kidney disease (CKD) is known to result in phosphate retention secondary hyperparathyroidism (SHPT) and increased bone fragility, the molecular causes that contribute to skeletal changes are poorly understood. Based on evidence that FGF23, a regulator of phosphate homeostasis, is a key player of disordered mineral metabolism in CKD, we tested the hypothesis that elevated FGF23 is associated with SHPT in a nephrectomized model of renal failure. At 4 wks of age, 27 rats underwent 2-stage 5/6 nephrectomy (Nx) while 12 rats underwent sham Nx (Intact-control). Nx rats were fed either a standard rodent diet (Nx-control, N=13), or a high phosphorus diet to induce advanced SHPT (Nx-phos, N=14). There were no differences in femur length or gain in body length/weight between the 3 groups. Serum creatinine levels were elevated 2-fold ($P<0.01$) in the Nx groups. Serum iPTH levels were 50% and 180% higher ($P<0.03$) in Nx-control and Nx-phos compared to Intact-control at 12 days post Nx. After 25 days post Nx, iPTH levels further increased (5.7 and 1.6 fold, $P<0.04$) in the Nx-phos and Nx-control compared to Intact-control. Serum FGF23 levels were elevated in the Nx-phos compared to Intact-control at 12 days and correlated highly ($r=0.71$, $P<0.01$) with iPTH, thus suggesting that elevated FGF23 could in part contribute to SHPT in Nx-phos. MicroCT measurements of cortical bone at femoral mid-diaphysis revealed 3.9% ($P=0.06$) and 9% ($P<0.01$) reductions in total vBMD in the Nx-control and Nx-phos, respectively, compared to Intact-control. Analyses of trabecular (Tb) bone at the femoral metaphysis revealed a 16% ($P= 0.3$) and 37% ($P<0.001$) reduction in Tb bone volume adjusted for total volume in Nx-control and Nx-phos, respectively. The significant reduction in Tb. bone mass in Nx-phos is caused by a 36% reduction in Tb number ($P=0.01$) and a 29% increase in Tb. separation ($P=0.01$). Accordingly, connectivity density was decreased by 41% in the Nx-phos compared to Intact-control. Furthermore, Tb bone volume changes showed significant negative correlations with both iPTH ($R=-0.66$, $P<0.01$) and FGF23 ($r=-0.55$, $P<0.01$) levels, suggesting that the acute changes in serum iPTH and/or FGF23 contributed to changes in Tb bone mass. Based on these data, we conclude that the initial rise in FGF23 may contribute to PTH elevation that leads to significant loss of cortical bone and increased turnover of Tb bone resulting in deterioration of trabecular architecture in CKD.

Two-year bisphosphonate treatment of renal osteodystrophy in a dialysis patient with chronic kidney disease. Jerzy Przedlacki*[1], Kamilla Nawrot-Wawrzyniak[2], Andrzej Sawicki[3], Paul Roschger[4], Andrzej Dębiński[5], Monika Staszków[6], Ireneusz Nawrot[6], Joanna Matuszkiewicz-Rowińska[6], Klaus Klaushofer[7]. [1]Medical University of Warsaw, Poland, [2]Ludwig Boltzmann Institute of Osteology, Austria, [3]Synexus Poland, Poland, [4]L. Boltzmann Institute of Osteology, Austria, [5]Medical Centre Synexus, Poland, [6]Warsaw Medical University, Poland, [7]Hanusch HospitalLudwig Boftzmann Institute of Osteology, Austria

KDIGO group suggests administration of, e.g., bisphosphonates in dialysis patients with chronic kidney disease with an increased risk for bone fractures only after excluding adynamic bone disease (ABD) on bone biopsy because of their antiresorptive action. The objective of the study was to assess the effectiveness and safety of a two-year alendronate treatment in a 49-year old man receiving a 30-year dialysis course sustaining four low-energy fractures (left and right hip, left metacarpal bone and one rib, the last one 10 days before starting treatment) during last 8 years. After excluding ABD and diagnosing osteomalacia by means of a transiliac bone biopsy, alendronate was started at a weekly oral dose of 70 mg. Simultaneously, daily oral administration of calcium carbonate (3x1.0) and alfacalcidol (0.25 μg) was continued. The alendronate tolerance was good, bone pain decreased, the patient's physical fitness had improved. No new fracture occurred during the therapy. Bone biopsy performed after 1 year of treatment showed recurrent osteomalacia without ABD. There was an increased bone volume, increased trabecular number and thicknesss, decrease of osteoid volume and surface. The bone matrix mineralization density distribution measured by quantitative backscattered electron imaging exhibited: mean and mode calcium content was increased; the width of the distribution was reduced; the fraction of low mineralized bone areas were reduced and that of high one was increased. BMD of radial ultradistal site sustained markedly reduced during 2 years of treatment (Z-score -4.0 to -3.9) but BMD of the shaft was increased for 5.6% (from 0.479 g/cm2, Z-score -6.0 to 0.506 g/cm2, Z-score -5.4) at the end of the second year. Serum osteocalcin significantly decreased from 33.0 ng/ml to 21.2 ng/ml (35.8%) after 6 months and to 4.57 ng/ml after 2 years (86.2%); bone alkaline phosphatase activity remained unchanged up to the end of the first year but significantly decreased after the second year: from 111 IU/l to 39 IU/l (reduction of 64.9%); CTX increased at the end of the first year, from 2.82 ng/ml to 4.5 ng/ml (increase of 59.6%) but returned to the basic value in the end of the second year (2.37 ng/ml). Serum PTH was in optimal range during treatment. In summary, the two-year alendronate treatment of the haemodialysis patient with chronic kidney disease has been effective and safe and is being continued.

MO0168

An Unusual Discrepancy in Bone Density in a Case of Congenital Hypophosphatemic Rickets. Aren Skolnick*[1], Stuart Weinerman[2], Dennis Carey[3]. [1]North Shore-LIJ Health System, USA, [2]Division of Endocrinology, USA, [3]Cohen Children's Medical Center of New York, USA

Background: Hypophosphatemic rickets (HR) is characterized by renal phosphate wasting and defective bone mineralization, resulting in short stature and skeletal abnormalities. It is most commonly caused by an X-linked mutation in the phosphate-regulating endopeptidase gene (PHEX). It has been established that bone mineral density (BMD) results appear to be site-specific with elevated BMD at the lumbar spine and low BMD at the radius. This pattern is felt to be due to secondary hyperparathyroidism. We present a case of congenital HR with a large discrepancy in bone density between the spine and proximal radius in a patient with a normal, intact parathyroid hormone (PTH) on long-term oral phosphate and calcitriol supplementation.

Case: A 20-year-old male was referred for evaluation of HR. He was initially diagnosed as a child with bone deformities, taking calcitriol and sodium potassium phosphorous since diagnosis, with subsequent normal growth and development. Family history was insignificant. Examination revealed a well-nourished male with height 70 inches, weight 111 kg and a body mass index of 35 kg/m. General medical exam was unremarkable with normal dentition and no rachitic rosary. Biochemical investigations revealed total calcium: 9.1 mg/dL, phosphorus: 2.2 mg/dL, albumin: 4.7 g/dL, creatinine: 1.03 mg/dL alkaline phosphatase: 171 U/L, bone specific alkaline phosphatase (BSAP) 54mcg/l(0-20), 1,25-dihydroxyvitamin D: 43.3 pg/ml, 25-hydroxyvitamin D 15.5 ng/mL (PTH): 47 pg/mL, fibroblast growth factor (FGF)23: 84 RU/mL (<180 RU/ml).

BMD revealed a markedly elevated T-score in the spine at +7.2 and total hip +4.1, but -2.6 at the proximal radius. He was given 50,000 IU of ergocalciferol weekly; a 24-hour urine for calcium and phosphorus and genetic testing are planned.

Conclusion: This unusual case is the first reported of a discrepancy of almost 10 standard deviations between the spine and proximal radius BMD in a patient with a normal PTH and FGF-23. The bone turnover appears elevated, based on the high BSAP despite a normal PTH. It is possible that this patient may have an alternative form of HR such as a disorder of the sodium-dependent phosphate transporter in the kidney. The BMD pattern in other HR syndromes has not been studied. Further genetic testing may help establish a specific diagnosis.

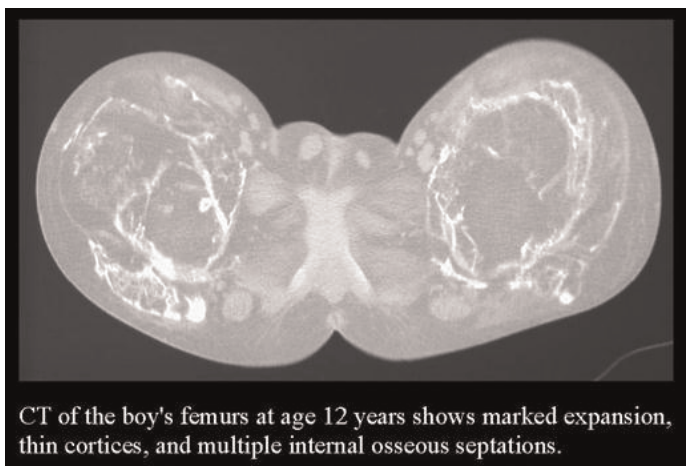
Expansile Ankylosing Skeletal Disease: Phenotype Delineation and Identification of the *IFITM5* Mutation That Causes Osteogenesis Imperfecta, Type V. Michael Whyte*[1], James Aronson[2], William McAlister[3], Robert Weinstein[4], Deborah Wenkert[5], Karen Clements[6], Alexander Pruitt[7], Gary S Gottesman[1], Katherine Madson[1], Horacio Plotkin[8], Steven Mumm[9]. [1]Shriners Hospital for Children-Saint Louis, USA, [2]University of Arkansas for Medical Sciences at Arkansas, Children's Hospital, USA, [3]Mallinckrodt Institute of Radiology at St. Louis Children's Hospital, USA, [4]Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, USA, [5]Amgen, Inc., USA, [6]Shriners Hospital for Children, USA, [7]Northwest Iowa BOne, Joint & Sports Surgeons, USA, [8]Genzyme, USA, [9]Washington University School of Medicine, USA

In 2003, we briefly reported the unique osteopathy of a 12-year-old boy who beginning in infancy suffered recurrent fractures with hypertrophic callus formation and extraordinary bone expansion followed by skeletal fusion [JBMR 18 (Suppl 2): S286]. We called this "expansile ankylosing skeletal disease" (EASD). In utero, his femurs were short. At age two months, the first of many extremity fractures accompanied this sequence. By age 10 years, the major bones of the lower limbs and pelvis were a single structure. Skin, but almost no other soft tissue, covered the widened bones. Computed tomography revealed shell-like bones that could be cystic and fat-filled with hyperdense cortical areas. Marked hyperphosphatasemia followed major fractures. Bone turnover markers indicated accelerated skeletal remodeling. Histological examination of the cortical and medullary regions of major long bones demonstrated woven bone, cartilage, and fibrovascular tissue with little overlying muscle, fascia, or subcutaneous fat. A brief course of alendronate therapy improved the radiographic appearance of small tubular bones in his hands, but not the generalized pain in his expanded bones. At age 22 years, amputation of a leg showed joint structures encased by bone. Mutation analysis was negative for RANKL, RANK, OPG, SQSTM1, ANKH, GNAS1, and ENPP1. Then, we characterized EASD lifelong in an unrelated woman who succumbed at age 51 years to sepsis from her profound skeletal deformities. Our patients shared with osteogenesis imperfecta, type V (OI-V), calcification of forearm interosseous membranes, dislocation of radial heads, wormian bones, and densely packed osteocytes. In 2012, when OI-V was discovered to be caused by heterozygous mutation (c.-14C>T) of the 5′-UTR of *IFITM5* encoding interferon-induced transmembrane protein 5, we documented this identical mutation in both EASD patients. Here, we delineate the clinical, radiologic, biochemical, and histopathological features of EASD.



CT of the boy's femurs at age 12 years shows marked expansion, thin cortices, and multiple internal osseous septations.

Osteopathia Striata with Cranial Sclerosis – A rare osteosclerotic bone disorder. Mariana Marin*[1], Bridget Sinnott[2]. [1]UT Southwestern, USA, [2]UTSW Dallas, USA

We present a case of osteopathia striata with cranial sclerosis (OS-CS) in an 18 year old female who presented to our clinic for evaluation of cranial sclerosis (CS).

The diagnosis of CS followed work-up for sensorineural hearing loss, which revealed bilateral internal auditory canal stenosis. On presentation, she complained of daily frontal headaches, weekly migraines and right knee pain. Medical history was remarkable for a cleft palate, delayed dental eruptions, hearing loss necessitating hearing aids and irregular menses. She had not sustained any fractures. Family history was negative for bone disorders, neurological disorders or endocrinopathies.

Examination revealed a well-nourished female below the mid-parental height who was normocephalic with evidence of a prominent jaw, blue sclera and hypertelorism. Musculoskeletal exam was remarkable for scoliosis and shortened 4th and 5th metacarpals. Neurologic exam was remarkable for myopia and deafness. She had a normal intellect.

Work-up revealed normal bone specific alk phos, TRAP, calcium, phosphate, PTH and IGF-1 levels. 24 hr urine calcium studies were normal. Vitamin D level was 21ng/ml.

Head CT imaging revealed diffuse osteosclerosis of the calvarium and the skull base with osseous encroachment of the bilateral middle ear cavities. There was hypopneumatization of the mastoid, maxillary and sphenoid sinuses. DXA scan showed Z scores of: 4.1 at lumbar spine, 2.0 at left total hip, 4.7 at left femoral neck and -1.5 at 1/3 radius. Thoracic spine X-ray showed mild scoliosis. Radiographs of the femurs revealed vertically orientated sclerotic striations extending from the metaphysis to the diaphysis. Radiographs of the pelvis revealed radiating striations extending into the iliac crests.

OS-CS, also known as Horan-Beighton syndrome, is a rare X-linked dominant sclerosing bone dysplasia, characterized by dense linear striations of long bones & pelvis, CS and extra-skeletal anomalies such as congenital heart disease, respiratory & renal tract abnormalities. It is caused by a mutation in the WTX (Wilm Tumor on X chromosome) gene and is often lethal in males (1). Patients may remain asymptomatic or present with complications secondary to CS, namely cranial nerve entrapment. It is important to make a diagnosis of OS-CS to enable appropriate genetic testing and enable further testing for extra-skeletal anomalies.

Rapid Response to Denosumab in Fibrous Dysplasia of Bone: Report of Two Cases. Kirtan Ganda*[1], Markus Seibel[2]. [1]Concord Hospital, Australia, [2]Bone Research Program, ANZAC Research Institute, University of Sydney, Australia

Purpose: Fibrous dysplasia (FD) of bone is a non-heritable genetic condition characterized by bone pain, skeletal deformities and pathological fractures. So far, the only treatment shown to significantly alleviate pain, suppress bone turnover and improve radiological features in FD has been bisphosphonate therapy. We here report on clinical and biochemical outcomes in two patients with active polyostotic FD treated with the RANKL inhibitor, denosumab, following unsatisfactory responses to prior long-term bisphosphonate therapy.

Patient and Methods: A 44-year-old female who had received a cumulative dose of 20mg zoledronic acid over 2.5 years, and a 48-year-old male who had received a cumulative dose of 45mg zoledronic acid over 8 years both experienced minimal reductions in pain scores and markers of bone turnover. Following initiation of denosumab 60mg s.c., changes in bone pain, bone turnover (assessed by serum amino-terminal propeptide of type I collagen (PINP) and urinary deoxypyridinoline (DPD)) and whole body radioisotope bone scans were monitored over a period of 14 and 6 months in the female and male patient, respectively.

Results: Following administration of denosumab, both patients demonstrated a rapid and pronounced biochemical response. Within 4-7 weeks, bone turnover markers fell to levels within the respective reference range. The female patient experienced a reduction in pain whilst the male demonstrated a reduction in tracer uptake on bone scan. Dosing intervals varied significantly between the two patients, depending on disease activity at baseline.

Conclusions: Our observations suggest that denosumab is a potential therapeutic option for fibrous dysplasia, particularly in patients who respond insufficiently to treatment with bisphosphonates.

Prevalence of Hypercalcemia of Malignancy in the United States. Victor Gastanaga*[1], Rajul Jain[1], Melissa Pirolli[2], David Quach[2], Jane Quigley[2], Scott Stryker[1], Alexander Liede[1]. [1]Amgen, USA, [2]IMS, USA

Background: Hypercalcemia of malignancy (HCM; CTCAE grade ⩾1, CSC >10.7 mg/dL) is a serious metabolic complication whose prevalence has not been quantified. Rates of HCM differ by tumor type, with highest rates reported in multiple myeloma (MM) and lowest among prostate cancer patients (pts). This analysis estimates HCM prevalence in the US.

Methods: This retrospective study used the Oncology Services Comprehensive Electronic Records (OSCER) warehouse of electronic health records (EHR) including laboratory values from >640,000 pts treated at 525 oncology outpatient sites. OSCER data were projected to the national level by linking EHR to claims data. Cancer pts included were ⩾18 years, and had serum calcium (Ca) and albumin (for corrected serum Ca [CSC]) records. Period prevalence was estimated by HCM CTCAE grade, tumor type, and year (2007-2011). Estimates were adjusted to capture pts diagnosed with HCM outside oncology practices using a subset of pts linkable to office/hospital data.

Results: The analysis included 50912 (2007) to 100449 pts (2012), projected to 3.3 to 3.6 million cancer pts. In 2012, pts with HCM had a median of 5 Ca tests, 54% had chemotherapy, and 35% had bone modifying agents. HCM rates were highest for MM (7.6-10.7%), lowest for prostate (1.4-1.8%). Estimated annual 2007-2012 (adjusted) prevalence of HCM was 72382, 86213, 103746, 105119, 98058, and 98997, respectively. HCM is estimated to have affected 2.7% of cancer pts in 2011.

Conclusions: This study of EHR data from oncology practices across the US found that HCM was more common among MM and lung cancer pts. Approximately 100,000 U.S. cancer pts are affected by HCM each year. These pts would benefit from additional treatment options.

MO0173

Increased Frequency of Renal Stones and Nephrocalcinosis in Heterozygous and Homozygous Carriers of Sequence Variations in SLC34A3/NPT2c. Clemens Bergwitz*[1], Monica Reyes[2], Amita Sharma[2], Thomas Carpenter[3], Marco Janner[4], Andrew Biggin[5], Shamir Tuchman[6], H. Jorge Baluarte[7], Shoji Ichikawa[8], Craig Munns[5], Harald Jueppner[2]. [1]Massachusetts General Hospital & Harvard Medical School, USA, [2]Massachusetts General Hospital, USA, [3]Yale University School of Medicine, USA, [4]University Children's Hospital, Switzerland, [5]The Children's Hospital at Westmead, Australia, [6]Children's National Medical Center, USA, [7]The Children's Hospital of Philadelphia, USA, [8]Indiana University School of Medicine, USA

Homozygous and compound heterozygous mutations in *SLC34A3*, the gene encoding the sodium-dependent co-transporter NPT2c, cause hereditary hypophosphatemic rickets with hypercalciuria (HHRH), a disorder characterized by renal phosphate-wasting resulting in hypophosphatemia, elevated $1,25(OH)_2$ vitamin D (1,25D) levels, hypercalciuria, and rickets/osteomalacia. Similar albeit less severe biochemical changes are also observed in heterozygous carriers, which are furthermore indistinguishable from those encountered in idiopathic hypercalciuria (IH). We here report three HHRH kindreds, in which novel *SLC34A3* mutations were found (c.1304delG in exon 12, c.1357delTTC p.F453del, and c.G1369A p.G457S in exon 13). Review of the clinical records suggests that individuals with mutations in the current and previously reported kindreds affecting one or both *SLC34A3* alleles have a significantly increased risk for the formation of renal stones or nephrocalcinosis (17% (p=0.26) and 50% (p=0.0009), respectively) compared to normals (6%). Prevalence of renal calcifications was associated with increased urinary calcium excretion (p=0.047) due to increased serum levels of 1,25D (p=0.0042), which appears to be a biomarker of adequate oral phosphate supplementation (Yu et. al., Bone, 2012). Urine calcium/creatinine of stone carriers was furthermore inversely correlated with serum parathyroid hormone (PTH) levels (p=0.032). Careful adjustments of oral phosphate therapy on the basis of serum 1,25D and PTH levels may be important for carriers of *SLC34A3* mutations to prevent formation of renal calcifications and possibly chronic kidney disease.

MO0174

Quantifying Tissue Mineralization In Vivo for Diagnosing Osteomalacia. Cherie Chiang*[1], Jeffrey Zajac[2], Yu Peng[3], Xiao-Fang Wang[4], Yohann Bala[5], Ali Ghasem-Zadeh[6], Roger Zebaze[6], Ego Seeman[6]. [1]Austin Health, Australia, [2]Austin Hospital, Australia, [3]Straxcorp, Australia, [4]University of Melbourne, Austin Health, Australia, [5]University of Melbourne, Dept. of Medicine, Australia, [6]Austin Health, University of Melbourne, Australia

Purpose: Vitamin D deficiency is the most common cause of osteomalacia worldwide, but whether a circulating level of 25(OH)D of <30 ng/ml is associated with bone disease, and so justifying this diagnostic threshold, is unknown due to lack of studies with bone biopsy evidence of osteomalacia . We hypothesized that non-invasive imaging can be used to quantify tissue under-mineralization associated with osteomalacia.

Methods: We applied a novel nonthreshold based image analysis method (StrAx1.0) to images acquired using high resolution peripheral quantitative computed tomography (HR-pQCT) scans of distal radius, tibia and fibula to quantify tissue mineralization in vivo in 3 kindreds with Vitamin D resistant rickets and 6 age and sex matched healthy controls. Attenuation of voxels containing only void (porosity), only bone matrix at varying degrees of mineralization, or both, was quantified as reported (Zebaze et al 2013). Mineralization level was calculated as the ratio of attenuation by mineralized bone matrix to that produced by 1200 mgHA/cc (maximally mineralized bone matrix) and expressed as a Z-score (standard deviation, SD) away from the mean of age and sex matched controls. Analysis was made of voxels with > 80% maximum attenuation which excludes porosity (as porosity will lower the attenuation to <80% of maximum) and so allows unambiguous assessment of tissue mineralization heterogeneity.

Results: Distal radius mineralization level in the cases was 2.7 to 12 SD lower than controls. In the 25 year old patient with biopsy proven rickets, the voxels within the compact-appearing cortex with attenuation 90-100% of fully mineralized bone matrix was 0.003% compared to 5.38% in the controls. The void-bone matrix curves of the patient illustrates a shift to the left (Fig 1) which could be due to increased porosity, decreased mineralized tissue mass, or decreased level of mineralization of that tissue. After confining analysis to voxels with >80% maximum attenuation (to avoid confounding by porosity), a distinct separation of the patient and control's mineralization distribution was consistent with the presence of matrix under-mineralization. (Fig 2) Data in the tibia and fibula were similar.Conclusions: StrAx1.0 analysis of HR-pQCT images permits identification of undermineralized bone in osteomalacia without the need for invasive bone biopsy.

Skeletal Fluorosis Progression Revealed by the Analysis of Bone Biopsies. Case Report. Louis-Georges Ste-Marie*[1], Natalie Dion[1], Delphine Farlay[2], Algis V. Jovaisas[3], Georges Boivin[2]. [1]CHUM, Canada, [2]INSERM, UMR1033; Université De Lyon, France, [3]University of Ottawa, Canada

This study describes the progressive development of skeletal fluorosis in a 60-year-old white woman. Thirty years ago, elevated levels of fluoride were found in serum and urine of this patient. In 1983 and 1994, she underwent posterior iliac biopsies which revealed bone quality alterations due to idiopathic fluorosis. In 2008, further investigation on bone remodelling status was initiated by performing a transiliac bone biopsy for histomorphometric analysis. In addition to osteoporosis, the histomorphometric pattern confirmed a mild fluorosis shown by hyperosteoidosis, presence of woven bone and focal mineralization impairment. Moreover, the fluoride content in bone ashes was 4X the upper level of normal (cf Table 1;NI: 0.10 ±0.07). Recently, after sustaining a fragility fracture, a second transiliac biopsy was performed and confirmed the development of the bone disorder which correlates with the accumulation of fluoride content in bone ashes reaching 9X the upper level of normal (cf Table 1). Microhardness analysis (Hv;Table 2) revealed that Hv was first high then decreased to normal values in cancellous (Cc) and total (cortical + cancellous) bone. Characteristics of bone mineral at tissue and crystal levels are in progress to precise the impact of fluoride. Taken together, these results suggest that if the source of fluoride is not found and removed, bone alterations will continue to progress with impaired bone matrix quality leading to decreased bone strength. This could lead to the establishment of a severe osteoscleorosis comparable to a case we presented at the ASBMR meeting in 1995 (Ste-Marie LG *et al*., JBMR 1995; 10 (Supp. 1):S499, Abstract #T580) where fluorosis was induced by the regular and prolonged ingestion of toothpaste.

Biopsies	BV/TV %	OV/BV %	OS/BS %	ES/BS %	MS/BS %	Fluoride % ashes

MO0176

X-linked hypophosphatemia in adults and rheumatological manifestations: cross-sectional survey of the Bone Section of the French Society of Rheumatology SFR-OS. Rose Marie Javier*[1], Karine Briot[2], Martine Cohen-Solal[3], Bernard Cortet[4], Capucine Eloy[5], Michel Laroche[6], Pierre Lafforgue[7], Marie-Christine De Vernejoul[8]. [1]University Hospital, France, [2]Paris Descartes University, Cochin hospital, Rheumatology Hospital, France, [3]Centre Viggo Petersen, France, [4]Service de Rhumatologie, France, [5]University Hospital Lille, France, [6]University Hospital Toulouse, France, [7]Hôpital Sainte-Marguerite, France, [8]Fédération De Rhumatologie Et INSERM U606, France

X-linked dominant hypophosphatemia (XLH) is the most common (prevalence 1:20,000) heritable vitamin D resistant rickets. It is caused by mutations in the PHEX gene. In children, the classic triad (shortness of stature, deformities of the lower limbs, hypophosphatemia) allows the diagnosis. Since the end of the 1970s, early and systematic treatment (phosphate derivatives and 1-hydroxylated vitamin D) partially corrects mineralization disorders, leg deformities with improvement of adult height but without modifying the evolution of osteoarticular complications (early osteoarthritis, enthesopathies). Continued treatment in adults is not systematic. Sometimes the discovery is made in adulthood, mainly during a rheumatologic consultation for osteomalacia or osteoarthritis.

The purpose of this study is to 1) describe and determine the frequency of rheumatological disorders (location, pain intensity) in adults XLH ; 2) better manage these adult patients.

MATERIALS AND METHODS: This study was conducted by members of the Bone Section of the French Society of Rheumatology who included adults XLH consulting in a rheumatology department for any reason. Questionnaires including body schema of painful areas, visual analogic scale (VAS) score for pain and fatigue, current and past treatments, X-rays datas, were delivered to the patients.

RESULTS: Forty-three adults XLH (74.4% women, average age of 42 years [21-80years]) were included. Twenty-six patients (60%) (including young patients treated during childhood) reported pain in the last 6 months (mean pain VAS: 5.9 / 10 [1.2 to 10]). Analgesic treatments were prescribed in about 50% of patients with (most often mild analgesics of level 1 or NSAIDs). Most of this painful symptoms were osteoarticular, located with decreasing frequency in knees (54%), hips (50%), lumbar spine (41%), the rest of the lower limbs (ankles) often with limitation in motion. X-rays showed features of early osteoarthritis and calcified enthesopathies. Significant fatigue (VAS fatigue 5.6 / 10 [0.2 to 9.2]) was present in 58% of patients. Most patients did not receive phosphate and / or derivatives 1-hydroxylated vitamin D.

CONCLUSION: XLH adult patients have frequent disabling skeletal pain secondary to articular and pararticular involvement.

MO0177

Changes in Bone Microarchitectural Texture Assessed by Trabecular Bone Score After Parathyroidectomy in Primary Hyperparathyroidism. Barbara Silva*[1], Natalie Cusano[2], Chiyuan Zhang[3], Alice Abraham[3], Stephanie Boutroy[4], Wen-Wei Fan[1], Didier Hans[5], John Bilezikian[2]. [1]Columbia University Medical Center, USA, [2]Columbia University College of Physicians & Surgeons, USA, [3]Columbia University, USA, [4]INSERM U1033 & Université de Lyon, France, [5]Lausanne University Hospital, Switzerland

Following parathyroidectomy (PTX), BMD improves in patients with primary hyperparathyroidism (PHPT), but little is known about changes in bone microarchitectural texture by trabecular bone score (TBS). We have recently shown that TBS is associated with HRpQCT measures of bone microstructure in PHPT. Moreover, TBS predicts fracture risk, independent of BMD. In this study, we investigated whether TBS improves over time after PTX in a group of men and women with PHPT, and examined the sex-specific differences in TBS changes after surgery.

We studied 17 subjects with PHPT followed for at least 6 and up to 12 months after successful PTX. Site-matched spine TBS was extracted from the DXA image (Hologic) using TBS iNsight software. Linear mixed model for repeated measures was performed to assess the % change in TBS relative to the baseline over 12 months. Sex-specific differences were evaluated by using sex as a covariate in the model.

The mean age was 65±14 yrs. Only 3 subjects had nephrolithiasis (n=2) and/or fragility fracture (n=2). At baseline, mean serum calcium level was elevated at 10.8±0.6 mg/dl. All subjects became and remained normocalcemic at 6 and 12 months after PTX. Men (n=5) and women (n=12, 11 postmenopausal) did not differ in age, BMI or serum calcium levels. Men had a shorter duration of the disease (0.8±0.3 vs 11±10 yrs; p=0.006). At baseline, the mean TBS was low at 1.218±0.158 (normal ⩾1.35). TBS was lower in men than in women (1.024±0.038 vs 1.299±0.108; p<0.001). In the entire cohort, there was an increase in TBS after 6 months (+2.9±7.0%; p=0.04), which was sustained at 12 months (+2.8±11.1%; p=0.1). Sex was a predictor of the % change in TBS over time (p<0.001). Between-sex differences in the % change of TBS were seen at 6 (p=0.003) and 12 (p=0.005) months. While TBS markedly improved at 6 (+10.4±9.5%; p<0.001) and 12 (+10.3±15.2%; p<0.001) months post PTX in men, it did not change in women (-0.3±6.1%; p=0.8 at 6 months; and -0.6±10.4%; p=0.7 at 12 months) (Fig). There was no correlation between the % change in TBS and the % change in aBMD or HRpQCT measures at any site or time point.

These data demonstrate that TBS increases after PTX in men, while it does not change in women over a 12-month period. The results not only confirm the previous findings by histomorphometry and HRpQCT of similar or better trabecular microstructure in PHPT after PTX, but also reveal marked differences between men and women not described before.

Figure: Percent change in TBS in men and women at 6 and 12 months after PTX (Mean ± SEM; *p<0.01 from baseline, #p<0.01 men *vs* women)

MO0178

Continuous Infusion of PTH is superior to PTH Injections in the Treatment of Severe Hypoparathyroid Neuromuscular Symptoms. Erik Fink Eriksen*[1], Helen Dahl-Hansen[2], Lena Seland[1], Daysi Duarte-Sosa[1]. [1]Oslo University Hospital, Norway, [2]Norwegian hypoparathyroidism organisation, Norway

Most patients with hypoparathyrodism achieve normocalcemia on conventional treatment with Vitamin D analogues combined with magnesium and calcium supplementation. PTH once daily or on alternate days has recently been introduced as a new treatment option, but neither this new modality, nor conventional treatment improve neuromuscular symptoms (in particular painful muscle cramps) accompanying the disease,. In this study we tested whether continuous infusions of PTH to mimic physiological PTH secretion more closely would provide better symptomatic relief in patients with severe hypoparathyroid symptoms.

We studied 4 patients with severe postoperative hypoparathyroidism (undetectable PTH for more than 2 years, and severe neuromuscular symptoms despite stable S-calcium at the lower range of normal). The patients were first switched to PTH(1-84) (Preotact®) injections every or every other day due to either severe subjective symptoms or in one case due to progressive renal insufficiency, while on Rocaltrol. None of the patients experienced significant symptomatic relief after the switch to PTH injections (Fig. 1), but renal function returned to normal in the patient with renal insufficiency. In order to test the effects of continuous PTH infusions the patients were equipped with an insulin pump (Omnipod® or Dana®), where the infusion syringe was loaded with PTH extracted from the (PTH(1-84) ampules (0.25 ml diluted in 1.5 ml of NaCl). Infusion rates were adjusted to achieve S-Ca in the lower to mid-range of normal (usually 20-30 IU/24h).

Infusions caused significant relief of neuromuscular symptoms after a few weeks. Muscle pain/cramps VAS was reduced from 8-9 to 2-3 within 3 months (Fig. 1), and fatigue improved significantly too. The symptoms were all assessed during normocalcemia.

Thus, in this short term study on a small subset of patients with severe hypoparathyroidism, we found that continuous PTH infusions provided better symptomatic relief than conventional treatment or PTH injections. This observational study warrants a larger randomized study and suggests that the neuromuscular symptoms are intimately related to low concentrations of PTH, rather than being adverse effects of hypocalcemia

MO0179

Effect of Long Term Stable Hypercalcemia on Kidney Function in the Elderly. Sharon Lahiri, Tarlisha Eskridge, Manjari Devidi, Sudhaker Rao*. Henry Ford Hospital, USA

Background: Advancing age is a well known risk factor for declining renal function, but the additional effect of stable hypercalcemia due to primary hyperparathyroidism (PHPT) is unknown. It is argued that elderly patients are less likely to receive parathyroidectomy (PTX) because of concerns about surgical risk. Accordingly, we retrospectively reviewed the effect of chronic stable moderate to severe hypercalcemia on renal function as assessed by serum creatinine (Cr) in the elderly.

Materials & Methods: Twenty three patients, all women, >75 years (mean age of 80 ± 4 years), were followed for at least 10 years. They represented 25% of all patients with PHPT seen in 2003 and 40% of those >75 yrs. Serum calcium (Ca; adjusted for albumin), ionized Ca (iCa), PTH, and Cr were measured periodically to monitor the disease. Three of the 23 had failed surgeries (1-3 PTXs) in expert hands and refused further surgery; the others 20 did not want PTX believing that they were "well and did not need surgery". None of the 23 had kidney stones or bone fractures despite moderate to severe PHPT and low bone density.

Results: The mean serum Ca at entry was 11.0 ± 0.65 mg/dl, iCa 1.45 ± 0.11 mmol/l, Cr 1.05 ± 0.26 mg/dl and PTH 84 ± 37 pg/ml with no regression of serum Cr on serum Ca, iCa or PTH, or age. None developed any of the known complications traditionally associated with PHPT or hypercalcemic crisis. All were on adequate calcium and vitamin D supplements (mean serum 25-OHD was 34.3 ± 11.9 ng/ml). After 10 years of follow-up without PTX (or failed PTX in 3), mean serum Ca was 10.7 ± 0.75 mg/dl, Cr 1.09 ± 0.32 mg/dl (p=ns), and PTH 118 ± 58 pg/ml (p=ns for all). The mean lowest BMD T-score (spine or femoral neck) at entry was -2.4 ± 1.3 SD. Five patients died of unrelated causes during follow-up mostly related to advanced age as each of these 5 patients was older than 80 years at entry in 2003.

Conclusions: Despite the traditional concerns, there appears to be no adverse effects of hypercalcemia on renal function in the elderly. Our study is limited by relatively small sample size and lack of more sensitive measures of renal function. Adequate Ca and vitamin D supplements during follow-up may have mitigated some of the adverse effects. Finally, there appears to be no compelling reason to recommend PTX in asymptomatic PHTP elderly patients since the benefits of surgery may not outweigh the potential risks in these elderly subjects, especially after failed PTX.

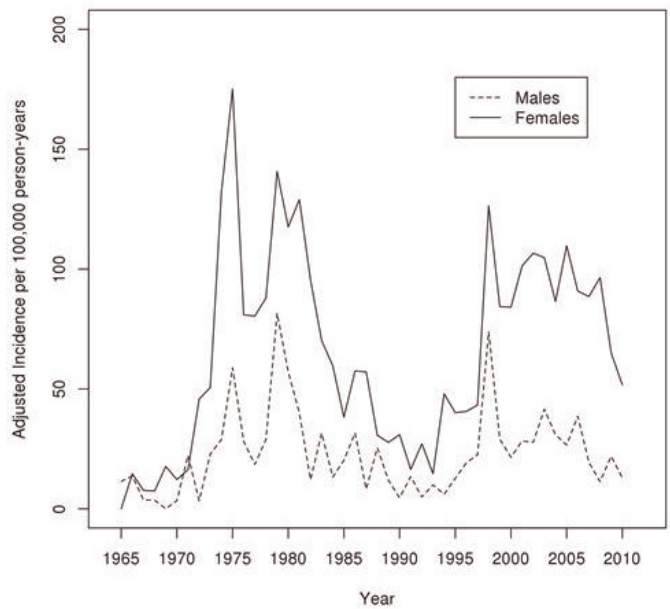
Increased Incidence of Primary Hyperparathyroidism in Rochester, Minnesota after 1997: An Update on the Changing Epidemiology of the Disease. Marcio Griebeler*[1], Ann Kearns[2], Eujung Ryu[1], Matthew Hatchcock[1], L. Joseph Melton[2], Robert Wermers[2]. [1]Mayo Clinic Rochester, USA, [2]Mayo Clinic, USA

Purpose: Introduction of automated serum calcium measurements in the early 1970s resulted in a dramatic rise in primary hyperparathyroidism (PHP) incidence, followed by a decrease afterwards. Recent studies from North America and Europe report an increasing PHP incidence. Our objective was to evaluate secular trends in the incidence of PHP.

Methods: In this population-based descriptive study, residents from Rochester, MN who met previously defined diagnostic criteria for PHP from Jan 2001 through Dec 2010 were identified through the medical record system of the Rochester Epidemiology Project and added to our historical cohort beginning in 1965. Incidence was calculated per 100,000 person-yrs using age and sex distribution of the 2010 US white population and differences between groups were tested using Pearson chi-square test for categorical and t-test for continuous variables.

Results: 391 residents were newly diagnosed with PHP from 2001 to 2010 for a total of 1152 patients since 1965. As shown in the figure, two peaks were observed, one in 1974 (121.7 per 100,000 person-yrs) associated with the introduction of automated serum calcium measurements and a second one beginning in 1998 (101.2 per 100,000 person-yrs). To better understand differences in patient profiles, two time periods were analyzed (group 1: 1985-1997: 194 pts vs group 2: 1998-2010: 523 pts). There was no significant difference in sex (73% women in group 1 vs 78% group 2) but significant differences in mean age (55.4 yrs vs 60.1 yrs), symptoms/signs associated with the diagnosis (9% vs 31%), PHP surgery (22% vs 35%) and diagnosis in patients older than 55 yrs (54% vs 67%). Although more patients had surgery in 1998-2010, the mean serum calcium of 10.9 mg/dL wasn't significantly higher than in the preceding era (10.8 mg/dL). In addition, more subjects were diagnosed on the basis of inappropriately elevated parathyroid hormone (25% vs 50%) and histological evidence (25.7% vs 34.9%) in the most recent period.

Conclusions: A second sharp rise in PHP incidence in our community, similar to observations in 1974, has occurred since 1998 in a population that is older with more PHP complications. The abrupt increase in both men and women is inconsistent with several potential etiologic causes (e.g., estrogen discontinuation, increasing obesity, and systemic changes in vitamin D or calcium intake or sufficiency) and suggests a change in PHP epidemiology possibly related to case ascertainment bias.



Secular trends in PHP incidence among Rochester, Minnesota residents, 1965-2010

MO0181

Muscle Function and Quality of Life in Primary Hyperparathyroidism. Lars Rolighed*[1], Anne Kristine Amstrup[1], Niels Frederik Breum Jakobsen[2], Tanja Sikjaer[3], Leif Mosekilde[4], Peer Christiansen[5], Lars Rejnmark[4]. [1]Aarhus University Hospital, Denmark, [2]Dept. of Endocrinology & Metabolisb MEA, Denmark, [3]Department of Medicine & Endocrinology, MEA Aarhus University Hospital, Denmark, [4]Aarhus University Hospital, Denmark, [5]Dept. of Surgery P, Denmark

Introduction: In spite of the frequent encounter of ''asymptomatic'' primary hyperparathyroidism (PHPT), the patients often describe various relevant improvements postoperatively suggesting a subclinical biological effect of elevated PTH or hypercalcaemia.

Materials and Methods: To evaluate muscle function, postural stability, and quality of life (QoL) in untreated PHPT, we assessed maximal isometric muscle strength in upper and lower extremities, time of 10 repeated-chair-stands (RCS), time to walk 3 m and back (TTW), balance function, and questionnaires of QoL in 58 untreated PHPT patients and 58 controls matched on age, sex, and menopausal status.

Results: Patients and controls had a mean age of 59 years and 47 (81%) were women. We found marked differences between groups in PTH (13.9 vs. 4.8 pmol/l) and ionized calcium levels (1.45 vs. 1.24 mmol/l), whereas plasma creatinine and 25(OH)D levels did not differ. In PHPT, the SF-36 questionnaire showed a lower QoL in all 8 domains ($p<0.05$) and the WHO-5 index showed a reduced well-being ($p<0.001$). Postural stability was impaired in PHPT during normal standing with eyes open ($p<0.05$) and eyes closed ($p<0.001$). Female patients spent significantly longer time on performing the RCS- and TTW-tests, and had a lower muscle strength in upper ($p<0.01$) and lower extremities ($p<0.001$) compared with female controls. In men, muscle function and strength did not differ between groups.

Conclusions: In PHPT, constantly elevated PTH and calcium levels seem to have deleterious effects on muscle strength, muscle function, postural stability and QoL. The increased risk of fracture in PHPT may therefore both be related to a decreased BMD and a reduced postural stability and muscle strength.

MO0182

Two-years effects of PTH (1-84) on bone microstructure in post-menopausal women with hypoparathyroidism. Silvia Chiavistelli*[1], Barbara Silva[2], Mishaela Rubin[3], Natalie Cusano[4], Aline Costa[3], Chiyuan Zhang[3], James Sliney jr[2], Laura Beth Anderson[3], Didier Hans[5], John Bilezikian[4]. [1]Azienda Ospedaliera Pisana, Italy, [2]Columbia University Medical Center, USA, [3]Columbia University, USA, [4]Columbia University College of Physicians & Surgeons, USA, [5]Lausanne University Hospital, Switzerland

Hypoparathyroidism (HypoPT), an uncommon disorder of parathyroid hormone (PTH) deficiency, is characterized by hypocalcemia and abnormal structural and dynamic skeletal properties. We previously found in a combined cohort of HypoPT men, pre- and postmenopausal women that PTH therapy is associated with increased areal bone mineral density (aBMD) at the lumbar spine (LS) and reduction at the 1/3 radius. Yet, little is known about the effects of PTH on trabecular and cortical microarchitecture in HypoPT. To address this question, we used 3 different imaging modalities to better characterize changes in areal and volumetric densities and bone microstructure in a homogenous cohort of PTH-treated postmenopausal women. Postmenopausal HypoPT women (n=23, mean age 63 ± 7.8 yrs; 12.6 ± 7.5 yrs since menopause) were treated with PTH(1-84) for up to 2 yrs. aBMD was assessed by DXA (Hologic); cortical (Ct) and trabecular (Tb) volumetric density (vBMD) and microstructure were evaluated by high resolution peripheral quantitative computed tomography (HRpQCT; Scanco); trabecular bone score (TBS) was extracted from the LS DXA image (TBS iNsight software). At 12, 18, and 24 months, aBMD at the 1/3 radius fell by -2.2%, -3%, and -3.7% respectively ($p<0.001$ for all). Ultradistal radius aBMD also declined with the same trend ($p<0.001$ for all). LS aBMD increased at 18 (1.44%, p=0.01) and 24 (2.52%, p=0.025) months. An increase in TBS became apparent at 18 months (+3.1%, p=0.03), which tended to remain above baseline at 2 yrs (+2.6%, p=0.09). By HRpQCT at the radius, declines in total (-0.5%, p=0.008) and Ct area (-5%, p = 0.015) were noted at 24 months. Ct vBMD also decreased (-3.8%, p=0.004) at 2 yrs, while Tb vBMD increased (4.9%, p=0.012). Ct thickness (Ct Th) fell progressively, to -6% by 18-24 months (p=0.03), whereas Tb bone volume fraction (BV/TV) increased (5%, p=0.01) at 2 yrs. By HRpQCT at the tibia, total area fell by 1 and 2 yrs, as did Ct area, total vBMD, Ct vBMD, and Ct Th ($p<0.05$ for all), while Tb vBMD was unchanged. In summary, PTH therapy in postmenopausal HypoPT women was associated with increases in trabecular indices by HRpQCT and TBS, consistent with improvements in aBMD at the LS. In contrast, there was a decrease in cortical measures by HRpQCT at the radius and tibia, as well as aBMD at the cortical 1/3 radius site. Future studies are necessary to determine how these changes alter bone strength in HypoPT.

MO0183

Vertebral Bone Marrow Fat Associated with Lower Bone Mass in Primary Hyperparathyroidism. Francisco Jose De Paula*[1], Maira Mendonça[2], Carlos Salmon[3], Marcello Nogueira-Barbosa[2]. [1]School of Medicine of Ribeirao Preto - USP, Brazil, [2]School of Medicine of Ribeirao Preto, University of Sao Paulo, Brazil, [3]University of Sao Paulo, Brazil

Recently, a remarkable advance occurred on the knowledge about the molecular and cellular action of parathyroid hormone (PTH) on bone, while scarce progress was observed regarding the physiological role of PTH on bone mass development and maintenance. In primary hyperparathyroidism (PHPT), bone catabolism occurs in trabecular and cortical bone. Recently, bone marrow fat content has been associated negatively with bone mass and positively with visceral fat. There is no data about the bone marrow fat in patients with PHPT. The present study was designed to evaluate bone marrow fat in lumbar spine (L3) in PHPT patients and its relationship with bone mass and bone remodeling.

Material and Methods: the study comprises 11 PHPT patients (4 Males and 7 females), and 11 controls (CG, 5 Males and 6 Females) matched for age ($C=48.8\pm8.5$ vs $HPTP=48.9\pm8.8$years), weight ($C=82.1\pm14.5$ vs $HPTP=80.6\pm21.5$ kg), height ($C=1.67\pm0.1$ vc $HPTP=1,61\pm0.1$ m) and body mass index (BMI: $C=28.9\pm3.2$ vs $PHPT=31.1\pm5.6$ kg/m^2). Laboratory measurements included calcium, phosphorus, creatinine, PTH, 25-OHD, IGF-I, osteocalcin and CTX. Bone mineral density was determined in L1-L4, femoral neck, total hip, 1/3 forearm, total body, and vertebral morphometry. Bone marrow fat was estimated by magnetic resonance spectroscopy.

Results: PHPT patients exhibited normal serum levels of creatinine ($1.04\pm0,3$ mg/dl). Serum levels of calcium ($C=9.4\pm0.6$ vs $PHPT=11.6\pm0.9$ mg/dl) and PTH ($C=43.3\pm13.8$ vs 304.1 ± 278.2) levels were increased in PHPT patients $p<0.05$. BMD was significantly higher in control group in lumbar spine ($C=0.995\pm0.09$ vs $PHPT=0.876\pm0.16$ g/cm^2, $p<0.05$) and 1/3 radius ($C=0.700\pm0.057$ vs $PHPT=0.606\pm0.113$ g/cm^2). BMD in femoral neck was not different ($C=0.936\pm0.17$ vs $PHPT=0.799\pm0.19$). Bone marrow fat was slightly increased in PHPT patients ($C=52.4\pm20.1$ vs $PHPT=57.2\pm29.6$ %). There was a negative correlation between bone mass in lumbar spine with bone marrow fat in L(3) in PHPT group, $p<0.05$, $r=-0.65$. Remarkably, a patient with a severe bone disease showing fragile fracture exhibited very high bone marrow fat.

Conclusion: Previous studies have showed a negative association between bone marrow fat and bone mass in young females. Recently, higher bone marrow fat has been associated not only with lower trabecular BMD but also with prevalent fracture. We originally demonstrated that bone marrow fat is negative associated with lumbar spine BMD in patients with primary hyperparathyroidism.

Impact of High Calcium Intake from Calcium Carbonate or Dairy on Cardiovascular Function and the Progression of Coronary Artery Disease in Ossabaw Miniature Swine. Alyssa Phillips*[1], Mikaela McKenney[2], Martin Bahls[3], Sean Newcomer[4], Berdine Martin[5], William Van Alstine[6], Scott Radcliffe[7], Meryl Wastney[8], George Jackson[9], Michael Sturek[2], Connie Weaver[1]. [1]Purdue University, Department of Nutrition Science, USA, [2]Indiana University School of Medicine Department of Cellular & Integrative Physiology, USA, [3]Purdue University Department of Health & Kinesiology, USA, [4]California State University San Marcos Department of Kinesiology, USA, [5]Purdue University, USA, [6]Purdue University Department of Comparative Pathobiology, USA, [7]Purdue University Department of Animal Sciences, USA, [8]Metabolic Modeling Services, USA, [9]Purdue University Department of Physics, USA

Calcium supplements have been regarded as safe and effective in promoting bone health. However, recent secondary analyses have linked calcium supplementation to increased risk for heart attack and cardiovascular-related death in older, healthy adults. One putative mechanism is that an acute spike in circulating calcium following excessive intake leads to increased calcium deposition in the coronary arteries and subsequent cardiovascular dysfunction. However, evidence to support this hypothesis is lacking. The Ossabaw swine model mimics human metabolic syndrome and coronary artery disease (CAD) when fed an atherogenic diet. The aim of this study was to investigate the impact of high calcium intake from calcium carbonate or dairy on cardiovascular function and the progression of CAD utilizing Ossabaw swine. All pigs (n=24) were fed an atherogenic diet and randomized to control calcium (0.5%Ca by weight), high calcium from calcium carbonate (2%Ca), or high calcium from dairy (2%Ca) diets. Conscious systolic and diastolic blood pressures did not differ among dietary groups. After 6 months of dietary intervention, simultaneous Positron Emission Tomography Computed Tomography (PET-CT) was performed to assess cardiac function and soft tissue calcification. Stroke volume and ejection fraction did not vary among groups. Uptake of 18F-NaF was measured as standard uptake values (SUVs) utilizing PET-CT. SUV in all tissues did not differ among diet groups and there was no significant SUV in the heart; suggesting no evidence of calcification in the heart soft tissues. Intravascular ultrasound was performed to quantify CAD and showed no difference in plaque wall coverage of the left anterior descending artery (LAD) among groups. Following euthanasia, segments of LAD were excised and mounted on an *in vitro* wire myograph. Endothelium-dependent and –independent

responses were assessed with increasing doses of bradykinin and sodium nitroprusside, respectively. Endothelial-dependent and –independent vasodilation were similar among groups. These data suggest calcium intake below the upper limit recommended by the Institute of Medicine is not likely to adversely impact cardiovascular health and function. Prospective data assessing the impact of calcium intake on vascular calcification using sensitive ^{41}Ca kinetic modeling in the Ossabaw swine will further contribute to our understanding of the relationships between calcium intake and cardiovascular health.

Up-regulation of Osteocyte Markers by Muscle Secreted Factor(s) but Lack of any Effect on Osteoblast proliferation/differentiation. Ning Zhao*[1], Matthew Prideaux[1], Marco Brotto[1], Leticia Brotto[2], Lynda Bonewald[1]. [1]University of Missouri Kansas City, USA, [2]School of Nursing, university of missouri kansas city, USA

The spatial proximity and co-ordinated actions of bone and muscle during exercise led to the hypothesis that communication between bone and muscle cells play an important role in regulating bone modeling. We have previously shown that muscle secreted factors preserve osteocyte viability. In this study we examined the effect of muscle factors on osteoblast proliferation, viability, and differentiation and the expression of osteocyte biomarkers, Dmp1, E11/gp38, and sclerostin. The MC3T3 osteoblasts and the IDG-SW3 cell line were used, the IDG-SW3 as a model of osteoblasts that can fully differentiate into mature osteocytes. Conditioned media from C2C12 myotubes (MT-CM) and ex-vivo contracted mouse EDL and SOL muscle (10%) was added to IDG-SW3 cultures every 3 days for up to 28 days of culture. Non-conditioned media was used as a control. No effect was observed on osteoblast (either MC3T3 or IDG-SW3 cell) proliferation, metabolic activity using the MTT assay, nor mineralization. However, MT-CM (1%) increased expression of Dmp1- GFP in IDG-SW3 cells by over 3-fold ($P<0.001$) after 14 days. E11/gp38 and sclerostin were not only elevated in IDG-SW3 cells by MT-CM, but also by 10% EDL or SOL CM at 28 days. These data suggest that a factor(s) secreted by muscle cells influences osteoblast to osteocyte differentiation or can influence mature osteocyte function while having no effects on osteoblast proliferation or mineralization.

MO0186

Exploring the Relationship between Changes in Bone Mineral Density, Lean Body Mass, and Hormones in Active, Adult Males with Osteopenia after a 12-month Exercise Intervention. Melissa Carter*, John Thyfault, Tim Sinak, Peggy Nigh, Lynn Eaton, Jun Jiang, Pamela Hinton. University of Missouri, USA

Weight-bearing exercise may positively affect bone via muscle contractions, impact forces, and hormonal changes; however, the relative importance of these factors remains controversial. We examined the effects of 12-months of resistance training (RT, 2x/wk, N= 10) or plyometric exercise (PLY, 3x/wk, N= 10) on bone mineral density (BMD) and hormones (testosterone, TEST; free testosterone, fTEST; estradiol, E2; and insulin-like growth factor-1, IGF-1) in physically active (≥4hr/wk), osteopenic, but otherwise healthy men between 25 and 60y (mean: 42 ± 9.7y) who were provided daily supplemental calcium (1200 mg) and vitamin D (10 μg). We examined relationships between percent changes (%Δ) in lean body mass (LBM), hormones, and BMD of the whole body (WB), weight-bearing (leg, hip) and non-weight-bearing (arm) sites. LBM and BMD were measured using dual-energy X-ray absorptiometry, and plasma hormone concentrations were assessed using ELISA. Effects of RT or PLY on changes in WB and regional (i.e., arm and leg/hip) LBM and BMD and hormone concentrations were evaluated using 2x2 repeated measures ANOVA (time, group). Relationships between %Δ in LBM or hormones and BMD were assessed using Pearson's product moment correlations. WB (time, p= 0.025) and leg (time, p= 0.024) BMD significantly increased post-intervention with no differences between RT and PLY. By contrast, hip BMD increased in RT, but remained unchanged in PLY (group x time, p= 0.068). Whole body and leg LBM did not change significantly after RT or PLY; arm LBM significantly decreased in PLY and remained unchanged in RT (group x time, p= 0.080). The %Δ in WB LBM was positively correlated with %Δ in leg (r= 0.581, p= 0.039) and hip BMD (r= 0.565, p= 0.044) in PLY only. The %Δ in arm LBM was positively correlated with %Δ in arm BMD (r= 0.577, p= 0.047) in RT only. There were no significant changes in TEST, fTEST, or E2; IGF-I increased in both RT and PLY with a greater increase in RT vs. PLY (group x time, $p<0.001$). %Δ in the hormones was not associated with increases in BMD in either RT or PLY. In conclusion, weight-bearing exercise that elicits either high-muscle-contraction forces or high-impact forces may positively affect whole body and leg BMD, while hip BMD increased following high-muscle-contraction force exercise in physically active men with osteopenia.

MO0187

From GWAS to cell-based studies in search of common pleiotropic pathways for bone-muscle crosstalk. Jian Huang*[1], Chenglin Mo[1], Yi-Hsiang Hsu[2], Eduardo Abreu[1], Dauglas P kiel[3], Lynda Bonewald[1], Marco Brotto[1], David Karasik[4]. [1]University of Missouri-Kansas City, USA, [2]Hebrew SeniorLife Institute for Aging Research & Harvard Medical School, USA, [3]Hebrew Senior Life, USA, [4]Hebrew SeniorLife; Bar Ilan University, USA

Sarcopenia and osteoporosis are among the most serious and costly public health problems and normally occur concurrently. A bivariate genome-wide association study (GWAS) using meta-analysis data from two consortia of mostly Caucasian cohorts identified *METTL21C* as a suggestive pleiotropic gene for bone and muscle phenotypes. METTL21 methylates chaperone proteins involved in the etiology of both Inclusion Body Myositis and Paget's Disease. To validate GWAS results, using siRNA to silence *METTL21C* in murine C2C12 myoblasts and osteocyte-like cell line MLO-Y4 was conducted. After 24h of transfection, quantitative real-time PCR revealed that *Mettl21C* expression was reduced by 36.1 ± 4.0% in the siRNA-treated cells (siRNA-cells). In addition, 3 days after the onset of myoblast differentiation into myotubes, a significantly reduced number of myocytes aligning/organizing for fusion in the siRNA-cells (30.8 ± 3.6/per random image area, PRIA) was observed compared to control-cells (61.8 ± 7.4/PRIA) ($p < 0.05$). At day 5 of differentiation, both fewer and smaller early myotubes were observed in the siRNA-cells (51.5 ± 6.9/PRIA) compared to control-cells (79.8 ± 8.0/PRIA) ($p < 0.05$). By day 7, fully matured and developed myotubes were observed in the control but not in the siRNA-cells. These results were also confirmed by double staining of myosin heavy chain and nuclei. Since intracellular calcium (Ca) homeostasis is essential for both muscle and bone function, at day 5 of differentiation, we measured intracellular Ca using Fura-2, and found that the maximal amplitude peak Ca response to 20mM caffeine decreased by approximately 500nM, and the time of return from peak levels to basal Ca levels was 20% shorter in the siRNA-treated cells, suggesting that less Ca is available for release after partial silencing of *METTL21C*. In siRNA-treated MLO-Y4 cells, no obvious morphological phenotypic charges were detected, but when, MLO-Y4 cells were treated with dexamethasone 48 hours after transfection, the percentage of cell death induced with dexamethasone significantly increased in siRNA-cells (18.2 ± 1.4%) compared to control-cells (13.1 ± 1.2%) ($p < 0.05$). These results suggest that *Mettl21C* plays previously unrealized roles in bone and muscle cells. These results warrant additional cell based studies to advance our understanding of the functions of Mettl21C in musculoskeletal biology and provide solid rationale for cellular and molecular validation of GWAS studies.

MO0188

Muscle microstructure: a new point of view on osteoporosis-related muscle atrophy. Umberto Tarantino*[1], Monica Celi[2], Jacopo Baldi[1], Francesca Mastrangeli[1], Federico Maria Liuni[1], Giulia Di Pietro[3], Elena Gasbarra[1], Silvia Capuani[3]. [1]Università degli Studi di Roma Tor Vergata, Italy, [2]University of Rome Tor Vergata, Italy, [3]Università degli Studi di Roma "La Sapienza", Italy

Osteoporosis and sarcopenia are considered two of the hallmarks of the aging process. Aim of this study was to investigate the microstructural features in muscles of osteoporotic and osteoarthritic women by using Magnetic Resonance (MR) diffusion tensor imaging (DTI). Towards this goal we examined in vitro at 9.4T the vastus lateralis biopsy of osteoporotic and osteoarthritic subjects (extracted during a surgical operation of femoral head replacement) by measuring mean diffusivity (MD), fractional anisotropy (FA), the three eigenvalues (l_1 l_2 l_3) of muscles and assessing associations between DTI parameters, subjects age, subjects bone mineral density (BMD) and subjects body mass index (BMI). Moreover we performed an histological evaluation of muscle fibers pattern using anti-slow skeletal myosin and anti-fast skeletal myosin immunohistochemistry reaction.

After informed consent, we performed vastus lateralis biopsy in 10 women with osteoporosis (mean-age=82.3±4.5) underwent primary Total Hip Arthroplasty (THA) for hip fracture, and 10 age-matched women (mean-age=75.0±5.5) underwent surgery for hip osteoarthritis. A 9.4T MR system with a micro-imaging probe was used to investigate muscle samples. Each muscle of 2cm in length was stored in a 4%-paraformaldeyde and PBS. The DTI protocol with b-values = 400 and 700 s/mm2 was applied, using a PGSTE-imaging sequences (TE/TR=14.5/2500ms, diffusion delay D=40ms, diffusion gradient pulse duration δ=2ms, field-of-view FOV= 0.75cm, number of average NS=4, slice thickness, ST=1mm, twelve axial slices). Mean values and standard deviation were obtained for each variable for osteoporotic and osteoarthritic subjects. Between-group comparisons to assess group differences and Pearson correlation analysis were performed. P values<0.05 were considered statistically significant.

FA was significantly higher in OA compared to OP subjects while MD, l_2 and l_3 were lower in OA compared to OP subjects (P=0.039, P=0.040 P=0.022, respectively). A significant linear correlation was found between FA and BMI in OP subjects only. No significant correlation was found between DTI parameters, BMD and age.

Our in vitro preliminary results highlight differences in DTI parameters of OP patients: DTI images show the loss of the typical longitudinal orientation of muscle fibers confirming previous histological evidences. This data encourages further analysis of muscle microstructure investigation by means of MR imageing.

MO0189

Radiation Exposure Prevents Recovery of Cancellous Bone in Mouse Vertebrae following Partial Weightbearing. Ray Boudreaux*[1], Katherine Elmer[1], Corinne Metzger[1], Brandon Macias[2], Matthew Allen[3], Leslie Braby[1], Harry Hogan[1], Susan Bloomfield[1]. [1]Texas A&M University, USA, [2]UC San Diego, USA, [3]Indiana University School of Medicine, USA

We have previously demonstrated that partial weightbearing (PWB) in simulated Lunar gravity (1/6th-g) does not protect against disuse bone loss seen with tail suspension simulating 0-g. Further, high energy radiation simulating galactic cosmic radiation leads to dramatic reductions in cancellous bone mass. Since exercise is a well-known osteogenic stimulus via strains imparted upon the skeleton by contracting muscles, the purpose of this study was to investigate whether resistance exercise could enhance the recovery of bone lost during 21-d of PWB with and without previous low-dose, high-energy radiation exposure.

Female BALB/cByJ mice (4-mo-old) were assigned to age-matched cage controls (CC) or PWB (G/6). Half were then assigned to acute 0.5 Gy 56Fe, 1 GeV/n radiation (RAD) or SHAM exposure applied 3-d prior to PWB. After 21-d PWB, two G/6 groups were allowed 21-d recovery with normal activity (No EX) or with tower climbing resistance exercise (EX), 5 days/wk. EX mice performed repeat climbs of a 1-m vertical wire-mesh tower with progressively heavier weights attached to the tail. Micro-computed tomography (μCT) and axial compression of L4 spine were performed to assess recovery of bone properties lost from 21-d PWB.

Exercise during recovery from 21-d PWB in non-irradiated mice (EX SHAM) resulted in increased cancellous BV/TV (+21%) and trabecular thickness (Tb.Th)(+16%) over 21-d of recovery. Exercising mice previously exposed to radiation (EX RAD) experienced absolute declines in cancellous BV/TV (-8.9%) and Tb.Th (-11%). Trabecular number, spacing, and connectivity density were not significantly affected by either EX or No EX recovery. Ash weights of L5 vertebrae increased during recovery except in EX RAD mice. There was also a main effect of radiation: after 21-d recovery, SHAM exposed animals had higher ash weights than did EX RAD mice. Mechanical compression testing results follow similar trends as ash weight, but inter-group comparisons did not reach significance.

Radiation exposure caused a decline in measures of bone volume and mineralization in lumbar vertebrae (with and without exercise) after 21-d of PWB and recovery. Based on these data, we conclude that resistance exercise effectively stimulates bone recovery following PWB but not PWB coupled with RAD. Future studies should address how simulated GCR impairs osteoblast responsiveness to mechanical loading imposed by high-intensity muscle contractions during resistance exercise.

The Effect of a Single High Dose of Cholecalciferol on Oxidative Stress in Post-Menopausal Women: a Double Blind Randomized Study. Marcia Regina Scalcon[1], Manuela Sangoi[2], Aline Cocco[3], Priscila Borges[3], Lucas Zottele[3], Karen Koff da Costa[3], Giovani Sartori[3], Jose Mainardi[4], Rafael Moresco[5], Melissa Premaor*[4]. [1]Pos-graduacao em Farmacologia - Universidade Federal de Santa Maria, Brazil, [2]Pos-graduacao em Farmacia - Universidade Federal de Santa Maria, Brazil, [3]Department of Clinical Medicine - Federal University of Santa Maria, Brazil, [4]Federal University of Santa Maria, Brazil, [5]Programa de Pós-Graduação em Farmacologia - Universidade Federal de Santa Maria, Brazil

Vitamin D has been shown to reduce oxidative stress in vitro. Moreover, observational studies have found reduced oxidative stress in individuals with vitamin D deficiency. We hypothesized that a high dose of cholecalciferol might be able to improve oxidative stress in healthy subjects. The aim of our study was to evaluate the effect of a single high dose of cholecalciferol on oxidative stress markers in healthy post-menopausal women. We carried out a double blind randomized clinical assay in 40 post-menopausal women. Women aged >= 60 were recruited from the Catholic Church parish member lists. Those with acute diseases, cancer, renal diseases, and bone diseases, were excluded. Each group (20 subjects) was randomized to receive a single dose of cholecalciferol 300,000 UI (vitD) or placebo (P). Oxidative stress was evaluated by ischemia modified albumin (IMA) and advanced oxidation protein product (AOPP). The outcomes were assessed at days 0, 30, 60, and 90. The variables were transformed to their natural logarithm (LN). Generalized linear model was used to evaluate the differences between the groups. There were no baseline differences between the groups [mean(SD); vitD vs. P, respectively]: age 67.5(4.7) yrs vs. 66.7(6.1) yrs, BMI 27.9 (4.0) kg/m2 vs. 27.8 (4.8) kg/m2, LN IMA -0.64(0.2) vs. -0.61(0.2), and LN AOPP 2.40(0.6) vs. 2.52(0.7). Thirty-nine women completed the study (P=20 and vitD=19) and there were no effects on LN IMA (p=0.99). Nevertheless, LN AOPP was significantly lower at the vitD group (p=0.11) during all the evaluation and at the last visit [0.46(1.2) vs. 1.25(1.2), p=0.03]. In conclusion, a high dose of vitamin D was able to reduce oxidative stress evaluated by AOPP on healthy post-menopausal women.

A Novel Mouse Model of Heterotopic Ossification with Spinal Cord Injury. Xuhui Liu*[1], Heejae Kang[2], Alexis Dang[1], Hubert Kim[1], Robert Nissenson[3], Bernard Halloran[4]. [1]University of California, San Francisco, USA, [2]San Francisco Veterans Affairs Medical Center, USA, [3]VA Medical Center & University of California, San Francisco, USA, [4]VA Medical Center (111N), USA

Introduction: Heterotopic ossification (HO) is a frequent complication following spinal cord injuries (SCI). The prevention and treatment of HO after SCI are challenging. A major barrier to the development of more effective prevention and treatment methods for SCI-induced HO is the lack of clinically relevant animal models. In this study, we sought to develop a novel mouse model of HO by introducing an intramuscular injection of a sub-threshold dose of bone morphogenetic protein-2 (BMP-2) to mice after SCI.

Methods: 3-month-old male C57/BL6 mice were divided into 3 groups: the control group (dorsal midthoracic spine process removal); the laminectomy group (dorsal midthoracic laminectomy); and the spinal cord injury (SCI) group (dorsal midthoracic spinal cord contusion). The animals received 0.5 μg or 0.25 μg of BMP-2 injections in the bilateral quadriceps muscles immediately after surgery/treatment. Two weeks later, animals were sacrificed and the hindlimbs were harvested for μCT scans to evaluate ectopic bone formation.

Results: The mean ectopic bone volumes for the control, laminectomy, and SCI groups received 0.5 μg BMP-2 were 0.1463 mm^3, 1.219 mm^3, and 1.116 mm^3 respectively. One-way ANOVA and Tukey's HSD post-hoc tests showed significant difference between the control and laminectomy groups (p=0.012) and between the control and SCI groups (p=0.021), but not between the laminectomy and SCI groups (p=0.956). In the mice receiving 0.25 μg of BMP-2, no HO was observed in the control group. The mean ectopic bone volumes for laminectomy and SCI groups were 0.615 mm^3 and 0.505 mm^3 respectively. T-test showed no significant difference between these two groups (P=0.808).

Discussion: In this study, we have successfully developed a novel mouse model of SCI-induced HO. This novel murine model will serve as a powerful tool to devise effective prophylactic measures and treatment for HO. One interesting finding in this study is that the mice with laminectomy have significantly increased HO compared to the control mice. Though no functional deficiency was observed, laminectomy may cause neuroinflammation at the midthoracic region of spinal cord. This result implies that neuroinflammation alone may induce HO by sensitizing soft tissues to BMP-2 signaling.

Autocrine role of PGE_2 Signaling in Cell Cycle Regulation of C2C12 Myogenic Differentiation. Chenglin Mo*[1], Lori Wetmore[2], Lynda Bonewald[1], Orisa Igwe[1], Marco Brotto[1]. [1]University of Missouri-Kansas City, USA, [2]William Jewell College, USA

Previously we have shown that addition of exogenous PGE_2 in amounts similar to osteocyte conditioned media (~10 nM) dramatically enhanced C2C12 myogenic differentiation via EP1 and EP4 receptors. Inhibition of these two receptors significantly attenuates myotube development and myotube fusion in C2C12 cells. Cell cycle progression during myoblast proliferation and cell cycle withdrawal after the onset of myogenic differentiation are two important steps in skeletal muscle repair or regeneration. To investigate whether PGE_2 signaling regulates C2C12 proliferation, dose-response studies were performed using five different concentrations of PGE_2 (10nM to 10μM), EP1 agonist 17-phenyl trinor PGE_2 (10nM to 2.5μM), and EP4 agonist CAY10598 (10nM to 2.5μM). The MTT assay confirmed that all these treatments did not alter C2C12 proliferation, since optical densities at 570nm were between $86.9 \pm 5.5\%$ and $101 \pm 3.5\%$ compared with control at 48h of proliferation. However, treatment with EP1 antagonist SC 51322 or EP4 antagonist L161,982 inhibited C2C12 growth by 30% at 48h. Flow cytometry was then used to study the mechanism(s) behind the inhibitory effect of SC 51322 and L161,982. C2C12 cells were first serum-starved with Dulbecco's Modified Eagle Medium (DMEM) containing 1% fetal bovine serum (FBS) for 24h to synchronize cells in G0/G1, which effectively translated into 75-80% cells stuck in G0/G1 phase. Cells were then switched to a complete growth medium (DMEM with 10% FBS) to reinitiate proliferation resulting in the reduction of percentage of cells in G0/G1 phase to 45% at 12h. However, treatment with SC 51322 or L161,982 increased the percentage of cells in the G0/G1 phase by 12% and 10%, respectively. These data suggest that autocrine PGE_2 signaling is important for cell cycle progression from G0/G1 phase. On the other hand, withdrawal from cell cycle (G0/G1 phase arrest) is critical for transition from proliferation to myogenic differentiation. After 24h in differentiation medium (DMEM with 2.5% horse serum), the relative percentages of C2C12 cells in G0/G1 were approximately 75% for control, SC 51322, and L161,982 treated groups, suggesting PGE_2 signaling may not be involved in the regulation of cell cycle withdrawal. In conclusion, whereas exogenous PGE_2 such as from mechanically loaded osteocytes stimulates myogenic differentiation, endogenous low level (~1nM) PGE_2 plays an important role in maintaining C2C12 myoblast proliferation.

Distribution of reference values for components of sarcopenia among postmenopausal women – results from the OSTPRE study. Samu Sjöblom*[1], Juha Suuronen[1], Toni Rikkonen[1], Risto Honkanen[1], Heikki Kröger[2], Joonas Sirola[3]. [1]University of Eastern Finland, Finland, [2]University of Eastern Finland & Kuopio University Hospital, Finland, [3]University of Eastern Finland / Kuopio, Finland

Abstract

PURPOSE: The aim of the study was to determine the distribution of measures of sarcopenia among postmenopausal women.

METHODS: The present study was based on 1) Young reference population (YRP), 197 healthy women aged 20 to 40 years (mean 27.4, SD 6.4) and 2) postmenopausal women from the population-based OSTPRE study (N=397), aged 63 to 75 years (mean 68.6 years, SD 2.9). Both samples underwent weight, height, grip strength (GS), quadriceps strength (QS) and total body DXA (TBDXA) measurements. Upper body muscle quality (UMQ) and lower body muscle quality (LMQ) were determined as upper/lower body muscle strength divided by upper/lower body appendicular muscle mass. Relative skeletal muscle index (RSMI) was determined as appendicular muscle mass divided by square of height. Based on the distributions (SD) of the indices in the YRP, the distributions of GS, QS, MQ and RSMI were determined in the OSTPRE sample. Both study populations were divided into three groups (A<-3SD, -3SD<B>-2SD C > -2SD) based on the distribution of the measures in the YRP.

RESULTS: In the YRP sample, the mean (SD) values were: RSMI 6.5 (0.74) kg/m^2, GS 35.0 (5.0) kPa, QS 466.5 (92.2) Nm, UMQ 8.6 (1.0) kPa/kg and LMQ 34.1 (6.6) Nm/kg, while in the OSTPRE sample these were: RSMI 6.6 (0.8), GS 24.7 (6.0), QS 290.7 (9.9), UMQ 6.1 (1.5) and LMQ 23.3 (8.5), respectively.The cut-off points based on the YRP data .The distribution of the population in the YRP and OSTPRE are presented in table 1. Consequently, the UMQ was mostly affected among the postmenopausal women (30.1% in comparison to 0% in the YRP).

CONCLUSIONS: Among postmenopausal women, upper body muscle quality is mostly deteriorated. UMQ may provide to be a new tool for diagnostics of sarcopenia.

MO0194

Relationships between Leptin, Muscle Fat, and Muscle Strength in Healthy Children. Richard Kremer*[1], Nicole Mueske[2], Arutyun Pogosyan[2], Patricia C. Aggabao[2], Jing Lian[1], Skorn Ponrartana[2], Vicente Gilsanz[2], Tishya Wren[2]. [1]McGill University, Royal Victoria Hospital, Canada, [2]Children's Hospital Los Angeles, USA

Levels of circulating leptin are positively related to body weight and recent studies suggest a negative association between leptin and muscle strength in elderly men and women. We prospectively examined the relation between leptin, muscle fat, and muscle strength in healthy children; 47 girls ages 11.8 $\pm$ 3.1 years; 47 boys ages 11.4 $\pm$ 3.1 years. Measures of leptin were determined using a commercially available RIA kit (Linco Research, Inc., St. Charles, MO); calf musculature density (surrogate of muscle fat) was measured using computed tomography (CT) (Hilite Advantage; GE Medical Systems, Milwaukee, WI); and jumping mechanography was used to measure maximum jumping height as an index of muscle strength using 3D motion capture technology (Vicon Motion Systems, Oxford, UK). As expected, there was a positive relation between leptin and measures of fatness (weight, BMI, % body fat) overall (r's = 0.46, 0.71, 0.79), in boys (r's = 0.46, 0.75, 0.82) and girls (r's = 0.61, 0.76, 0.74), and between leptin and insulin in all children (r = 0.69), in boys (r = 0.76) and girls (r = 0.61); all P's $\leq$ 0.001. As hypothesized, a significant negative correlation was observed between muscle density and leptin and between maximum jumping height and leptin (r's = -0.49 and -0.53, respectively; both P's $<$ 0.0001) which were independent of gender, age, BMI %, and insulin (see table below). These results provide strong evidence that in healthy boys and girls, higher levels of circulating leptin are strongly related to increases in muscle fat and decreases in muscle strength. Although prior studies have shown that muscle strength diminishes in response to muscle fat accumulation, further studies are needed to determine whether the positive association between leptin and muscle fat is mechanistically related.

The Effect of Vitamin D Supplementation on Physical Performance and Activity in non-Western Immigrants. Mirjam Oosterwerff[1], Rosa Meijnen*[1], Natasja van Schoor[2], Dirk Knol[2], Mark Kramer[1], Mireille van Poppel[3], Paul Lips[4], Elisabeth Eekhoff[4]. [1]Department of Internal Medicine, Endocrine Section, VU University Medical Center, Netherlands, [2]Department of Epidemiology & Biostatistics, VU University Medical Center, Netherlands, [3]Department of Public & Occupational Health, EMGO Institute for Health & Care Research, VU University Medical Center, Netherlands, [4]VU University Medical Center, The Netherlands

Objective: Physical inactivity has been identified as the fourth leading risk factor for global mortality, while overweight and obesity are in the fifth place. Both factors are more prevalent among non-western immigrants in the Netherlands, compared to the indigenous population. Vitamin D deficiency, associated with poor physical performance, is highly prevalent in non-western immigrants. The aim of this study was to assess the supplementation effect of vitamin D on physical performance, exercise capacity and daily physical activity in vitamin D deficient, overweight non-western immigrants.

Methods: A randomized, double-blind, placebo-controlled trial primarily designed for glucose tolerance parameters was conducted. Eligibility criteria included overweight (BMI $>$ 27 kg/m^2), 25-hydroxyvitamin D (25(OH)D) $\leq$ 50 nmol/l, age 20- 65 yr, an impaired fasting glucose (IFG 5.6-6.9 mmol/l) and/or impaired random serum glucose (IRG: 7.8-11 mmol/l). A total of 130 participants received 1200 IU vitamin D3 or placebo. All participants received 500 mg calcium as calcium carbonate per day for four months. Change in physical performance score, six minutes walk test and average daily physical activity by questionnaire and accelerometer were measured. Intention-to-treat analyses were performed for each follow-up moment using linear mixed models. Next, per-protocol analyses were conducted.

Results: There was no significant effect on physical function. There was, however, an (non-significant) improvement of 7 meter in the distance walked on the 6-minutes walk test in the intervention group, compared to the placebo group. This difference increased to 14 meter in per-protocol analysis (p=0.17). The percentage of participants meeting international physical activity guidelines was extremely low.

Conclusions: Vitamin D supplementation did not significantly improve physical performance, exercise capacity or physical activity. However, especially in per protocol analysis, we found an (non-significant) improvement of exercise capacity. A promising result, since all participants were overweight and did not improve their overall activity levels.

Wnt Signaling Regulates Osteoblast Growth through miR-27a. Mohammad Hassan[1], Bhaskar Roy*[2]. [1]University of Alabama, USA, [2]School of Dentistry, University of Alabama, USA

MicroRNA (miR) are evolutionarily conserved non-coding RNA of ~22 nucleotides that regulate gene expression by facilitating translational repression and mRNA degradation. Recently, several groups reported that miR-27a is a key miRNA in controlling cell proliferation and several forms of cancer pathogenesis. Wnt-β-catenin cellular signaling is also equally important in regulating numerous biological processes, including cellular growth and cancer. However, the mechanism(s) of

miR-27a regulation for cell growth is not clear. In this study we observed that Wnt signaling directly upregulates miR-27a expression and over expression of miR-27a in MC3T3-E1 also enhanced the expression of Wnt activators TCF and LEF but suppressive for GSK3β, DKK1 and APC expression, the potential antagonists of Wnt pathway. These findings reinforce a positive proliferative ambience involving both miR-27a and Wnt signaling. MiR-27a gain of function in pre osteoblast MC3T3-E1 cells increases RB1 phosphorylation that promotes G1-S cell cycle transition and activates cell growth while miR-27a loss of function decreases RB1 phosphorylation leading to cell cycle arrest. Immunoblot analysis of miR-27a stable MC3T3 cells showed enhanced expression for CyclinD1 and c-Myc. Increased association of histone H3K4 (activating) and decreased recruitment H3K27 (repressive) on c-Myc promoter, suggesting a significant enhancement of c-Myc gene transcription in miR-27 overexpressed cells. Cell cycle synchronization assay with nocodazole block and release in miR-27a stable cell lines revealed that c-Myc, Cyclin D1 expression peaked around 6hr after release. Western blot analysis with anti phospho RB1 antibody indicates a sharp increase at 6hrs after release. Therefore, our findings suggest that miR-27a gain of function induces the cell to progress from G1 to S phase by CyclinD1 induced Rb1 phosphorylation where c-Myc is maintaining increased level CyclinD1 expression. Taken together, our results establish a key role for Wnt signaling-miR-27a regulatory circuit to promote osteoblast cell cycle during proliferation by RB1 phosphorylation and c-Myc amplification. A feed forward and feedback loop between Wnt and activated miR-27a most probably inducing c-Myc and CyclinD1 expression to promote Rb1 phosphorylation and releasing E2F from Rb1 sequestration that constantly propels and maintains the cells in proliferation.

MO0197

Adipogenic and osteogenic differentiation/conversion in 3D collagen gels as a model for osteoporosis research. Solange Le Blanc*[1], Meike Simann[2], Norbert Schuetze[2], Tatjana Schilling[3]. [1]Universitat Wurzburg, Germany, [2]University of Wuerzburg, Orthopedic Center for Musculoskeletal Research, Germany, [3]University of Wuerzburg, Germany

It has been suggested that one factor contributing to the bone loss and the accumulation of fat tissue in bone marrow of osteoporotic patients is the misregulation in the differentiation processes of bone marrow mesenchymal stem cells (BM-MSCs). An increase of adipogenesis in BM-MSCs as well as the conversion of pre-osteoblasts into adipocytes may contribute to this fatty degeneration and bone loss. There is increasing evidence that the characteristics and behaviour of cells may greatly differ in 3D versus 2D environments and therefore the need to move from 2D culture systems to 3D is becoming more relevant. Since type I collagen is the major component of the extracellular matrix of bone, 3D culture using collagen could better mimic the native bone marrow environment, allowing the study of factors that modulate adipogenesis and osteogenesis of BM-MSCs in conditions closer to the native physiology.

In this work, we investigated the adipogenic and osteogenic differentiation of primary human BM-MSCs embedded in 3D type I collagen gels, as well as the conversion capacity of the population after switching of the differentiation cocktail. Two different formats were studied, floating and attached collagen gels. Differentiation/conversion was analysed by histochemical staining with Oilred O and Alizarin Red S.

As expected, in the presence of adipogenic cocktail BM-MSCs cultured in type I collagen gels underwent adipogenesis as confirmed by Oilred O staining of lipid droplets. Similarly, after osteogenic induction BM-MSCs produced mineralized matrix stained by Alizarin Red S. Conversion was also possible in collagen gels, i.e. adipocytes were detected in BM-MSCs previously induced to differentiate into osteoblasts and vice versa.

Despite reports on type I collagen enhancing osteogenesis and inhibiting adipogenesis in BM-MSCs, our study shows that floating and attached 3D type I collagen gels allow for osteogenesis and adipogenesis of BM-MSCs under chemical induction as well as for conversion. Our *in vitro* 3D models of BM-MSC cultivation better mimic the spatial tissue environment and will therefore aid to understand the osteoporosis-associated misregulation of osteogenesis and adipogenesis *in vivo*.

Analysis of Human *SOST* Gene Expression Using Large Minigenes Reveals the Potential for Multiple Enhancers. Hillary St John*, Sydney Hansen, Nancy Benkusky, Mark Meyer, J. Pike. University of Wisconsin-Madison, USA

Sclerostin (SCL) is an osteocyte-derived negative regulator of bone formation. Transcribed from the *SOST* gene, SCL inhibits osteoblastogenesis via blockade of LRP5/6 co-receptors and antagonism of the Wnt pathway. SCL is a promising therapeutic target for low bone mass diseases and several neutralizing antibody therapies that suppress SCL are in development. Physiologically, the anabolic effects of both mechanical strain and PTH (and forskolin) are known to be involved in suppression of SCL levels. In the studies presented here, we conducted a high throughput screen to identify novel regulators of *SOST* expression and then characterized the distal enhancer regions that mediated the regulation by several of these compounds. We first created a series of stable cell lines that contained either the full-length or enhancer-mutated minigene versions of the *SOST* gene locus in a MC3T3-E1 cell host. Each minigene contained an IRES luciferase reporter/neomycin selectable marker cassette inserted into the 3' UTR. As anticipated, the full-length minigene was upregulated by BMP-2 and downregulated by forskolin, both known regulators of *SOST*. A screen of the full length *SOST* minigene stable MC3T3-E1 cell line with over 2000 compounds revealed regulators with both positive and negative activity. Negative-regulatory compounds for *SOST* included Wnt3a, $1,25(OH)_2D_3$, OSM, and $TGF\beta_1$, as well as a number of natural and synthetic glucocorticoids. To explore the mechanisms by which these compounds regulated *SOST* expression, we examined their ability to induce or suppress *SOST* mutant minigenes containing deletion of the promoter proximal enhancer (-1/-2 kb), ECR2, or ECR5, or two point mutations in the MEF2 binding site of ECR5 (ECR5/MEF2). Previous reports suggest that both PTH and $TGF\beta_1$ effects of *SOST* are mediated through ECR5 and that the action of PTH is mediated specifically via the MEF2 binding site at ECR5. Consistent with these reports, the suppressive effects of forskolin were abrogated following both ECR5 deletion and ECR5/MEF2 mutation. In contrast, we found that $TGF\beta_1$ negatively regulated *SOST* and that neither ECR5 nor ECR5/MEF2 was involved. Surprisingly, none of these four mutations abrogated the suppressive effects of Wnt3a, $1,25(OH)_2D_3$, OSM, dexamethasone, or $TGF\beta_1$, or the positive effects of BMP-2. These data suggest that with regard to regulation it is clear that in order to understand the effects of regulators other than PTH we need to move beyond ECR5.

Clopidogrel enhances periodontal repair through decreased inflammation. Denise Spolidorio*[1], Joao Paulo Steffens[2], Carlos Rossa Junior[2], Dana Graves[3], Luís Carlos Spolidorio[2], Leila Coimbra[4]. [1]Araraquara Dental School, São Paulo State University-UNESP, Araraquara, Brazil, [2]Araraquara Dental School, São Paulo State University-UNESP, Brazil, [3]University of Pennsylvania, School of Dental Medicine, USA, [4]University of São Paulo State, Brazil

Platelet degranulation causes the release of an array of biological mediators including chemokines, cytokines and growth factors that can modulate the repair process. We hypothesized that platelet inactivation induced by drugs might interfere with periodontal repair in experimental periodontitis by suppressing the release of biological mediators from platelets at the site of injury. To evaluate the effects of antiplatelet drugs on experimental periodontal repair 60 rats were randomly assigned to 6 groups (n=10) and ligatures were placed around lower first molars of three groups. The other three groups were not subjected to the induction of periodontal disease and were used as negative controls. Ligatures were removed after 10 days of periodontitis induction and aspirin (Asp) (30 mg/kg) or clopidogrel (Clop) (75 mg/kg) was given intragastrically once daily for 3 days. Periodontal tissue was assessed by the measurement of CXCL12, CXCL4, CCL5 and PDGF by ELISA; histomorphometric analysis of PMN infiltration, attachment loss, bone loss and osteoclast numbers and quantification of blood vessels by imunnohistochemistry.

During periodontal repair gingival content of CCL5 was significantly decreased and CXCL12 increased when compared to negative control groups. Asp and Clop decreased CXCL12 expression but only Clop decreased CXCL4 and PDGF-AB content. Clop treatment appears to have improved the repair process as shown by an increase in blood vessel number (Factor VIII+), a reduced polymorphonuclear leukocyte (PMN) count, and decreased attachment and bone loss. Clop also impaired bone resorption demonstrated by a significant decrease in the osteoclast number (TRAP+) in animals submitted or not to periodontal repair.Systemic administration of Clop during 3 days improved the repair process associated with experimental periodontal disease.

MO0200

Demineralized Bone Matrix Concurrently Induces Vascular Tissue Formation and Endochondral Bone Formation Adjacent to the Periosteum. Beth Bragdon*[1], Sherif Aly[2], Anthony De Giacomo[2], Elise Morgan[3], Louis Gerstenfeld[1]. [1]Boston University School of Medicine Department of Orthopaedics, USA, [2]Boston University School of Medicine, USA, [3]Boston University, USA

Introduction: The osteoinductive property of demineralized bone matrix (DBM) is believed to arise from bone morphogenetic proteins (BMPs) that drive osteogenesis in mesenchymal stem cells (MSCs). It is thought that the MSCs express vascular endothelial growth factor A (VEGFA), which in turn attracts endothelial cells that further promote BMP expression. However, the exact molecular factors in DBM that are needed for *de novo* bone growth and crosstalk between osteogenesis and angiogenesis during DBM-induced bone formation are poorly understood.

Methods: HumanDBM was obtained with an MTA from Medtronics Inc. Fifty milligrams was implanted adjacent to the periosteal surface of the femur of B6,129S7-$Rag1^{tm1/MOM}$/J. Ectopic bone formation was followed for 31 days. Micro-CT quantified new bone formation, and vascular tissue was assessed by Microfil perfusion followed by micro-CT. RNA was isolated from the implant, femur, and surrounding

muscle at various time points (2-31 days). RT-qPCR was used to quantify mRNA expression describing stem cell recruitment (Nanog, Oct4, Sox2), chondrocyte (Aggrecan and Collagen10a), osteoblast/osteocyte (Osteocalcin and SOST), and vascular (VEGFA, Ve-Cadherin, and SMA) development.

Results: Extensive *de novo* bone and vascular tissues were induced by the DBM implant (Fig. 1). The volume of mineralized tissue increased from day 12 to day 24, after which the levels were constant. Blood vessel formation was detected within the DBM implant. Molecular assessment (Fig. 2) showed peak expression of stem cell markers at the implant within the first 4 days, followed by peak expression for chondrocytes at day 8 and osteoblasts/osteocytes at day 16. VEGFA and SMA expression were concurrent with the expression of the stem cell markers, while endothelial cell markers showed peaks at 2 and 8 days. In contrast to this dynamic mRNA expression for the various stages for endochondrogenesis in the implant, only basal levels of mRNA expression were observed in the femur itself.

Discussion: DBM implanted on the femur concurrently initiated vascular and endochondral bone development. Interestingly the femur itself did not respond to the DBM; rather, stem cells appear to arise from the periosteum. The implant site appeared to be the source for VEGFA. These data suggest a population of SMA-positive cells express VEGFA, facilitating the invasion of endothelial cells into the implant site, with blood vessels developing within the *de novo* ectopic bone.

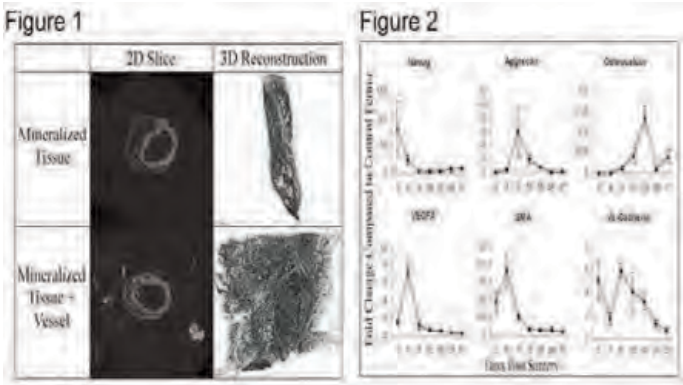

Figure 1. Micro-CT 2D slice (left) and 3D reconstructed (right) image at day 24. Top panel shows the 2D slice of the native and *de novo* bone. 3D reconstruction shows only the newly formed mineralized tissue (cortex removed from the image). Bottom panel depicts the blood vessels and the native and *de novo* bone. **Figure 2.** Expression of selected genes across time at the implant site.

Enhanced bone healing with local delivery of a GSK3β inhibitor. Masahiko Sato*[1], Nicoletta Bivi[2], Matthew Hamang[3], Lowell Gibson[2], Qing Qiang Zeng[2], Ricky Cain[3], Mary Adrian[3], Jonathan Lucchesi[3], Thomas Engler[2], Christian Clarke[2], Timothy Richardson[2], Yanfei Ma[2]. [1]Lilly Research Labs, USA, [2]Eli Lilly & Co., USA, [3]Musculoskeletal Research, Lilly Research Laboratories, USA

GSK3β inhibitors were shown previously to increase bone mass and to enhance fracture repair in rodents; therefore we explored the feasibility of local delivery bone healing with a bisarylmaleimide as a strategy to enabling skeletal efficacy while minimizing toxicity. The GSK3β inhibitor was shown to potently enhance mineralization in a dose-dependent manner until 0.32 nM when rat bone marrow stromal cells were cultured in osteogenic media containing ascorbate and β-glycerophosphate for 5 days. However, at doses above 1.6 nM, reduced mineralization was observed. Quantification of DAPI-stained nuclei showed no reduction in cell number at the higher doses; however, viability assays based on the dye formazan suggested cytotoxicity concerns. The bisarylmaleimide was then formulated in PLGA to control the rate of inhibitor release in 2 rat cortical defect models. Cancellous bone healing was evaluated in young (14 week old) male rats (Sprague-Dawley) which had 2 mm holes drilled through the secondary spongiosa of both proximal tibia before injection of 3, 10, or 30 μg of bisarylmaleimide in 50% PLGA/50%NMP, using positive displacement pipettes. After 3 weeks post-surgery, μCT analyses showed dose-dependent increases in cancellous BMD, cortical BMC, and total BMD relative to vehicle controls. Cortical bone healing was evaluated of the same formulations in mature (8 month old) osteopenic (Ovx at 6 months) rats in which 2 mm holes were drilled into both femura before pipetting of compounds into the cortical defect. Longitudinal μCT analyses showed that the high dose increased whole femur BMC at the cortical defect site from 3 to 5 weeks post-surgery. Interestingly, whole femur BMD decreased as marrow area, cortical area and total area increased faster than BMC. μCT confirmed considerable bone formation activity, but outside the confines of the cortical defect. In summary, these data taken together suggest interesting potential for local delivery of a GSK3β inhibitor at bone healing sites to significantly enhance repair efficacy while reducing systemic exposure and safety concerns.

MO0202

Frizzled-4 expression by the mature osteoblast is required for normal trabecular bone acquisition. Ryan Riddle*[1], Julie Leslie[2], Jeremy Nathans[1], Thomas Clemens[2]. [1]Johns Hopkins University School of Medicine, USA, [2]Johns Hopkins University, USA

Initiation of Wnt/β-catenin signaling requires the interaction of Wnt ligands with a seven trans-membrane frizzled (Fzd) receptor. The specific biological roles of these receptors in bone, however, remain poorly defined, despite the well-accepted role of Wnt signaling in skeletal development. To begin to define the contribution of individual frizzled proteins to osteoblast function, we profiled the expression of all 10 mammalian receptors in calvarial osteoblasts. While the expression of Fzd8 and Fzd9 increased modestly during *in vitro* differentiation, Fzd4 was the most highly up-regulated, with mRNA levels increasing more than 7-fold as cells matured. To determine the function of this receptor in bone, mice lacking Fzd4 (ΔFzd4) in mature osteoblasts were generated by crossing $Fzd4^{flox}$ mice with mice expressing Cre-recombinase under the control of the human osteocalcin promoter. Trabecular bone architecture in young ΔFzd4 mice (3weeks) was comparable to control littermates, but the mutant mice failed to acquire normal amounts of trabecular bone, as bone volume in the distal femur was reduced by approximately 25% when compared to controls at both 6 and 12 weeks of age. By contrast, cortical bone morphology was unaltered in Fzd4 mutants. Osteoblast numbers per bone perimeter were higher in ΔFzd4 mice relative to controls, but the mineralizing surface was decreased and the mineralization lag time was increased, suggestive of a defect in the mineralization process. Consistent with this idea, matrix calcification was impaired in cultures of primary calvarial osteoblasts rendered deficient for Fzd4 and the expression levels of markers of osteoblast maturation, including Runx2, Sp7, and Bglap, were uniformly decreased when compared to cultures of control osteoblasts. Despite a compensatory increase in the expression of other frizzled receptors, including Fzd8, which acts redundantly with Fzd4 in other tissues, Fzd4-deficient osteoblasts also exhibited an impaired ability to respond to Wnt ligands. In this regard, the ability of Wnt3a to inhibit β-catenin phosphorylation and stimulate Axin2 expression was reduced in the mutant osteoblasts relative to controls. To our knowledge, these data represent the first attempt to examine the function of a Fzd receptor in bone in a tissue-specific manner, and suggest that Fzd4 exerts envelope-specific effects on bone structure that are indispensible during the acquisition of trabecular bone mass.

IGF-1 enhances osteoblastic function by stimulating oxidative phosphorylation: Insights from a spontaneous mutation in the *Irs1* gene. Anyonya Guntur*[1], Victoria Demambro[1], Clifford Rosen[2]. [1]Maine medical center research institute, USA, [2]Maine Medical Center, USA

We previously showed that Insulin Like growth factor -1 (IGF1) and its downstream signaling system play a key role in osteoblast differentiation. To understand the potential mechanisms involved in IGF1 induced differentiative function we studied a spontaneous mouse mutant that has a single nucleotide deletion in Insulin receptor substrate 1 (*Irs1*) a key adaptor protein involved in IGF1 signaling. The characterization of the metabolic and skeletal phenotype of this mutant was done on two different genetic backgrounds in mice C3-$Irs1^{sml}/Irs1^{sml}$ and B6-$Irs1^{sml}/Irs1^{sml}$. Mice with this mutation have decreased body weight, lower % fat mass and decreased energy expenditure. Comprehensive skeletal phenotyping revealed that mutant mice have very low bone mass and reduced bone formation by histomorphometry despite equal numbers of osteoblasts compared to wildtype (WT) mice. Developmentally the bones that form through endochondral and intramembranous ossification of the mutant mice are smaller. Both the hindlimbs and the skull base have shorter bones with smaller hypertrophic zones. We could identify a loss of IRS1 protein in both osteoblasts and chondrocytes suggesting that the defects are because of loss or attenuation of IGF1 signaling in the mutant limbs. Since the bone formation rates in the mutant mice are low despite adequate numbers of osteoblasts (which is similar to deletion of the IGF1R in late osteoblasts), we examined the metabolic activity of calvarial osteoblasts by studying their oxygen consumption rates (Oxidative phosphorylation,OCR) using the Seahorse XF24. Calvarial osteoblasts from both WT strains (i.e. *C3H/HeJ* and *C57BL/6J*) have increased OCR during differentiation compared to non differentiating cells. On the other hand, mutant calvarial osteoblasts have a markedly blunted OCR response during differentiation compared to WT calvarial osteoblasts. Mechanistically, we observed a decrease in IGF1 induced protein synthesis in the mutant osteoblasts as evidenced by decreased pAKTser473 and pP70S6K in response to IGF1 stimulation. In sum these data suggest that an intact IGF1 signaling pathway is necessary not only for osteoblast differentiation but also for the "work" required to induce collagen synthesis and matrix mineralization.

In vivo Microenvironment pH of biomaterials influence their performance in osteoporotic bone defect repair. Wenlong Liu*[1], Haobo Pan[2], Ting Wang[1], Jianbin Wu[3], Jiang Chang[4], William Lu[1]. [1]The University of Hong Kong, Hong Kong, [2]Shenzhen Institutes of advanced technology, Chinese academy of sciences, China, [3]The University of Hong Kong Shenzhen Hospital, China, [4]Shanghai Insitute of Ceramics, Chinese Academy of Sciences, China

Traditional characterization methods to evaluate the performance of orthopedic biomaterial in repairing bone defect mainly focus on mechanical behavior, degradation properties, surface chemistry and so on. However, though researchers have realized that the degradation products of implants should be non-toxic, the changes and influence of in vivo microenvironment pH (Micro-pH) brought by their degradation on bone remodeling has often been neglected. The aim of this study is to monitor the relationship between the repairing performance of implants and its Micro-pH, and propose the new idea to take Micro-pH as a new evaluation index.

Different biomaterials powders are filled into rat models of osteoporotic bone defect. The Micro-pH surrounding biomaterials-biology interface was monitored with needle combination pH microelectrodes, at different phases of healing. Micro-CT scanning, goldner's trichrome and TRAP staining were employed to detect the performance of specific implants. However, besides Micro-pH, other parameters, such as beneficial element, would influence in vivo performance of implants. So, the in vitro experiments with strickly controlled variables were performed to examine the effect of pH on oBMSCs and RAW 264.7 cells.

After TCP, CS and Sr-CS implantation, the Micro-pH surrounding bone defect area increased immediately (TCP: 7.77 ± 0.15; CS: 8.17 ± 0.06; Sr-CS:9.16 ± 0.10; n=4). CS and Sr-CS showed higher initial Micro-pH compared with TCP group (Fig.1). A higher osteoid formation activity and late response of TRAP-positive cells in vivo were observed in CS and Sr-CS groups. In vitro results shows that, alkaline environment inhibit oBMSCs proliferation activity, while stimulates their osteogenesis differentiation potential. On the other hand, the proliferation efficiency of RAW 264.7 osteoclast precursor, and their capability of forming multi-nucleus osteoclasts were inhibited under alkaline culture condition.

Our results indicate that, though other parameters would influence the performance of orthopedic implants, weak microenvironment pH is also an indispensible factor, which is vital to ameliorate the imbalance between bone formation and absorption under osteoporotic bone remodeling microenvironment. Besides, needle combination pH microelectrode can be employed to detect biomaterials in vivo Micro-pH, and could help to find specific suitable Micro-pH condition for specific biomaterials.

Osteoblastic p38alpha MAPK Signaling Mediates Ovariectomy-Induced Bone Loss by Stimulating Interleukin-6 Expression. Cyril Thouverey*, Joseph Caverzasio. Service of Bone Diseases - Dpt of Internal Medicine Specialties - University Hospital of Geneva, Switzerland

Selective p38alpha inhibitors were found to prevent bone loss induced by estrogen deficiency but implicated mechanisms remained to be identified. The p38 MAPK pathway was suggested to influence bone resorption at different regulatory levels. In osteoblasts, p38alpha was reported to stimulate the production of osteoclastogenic interleukin-6 and Rankl in response to various bone-resorptive agents *in vitro*. Therefore, we investigated whether p38alpha in osteoblasts may contribute to ovariectomy-induced bone loss in mice.

Mice lacking *p38alpha* in osteoblasts (*Ocn-Cre;p38alpha$^{f/f}$*) and their control littermates (*p38alpha$^{f/f}$*) were either sham-operated or ovariectomized at 12 weeks of age. Their bone phenotypes were assessed 6 weeks after operations by dexa, microCT, histomorphometry and gene expression analyses (n=7 per group). Data were analyzed by two-way ANOVA and *post hoc* analyses were performed using the Holm-Sidak method.

Ovariectomy caused a decrease in bone mineral density in the spine (-13.1 %; $p<0.001$ versus sham) and to a lesser extent in the femur (-1.8 %; $p<0.001$ versus sham) of control mice but not in *Ocn-Cre;p38alpha$^{f/f}$* mice (+12.7 % in the spine; +8.1 % in the femur; $p<0.01$ versus *p38alpha$^{f/f}$*). Ovariectomy decreased vertebral cancellous bone volume (-45.8 %; $p<0.01$ versus sham), trabecular thickness (-16 %; $p<0.01$) and trabecular number (-20.6 %; $p<0.01$) in control mice but not in *Ocn-Cre;p38alpha$^{f/f}$* mice, indicating that mice lacking *p38alpha* in osteoblasts were protected from ovariectomy-induced bone loss. Consistent with this, ovariectomy caused significant increases in osteoclast surface (4-fold), osteoclast number (3-fold) and serum level of CTX (1.4-fold) in *p38alpha$^{f/f}$* mice but not in *Ocn-Cre;p38alpha$^{f/f}$* mice. Moreover, ovariectomy induced a 2-fold increase in interleukin-6 expression in the long bones of *p38alpha$^{f/f}$* mice ($p<0.05$), whereas expression of this osteoclastogenic cytokine remained unchanged in *Ocn-Cre;p38alpha$^{f/f}$* mice. Finally, tumor necrosis factor alpha, interleukin-1 and CD40 ligand which are overproduced in the bone marrow under estrogen deficiency, stimulated interleukin-6 expression in control osteoblasts but not in those lacking *p38alpha in vitro*.

Our findings indicate that the p38alpha MAPK signaling in osteoblasts mediates ovariectomy-induced bone loss by upregulating interleukin-6 expression.

Protein Tyrosine Kinase 7 (PTK7): A Novel "Molecular Switch" Regulating Differentiation Fate of Human Skeletal (Mesenchymal) Stem Cells into Osteoblasts versus Adipocytes. Abbas Jafari*[1], Majken S. Siersbæk[1], Kenneth Larsen[2], Matthias Dobbelstein[3], Moustapha Kassem[1]. [1]Odense University Hospital, Denmark, [2]Syddansk Universitet, Denmark, [3]Göttingen Center of Molecular Biosciences, Faculty of Medicine, University of Göttingen, Germany

Intracellular signaling proteins (kinases) that act as molecular switches regulating human skeletal (mesenchymal) stem cells (hMSC) differentiation into osteoblasts (OB) versus adipocytes (AD) are not known. Thus, we performed RNAi-based screening of the human Kinome, using Silencer® V3 Human Kinase siRNA Library against 800 known kinases (n=3 siRNA per individual kinase) and identified Protein Tyrosine Kinase 7 (PTK7) as regulating hMSC differentiation, with no effects on cell proliferation. In the follow up experiments, siRNA knock-down of PTK7 in hMSC enhanced OB differentiation upon *in vitro* OB induction, evidenced by increased alkaline phosphatase (ALP) activity, gene expression of osteoblastic markers: ALP, osteocalcin, and collagen type I and *ex vivo* matrix mineralization. On the other hand, PTK7-deficient hMSC exhibited impaired AD differentiation when cultured under AD induction, evidenced by reduced expression of adipogenic markers: PPARγ, C/EBPα, PLIN, ADN, and AP2 as well as reduced formation of mature adipocytes. Stable over-expression of PTK7 in hMSC, led to opposite effects with reduced osteoblast differentiation and enhanced adipocyte differentiation. To identify down stream targets, PTK7-deficient hMSC exhibited increased canonical Wnt signaling, measured by TCF dual luciferase reporter assay, that was associated with increased expression of Wnt target genes: CCND1 and NKD1. In contrast, decreased Wnt signaling and CCND1 and NKDI gene expression were observed in PTK7-overexpressing hMSC. To test the effect of *in vivo* targeting of PTK7 in a pre-clinical *in vivo* bone formation model, shRNA-based PTK7-deficient hMSC exhibited increased bone formation when implanted subcutaneously in immune deficient mice. Our results demonstrate that PTK7 is a molecular switch regulating hMSC differentiation balance between OB and AD through changes in canonical Wnt signaling and can be targeted to enhance *in vivo* bone formation.

MO0207

Role of Menin in Bone Development. Ippei Kanazawa*[1], Lucie Canaff[2], Aarti Angrula[2], Jingjing Li[2], Monzur Murshed[2], Geoffrey Hendy[3]. [1]Shimane University Faculty of Medicine, Japan, [2]McGill University, Canada, [3]McGill University, Royal Victoria Hospital, Canada

Background: The tumor suppressor menin is widely expressed including in bone. Homozygous *Men1* inactivation in mice is embryonic lethal at 12 days and the small fetuses exhibit cranial and facial defects consistent with a role for menin in bone formation. The heterozygous *Men1* phenotype mirrors that of the human multiple endocrine neoplasia type 1 (MEN1) with normal development and endocrine tumors developing later in life. Although previous *in vitro* studies showed that menin has important roles in the osteoblast lineage, little is known about the *in vivo* role of menin in the skeleton. Methods and Results: We conditionally inactivated *Men1* in osteoblasts by crossing *Osteocalcin*-Cre mice with those having a floxed *Men1* gene to generate mice lacking menin in differentiating osteoblasts. Nine-month-old *Men1$_{ob}^{-/-}$* mice displayed significant reduction in bone mineral density by dual-energy X-ray absorptiometry and in trabecular bone volume and cortical bone thickness by micro-computed tomography (μCT) compared to their control littermates. By histomorphometry, bone volume/total volume, osteoblast and osteoclast number, as well as mineral apposition rate (MAR) were significantly reduced whereas osteocyte number was increased. Primary calvarial osteoblasts of *Men1$_{ob}^{-/-}$* mice proliferated more quickly but had deficient mineral apposition and alkaline phosphatase activity. The expression of osteoblast marker genes, BMP-2, Runx2, Osterix, Dlx5, type I collagen, and osteocalcin was all decreased with reduced responsiveness to TGF-β and BMP-2 defined by promoter/reporter assay. Moreover, cyclin-dependent kinase inhibitor expression was reduced, whereas cyclin dependent kinase expression was increased. The gene expression of Phex and sclerostin was significantly increased, while that of RANKL was decreased. In contrast to the *Men1$_{ob}^{-/-}$* mice, 12-month-old transgenic mice specifically overexpressing a human menin cDNA in osteoblasts had a gain of bone mass by μCT and histomorphometry with increased MAR and osteoblast number. Conclusion: Taken together, depletion of menin in the osteoblast leads to decreased bone formation by reducing TGF-β/BMP-2 responsiveness and increasing sclerostin expression as well as impaired bone remodeling, resulting in a reduction in trabecular and cortical bone whereas overexpression increases bone mass by enhancing bone formation. Therefore, maintenance of menin expression and function in the osteoblast is important to avoid decreased bone mass.

Syndecan-2 Controls the Fate of Osteoblast and Osteoclast Precursors Cells in the Bone Marrow and Modulates Wnt Signaling in Mice. Rafik MANSOURI*[1], Caroline Marty[2], Pierre Marie[3], Dominique Modrowski[2]. [1]INSERM, France, [2]INSERM U606, France, [3]Inserm Unit 606 & University Paris Diderot, France

Syndecan-2 (Sy2) is a proteoglycan that modulates growth factor activity as well as attachment to and assembly of the matrix. We previously showed that Sy2 controls apoptotic pathways in osteosarcoma cells. To determine the role of Sy2 in normal bone, we analyzed the effects of 2.3 kb Col1A1 promoter-driven Sy2 overexpression on the bone phenotype in transgenic (TG) mice. Sy2 overexpression was found in mature osteoblasts and bone marrow (BM) stromal cells. TUNEL staining showed that the number of apoptotic cells was increased in BM of TG mice compared to wild type (WT) mice. Histomorphometric analyses showed that the number of TRAP+ cells was strongly decreased in TG compared to WT mice. Ex vivo studies showed that the number of TRAP+ cells in TG BM-derived cells was lower than normal when cultured in the presence of RANKL and M-CSF to promote osteoclast differentiation, or when cultured in the presence of vitamin D and ascorbic acid to promote osteoblast-mediated osteoclast differentiation, demonstrating a defect in osteoclast precursor differentiation in the BM of TG mice. Interestingly, the fibroblast-like layer was missing in TG BM cell cultures, suggesting an alteration of the stromal cell population. In support of this hypothesis, RT-qPCR analyses showed a striking decrease in RANKL mRNA in BM of TG mice compared to WT mice. Additionally, BM cell viability and proliferation were reduced in TG mice compared to WT mice, as assessed by crystal violet and BrdU incorporation, and the number of fibroblast-like colony-forming units. However, the in in vitro osteoblastic differentiation capacity of BM cells, and the activity of mature osteoblasts (mineral apposition rate) were unchanged in TG mice. Collagen type 1, RUNX2 and alkaline phosphatase mRNA expression also did not differ in bone marrow of TG and WT mice. In contrast, the expression of Wnt effectors was altered. The expression of Wnt3a, Wnt11 and bcatenin were down-regulated and DKK1 was increased. Consistently, crossing TG mice with mice bearing the Wnt reporter system (TOP-GAL mice) demonstrated that Sy2 overexpression decreased Wnt/βcatenin signaling. Altogether, these results show that Sy2 overexpression in osteoblastic cells induces the death of proliferating osteoblast precursors and thereby alters RANKL-mediated osteoclast precursor cell differentiation. Furthermore, the Sy2-mediated alteration of the osteoblast precursor fate is related to alteration of Wnt/βcatenin signaling.

Systemic Sclerostin Antibody Treatment Reduces Alveolar Bone Loss in Rice Rats with Active Periodontitis. Jose Aguirre*[1], Donald Kimmel[2], Mohammed Akhter[3], Kathleen Neuville[1], Carley Trcalek[1], Alicia Leeper[1], Alyssa Williams[1], Mercedes Rivera[4], Lakshmyya Kesavalu[4], Hua Zhu (David) Ke[5], Min Liu[5], Thomas Wronski[1]. [1]University of Florida, USA, [2]Kimmel Consulting Services, USA, [3]Creighton University Osteoporosis Research Center, USA, [4]Department of Periodontology & Oral Biology, College of Dentistry, UF, USA, [5]Amgen Inc., USA

Inhibition of Sclerostin (Scl), a negative modulator of the Wnt/β-catenin pathway, by a neutralizing antibody (SAB) stimulates bone formation and increases bone mass. Moderate or worse periodontitis (PD) is prevalent in one-third of dentate US adults. Mechanical debridement is the principal method proven to slow PD-related alveolar bone loss (ABL). No known bone-active systemic medication reduces the rate of ABL in animals or humans with active PD. Rice rats (*Oryzomys palustris*) develop spontaneous PD that requires no local manipulation, and is accelerated by a high sucrose/casein (HSC) diet. We hypothesize that systemic treatment with SAB reduces PD-related ABL in rice rats. At age 28 days, male rats (n=12-16/grp) were fed standard (STD) or HSC diets during an 18wk PD-establishment period (PEP). Rats then began an 8wk PD-treatment period (PTP). During the PTP, rats continued their PEP diets (STD-STD and HSC-HSC). In addition, half that were fed HSC during the PEP were switched to STD (HSC-STD) to remove the acceleratory stimulus for PD. The STD-STD, HSC-HSC and HSC-STD groups were divided in half and treated SC with vehicle (Veh) or SAB [ratized Scl-AbIII (Amgen, Inc.), 25mg/kg, 2X/wk]. At necropsy, femurs were collected to measure BMD. Mandibles were used to study vertical (v) ABL by histomorphometry and MicroCT, and overall PD status by qualitative histology [PD Score (0-4; 4 = worst)].(1) vABL was assessed as the distance from the cemento-enamel junction to the alveolar bone crest between the first and second, and the second and third molars.

BMD values verified expected SAB bioactivity in all rats. As shown by two-factor ANOVA, diet significantly affected PD score and vABL. SAB treatment also had a significant effect on both PD score and vABL. Student's t-test revealed that all SAB treatment groups had at least a strong trend for slower vABL compared to their respective Veh-treated controls fed the same diet regimen. Our data suggest that systemic treatment with SAB, a powerful bone formation stimulator, reduces vABL in rice rats with active mild, moderate, or severe diet-induced periodontitis. Combined systemic bone-active medication and long-proven standard mechanical therapy for periodontitis, that may act by independent mechanisms, could save periodontally-compromised teeth by increasing alveolar bone support more than is now possible.

The HtrA1 and DDR2 pathway is activated during mechanical instability and impairs bone formation during Fracture Healing. Paul Fanning*[1], Marie Walcott[1], Christopher Raskett[1], John Wixted[2], David Ayers[3]. [1]University of Massachusetts Medical School, USA, [2]University of Massachusetts, USA, [3]UMass Memorial Medical Center, USA

There is a clinical need to understand the relationship between mechanical stability and pathological nonunion. The transition from chondroid to bone is critical for normal healing and is influenced by mechanical rigidity at the fracture site. The molecular mechanisms that mediate cartilage turnover in varying states of mechanical stability in fracture healing are not understood. We hypothesize that expression of HtrA1, an antagonist of TGFb and BMP signaling, and a chondrocyte mechanoreceptor, DDR2 contributes to nonunion during fracture healing. Reproducible transverse femur fractures were generated using controlled injury level in 8-week old C57BL/6 male mice using rigid (normal healing) or flexible (nonunion) fixation. On sacrifice days 5, 7, 10 and 14, the fracture callus was dissected and total RNA isolated. Relative transcript levels were measured (qPCR) and normalized to 18S RNA levels. Vasculature formation was assessed by μCT using a Scanco μCT 40 system, following perfusion with a lead chromate radiopaque silicone compound. Morphometric analysis of the callus, revealed that both total and percent cartilage areas were increased in unstable fractures at all time points. Calluses also showed delayed expression of cartilage formation markers (Col2a1; Acan) in flexible- vs. rigid-fixed fractures. HtrA1 mRNA levels were increased in flexibly-fixed fractures at all time points following the initial inflammatory phase. Ddr2 was expressed at a significantly higher level in flexibly-fixed fractures at day 10, the peak day of cartilage formation. Vegf-A, an angiogenic marker was significantly decreased at all time points following the initial inflammatory phase. μCT similarly showed significantly reduced vascular formation at day 17. These data suggest that the mechanically unstable fracture callus reaches the cartilage stage however, it is not resorbed, persisting as a prolonged chondrogenic phase, preventing osseous bridging. Neovascularization is also delayed allowing reduced recruitment of osteogenic cells to the fracture site. HtrA1 activation via the Ddr2 mechanoreceptor in unstable fractures concomitant with antagonism of bmp molecules arising from the callus and the vascular cells antagonism could impair bone formation. In summary, our data proposes that an increase of this HtrA1-Ddr2 signaling pathway is associated with the mechanically unstable fracture environment, prolonging the chondrogenic phase and delaying bone repair.

MO0211

The Role of TGR5 Receptor in Bile Acid-mediated Bone Metabolism. Hyojung Park*[1], Jae-Yeon Yang[1], Sun Wook Cho[2], Jung Hee Kim[1], Seung Hye Kim[1], Mi Gyeong Jang[1], Sang Wan Kim[1], Mijung Yim[3], Chan Soo Shin[1]. [1]Seoul National University College of Medicine, South Korea, [2]National Medical Center, South Korea, [3]Sookmyung Women's University, South Korea

Bile acids have established as hormones involved in the regulation of various metabolic processes including glucose and lipid metabolism. Previously, we have demonstrated that several endogenous bile acids play positive roles in osteogenesis. However, their mechanisms are still elusive. The aim of this study was to investigate the role of TGR5, a G protein-coupled receptor for bile acids, in bone metabolisms. To verify the physiologic role of TGR5 in bone tissues, we first demonstrated the endogenous expressions of TGR5 in osteoblasts. Interestingly, mRNA expressions of TGR5 genes were significantly increased by chenodeoxycholic acid (CDCA) treatments in calvarial cells. Additionally, TGR5 gene expressions were also increased during osteoblastic differentiation of mesenchymal stem cells (C3H10T1/2 cells), suggesting functional roles of TGR5 in osteoablasts. To further evaluate the role of TGR5 in osteoblast differentiations, natural agonist, oleanolic acid (OA) and synthetic agonist, Isoxazolecarboxamides were used. When C3H10T1/2 cells were differentiatied with osteogenic medium with both TGR5 agonists, alkaline phosphatase (ALP) activities were significantly increased compared to vehicle-treated group. Moreover, this positive effect of Isoxazolecarboxamides in osteoblastic differentiation was significantly attenuated by knockdown of TGR5 with siRNA. These results validated that TGR5 involved in osteoblast differentiation. To examine the effect of TGR5 in osteoclast differentiation we used mouse bone marrow macrophages. Osteoclasts formation from BMMs was significantly decreased by OA or Isoxazolecarboxamides in a dose dependant manner and osteoclast marker gene expression was inhibited notably. Furthermore, knockdown with TGR5-siRNA increased osetoclasts formation and this increase was inhibited by Isoxazolecarboxamides treatment. In molecular insight, the expression of NFATc1 and c-fos, a master regulator of osteoclast differentiation, was attenuated by OA or Isoxazolecarboxamides. Consistent with in vitro results, Isoxazolecarboxamides blocked LPS-induced osteoclast formation in mouse calvaria. Taken together, these results suggest that TGR5 play a pivotal role in bone metablolism through regulating both arms of bone remodeling, ie. bone formation and resorption. These findings provide a better mechanistic understanding of bile acid actions in bone metabolism.

TRIP-TRAP Interactions Control Spatial Coupling During Remodeling. J. Edward Puzas*[1], Diana Metz-Estrella[2], Tzong Jen Sheu[1]. [1]University of Rochester School of Medicine, USA, [2]Hospital for Special Surgery, USA

Introduction: TRIP-1 is a 36 kDa protein with a dual function in cells. It is part of the initiation complex for protein synthesis (eIF3i) as well as a substrate for the type II TGF beta (where it is known as TGF beta receptor-interacting protein). Its function as either a regulator of translation or gene transcription is modulated by its phosphorylation state which also determines whether it can be found in the nucleus or cytoplasm.

We have previously shown that TRIP-1 has an extremely high affinity for the catalytic region of type 5 tartrate resistant acid phosphatase (TRAP). Our early hypothesis is that TRAP can de-phosphorylate TRIP-1 and prepare it for translocation into the nucleus.

In this work we show that loss of function of TRIP-1 compromises osteoblast activity and treatment of osteoblasts with TRAP activates them. We have also characterized the movement of TRIP-1 between the nucleus and cytoplasm and correlated it with its phosphorylation state.

Methods: Isolated osteoblasts from calvaria and marrow as well as bone cell lines were used for these experiments. Phosphorylation state for TRIP-1 was evaluated with Western blot analysis after using phospho-enrichment protocols. Sub-cellular localization was performed with con-focal microscopy.

Results: Ablation of TRIP-1 in osteoblasts using siRNA methodology led to a decrease in gene expression for alkaline phosphatase, Runx 2, type 1 collagen, osteopontin and osteocalcin. Overall protein synthesis was not affected as evidenced by a lack of change in beta actin levels.

TRIP-1 levels were themselves decreased by dexamethasone and increased by vitamin D and PTH.

Phosphorylation of TRIP-1 occurred rapidly (15 min.) after treatment of the cells with TGF beta. This activation is consistent with TRIP-1's role in the immediate preparation for new protein synthesis after TGF beta treatment. Virtually, all of the phosphorylated TRIP remains in the cytoplasm. However, within 30 min. TRIP-1 is dephosphorylated and appears to migrate into the nucleus where we believe it becomes a co-factor for Smad signaling.Conclusion: As osteoblasts are known to endocytose TRAP via M-6-P receptors and the catalytic domain of TRAP binds avidly to TRIP-1 we speculate that the TRAP-coated resorption pit provides the key dephosphorylation step for activating TRIP-1. This could explain, in part, why osteoblasts form bone only on prior resorbed surfaces during normal remodeling.

A Novel Lipidoid-MicroRNA Conjugate Promotes Osteogenic Differentiation. Lei Sui*[1], Leilei Zheng[1], Qianqian Han[1], Lan Zhang[1], Liming Yu[1], Qiaobing Xu[2], Qisheng Tu[1], Jake Jinkun Chen[1]. [1]Tufts University School of Dental Medicine, USA, [2]Tufts University, USA

We have shown that the microRNA (miR)-335-5p plays an important role in regulating bone development (JBMR 26:1953-63, 2011). It activates Wnt signaling pathway and promotes osteogenic differentiation by down-regulating Dickkopf-related protein 1 (DKK1). However, reliable delivery of microRNAs to specific cell types remains a concern. Although viral and commercial lipid delivery systems are available, the safety and efficiency of these vectors are still questionable. Thus, we created a combinatorial library of lipidoid nanoparticles as the amphiphilic nature of lipids enables them to penetrate through various cellular barriers. Therefore, lipidoids are an ideal carrier to facilitate the miR-335-5p delivery in promoting osteogenic differentiation. Briefly, miRNA at an initial concentration of 10 mg/mL was added to empty liposomes at a weight ratio of 10:1 total lipids-miRNA for particle characterization. After primary and secondary screening, we found the lipidoid with a specific structure, tightly packed with miR-335-5p, showed the highest transfection efficiency compared with other lipidoids as well as Lipofectamine 2000. Thus we used this particular lipidoid-miR-335-5p conjugate in this study. Transfection of the conjugate into ascorbic acid-induced C3H10T-1/2 murine mesenchymal stem cells significantly increased the expression levels of major osteogenic transcription factors Runx2, Osx, and Satb2. Our real-time RT-PCR analyses also indicated increased ALP and Col-1 expressions in these cells. The transfection was conducted in the presence of serum, which simulated an *in vivo* environment. Throughout the induction and transfection procedure, C3H10T-1/2 cells showed normal morphological characteristics. No obvious cytotoxicity of the lipidoid-miR-335-5p conjugates was observed. This study represents the first attempt to deliver microRNA using a lipidoid carrier and suggests that lipidoid conjugates are a promising system to implement the modulating function of specific microRNAs in osteogenic differentiation. To determine the feasibility and efficiency of this system in clinical application, lipidoids with multiple osteogenic miRNAs are currently used to enhance osteoblast differentiation and promote bone wound healing in animal models.

Alendronate Alters Single Cell Gene Expression of Cortical Osteoblast Lineage Cells in an Estrogen Deficiency Model of Bone Loss. James Flynn*[1], Ryan Murphy[1], Steven Spusta[1], Clifford Rosen[2], Simon Melov[1]. [1]Buck Institute for Research on Aging, USA, [2]Maine Medical Center, USA

Because of bone's mineralized cellular matrix it is often difficult to define specific cell populations or examine the biology within cortical bone using traditional molecular methods. Through the use of single cell genomics, we are able to analyze the gene expression profiles of individual cells from specific cell populations. In this study, we examined single cortical osteoblasts derived from femur shafts of female C57BL/6 mice. The mice used were either sham surgical controls, ovariectomized mice undergoing estrogen depletion bone loss, or ovariectomized mice treated with an anti-resorptive bisphosphonate drug (100 µg/kg alendronate) via weekly I.P. injections. A subset of these mice were euthanized at 4, 8, and, 16 weeks post-surgery at which point bone tissues were preserved for later molecular analysis (n=10 mice per treatment per timepoint). Cortical bone cells of these femurs were isolated via serial collagenase digestion, and the osteoblast lineage cells were enriched via FACS selection for $CD31^{-}/CD45^{-}/Alkaline\ Phosphatase^{+}$ cell markers. Subsequently, over 100 individual osteoblastic cells from each treatment group were analyzed via nanofluidic qPCR arrays for simultaneous detection of 82 bone specific transcripts. The resulting expression data revealed the single cell differential gene expression between the control mice and mice suffering bone loss. This was further confirmed via whole body *in vivo* microCT scans at 35 micron and *ex vivo* femur scans at 9 micron resolution. The alendronate treated mice demonstrated a unique expression signature in a subset of the osteoblastic cells. Single cell gene expression analysis reveals a unique genetic signature within cell populations undergoing bone loss. The analysis of these cell populations at the single cell level may reveal a greater understanding of the effects of anti-resorptives on cell populations derived from bone.

Endothelin Signaling Promotes Osteogenesis via Changes in the miRNA Environment which Induces IGF-1 and PGE2 while Derepressing Wnt Signaling. Michael Johnson*[1], Jasmin Kristianto[2], Anne Gustavson[1], Kathryn Konicke[2], Baozhi Yuan[1], Robert Blank[1]. [1]University of Wisconsin, USA, [2]University of Wisconsin–Madison, USA

Endothelin promotes the growth of osteoblastic breast and prostate cancer metastases, an effect previously shown to be due in part to derepression of canonical WNT signaling. Conversion of big ET1 to mature ET1, catalyzed primarily by endothelin converting enzyme 1 (ECE1), is necessary for ET1's biological activity. We previously identified *Ece1*, encoding ECE1, as a positional candidate gene for a pleiotropic quantitative trait locus affecting femoral biomechanics. To test the hypothesis that ET1 signaling regulates osteogenesis in the normal state as well as in cancer. We exposed TMOb osteoblasts to 25 ng/ml big ET1 prior to and over the course of *in vitro* differentiation. Cells were grown for 6 days in growth medium and then switched to mineralization medium for an additional 15 days, by which time they form mineralized nodules. Cells were harvested every three days following the switch to mineralization medium. We measured mRNA levels of genes involved in the ET1 signaling axis, production of paracrine factors involved in osteogenesis, and miRNA expression. TMOb cells exposed to big ET showed greater mineralization than control cells ($N = 6$, $p = 0.008$). The mineralization difference was specific to ET1 signaling, as it was blocked by pharmacological inhibition of ECE1 or endothelin receptor A. Under normal mineralization conditions, *Ece1* mRNA expression showed no change over the course of mineralization, ET1 was repressed and endothelin receptor A was induced. Addition of big ET1 repressed expression of all three genes. IGF-1 levels were significantly (1.3-1.8X) higher over time in the presence of big ET ($p<0.001$). PGE2 levels were significantly increased over time (1.2-1.4X) in the presence of big ET-1 while DKK1 and SOST production were repressed over time by 30-40% by big ET-1 ($p<0.001$). Big ET1 repressed anti-osteogenic miRNAs including miRNA 335-5p, which targets *Igf1*. MiRNAs that target proteins involved in bone catabolism were induced by big ET1 exposure. Modulation of canonical WNT signaling could not fully account for ET1's osteogenic effects, as big ET1 produced a greater mineralization than treatment with LiCl. Conclusion: Our data show that osteoblasts express all elements needed for ET1 signaling differentiation and that ET1 signaling promotes mineralization. Moreover, they suggest that ET1's osteogenic effects are mediated in part via IGF-1 and PGE2 induction, potentially through changes in miRNA expression, previously unrecognized ET1 osteogenic mechanisms.

Genome-wide changes in DNase-hypersensitivity during osteoblastogenesis reveal differential usage of DNA motifs: New perspectives in gene regulation. Phillip Tai*[1], Hai Wu[2], Troy Whitfield[3], Jonathan Gordon[4], Andre Van Wijnen[5], Jane Lian[2], Gary Stein[6], Janet Stein[7]. [1]University of Vermont, College of Medicine, Department of Biochemistry, USA, [2]University of Vermont, USA, [3]Dept. of Biochemistry & Molecular Pharmacology, University of Massachusetts Medical School, USA, [4]University of Vermont, Department of Biochemistry, USA, [5]Mayo Clinic, USA, [6]University of Vermont, College of Medicine, USA, [7]University of Vermont Medical School, USA

Gene regulation during the process of osteoblastogenesis has been well-described, yet the discovery of novel regulatory regions has been limited by how we currently predict the locations of functional *cis*-regulatory modules (CRMs). Historically, the *de novo* identification of sequences critical for the control of gene expression relied primarily on sequence conservation in promoters, querying for binding motifs based on position weight matrices of known transcription factors, and the identification of disease causing, non-coding mutations near critical genes. However, we now must consider that regulatory elements also rely on 3-dimensional chromosomal interactions between far-distal regions, epigenetic chromosomal modifications, and RNA:DNA interactions. Traditionally, DNaseI-hypersensitivity assays have been used for the identification of regulatory regions via preferential digestion at chromatin depleted or displaced of nucleosomes, as a result of transcription factor occupancy. With the advent of new sequencing technologies, we probed DNase hypersensitivity on a genome-wide scale, to determine whether differentiation and/or bone-related gene regulation is marked by the presence of commonly utilized DNA motifs within active CRMs. We thus sought to evaluate the gain or loss of motif representation within hypersensitive regions during osteoblastogenesis, from day-0 (growth-phase) to day-28 (mineralizing) MC3T3 cultures. We find that differentiation is marked by an increased enrichment of NFkB-p65, MEF2, and bHLH/E-box motifs within hypersensitive regions, while CTCF, NF1, TEAD, and AP1 motifs decrease. Furthermore, grouping hypersensitive regions based on genomic positioning (promoters, introns, exons, and far-distal regions) revealed significant differences in motif abundance in first introns versus other genomic positions. This finding suggests that the regulation conferred within first intron sequences may be somewhat distinct. Interestingly, the majority of motifs that were enriched regardless of genomic position or differentiation time-point, were not completely matched to currently known transcription factor motifs curated in the JASPAR database. Taken together, the changes in DNase-hypersensitive regions during osteoblastogenesis and the enrichment of distinct motifs within these regions indicate that osteoblasts utilize unique sets of motif rules for transcription factor binding or that regulatory control operates through undiscovered factors.

Genomic Occupancy of Runx2 Combined with Global Expression Profiling Identifies Novel Mechanisms Regulating Osteoblastogenesis. Hai Wu*[1], Troy Whitfield[2], Jonathan Gordon[3], Jason Dobson[2], Phillip Tai[4], Andre Van Wijnen[5], Janet Stein[6], Jane Lian[1], Gary Stein[7]. [1]University of Vermont, USA, [2]University of Massachusetts Medical School, USA, [3]University of Vermont, Department of Biochemistry, USA, [4]University of Vermont, College of Medicine, Department of Biochemistry, USA, [5]Mayo Clinic, USA, [6]Universityof Vermont Medical School, USA, [7]University of Vermont, College of Medicine, USA

Proliferation and differentiation of osteoblasts are highly regulated during bone development and formation, as well as normal turnover and repair in the adult skeleton. The epigenetic and transcriptional program leading to osteoblastogenesis, necessary for bone formation is coordinated through genomic occupancy of Runx2. While numerous Runx2 gene targets are known, here we have identified a broad spectrum of Runx2 functions by global analysis of Runx2 binding. ChIP-Seq was performed to characterize genome-wide Runx2 occupancy during commitment and stages of osteoblast differentiation in bone marrow stromal cells (BMSCs) and pre-osteoblasts (MC3T3-E1s). Using a peak-calling algorithm, we discovered close to 80,000 statistically confident Runx2 binding events throughout the mouse genome. These binding events revealed distinct spatiotemporal patterns during osteoblast differentiation that occur across the genome including proximal promoters but with a large percentage in upstream, introns, exons, transcription termination sites (TTSs), and intergenic regions. This result implicates these regions in Runx2-mediated gene regulation of osteogenesis which was further supported by reporter assays of non-promoter regulatory domains. Moreover, Runx2 binding patterns correlate in functional clusters, relating to biological changes in osteoblast differentiation. Using Affymetrix expression profiling of differentiating osteoblasts depleted of Runx2, we identified novel, primary Runx2 targets in a broad spectra of functional categories such as extracellular matrix remodelers (Adamts4), Vdr signaling components (Crabp2), epigenetic regulators (Ezh2), JAK-STAT signaling pathways (Stat1), Wnt signaling pathways (Dkk2), and immune-responsive genes with as of yet, unknown functions in osteoblasts (Stat2, Mitf, Irf7). Thus, combining ChIP-Seq data with gene expression profiling, we uncovered a comprehensive regulatory network by Runx2 of transcription corresponding to Runx2 binding events. Our data establishes that Runx2 interactions with chromatin across the entire genome reveals novel mechanisms for the control of phenotypic gene expression contributing to osteoblastogenesis.

MO0218

Pin1-mediated conformational change of Runx2 is required for skeletal development. WON JOON Yoon*[1], Rabia Islam[2], Woo Jin Kim[3], Young-Dan Cho[4], Toshihisa Komori[5], Gary Stein[6], Jane Lian[7], Je-Yong Choi[8], Hyun-Mo Ryoo[9]. [1]SEOUL NATIONAL UNIVERSITY, Rok, [2]School of Dentistry, Seoul National University, South Korea, [3]Seoul National University, Rok, [4]Seoul National University, South Korea, [5]Nagasaki University Graduate School of Biomedical Sciences, Japan, [6]University of Vermont, College of Medicine, USA, [7]University of Vermont, USA, [8]Kyungpook National University, School of Medicine, South Korea, [9]Seoul National University School of Dentistry, South Korea

Haploinsufficiency of RUNX2 is the genetic cause of cleidocranial dysplasia (CCD) that is characterized by hypoplastic clavicles and open fontanels. CCD is inherited as a completely penetrant trait with variable expressivity of the RUNX2 mutation. Previous reports have indicated that the Runx2 mRNA levels are directly related to the penetrance and to the expressivity of CCD phenotypes in mice. In this study, Pin1 mutant mice developed a range of CCD phenotypes similar to those of the Runx2+/- mice. We found that Pin1 interacts with the Runx2 C-terminus following a phosphorylation event. Pin1-mediated proline isomerization stabilizes the Runx2 protein by enhancing its acetylation and stimulating its transactivation activity. Importantly, Runx2 is a master transcription factor of osteogenesis. Thus, CCD phenotypes observed in the Pin1 mutant mice could be indirectly resulted from a decrease in the Runx2 protein stability and transactivation activity caused by Pin1 deficiency. Hence, the structural modification of Runx2 by Pin1 could be a novel therapeutic target for osteogenesis.

Post-transcriptional Control of the Lineage Commitment Factor Runx2 During Mitotic Division of Osteoprogenitors via its MicroRNA Dependent 3' Untranslated Region. Ozkan Aydemir[1], Hatem Elif Kamber[1], Rodrigo Grandy[2], Martin Montecino[3], Jennifer Westendorf[4], Jane Lian[2], Janet Stein[2], Gary Stein[5], Mario Galindo[6], Andre Van Wijnen*[4]. [1]University of Massachusetts Medical School, USA, [2]University of Vermont, USA, [3]Universidad de Concepcion, Chile, [4]Mayo Clinic, USA, [5]University of Vermont, College of Medicine, USA, [6]University of Chile, Chile

Expression of the bone-related master regulator Runx2 is tightly regulated during the cell cycle to control its osteogenic activity in expanding mesenchymal progenitor populations. Runx2 mRNA is upregulated prior to mitotic division in the G2 phase, but Runx2 protein accumulates only in progeny cells early during the ensuing G1 phase. Here, we characterized post-transcriptional mechanisms that regulate Runx2 protein levels during the cell cycle. Runx2 mRNA has an unusually long 3' untranslated region (UTR), which is targeted by multiple microRNAs (miRNAs) through both functional and predicted seed sequences. This 3'UTR is more easily detected during mitosis than in interphase relative to Runx2 coding mRNA sequences, suggesting that processing or stability of the 3'UTR varies depending on the cell cycle stage. The levels of at least 16 distinct miRNAs that are known or predicted to target the 3'UTR are constitutively expressed during the cell cycle. Hence, inhibitory interactions between miRNAs and the Runx2 3' UTR are restricted by the availability of Runx2 mRNA and the accessibility of seed sequences in the 3'UTR, but not by miRNA levels. Reporter/3'UTR assays in live cells using a destabilized enhanced green fluorescent protein (deGFP) reveal that the Runx2 3'UTR decreases deGFP expression by 40-70%. This suppression is more effective in G2 or M phases than during G1 or G0 phases. Thus, Runx2 protein expression is induced in early G1 phase in osteoprogenitors by relieving cell cycle dependent suppression of its miRNA dependent 3' UTR.

Role of DGCR8 inactivation in immature osteoblast during bone formation. Young-jin Choi*[1], Seon-Ae Jeon[1], Je-Yoel Cho[2]. [1]Seoul National University, South Korea, [2]College of Veterinary Medicine, Seoul National University, South Korea

MicroRNAs are known to significantly contribute to bone formation by post-transcriptional regulation of gene expression. Most of microRNAs occur in the study of canonical microRNAs that require two sequential cleavages by the Drosha/Dgcr8 heterodimer and Dicer to generate mature products. On the other hand, in the non-canonical pathway, miRNAs are generated by only one cleavage of Dicer. For the study of DGCR8 functions in osteogenesis, we generated mice of which DGCR8 is conditionally deleted in osteoprogenitor cells by Col1a1-Cre. We discovered increase of bone mass in long bones and vertebrae in mice of postnatal to 8-month old. Similar level of activity increase of both osteoblasts and osteoclasts has been detected. It has been already reported by other researchers that the deletion of Dicer at same period of Col1a1-Cre activation induces embryonic lethal. However, cKO DGCR8 mice did not show embryonic lethal and any bone deformity. From this result, it seems that the generations of most abundantly expressed bone microRNAs are dependent on both Dicer and DGCR8. In conclusion, our result shows that the importance of DGCR8 dependent microRNAs during the osteogenesis, especially Col1a1 period of bone formation. Further study for the specific miRNA discovery and validation of its functions might be needed for the deeper understanding of miRNA involvement in osteogenesis.

Rorβ, a Novel Regulator of Runx2, Modulates Bone Mass in Mice. Kristy Nicks*[1], Daniel Fraser[1], Matthew Roforth[1], Sundeep Khosla[2], David Monroe[3]. [1]Mayo Clinic, USA, [2]Mayo Clinic College of Medicine, USA, [3]Mayo Foundation, USA

The regulation of osteoblast (OB) differentiation requires the coordinate activities of numerous transcription factors. Although few are essential (Runx2/osterix), others act to fine-tune in response to external cues. Previously, we identified retinoic acid receptor-related orphan receptor beta (Rorβ) as a novel regulator of OB differentiation (JBMR (4):891, 2012). Rorb expression decreases during OB differentiation and sustained expression inhibits mineralization. Rorβ also increases in the pre-osteoblastic bone marrow cell population in aged mice and in bone biopsies from old compared to young women. Furthermore, we have demonstrated that Rorb antagonizes the transcriptional activity of Runx2. Therefore, we hypothesized that mice lacking Rorb would exhibit a high bone mass. Using a Rorb knockout (KO) model, we characterized the skeletal phenotype of Rorβ-KO mice (Rorb-/-) and littermate controls (Ror+/+; WT) in both genders at 12 weeks. Total aBMD was determined at the spine and femur using DXA, whereas measurement of cortical and trabecular bone parameters at the tibia was determined using pQCT. There were no observed differences in the anthromorphometric parameters in either gender, as body and gonad weights were similar. In Rorb-/- male mice, aBMD was decreased at the femur (-8.2%; p=0.007) and vertebrae (-8.1%; p=0.031), when compared to WT mice. In female Rorb-/- mice, no significant difference was found at the femur, however a decrease in vertebral aBMD (-7.0%; p=0.017) was observed. Total density (-4.9%; (p=0.008), cortical density (-2.6%; p=0.017), cortical thickness (-11.6%; (p=0.003) and cortical area (-14.8%; p=0.004) were decreased at the tibia diaphysis of Rorb-/- male mice. Similar decreases were observed in cortical parameters at the tibial diaphysis of Rorb-/- female mice: total density (-4.6%; p=0.021), cortical density (-2.4%; p=0.004), cortical thickness (-7.0%; p=0.008) and cortical area (-8.2%; p=0.011). In summary, we demonstrate that Rorβ loss results in decreased bone parameters, particularly in cortical bone. Although contrary to our initial hypothesis, we believe loss of Rorβ results in increased Runx2 activity and results in decreased bone mass, similar to what is observed in Runx2 transgenic models. Therefore, Rorβ may represent an important modulator of bone mass by optimizing Runx2 activity. Further characterization of Rorβ function in osteoblasts may define it as a potential clinical target to treat age-related bone loss.

MO0222

Smad8 is a novel type regulator of BMP signaling. Sho Tsukamoto*[1], Satoshi Ohte[2], Mai Fujimoto[3], Takato Mizuta[3], Arei Miyamoto[3], Kenji Osawa[3], Shoichiro Kokabu[3], Eiko Murata[4], Eijiro Jimi[5], Takenobu Katagiri[3]. [1]Saitama Medical University RCGM, Japan, [2]Harvard School of Dental Medicine, USA, [3]Saitama Medical University Research Center for Genomic Medicine, Japan, [4]Saitama Medical University, Health & Medical Care, Japan, [5]Kyushu Dental College, Japan

Smad1 through Smad8 are critical transcription factors for bone formation regulated by BMPs. Smads are classified in 3 subgroups according to their functions: Smad1, Smad5 and Smad8 are phosphorylated at C-terminal SVS motif by BMP receptors (R-Smads). Smad4 acts as a co-activator of the phosphorylated R-Smads to regulate transcription of target genes. Smad6 and Smad7 directly bind to BMP receptors and competitively inhibit the phosphorylation of R-Smads, thus they are classified in I-Smads. Recently, we have established constitutively active forms of Smad1, Smad5 and Smad8 and found that Smad8 is less active than other BMP-regulated R-Smads, owing to a deletion in the linker region. In the present study, we further examined the functions of Smad8 using C2C12 myoblasts. At the basal condition, real-time PCR analysis showed that C2C12 cells express abundant mRNAs of Smad1 and Smad5, but negligible Smad8. When the cells were treated with BMP-4, the BMP target genes, such as Id1 and osterix, were induced within 1 h and 3 h, respectively. During the induction, Smad8 mRNA was also induced within 3 h without changing mRNA levels of Smad1, Smad5 or Smad4. The time-course changes in Smad8 mRNA were similar to those of Smad6 and Smad7. The BMP-specific luc reporter activated by a constitutively active BMP receptor was inhibited by the over-expression of not only Smad7 but also Smad8. Moreover, Smad8 inhibited the luc activity activated by a constitutively active Smad1, suggesting that Smad8 targets downstream of BMP receptors. Smad8 formed a complex with Smad4 and bound to a BMP-responsive element in EMSA as R-Smad, but Smad8 showed much weaker transcriptional activity than Smad1 or Smad5. The expression of Smad8 mRNA was induced by BMP signaling similar to I-Smads. In contrast to I-Smads, however, Smad8 did not target BMP receptors and inhibited R-Smad activity. Taken together, our findings suggest that Smad8 is a novel type regulator of BMP signaling that is phosphorylatable by BMP receptors and represses BMP signaling through affecting other Smads.

MO0224

SUMOylated αNAC Potentiates Transcriptional Repression by FIAT. Bahareh Hekmatnejad*[1], Omar Akhouayri[2], Rene St-Arnaud[3]. [1]Shriners Hospitals for Children - Canada, Canada, [2]Ibn Tofail Sciences Faculty, Morocco, [3]Shriners Hospital for Children & McGill University, Canada

The transcriptional coregulator αNAC (Nascent polypeptide associated complex And Coregulator alpha) and the transcriptional repressor FIAT (Factor Inhibiting ATF4-mediated Transcription) interact but the biological relevance of this interaction remains unclear. The activity of αNAC is extensively modulated by post-translational modifications (PTMs). We identified a novel αNAC PTM through covalent attachment of the Small Ubiquitin-like MOdifyer, SUMO1. Recombinant αNAC was a SUMO1 target in *in vitro* SUMOylation assays and we confirmed that αNAC is conjugated to SUMO1 in cultured osteoblasts and in calvarial tissue. The amino acid sequence of αNAC contains one copy of the composite 'phospho-sumoyl switch' motif that couples sequential phosphorylation and SUMOylation. We found that αNAC is selectively SUMOylated at lysine residue 127 within the motif and that SUMOylation is enhanced when a phosphomimetic mutation is introduced at the nearby serine residue 132. SUMOylation did not alter the subcellular localization, protein stability,

or DNA-binding capacity of αNAC. The S132D, hyper-SUMOylated αNAC mutant specifically interacted with histone deacetylase-2 (HDAC2) and enhanced the inhibitory activity of FIAT on ATF4-mediated transcription from the *Osteocalcin* gene promoter. This effect required binding of SUMOylated αNAC to the target promoter. We propose that maximal transcriptional repression by FIAT requires its interaction with SUMOylated, HDAC2-interacting αNAC.

MO0225

The Endogenous Bmp2 Gene Is required for α-SMA Positive Bone Marrow Stromal Cells to Form Bone In Vivo and Osteoblast Differentiation In Vitro. Stephen Harris*[1], Yong Cui[2], Marie Harris[1], Xiao-Dong Chen[1], Ivo Kalajzic[3]. [1]University of Texas Health Science Center at San Antonio, USA, [2]UTHSCSA, USA, [3]University of Connecticut Health Center, USA

Using the α-SMA-CreERt2 model, we deleted the Bmp2 gene in α-SMA+BMSC that has been shown by lineage studies to be at least one major pool of mesenchymal stem cells.. We activated the Cre at 5-6 days after birth with administration of Tamoxifen (Tam) at 100μg/gm. Bmp2 conditional knock-outs in the α-SMA+ cells leads to thinner long bones with reduced cortical thickness and reduced trabecular bone. One injection at 7 days with Tam and assayed at 17 days also leads to a significant reduced size of the bones and reduced trabecular structures. We then expanded bone marrow stromal cells from Bmp2fx/Bmp2fx mice on a special extracellular matrix (XC-marrowECM, stembiosys.com) that maintains the Mesenchymal Stem Cell (MSC) phenotype. These cells are over 85% α-SMA positive and have high capacity to form a well mineralized matrix within 7-10 days (α-SMA+BMSC$^{bmp2fx/bmp2fx}$); and addition of recombinant Bmp2 greatly accelerates their differentiation process. When the endogenous Bmp2 gene is removed by Adenovirus-Cmv-Cre pretreatment or control pretreatment with Adenovirus-Cmv-GFP, the Cre treated cells fail to differentiate to mineralizing osteoblasts and have greatly reduced expression of Osterix, Col1a1, Osteocalcin, Dmp1, and VegfA. The control α-SMA+BMSC$^{bmp2fx/bmp2fx}$ cells differentiate normally with increased levels of Bmp2, Col1a1, Dmp1, Osteocalcin, and respond to rBmp2. These data suggest a model in which Bmp2 from mature cells activate the Bmp2 gene in MSC that functions in an intracrine fashion , since the addition of rBmp2 could not rescue the deletion of the endogenous Bmp2 in these α-SMA+ BMSC.

Zinc finger protein 521 recruits the NuRD complex together with transglutaminases and regulates mesenchymal stem cell differentiation. Ken-ichi Takeyama*[1], Harikiran Nistala[1], Steven Gygi[2], Bernard Boback[1], Francesca Gori[3], Roland Baron[4]. [1]Harvard school of dental medicine, USA, [2]Harvard Medical School, USA, [3]Harvard School of Dental Medicine, Massachusetts General Hospital, USA, [4]Harvard School of Medicine & of Dental Medicine, USA

Zinc finger protein 521 (Zfp521) represses the activity of several transcription factors (TFs) to regulate the differentiation of mesenchymal stem cells into osteoblasts or adipocytes, respectively (Hesse et al, 2010; Kang et al., 2013; Kiviranta et al., 2013). It has been suggested that Zfp521 associates with Nucleosome Remodeling and Deacetylation (NuRD) complex components, including HDACs and MTAs, to induce transcriptional silencing and possibly chromatin organization. How Zfp521 interacts with NuRD components and how this interaction modifies the molecular functions of both partners is however still largely unknown.To further elucidate the molecular roles of Zfp521, mass spectrometry was performed after purification by immunoprecipitation and size fractionation of nuclear extracts from human embryonic kidney 293A cells stably expressing Zfp521. We found that Zfp521 forms a tight complex with all the core components of NuRD. Most importantly, this Zfp521-NuRD complex also contained novel subunits, i.e. the transglutaminase (TGM) 1 and 3, enzymes that catalyze the formation of a covalent bond between a free amine group and the gamma-carboxamid group of protein-bound glutamine. These findings were validated by purification of TGM3 and confirmed by affinity purification of endogenous Zfp521 in mouse mesenchymal stem cells. In vitro pull-down analysis showed that Zfp521 binds to NuRD through direct interaction with RBBP4, a NuRD component, mediated by the N-terminal 13 amino acids of Zfp521. TGM3 also directly binds to RBBP4, but not to Zfp521, suggesting that the complex formation of Zfp521 with TGM3 and the NuRD complex is mediated by RBBP4. Furthermore, the Zfp521-NuRD-TGM complex exhibits not only HDAC activity, but also transglutaminase activity. Considering the fact that RBBP4 also provides histone H4 binding ability and that Zfp521 acts as a gene silencer during cell differentiation, we propose that the formation of a Zfp521 complex with NuRD and TGM3 leads to a particular set of post translational modifications and epigenetic regulation resulting in gene silencing. Indeed, depletion of Zfp521 or TGM3 leads to alterations of germ layer determination in teratoma assays and altered pluripotency in mesenchymal cells reprogramming. Thus, the mechanisms by which Zfp521 regulates mesenchymal cell lineage determination between bone and fat through repression of TFs such as Ebf1 and PPARg, may involve the recruitment of this novel complex.

Activation of Hedgehog signaling by loss of Gαs causes heterotopic ossification. Deepti Malhotra*[1], Jean Regard[2], Jelena Gvozdenovic-Jeremic[3], Min Chen[4], Lee Weinstein[5], Eileen Shore[6], Frederick Kaplan[7], Yingzi Yang[3]. [1]NHGRI, NIH, USA, [2]National Institutes of Health, USA, [3]NIH, USA, [4]NIDDK, USA, [5]National Institute of Diabetes & Digestive & Kidney Diseases, USA, [6]University of Pennsylvania, USA, [7]University of Pennsylvania Hospital, USA

Bone formation is exquisitely controlled in space and time. Heterotopic ossification (HO), the pathologic formation of extra-skeletal bone, occurs as a common complication of trauma or in rare genetic disorders, and is highly disabling and lethal. However, there are no good treatments since, the molecular mechanisms that spatially restrict bone formation remain unknown. While our previous work in the bone deformation disorder, fibrous dysplasia (FD) showed that gain of function mutations in the G protein, Gαs leads to pathological upregulation of Wnt/β-catenin signaling; here, we demonstrate another fundamental role of Gαs in spatially restricting bone formation to the normal skeleton by inhibiting Hedgehog (Hh) signaling in mesenchymal progenitor cells. We find that in the human disease progressive osseous heteroplasia (POH), which results from null mutations of *GNAS* that encodes Gαs, Hh signaling is upregulated in ectopic osteoblasts and progenitor cells. We further show that ectopic activation of Hh signaling is sufficient to induce HO, while genetic or pharmacological inhibition of Hh signaling blocks HO in animal models. Our findings identify Gαs signaling as centrally important in regulating osteoblast differentiation from mesenchymal progenitors by maintaining a delicate balance between the two key signaling pathways: Wnt/β-catenin and Hh. These findings further suggest that the Hh signaling inhibitors developed for cancer therapy may also be applied to treat HO spectrum disorders.

MO0228

Blockade of Receptor Activated Gi Signaling in Osteoblasts Enhances the Anabolic Effect of PTH. Liping Wang*[1], Dylan O'Carroll[2], Theresa Roth[2], Robert Nissenson[3]. [1]VA Medical Center, San Francisco, USA, [2]Endocrine Unit, VA Medical Center & Departments of Medicine & Physiology, University of California, USA, [3]VA Medical Center & University of California, San Francisco, USA

Intermittent PTH is the only FDA approved anabolic therapy for osteoporosis. PTH is presumed to increase Gs signaling and activate cAMP-dependent pathways in osteoblasts (OBs). In contrast, Gi signaling in OBs is believed to antagonize Gs-mediated increases in cAMP. Previous studies have demonstrated that endogenous Gi signaling in OBs restricts bone formation in adult mice and blockade of receptor activated Gi signaling in OBs achieved by target expression of pertussis toxin (PTX) increases both trabecular and endocortical bone formation and prevents age-related bone loss. Therefore, we hypothesized that effectiveness of PTH as an anabolic agent in aged mice would be markedly enhanced by blocking of endogenous Gi signaling in OBs. We examined the effects of intermittent injection of PTH (1-34) on bone metabolism in 4.5 month old female littermate wild type (WT) and Col12.3.PTX mice in which expression of PTX gene is driven by an inducible (tet-off) 2.3 kb Collagen I α promoter (Col12.3). Two weeks after induction of PTX expression, PTH (80μg/kg body weight/day, 5 days/week, s.c.) or solvent vehicle was given to the Col12.3PTX and WT mice for 4 weeks. The distal femur and tibiofibular junction were assessed by μCT in vivo. Compared with age-matched, vehicle treated WT mice, PTH treatment resulted in a 40% ($p<0.01$) increase in cancellous bone fractional volume (BV/TV), a 13.6 % ($p<0.01$) increase trabecular number (Tb.N), and a 12 % ($p<0.05$) decrease in trabecular separation (Tb.SP) in WT mice. There were no significant changes in bone structure in Col2.3.PTX mice treated with vehicle alone. However, PTH treatment increased cancellous BV/TV by 92% ($p<0.001$), increased Tb.N by 33.5% ($p<0.001$), increased trabecular thickness by 11.1 % ($p<0.05$), and decreased Tb.SP by 23 % ($p<0.001$) in Col12.3.PTX mice. PTH increased cortical bone thickness by 5% ($p<0.05$) in Col2.3PTX, not in WT, mice. Thus, PTH produced a significantly greater anabolic effect in Col2.3PTX compared to WT mice. Serum analysis showed that PTH treatment did not affect levels of Ca and P, but increased alkaline phosphatase (ALP) by 11.6% ($p>0.05$) in WT and by 24.3% ($p<0.05$) in Col12.3PTX mice. In conclusion, our results demonstrate that blockade of Gi signaling in osteoblasts greatly enhances the anabolic response to PTH, suggesting a new therapeutic approach for osteoporosis.

Direct Actions of Adiponectin on Mature Osteoblasts May Contribute to Negative Regulation of Skeletal Homeostasis. Marcia Abbott*[1], Dylan O'Carroll[1], Liping Wang[2], Theresa Roth[1], Robert Nissenson[3]. [1]University of California, San Francisco, USA, [2]VA Medical Center, San Francisco, USA, [3]VA Medical Center & University of California, San Francisco, USA

Epidemiological studies show that high circulating levels of the adipokine adiponectin (APN) are associated with low BMD and increased fracture risk. It is unclear if the skeletal effects of APN are site-specific due to local production by marrow adipocytes and if these effects are direct on osteoblasts. To address these issues, we compared the skeletal phenotype of 3 mo old female wild type (WT) mice and transgenic mice in which secretion of endogenous APN is increased by adipocytes (AdTg), provided by Philipp Scherer, UT Southwestern. Increases in circulating APN in AdTg mice was verified (WT 31.9 ± 6.6 vs AdTg 52.5 ± 8.6 ug/ml; $p<0.05$). MicroCT analysis showed 16% decrease ($p<0.05$) in fractional bone volume (BV/TV) in AdTg mice at the proximal tibia with no reduction in BV/TV at the distal femur when compared to WT mice. Histomorphometric analysis revealed 22% reduction ($p<0.05$) in BV/TV in the proximal tibia of AdTg mice. Cortical thickness at the TFJ was 4% smaller ($p<0.05$) in AdTg mice when compared to WT mice. Both the femurs (WT 15.33 ± 0.58 vs AdTg 13.88 ± 0.14 mm) and tibiae (WT 18.89 ± 0.25 vs AdTg 17.20 ± 0.08) from AdTg mice were shorter ($p<0.05$) and the growth plates appeared disorganized when compared to bones from WT mice. H&E staining showed more adipocytes in the proximal tibia in AdTg mice when compared to WT mice. APN concentration in the marrow from the tibia was higher when compared to marrow from the femur isolated from AdTg mice (9.9 vs 4.3 ug/ml/ug protein). Bone marrow stromal cells (BMSCs) from AdTg mice had the same propensity to differentiate into either osteoblasts or adipocytes as WT BMSCs. Treatment of WT BMSCs with APN (2.5 ug/ml) from day 14-28 of osteoblastic differentiation resulted in a reduction of colony formation and mineralized nodules. With the APN treatment mRNA of osterix, runx2, alkaline phosphatase, Col1, and osteocalcin were reduced ($p<0.05$). Surprisingly, APN treatment resulted in an increase ($p<0.05$) in mRNA of PPARγ and C/EBPα and an increase in lipid droplet size and colony formation, as visualized by Oil Red O, in the osteoblastic cells. These data show a negative role for APN in regulating trabecular bone volume in a site specific manner. APN may stimulate cellular plasticity of osteoblasts towards adipocytes both in vivo and in vitro. These data indicate that the negative association between APN and BMD in humans may be at least in part due to direct effects of APN to alter the phenotype of mature osteoblasts.

Elucidating the Role of O-GlcNAcylation on RUNX2-Mediated Transcriptional Programs in Bone-Marrow Derived Mesenchymal Stem Cells. Alexis Nagel*, Lauren Ball. Medical University of South Carolina, USA

The *runt*-related transcription factor 2 (RUNX2) activates osteogenic transcriptional processes key to bone development, and its function is modulated by post-translational modifications such as phosphorylation and acetylation. A single study [Kim *et al.* (2007) Biochemical and Biophysical Research Communications, vol. 362, pp. 325-329] suggests that RUNX2 is modified by O-linked N-acetylglucosamine, a post-translational mechanism which modulates cellular nutrient- and stress-induced transcriptional pathways. In addition to identifying a number of O-GlcNAcylated proteins in differentiating osteoblasts, we confirm O-GlcNAcylation on exogenously expressed RUNX2. Further supporting a role for O-GlcNAc in the regulation of osteogenesis, we observe enhanced activity of the matrix marker alkaline phosphatase (ALP) in osteogenic bone marrow mesenchymal stem cells (bmMSCs) cultured in the presence of Thiamet G, a selective inhibitor of the O-GlcNAcase (OGA) cycling enzyme. Continuing studies are focused on elucidating exact sites of RUNX2 Ser/Thr O-GlcNAcylation, determining upstream factors which modulate the extent of RUNX2 glycosylation in bmMSCs, and the impact of RUNX2 O-GlcNAcylation on pathways supporting osteogenesis. This work is supported by NIH/NIDCR grant nos. RO1-DE020925-01A1 and T32-DE017551-05.

Osteolineage Jagged1 is a critical component of the PTH activated hematopoietic stem and progenitor cell niche. Rialnat Lawal*[1], Laura Calvi[2], Alexandra Goodman[3], Benjamin Frisch[3]. [1]University of Rochester Medical Center, USA, [2]University of Rochester School of Medicine, USA, [3]University of Rochester, USA

Hematopoietic stem and progenitor cells (HSPCs) have vast regenerative potential, which is vital for transplantation therapies in bone marrow failure and hematopoietic malignancies. However, HSPC numbers are limited, therefore strategies for their expansion are needed. We previously demonstrated that osteoblastic cells expressing a constitutively active parathyroid hormone receptor (PTH-receptor) or systemic PTH treatment expands HSPCs. Activation of Notch signaling in HSPCs was required for this action of PTH. Moreover, PTH increased expression of the Notch ligand Jagged1 in osteolineage cells. However, the role of Jagged1 up-regulation in PTH-dependent HSPC expansion is only partially understood. To determine if osteoblastic Jagged1 mediates PTH-dependent HSPC expansion, we utilized genetic mouse models with Cre –loxP- mediated inactivation of the Jagged1 gene. In this model, the Cre recombinase is driven by Prx1, targeting it to mesenchymal progenitors. Mice with osteolineage Jagged1 inactivation (*Prx1-cre;Jag1$^{fl/fl}$* mice) showed a significant decrease of Jagged1 mRNA with qRT-PCR ($p<0.0001$) compared to control littermates. At baseline, *Prx1-cre;Jag1$^{fl/fl}$* mice were viable and fertile. There were no differences between *Prx1-cre;Jag1$^{fl/fl}$* mice and control littermate in phenotypic HSPC frequency by flow cytometric analysis, peripheral blood counts by HESKA analyses and bone phenotype by micro-CT. These data demonstrate that osteoblastic Jagged1 is not essential at homeostasis for maintaining hematopoiesis, HSPCs and bone growth. However, PTH treatment of *Prx1-cre;Jag1$^{fl/fl}$* mice failed to recapitulate the PTH-dependent expansion in phenotypic HSPCs (lin- Sca1+ cKit + frequency: 0.0644 ± 0.00428 vs 0.07367 ± 0.006458 % Vehicle vs PTH $p=0.2338$ $N \geqslant 6$ mice/group) as seen in wild-type littermates (0.0581 ± 0.00530 vs 0.1250 ± 0.0209 % Vehicle vs PTH $p = 0.0028$ $N \geqslant 5$ mice/group), with a significant decrease in LSK frequency in PTH- treated *Prx1-cre;Jag1$^{fl/fl}$* mice compared to wild-type littermates ($p<0.05$). However, the bone anabolic effect of PTH is maintained. Thus, osteolineage Jagged1 is necessary for PTH-dependent phenotypic HSPC expansion. Moreover, these data support a central role of osteolineage cells in activating the HSPC niche. Together, these data suggest that the PTH initiated increase of Jagged 1 in osteolineage cells is critical as a microenvironmental regulator of HSPCs. Therefore these data identify Notch ligand Jagged1 as an essential component of the PTH stimulated HSPC niche and a potential therapeutic target for pharmacologic HSPC expansion.

MO0232

The Effects of OA Signaling Pathways on Osteoblast Differentiation and Migration. Fayez Safadi, Gregory Sondag*, Omar Ali, Samir Abdelmagid. Northeast Ohio Medical University, USA

Osteoactivin (OA) is a type I transmembrane protein (576 amino acids) that stimulates osteoblast differentiation and function. Our lab has previously shown that there are two isoforms of Osteoactivin, transmembrane and secreted forms. In addition, we also showed that overexpression of Osteoactivin in MC3T3-E1 increases osteoblast differentiation and matrix mineralization. In this study, we tested the effects of the recombinant Osteoactivin (rOA) on osteoblast function and determined the signaling pathways responsible for OA function in osteoblasts . MC3T3-E1 osteoblast-like cells and primary mouse osteoblasts were used in this study. Cells were treated with different concentrations of rOA and cell proliferation and survival were evaluated using CyQuant and MTT assays, respectively. rOA had no significant effects on cell proliferation or survival. Next, we examined the effects of OA treatment on osteoblast differentiation and function. Osteoblast treated with rOA showed significant increase in mRNA expression of osteoblast differentiation markers (Runx2, Osterix, Osteocalcin (OC) and Type I Collagen (Col1))at days 7 and 14. In addition, we tested the effects of rOA on osteoblast migration using a modified boyden chamber and scratch assay. rOA significantly induces osteoblast cell migration in a dose- and time-dependent manner,. Various signaling molecules including Src, MAPK, AKT, and FAK have been shown to be involved in various stages of osteoblast differentiation and function. Therefore, we examined differentsignaling pathways that mediate OA function in osteoblasts. rOA treatment showed a time-deponent increase in Src, MAPK, AKT, and FAK activation using Western Blot analysis. . Furthermore, using MAPK and AKT specific inhibitors, we showed that OA effects on osteoblast differentiation and function is MAPK-dependent and it effects of cell migration is AKT-dependent. Taken together, these data suggest that OA stimulates osteoblast differentiation and migration independent of cell proliferation.

MO0233

A comparative study of the bone regeneration capacity of human muscle derived stem cells and bone marrow mesenchymal stem cells. Xueqin Gao*[1], Arvydas Usas[1], Ying Tang[1], Aiping Lu[1], Jian Tan[1], Johannes Schneppendahl[1], Nicholas Oyster[1], Bing Wang[1], James Cummins[1], Johnny Huard[2]. [1]University of Pittsburgh, USA, [2]Orthopaedic Surgery, USA

Introduction: Human muscle-derived stem cells (hMDSCs) possess multi-lineage differentiation capacity in vitro and form bone in vivo when transduced with BMP2. In order to test whether hMDSCs are as effective as human bone marrow mesenchymal stem cells (hBMMSCs) for bone regeneration, we compared hMDSCs and hBMMSCs for their in vitro osteogenesis and in vivo bone regeneration in a mouse calvarial defect model. Methods: (1) 4 populations of hMDSCs and hBMMSCs were isolated using an established protocol. (2) Both hMDSCs and hBMMSCs were infected with lenti-BMP2 virus and the cells were then selected with 10μg/ml blasticidin for 24hrs. BMP2 secretion levels were measured using ELISA. (3) Comparison of gene expression via RT-PCR. Alkaline phosphatase (ALP) staining

was performed. (4) In vitro osteogenesis were compared using pellet culture. (5) Comparison of in vivo bone regeneration of hMDSC and hBMMSC without or with lenti-BMP2 transduction in critical size calvarial bone defect model using fibrin sealant as the scaffold. (6)MicroCT scans was performed biweekly.(7) Herovici's staining was used to identify type I collagen. Results: (1) The BMP2 secretion levels were: 2.8, 1.2, 0.48, 0.3 ng/million/24hrs for 4 populations of hMDSC respectively and 29.9, 12.7, 14.1, 14.1 ng/million/24hrs for 4 hBMMSCs respectively. (2) hMDSCs exhibited similar expression level of BMPR2,BMPR1b, COX-2 and SOX-9 as hBMMSCs. Lenti-BMP2 transduction increased COX-2 expression in both cell groups. ALP was expressed in a small percentage of hMDSCs and hBMMSCs and was slightly increased after lenti-BMP2 transduction. (3)MicroCT and von Kossa staining indicated both hMDSCs and hBMMSC undergo osteogenesis and enhanced by lenti-BMP2 transduction. (4) Both hMDSC and hBMMSC formed limited bone without gene transduction in vivo. (5) hMDSCs displayed equal bone defect repair capacity as the hBMMSCs when transduced with lenti-BMP2 as shown by the newly formed bone volume and bone defect coverage. (6) Histological analysis revealed formation of the main bone matrix-type I collagen in the defect area in both the hMDSC and hBMMSC groups.

Conclusion: Our results indicated that the hMDSCs exhibited equal capacity as hBMMSCs of osteogenesis in vitro and bone regeneration in vivo. Genetically modification with lent-BMP2 is required for efficient in vivo bone repair for both hMDSC and hBMMSC. Therefore, hMDSCs could be used as an alternative source of human adult stem cells for bone repair.

Dexamethasone shifts bone marrow mesenchymal stem cell differentiation to favor adipocyte lineage over osteoblast lineage through C/EBPalpha promoter methylation mechanism. Jiao Li*[1], Ning Zhang[1], Kerong Dai[2], Xiaoling Zhang[1]. [1]The Key Laboratory of Stem Cell Biology, Institute of Health Sciences, Shanghai Institutes for Biological Sciences (SIBS), Chinese Academy of Sciences (CAS) & Shanghai Jiao Tong University School of Medicine (SJTUSM), China, [2]Shanghai Key Laboratory of Orthopaedic Implant, Department of Orthopaedic Surgery, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine (SJTUSM), China

Dexamethasone (Dex), a potent synthetic member of the glucocorticoid (GC) class of steroid drugs, is widely used as an immune suppressor. However, chronic Dex therapy is clearly associated with side effects, including bone loss, low bone mineral density (BMD), and increased fracture risk, which has been described as the most severe complication of long-term GC therapy. Till now, no effective method exists to treat these side effects of Dex. Clinical investigation has shown that Dex-induced osteoporosis is accompanied by increased bone marrow adiposity, Osteoblasts and adipocytes both arise from the same progenitor cells and bone marrow mesenchymal stem cells (BMSCs); a reciprocal relationship exists between osteoblast and adipocyte differentiation, so BMSCs differentiating into one lineage gradually lose the ability to differentiate to the other. Decreased bone formation and increased marrow adiposity increase the possibility that the differentiation balance between osteoblast and adipocyte is shifted by Dex, but the underlying mechanisms are still unknown. To test this hypothesis, we established a Dex-induced osteoporotic mouse model, and found that BMSCs from Dex-treated mice are more likely to differentiate into adipocyte than those from control mice, even under the induction of bone morphogenetic protein-2 (BMP2). We also discovered both in vitro and in vivo that the expression level of adipocyte regulator CCAAT/enhancer-binding protein alpha (C/EBPalpha) is significantly up-regulated in Dex-induced osteoporotic BMSCs during osteoblastogenesis by a mechanism that involves inhibited DNA hypermethylation of its promoter, Dex up-regulated C/EBPalpha expression level by preventing DNA methyltransferases 3a and 3b (Dnmt 3a/3b) from binding to C/EBPalpha promoter, thereby inhibiting its hypermethylation during osteoblast differentiation. Knockdown of C/EBPalpha in Dex-induced osteoporotic cells rescues their differentiation potential, suggesting that Dex shifts BMSC differentiation by inhibiting C/EBPalpha promoter methylation and up-regulating its expression level. We further found that the Wnt/beta-catenin pathway is involved in Dex-induced osteoporosis and C/EBPalpha promoter methylation, and its activation by LiCl rescues the effect of Dex on C/EBPalpha promoter methylation and osteoblast/adipocyte balance. This study revealed the C/EBPalpha promoter methylation mechanism and evaluated the function of Wnt/beta-catenin pathway in Dex-induced osteoporosis, providing a useful therapeutic target for this type of osteoporosis.

Differential Intracellular Processing Of Fluorescently-Labeled Bisphosphonate In Human Bone Mesenchymal Stem Cells. Pinky Salat, Frank Stefano, Kathleen Boesze-Battaglia, Sunday Akintoye*. University of Pennsylvania School of Dental Medicine, USA

Objectives: Bisphosphonates and denosumab used to control skeletal cancer metastasis have been associated with osteonecrosis of the jaws (ONJ). A common ONJ pathophysiologic theory relates to actions of antiresorptives on osteoclast-osteoblast balance. Bone mesenchymal stem cells (MSCs) are postnatal stem cells that repopulate osteoprogenitors vital for home healing but orofacial/jaw MSCs (OFMSCs) are disproportionately more sensitive to nitrogen-containing bisphosphonates (nBP) than MSCs from non-oral bones. If the jaw is disparately targeted by ONJ, disproportionate nBP uptake by OFMSCs with consequent apoptosis will reduce jaw osteoprogenitors essential for bone healing and homeostasis. We tested the hypothesis that MSC bisphosphonate uptake and internalization is skeletal site dependent.

Methods: Normal human OFMSCs and iliac crest MSCs (ICMSCs) from same individuals were exposed to 0.25mg/ml fluorescently labeled pamidronate (FL-nBP) [OsteoSense®680, Perkin Elmer, Boston MA]. Live cell imaging was used to visualize cellular components and track FL-nBP intracellular uptake. Nuclei, lysosomes and plasma membrane were visualized with Hoechst 33342 [2μM], Lysotracker Green DND26 [50nM] and Wheat Germ Agglutinin (WGA) [5μg/ml] respectively. Nikon A1R Laser Scanning Confocal microscope was used to capture images every 2 minutes for 3 hours at 37℃, 5% CO2 and constant humidity in four channels using these probes: Blue (405nm)- Nuclei; Green (488nm)-Lysotracker; Red (561nm)-WGA and Far Red (640)- FL-nBP. In parallel experiments, cells were pre-cultured with and without monodansyl cadaverine [MDC, 100μM] for 3 hours before exposure to FL-nBP to assess the role of fluid-phase endocytosis on differential FL-nBP uptake by OFMSCs and ICMSCs.

Results: FL-nBP was internalized within 8 minutes by ICMSCs and OFMSCs. Total FL-nBP uptake displayed dual peak pattern at 15 and 40 minutes in ICMSCs and 40 and 120 minutes in OFMSCs. Lysosomal localization of FL-BP was rapid in ICMSCs but a delayed gradual increase was displayed by OFMSCs. There were no differences in the plasma membrane permeability and adsorptive endocytosis based on uptake of WGA. However, inhibition of fluid-phase endocytosis with MDC demonstrated 10% and 50% increase in lysosomal FL-nBP in ICMSCs and OFMSCs respectively.

Conclusion: Internalized nBP is differentially processed by OFMSCs and ICMSCs.

Differentiation Stage- and Cell Type-Specific Expression of Claudin Family Members During In Vitro Differentiation of Osteoblasts and Osteoclasts. Fatima Alshbool*[1], Shin-Tai Chen[2], Subburaman Mohan[3]. [1]Loma Linda University, USA, [2]Jerry L. Pettis VA Medical Center, USA, [3]Jerry L. Pettis Memorial VA Medical Center, USA

Claudins (Cldns), a family of 24 known transmembrane proteins, represent major components of tight junctions. The canonical function of Cldns involves regulation of paracellular permeability of ions and small molecules. In a recent study, we found that Cldn-18 is a novel negative regulator of bone resorption and acts non-canonically to modulate RANKL-induced osteoclast (OC) differentiation. In this study, we examined the hypothesis that the expression of Cldns is differentiation stage- and cell type-dependent in bone. The expression of Cldns were examined during ascorbic acid (AA)-induced differentiation of fetal calvarial cells into osteoblasts (OBs) at days 0, 4, 6 and 8 and RANKL-induced differentiation of bone marrow precursors into OCs at days 0, 1 and 6 by real-time PCR. Expression of several of the Cldns (-1, -2, -5, -8, -10, -11, -13 and -14) were increased more than 10-fold ($P<0.01$) during OB differentiation with some showing peak expression at day 6 while others at day 8. By contrast, expression levels of Cldn-4, -12, -15 and -22 were decreased significantly ($P<0.01$) during OB differentiation. Surprisingly, several of the Cldns including -1, -7, -11 and -15 were significantly down regulated at day 1 of OC differentiation. Only expression of Cldn-6 was increased at day 1. At day 6, however, expression of Cldn-1, -2, -3, -5, -6, -12, -13, -15 and -22 were increased 3 to 7-fold compared to day 0 cultures. Because Cldn-1 expression was increased by >15-fold during OB differentiation and targeted knockout of Cldn-1 results in perinatal lethality, we determined the consequence of lentiviral shRNA mediated knockdown of Cldn-1 expression on differentiation of MC3T3-E1 osteoblasts. Cldn-1 expression was increased by 3-fold ($P<0.01$) by AA treatment at day 6 in MC3T3-E1 cells and was blocked by 60% by Cldn-1 shRNA. Furthermore, ALP and BSP mRNA levels were reduced by 90% ($P<0.01$) in lentiviral Cldn-1 shRNA vs control shRNA treated cultures. We next determined if Cldn-1 regulated expression of Runx2 and osterix, master transcription factors of osteoblast differentiation. We found that expression levels of both Runx2 and osterix mRNA was reduced significantly as a consequence of Cldn-1 knockdown. Conclusions: 1) Regulation of expression of Cldn family members during bone cell differentiation is complex and involves cell type and differentiation stage-dependent regulation. 2) Cldn-1 is a positive regulator of osteoblast differentiation.

Effects of Therapeutic Radiation on the Differentiation Potential of Human Embryonic Stem Cell Derived Mesenchymal Stem Cells. Mohammad Islam*[1], Melissa Stemig[1], Yutaka Takahashi[2], Susanta Hui[1]. [1]University of Minnesota School of Dentistry, USA, [2]University of Minnesota, USA

Human embryonic stem derived mesenchymal stem cells (hESMSC) have been shown to have similar properties of bone marrow MSCs (BMMSC). The purpose of this study was to learn the effects of therapeutic radiation on the hESMSC. We used human embryonic stem cell line WA-09 and differentiated them in presence of 15% serum. hESMSCs were isolated based on CD73 expression using magnetic sort. Cells were irradiated as follows: 0 Gy (no radiation), 2 Gy, 4 Gy and 16 Gy using Varian Linear accelerator at the dose rate (400 cGy/min) commonly used for patient treatment. Cells were analyzed at post radiation day 1 and day 5. We studied 1. the expression of MSC specific cell surface markers; 2. cell cycle profile; 3. the expression of osteoblastic, adipogenic and oxidative stress related genes and 4. osteogenic and adipogenic differentiation potential of irradiated hESMSCs. Bone marrow MSCs were used as control cells. Radiation did not significantly affect the expression of MSC specific CD90, CD105 and CD146 in irradiated and non-irradiated cells. We observed accumulation of cells in G2/M phase at higher radiation doses, compared to no radiation group. This observation was consistent in post radiation day 1 and day 5 groups. Starting at post radiation day 1 and day 5, differentiation towards osteogenic and adipogenic lineage (for 2 to 3 weeks) showed that cells were differentiating in lineage specific manner when treated with 2 Gy and 4 Gy, but not with 16 Gy. Adipogenic oil red O staining showed fat cells formed in clusters in the culture, different from adipogenesis in BMMSCs. We found that radiation changes the expression of osteoblast lineage specific Runt related transcription factor 1 (RUNX2) and adipogenic Peroxisome proliferator-activated receptor Gamma (PPARG) expression. Oxidative stress related superoxide dismutase 1 (SOD1) expression was inversely related to the ratio of PPARG and RUNX2 expressed in irradiated cells. This pattern was observed in both day 1 and day 5 post radiation studies. We conclude that, at different radiation doses hESMSCs retain properties of MSCs. Radiation induced gene expression changed the lineage specific gene expression pattern in the culture.

MO0239

Identification of differentiation-stage specific molecular markers for the osteoblastic phenotype. Natalie Twine*[1], Chi Pang[1], Li Chen[2], Marc Wilkins[1], Moustapha Kassem[3]. [1]NSW Systems Biology Initiative, University of New South Wales, Australia, [2]Medical Biotechnology Center (MBC), Denmark, [3]Odense University Hospital, Denmark

The phenotype of osteoblastic (OB) cells in culture is currently defined using a limited number of markers of low sensitivity and specificity which belong mostly to extracellular matrix proteins. Also, for clinical use of human skeletal (mesenchymal) stem cells (hMSC) in bone regeneration, there is a need to identify predictive markers for *in vivo* bone forming capacity.

Thus, we employed Illumina RNA sequencing (RNASeq) to examine changes in gene expression across 8 time points between 0-12 days of *ex vivo* OB differentiation of hMSC. We identified a subset of expressed genes as potentially sensitive markers of *ex vivo* differentiating OB (n=123) based on: i) identified in literature and/or had the Gene Ontology (GO) category: 'osteoblast differentiation' ii) exhibited significant changes in expression (> 2 Fold Change (FC), FDR <0.1) at any one time point during OB differentiation.

Pearson's correlation of the 123 expression profiles, followed by hierarchical clustering, resulted in 4 groups of markers: early differentiating OB markers (n= 28), which had a peak expression during 0-24 hours and were enriched for GO 'extracellular matrix organisation' e.g. *COL1A1, LOX, SERPINH1*; middle stage differentiating OB markers (n=20), which had a peak expression during 3-6 days and were enriched for GO 'extracellular matrix' and 'skeletal system development' e.g *BMP4, CYP24A1, TGFBR2*; late stage differentiating OB markers (n=27), which had a peak expression 9-12 days and enriched for GO 'bone development/osteoblast differentiation' e.g. *BMP2, IGF2* and a pleitropic group of marker genes (n=13) with peak expression during early and late time points that included growth factors e.g. *VEGFA, PDGFA, FGF2*.

In addition, a subset of these OB markers (n=21) e.g. *CLEC3B, SMAD6, BMP4, NRP3, DLX5* were able to predict hMSC *in vivo* bone forming capacity as they were upregulated by more than 1.5 FC in hMSC-derived clones with high bone forming capacity compared to low bone forming clones. Interestingly, 33 OB markers were significantly up-regulated (>2FC, FDR<0.1) in cultured hMSC obtained from patients with osteoporosis (n=5) compared to age-matched control (n=4).

Using RNA-seq and cluster analysis, we identified a set of stage-specific molecular markers that define the progression of OB phenotype during *ex vivo* culture of hMSC, predict *in vivo* bone formation capacity of hMSC and can be employed to study the mechanisms of impaired bone formation in patients with osteoporosis.

Intravital imaging of osteogenesis and angiogenesis in repair and regeneration. Xinping Zhang*[1], Chunlan Huang[1], Vincent Ness[1], Edward B Brown[2]. [1]University of Rochester Medical Center, USA, [2]University of Rochester, USA

Bone defect healing is a progenitor cell-driven tissue morphogenetic process marked by coordinated osteogenesis and angiogenesis at the site of repair. The progenitor cells dynamics and spatiotemporal regulation of bone defect repair remain poorly understood, largely due to the lack of an animal model that permits high resolution and non-destructive analyses of progenitors and the surrounding microenvironment at the site of repair. We have recently established a chronic cranial defect window chamber model in mice that permits high-resolution, dynamic tracking of progenitors and their surrounding neovasculature via two-photon microscopy. By simultaneously probing the intrinsic optical signatures of collagen matrix from new bone via second harmonic generation (SHG) and fluorescence-labeled osteoblasts via 2.3kb collagen type I promoter driven GFP (Col2.3GFP), we showed that angiogenesis preceded osteogenesis. Differentiation of osteoblasts was initiated at the edge of the defect in close proximity of the invading blood vessels. The expansion and migration of the osteoblastic cells were closedly associated with microvessels less than 10 mm in diameter during the first 4 week of healing. Quantitaive and histomorphometric analyse showed that vessel length and volume were markedly increased at week 1, peaked at week 3 and reduced at week 6, coincided with early expansion and migration of the osteoblasts. By week 9, volume of $Col2.3^{+}GFP$ cells were markedly reduced, yet SHG continued to climb suggesting that late stage collagen fiber assembly could be independent of osteoblasts. Similar spatiotemporal interaction between Col2.3GFP cells and neovascularization was observed when bone marrow stromal cells isolated from Col2.3GFP mice were implanted into the cranial defect window chambor model. The surviving $Col2.3GFP^{+}$ cells were found in colonies surrounded by microvessels. Longitudinal tracking of the cells and collagen matrix revealed formation of criss-crossing collagen fiber arrays which served as a porous template for bone regeneration. Taken together, the cranial defect window chambor model provided a live imaging platform for tracking and quantitative analyses of spatiotemporal cordination of osteogenesis and angiogenesis at a microscopic resolution. The establishment of the model could aid in the development of material-based approaches to engineering suitable microenvironment to modulate progenitor cell behavior for enhanced bone repair and reconstruction.

MO0241

Phenotypic and Functional Characterization of an Osterix-Cherry+ Bone Marrow Cell Population. Sara Strecker*[1], Peter Maye[2]. [1]University of Connecticut, USA, [2]University of Connecticut Health Center, USA

Objectives: Osterix is a zinc finger transcription factor, which functions as a master regulator of osteoblast differentiation. We created Osterix-Cherry reporter mice, which revealed the marking of a bone marrow cell population retaining low Osterix reporter expression (referred to as LORE cells). The goal of this study was to determine whether LORE cells are a multipotent bone marrow stromal cell (BMSC) population.Methods: In order to resolve Osterix expression in the context of the skeletal lineage, we intercrossed our Osterix-Cherry mice with *Connective Tissue Growth Factor* (CTGF)- eGFP, *Bone Sialoprotein* (BSP)- Topaz and *Collagen 3.6* (Col 3.6) Cyan reporter mice. We carried out *in vitro* differentiation studies of sorted cells to confirm the multipotency of this LORE population in the context of other skeletally specific reporters. Immunostaining studies and flow analysis have been used to determine the localization and identity of these LORE cells within the marrow.

Results: Osterix reporter expression proceeds both BSP and Col 3.6 and appears to co-localize with CTGF. Both CTGF+ and Osterix+ populations are multipotent *in vitro*, differentiating into bone, fat, and cartilage. LORE cells isolated from the marrow first express Col 3.6 then express BSP in culture. LORE cells localize near, but are not on, the bone surface. Immunostaining and flow suggests that these cells are similar to reticular cells. This data suggests that the LORE cell is marking an uncommitted skeletal progenitor population. The Osterix-Cherry mouse is the first skeletally specific reporter mouse to show a distinct, multipotent, reporter positive population within the bone marrow.

Conclusions: We observed a LORE cell population in the bone marrow which marks an early osteoprogenitor that is required for supporting postnatal skeletal growth and bone maintenance. Osterix reporter mice may provide us with a means to isolate and study the earliest cells of the osteoblast cell lineage, which remain poorly understood.

Repeated Osteoblast Depletion Decreases Osteogenic Potential of Bone Marrow Stromal Cells in Mice. Adeline Ng*[1], Gurpreet Baht[2], Marc Grynpas[3], Benjamin Alman[2]. [1]University of Toronto Samuel Lunenfeld Research Institute, Canada, [2]Program in Developmental & Stem Cell Biology, Hospital for Sick Children, Canada, [3]Samuel Lunenfeld Research Instituteof Mount Sinai Hospital, Canada

Background: Literature has suggested factors that sustain stem cell levels in the bone marrow decline with age and this deficit may be related to age-associated bone loss. Using the Col2.3Δtk (DTK) transgenic mouse, we investigated the consequences of repeated ablation of differentiated osteoblasts on osteogenic progenitor cells in the bone marrow. The DTK transgenic mouse takes advantage of the HSV-tk (herpes simplex virus thymidine kinase)/GCV (ganciclovir) system to conditionally ablate differentiated osteoblasts.

Methods: 4-month old DTK mice were treated with ganciclovir (GCV) to conditionally ablate differentiated osteoblasts or treated with saline control. Bone marrow from GCV-treated donors was transplanted into treated- or control-recipients and vice versa. Bone marrow transplant recipients were sacrificed at the end of a 12-week engraftment period. At sacrifice, bone marrow stromal cells (BMSCs) were harvested for cell culture and whole bones were excised for bone quality assessment. Colony forming unit (CFU) assays were conducted to investigate BMSC osteogenic potential. RNA was extracted from cell culture to assess the expression of genes defining BMSC lineage. *Ex vivo* bone quality assessments included bone histomorphometry, TRAP-staining, dual energy x-ray absorptiometry, microcomputed tomography, and biomechanical testing.

Results: There were no differences in CFU-F (fibroblast) counts between any of the treatment groups. However, GCV-treated animals had lower CFU- ALP (alkaline phosphatase and CFU-VK (von Kossa) counts, indicative of decreased osteoblast activity. Interestingly, there were no statistical differences in bone mineral density (vertebrae and femurs) between any of the treatment groups despite differences in BMSC osteogenic capacity *in vitro*. Furthermore, histological analyses showed no differences in bone formation or bone structure.

Discussion: This study aims to connect *in vitro* cell culture data with *in vivo* skeletal phenotypes. Early results suggest that the number of healthy bone marrow stromal cells (BMSCs) do not decline with depletion of differentiated osteoblasts; however, the osteogenic potential of BMSCs decline significantly with repeated osteoblast ablation. This decline is only partially rescued with bone marrow transplantation into healthy recipients. We are currently investigating the mechanisms responsible this decrease in osteogenic potential and its effects on skeletal phenotype.

Sex and Genetic Factors Determine Bone Remodeling and Osteoblastogenesis. Stefano Zanotti*[1], Ivo Kalajzic[2], Ernesto Canalis[1]. [1]St. Francis Hospital & Medical Center, USA, [2]University of Connecticut Health Center, USA

Sex determines cancellous bone mass of C57BL/6 mice and the differentiation of bone marrow stromal cells toward the osteoblastic lineage. To explore the mechanisms that mediate the effects of sex on bone mass, cancellous bone of femurs from 1 to 6 month old C57BL/6 mice was analyzed by histomorphometry. Trabecular bone volume was comparable between sexes at 1 month of age but it declined rapidly in maturing female mice whereas it remained stable in maturing male littermates. Osteoclast number and bone resorption declined as mice of both sexes matured but were always higher in female than in male mice. Moreover, whereas osteoblast number declined in male mice, it increased in maturing female mice. A limited number of tropism for Friend leukemia virus-B mice were available for study and showed similar trends, but differences between male and female mice were not statistically significant. The results indicate that female mice remodel at a higher rate than male littermates and consequently lose cancellous bone. Since the increase in osteoblast number was not sufficient to prevent the decline in bone mass, we questioned whether sex determines the potential for osteoblastic differentiation of mesenchymal progenitor cells. To this end, bone marrow stromal cells from C57BL/6 mice where the *a*-smooth muscle actin (*aSma*) promoter, active in mesenchymal progenitors, directs green fluorescent protein (GFP) expression (*aSmaGFP*) were cultured. Fluorescence activated cell sorting revealed fewer GFP expressing cells in cultures from female than from male *aSmaGFP* littermates. Furthermore, *Runx2*, *Alpl*, *Osteocalcin* and *Osteopontin* expression was higher in GFP expressing cells from male mice than from female littermates. To test whether genetic factors modify the impact of sex on osteoblastogenesis, bone marrow stromal cells from C3H/HeJ and BALB/c mice were cultured. Mineralization and *Alpl* expression and activity were lower in cultures from female than from male littermates of both genetic backgrounds. *Osteocalcin* expression was lower in cells from female than from male C3H/HeJ, but not BALB/c, littermate mice. In conclusion, cancellous bone declines in maturing female mice because of increased bone remodeling and reduced potential for osteoblastogenesis in comparison to male littermates and genetic factors determine the magnitude of these effects.

Study of Mesenchymal Stem Cells and Endothelial Progenitor Cells in Osteonecrosis of the Femoral Head. Myrielle Mathieu[1], Delphine Spruyt[1], Sabrina Rigutto[1], Aude Ingels[1], Nadia Stricwant[1], Valentina Albarani[2], Joanne Rasschaert[3], Enrico Bastianelli[2], Valerie Gangji*[4]. [1]Université Libre de Bruxelles, Belgium, [2]Bone Therapeutics, Belgium, [3]Laboratory of Bone & Metabolic Biochemistry, Belgium, [4]Hôpital Erasme, Université Libre de Bruxelles, Belgium

Introduction: Osteonecrosis of the femoral head (ONFH) is a painful disorder of the hip affecting young active patients. The disease is characterized by a necrosis of the osteomedullary tissue leading to subchondral bone collapse and joint destruction. We postulated that alterations in the number, proliferation and function of mesenchymal (MSCs) and endothelial progenitor cells (EPCs) might play a role in the pathophysiology of ONFH. Moreover, we analyzed the serum levels of growth factors and chemokines involved in their recruitment, proliferation and differentiation. Methods: Fifty-two osteonecrosis patients (ONFH) and eighty healthy volunteers (HV) were included in this study. The number, morphology phenotype and biological activity of bone marrow-derived MSCs and circulating EPCs were compared between groups. Serum levels of growth factors and chemokines were assessed by ELISA.Results: In ONFH patients, the pool of hMSCs was decreased (25.2 ± 7.2 CFU-F in ONFH vs 51.8 ± 7.6 CFU-F in controls, $p < 0.05$) and their proliferation delayed ($5.3\% \pm 1.5\%$ in ONFH vs $13.7\% \pm 2.3\%$ in HV, $p < 0.05$). Once committed, hMSCs from ONFH mineralized less than hMSCs from HV as observed by ARS scoring (0.44 ± 0.19 in ONFH vs 1.21 ± 0.23 in HV, $p < 0.05$). Moreover, the number of early outgrowth EPCs was not affected while the frequency of late outgrowth EPCs was increased in ONFH patients. Granulocyte colony-stimulating factor (G-CSF, $p < 0.05$), interleukin-8 (IL-8, $p < 0.001$), and interleukin-6 (IL-6, $p < 0.05$) were increased and leptin tended to be increased ($p = 0.06$) in ONFH as compared to controls. Platelet-derived growth factor-BB (PDGF-BB, $p < 0.005$), and insulin like growth factor binding protein 3 (IGF-BP3 $p = 0.006$) were decreased and angiopoietin-1 tended to be decreased (Ang-1, $p = 0.05$) in ONFH. Conclusion: ONFH patients showed an increased pool of late outgrowth EPCs, a decreased pool, proliferation and function of hMSCs in ONFH patients. These altered progenitor cells and function were associated with altered serum chemokines, and cytokines that suggest a negative interplay between endothelial cell function and mesenchymal cell function. We showed an altered endothelial cell function associated with an altered endocrine environment that could be detrimental to MSCs recruitment, migration and function.

Visualization of Osteoblast-Derived Trabecular and Endosteal Bone Lining Cells. Marc Wein*[1], Forest Lai[2], Henry Kronenberg[1]. [1]Massachusetts General Hospital, USA, [2]MGH, USA

Intermittent administration of parathyroid hormone (PTH) leads to a net osteoanabolic effect associated with increased numbers of osteoblasts. The precise molecular and cellular mechanisms whereby this occurs remain to be determined. Our laboratory investigated whether PTH might convert quiescent bone lining cells into active osteoblasts. In a previous report, dual transgenic mice expressing tamoxifen-inducible DMP1-Cre and a Cre-activated ROSA26R X-gal reporter were studied. When these animals were analyzed 3 weeks after tamoxifen administration, flat X-gal positive bone lining cells were observed in the periosteal surfaces of the calvariae and tibiae. Brief intermittent PTH treatment converted these flat quiescent cells into active osteoblasts. However, only periosteal osteoblasts were labeled with this approach. In order to study endosteal and trabecular bone lining cells at additional skeletal sites, we now have generated dual transgenic mice expressing tamoxifen-inducible osteocalcin-Cre and floxed-stop tdTomato Cre reporter transgenes. These dual transgenic mice were treated with tamoxifen at 6 weeks of age to label osteocalcin-expressing cells. The subsequent behavior of these labeled cells was then analyzed over time using fluorescence microscopy. As expected, 3-4 days after tamoxifen administration, many red "plump" cuboidal cells on trabecular, endosteal, and (to a lesser extent) periosteal surfaces of the tibiae and vertebrae were observed. In the tibia, after 2, 4, and 6 weeks of chase, the majority of these labeled cells disappeared. Red osteocytes did appear over this interval, along with labeled endosteal and trabecular cells with a distinct, flat morphology. In the vertebrae, the rate of decay of "plump", cuboidal cells over the same chase period was much less pronounced than in the appendicular skeleton. Studies are now underway to determine the effects of intermittent PTH administration on endosteal and trabecular bone lining cells.

MO0247

Novel Therapeutic Effects Of Endoxifen In Pre-Clinical Models Of Type 1 Osteoporosis. Anne Gingery*[1], Malayannan Subramaniam[2], Kevin Pitel[2], Laurence Lindenmaier[3], James Ingle[4], Matthew Goetz[4], Russell Turner[3], Urszula Iwaniec[3], Thomas Spelsberg[2], John Hawse[4]. [1]Mayo Clinic School of Medicine, USA, [2]Mayo Clinic, USA, [3]Oregon State University, USA, [4]Mayo Clinic College of Medicine, USA

Endoxifen is a selective estrogen receptor modulator (SERM) currently being developed as a novel breast cancer therapy. Since SERMs are approved for the treatment and prevention of osteoporosis, it was of interest to characterize the effects of endoxifen on the skeleton. As a first step, we analyzed the effects of endoxifen (50mg/kg/day, for 30 days) on the mouse skeleton using ovariectomized (OVX) C57BL/6 mice. Total body bone mineral density (BMD) and content (BMC) were significantly elevated in the endoxifen treated group as were numerous trabecular and cortical parameters in the vertebrae and long bones. Histomorphometric analysis of the L5 vertebrae revealed significant increases in both osteoblast and osteoclast perimeter per tissue area in endoxifen treated animals which correlated with a nearly 2-fold increase in the serum levels of P1NP and CTX-1. To expand upon these observations, we next employed a pre-clinical rat model to study the effects of endoxifen in both intact and ovariectomized animals. Briefly, four month old Sprague-Dawley rats (n=40) underwent either sham or OVX surgeries and were randomized to placebo or endoxifen (10mg/kg/day, for 35 days). Micro-CT analysis of the proximal tibial metaphysis revealed that BV/TV, connectivity, density, and trabecular number were significantly greater, while trabecular spacing was significantly lower, in endoxifen treated OVX rats compared to placebo treated controls. Interestingly, BV/TV and trabecular thickness were also significantly greater in sham operated ''premenopausal'' animals treated with endoxifen compared to placebo. This observation is in stark contrast to other SERMs, where in the ''premenopausal setting'', SERMs induce bone loss. Endoxifen treatment had no impact on serum levels of P1NP and CTX-1 in sham operated rats but significantly repressed both of these markers in OVX animals. Interestingly, endoxifen treatment also repressed serum sclerostin levels in both the intact and OVX setting. These studies are the first to examine the *in vivo* impact of endoxifen on the skeleton and suggest that endoxifen functions differently than tamoxifen and raloxifene. Based on these data, endoxifen may represent a novel and effective therapy for the prevention and treatment of osteoporosis and/or other bone related disorders.

Prevention of Glucocorticoid Induced-apoptosis of Osteoblasts and Osteocytes by Protecting Against Endoplasmic Reticulum (ER) Stress. Amy Sato*, Lilian Plotkin, Teresita Bellido. Indiana University School of Medicine, USA

Increased oxidative stress, such as with excess of glucocorticoids (GC) or during aging, has been associated with endoplasmic reticulum (ER) stress, due to accumulation of misfolded or unfolded proteins, leading to cellular apoptosis. The double-stranded RNA-activated protein kinase-like ER kinase (PERK) is activated to alleviate ER stress and phosphorylates the eukaryotic translation initiation factor 2 alpha subunit (eIF2α). Phosphorylated eIF2α in turn inhibits global protein translation to provide time to the ER to recover from the unfolded protein load, promoting cell viability. We hypothesized that the pro-apoptotic effect of GC on osteoblasts and osteocytes are at least in part due to induction of ER stress. To test this hypothesis, we used MLO-Y4 osteocytic cells, OB-6 osteoblastic cells, and primary osteoblastic cells derived from neonatal murine calvaria. We found that the synthetic GC dexamethasone (DEX) significantly increased the percentage of apoptotic cells in cultures of MLO-Y4, OB-6, and primary osteoblastic cells. Similarly, the specific ER-stress inducing agents brefeldin A, an inhibitor of ER-golgi apparatus vesicle transport, and tunicamycin, a protein glycosylation inhibitor, significantly increased OB-6 cell apoptosis. We then tested the effect of salubrinal, an agent that protects against ER stress by inhibiting the dephosphorylation of eIF2α, on bone cell apoptosis. Salubrinal blocked apoptosis induced by the ER stressors brefeldin A and tunicamycin in OB-6 cells. Salubrinal was also effective in blocking apoptosis induced by DEX in MLO-Y4, OB-6 and primary osteoblastic cells. Optimal responses were found at 10 μM salubrinal, after either 6 or 24 h. Guanabenz, another inhibitor of eIF2α dephosphorylation, also blocked DEX and tunicamycin-induced apoptosis of primary osteoblastic cells. Furthermore, addition of DEX to mineralizing OB-6 or primary osteoblastic cells markedly decreased mineral deposition and hydroxyapatite formation. In contrast, treatment with guanabenz increased mineralization of OB-6 cell cultures and prevented the inhibitory effect of DEX. We conclude that part of the pro-apoptotic actions of GC on osteoblastic cells are mediated through ER stress and that interventions that prevent dephosphorylation of eIF2α could potentially prevent the deleterious effects of GC on bone.

Cathepsin K null mice exhibit altered frequency of hematopoietic precursors in the bone marrow and in the periphery. Christian Jacome[1], Do Soung*[1], Maureen Pickarski[2], Le Thi Duong[3], Joseph Lorenzo[1], Hicham Drissi[1]. [1]University of Connecticut Health Center, USA, [2]Merck & Co., Inc., USA, [3]Merck Research Laboratories, USA

Cathepsin K (CatK) is a lysosomal cysteine protease, highly expressed by osteoclasts (OC), that is important for degrading bone matrix during bone resorption. In humans, mutations in the *CatK gene (Ctsk)* causes pycnodysostosis, characterized by osteopetrosis due to impaired OC bone resorption. Gene-targeted disruption of Cat K in mice produces a similar bone phenotype. Differentiation of myeloid hematopoietic precursors into OCs, macrophages or dendritic cells, depends on the stimuli it is exposed to. We investigated whether the lack of CatK modulated the number of OC precursors versus other hematopoietic cells. We utilized two mouse models that lack functional CatK protein, a gene-targeted knock-out ($CatK^{-/-}$) that results in the absence of the protein and a knock-in mouse model in which *Ctsk* is replaced by the *cre recombinase*. In both models, the bone resorbing activity of individual OC is decreased. However, the number of non-resorbing OC on bone significantly increases. In the bone marrow, we found that hematopoietic stem cells ($Lineage^{-}c\text{-}Kit^{+}Sca\text{-}1^{+}$, LKS) and early OC precursors defined as PIV, PV and PVI (Jacquin et al., JBMR 2006) were unchanged in $CatK^{cre/cre}$ and $CatK^{-/-}$ compared to wild type (WT) mice. However, we found an increase in CD11b+ (% committed OC precursors) and decreased F4/80+ (% committed macrophages) and CD11c+ (% committed dendritic cells). However, in the spleen we found a significant increase in LKS and a decrease in OC precursors defined as $B220^{-}CD3^{-}NK1.1^{-}CD11b^{hi}Ly\text{-}6C^{hi}CD115^{+}$ (Jacome-Galarza et al., JBMR 2012) in CatK null mice vs. WT. We also found an increase in F4/80+ but no changes in CD11c+ cells. In addition, circulating OC precursors was decreased in the CatK null mice. In conclusion, the high bone mass phenotype in the CatK null mice was not associated with changes in early hematopoietic precursors or early OC precursors, but was associated with an increase frequency of committed OC precursors (CD11b+) in the bone marrow, increased LKS in the spleen and a decreased frequency of peripheral OC precursors. Taken together the absence of functional CatK limits the number of committed peripheral OC precursors migrating to bone marrow. Hence, this contributes to the increased number of TRAcP+ multinuclear osteoclasts that are observed on bone surfaces in the CatK null mice.

Absence of interleukin-22 interferes with the progression of periapical inflammation and bone loss related to endodontic infection. Raquel Silva*[1], Katharina de Oliveira[2], Sandra Fukada[3], Andiara De Rossi[4], Lea Silva[2], Paulo Nelson-Filho[2]. [1]School of Dentistry of Ribeirao Preto - University of Sao Paulo, Brazil, [2]University of Sao Paulo - School of Dentistry of Ribeirao Preto, Brazil, [3]University of Sao Paulo -School of Pharmaceutical Sciences of Ribeirão Preto, Brazil, [4]Faculty of Dentistry of Ribeirão Preto, University of São Paulo, Bra

The aim of this study was to characterize the lesions related to endodontic infection experimentally induced in interleukin-22 knockout mice (IL-22 KO) compared to wild-type (WT) animals. The lesions were induced in the inferior first molars of the mice and, after the periods of 7, 21 and 42 days, the animals were euthanized in a CO2 chamber. Sections were subjected to histotechnical processing and stained with: (1) hematoxylin and eosin (HE) for description of the pulp tissue, apical and periapical regions in conventional optical microscopy and measurement of the area of periapical lesions in fluorescence microscopy; (2) histoenzimology for osteoclasts (TRAP); (3) Brown & Brenn staining (presence/abscence of bacteria); and (4) immunohistochemistry (for osteoclastogenesis markers). The numerical results of the morphometric analysis of the area of the periapical lesions and the number of osteoclasts were subjected to statistical analysis one-way ANOVA and Bonferroni's post-test (level of significance of 5%). Concerning the microscopical analysis, the group of WT mice showed a statistically significant difference between 7 and 42 days and between 21 and 42 days ($p<0.05$), with a gradual increase in the size of periapical lesions and number of osteoclasts. In the group of IL-22 KO animals, an increase in lesion size and number of osteoclasts between 7 and 21 days was observed, followed by a decrease of these parameters between 21 and 42 days, with significant differences between 7 and 21 days ($p<0.05$). Moreover, when comparing the two types of animals, significant differences were found ($p<0.05$) related to the size of the lesions and number of osteoclasts at 42 days, without differences in localization of bacteria and immunolocalization of the osteoclastogenesis markers. This study showed that the absence of IL-22 in mice interfered with the progression of periapical inflammation and bone loss related to endodontic infection suggesting the involvement of this cytokine in host's immune and inflammatory response to the infection of the tooth.

MO0252

Comparative Analysis of Osteoclastic Gene Expression in Mucosal Tissues with Aging and Periodontitis in Nonhuman Primates. Sudha Gudhimella[1], Sreenatha Kirakodu[1], Luis Orraca[2], Janis Gonzalez Martinez[3], Sarandeep Huja*[1], Jeffrey L Ebersole[1], Octavio A. Gonzalez[1]. [1]University of Kentucky, USA, [2]University of Puerto Rico, Puerto Rico, [3]Caribbean Primate Research Center, Puerto Rico

Osteoclastic activity plays a vital role in physiologic bone remodeling. Currently we know little about the complex molecular interactions that occur within the gingival milieu with aging and during bone destruction which is the hallmark of periodontitis.The objective of this study was to use a systems biology approach to determine age-related changes in osteoclastic gene expression profiles in gingival tissues with aging and in naturally occurring periodontitis.The study groups included 34 (14 F: 20 M) systemically healthy *Macaca mulatta* grouped as follows: Healthy - young (<3 y, n=5), adolescent (3-7 y, n=5), adult (12-15 y, n=7) and aged (18-22 y, n=6); Periodontitis – adult (n=5) and aged (n=6). Interdental papilla (2nd premolar/1st molar) from maxilla or mandible were excised and subjected to RNA extraction and microarray analysis (Rhesus Macaque Genome Array, Affymetrix). The expression levels of 84 genes involved in osteoclast regulation were evaluated. For each gene, statistical differences were determined between healthy aged tissues and all other groups or between periodontitis tissues and all healthy tissues. Additionally, a linear regression model compared expression levels using age as a continuous variable. A $p \leq 0.05$ was used to identify significant differences and correlations. Among the 84 evaluated genes approximately 13 were altered in healthy aging tissues and 31 in periodontitis tissues with only 7 overlapping genes. Substantial up-regulation (>2-fold) was noted in periodontitis with CASP9, c-Fos, IL-17A, IL-1β, IL-20, IL-6, RAC2, SPP1, DC-STAMP, MMP9 and MMP1. Moreover, IL-6 ($r=0.59$, $p=0.003$,), IL-17A ($r=0.48$, $p=0.020$), MAP2K1 (MEK1; $r=0.72$, $p<0.0001$), ARPC3 ($r=0.56$, $p=0.003$) and M-CSF (CSF1; $r=0.53$, $p=0.009$) showed significant positive correlations with age. While various genes related to up-regulation of osteoclast functions were observed in healthy gingival tissues with aging, the profile of numerous genes that would mitigate the osteoclast functions or enhance osteoblast activities was also found in these healthy tissues. Thus, this transcriptome environment may reflect a more general osteogenic homeostasis. In contrast, alterations in gene expression in periodontitis particularly in aged animals, was skewed towards creating an environment with substantial osteoclastogenic potential consistent with bone resorption in periodontitis.

Expression of C-C chemokine ligands for osteoclastogenesisinduced by hyperocclusion. Takashi Tsutsumi*, Hiroshi Kajiya, Kazuko Goto, Yutaka Takahashi, Koji Okabe. Fukuoka Dental College, Japan

BACK GROUND: Excessive mechanical stress (MS) is a representative invasive factor in tooth and periodontal tissues in oral and periodontal diseases. It is well known that excessive MS in hyperocclusion resulted in destruction of alveolar bone. We hypothesized that MS induces expression of osteoclastogenesis-associated chemokines, resulting in alveolar bone destruction during occlusal traumatism. We have previously reported that MS induced expression of C-C chemokine ligand (CCL) 2 in periodontal ligament (PDL), resulting in MS-dependent alveolar bone resorption. Therefore, we examined that the effect of ablation of CCL2 and it receptor CCR2 signaling pathway on MS-dependent osteoclastogenesis, using *in vivo* and *in vitro* hyperocclusion models with wild-type (WT), CCL2-deficient ($CCL2^{(-/-)}$)and CCR2-deficient ($CCR2^{(-/-)}$) mice.

MATERIAL AND METHODS: All animal experiments and procedures followed guidelines of the Animal Care Committee, Fukuoka Dental College, Japan. *In vivo* model: The stainless steel wire (diameter 0.3mm) was bonded on the occlusal surfaces of the right maxillary molars in 5 week old mice for a week. After fixation and decalcification for 2 weeks the specimens were prepared 6μm thickness tissue and stained for TRAP staining, HE staining and immunohistostaining. The bone morphological analysis was photographed and analyzed by micro-CT. *In vitro* model: The first molar in mandibular bone was extracted and treated with trypsin for 2 h. PDL cells were cultured in a silicone chamber and subjected to stretching MS until 7days. CCL expression was detected by RT-PCR, western blotting and ELISA analysis.

RESULTS AND DISCUSSION: *In vitro* hyperocclusion model stretching MS increased significantly expression of CCL2, but slightly CCL3 in PDL cells isolated from WT mice. *In vivo* hyperocclusion model, MS increased dominantly the expression of CCL2 in PDL and the number of TRAP positive cells in the alveolar bone in WT mice. In contrast, the expression of CCL3 and the number of TRAP positive cells were spontaneously more in $CCL2^{(-/-)}$ and $CCR2^{(-/-)}$ mice than WT mice. Furthermore, MS significantly increased the number of TRAP positive cells and bone resorption in all types of mice. The results are suggested that CCL2 has a significant role in MS-induced osteoclastogenesis. If CCL2 signaling pathway was suppressed the expression of CCL3 was significantly increased in PDL, leading to compensatory role for osteoclastogenesis.

Autophagy Is Impaired in Osteoclasts from Osteopetrotic Mice with the V-ATPase a3 R740S Mutation. Elena Bajenova[1], Noelle Ochotny[2], Celeste Owen[3], Irina Voronov*[2]. [1]Faculty of Dentistry, University of Toronto, Canada, [2]University of Toronto, Canada, [3]Centre for Modeling Human Disease, Samuel Lunenfeld Research Institute, Mt Sinai Hospital, Canada

Vacuolar H^+-ATPases (V-ATPases) are multisubunit enzymes necessary for acidification of intracellular and extracellular compartments. Mice with an R740S mutation in the V-ATPase a3 subunit have defective V-ATPase activity resulting in mild osteopetrosis in heterozygous (+/R740S) and severe osteopetrosis in homozygous (R740S/R740S) animals. We previously demonstrated that +/R740S osteoclasts (OCs) have increased lysosomal pH and impaired *in vitro* OC differentiation. Furthermore, +/R740S OCs had decreased NFATc1 nuclear translocation. This inhibition was due, in part, to accumulation of regulator of calcineurin 1 (RCAN1), an endogenous NFATc1 inhibitor. Upon signaling, RCAN1 is degraded via the autophagic-lysosomal pathway, suggesting impairment of this pathway in +/R740S OCs. Based on these results, we hypothesized that autophagy is inhibited in +/R740S OCs.

To test our hypothesis, +/R740S and +/+ bone marrow-derived OCs were differentiated in the presence of M-CSF and RANKL for 4 or 6 days. To assess the state of autophagy in the cells, we looked at protein expression of two key molecules, microtubule-associated protein light chain 3 (LC3) and sequestosome 1 (p62/SQSTM1). LC3 is necessary for formation of autophagosomal membranes and is cytosolic; upon induction of autophagy, LC3-I is lipidated to the LC3-II form which associates with the autophagosomal membrane. p62 is a scaffold protein that targets ubiquitinated proteins for degradation via autophagy; it is degraded within an autophagosome and is used as an indicator of autophagic protein degradation.

Immunoblotting demonstrated that the LC3-II/LC3-I ratio was consistently increased in +/R740S compared to +/+ cells, both at day 4 and day 6. The levels of p62 were also increased in +/R740S cells. Immunofluoresence confirmed higher LC3 expression in +/R740S OCs; furthermore, the pattern of LC3 expression was punctate in +/R740S cells compared to a more diffuse cytosolic staining in +/+ OCs. +/+ OCs treated with chloroquine, known to increase lysosomal pH, demonstrated a similar punctate LC3 staining pattern.

Accumulation of LC3 and p62 in +/R740S OCs is consistent with a block in late stages of autophagy, supporting our hypothesis. Future experiments will look at precise mechanisms of this inhibition, as well as at the induction of autophagy via mTOR signaling pathway in OCs with R740S mutation. These studies will help to elucidate precise roles of the V-ATPases and autophagy in OC differentiation.

Bisphenol A reduces differentiation and stimulates apoptosis of osteoclasts and osteoblasts. Ho-Yeon Chung*[1], Kwan Hee Min[1], Kyoung Hee Choi[1], You Cheol Hwang[1], In-Kyung Jeong[1], Kyu Jeung Ahn[1], Hyoung-Moo Park[2]. [1]Kyung Hee University, South Korea, [2]Chung-Ang University, South Korea

Bisphenol A, a known endocrine-disrupting chemical, is a major component of the epoxy resins used in protective coatings. This compound binds to estrogen receptors. We examined the direct effects of bisphenol A on in vitro osteoclast and osteoblast culture systems. We evaluated the effects of bisphenol A on osteoclast formation using bone marrow-derived macrophage and RAW 264.7 cells and osteoblast differentiation using MC3T3-E1 cells. Bisphenol A significantly inhibited RANKL-induced TRAP-positive multinucleated cell formation in bone marrow-derived macrophages and RAW 264.7 cell cultures in a dose-dependent manner (0.5 uM to 12.5 uM). The suppression of ERK, JNK, AKT, and p38 mitogen-activated protein kinases engaged by RANK were observed in Western blotting after bisphenol A treatment in RAW 264.7 cells. Furthermore, bisphenol A suppressed Bcl-2 (anti-apoptotic) and stimulated Bax (pro-apoptotic) protein expression in RAW 264.7 cells. Bisphenol A also significantly suppressed ALP activities and bone nodule formation in MC3T3-E1 cell cultures. Specifically, the expression of Bcl-2 protein was decreased, but the expression of caspases 3, 8, and 9 were increased by bisphenol A treatment in MC3T3-E1 cells. We found that cell death was stimulated with BPA in a dose-dependent manner. These results demonstrate that bisphenol A may cause toxicity through anti-differentiation and pro-apoptosis in bone cells through MAPK cascades and death receptor pathways.

MO0256

C/EBPα Is a Novel Regulator in Osteoclast Lineage Commitment and Regulates Both Bone Resorption and Bone Formation Synchronously. Guochun Zhu*[1], Wei Chen[2], Mengrui Wu[2], Joel Jules[2], Liang Hao[1], Yi-Ping Li[2]. [1]Department of Pathology, University of Alabama at Birmingham, USA, [2]University of Alabama at Birmingham, USA

Current osteoclast inhibitors used to treat osteoclast-related bone diseases display the negative side effects (*e.g.* jaw osteonecrosis and increased bone fragility). It is thus crucial to identify novel therapeutic targets that can regulate both bone resorption and bone formation synchronously. To search for such a regulator, we mapped the critical cis-regulatory elements (CCREs) in the promoter of *Cathepsin K (Ctsk)*, which is expressed specifically in osteoclasts (OCs). We found that CCAAT/enhancer binding protein α (C/EBPα) is the critical cis-regulatory element binding protein. Our results indicate that C/EBPα is highly expressed in pre-OCs, OCs and osteoblasts. The combined presence of M-CSF and RANKL significantly induces C/EBPα expression. Surprisingly, *C/EBPα*$^{-/-}$ newborn mice have a bone volume increase of approximately 450%. Our results show that *C/EBPα*$^{-/-}$ newborn mice exhibit the severe osteopetrosis due to impaired osteoclastogenesis. Interestingly, although osteoclast formation is reduced to less than 10% *in vivo* and is completely blocked *in vitro* compared to wild-type, monocyte/macrophage development is not affected. This indicates a unique role for *C/EBPα* in osteoclast lineage commitment. The impaired osteoclastogenesis of *C/EBPα*$^{-/-}$ mouse bone marrow (MBM) cells can be rescued by *c-fos* overexpression, suggesting that *c-fos* is the major downstream targeted gene of *C/EBPα*. Ectopic expression of C/EBPα in MBM cells and monocyte/macrophage cells (in the absence of RANKL) induces expression of *RANK, c-fos, Nfatc1*, and *Ctsk*, and reprograms monocyte/macrophage cells to OC-like cells. These data indicate that *C/EBPα* is the downstream gene of RANKL signaling and the key transcription factor that regulates osteoclast lineage commitment. Our results demonstrate that C/EBPα directly upregulates *c-fos* expression at the transcriptional level. Importantly, C/EBPα$^{+/-}$ mice exhibit about a 40% increase in bone density, a 26% increase in the number of osteoblasts per bone surface, and a 40% decrease in the number of osteoclasts per bone surface, compared to the C/EBPα$^{+/+}$ control. Notably, C/EBPα$^{+/-}$ mice with Haploinsuffciency for C/EBPα exhibited significant protection against ovariectomy-induced osteoporosis. These discoveries establish C/EBPα as a key transcriptional regulator that regulates both bone resorption and formation synchronously, providing a unique therapeutic target for diseases of excessive bone resorption such as osteoporosis and arthritis.

CD97 Expression on Osteoclasts Enhances Osteoclastogenesis and Regulates Bone Mass. Hee Yeun Won*[1], SeHwan MUN[2], Sun-Kyeong Lee[1]. [1]University of Connecticut Health Center, USA, [2]Department of Medicine, University of Connecticut Health Center, USA

Receptor activator of nuclear factor κB ligand (RANKL) induces osteoclast formation by stimulating the fusion of mononuclear osteoclast precursor cells. CD97 is a member of the epidermal growth factor-seven transmembrane (EGF-TM7) family of adhesion receptors. It was identified as an early T cell activation marker and a ligand for CD55 (decay accelerating factor, DAF) that is expressed on myeloid cells at high levels. We found that CD97 was selectively induced by RANKL in FACS sorted murine bone marrow osteoclast precursor cells. To elucidate the functions of CD97 in bone, we examined osteoclastogenesis in bone marrow cultures from WT and CD97-deficient (CD97 KO) mice and compared their bone mass.

RANKL induced CD97 mRNA and protein expression in bone marrow macrophage (BMM) by 6.7 fold and 9.9 fold, respectively ($p<0.01$). Furthermore, reducing CD97 expression using CD97 targeted siRNA in BMM cells inhibited osteoclastogenesis. Conversely, CD97 protein (30 ng/ml) enhanced OCL formation in BMM cultures that were treated with M-CSF (30 ng/ml) and RANKL (30 ng/ml). Trabecular bone volume measured by μCT in the femurs of CD97 KO female mice was increased by 33% ($p<0.05$) compared to WT mice and was associated with a decrease in osteoclast number *in vivo* (49%, $p<0.05$). BM and BMM cells from CD97 KO mice that were stimulated with M-CSF and RANKL at 30 ng/ml each had significantly fewer OCL (22% and 20%, respectively) compared to WT cells ($p<0.05$) without differences in proliferation rates. Furthermore, OCL that formed from CD97KO mice were significantly smaller in size (20%, $p<0.01$) and had drastically reduced (67%, $p<0.01$) bone resorption activity by pit assay compared to cells from WT mice. In addition, the number of CFU-GM and osteoclast precursor population in bone marrow of CD97 KO mice was 26% and 18% less ($p<0.05$) than in WT mice, respectively. Deletion of CD97 in BMM cells also resulted in a significant attenuation of NFATc1 and macrophage fusion receptor (MFR) expression, indices, respectively, of osteoclast differentiation and fusion.

These results demonstrate that CD97 is a positive regulator of OCL differentiation and function. Bone marrow cell cultures from CD97 KO mice had a decreased capacity to form osteoclasts and resorb bone. Furthermore, CD97 KO mice had significantly increased trabecular bone mass, which is consistent with decreased osteoclast activity. We conclude that CD97 enhances osteoclastogenesis and regulates bone mass *in vivo*.

MO0258

Genome-wide Comprehensive Epigenetic Analysis Reveals that TGF-beta Works as an Essential Mediator for RANKL-induced Osteoclastogenesis Cooperating with c-FOS. Yasunori Omata*[1], Tetsuro Yasui[1], Yuho Kadono[1], Takumi Matsumoto[1], Hironari Masuda[1], Jun Hirose[2], Naoto Tokuyama[1], Hisataka Yasuda[3], Yuuki Imai[1], Hiroyuki Aburatani[1], Kozo Nakamura[1], Sakae Tanaka[1]. [1]The University of Tokyo, Japan, [2]Research Hospital, The Institute of Medical Science, The University of Tokyo, Japan, [3]Oriental Yeast Company, Limited, Japan

Previous studies found that TGF-beta promotes RANKL-induced osteoclastogenesis. However the molecular mechanism remains unclear. We employed chromatin immunoprecipitation sequencing (ChIPseq) method and comprehensively analyzed the genes regulated by TGF-beta. Smad2/3 work as transcription factors in TGF-beta signal transduction. To identify Smad2/3 binding sites globally, the immunoprecipitates were subjected to massively parallel DNA sequencing and the obtained data were mapped to the genome. After treating BMMs with 2 ng/ml TGF-beta for 1.5 hrs, cells were collected and chromatin immunoprecipitation using anti-Smad2/3 antibody was performed. 2,786 Smad2/3 binding sites were detected, and 992 of them (903 genes) existed around the promoter regions of RefSeq genes. Microarray analysis demonstrated that the expression of the Smad2/3 target genes was significantly up-regulated by TGF-beta. The analysis of the Smad binding motif revealed that the *AP-1* binding motifs well existed close to the Smad binging sites. c-Fos plays an essential role in osteoclast differentiation, and the nuclear translocation of c-Fos during the osteoclastogenesis was promoted by TGF-beta and also confirmed that Smad and c-Fos were co-localized in the immunocytochemistry assay and Smads bind to c-Fos in the immunoprecipitate assay. The proximity ligation assay which enables the visualization of protein-protein interaction in the immunocytochemistry revealed that the two molecules located close in the nucleus during the RANKL stimulation with TGF-beta, on the other hand no proximity spot was detected in nucleus during the inhibition of TGF-beta receptor using SB431542. Furthermore the ChIPseq method demonstrated that Smad bind to the promoter region of *NfatC1* which is a master key regulator of osteoclastogenesis, and the region was close to an *AP-1* site. In addition, the histone modification profiles at the Smad binding site was converted from H3K4me3/K27me3 bivalent to H3K4me3 monovalent by TGF-beta, indicating that the gene is in a state of up-regulation. These results suggest that TGF-beta promotes the osteoclastogenesis via Smad's cooperation and support to the nuclear transinduction of c-Fos. In summary, we performed the comprehensive analysis using the novel ChIPseq method and revealed a mechanism that TGF-beta mediates RANKL-induced osteoclastogenesis. Here is a new insight that Smads play an essential role by binding and cooperating with c-Fos to promote osteoclastogenesis.

MO0259

Hydrogen Sulfide Inhibits Osteoclast Differentiation Through NRF2 Activation and Reduced ROS Signaling. Francesco Grassi*[1], Laura Gambari[2], Cristina Manferdini[2], Andrea Facchini[2], Gina Lisignoli[2]. [1]Istituti Ortopedici Rizzoli, Italy, [2]Istituto Ortopedico Rizzoli, Italy

Hydrogen Sulfide (H_2S) is a gaseous molecule long known as a toxic agent for living organisms. Even so, H_2S is released endogenously in mammalian tissues within the so called 'transsulfuration pathway' by two pyridoxal-5'-phosphate-dependent enzymes both responsible for the metabolism of L-cysteine: cystathionine b-synthase (CBS) and cystathionine g- lyase (CSE). H_2S has been recently shown to play a critical role in the regulation of organs and tissues and several correlations were described between low levels of plasmatic H_2S, reduced activity of H_2S-generating enzymes and diseases such as diabetes, GI-tract irritations, cancer. However, the role of H_2S in the regulation of bone cells is still elusive. Here we investigated whether H_2S can modulate differentiation and function of human osteoclasts (OC) in vitro. CD11b+ OC precursor cells were obtained by immunomagnetic positive selection of human PBMC isolated from healthy donors. Mature OC were then obtained by stimulation with M-CSF (10ng/ml) and RANKL (75ng/ml) in the presence or absence of a common H_2S-donor, NaHS, added to cell cultures at concentrations ranging from 50 to 300mM. Pit assays were performed to assess OC activity, NaHS dose-dependently decreased OC differentiation and activity ($p<0.01$ at 200 and 300 mM NaHS). Attesting to specificity, NaHS did not affect viability of OC precursors as measured by annexinV/PI and LDH cytotoxicity assay after 24 or 72h of stimulation.

As H_2S works predominantly as a reducing agent within cells, we investigated whether NaHS stimulation can affect RANKL-dependent ROS signaling in OC precursors, a key step in OC differentiation. ROS were measured within 30 minutes of RANKL stimulation by dichlorodihydrofluorescein diacetate (DCF) staining, and found that pre-stimulation of OC precursors with NaHS (50-300mM for 10') dose-dependently inhibited RANKL-dependent increase in intracellular ROS. Furthermore, NaHS stimulation significantly increased activation and nuclear translocation of NRF-2, the master regulator of antioxidant response and ROS inhibition in cells. To establish if NRF2 is required for NaHS inhibition of OC, siRNA were used to silence NRF2 expression in OC precursors throughout osteoclastogenic differentiation. NRF2-silencing completely prevented the ability of NaHS to inhibit OC differentiation, suggesting that NRF-2 antioxidant response is critical to OC inhibition by NaHS. In conclusion, H_2S inhibits OC differentiation by blunting ROS and triggering an antioxidant response in OC precursor cells.

OC Fusion: Regulation through Collagen and Mineral Contacts at the Marrow/Bone Interface? Kent Soe*[1], Thomas Andersen[2], Jean-Marie Delaisse[2]. [1]Vejle Hospital, University of Southern Denmark, Denmark, [2]Vejle Hospital, IRS, University of Southern Denmark, Denmark

Mono-nucleated pre-osteoclasts (preOCs) move from the bone marrow to the bone surface where they fuse to form multinucleated OCs. PreOCs situated in the bone marrow are obviously in contact with a very distinct extracellular matrix (ECM) compared with fusing OCs on a mineralized bone surface. Since fusion occurs only on the bone surface, it is possible that contact of the preOC with the respective ECMs of the bone surface and the bone marrow may induce different fusion competent states and thereby favor fusion.

First, we performed immunofluorescent staining of human iliac crest biopsies for collagen type I and $TRAcP^+/OSCAR^+$ cells, and found that 75% of $TRAcP^+/OSCAR^+$ preOCs in the bone marrow are in direct contact with collagen type I fibers while 95% are within two cell layers distance. Next we tested the influence of collagen (demineralized bone slices) or mineral (NaOCl treated bone slices) on the fusion of preOCs generated from $CD14^+$ human peripheral blood monocytes. We found that contact with collagen for 24 or 48 hrs stimulated fusion of preOCs compared to mineral. The average number of nuclei per OC ($\geqslant$2 nuclei) after 48 hrs was found to be 1.6 to 2.3 fold larger on collagen compared to mineral. Actually, it appears that fusion is slowed down dramatically on mineral since the average number of nuclei per OC did not increase from 24 to 48 hrs but clearly did on collagen. Expression levels of factors known to be involved in OC fusion were tested in preOCs by Q-RT-PCR 2 hrs after seeding on either mineral or collagen and proved to be different in these two conditions. On collagen the expression of IL1β was increased by 3.5-fold and TNFα was increased 12-fold compared to mineral. Furthermore, preliminary results suggest that also syncytin-1 and ASCT2 were induced on collagen while DC-STAMP and OSCAR did not seem to be induced.

Our data can lead to the following model: preOCs in contact with collagen in the marrow are put in a fusion competent state so that upon arrival to the bone surface they function as a ''fusion donor'' while the OCs on mineral serve as a ''fusion acceptor''. The existence of fusion acceptors and donors is already established for other fusing cell types such as trophoblasts and myoblasts. Our findings may help to understand the site restricted fusion of OCs in vivo.

RBP-J imposes a requirement for ITAM-mediated co-stimulation of RANKL and TNF signaling during osteoclastogenesis. Susan Li*, Xiaoyu Hu, Lionel Ivashkiv, Baohong Zhao. Hospital for Special Surgery, USA

Osteoclastogenesis requires not only RANK signaling but also co-stimulatory signals from immunoreceptor tyrosine-based activation motif (ITAM) -containing receptors/adaptors, predominantly DAP12 and FcRγ in osteoclast precursors. The mechanisms by which co-stimulatory signals are regulated and integrated with RANK signaling are not well understood. We recently identified RBP-J as a key inhibitory regulator of inflammatory osteoclastogenesis and bone resorption. In the present study, we investigated whether RBP-J regulates ITAM-mediated co-stimulation and controls the crosstalk between ITAM and RANK signaling. To address these questions, we generated DAP12 and RBP-J double knockout (KO) mice (R-DKO) and DAP12, FcRγ and RBP-J triple KO mice (TKO). Strikingly, we found that the osteopetrotic bone phenotype shown in DAP12 KO mice or DAP12/ FcRγ DKO mice was rescued by RBP-J deficiency in R-DKO or TKO mice due to significantly recovered osteoclast formation. Thus, RBP-J deficiency relieves the requirement for ITAM-mediated co-stimulation in osteoclastogenesis during homeostatic bone remodeling. RBP-J deficiency almost completely rescued osteoclast differentiation in DAP12 and FcRγ deficient osteoclast precursors in vitro, resulting in formation of TRAP positive multinuclear cells and induction of osteoclastogenic genes, such as TRAP, cathepsin K and β3 integrin. Mechanistically, RBP-J deficiency allowed the induction of key osteoclastogenic factors NFATc1, Blimp1 and c-Fos in DAP12/ FcRγ DKO cells in response to RANKL or TNF-α stimulation. RBP-J suppressed induction of NFATc1 and Blimp1 by downregulating PLCγ expression and downstream calcium-CaMKK-PyK2 signaling during osteoclastogenesis. These results indicate that RBP-J plays an important role in suppressing ITAM-mediated co-stimulation, thereby limiting crosstalk between ITAM and RANK signaling. In addition, RBP-J deficiency resulted in increased TNF-α induced multinuclear osteoclast formation and NFATc1/Blimp1 expression in vitro, and increased inflammatory bone resorption in vivo in DAP12 deficient mice. Our findings identified RBP-J as an important factor in restraining the crosstalk between RANK/ TNFR signaling and co-stimulatory signals. Environmental cues attenuating RBP-J expression or activity can bypass the requirement for co-stimulation in osteoclastogenesis.

Specific Modulation of NEMO SUMOylation Regulates Osteoclastogenesis and Bone Resorption. Yousef Abu-Amer[1], Kyuhwan Shim*[2]. [1]Washington University in St. Louis School of Medicine, USA, [2]Washington University school of medicine, USA

IKKγ/NEMO is the regulatory subunit of IκB kinase complex and regulates NF-κB activation. Expression and function of NEMO itself is tightly regulated by poly-ubiquitination (pUB) and SUMOylation events. *Nemo* is X-linked, and certain mutations in this gene result in Incontinentia Pigmenti and skeletal defects in human hemizygous females suggesting that NEMO regulates bone metabolism. To elucidate the role of NEMO in the skeleton, we used myeloid conditional deletions of *nemo* floxed mice. Phenotypic and molecular analyses showed that NEMO-deficiency in the myeloid compartment caused osteopetrosis owing to defective osteoclastogenesis. The function of NEMO is governed by post-translational modifications, primarily UB and sumoylations at multiple lysine residues which appear to be cell and signal specific. To this end, several viral constructs representing strategic point mutations at key residues in coiled-coil-2 and leucine zipper domains were utilized to examine their osteoclastogenic potential in NEMO deficient osteoclast precursors (OCPs). Of these mutants, K270A-NEMO (K270 SUMOylation-deficient) elicited higher osteoclastogenesis in NEMO-null compared to wild type cells. In contrast, expression of the mutant K319A NEMO into NEMO-null cells was lower and failed to restore osteoclastogenesis, indicating that K319-modification is essential for NEMO stability and function. To further investigate the physiological significance of K270-mediated osteoclastogenesis, we utilized the SUMO inhibitor ginkgolic acid (GA). SUMOylation of NEMO has been known as important for localization of NEMO in the nucleus, and SUMO-free NEMO is directed to the cytosol where it stages IKKβ activation. GA showed enhanced osteoclastogenesis *in vitro* compared to DMSO (carrier)-treated control. The nuclear form of NEMO was approximately 14kDa higher in molecular mass due to SUMOylation compared to the cytosolic form. Upon treatment of OCPs with GA for two hrs, the nuclear form of NEMO-SUMO was diminished, probably due to inhibition of NEMO SUMOylation. These results support our previous finding that SUMO-free K270A NEMO shows higher stability. We also tested the in vivo effects of GA on mouse bone remodeling and osteolysis. TRAP-stained histological sections of tibia indicated that the GA-treated mice showed significant increase in osteoclast number along the growth plates and decrease in trabecular bone mass. Thus, NEMO SUMOylation is crucial for regulation of osteoclasts and bone loss.

MO0263

Steap4 is Critical for Osteoclast Differentiation via Regulating Cellular Iron/ ROS and CREB Activation. Jian Zhou*[1], Shiqiao Ye[2], Toshifumi Fujiwara[3], Stavros Manolagas[2], Haibo Zhao[2]. [1]UAMS, USA, [2]Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, USA, [3]Center for Osteoporosis & Metabolic Bone Diseases, University of Arkansas for Medical Sciences & the Central Arkansas Veterans Healthcare System, Little Rock, AR, USA

Iron overload causes loss of bone mass and fractures in patients with hemochromatosis, hemosiderosis, thalassemia, and also accelerates bone loss in postmenopausal women. Iron overload leads to an imbalance in bone remodeling caused by an increase in osteoclastic bone resorption and a decrease in osteoblastic bone formation. It has recently been shown that iron uptake via the transferrin/transferrin receptor (Tf/TfR1) pathway, in concert with the peroxisomes proliferator-activated receptor-γ 1β (PGC-1β), regulates mitochondrial biogenesis, the generation of reactive oxygen species (ROS), and CREB activation during osteoclastogenesis. However, the molecular mechanisms controlling cellular iron metabolism in osteoclast lineage cells remain largely unknown. Mammalian cells acquire iron mainly through the Tf cycle, in which ferric iron (Fe^{3+})-loaded Tf binds to TfR1 on the cell surface, and the complex is then internalized via receptor-mediated endocytosis. Fe^{3+} is released from Tf due to acidic pH in endosomes. Before Fe^{3+} can be transported across the endosomal membrane to the cytoplasm for cellular utilization, it must be reduced to ferrous iron (Fe^{2+}). In this study, we have elucidated that expression of Steap4, an endosomal ferrireductase of the six-transmembrane epithelial antigen of prostate (Steap) family proteins, is increased during osteoclast differentiation, as revealed by both gene-array analysis and quantitative real-time PCR. Knocking down Steap4 expression by lentivirus-mediated shRNAs in macrophages inhibits osteoclast formation, as determined by TRAP staining, TRAP activity measurements, and quantitative expression of osteoclast marker genes. Loss of Steap4 in osteoclast lineage cells resulted in reduced ferrous iron level, decreased ROS generation, as measured by fluorescent dyes, PG SK and dichlorodihydrofluorescein, respectively. In line with previous reports, CREB activation was decreased in Steap4-deficient osteoclast precursors. Moreover, the induction of PGC1-β/ mitochondrial mRNA expression, two downstream pathways regulated by CREB, was attenuated in the absence of Steap4. In conclusions, our results indicate that Steap4 is the major endosomal ferrireductase in osteoclasts. Coupled with the up-regulated Tf/TfR pathway, Steap4 enhances cellular iron uptake and utilization, and therefore may play a critical role in osteoclast development and activation under physiological and pathological conditions.

MO0265

TMEM178 is a novel negative regulator of osteoclastogenesis and inflammatory bone loss via specific modulation of the RANKL- NFATc1 axis. Corinne Decker*[1], Deborah Novack[2], Roberta Faccio[2]. [1]Washington University in St. Louis, USA, [2]Washington University in St. Louis School of Medicine, USA

Although pro-osteoclastogenic mechanisms are well-defined, relatively few negative regulators of osteoclast (OC) formation and function have been described. Here we show that transmembrane protein 178 (TMEM178), a previously unstudied and uncharacterized integral membrane protein, acts in a negative feedback loop to restrain osteoclastogenesis (OCG) in basal and pathological conditions. By quantitative RT-PCR, we found that TMEM178 induction in response to RANKL treatment is dependent on the lipase PLCγ2, thus positioning TMEM178 downstream of RANKL-PLCγ2 pro-osteoclastogenic signaling pathways. In opposition to the osteopetrotic phenotype of PLCγ2-/- mice however, unmanipulated 16-week old TMEM178-/- mice show a surprising 25% loss in trabecular bone volume and significant cortical thinning compared to WT controls, suggesting that TMEM178 is actually a negative regulator of the OC. Indeed, TMEM178 ablation accelerates OC formation *in vitro* in a RANKL dose-dependent manner; OC markers including TRAP, β_3 integrin, DC-STAMP, and calcitonin receptor are induced earlier and to higher levels in TMEM178-/- OC compared to WT. Consistent with increased number of OC, resorptive pit area is nearly doubled in TMEM178-/- OC cultures on bone slices *in vitro*. To assess inflammatory bone loss *in vivo*, we utilized supracalvarial LPS and K/BXN serum-transfer arthritis. LPS induced 3.5 times the amount of eroded area and increased OC number in TMEM178-/- mice compared to WT. Similarly, TMEM178-/- mice suffer more bone loss correlated to a significant increase in TRAP+ OC during arthritis. To uncover the mechanism of TMEM178 activity, we examined RANKL signaling cascades. Strikingly, TMEM178-/- OC display dramatically elevated NFATc1 protein levels throughout OCG while NFκB and MAPK activation are remarkably unaffected. Moreover, ratiometric imaging of Fura-2-loaded cells shows significantly higher $[Ca^{2+}]_i$ in TMEM178-/- preOC compared to WT, further implying that TMEM178 explicitly antagonizes RANKL-induced Ca^{2+} fluxes to restrain NFATc1 activation and amplification. In sum, our results define TMEM178 as a critical mediator of a novel negative feedback loop specifically targeting the RANKL-Ca^{2+}-NFATc1 pathway and establish the importance of TMEM178 *in vivo* for maintenance of normal bone mass and protection from pathological bone loss.

Zinc inhibits Osteoclast Differentiation by Suppression of Ca^{2+}-Calcineurin-NFATc1 Signaling Pathway. Kwang Hwan Park*[1], Jae Hyuck Shim[2], Jin Woo Lee[1], Jae Myun Lee[1]. [1]Yonsei University College of Medicine, South Korea, [2]Weill Cornell Medical College, USA

Zinc, an essential trace element, has been found to inhibit osteoclast differentiation in vitro and in vivo. The molecular mechanism for the inhibitory effect of Zinc , however, has been poorly understood. The purpose of this study was to investigate the effect of Zinc and its molecular mechanism on the receptor activator of NF-κB ligand (RANKL)-induced osteoclastogenesis in mouse bone marrow-derived monocyte cells (BMMs) and RAW264.7 cells.

In BMMs, Zinc treatment during osteoclast differentiation decreased RANKL-induced osteoclast formation in a dose dependent manner. We showed that Zinc suppressed the mRNA levels of the nuclear factor of activated T-cells, cytoplasmic 1 (Nfatc1). Zinc also dose-dependently accumulated phospho-Nfatc1 (p-Nfatc1) in the cytosol and inhibited the translocation of Nfatc1 to the nucleus in RAW264.7 cells. Zinc suppressed the activities of Nfatc1 in the nucleus without changing the activities of NF-κB in RAW264.7 cells. On the other hand, the calcineurin activity was decreased due to Zinc but its protein level was unchanged. Moreover, RANKL-induced Ca^{2+} oscillations were inhibited by Zinc treatment, but phospho-phospholipaseCγ1 (p-PLCγ1), the upstream signaling molecule of the Ca^{2+} oscillations was not affected.

Taken together, this study, for the first time, demonstrates that the inhibitory effect of Zinc during osteoclastogesis is caused by suppressing Ca^{2+}-Calcineurin-NFATc1 signaling pathway. Thus, Zinc may be a useful candidate of therapeutics for the prevention of bone loss caused by NFATc1 activation in osteoclasts.

Effects of alendronate binding to bovine bone slices and smear layer removal on cultured mouse marrow-derived osteoclasts. Vivian Bradaschia-Correa*, Giovanna Ribeiro-dos-Santos, Victor Arana-Chavez. University of São Paulo - School of Dentistry, Brazil

Most *in vitro* resorption assays employ bone slices for supplying the mineralized substrate on which cultured osteoclasts are tested. However, the cutting procedures for obtaining the bone slices result in the formation of a smear layer (SL), which is not present during in vivo conditions. It is possible that the presence of SL may interfere with the osteoclast behavior. Based on this premise, the present study aimed to analyze whether the presence of SL interferes on the resorptive activity of mouse marrow-derived osteoclast-like cells. Additionally, it was analyzed whether the SL removal may affect the binding affinity of the bisphosphonate alendronate (ALN) to bone slices, osteoclast differentiation, viability and survival. Disk-shaped 0.1mm-thick slices with 0.5mm diameter were prepared from freshly obtained bovine bones by using an Isomet 1000 slow-speed precision saw equipped with a diamond-impregnated disk under refrigeration with copious water. They were treated with 1% sodium hypochlorite solution followed by 4.13% ethylidenediaminotetraacetic acid, rinsed thoroughly with deionized water and air dried. The SL removal was confirmed by scanning electron microscopy (SEM) examination. Bone slices were treated in O-phthalaldehyde-labeled ALN solutions at varied concentrations (1μM – 10mM) for 24h. The initial and final concentrations in media were analyzed by spectrophotometry. Marrow cells obtained from 30 days-old Balb c mice were cultured in α-MEM supplemented with calcitriol onto bone slices with or without SL for 5 days, and bone resorption was analyzed by SEM. Additional mouse marrow cells were cultured onto ALN-saturated SL-free bone slices during 3 days and bone resorption was analyzed by SEM; the cells that remained on the plate were incubated for TRAP, TUNEL and submitted to MTT assay. The resorbed areas decreased in SL-free samples, while SL did not affect the binding affinity of the bone slices to ALN. Bone slices in both conditions were saturated by 1mM ALN. SL removal followed by ALN treatment did not interfere in the number of TRAP positive cells and cell viability, but the resorbed area significantly reduced, while TUNEL positive cells increased compared to controls. It is concluded that the presence of SL on the bone substrate increases the in vitro resorptive activity of osteoclat-like cells, whereas the presence of ALN decreases cell viability and resorption activity.

MO0268

H_2O_2 Production in Osteoclast Mitochondria Promotes Bone Resorption and Mediates the Effects of Estrogen Deficiency. Shoshana Bartell*[1], Li Han[1], Aaron Warren[1], Julie Crawford[1], Semahat Serra Ucer[2], Stavros Manolagas[1], Maria Jose Almeida[1]. [1]Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, USA, [2]University of Arkansas for Medical Sciences, USA

Osteoclastogenesis requires mitochondrial biogenesis and H_2O_2, and catalase is a critical enzyme for the elimination of H_2O_2. Estrogens attenuate osteoclastogenesis and promote osteoclast apoptosis, at least in part, via anti-oxidant mechanisms. Furthermore, the anti-resorptive effects of estrogens on cancellous and cortical bone mass are mediated by distinct mechanisms: cell autonomous effects in the former and indirect effects via osteoblast progenitors in the latter. We have tested here the hypothesis that mitochondria-derived H_2O_2 in cells of the osteoclast lineage is an important mediator of bone resorption. To do this, we generated transgenic mice expressing human catalase targeted to the mitochondria in cells of the monocyte/macrophage lineage, using the LysM-Cre strain. We found that the number of osteoclasts formed in bone marrow cultures from MitoCat;LysM-Cre (mitoCAT) mice was lower as compared to LysM-Cre littermate controls, due to an increase in macrophage and osteoclast apoptosis. Consistent with the decreased lifespan, the activation of the pro-survival kinases Akt and Erk in response to M-CSF or RANKL was attenuated in osteoclasts from the mitoCAT mice. Under basal conditions, both male and female mitoCAT mice had higher cancellous bone volume due to an increase in trabecular number and decreased trabecular separation as determined by micro-CT. MitoCAT mice also had increased femoral cortical thickness due to decreased endosteal resorption as well as a decrease in the number of osteoclasts per cancellous bone perimeter. Six weeks following ovariectomy (OVX) of 3 month old mice, oxidative stress was increased and DEXA BMD was decreased at the spine and femur in the LysM-Cre littermate controls. All of these changes were abrogated in the mitoCAT mice. Furthermore, the mitoCAT mice were protected against the OVX-induced cortical bone loss and porosity, but not the loss of cancellous bone, as determined by micro-CT. These results demonstrate that H_2O_2 is required for optimal signaling by both RANKL and M-CSF and that H_2O_2 formation in the mitochondria promotes osteoclast generation and survival, and thereby bone resorption. In addition, they show that estrogens decrease bone resorption at the endocortical, but not the cancellous, surface via an anti-oxidant mechanism. Mitochondria H_2O_2 production, therefore, represents a potentially important pharmacotherapeutic target for the treatment of diseases caused by increased bone resorption.

Individual and Combining Effects of Anti-RANKL Monoclonal Antibody and Teriparatide in Ovariectomized Mice. Naoto Tokuyama*[1], Hironari Masuda[1], Jun Hirose[2], Yasunori Omata[1], Yuho Kadono[1], YURIKO FURUYA[3], Hisataka Yasuda[3], Nobuyuki Udagawa[4], Hiroshi Takayanagi[5], Sakae Tanaka[1]. [1]The University of Tokyo, Japan, [2]Research Hospital, The Institute of Medical Science, The University of Tokyo, Japan, [3]ORIENTAL YEAST CO., LTD, Japan, [4]Matsumoto Dental University, Japan, [5]The University of Tokyo, Department of Immunology, Japan

Introduction: Receptor activator of nuclear factor-kappaB ligand (RANKL) is a member of the tumor necrosis factor (TNF) superfamily cytokines and an essential mediator of osteoclast formation, bone-resorbing function and survival. RANKL plays a major role in the pathogenesis of postmenopausal osteoporosis and other diseases associated with bone loss. Antiresorptive agents such as bisphosphonates have been most commonly used for osteoporosis therapy. However, previous studies showed that combining alendronate with teriparatide rather attenuated the anabolic effect of teriparatide. In this study, we examined the individual and combined effects of teriparatide and anti-RANKL monoclonal antibody in ovariectomized mice.

Materials and Methods: Three-month-old female C57BL/6 mice were ovariectomyzed (OVX) or sham operated. Four weeks after OVX, they were assigned to 3 different groups to receive anti-RANKL mAb alone (5 mg/kg single injection at 4 weeks after OVX, Ab group), teriparatide alone (80 μg/kg daily injection for 4 weeks from 4 weeks after OVX, PTH group), or mAb plus teriparatide (Ab+PTH group). Mice were sacrificed 8 weeks after OVX. Bone mineral density (BMD) was measured at the femur and lumber spine. Hind limbs were subjected to histological and immunohistological analysis. Bone marrow cells were analyzed with a flow cytometer to evaluate the quantity of osteoclast precursors. Serum osteocalcin and CTX-I levels were measured to investigate the bone turnover.

Results: Compared with Ab group, Ab+PTH group showed a significant increase in BMD at distal femur, femoral shaft and lumber spine. Cancellous bone volume reached a maximum after 4 weeks of Ab injection and gradually decreased thereafter. Cortical bone volume was significantly increased in Ab+PTH and PTH groups compared with Ab group. Bone turnover in Ab+PTH group was suppressed to the same degree as in Ab group. The number of TRAP-positive multinucleated cells was markedly reduced in Ab group, while it was maintained in Ab+PTH group. The number of osteoclast precursors was increased in Ab group compared with other groups as determined by immunohistochemical analysis and flow cytometric analysis. These results suggest that combined treatment of teriparatide with anti-RANKL antibody had additive effects on BMD in OVX mice compared with individual treatment.

Losartan increases bone mass by direct inhibition of osteoclasts: evidence from murine and human data. Shan Chen*[1], Tarek Sibai[1], Nahid Rianon[2], Tao Yang[3], Jennifer Black[4], Elda Munivez[1], Terry Bertin[1], Brian Dawson[1], Yuqing Chen[1], Brendan Lee[5]. [1]Baylor College of Medicine, USA, [2]UTHealth The University of Texas Medical School at Houston, USA, [3]Van Andel Research Institute, USA, [4]Department of Pathology, Microbiology & Immunology, Vanderbilt University, USA, [5]Baylor College of Medicine & Howard Hughes Medical Institute, USA

Introduction: Osteoporosis and hypertension are two major chronic diseases of advanced age. Although traditionally these diseases are viewed as separate entities, increasing evidence suggests an overlapping etiology. One important determinant for both hypertension and osteoporosis is renin-angiotensin signaling. Inhibition of this signaling pathway lowers blood pressure and has demonstrated potential for bone loss prevention. We investigated the molecular mechanism underlying regulation of bone mass by the renin-angiotensin pathway through both animal and human studies.

Methods: Wild type mice were treated with Losartan, an antihypertensive drug that inhibits the angiotensin type 1 receptor, from birth until 6-weeks of age, after which bones were collected for microCT and histomorphometry analyses. Elderly hypertensive women treated with Losartan were examined by DXA and serum P1NP, N-UTX levels at 6 and 12 months after the onset of treatment. Osteocalst culture and Western blot assays were performed to determine the effects of Losartan on osteoclast differentiation and RANKL-induced ERK1/2 signaling.

Results: Losartan increased trabecular bone volume vs. tissue volume (a 98% increase) and cortical thickness (a 9% increase) in 6-week old wild type mice. The bone changes were attributed to decreased osteoclastogenesis as demonstrated by reduced osteoclast number per bone surface in vivo and suppressed osteoclast differentiation in vitro. At the molecular level, RANKL-induced ERK1/2 phosphorylation was attenuated by Losartan, suggesting a convergence of RANKL and angiotensin signaling at the level of ERK1/2 regulation. This also suggests that Losartan acts on ERK1/2, the essential mediator of RANKL signaling, and influences osteoclast differentiation. In the two women (Age 81 and 74) were prospectively treated for idiopathic hypertension with Losartan. Interestingly, both showed evidence of decreased bone resorption as measured by the urinary N-telopeptide.

Conclusion: Inhibition of the angiotensin pathway by Losartan has beneficial effects on bone beyond reducing blood pressure. Our study adds evidence to support the relationship between angiotensin receptor blockers (Losartan) and age-related bone loss that increases the risk of fractures in the elderly.

Pin1 regulates osteoclast fusion through the suppression of the master regulator of cell fusion DC-STAMP. Rabia Islam*[1], Won-joon Yoon[2], Kyung-Mi Woo[2], Jeong-Hwa Baek[3], Hyun-Mo Ryoo[3]. [1]School of Dentistry, Seoul National University, South Korea, [2]Seoul National University, South Korea, [3]Seoul National University, School of Dentistry, South Korea

Cell fusion is a fundamental biological event and an essential process for the development of multinucleated cells such as osteoclasts which originate from bone marrow hematopoietic precursors of the monocyte lineage. Fusion failure leads to accumulation of dense and fragile bone such as in osteopetrosis, demonstrating the importance of fusion in osteoclast maturity and bone remodeling. Previously, we discovered a role of Pin1, a peptidyl-prolyl isomerase catalyzing cis-to-trans conformational switches of target proteins presenting the Ser/Thr-Pro motif, in regulation of osteoblastogenesis and bone development. To explore its role in osteoclast formation and bone resorption we examined an in vivo mouse genetic model and found that mice null for Pin1 have low bone mass and increased amount of TRAP staining in histological sections of the upper metaphyseal region of the tibia, compared to Pin1 wild type mice; but *in vitro* culture of Pin1 deficient bone marrow-derived osteoclasts did not show a significant amount of increase in the number of TRAP positive multinucleated cells except in case of cells which have more than thirty nuclei. Pin1 deficient osteoclasts are larger than wild type osteoclasts and have higher nuclei number indicating higher fusion rate. Pin1 deficient foreign body giant cell formation was also highly increased both *in vitro* and *in vivo*. Among the known fusion proteins only DC-STAMP was highly increased in Pin1 null osteoclasts during osteoclastogenesis. DC-STAMP expression was also seen to be highly increased by immunohistochemistry in upper tibial section of Pin1 KO mice. With real time PCR we also found that mRNA of genes known to be regulated by DC-STAMP like *ACP5* and *CD9* were highly increased in Pin1 null osteoclasts after four days of culture in RANKL and MCSF supplemented media, compared to wild type osteoclasts. We found that DC-STAMP is post-translationally modified by proline directed serine threonine phosphorylation and Pin1 binds and isomerizes DC-STAMP affecting its stability and localization at the plasma membrane. Taken together our data, derived using a genetic approach, indicate that Pin1 is a determinant of bone mass through its regulation of osteoclast fusion protein DC-STAMP. The identification of Pin1 as a factor involved in cell fusion contributes to the understanding of osteoclast-associated diseases, including osteoporosis and opens new avenues for therapeutic targets.

MO0272

The Link module from Human TSG-6 is a Potent Inhibitor of Osteoclast-Mediated Bone Resorption; Towards a Novel Therapy for Osteoporosis. Jennifer Thomson*, Caroline Milner, Anthony Day. University of Manchester, United Kingdom

The TSG-6 protein has been identified as an endogenous protector of tissues during acute inflammation, e.g. in the context of inflammatory arthritis (see [1]). We showed previously that full-length recombinant human TSG-6 (rhTSG-6) is a potent inhibitor of RANKL-mediated osteoclastic bone resorption and works in synergy with OPG [1,2]; the isolated Link module from human TSG-6 (Link_TSG6) was found to be less active that rhTSG-6 and showed no synergistic effect. We also found that TSG-6 produced by osteoclasts in response to inflammatory cytokines (e.g. TNFα) acts as an autocrine regulator of their activity [1]. rhTSG-6 was found to inhibit F-actin ring formation, but had no measurable effect on the foramtion of TRAP-positive multinucleated cells from osteoclast precursors [1,2]. This suggests that TSG-6 mediates its inhibitory effect at the level of osteoclast activation, in contrast to OPG, which also suppresses osteoclast formation. In light of its anti-resorptive effects, TSG-6 represents a target for the development of novel treatments for conditions, such as osteoporosis, that are associated with excessive osteoclast-mediated bone loss. Even though Link_TSG6 may be less potent that rhTSG-6 *in vitro* [2], its greater ease of production (in *E. coli*) could make it more suitable for clinical development. Therefore, the aim of this study was to further compare the anti-resorptive activities of Link_TSG6 and rhTSG-6 and their mechanism of action.

Here we have shown (surprisingly) that Link_TSG6 has a similar potency to rhTSG-6 at inhibiting lacunar resorption of dentine by osteoclasts derived from human $CD14^+$ mononuclear cells (in the presence of M-CSF/RANKL); e.g. with ⩾90 %inhibition at 0.85 nM. Link_TSG6 also suppressed the resorptive activity of osteoclasts derived from mouse bone marrow, whereas rhTSG-6 did not. Like rhTSG-6 [1], Link_TSG6 was found to inhibit F-actin ring formation, providing a mechanism for its anti-resorptive properties.

Thus, Link_TSG6 might have therapeutic potential and work is now in progress to determine its efficacy in experimental models of osteoporosis and develop a scalable manufacturing process for this recombinant domain.

Trapidil, a platelet-derived growth factor antagonist, prevents osteoclastogenesis by down-regulating Ca^{2+}-NFATc1 axis and suppressed bone loss in mice. Sun-Don Kim*[1], Ha-Neui Kim[1], Zang Hee Lee[2]. [1]School of Dentistry, Seoul National University, South Korea, [2]Seoul National University School of Dentistry, South Korea

Trapidil, a platelet-derived growth factor antagonist, originally developed as a vasodilator and anti-platelet agent and has been used to treat patients with ischemic coronary heart, liver and kidney disease. In addition, Trapidil has been reported to inhibit glioma cell proliferation. In this study, we investigated effects of Trapidil on osteoclastogenesis and elucidated possible mechanism of Trapidil by RANKL stimulation in osteoclast precursors BMMs. Trapidil strongly inhibited osteoclast formation in co-culture of bone marrow cells and osteoblast without affecting RANKL and OPG expression in osteoblasts. In addition, Trapidil suppressed the RANKL-induced osteoclast formation from osteoclast precursors BMMs. Trapidil reduced the RANKL-induced NFATc1expression, a master transcription factor, in BMMs, whereas those of NF-kB and c-Fos, which are also transcription factors involved in osteoclast differentiation, were not affected. Ectopic expression of constitutively active form of NFATc1 reversed the Trapidil-induced anti-osteoclastogenic effect. Trapidil inhibited RANKL-induced phosphorylation of CREB, which is necessary for osteoclast differentiation. In addition, we found that Trapidil decreased formation inactive form of GSK3β, modulator of NFATc1 in osteoclast differentiation. Furthermore, Trapidil reduced protein level of TRPV5 calcium channel, which is involved in Ca^{2+} influx on osteoclast and significantly inhibited calcium influx by RANKL stimulation. Consistent with the in vitro anti-osteoclastogenic effect, Trapidil had potent inhibitory effect on osteoclast formation and bone resorption and induced by IL-1 in an animal model. Taken together, our data demonstrate that Trapidil may influence Ca^{2+} entry through TRPV-5 calcium channel, resulting in down-regulation of NFATc1 and CREB phosphorylation involved in osteoclast formation and bone resorption in osteoclasts.

Bone is organized by several organs through the endocrine and nervous systems. Since bone is a highly vascularized organ, angiogenesis is a vital process during skeletal development. Recent studies demonstrated that the interaction of osteoblasts and endothelial cells has been essential for bone fracture repair. However, the role of vascular system in bone metabolism is not fully elucidated. Here we investigate whether vascular endothelial cells communicate with osteoclasts directly. We found that osteoclast differentiation was inhibited in the co-culture system of vascular endothelial cells and bone marrow macrophages under RANKL stimulation. Then we examined the expression of netrin family, which vascular endothelial cells robustly express, and found that vascular endothelial cells expressed netrin 4 and osteoclast expressed the receptors for netrin family. We showed that TRACP positive cells were significantly reduced and gene expression of osteoclast differentiation markers was significantly decreased in osteoclasts treated with netrin 4, suggesting that netrin 4 inhibited osteoclast differentiation. Next we examined gene expression of netrin receptors of osteoclast in the co-culture system and found that Down syndrome cell adhesion molecule (DSCAM), which was one of the netrin receptors, was strongly up-regulated in osteoclasts co-cultured with vascular endothelial cells. Moreover, the blockade of osteoclast differentiation by netrin 4 produced from vascular endothelial was neutralized with treatment with anti-netrin 4 antibody, resulting in the augmentation of osteoclast differentiation. Finally, immunostaining revealed that netrin 4-positive cells were consistent with PECAM 1-positive cells. Our results demonstrated that netrin 4 derived from vascular endothelial cells inhibit osteoclast differentiation via DSCAM receptor of osteoclasts.

Age Effects on Bone Microarchitecture and Osteocyte Sensing of Skeletal Loading. Teri Cline*[1], Matthew Stern[1], Mark Van Dyke[2], Christopher Bergman[3], Ying Liu[1], Amber Stern[1]. [1]University of Missouri - Kansas City, USA, [2]Virginia Tech, USA, [3]Wake Forest Institute for Regenerative Medicine, USA

At the cellular level, bone adaptation is controlled by osteocytes. Studies have shown that in the absence of mechanical loading, osteocytes send signals of bone resorption. Understanding the microarchitecture of bone is essential to the study of the mechanotransduction of these signals within the osteocyte lacanocanalicular network. The purpose of this study was to analyze the effect of age on the microarchitecture of bone and its role in strain transmission to the osteocyte.

Ten murine femur bone samples were studied; 5 old (2-yr-old), and 5 young (5-mo-old). Each sample was resin-embedded, acid etched, and imaged using Scanning Electron Microscopy (SEM). ImageJ was utilized to analyze the samples and quantitatively assess changes in canaliculi number, canaliculi diameter, lacunar size, and lacunar density. The samples were also analyzed based on the location of the osteocyte within the bone: periosteal versus endosteal regions. All results reported are significant based on t-tests ($p<0.05$). Representative finite element (FE) models of the bone microarchitecture were then created.

The microarchecture of young bone was found to be significantly different than that of old bone. Differences were also found between the endosteal and periosteal regions. The number of canaliculi/lacuna were found to decrease with age, while a greater number of canaliculi were found the periosteal regions of the young bone samples when compared to the endosteal regions. The diameter of the canaliculi increased with age. The canaliculi diameter also increased in the periosteal region from young to old. In the old murine bone samples, the canaliculi diameter decreased from the periosteal to the endosteal regions. The lacunar size decreased in the periosteal region from young to old. Lacunar size also decreased from the endosteal to the periosteal regions in the young bone. The overall lacunar density was found to increase with age. The resulting FE models predicted lower levels of strain being transmitted to osteocytes in the old bone and also those located in the endosteal region.

These results provided the necessary data to create a more anatomically accurate parametric FE analysis to study the microscopic strains sensed by osteocytes *in vivo*. Osteocytes in old murine bone experience lower strain levels than their young bone counterparts. Additionally, murine bone may remodel differently than primate bone, as the lacunar density was significantly higher in the old bone.

Summary of Properties	Young	Old
Canaliculi Count	73	63*
Canaliculi Diameter (um)	0.2641	0.2771*
Lacunar Cross sectional area (um^2)	92.7	88.6*
Density (lacunae/mm^2)	1345	1492*

MO0276

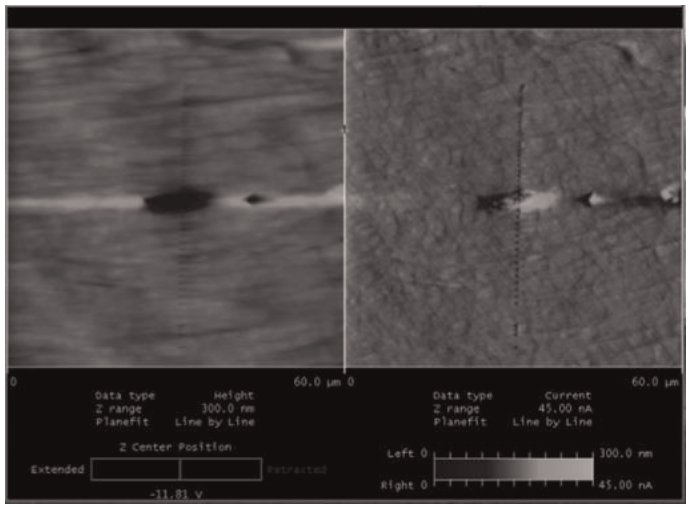
Age Effects on the Macromechanical and Micromechanical Properties of Bone. Craig Meers*[1], Mark Johnson[2], Ying Liu[1], Thomas Register[3], Amber Stern[1]. [1]University of Missouri - Kansas City, USA, [2]University of Missouri, Kansas City Dental School, USA, [3]Wake Forest School of Medicine, USA

It is known that bone remodels itself in response to changes in its mechanical environment, with osteocyte mechanotransduction playing a major role. It has been shown that the modulus of the perilacunar region has an effect on the force transmitted to the embedded osteocyte. As the modulus increases, the bone deforms less to an applied force and less force is perceived by the osteocyte. This study examines bone microstructure directly around the lacunae in the perilacunar region and how its biomechanical properties change with age and the resulting effects on the osteocyte.

Femurs from 6 young (4-mo-old) and 5 old (24-mo-old) female mice (C57Bl/6) were harvested. Right femurs were used to determine overall bone biomechanical properties via 3-point bending. Nanoindentation was performed on the left femurs every 1 μm for 20 μm radially out from 3 mid-shaft lacunae/femur in the endosteal and periosteal directions (figure below). Additionally, lacunae from 10 female non-human primate (NHP) (vervet) femurs, 5 young and 5 old, were used for nanoindentation. Student's t-tests for paired/unpaired samples were conducted ($p<0.05$). All results reported are statistically significant.

The 3-point bending experiments resulted in a modulus in the young bones of 4.68 ± 0.37 GPa and 2.24 ± 0.17 GPa for the old and an ultimate strength of 14.10 ± 0.2 MPa for young and 8.66 ± 0.39 MPa for the old. A difference between young and old perilacunar and non-perilacunar regions were seen in both species. Mice had a perilacunar modulus of 21.5 ± 0.42 GPa for young and 22.1 ± 0.47 GPa for old while NHPs had a perilacunar modulus of 30.6 ± 0.40 GPa for young and 31.3 ± 0.37 GPa for old. The moduli in the endosteal direction were significantly higher than in the periosteal direction.

Overall bone strength deteriorated with age with decreases in both modulus and ultimate force for the whole bone. However, the nanoindentation results revealed that there was actually an increase in modulus surrounding the lacunae in the old bone. By applying these values to a finite element model created for an individual lacuna, we have also shown that the forces imposed on the embedded osteocyte are lower for the older animals than that of the younger. If the osteocytes are not experiencing the same loading signals as they age, they may not be reaching the signaling threshold required to initiate bone remodeling, leading to the deterioration of bone strength and unresponsiveness to exercise with age.



Nanoindentation/AFM of Osteocyte Lacuna

Feasibility Studies on In Situ Imaging-Based Quantification of the Density of Osteocyte Pericellular Matrix. Xiaohan Lai*, Christopher Price, Liyun Wang. University of Delaware, USA

Osteocytes are believed to detect external mechanical loads through sensing the interstitial fluid flow through their pericellular matrix (PCM), which can be deformed under load-induced fluid flow, like trees bent in wind. The PCM also can modulate the transport of signaling molecules and nutrients in bone. Despite its physiological importance, quantitative study of the PCM *in situ* and *in vivo* is challenging, since the PCM is encased in the mineralized matrix, is extremely thin, is very fragile, and often damaged by histological techniques. Our lab has recently developed an approach combining fluorescence recovery after photobleaching (FRAP) and mathematical modeling to quantify the osteocyte PCM. However, in our previous one-tracer FRAP approach (Wang et al., 2012 JBMR doi: 10.1002/jbmr.1804), velocities of fluid and solute were measured individually in different bone samples, which introduced variability from both anatomical and loading inconsistency. To address these limitations, we propose a novel dual-colored FRAP approach, which allows simultaneous measurements of both fluid and solute velocities.

In this study, the feasibility of dual-colored FRAP in detecting changes in PCM ultrastructure was tested using mathematical simulations. Using a three-compartment model developed previously (*Fig 1, Table 1*), we examined the ratio of transport rates for two differently sized tracers (sodium fluorescein, radius 0.5nm; parvalbumin, radius 1.3nm) under dynamic loading as we parametrically varied the PCM fiber density (0.5% to 50% fiber volume fraction) and the anatomical parameters (lacunar size and spacing and canalicular number) at 50%, 100%, and 200% of mean values obtained in adult B6 tibiae. The tracer diffusivities in the PCM were estimated from their free diffusivities in water using Monte-Carlo simulation (*Fig 2*). Load-induced flow velocities were obtained from a previous tissue-level poroelasticity model.

We found that the transport ratio of larger to smaller probe monotonically decreased with increasing PCM fiber density. The transport ratio was also affected by mechanical loading magnitude and the lacunar spacing, but was insensitive to the lacunar size and canalicular number (*Figs 3, 4*). The results suggest that dual-colored FRAP could be feasible in detecting changes in PCM ultrastructure, which may account for the genetic- and site-specific bone sensitivity to mechanical loading.

Sclerostin Directly Abrogates Mechanical Loading-Induced Bone Formation in an Ex Vivo Bovine Bone Model. Masakazu Kogawa*, Kamarul Khalid, Asiri Wijenayaka, David Findlay, Gerald Atkins. University of Adelaide, Australia

Sclerostin is expressed exclusively by mature osteocytes in bone. Our recent findings indicate that sclerostin targets pre-osteocytes/osteocytes to regulate bone mineralization(1), osteoclast activity(2) and also osteocytic osteolysis(3). Sclerostin expression *in vivo* is associated with the osteocyte response to mechanical loading/unloading(4). The aim of this study was to examine the direct effects of sclerostin on loading-induced bone growth *ex vivo*.

Bovine sternum trabecular bone cores were perfused with osteogenic media at 37℃ for up to 3 weeks in individual bone culture chambers. The cores were divided into 3 groups; a) mechanically loaded (300 cycles, 4000 μstrain, 1 Hz/day), b) identical loading regime with continuous perfusion of 50 ng/ml recombinant human sclerostin and c) unloaded controls. Loading was accomplished using a second-generation Zetos bone loading system. Daily measurements of bone stiffness, media pH and ionic calcium concentrations were made. Histomorphometric assessment, including fluorochrome labelling analysis, was made of resin-embedded, non-decalcified samples at the end of the experiment. Gene expression in the bovine bone was examined by real-time RT-PCR.

Bone stiffness increased with daily mechanical loading. This increase in stiffness was blocked by the co-addition of sclerostin. Sclerostin also induced bone acidification and a net release of bone calcium, indicated by the decrease in media pH and the relative increase in ionic calcium concentrations in the presence of sclerostin. Sclerostin also completely abrogated loading-induced calcium/calcein uptake. Sclerostin induced an increase in the expression of the bone resorption genes, tartrate resistant acid phosphatase (TRAP), carbonic anhydrase and cathepsin K. Consistent with osteocyte involvement in this effect, osteocyte lacunar size was significantly increased in SCL-treated loaded bone cores.

Together, this study demonstrates that sclerostin directly antagonizes mechanical loading induced bone growth and is consistent with loading induced reduction of endogenous sclerostin expression being essential for a growth effect.

MO0279

Dichotomy in osteocyte regulation of anabolic action of mechanical loading challenge and that of bone repletion after a low dietary calcium challenge. Matilda Sheng*[1], Kin-Hing William Lau[2], Xiao-Dong Zhou[1], Denise Rodriguez[1], Adam Finck[1], David Baylink[1]. [1]Loma Linda University, USA, [2]Jerry L. Pettis Memorial VA Medical Center, USA

Skeletal tissue has 2 major skeletal anabolic functions apart from fracture healing: 1) anabolic response to mechanical loading and 2) anabolic repletion of bone after a period of calcium deficiency. Numerous recent publications suggest that osteocytes are pivotal in both mechanisms. Recently we developed mice with conditional knockout (KO) of IGF-I in osteocytes, which showed marked reduction in immunohistochemical staining of IGF-I in osteocytes but not in osteoblasts. These mutant mice displayed an almost complete resistance to the anabolic effects of mechanical loading. Accordingly, a progressive increase in loading strain from 2,000 to 5,000 με on the tibia showed a dose-dependent increase in anabolic endosteal bone formation in the wild-type (WT) animal but no anabolic response in the conditional osteocyte IGF-I KO mice (1.26 ± 0.30 vs. 2.42 ± 0.43 mm^2 x 10^{-3}/day in WT, 1.02 ± 0.30 vs.1.08 ± 0.29 mm^2 x 10^{-3}/day in KO; Fig. 1). We then sought to use this mouse model to test the hypothesis that the regulation of bone formation by mechanical loading and bone repletion after a low calcium dietary challenge is independent of each other. In sharp contrast to mechanical loading response, both WT and KO animals showed an increase in endosteal bone formation ($+40 \pm 2$% of control in WT vs. $+50 \pm 5$% in KO, p=N.S.; Fig. 1) attended by a sharp reduction in osteoclast number (-63 ± 8% of control in WT vs. -56 ± 8% in KO, p=N.S.), at 1 week calcium repletion following 2 weeks of dietary calcium restriction. Consistent with the bone repletion response, dietary calcium restriction also did not cause significant differences in the WT and KO mice, as similar decrements in serum calcium (-9.9 ± 1.5% of control in WT vs. -8.1 ± 1.8% in KO) and similar increments in serum PTH ($+301 \pm 32$% of control in WT vs. $+380 \pm 54$% in KO). There was also no significant difference in the increase in endosteal/trabecular osteoclast number in response to calcium deficiency (+25% in WT vs. +9% in KO, p=N.S.). In conclusion, 1) there is a dichotomy between the mechanisms necessary for anabolic responses to mechanical loading and the regulatory hormonal and anabolic skeletal repletion following low dietary calcium challenge. 2) Osteocyte-derived IGF-I is essential for anabolic bone response to mechanical loading but not for bone repletion after a low calcium challenge.

MO0280

Initial Activation of β-catenin Signaling in Osteocytes is Prostaglandin Dependent. Nuria Lara*[1], Mohamed Kamel[1], Behzad Javaheri[2], Mark Johnson[3]. [1]University of Missouri - Kansas City, USA, [2]The Royal Veterinary College, United Kingdom, [3]University of Missouri, Kansas City Dental School, USA

Bone increases its mass in response to mechanical loading. Activation of the Lrp5/Wnt/β-catenin signaling pathway has been shown to be critical for this process. Previously we have shown using the TOPGAL (β-catenin reporter) mouse that after forearm loading there is a rapid activation of the β-catenin signaling pathway in osteocytes and eventually to cells on the bone surfaces. Moreover, we observed that cells activate the Wnt/β-catenin pathway even in the presence of the two well-known Lrp5/6 inhibitors, sclerostin and Dkk1. We have shown that the prostaglandin signaling pathway can crosstalk with β-catenin signaling through Akt mediated inhibition of GSK-3β *in vitro*. In this study we sought to determine if production of prostaglandin is required for the initial activation of β-catenin signaling pathway and

if Akt is a key mediator of this activation. *In vivo* mechanical loading of the forearm was performed on anesthetized TOPGAL mice using compression loading of the right forearm (100 cycles, 2 Hz, 2500 μ?) with the left arm as non-loaded control. Mice were euthanized at 24 hours post loading and activation of the β-catenin signaling was monitored by β-gal staining. Mice were treated with the COX-2 inhibitor Carprofen (5mg/Kg) or vehicle three hours prior to forearm loading. For *in vitro* loading studies, MLO-Y4 cells were subjected to flow fluid shear stress (2 dynes/cm^2) for 2 hours in the presence or absence of Akti (an Akt inhibitor), immunocytochemistry was used to detect β-catenin translocation to the nucleus. Activation of β–catenin signaling in osteocytes reaches a peak at 24 hours and reaches basal levels by 72 hours. At 24 hours post-load the number of β-catenin activated osteocytes increased to 176% of unloaded ulnae in vehicle treated mice, but in Carprofen treated mice there was no increase in the number of activated osteocytes in loaded versus unloaded ulnae ($p<.01$, n=4). In our *in vitro* model of loading, there was an increase in the translocation of β-catenin to the nucleus by 196%, but in the presence of Akti this effect was reduced to static, non-flow treated levels ($p<0.05$, n=3); indicating that β-catenin translocation to the nucleus in response to mechanical loading can be blocked by inhibiting the Akt pathway. These data support our hypothesis that prostaglandins play an important role in the early activation of the β-catenin/Wnt pathway and can activate signaling even in the presence of the Lrp5/6 inhibitors, sclerostin and Dkk1.

MMP13-mediated osteocyte remodeling during glucocorticoid induced osteonecrosis. Faith Hall-Glenn*, Aaron Fields, Ellen Liebenberg, Jeffery Lotz, Thomas Vail, Tamara Alliston. University of California, San Francisco, USA

The maintenance of subchondral bone is essential for articular cartilage health. Osteonecrosis (ON) is a painful progressive joint disorder in which subchondral bone sclerosis and failure leads to the collapse of the overlying cartilage. Although glucocorticoid (GC) treatment and vascular defects have been implicated in ON, many questions remain about the cellular mechanisms that lead to the deposition of the disorganized, hypermineralized subchondral bone matrix in this disease. Nor is it known how these cellular defects can be reversed to prevent ON progression. We recently found that matrix metalloproteinase-13 (MMP-13) is essential for the ability of osteocytes to maintain cortical bone matrix composition, organization and function through a process called perilacunar remodeling (PLR). MMP-13-deficient bone shows hallmarks of defective PLR including disorganized collagen matrix, hypermineralization, and degeneration of the canalicular network that facilitates osteocyte nourishment, cellular communication and mechanosensation. Based on similarities between bone from MMP-13-deficient mice and human ON femoral heads, we hypothesized that osteocyte mediated PLR remodeling is required for subchondral bone health and is disrupted in ON. To that end, outcomes of PLR were examined in subchondral bone from human ON femoral heads from hip arthroplasties, as well as in an established mouse model of GC-induced ON. MMP-13 and TRAP expression, and canalicular organization were evaluated histologically. Mineralization was assessed by micro-CT and collagen organization by second harmonic generation microscopy. MMP-13 mRNA expression was evaluated in mouse tibiae and in murine osteocyte-like (MLO-Y4) cells treated with GC for 24 hours. Each outcome measure showed that PLR was disrupted in subchondral bone of ON human femoral heads, with hypermineralization, collagen disorganization, degenerated canaliculi, and abnormal MMP-13 expression. Similar defects were apparent in bone from GC-treated mice relative to control littermates. GC repressed MMP-13 RNA and protein expression in mice and in MLO-Y4 cells. These studies suggest that osteocyte-mediated PLR is deregulated in ON, and further, that this deregulation may result from GC-mediated repression of the essential PLR enzyme MMP-13. Elucidation of the role of PLR in ON may reveal novel ON therapeutic targets.

Strontium Ranelate accelerates MLOY4 osteocyte lineage wound healing. Hechmi Toumi[1], Priscilla Aveline[2], Chloé Leduc[3], Eric Lespessailles*[4], Chantal Pichon[3], Claude Laurent Benhamou[5]. [1]EA 4708 I3MTO, France, [2]Centre Hospitalier Régional D'Orléans, France, [3]CBM Orléans, CNRS UPR4301, France, [4]Centre Hospitalier Regional, France, [5]CHR ORLEANS, France

Since pre-osteocyte wound healing may play an indirect but important role in bone fracture or microcrack repair. We have recently settled a wound healing experiment on in vitro cell culture. This experiment permits subsequent study of cell proliferation and migration during the healing process. Strontium Ranelate (SrRan) is known to act on the bone forming lineage. Purpose: The aim of the present study was to investigate the wound healing process on MLOY4 cell culture with or without SrRan.Method: Osteocyte woung healing was analysed by a MLOY4 cell culture in 24-well plates each containing inserts (Wound healing assay kit, Cell Biolabs). Cells were incubated 3 days with or without SrRan (0, 0.1, 1 and 5mM) before removing insert to generate a wound field. 2 pictures per well were taken every hour during 72h. Changes in cells density between T0h and T48h were avaluated by counting the number of cells per well.Results: MLOY4 cells were multiplied by 5.7 and 4.8 at T48h compared to T0h respectively for 0 and 0.1mM groups and by 3.4 for both 1 and 5mM groups. Concerning MLOY4 culture healing, all wound fields with SrRan were closed at T35h after baseline. While, the control group (0mM) was not completely haeled at T35h nor at T48h. The healing kinetics showed a dose effect of SrRan.Conclusions: SrRan has a positive dose dependent effect on wound healing and negative dose response on cell density in MLOY4 cell cultures. Whether this effect is related to proliferation or migration (or change in their balance) remains to be evaluated.

Deletion of Cx43 in osteocytic cells increases autophagy: a potential mechanism for accumulation of empty lacunae in mice lacking Cx43 in osteoblastic cells. Rafael Pacheco Da Costa[1], Iraj Hassan*[2], Wonjin Kim[3], Rejane D Reginato[4], Teresita Bellido[5], Lilian Plotkin[5]. [1]Indiana University/Universidade Federal de Sao Paulo - Brazil, Brazil, [2]Dept. Anatomy & Cell Biology, USA, [3]College of medicine, Yonsei university, South Korea, [4]Department of Morphology & Genetics, Federal University of São Paulo, Brazil, [5]Indiana University School of Medicine, USA

Mice lacking connexin (Cx) 43 in osteoblasts/osteocytes or only in osteocytes exhibit high prevalence of osteocyte apoptosis and accumulation of empty lacunae, features that resemble the consequences of aging in bone from rodents and humans. Empty lacunae accumulation in Cx43 deficient mice contrasts with other models of increased osteocyte apoptosis, i.e. sex steroid deficiency or glucocorticoid excess in which lacunae remain occupied by the apoptotic osteocytes. We hypothesized that osteocyte disappearance from their lacunae in Cx43 deficient mice is due to elevated autophagy, a catabolic mechanism that involves degradation of cellular components and can be associated with apoptosis. To test this hypothesis, we used MLO-Y4 osteocytic cells in which Cx43 expression was silenced by shRNA [Cx43(-) cells]. Cultured Cx43(-) MLO-Y4 cells exhibit spontaneous loss of viability, demonstrating that apoptosis is a cell autonomous outcome of Cx43 deletion. In addition, Cx43 shRNA lead to 3-fold higher expression of p62/SQSTM1, a mediator of autophagy, compared to scramble-shRNA transfected cells. Further, the percentage of cells with LC3 in the autophagic compartment (a marker of autophagy visualized by punctuated LC3-GFP expression) was 2-fold higher in Cx43(-) MLO-Y4 cells compared to scramble-transfected cells. Conversely, the percentage of Cx43-naïve HeLa cells exhibiting punctuated LC3-GFP is reduced by Cx43 transfection. In addition, autophagy is increased in scramble- and Cx43-silenced MLO-Y4 cells treated with 30nM rapamycin, 0.1μM dexamethasone, or serum-starved, all known to increase cellular autophagy. Since autophagy can increase or decrease cell death depending on the cell type and intensity of the proautophagy stimuli, we tested whether rapamycin, a specific autophagy inducer, affected apoptosis of MLO-Y4 osteocytic cells. Rapamycin further increases the already elevated levels of apoptosis in Cx43(-) MLO-Y4 cells, whereas it did not affect scramble-shRNA cells. Our results demonstrate that Cx43 deficiency increases osteocyte autophagy and that autophagy exacerbates osteocytic cell death. We conclude that accumulation of empty lacunae in bones from Cx43-deficient mice might result from concomitant increases in osteocyte apoptosis and autophagy. Because Cx43 expression is reduced in bones from old mice, these findings raise the possibility that Cx43 deficiency could contribute to accumulation of empty lacunae and increased fragility with skeletal aging.

Kalirin: Novel Role in Osteocyte Function and Bone Cell Signaling. Kornchanok Wayakanon*, Pierre Eleniste, Su Huang, Matthew Allen, Angela Bruzzaniti. Indiana University School of Dentistry, USA

Communication between bone cells is important for the maintenance of bone mass. Although osteocytes are embedded within the mineralized matrix, they play an essential role in the regulation of osteoblast and osteoclast (OC) function. However, the intracellular proteins that control the morphology and function of osteocytes, and their ability to communicate with other bone cells are still unknown. Kalirin is a novel GTP exchange factor (GEF) protein that activates Rac1 and RhoA. Recently, micro-CT analysis of 14 week old female Kalirin knockout (Kal-KO) mice revealed a 45% decrease in trabecular bone density, as well as significantly lower cortical area, perimeter, thickness and polar cross-sectional moment of inertia (-12.6%, -7.2%, -7.6% and -21.9%, respectively, $p<0.05$), compared to WT mice. Moreover, we found a 42% increase in TRAP-stained OCs/bone surface in femoral trabecular bone *in vivo*, as well as increased OC differentiation with RANKL and MCSF *in vitro*. However, the function of Kalirin and its mechanisms of action in bone cells are still unclear. In this study we examined the role of Kalirin on the morphology and function of osteocytes. Primary osteocytes were isolated by sequential collagenase digestions from long bones (femurs and tibias) of 10-week old female WT and Kal-KO mice. Quantitative real-time PCR demonstrated that the expression RANKL mRNA, which is important for OC differentiation, was increased 5.4 ± 3.0 fold in Kal-KO mice compared with WT mice ($p<0.05$), whereas the expression of OPG was unchanged. In contrast, the expression of SOST, which is important for controlling Wnt signaling and bone formation by osteoblasts, was decreased (0.6 ± 0.2 fold, $p<0.05$) in Kal-KO mice. Microscopic analysis of primary osteocytes isolated from long bones of Kal-KO and WT mice revealed 50% fewer cytoplasmic processes ($n=100$ cells, $p<0.01$) in Kal-KO osteocytes, compared with WT cells. Moreover, using the osteocytic cell line MLO-Y4, we demonstrated that activation of Rac1-GTP and RhoA-GTP, which are substrates of Kalirin, led to an increase in the length of osteocyte cytoplasmic processes. Together, these results suggest that Kalirin may control osteocyte function and signaling to OCs by regulating RANKL secretion, leading to an increase in osteoclastogenesis. Kalirin deficient osteocytes may also alter the balance of bone formation via the Wnt signaling pathway in osteoblasts.

Sclerostin Exerts a Coordinated Pro-osteoclastogenic Effect via its Action in Osteocytes. Asiri Wijenayaka*[1], Masakazu Kogawa[1], Lynda Bonewald[2], David Findlay[1], Gerald Atkins[1]. [1]University of Adelaide, Australia, [2]University of Missouri - Kansas City, USA

Sclerostin (SCL) is a product of mature osteocytes and a potent negative regulator of bone formation.(1) Our recent study showed that SCL affects osteoblasts in an anti-anabolic manner.(2) However, studies employing a neutralising antibody against SCL have reported decreased bone resorption markers,(3) indicating that SCL may also have a catabolic action. In recent studies, osteocyte expression of RANKL has been shown to be critical for osteoclastic remodelling of bone.(4) We have reported that SCL stimulated RANKL expression in human bone, in human primary osteocyte-like cultures and in MLO-Y4 cells. SCL stimulated osteoclast activity in a dose-dependent manner in co-cultures of MLO-Y4 cells and osteoclast precursors.(5) The aim of the current study was to further examine the pro-osteoclastogenic effect of SCL in this latter model.

To examine the individual contributions of osteocytes and osteoclast precursors, MLO-Y4 cells were co-cultured with human peripheral blood mononuclear cells (PBMC) in the absence or presence of human recombinant sclerostin (rhSCL). We used species-specific PCR primers to amplify osteocyte or osteoclast-derived markers. Human bone samples were obtained from patients undergoing hip arthroplasty and cultured in the absence or presence of rhSCL; total RNA was extracted and histology conducted to study the effects of rhSCL on human bone. Since SCL has shown to bind to three known low density lipoprotein receptor-related protein (LRP) receptors, we also performed siRNA knockdown of *Lrp4*, *Lrp5*, and *Lrp6* respectively in MLO-Y4 cells to elucidate which receptor or receptors were important for the pro-osteoclastogenic effect.

Interestingly, rhSCL was capable of inducing mRNA levels of a number of pro-osteoclastogenic mediators, such as *Rankl, Csf1* and *Il6* in MLO-Y4 cells in co-cultures. In the osteoclast fraction *CA2, ACP5* (TRAP) and *CATK* mRNA increased with rhSCL treatment. Human bone treated with rhSCL also had increased expression of *RANKL* and *CSF1* mRNA. siRNA knockdown studies indicated that all of LRP4, LRP5 and LRP6 receptors were required for the pro-osteoclastogenic response to SCL in MLO-Y4 cells. Together, these findings suggest that sclerostin exerts a coordinated pro-osteoclastogenic effect via its action on the osteocyte, in a manner consistent with inhibition of Wnt signalling.

MO0286

Tartrate-Resistant Acid Phosphatase (TRAP) Co-localize with Receptor Activator of NF-κ Ligand (RANKL) in Osteoblasts and Osteocytes: a Potential Role for TRAP in Regulation of Osteoclast Differentiation. Lene Solberg*[1], Espen Stang[1], Sverre-Henning Brorson[1], Goran Andersson[2], Finn Reinholt[3]. [1]University of Oslo & Oslo University Hospital, Norway, [2]Karolinska Institute, Sweden, [3]University of Oslo, Norway

TRAP is a well known osteoclast marker with several biological abilities in bone; i.e., dephosphorylation of osteopontin, bone sialoprotein and osteonectin as well as dephosphorylation of Man-6-P recognition marker on lysosomal proteins and bone matrix degradation via generation of reactive oxygen species. In addition to osteoclasts, osteoblasts and osteocytes in discrete bone areas show TRAP protein expression and enzyme activity. The origin and function of TRAP in these cells are debated however; demonstration of TRAP mRNA implies some endogenous production. The most prominent hypothesis has been that osteoclasts initiate TRAP expression in osteoblasts and osteocytes. Alternatively, it has been suggested that osteoblast-like cells engulf osteoclastic TRAP for inactivation. Recent data indicate that TRAP is involved in osteocytic osteolysis under specific metabolic conditions, e.g. lactation. TRAP+ vesicles have been observed in osteoblasts *in vivo* indicating that TRAP could either be excreted from the cell, involved in lysosomal processes or internalized from the matrix. In order to explore the function of TRAP in osteoblasts and osteocytes, we used long bones from 3 days old rats. Undecalcified sections from tibia metaphysis and diaphysis were subjected to immunogold labeling and immunofluorescence. Transmission electron microscopy demonstrated TRAP in osteoblasts and osteocytes in electron dense vesicles (200-500nm). LAMP1 was observed in the vesicle membrane (A) indicating that the TRAP+ vesicles may be late endosomes, degradative lysosomes or secretory lysosomes. TRAP and RANKL were found co-localized in the vesicles in both osteoblasts and osteocytes; confocal fluorescence microscopy demonstrated co-localization of TRAP and RANKL in osteocytes (B). Our results do not support the notion that the TRAP+ vesicles represent late endosomes since RANKL is produced for secretion by osteoblasts and osteocytes. Recent studies have demonstrated that the majority of RANKL in osteoblasts and osteocytes is sorted to secretory lysosomes with stimulation dependent release to the cell surface. We propose that the TRAP+ vesicles observed in osteoblasts and osteocytes *in vivo* may either represent lysosomes involving TRAP in intracellular degradation of RANKL, or secretory lysosomes suggesting a regulatory role for TRAP in the secretion of RANKL or in the early stage of osteoclast differentiation and activation.

The "unfolded protein response" stimulates RANKL production: a potential mechanistic link between osteocyte apoptosis and cortical porosity. Robert Jilka*, Kanan Vyas, Michela Palmieri, Yu Liu, Charles O'Brien, Stavros Manolagas. Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, USA

Cortical bone porosity increases with advancing age in humans and mice, but the underlying molecular and cellular mechanisms are unknown. Earlier work in rodents indicated that osteocyte apoptosis is associated with increased RANKL synthesis by neighboring osteocytes, induction of intracortical remodeling, and the development of cortical porosity, raising the possibility that the same intracellular signaling pathways involved in regulation of osteocyte apoptosis may modulate the expression of RANKL. To elucidate a mechanistic link between osteocyte apoptosis and RANKL production, we have investigated the role of the unfolded protein response (UPR) to endoplasmic reticulum (ER) stress, a mechanism by which cells adapt to a variety of toxic conditions including oxidative stress and hypoxia. The UPR increases synthesis of proteins that reduce ER stress and thereby prevents apoptosis. If stress is not alleviated, the UPR stimulates the production of pro-inflammatory cytokines and activates pro-apoptotic pathways. We report that the ER stress-inducing agent tunicamycin increased UPR transcripts such as Xbp-1s within 4 h in cultures of osteoblastic/osteocytic cells obtained from neonatal murine calvaria. These changes were associated with increased expression of RANKL, the pro-apoptotic transcription factor CHOP, and induction of apoptosis as measured by caspase-3 activation. Tunicamycin, as well as hypoxia, also activated the UPR and stimulated the expression of TNF and RANKL in neonatal calvaria organ cultures. OPG expression was unaffected. Treatment of calvaria with tunicamycin for 4 hours per day for 4 days increased osteoclastogenesis as indicated by cathepsin K expression and secretion of TRAPase, and stimulated bone resorption as evidenced by release of calcium into the culture medium. Moreover, a single injection of tunicamycin to 3-mo-old female C57BL/6 mice increased expression of UPR transcripts and RANKL in osteocyte-enriched femoral bone, and increased the number of osteoclasts within 7 days. Based on these findings, we propose that an increase in the intensity and/or duration of the UPR in osteocytes with advancing age may contribute to the development of cortical bone porosity by stimulating the production of pro-inflammatory cytokines like TNF, leading to the local synthesis of RANKL.

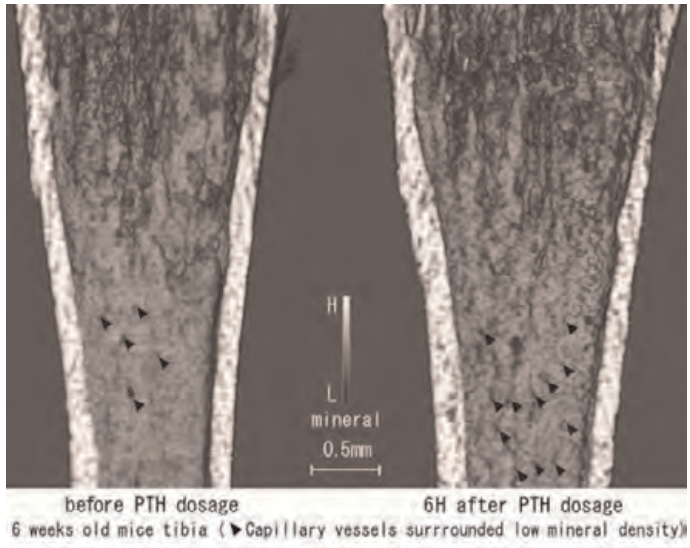
MO0288

A Single PTH Administration Induces Bone Mineral Dissolution around Capillary Vessels Entrances at the Endosteal Surface. Nobuhito Nango*[1], Shogo Kubota[1], Wataru Yashiro[2], Atsushi Momose[2]. [1]Ratoc System Engineering Co., Ltd., Japan, [2]Institute of Multidisciplinary Research for Advanced Materials, Tohoku University, Japan

Parathyroid hormone (PTH) is known to promote bone resorption, and to increase Ca2+ concentration in blood when continuously administered. On the other hand, intermittent administration of PTH promotes bone formation and is used to treat osteoporosis. However, its mechanism of action remains unclear. Using synchrotron X-ray microscope, we previously reported that osteocytes dissolve bone mineral through their canaliculi. In this report, we examined the impact of a single PTH administration that might dissolve mineral through osteocytes and canaliculi. Sixty seven wild-type male mice were divided into the control (placebo) groups and PTH-treated groups. PTH dosage was 160μg/kg. The tibial bone specimens were isolated at 0, 6, 9, and 12 hours after placebo or PTH treatment. Each group was represented by 3 ~ 8 mice. Bone mineral density (BMD) and three dimentional bone morphometry of proximal tibia were measured using μCT. Hydroxyapatite calibration phantom was also scanned. Furthermore, synchrotron multi-scan X-ray microscope was built at SPring-8, and the BMD around osteocytes and osteocytic canaliculi were quantified. The figure shows a cross section of μCT images of mouse tibia. The image contrast represents the mineral density. Left shows the endosteal surface of tibia before PTH administration, and Right shows 6 hours after administration. Capillary vessels of the mouse before administration were not much outstanding, whereas these of the mouse 6H after PTH treatment stand out as many black dots (arrow heads) on the endosteal surface. These are capillary vessels appearing to bone marrow from the endosteal side. The contrast indicates that the BMD around capillary vessels was decreased at the endosteal space to marrow. Compared with before administration, trabecular bone BMD significantly decreased 2% after 6 hours, recovered after 9 to 12 hours. BV/TV tended to decreased 10~15% by 6 to 12 hours. As we reported at the last ASBMR meeting, osteocytes dissolve mineral through canaliculi. On the other hand, osteocytes are connected with the capillary vessels in bone through canaliculi. The phenomenon of bone mineral dissolution around capillary vessels at the endosteal surface after single PTH treatment indicates that bone mineral dissolution by the osteocyte is related to the action of PTH. We will report the action of PTH and involvement of osteocyte and canaliculi in this phenominon.



A Single PTH Administration Induces Bone Mineral Dissolution around Capillary Vessels

MO0289

Circulating Periostin: a novel serum marker of cortical bone structure in human. Nicolas Bonnet*[1], Claire Durosier[2], Patrick Garnero[3], Serge Ferrari[4], Rene Rizzoli[4]. [1]University Geneva Hospital-Department of Internal Medecine Specialities, Switzerland, [2]Division of Bone Diseases, Geneva University Hospital & Faculty of Medicine, Switzerland, [3]INSERM Research Unit, France, [4]Geneva University Hospital & Faculty of Medicine, Switzerland

Periostin is a matricellular protein, which is mainly expressed by periosteal cells and osteocytes in bone. Periostin down-regulates Sost gene expression and is necessary for the cortical bone response to loading and to PTH treatment. We previously reported that circulating periostin levels (cPostn) correlate with periosteal bone formation and cortical thickness (CtTh) independently of bone turnover in mice treated with PTH. In the present study, we investigated the relationship between cPostn and cortical structure in human healthy subjects.

We measured cPostn, bone turnover markers, aBMD by DXA, bone trabecular (Tb) and cortical (Ct) parameters at the distal radius and tibia by HRpQCT (XtremeCT) in 242 healthy women and 59 men, aged 64.9±1.4SD years. To test the association between cPostn and bone parameters, we divided the subjects into 3 tertiles of cPostn (low: 1277±148, medium: 1636±94, high: 2140±311 ng/ml), and applied an ANOVA and ANCOVA with adjustment for gender. Multiple regressions were used to assess the relation between cPostn, bone mineral mass, microstructure and turnover markers.

Mean cPostn was 1633±410 ng/ml (min. 814, max 3490 ng/ml). cPostn was higher in men than women (+8.6%, $p<0.01$), whereas P1NP and CTX were lower in men than women (-20% and -21%, $p<0.01$). Distal radius total bone area, cortical area (Ct.area) and perimeter were higher in the highest vs lowest cPostn tertile (+6.4%, +7.7% and +3.8%, $p<0.05$; p=0.12-0.34 after adjustment for gender). BV/TV was higher in the highest tertile (+12.4% vs low tertile, $p<0.01$) and disappeared after sex-adjustment. cPostn positively correlated with Ct.area and Ct. perimeter of distal radius (r=0.12, $p<0.05$, both) and tibia (r=0.15, $p<0.05$, both). These correlations remained significant after adjusting for P1NP, CTX or whole body bone mineral mass, but not for gender. There was no difference in whole body bone mineral mass, spine and proximal femur aBMD, PTH, P1NP and CTX between cPostn tertiles. Separate analyses per tertile in men and women indicated similar, but non-significant trends. cPostn was associated with PTH levels, but only in the subgroup of subjects with higher PTH levels (>6.3pM, $r^2=0.09$, $p<0.01$).These results recorded in a homogeneous population of healthy 65-year old subjects indicate a positive correlation of cPostn with cortical bone structure, independently of bone turnover markers as previously observed in mice, but likely through a sex-dependent effect.

Vitamin D Status in Obesity: Evaluation of Free 25(OH)D. Amy Evans*[1], Fatma Gossiel[1], Kim Naylor[2], Jennifer Walsh[3], Richard Eastell[3]. [1]Academic Unit of Bone Metabolism, University of Sheffield, United Kingdom, [2]The University of Sheffield, GBR, [3]University of Sheffield, United Kingdom

Obese individuals have lower circulating 25(OH)D levels than normal weight individuals. The binding proteins vitamin D binding protein (DBP) and albumin are important determinants of vitamin D action, namely free 25(OH)D. Parathyroid hormone (PTH) is increased in response to 25(OH)D deficiency. We aimed to investigate total and free 25(OH)D, DBP and PTH levels in obese individuals.

In September 2012, fasting serum samples were obtained from 99 men and women aged 55 to 75 years. 54 individuals (48% women, 52% men) were obese (BMI ⩾30 kg/m^2) and 45 (49% women, 51% men) were lean (BMI 18.5-24.9 kg/m^2). Total 25(OH)D was measured by automated immunoassay (Cobas e411, Roche Diagnostics). Free 25(OH)D index was determined using the equation (Free 25OHD = total 25OHD/1+ (6*103 *albumin) + (7*108*DBP)) (Powe et al). PTH was measured by automated immunoassay (IDS-iSYS), albumin by automated immunoassay (Cobas c311, Roche Diagnotics) and DBP by immunoassay (R&D Systems). Standard deviation scores were calculated by standardising the mean difference between lean and obese groups against the standard deviation of the lean group. Independent samples t-tests were used to determine significant differences ($p<0.05$) between lean and obese groups.

Total 25(OH)D was lower in obesity (mean difference (95% CI) -0.47 (-1.05 to 0.11) SD scores in men, -0.71 (-1.40 to -0.02) in women)). There was no significant difference in free 25OHD index between groups. No difference in DBP was observed in obesity (mean difference (95% CI) -0.33 SD scores (-0.98 to 0.32) in men, -0.28 (-0.93 to 0.37) in women). Albumin was significantly lower in obese women (mean difference (95% CI) -0.91 (-1.71 to 0.10) SD scores) but not in obese men (mean difference (95% CI) -0.41 (-0.97 to 0.15) SD scores). No differences in PTH were observed between the groups.

25(OH)D levels are low in obesity and yet there is no increase in PTH. This is most likely because free 25(OH)D is not low and this is because serum albumin, a binding protein for 25(OH)D, is low in obesity.

		Mean (SD) Lean	Mean (SD) Obese	Standardised Difference
Total25(OH)D, nmol/L	Men	71.24 (27.75)	52.53 (19.85)	-0.469**

A Comparison of Two Methods for Analyzing Change in Trabecular BMD from QCT Spine Scans over 2 Years of Treatment. Dennis Black*, Lucy Wu, Lisa Palermo. University of California, San Francisco, USA

Background: Unlike DXA BMD, QCT of the spine and hip can provide separate assessments of trabecular and cortical bone density and structure. Therefore, QCT of bone is frequently used in clinical trials of medications in order to gain insight into mechanisms of action for new treatments. There are several different programs available for analysis of QCT spine and hip scans but they have not been compared with respect to changes seen in treatment.

Methods: We used spine QCT scans from the PTH and alendronate (PaTH) trial which compared 4 different combinations of PTH(1-84) and alendronate over two years (1). A total of 187 women had QCT scans obtained at baseline and during follow-up. For this analysis, we used the 2 year follow-up scans only. The original analysis of QCT was done using software developed at UCSF (2). For this re-analysis, the scans were analyzed using Mindways software (Austin, Tx). Results from Mindways analyses were compared to those from the original analysis.

Results: For trabecular BMD at the spine, there was a strong correlation between the original measurements and the reanalyzed values at baseline ($r=0.92$, $p<.0001$). Similarly, 2 year % change was strongly correlated by the two methods ($r=0.89$, $p<.0001$). Within treatment groups, the estimates of % change were generally similar when the different methods were used (see table). While the statistical significance of the differences across treatment were similar for the two methods, the mean % differences across treatments varied somewhat.

Conclusions: Analysis of QCT spine scans in treatment studies should yield similar treatment effects, regardless of which of these two programs are used. However, small differences suggest caution should be used in comparing mean % change across trials when different methods for QCT analysis at the spine have been used.

Agreement of Distal Femur Bone Mineral Estimates From Two Different Procedures in Adults with Spinal Cord Injury. Michael Porter*[1], Therese Johnston[2], Ralph Marino[3], Christopher Modlesky[4]. [1]Department of Kinesiology & Applied Physiology, University of Delaware, USA, [2]Department of Physical Therapy, Thomas Jefferson University, USA, [3]Department of Rehabilitation Medicine, Thomas Jefferson University, USA, [4]University of Delaware, USA

Conditions that result in loss of ambulatory status, such as spinal cord injury, are associated with low bone loss and a high rate of fracture in the lower extremities, especially the distal femur. Different procedures for assessing areal bone mineral density (aBMD) in the distal femur using dual-energy X-ray absorptiometry (DXA) have been proposed. The aim of this study was to assess the agreement in aBMD, bone mineral content (BMC) and bone area between two different DXA procedures in individuals with complete spinal cord injury. A second aim was to assess the validity of the aBMD measurements using magnetic resonance imaging as a comparison. Sixteen adults with complete spinal cord injury and were recruited for the study. aBMD, BMC and bone area in the distal femur were determined using DXA (Delphi C; Hologic Inc) and two different procedures on the same day during the same test session. Procedure 1 involved the spine protocol with the participants lying in the supine position. Procedure 2 involved the forearm protocol with the participants lying in on their side. Apparent bone volume to total volume (appBV/TV) of the distal femur was determined using magnetic resonance imaging (MRI; 1.5 T, GE) at the same site as evaluated using DXA. There were moderate-to-strong relationships between aBMD ($r = 0.85$), BMC ($r = 0.81$) and bone area ($r = 0.72$) from procedure 1 vs. procedure 2 (all $p < 0.01$). However, aBMD was 15 % lower, BMC was 39 % higher and bone area was 64 % higher using procedure 1 vs. procedure 2 (all $p < 0.001$). Furthermore, aBMD determined using procedure 1 vs. procedure 2 was not as strongly related to appBV/TV from MRI ($r = 0.72$, $p = 0.002$ vs. 0.85, $p < 0.001$, respectively). The findings suggest that bone measurements from DXA are strongly dictated by the procedure used to collect the data. The procedure using the forearm protocol with participants lying on their side vs. the procedure using the spine protocol and participants lying supine may provide better estimates of bone mineral.

MO0293

Assessing Age, Sex, and Racial Differences in Cortical Porosity Requires Adjustment for Site-Specific Variation in the Selected Region of Interest. Ali Ghasem-Zadeh*[1], Roger Zebaze[1], Ashild Bjornerem[2], Xiao-Fang Wang[3], Yohann Bala[4], Ego Seeman[1]. [1]Austin Health, University of Melbourne, Australia, [2]University of Tromsø, Norway, [3]University of Melbourne, Austin Health, Australia, [4]University of Melbourne, Dept. of Medicine, Australia

High-resolution peripheral quantitative computed tomography (HR-pQCT) measures micro-architecture in a region of interest (ROI) at the distal radius and tibia. Bone width and micro-architecture vary slice by slice along the length of a bone so differences in micro-architecture by age, pubertal stage, sex and racial group may be the result of differences in the placement of the ROI rather than the characteristics of the subjects. To assess the slice-by-slice variation in cortical porosity we used images of the distal tibia, fibula and radius acquired by HR-pQCT and assessed cortical porosity using Strax 1.0 software in 69 women aged 40 to 61 years. The mean (SD) cortical porosity at the distal tibia, fibula and radius were 57.6% (5.4), 38.1% (7.3) and 46.9% (6.2).Each 1 mm (12 slices) more distal ROI increased porosity as shown: Tibia Fibula Radius

Mean ±SE Mean ±SE Mean ±SE Total 1.22%±0.06 0.89%±0.06 2.43%±0.09
Compact cortex 1.27%±0.06 0.68%±0.09 2.01%±0.08
Outer transitional zone 0.67%±0.11 0.51%±0.12 1.25%±0.08
Inner transitional zone 0.16%±0.05 0.58%±0.10 0.34%±0.05

We infer that a more distal ROI has a significant effect on cortical porosity which may result in erroneous age, sex and racial differences being reported. This variation needs to be considered when interpreting data in persons who differ in bone length.

MO0294

Associations between Birth Weight and Bone Microarchitecture in the Radius and Tibia of Older Adults from the Hertfordshire Cohort Study. Mark Edwards*[1], Kate Ward[2], Camille Parsons[1], Jennifer Thompson[2], Ann Prentice[2], Elaine Dennison[1], Cyrus Cooper[1]. [1]MRC Lifecourse Epidemiology Unit, University of Southampton, United Kingdom, [2]MRC Human Nutrition Research, United Kingdom

Evidence is accruing that environmental factors in early life have a critical influence on the magnitude of peak bone mass achieved, and on later risk of fracture. To date, no studies have investigated the relationship between birth weight and bone microarchitecture in human populations. High resolution peripheral quantitative computed tomography (HRpQCT) scanners permit the non-invasive assessment of cortical and trabecular structure; we used HRpQCT to investigate the relationship between birth weight and bone macro- and micro- architecture and volumetric BMD (vBMD) in older age in the Hertfordshire Cohort Study. 198 men and 178 women born between 1931 and 1939 were studied. Birth weight was obtained from birth records. Ages at the time of scanning ranged from 72.1 to 81.4 years. HRpQCT images (voxel size 82μm) of the non-dominant distal radius and tibia were acquired with an Xtreme scanner (Scanco Medical). Standard morphological analysis was performed for assessment of macrostructure, vBMD, cortical porosity and trabecular microarchitecture. Anthropometric measurements were taken and information on demographics, lifestyle, and comorbidities were obtained from study questionnaires. The mean(SD) age of participants was 76.1(2.5) and 76.5(2.6) years in men and women respectively. There was a positive association between birth weight and bone area (total and trabecular) in men and women at both the radius and tibia ($p<0.05$). In women, birth weight was negatively associated with trabecular BMD (β(95%CI) radius -16.8(-29.4,-4.2)mg/cm^3/kg; tibia -12.5(-24.3,-0.8)mg/cm^3/kg) and trabecular thickness (β(95%CI) radius -3.47(-6.63-0.32)μm/kg; tibia -6.09(-9.56,-2.63)μm/kg) ($p<0.05$ for all). With the exception of radial trabecular thickness, these associations were robust to adjustment for adult height and weight. There was no evidence of an association between birth weight and cortical area, vBMD or porosity in either sex. In summary, we have observed relationships between early life and bone area in both men and women in their eight decade. Associations between birth weight and trabecular architecture were identified in women and all but radial trabecular thickness were maintained after adjustment for body size. This may suggest an estrogen dependent effect. Further work in larger groups is indicated to reproduce these findings, and to relate their significance to fracture incidence.

Automated Scan Prescription For HR-pQCT: A Multi-Atlas Prospective Registration Approach. Julio Carballido-Gamio*[1], Serena Bonaretti[2], Margaret Holets[3], Isra Saeed[2], Louise McCready[3], Sharmila Majumdar[2], Thomas F. Lang[2], Sundeep Khosla[3], Andrew J. Burghardt[2]. [1]University of California, San Francisco, USA, [2]Musculoskeletal & Quantitative Imaging Research Group, Department of Radiology & Biomedical Imaging, University of California, San Francisco, USA, [3]Division of Endocrinology, Metabolism & Nutrition, Department of Internal Medicine, College of Medicine, Mayo Clinic, USA

Bone density and geometry vary dramatically along the distal radius. Consequently, the prescription of a scan by an operator introduces a significant—but underappreciated—source of variability in HR-pQCT measurements, increasing the scatter in cross-sectional and normative datasets, and complicating the translation of HR-pQCT to multicenter studies. To address this issue, we developed an automatic technique to *prospectively* prescribe patient HR-pQCT scans by automatically mapping scanning landmarks of a set of reference atlas radiographs of the forearm to their scout radiographs.

Scan-reposition-rescans of 60 radii of adult men and women from two different imaging centers were used to quantify root mean square coefficients of variation (RMSCVs) of integral BMD, Ct.Th and Tb.N, and slice-wise offsets between baseline and repeat scans for subvolumes identified by manual prescription in the scouts, and by the default *post hoc* slice-matching registration method—assumed to reflect ideal positioning. Repeat 330-slice scans of 5 cadaveric radii were used to validate the subvolume identification using the prospective method and similar metrics. Five atlases were generated, each based on ten scout radiographs randomly selected from a normative population. The automatic positioning of the scanning landmarks was computed with affine and nonlinear transformations between the scout radiographs and the atlases (Fig. 1A-E). Sub-volumes for bone quantification were identified by retrospectively applying the registrations to the scout radiographs.

Based on RMVCVs and mean slice offsets, a single atlas performed better than the others, however, values were also calculated for different atlas combination strategies. The ex vivo manual mean slice offset was 0.5 mm (93% overlap), with RMSCVs exceeding 9% for Ct.Th. The prospective mean slice offset was 0.1 mm (99% overlap) with RMSCVs equivalent to slice-matching (Fig. 1F).True precision errors (in vivo and ex vivo) for BMD and Ct.Th in HR-pQCT are greater than previously reported (Fig. 1F) once variability due to operator positioning is considered. Results indicate that scan prescription by prospective atlas-based image registration can minimize this error and potentially improve standardization of HR-pQCT acquisitions. While mainly advantageous for cross-sectional studies, standardized positioning would also benefit longitudinal studies where periosteal bone changes make the default slice-matching method undesirable.

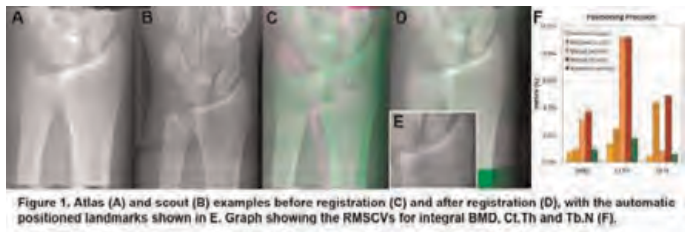

Figure 1. Atlas (A) and scout (B) examples before registration (C) and after registration (D), with the automatic positioned landmarks shown in E. Graph showing the RMSCVs for integral BMD, Ct.Th and Tb.N (F).

MO0296

Comparison of Incident Clinical Vertebral Fracture Identified Using Medicare Administrative Claims and from Self-report Confirmed by Medical Record Review. Jie Zhang*[1], Elizabeth Delzell[1], Kristine Ensrud[2], John Schousboe[3], Brent Taylor[4], Misti Paudel[4], Cora Lewis[1], James Shikany[1], Peggy Cawthon[5], Jeffrey Curtis[1]. [1]University of Alabama at Birmingham, USA, [2]Minneapolis VA Medical Center / University of Minnesota, USA, [3]Park Nicollet ClinicUniversity of Minnesota, USA, [4]University of Minnesota, USA, [5]California Pacific Medical Center Research Institute, USA

Purpose: The definition and complete ascertainment of incident clinical vertebral fracture is challenging. We used data from the Osteoporotic Fractures in Men (MrOS) study participants, a cohort of men aged > 65 years, to examine the agreement between incident clinical vertebral fractures identified using Medicare claims vs. those self-reported to the study and confirmed with medical record review.

Methods: We conducted a retrospective cohort study among MrOS participants linked to their Medicare claims between 2000 and 2007. The study period was the time when a participant had Medicare fee-for-service coverage and was under active follow-up in the MrOS study. The claims-based algorithm required at least one of the following: vertebral fracture diagnosis as the primary discharge diagnosis from a hospitalization, on a physician evaluation & management claim preceded by spinal imaging <= 10 days, or on a kyphoplasty or vertebroplasty claim. In the MrOS study, participants were queried by mail and/or phone every 4 months and self-reported fractures were confirmed by comparing spine film obtained from medical record to the baseline study spine film. We examined the proportion of concordant cases (men identified to have had an incident clinical vertebral fracture from both the claims-based algorithm and from radiographically confirmed self-report) and discordant cases (from only one method and not the other).

Results: We identified 3,601 men eligible for the current analysis. During the study period, 58 men had one or more self-reported radiographically confirmed clinical vertebral fracture in MrOS study and 95 from the claims-based algorithm. We identified 36 concordant cases, which accounted for 62% of the 58 men with self-reported radiographically confirmed fractures and for 38% of the 95 men identified from the claims-based algorithm. When an expanded definition was used (any claim with a diagnosis of vertebral fracture), claims identified 85% of self-reported radiographically confirmed fractures.

Conclusions: Our findings suggest that relying on one method for identification of incident clinical vertebral fracture would likely have missed a significant proportion of cases. Despite the limitation that fractures identified from the claims are not validated unlike those from the self-report, future studies that also include participant consent to obtain Medicare claims might aid more complete study endpoint ascertainment.

Detection of Incomplete Non-displaced Atypical Femur Fractures by Densitometer. Angela M. Cheung*[1], Robert Bleakney[2], Harry Genant[3], Rowena Ridout[4], Heather McDonald-Blumer[5], Diana Yau[6], Lianne Tile[6], George Tomlinson[5]. [1]University Health Network-University of Toronto, Canada, [2]Mount Sinai Hospital, Canada, [3]UCSF/Synarc, USA, [4]Toronto Western Hospital, Canada, [5]University of Toronto, Canada, [6]University Health Network, Canada

Background: Complete atypical femur fractures (AFFs) are rare, but patients often have prodromal symptoms for months to years prior to a complete break. Recent studies suggest that incomplete AFFs are more common and imaging with plain radiographs may detect them prior to a complete break. We conducted a cross-sectional study to test the diagnostic characteristics of high definition single energy scans by densitometer (HD-DXA) to detect incomplete AFFs.

Methods: We recruited from two cohorts of patients, the Ontario AFF Cohort and from bone density laboratories. From the AFF cohort, we recruited patients with unilateral or bilateral femurs with no surgical hardware who may or may not have abnormal radiographic findings consistent with incomplete AFFs. From the second cohort, we recruited postmenopausal women or women over age 50 with pain, discomfort or weakness in their leg who had been on 5 or more years of bisphosphonate therapy. All patients received a HD-DXA scan using Hologic Discovery A densitometers, scanning from above the lesser trochanter to the medial condylar flare, and a plain radiograph of the affected femur. Two musculoskeletal radiologists, blinded to patient identifiers, read the HD-DXA scans and the radiographs independently. Using plain radiographs as the reference standard, the diagnostic accuracy of HD-DXA (sensitivity, specificity, positive and negative predictive values, positive and negative likelihood ratios) was assessed separately for each reader and then averaged. For each abnormal finding (generalized cortical thickening, focal cortical thickening, endosteal thickening, lucent cleft, cortical beaking), inter-rater agreement on HD-DXA and plain radiographs were measured with the kappa statistic.

Results: A total of 61 subjects with 86 femurs were included in this study. Using HD-DXA for the identification of any bone abnormality, the average sensitivity was 75% and the average specificity was 92%. The average positive and negative predictive values were 87% and 81.9%. The average positive and negative likelihood ratios were 9.3 and 0.28. For HD-DXA, kappa was highest for the presence of lucent cleft [0.63, 95% CI (0.37 to 0.90)], followed by focal cortical thickening [0.55, 95%CI (0.38 to 0.72)]. For plain radiographs, kappa was highest for focal cortical thickening [0.59, 95%CI (0.41-0.76)], followed by endosteal thickening [0.53, 95%CI (0.30 to 0.76)].

Conclusions: HD-DXA is a promising point-of-care diagnostic tool for detecting incomplete AFFs.

MO0298

Differences in Bone Geometry, Mass and Microarchitecture between Asian and Caucasian Young Men. Anna Kepley*[1], Chiyuan Zhang[2], Bin Zhou[2], Donald McMahon[3], X Guo[2], Elizabeth Shane[3], Thomas Nickolas[3]. [1]Columbia University Medical Center, USA, [2]Columbia University, USA, [3]Columbia University College of Physicians & Surgeons, USA

Chinese-American and Caucasian premenopausal women have similar areal BMD (aBMD) by DXA, but different bone microarchitectural properties by high resolution peripheral quantitative CT (HRpQCT). At the radius and tibia, Chinese-American premenopausal women have lower total area, and higher cortical and trabecular density and thickness. To investigate whether Asian men differ from Caucasian men in a pattern similar to women, we evaluated 62 healthy Asian (n=24) and Caucasian (n=38) men between ages 25 and 35 with aBMD by dual energy X-ray absorptiometry (DXA) of the lumbar spine (LS), total hip (TH), femoral neck (FN), 1/3- and ultra-distal radius (1/3R and UDR, respectively). HRpQCT was used to assess bone geometry, mass and microarchitecture at the distal radius and tibia. Results are expressed as Means $\pm$ SD. Univariate comparisons were made with Students T-Test; multivariate comparisons were made with generalized linear models adjusted for differences in height, weight and their first order interaction. Asians were shorter ($p<0.0001$) and lighter ($p<0.001$) than Caucasians, but did not differ by age or BMI (*Table*). In uni- and multi-variate models, there were no between group differences in aBMD. By HRpQCT at the radius, univariate models demonstrated that Asians had smaller total ($p<0.001$) and trabecular area ($p=0.0001$), fewer trabeculae ($p<0.05$), but greater cortical density ($p<0.001$), thicker cortices ($p<0.05$) and trabeculae ($p<0.05$), and more trabecular heterogeneity ($p<0.01$). In multivariate models, race remained a significant predictor of differences in total and trabecular area, cortical density and thickness, and trabecular network heterogeneity, but racial differences in total density, and trabecular thickness and number were no longer significant. At the tibia, in univariate models Asians had smaller total ($p<0.01$) and trabecular area ($p<0.01$), but thicker cortices ($p<0.05$). In multivariate models between group differences were no longer significant. In conclusion, Asian men have smaller bones with thicker and denser cortices, differences that could lead to greater bone strength. These cortical differences were similar to those previously reported for Chinese-American women, but trabecular characteristics may differ between men and women. Further studies are needed to elucidate genetic, biochemical and metabolic factors that could lead to differences in skeletal structure between Asians and Caucasians

MO0299

Fracture discrimination is improved by combiningMicro-architectural Texture analysis as assessed by H or TBS and Spine or hipBMD. Jerome Touvier*[1], Renaud Winzenrieth[2], Helena Johansson[3], Hech Toumi[1], Jean-Paul Roux[4], Jean Chaintreuil[5], Didier Hans[6], Eric Lespessailles[7]. [1]EA4708 - I3MTO - Orleans University, France, [2]Med-imaps, Hôpital X. Arnozan, PTIB, Pessac, France, [3]Swedish University of Agricultural Sciences, The Biomedical Center, Sweden, [4]INSERM, UMR 1033, Université de Lyon, France, [5]R&D department, D3A, France, [6]Lausanne University Hospital, Switzerland, [7]Centre Hospitalier Regional, France

Purpose: The aim of the study was to assess the clinical performance of a model combining bone mineral density (BMD) and microarchitectural texture (spine TBS and Calcaneus H) for the detection of the osteoporotic fractures at the spine and hip joints.

Method: Trabecular Bone Score was assessed in 272 women aged 40 yrs, who had a lumbar spine (LS) and total Hip (TH and FN) DXA scan as well as texture analysis of the calcaneus as assessed by H. Ninety six women had prevalent fragility fractures. The additional clinical values of BMD and TBS or H combinations were evaluated using a 2 steps classification tree approach based on BMD T-score stratification followed by a TBS or H or by the minimum of TBS or H (Min_TBS_H) tertile classification. Combinations add-values were evaluated using the Net Reclassification Index approach (NRI).

Results: Women with prevalent fracture were older (71 ± 10 vs. 62 ± 10 yrs, $p<0.001$), had lower TBS (1.165 ± 0.11 vs. 1.270 ± 0.10, $p<0.001$), H (0.607 ± 0.03 vs. 0.630 ± 0.03, $p<0.001$),Spine BMD (0.842 ± 0.14 vs. 0.931 ± 0.14, $p<0.001$) and TH BMD (0.736 ± 0.13 vs. 0.855 ± 0.12, $p<0.001$) than women without fracture. No significant difference was found in BMI. Correlation between BMD versus texture parameters were modest (range from 0.3 to 0.5) while TBS was poorly correlated to H ($r = 0.29$). Age-adjusted ORs per SD decrease (95% CI) were 1.73 (1.27-2.35), 1.68 (1.16-2.44) and 1.98 (1.35-2.90) for spine, neck and TH BMD respectively and 2.22 (1.58-3.11) and 1.86 (1.35-2.54) for TBS and H respectively. Both TBS and H remained significant after additional adjustment for TH BMD : OR=2.09 (1.43-3.06)

and 1.48 (1.03-2.13) respectively. When using BMD T-score of -2.5 (TH-BMD) combined with lowest TBS tertile (model 1) or lowest H tertile (model 2) thresholds, NRI of the model 1 or 2 were significantly improved in comparison with BMD (+32% and +31% respectively). Combining TH-BMD and Min_TBS_H lowest tertile (model 3), NRI reached +37%. Although the NRI increase was slight, model 3 significantly improved fracture detection since 73% of the overall fracture were in the first tertile (vs. 48 and 52% for model 1 and 2) and 2% were in the 3rd tertile (vs. 20 and 15% for model 1 and 2).

Conclusions: Both H and TBS have a significant clinical add-value over the BMD for osteoporotic fracture detection. H and TBS combination in addition to the BMD improve fracture detection compared with their combination with BMD alone.

	Two-sided p-value	OR per 1 SD (95% CI)	
TH BMD	0.0093	1.69 (1.14 - 2.51)	Adjusted for age and TBS
TBS	<0.001	2.09 (1.43 - 3.06)	Adjusted for age and TH BMD
TH BMD	0.012	1.68 (1.12 - 2.52)	Adjusted for age and H
H	0.033	1.48 (1.03 - 2.13)	Adjusted for age and TH BMD

In Vivo Characterization of Cortical Bone at Distal Tibia Using Multi-Detector CT Imaging – Validation and Results of Application in Healthy Young Adults. Cheng Li*, Dakai Jin, Elena Letuchy, Trudy Burns, Kathleen Janz, James Torner, Steven Levy, Punam K. Saha. University of Iowa, USA

Cortical bone plays an important role in determining bone strength and fracture risk. Segmentation of cortical bone is needed for its volumetric and structural analyses. This task is nontrivial for *in vivo* multi-row detector CT (MD-CT) imaging due to limited resolution and partial volume effects. An automated cortical bone segmentation algorithm for *in vivo* MD-CT imaging of the distal tibia is presented and its accuracy and reproducibility are examined using cadaveric ankle specimens. The algorithm is applied in a pilot study evaluating volumetric and structural differences in cortical bone among healthy male and female young adults.

Three repeat MD-CT scans of fifteen cadaveric ankle specimens were acquired on a 128 slice Siemens Flash scanner at 120kV, 200mAs, pitch: 1, 0.3mm slice-thickness and 10cm scan-length. A Gammex calibration phantom was used to transform CT Hounsfield units into BMD (mg/cc). Cortical bone thickness and porosity were measured using the new cortical bone segmentation algorithm. Accuracy of the algorithm was defined as the percentage of agreement between manual and automatic segmentations of cortical bone. Repeat scan reproducibility of cortical bone measures was evaluated. Forty-five pairs of age similar (18 to 23 year old) height order-matched healthy male and female pairs who had MD-CT scans were selected from the Iowa Bone Development Study (IBDS) cohort.

In the cadaveric study, the agreement between manual and automatic segmentations of cortical bone showed a mean accuracy of 95.1%, and a repeat MD-CT scan intraclass correlation coefficient of 98.2%. Application of the segmentation algorithm to MD-CT scans for one of the age- and height-order matched representative IBDS (male-female) pairs (Figure 1) suggests that the male IBDS cohort member has thicker, but more porous cortex as compared to the female. In fact, a pairwise t-test comparing the 45 healthy male-female IBDS pairs showed that, on average, males had 16.3% thicker cortex but 4.7% increased porosity.

MD-CT imaging, together with an advanced segmentation algorithm, is suited for volumetric and structural analyses of cortical bone *in vivo*. The human study indicates that, on average, bones for males are substantially larger with thicker cortical shell than for females. The relatively higher porosity in males may increase big bone flexibility such as bending strength.

Precise 3D Localisation of Cortical Defects Associated with Subcapital, Trans-cervical and Trochanteric Hip Fractures in Life. Kenneth Poole*[1], Graham Treece[1], Karen Blesic[1], Paul Mayhew[1], Thomas Turmezei[1], Fjola Johannesdottir[1], Madhavi Vindlacheruvu[1], Simon Donell[2], Jan Vaculik[3], Pavel Dungl[3], Martin Horak[4], Jan Stepan[5], Andrew Gee[1]. [1]University of Cambridge, United Kingdom, [2]University of East Anglia, United Kingdom, [3]Charles University Prague, Czech Republic, [4]Homolka Hospital, Czech Republic, [5]Charles University, Czech Republic

The precise distribution of cortical bone is likely to determine the location and type of hip fracture sustained during a trip, stumble or fall. Since osteoporosis medications and exercise also enhance cortical bone in key areas (Poole et al 2011), each person may need a tailored hip fracture prevention strategy depending on their existing bone structure. We applied 3D cortical bone mapping to ordinary clinical CT scans in order to identify average focal bone defects in women with the three commonest types of acute hip fracture versus healthy controls without fracture. By extending recruitment to our case-control studies in England and the Czech Republic, we could pinpoint systematic differences and visualise the magnitude of the differences in cortical bone between each fracture type and controls with a colour map displayed on an average femur model.We analysed Siemens or GE CT scans from 144 older women volunteers with acute fracture and 124 age-matched controls from both the Prague Study of Hip Joint in Trauma and the UK FEMCO study. Fractures were diagnosed using the Muller AO classification of fractures into trochanteric (code AO31-A, n=53), transcervical (AO31-B2, n=37) or sub-capital (AO31-B1,B3, n=54) before creating cortical thickness maps of the unfractured contralateral hip. After non-rigid registration to an average femur shape and statistical parametric mapping (SPM), we were able to pinpoint statistically significant foci of lower cortical mass and thickness associated with each fracture type. The generalised linear SPM model allowed for age, weight and country.The major finding was a marked difference between women with trochanteric fractures, who had an extensive trochanteric cortical defect (fig. 1a) compared with controls, and those with intracapsular fractures (fig 1b & 1c) who had cortical defects located on the superior femoral neck. Closer examination of the two intracapsular fracture types reveals a subtler difference in that the principal cortical defect in transcervical fractures is mostly confined to the upper neck, whereas the defect in subcapital fractures spreads across the anterior femur.Alongside recent evidence that osteoporosis treatments and exercise have focal effects on the proximal femoral cortex, these results suggest that hip fracture prevention strategies may need to be tailored to improve the focal cortical deficits which are characteristic of each fracture type.

Reading Between the Lines of Bone Mineral Density: the Significance of Changes in BMD of Individual Lumbar Vertebrae. Sumiaki Okamoto*[1], Hitoshi Noguchi[2], Hiroyuki Suzuki[3], Akira Itabashi[4], Sumitada Okamoto[1]. [1]Okamoto Clinic SORF, Japan, [2]Noguchi Thyroid Clinic & Hospital Foundation, Japan, [3]Suzuki Orthodontic Office, Japan, [4]Saitama Center for Bone Research, Japan

As previously reported, bone mineral density (BMD) of individual vertebrae from L1 through L4 sequentially increase in young healthy controls and the disruption of this sequence implies vertebral fracture. A refinement of this observation and a potential new arsenal in the analysis of vertebral fracture is presented. We first took lumbar DXA measurements of 20 young volunteers, aged 22-28, and found that L1 had lower BMD than L2 in all subjects , L2 had lower BMD than L3 in 16 of 20 subjects (80%), L3 had lower BMD than L4 in 12 subjects (60%) and the BMD of L3 was never higher than L4 by more than 5%. L1toL2, L2 toL3 andL3 toL4 ratios in average were 0.90, 0.95 and 0.99, respectively. Aberration from this norm was studied in 1680 patients of osteoporosis who were examined by DXA and three dimensionally analyzed by CT under fully informed consent. We present a series of cases in which the disruption in the sequence of BMD in the lumbar vertebrae was verified for vertebral fracture by CT. The diagnostic value of the sequence is diminished, however, when every vertebrae is equally compromised. But sudden changes in the sequence may alert the astute observer of newly formed fractures. Sudden increase of BMD is often seen after new lumbar vertebral fracture often followed by false rapid decrease of apparent BMD in the same vertebrae. The sudden increase is the product of the compaction of the vertebrae and attendant decrease of the region of interest (ROI), callus formation and sclerotic change of the vertebral rim, angle induced mixing of the posterior element of the vertebrae into the ROI area and the formation of traction spurs or sclerosis due to the instability of the vertebrae after fracture. The false decrease of BMD is the product of the parting of the spinous process following kyphosis resulting in the removal of the spious process from the ROI area. Also, the unloading at the posterior intervertebral joint may result in the absorption of sclerotic changes or inflammatory high density lesions. As we had reported, Osteophytes and vertebral selerosis are found in more than 99% of spines, with equal frequency to osteoporosis in elderly women. Even minor indentations of vertebra might induce falsely high BMD scores, which will be followed by the false decrease. Misinterpreting non-responders by vertebral BMD might occur, when these phenomenons are not fully understood.

Sensitivity, specificity and accuracy improvement by combining TBS and spine BMD: The Eastern European Study. Jelena Vasic[1], T Petranova[2], Carmen Gabriela Barbu[3], Vladyslav Povoroznjuk[4], F Gojkovic[1], Renaud Winzenrieth*[5], Didier Hans[6], J Elez[1], V CulaficVojinovic[1], Catalina Poiana[3], R Rashkov[2], Aleksandar Dimic[7]. [1]Bone Diseases, Railway Healthcare Institute, Serbia, [2]Rheumatology Clinic, the Medical University, Bulgaria, [3]Department of Endocrinology, Carol Davila University of Medicine & Pharmacy, Romania, [4]Department of Clinical Physiology & Pathology of Locomotor Apparatus, Institute of Gerontology AMS, Ukraine, [5]Med-imaps, Hôpital X. Arnozan, PTIB, Pessac, France, [6]Lausanne University Hospital, Switzerland, [7]Institute for Treatment & Rehabilitation ''NiskaBanja'', Serbia

The aim of the study was to assess the clinical performance of the model combining bone mineral density (BMD) at spine and microarchitecural texture (TBS) for the detection of the osteoporotic fracture.

The Eastern European Study (EES) is a multicenter study (Serbia, Bulgaria, Romania and Ukraine) evaluating the role of TBS in routine clinical practice as a complement toaBMD. All scans were acquired on Hologic Discovery and GEHC Prodigy densitometers in a routine clinical manner. Lumbar spine TBS (TBS iNsight®) was derived from each spine DXA examination blinded to clinical parameters and outcomesby the University of Lausanne (Switzerland). Age- and BMI-adjusted odds ratios (OR) per standard deviation decrease are reported for aBMD and TBS. The correlation between aBMD and TBS was calculated. The additional clinical values of aBMD and TBS were analyzed using2 steps classification tree approach (aBMD followed by TBS tertiles) for all type of osteoporotic fracture (All-OP Fx). Sensitivity, specificity and accuracy of fracture detection as well as the Net Reclassification Index (NRI) were calculated.

We recruited 1762 women from routine clinical practice, of whom 1253 were deemed eligible: mean age 63.3±8.8 y, BMI 26.3±3.9, aBMD 0.894±0.171, TBS 1.199±0.127. No significant differences between centers in baselines characteristics were found. As such data were merged. As expected, aBMD and TBS were only moderately correlated (r^2=0.15). Prevalence rate forAll-OP Fxwas 29% (mainly forearm and clinical vertebral fractures). Age and BMI-adjusted ORs were 1.48 (1.29-1.70) for aBMD and 1.55 (1.35-1.78) for TBS. TBS remained significant after additional adjustment for Spine BMD: OR=1.41(1.21-1.63).When using aBMD T-score of -2.5 and the lowestTBS tertile thresholds, both BMD and TBS were similar in terms of sensitivity (38% vs. 43%), specificity (76% vs. 78%) and accuracy (62% vs. 66%). When combined, a significant improvement in sensitivity was observed (+28% and +22%, in comparison with 2.5 aBMD T-score and first TBS tertile thresholds). NRI of the combined model compared with BMD and TBS alone exhibit a significant improvements of +38% and +31% respectively.

In a multi-centre Eastern European cohort, we have shown that combining TBS and BMD significantlyimproves the sensitivity and overall accuracy of osteoporotic fracture detection, even after adjusting for age and BMI.

Simplified Criteria for Selecting Patients for VFA Imaging. Tamara Vokes*[1], John Schousboe[2], Harold Rosen[3]. [1]University of Chicago, USA, [2]Park Nicollet Clinic, University of Minnesota, USA, [3]Beth Israel Deaconess Medical Center, USA

Purpose: We have previously shown that among women referred for BMD testing selection of patients who should have VFA is best achieved using a multivariate regression model[1]. Similarly, the 2007 ISCD position development conference (PDC) proposed accurate but complicated criteria for selecting patients for VFA[2], which included different combinations of cut-off points for age and height loss, use of glucocorticoids, prior fractures, diseases and medications known to cause bone loss (http://www.iscd.org/official-positions/2007-iscd-official-positions-adult/). We now examine whether simpler criteria could be equally effective in identifying patients with prevalent vertebral fractures (VFx).

Methods: We compared the discrimination between those with and without VFx using 3 different models: 1. previously reported ''Full model'' (age, T-score, height loss, self-reported vertebral fracture, history of non-vertebral fracture, and glucocorticoid use)[1] at cut-off corresponding to 10% VFx prevalence, 2. ISCD PDC2007 indications[2], and 3. ''Simple criteria'' where VFA is indicated if T-score<-1 plus any of the following: age over 70 in women or 80 for men; height loss>4 cm, self-reported vertebral fracture, glucocorticoid use.

Results: Among 860 female densitometry patients 163 (19%) had VFx. The ''Full model'' performed slightly better likely because it was derived and tested in the same population. Overall the measures of performance were similar for the 3 models and simple criteria were no worse than the more complicated PDC2007 indications (Table).

Conclusion: Selecting patients for VFA using simplified criteria (age, height loss, self-reported vertebral fractures, glucocorticoid use) performed as well as the more complex models in identifying densitometry patients with VFx.

MO0305

Trabecular Bone Score is Associated With Vertebral and Non Vertebral Fracture in Men - The STRAMBO Study. Stephanie Boutroy*[1], Didier Hans[2], Renaud Winzenrieth[3], Roland Chapurlat[4], Pawel Szulc[5]. [1]INSERM U1033 & Université de Lyon, France, [2]Lausanne University Hospital, Switzerland, [3]Med-imaps, Hôpital X. Arnozan, PTIB, Pessac, France, [4]E. Herriot Hospital, France, [5]INSERM UMR 1033, University of Lyon, Hopital E. Herriot, Pavillon F, France

Areal BMD (aBMD) is a less powerful predictor of fracture in men than in women. TBS, a gray-level measurement derived from lumbar spine DXA image texture, is related to microarchitecture and fracture risk in women independently of BMD. Our goal was to assess the ability of TBS to improve discrimination of prevalent vertebral and peripheral fractures in men, over aBMD.

TBS was assessed in 886 men aged 50 yrs and over from the STRAMBO cohort, who had a lumbar spine (LS) DXA scan (Hologic Discovery A) at baseline. 164 men had prevalent fragility fractures (vertebral = 70, peripheral = 74, both = 20).

Men with prevalent fracture were older (73 ± 8 vs. 70 ± 9 yrs, $p<0.001$), had lower LS_TBS (-5.5%, -0.6 SD, $p<0.001$), LS_aBMD (-7.9%, -0.5 SD, $p<0.001$) and total hip (TH) aBMD (-8.1%, -0.6 SD, $p<0.001$) than men without fracture. After adjustment for age, height, weight and treatment, the magnitude of association with peripheral, vertebral and all types of fracture jointly was similar for LS_TBS, LS_aBMD and TH_aBMD with OR per 1SD decrease [95% CI] of 1.7 [1.4;2.0], 1.5 [1.3;1.7] and 2.0 [1.6;2.5] respectively. In multivariate analysis including the above covariables as well as LS_aBMD and/or TH_aBMD, LS_TBS remained significantly associated with an increased prevalence of peripheral and vertebral fracture alone and in combination (OR = 1.7 [1.3;2.1], 1.6 [1.2;2.1] and 1.6 [1.3;1.9] respectively).

When using the WHO classification, 13.4% of fractures occurred in osteoporotic (fracture rate=42.3%), 57.3% in osteopenic (fracture rate=23.4%) and 29.3% in men with T-score>-1 (fracture rate=11.1%). 44.5% of fractures occurred in the lowest quartile of LS_TBS, regardless of BMD. By combining osteoporotic men with osteopenic men in the lowest quartile of TBS, we were able to depict three times as many fractures as in the osteoporotic men alone (40.9% vs. 13.4%) with a rather small decrease of the fracture rate: 38.3% vs. 42.3%.

In conclusion, LS_TBS is a useful tool to discriminate men with and without prevalent fracture, even in addition to aBMD measured either at the lumbar spine or total hip. Its use in prospective studies in men should confirm its ability to predict fracture independently of aBMD.

MO0306

Trabecular Bone Score: A Tool for Identification of Severe Spinal Osteoporosis. Kawtar Nassar[1], Simon Paternotte[1], Sami Kolta[1], Jacques Fechtenbaum[1], Christian Roux[1], Karine Briot*[2]. [1]Paris Descartes University, Cochin Hospital, Rheumatology Department, France, [2]Paris Descartes University, Cochin hospital, Rheumatology Hospital, France

Vertebral fractures (VFs) are the hallmark of osteoporosis and are more predictive of future fracture than areal Bone Mineral Density (aBMD). Number and severity of VFs are related to bone microarchitecture deterioration. Trabecular Bone Score (TBS), derived from the texture of the DXA image, has been shown to be related to bone microarchitecture and fracture risk. Our objective was to evaluate performance of TBS, alone or added to aBMD, in the prediction of the presence of VFs and of the severity of these fractures.

Patients and methods: Patients were selected from the Fracture Liaison Service of our department, aiming at providing assessment of osteoporosis to patients over the age of 50 years who had sustained low trauma fractures. aBMD and Vertebral Fracture Assessment (VFA) were performed one week to 3 months after the fracture using DXA. VFs were classified using the Genant's semiquantitative evaluation and severity was assessed using the spinal deformity index (SDI), i.e. the sum of number and grades of VFs. TBS was obtained after re-analysis of DXA lumbar spine (L2-L4) scans. Performance of TBS, BMD and their combination was assessed using Receiver operator characteristic (ROC) and areas under receiver operating characteristics curves (AUCs).

Results: 362 patients (77.3% women; mean age 74.3 ± 11.7 years) were analysed; 182 (50.3%) had hip fractures and 49 (13.5%) received an anti-osteoporotic treatment. Prevalence of VFs by VFA was 36.7%; 189 (52.2%) patients were osteoporotic (T score≤-2.5 at at least one site). TBS was lower in the patients with VFs than in patients without VFs in the whole population (1.156 ± 0.11 vs 1.227 ± 0.11, $p<0.0001$) and in non osteoporotic patients (1.187 ± 0.12 vs 1.253 ± 0.10, $p=0.001$). In whole population, performance of TBS (AUC=0.677) was similar to lumbar spine (LS) BMD (AUC= 0.669) and hip BMD (AUC= 0.692) for the identification of VFs. However combination of TBS and LS BMD improves the discrimination as compared to LS BMD alone (AUC=0.707, $p=0.043$). In the non osteoporotic population (n=173), AUC of TBS for the discrimination of VFs was higher than AUC of LS BMD (0.67 0vs 0.541, $p=0.035$). There was a negative correlation between TBS and SDI: r= -0.31 ($p<0.0001$).

Conclusion: in a population of patients with a recent non traumatic fracture, TBS added to lumbar spine aBMD improves the detection of patients having vertebral fracture, thus receiving spine imaging.

Using Body Composition Phantoms to Validate Performance of Dual Energy X-Ray Absorptiometry (DXA) instrument. Colin Miller*[1], Hui Jing Yu[1], Blaine Horvath[1], Jessie Libber[2], Diane Krueger[2], Neil Binkley[2]. [1]BioClinica, Inc., USA, [2]University of Wisconsin-Madison, USA

BACKGROUND: The purpose of this study was to assess the use of Dual Energy X-Ray Absorptiometry (DXA) phantoms as part of the validation process of a newly installed iDXA instrument. METHODS: An in vitro calibration was carried out using four DXA phantoms: the GE (Lunar) encapsulated spine phantom, the Hologic encapsulated spine phantom, the Bona Fide Phantom (BFP, BioClinica, Inc., Newtown, PA), and the BioClinica Body Composition Phantom (BBCP, BioClinica, Inc., Newtown, PA). Each phantom was scanned 30 times consecutively on an existing iDXA instrument, with 15 minutes wait between each scan series. Total Bone Mineral Density (BMD) values for L1-L4 were calculated for the Lunar phantom, Hologic phantom and BFP, and total BMD values for whole body were calculated for the BBCP. This was repeated on a newly installed iDXA instrument. The coefficient of variation (%CV) was calculated for each of the scan series. A Pearson Correlation plot was used to calculate the degree of agreement between the two instruments for each phantom. The mean difference between the two instruments was also calculated. RESULTS: There was a systematic increase in %CV observed for the new iDXA instrument when compared to the existing iDXA instrument. The %CVs for the new iDXA were 0.19% for Lunar phantom, 0.33% for Hologic phantom, 0.21% for BFP, and 0.46% for BBCP, whereas the %CV for the old iDXA were 0.12% for Lunar phantom, 0.20% for Hologic phantom, 0.18% for BFP, and 0.27% for BBCP. BMD measured on the new iDXA instrument was approximately 1% higher than the existing instrument for L1-L4 and about 2% higher for whole body measure, although the correlations were not statistically significant between the two instruments. Moreover, similar findings were observed for Total Fat Mass and Total Lean Mass when comparing the two instruments using the BBCP. Subsequently, these results were sent to GE for evaluation. GE staff confirmed the scanner requires adjustment, and adjustments were made to the new instrument. DISCUSSION: This study demonstrated the importance of performing repeated phantom analyses for in vivo BMD calibration and validation activity with new scanners before replacing any existing instruments in the clinic or clinical trials.

MO0308

Alterations in Lean Mass Predict Development of Trabecular Bone Density and Cortical Bone Size in Young Adult Men. ROBERT RUDANG*[1], Dan Mellstrom[2], Claes Ohlsson[3], Mattias Lorentzon[4]. [1]INSTITUTE OF MEDICINE, SAHLGRENSKA ACADEMY, Sweden, [2]Sahlgrenska University Hospital, Sweden, [3]Center for Bone & Arthritis Research at the Sahlgrenska Academy, Sweden, [4]Geriatric Medicine, Center for Bone Research at the Sahlgrenska Academy, Sweden

Increased body weight has been associated with higher bone mineral density (BMD), but whether alterations in lean mass (LM) or fat mass (FM) predict the development in bone size and volumetric BMD (vBMD) is unclear. The aim of this study was to longitudinally investigate the associations between changes in LM and FM and the development of cortical and trabecular parameters of the radius and tibia in a 5-year longitudinal population-based study of 828 young men (18-20 years (baseline)). Areal BMD (aBMD) of the total hip and lumbar spine, and total body LM and total body FM were assessed using Dual-photon X-ray Absorptiometry (DXA). Trabecular vBMD, and cortical cross-sectional area (CSA) were obtained using peripheral quantitative computed tomography (pQCT) at the radius and tibia, respectively. Physical activity was obtained as hours/week using a standardized questionnaire.

The mean 5-year increase in LM was 2.3% (interquartile range -1.0% to 5.0%) and in FM 38,2% (3.4% to 61.0%). Changes in LM and FM were weakly correlated ($r=-0.1$, $p<0.01$). Using a stepwise linear regression model, including age at baseline, 5-year change in LM and FM, and 5-year change in height and physical activity as independent predictors, the 5-year change in LM was positively associated with aBMD of the total hip ($R^2=20.6\%$, $p<0.001$) and lumbar spine ($R^2=20.0\%$, $p<0.001$). The 5-year change in FM was only weakly positively associated with aBMD of the total hip ($R^2=0.6\%$, $p<0.05$). Using the same model, the change in LM was also positively associated with the 5-year development of CSA and trabecular vBMD at the radius (R^2 =6.8%, $p<0.001$, and $R^2=3.3\%$, $p<0.001$, respectively) and tibia ($R^2=8.3\%$, $p<0.001$, and $R^2=4.3\%$, $p<0.001$, respectively), whereas FM was only weakly associated with trabecular vBMD development at the tibia ($R^2=1.3\%$, $p<0.001$).

We conclude that alterations in lean mass predict the development of aBMD, bone size and trabecular vBMD in young adult men, indicating that lean rather than fat mass increments are beneficial for optimal bone development in young men.

MO0309

Association between Metabolic Syndrome and Bone Mineral Density in a Community-dwelling Older Women: the São Paulo Ageing & Health Study (SPAH). Luana Machado*[1], Diogo Domiciano[1], Jaqueline Lopes[2], Camille Figueiredo[1], Valéria Caparbo[1], Liliam Takayama[1], Rosa Pereira[2]. [1]University of São Paulo, Brazil, [2]Faculdade De Medicina Da Universidade De São Paulo, Brazil

Purpose:Recent studies have shown a link between metabolic syndrome (MS) and bone mass. However, these results are uncertain about the positive/negative effect of the components of MS on bone mineral density (BMD) and risk of fragility fractures. Furthermore, the higher prevalence of MS among subjects with higher body mass index (BMI) is a confounding factor, since previous findings have demonstrated that obesity could be a protective factor against bone loss. In this way, the aim of this study was to evaluate the prevalence of MS in a community-dwelling older women with high frequency of overweight/obesity and its association with bone parameters.

Methods: 343 women aged over 65 years were evaluated by specific questionnaire (including history of clinical fractures and cardiovascular risk factors). Lumbar spine, femoral neck and total hip BMD were evaluated by DXA. Laboratory tests, including calcium, phosphorus, creatinine, lipid profile and glucose were also performed. Thoracolumbar spine X-rays were assessed to identify vertebral fractures. National Cholesterol Education Program-Adult Treatment Panel III (NCEP-ATPIII) criteria were used to define MS. Logistic regression models were used to analyze the relationship between MS and bone parameters.

Results:The prevalence of MS was high (62.1%). Women with MS had higher BMI (30.7 ± 4.9 vs. $27.2 \pm 4.9 kg/m^2$, $P<0.001$), body fat percentage (37.7 ± 5.0 vs. $34.9 \pm 6.5\%$, $P<0.001$), lumbar spine BMD (0.881 ± 0.171 vs. $0.837 \pm 0.178 g/cm^2$, $P=0.025$), femoral neck BMD (0.684 ± 0.120 vs. $0.629 \pm 0.121 g/cm^2$, $P<0.001$) and total hip BMD (0.814 ± 0.131 vs. $0.743 \pm 0.140 g/cm^2$, $P<0.001$) compared to women without MS. After adjustments for BMI, logistic regression analyses demonstrated that hip BMD remained as an independent factor associated with MS (OR:10.73 95% CI:1.33-86.55, P=0.026). No significant difference concerning the prevalence of vertebral or nonvertebral fractures was observed between the two groups.

Conclusion: A positive association between total hip BMD and MS was found, even after adjustment for BMI. Nevertheless, the frequency of vertebral and nonvertebral fractures was similar in women with and without MS. Taken together, these results suggest that higher BMI per se does not explain the positive association between higher BMD and MS and does not protect against osteoporotic fractures. Further studies are necessary to elucidate the effect of MS on bone mass and fracture risk, possibly related to bone quality.

Bone Mineral Density (BMD), Vertebral Marrow Fat, and Markers of Metabolism in Older Men and Women: Results from the AGES-BMA study. Trisha Hue*[1], Xiaojuan Li[1], Clifford Rosen[2], Vilmundur Gudnason[3], Sigurdur Sigurdsson[4], Kristin Siggeirsdottir[4], Gunnar Sigurdsson[5], Gudný Eiríksdóttir[4], Tamara Harris[6], Lisa Palermo[1], Thomas Lang[1], Ann Schwartz[1]. [1]University of California, San Francisco, USA, [2]Maine Medical Center, USA, [3]Icelandic Heart Association Research Institute, Iceland, [4]Icelandic Heart Association, Iceland, [5]Landspitali University Hospital, Iceland, [6]Intramural Research Program, National Institute on Aging, USA

Higher levels of marrow fat (MF) are associated with osteoporosis, but little is known about the mechanisms governing MF accumulation. Endocrine factors involved in metabolic regulation may play a role in both MF accrual and bone density/strength. Ghrelin stimulates appetite, as well as osteoblast activity and affects adipogenesis, while preadipocyte factor-1 (pref-1), an inhibitor of differentiation, has been associated with increased MF and low bone mineral density (BMD). Insulin-like growth factor-1 (IGF-1), which responds to available energy from diet and body reserves, has also been found to be involved in bone formation, in contrast to insulin-like growth factor binding protein-2 (IGFBP-2), which is elevated with poor energy status and associated with increased MF and low BMD.

We assessed the relationship between markers of metabolism, MF and BMD in older men and women in the Bone Marrow Adiposity, Bone and Body Composition (BMA) study. BMA is a cross-sectional ancillary study to Age Gene/Environment Susceptibility-Reykjavik (AGES-Reykjavik), an ongoing population-based cohort study in Iceland. This analysis excluded those who reported current bone-active medication use (n=44), diabetes (n=17), or had inadequate serum (n=2). Blood was drawn fasting and serum was stored at -70˚C until batched assays for IGF-1, IGFBP-2, pref-1, and ghrelin were performed at the end of the study. Vertebral (L1-L4) MF content was measured with single voxel proton magnetic resonance spectroscopy. Other measures included: areal-BMD assessed by dual-energy X-ray absorptiometry, volumetric-BMD by quantitative computed tomography, and body mass index (BMI).

In this cohort of older adults, vertebral MF was modestly correlated with ghrelin in women (r=0.21, p=0.07), but not in men. The other markers were not correlated with MF. Pref-1 was positively correlated with BMD in men, ghrelin was inversely correlated with BMD in women, and IGFBP-2 was inversely correlated with BMD in men. IGFBP-2 was also inversely correlated with BMI in both men and women. We found no significant correlations (not shown) between IGF-1 and BMD.

With the exception of ghrelin in women, there was no evidence of an association between these markers of energy status and MF in older adults. These data also show that ghrelin, pref-1 and IGFBP-2 have gender-dependent patterns of association with trabecular and cortical bone density.

The Effect of Bone-Active Medication Use on Bone Mineral Density Post-Hip Fracture. Denise Orwig[1], Emma G. Sheldon*[2], Rasheeda Johnson[1], Marc Hochberg[2], William G. Hawkes[2]. [1]University of Maryland, Baltimore, USA, [2]University of Maryland School of Medicine, USA

Bone-active medications (BAMs), including prescription (RxBAM), calcium and vitamin D, have been shown to increase bone mineral density (BMD) and reduce the risk of fractures, yet utilization rates post hip fracture are still low. Studies examining the overall benefit of this group of medications on BMD in a hip fracture population are lacking, aside from a single specific randomized trial of zolendronic acid which has not translated as yet into standard clinical care. This study sought to identify trends in BAM use and determine if BAMs impact BMD in women during the 1-year post hip fracture period. Participants were 180 community-dwelling women aged 65 and older with surgical repair of an incident non-pathologic hip fracture from the fourth cohort of the Baltimore Hip Studies (BHS-4) that tested an in-home exercise intervention. Participants reported medication use and BMD at the total hip was measured within 22 days of fracture and at 2, 6, and 12 months post fracture. RxBAMs assessed were those available during the study time period (1998-2004) including: estrogen, etidronate, calicitonin, alendronate, and risendronate. Prior to the hip fracture, 85 (47%) took calcium/vitamin D only, 5 (3%) took RxBAM only, 50 (28%) took both calcium/vitamin D and RxBAM, and 39 (22%) took neither. Over 12 months post fracture, only 29 (16%) participants took RxBAMs during the entire study period. Of those who were using RxBAMs at any time post fracture (81) only 26 (32%) were new users while many participants started and stopped treatment or never started. A longitudinal analysis using a mixed effect model was performed. A two way interaction between BAM use and time was statistically significant ($p<.05$). While BAM users had lower total hip BMD at baseline [0.645 (0.01) vs. 0.657 (0.01) gm/cm2] compared to nonusers, BAM users had higher BMD at 12 months [0.635 (0.01) vs. 0.619 (0.01) gm/cm2]. These results show the beneficial effect of BAMs post fracture in preserving BMD over time.

MO0312

Hip fracture incidence is much higher in Hong Kong Chinese women than Beijing Chinese women despite higher bone density in Hong Kong women: Major implications for hip fracture prevention. Rick Chung*[1], George Qin[2], Peng Cheng Ha[2], Edith Lau[1]. [1]Center for Clinical & Basic Research (CCBR) (Hong Kong), Hong Kong, [2]Center for Clinical & Basic Research (CCBR), China

Back ground and objectives: Hong Kong has the highest incidence of hip fracture in Asia, while mainland China still has very low incidence of hip fracture. However, it has been predicted there will be a major epidemic of hip fracture in China. The objective of the current study is to compare the bone mineral density at the hip between a large population sample of Hong Kong and mainland Chinese women, so that insight can be gained into the etiology of hip fracture.

Subjects and Methods: 7130 ambulatory Hong Kong Chinese women and 7037 mainland Chinese women living in Beijing (aged 50 to 96) were recruited from the community. They volunteered for the study. BMD was measured by Lunar Prodigy Advance Whole Body Bone Densitometers. Cross calibration was carried out by a phantom. The prevalence of osteoporosis was calculated according to the World

Health Organization criteria. BMD at the total spine and femoral neck were adjusted for age, height and weight and compared between the 2 populations.

Results: According to published data, the incidence rate of hip fracture was 465/100,000 in Hong Kong Chinese women and 229/100,000 in Beijing Chinese women. The prevalence of osteoporosis at the total hip in our study was 24.8% in Hong Kong Chinese women and 20.0% in Beijing Chinese women, but these did not account for difference in weight and height. After adjustment for age, height and weight, the BMD of Hong Kong Chinese women was 2.8% higher at the hip and 1.5% higher at the femoral neck than Beijing Chinese women. This implies that BMD is a poor measurement of bone strength, and also that there are many extraskeletal factors causing hip fracture.

Conclusion: The difference in hip fracture incidence between Hong Kong Chinese and Beijing Chinese women cannot be explained by difference in BMD. Further research should focus on better measurement of bone strength in Chinese women, as well as extraskeletal factors for hip fracture, so that recommendations can be made to prevent the imminent epidemic of hip fracture in mainland China.

		Mean (g/cm²)		
Total hip	Age group	Hong Kong (n=7130)	Beijing (n=7037)	P Value by t-test

MO0313

Increased Bone Loss is Associated with Post-Fracture Mortality. Dana Bliuc*, Nguyen Nguyen, Tuan Nguyen, John Eisman, Jacqueline Center. Garvan Institute of Medical Research, Australia

Background: Mortality risk is increased following all major osteoporotic fractures, however the mechanism of this risk is unknown. Bone loss, a risk factor for osteoporotic fracture is associated with mortality in the general population. However, the role of bone loss in mortality risk post-fracture is unknown. This study aims to examine the effect of bone loss on post-fracture mortality.

Methods: Women and men aged 60+ from Dubbo Osteoporosis Epidemiology Study with incident fractures followed prospectively from April 1989 to December 2012. Bone density at the hip was measured at baseline and 2-yearly. Bone loss was assessed by linear regression for each participant. Quartiles of bone loss were assessed using Kaplan-Meier survival curves. Bone loss was also assessed as a continuous variable using Cox Proportional Hazards Models.

Results: 462 women and 149 men with incident fracture and at least 2 BMD measurements were included. Women and men had a similar age and fracture distribution. The rate of bone loss was similar for women and men (women: mean -0.75%/year and highest quartile: -1.38%/yr; men: mean -0.74%/yr and highest quartile: -1.34%/year). Using Kaplan-Meier analysis, survival was lowest for the highest quartile of bone loss for both women and men (women, p<0.005; men, p=0.05). When analysed by fracture type, the association of bone loss with mortality was observed for vertebral (highest quartile vs. lower 3 quartiles of bone loss, women p=0.03 and men p=0.03) and non-hip non-vertebral fractures (highest quartile vs. lower 3 quartiles of bone loss, women p=0.03 and men p=0.05), but not for hip fractures (highest quartile vs. lower 3 quartiles of bone loss, women p=0.5 and men p=0.7).

When bone loss was assessed as a continuous variable in a Cox Proportional Hazards Model, a decrease in bone mass by 1%/per year was associated with 13% increased mortality risk in women [HR: 0.87 (95% CI, 0.80- 0.94)] and 8% in men [HR 0.92 (95% CI, 0.80- 0.98)]. The effect of bone loss on mortality risk was maintained after adjusting for age in women [age-adjusted HR 0.87 (95% CI, 0.80- 0.96)] but not in men [age-adjusted HR 0.91 (95% CI, 0.80- 1.39)].

Conclusion: In this study bone loss was associated with increased mortality risk in both women and men, particularly for vertebral and non-hip non-vertebral fractures. The effect of bone loss on mortality was less clear for hip fractures.

MO0314

Ethnic Difference in Lumbar Spine TBS Between White, Black and Asian Women: Towards Explaining a Paradox?. William Leslie*[1], Olivier Lamy[2], Didier Hans[3]. [1]University of Manitoba, Canada, [2]University Hospital, Switzerland, [3]Lausanne University Hospital, Switzerland

Asian women have lower fracture rates than White women despite lower areal BMD. Black women have lower fracture rates than both White and Asian women but also have higher areal BMD. Both Asian and Black women tend to have stronger cortical parameters than White women at the axial site, but little is known about axial trabecular microarchitecture. TBS, a novel gray-level measurement of lumbar spine DXA image texture, is related to microarchitecture and fracture risk independently of BMD. Our aim was to evaluate ethnic difference in lumbar spine TBS.

41 147 White, 739 Asian and 152 Black women age ⩾50 years at the time of baseline hip (femoral neck) and spine (L1-4) DXA were identified from a database containing all clinical results for the Province of Manitoba, Canada. Spine TBS (TBS iNsight®) was derived from each spine DXA examination blinded to clinical parameters and outcomes. ANCOVA models were used to estimate least squares mean (LSM) ethnic TBS and BMD adjusted for FRAX variables (age, BMI, prior fracture, parental hip fracture, COPD, recent glucocorticoid use, rheumatoid arthritis, alcohol/substance abuse diagnosis), prior osteoporosis treatment, and bone area. Health service records were assessed for incident non-traumatic fracture codes after BMD testing.

Mean age of the women was 65.4 ± 9.2 y. Spine and hip BMD LSM showed significant between-ethnicity differences: Black > White > Asian (all p<.001). Spine TBS LSM showed a different pattern: Asian = White > Black (p<.01). Ethnic differences were unaffected by further adjustment for spine or hip bone area. During mean 5.6 y of follow up major osteoporotic fractures (MOF) occurred in 2626 (6.4%) White versus 22 (3.0%) Asian women (p<.001), despite similar estimated fracture risk from FRAX with BMD: MOF White 10.8% (±7.1) versus Asian 10.2% (±6.5), p=0.027; hip fracture White 2.6% (±4.2) versus Asian 2.5% (±3.6), p=0.425.

In conclusion, we observed significant ethnic differences in spine TBS, a correlate of trabecular bone structure. These differences were unrelated to skeletal size, BMI or other covariates and showed a different pattern from BMD differences. Our results suggest that TBS may be useful for assessing ethnic differences in bone quality, and may be less sensitive to skeletal size differences than areal BMD. The finding of lower spine TBS in Black women was unexpected, and requires confirmation. Studies in larger populations with more fracture events and greater ethnic diversity are warranted.

Ethnicity	Hip BMD T-score	p-value vs White	Spine BMD T-score	p-value vs White	Spine TBS unitless	p-value vs White
Adjusted for FRAX covariates and prior treatment						
Asian	-1.72	<.001	-1.48	<.001	1.232	0.466
White	-1.44		-1.15		1.235	
Black	-0.81	<.001	-0.89	0.022	1.210	0.007
Adjusted for bone area, FRAX covariates and prior treatment						
Asian	-1.65	<.001	-1.32	<.001	1.211	0.308
White	-1.45		-1.15		1.236	
Black	-0.77	<.001	-0.82	<.001	1.200	0.013

Associations among Dietary Phosphorus Intake and Bone Turnover Markers in 37-to-47-year-old Caucasian Population - The PHOMI Study. Suvi Itkonen*[1], Elisa Saarnio[1], Virpi Kemi[1], Heini Karp[1], Merja Kärkkäinen[1], Minna Pekkinen[2], Juha Risteli[3], Marja-Kaisa Koivula[4], Kaisa Ivaska[5], Christel Lamberg-Allardt[1]. [1]University of Helsinki, Finland, [2]Folkhälsan Institute of Genetics, University of Helsinki, Finland, [3]University of Oulu, Finland, [4]NordLab Oulu & Department of Clinical Chemistry, Institute of Diagnostics, University of Oulu, Finland, [5]University of Turku, Finland

Phosphorus (P) intake in Western countries is high due to abundant intake of animal protein and also because of the expanding use of highly absorbable P salts as food additives. In short-term studies high P intake has had negative effects on bone metabolism but the long-term effects are unknown. The aim of the study was to investigate the associations among dietary P intake and bone turnover markers in a cross-sectional Caucasian population in Finland.

A sample of 370 37-to-47-year-old pre-menopausal females who participated in the PHOMI Study was included in the analyses. Fasting blood samples were collected, as well as habitual dietary intake by 3-day food records and background data by a questionnaire. Serum osteocalcin (OC) and intact pro-collagen type I amino-terminal propeptide (iPINP) (both characteristics of bone formation), bone resorption marker collagen type 1 cross-linked C-terminal telopeptide (CTX) and some other biomarkers related to bone metabolism were analysed. The data was statistically analysed by analysis of variance (ANOVA) and analysis of covariance (ANCOVA) in tertiles of P intakes using different combinations of covariates (contraceptive use (CU), age, 25-hydroxy vitamin D (25OHD), smoking, weight). Linear trends were tested by contrast analyses.

In unadjusted analyses, P intake was inversely associated with iPINP and CTX over the tertiles (p=0.003 and p=0.049, ANOVA), and between P intake and OC existed a negative linear trend (p=0.034). In the covariate-adjusted models the most significant results were found using CU, age, smoking and 25OHD as covariates: P intake was adversely associated with iPINP (p=0.005, ANCOVA), between P intake and CTX existed a negative linear trend (p=0.020), and between P intake and OC an almost statistically significant negative linear trend was found (p=0.057). When weight was introduced as a covariate among above-mentioned ones, the significance weakened: between P intake and iPINP a negative linear trend (p=0.005) was found while the results between P intake and CTX or OC were non-significant (p>0.05).

High P intake seems to be associated with lower concentrations of iPINP, a linear trend towards lower concentrations of CTX was found, and a tendency towards a linear trend to lower concentrations of OC emerged, altogether indicating lower bone turnover with higher P intake.

Keywords: phosphorus, phosphate, osteocalcin, iPINP, CTX, bone turnover markers

Associations between Serum Concentrations of Vitamin B12, Folate and Iron, and Body Composition in Adults Aged ⩾ 45 years: An Analysis of NHANES 1999-2002. Maryam Hamidi*[1], Jeevitha Srighanthan[1], Angela M. Cheung[2]. [1]University Health Network, Canada, [2]University Health Network-University of Toronto, Canada

Background: There is evidence that vitamin B12, folic acid and iron can influence lipid, bone and muscle metabolism by different mechanisms. However, very few studies have examined the associations between serum concentrations of B12 (sB12), folate (sFol) and iron (sFe) and body composition.

Objectives: To examine the associations between serum concentrations of sB12, sFol and sFe, and body composition (measured by dual energy X-ray absorptiometry (DXA)), BMI and waist circumference (WC) among men and women aged ⩾ 45 years in a population-based study.

Methods: We used cross-sectional data from the National Health and Nutrition Examination Survey (NHANES) 1999-2002. Weighted survey procedures with adjustments for age, ethnicity, physical activity, nicotine exposure and income were used for all analyses. The study sample included 666 postmenopausal women and 1326 men who were not taking hormones, steroids or medications that may affect body composition; and were free from kidney and liver disease, cancer and rheumatoid arthritis. DXA was used to measure trunk and total body fat and lean mass (g), trunk and total body fat percent, and BMD of lumbar spine and sub-total body (total body BMD-head BMD).

Results: Mean age for men and women was 56.8 ± 0.33 and 64.78±0.51 years, respectively. We found significant negative associations between sB12 and fat mass variables ($p < 0.05$) in women and men. In women, there were also significant negative associations between both sB12 and sFol, and WC and BMI ($p<0.05$). In men, sFe had significant positive associations with lean mass variables and sub-total body BMD ($p<0.05$).

Conclusions: To our knowledge, this is the first population-based study that examined the associations between sB12, sFol and sFe and body composition. Our results suggest that high sB12 may be associated with low fat mass in men and women; also that the associations between sFol and sFe, and body composition may be different between men and women. Further investigations into the associations between sB12, sFol and sFe, and body composition are warranted.

Dietary Fatty Acid Intake Does Not Interact with the Association between Tumor Necrosis Factor-α Soluble Receptors and Incident Hip Fracture in The Women's Health Initiative. Steven Ing*[1], Tonya Orchard[1], Andrea Lacroix[2], Charles Kooperberg[2], Aaron Aragaki[2], Martha Belury[1], Bo Lu[1], Rebecca Jackson[1]. [1]The Ohio State University, USA, [2]Fred Hutchinson Cancer Research Center, USA

Background: Inflammatory biomarkers, tumor necrosis factor-a soluble receptor (TNFa-sR) 1 and 2 are positively associated with incident hip and total fracture. Polyunsaturated fatty acids (PUFA) are inversely associated with these markers of inflammation and could modify this association.

Methods: A nested case-control study from the Women's Health Initiative Clinical Trial and Observational Study of hip fracture cases and matched controls (400 pairs matched on age, year of enrollment, randomization to hormone therapy or self-reported hormone use). The outcome variable was centrally adjudicated incident hip fracture. Predictors were baseline serum TNFa-sR1 and TNFa-sR2 concentration. Candidate effect modifiers were dietary intake of fatty acids determined by baseline Food Frequency Questionnaire: saturated fatty acids, mono-unsaturated fatty acids (MUFA), poly-unsaturated fatty acids (PUFA), total n-3 fatty acids, total n-6 fatty acids, eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA), and alpha linoleic acid (ALA). Data were analyzed using logistic regression models accounting for the paired design. Models were adjusted for hip fracture risk (composite FRAX score), other nutritional variables (total calcium intake, total vitamin D intake, total energy intake, total protein intake, multivitamin use) and factors impacting inflammation (NSAID use, arthritis, depression).

Results: Highest quartile of TNFa-sR1 and TNFa-sR2 were associated with greater risk of incident hip fracture in the fully adjusted base model (Table). The sample size decreased from the initial 400 pairs after exclusion of subjects with missing data and the consequent occurrence of partial pairs, yielding a final sample of 290 and 285 pairs for TNFa-sR1 and TNFa-sR2, respectively. These associations were confirmed using tests for linear trend (p for trend, 0.0069 and 0.0010 for TNFa-sR1 and TNFa-sR2, respectively). Testing the association of incident hip fracture using log TNFa-sR1 and log TNFa-sR2 as predictor also showed significant results (p=0.0055 and p=0.0034, respectively). Addition of fatty acid intakes into the fully adjusted model did not alter quartile-specific hip fracture risk (all changes <10%).

Conclusion: Highest baseline quartiles of TNFa-sR1 and TNFa-sR2 were associated with greater adjusted risk of incident hip fracture, but dietary fatty acid intakes did not modulate this association, perhaps related to limited narrow range of fatty acid intakes.

Higher Dairy Intakes are Associated with Improved Bone Health in a Population-based Study - CaMos. Claudie Berger*[1], Lisa Langsetmo[2], Susan I Barr[3], Jonathan Adachi[4], David Hanley[5], Jerilynn Prior[3], Christopher Kovacs[6], Elham Rahme[7], Stephanie Kaiser[8], Robert Josse[9], Alexandra Papaioannou[10], Nancy Kreiger[11], David Goltzman[7]. [1]CaMos, McGill University, Canada, [2]Canandian Multicenter Osteoporosis Study, Canada, [3]University of British-Columbia, Canada, [4]St. Joseph's Hospital, Canada, [5]University of Calgary, Canada, [6]Memorial University of Newfoundland, Canada, [7]McGill University, Canada, [8]Dalhousie University, Canada, [9]St. Michael's Hospital, University of Toronto, Canada, [10]Hamilton Health Sciences, Canada, [11]University of Toronto, Canada

Background: Calcium and vitamin D are essential for bone health. Dairy products are sources of both nutrients, but associations between dairy products and the primary measures of bone health remain to be elucidated.

Objective: To determine associations between total dairy intake (milk, milk dessert, yogurt, cheese, cream soup) and bone health outcomes (blood biomarkers, bone mineral density [BMD], incident fracture).

Methods: We used data from 984 youth aged 16-24 years (y), 1625 adults aged 25-49 y, and 6937 adults aged >50 y from the Canadian Multicentre Osteoporosis Study, a prospective population-based cohort. Youth and adult (>25 y) participants had an interviewer-administered questionnaire with clinical assessments including BMDs at baseline, Year 2 in youth and Years 5 and 10 in adults. A subgroup of each cohort had fasting blood drawn. Participants were contacted annually to ascertain incident fracture up to Year 15. Hierarchical models (over 2 y in youth and 10 y in adult), multiple linear regression (baseline and over 2 and 10 y) and Cox proportional hazards (over 15 y) were used to assess the association of total dairy intake with biomarkers (25-Hydroxyvitamin D [25OHD],parathyroid hormone [PTH], bone specific alkaline phosphatase [BSAP], C-terminal telopeptide of type I collagen [CTX], Insulin-like growth factor-1 [IGF-1]), BMDs and incident main fracture (hip, clinical spine, forearm, humerus). All analyses were adjusted for possible confounders.

Results: *Biomarkers*: Using hierarchical models and data available at all interviews, higher total dairy intake per day was associated with higher 25OHD levels in men 16-24, women 25-49 y, and women and men >50 y (Table 1). Higher total dairy intake was also associated with a lower PTH levels in men 25-49 y; higher IGF-1 in women 25-49 y; and lower BAP and CTX in women and men >50 y.

BMDs: Higher baseline total dairy intakes were associated with higher baseline total hip and/or femoral neck BMD in men 25-49 y and in women and men > 50 y (Table 2).

Fractures: Among men >50 y, overall higher dairy intake was associated with a lower risk of incident main fracture with HR=0.80 (95% CI: 0.64; 0.99). In contrast, among women >50 y, overall dairy intake was not associated with risk of main fracture.

Conclusion: Higher total dairy intake is associated with apparent better bone health as reflected by improved blood biomarkers, maintenance of or increased BMD, and reduced risk of fracture in men over age 50.

Table 1: Hierarchical models (using data available at all interviews) assessing associations among total dairy intakes per day with the Vitamin D (25OHD), Parathyroid Hormone (PTH) levels, growth factors (IGF-1) and bone turnover biomarkers: bone specific alkaline phosphatase (BSAP) and C-telopeptide (CTX) in men and women in the youth (ages 16-24) and adult (ages ≥25) cohorts of the Canadian Multicentre Osteoporosis Study.

Estimates and 95% C.I.	25(OH)D (nmol/L)	PTH (log-scale)	IGF-1 (log-scale)	BSAP (log-scale)	CTX (log-scale)

Prediction Model for Normal Vitamin D in Elderly Women. Thomas Merlijn*, Petra Elders, Coen Netelenbos. VU medical center, The Netherlands

Introduction: Vitamin D insufficiency is common in elderly and results in increased risk of falls and fractures. Several guidelines advise suppletion of vitamin D in elderly. Possibly not all elderly women are at risk for vitamin D insufficiency or deficiency.

Goal: The goal of this study is to develop a model to distinguish elderly women with normal serum 25-hydroxyvitamin D levels (> 50nmol/l).

Methods: For modelling we used data of the participants of the first included regions of the SOS-trial. This is a primary care population of women ⩾65 years with at least one risk factor for osteoporosis. All women completed a questionnaires and subsequently bone densitometry and laboratory tests (including 25-hydrxoyvitamin D, Diasorin) were performed. Vitamin D levels and other variables were categorized or dichotomized. Multiple logistic regression with backward selection was applied to select the predictors for the model. The model will be validated in two extern populations.

Results: Data of 2301 women were available for modelling. The AUC of the model was 0,737. Table 1 shows the predictors and a risk score. Table 2 shows the results at different cut-off points.

Discussion

We formulated a model to predict normal vitamin D levels. This model shows the important role of the seasons. All elderly women without vitamin D suppletion, even in absence of risk factors, are at risk for vitamin D insufficiency in winter.

Table 1. Predictors in the model and risk score

Risk factor	Score
Age> 75 years	2
BMI >kg/m2	1
Length < 160cm	1
Smoking	1
Actual prescriptions≥ 7 /day	1
Time outdoor in summer < 1hour/day	2
Walking aid	2
Season spring/ autumn (Nov, Dec, Jan, May, June)	2
Season winter (Feb, March, April)	4
Vitamin D,prescription	-7
Vitamin D, self administered	-2
Multivitamin use	-2

Table 2. Positive predictive value of the total risk score

Cut-off	≤-2	≤-1	≤0	≤1	≤2	≤3	≤4	≤5	≤6	≤7
N	142	215	364	616	823	1135	1375	1680	1878	2032

Vitamin D Levels and Calcium Supplementation One-Year Follow up in Osteopenic Patients in West Bohemia. Vaclav Vyskocil*[1], Tomas Pavelka[2]. [1]Center for Metabolic Bone Diseases, Czech Republic, [2]Department of Orthopaedic Surgery, Czech Republic

Authors observed the group of 2900 patients in age between 18 - 91, who were examined by DXA in period from February 2011 to February 2012. All patients had at any of the measured points BMD lower than -2.0 SD.

The aim of the study was to determine vitamin D saturation according to preselected age categories and simultaneously determine existing relation between vitamin D level and bone density. In the second phase we planned to evaluate calcium and vitamin D intake from supplementation and food in order to confirm effect on study results.

Patients were divided into age groups: 18-25 years (15 patients), 26-55 (307 patients), 56-80 (1469 patients), 81 and more (112 patients).

Vitamin D levels were significantly higher in summer months in patients between 18-25 years, mostly in women. Increased values in summer season were also detected in the 26-55 year category and in patients between 56-80 years were the vitamin D values constant.

Lower level of vitamin D (25(OH)D<50 nmol/l) was present in 80% of patients in the group 18-25 years, 71% in the group of 26-55 years, 64.7% in the group of 56-80 years and only 59.5% in the group of older than 80 years.

Our analysis of more than 2000 patients confirmed the effect of insolation on vitamin D levels in summer months in the group 18-25 years and a partial effect on the group 26-55 years.

Further we found strong deficiency of 10-40 nmol/ml vitamin D in men older than 80 years, whereas in other age groups were the values sufficient, average value about 80 nmol/ml.Calcium and vitamin D intake was evaluated by questionnaire. We collected above mentioned parameters in 2000 patients. We evaluated the effect of supplementation on vitamin D level in those patients one year after initial measurement. Patient with low level of vitamin D were divided into 2 groups according to BMI (BMI ≤25 and BMI ⩾ 30). Effect on vitamin D level was corrected with respect to different BMI. Higher doses of vitamin D were required to normalize vitamin D level in obese patients. Higher calcium intake correlated with higher BMD increase in lumbar spine.

MO0321

Updated Non-hip to Hip Fracture Ratios in Canadian Men and Women with Potential Implications for FRAX Calibration: A Population Based Analysis.

William Leslie*[1], Lisa M Lix[1], Marina Yogendran[1], Anna Lam[1], Suzanne Morin[2], Colleen Metge[1], Sumit Majumdar[3]. [1]University of Manitoba, Canada, [2]McGill University, Canada, [3]University of Alberta, Canada

Background: FRAX tools are calibrated from country-specific fracture epidemiology, but data on non-hip fractures are difficult to collect. Where accurate non-hip fracture information is lacking, rates can be estimated assuming that a similar relationship with hip fractures exists as in 1987-1994 data from Malmo, Sweden (Kanis: OI 2000;11:669). Evidence to support this assumption in other populations is limited and ratios may have changed given secular changes in hip fractures which are declining in North America.

Objective: To examine ratios of osteoporotic fractures in the Province of Manitoba, Canada and compare these to older Swedish ratios.

Methods: We used 2000-2007 data from the Manitoba Population Health Research Data Repository to identify incident major osteoporotic fractures using definitions that approximate population-based Canadian rates from CaMos (Lix: BMC Public Health 12:301, 2012). Age (5 year subgroups) and sex specific ratios in fracture counts (clinical vertebral, forearm, humerus versus hip) with 95% confidence intervals were calculated and compared with the equivalent Swedish ratios.

Results: During 7-years of observation, 14 191 incident fractures were identified (men versus women: 1611 / 3285 vertebral, 1090 / 4387 forearm, 844 / 2699 humerus, 1373 / 3820 hip). All non-hip/hip ratios decreased with age for both sexes (Figure). Men and women showed similar vertebral/hip ratios (all $p > 0.1$, odds ratios [ORs] 0.80-1.31). Forearm/hip ratios were significantly lower among men than women for all ages (all $p < 0.001$, ORs 0.31-0.57), and also significantly lower in eight of nine age subgroups for humerus/hip (ORs 0.45-0.65, NS for age 80-84 years). A similar pattern was observed for any non-hip/hip ratios which were significantly lower among men than women in seven of nine age subgroups (ORs 0.45-0.83, NS for age 80-84 years and 90+ years). Compared to Swedish ratios, Canadian ratios were significantly higher among younger age subgroups in both men and women, but showed closer agreement for older age subgroups.

Conclusions: All non-hip to hip fracture ratios decreased with age in both sexes, with non-vertebral to hip fracture ratios significantly greater in women than men. Non-hip to hip fracture ratios were higher in younger Canadian men and women than ratios computed from previously reported Swedish data. FRAX tools calibrated using these older ratios may underestimate fracture risk in younger individuals.

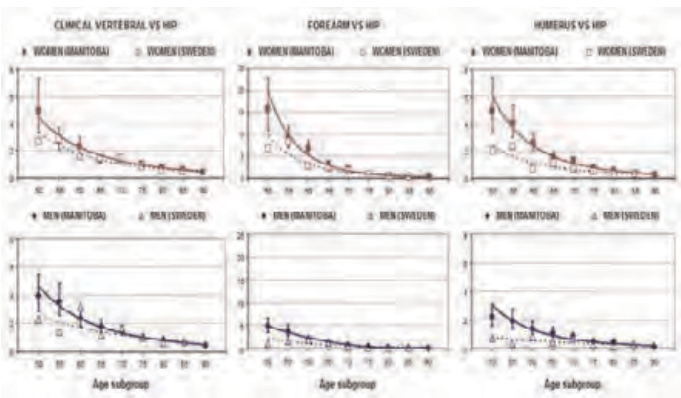

Figure: Non-hip to hip fracture ratios by age and sex

Can we improve the reproducibility of vertebral fracture assessment (VFA) readings?An exploratory study based on the OsteoLaus Cohort.

Bérengère Aubry-Rozier*[1], Katia Iglesias[2], Marc-Antoine Krieg[1], Olivier Lamy[1], Bernard Burnand[2], Didier Hans[1]. [1]Center for Bone Diseases. Lausanne University Hospital, Switzerland, [2]Département de médecine sociale et préventive, Lausanne University Hospital, Switzerland

Osteoporotic vertebral fractures are highly prevalent and a major cause of morbidity and mortality in industrialized countries. The *vertebral fracture assessment* (VFA), obtained with bone mineral density testing via dual energy X-Ray absorptiometry (DXA) has been validated for vertebral fracture diagnosis in clinical settings. The International Osteoporosis Foundation (IOF) and the International Society of Clinical Densitometry (ISCD) both proposed specific guidelines for VFA interpretation. But the reproducibility of VFA reading is not known in population based cohort screening. The aim of this study was to estimate the benefits of using IOF/ISCD guidelines for VFA reading and to estimate the level of reproducibility within and between raters for VFA in a population based cohort. To assess these estimations, two statistical tolls were used: Cohen's and uniform kappa coefficients.

360 women were randomly selected from the larger cohort OsteoLaus. We calculated inter- and intra-reading reproducibility of the two kappa statistics both before and after applying an IOF/ISCD adapted guideline (IIR). All readings were performed independently by two osteoporosis experts with extensive experience reading VFA but no prior training in the IOF/ISCD courses.Overall, 12% of vertebrae were unreadable, with this percentage as high as 48% for levels T4 and T5. Depending on the reader, the prevalence of VF varied from 3% to 4% with 3 to 4% grade 1, 0.6 to 1.3% grade 2 and 0.03% to 0.2% grade 3 VF. Before IIR application, inter-reader reproducibility with Cohen's kappa was 0.35 to 0.71 and 0.74 to 0.98 with the uniform kappa coefficient for all criteria. After applying the IRR recommendations, inter-reader reproducibility was 0.28 to 0.68 and 0.70 to 0.99, respectively. All the results were better for lumbar spine as for dorsal spine. We concluded that kappa uniform is better adapted for the screening in a population-based cohort (events rare and repartition not uniform) than kappa of Cohen. The uniform kappa statistic is more accurate as a measure of reproducibility than Cohen's kappa for VFA reading. Moreover the IOF/ISCD guidelines did not increase reproducibility in VFA reading when readers are already experts in osteoporosis

Characteristics Influencing Quality of Life in Women 6 Months After Suffering a Fragility Fracture.

Claudia Beaudoin*[1], Sonia Jean[2], Louis Bessette[3], Louis-Georges Ste-Marie[4], Jacques P. Brown[3]. [1]Centre de recherche du CHU de Québec, Canada, [2]INSTITUT NATIONAL DE SANTÉ PUBLIQUE DU QUÉBEC, Canada, [3]CHU de Quebec Research Centre, Canada, [4]CHUM, Canada

Purpose: To identify the socio-demographic and clinical characteristics associated with a decrease in quality of life in a cohort of women $\geq$ 50 years who suffered a fragility fracture (FF). Methods: In the Recognizing Osteoporosis and its Consequences in Quebec Programme, women who suffered a FF were recruited from hospitals and an administrative database-generated list. Women were contacted 6-8 months after a FF to complete a questionnaire detailing personal and clinical characteristics related to osteoporosis (diagnosis, treatment, comorbidities, risk factors, etc.). An EQ-5D health questionnaire was also sent to women to assess their health-related quality of life (HRQoL). In this questionnaire, 5 dimensions of health were covered (mobility, self-care, usual activities, pain/discomfort, and anxiety/depression) and collected data were used to construct a global index of health score ranging from -0.59 to 1 (0=dead, 1=full health). General perception of health was also evaluated with a visual analogue scale where 0 represents the worst health and 100, perfect health. To identify the characteristics associated with HRQoL, linear regression models were constructed using the health perception and global index scores as dependent variables as well as the socio-demographic and clinical characteristics as independent variables. Differences in the EQ-5D index score ranging from 0.03 to 0.07 were considered to be the minimal clinically important differences, as proposed by previous studies. Results: 1979 women completed both questionnaires. The characteristics associated with a decrease in the EQ-5D index score were: having suffered a hip/femur or humerus fracture, history of fractures after 40 years, kyphosis, comorbid conditions, being underweight or obese, being retired, unemployed, homemaker or disability, smoking tobacco, living alone, early menopause, and having received a diagnosis or treatment for osteoporosis (Table 1). Except for a history of fractures, the same characteristics were associated with a decrease in the health perception score (Table 2). Regular use of medications that decrease bone mineral density was also associated with a decrease in the health perception score. Conclusions: Hip, femur or humerus fractures have a significant influence on HRQoL 6-8 months after the event. Other characteristics related to bone health such as history of fracture after 40 years and having a kyphosis are also associated with a significant reduction in HRQoL.

MO0325

Could Fracture Risk Assessment in Elderly Men Be Improved by Adiponectin? Mr Os Sweden. Helena Johansson*[1], Anders Odén[2], Magnus Karlsson[3], Eugene McCloskey[4], John Kanis[5], Claes Ohlsson[6], Dan Mellström[7]. [1]Swedish University of Agricultural Sciences, The Biomedical Center, Sweden, [2]WHO Collaborating Centre, University of Sheffield, United Kingdom, [3]Skåne University Hospital Malmö, Lund University, Sweden, [4]University of Sheffield, United Kingdom, [5]University of Sheffield, Belgium, [6]Center for Bone & Arthritis Research at the Sahlgrenska Academy, Sweden, [7]Centre for Bone & Arthritis Research (CBAR), Sahlgrenska Academy, University of Gothenburg, Sweden, Sweden

Several studies suggest that high serum adiponectin is associated with an increased risk of fracture in elderly men. The aim of the present analysis was to determine the impact of serum adiponectin on the 10 year probability of fracture.

The 10 year probability of osteoporotic fracture was computed in 989 elderly men recruited to the MrOS study in Gothenburg, Sweden. Baseline data included clinical risk factors for fracture, femoral neck BMD and serum adiponectin. Poisson regression was used to model the hazard function for osteoporotic fracture and death. By using the hazard functions and extrapolation in time, the 10 year probability of fracture was calculated.

Men were followed for up to 7.4 years (average 5.3 years), during which 124 (13%) men sustained one or more osteoporotic fractures. The risk of fracture (adjusted for age and BMD) increased by 40% for each SD increase in serum adiponectin (gradient of risk =1.40; 95% CI = 1.16-1.68). The ten year probability of osteoporotic fracture was 21% for a man aged 75 years with a BMD T-score of -2.0 SD and an adiponectin value of 5.6μg/ml (10^{th} percentile). When adiponectin was 20.1μg/ml (90^{th} percentile) for the same age and BMD the probability was 39%. There was, however, a significant interaction between adiponectin and time since baseline (p=0.026), such that the longer time since baseline the lower the GR. When using this interaction in the calculation of 10 year probability of fracture, the ten year probabilities of osteoporotic fracture were almost identical in the examples above (probability was 32% for an adiponectin value of 5.6μg/ml and 33% for an adiponectin value of 20.1μg/ml).

Serum adiponectin is a risk factor for fracture, at least in the short term, but its predictive value attenuates with time. Its use for fracture risk assessment in the long term (10 years) is questionable. This study underlines the importance of testing the long term stability of potential risk factors in risk assessment.

MO0326

Exome chip analysis for osteoporotic fracture: Results from the CaMos/ ManMc consortium. Hou-Feng Zheng*[1], Vincenzo Forgetta[1], William Leslie[2], David Goltzman[1], Alexandre Montpetit[1], Mark Lathrop[1], Brent Richards[1]. [1]McGill University, Canada, [2]University of Manitoba, Canada

Background: Genome-wide association studies (GWAS) have identified loci associated with bone mineral density. However the influence of coding variation on osteoporotic fracture has not been systematically interrogated using standardized genotyping arrays.

Aim: To examine the effect of coding variants on the risk of osteoporotic fracture.

Methods: Using the Illumina HumanExome BeadChip we genotyped 1,202 osteoporotic fracture cases (83.5% occurring at distal forearm) and 862 controls at 247,870 coding variants. Cases had sustained x-ray or surgically confirmed osteoporotic fractures and controls were followed prospectively for ten years without sustaining any type of fracture. Accuracy of genotyping was assessed using duplicate samples, which had an average concordance rate of 99.99%. Population stratification was assessed using SmartPCA. After quality control, 1102 cases and 818 controls assayed at 244,030 variants remained for analysis. We tested for trait-SNP associations assuming an additive genetic model using a linear mixed model to correct for relatedness as implemented in the GEMMA software package. Given power considerations, only variants with a minor allele frequency greater than 0.5% (N = 41,263) were assessed.

Results: 133,207 (54.59%) variants were monomorphic in the studied individuals, 69,560 (28.5%) variants had a MAF <0.5%, 14,637 (6%) had a MAF between 0.5% and 5% and the remaining variants were common. We identified one missense variant to be genome wide significant for risk of fracture at C16orf71 (MAF=0.04, P= 1.74x10-8, OR=3.37) and two variants to be genome-wide suggestive ($P < 5x10-6$) at gene MDC1 (MAF=0.01, P= 5.13x10-7, OR=8.42), and at HLADPB1/HLADPA1 (MAF=0.22, P= 1.22x10-6, OR=1.51).

Conclusion: While replication of these findings are on-going, this study demonstrates the utility of exome array genotyping to identify coding variants contributing to osteoporotic fracture—a clinically relevant osteoporotic outcome.

MO0327

In men, bone microarchitecture measured by high resolution pQCT improves fracture prediction - the prospective STRAMBO study. Pawel Szulc*[1], Stephanie Boutroy[2], Roland Chapurlat[3]. [1]INSERM UMR 1033, University of Lyon, Hopital E. Herriot, Pavillon F, France, [2]INSERM UMR 1033, Université de Lyon, France, [3]E. Herriot Hospital, France

Areal bone mineral density (aBMD) measured by DXA is a suboptimal fracture predictor in older men, because low aBMD identifies only about 20% of men who will sustain subsequently a fragility fracture. Our aim was to assess the value of bone microarchitectural parameters for the fracture prediction in older men.

Bone microarchitecture was assessed at the distal radius and distal tibia by high resolution peripheral quantitative computed tomography (HR-pQCT, XtremeCT device, Scanco Medical AG, Brüttisellen, Switzerland) in a cohort of 819 men aged 60 to 87 yrs. During the average follow-up of 4.9 years, 76 men sustained at least one vertebral or peripheral fracture. Lower total volumetric BMD (vBMD), trabecular vBMD (Tb.vBMD, including Tb.vBMD assessed separately in the central and subendocortical compartments) and trabecular number (Tb.N) as well as higher separation (Tb.Sp) and distribution (Tb.Sp.SD) were associated with higher risk of fracture. After adjustment for age, weight, fall history and prior fracture, HR varied from 1.29 to 1.61 per SD change according to the parameter ($p<0.05$ to $p<0.001$). The trends were similar for both skeletal sites. After additional adjustment for ultradistal radius aBMD, Tb.N, Tb.Sp and Tb.Sp.SD of the distal radius remained

significantly associated with higher fracture risk (e.g., Tb.N: HR= 1.61 per SD decrease, 95%CI: 1.23-2.13, p<0.001). After additional adjustment for total hip aBMD, lower central Tb.vBMD and higher Tb.Sp.SD of the distal tibia remained associated with a significantly higher risk of fracture (e.g., central Tb.vBMD: HR= 1.38 per SD, 95%CI: 1.03-1.86, p<0.05). Cortical thickness and vBMD (assessed using the standard algorithm) as well as trabecular thickness did not predict fractures. In comparison with the lowest quartile of ultradistal radius aBMD, the lowest Tb.N quartile improved the sensitivity of the identification of fractures (46 vs 33%) without influencing specificity and better identified men at high risk of fracture (p<0.05). Similar results were obtained in the analyses limited to the fragility fractures (68 men) and low trauma fractures (69 men).

This is the first prospective analysis showing that assessment of bone microarchitecture by HR-pQCT may improve the fracture prediction in older men in comparison with DXA.

MO0328

Long-Term Proton Pump Inhibitor Therapy: Large Effects on Falls and Fractures in Elderly Women. Joshua Lewis*[1], Deka Barre[2], Kun Zhu[1], Jeff Hughes[2], Richard Prince[3]. [1]University of Western Australia, Sir Charles Gairdner Hospital, Australia, [2]Curtin University, School of Pharmacy, Australia, [3]Sir Charles Gairdner Hospital, Australia

Proton pump inhibitors (PPIs) are widely used in the elderly. Recent studies have suggested long-term PPI therapy is associated with hip and spine fractures, however the mechanism remains unknown. We sought to determine the association between long-term PPI therapy greater than one year for fracture outcomes and fracture risk factors including bone structure, falls and balance-related function. The initial study was a post hoc analysis of a longitudinal prospective cohort of 1,025 elderly women followed for 5 years from 2003 (baseline) to 2008 with a pre-planned replication in a second prospective 9-month study of falling in 686 elderly postmenopausal women (replication study).

In Study 1 the adjusted odds ratio (AOR) for 5-year falls and fracture-related hospitalizations in participants on long-term PPI therapy (n = 120) compared to no long-term use at baseline (n = 905) was 2·168; 95% CI, 1·248-3·766; P = 0·006 and 1·947; 95% CI, 1·201-3·157; P = 0·007 respectively. In the replication study, long-term PPI therapy (n= 132) compared to no long-term PPI therapy (n = 554) was also associated with increased risk of falling, AOR, 1·509; 95% CI, 1·002 -2·273; P = 0·049. The number needed to cause harm (NNH) with long-term PPi therapy for injurious fall or fracture-related hospitalizations over the 5-year period in Study 1 was 11 and 14 respectively, while in the replication study the NNH was 11. Using mediation analyses the association of long-term PPI for fracture outcomes was completely mediated by the observed increased falling. Regarding mechanism in Study 1, bone structure determined from heel ultrasound, hip DXA and total body DXA did not differ by PPI use category, however falls associated metrics assessed by questionnaire and objective clinical measurements including; fear of falling indoors and outdoors, dizziness, numbness of the feet, timed up and go test and Romberg eyes closed test were all significantly impaired in long-term PPI users. In conclusion, long-term PPI therapy at baseline in elderly women doubled the risk of falling and fracture over 5 years compared to those with no long-term PPI use at baseline. PPI therapy was also associated with impaired balance, dizziness, numbness of the feet and increased fear of falling.

This substantial increase in risk of falls and fracture in individuals, already at high risk of falling, should be considered when prescribing PPI therapy in this patient group.

MO0329

Mortality After a Hip Fracture in the United Kingdom: 2000 – 2011. Corinne Klop*[1], Paco Welsing[2], Cyrus Cooper[3], Johannes Bijlsma[4], Hubert Leufkens[1], Frank de Vries[1]. [1]Utrecht Institute for Pharmaceutical Sciences, Division of Pharmacoepidemiology & Clinical Pharmacology, Utrecht University, Netherlands, [2]Julius Center for Health Sciences & Primary Care, University Medical Center, Netherlands, [3]University of Southampton, United Kingdom, [4]Department of Rheumatology & Clinical Immunology, University Medical Center, Netherlands

Purpose: There are limited data on recent trends in mortality risk after hip fracture and this risk is often not adjusted for co-morbidities, medication use and lifestyle factors. Aims of this study were to examine trends in all-cause one-year mortality after hip fracture from 2000 to 2011 and to report on gender differences in cause-specific mortality.

Methods: A cohort study was conducted within the Clinical Practice Research Datalink (CPRD), which is the world's largest primary care database including more than 5 million patients in the United Kingdom. Patients with a first hip fracture between April 1st 2000 and March 31st 2011 (n=32,031) were matched to up to four controls (n=118,637) by age, sex, index date, and practice. Changes in all-cause one-year mortality in hip fracture patients and relative to control subjects were evaluated using Cox regression. Hazard Ratios [HRs] were adjusted for age, co-morbidities, lifestyle factors (body mass index, smoking status, alcohol use) and medication use. In order to estimate adjusted HRs of cause-specific relative mortality the CPRD database was linked to death certificates for 57% of all patients to assess the primary cause of death.

Results: As compared to 2000 – 2001, the all-cause one-year mortality risk after hip fracture tended to be lower for men in 2008 – 2009 (adj. HR 0.79, 95% Confidence Interval [CI]: 0.63 – 1.00) and was significantly decreased in 2009 – 2010 (adj. HR 0.79, 95% CI: 0.63 – 0.98) and 2010 – 2011 (adj. HR 0.68, 95% CI: 0.54 – 0.86). In contrast, no decrease in mortality risk was observed for women. The decline in men was attributable to patients aged 75 – 84 years and ⩾ 85 years with a decrease in cumulative mortality of respectively 26% (31% in 2000 – 2008, 23% in 2008 – 2011) and 17% (from 46% to 38%). Because of increased survival in the controls, the relative all-cause mortality risk remained stable for men and was slightly increased for women. Finally, the cause-specific relative mortality risk was significantly higher for men as compared to women for respiratory infections, non-infectious respiratory diseases, cardiovascular diseases, malignant neoplasms, and diseases of the musculoskeletal system.

Conclusions: In the United Kingdom, all-cause one-year mortality rates after hip fracture have declined in men but not in women. This may be related to better treatment of postoperative complications such as heart failure and chest infection for which male gender is a risk factor.

MO0330

Obese Older Adults Have a Lower Adjusted Risk of Incident Hip Fracture. Jennifer Lloyd*[1], Dawn Alley[1], William Hawkes[1], Marc Hochberg[2], Shari Waldstein[1], Denise Orwig[1]. [1]University of Maryland, Baltimore, USA, [2]University of Maryland School of Medicine, USA

Higher body mass index has been associated with lower risk of hip fracture, but recent studies have documented a growing prevalence of hip fracture among overweight and obese persons, who make up the majority of the older population. The objective of this study was to determine the risk of hip fracture among overweight and obese older adults in a nationally representative sample of U.S. older adults. Data from 2,790 adults age >= 65 examined in the National Health and Nutrition Examination Survey (NHANES) III from 1991-1994 were linked to Medicare claims data (1991-2007) to assess incident hip fractures [ICD-9 codes (820.*xx*) of first hip fracture from Medicare claims]. Subjects were defined as overweight and obese based on BMI of 25.0 to 25.9 and >=30.0 kg/m^2, respectively. Cox proportional hazard models were used to test whether risk for incident hip fracture differed by body mass index (BMI) categories [measured during NHANES III, kg/m^2], controlling for baseline measures of sociodemographic factors, low bone mineral density (BMD), physical activity, chronic conditions, prior hip fracture, fall frequency, self-reported health status, cognition, bone-related vitamins and medications, performance measures, current smoking status, and alcohol use. Effect modifiers such as age, sex, race, and low BMD [femoral neck DXA at baseline] were also examined. The majority of subjects were either overweight (40%) or obese (23%). Hip fractures occurred in 13% during follow-up. The crude risk of hip fracture for overweight (Hazard Ratio [HR] =0.99, 95% confidence interval [CI]: 0.91, 1.08) and obese (HR=0.93, 95% CI: 0.85, 1.03) older adults were not significantly different than for normal weight older adults. Obese older adults did have an adjusted 15% lower risk of hip fracture (HR=0.85, 95% CI: 0.76, 0.96) compared to normal weight older adults; the adjusted risk in overweight participants did not differ from risk in normal weight older adults (HR=0.94, 95% CI: 0.85, 1.04). The relationship between BMI categories and hip fracture did not differ by age, gender, race, or low BMD (all interaction terms were not-significant). Adjusted study results confirm obesity is protective against risk of hip fracture and that this effect is mediated, in part, by higher BMD. Findings from this study add to the literature with results from a nationally representative, U.S. sample.

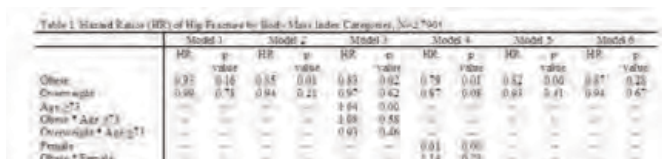

Table 1. Hazard Ratios (HR) of Hip Fracture by Body Mass Index Categories, N=2,790

Outcomes of an Orthopaedic Post Fracture Bone Health Assessment Program. Victoria Elliot-Gibson*[1], Earl Bogoch[1], Dorcas Beaton[2], Robert Josse[3]. [1]St. Michaels Hospital, Canada, [2]Keenan Research Centre, St Michael's Hospital, Canada, [3]St. Michael's Hospital, University of Toronto, Canada

Purpose: To present the outcomes of a coordinator based post fracture osteoporosis (OP) intervention program in an orthopaedic unit. Methods: A university teaching hospital implemented an OP Exemplary Care Program to improve OP recognition and intervention rates in patients with a fragility fracture. A coordinator screens Fracture Clinic outpatients and orthopaedic inpatients: males ⩾ 50 years; females ⩾ 40 years; fracture sites: wrist, shoulder, hip and spine. Patients receive OP education and may be referred for further investigation/treatment. Data were from self-report questionnaires, coordinator chart notes and general chart audits. Results: Data presented are from the period December 1, 2002 to November 30, 2011. There were 2511 patient identified in which 1803/2511 (71%) were not prescription medication for their bone health at baseline and are the focus of this report. There were 497 males, mean age 70.4 (SD 11.9) years, and 1306 females, mean age 70.2 (SD 14.6) years. There were 679 hip, 719 wrist, 368 shoulder and 37 vertebral fractures. Outpatient referrals to a specialist or family doctor for secondary bone health assessment was recommended for 1206/1803 (67%) patients; the orthopaedic surgeon initiated treatment for 44 (2%); and 227 (13%) received an inpatient assessment by a specialist . The overall bone health assessment rate was, 1173/1803 (65%), which represents 79% of those who had an assessment recommended. Bone mineral density (BMD) testing was recommended for 1323/1803 (73%) of patients with an overall BMD testing rate of 1102/1803 (61%) which represents 83% of those who had BMD testing recommended. Of the 1803, 689 (38%) were prescribed a specific anti OP therapy in addition to Vitamin D and calcium; 112 (6%) patients were not prescribed medication due to contraindications; 661 (37%) of patients were recommended adequate vitamin D and calcium as their definitive treatment; 2 (<1%) enrolled in a clinical trial; and 339 (19%) were unavailable/unable to participate in follow up had the recommendation for Vitamin D and calcium at baseline. Conclusions: This program has found that a dedicated coordinator, and an engaged orthopaedic and metabolic bone disease unit has bone health assessment, BMD testing and treatment post fracture that is comparable to other published programs.

MO0332

Subsequent Fracture Risk and Mortality in the Glasgow Fracture Liaison Service: an 8-year Follow-Up Study. Tineke Van Geel*[1], Dana Bliuc[2], Piet Geusens[3], Jacqueline Center[2], Geert-Jan Dinant[1], John Eisman[2], Joop Van Den Bergh[4], Alastair McLellan[5]. [1]Maastricht University, The Netherlands, [2]Garvan Institute of Medical Research, Australia, [3]University Hasselt, Belgium, [4]VieCuri MC Noord-Limburg & Maastricht UMC, The Netherlands, [5]Western Infirmary, United Kingdom

Purpose: The Glasgow Fracture Liaison Services (FLS) is a model of care for fracture assessment. In this study, the risk of re-fractures and mortality over an 8-year follow-up period was evaluated in patients aged 50 years and over who attended the Glasgow FLS.

Method: Between 1999 and 2007, patients with a low trauma fracture were identified by nurse practitioners and invited to attend the FLS. Their treatment recommendations were based on national osteoporosis guidelines. The present study evaluated the risk of re-fracture and mortality risk.

Results: The 9394 patients with a non-vertebral fracture (mean age: 71.9 ± 12.1, 77.8% women) were categorised according to the following FLS outcome groups: A. 5081 (54.1%) were assessed by FLS incl. DXA; B. 497 (5.3%) were assessed by FLS without DXA - review previous treatment; C. 1794 (19.1%) were assessed by FLS without DXA - for calcium and vitamin D; and D. 2022 (21.5%) declined or were not assessed by FLS. The distribution within these groups, particularly into group A, related to their longer expected survival. In group A, 659 (13.0%) patients re-fractured, and 601 (11.8%) patients died. In group B, 49 (9.9%) patients re-fractured and 99 (19.9%) patients died. In group C, 196 (10.9%) patients re-fractured and 773 (43.0%) patients died. In group D, 175 (8.7%) patients re-fractured and 417 (20.6%) patients died.

In all groups, longer survival was associated with higher re-fracture rates. More than half of these occurred within 24 months after the initial fracture. Mortality, as expected, differed by group but also by time. For group A, half of the 12.8% who died did so within 30 months; for group B half of the 19.9% who died did so within 18 months; for group C half of the 43% who died did so within 12 months; and group D half of the 20.6% who died did so within 24 months (Figure 1).

Conclusion: Re-fractures and mortality occur soon after the initial fracture. Over an 8 year follow-up period, more than 50% of the re-fractures occurred within 2 years of follow-up, regardless of the FLS outcome group. However, mortality was substantially less and later in the group who were selected for active assessment and intervention. It remains to be shown to what extent this mortality difference reflects the effect of treatment versus the selection process.

MO0334

"Such terrible bone":weight-bearing orders following hip fracture surgery. Leslie Carlin*[1], Kathryn Sibley[2], Pia Kontos[2], Susan Jaglal[1]. [1]University of Toronto, Canada, [2]Toronto Rehabilitation Institute, Canada

OBJECTIVES: Immediate weight-bearing (IWB) following hip fracture surgery is associated with decreased mortality, fewer complications, improved recovery, and is deemed best practice. However, IWB has yet to be systematically implemented in Canada. In this qualitative study, we explore barriers and facilitators to IWB prescription by orthopedic surgeons. APPROACH: Twenty orthopedic surgeons and 8 physical therapists from across Canada participated in semi-structured interviews conducted by one researcher (LC), by phone or in person. Topics varied for the two populations, but included the role of weight-bearing in decisions about surgical procedure, influences on post-operative weight-bearing orders, implementation of the orders, and attitudes toward evidence-based 'best practice' with respect to weight-bearing. Interviews were professionally transcribed and each read by two or more of the authors. Thematic codes were created using an iterative, phenomenological approach and used as units of analysis. Data analysis informed the development of a survey currently underway, targeting all orthopedic surgeons in Canada who perform hip fracture surgery. RESULTS: While almost all surgeons interviewed agreed that IWB is indeed best practice for hip fracture repair or replacement, they each had a rubric for 'rules to break the rule' that allowed them to avoid or delay weight-bearing for certain patients in order to protect the surgeon's repair. Factors that influenced them included 1) 'weak bones' (osteoporosis); 2) the fracture pattern (comminuted, displaced); 3) expectations of recovery for that patient, considering age and mental status, and 4) surgeons' own experience of having seen a repair fail. 'It taints you,' said one doctor; another described walking 'a fine balance' between IWB and repair failure.' Most surgeons reported having no data on patient outcome by weight-bearing orders for their own institution. Physical therapists, conversely, felt that IWB was always appropriate because 'the weight actually helps with the healing'. They expressed frustration about surgeons' limitations on weight-bearing. CONCLUSIONS: Surgeons fear repair failure and its cost to their patients, whereas the benefits to bone healing and to general patient welfare from immediate weight-bearing are more 'visible' to the physical therapists. Institutional chart audits tracking patient outcome based on their weight-bearing orders may prove helpful.

MO0335

A web repository and browser to search results of Genome-wide association studies (GWAS) for multiple musculoskeletal aging phenotypes. Yi-Hsiang Hsu[1], Chia-Ho Cheng[2], Jason Rightmyer[2], Douglas Kiel[3], Joanne Murabito[4], David Karasik*[5]. [1]Hebrew SeniorLife Institute for Aging Research & Harvard Medical School, USA, [2]IFAR HSL, USA, [3]Hebrew SeniorLife, USA, [4]Boston University, USA, [5]Hebrew SeniorLife; Bar Ilan University, USA

GWAS are successful in identifying loci associated with common disorders. However, to date, investigators are able to access only the top GWAS results that are published, while less significant associations with the millions of single-nucleotide polymorphisms (SNPs) are usually not available. Furthermore, it is not possible to easily interrogate SNPs that may be important for more than a single phenotype. Therefore, we developed a web repository and browser to search GWAS results on musculoskeletal aging phenotypes. This database is called GWAS Resource for Aging-related Traits (''GREAT'').

The resource was developed using open source Web, database and analytical technologies (Linux, PHP, MySQL) and is hosted on secure infrastructure. The system is HIPAA-compliant as it contains only aggregate statistics (mostly from meta-analyses) and hyperlinks to gene and variant annotation resources (e.g. NCBI dbSNP, UCSC genome browser etc.) The GWAS data are transferred from the respective coordinating centers from large consortia to us for uploading. Access to the data requires approval of the Research Steering Committee (RSC) consisting of a 5-person multidisciplinary panel of researchers and technical experts. The RSC reviews the investigator's application and IRB approval. In turn, users can provide feedback on the database to enhance the search function and allocate resources according to the need. Querying is available for multiple traits from several major musculoskeletal phenotypes: e.g. whether a SNP related to a BMD trait is also associated with a trait in another domain, such as lean mass, to identify shared genetic determinants for BMD and lean mass. In addition, GREAT will be incorporating information, such as expression quantitative trait loci and functional annotation for the associated SNP, obtained from a variety of private databases. We plan to add software for multivariate analyses, to provide the user with the opportunity to identify potentially pleiotropic genetic loci.

In conclusion, the ''GREAT'' resource provides a user-friendly interface for searching, filtering, and visualizing the results from GWAS meta-analyses of musculoskeletal aging-related phenotypes. Importantly, the GREAT system is inherently scalable, given sufficient storage and processing capacity. The generation of the GREAT resource has the potential to provide a unique platform for exploring and sharing multiple GWAS results and their functional interpretation.

Association of GC and CYP2R1 Genetic Variants and Serum Vitamin D Concentrations in Chinese Postmenopausal Women. Weibo Xia*[1], Wen Xu[2], Jing Sun[2], Wenbo Wang[3], Xiran Wang[4], Yan Jiang[2], Wei Huang[5], Xin Zheng[6], Qiuping Wang[7], Yu Pei[8], Zhiwei Ning[9], Mei Li[2], Ou Wang[10], Xiaoping Xing[2], Ling Xu[11]. [1]Peking Union Medical College Hospital, Department of Endocrinology, Peoples Republic of China, [2]Department of Endocrinology, Key Laboratory of Endocrinology, Ministry of Health, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, China, [3]Department Endocrinology, Peking University Shougang Hospital, China, [4]Department of Cadre Unit, General Hospital of the second Artillery Force, China, [5]Department of Endocrinology BeiJing Haidian Hospital, China, [6]Department of Endocrinology, China Rehabilitation Research Center, China, [7]Department of Endocrinology, Beijing Liangxiang Hospital, China, [8]Department of Geriatric Endocrinology, Chinese PLA General Hospital, China, [9]Department of Endocrinology, Beijing Chaoyang Hospital, China, [10]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Peoples Republic of China, [11]Department of Gynaecology & Obstetrics, Key Laboratory of Endocrinology, Ministry of Health, Peking Union Medical College Hospital, Chinese Academy of Medical Science, China

Purpose: To determine if GC and CYP2R1 genetic variants have association with serum 25-OHD_3 level, BMD, or bone turnover markers in Chinese postmenopausal women.

Methods: We randomly selected 1494 postmenopausal women of Han ethnic group from 7 communities in Beijing. BMD of L2-4, FN and total hip was determined by DXA; Serum bone turnover markers and 25-OHD_3 were measured by automated Roche electrochemiluminescence system; Genotypes of GC and CYP2R1 were detected by TaqMan allelic discrimination assay. Multiple statistic methods were used to test the associations of SNP genotypes andVitamin D levels.

Results:In our sample 1338 women had vitamin D deficiency and another 146 women had vitamin D insufficiency, accounting for 89.6% and 9.8% of total sample, respectively. The variants of rs222020 (P=0.003) and rs2298849 (P=3.73×10^{-4}) at GC were significantly associated with serum 25-OHD_3 level. Allele C of rs222020 and allele G of rs2298849 might be protective for serum 25-OHD_3 level. Among the haplotypes of rs222020-rs2298849, CG (β=0.138,P=0.001) and TA (β=-0.118,P=0.002) corresponded to increasing and decreasing serum 25-OHD_3 concentrations, respectively. We didn't find significant association between CYP2R1 polymorphisms and serum 25-OHD_3 level. No significant association was found between GC polymorphisms and β-CTX, P1NP or BMD of L2-4, FN, and total hip. CYP2R1 polymorphisms had similar results except its significant association with β-CTX and P1NP.

Conclusions: We found that GC variants had significant association with serum 25-OHD_3 level among postmenopausal women of Han ethnic group in Beijing while CYP2R1 variants weren't found significant. Association of CYP2R1 genetic variants with β-CTX and P1NP needed to be proven.

Keywords: GC, CYP2R1, 25-OHD_3, bone turnover markers

Gene by genome-wide interactions on femoral neck BMD in MrOS and SOF: a synergistic effect of polymorphisms in the alkaline phosphatase (*ALPL*) and lecithin retinol acyltransferase (*LRAT*) genes. Carrie Nielson*[1], Priya Srikanth[1], Joseph Zmuda[2], Jian Shen[1], Robert Klein[3], Eric Orwoll[1]. [1]Oregon Health & Science University, USA, [2]University of Pittsburgh Graduate School of Public Health, USA, [3]Portland VA Medical Center, USA

Gene-by-gene interactions are expected to account for some of the unexplained variability in bone mineral density in humans. We analyzed interactions between single nucleotide polymorphisms (SNPs) in a gene known to affect mineralization, *ALPL*, with SNPs in the rest of the genome in two cohorts of older adults.

Methods: 4,704 non-Hispanic white men in the Osteoporotic Fractures in Men (MrOS) cohort and 3,625 women in the Study of Osteoporotic Fractures (SOF) cohort (ages ⩾65) had femoral neck BMD measured by DXA and genome-wide genotyping data from the Illumina Human Omni1-Quad, for 699,502 SNP genotypes with minor allele frequency ⩾5%. 38 SNPs in the *ALPL* gene were tested for epistatic interactions with all remaining SNPs in the genome-wide dataset, for a total of ~25 million tests. Meta-analysis of interaction terms was performed on models adjusted for age, BMI, and principal components for population stratification. SNP combinations that resulted in fewer than 30 participants in any cell of the cross-tabulation of genotypes were excluded. R^2 were calculated for linear regression models containing each SNP alone and compared to the R^2 for models containing both SNPs and their interaction term.

Results: In MrOS, the mean BMD was 0.84 g/cm^2 (SD = 0.13), and in SOF, mean BMD was 0.73 (SD = 0.11). We observed an interaction between a SNP in *ALPL* (rs12145027) and a SNP in *LRAT* (rs201821), a gene involved in retinoic acid metabolism (meta-p for interaction = 1.08×10^{-8}). For those participants who were

homozygote wild type or heterozygous at the *ALPL* SNP there was little effect of *LRAT* genotype on BMD. However, for those who were homozygous for the *ALPL* SNP minor allele, the additive effect of the *LRAT* SNP minor allele was -0.03 g/cm^2 (meta-p = 0.004). Neither SNP had a main additive effect on BMD (meta-p $\geq$ 0.13), and R^2 for each SNP separately was $\leq$ 0.07%. However, the R^2 for the interaction between the two SNPs was 0.32% in MrOS and 0.48% in SOF.

Discussion: An interaction between a SNP in the *ALPL* first intronic region and an intronic SNP in the *LRAT* gene resulted in a synergistic effect on BMD in two cohorts of older men and women. The interaction is plausible due to the presence of a retinoic acid response element in the promoter region of *ALPL*, which may be marked by the SNP. Retinoic acid effects on *ALPL* expression or function may be a source of heritable BMD variation in older adults.

Genome-Wide Association Study Meta-Analysis Identifies the *SOAT1/AXDND1 Locus* To Be Associated With Hip and Forearm Fracture Risk. Ulrika Pettersson-Kymmer*[1], Samuel Handelman[2], Joel Eriksson[3], Ulrica Bergstrom[4], Beatrice Melin[5], Carl Wibom[5], Liesbeth Vandenput[7], Preetha Rajaraman[8], Patricia Hartge[9], Stephen Chanock[9], Goran Hallmans[11], Andrea Lacroix[12], David Duggan[13], Charles Kopperberg[14], Aaron Aragaki[14], Maria Nethander[15], Andre Uitterlinden[16], Fernando Rivadeneira[17], Rebecca Jackson[18], Claes Ohlsson[19]. [1]Clinical Pharmacology, Sweden, [2]Mathematical Biosciences Institute, The Ohio State University, USA, [3]Centre for Bone & Arthritis Research, Sweden, [4]Umea University Hospital, Sweden, [5]Radiation Sciences, Oncology Umeå University, Sweden, [7]University of Gothenburg, Sweden, [8]Center for Global Health, US National Cancer Institute, USA, [9]Division of Cancer Epidemiology & Genetics, National Cancer Institute, NCI, USA, [11]Public Health & Clinical Medicine, Umea University, Sweden, [12]Fred Hutchinson Cancer Research Center, USA, [13]Translational Genomics Research Institute, USA, [14]Public Health Sciences, Fred Hutchinson Cancer Research Center, USA, [15]Bioinformatics Core Facility, Sahlgrenska Academy, University of Gothenburg, Sweden, [16]Rm Ee 575, Genetic Laboratory, The Netherlands, [17]Erasmus University Medical Center, The Netherlands, [18]The Ohio State University, USA, [19]Center for Bone & Arthritis Research at the Sahlgrenska Academy, Sweden

Hip- and forearm fractures are the two most clinically important non-vertebral fractures. Twin studies have demonstrated a high heritability of these fractures and this heritable component is largely independent of bone mineral density (BMD).

To identify common genetic variants associated with hip and forearm fractures, we performed a genome-wide association study (GWAS ~ 2.5 million SNPs) meta-analysis of two large fracture data sets within the well-characterized Umeå Fracture and Osteoporosis (UFO) cohort (UFO-forearm; 1,060 forearm fractures and 1,055 controls, and UFO-hip; 1,014 hip fractures and 862 controls). All fractures were confirmed through radiographic reports. Replication was performed in the Women's Health Initiative (WHI) cohort (1,845 hip fractures verified by blinded review of medical records and 2,120 controls).

We identified one single nucleotide polymorphism (SNP), within the *SOAT1/AXDND1 locus* (1q25.2) that was associated with fracture risk at genome wide significance (OR per G allele = 1.33; P = 3.1 x 10^{-8}) in the UFO discovery meta-analysis. This SNP was associated with fracture risk both in the WHI replication cohort (OR 1.16, P = 2.2 x 10^{-3}) and in the combined analyses comprising 7,956 subjects (3,919 cases and 4,037 controls; OR = 1.24, P = 4.8 x 10^{-10}). It was significantly associated with fracture risk in both genders and with a similar magnitude at both hip and forearm.

The *SOAT1/AXDND1 locus* has been implicated in cholesterol metabolism and cognition but this loci and the identified SNP has not been reported to be associated with BMD in previous GWAS. To further explore whether the association of the SNP in the *SOAT1/AXDND1 locus* is independent of BMD, we generated a genetic risk score (GS) which includes 63 SNPs previously identified to be reproducibly associated with BMD. Although this GS, was significantly associated with both hip (p=7.9 x 10^{-4}) and forearm (p=8.6 x 10^{-5}) fractures, models including both the SNP in the *SOAT1/AXDND1 locus* and the GS demonstrated that the impact of the SNP in the *SOAT1/AXDND1 locus* on fracture risk was independent of the BMD-associated GS.

In summary, we have identified a non-BMD associated genetic variant in the *SOAT1/AXDND1 locus* associated with hip and forearm fractures.

MO0339

Reduced Serum Osteocalcin Concentrations Are Associated with Type 2 Diabetes Mellitus and the Metabolic Syndrome Components in Postmenopausal Women: The Crosstalk between Bone and Energy Metabolism. Rajib Bhattacharya*[1], Kamyar Asadipooya[2], Iraj Nabipour[3], Ali Movahed[3], Bagher Larijani[4], Mohammadreza Kalantarhormozi[3], Katayoun Vahdat[3], Samad Akbarzadeh[3], Maryam Farrokhnia[3], Majid Assadi[3], Roya Amirinejad[3], Afshar Bargahi[3], Zahra Sanjdideh[3]. [1]KU Medical Center, USA, [2]University of Kansas Medical Center, USA, [3]Bushehr University of Medical sciences, Iran, [4]Tehran University of Medical Sciences, Iran

Introduction: Although it has been shown that osteocalcin functions as a regulatory hormone in glucose metabolism and fat mass, few population-based study to date has addressed serum osteocalcin levels in relation to energy metabolism concurrent with bone metabolism in postmenopausal women.

Materials and Methods: This study measured cardiovascular risk factors, high-sensitivity C-reactive protein (hs-CRP), osteoprotegerin, receptor activator of nuclear factor-jB ligand, osteocalcin, CrossLaps, alkaline phosphatase, and bone mineral density (BMD) at the lumbar spine (L2–L4) and the proximal femur were measured in 382 Iranian postmenopausal women.

Results: In multiple logistic regression analysis, lower osteocalcin (lower than median) and CrossLaps (less than 0.242 ng/ml) levels were associated with a higher odds ratio (OR) of having type 2 diabetes mellitus when adjustments were made for age, hs-CRP, cardiovascular risk factors, BMD, and markers of bone metabolism [OR 5.17, CI (2.66–10.04), p\0.0001 and OR 2.51, CI (1.37–4.61), p = 0.003, respectively]. However, lower alkaline phosphatase levels were associated with a lower OR of having type 2 diabetes mellitus [OR 0.28, CI (0.15–0.52), p<0.0001] in regression analysis. No significant difference was found between serum osteocalcin levels of those with and without metabolic syndrome. Among the metabolic syndrome components, low osteocalcin levels had significant associations with elevated blood glucose [OR 1.89, CI (1.16–3.07), p = 0.010] and elevated waist circumference [OR 2.53, CI (1.13–5.67), p = 0.024] in multivariate analyses.

Conclusion: Serum osteocalcin was independently associated with glucose intolerance and increased waist circumference and type 2 diabetes mellitus in postmenopausal women. Since CrossLaps andalkaline phosphatase levels were independently associated with the presence of type 2 diabetes mellitus, the uniquecontribution of osteocalcin in glucose metabolism could not be concluded.

MO0340

High cardiorespiratory fitness is associated with reduced risk of osteopenia and osteoporosis in women: Cooper Center Longitudinal Study. Chwan-Li Shen*[1], Laura Defina[2], David Leonard[3], Benjamin Willis[2], Carolyn Barlow[2], Marjorie Jenkins[1], Barbara Pence[1], Yan Zhang[1], Ming-Chien Chyu[4], E. Michael Lewiecki[5]. [1]Texas Tech University Health Sciences Center, USA, [2]The Cooper Institute, USA, [3]UT Southwestern Medical Center, USA, [4]Texas Tech Univeristy, USA, [5]University of New Mexico School of Medicine, USA

Current common belief is that all types of physical activity are beneficial to bone health of women, including reducing risk for bone loss. However, there is no conclusive scientific evidence demonstrating that women with higher cardiorespiratory fitness (CRF) levels have lower risk for bone loss. This study was to determine the association between the CRF level and risk for osteopenia or osteoporosis in women (age $\geq$ 40 years) using existing Cooper Center Longitudinal Study data. A cohort of 3353 predominately healthy Caucasian women (50.8 $\pm$ 7.9 years) who underwent a preventive medical examinations that included CRF by maximal Balke treadmill exercise testing and femoral neck bone mineral density (FN-BMD) by DXA. CRF was defined as a continuous variable expressed as total time achieved on a treadmill in minutes and also categorized into quintiles of CRF (1-5 with 1 being low fit). Logistic regression was used to characterize the association between CRF and osteopenia or osteoporosis adjusting for age, weight, physical activity level, resistance activity level (defined by number of days/week), menopausal status, and smoking status. Overall the mean BMI for all subjects was 24.5 $\pm$ 4.5 kg/m^2. However, in the moderate fit group, the average BMI was in the overweight range and in the low fit group, in the obese range. The prevalence of osteopenia and osteoporosis was greatest in the low fit group at 33.7% and 3.4%, respectively. Fully adjusted logistic regression models showed an inverse association between CRF and osteopenia (moderate, OR 0.45, 95% CI 0.31-0.65); high, OR 0.31, 95% CI 0.21,0.46). A similar relationship was seen with osteoporosis (moderate, OR 0.25, 95% CI 0.09-0.70; high, OR 0.25 95% CI 0.10-0.65). As expected, in both osteopenia and osteoporosis, age and weight had the expected relationship. Menopause had a inverse relationship with osteopenia (OR 1.52 95% CI 1.23-1.88). Furthermore, resistance activities did not show a significant relationship with osteopenia (OR 0.95, 95% CI 0.80-1.13) or osteoporosis (OR 0.74, 95% CI 0.39-1.39). In summary, CRF levels are inversely associated with the reduce risk for osteopenia and osteoporosis for women aged 40 years and older. Although prior research suggests that strength training is of great importance in the prevention of osteoporosis, in this cohort the association of resistance activity with the outcomes was attenuated in the fully adjusted model. Further prospective studies are warranted.

MO0341

Impact of Lifestyle Factors on Fracture Risk in Older Patients with Cardiovascular Disease and Diabetes: A Prospective Cohort Study of 26,335 Individuals from 40 Countries. Alexandra Papaioannou*[1], Alexandra Papaioannou[2], Salim Yusuf[3], Joshua Barzilay[4], Peggy Gao[5], Philip Joseph[3], Koon Teo[3], Andrew Mente[3]. [1]Hamilton Health Sciences, Canada, [2]Department of Clinical Epidemiology & Biostatistics, McMaster University, Canada, [3]Population Health Research Institute, McMaster University & Hamilton Health Sciences, Canada, [4]Kaiser Permanente of Georgia & Emory University School of Medicine, USA, [5]Population Health Research Institute, Canada

Introduction: Fractures are a major health concern among the elderly and are associated with morbidity and mortality. The impact of common modifiable lifestyle risk factors on incident fracture risk has not been evaluated in patients with cardiovascular disease and diabetes.

Objectives: The aim of this study is to assess the individual and combined effect of the common modifiable risk factors (smoking, alcohol consumption, and physical activity) on fracture risk in a large sample of older (≥ 55 years) individuals with cardiovascular disease or diabetes with end organ damage.

Methods: Observational analyses of 26,335 women and men (mean age of 66.5 years) without any previous fracture and enrolled in two randomized trials (ONTARGET and TRANSCEND). Lifestyle factors were assessed by questionnaire. The effect of lifestyle factors (current smoking, alcohol intake of >3 in men and >2 in women), and less than 5 days of physical activity) was assessed individually and in combination, on incident fracture risk using logistic regression analyses adjusting for age, sex, trial enrolment, region, and other known potential risk factors for fractures. The predictive model was internally validated by bootstrapping.

Results: During the 56 month follow up, 1,079 incident fractures occurred; 508 (6.51%) occurred among women and 571 (3.08%) occurred among men. Smoking (relative risk [RR]: 1.46, 95% confidence interval [CI]: 1.22-1.76) and low physical activity (RR: 1.17, 95%CI: 1.03-1.33) were associated with an increased risk of any fracture, while high alcohol intake showed a directional but nonsignificant relationship with fracture risk (RR: 1.12; 95%CI: 0.65-1.92). Compared to participants with no lifestyle risk factors, those having two or three risk factors had an increased risk of a future fracture (RR: 1.64, 95%CI: 1.31-2.07 for two risk factors; and RR: 2.30; 95%CI: 0.83-6.40 for three risk factors; p for trend<0.001). The pattern of effects was similar for osteoporotic fractures (RR: 1.76, 95%CI: 1.34-2.31 for two risk factors; and RR: 2.68; 95%CI: 0.83-8.69 for three risk factors; p for trend<0.001). An estimated 10.2 (95% CI: 2.9-18.2) events could be prevented for every 100 fractures occurring in the population if every person followed a healthy lifestyle.

Conclusions: A healthier lifestyle advocated reducing the risk of cardiovascular disease and diabetes could be associated with a significant and graded reduction in fracture risk.

MO0342

Measuring Compliance with Oral Bisphosphonates: Potential Impact of Days Supply Errors in Pharmacy Data. Andrea Burden*[1], J. Micheal Paterson[2], Andrea Gruneir[3], Suzanne Cadarette[1]. [1]University of Toronto, Canada, [2]Institute for Clinical Evaluative Sciences, Canada, [3]Women's College Research Insititute, Canada

Background: Days supply (DS) values are commonly used to identify drug utilization, estimate drug exposure and quantify adherence to therapy. We recently identified potential reporting errors in DS values for weekly, monthly, and cyclical osteoporosis medications, particularly in long-term care (LTC).

Objectives: To examine the potential impact of DS reporting errors on measurement of compliance with oral bisphosphonate therapy.

Methods: We identified all oral bisphosphonate prescriptions for osteoporosis dispensed through the Ontario public drug plan for seniors (66+ years) from April 2000 to March 2011. DS values were examined by dosing regimen, and illogical values for weekly, monthly and cyclical regimens (e.g., 1 DS for weekly regimens) were flagged for data cleaning. DS values were cleaned using dose specific algorithms (e.g., 7 DS value was imputed if 1 DS value was observed for a weekly regimen). Compliance with therapy was estimated using the proportion of days covered (PDC), calculated as the total DS in 1-year divided by 365 days. Mean PDC and proportion with high compliance (PDC ⩾80%) were compared using the observed and cleaned DS values. Results were examined separately for patients residing in LTC and community.

Results: A total of 356,134 eligible new users were identified, 25% in LTC. Among LTC users, mean PDC increased from 60% to 77% following data cleaning, and the proportion identified with high compliance (PDC⩾80%) increased from 48% to 79%. Fewer DS errors were noted in the community setting; mean PDC increased from 79% to 81%, and high compliance increased from 60% to 65% after data cleaning.

Conclusions: Results suggest that compliance with oral bisphosphonate therapy is underestimated in LTC. With 25% of oral bisphosphonates dispensed in LTC, careful attention to potential exposure misclassification is important. For example, differential exposure misclassification would exaggerate the association between better compliance and drug effectiveness since oral bisphosphonate exposure is underestimated in LTC patients, who are also more likely to experience a hip fracture than community-dwelling patients. Similarly, the safety of oral bisphosphonate exposure (e.g., esophageal cancer) may be underestimated if more common among LTC patients. Better understanding of potential errors in the DS field in pharmacy claims data is needed to inform pharmacoepidemiologic analyses of the safety and effectiveness of oral bisphosphonates.

MO0343

Undertreatment with Anti-osteoporosis Medications among Women Diagnosed with Osteoporosis in the United States Medicare Population. Ethel Siris[1], Ankita Modi[2], Jingbo Yu*[2], Renee Arnold[3], Katalin Bognar[4]. [1]Columbia University College of Physicians & Surgeons, USA, [2]Merck & Co., Inc., USA, [3]IMS Health, USA, [4]Precision Health Economics, USA

Objective: To describe characteristics and treatment initiation among women diagnosed with osteoporosis (OP) in the Medicare population

Material and Methods: A retrospective cohort study using the 20% Medicare claims data from the Centers for Medicare and Medicaid Services (CMS) from January 1, 2006 to December 31, 2009 (study period) was conducted. Women 66 years of age or older, who had a first diagnosis of OP (Index date) found in outpatient or inpatient claims during 2007 to 2008, who were continuously enrolled in Medicare parts A, B and D for at least one year pre-index (baseline) and one year post-index date (follow-up), and who were naïve to OP medication in the baseline period, were included. Those who had a claim of Paget's disease or estrogen use during the baseline period, or a diagnosis of malignant neoplasm during the baseline or follow-up periods, were excluded. OP medications were identified based on NDC and HCPCS codes and included pharmacological treatment such as: alendronate, ibandronate, risedronate, calcitonin, raloxifene, zoledronic acid, and teriparatide. Subjects were characterized as 'treated' if they received at least one OP medication within the follow-up period. The proportion of individuals receiving OP medication was determined in this population. Patient characteristics such as age, Charlson comorbidity index, OP fracture history, gastrointestinal problem history, renal disease history, glucocorticoid use, estrogen use and NSAID use in the baseline period were assessed for all patients.

Results: Among 126,188 patients meeting study criteria with a mean [SD] age of 78.5 [7.9] years, 72.1% of patients did not receive any pharmacological treatment within the one-year following OP diagnosis. 21.6% of patients initiated treatment with bisphosphonates and 6.3% initiated a form of treatment other than bisphosphonates. The mean [SD] time to any OP treatment initiation was 75.4 [88.9] days from the Index date. Approximately 12.1% of the patients had a history of OP fractures and 41.6% of women had a history of gastrointestinal problems during the baseline period.Conclusion: This analysis showed that a large proportion of elderly women with osteoporosis did not receive any pharmacological treatment after their diagnosis, suggesting a need for further understanding of the reasons for non-treatment despite diagnosis.

MO0344

Differences In Osteocalcin Between Osteoporosis Patients In An Ambulatory Clinic Without Fracture And Hospitalized Trauma Patients With Fractures. Matthew Hnatow*[1], Catherine Ambrose[2], Milan Sen[2], Nahid Rianon[3]. [1]Univeristy of Texas Health Science Center at Houston - Medical School, USA, [2]University of Texas Health Science Center at Houston, USA, [3]UTHealth The University of Texas Medical School at Houston, USA

Fractures are devastating consequences of osteoporosis. Despite known risk factors, the ability to predict a fracture remains elusive and is a public health concern. Osteocalcin (OC), a bone turnover marker, has been correlated with bone mineral density and other secondary risk factors of fracture. Whether or not OC can predict fracture in patients with osteoporosis is unknown. We compared serum OC between ambulatory patients visiting our osteoporosis clinic and hospitalized patients temporarily bed-bound with an acute fracture from low-impact trauma to identify a possible predictor of fracture.

The ambulatory group consisted of 27 patients diagnosed with osteoporosis who were seen in an outpatient geriatric-osteoporosis clinic between September 2011 and November 2012. The hospitalized group consisted of 37 trauma patients admitted with fracture and were treated under an ''Own the Bone'' protocol implemented by the orthopaedic trauma team to reduce post-fracture morbidity and mortality between June and December 2011. Serum OC was obtained as part of osteoporosis work up. An independent sample t-test was used to compare OC between the two groups. Multivariate regression adjusted for age, height, weight, sex, race, serum calcium, magnesium, phosphate, parathyroid hormone, 25-hydroxy vitamin D, glomerular filtration rate and bisphosphonate (BP) use (usage defined as current or past usage and no usage) confirmed an association between low osteocalcin level and positive fracture status.

The mean (SD) age were 82.7 (7.6) years (86% women) for the ambulatory and 77.6 (13.2) years (71% women) for the trauma group. The most frequent fractures in the trauma group were proximal femur (41%) and distal femur (16%). Ambulatory patients reported no fractures; 3 reported current and 21 reported previous BP use. In the trauma group, 6 reported current and 4 reported past BP use. There was

significant difference in serum OC levels between the groups ($p<0.01$) with mean (SD) 25.8 (19.8) ng/mL for the ambulatory and 16.1 (9.8) ng/mL for the trauma patients. Low OC was associated with positive fracture state (regression coefficient -11.06, 95% CI -20.76 to -1.35). In stratified models, t-test remained significant only for those who used BP. Small sample size limited further multivariate regression with stratified model by BP use.

Lower serum OC in fracture patients indicates the need to continue investigation to see if osteocalcin can be used as a predictor of fracture.

MO0345

Does a Hip Axis Length Assessment Alter the T-score Based Treatment Strategy. Cesar Graf[1], Walter Rial[1], Marcelo Obai[1], Pedro Rial[1], Cesar Wouterlood[1], Cecilia Sprengel[1], Giorgina Cavello[1], Tom Sanchez*[2]. [1]ITEO SRL, Argentina, [2]Norland - A Cooper Surgical Company, USA

Hip Axis Length (HAL) has been proposed as a significant parameter in fracture risk with Faulkner and associates (J Bone Mineral Res. 9:1065, 1994) noting that a HAL of 11.5cm is associated with a 4X greater hip fracture risk than a HAL of 10.5cm. We examined how consideration of HAL in a population might change the clinical recommendation of a DXA study based on a T-score only.

The study included 1,620 women between 21 and 79 years of age with HAL assessments grouped into three risk defined groups based on the Faulkner and associates report—HAL <10.75cm associated with a low risk, a HAL between 11.0 and 11.749cm associated with a moderate risk , and a HAL >11.749cm associated with a high risk. A WHO based Femur Neck T-score grade of Normal, Osteopenic or Osteoporotic was also assessed for each subject. The study then determined how many subjects saw a shift to increase treatment strategy from the T-score based treatment strategy as a result of HAL risk estimate.

The table below details the number of subjects in each HAL risk level and the number of subjects that based on T-score would have entered a particular treatment strategy. Based on these numbers, 559 (34.5%) of the subjects would not see a HAL-based change from T-score based treatment strategy while 98 (6.0%) subjects would see their T-score based strategy elevated to a more aggressive treatment strategy and 115 (7.1%) subjects would see their T-score based strategy elevated to a preventive treatment strategy. Agreement between the HAL based classification and the T-score based classification was poor with a Kappa value of 0.0247. T-score

HAL Normal Osteopenic Osteoporotic

<10.75cm 238 502 213

11-11.749cm 115 275 133>11.749cm 27 71 46

HAL based risk assessment has poor agreement with Femur Neck T-score value based assessment and, to the extent that HAL can be considered a significant factor in hip fracture, the present survey suggests that a HAL assessment should be included when developing a treatment strategy for the patient.

MO0346

Effect of Walking Difficulty on Bone Mass and Bone Turnover in Japanese People Aged 40 Years and Over. Yasuyo Abe*, Kiyoshi Aoyagi, Kazuhiko Arima. Nagasaki University, Japan

Low bone mass and accelerated bone turnover contribute to osteoporotic fractures. However, the effect of walking difficulty on bone mass or bone turnover has not well been studied.

We studied 1097 community-dwelling Japanese people aged 40 years and over (379 men and 718 women) to examine the association of walking difficulty, which is defined as having difficulty walking 100-meter on a level surface, with calcaneal stiffness index (bone mass) measured by quantitative ultrasound, and with urinary N-terminal cross-linking telopeptide of type-I collagen (NTx) devided by creatinine (Cre), a marker of bone resorption.

Stiffness index significantly decreased with age in both sexes (p for trend<0.001), and the decline was steeper in women than in men. Urinary NTx/Cre did not differ among age groups in men (p for trend=0.25), but significantly increased in women 50 years and above (p for trend<0.001).

The prevalence of walking difficulty was significantly higher in women than in men (7.4% vs. 3.4%, p=0.011), and significantly increased with age in men (p for trend=0.02) and women (p for trend<0.001).

In univariate analysis, men and women with walking difficulty were older ($p<0.001$) and had lower stiffness index ($p<0.001$) compared to those without walking difficulty. Among women, individuals with walking difficulty had significantly higher urinary NTx/Cre than those without walking difficulty ($p<0.001$), but not among men (p=0.41).

Multiple regression analysis adjusting for age and BMI showed significant association between walking difficulty and lower stiffness index in men ($\beta=-14.2$, p=0.002) and women ($\beta=-4.5$, p=0.007). In women, walking difficulty was significantly associated with higher NTx/Cre ($\beta=12.6$, p=0.001), but not in men ($\beta=6.5$, p=0.17).

In conclusion, walking difficulty may contribute to low bone mass in both sexes, but might affect bone turnover only in women.

MO0347

Effects of Escitalopram on Biochemical Markers of Bone Turnover: A Randomized Controlled Trial. Susan Diem*[1], Hadine Joffe[2], Joseph Larson[3], Katherine Guthrie[3], Joy Tsai[2], Andrea Lacroix[3], Kristine Ensrud[4], Benjamin Leder[5]. [1]University of Minnesota, USA, [2]Massachusetts General Hospital, USA, [3]Fred Hutcinson Cancer Research Center, USA, [4]Minneapolis VA Medical Center / University of Minnesota, USA, [5]Massachusetts General Hospital Harvard Medical School, USA

Some, but not all, observational studies have reported that use of selective serotonin reuptake inhibitors (SSRIs) is associated with higher rates of bone loss and increased fracture risk. To date, findings are limited to observational studies, which are limited by the potential for residual confounding.

To determine the effect of SSRIs on markers of bone metabolism, we measured serum carboxy-terminal collagen crosslinks (CTX) and serum amino-terminal propeptide of type I collagen (P1NP) in healthy peri- and post-menopausal women enrolled in a placebo-controlled randomized controlled trial (RCT) of the SSRI escitalopram (10-20 mg/day) for the treatment of vasomotor symptoms (VMS).

141 peri- or post-menopausal non-depressed women (mean age 53.7 $\pm$ 4.1) enrolled in the RCT with baseline and 8 week follow-up serum specimens were included in the study. 69 women were assigned to escitalopram, 72 to placebo. The between-group differences in the change in sCTX and P1NP from baseline to Week 8 were compared by a repeated measures linear model after adjustment for race, clinical center, and baseline measurement.

Treatment groups were balanced across baseline characteristics, including age, race, BMI, smoking status, and levels of 25-OHD and TSH.

There were no between-group differences in mean change in serum CTX (p=0.24) or serum P1NP (p=0.65) over the 8-week treatment period. Results were similar when the analysis was restricted to those women whose adherence to study medication was $\geqslant$ 70% (N=127).

In this randomized, placebo-controlled 8-week trial of escitalopram in healthy peri- and post-menopausal women with VMS, there was no evidence of an effect on biochemical markers of bone formation or resorption. These results demonstrate that escitalopram has no short-term effect on markers of bone metabolism and, if confirmed in trials evaluating other SSRIs, would suggest that reported adverse effects of these medications on skeletal health may be largely due to confounding influences.

	Escitalopram		Placebo		Difference	
Bone Turnover Marker	N	Mean (95% CI)	N	Mean (95% CI)	Mean (95% CI)	P value
CTX						0.24

Factors Associated with Osteoporosis Treatment Following Fragility Fracture. Cynthia O'Malley*[1], Akhila Balasubramanian[1], Douglas Dirschl[2], Pei-Ran Ho[1], Joseph Lane[3], Laura Tosi[4]. [1]Amgen Inc., USA, [2]University of Chicago Medicine & Biological Sciences, USA, [3]Hospital for Special Surgery, USA, [4]Children's National Medical Center, USA

Introduction: Despite guidelines for post-fracture osteoporosis (OP) care, treatment rates after a fragility fracture remain low. To explore why most subjects were not treated, we assessed patient and clinical characteristics associated with OP treatment initiation post-fracture.

Methods: Using 2000-2010 data from a large US commercially-insured population, community-dwelling individuals aged $\geqslant$50 years with a newly diagnosed fragility fracture and no evidence of OP treatment or fragility fracture in 12 months pre-fracture baseline were identified. Baseline demographics, health services utilization and clinical characteristics were evaluated as predictors of OP treatment in the 12 months post-fracture. Multivariable logistic regression was used to derive odds ratios (OR) and 95% confidence intervals (CI) to assess the association of risk factors with treatment initiation.

Results: Only 18.6% of the 88,571 women and 9.6% of the 41,984 men initiated treatment post-fracture; rates of treatment declined significantly over the study period (Table1). Subjects with hip or spine fractures were 1.8 and 3.8 times more likely to be treated, respectively, than those with wrist fractures. Compared to women, men were less than half as likely to be treated (OR=0.40, CI 0.38-0.41).The odds of treatment increased with age and with increasing number of other medications. Liver disease, rheumatoid disease, steroid use $\geqslant$90 days and hyperthyroidism were associated with increased treatment likelihood as was having a dual-energy x-ray absorptiometry (DXA) test pre-fracture. Diabetes, renal failure and paralysis were associated with decreased odds of treatment.

Conclusion: While those with certain high risk factors for fracture such as older age, rheumatic disease and steroid use were more likely to receive treatment, most

subjects did not receive treatment despite being at high risk for repeat fracture. Moreover, treatment rates decreased significantly over time. Disparities by gender and fracture site were glaring. DXA prior to fracture was a strong predictor of treatment initiation after fracture, suggesting that a fracture in the setting of an on-going OP evaluation may be more likely to trigger treatment. Our results highlight the need for greater recognition of secondary fracture risk and for quality improvements in post-fracture treatment, particularly since treatment rates declined significantly over the last decade.

FRAX Calculator and Garvan Nomogram in Male Osteoporotic Population.
Wojciech Pluskiewicz*[1], Piotr Adamczyk[2], Edward Franek[3], Ewa Sewerynek[4], Piotr Leszczynski[5], Hanna Wichrowska[3], Luiza Napiórkowska[3], Michał Stuss[4], Aleksandra Ptaszek[4], Tomasz Kostyk[6], Krzysztof Golba[7], Wioleta Garbacz[8], Bogna Drozdzowska[9]. [1]Medical University of Silesia, Katowice, Poland, [2]Dept. & Clinic of Paediatrics, Medical University of Silesia, Katowice, Poland, [3]Dept. of Endocrinology, Medical Res. Centre, Polish Academy of Science, Warsaw, Poland, [4]Dept. of Endocrine Disorders & Bone Metabolism, Medical University, Lodz, Poland, [5]Dept. of Physiotherapy, Rheumatology & Rehabilitation, Medical University, Poznan, Poland, [6]Dept. of Rheumatology & Osteoporosis, Hospital J. Strusia, Poznan, Poland, [7]Dept. of Cardiology, Medical University of Silesia, Katowice, Poland, [8]Military hospital, Gliwice, Poland, [9]Dept. of Pathomorphology, Medical University of Silesia, Katowice, Poland

Purpose. The aim of the study was the analysis of osteoporotic fracture prediction in men.

Methods. Eight hundred and one (801) patients of four outpatient osteoporotic clinics were examined. The mean age was of 70.8 ± 9.31 years. A ten-year fracture prediction period was established, using the FRAX calculator and Garvan nomogram.

Results. The mean value for any and hip fracture probabilities, calculated by the FRAX method, were 7.26 ± 5.4% and 3.68 ± 4.25%, respectively and 26.44 ± 23.83% and 12.02 ± 18.1%, respectively in Garvan nomogram. Assuming the threshold of 20% (any fracture) and 3% (hip fracture), the mean conformity between both methods for any and hip fracture prediction was 55.8% and 79.65%, respectively. A ROC analysis showed the following areas under the ROC curves (AUC) for any fractures: FRAX 0.808 and Garvan nomogram 0.843 (p=0.059). The AUC values for hip fractures were 0.748 and 0.749 for Garvan nomogram and FRAX, respectively, thus showing no differences.

On the basis of the ROC data, cut-off values were established for fracture prediction by both methods, giving 20.2% for any fracture by the Garvan method and 7.6% by FRAX, while for hip fracture, the respective results were 4.9% and 3.8%. The conformity between the two methods was 72.5% for any and 77.7% for hip fractures, taking into account the thresholds from ROC analysis.

Conclusion. The conformities between FRAX and Garvan methods with regards to hip fracture prediction were acceptable for the threshold of 3% and the thresholds, derived by ROC analysis, while for any fracture, it is recommended to use the thresholds from ROC analysis. This may suggestive of some misleading character of the 'universal' cut-off points. It is necessary to establish a cut-off point, according to the results of the sensitivity-specificity analysis, separately for each method and each population.

MO0350

Incidence and characteristics of atypical femoral fractures.
Zeineb Mahjoub*[1], Sonia Jean[2], Jean-Thomas Leclerc[3], Jacques P. Brown[4], Dominic Boulet[3], Stephane Pelet[3], Charlotte Grondin[1], Jeannette Dumont[5], Etienne Belzile[1], Laetitia Michou[3]. [1]CHU de Québec, Canada, [2]INSTITUT NATIONAL DE SANTÉ PUBLIQUE DU QUÉBEC, Canada, [3]Université Laval, Canada, [4]CHU de Québec Research Centre, Canada, [5]Centre de recherche du CHU de Québec, Canada

Introduction: Many publications have reported the emergence of atypical subtrochanteric or shaft femoral fractures (AFF). Such fractures are characterised by a unique fracture line, generally affecting the proximal third of the femur, a medial bone spike and a localised periosteal reaction of the lateral cortex. The objective of this study was to estimate the incidence of AFF on a 18 month period in Quebec City, and to collect all clinical characteristics likely to constitute an AFF risk factor.

Methods: We reviewed medical records of patients hospitalised for hip or femoral fracture, in Quebec City between June 1st, 2009 and December 31st, 2010. We selected AFF according to the ASBMR task force criteria, and calculated their incidence. We collected all data likely to influence an AFF occurrence, from medical, pharmacological records, proximal femur measurements on X-rays and patient interviews. For each variable, data analysis consisted of comparing patients with an AFF during the last five years (including the observation period for the incidence estimation), with two controls with hip or femoral osteoporotic fracture or traumatic fracture, paired for age and gender.

Results: We identified 36 atypical fractures during the observation period, corresponding to an AFF incidence of 0.034 [0.024-0.047] case per 1000 persons-years. We collected 56 AFF in the last five years, including the observation period, and we found a significant association with the use of bisphosphonates: p = 0.0001, OR = 29.03 [6.98-120.84], of proton pump inhibitors: p = 0.02, OR = 2.33 [1.12-4.84], of statins: p = 0.03, OR = 2.05 [1.06-3.97]. There was a significant association with a personal history of osteoporosis: p = 0.0002, OR = 5.16 [2.20-12.08], and a higher body mass index: p = 0.03, OR = 1.18 [1.02-1.36] (Table 1). Patients with AFF had excessive femoral offset (43.0 vs 38.3, p=0.0009), proximal femoral varus (129.1 vs 133.8, p=0.0001) and greater proximal cortical thickness (Table 2).

Conclusion: The incidence of AFF in our city was similar to others reported in the literature. Our retrospective study showed a significant association between AFF and exposure to bisphosphonates and pump proton inhibitors. Surprisingly, we observed an association of AFF with statins intake, although these drugs are known to have a protective effect against osteoporotic fractures. The proximal femoral geometry may play an important role in the AFF occurrence.

Variable	Cases (N=56) % (N)	Controls (N=112) % (N)	OR (95% CI)	P
Mean BMI (±SD)	26.2 (5.1)	23.6 (6.2)	1.18 (1.02-1.36)	0.0314

MO0351

Incidence of subtrochanteric and femoral shaft fractures in 3 French centers. Thomas Funck-Brentano*[1], Agnes Ostertag[2], Francoise Debiais[3], Patrice Fardellone[4], Louis-Etienne Gayet[5], Patrice Mertl[5], Remy Nizard[5], Philippe Orcel[6], Martine Cohen-Solal[7]. [1]Department of rheumatology, hopital Lariboisiere, France, [2]INSERM U606, France, [3]Hopital Jean Bernard, France, [4]Service de rhumatologie, CHU Hôpital Nord, France, [5]department of orthopedic surgery, France, [6]University Paris Diderot, France, [7]Centre Viggo Petersen, France

Purpose: Subtrochanteric and femoral shaft (ST/FS) fractures are rare fragility fractures. Atypical ST/FS fractures have been reported in patients with long duration of bisphosphonate use although they can be observed in osteoporotic patients independently of any treatment. We here assessed the incidence of atypical and typical ST/FS fractures in orthopedic departments of 3 academic hospitals and analyzed the associated risk factors and treatments in these populations. Methods: We first retrieved the files in the databases from 3 French using ICD-10 codes (S72.2 for ST and S72.3 for ST/FS) from January 2007 to December 2010. Characteristics of ST/FS fractures (atypical or non-atypical) were identified in X-Rays obtained before surgery. Information on age, sex, weight, height, history of diseases, falls and treatments were collected. The use of bone-related treatments was confirmed by patient phone calls. Results: ST/FS fractures (S72.2 / S72.3) were initially declared for 389 patients. Among them, 179 (46%) occurred in the presence of materials (prosthesis or nails), 89 (22%) were traumatic, pathologic or misclassified fractures. Finally, low trauma ST/FS fractures were found in 121 patients (mean age: 78 $\pm$ 11 years), in particular 14 (12%) were atypical fractures while 107 (88%) were typical fractures. Several associated diseases were present at the time of the fractures, but there were no difference in the prevalence of hypertension, diabetes, cognitive function, troubles of rhythm and lipid diseases. Nine patients with atypical and 102 patients with typical fractures were naïve of any bone treatment. Atypical fractures occurred in 5 patients (5/14; 36%) treated with alendronate (n=3), strontium ranelate (n=1) and raloxifene (n=1) while typical fractures occurred in 5 patients (5/107; 5%) treated with alendronate (n=3), risedronate (n=1), zoledronic acid (n=1) (Fisher exact test, $p<0.01$). Conclusions: ST/FS fractures are rare events and frequently occur in the presence of materials. They are mostly typical fractures and can be observed in the absence of any treatment for bone. However, atypical fractures characterized by ASBMR features are more frequent in patients receiving anti-fracture treatment.

MO0352

Increased fracture risk among women with diabetes mellitus is not mediated by increased falls risk or decreased functional status. Richard Lee*[1], Cathleen Colon-Emeric[2]. [1]Duke University, USA, [2]Duke University Medical Center, USA

Background: Prior studies have shown that despite having a higher average bone mineral density (BMD), persons with diabetes mellitus type 2 (DM2) have a 1.5 to 2-fold increase in the risk of fracture, compared to those without DM2. The underlying mechanism for this paradoxical observation may result from increased fall risk and decreased functional status among persons with DM2.

Method: This is a secondary analysis of the Women's Health Initiative Clinical Trial cohort. The analysis was limited to those women who had BMD testing during the trial period (N =4644). Falls risk and functional status were determined in the annual and semi-annual questionnaires. Increased falls risk was defined as 2 or more falls in the preceding year. Decreased functional status was determined by self-reported difficulties in activities of daily living including bathing and transferring, as well as physical performance including bending/stooping, carrying groceries, and moving large objects. The association between DM2 and the incidence of any clinical fracture was determined, controlling for multiple factors including falls risk and functional status.

Results: Compared to women without DM2, the risk of any clinical fracture during the study period was increased among women with DM2, after controlling for age, race/ethnicity, and body mass index (HR 1.40, 95% CI 1.08 - 1.80). After controlling for medications and BMD at the hip and spine, the increased risk in fracture among persons with DM2 remained significant (HR 1.48, 95%CI 1.09-2.01). Inclusion of falls risk and functional status did not significantly change the association between DM2 and the risk of any clinical fracture (HR 1.44, 95% CI 1.06-1.95).

Conclusion: Women with DM2 are at increased risk of clinical fractures, independent of BMD. The increased risk is not mediated by increased falls risk or by decreased functional status in these persons.

MO0353

Insulin-like Growth Factor Binding Protein 1 (IGFBP-1), FRAX and the prediction of hip fractures. Hans Lundin*[1], Maria Saaf[2], Lars-Erik Strender[3], Sven Nyren[2], Sven-Erik Johansson[3], Helena Salminen[1]. [1]Karolinska Institutet, Sweden, [2]Department for Molecular Medicine an Surgery, Karolinska Institutet, Sweden, [3]Centre for Family Medicine, Karolinska Institutet, Sweden

Insulin-like growth factor binding protein 1 (IGFBP-1)is a serum protein which binds circulating insulin-like growth factor 1 (IGF-1) and thereby decreases its bioavailability. IGF-1 has been shown to stimulate bone formation and a low serum concentration of IGF-1, adjusted for BMI and bone mineral density (BMD), has been shown to increase the risk of a future osteoporotic fracture. IGFBP-1 is inversely correlated to body mass index (BMI) and a low BMI is a well established risk factor for both low BMD and for osteoporotic fractures, including hip fractures. To our knowledge there are no previous studies published on the relation between IGFBP-1 and fractures.

FRAX is the most used fracture prediction tool worldwide. It was developed by WHO and it is freely available on the Internet.

This is a population-based prospective cohort study on 351 Swedish women aged 69-79 years at inclusion. These women were tested for serum IGFBP-1 and with FRAX including bone mineral density (BMD) at inclusion between 1999-2001. Follow up was performed ten years later through Swedish medical records. The main outcome was a hip fracture.

The aims of this study were to evaluate whether IGFBP-1 could predict hip fractures and further to compare predictive ability of IGFBP-1 with the standard method FRAX.No participant was lost to follow up. The data was analyzed with Cox regression.

The relation between IGFBP-1 and the risk of a hip fracture was found to be positively linear. The age-adjusted risk of a hip fracture increased significantly by 2% for every unit increase in IGFBP-1 (Hazard ratio (HR) 1.020, 95% CI 1.004-1.036). This HR was not significantly altered by further adjusting for either BMI, the serum concentration of IGF-1 or for BMD of the femoral neck (Figure 1). The age-adjusted IGFBP-1 had a Harrells c of 0.63 compared to 0.59 for FRAX which indicates that IGFBP-1 has a predictive ability similar to that of FRAX. Harrell's c is the equivalent to the area under curve (AUC) used in logistic regression, but designed for Cox regression models. For a model combining IBFBP-1 with FRAX, Harrell's c was 0.64.

In conclusion, IGFBP-1 could predict hip fractures as good as FRAX and the relation could not be explained by differences in BMI, IGF-1 or BMD of the femoral neck.Keywords: Hip fractures, Insulin-Like Growth Factor Binding Proteins, Insulin-Like Growth Factor Binding Protein 1, Risk assessment, Osteoporosis.

	Hazard Ratio for hip fracture (95% CI)
IGFBP1 adjusted for age	1.020 (1.004- 1.036)
IGFBP1 adjusted for age and BMI	1.023 (1.006-1.041)
IGFBP1 adjusted for age and IGF-1	1.023 (1.006-1.039)

MO0354

Is lower income associated with an increased likelihood of qualification for treatment for osteoporosis in Canadian women?. Sharon Brennan*[1], William Leslie[2], Lia Lix[3], Helena Johansson[4], Anders Oden[5], Eugene McCloskey[6], John Kanis[7]. [1]The University of Melbourne, Australia, [2]University of Manitoba, Canada, [3]Department of Community Health Sciences, University of Manitoba, Canada, [4]Swedish University of Agricultural Sciences, The Biomedical Center, Sweden, [5]World Health Organization (WHO) Collaborating Centre, University of Sheffield, United Kingdom, [6]University of Sheffield, United Kingdom, [7]University of Sheffield, Belgium

Background: Lower income has been associated with increased fracture risk. We examined whether lower income in women was associated with an increased likelihood of treatment qualification determined by Canada FRAX®.

Methods: We calculated 10-year FRAX probabilities in 51,327 Canadian women aged ⩾50years with baseline femoral neck BMD measured by dual energy x-ray absorptiometry 1996-2011, identified from the Manitoba Bone Density Program, Canada. Mean household income was extracted from 2006 Canada Census public use files and the population was categorized into quintiles. Age, weight and height were recorded at the time of DXA. Medically diagnosed conditions prior to BMD testing (rheumatoid arthritis, and prior fracture since 1987) were ascertained through a combination of hospital discharge abstracts. A diagnosis of chronic obstructive pulmonary disease was used as a proxy for smoking status, and a diagnosis of alcohol or substance abuse was used as a proxy for high alcohol intake. Prolonged glucocorticoid use was obtained from a province-wide retail pharmacy system. Adjustments were made for incomplete history of parental hip fracture using age- and sex-specific adjustment factors. FRAX probabilities for hip fracture ⩾3% or major osteoporotic fracture (MOF) ⩾20% were used to define treatment qualification. Logistic regression analyses were used to model associations between income and treatment qualification.

Results: Percentages of women who qualified for treatment based upon high hip fracture probability (defined with BMD) in income quintiles 1 (lowest income) through 5 (highest income) were 34.6%, 28.2%, 24.9%, 19.9% and 17.3%, respectively. Similar negative linear associations were observed for MOF, where percentages ranged from 13.5% in quintile 1 to 5.8% in quintile 5 ($p<0.001$). Compared to the highest income quintile, women in the lowest income quintile had a 2.5-fold greater likelihood of treatment qualification based upon high hip fracture probability (adjusted odds ratio [OR] 2.47, 95%CI 2.32-2.63 without BMD, and OR 2.53, 95%CI 2.37-2.71 with BMD in FRAX calculation) (Figure 1). Similar results were observed for MOF probability (Figure 2).

Conclusions: FRAX identifies a larger proportion of lower income women as qualifying for treatment than higher income women. The strong negative linear associations between income and treatment qualification has implications for clinical practice and public health outcomes.

HIPC File Number: 2012/2013-15

Figure 1: Logistic regression analysis results for the association between income quintile and treatment qualification based upon high 10-year probability of hip fracture (=3%) defined with and without BMD. Results are presented as odds ratios (ORs) with error bars indicating 95% CI. Quintile 5 (highest income) is the referent.

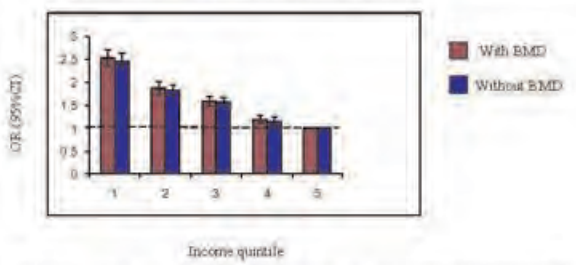

Figure 2: Logistic regression analysis results for the association between income quintile and treatment qualification based upon high 10-year probability of major osteoporotic fracture (=20%) defined with and without BMD. Results are presented as odds ratios (ORs) with error bars indicating 95% CI. Quintile 5 (highest income) is the referent.

MO0355

Racial/ethnic Differences in Bone Microarchitecture among Middle-aged and Elderly Men. Andre Araujo*[1], Gretchen Chiu[1], Benedetta Bartali[1], Thomas Travison[2], Joseph Zmuda[3], Mary Bouxsein[4]. [1]New England Research Institutes, USA, [2]Brigham & Women's Hospital, USA, [3]University of Pittsburgh Graduate School of Public Health, USA, [4]Beth Israel Deaconess Medical Center, USA

Although there are known differences in rates of osteoporotic fractures and bone mass among racial/ethnic groups, few studies have examined the relationship between race/ethnicity and bone microarchitecture, especially among men. We obtained cross-sectional data from the BACH/Bone Survey, a population-based cohort study of racially diverse men aged 38-86y. Microarchitecture at the distal radius (N=459) and tibia (N=487) was measured by high-resolution peripheral quantitative computed tomography (HR-pQCT, XtremeCT, Scanco). Outcomes considered were trabecular volumetric bone mineral density (vBMD), trabecular number, cortical vBMD, cortical thickness, and total area in the distal radius and tibia. Multivariable linear regression was used to examine the associations of race/ethnicity with these outcomes, controlled for age, household income, smoking, self-rated health, diabetes, physical activity, and BMI. Mean(SD) age was 58.0(11.6)y, with Black, Hispanic, and White men representing 30.9%, 29.5%, and 39.6% of the sample, respectively. Most radius parameters (except trabecular number and total area) were lower with increased age; whereas only cortical vBMD and cortical thickness were associated with age at the tibia. Furthermore, we found cross-sectional age-related differences varied significantly by race/ethnicity for trabecular vBMD (p=.006) and trabecular number (p=.02); these particular age-related differences were more than two times greater in Hispanic men. Controlled for covariates, racial/ethnic differences were evident in both the radius and tibia (3%-17%), with a larger number of differences in tibia parameters (Table). While cortical parameters were higher in minority vs. White men, trabecular parameters were generally lower in minority men. In conclusion, cross-sectional racial/ethnic differences in bone microarchitecture are most evident in the weight-bearing tibia (even after adjustment for BMI), which is consistent with the important role of mechanical loading in determining potential racial/ethnic differences in bone strength. In addition, the relative advantage of Blacks and Hispanics in cortical density and microarchitecture appears consistent with reported racial/ethnic differences in non-vertebral fracture rates.

Table. Multivariable-adjusted mean (SE) in bone microarchitectural parameters by race/ethnicity. Column Ns are no. subjects with complete radius and covariate data.

Site	Parameter	Black (N=138)	Hispanic (N=141)	White (N=180)

The Association between Higher Serum Ferritin Level and Lower Bone Mineral Density is Prominent in Women ⩾ 45 Years of Age (KNHANES 2008-2010). Beom-Jun Kim*[1], Seung Hun Lee[2], Jung-Min Koh[1], Ghi Su Kim[2], Seong Hee Ahn[3]. [1]Asan Medical Center, South Korea, [2]Asan Medical Center, University of Ulsan College of Medicine, South Korea, [3]University of Ulsan, Asan Medical Center, South Korea

Introduction: Despite extensive in vitro and in vivo studies showing the detrimental effects of iron on bone metabolism, the clinical studies relating to osteoporosis-related phenotypes have not been evaluated extensively. In the present study, we investigated and compared the association between serum ferritin and bone mineral density (BMD), depending on the stratified age groups in both genders.

Methods: This is a population-based, cross-sectional study from the Korea National Health and Nutrition Examination Surveys, including 14,017 Koreans (6,817 men and 7,200 women) aged 10-80 years. BMD was measured using dual X-ray absorptiometry, and osteoporosis was diagnosed by the WHO definition.

Results: Initially, we divided the subjects into three age groups, based on the patterns of age-related BMD changes in this national cohort (i.e., ≤ 24, 25–44, and ⩾ 45 years old). Serum ferritin concentrations were inversely associated with BMD values at all measured sites after adjustment for confounders, only in women ⩾ 45 years of age (P = 0.041 to <0.001). Furthermore, when we divided these women into serum ferritin quartiles, the odds for prevalent osteoporosis and fractures were

1.55-fold (95% CI = 1.09–2.23) and 1.52-fold (95% CI = 1.02–2.27) higher, respectively, in subjects in the highest quartile compared with those in the lowest quartile.

Conclusions: These results provide the first clinical evidence that the associations between serum ferritin level and bone parameters could be the most prominent in women ⩾ 45 years of age.

MO0357

The Effect of Anticholinergic Medications on Fracture Risk, Bone Mineral Density, and Falls over a Ten Year Period. Lisa-Ann Fraser*[1], Jonathan Adachi[2], William Leslie[3], David Goltzman[4], Robert Josse[5], Stephanie Kaiser[6], Nancy Kreiger[7], Christopher Kovacs[8], Tassos Anastassiades[9], Alexandra Papaioannou[10]. [1]Western University, Canada, [2]St. Joseph's Hospital, Canada, [3]University of Manitoba, Canada, [4]McGill University, Canada, [5]St. Michael's Hospital, University of Toronto, Canada, [6]Dalhousie University, Canada, [7]Division of Epidemiology, Dalla Lana School of Public Health, Canada, [8]Memorial University of Newfoundland, Canada, [9]Queen's University, Canada, [10]Hamilton Health Sciences, Canada

Purpose: Many medications used in older adults have strong anticholinergic (ACH) properties. There has been concern that these medications may increase the risk of falls and fractures in this already vulnerable population; although results of studies have not been definitive.

Methods: We examined a large population-based Canadian cohort, the Canadian Multicentre Osteoporosis Study, over 10 years. Use of oral medications with previously proven strong ACH effects (as per Ancelin BMJ 2006; Rudolph ArchIntMed 2008) were identified at baseline, year 5, and year 10. Cross sectional regression analyses of the cohort were performed at years 0, 5, and 10 to examine associations between ACH medication use and falls. Time-dependent Cox-Regression was used to prospectively examine time-to-first non-traumatic fracture; and differences in the mean change in BMD over 10 years was examined in ACH medication users compared to non-users. Analyses were adjusted for potentially confounding variables.

Results: Strongly ACH medications were used by 614 of 9423 participants (6.5%) at study baseline, 596 of 7652 (7.8%) at year 5, and 361 of 5569 (6.5%) at year 10. Unadjusted, ACH medications were found to be associated with falls at study baseline (OR=1.47, 95% CI 1.10-1.96, p=0.009) but the association was lost after adjustment. Similar results occurred at years 5 and 10, with an association present prior to adjustment (OR=1.52, CI 1.27-1.82, p<0.001; OR = 1.45, CI 1.16-1.82, p=0.001, respectively), but not after. ACH medication use was associated with an increased incident fracture rate (HR=1.35, CI 1.08-1.69, p=0.01) but not after adjustment. Parkinson's disease was strongly associated with both falls (OR=4.02, CI 1.71-9.48, p=0.001, at baseline) and incident fracture (HR=5.58, CI 2.98-10.46, p<0.001). Mean (SD) change in femoral neck BMD T-score over 10 years, in those using ACH medications at both years 0 and 5, was -0.599(0.631) in ACH users vs. -0.503(0.454) in non-users (p=0.056).

Conclusions: In this Canadian cohort, we did not find strongly ACH medications to be independently associated with an increased risk of falling, fractures, or BMD loss. Instead, underlying conditions associated with ACH medication use (eg. Parkinson's disease) were independently associated with increased falls, which may explain why previous studies have found an association between ACH medications and falls.

Which Patients with Ankle Fractures Are at Risk for Recurrent Fragility Fractures? Results from the OPTIMUS Initiative. François Cabana[1], Nathalie Carrier[2], Marie-Claude Beaulieu[3], Michèle Beaulieu[4], Sophie Roux[5], Gilles Boire*[6]. [1]Division of Orthopaedics, Centre hospitalier universitaire de Sherbrooke, Canada, [2]Division of Rheumatology, Centre hospitalier universitaire de Sherbrooke, Canada, [3]Université de Sherbrooke, Canada, [4]Merck Canada Inc, Canada, [5]University of Sherbrooke, Canada, [6]Centre Hospitalier Universitaire De Sherbrooke, Canada

Introduction. Some but not all guidelines consider ankle fractures as fragility fractures (FF). Objectives. To analyze the characteristics of patients with low-trauma ankle fractures presenting new low-trauma fractures during follow up. Methods. The OPTIMUS study is an ongoing prospective cohort of men and women over 50 years of age, designed to increase the rate of initiation and persistence of osteoporosis treatment after a FF leading to an orthopaedic consultation. The occurrence of novel FF was collected during regular phone follow-ups up to 48 months after inclusion. FRAX scores were calculated without BMD at the time of the ankle fracture, without accounting for this fracture. Ankle x-rays were reviewed and classified as unimalleolar (lateral (Weber A, B or C) or medial), bimalleolar or trimalleolar. Results. 265 patients (190 women; median (IQR) age 61 (55-69); median (IQR) BMI 27.0 (24.6-30.1)) with low-trauma ankle fracture were included. New low-trauma fractures occurred in 11 (4.2%) patients over 716 patient-years of observation, at hip (1), vertebra (1), knee (1), shoulder (2), wrist (2), ankle (2) and other sites (2). 55% of ankle fractures were uni-, 18% bi-, and 27% trimalleolar with rates of recurrent FF of 1.4, 1.4, and 2.2 / 100 patient-years, respectively. Of the 11 recurrent FF, 8 occurred in women (Relative Risk (RR) 1.05 [0.29-3.86], NS), 6 in patients with FF prior to the ankle fracture (RR 6.72 [2.15-20.97], p=0.001) and 7 in patients at high risk according to pre-ankle fracture FRAX (RR 5.98 [1.81-19.74], p=0.003). Incidence of recurrent FF (per 100 patient-years) was highest in patients with FF prior to the ankle fracture (4.90), intermediate in patients without previous FF but with a High risk FRAX score (1.87), and lowest in patients without previous FF and with Low or Moderate risk (0.62). Conclusions. Most recurrent fractures occurring in older individuals after low-trauma ankle fractures are at typical sites of FF. Recurrent fractures occur at about 1.5 per 100 patient-years, with highest rates (4.90) in patients with previous FF, and lowest rates (0.62) in those without previous FF and with pre-fracture Low or Moderate risk. Gender, BMI and severity of bone damage were not predictors for recurrent fractures. Low-trauma ankle fractures represent clinical opportunities to identify patients with previous FF and patients with FRAX estimated high risk, two groups in need for preventive treatment.

MO0359

Bone Mineral Distribution in the Tibiae of Stroke Survivors During the First Year of Recovery: A pQCT Study. Norma MacIntyre*[1], Arpita Parmar[1], Gregory Wohl[1], Brenda Brouwer[2]. [1]McMaster University, Canada, [2]Queen's University, Canada

Purpose: Spatial adaptation of volumetric cortical bone density (CoD) in the paretic limb of stroke survivors has not been reported. This study describes and contrasts spatial distribution (polar divisions, radial divisions), CoD and resistance to torsion (Strength Strain Index, SSI) at the 66% site of the tibia in the paretic and nonparetic limbs of subacute stroke survivors followed for one year after a unilateral stroke.

Methods: Adults being discharged from a rehabilitation hospital following their first hemispheric stroke were recruited. Bilateral images were acquired bilaterally at the tibial 66% site at baseline, 6 mo and 12 mo using pQCT (XCT 2000L, Stratec). Image analysis was conducted using BoneJ (www.bonej.org), to quantify total CoD, distribution in 36 equal polar subdivisions (10° each) and radial divisions (endocortical, mid, periosteal), and SSI. Mineral distribution in the 36 polar subdivisions were characterized by calculating mean CoD for 4 polar anatomic divisions: posterior (0-5,33-35), anterior (15-23) lateral (6-14), and medial (24-32) as shown in Fig. 1. Descriptive statistics were used to characterize the bone variables in each limb at each timepoint. To minimize the difference in variance in paretic limb measures, the main effect of time was determined for between-limb differences (paretic-nonparetic) using RM ANOVA. To contrast distribution within the polar and radial divisions over time, 2-way RM ANOVAs were used. Significance level was set at $p \leq 0.05$

Results: Data were obtained for 17 subjects (mean age: 61.2(9.9)y; sex: 13M/4F; Paretic Limb: 9 right/8 left). Table 1 summarizes the bone outcomes. No main effect due to time was observed for CoD ($F(2, 32)=1.14$, $p=0.33$), mineral distribution in polar divisions ($F(2, 32)=0.325$, $p=0.73$) or radial divisions ($F(2, 32)=0.57$, $p=0.57$), or SSI ($F(2,32)=1.10$, $p=0.34$). Mineral was not significantly redistributed within the polar ($F(2,48)=0.587$, $p=0.63$) or radial ($F(2,32)=0.214$, $p=0.81$) divisions. Observed power for all contrasts ≤ 0.23.Conclusions: This study is the first to describe spatial distribution of bone mineral at the 66% site of the tibiae in stroke survivors. Our study is underpowered to detect changes during the first year following a unilateral stroke. On average, the paretic limb had insignificantly lower values for all bone outcomes at 6 mo; this trend was not observed at 12 mo. Changes in mobility ability over the 1y study may explain these results.

Is Low Bone Mineral Density a Reason for Schmorl's Node?. Sevinc Kulekcioglu*[1], Alp Cetin[2]. [1]Specialist of Physical Medicine & Rehabilitation Sevket Yilmaz Education & Research Hospital, Turkey, [2]Proffessor of Physical Medicine & Rehabilitaion, Hacettepe University Medical School, Turkey

Inroduction: Schmorl's node is described as intravertebral herniation of intervertebral disc tissue. It can be considered that any process which weakens the subchondral trabeculae of the vertebra results with development of these nodes. One of the reason for this weakness is osteoporosis. As far as our knowledge the role of bone mineral density (BMD) on development of schmorl's node has not been studied yet. So the aim of this study was to investigate if there is any relation between bone mineral density and schmorl's node development.

Materials and Methods: Thirtysix patients (23 female, 13 male, mean age 49.3 $\pm$ 15.2) who had schmorl's node on magnetic resonance inaging (MRI) examination were included in this study. Control group consisted of 35 (22 female, 13 male, mean age 46.5$\pm$14.4) subjects without any schmorl's node on MRI. Bone mineral densities of both groups were measured with dual energy X-ray absorptiometry (DXA) at lomber spine and proximal femur.

Results: Ages and other demographic parameters of study and control groups were similar. Both, proximal femur (0.763 ± 0.109g/cm^2 vs 0.830 ± 0.141g/cm^2 for femoral neck, p=0.026 and 0.835 ± 0.106g/cm^2 vs 0920 ± 0.116g/cm^2 for femur total and p=0.010) and lomber spine (0.859 ± 0.116g/cm^2 vs 0.989 ± 0.140g/cm^2 for L1-L4 and p=0.000) BMD values in patients with Schmorl's node were significantly lower than control group. BMD difference was more marked at lomber spine.

Conclusion: The results of this preliminary study showed that development of schmorl's node might be related with low BMD. These findigs supports the hypothesis that weakness of subcondral trabeculae of the vertebra is related with schmorl's node.

MO0361

Higher Serum Osteocalcin is Associated with Metabolic Syndrome Severity in Men from the MINOS Cohort. Cyrille Confavreux*[1], Pawel Szulc[2], Romain Casey[3], Annie Varennes[4], Joelle Goudable[5], Roland Chapurlat[6]. [1]INSERM UMR1033 - Universite de Lyon, France, [2]INSERM UMR 1033, University of Lyon, Hopital E. Herriot, Pavillon F, France, [3]OFSEP-Université de Lyon, France Hospices Civils de Lyon, France, [4]Université de Lyon, Central Biochemical Laboratory, Hospices Civils de Lyon, France, [5]INSERM U1060 – Université de Lyon, France, [6]E. Herriot Hospital, France

Objectives. Recently bone has emerged as an endocrine organ that regulates energy metabolism through the secretion of osteocalcin favoring insulin secretion and insulin sensitivity. Several epidemiological studies reported a negative association between osteocalcin level and the presence of metabolic syndrome (MetS). Therefore, we evaluated whether osteocalcin may be quantitatively associated to MetS severity in men.

Material and methods. We included 798 men aged 51-85 with fasting serum total osteocalcin measurement. MetS diagnosis was based on the presence of at least 3 out of the 5 criteria of the current consensus definition (Alberti Circulation 2009). The number of criteria (3, 4 or 5) was used to define MetS severity. We used a polytomous logistic regression model to assess the relationship between gravity of MetS and osteocalcin.

Results. Thirty percent of the cohort (n= 247) had MetS. After adjustment for age, 25OHD, testosterone, physical activity, smoking and alcohol consumption, in logistic regression model, higher serum concentrations of osteocalcin were associated with lower MetS prevalence (OR=0.75 per 10 ng/ml increase, 95%CI: 0.58-0.97; p=0.028). In the stepwise logistic regression including the previously used variables and bone turnover markers (BTM: PINP, Bone ALP, serum CTX-I), osteocalcin was the first BTM retained in the model (OR= 0.81 [0.67-0.97], p=0.02).

In patients with MetS, the higher the number of the MetS traits were present, the lower was the average osteocalcin level (0-2 criteria: 551 men:19.5 ng/ml, 3 criteria, 155 men: 19.3ng/ml, 4 criteria, 72 men: 17.3ng/ml, 5 criteria, 20 men: 15.0 ng/ml; adjusted p for trend=0.02). In polytomous logistic regression model after adjustment on the variables specified above, higher osteocalcin (by 10 ng/ml) level was associated with a lower prevalence of MetS proportionally to the MetS severity: OR=0.93 [0.70-1.24] for 3 criteria, 0.54 [0.34-0.84] 4 criteria and 0.28 [0.10-0.82] 5 criteria; p=0.008.

Conclusion. Total osteocalcin level was associated with MetS severity in older Caucasian men. MetS was associated with osteocalcin more strongly than with other BTM, which suggests a specific link independent of the general bone turnover rate. These data suggest that osteocalcin might be an indicator of global health outcome.

MO0362

Suppression of autophagy in Osx1-Cre-expressing cells causes low bone mass and spontaneous fractures in mice. Marilina Piemontese*[1], Melda Onal[2], Yiying Wang[1], Jinhu Xiong[3], Priscilla Baltz[1], Rajamani Selvam[1], Stuart Berryhill[1], Li Han[3], Stavros Manolagas[3], Charles O'Brien[3]. [1]University of Arkansas for Medical Sciences, USA, [2]university of wisconsin, USA, [3]Central Arkansas VA Healthcare System, Univ of Arkansas for Medical Sciences, USA

Autophagy is a stress-activated pathway that maintains cellular health and viability by recycling intracellular components, such as damaged proteins and organelles, via a lysosomal pathway. Previous studies have shown that genetic suppression of autophagy in mature osteoblasts and osteocytes using a Dmp1-Cre transgene caused low bone mass and strength associated with increased oxidative stress in the bone marrow microenvironment. However, whether autophagy plays an important role in osteoblast progenitors remains unknown. To address this question, we deleted the Atg7 gene, which is essential for autophagy, using Osx1-Cre transgenic mice. Female conditional knockout mice (Osx1-Cre;Atg7f/f), and their control littermates (Atg7f/f, Osx1-Cre, or wild-type) were subjected to serial BMD measurements from 8 to 24 weeks of age and then euthanized. Femoral, vertebral, and total BMD were low in conditional knockout mice compared to control groups at all time-points, with no differences in body weight between Osx1-Cre;Atg7f/f and Osx1-Cre, which were both slightly smaller than wild-type controls consistent with previously reported effects of the Osx1-Cre transgene on body weight. Abundance of the loxP-flanked Atg7 exon was significantly reduced in genomic DNA isolated from cortical bone but not spleen, demonstrating the specificity of deletion. Cancellous bone volume was low in the femur and spine of Osx1-Cre;Atg7f/f mice compared to controls, as was femoral cortical thickness. Consistent with this, bone strength was low at both sites as revealed by compression and 3-point bending analysis. Moreover, 48% of Osx1-Cre;Atg7f/f mice, but not controls, displayed healed or healing fracture calluses in the tibia, indicative of spontaneous fractures and a profound loss of bone strength. Lastly, reactive oxygen species levels in the bone marrow and phosphorylation of the p66shc protein in L4 vertebra, both markers of oxidative stress, were elevated in Osx1-Cre;Atg7f/f mice compared with Atg7f/f mice. The similarity of the low bone mass phenotype in this model with that observed after deletion of Atg7 using a Dmp1-Cre transgene suggests that autophagy in post-mitotic osteoblast-lineage cells is largely responsible for the low bone mass. However the presence of spontaneous fractures in the Osx1-Cre;Atg7f/f mice indicates that failure of autophagy in osteoblast progenitors may have additional deleterious effects on bone quality, the composition of bone cells, or both.

MO0363

Increased Cortical Porosity in Older Men with Fracture. Mattias Lorentzon*[1], Daniel Sundh[2], Magnus Karlsson[3], Claes Ohlsson[4], Dan Mellstrom[5]. [1]Geriatric Medicine, Center for Bone Research at the Sahlgrenska Academy, Sweden, [2]Geriatric Medicine, Dept. of Internal Medicine & Clinical Nutrition, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [3]Skåne University Hospital Malmö, Lund University, Sweden, [4]Center for Bone & Arthritis Research at the Sahlgrenska Academy, Sweden, [5]Sahlgrenska University Hospital, Sweden

Cortical porosity increases with ageing and experimental studies have reported that this bone trait is highly correlated to bone strength but whether it contributes to fracture risk has not been reported. The aim with the present study was to investigate whether cortical porosity was associated with x-ray verified fractures in older men.

The MrOS Gothenburg study is a prospective population based study from which a sub population consisting of 457 men, 80.1±3.5 (mean±SD) years, with available High Resolution pQCT (XtremeCT, Scanco Medical) measurements at the follow up exam (45 (15-73) months after study inclusion), was used in the present study. DXA (Hologic) was used to measure areal BMD of the hip. Fractures during the 45-month study were X-ray verified and information concerning physical activity, calcium intake and smoking was collected using questionnaires at the follow up exam.

During the study period 50 (10,9%) men had suffered a fracture. There were no differences in age, height, or weight between men with and without prevalent fractures at the end of study.

Using independent samples T-test, men with fracture during the study period had 10.0% lower areal BMD of the femoral neck (0.71±0.14 vs. 0.79±0.13 g/cm^2; $p<0.01$), 9.5% lower trabecular bone volume fraction (13.6±2.7 vs. 15.0±2.8 %; $p<0.01$), 20.6% thinner cortices (1.01±0.30 vs. 0.80±0.33 mm; $p<0.01$) and 21.0% higher cortical porosity (13.9±5.1 vs. 11.5±3.8 %; $p<0.01$) than men without fracture.

The independent associations between the above bone variables and fracture were tested using a logistic regression model with age, height, weight, calcium intake, smoking, physical activity and time in study as covariates. Cortical porosity (Odds Ratio 1.76 (95% CI 1.32-2.35) per SD increase), cortical thickness (OR 2.25 (1.51-3.20) per SD decrease), trabecular bone volume fraction (OR 1.65 (1.19-2.28) and femoral neck aBMD (OR 1.99 (1.32-3.00)) were independently associated with fracture. When entering all microstructure variables simultaneously in the model, cortical porosity and thickness remained independently associated with fracture. When adding femoral neck aBMD to the model, only cortical porosity (OR 1.63 (1.20-2.23)) and femoral neck aBMD (OR 1.80 (1.22-2.34)) were significantly related to fracture.

In conclusion, cortical porosity was associated with fracture independently of femoral neck BMD, suggesting a substantial contribution of cortical porosity to bone strength and fracture risk.

Loss of BromoDomain2 Function Leads to the Development of Sex-Linked Osteoporosis. Elise Morgan[1], Beth Bragdon[2], Robert Burns[3], Patrick Diviney[3], Amelia Baker[3], Anna Belkina[3], Gerald Denis[3], Andre Van Wijnen[4], Jennifer Schlezinger[5], Louis Gerstenfeld*[3]. [1]Boston University, USA, [2]Boston University School of Medicine Department of Orthopaedics, USA, [3]Boston University School of Medicine, USA, [4]Mayo Clinic, USA, [5]Boston University School of Public Health, USA

Osteoporosis is age and sex dependent and is exacerbated by obesity. Mice with reduced expression of the transcriptional regulator, bromodomain 2 (BrD2), are obese but do not develop insulin resistance. These mice provide an excellent model to assess the effects of obesity on bone loss, not confounded by Type II diabetes.

Methods: Male and female C57BL6 (WT) and BrD2lo mice, ages 3-18 months, were studied (N=4-7/group). Trabecular bone in the right tibia and L5 vertebra was assessed by microCT. Immunohistology for perilipin was used to assess marrow fat. RNA was isolated from the humeri, and the expression of mRNAs for osteoblasts/osteocytes (RUNX2, osteocalcin, DMP1 and SOST), and adipocytes (PPARγ, Adipsin, FABP4, Perilipin) was quantified by qRT-PCR. Primary bone marrow stromal cells (BMSCs) were cultured from the remaining hindlimb long bones to assess osteogenic and adipogenic potential. BrD2 expression was assessed in human adipose-derived MSCs.

Results: From 3 to 18 months of age, trabecular bone volume fraction (BV/TV) decreased by ~50% in both WT and BrD2lo males (Fig. 1). In contrast, both WT and BrD2lo females started with ~30% lower BV/TV than the males, and then exhibited age-related bone loss dependent on BrD2 activity. While BV/TV declined by only ~25% by 18 months in WT females, BV/TV in the BrD2lo females dropped to only ~45% and ~30% of the BV/TV in age-matched females and males, respectively. Both WT and BrD2lo females had greater fat content in the marrow (Fig. 2). Peak expression of osteoblast markers was seen in males and females at 6 months, with the females always showing the highest levels (Fig. 3). Levels of fat-associated genes were very low in the WT males, were much higher in the females, and were higher in BrD2lo vs. WT. Low BrD2 expression had no effect on bone gene expression in females but produced a marked increase in males. BMSCs from WT females maintained these sex- and genotype-specific differences in gene expression (Fig. 4). Both sets of lineage markers were greatly diminished in BrD2lo female cultures compared to WT female, WT male, and BrD2lo male cultures. In human adipose-derived MSCs, expression of BrD2 was 2- to 5-fold higher than that of any other family member.Conclusions: Maintenance of BrD2 expression is protective against bone loss in females. The expression of BrD2 in human adipose MSCs suggests that this transcriptional regulator may have functional importance in sex-linked bone loss in humans.

Trabecular Bone Loss is Underestimated in Postmenopausal Women. How to Improve the Assessment. The OFELY Study. Rafaa Ellouz*[1], Roland Chapurlat[2], Elisabeth Sornay-Rendu[1], Pawel Szulc[3], Stephanie Boutroy[4]. [1]INSERM UMR 1033, Université de Lyon, France, [2]E. Herriot Hospital, France, [3]INSERM UMR 1033, University of Lyon, Hopital E. Herriot, Pavillon F, France, [4]INSERM U1033 & Université de Lyon, France

Definition of cortical and trabecular compartments is crucial for bone loss assessment, especially in longitudinal studies. Age-related cortical thinning produces cortical remnants that are artefactually considered as trabecular bone. In longitudinal studies, accurate assessment of cortical and trabecular bone loss in their original compartments would permit to determine true bone loss.

Our goal was to compare cortical and trabecular bone loss assessed by HRpQCT at the distal radius over 6 years, using the standard procedure and baseline-defined compartments after 3D registration.

Forty-six postmenopausal women (60±7 yrs) were measured by HRpQCT at the distal radius at baseline and after 6 years. The longitudinal analysis was performed using three methods: 1. standard software which identifies the volume of interest (VOI) based on cross-sectional area (CSA) matching and involves Laplace-Hamming filtering and thresholding to separate cortical from trabecular bone. 2. VOI based on CSA matching and double contouring of the cortical compartment and 3. VOI based on 3D registration and double contouring of the baseline compartment used for both baseline and follow-up scans.

Trabecular bone compartment (Tb.TV) increased with both CSA-based matching algorithms (2.6 and 2.1%, $p<0.001$ for both) which confirms that, over a 6 years period, cortical remnants are considered as trabecular bone. Trabecular volumetric BMD (Tb.vBMD) decreased by -4% and -3% with standard and double contouring method respectively ($p<0.005$) but was not significantly different between the two methods. Albeit both significant ($p<0.001$), decrease in cortical thickness was lower using double contouring than with the standard software (-6% vs -15%; $p<0.001$). When Tb.TV was kept constant with 3D registration, the decrease in Tb.vBMD was markedly higher than those obtained using CSA matching and either standard or double contouring procedure (-10% vs -4% and -3% respectively, $p<0.01$). Moreover, the increase in cortical porosity (Ct.Po) was greater (92 vs 65 %, $p<0.01$) and consistent with a greater decrease in cortical vBMD (-6% vs -5%; $p<0.01$) than that obtained with double contouring based on CSA matching VOI.

In conclusion, we have shown that with an accurate registration technique (3D registration) trabecular and cortical bone loss can be assessed in their original compartments, therefore precluding the artefactual underestimation of trabecular bone loss and Ct.Po increase observed with standard procedures.

MO0366

Alternative Methods to Measure Fractional Intestinal Magnesium Absorption (FMA). Karen Hansen*[1], Andrea Nabak[1], Rachael Johnson[1], Martin Shafer[2], Steven Abrams[3]. [1]University of Wisconsin, USA, [2]Wisconsin State Lab of Hygiene, USA, [3]Baylor College of Medicine, USA

Animal and human studies, though few in number, link low magnesium intake to osteoporosis pathogenesis. A major barrier to more conclusive research on the relationship between magnesium status and osteoporosis relates to challenges in

measuring fractional intestinal magnesium absorption (FMA), which requires use of dual isotopes and a 72-hour urine collection. We evaluated alternative methods of measuring FMA, hypothesizing that shorter or spot urine collections or serum isotope values would provide data similar to 72-hour FMA values.

We administered two stable magnesium isotopes to 15 postmenopausal women with 25(OH)D levels between 16 and 25 ng/mL. Subjects fasted from midnight until 0700 when they arrived on the research ward and consumed breakfast along with ~23 mg ^{26}Mg orally and ~11 mg ^{25}Mg intravenously. We measured magnesium isotope levels in a 72-hour urine collection (collected as three 24-hour urine specimens), in spot urine samples at 36, 48, 60 and 72 hours and in serum samples collected 1, 3 and 5 hours after isotope dosing. We calculated FMA using the fraction of the oral divided by iv tracers from the 72-hour urine isotope values (J Nutr 1994;124:674-682). The fraction label was the [volume (urine or serum) x magnesium concentration in the sample x delta-excess label], divided by the tracer dose. The delta-excess label for each day was 100 x [observed isotope ratio – natural abundance ratio]/natural abundance ratio.

Among 15 Caucasian women ages 62 $\pm$ 7 years with an average dietary magnesium intake of 345 $\pm$ 70 mg per day, FMA based on the gold-standard 72-hour urine collection was 0.28 $\pm$ 0.08. 72-hour FMA correlated most highly with 24-hour urine values (rho 0.95, $p<0.001$) and the average of the 24-hour urine and 5-hour serum isotope values (rho 0.96, $p<0.001$, Table). FMA values based on the 24-hour urine collection and a formula (Value x 0.958 + 0.05 = FMA) explained 93% of the variance in 72-hour FMA values. The average of the 24-hour urine and 5-hour serum isotope levels (Value x 0.953 – 0.008 = FMA) explained 95% of the variance in 72-hour FMA values.

Our results suggest that FMA can be accurately measured using a 24-hour urine collection. Validation is underway; if confirmed in an additional sample of subjects, the new method could provide a more convenient option for researchers to measure FMA.

Table: Relationship Between Gold-Standard and New Measurements of Fractional Intestinal Magnesium Absorption

	New Method	Fractional Magnesium Absorption	Spearman Correlation Coefficient	p-value	Bland-Altman Bias	p-value	Linear Regression Equation	R^2
Urine Values	24-hour Urine Collection	0.24 ± 0.08	0.95	<0.001	-0.039	<0.001	**Value x 0.958 + 0.050 = FMA**	**0.93**

	24-Hour Urine, 5 Hour/3 Hour Serum	0.26 ± 0.07	0.83	<0.001	-0.028	0.009	Value x 0.989 + 0.031 = FMA	0.78
	1 Hour Serum, 3 Hour Serum	0.19 ± 0.05	0.82	<0.001	-0.093	<0.001	Value x 1.240 + 0.048 = FMA	0.71
	1 Hour Serum, 5 Hour Serum	0.22 ± 0.05	0.94	<0.001	-0.060	<0.001	Value x 1.389 – 0.026 = FMA	0.87
	3 Hour Serum, 5 Hour/3 Hour Serum	0.28 ± 0.07	0.77	0.001	**0.001**	**0.936**	Value x 0.921 + 0.022 = FMA	0.70

We used dual stable isotopes and a 72-hour urine collection as the gold-standard method to measure intestinal magnesium absorption (mean ± SD = 0.28 ± 0.08) in 15 subjects. We summarize new methods to estimate magnesium absorption above, with all comparisons to the gold-standard measurements. All data exhibited a normal distribution except for the spot 72-hour urine level (median -8.87, range -20.97 to 147.93).

MO0367

Definition and determinants of a normal reference range for 24-hour urine calcium for caucasian and african american women. Prachi Jindal*[1], J. Christopher Gallagher[1], Munro Peacock[2], SRI HARSHA TELLA[3], Lynette Smith[4]. [1]Creighton university medical center, USA, [2]Indiana University Medical Center, USA, [3]Creighton University School of Medicine, USA, [4]University of nebraska medical center, USA

Background- Different recommendations exist for a normal range for 24-hour urine calcium that varies from 50-300mg.

Objective- The objective of this analysis is to establish a normal range in older women for 24-hour urine calcium and examine the relationship between calcium intake, vitamin D metabolites and calcium absorption and 24h urine calcium.

Design-In two randomized, prospective trials we collected at baseline 24 hour urine calcium and creatinine, 7 day food diary for calcium, serum 25-hydroxyvitamin D (25OHD) and 1,25dihydroxyvitamin D ($1,25(OH)_2D$. In study 1(STOP IT) there were 489 normal women, age 65-77 years. In Study 2(ViDOS) there were 163 Caucasian (C) and 110 African American (AA) women, age 57-90 years. The main inclusion criterion for study I was normal femoral neck bone density for age and for study II a serum 25OHD < 20ng/ml (50nmol/l) and 24h urine calcium< 300mg. Serum and 24 hour urine were collected at baseline.

Methods- Urine calcium was measured on Roche Auto analyzer. Calcium absorption was a single isotope method. In study 1 Serum 25OHD and $1,25(OH)_2D$ were measured by competitive protein binding assay and in study 2 by radio-immunoassay RIA(Diasorin). The 24-hour urine calcium did not fit a normal distribution,, the 95% reference interval (RI) was found using non-parametric methods and 90% non-parametric confidence intervals (CI) are provided for the endpoints of the RI. SAS software was used to estimate the normal range. P-values < 0.05 were significant.

Result (Table)-Age range for both studies was 57-90 years. There was no difference in the reference range for 24h urine calcium for two Caucasian studies so the data were combined for 652 women. The reference range was 37 to 275mg. The reference range for African American women was 7-225mg, with mean 24h urine calcium significantly lower than Caucasians, $p< 0.001$. In Caucasians the correlations for24h urine calcium with serum $1,25(OH)_2D$ was r=0.2 ,$p< 0.001$; serum 25OHD r=0.07, p=0.066; calcium intake r=0.124,p=0.0018 and calcium absorption r=0.141, p=0.0008. In African Americans the correlation for24h urine calcium with serum 25OHD was r=0.11, p=0.28 and calcium intake was r=0.17, p=0.078.

Conclusion- 24h urine calcium was correlated with calcium intake, calcium absorption, serum $1,25(OH)_2D$ but not serum 25OHD. In the combined data the normal reference interval for 24-hour urine calcium for Caucasian women is 37-275mg and for African American women is 7- 225mg.

Key words- 24-hour urine calcium, normal reference interval, calcium absorption, Vitamin D metabolites, Caucasian, African American

Reference Interval for 24h urine calcium (mg)
C=Caucasian, AA= African American

	24h Urine calcium		
Study	Reference Interval	90% CI for lower value	90% CI for upper value
STOP IT(C)	37 – 275	29 – 49	263 – 282
VIDOS(C)	39 – 274	17 – 43	266 – 304
Overall(C)	37 – 275	31 – 40	266 – 282
AA	7-225	2-10	216-270

MO0368

Importance of serum 25(OH)D2 levels as a risk factor for incident vertebral fractures in glucocorticoid-induced osteoporosis in Japan. Ikuko Tanaka*[1], Mari Ushikubo[2], Shigenori Tamaki[1], Harumi Kuda[2], Sayaka Kubo[2], Keisuke Izumi[2], Kumiko Akiya[2], Hisaji Oshima[2]. [1]Nagoya Rheumatology Clinic, Japan, [2]Tokyo Medical Center, Japan

Background: Serum 25-hydroxyvitamin D (25(OH)D) assay is now a highly reliable method for evaluating vitamin D stores in individual patients. A critical review of available evidences indicates that a relationship exists between sufficient vitamin D status and bone fracture. However, Japanese population showed ethnic difference even in bone fracture. In this study, we evaluated serum 25(OH)D2 as a risk factor for incident vertebral fractures in glucocorticoid-induced osteoporosis in Japan

Patients and Methods: Subjects with connective tissue disease except rheumatoid arthritis were 15 males and 71 females, showing 60$\pm$15 y.o. of mean age, 11$\pm$10 years of mean disease duration, 36$\pm$34 g (predonisolone; equivalent) of mean total glucocorticoid medication, and 9$\pm$6 mg of mean daily dose. Prevalent vertebral fractures were seen in 37 % of the patients. Other medications were bisphosphonate (59 cases) and menatetrenone (vitamin K analog) (2 cases). 25 subjects had no medication. None of subjects had a medication of natural vitamin D. In this 2-year longitudinal study, an incident vertebral fracture was diagnosed with a conventional spine radiography using semiquantitative criteria by Genant (JBMR, 1993). Bone mineral density (BMD) was assessed by the radial DXA.

Results: 1) 32 subjects (37%) had an incident vertebral fracture. 2) The distribution of serum 25(OH)D2 concentration was 5.9-36 pg/ml and the mean was 17.5$\pm$7.2 pg/ml. 3) There was no significant difference in the serum level of 25(OH)D2 between subjects with a incident fracture and subjects without fracture. 4) The decrease of serum 25(OH)D2 concentration was an independent risk factor for an incident vertebral fracture with statistical significance (OR 1.2/2pg, $P<0.01$), after adjustment for age, total glucocorticoid dosage, mean daily glucocorticoid dosage, BMD, previous fracture, and therapeutic agents. The decrease of serum 25(OH)D2 was a significant independent risk factor (OR 2.4/2pg, $P<0.05$) in the cases with fracture progression of SQ 2 and over.

Conclusions: These data suggests that the decrease of serum 25(OH)D2 level is an independent risk factor and the severity of incident fractures in Japanese subjects with glucocorticoid-induced osteoporosis. In further study, clinical utility of 25(OH)D3 should be evaluated.

MO0369

Bone Phenotype of Casp2-/- mice is Defined by Gender and Genetic Background. Ramaswamy Sharma*[1], Difernando Vanegas[2], Clair Martin[2], Diane Horn[2], Roberto Fajardo[3], Sherry Werner[2], James Lechleiter[2], Brian Herman[5]. [1]University of Texas Health Sciences Center At San Antonio, USA, [2]University of Texas HSC at San Antonio, USA, [3]UT Health Science Center, San Antonio, USA, [5]UT HSC San Antonio, USA

Genetic determinants of bone mineral density (BMD) are not fully known. Such knowledge is critical for the diagnosis and treatment of osteoporosis. We have previously shown that ablation of the apoptotic cysteine aspartate protease, caspase-2, in mice with mixed genetic background resulted in significant decreases in BMD, bone volume, trabecular number, cortical thickness and bone mechanical strength in old (24-27 month) but not young or middle-aged male *Casp2*$^{-/-}$ mice. Herein, we show that male and female *Casp2*$^{-/-}$ mice on pure C57Bl/6 background exhibit significant bone loss at younger ages. Specifically, male *Casp2*$^{-/-}$ mice exhibited significant bone loss from 5 months onwards whereas female *Casp2*$^{-/-}$ mice exhibited consistently decreased BMD from 2-3 months. Further characterization of female *Casp2*$^{-/-}$ mice by dual X-ray absorptiometry (DXA) indicated decreases in BMD in tibia, femur, lumbar vertebrae and total body. Micro-CT measurements of tibial trabecular bone in 4 month old female *Casp2*$^{-/-}$ mice showed significantly decreased trabecular bone volume (BV/TV) and trabecular number (Tb.N). Micro-indentation analyses showed increased indentation distance increase (IDI), suggesting material changes in bone. Female *Casp2*$^{-/-}$ femoral bone length was significantly shorter in young (4 month) and old (16 month) female mice. To determine if the observed trabecular bone loss was related to decreased bone formation or increased bone resorption, we performed histomorphometric counts of osteoblasts and osteoclasts on 4 month bones. A significant decrease in osteoblast numbers (OB/mm bone surface) was observed. Serum levels of 1, 25 (OH) vitamin D were also significantly decreased in young female *Casp2*$^{-/-}$ mice. Surprisingly, female mice overexpressing caspase-2 in osteoclasts exhibited higher BMD at young and older ages, perhaps due to indirect effects on osteoblast-osteoclast interactions. In conclusion, our data highlight the influence of genetic background and gender in determining the bone phenotype observed due to deficiency of caspase-2.

MO0370

Replicative senescence of circulating osteogenic cells in young men with perinatal HIV infection. John Manavalan*[1], Stephen Arpadi[1], Jayesh Shah[1], Jannine Chan[1], Liana Greer[1], Marc D. Foca[1], Natalie M. Neu[1], David Bell[1], C.Amy Zhang[1], Stavroula Kousteni[2], Michael Yin[1]. [1]Columbia University, USA, [2]Columbia University Medical Center, USA

HIV infection is characterized by chronic T cell activation and proliferation, leading to senescence of immune cells. We hypothesize that chronic HIV infection is also associated with accelerated replicative senescence and exhaustion of the cellular proliferative capacity of bone cell precursors, which may negatively impact bone formation, especially in children infected with HIV early in life.A cross-sectional study was performed in 30 HIV-infected, on stable ART, and 15 HIV-uninfected men aged 20-25 years utilizing dual-energy x-ray absorptiometry (DXA) and flow cytometry to identify circulating ostegeogenic cells in peripheral blood mononuclear cells (PBMCs). Among HIV-infected men, 15 were perinatally-infected (PNI) and 15 were infected during adolescence (ADI). *Runx2*, osteocalcin (OCN) and CD34 antibodies, were used to identify specific osteogenic cell populations in lineage (LIN) negative PBMCs enriched for stem and progenitor cells. Our previous studies suggest that OCN+CD34- cells are more mature osteogenic cells than OCN+CD34+ cells, since they have lost the hematopoietic CD34 marker and express higher mRNA levels of *Runx2* and alkaline phosphatase. Relative average telomere length was measured in sorted osteogenic cells (LIN-/OCN+/Runx2+) using qPCR, and expressed as the relative ratio of telomere (T) to nuclear DNA (S) copies.DXA derived aBMD Z scores were 0.4-1.2 lower in HIV-infected men at the spine, femoral neck, total hip and radius (all $p<0.05$). The percentage of circulating osteogenic cells (LIN-/OCN+/*Runx2*+) in PBMCs, was significantly lower in both the PNI group (0.15+0.10%) and the ADI group (0.22+0.12%) than in uninfected controls (0.39+0.26%; $p<0.05$); but did not differ between HIV-infected groups. In contrast, the PNI group had a significantly lower percentage of mature osteogenic cells (LIN-/OCN+/*Runx2*+/CD34-; 55.6+27.3%) than both the ADI group (73.2+11.4%; $p<0.05$) and uninfected controls (67.2+6.8%; $p<0.05$). Similarly, the PNI group had shorter telomere lengths (T/S ratio: 2.3+0.2) in LIN-/OCN+ cells than both the ADI group (T/S ratio: 2.5+0.2; $p<0.05$) and uninfected controls (T/S ratio: 2.6+0.4; $p<0.05$).These data suggest that HIV infection, especially perinatal infection, is associated with replicative senescence, decreased numbers and maturation of circulating osteogenic cells, which may result in decreased number and function of osteoblasts at the bone, contributing to the observed decreased BMD in HIV-infected individuals.

MO0371

The Postprandial Response of Bone Turnover Markers in Patients with Inflammatory Bowel Diseases. Maria Yavropoulou*[1], Ioannis Karatzoglou[2], Maria Pikilidou[3], George Germanidis[2], John Yovos[3]. [1]Aristotle University of Thessaloniki, Greece, [2]Department of Gastrenterology, AHEPA Univ. Hospital, Aristotle University of Thessaloniki, Greece, [3]Department of Endocrinology & Metabolism, AHEPA Univ. Hospital, Aristotle University of Thessaloniki, Greece

Inflammatory bowel diseases (IBD) disturb bone metabolism through multiple mechanisms, such as malnutrition, corticosteroid treatment and disease-related inflammation. The exact underlying pathophysiology, however, is still not completely understood and data on the physiological skeletal responses, as is the postprandial reduction of bone resorption, in these patients are missing. To address this issue we studied the effect of oral glucose in bone turnover markers in patients with ulcerative colitis (UC) and Crohn's disease (CD).

Thirty patients with UC, 59 patients with CD and 45 healthy individuals matched for age and BMI were included in the study. Activity of the disease was assessed by calculation of the CD activity index (CDAI) and Mayo score for patients with CD and UC, respectively. All participants underwent an oral glucose tolerance test (OGTT) and serum levels of procollagen type 1 amino-terminal propeptide (P1NP) and β-carboxy-terminal cross-linking telopeptide of type I collagen (β-CTX) were measured at 0, 60 and 120 min.

Serum β-CTX was significantly lower in patients with UC compared to controls (278 $\pm$ 18 pg/ml vs. 380 $\pm$ 28 pg/ml p=0.004, respectively), while patients with CD had significantly higher values of serum β-CTX and P1NP compared to controls (β-CTX: 573 $\pm$ 24 pg/ml vs. 380 $\pm$ 28 pg/ml, and P1NP: 57 $\pm$ 6 ng/ml vs. 45 $\pm$ 4 ng/ml, $p<0.001$, respectively). Nevertheless, serum β-CTX was significantly correlated with serum P1NP levels in both patient groups (UC: r=0.439, p=0.015, CD: r=0.271, p=0.038) (Figure 1).

Oral glucose significantly suppressed β-CTX levels in patients and controls. Despite the significant differences in baseline values, the percentage decrease of serum β-CTX at 2h after glucose load did not differ significantly between patients with UC or CD and the controls (41.7% and 40% vs. 43.9%, respectively). Disease activity was significantly related to the degree of β-CTX suppression 2h after oral glucose in both diseases (r=0.913, $p<0.001$ in CD and r=0.953, $p<0.001$ in UC).

The physiological skeletal response of postprandial reduction of bone resorption is preserved in patients with IBD and is strongly related to the activity of the disease, probably reflecting a compensatory mechanism of the skeleton against the negative effects of IBD in bone metabolism.

Effectiveness of Teriparatide in the Treatment of Osteoporosis, Data from Real-World Clinical Practice. George Tsoukas[1], Philippe Tsoukas[2], George O. Tsoukas*[3], Louise Ullyatt[3]. [1]McGill University Health Center, Canada, [2]Department of Medicine, University College Dublin, Ireland, [3]Division of Endocrinology,McGill University Health Center, Canada

Objective: Although the efficacy of teriparatide in bone metabolism has been demonstrated in multiple controlled clinical trials, data from longitudinal observational studies are limited. Such studies are essential in understanding the real-world effectiveness of therapeutic interventions. In this study, we aim to demonstrate true population-based benefits of teriparatide in a clinical practice setting.

Methods: We conducted a retrospective chart review on patients treated with teriparatide for osteoporosis. Data was obtained from four endocrine clinics specialized in the treatment of osteoporosis. Patients were treated according to Canadian osteoporosis guidelines. We specifically examined interval changes in BMD, osteocalcin, total alkaline phosphatase, and type 1 collagen C-terminal telopeptide in patients treated with teriparatide for a mean of 18 or 24 months. Statistical analysis was performed using linear mixed model with repeated measures.

Results: A total of 286 patients were included in our analysis with a mean age of 71 years. Among these, 253 (88%) were female and 33 (12%) were male. At baseline, 65% of all patients had a documented history of two or more fractures. Vertebral fractures represented 60% of all prevalent fractures at baseline. Prior to initiating teriparatide, 70% of all patients had been treated with bisphosphonates. At baseline, the mean T-score was -3.7 for spine (L1-L4) and -2.3 for the hip (femoral neck). Duration of treatment varied with 60% of the patients receiving teriparatide for 18 months and 40% for 24 months. After an 24-month course of teriparatide, there was a net increase in BMD of 9% at the spine and 5% at the hip, corresponding to a change in T-score of +1.0 at the spine and no change at the hip. The results was maintained at 24 months. The total alkaline phosphatase, osteocalcin, and C-terminal telopeptide increased by 26.5%, 110.6%, and 105.9%, respectively, at 18 months. Compliance to therapy was reported to be 85% at 18 months.

Conclusions: Our results suggest that treatment with teriparatide for a mean duration of 18 months and 24 months significantly increased BMD of the spine in patients with osteoporosis. Changes in bone turnover markers were positively associated with BMD changes, indicating bone formation. Our findings are consistent with larger controlled clinical trials. We are currently examining fracture outcomes in these patients.

MO0373

Effects of Recombinant Human Parathyroid Hormone on the Anabolic Window and Lower Extremity Stress Fracture Healing in Premenopausal Women: A Pilot Study. Ellen Almirol*[1], Lisa Gao[1], Shelley Hurwitz[1], Bharti Khurana[1], Jennifer Baima[1], Eric Bluman[1], Christopher Chiodo[1], Meryl Leboff[2]. [1]Brigham & Women's Hospital, USA, [2]Brigham & Women's HospitalProfessor of Medicine, Harvard Medical School, USA

Stress fractures are the most common overuse injuries of the lower extremities and are 5 times more common in women than men. Although the anabolic therapy Teriparatide (TPTD) has advanced osteoporosis care, there are no approved systemic therapies for stress fractures. In this pilot study, we evaluated whether TPTD compared to placebo: increased markers of bone formation in advance of resorption, creating an anabolic window and hastened stress fracture healing on MRI.

Premenopausal women (aged 21-45 years) with lower extremity stress fractures diagnosed within 1 month of screening were eligible. Bone formation markers amino terminal propeptide of type 1 collagen (P1NP) and osteocalcin (OC), and resorption markers serum C-telopeptide (CTX) and urinary N-telopeptide (NTX) were measured at baseline, 4 and 8 weeks. To assess stress fracture severity, we used a MRI grading system. Grade 4 was most severe with a low-signal fracture line, while Grade 0 showed no edema or bone lesions. Groups were compared using the Wilcoxon Rank-Sum Test or Chi Square test, where appropriate.

Among 101 women screened, 13 women were randomized to TPTD, 20 μg s.c./d (n=6) or daily placebo injection (n=7) for 8 weeks. In the TPTD-treated group at 4 and 8 weeks, P1NP increased by 133.6 and 179.6% and OC by 409.6 and 859.1%, respectively. In contrast, the placebo-treated group at 4 and 8 weeks showed a smaller increase in P1NP of 8.5 and 15.2% ($p \leq 0.01$) and OC of 20.4 and 25.9%, ($p \leq 0.03$), respectively. There were no significant differences between groups in changes of bone resorption markers. The anabolic window was defined as the area between P1NP and CTX over the duration of the study. In the TPTD-treated groups vs. the placebo-treated group, the anabolic window was significantly greater (mean area $\pm$SEM of 145.82 ± 50.24 vs. 5.99 ± 18.30, $p \leq 0.05$) [Fig. 1]. According to the MRI grading scale at 8 weeks, 83.3% of the TPTD group and 57.1% of the placebo-treated group had improved or healed stress fractures with changes in MRI grading of $m=2.17 \pm 0.8$ vs. 1.86 ± 0.9, respectively ($p=0.31$); these differences were not significant.

In summary, use of TPTD compared to placebo in premenopausal women with lower extremity stress fractures resulted in early and robust rises in bone formation markers and a larger anabolic window. While the changes in bone healing are promising, larger prospective, controlled studies are needed to fully assess the potential effects of TPTD on stress fracture healing.

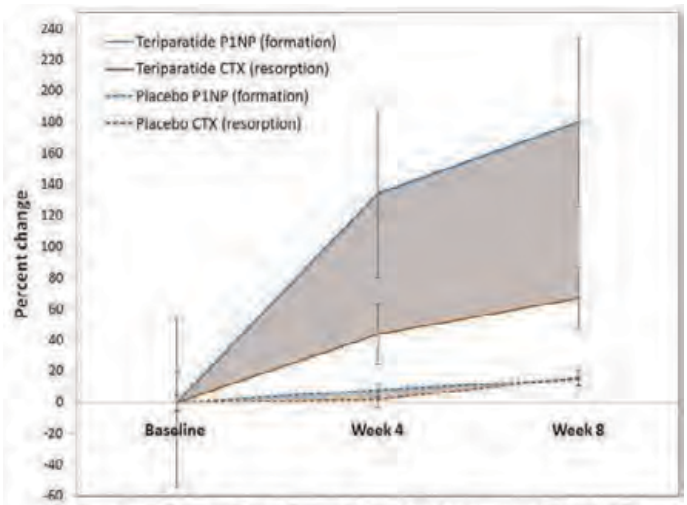

Figure 1: Mean Percent Change in Formation Marker P1NP and Resorption Marker CTX for Teriparatide and Placebo. Shaded Area between P1NP and CTX over 8 weeks indicate an anabolic window.

MO0374

Enhanced Bioavailability of a Nasal Formulation of Teriparatide with CriticalSorb™ Compared to a Subcutaneous Injection: A Non -invasive Approach for the Treatment of Osteoporosis. Faron Jordan*[1], Gareth King[2], Allan Williams[3], Richard Pearson[4], Alan Perkins[4], Tahir Masud[5]. [1]Critical Pharmaceuticals Ltd, United Kingdom, [2]Critical Pharmaceuticals, United Kingdom, [3]University of Nottingham, Vanuatu, [4]University of Nottingham, United Kingdom, [5]Nottingham University Hospitals NHS Trust, United Kingdom

Parathyroid Hormone (PTH) is an effective treatment for osteoporosis and unlike other therapies that reduce bone resorption, PTH increases bone formation resulting in greater bone mineral density. The biological activity of PTH resides in the N-terminal sequence with the 34 amino acid peptide (PTH1-34), [teriparatide]. Currently administration requires a subcutaneous injection and an intranasally delivered formulation would potentially improve patient convenience and may improve efficacy. In certain patient groups, it has been shown that nasal delivery is preferred over injections (Illum *et al.*, 2012).

CriticalSorb is an advanced nano-enabled nasal delivery system that facilitates the absorption of macromolecules across biological membranes. We have used this technology to develop CP046, a nasal spray formulation of teriparatide. Solutions of CriticalSorb and teriparatide were prepared and administered intranasally to Sprague Dawley rats and New Zealand white rabbits. The animals also received a subcutaneous injection of teriparatide in order to compare bioavailability. Blood samples were collected for up to 6 hours after administration and teriparatide concentrations in the plasma were analysed by LCMS/MS.

CriticalSorb proved to be highly effective at enhancing the transport of teriparatide across the nasal mucosa in both rats (Fig 1) and rabbits with a relative bioavailability of 79 and 64% respectively. When teriparatide was administered intranasally to rats without CriticalSorb the bioavailability was below 6%.

In conclusion, CriticalSorb is an effective absorption promoter for the systemic delivery of teriparatide via the nasal cavity and offers a non-invasive route for delivery. The pulsatile pharmacokinetics obtained following nasal delivery of teriparatide may further improve efficacy. Proof of concept has been demonstrated in animal models and a clinical trial is being carried out in post menopausal women to assess nasal deposition and clearance using gamma scintigraphy and to provide pharmacokinetic data comparing nasal and subcutaneous delivery in humans.

Higher Rates of Union in Older Patients with Type 2 and Type 3 Odontoid Fractures Treated with Teriparatide. Debra Sietsema*[1], Michael Merrick[2], Casey Smith[2], Tan Chen[3], Scott Russo[4], Clifford Jones[1], James Stubbart[1]. [1]Orthopaedic Associates of Michigan; Michigan State University, USA, [2]Grand Rapids Medical Education Partners, USA, [3]Michigan State University, USA, [4]Orthopaedic associates of Michigan, USA

Purpose: High rates of morbidity and mortality are a major concern in older patients with odontoid fractures. Teriparatide is an anabolic drug approved for use in patients with osteoporosis at high risk for fracture. The only published evidence of teriparatide use in patients with odontoid fractures is a case report of three patients who went on to union after delayed healing. The purpose of this study was to determine the effect of teriparatide on union rates in older patients with odontoid fractures.

Methods: Between 2002 and 2011, 97 consecutive patients, age 65 years and over, with type 2 and type 3 odontoid fractures were treated at a single Level I trauma center, were followed in a single private practice, and retrospectively evaluated. Eight patients were treated with teriparatide for osteoporosis and were at high risk for a subsequent fracture. Radiographs were reviewed and fusion was determined by flexion/extension x-rays, CT scan, or both. Twenty-three mortalities were excluded from the union analysis and one patient was lost to follow-up prior to fusion evaluation.

Results: Of the 8 patients receiving teriparatide, there were 2 males and 6 females with an average age of 79 (range 67-88) and body mass index (BMI) of 25.9 (range 19.9-34.0). In the non teriparatide group, there were 29 males and 36 females with an average age of 80 (range 65-93) and BMI of 27.1 (17.1-37.5). The Charlson score was 1.5 (range 0-3) in the teriparatide group as compared to 2.0 (range 0-9) in the non teriparatide group. Odontoid classification was six Type 2 and two Type 3 in the teriparatide group and 49 Type 2 and 16 Type 3 in the non teriparatide group. Operative treatment was performed in 3 (38%) of the teriparatide group and in 19 (29%) of the non teriparatide group. The T-score in the teriparatide group averaged -3.2 (-2.4 to -3.9) compared to -2.4 (-1.0 to -4.9) in the non teriparatide group. Patients treated with teriparatide had a higher rate of union (7/8, 87.5%) compared to patients who did not receive teriparatide (45/65, 69.2%). The time from initiating teriparatide to fusion averaged 97 days (range 36-206 days).

Conclusion: Teriparatide may lead to higher union rates in type 2 and type 3 odontoid fractures. Teriparatide should be considered as a supplemental treatment in the elderly with odontoid fractures at high risk for subsequent fracture. More studies with larger sample sizes including other contributing factors are needed to confirm this finding.

MO0376

Progression of Vertebral Compression Fractures during Anti-Osteoporotic Therapy: Bone Turnover Markers and Radiographic Evidences in the First Six Months. Costantino Corradini*[1], Cesare Verdoia[2]. [1]State University of Milan, Italy, [2]Orthopaedic Clinic University of Milan, Italy

Introduction: In postmenopausal women with vertebral compression fractures (VCF) the mechanisms regulating healing processes and an anti-osteoporotic treatment are not completely clarified. The aim of this prospective study was the evaluation of bone turnover markers, bone mineral density and radiographic progression of one or more VCF during assumption of risedronate, strontium ranelate or teriparatide. Materials and methods: Women with recent osteoporotic VCF verified through magnetic resonance were assigned to receive either risedronate (RIS group, n = 19) or strontium ranelate (SR group, n= 16) or teriparatide (TPTD group, n = 24) following guidelines of Italian regulatory agency. Serum and urinary bone turnover markers and lateral thoraco-lumbar spine X-rays were obtained at 0, 1, 3 and 6 months of therapy. Lumbar BMD was measured by DEXA before and 6 months after treatment initiation. Results: At time 0 serum markers of bone formation alkaline phosphatase (ALP), osteocalcin (OC) and of bone resorption desoxipiridoline (DPD) but also osteoprotegerin (OPG) were around higher level of normality, while sclerostin (SOST) was substantially unchanged. Between 1st and 3rd month within the consolidation process OC peaked in TPTD group while those in RIS group and SR group remained significantly lower. In the same period ALP levels decreased in RIS group, unchanged in SR group and increased in TPTD group. DPD remain high in TPTD group; while in all groups were significantly and constantly reduced in 6 month. Serum OPG levels remained unchanged in RIS group and SR group while reduce in TPTD group. SOST was significantly increased 6 months in RIS group, whereas remained statistically unaffected in the TPTD group. Lumbar BMD increased at 6 month in all groups and significantly in TPTD group. An inconstant progression in VCF on radiograms were detected in RIS and SR groups. Some levels were more involved of others.Conclusions: In recent osteoporotic VCF a divergence between the formation and resorption markers has been revealed between anti-osteoporotic therapies with a different radiographic progression. The clinical relevance is the possibility of choice different anti-osteoporotic treatments on radiographic and metabolic behaviour of VCF. Bibliography: Corradini C. Aging Clin Exp Res. 2011;23(2 Suppl):45-6.

MO0377

Bisphosphonates and Alveolar Bone with Reference to Bone Mineral Density and Osteoporotic Fracture. Takuo Fujita*[1], Yoshitomo Takaishi[2], Mutsumi Ohue[1], Takami Miki[3], Yoshio Fujii[4], Tsuyoshi Jotoku[5]. [1]Katsuragi Hospital, Japan, [2]Takaishi Dental Clinic, Japan, [3]Osaka City University Medical School, Japan, [4]Calcium Research Institute Kobe Branch, Japan, [5]Department of Orthopedic Surgery, Osaka Medical College, Japan

Background: Osteoporosis and periodontal disease tend to occur in parallel. Alveolar bone mineral density (al-BMD) measured by computed densitometry (Bone Right) was reported to be more closely associated with osteoporotic fracture than widely used lumbar bone mineral density (LBMD). In view of the high al-BMD at the site of jaw bone necrosis on Bisphosphonate (BP) use (Takaishi et al 2010), BP effect on alBMD was studied.

Methods: Among 148 women consulting the Osteoporosis and Osteoarthritis Clinic of Katsuragi Hospital, BP (etidronate, alendronate, risedronate and minodronate) were given in 83 (mean age $\pm$SD, 68 $\pm$7), but not in 65 others (63 $\pm$11). Except for the higher age, no significant difference was seen between the two groups as to al-BMD, LBMD, FNBMD and fracture frequency (47.6% in N and 47.0% in B).

Results: Significant positive correlation was found between the duration of BP treatment and al-BMD (r=0.225, p=0.0428), LBMD(r=0.256, p=0.0185) and FNBMD (r=0.204, p=0.0367). ROC curves constructed to assess the predictability of facture stayed similar regardless of the use of BP as to LBMD and FNBMD, but markedly differed for al-BMD. On the use of BP (Group B), predictability for fracture almost disappeared with he AUS-0.5 value of 0.15 exhibiting a drastic fall from 0.148, contrasted to the corresponding values indicating fluctuations from 0.118 to 0.158 for LBMD and 0.123 to 0.146 for FNBMD. BMD fall along with fracture was 9.9% for BR, evidently higher than -1.7% for LBMD, and 2.7% for FNBMD. A possible explanation is a marked sensitivity of alveolar bone to BP with sustained increase of al-BMD compared with other sites, interfering with the evaluation of BMD-fracture relationship. One way analysis of variance revealed significantly greater rise of BR in response to BP than LBMD (p=0.0040) and FNBMD (p=0.0031). Compared with the group without BP treatment, only the subgroup treated with etidronate for more than 6 months achived a significantly higher al-BMD, but not LBMD or FNBMD, suggesting a role of etidronate augmenting the action of N-containing BP.

Conclusion: Decrease of al-BMD seems to be more intimately associated with fracture than that of LBMD and FNBMD without, but not with BP treatment. Alveolar bone appear to respond to BP differently from LBMD and FNBMD with more pronounced and sustained increase.

MO0378

Comparison of the Efficacy, Adverse Effects and Cost of Zoledronic Acid and Denosumab In the Treatment of Osteoporosis. Kellen Sheedy*[1], Isabel Camara[2], Pauline Camacho[3]. [1]Loyola University Stritch School of Medicine, USA, [2]University of Notre Dame, USA, [3]Loyola University of Chicago, USA

Injectable osteoporosis drugs are increasing in popularity due to their efficacy and convenient administration. There are currently two injectable osteoporosis treatments administered in an outpatient setting, denosumab (Prolia®) and zoledronic acid (ZA, Reclast®). In this first direct comparison of these two treatments, we aimed to determine and compare the efficacy and tolerability of denosumab and zoledronic acid.

Patients who received denosumab and ZA at Loyola University Medical Center were included in this retrospective study. The charts of both groups were reviewed and adverse events were noted. Of primary interest were myalgias, flu-like symptoms, back pain, and fractures. A questionnaire regarding the efficacy, tolerability and cost of treatment supplemented this chart review in a subset of the study participants. Statistical analysis was used to compare bone mineral density changes, bone turnover markers, and questionnaire results.

The study cohort consisted of 107 patients, 51 patients in the denosumab group and 56 patients in the ZA group. A subset of 29 patients responded to the questionnaire. The denosumab group had a greater mean increase in spine BMD at one year of 0.060g/cm^2 than the ZA group, 0.021g/cm^2 (p=0.04, two sample t-test). The change in femur T-score and BMD, and change in spine T-score at one year were not significantly different between the two groups. The ZA group had a significantly greater incidence of mild flu-like symptoms compared to the denosumab group (29% ZA group, 0% D group; p=0.04, Fisher's exact test). No significant differences in bone specific alkaline phosphatase, back pain, muscle pain, or patient satisfaction were observed. Of the questionnaire respondents, all of the ZA treatments were covered by insurance and only two participants had a copayment ($150 and $1500); 93% of the denosumab treatments were covered by insurance and three participants had a copayment ($70, $200, and $1800 for two treatments).

The denosumab group had a higher mean increase in spine BMD, and the ZA group had a higher incidence of flu-like symptoms, but the two study groups were statistically similar in patient satisfaction. Since denosumab is still a relatively new therapy, there were a limited number of patients with post-treatment data available for comparison. As more post-therapy data becomes available, the categories that were significantly different can be further investigated.

MO0379

Denosumab is here – do intravenous bisphosphonates still have a role?. Rosaleen Lannon*[1], Michael O'Callaghan[2], Nessa Fallon[2], Miriam Casey[2], James Bernard Walsh[3]. [1]St James's Hospital, Ireland, [2]Bone Health Unit, St James's Hospital, Ireland, [3]Trinity College Dublin, The University of Dublin, Ireland

Denosumab is here - do intravenous bisphosphonates still have a role?

Background: Denosumab is available to treat severe osteoporosis in Ireland for 30 months. Prior to release our options with regard to patients who were intolerant, non complaint or unresponsive to oral therapies were recombinant parathyroid hormone therapy or intravenous bisphosphonates. The former has certain specific indications and is costly leaving the later to ''fill the gap'' so to speak; that is until the introduction of denosumab.

Method: We reviewed our rates of first prescription of iv zoledronic acid and denosumab since the introduction of denosumab in late 2010 in our specialist bone clinic. We compared this to the rate of first prescription of iv zoledronic acid in the one year prior.

Results: Rate of prescription of iv zolendronic acid has declined significantly as denosumab use has increased. However iv zoledronic acid still plays a major role in our treatment of osteoporosis. In 2010 iv zoledronic acid was prescribed for the first time in 267 patients. Denosumab was prescribed 7 times towards the end of the year. In 2011 iv zoledronic acid was prescribed 211 times with denosumab issued 80 times. In 2012 iv zolendronic acid was prescribed 146 times with denosumab prescribed 153 times. Interestingly use of drugs combined remains similar over these two years.

Conclusion: Denosumab is a very useful addition to the treatments for osteoporosis which is convenient and cost effective as it can be administered in the community rather than a day ward setting. It has led to a 46% reduction in use of iv zoledronic acid in our service. It is also well tolerated. No dose adjustment is necessary and it is suitable for patients with chronic kidney disease. Nevertheless iv zoledronic acid remains available as a potent antiresorptive. It is the treatment of choice in complex medical patients attending our service such as those with transplants or autoimmune conditions as well as useful in augmenting the gains of 2 years of anabolic treatment with recombinant PTH. Denosumab has emerged as a competitor in this domain.[1] We conclude that iv zoledronic acid remains pivitol in our treatment options for osteoporosis.

Development of a Claims-based Algorithm to Identify Prolia Use in Medicare Data. Nicole Wright*, Rui Chen, Tarun Arora, Huifeng Yun, Elizabeth Delzell, Jeffrey Curtis. University of Alabama at Birmingham, USA

Purpose: Prolia, a new biologic agent for osteoporosis (OP) launched May 26, 2010, was originally billed in Medicare Part B with non-specific Healthcare Common Procedure Coding System (ns-HCPCS) codes. These codes do not uniquely identify the drug being administered. Our objective was to develop a claims-based algorithm to identify Prolia and distinguish it from other injection or infusion medications using ns-HSCPS codes in Medicare data.

Methods: We used 2010 Medicare Part B data from a cohort of beneficiaries with OP age 65 years and older with at least one month of Medicare Parts A, B, and D coverage, without Medicare Advantage. We selected Part B claims with ns-HCPCS codes from launch date to 12/31/2010. We reviewed information such as service date, units given, allowed amount, submitted amount, and associated diagnosis codes from claims with the specific Prolia HCPCS code, in limited use since 10/2010, to derive the algorithm. We evaluated claims for two other agents with attributes similar to Prolia using ns-HSPCS in 2010 (tocilizumab (TCZ) & Ozurdex (OZD)). The final algorithm classified each ns-HCPCS claim as Likely, Probably, Possibly, or Unlikely Prolia. We evaluated differences in characteristics between the groups, focusing on the Likely and Unlikely claims.

Results: Our study included 89,581 beneficiaries with 197,043 claims with ns-HCPCS codes. We identified 11,557 duplicate/redundant claims, 1,610 TCZ, and 296 OZD claims. Algorithm development used 1,061 Prolia claims with the specific HCPCS code. Our final algorithm identified 10,438 Likely, 483 Probably, 134 Possibly, and 174,381 Unlikely Prolia claims. A larger proportion of Likely claims had an OP diagnosis code on the same claim than the Unlikely claims (99.4% vs 8.5%). Similarly, the proportion of Likely claims (85.3%) with the appropriate Prolia allowed amount, $874.50-$874.80, was larger than that of the Unlikely claims (0.0%).

Conclusions: Our algorithm appeared successful at identifying Prolia users in Medicare with good internal validity. An external source to examine the sensitivity and specificity of the algorithm is needed for further validation.

MO0381

DEVIDE-Study: DEnosumab Versus Intravenous Ibandronate – a 24 months retrospective head to head real life study - Study Design. Astrid Fahrleitner-Pammer*[1], Christian Muschitz[2], Heinrich Resch[3], Doris Wagner[4], Karin Amrein[5], Stefan Pilz[5], Andreas Tomaschitz[5], Thomas Pieber[5], Hans Dimai[1]. [1]Medical University Graz, Austria, [2]St. Vincent's Hospital, Austria, [3]Medical University Vienna, Austria, [4]Department for Transplantation, Medical University Graz, Austria, [5]Medical University Graz, Department for Internal Medicine, Austria

Purpose: Effective treatment of postmenopausal osteoporosis (PMO) is frequently compromised by poor persistence and adherence to short-term (≤ 1-monthly) medications. Several head to head trials comparing the efficacy of Denosumab with that of oral Bisphosphonates (BP) are available so far, indicating a superior effect of Denosumab on bone markers and BMD (STAND, DECIDE, TTR, TTI). All of these studies have been conducted as randomized controlled clinical trials and compare the effect of an oral with a parenteral therapy. Aim of this study which has been performed in a real-life setting, is to investigate the effect of parenteral ibandronate (IBN) compared to denosumab treatment in a cohort of IBN pretreated PMO patients.

Methods: In a retrospective analysis, a total of 808 patients with PMO were analyzed. All women are regularly monitored at the osteoporosis outpatient clinic at the Medical University of Graz (Austria) or the St. Vincent Hospital of Vienna (Austria). All patients had received parenteral IBN therapy due to intolerance or contraindications to oral BP therapy. After Denosumab was launched for treatment of OPO, 366 women were switched to receive this therapy due to their own or their physician's decision, whereas the remaining 442 stayed on IBN intravenously every three months. Effectiveness in terms of fracture incidence, BMD, BTM, as well as adherence and safety of these two parenteral therapies are analyzed.

Results: Mean age of the population at baseline was 66 + 7 years. All patients had primary PMO, and were treated with quarterly IBN injections for a median time period of 27 + 6 months. BMD readings, fracture status, age, body mass index, bone turnover markers (BTM) as well as safety laboratory parameters were comparable among the two treatment groups. Laboratory testing, recording of adverse events was done every 6 months, and BMD readings, spinal X- ray and fracture assessment were performed at baseline as well as after 12 and 24 months of IBN or Denosumab therapy.

Conclusion: The results of this study not only will provide clinicians with insight into persistence with denosumab in comparison to IBN therapy, but will also compare the effect of denosumab with a parenteral administered BP.

MO0382

Evaluation of odanacatib in subjects with hepatic insufficiency. Stefan Zajic[1], Michelle Trucksis[2], Graig Garrett[2], Anish Mehta[2], Patrice Auger[3], Nancy Wang[3], Daria Stypinski[3], Anne Hohnstein[3], Megan Kozisek[3], Bruce DeGroot[3], Gautam Baheti[4], Cindy Dempsey[3], Richard A. Preston[5], Aubrey Stoch*[6]. [1]Merck Research Laboratories, USA, [2]Merck Sharp & Dohme Corp., USA, [3]Celerion, USA, [4]Parexel, USA, [5]University of Miami, USA, [6]Merck Sharp & Dohme, USA

Objectives: Hepatic elimination is an important metabolic pathway for odanacatib, a cathepsin-K inhibitor in development for the treatment of osteoporosis. We conducted 2 clinical studies to determine the effect of hepatic insufficiency (HI) on the pharmacokinetics (PK) of odanacatib.

Methods: Two open-label studies compared the PK of single-dose odanacatib 25 mg (Study 1) and single-dose 50 mg (Study 2) in subjects with HI versus healthy matched control subjects. Study 1 evaluated mild HI subjects (score of 5-6 on Child-Pugh's scale) and matched control subjects in Part I after dosing with odanacatib 25 mg; if data demonstrated acceptable tolerability and PK levels, subjects with moderate HI (score of 7-9 on Child-Pugh's scale) and matched control subjects were evaluated after dosing with odanacatib 25 mg. Study 2 evaluated moderate HI subjects after dosing with odanacatib 50 mg. The primary PK measurement was $AUC_{0-\infty}$. Blood and urine samples were analyzed for serum CTx and urine NTx/Cr in Study 1. Vital signs and adverse events (AE) were monitored throughout the studies.

Results: Subjects –Study 1 included 40 male and female subjects (ages 41-62 years), 10 with mild HI, 10 with moderate HI and 20 healthy matched control subjects. Study 2 included 17 male and female subjects, 8 with moderate HI and 9 healthy matched control subjects. In Study 1, the $AUC_{0-\infty}$ geometric mean ratio (GMR) (90% CI) was 0.95 (0.68, 1.31) for mild HI/healthy controls and 0.81 (0.62, 1.06) for moderate HI/healthy controls after administration of odanacatib 25 mg. In Study 2, the $AUC_{0-\infty}$ GMR (90% CI) was 0.85 (0.61, 1.19) for moderate HI/healthy controls after administration of odanacatib 50 mg. Biomarker data in Study 1 showed that, at 168 hours postdose (odanacatib 25 mg), the LS Mean (95% CI) change in serum CTx was -63.7 (-75.1, -47.2) in mild HI subjects and -41.0 (-59.5, -13.9) in healthy controls, while LS Mean (95% CI) change in serum CTx was -62.2 (-73.0, -47.2) in moderate HI subjects and -39.8 (-56.7, -16.3) in healthy controls; Urine NTx results were consistent with those observed for serum CTx. There was one subject with serious AEs (sinusitis, mastoiditis, otitis followed by pneumococcal meningitis) in Study 1. There were no serious AEs in Study 2.

Conclusions: The $AUC_{0-\infty}$ of odanacatib 25 mg and 50 mg was not meaningfully altered in subjects with mild or moderate HI. The slightly decreased PK in moderate HI subjects may reflect differences in odanacatib plasma protein binding in this group. Preliminary biomarker data (serum CTx, urine NTx/Cr) demonstrate comparable pharmacodynamic efficacy with odanacatib in patients with mild or moderate HI when compared to healthy matched controls. Odanacatib was generally well tolerated.

Intravenous Ibandronate Increases Femoral and Vertebral Strength Measured by Finite Element Analysis in Male Patients with Idiopathic Osteoporosis and Fragility Fractures. Christian Muschitz*[1], Dieter Pahr[2], Michael Kinzl[2], Benoit Luiser[2], Afrodite Zendeli[3], Roland Kocijan[4], Judith Haschka[4], Wolfgang Schima[5], Heinrich Resch[6]. [1]St. Vincent's Hospital, Austria, [2]Institute of Lightweight Design & Structural Biomechanics University of Thechnology, Austria, [3]The VINFORCE Study Group - St. Vincent Hospital - Medical Department II, Austria, [4]St. Vincent Hospital Vienna, Austria, [5]Institute of Radiology - St. Vincent Hospital, Austria, [6]Medical University Vienna, Austria

Purpose: Male idiopathic osteoporosis (MIO) is a metabolic bone disease characterized by low BMD, micro structural alterations, reduced mineralization of cortical structures resulting in increased fracture risk in otherwise healthy men. The evidence of antiresorptive treament for MIO is lower than those for postmenopausal osteoporosis. Volumetric BMD measurements and strength predictions using voxel-based finite element (FE) simulations of the vertebral body and the proximal femur predict alterations in strength and stiffness. The hypothesis of this study was to test if ibandronate (IBN) improves biomechanical properties of femoral and vertebral bone in MIO.

Methods: 13 treatment naïve MIO patients from a prospective paired biopsy study - mean age 53.0 [44.5; 57.0] years - with prevalent fragility fractures and low BMD received 3mg intravenous IBN for 24 months quarterly. QCT (baseline/month 24) of Th12 and hip were assessed to compare BMC, vBMD, BV/TV, areal bone volume fraction (aBMD), stiffness and ultimate force by using FE simulations for fall (femur) and compressive (vertebra) loading.

Results: At the proximal femur the average strength increase (%) was 4.9 ± 8.9 (range -8.4 to 16.5, $p<0.01$; 3 patients below 0). Pronounced increases were observed for trochanteric aBMD (2.9 ± 2.6) and BV/TV of FE models (3.7 ± 1.7, $p<0.05$), with less effect in the neck region (0.7 ± 1.5). Most hip fracture types observed by FE simulated side-fall scenarios were discovered in the trochanteric region. Regressions between strength increase and vBMD increases showed no correlation for BMC, BMD, BV/TV or aBMD ($R2<0.04$). In the vertebral body the mean strength increase was 7.3 ± 9.2 (range -2.7to 31.9, 2 patients below 0) with most pronounced increase for BMC ($9.4 \pm 10.5\%$); BV/TV distributions increased both at cortical shell and trabecular center ($p<0.01$). A strong correlation was found for increase in strength and BV/TV ($R2=0.80$) and between BV/TV, BMD and BMC ($R2>0.65$). Predicted fracture locations based on damage patterns by FE simulation were similar between baseline and follow up.

Conclusions:

This study clearly shows decisive positive effects of intravenous IBN treatment on biomechanical properties at the hip and spine in patients with MIO comparable postmenopausal osteoporosis. FE simulations are more sensitive and provide improved detailed insight than BMD measures alone, especially for side-fall simulations, since the fracture position and the local BMD increase can be considered.

Lycopene Supplementation Improved the Response of Postmenopausal Women With Osteoporosis to Alendronate Therapy: A 12-Month Follow-Up Study. Mohammed-Salleh Ardawi*[1], Mohammed Qari[2], Abdulrahim Rouzi[1], Sharifa Al-Sibiani[3], Nawal Al-Senani[3], Bader Mustafa[4]. [1]Center of Excellence for Osteoporosis Research & Faculty of Medicine, Saudi Arabia, [2]Center of Excellence for Osteoporosis Research & Department of Haematology & KAU Hospital,Faculty of Medicine, King Abdulaziz University, Saudi Arabia, [3]Center of Excellence for Osteoporosis Research & Department of Obstetrics & Gynecology, Faculty of Medicine & KAU Hospital, King Abdulaziz University, Saudi Arabia, [4]Center of Excellence for Osteoporosis Research, King Abdulaziz University, Saudi Arabia

Background: Alendronate (ALN),a potent inhibitor of bone resorption, has been shown to be very effective in the treatment of osteoporosis. Lycopene is a potent antioxidant. No information is available on the combined effects of ALN therapy with lycopene supplementation. We studied the effect of lycopene supplementation on ALN therapy in relation to bone mineral density (BMD) and bone turnover markers among postmenopausal women with osteoporosis.

Methods: This is a randomized prospective study with a 12-month follow-up. A total of 180 postmenopausal women (aged 61.2 ± 5.5 years) with osteoporosis were randomized into two groups: ALN-Lyco (70 mg/week) and lycopene (30 mg/day) (n=90) as compared with ALN only (70 mg/week) (n=90). All women were supplemented with calcium (600 mg) and vitamin D3 (400 IU) daily. BMD (measured by DXA) and levels of bone turnover markers (BTMs) including: serum osteocalcin (s-OC), serum procollagen type 1 N-terminal (s-P1NP), serum bone-specific alkaline phosphatase (s-bone ALP), plasma cross-linked C-terminal telopeptide of type 1 collagen (p-CTX), urinary N-telopeptide of type 1 collagen (u-NTX) were measured at baseline and at 3, 6 and 12 months of therapy. BMD and BTMs were compared between the baseline and the end of therapy, and the changes in BMD and BTMs were also compared between the two treatment groups.

Results: After 12-month therapy, ALN-Lyco group showed significantly higher percentage increases in BMD at lumbar spine (L_1-L_4), neck femur and total hip (5.35%, 4.12% and 3.74%, respectively) as compared with ALN therapy group (4.92%, 3.81% and 3.22%, respectively; $P<0.001$, each). Relative to baseline, by 12 months the ALN-Lyco group had greater reductions in s-OC (-46% vs -136%), s-bone-ALP (-58% vs -42%), s-P1NP (-65% vs -45%), p-CTX (-75.2% vs -58.5%), u-NTX (-66.1% vs -49.2%) compared with ALN group, respectively ($P<0.001$, each). There was no difference between groups and those who experienced falls or fractures, and adverse events were similar among the two groups.

Conclusions: Lycopene supplementation with ALN therapy produced greater gains in BMD and greater reductions in BTMs than ALN treated group. We suggest the addition of lycopene supplementation to antiresorptive therapy in postmenopausal women with osteoporosis.

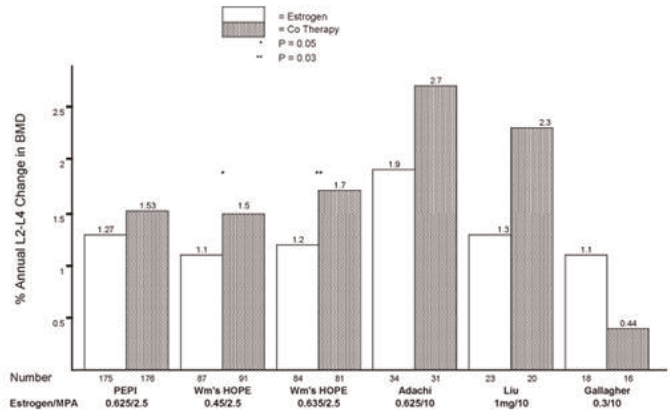
MO0385

Randomized Trials Show Greater Bone Mineral Density Increase on Estrogen plus Progestin Versus Estrogen Alone—progestin effect on bone formation?. Jerilynn Prior*, Shirin Kalyan. University of British Columbia, Canada

Progesterone and progestins including medroxyprogesterone (MPA) sit on osteoblast receptors and increase osteoblast numbers and proliferation. However, progesterone and non-androgenic progestins do not suppress bone resorption, the more rapid phase of human bone remodelling and thus alone are ineffective osteoporosis therapy. Current bone-formation stimulating osteoporosis therapy is via daily injection and expensive. However, if co-therapy of an antiresorptive plus progesterone increased areal bone mineral density (aBMD) more than the antiresorptive alone, this co-therapy might provide effective fracture prevention at a lower cost. Purpose: to review randomized controlled trials (RCT) of estrogen alone (CEE) versus co-therapy with MPA (CEE-MPA) on annual change in spinal aBMD. Methods: Data from all RCTs including an estrogen and an estrogen-MPA arm were reviewed (PEPI, Women's Hope, Liu NIH progestin-bone, Adachi and Gallagher trials). Results: Of these six, five showed numerically greater co-therapy spinal aBMD

increases over CEE alone and two reported significant differences (See*in Figure). The PEPI intent-to-treat analysis also showed significantly greater aBMD increases on CEE-low dose MPA than CEE alone. These RCTs tested full dose CEE (0.625 mg/d) or estradiol plus 2.5 mg/d MPA vs. estrogen alone (PEPI, Women's Hope, Liu) except for CEE 0.3 in the negative trial (Gallagher). The Women's HOPE RCTs showed significantly greater 2-y L2-4 aBMD gains on combined CEE 0.625 mg/MPA 2.5 mg vs. CEE 0.625 therapy alone (3.5% vs. 2.4%, P=0.03); CEE 0.45/MPA was also significant. Co-therapy with both full-dose CEE or estradiol and MPA (10 mg) caused 44% and 77% greater aBMD gains respectively in the Adachi and Liu studies but did not reach significance due to a lack of power. Summary: combined CEE-MPA therapy appears to increase lumbar aBMD more than CEE alone. Additionaltrials are needed that combine antiresorptives such as bisphosphonates [SK1] with physiological progesterone that assess changes in aBMD and bone strength.



n this Figure estrogen-only therapy is shown in open boxes and estrogen-MPA co-therapy in the stippl

MO0386

Results of Secondary Fracture Prevention Program in Patients with Severe Osteoporosis in Rambam Health Care Campus. Sophia Ish-Shalom*[1], Elena Segal[1], Marina Nodelman[2], Marina Hefetz-Kustanovich[1], Doron Norman[1]. [1]Rambam Health Care Campus, Israel, [2]Western Galilee Hospital, Israel

The risk of additional osteoporotic fractures in a patients that underwent a fragility fractures is at least 6 fold higher than in age and gender matched adults. Treatment strategies should be directed to provide intensive fracture prevention treatment to patients with osteoporotic fractures.

A collaborative (ortopedics and bone metabolism) fracture prevention program for patients that were hospitalized with osteoporotic fractures was initiated in Rambam Health Care Campus in 2008. All patients that were hospitalized with fractures were offered fracture prevention treatment after surgical fracture repair.

Results: 1647 patients, aged median 78 (range 23-103), 1165 (71%) women aged 78 (33-100) and 482 (29%) men aged 77 (23-103) were enrolled in the program between 2008 – 2013. Proximal femoral fractures were sustained by 1115 (68%) of all patients: 769 (66%) of women and 346 (72%) of men; 256 (16%) of patients died during the study period, 152 (13%) of women and 104 (22%) of men; in hip fracture patients 123 (16%) of women and 89 (26%) of men. The relative risk (RR) of men to die after a hip fracture was 1.61 (95% CI 1.26-2.05) compared to women. The major predictors of death in women were greater age, number of medications, creatinine and lower albumin; in men, greater age, number of medications, and creatinine. 264 (23%) of all women and 10 (2%) of all men were treated for osteoporosis before admission and 171 (22%) of women with hip fractures and 6 (2%) of all men with hip fractures. After discharge 404 (35%) of all women and 42 (9%) of all men received treatment; of hip fracture patients, 247 (32%) of women and 31 (9%) of men received treatment. While no factors were related to increased likelihood of men being treated, women were more likely to be treated if they had any previous fractures, previous treatment, higher vitamin D or albumin, and lower creatinine. Treatments distribution in all patients was: 319(19.3%) received oral bisphosphonates, 73 (4.45%) IV bisphosphonates (Zoledronate), 2 (0.12%) pamidronate), 47 (2.87%) teriparatide, 5(0.31%) raloxifen.

We conclude that in spite of a marked increase in the rate of patients that were treated after an index fracture, in a hospital initiated collaborative treatment program, it is still unsatisfactory . The use of of IV bisphosphonates, approved as first line therapy after hip fracture in Israel, is still very low.

Risedronate Improves Proximal Femur Bone Mineral Density and Geometry Parameters Over 5 Years in Patients with Osteoporosis or Osteopenia and Clinical Risk Factors of Fractures: A Practice-Based Observational Study. Masayuki Takakuwa[1], Jun Iwamoto*[2]. [1]Takakuwa Orthopedic Nagayama Clinic, Japan, [2]Keio University School of Medicine, Japan

Advanced Hip Assessment (AHA) software installed in a dual-energy X-ray absorptiometry (DXA, GE-Lunar) can be used to evaluate bone strength indices as well as bone mineral density (BMD) of the proximal femur. In particular, Femur Strength Index (FSI) is calculated using structural geometric properties, neck shaft angle, height, and body weight. The purpose of this study was to investigate the 5-year effects of risedronate treatment on AHA parameters of the proximal femur and BMD of the lumbar spine and proximal femur in patients with increased risk of fractures. In total, 181 patients (mean age: 68.1yrs; 172 females and 9 males) with osteoporosis or osteopenia and clinical risk factors of fractures were treated with risedronate for 5 years in our outpatients clinic. AHA parameters of the proximal femur and BMD of the proximal femur and lumbar spine (L1-L4) were evaluated every 1 year over 5 years. The mean percentage changes from baseline in FSI after 12 months of risedronate treatment were 7.9% ($p<0.001$) for the right femur and 7.0% ($p<0.001$) for the left femur. The respective values for the right femur after 24,36,48 and 60 months of treatment were 12.3%, 14.5%, 10.9% and 11.0% ($p<0.001$) and those for the left femur were 10.8%,13.3%, 18.8 ($p<0.001$)% and 9.7% ($p<0.01$). Cross-sectional moment of inertia (CSMI : right femur 9.3%, left femur 13.0% after 60months $p<0.001$), cross-sectional area (CSA), mean neck width(d3) in the femoral neck, and BMD of the right and left proximal femur and BMD of the lumbar spine also continued to increase during 5 years of treatment. The increases in FSI and CSMI in the proximal femur at each time point were apparently greater than those in the proximal femur and lumbar spine BMD. These results suggest that risedronate treatment may more significantly improve femoral strength parameters than BMD of the proximal femur and lumbar spine over 5 years. Thus, it has been demonstrated that risedronate dose not only increase lumbar spine and proximal femur BMD, but also more significantly improves bone strength indices of the proximal femur in patient with increased risk of fractures.

MO0388

The change of serum osteocalcin is not associated with the changes of insulin secretion or resistance in osteoporotic patients treated with bisphosphonate. Deog-Yoon Kim*[1], Seong-Hun Hong[2], Jin Kyung Hwang[2], You-Cheol Hwang[2], In-Kyung Jeong[2], Kyu Jeong Ahn[2], Ho-Yeon Chung[3]. [1]Kyung Hee University Hospital, South Korea, [2]Kyung Hee University School of Medicine, South Korea, [3]Kyung Hee University, South Korea

Osteocalcin, a protein secreted by osteoblasts and released from the bone matrix during osteoclastic bone resorption, has been found to control blood glucose levels by increasing insulin production and sensitivity. Bisphosphonate is used in osteoporosis treatment to repress osteoclast activity, which then decreases levels of osteocalcin. The question addressed by this study is whether decreasing osteocalcin by bisphosphonate treatment can provoke a change in glucose homeostasis.

Eighty-four patients with osteoporosis were treated with once-weekly risedronate 35 mg and cholecalciferol 5600 IU. We measured fasting plasma glucose, insulin, and undercarboxylated and carboxylated osteocalcin at baseline and after 16 weeks. To estimate insulin sensitivity and β-cell function, HOMA-IR and HOMA-B% were calculated, respectively.

The mean fasting plasma glucose of all subjects increased significantly from 5.3 to 5.5 mmol/L, but no changes in blood glucose were noted in 24 subjects with impaired fasting glucose. The levels of undercarboxylated and carboxylated osteocalcin declined significantly after treatment. However, no correlation was observed between changes in osteocalcin and changes in glucose after multiple regression analysis.

Bisphosphonate treatment for osteoporosis reduced osteocalcin and this change was not associated with changes in glucose metabolism.

The Effect of Calcitonin Therapy on Postoperative Rehabilitation in Patients with Femoral Neck/Trochanteric Fractures. Tetsuo Nakano*[1], Shinya Tanaka[2]. [1]Tamana Central Hospital, Japan, [2]Saitama Medical University, Japan

Introduction: Management of a bedridden state and depressed walking ability due to femoral neck/trochanteric fractures involves a complex, long-term system of therapy comprising surgical intervention, perioperative management, rehabilitation, etc., all of which are necessary for avoiding an unfavorable prognosis. Regarding rehabilitation, studies on the training methods and influence of timing of initiation and frequency of rehabilitation have been reported; however, few studies concerning the effects of pharmaceutical therapy on rehabilitation have been conducted.

Subjects and Methods: A total of 352 patients with femoral neck/trochanteric fractures surgically treated at this hospital were classified into two groups, of which only one group received calcitonin in a dose of 20 units intramuscularly once a week during hospitalization. Other treatments and rehabilitation were provided in the same manner in the two groups.

Results: Of all the patients treated, a total of 242 patients were included in the data analysis. A further analysis was made on these eligible patients divided into the following 3 groups according to pre-injury walking ability (independent outdoor walking group, independent indoor walking group, dysbasia group).

The percentage of patients achieving improvement in walking ability over time was compared between these two groups. The calcitonin-treated group exhibited a significant improvement of walking ability at Weeks 2 and 3 post-operation. The same assessment parameter was compared among the 3 groups classified according to degree of pre-injury walking ability. In the independent outdoor walking group, patients who were treated with calcitonin showed a significant improvement of walking ability at Weeks 2 and 3 post-operation, as was the case with the whole population analysis.

Discussion: Calcitonin has a pain-relieving effect mediated by the central serotonergic nervous system. Depression of cognitive function is a representative factor contributing to inhibition of rehabilitation in patients with femoral neck/trochanteric fractures, and pain is also considered a noticeable inhibitory factor. Assuagement of painfulness may therefore improve the rehabilitation of fracture patients. The present results demonstrate the usefulness of calcitonin therapy during early postoperative rehabilitation only in patients had had high pre-injury walking ability before fracture.

MO0390

The Effects of Intravenous Aminobisphosphonates on Carotid Atherosclerosis could Be Influenced by the Changes in FGF23 Serum Levels. Stefano Gonnelli*, Carla Caffarelli, Loredana Tanzilli, Maria Dea Tomai Pitinca, Alice Cadirni, Barbara Lucani, Maria Beatrice Franci, Ranuccio Nuti. University of Siena, Italy

Some, but not all studies have reported a positive effect of aminobisphosphonates on atherosclerotic lesions. However, no convincing explanations exist regarding this finding. Recently it has been reported that the levels of FGF23 are positively related to the progression of atherosclerosis and to the calcification of atherosclerosis plaque.

Sixty postmenopausal osteoporotic women (mean age: 66.4 ± 7.6 years), not previously treated with drugs for osteoporosis and with normal levels of 25OHvitamin D, were randomly allocated to receive zoledronate 5 mg i.v. annually or ibandronate 3 mg i.v. every 3 months.

At baseline and at month 12 we measured serum lipids, bone isoenzyme of alkaline phosphatase, parathyroid hormone, 25-hydroxy-vitamin D, the terminal fragment of collagen type 1, the fibroblast growth factor-23 (FGF23) and osteocalcin. Patients with impaired renal function were excluded from the study. Bone Mineral Density (BMD) at lumbar spine and at femur (neck and total sub regions) and total body were also measured (DXA method, Prodigy GE Lunar, USA). An ultrasound examination of carotid vessels was performed to assess intima-media-thickness (IMT), presence of plaque and the degree of calcification.

Patients with atherosclerotic plaques were found to have significantly lower BMD values ($p < 0.05$) than those without plaques. Serum levels of FGF23 were reduced in osteoporotic women who presented with carotid plaques but without reaching any statistical significance (26.6 ? 14.6 vs 18.9 ? 8.1 RU/ml). Also serum levels of osteocalcin were reduced in women with carotid plaques (4.3 ? 2.5 vs 4.7 ? 1.2 ng/ml; p=n.s.). Both FGF23 and osteocalcin were negatively correlate with IMT (r =-0.42 $p < 0.05$ and r =-0.35 $p < 0.05$, respectively). In addition the serum levels of FGF23 were significantly correlated with BMD at all femoral subregions ($p < 0.05$).

At month 12 a significant increase in HDL-cholesterol and HDL/LDL-cholesterol ratio was observed. Moreover at month 12 both zoledronate and ibandronate induced a reduction in IMT (-4.73% $p<0.05$; and -1.75% p=n.s. respectively). FGF23 serum levels showed a significant decrease with respect to baseline in both zoledronate (-40.2% $p<0.01$) and ibandronate (-31.2% $p<0.05$) groups.

Our findings seem to support a crosstalking between bone and atherosclerotic lesions, however, further studies are warranted to confirm as to whether FGF23 may play an important role in this.

The Occurrence of Renal Insufficiency and Hypocalcemia after Zoledronic Acid Infusion. Laurae Hicks*[1], Pauline Camacho[2]. [1]Loyola University, USA, [2]Loyola University of Chicago, USA

Zoledronic acid (ZA) is an effective injectable bisphosphonate medication that was approved by the FDA for treatment of osteoporosis in 2007. In the United States, osteoporosis is a major concern, impacting almost 44 million people; 80% of these are post-menopausal women. The incidence is likely to increase as the population ages. Although zoledronic acid has been found to reduce the risk of vertebral fracture by 70% and hip fractures by 41% in affected patients, there are potential side effects, such as renal insufficiency and hypocalcemia. In this study, we aimed to determine the incidence of renal insufficiency and hypocalcemia after ZA infusion for osteoporosis treatment. 237 charts of osteoporotic patients were reviewed; 141 patients had 2 zoledronic acid infusions and 58 had 3. McNemar's Test revealed no significant difference between pre- and post- eGFR for all infusions (p= 0.07, 0.41, and 0.41). Paired t-test between pre- and post-creatinine clearance values showed no significant difference (p= 0.4269, 0.2742, 0.8949). In regards to hypocalcemia, paired t-test of 244 pre- and post- corrected serum calcium levels (corrected with plasma albumin) and 86 pre- and post- ionized calcium levels showed a significant difference with the 1st infusion, but not the 2nd or 3rd (p= <0.0001, mean = -0.1739 for corrected calcium and p= 0.0272, mean = -0.0143 for ionized calcium). Overall results indicate that use of zoledronic acid does not significantly alter renal function. During the first infusion, however, significant changes in serum calcium occurred, but serious hypocalcemia was not seen in this vitamin D replete population.

Keywords: zoledronic acid, osteoporosis, renal, hypocalcemia

Infusion	Average Age	Males	Females	Total Number
1	69.97	27	210	237
2	70.74	11	130	141
3	71.98	7	51	58

Vitamin D Repletion in Korean Postmenopausal Women with Osteoporosis. Yoon-Sok Chung*[1], Han-Jin Oh[2], Il Hyung Park[3], In-Ju Kim[4], Jung-Min Koh[5], Moo-Il Kang[6], Sung-Kil Lim[7], Yong-Ki Min[8], Yil-Seob Lee[9], Barbara Kravitz[10], Brian Waterhouse[10], Lorraine Fitzpatrick[10], Antonio Nino[10]. [1]Ajou University School of Medicine, South Korea, [2]Cheil General Hospital, Kwandong University, South Korea, [3]Kyungpook National University Hospital, South Korea, [4]Pusan National University Hospital, South Korea, [5]Asan Medical Center, South Korea, [6]Seoul St. Mary's Hospital, South Korea, [7]Yonsei University College of Medicine, South Korea, [8]Samsung Medical Center, South Korea, [9]GlaxosmithKline Pharmaceuticals, South Korea, [10]GlaxosmithKline Pharmaceuticals, USA

Purpose: To assess the effect of daily, oral vitamin D supplementation in Korean postmenopausal women with osteoporosis with serum levels of vitamin D 25(OH)) < 50 nmol/L during a clinical trial.

Methods: Korean postmenopausal women aged 60-90 years were screened for study participation in a randomized, double-blind trial with denosumab in osteoporosis patients. Participants were required to have vitamin D levels ⩾ 50 nmol/L for randomization. Repletion with 1000 IU capsules of vitamin D was allowed. For those subjects whose vitamin D levels were < 50 nmol/L, the investigator determined the dose, frequency, and duration of the vitamin D repletion for the subject. When the repletion regimen completed (maximum 75 days were allowed), a second blood sample was obtained and tested for 25(OH) vitamin D levels. All sites obtained approval from their Ethics Committees and all subjects signed informed consent.

Results: Of 371 subjects screened, 191 subjects needed repletion because of serum levels of 25(OH) vitamin D <50 nmol/L. Of the subjects who required repletion,168 (88%) were successfully repleted and 77 met study entry criteria and were randomized. Fourteen subjects did not reach 50 nmol/L and no sample was available for 9 subjects. An additional 180 subjects did not require repletion as their baseline vitamin D level was ⩾50 nmol/L; of these, 58 subjects met study entry criteria and were randomized. Repletion results are presented (Table 1). Mean time to successful repletion was 31 days (SD 8.4; Min 11 days, Max 48 days). Median dose of vitamin D for successful repletion was 2000 IU daily (min 1000 IU and max 9000 IU daily).

Conclusions: Successful vitamin D repletion in Korean postmenopausal women with osteoporosis was achieved to levels of ⩾ 50 nmol/L by a maximum observed 48 days using daily doses of oral vitamin D ranging from of 1000 to 9000 IU with a median dose of 2000 IU daily.

This study was sponsored by GlaxoSmithKline Pharmaceuticals.

Table 1 Vitamin D Laboratory Assessments by Status at Initial Screening

Subjects with serum level vitamin D ≥50 nmol/L at initial screening

Lab Test	Status	N	Visit	n	Mean	SD
25(OH) vitamin D (nmol/L)	Randomized	58	Screening 1	58	71.5	15
	Non-randomized	122	Screening 1	115	52.6	22.91

Subjects with serum level of vitamin D <50 nmol/L at initial screening and achieved levels of ≥50 nmol/L after repletion

Lab Test	Status	N	Visit	n	Mean	SD
25(OH) vitamin D (nmol/L)	Randomized	77	Before repletion	77	29.7	9.75
			After repletion	77	71.4	15.38
	Non-randomized	91	Before repletion	90*	29.4	10.56
			After repletion	91	70.4	15.82

* One patient was discontinued for repletion in error, their vitamin D level was >50 nmol/L

Subjects with serum levels of vitamin D <50nmol/L at initial screening, received vitamin D repletion, and did not reach ≥50 nmol/L or did not have a second assessment

Lab Test	Status	N	Visit	n	Mean	SD
25(OH) vitamin D (nmol/L)	2nd lab sample available	14	Before repletion	14	22.8	9.25
			After repletion	14	40.8	9.65

In Patients with Different Forms of Osteoporosis Excellent Adherence to 6-Monthly Denosumab Injections Can be Achieved by Positive Feedback Based on 6 and 12 Months BMD Increases and Rare Adverse Events. Johann D. Ringe*, Parvis Farahmand. West German Osteoporosis Center (WOC), Klinikum Leverkusen, University of Cologne, Germany

Introduction: More than 50% of osteoporosis patients discontinue bisphosphonate therapy within the first year of treatment. Denosumab's (Dmab) longer dosing interval with its s.c. administration every 6 months might result in a better real life treatment adherence and persistence than weekly or monthly oral bisphosphonate treatment regimen.

Methods: In an open investigator-initiated prospective observational study in routine clinical practice we aimed to assess whether a careful medical explanation of treatment results 6 and 12 months after the first Dmab injection focussing on no or only mild and probably not drug related AEs, changes in back pain and on significant BMD increases have effects on patients' drug perception and future adherence with further Dmab injections. We included 142 patients (69 with postmenopausal, 42 with male, and 32 with GC-induced osteoporosis).

Results: At onset almost all patients had concerns about possible AEs, but 93% reported no negative changes in their health condition at all after two injections of Dmab, and only 7.0% reported AEs. These were all mild to moderate, disappeared without intervention and were obviously not drug related. Besides this good tolerability patients were very impressed by demonstrating and carefully explaining to them the original DXA-protocols showing a significant increase in lumbar spine (LS) and/or total hip (TH) BMD. The therapeutic effect of Dmab on BMD did not differ between the three different types of osteoporosis. The mean increase rates at month 6 were +4.7% at the LS site and +2.1% at the TH area and at month 12 +7.8% at the LS site and +3.7% at the TH area, respectively. There were only 5 vertebral and 4 non-vertebral fractures during the 142 patient years follow-up. The back pain score measured by VAS 0-10 decreased in all 3 groups significantly after 6 and 12 months. This clinical effect together with the scarcity of AEs and the positive feedback of a rapid BMD-increase at both sites resulted for 141 (99%) patients after 6 months and 139 (97%) after 12 months in a willingness to accept a further injection.Conclusion: Results indicate that the convenient treatment regime together with back pain improvements, rarity of adverse events and the consistency of rapid and highly significant BMD-increases after 6 and 12 months of Dmab therapy used as a positive reinforcement had a significant, positive impact on patient's adherence to continue with the 6-monthly s.c. Dmab injections.

MO0394

Long-term (up to 5 years) persistence with different anti-osteoporosis medications in Catalonia (Spain): a population-based cohort study. Cristina Carbonell*[1], Aina Pages-Castella[2], Pilar Estrada[2], Xavier Nogues[3], Adolfo Diez-Perez[4], Daniel Prieto-alhambra[5]. [1]Facultat de Medicina Universitat de Barcelona, Spain, [2]GREMPAL Research Group (USR Barcelona), IDIAP Jordi Gol, Universitat Autònoma de Barcelona, Spain, [3]Institut Municipal D'Investigació Mèdica, Spain, [4]Autonomous University of Barcelona, Spain, [5]University of Oxford, United Kingdom

Purpose: Although reports from different countries suggest very low persistence with oral bisphosphonates, there is a scarcity of data regarding other anti-osteoporosis (OP) medications. Our aim is to compare persistence to all available outpatient oral anti-OP drugs up to five years after therapy initiation.

Methods: We conducted a population-based retrospective cohort study using data from primary care computerized records in SIDIAP (www.sidiap.org). SIDIAP includes clinical information (diagnoses, referrals, etc) recorded by GPs together with pharmacy invoice data. We included all SIDIAP participants starting an anti-OP drug at anytime between 1/1/2007 and 30/06/2011. Users of any of these drugs in the previous 2 years were excluded. We analysed persistence, rate of discontinuation and switching to alternative therapies at up to 5 years follow-up. Fine and Gray survival modelling was used to estimate risk of therapy discontinuation (sub-hazard ratios = SHR) for each drug compared to weekly alendronate, after adjustment for the following confounders: age at therapy initiation, gender, fracture history, Charlson co-morbidity Index, use of oral glucocorticoids, use of aromatase inhibitors, smoking, alcohol drinking, and body mass index.

Results: We identified 124,827patients who started any anti-osteoporotic drug in the study period. The most commonly prescribed drug was weekly alendronate (N=55,399). Persistence at five years ranged from 26.7% (monthly risedronate) to 9.3% (strontium ranelate). Only monthly risendronate had better persistence than weekly alendronate at 5 years: adjusted SHR 0.80 [95%CI 0.86-0.92]. Conversely, daily drugs were the ones with worst persistence: adjusted SHR 1.45 95%CI 1.42-1.47), 1.46 [95%CI 1.42-1.48], and 1.73 [95% CI 1.57-1.87] for strontium ranelate, daily raloxifene, and daily risedronate respectively. [Table 1]

Conclusions: Persistence at five years with available therapies for Osteoporosis is very low, ranging from 9% to 27%. There are significant differences in persistence at 5 years of treatment: whilst only monthly risedronate has 20% lower discontinuation rates, all daily drugs have 45% to 70% lower persistence than weekly ALN.

TABLE. MULTIVARIABLE ADJUSTED SUB HAZARD RATIOS (SHR) FOR THERAPY DISCONTINUATION ACCORDING TO DRUG USED

Therapy	Number of drug users	N (%) Discontinued	Adjusted SHR (95%CI)
weekly alendronate	53,317	36,460 (68.2%)	REF
weekly risedronate	25,312	17,646 (69.5%)	1.16 (1.15-1.16)
monthly ibandronate	13,270	9,596 (64.79%)	1.03 (1.00-1.05)
monthly risedronate	5,100	2,564 (50.27%)	0.80 (0.77-0.82)
daily alendronate	497	359 (61.97%)	1.33 (1.20-1.47)
daily risedronate	430	307 (71.40%)	1.73 (1.53-1.97)
raloxifene	10,377	8,057 (77.66%)	1.46 (1.42-1.49)
ibandronate	551	328 (59.53%)	1.15 (1.04-1.26)
strontium ranelate	14,173	10,501 (74.09%)	1.45 (1.43-1.47)

Predictors of Medication Use in Australian Men and Women Following a Low Trauma Fracture. Kerrie Sanders*[1], Julie Abimanyi-Ochom[2], Jennifer Watts[3], Catherine Shore-Lorenti[4], Geoffrey Nicholson[5], Amanda Stuart[6], Yu Zhang[7], Ego Seeman[8], Sandra Iuliano-Burns[8], Richard Prince[9], Lynn March[10], Marita Cross[10], Tania Winzenberg[11], LL Laslett[12], Gustavo Duque[13], Peter Ebeling[14], Fredrik Borgstrom[15]. [1]NorthWest Academic Centre, The University of Melbourne, Western Health, Australia, [2]Deakin University, Australia, [3]Health Economics, Deakin University, Australia, [4]The University of Melbourne, Department of Medicine, NorthWest Academic Centre, Australia, [5]The University of Queensland, Australia, [6]Deakin University, Barwon Health, Australia, [7]Department of Medicine, The University of Melbourne, Australia, [8]Austin Health, University of Melbourne, Australia, [9]Sir Charles Gairdner Hospital, Australia, [10]Royal North Shore Hospital, University of Sydney, Australia, [11]Menzies Research Institute Tasmania, Australia, [12]Menzies Research Institute Tasmania, Musculoskeletal Unit, Australia, [13]Ageing Bone Research Program, University of Sydney, Australia, [14]The University of Melbourne, Australia, [15]Karolinska Institutet, Medical Management Centre, Sweden

Access to appropriate medication following a low trauma fracture (LT Fx) is critical to preventing further LT Fx in adults but treatment rates are frequently low. We aim to identify predictors of commencing bone-related medication (bone-meds) including calcium and vitamin D supplements (CaD) following a LT Fx in adults aged 50+ years.

The AusICUROS study is part of an international cost and outcomes study. Medication use was collected 4-months post-Fx in 796 participants treated at 8 Australian teaching hospitals. Bone-meds commenced as a consequence of the Fx were recorded from patient and hospital data. Other medical and demographic data were also collected. Binary logistic regression was used to identify predictors of commencing bone-meds.

Outcomes were any bone-meds including CaD (Y/N) with a sub-analysis of bisphosphonates (Y/N). Predictors tested were age, Fx type (hip, wrist, vertebral, other), income (low, medium, high), education (4 levels), Fx in last 5 years (Y/N) and gender.

Participant profile was: 69 years (IQR: 59 to 78 years) 76% female; 18% had a previous Fx in last 5 years and few were on bone meds. Fx type at study entry were: hip 21% (171); wrist 36% (288); vertebral 10% (80); other 32% (257). Only 35% (n=275/796) commenced any bone-meds; 27% (215) commenced CaD; 9% (74) bisphosphonates; 5% (38) strontium. Odds ratios (OR) for the final model predictors were: female 2.1 [95% CI: 1.4, 3.1] and Fx type hip 1.7 [CI: 1.1, 2.5]; wrist 0.6 [CI: 0.4, 0.9]; vertebral 2.1 [CI: 1.3, 3.6]. Final predictors for bisphosphonates were: age 1.04 [CI: 1.01, 1.06] and Fx type: hip 2.2 [CI: 1.1, 4.5], vertebral 4.3 [CI: 2.0, 9.3].

Our findings demonstrate that medical treatment post LT Fx remains suboptimal. Only a third of LT Fx patients were commenced on any bone-meds and less than half of these commenced specific anti-osteoporosis medications with proven efficacy for secondary fracture prevention. Importantly, we also identified subgroups at higher risk of not receiving appropriate treatment, namely males, and those with wrist Fx, and for bisphosphonates, younger age. Of concern, those with a past Fx were not more likely to commence meds despite being at increased Fx risk. The analysis does not account for those already on bone meds prior to this Fx. These gaps in the management of osteoporosis in a high risk population need to be urgently addressed, including highlighting the need to treat men, those with wrist and multiple Fx and younger people.

Treatment of Osteoporosis at an Academic Center in a Major Metropolitan Area. Lance Freeman*[1], Phillip Orlander[2], Nahid Rianon[3]. [1]University of Texas Health Science Center at Houston, Medical School, USA, [2]University of Texas Houston Health Science Center, Medical School, USA, [3]UTHealth The University of Texas Medical School at Houston, USA

Endocrinology is considered the main specialty involved in the study and treatment of osteoporosis. However, the chronic nature of this disease combined with an aging population, has created a chasm between the number of Endocrinologist and the number of patients with osteoporosis requiring treatment. This gap has of course been filled by many different types of physicians from non-endocrine backgrounds such as Internist, Family Physicians, Geriatricians, Rheumatologists and Gynecologists to name a few. As a disease entity, osteoporosis and its main complication of fractures have staggering health care implications. Given the multitude of physicians treating osteoporosis, and all that is at stake for patients and the health care system, quality assurance is a necessity as we move forward. Identifying treatment differences among specialties and standardizing proper treatment protocols will prove beneficial for all involved. We investigated differences in patient characteristics and types of treatment for patients being treated by endocrinologist and non-endocrine physicians in an academic institution at the University of Texas Medical School at Houston (UT).

Retrospective chart review identified patients seen in all UT clinics in December 2012 for osteoporosis or related fractures. Data for 35 patients from an ongoing project were analyzed. Patient characteristics and prescribed treatment were described by treating specialty [Endocrinology vs. non-endocrinology].

Mean $\pm$ SD of patients were 66 ± 13 (range 43 to 90) years. Only 9% were male and 63% were treated by Endocrinologists. All Patients managed by Endocrinologists also had concomitant diabetes mellitus ($P<0.01$), 90% had hypothyroidism ($p<0.01$) and 83% had a history fracture ($p=0.24$) as compared with those managed by other services. Despite no significant differences, about 60% and 30% of patients treated by all physicians were not taking calcium or vitamin D supplements, respectively. There were no differences in types of medications and osteoporosis status by T-score between patients being treated by endocrinologists and other physicians.

Physicians are not consistently treating at risk patients with calcium and vitamin D supplementation which are recommended by the Institute of Medicine as essential for optimum bone health. The data also indicates that the majority of patients with a previous fracture, diabetes and hypothyroidism are in fact being funneled to Endocrinologist for more specialized care.

Dietary Calcium versus Calcium Supplementation on Vascular and Bone Health in Postmenopausal Women; Preliminary Results of a Pilot Study. Rouba Hadad[1], Hope Weiler[2], Michelle Wall[3], Stella S Daskalopoulou[1], David Goltzman[1], Suzanne Morin*[1]. [1]McGill University, Canada, [2]McGill University, USA, [3]McGill University Health Center Research Institute, Canada

Background: There are reports thatcalcium supplementation, with or without vitamin D, is associated with increased rates of cardiovascular events. However, whether calcium intake from supplements has similar effect to that from dietary sources on vascular and bone health markers is unknown.

Objectives: A 12-month randomized trial was piloted to estimate the effect of dietary calcium intake versus supplemental calcium on vascular and bone health in postmenopausal women. Feasibility of the study was assessed by examining the ability of the participants to adhere to the study interventions. The objectives were to examine 1) associations between baseline anthropometry, vascular markers and dietary calcium and vitamin D intakes and 2) whether a short nutrition education session followed by monthly telephone contacts successfully modified dietary intakes between groups and compared to baseline.

Methods: Healthy post-menopausal women, not on calcium or vitamin D supplement, were randomized to dietary (DI) intake of 1200 mg Ca + 400 IU supplemental vitamin D or a supplemental (S) intake 750 mg supplemental $CaCO_3$ (and of 450 mg dietary Ca) + 800 IU supplemental vitamin D. Correlations were conducted to determine associations between dietary intakes, anthropometry and vascular markers (arterial stiffness and carotid intima-media thickness measured via ultrasound) at baseline. Using repeated measures ANOVA, between- groups differences in dietary calcium, vitamin D intakes were measured at baseline and up to 5 months.

Results: Thus far, we have recruited12 participants (63 SD 2 years, BMI 24.7 SD 0.9 kg/m^2; WC 81.8 SD 2.3 cm; body fat 31.5 SD 1.4 %, systolic BP 112 SD 4 mmHg; diastolic BP 74 SD 3 mmHg). Using food frequency questionnaire we estimated baseline energy 2379 ± 178 kcal and calcium 1134 ± 70 mg; vitamin D 553 ± 90 IU intakes. There were no between group differences. No associations were found between calcium and vitamin D intake and baseline vascular measures. At every month post-randomization, higher dietary calcium and vitamin D intake was observed in the DI group compared with the S group (Figure 1). Compliance with calcium and vitamin D supplements at 5 months was found to be 85% overall.

Conclusion: A brief education session and monthly contacts were effective in changing dietary calcium intake and ensuring compliance with the study interventions, supporting the feasibility of this trial.

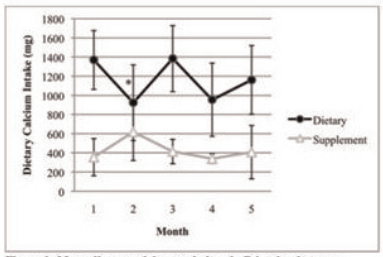

Figure 1: Mean dietary calcium and vitamin D intakes between intervention groups (24 hr recall)
All between group comparisons: p<0.05 except for * where p=0.26

MO0398

Uptake of Evidence-based Osteoporosis Practices in Canadian Long-term Care (LTC). Courtney Kennedy*[1], George Ioannidis[1], Lehana Thabane[1], Denis O'Donnell[2], Lora Giangregorio[3], Jonathan Adachi[4], Alexandra Papaioannou[5]. [1]McMaster University, Canada, [2]Medical Pharmacies Limited, Canada, [3]University of Waterloo, Canada, [4]St. Joseph's Hospital, Canada, [5]Hamilton Health Sciences, Canada

Background: Knowledge translation of best practices in long-term care (LTC; i.e. nursing homes) presents unique challenges. These include applying practice guidelines not developed for the frail elderly and physicians who are frequently off-site and rely on the multidisciplinary healthcare team to monitor residents. In 2007, the Ontario Osteoporosis Strategy for Long-term Care initiated a program of outreach activities across the province (approximately 630 LTC homes) to increase uptake of evidence-based osteoporosis and fracture prevention strategies (www.osteoporosislongtermcare.ca). At that time, an environmental scan revealed a wide spectrum of prescribing practices between LTC homes likely reflecting the lack of standardized guidelines. The objective of the present study was to describe osteoporosis prescribing practices across Ontario LTC homes in 2012. Methods: Individual-level, de-identified medication/demographic data were downloaded from Medical Pharmacies, a pharmacy provider for approximately one-third of Ontario LTC homes. After excluding 40 LTC homes participating in the Vitamin D and Osteoporosis (ViD*OS*) trial, we analyzed data for 166 unselected LTC homes. For each LTC home, we calculated the proportion of residents receiving 1) Vitamin D (⩾800 IU/day), 2) calcium supplements (⩾500 mg/day), and 3) osteoporosis medication. Mean [95% confidence interval (CI)] LTC home prescribing rates and ranges are reported. Results: The analysis cohort was 21,699 residents, mean age 83.5 (SD: 10.7) years, 70% women. Fifty-seven percent of LTC homes were for-profit, 45% affiliated with a corporate chain, 61% had ⩾100 residents. Overall, there were 967 physician prescribers. Mean LTC home prescribing rates were 59.9% (95% CI: 57.2, 62.6) for vitamin D, 32.2% (95% CI: 30.2, 34.2) for calcium, and 18.5% (95% CI: 17.4, 19.7) for osteoporosis medications. Home-level prescribing rates were normally distributed and ranged from 22.3-94.9% for vitamin D, 1.6-78.4% for calcium, and 0-55.9% for osteoporosis medications (Figure 1). Discussion: Although there was a range in prescribing between LTC homes, our results indicate that wide-scale implementation of outreach activities resulted in uptake by many LTC homes, particularly for Vitamin D, with half the homes prescribing at approximately 60% or better. Currently, osteoporosis consensus guidelines for LTC are being developed and will be the focus of future knowledge translation activities.

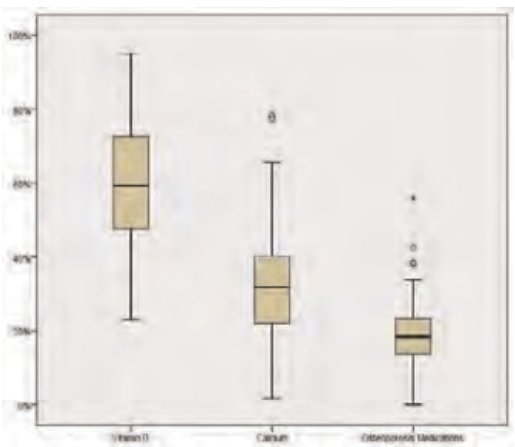

Figure 1: Box plot of the distribution of mean prescribing rates in 166 LTC homes

MO0399

Significant Reduction of Osteoporosis Fracture-related Hospitalization Rate Due to an Intensified, Multimodal Treatment - Results from the Integrated Health Care Network Osteoporosis North Rhine / Germany. Christopher Niedhart*[1], Anne Preising[2], Christoph Eichhorn[3]. [1]Germany, [2]AOK Northrhine, Germany, [3]Practice, Germany

Introduction: Osteoporosis is known as undertreated in Germany. Aim of the integrated health care model osteoporosis" was the improvement of patient care by multimodal treatment within an integrated health care network. This paper shows the results of the accompanying evaluation.

Methods: A retrospective cross-sectional analysis was performed using routine data from the AOK Rheinland/Hamburg fort the years 2007-2010. Patients were included, if they were 50-89 years old and had a diagnosis of osteoporosis (ICD 10 M80 or M81) and at least two presciptions of osteoporosis-specific medication/year. Data were analysed separately for integrated health care and regular health care.

Results: 22.040 patients were detected, thereof 3.173 patients in the integrated health care group (IV). The hospitalization rate for hip fractures was significantly lower in the IV group: 5.93/1.000 patient years versus 22.96/1.000 patient years (-74 %, $p<0.05$). Also the hospitalization rate of all other osteoporosis-related fractures was 73 % reduced: 46.92/1.000 patient years versus 172.88/1.000 patient years ($p<0.05$). Osteoporosis-related medication costs were doubled in the IV group, while total medication costs were lower in the IV group (1438 € vs. 1702 €).

Discussion: This observational, cross-sectional study shows, that an intensified, multimodal treatment of osteoporosis within an integrated health care network of highly qualified physicians can reduce the hospitalisation rate due to osteoporosis-associated fractures and simultaneously reduces direct costs even in the short run.

Nasal Salmon Calcitonin prevents bone microstructure alterations in early postmenopausal women. Rene Rizzoli*[1], Anne Sigaud[2], Moise Azria[3], Francois Herrmann[2]. [1]Geneva University Hospitals & Faculty of Medicine, Switzerland, [2]Geneva University Hospitals, Switzerland, [3]Novartis Pharma AG, Switzerland

Calcitonin decreases bone resorption, by reducing osteoclast activity. At a dose of 200 IU/day, nasal salmon calcitonin (NSC) has been shown to lower vertebral fracture risk by 33%, with an only 1.5% increase in spine BMD. This suggests that, in addition to BMD, NSC may also influence microstructure, as another determinant of bone strength. In a randomized, double-blind, placebo-controlled, two-year duration trial (ClinTrial. Gov : NCT00372099), we investigated the effects of 200 IU/day NSC on bone microstructure, areal BMD and bone turnover markers in early postmenopausal women. All received 880 IU vitamin D and 1000 mg calcium daily. Distal radius and tibia bone microstructure variables were quantified by HR-pQCT (XtremeCT, Scanco Medical). Mean age was 57.6 ± 0.8 (± SEM) and 57.4 ± 0.7 in the NSC group (n=45) and placebo controls (n=45), respectively. Femoral neck T-Score was -1.23 ± 0.07 and -1.01 ± 0.10, with 4% prevalent vertebral fracture in each group. More than 67% of the subjects had 25-hydroxyvitamin D levels above 50 nmol/l. By 1 year, 91 and 89% of subjects were still in the trial, and 73 and 87% by 2 years, in the NSC and placebo groups, respectively. By 6 and 12 months, serum CTX decreased by -17.3 ± 6.2% and -19.1 ± 6.6% (both $p<0.05$, vs baseline) on NSC, respectively, vs +3.6 ± 4.6 and -6.0 ± 3.7% in the controls (NS vs baseline). By 2 years, distal radius total density changes vs baseline were -2.1 ± 0.6 in NSC group and -4.4 ± 0.7% in controls (between group: $p<0.05$). The 2-year distal radius and tibia cortical thickness decrease of -3.7 ± 1.0 and -2.4 ± 0.5% in the controls ($p<0.05$ vs baseline for both), did not occur in the NSC group (NS). At distal tibia, BV/TV decreased by -1.7 ± 0.6% in the placebo ($p<0.05$ vs baseline), but not in NSC group (-1.1 ± 0.6, NS) by 1 year. Corresponding values were -2.5 ± 0.7 and -1.4 ± 0.6% (both : $p<0.05$ vs baseline, between group: NS) by 2 years. There was no difference in areal BMD changes between NSC and controls. The -0.1% decrease in height in controls, did not occur in the NSC group. Two fractures were recorded in controls and 1 in NSC group. NSC was well tolerated, with a lower incidence of arthralgia (14 vs 26 in placebo, $p<0.05$). One cancer was recorded in each group. Thus, the degradation of bone microstructure in early postmenopausal women, was attenuated or prevented by 200 IU/day nasal salmon calcitonin, together with a lowering of bone resorption, and less arthralgia.

MO0401

Retrospective study of the nephrotoxicity of Pamidronate in CKD. Wael Taha, Basel Taha*, Ali Achira. Wayne State University, USA

Background: Bisphosphonates are anti-absorptive agents that reduce the rate of bone turnover and are also first line drugs for the treatment of cancer related hypercalcemia, Pagets' disease and osteoporosis. However, their usage is restricted due to the prevailing concern regarding their nephrotoxicity.

Objectives: To study the safety of intravenous Pamidronate in patients with Chronic Kidney Disease (CKD) with estimated Glomerular Filtration Rate (eGFR) ≤ 50

Methods: Our study is a retrospective review of patients, aged 18 to 80 years, with chronic kidney disease with eGFR $\leq$ 50 mL/min/1.73m2 based on the MDRD formula, who were treated in Detroit Medical Center with IV Pamidronate between 2007 to 2012. We excluded patients who were on dialysis before the treatment, who had nephrotoxic treatment and who had insufficient data to analyze. We compared creatinines at up to 12 months before and 1 to 6 months after treatment with IV Pamidronate. The baseline renal function is defined as the best one (up to 12 months) before the admission date. The post treatment creatinine is considered the highest in the period of one to six months of the infusion. We considered a minimum of 10 mL/min/1.73m2 change of eGFR to be significant. We consider acute renal failure if Cr is $\geqslant$ 15% from baseline.

Results: We found 358 patient who were treated with pamidronte. So far we reviewed 123 charts, of which, 9 patients had eGFR of $\leq$ 50 and had enough data for analysis (average eGFR 38.7). None of which had significant decrease in eGFR in the 12 month period before the infusion. The rest were excluded due to eGFR $>$ 50, or not available at baseline. All 9 patients had hypercalcemia.

Five of these nine (the first group, 55.6%) had maintained stable, or had some improvement of creatinine levels. This five patients had average baseline eGFR of 37.4 (range 20-50). Three of them were diagnosed with acute on chronic renal failure at the infusion time.

The second group were four patients (44.4%) had increased creatinine levels, eGFR dropped by range of 10 to 18. The latter group had average eGFR of 40.25 at baseline (range 25-50). Two of this group had acute on chronic renal failure.

Conclusion: Whether IV pamidronate causes deterioration of renal function to patients with advance CKD patients is not clear. Other factors that play a role need to be studied such as the calcium levels and the cause of hypercalcemia (i.e. malignancy)

Strontium Ranelate Effect on Bone Mineral Density is Modified by Previous Bisphosphonate Treatment. Lucas Ricardo Brun[1], Ana María Galich[2], Laura Maffei[3], Valeria Premrou[4], Eduardo Vega*[5], Helena Salerni[6], Marcelo Alfredo Sarli[7], Pablo Costanzo[6], Paula Rey[7], María Silvia Larroude[8], María Susana Moggia[9], María Lorena Brance[10], Ariel Sánchez[11]. [1]Laboratorio de Biología Ósea. Facultad de Ciencias Médicas. Universidad Nacional de Rosario., Argentina, [2]Servicio de Endocrinología del Hospital Italiano de Buenos Aires., Argentina, [3]Consultorios Associados De Endocrinologia, Argentina, [4]Consultorios Asociados de Endocrinología Dra. Laura Maffei., Argentina, [5]CESAN, Buenos Aires. Instituto de la Mujer, Campana, Argentina, [6]Consultorios de Investigación Clínica Endocrinológica y del Metabolismo Óseo (CICEMO)., Argentina, [7]Instituto de Investigaciones Metabólicas, Dr. Zanchetta., Argentina, [8]Hospital César Milstein, Argentina, [9]Centro Tiempo, Argentina, [10]Consultorios de Reumatología, Argentina, [11]Centro de Endocrinología., Argentina

Strontium ranelate (SrR) is an effective treatment for osteoporosis that reduces the incidence of vertebral and non-vertebral fractures. The aim of this study was to evaluate the effect of SrR on bone mineral density (BMD) and bone turnover markers after 1 year of treatment in clinical practice conditions. Additionally, the effect of SrR in bisphosphonate-naïve patients (BP-naïve) compared to patients previously treated with bisphosphonates (BP-prior) was analyzed. This retrospective study analyzed records from 482 postmenopausal women treated with SrR (2 g/day) for 1 year in eleven Argentine centers; 41 patients were excluded due to insufficient data, while 441 were included. All patients received calcium (1000 mg/day) and vitamin D (800 U/day). BMD (g/cm^2) was measured by dual-energy X-ray absorptiometry (DXA) GE Lunar Prodigy. Data are expressed as mean$\pm$SEM, and changes were analyzed with Mann-Whitney test or Wilcoxon signed rank test as appropriate. Results: the whole population main characteristics were: age (years): 67.20$\pm$0.50; body mass index (kg/m^2): 24.55$\pm$0.18; serum calcium (mg/dl): 9.36$\pm$0.02; serum phosphate (mg/dl): 3.97$\pm$0.03; 25(OH)vitamin D (ng/ml): 32.04$\pm$1.0; PTH (pg/ml): 51.00$\pm$3.11; total alkaline phosphatase (tAP, UI/L): 59.70$\pm$1.36; serum osteocalcin (BGP, ng/ml): 17.02$\pm$0.98; serum C-telopeptide (s-CTX, ng/l): 331.10$\pm$16.03. After 1 year of treatment with SrR, tAP (65.76$\pm$1.57) and BGP (22.93$\pm$1.46) as bone formation markers, were increased ($p<0.0001$), while s-CTX (305.60$\pm$16.31) as bone resorption marker, was decreased (p=0.0579). SrR after 1 year of treatment increased BMD at the lumbar spine (LS), femoral neck (FN) and total hip (TH) ($p<0.0001$). The change in BMD was: LS= 3.73$\pm$0.26%, FN= 2.00$\pm$0.24% and TH= 1.54$\pm$0.24%. These increments were significant ($p<0.0001$) both among BP-naïve (n=86) and BP-prior (n=320) patients; 35 patients were not included in this analysis because the use of other drugs different as BP or insufficient data. Interestingly, the change in BMD after 1 year of SrR treatment was higher in BP-naïve patients: LS: BP-naïve= 4.58$\pm$0.62%; BP-prior = 3.37$\pm$0.30% (p=0.0686). FN: BP-naïve= 2.61$\pm$0.55%; BP-prior= 1.72$\pm$0.28% (p=0.0961). TH: BP-naïve= 2.77$\pm$0.50%; BP-prior= 1.22$\pm$0.26% (p=0.0011). In conclusion, SrR treatment increased BMD and bone formation markers and decreased bone resorption markers in the whole group with better response in patients BP-naïve, suggesting that SrR could be considered as first-line treatment.

Responsiveness of the Japanese Osteoporosis Quality of Life Questionnaire to Raloxifene Treatment in Women with Postmenopausal Osteoporosis. Kousei Yoh[1], Etsuro Hamaya*[2], Masanori Taketsuna[3], Hisashi Urushihara[4], Kiyoshi Tanaka[5]. [1]Department of Orthopedic Surgery, Sasayama Medical Center, Hyogo College of Medicine, Japan, [2]Eli Lilly, Japan, [3]Eli Lilly Japan K.K., Japan, [4]Eli Lilly Japan K.K.and Ethics Committee, Graduate School & Faculty of Medicine, Kyoto University, Japan, [5]Kyoto Women's University, Japan

Objective: The Japanese Osteoporosis Quality of Life Questionnaire (JOQOL) is a disease-specific QOL measure of osteoporosis developed by the Japanese Society for Bone and Mineral Research. The psychometric properties of the overall JOQOL total score have been investigated in part (Kumamoto *et al*. 2010). However, responsiveness, an important psychometric property required for a patient-reported outcome measure, of each JOQOL subdomain to treatment has yet to be assessed. Using data from a previously reported QOL study in Japanese women receiving raloxifene treatment for postmenopausal osteoporosis (Yoh *et al*. 2012), we examined responsiveness of each domain of the JOQOL questionnaire to treatment changes related to raloxifene administration.

Method: A total of 506 eligible patients (mean age: 70.7 years) were stratified into those who did or did not achieve a minimal clinically important change (MCIC) in pain, as assessed by Visual Analog Scale for pain reduction ($\geqslant$ 20 mm or $<$ 20 mm). Summary statistics and Standardized Response Mean (SRM) for changes in JOQOL domain scores over 24 weeks were compared. The correlation of changes in JOQOL domains with those of Short Form-8 Health Survey (SF-8) and European Quality of Life Instrument (EQ-5D) were also assessed.

Results: The mean changes of several JOQOL domains (pain, activities of daily living, overall health, falls/psychological factors) and total score in patients who achieved MCIC were significantly larger than those who did not ($p<.001$, Student t-test). Moderate to large (0.5-0.9) SRM values in patients who achieved MCIC were seen for domains with significantly larger changes, indicating adequate responsiveness of these domains to treatment. SRMs were close to 0 (0.1-0.2) for those domains that were not significantly different (recreation/social activity, posture/physique). The SRMs and mean changes of SF-8 subscales and EQ-5D indicated sufficient responsiveness of these reference instruments. Correlation analysis with the reference instruments supported responsiveness of some of the JOQOL domains (r=0.3-0.5).

Conclusion: Some of the JOQOL domains showed adequate responsiveness to treatment changes in postmenopausal women with osteoporosis. Further scrutiny of JOQOL domains may be warranted to ensure adequate validity.

The National Bone Health Alliance: An Instrumental Force in Improving the Nation's Bone Health Through Partnership. David Lee*. National Bone Health Alliance, USA

The U.S. National Bone Health Alliance (NBHA) is a public-private partnership launched in 2010 that brings together the expertise and resources of its member organizations to collectively promote bone health and prevent disease; improve diagnosis and treatment of bone disease; and enhance bone research, surveillance and evaluation.

NBHA membership currently includes 50 members (35 non-profit organizations and 15 companies) as well as liaisons representing the CDC, FDA, NASA and NIH. ASBMR is among NBHA's founding members.

The operations and major activities of NBHA are funded through financial support from its members, which may include but are not limited to corporations, academic and medical institutions, professional and membership organizations, associations, advocacy groups and non-profit and philanthropic organizations.

NBHA is implementing three major initiatives in 2013:

1. Fracture Prevention CENTRAL Resource Center

NBHA is advocating for the widespread implementation of a fracture liaison service (FLS) model of care in which a FLS coordinator ensures that individuals who suffer a fracture receive appropriate diagnosis, treatment and support. NBHA launched Fracture Prevention CENTRAL (www.FracturePreventionCENTRAL.org) in March 2013, a resource center for institutions interested in implementing a FLS.

2. 2Million2Many Awareness Campaign

In April 2012, NBHA launched the 2Million2Many campaign. Its centerpiece Cast Mountain is a thought-provoking 12-foot tall by 12-foot wide installation representing the 5,500 bone breaks that every day in the U.S. (totaling 2 million bone breaks annually). Cast Mountain has traveled to several events across the country and the campaign has been featured in online and print stories through national media outreach activities. Learn more at www.2Million2Many.org.

3. Bone Turnover Marker Standardization Project

NBHA is leading the U.S. effort to standardize bone turnover marker assays to improve their use in clinical laboratories to help monitor osteoporosis treatment and assess future fracture risk. The project team published a position paper in Osteoporosis International in 2012 that describes the next steps in the standardization project, which is now underway.

In addition to these projects, NBHA convenes a rare bone working group and provides a platform for its collective voice to weigh in on subjects important to bone health, particularly vitamin D, calcium, and DXA reimbursement and utilization.

Development of a Novel Prostaglandin EP4 Agonist Which Stimulates Local Bone Formation *in vivo*. Jim O'Malley*[1], Adam Uzieblo[2], Bradlee Germain[2], Andrei Kornilov[2], Joseph Colombo[2], James Kramer[2], Gregory Endres[2], Stephen Barrett[2], Thomas Owen[1]. [1]Myometrics, LLC, USA, [2]Cayman Chemical Company, Inc., USA

Prostaglandin E1 (PGE1) and prostaglandin E2 (PGE2) are produced from arachidonic acid through the actions of cyclooxygenases in many cell types. These molecules interact with four G-protein coupled cell surface receptors (EP1-EP4) with equal affinity, producing a multitude of effects on a wide range of cells and tissues. Both PGE1 and PGE2 have been long known to stimulate bone formation both *in vitro* and *in vivo*. This stimulation was first observed in humans and its mechanism of action has been widely studied in a variety of species including rats, dogs, and humans. It has been well established that it is stimulation of the EP2 and EP4 receptor subtypes which leads to bone formation while stimulation of the EP1 and EP3 subtypes leads to unwanted effects on animals such as induction of pain and diarrhea. EP4 and EP2 receptors agonists have previously been developed for treatment of osteoporosis. However these agents also lead to decreased blood pressure, preventing their use as systemic bone anabolic agents. We have therefore focused on developing an EP4 agonist for stimulating bone formation following local delivery to specific bone sites. Our novel EP4 agonist demonstrates potent and specific binding to the EP4 receptor, stimulation of cAMP formation in cell culture, and stimulation of osteoblastic differentiation as demonstrated by a dose-dependent increase in alkaline phosphatase activity and mineralized colony formation in a rat bone marrow assay system. This agonist was used *in vivo* in several bone repair models including the critical calvarial defect in rats. Following treatment of the rats at the time of surgery, images were obtained at weekly intervals using a cone-beam CT scanner and bones were processed for histological analysis at the end of the studies. In these models, our agent demonstrated repair rates approximately four-fold that of controls and equal to those of BMP-2 delivered in the same matrix.

Effects of anti-resorptive agents on ovariectomised (OVX) rat cortical bone: Raman spectroscopy and multivariate analyses. Xiaomei Yao*[1], Wei Yao[2], Xinyan Bai[1], Amber Stern[1], Mark Johnson[3], Yong Wang[1], Nancy Lane[2]. [1]University of Missouri-Kansas City, USA, [2]University of California, Davis Medical Center, USA, [3]University of Missouri, Kansas City Dental School, USA

Osteoporosis is a syndrome of extreme skeletal fragility frequently resulting from estrogen deficiency and aging. Patients are often cycled through these different types of bone active medications for a number of years such as anti-resorptive (AR) agents and more recently the anabolic therapeutic, hPTH. The prolonged effects of these agents on bone quality is unknown. In this study, we utilized Raman microspectroscopy and multivariate analysis methods to evaluate the influence of cyclical therapies on cortical bone structural changes based on the organic and mineral molecular composition.

Six-month old female SD rats were either OVX or sham operated. The OVX rats were untreated for two months to develop osteopenia then treated with SQ injections of either vehicle (OVX) 0.1ug/kg,3x/wk; hPTH (1-34)(PTH) 20ug/kg/d,3x/wk; alendronate (Ale) 0.5ug/kg/2x/wk; or Raloxifene (Ral) 5mg/kg, po 3x/wk. We studied four sequential treatment regimens in three 90 day cycles (Veh-Veh-Veh,PTH-Veh-Veh, Ale-Ale-Ale, Ral-Ral-Ral) (n=3). The Raman spectra were recorded from 877 to 1785 cm^{-1} range, allowing acquisition of peaks attributed to the bone mineral and proteins. Two osteocyte lacunae per sample were chosen from the tibial midshaft. For each lacuna, four line mappings with 1 μm steps were acquired from the edge of the lacuna, and 16 spectra were used. The integrated area ratios of the hydroxyapatite peak (960 cm^{-1}) to matrix amide I peak (1630 cm^{-1}) were measured. The datasets of 240 Raman spectra were built in and normalized. Multivariate data analyses using principal component analysis (PCA) and discriminant analysis in combination with MANOVA were performed to distinguish among the groups. Mechanical testing was performed on the cortical bone and whole bone strength was measured.

The mineral/matrix ratios and mechanical testing corresponding to the five groups were not significantly different. However, using the more powerful PCA-discriminant analyses of the cortical bone, the Sham group was different from OVX group (Figure below). Also, based on scatter plots, the Ale and Ral groups were more closely associated with the Sham group, while the PTH and OVX groups were more similar, indicating different treatment effects on the combined parameters.

Mulitvariate analysis of the Raman spectroscopy data detected changes in the chemical compositional of the cortical bone after various treatments with bone active agents.

Endothelial Cell Removal Completely Eliminates Vasodilation of Bone Arteries to PTHrP While Slight Vasodilation Remains in Response to PTH 1-34. Rhonda Prisby*[1], Ashley Bice[2]. [1]University of Delaware, USA, [2]University of Delaware, Department of Kinesiology & Applied Physiology, USA

BACKGROUND: Vasodilation of the femoral principal nutrient artery (PNA) to PTHrP is augmented in comparison to PTH 1-84 and PTH 1-34 (Benson et al., 2012). Moreover, inhibition of NO production with L-NAME reduced vasodilation by 81%, 92% and 54% in response to PTH 1-84, PTH 1-34 and PTHrP, respectively. Recently, we demonstrated that vasodilation to PTH 1-84 peaked at 5% of the maximal diameter in the PNA following endothelial cell removal (Benson & Prisby 2013). These data indicate that vasodilation to PTH 1-84 is completely reliant upon the vascular endothelium. Thus, we sought to determine whether vasodilation of the PNA to PTHrP and PTH 1-34 is also exclusively reliant upon vascular endothelial cells. *METHODS:* Right femoral PNAs were isolated from male Wistar rats (4-5 months, 558 $\pm$ 33g; n=6), cannulated on glass micropipettes and denuded (i.e., removed of the endothelial cells). PNAs were considered adequately denuded if they dilated $\leq$ 5% to a bolus does of acetylcholine ($5x10^{-5}$ M). Vasodilation to PTHrP (10^{-13} – 10^{-8} M) and PTH 1-34 (10^{-13} – 10^{-8} M) was assessed in the presence of 1) PSS buffer, 2) PSS buffer with L-NAME, and 3) PSS buffer with L-NAME + indomethacin (Indo; a cyclooxygenase inhibitor). To ensure that the smooth muscle cells were not damaged during endothelial cell removal, endothelium-independent vasodilation to sodium nitroprusside (SNP; 10^{-10} – 10^{-4}) was determined. *RESULTS:* Vasodilation to cumulative doses of PTHrP and PTH 1-34 peaked at 2% and 16%, respectively, of maximal diameter. Inhibition of NO and prostacyclin production with L-NAME and L-NAME + Indo, respectively, did not alter vasodilation in response to PTHrP or PTH 1-34 alone. Vasodilation to SNP of denuded PNAs rose to 57% of maximal diameter and did not differ from vasodilation of intact PNAs, indicating that smooth muscle cell responsiveness was not altered with endothelial denudation. *CONCLUSION:* Vasodilation of the bone resistance vasculature in response to PTHrP occurs via endothelium-dependent, rather than endothelium-independent signaling pathways. Further, even though vasodilation was dramatically impaired in response to PTH 1-34, some dilatory capacity remained following endothelial cell removal. In totality, data suggest that vasodilation of the bone resistance vasculature to the endogenously produced peptide and hormone (i.e., PTHrP and PTH 1-84) relies exclusively on vascular endothelial cells.

MO0408

Fixation Stiffness Modulates the Efficacy of Sclerostin-Neutralizing Antibody Treatment during Bone Healing. Bettina Kruck*, Georg Duda, Sophie Damerow, Florian Wichlas, Serafim Tsitsilonis, Bettina Willie. Charité – Universitätsmedizin Berlin, Germany

Bone healing is influenced by mechanical strain. Inhibition of SOST/sclerostin may be partially responsible for the anabolic action of mechanical loading. The protein sclerostin is thought to reduce bone formation by inhibiting Wnt signaling and decreasing osteoblast function. We examined the efficacy of sclerostin neutralizing antibody (Scl-Ab) to enhance bone healing and the influence of interfragmentary movement on the healing response to Scl-Ab.

A 0.5mm femoral osteotomy was performed on 26wk old female C57BL/6J mice, stabilized with a rigid or semi-rigid external fixator, allowing different magnitudes of interfragmentary movement at the osteotomy during weight bearing. Scl-Ab VI or vehicle was administered (25 mg/kg), twice per week by subcutaneous injection, starting one day post-op. Bone healing was assessed by in vivo microCT (n=10-12 mice) after 3, 7, 14, and 21d for mineralized callus volume (BV), total callus volume (TV), mineralized callus volume fraction (BV/TV), callus tissue mineral density (TMD), and bone/calcified cartilage mineral density (BMD). After 21 days, osteotomized and contralateral femurs (n=6-8 mice) underwent torsion testing to determine ultimate torque, stiffness, and energy to failure. At 7, 14, 21d osteotomized femurs (n=7-12 mice/time point) were decalcified, paraffin embedded and analyzed for bony bridging and callus tissue area (bone, cartilage, fibrous tissue formation, bone marrow). Effects of treatment, fixation stiffness and interactions were assessed by ANOVA.

Scl-Ab significantly enhanced BV, BV/TV, TMD, (14, 21d), and bone area (21d) compared to vehicle treated groups with both rigid and semi-rigid fixation (Table 1, 2). Rigid fixation enhanced BV/TV, BMD, TMD, bone area (14, 21d), BV (14d), bone marrow area (7, 14, 21d), and decreased cartilage and fibrous tissue area (7, 14, 21d). Neither fixator stiffness, nor Scl-Ab influenced mechanical properties of osteotomized femurs at 21d, although intact femurs treated with Scl-Ab had significantly greater mechanical properties. The rigidly fixed Scl-Ab group had the greatest number of bridged cortices (63% vs. 43%) at day 14, although the rigidly fixed vehicle group was similar at 21d (46% vs.44%, Table 2). In summary, fixation stiffness modulated the healing response to Scl-Ab. Scl-Ab under more rigid fixation appeared to accelerate healing (14d). By 21 days, rigidly fixed vehicle and Scl-Ab groups had similar healing, although the Scl-Ab group exhibited more bone.

LLP2A-Ale Directs Mesenchymal Stem Cells to Bone to Reverse Bone Loss in Ovariectomized Rats. Wei Yao*[1], Li Jiang[2], Evan Yu-An Lay[2], Weiwei Dai[3], Sarah Amugongo[4], Nancy Lane[1]. [1]University of California, Davis Medical Center, USA, [2]UC Davis Medical Center, USA, [3]Shriner's Hospital for Children, USA, [4]University of California, Davis, USA

Aging is associated with a reduction in the number of mesenchymal stem cells (MSCs) and with a decrease in their osteogenic potential that may be responsible for reduced bone formation. However, systemic MSCs tranplantation had limited sucess for bone regeneration as they fail to home to the bone surface. Our research group has developed a compound, LLP2A-Ale that has high affinity for both the activated α4β1 integrin on the MSC surface and hydroxyapatite, and alendronate (Aln) that directs the MSCs to the bone surface. We have previously reported that LLP2A-Ale directed transplanted MSCs to bone and increases the retention of the transplanted MSCs in bone in multiple in vivo mouse models that included estrogen deficiency and aging. The purpose of these studies were to evaluate the effects of LLP2A-Ale in the combination of MSC transplantation in an osteopenic rat model.

Four-month-old ovariectomized (OVX) rats were allowed to develop bone loss for two months and then treated with PBS, LLP2A-Ale (200μg/kg, IV/month), MSC (3x105, GFP and luciferase transduced, IV at day 0), hPTH (1-34) (25 μg/kg, 5x/wk x 4 wks), LLP2A-Ale + MSC or one IV LLP2A-Ale + MSC followed by PTH (1-34) from day7 (25 μg/kg, 5x/wk x 3 wks). The dose of LLP2A-Ale was chosen from a prior dose-finding study ranging from 50-300 μg/kg in 6-month-old OVX rats. After 4 weeks of treatment, BV/TV loss at the proximal tibiae was 40% ($p<0.01$ from baseline) in the OVX and OVX+MSC groups. Treatment with LLP2A-Ale, LLP2A-Ale + MSC or PTH increased the PTM BV/TV by 35, 53, and 70%, compared to the OVX-PBS; and BV/TV was increased by nearly 200% with LLP2A-Ale + MSC followed by PTH treatment compared to OVX + PBS ($p<0.01$). PTH, LLP2A-Ale +MSC or LLP2A-Ale + MSC followed by PTH treatment also increase tibial cortical bone thickness by 2%, 2% and 8%, respectively, as compared to OVX group that was primary the results of the periosteal expansion.

In summary, LLP2A-Ale by itself prevented and partially restored trabecular bone loss in an acute estrogen deficiency model. Treatment with one IV LLP2A-Ale + MSC transplantation and daily PTH injections for four weeks had similar gains in bone volume. Greater gains in bone bone volume was obtained with one treatment of IV LLP2A-Ale + MSC transplantation was followed by three weeks of daintly PTH injections. Additional studies that quantitate the efficacy of MSC homing and their contributions to bone formation and strength are currently in progress.

Nmp4/CIZ-knockout Mice Are Hyperresponsive to Anabolic Agonists But Susceptible to Ovariectomy-induced Bone Loss. Paul Childress, Marta Alvarez, Joseph Bidwell*. Indiana University School of Medicine, USA

Disabling Nmp4/CIZ ('Nmp4') in mice enhances the skeletal response to anabolic agonists; these mice are also resistant to unloading-induced bone loss. The untreated *Nmp4*-null phenotype includes a modest but significant increase in cancellous and cortical bone as well as expanded populations of bone marrow CD146+/nestin+ mesenchymal stem cells and CFU-F(alk phos+) cells. Null mice exhibit a small increase in CFU-GM cells, precursors to osteoclasts, and an augmented number of marrow-derived osteoclasts. The purpose of this study was to determine the susceptibility of *Nmp4*-KO mice to ovariectomy (ovx)-induced bone loss. Virgin female *Nmp4*-KO mice and their wild-type (WT) littermates were sorted into four treatment groups by body weight at 12wks of age (8-12 mice/group) and ovx or sham-operated. Additional mice (8-10/genotype) were used for baseline analysis. At 4wks post-op mice were euthanized and femurs prepared for micro-computed tomography analysis including bone volume/total volume (BV/TV), connectivity density (Conn D), structure model index (SMI), trabecular number (Tb N), thickness (Tb Th), and spacing (Tb Sp). For statistical analysis a 2-way ANOVA was employed using genotype and treatment as the independent variables followed by a Tukey HSD if a genotype x treatment interaction was indicated. Statistical significance was set at $p \leq 0.05$. Both the ovx WT and *Nmp4*-KO mice gained body weight compared to the sham-operated animals. There was a strong treatment effect as both genotypes exhibited significant ovx-induced bone loss as indicated by changes in BV/TV, Conn D, SMI, Tb N, and Tb Sp. A strong genotype effect was observed for all parameters since the null mice had significantly more cancellous bone throughout the study. The parameter Conn D showed a genotype x treatment interaction (Prob >ItI 0.005) since the decrease in this parameter was greater in the null mice. Similarly, the genotype x treatment interaction term approached significance for BV/TV (Prob > ItI 0.06). We conclude that disabling Nmp4 does not protect mice from ovx-induced bone loss as it does for disuse-associated osteopenia. The *Nmp4*-null mice show a very modest heightened sensitivity to ovx for some parameters. This phenomenon may derive from the small surplus of null osteoclast precursors. These results raise the question as to whether ovx *Nmp4*-KO mice exhibit an enhanced response to therapeutic PTH like the intact null mice.

Sclerostin Antibody Prevented Severe Bone Loss in Ovariectomized Rats with Concurrent Mechanical Unloading. Dongye Zhang*[1], Minyi Hu[1], Liangjun Lin[2], Xiaodong Li[3], Hua Zhu (David) Ke[3], Yi-Xian Qin[2]. [1]Stony Brook University, USA, [3]State University of New York at Stony Brook, USA, [3]Amgen, Inc., USA

Osteoporosis most often occurs with aging populations that have significantly reduced physical activities and diminished load to their skeletons. Sclerostin antibody (Scl-Ab) increases bone formation and bone mass, and decreases bone resorption in animal models of bone loss due to either estrogen deficiency (ovariectomy; OVX) or immobilization. The objective of this study was to evaluate the effect of Scl-Ab in a bone loss model from both estrogen deficiency and immobilization (OVX rats with concurrent hindlimb suspension (HLS)). Four-month-old female Sprague Dawley rats were divided into 7 groups (n=11 per group) as shown in Figure 1, HLS was introduced 2 weeks after sham and OVX. Scl-Ab (25 mg/kg) or vehicle was injected sc twice weekly for 5 weeks starting at the time of HLS. The metaphyseal trabecular bone of the distal femurs was analyzed with micro-CT (μCT). Four-point bending mechanical testing was performed at the midshaft of the femur. HLS or OVX alone resulted in significant loss of trabecular bone volume (BV/TV, -29% and -71%, respectively) compared to sham control (Fig. 1a), whereas the OVX+HLS resulted in the greater bone loss at 87%. Scl-Ab fully preserved BV/TV in rats with HLS or OVX (Fig. 1a, 2), and partially prevented trabecular bone loss in rats with combination of OVX plus HLS (Fig.1a, 2). Tb.Th was increased to similar extent in HLS, OVX and OVX plus HLS rats treated with Scl-Ab. HLS or OVX+HLS was associated with significantly lower stiffness as compared with Sham controls (Fig. 1c). Scl-Ab prevented the decrease in stiffness due to HLS, OVX or OVX+HLS. Ultimate load was not significantly lower in HLS, OVX or OVX plus HLS as compared with Sham controls, but it was significantly greater in Scl-Ab-treated HLS or OVX rats as compared with respective vehicle controls and sham group (Fig. 1d). Scl-Ab-treated HLS plus OVX showed increased ultimate load, but not significant compared with OVX control. In summary, Scl-Ab prevented the loss of trabecular bone mass and cortical bone strength in OVX rats with concurrent immobilization. The data suggested that sclerostin inhibition may represent a therapeutic option for the osteoporosis with concurrent immobilization or decreased skeletal loading.

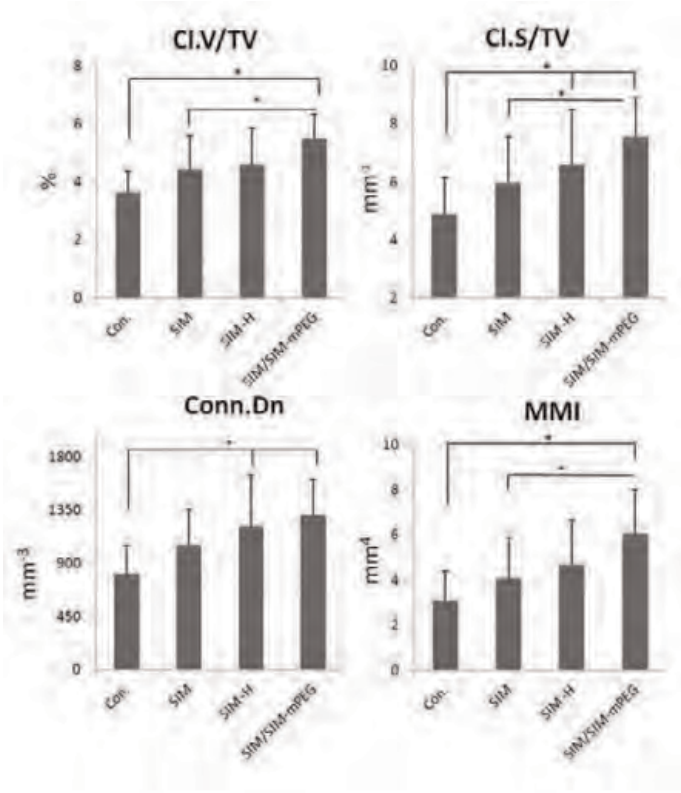
Simvastatin Prodrug Promotes Bone Fracture Repair in a Closed Fracture Mouse Model. Yijia Zhang*[1], Zhenshan Jia[1], Hongjiang Yuan[1], Ke Ren[1], Aaron Daluiski[2], Edward Fehringer[1], Steven Goldring[2], Dong Wang[1]. [1]University of Nebraska Medical Center, USA, [2]Hospital for Special Surgery, USA

Purpose. Though known for their bone anabolic effect, statins have not been used clinically for metabolic skeletal diseases due to the lack of tissue specificity to the skeleton. Recently, we have developed a novel micelle-forming macromolecular prodrug of simvastatin (SIM). When administered systemically, the prodrug formulation would passively target to the fracture site and provided a potent and locally sustained bone anabolic effect in an osteotomized mouse model. In the present study, the prodrug formulation was further optimized and evaluated in a closed fracture mouse model.

Method. The simvastatin-containing prodrug, SIM-mPEG was synthesized and further formulated into micelles loaded with free SIM (SIM/SIM-mPEG). Unilateral transverse femoral closed fracture wascreated by a three-point bending device. Forty male CD-1 mice were fractured and randomly assigned into four groups (n = 10): SIM/SIM-mPEG (equiv. SIM 3 mg/kg/d, weekly i.v.), SIM (equiv. SIM 3 mg/kg/d, daily i.p.), SIM-H (high dose SIM, equiv. SIM 6 mg/kg/d, daily i.p.) and saline treated control group (CON). The treatments were initiated on day 2 post-op and the mice were euthanized on day 22. The fractured femurs were processed for μ-CT analysis. The data were analyzed for the histomorphometric parameters of the longitudinal fracture callus.

Results. μ-CT morphometric parameters, such as callus volume (Cl.V), callus surface (Cl.S), connective density (Conn.Dn) and mean polar moment of inertia (MMI) values of the SIM/SIM-mPEG group were all significantly higher than the CON mice ($p<0.003$), suggesting enhanced callus formation, organization and strength. For SIM group, these parameters (except Conn.Dn) were significantly lower than SIM/SIM-mPEG treated group ($p<0.05$). No significant difference was found

between SIM and CON. Comparing to CON, SIM-H could only significantly increase Cl.S and Conn.Dn, while a significant body weight decline ($p < 0.05$) was found during the treatment in this group suggesting the potential toxicity of SIM-H.*Conclusions*. Passive-targeting of SIM to fracture site using the SIM/SIM-mPEG formulation provides potent local bone anabolic effect and accelerates the healing of closed fracture without any noted side effect. This outcome suggests the potential benefits of this nanomedicine formulation in clinical management of impaired fracture healing.



Simvastatin Prodrug Promotes Bone Fracture Repair in a Closed Fracture Mouse Model

MO0413

Subcutaneous and Intravenous Single Dose Pharmacokinetics of PTH(1-34) and PTH-CBD, a Long-Acting Parathyroid Hormone Analog, in Sprague Dawley Rats. Tulasi Ponnapakkam*[1], Ranjitha Katikaneni[2], Robert Stratford[3], Joshua Sakon[4], Robert Gensure[2]. [1]Childrens Hospital at Montefiore, New York/Albert Einstein College of Medicine, USA, [2]Childrens Hospital at Montefiore/Albert Einstein College of Medicine, USA, [3]Xavier University, USA, [4]University of Arkansas, USA

PTH-CBD is a novel hybrid protein of PTH(1-33) and a bacterial collagen binding domain designed to accumulate in collagen rich areas such as bone. PTH-CBD has been shown in rodents to have a sustained (6-9 month) anabolic action in bone after a single subcutaneous injection, which we hypothesize is the result of prolonged retention in the bone rather than a depot effect. We previously reported subcutaneous single dose pharmacokinetics of PTH-CBD and PTH(1-34) at molar equivalent doses (320 ug/kg and 80 ug/kg, respectively). Both drugs showed similar bioavailability using a one-compartment model with 1st order absorption. While the initial phase half-lives were similar, the terminal phase half-life of PTH-CBD was 3 times greater. This together with lower peak levels suggested there was prolonged absorption. PTH-CBD was not completely eliminated by the last (6 hr) time point in this study, but the model predicted that it would be completely eliminated by 24 hours. We next conducted a longer term study to test this prediction. The results showed the expected high levels of serum PTH-CBD at 1 hour, and levels remained elevated above the normal range at 6 hours, similar to the initial study. At 12 hours, PTH-CBD levels had fallen to within the normal range. At 24 hours, there was no detectable PTH-CBD in the serum, as predicted. To determine if prolonged absorption or slower elimination was responsible for the longer terminal phase half life of PTH-CBD observed in the subcutaneous studies, we bypassed any absorptive effects by comparing IV single-dose pharmacokinetics of PTH(1-34) and PTH-CBD, again at molar-equivalent doses. PTH(1-34) and PTH-CBD had similar terminal-phase half lives, and both were completely eliminated by 6 hours after IV dosing, thus confirming that the increased terminal phase half-life seen after subcutaneous dosing was indeed the result of prolonged absorption. There was no hypercalcemia observed in any of our studies. Importantly, the overall pharmacokinetic analysis show that subcutaneously administered PTH-CBD (vs. PTH(1-34)) shows lower peak and only mildly prolonged elevated serum PTH levels which do not result in sustained hypercalcemia. As the number of injections required to achieve an anabolic bone effect is also markedly reduced with PTH-CBD, this would result in a reduced overall systemic exposure to PTH during the course of therapy, presumably corresponding to a reduced risk of any systemic side-effects.

MO0414

***In vivo* assessment of skeletal biomechanical properties reveals beneficial effects of combination anti-remodeling drug treatment.** Jason Organ*[1], Maxime Gallant[1], Mohammad Aref[1], Joseph Wallace[2], David Burr[1], Christopher Newman[1], Drew Brown[1], Matthew Allen[1]. [1]Indiana University School of Medicine, USA, [2]Indiana University Purdue University Indianapolis (IUPUI), USA

Pharmaceutical agents used to treat osteoporosis significantly reduce fracture risk via different mechanisms. Bisphosphonates, such as alendronate (ALN), increase bone volume and density, whereas raloxifene (RAL) improves material-level properties. This study was designed to assess whether combination treatment improves mechanical properties more than either monotherapy. Skeletally mature female dogs (n=24) were treated with vehicle, ALN, RAL, or ALN+RAL at clinical doses used for treating post-menopausal osteoporosis. After 6 months of daily treatment, all animals underwent *in vivo* biomechanical assessment using reference point indentation (RPI) on the anterior tibial cortex. Indentation distance increase (IDI), a measure of cyclic indentation resistance of the bone, was significantly lower in animals treated with RAL monotherapy (-17%) and ALN+RAL (-26%) compared to vehicle-treated animals, whereas ALN alone had no significant effect. Reductions in IDI represent an improvement in material-level mechanical properties. All three treatment groups exhibited significantly reduced first cycle indentation distance (ID) (-30-40%), total ID (-28-40%), and first cycle energy absorption (-20-28%) compared to vehicle-treated animals. These data suggest that RAL, and its combination with ALN, improves bone resistance to damage initiation and propagation. Results also indicate that RPI can detect treatment-induced alterations in skeletal mechanical properties *in vivo* – something previously restricted to *ex vivo* assessment.

Can Bisphosphonates extend Life Span? Effects on Stem Cell survival, DNA Repair and Tissue Regeneration. Juhi Misra*[1], Sindhu T Mohanty[2], Sanjeev Madan[3], James A Fernandes[3], Frank H Ebetino[4], Henry Roehl[5], R Graham Russell[6], Ilaria Bellantuono[1]. [1]Mellanby Centre for Bone Research; CIMA, The MRC-Arthritis Research UK Centre for Integrated research into Musculoskeletal Ageing, Dept. of Human Metabolism Medical School, University of Sheffield, United Kingdom, [2]Mellanby Centre for Bone Research, Dept. of Human Metabolism, Medical School, University of Sheffield, United Kingdom, [3]Department of Paediatric Orthopaedic & Trauma Surgery, Sheffield Childrens Hospital, United Kingdom, [4]Structural Genomics Consortium, University of Oxford, United Kingdom, [5]Dept. of Biomedical Science, MRC Centre for Developmental & Biomedical Genetics, University of Sheffield, United Kingdom, [6]University of Oxford, United Kingdom

Several lines of experimental and clinical evidence have recently raised the intriguing possibility that bisphosphonates (BPs) may extend life span. The observations include a pronounced extension of life span with a combination of zoledronate (Zol) and statins in a murine progeria model of accelerated aging (Varela et al 2008, 10.1038/nm1786), a 28% reduction in mortality in the Zol Horizon study in osteoporotic patients (Lyles et al 2007, 10.1056/NEJMoa074941), and several observational studies suggesting that alendronate and other BPs reduce cardiovascular events and deaths (eg Center et al 2011, 10.1210/jc.2010-2730; Wolfe et al 2012, 10.1002/jbmr.1792; Kang et al 2012, 10.1007/s00198-012-2213-5). In studies designed to explore potential underlying mechanisms, we have now found that BPs have hitherto unknown effects on stem cell survival, DNA repair and tissue regeneration.

We used human bone marrow mesenchymal stem cells (hMSC) and showed that Zol extended the life span of hMSC cultures (n=3) in vitro by more than 30% at 1μM, and significantly enhanced their clonogenic ability. Moreover Zol significantly enhanced repair of DNA damage (γH2AX) foci in hMSCs induced by cellular ageing or by gamma irradiation (1-5Gy; n=3) by as much as 84% at 1Gy; 40% at 3Gy and 19% at 5Gy that resulted in rescue of their proliferation and differentiation ability within 4-48 hours. In an in vivo model utilising Zebrafish embryos Zol significantly restored tail regeneration following amputation and irradiation (1-5Gy; n=15). All these effects appear to be mediated by inhibition of the mevalonate pathway, since they could be reversed by adding back appropriate isoprenoid metabolites (eg farnesol or geranylgeraniol), and the effects of other N-containing BPs were related to their known potencies as inhibitors of farnesyl pyrophosphate synthase in this pathway.

Downstream mechanisms were dependent on inhibition of TORC1 and TORC2 mediated mTOR signalling, leading to increased nuclear translocation of FOXO-3a and phosphorylation of ATM resulting in an activated DNA damage response.

In conclusion these remarkable effects of BPs on stem cell aging and survival and on DNA repair and tissue regeneration may help to explain some of the observations already made about non-skeletal effects of BPs. Furthermore, they open up a range of exciting new potential applications for utilizing these novel effects in repair of damaged tissues, and more widely in biology and medicine.

MO0416

Intermittent Minodronic Acid Treatment with Sufficient Bone Resorption Inhibition Prevents Reduction in Bone Mass and Strength in Ovariectomized Rats with Established Osteopenia Comparable with Daily Treatment. Makoto Tanaka*[1], Aishi Kimoto[2], Masamichi Mori[2], Kazutoshi Nozaki[3], Shinji Fukushima[2], Hiroshi Mori[1], Tsutomu Shiroya[4], Toshitaka Nakamura[5]. [1]ONO Pharmaceutical Co., Ltd., Japan, [2]Pharmacology Research Laboratories, Drug Discovery Research, Astellas Pharma Inc., Japan, [3]Medical Affairs, Astellas Pharma Inc., Japan, [4]Discovery Research Laboratories, Ono Pharmaceutical Co., Ltd., Japan, [5]University of Occupational & Environmental Health, Japan

This study examined to compare the effects of four-week intermittent and daily administrations of minodronic acid, a highly potent nitrogen-containing bisphosphonate, on bone mineral density (BMD), bone strength, bone turnover, and histomorphometry on established osteopenia in ovariectomized (OVX) rats.

Female rats were OVX or sham-operated. At 12 weeks post surgery, minodronic acid was orally administered once every 4 weeks at 0.2, 1, and 5 mg/kg and once daily at 0.006, 0.03, and 0.15 mg/kg for 12 months. The total dosing amount was comparable between two dosing regimens. The levels of bone turnover markers were measured. BMD as assessed via DXA, bone structure and dynamical changes in vertebral trabecular and biomechanical properties were measured ex vivo at 12 months. Minodronic acid ameliorated the decrease in BMD of lumbar and the femur in both treatment regimens similarly. Minodronic acid suppressed elevated urinary deoxypyridinoline levels, a bone resorption marker, and reduced serum levels of osteocalcin, a bone formation marker. In the mechanical test at 12 months, minodronic acid ameliorated the reduction in bone strength in femur and vertebral body. There is no significant difference in parameters between two regimens except maximal load of lower doses in lumbar vertebral body and absorption energy of middle doses in femur. These parameters with significant difference, values in intermittent regimen were significantly lower than that in daily repeated regimen. Bone histomorphometric analysis showed that minodronic acid significantly ameliorated the decrease in bone mass, trabecular thickness and number, and increased in trabecular separation, bone resorption indices, and bone formation indices in both regimens. Minodronic acid suppressed OVX-induced increases in bone turnover at the tissue level and ameliorated all structural indices, thereby improving the deterioration in bone quality under osteoporotic disease conditions regardless of the regimen.In conclusions, four-week intermittent treatment of minodronic acid suppressed increased bone resorption as daily treatment when considering the total administered dose. The improvement of microarchitectural destruction in low dose of intermittent treatment was weaker than that observed in a daily repeated regimen; however the effect in high and middle doses of intermittent treatment were equivalent with that observed in a daily repeated regimen accompanied sufficient bone resorption inhibition.

MO0417

Periprosthetic Bone Response to Mechanical Loading with Administration of an Anti-Catabolic Agent, Osteoprotegerin (OPG). James Sutherland*[1], Hayden-William Courtland[1], Chad Ishmael[2], Joseph Choi[1], Kirsten Stoner[1], Alex Sarkisian[2], Joe Nguyen[1], Marjolein Van Der Meulen[3], F. Patrick Ross[1], Mathias Bostrom[1]. [1]Hospital for Special Surgery, USA, [2]Weill Cornell Medical College, USA, [3]Cornell University, USA

Osseointegration is crucial to the success of implant fixation in uncemented total joint arthroplasty and depends on the integrity and quantity of periprosthetic bone. Mechanical loading has been proven to increase periprosthetic cancellous bone volume, thereby enhancing osseointegration. However, while mechanical loading is a known anabolic therapy, the contribution of osteoblast-osteoclast coupling to its anabolic effect is not well understood. Recent findings reveal that osteoclasts not only degrade bone but also secrete anabolic factors. Thus, we hypothesized that the inhibition of bone resorption with an anti-catabolic agent (osteoprotegerin, OPG) may diminish the beneficial effects of mechanical loading on cancellous bone volume. A porous titanium disc and mechanical loading device were bilaterally implanted on cancellous bone in the distal femurs of adult rabbits (n=28). The right femur was loaded daily, while the left femur received a sham loading device. Half of the rabbits received OPG (10 mg/kg, weekly), and half received saline (daily). Periprosthetic cancellous bone was harvested at 7 and 14 days for microcomputed tomography. At 14 days, mechanical loading significantly increased periprosthetic cancellous bone volume within 500 μm of the implant interface, with and without OPG treatment (29% and 35% respectively, p = 0.008). No effect of OPG was observed on any outcome parameters, and no synergistic effects of combined OPG and loading treatment were observed. Inhibition of bone resorption with an anti-catabolic agent (OPG) neither diminished nor enhanced the beneficial effects of mechanical loading on cancellous bone volume. This finding suggests that mechanical loading increases bone volume by upregulation of new bone formation, not by maintenance of bone mass through the inhibition of resorption.

Switching from Alendronate to RANKL Blockade alters Bone Properties after 14 Weeks of Therapy in the *oim/oim* Mouse. Josephine Marino*[1], Nancy Pleshko[2], Steve Doty[1], Erin Carter[1], Adele Boskey[1], Cathleen Raggio[1]. [1]Hospital for Special Surgery, USA, [2]Temple University, USA

The purpose of this study was to determine whether Osteogenesis Imperfecta(OI) patients entering adulthood should continue bisphosphonate therapy or would benefit from switching to a RANKL blockade therapy. To address this question, we used a mouse model of type III OI.

METHODS: Animal studies were performed under IACUC approval. OI(*oim/oim*) and wild-type(WT) mice were treated from 2-26 weeks with 1)Saline; 2)Alendronate(ALN; 0.21 mg/kg/dose weekly); or 3)ALN from 2-14 weeks followed by 1.5 mg/kg/dose biweekly RANK-Fc from 14-26 weeks(ALN+RANK-Fc). Fracture number was calculated from high-resolution faxitrons obtained in the anterior-posterior and medial-lateral planes at 14 weeks and sacrifice. Femurs were analyzed by microcomputed tomography using a Scanco μCT 35 system(Scanco Medical, Basserdorf, Switzerland). A subset of femora were embedded in poly methyl methacrylate and sectioned at 2 μm for Fourier transform infrared imaging analysis. Nine images of cortical and trabecular bone were taken from each femur using a Perkin Elmer Spotlight Imaging Spectrometer and ISys(Malevern Instruments) software. Results are statistically significant $p<0.05$ by two-way ANOVA(SigmaStat).

RESULTS: At 14 weeks, both *oim/oim* treated groups had fewer fractures compared to saline. At 26 weeks, both treatment groups had fewer fractures compared to saline. There were no differences between treatment groups at either time-point and no new fractures after 14 weeks in either group(fig1).

There were no differences in cortical bone in any parameters studied. Trabecular number was increased in *oim/oim* for both treatment groups compared to saline(fig2). ALN+RANK-Fc increased trabecular number compared to ALN. Trabecular spacing decreased and bone volume fraction increased in both treated *oim/oim* groups compared to saline. Changes in WT mirror *oim/oim*.

oim/oim trabecular bone: ALN treatment increased mineral:matrix ratio compared to saline and both treatment groups increased collagen maturity compared to saline(fig3). *oim/oim* cortical bone mineral:matrix ratio was increased in ALN compared to ALN+RANK-Fc treatment. WT cortical bone: ALN+RANK-Fc treatment resulted in more perfect crystals compared to saline.DISCUSSION Based on our current data, treatment with ALN or ALN+RANK-Fc comparably reduces fracture number, increases bone quantity, and alters bone quality in *oim/oim* mice. Mechanical testing will be essential in determining the implication of these changes on patient life.

Probiotics Protect Mice from Ovariectomy Induced Bone-Loss. Klara Sjogren*[1], Cecilia Engdahl[2], Frida Fåk[3], Annica Andersson[4], Sara Windahl[2], Helen Farman[5], Sofia Moverare Skrtic[6], Ulrika Islander[4], Claes Ohlsson[6]. [1]Centre for Bone & Arthritis Research, Sweden, [2]Center for Bone & Arthritis Research, Sahlgrenska Academy, Sweden, [3]Applied Nutrition & Food Chemistry, Department of Food Technology, Engineering & Nutrition, Lund University, Sweden, [4]Centre for Bone & Arthritis Research, Institute of Medicin, Sahlgrenska Academy at University of Gothenburg, Sweden, [5]University of Gothenburg, Sweden, [6]Center for Bone & Arthritis Research at the Sahlgrenska Academy, Sweden

Absence of gut microbiota in germ-free mice leads to increased bone mass in combination with decreased osteoclastogenesis and altered immune status in bone marrow suggesting that the gut microbiota can regulate bone mass[1]. Probiotic bacteria are defined as live microorganisms which when administered in adequate amounts confer a health benefit on the host and are believed to alter the composition of the gut microbiota.

The purpose of this study was to test if probiotic treatment, via its effects on gut microbiota, could protect mice from ovariectomy (ovx) induced bone-loss. The probiotic strains were selected based on their anti-inflammatory properties in an earlier study[2]. Mice were treated with either a single Lactobacillus (L) strain, L. paracasei DSM13434 (L. para) or a mixture of three strains, L. paracasei DSM13434, L. plantarum DSM 15312 and DSM 15313 referred to as L. mix during 6 weeks, starting two weeks before ovx to study the preventive effect of probiotic treatment on ovx induced bone-loss. The L. strains were given in the drinking water at a concentration of 10^9 colony-forming units/ml while control mice only received tap water with vehicle. Ovx resulted in an expected increased body weight (16%, $p<0.01$) compared to sham mice that was similar for all treatments. Cortical bone parameters were measured by peripheral quantitative computed tomography (pQCT) in the mid-diaphyseal region of femur. In the vehicle treated mice, ovx decreased the cortical bone mineral content and cortical cross sectional bone area by 11% ($p<0.01$) and 7% ($p<0.01$), respectively. In contrast, ovx did not reduce corresponding cortical bone parameters in the L. para or the L. mix treated mice. Cortical bone mineral content was higher in both L. para ($p<0.05$) and L. mix ($p<0.05$) treated ovx mice compared to veh treated ovx mice.

In conclusion, these data show that probiotic bacteria in the drinking water prevents ovx induced cortical bone-loss suggesting a therapeutic potential for probiotics in the treatment of postmenopausal osteoporosis. In addition, this study supports a role of the gut microbiota for the regulation of bone mass.

The Efficacy of Dried Plum's Bioactive Components in Reversing Bone Loss. Jennifer Graef*, Elizabeth Rendina, Pitipa Chongwatpol, McKale Davis, Sandra Peterson, Stephen Clarke, Edralin Lucas, Brenda Smith. Oklahoma State University, USA

Dietary dried plum supplementation has been shown to be effective at preventing and reversing bone loss in animal models of osteoporosis, but the bioactive components that are responsible for these osteoprotective effects remain in question. Much of the focus has been on the phenolic compounds in dried plum due to their anti-inflammatory and antioxidant properties as well as non-digestible carbohydrates such as inulin that may lower colonic pH and increase calcium absorption. Therefore, the purpose of this study was to determine whether synthetic forms of the major chlorogenic isomers found in dried plum with or without inulin exert a similar beneficial effect on bone as dried plum in a model of postmenopausal osteoporosis. Twelve-week-old female C57BL/6 mice (n=50) were either sham-operated or ovariectomized (OVX) and allowed to lose bone two weeks prior to beginning an 8 wk treatment period in one of the following groups: Sham-control (Sham-CON), OVX-control (OVX-CON), OVX- 25% w/w dried plum (OVX-DP), OVX- synthetic phenolics (OVX-SP), or OVX- synthetic phenolics plus inulin (OVX-SP+I). DXA was used to assess whole body bone mass/density and microCT scans were performed to assess trabecular bone structure of the 4th lumbar vertebra and distal femur metaphysis and cortical bone structure of the femur mid-diaphysis. In agreement with previous findings, bone in the OVX-DP group was restored to the level of the Sham-CON as indicated by whole body bone densitometry measures (BMD, BMC, and BMA) and trabecular bone volume, trabecular number, and trabecular separation of the L4 vertebra and distal femur metaphysis. No effect on trabecular bone was observed in the OVX-SP and OVX-SP+I treatment groups. However, the OVX-SP treatment restored cortical thickness and cortical area to the level of the OVX-DP group and the cortical area was comparable to the Sham-CON group by the end of the study period. In conclusion, the OVX-SP with and without inulin did not restore trabecular bone properties in a manner comparable to dried plum, but the OVX-SP

group did experience some improvement in cortical bone parameters. This response was not enhanced with the addition of inulin. Further studies are needed to determine the mechanism involved in the restoration of cortical bone with the supplementation of these synthetic phenolic compounds and to identify the bioactive components in dried plum exerting osteoprotective effects on trabecular bone.

Long-Term Effect of Diet on the Ovariectomy Response in the Rat Model of Osteoporosis. Aurore Varela*, Elisabeth Lesage, Susan Y. Smith. Charles River Laboratories, Canada

Diet composition, restrictions or supplements have been proven to impact prevention and bone loss treatment. The study purpose was to compare long-term effects of two diets on bone turnover, mass and strength over a 12-month period in aged ovariectomized rats. Six months old rats were fed with PMI certified rodent chow 5CR4 (14% protein) or 5002 (21% protein) *ad libitum*. The effects of OVX vs. diets were monitored using body weight (BW), food consumption (FC), bone markers, DXA (whole body, lumbar spine), pQCT (proximal tibia metaphysis and diaphysis) and biomechanics. Eighteen females/group underwent OVX or Sham surgery (Sx).

Within 2/3 weeks after Sx, OVX rats gained BW vs. Sham (+15%). With 5CR4, BW differences stabilized after 6 months to +10%, whereas with 5002, BW differences continued to increase up to +22% 8 to 12 months after Sx up to 12 months. Sham controls fed with 5002 gained 20% more BW over 52 weeks, 5002 OVX gained FC was 10% larger in 5002 sham vs. 5CR4 sham and 22 % in OVX. Due to larger BW, cage size was 290 in^2 for 5002 rats vs. 180 in^2 for 5CR4 rats. Marker values were generally higher for 5002 Sham vs. 5CR4 Sham rats, therefore, differences were more marked between Sham and OVX in 5CR4 vs. 5002 fed rats. Differences between Sham and OVX were 2-fold higher in 5CR4 rats for osteocalcin and depxypyridinoline, and 25% higher in 5CR4 rats for C-telopeptide, vs. 5002 fed rats. Sham controls fed with 5002 had larger increases in DXA lumbar spine BMC and BMD during the second part of the study, after 6/8 months, vs. 5CR4 fed Sham rats. Also decreases in trabecular BMC and BMD at tibia metaphysis were less marked in 5002 vs. 5CR4 fed Sham rats. In OVX animals, the overall bone loss observed during the course of the study was generally similar in 5002 vs. 5CR4 fed OVX rats. This resulted in greater differences between Sham and OVX in terms of bone loss for 5002 (-46%) vs. 5CR4 fed rats (-18%) (tibia metaphysis trabecular BMD at the end of the study) and bone strength, -14 vs. -45% (peak load, vertebral compression).

These data suggested that diet and BW can influence the effects of aging and the OVX response in rats as evidenced by changes in bone turnover and bone mass measured by densitometry techniques. The influence of diet, calorie intake and BW should be taken into consideration in this model to better discriminate potential bone anabolic or anti-catabolic agents in the preclinical evaluation of potential anti-osteoporosis agents.

***L. reuteri* treatment suppresses osteoclast activity and bone loss in ovariectomized mice.** Laura McCabe*, Narayanan Parameswaran, Regina Irwin, Darin Quach, Laura Schaefer, Jing Zhang, Taehyung Lee, Robert Britton. Michigan State University, USA

Estrogen deficiency increases bone resorption and is a major risk factor for osteoporosis. Half of women over the age of 50 will experience an osteoporosis related fracture in their lifetime, thus novel therapies are needed to combat post-menopausal bone loss. Recent studies suggest an important role for the intestinal microbiota in bone health. The probiotic Lactobacillus reuteri ATCC PTA 6475 (L. reuteri) produces immunomodulatory factors as well as an antimicrobial compound, therefore we hypothesized that L. reuteri modulation of the gut microbiota and systemic and bone inflammation may suppress ovx-induced bone loss. As expected, Ovx caused significant bone loss compared to non-Ovx mice. Strikingly, L. reuteri treated Ovx mice did not display bone loss. Osteoclast markers and activators (Trap5 and RANKL) were decreased after L. reuteri treatment, suggesting that L. reuteri suppresses bone resorption. Consistent with this, Ovx-induced increase in bone marrow CD4+ T-cells (which promote osteoclastogenesis) were suppressed in L. reuteri treated Ovx mice. Furthermore, L. reuteri secreted factors directly suppress osteoclastogenesis in vitro. Finally, associated with these changes in the bone, the gut microbiota was distinct between the different groups of mice (ovx vs non-ovx $\pm$ L. reuteri). Taken together, our studies demonstrate that L. reuteri treatment modifies the gut microbiota and is capable of suppressing bone loss associated with estrogen deficiency, likely through suppression of osteoclastogenesis. Thus, L. reuteri treatment may be a straightforward and cost-effective approach to reduce post-menopausal bone loss.

Brief Daily Low Intensity Vibrations (LIV) Promote Osteoblast Activity in an Estrogen-Deficient Murine Model of Osteoporosis. Divya Krishnamoorthy*[1], Danielle Frechette[2], Benjamin Adler[2], M. Ete Chan[2], Clinton Rubin[3]. [1]SUNY Stony Brook University, USA, [2]Stony Brook University, USA, [3]State University of New York at Stony Brook, USA

The significant bone loss following ovariectomy (OVX) is considered a direct result of estrogen depletion and the downstream imbalance of bone remodeling. The lack of estrogen also results in a dramatic change in the bone marrow environment, disrupting the proliferation and differentiation of resident mesenchymal (MSCs) and hematopoietic (HSCs) stem cells. In addition to an impaired bone phenotype, OVX also leads to increased adiposity, not only in visceral depots, but also within the marrow cavity. Low intensity vibrations (LIV), representing a surrogate for exercise, may serve as an osteogenic mechanical signal by biasing the fate of MSCs away from adipogenesis and towards osteoblastogenesis. This study investigates the use of LIV as a non-invasive means to protect the bone phenotype in osteoporotic OVX mice. Eight week old female C57BL/6 mice underwent ovariectomy or SHAM surgery (AC); 2w later, ovariectomized mice were subject to 6w of LIV (0.3g at 90Hz, 15 min/d, 5 d/wk) (V) or SHAM LIV (O). Based on microCT evaluation of the proximal tibia, both O and V animals exhibited severe osteopenia compared to AC (-36% and -42%, respectively; $p<0.05$). OVX also caused a marked suppression of bone turnover markers, including osteoclast-specific tartrate-resistant acid phosphatase (TRAP5b; -32%, $p<0.05$) and osteoblast-specific alkaline phosphatase (ALP; -15%, $p>0.05$) suggesting decreased osteoclast and osteoblast activity. In contrast, V exhibited significantly greater ALP activity (26%, $p<0.05$) compared to O, suggesting increased osteoblast activity. Furthermore, TRAP5b concentrations of V were comparable to that of O, implicating that LIV is more anabolic than anti-catabolic in ovariectomized mice. The increase in ALP maybe a result of MSCs being driven towards osteoblastogenesis, leaving behind fewer stem cells in the marrow and increasing osteoblast number and therefore activity; however this hypothesis needs to be tested further. While the biologic responses evidenced here are encouraging, it may take longer-term studies to determine if mechanical signals can ultimately protect the skeleton from the harmful effects of estrogen deficiency. In conclusion, the results of this study corroborate the severe insult to bone as a result of estrogen depletion, while providing evidence of the ability of mechanical signals (LIV) to restore normal bone remodeling activity by promoting an osteogenic effect.

Effects of anti-diabetic drugs alone or in combination with risedronate on bone mass and architecture in Goto-Kakizaki rats, a spontaneous non-obese model of type 2 diabetes. Tetsuo Yano*[1], Mei Yamada[1], Makoto Shiozaki[2], Daisuke Inoue[3]. [1]Ajinomoto Pharmaceuticals Co., LTD, Japan, [2]Ajinomoto Pharmaceuticals, Japan, [3]Teikyo University Chiba Medical Center, Japan

Background/Aim: Patients with type 2 diabetes exhibit decreased bone strength and increased fracture risk in part independently of bone mineral density (BMD). However, molecular basis of the bone fragility and specific treatment for such diabetes-associated osteoporosis remain to be established. We previously demonstrated that risedronate (RIS) improved both bone mass and quality in Goto-Kakizaki (GK) rats, a spontaneous non-obese model of type 2 diabetes. In the present study, we examined effects on BMD and bone architecture of treatment with anti-diabetic drugs, each alone or in combination with RIS using GK rats.

Methods: GK rats and control Wistar rats at 48 weeks of age were used. Vehicle or RIS was administered subcutaneously, twice a week. And vehicle, metformin (Met), pioglitazone (Pio) or a DPP-4 inhibitor, sitagliptin (Sita) was administered orally, once a day. After 16 weeks of treatment, bone architecture in lumber vertebrae (L4) was evaluated by micro CT, measuring trabecular BMD, bone volume fraction, structure model index (SMI), trabecular number (TbN), trabecular separation and trabecular thickness (TbTh).

Results: At the start of treatment, blood glucose concentration was significantly increased in GK rats compared with Wistar rats both under fasting condition and after oral glucose load. Met and Sita significantly decreased the area under the curve of blood glucose concentration on after glucose load. Bone architecture in GK rats significantly deteriorated with the progression of diabetes, compared with that in Wistar rats, exhibiting decreased BMD, TbN and TbTh. RIS in combination with Met significantly decreased trabecular separation (-13.1%) and SMI (-9.1%) compared with vehicle, showing the best effect among the tested groups. In contrast, Pio was further detrimental to bone in GK rats as expected, and addition of RIS was minimally effective. Effect of Sita was more or less in between.

Conclusion: The results suggest that treatment with RIS in combination with Met is among the best therapeutic maneuvers of osteoporosis associated with type 2 diabetes, maintaining both bone mass and quality as well as good glycemic control.

MO0425

Low-intensity pulsed ultrasound lessons therapeutically bone loss on overiacteomized mice. Yoshitsugu Kojima*[1], Hiroki Yazawa[1], Takayuki Watanabe[1], Kazuki Terada[2], Nobuo Izumo[2], Yoshihiro Nishimura[1]. [1]Nippon Sigmax Co., Ltd, Japan, [2]Yokohama College of Pharmacy, Japan

Low-intensity pulsed ultrasound (LIPUS) has been widely used for bone fracture treatment. The recent studies have reported the usefulness of LIPUS on bone fracture site. However, mechanism of LIPUS on osteoporosis is less elucidated. In previous study, we demonstrated the protective effects of LIPUS on osteoporotic bone loss in ovariectomized (OVX) model mouse. In this study, we tested therapeutic recovery effects of LIPUS for existing bone loss in osteoporotic model.

Nine-week-old female ICR mice were ovariectomized or sham operated and allow for 8weeks to develop osteoporotic bone loss. OVX mice were divided into ultrasound exposed group and unexposed group before LIPUS irradiation. LIPUS condition was 2.0 MHz, duty 20%, 30mW/cm^2 for 20min/day and 5days/week for 8 weeks.Then the mice were sacrificed to collected ovaries and femora. The bone mineral density (BMD) and bone mineral content (BMC) of femora were measured with micro-CT (LCT-100Lite, Hitachi Aloka Medical, Ltd).Ovary weight was significantly decreased to 24% of sham group on both OVX group and OVX-LIPUS group. Although BMD and BMC were significantly decreased on OVX group against sham group (Fig. 1), BMD on trabecular bone of OVX-LIPUS group was significantly increased by 8.8% against OVX group.

In this study, we demonstrated the effects of LIPUS on Bone density even after osteoporotic bone loss. Our next step is to elucidate the mechanism of osteogenic responses of LIPUS through western blot analysis and real-time PCR analysis.

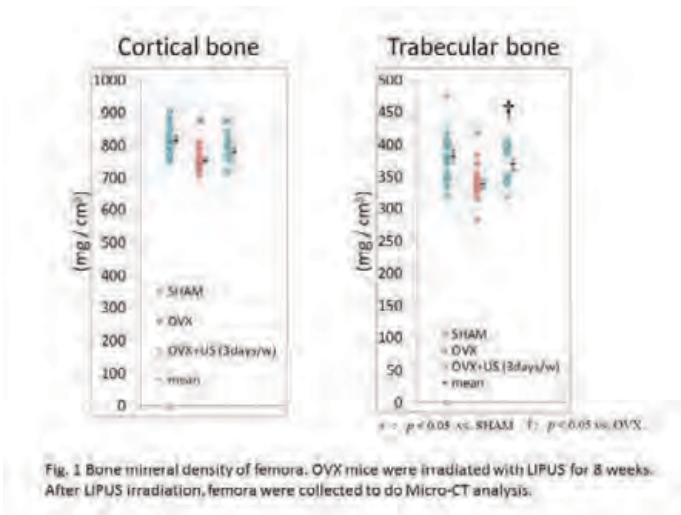

Fig. 1 Bone mineral density of femora. OVX mice were irradiated with LIPUS for 8 weeks. After LIPUS irradiation, femora were collected to do Micro-CT analysis.

MO0426

Molecular Basis of the Dual Effects of Thiazolidinediones (TZDs) on Osteoclastogenesis. Dongfeng Zhao*[1], Zhenqi Shi[2], Amy Warriner[1], Xu Feng[1], Yongjun Wang[3]. [1]The University of Alabama At Birmingham, USA, [2]University of Alabama, USA, [3]Longhua Hospital, Shanghai University of Traditional Chinese Medicine, China

Thiazolidinediones (TZDs) are synthetic peroxisome proliferation-activated receptor γ (PPARγ) agonists that have been used for treating Type 2 Diabetes Mellitus (T2DM). Accumulating clinical data indicate that TZD treatments augment the risk of bone fractures in T2DM patients. Moreover, emerging evidence supports the notion that PPARγ induces bone loss in part, if not primarily, by modulating osteoclastogenesis. However, the effect of TZDs on osteoclastogenesis is currently controversial. While a number of groups demonstrated that TZDs exert inhibitory effect on osteoclastogenesis, one study showed that TZDs stimulate osteoclastogenesis. To address this discrepancy, we further investigated the role of TZDs in osteoclastogenesis. As reported in last year's ASBMR meeting, we found that RANKL-mediated lineage commitment dictates the effect of TZDs on osteoclastogenesis. Specifically, while both rosiglitazone and pioglitazone dose-dependently inhibit osteoclastogenesis in tissue culture dishes and on bone slices from primary bone marrow macrophages (BMMs) freshly isolated from 6- to 8-week old C57BL/6 mice with complete inhibition of osteoclastogenesis at 40uM/ml of either TZD, the inhibitory effect of TZDs on osteoclastogenesis was significantly impaired when BMMs were pretreated with 100ng/ml RANKL for as short as 24 hours. Here, we report our new studies which aim to elucidate the molecular mechanism by which TZDs exert the dual effects on osteoclastogenesis. First, we determined the effect of rosiglitazone and pioglitazone on known RANK signaling pathways in fresh BMMs. We found that both agents at 40uM/ml exert no effect on the activation of the ERK, p38, JNK and I?B pathways. However, rosiglitazone and pioglitazone impair RANKL-induced expression of NFATc1 and four osteoclast genes (cathepsin K, matrix metalloproteinase 9, carbonic anhydrase 2 and tartrate acid resistant phosphatase) in freshly isolated BMMs. Next, we repeated the assays with BMMs pretreated with RANKL for 48 hours. Our data indicate that the ability of rosiglitazone and pioglitazone to suppress the expression of NFATc1 and the four osteoclast genes was significantly reduced in BMMs pretreated with RANKL for 48 hours. These findings demonstrate that RANKL-mediated lineage commitment determines the effect of TZDs on osteoclastogenesis through modulating the expression of NFATc1, a master transcriptional regulator of osteoclastogenesis.

Analysis of BMD, Hip Geometry and Trabecular Bone Score in Relation to Body Composition and Biochemical Markers in Adult Females with Severe Anorexia Nervosa. Judith Haschka*[1], Janina Patsch[2], Roland Kocijan[1], Didier Hans[3], Christian Muschitz[4], Afrodite Zendeli[5], Christina Bittighofer[1], Angela Trubrich[6], Julia Wild[1], Peter Weiss[4], Heinrich Resch[2]. [1]St. Vincent Hospital Vienna, Austria, [2]Medical University of Vienna, Austria, [3]Lausanne University Hospital, Switzerland, [4]St. Vincent's Hospital, Austria, [5]The VINFORCE Study Group - St. Vincent Hospital - Medical Department II, Austria, [6]BHS, Austria

Purpose: Anorexia nervosa (AN) is a psychiatric eating disorder associated with reduced body mass, estrogen deficiency, malnutrition and amenorrhea. The aim of the study was to investigate differences in hip geometry (HSA) and spinal bone microarchitecture as measured indirectly by trabecular bone score (TBS) in relation to body composition in patients with AN. TBS, a new texture measurement that can be applied to X-ray images and DXA, quantifies local variations in gray level and characterizes bone microstructure. HSA, derived from DXA, provides information about hip geometry and biomechanical strength.

Methods: DXA scans of femoral neck, lumbar spine and body composition (lean body mass [kg], body fat percentage [%], BMC [kg]) and HSA (CSMI cross-sectional moment of inertia, CSA cross-sectional area) were assessed by iDXA (GE Lunar) in 34 patients with AN (23.5 $\pm$ 4.5y, BMI 14.7 $\pm$ 1.3) and 26 controls (24.4 $\pm$ 2.5y, BMI 23.5 $\pm$ 3.7). The raw data of spinal DXA (L1-L4) were extracted and analysed with TBS iNsight software (v1.9, Medimaps SA, France). Serum parameter for bone formation (P1NP) and bone resorption (CTX), sclerostin levels (Scl), 25(OH)Vit.D, estradiol and cortisol were assessed.

Results: In patients with AN BMD was significantly decreased at all sites (femoral neck 0.850$\pm$0.14 vs 1.068$\pm$0.11; L1-L4 0.973$\pm$0.15 vs 1.292$\pm$0.15, $p<0.001$). Consequently mean TBS spine was significantly lower in AN (1.35$\pm$0.12 vs 1.56$\pm$0.08, $p<0.001$). CSMI (7.6$\pm$1.8 vs 10.8 $\pm$2 .7) and CSA (121.2$\pm$21.7 vs 161.6$\pm$19.7) were significantly lower in AN ($p<0.001$ for both). Body composition showed significantly lower BMC (2.0$\pm$0.3 vs 2.5$\pm$0.5), lean body mass (32.7$\pm$4.0 vs 42.6$\pm$5.1) and body fat percentage (14.1$\pm$8.0 vs 36.1$\pm$5.2, $p<0.001$ for all) in AN. In AN, lean body mass, BMC and hip BMD correlated positive with CSMI and CSA. Patients with AN had significantly higher Scl (41.7$\pm$17.7 vs 28.8$\pm$11.9, $p<0.05$) and CTX (0.767$\pm$0.4 vs 0.446$\pm$0.2, $p<0.001$) levels, while there was no difference in P1NP and cortisol. Vit.D (26.7$\pm$11.0 vs 32.9$\pm$9.5) and Estradiol (25.9$\pm$25.6 vs 75.4$\pm$81.1, $p<0.05$ for both) were significantly lower in patients with AN.

Conclusion: Apart of the expected significant decreased body composition, patients with AN show significantly reduced BMD, TBS, hip geometry and biomechanical strength compared to age-matched controls which may be partly explained by the elevated Scl expression and uncoupling in bone turnover.

MO0428

A Model for Assessment of Vitamin D_3 Deficiency & Implementation of Vitamin D_3 Regimen in a Skilled Nursing Facility. F. Michael Gloth*[1], Jennifer Coates[2], Kim Adams[3], Elizabeth Hidlebaugh[4]. [1]John Hopkins University School of Medicine, USA, [2]Moorings Park Healthy Living, Inc, USA, [3]The Chateau at Moorings Park, USA, [4]Hope College, USA

Purpose: To determine the prevalence of nursing home residents at high risk for vitamin D deficiency and to describe a process for implementing Vitamin D supplementation acceptable in the highly regulated nursing home environment demanding individualized care.

Design: A chart review of skilled nursing home patients was performed with the goal of identifying those at high risk for Vitamin D deficiency.*Setting*: The Chateau of Moorings Park in Naples, FL.

Subjects: Seventy Long-term Care nursing home resident.

Methods: During the chart review, risk factors such as hours of sunlight/day, skin pigment, inflammatory bowel disease diagnosis, fat malabsorption syndromes, obesity, kidney disease, Vitamin D rich foods, muscle weakness, muscle pain, osteoporosis diagnosis, history of bone fractures, bone pain, and menopause were collected. Data were also collected on whether or not the patient had been given a Vitamin D deficiency diagnosis, treated with Vitamin D and what dosage, and if there were 25-OH Vitamin D measures. A teleconference was conducted with the nursing

home regulartory agency for the State of Florida to discuss the prospect of writing a facility-wide order for all residents to receive vitamin D supplementation. Subjects with a diagnosis of vitamin D toxicity were excluded.

Results: Seventy charts were reviewed representing all long-term care residents of the nursing home. Hours of sunlight per day (60%), menopause (54%), and muscle weakness (69%) were found to be the most common risk factors present in this population and every patient met at least one risk factor beyond age (all residents were >70 y.o.). Also, prior to the assessement process, four patients had Vitamin D deficiency (defined by 25-OH Vitamin D blood concentration < 30 ng/mL) diagnosed and twenty patients were taking Vitamin D (2 or 3) of some dosage.

Conclusion: All long-term care residents in a representative nursing home in Florida were at high risk for vitamin D deficiency. Vitamin D supplemenation was provided for all. Further testing in additional facilities is warranted and, if results are similar, implementation of supplementation for all residents can be recommended without jeopardizing the individualization of care plans.

MO0429

Bone Material Strength by Microindentation in Patients Initiating Glucocorticoids and Effect of Treatments. Elisa Torres-Del-Pliego[1], Leonardo Mellibovsky[2], Xavier Nogues[3], Robert Guerri Fernandez[4], Laia Vilaplana[2], Fernando Mellibovsky[5], Daniel Prieto-alhambra[6], Adolfo Diez-Perez*[7]. [1]Internal Medicine Department, Hospital del Mar, Barcelona, Spain, [2]Servicio de Medicina Interna. Hospital del Mar, Spain, [3]Institut Municipal D'Investigació Mèdica, Spain, [4]Fundacio IMIM, Spain, [5]Engineer. Universidad Politecnica de Cataluña, Spain, [6]University of Oxford, United Kingdom, [7]Autonomous University of Barcelona, Spain

Fracture risk increases very early after starting glucocorticoids (GC) well before bone mineral density (BMD) shows any change. Microindentation can detect changes in Bone Material Strength (BMS) of bone tissue, related with bone fragility and fracture independent of BMD. We assess early changes in BMS in patients initiating glucocorticoids and the response to treatment.

A series of 26 consecutive patients were included in the study at the time of starting glucocorticoids (polymyalgia rheumatica/Horton arteritis 11, sarcoidosis 6, myasthenia gravis 2, rheumatoid arthritis 1, scleroderma 1, pemphigus 1, serositis 1, systemic vasculitis 1, adult Still's disease 1). A general laboratory workup, BMD by DXA, and BMS measurement at the anterior midtibia were performed with an Osteoprobe® (Active Life Scientific Sta Barbara CA) device. Measurements were performed at baseline and after 7+1.5 weeks of treatment with either calcium + vitamin D3 (Ca+D3) alone, bisphosphonates (BP) plus Ca+D3 or teriparatide (TPTD) plus Ca+D3 for the different risk categories, according to the official guidelines of the Spanish Bone and Mineral Society (SEIOMM). Median age for the different groups were: Ca+D3: 55.9+14.9, BP: 80+6, PTH: 62.2+27.6. Age adjusted no differences between groups. For the 14 patients treated with Ca+D3, BMS significantly declined from baseline (81.8+5.3) to the follow up visit (72.8+8.1, $p<0.001$). Non-significant increase was observed for the 6 cases treated with bisphosphonates (78.7+6.6 to 81.9+12.4) while teriparatide-treated patients (6 cases) significantly increased BMS from baseline to week 7 (72.8+7.5 vs. 85.2+4.9, $p<0.001$). No changes in BMD between baseline and follow up were observed in any of the groups. The main results are displayed in the figure1. Further follow up is underway at week 20.

We conclude that microindentation can detect very early changes in bone material strength at a tissue level induced by GC. Effect of different treatments iuis diverse in these cases and can be tracked prematurely. The effect of GC and the different treatments in bone tissue properties, related with fracture propensity, might offer an opportunity for monitoring changes induced by GC and their treatments well beyond what BMD currently allows.

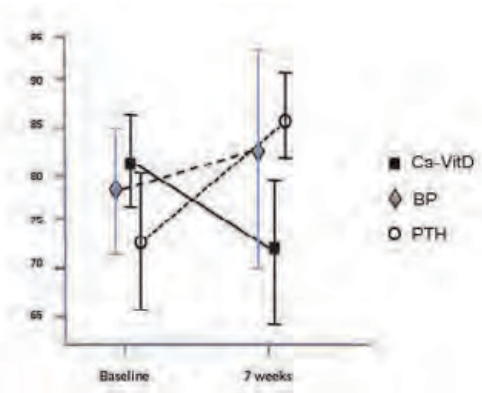

Figure 1. Bone material strenght changes in different treatment

MO0430

Bone Microarchitecture in Young Adults with Cystic Fibrosis: Differential Mechanisms of Fragility in Weight Bearing and Non-Weight Bearing Bone. Melissa Putman*[1], Nicholas Derrico[2], Leonard Sicilian[3], Ahmet Uluer[4], Allen Lapey[5], Catherine Gordon[6], Mary Bouxsein[7], Joel Finkelstein[8]. [1]Massachusetts General Hospital, Children's Hospital Boston, USA, [2]Endocrine Unit, Massachusetts General Hospital, USA, [3]Pulmonary & Critical Care Medicine, Massachusetts General Hospital, USA, [4]Division of Pulmonary & Respiratory Diseases, Boston Children's Hospital, USA, [5]Pediatric Pulmonary Medicine Massachusetts General Hospital for Children, USA, [6]Hasbro Children's Hospital & Brown University, USA, [7]Beth Israel Deaconess Medical Center, USA, [8]Massachusetts General Hospital, USA

Purpose: Young adults with cystic fibrosis (CF) are at risk for low bone density and fractures, but the underlying alterations in bone microarchitecture are currently unknown. High-resolution peripheral quantitative computed tomography (HR-pQCT) can provide detailed information regarding volumetric bone mineral density (vBMD), cortical and trabecular microarchitecture, and estimates of bone strength using microfinite element analysis (μFEA).

Methods: We performed HR-pQCT scans (Scanco Medical AG) of the radius and tibia in 22 young adults with CF ages 18-30 years to assess cortical and trabecular vBMD, bone microarchitecture, and bone strength by μFEA. Areal BMD measures by DXA of the hip, spine, and total body were also obtained. CF subjects were compared with 44 healthy volunteers matched by age (±3 years), gender, and race.

Results: Subjects with CF were 24.4±3.5 years old, and 59% were female. Most recent FEV1 was 73.1±28.9% predicted, and a broad range of cystic fibrosis transmembrane regulator (CFTR) genotypes were represented. Subjects with CF had a lower BMI than controls (20.7 vs 25.0 kg/m^2, $p<0.01$) and 37.5% reported a history of fracture. CF subjects reported adequate calcium (2162±1868 mg/day) and vitamin D intake (2050±1950 IU/day). Areal BMD was significantly lower at the femoral neck, total hip, and PA spine in CF compared to healthy volunteers ($p<0.05$ for all). At the distal radius, CF subjects had lower total area and cortical area ($p<0.05$ for all), but the remainder of vBMD and bone microarchitectural measures were similar to normals. At the tibia, CF subjects had lower total vBMD, cortical area and volume, trabecular vBMD, and trabecular number, along with higher trabecular separation and heterogeneity vs controls ($p<0.05$ for all). Cortical porosity of the radius and tibia did not differ between groups. μFEA revealed significantly lower stiffness and failure load at both the radius and tibia in CF subjects ($p<0.05$ for all).

Conclusions: Young adults with CF have compromised bone microarchitecture and estimated bone strength at both the radius and tibia. At the non-weight bearing radius, reductions in total and cortical area predominate, whereas trabecular microarchitecture and trabecular vBMD were compromised in addition to lower cortical area at the weight-bearing tibia. Further studies are needed to understand the underlying pathophysiology and clinical implications of these bone alterations.

Table 1: HR-pQCT Results (mean ± SD)

	Radius		Tibia	
	CF Subjects	Healthy Volunteers	CF Subjects	Healthy Volunteers

CTX as an early prediction on bone loss in women on aromatase inhibitors: the B-ABLE cohort study. Elisa Torres-Del-Pliego[1], Daniel Prieto-alhambra[2], Sonia Servitja[3], Raquel Soriano-Tomas[4], Iria González-Maeso[3], Natalia Garcia-Giralt[5], Maria Rodríguez-Sanz[6], Adolfo Diez-Perez[7], Ignacio Tusquets[3], Xavier Nogues*[8]. [1]Internal Medicine Department, Hospital del Mar, Barcelona, Spain, [2]University of Oxford, United Kingdom, [3]Medical Oncology Department, Parc de Salut Mar, Spain, [4]Internal Medicine Department, Parc de Salut Mar, Spain, [5]IMIM, Spain, [6]URFOA-IMIM Red Temática de Investigación Cooperativa en Envejecimiento y Fragilidad (RETICEF), Instituto de Salud Carlos III FEDER, Spain, [7]Autonomous University of Barcelona, Spain, [8]Institut Municipal D'Investigació Mèdica, Spain

Purpose: According to results from RCTs, the use of aromatase inhibitors (AI) in the adjuvant treatment of breast cancer results in decreased bone mineral density (BMD) and increased fracture risk. However, there is variability in the intensity of AI-related bone loss, making it difficult for the clinician to decide on who to treat with anti-resorptives based on other than baseline BMD measurements.

To address this issue, we analyzed the association between levels of C-telopeptide (CTX) at 3 months post-therapy initiation and bone loss at one year..

Methods: B-ABLE is a prospective cohort study including a consecutive sample of postmenopausal women at the time when they are started on AI treatment for hormone-sensitive early breast cancer. As recommended by current guidelines, women with a T score <-2.0 or with any clinical risk factor received oral bisphosphonates and Calcium and Vitamin D supplements. All others received only Calcium and Vitamin D supplementation. The latter were included for this study. A random sample of these women had CTX measured at baseline and 3-months, and all participants had a DXA scan at baseline and 1 year follow-up.

Main exposure was change in CTX at 3 months (ΔCTX3m) defined as 3-month CTX minus baseline. Main outcome was absolute bone loss at 1 year (ΔBMD1y), defined as Lumbar Spine (LS) BMD (in gr/cm2) at baseline minus 1-year BMD. We tested for the association between ΔCTX3 and ΔBMD using linear regression.

Results: 121 participants had CTX measurements available. Baseline and 3-months mean (SD) CTX levels were 0.472(0.244) and 0.565(0,265) ng/ml respectively. Similarly, LS BMD was 0.955(0.113) g/cm2 at baseline, and 0.942(0.115) after 1 year of AI therapy. ΔCTX3m was significantly associated with ΔBMD1y: beta 0.04 g/cm2 per 1 ng/ml [95%CI 0,0068-0,0180].

Conclusions: In women starting AI therapy for early breast cancer who do not require anti-resorptive treatment, 3-month CTX increments can be used to predict 1-year bone loss. This could be used to target patients with highest bone loss rates, who could potentially benefit from early preventative interventions to reduce fracture risk.

Decreased exercise capacity negatively affects bone mass in patients with acute decompensated heart failure. Yumie Rhee*[1], Jong-Chan Youn[2], Seok-Min Kang[2]. [1]Department of Internal Medicine, College of Medicine, Yonsei University, South Korea, [2]Division of Cardiology, Severance Cardiovascular Hospital, Yonsei University College of Medicine, South Korea

Heart failure is associated with increased risk of osteoporosis. However, the prevalence and predictors of osteoporosis in patients with acute decompensated heart failure (ADHF) are not well investigated. Fifty male patients with ADHF (60 ± 16 years, mean ejection fraction 28.0 ± 11.5%) were prospectively and consecutively enrolled. Quantitative CT scans for volumetric bone mineral density (vBMD) as well as biochemical, echocardiographic and cardiopulmonary exercise tests were evaluated. Sixteen patients (32%) had osteopenia (lumbar vBMD of 80-120 mg/cm^3) and six patients (12%) had osteoporosis (vBMD < 80 mg/cm^3). C-telopeptide of type I collagen (0.564 ± 0.323 ng/mL) was within normal range, however osteocalcin (18.7 ± 23.2 ng/mL) and 25-hydroxyvitamin D (13.8 ± 7.0 ng/mL) were low, while parathyroid hormone (65.3 ± 41.0 pg/mL) was increased. Lumbar vBMD was lower in ischemic patients than non-ischemic patients (107.9 mg/cm^3 *vs.* 144.7 mg/cm^3, p=0.007). Multivariate regression analysis revealed peak VO_2, which is a well known prognostic marker in ADHF, independently predicted low lumbar vBMD when controlled for age, BMI, etiology of heart failure (β=0.487, p=0.022, Figure 1). In conclusion, low bone mass is prevalent in ADHF patients, especially more in ADHF due to ischemia. The exercise capacity independently predicted low lumbar vBMD in patients with ADHF. These findings may explain the novel relationship between exercise capacity and BMD in ADHF patients.

Determination of the Role Autophagy on Bone Metabolism and Structure during the Initiation and Progression of Type 2 Diabetes. Elizabeth Rendina*[1], Jennifer Graef[1], McKale Davis[1], Jeffrey Gimble[2], Stephen Clarke[1], Edralin Lucas[1], Brenda Smith[1]. [1]Oklahoma State University, USA, [2]Pennington Biomedical Research Center, USA

Type 2 diabetes mellitus (T2DM) is a major public health problem affecting approximately 26 million Americans. Patients with T2DM have demonstrated a 1.5 - 3.5 fold increase in fracture incidence despite no change or an increase in bone mineral density (BMD). Although there has been a growing interest in the field, the mechanism associated with this disconnect has remained elusive. Macroautophagy, hereafter referred to as autophagy, is regulated by the signaling cascade downstream of the insulin receptor and cellular glucose availability. Metabolic changes occurring during the initiation and progression of T2DM may alter autophagy in osteoblasts and osteoclasts activity. To determine whether autophagy plays a role in the dysregulation of bone metabolism associated with T2DM, 4-week old, male C57BL/6 mice were fed a control or high fat diet (HFD) for 2, 8, and 16 wks. Animals on the HFD experienced an increase in body weight after 1 week and maintained a significantly higher body weight throughout the remainder of the study. Consistent with impaired insulin signaling, animals on the HFD demonstrated elevated blood glucose despite increased plasma insulin after 16 wks. The HFD resulted in impaired glucose tolerance which was exacerbated over time. Whole body BMD, determined by dual energy x-ray absorptiometry (DXA; PixiMUS GE Lunar), was decreased after 8 and 16 wks on the HFD. Micro-computerized tomography (μCT; SCANCO Medical) analyses revealed that the animals on the HFD had a lower trabecular bone volume (BV/TV) in the distal femur metaphysis and femoral neck at 8 and 16 wks. No changes were observed in trabecular bone of the vertebra at any time point. Cortical thickness and area of the femoral diaphysis was decreased only at the 8 wk time point in response to the HFD. PCR array sought to determine whether alterations in insulin signaling corresponded to transcriptional regulation of autophagic machinery in the bone marrow and mineralized portion of the flushed femur. Preliminary array results suggest alterations in genes associated with the down-regulation of autophagy (*i.e., Dram1* and *Tgfb*) occur after 2 wks on a HFD. However at 8 and 16 wks genes involved in autophagy, such as *Rb1*, *Becn1, Gabarapl2, Sqstm1*, and *Ulk1* were up-regulated. Further investigation of how autophagy alters osteoblasts and osteoclasts during the advancement of T2DM is warranted and could lead to innovative therapeutic options to reduce fracture risk.

Does The Choice Of Surgical Technique Affect Bone Turnover Changes After Bariatric Surgery?. Kaisa Ivaska*[1], Minna Soinio[2], Jarna Hannukainen[3], Pauliina Salminen[4], Pirjo Nuutila[2], Riku Kiviranta[5]. [1]University of Turku, Finland, [2]Department of Medicine, University of Turku & Turku PET Centre, Finland, [3]Turku PET Centre, Finland, [4]Department of Surgery, Turku University Hospital, Finland, [5]Department of Medical Biochemistry & Genetics & Department of Medicine, University of Turku, Finland

Bone and adipose tissue interact at multiple levels. Adipokines secreted by the fat tissue control both energy homeostasis and the skeleton while bone is also recognized as an endocrine organ that is capable of regulating energy metabolism. Bariatric surgery by either gastric bypass or sleeve gastrectomy has become a worthy option to treat severe obesity. It results in rapid weight loss often accompanied with normalization of plasma glucose levels in patients with type 2 diabetes (DM2), both of which have implications for bone health. Our aim was to evaluate the changes in bone turnover, particularly osteocalcin, in response to gastric bypass or sleeve gastrectomy.

23 morbidly obese subjects (mean BMI 43.1 +/- 3.7 kg/m2, 14 with DM2) underwent either gastric bypass (n=13) or sleeve gastrectomy (n=10). An oral glucose tolerance test (OGTT, 120 min) and hypersinsulinemic euglycemic clamp were performed and fasting serum samples collected before and 6 months after the operation. A panel of bone turnover markers, adipokines and cytokines were analyzed. Ten healthy subjects with normal body weight (BMI 23.7 +/- 1.8 kg/m2) were recruited as a reference group.

Bariatric surgery resulted in significant weight loss (mean -23.1 +/- 6.2 %) and a decrease in circulating leptin ($p<0.01$). Diabetes was in remission in 9 of the 14 diabetics after surgery.. All bone markers increased significantly after surgery, ranging from +65% to +270% depending on the marker ($p<0.01$ for all). There were no significant differences in weight loss, glucose or leptin values between the two procedures ($p>0.05$), but the increase in bone turnover was more pronounced in subjects that underwent gastric bypass ($p<0.05$ for PINP and CTX; $p<0.01$ for osteocalcin). Patients with DM2 before the operation had significantly lower osteocalcin values than the control group ($p<0.01$). Post-surgery increases in bone markers did not correlate with insulin sensitivity but appeared to be most pronounced in those whose DM2 was in remission after surgery, although the differences were not statistically significant.

Bone turnover is increased in response to bariatric surgery. The increase in turnover is more pronounced when proximal small intestine is bypassed in addition to reducing the stomach size, and in subjects with DM2 that achieve remission after surgery. Thus both diabetes status and the choice of surgical technique may affect the changes in bone turnover after bariatric surgery.

Lean Mass And Not Fat Mass Is Associated With Measures Of Better Bone Health In Type 2 Diabetes Mellitus. Indira Maisnam*[1], Deep Dutta[2], Anubhav Thukral[2], Rajesh Jain[2], Satinath Mukhopadhyay[2], Subhankar Chowdhury[2]. [1]IPGMER & SSKM Hospital, India, [2]IPGMER, India

Background

The fracture risk in type 2 diabetes mellitus is high. Studies have shown increased, decreased or normal bone mineral density (BMD) in type 2 diabetes compared to controls. This heterogeneity could be due to body composition (lean vs. fat mass), which may affect bone health differently. Type 2 diabetes is frequently associated with obesity and accelerated lean mass loss.

Purpose of the study

To compare the BMD and bone mineral content (BMC) in obese and non-obese type 2 diabetes; and to evaluate the relationship between fat mass and lean mass with BMD and BMC in type 2 diabetes

Methods: Cross-sectional observational study, conducted between January 2011 and January 2013. Type 2 diabetes 35 to 55 years were recruited. Conditions that may affect bone health were excluded from the study. Patient were obese if body mass index (BMI) was $\geqslant 25 kg/m^2$ (based on Indian criteria). Dual Energy X- Ray Absorptiometry (DXA) done with a GE Lunar DPX NT densitometer was used to measure BMD at the lumbar spine& both femur, BMC, lean and fat mass. Statistical analysis was done with SPSSv20.

Results: There were age-matched 76 type 2 diabetes and 44 controls. Obese controls and obese diabetes had significantly higher BMD at all sites compared to non-obese controls and non-obese diabetes respectively (Tables 1 and 2). Non-obese diabetes had similar BMD compared to non-obese controls except at one site (left femur) where non-obese diabetes had higher BMD (Table 3). Obese diabetes had similar BMD compared to obese controls except at one site (lumbar spine) where obese diabetes had higher BMD (Table 4). We looked for correlation between lean mass and fat mass with BMD and BMC. In diabetes there was a significantly positive strong correlation between BMI and BMC, and a stronger correlation of lean mass with BMC that persisted after adjusting for height, however there was no significant correlation between fat mass and BMC (Table 5). Also in diabetes, BMD positvely correlated with lean mass at both femur but not with fat mass. In controls lean mass and not fat mass positively correlated with BMC; and both lean mass and fat mass correlated with BMD at some sites (Table 5).

Conclusion: The positive correlation between body weight with BMD and BMC in type 2 diabetes was due to lean mass and not fat mass. Controls too had a positive correlation of lean mass with BMD and BMC. But the correlation was stronger and more significant in type 2 diabetes mellitus compared to controls.

Low Bone Density and Fractures Associated with Cannabis Use – A Population Based Prospective Study. Antonia Sophocleous*[1], James McKenzie[1], Roy Robertson[2], Stuart H Ralston[1]. [1]Rheumatic Disease Unit, Centre for Molecular Medicine, Institute of Genetics & Molecular Medicine, University of Edinburgh, United Kingdom, [2]Centre for Population Health Sciences, University of Edinburgh, United Kingdom

Preclinical studies have shown that the endocannabinoid system of ligands and receptors play a key role in the regulation of bone mass and bone turnover. Mice with targeted inactivation of the type 1 cannabinoid receptor have increased peak bone mass and are protected against ovariectomy induced bone loss due to reduced osteoclastic bone resorption. Conversely, cannabinoid receptor agonists have been found to increase osteoclast differentiation *in vitro*. Together these observations raise the possibility that cannabinoid receptor agonists might be detrimental for bone health. In this study therefore, we investigated the effects of recreational cannabis use on bone mineral density and fracture risk. The study was conducted in 113 regular cannabis users and 78 controls recruited from the local community. Cannabis use was quantified in terms of "joint-years", where 1 joint-year was defined as smoking 365 cannabis-containing cigarettes. The controls were selected on the basis that they smoked cigarettes but did not smoke cannabis. Information was collected on age, gender, tobacco smoking, alcohol, diet, weight, height and fractures. Bone mineral density was measured by DEXA at the lumbar spine and total hip. Heavy cannabis users (>57 joint-years) had a significantly lower total hip bone density Z-score than controls (-0.11 ± 0.83 *vs.* +0.41±0.95; p=0.007) with intermediate values (+0.18 ± 1.05) in the moderate users (≤57 joint-years). Cannabis users were about 10 years younger than controls (39.5 ± 9.8 *vs.* 49.6 ± 9.3 years; p<0.001). There was no difference between groups in spine Z-score values. Heavy cannabis users had a lower body mass index than controls (25.7 ± 5.8 *vs.* 29.6 ± 6.9; p=0.003) whereas values in moderate users were similar to controls (28.9 ± 7.4). Heavy cannabis users had a significantly higher dietary calcium intake than controls (1464 ± 1022 *vs.* 896 ± 439mg/day; p<0.001) with intermediate values in moderate users (1039 ± 609mg/day). There was no difference in cigarette smoking or alcohol intake between groups. There was a preponderance of males in the heavy cannabis users group (61.4%). Fractures were more common in cannabis users (56% *vs.* 43%; p=0.09), and multiple fractures (3 or more) were significantly more common (13.3% *vs.* 1.3%; p=0.014). We conclude that heavy cannabis use impacts negatively on bone health and is associated with reduced body mass index and an increased risk of multiple fractures.

MO0437

Study of Very Long Term (> 25 years) L-Thyroxine Suppressive Therapy in Postmenopausal Women With Differentiated Thyroid Cancer: Effect on Bone Mineral Density and Bone Turnover Markers. María Luísa de Mingo Domínguez*[1], Guillermo Martinez Diaz-Guerra[1], Sonsoles Guadalix Iglesias[1], Gonzalo Allo Miguel[1], Mercedes Aramendi[1], Federico Hawkins[2]. [1]University Hospital 12 De Octubre, Spain, [2]Hospital Universitario, Spain

Background: After initial therapy (thyroidectomy with or without radioiodine), all patients with differentiated thyroid cancer (DTC) are treated with high doses of L-thyroxine (LT4) aimed at suppressing thyrotropin (TSH) levels. However, there is uncertainty about the potential adverse effects of long-term suppressive therapy, particularly in relation to increased risk of developing osteoporosis. The objective of this study is to investigate the effects of very long-term treatment with LT4 on bone mineral density (BMD) and bone remodeling.Methods: 30 postmenopausal women (age 64.5± 10.2 years) with DTC were studied. All of them had undergone total thyroidectomy followed by radioiodine ablative therapy and were on TSH suppressive treatment for a median period of 27.8 ± 3.1 years. BMD was measured by dual energy X-ray absorption (DXA) at baseline and at the present time at lumbar spine (LS), Total hip (TH), femoral neck (FN), ultradistal radius (UDR), midradius (MDR) and distal third radius (1/3DR). Bone turnover markers (β-CTX and osteocalcin) and calcitropic hormones (PTH and 25OH vitamin D) were measured. For comparisons, patients were classified according to their menopausal status at baseline: premenopausal (group 1) or postmenopausal (group 2). For statistical analysis SPSS v.21 was used.Results: Group 1: n=17, age 57.6 ± 6.1; Group 2: n=13, age 73.6 ± 6.8 . Compared with baseline, we found a statistically significant decrease in BMD at LS (p=0.000), FN (p= 0.000) and 1/3DR (p=0.02) in group 1 . No significant changes were found in group 2. Percentage of BMD variation were: Group 1: LS -11.7± 9.0%; FN -12.8 ± 9.7%; TH -0.3 ± 12.1%; UDR -3.3 ± 10.0%. Group 2: LS 4.6 ± 19.7%; FN -6.9 ± 12.0%; TH 2.2 ± 5.3%; UDR 8.4 ± 4.3%. At the second DXA, group 2 had lower TH (p=0.02), UDR (p=0.047), MDR (p=0.002) and 1/3DR BMD (p=0.017) than group 1. Osteoporotic women were 46.7% (total), 29.4% (group 1) and 69.2% (group 2). No correlation was found between BMD and TSH, free T4, or LT4 dose (either total or adjusted per body weight). Only osteocalcin showed a weak negative correlation with UDR BMD (r= -0.46, p < 0.01).Conclusion: Very long-term LT4 suppressive therapy in postmenopausal women with DTC does not adversely affect bone mineral density. Estrogen deprivation appears to be the most important factor for bone loss in previous premenopausal women with DTC

MO0438

The Association of Serum Osteocalcin with Glucose Control, Pancreatic Function and Insulin Resistance in Type Two Chinese Diabetes Patients. Hui Sheng*[1], Xuefei Rui[2], Chunping Pan[2], Junlei Su[2], Chenyu Zhan[2], Shen Qu[3]. [1]Shanghai, Fudan University, Peoples Republic of China, [2]Department of Endocrinology & Metabolism, Shanghai Tenth People's Hospital, Tongji University School of Medicine, China, [3]Tongji University School of Medicine, Peoples Republic of China

This study is to investigate the association between serum osteocalcin and glucose control, pancreatic function and insulin sensitivity in the type 2 diabetes mellitus (T2DM) Chinese patients.

1019 T2DM patients were recruited (Male:432, Female:587, Average age: 65.96 ± 13.11 years). After measured BMI, the fasting plasma glucose(FPG), insulin(FINS), C peptide(F-CP), postprandial blood glucose (2hPBG) and C peptide (2hC-P), HbA1C and osteocalcin were determined. Homeostasis model assessment of β cell function (HOMA-β) and homeostasis model assessment of insulin resistance (HOMA-IR) were calculated based on the above parameters.

The difference in osteocalcin levels between male and female are significant [(13.51±12.37)ng/mL vs (16.22±10.40)ng/mL, P<0.001]. After adjustment for age and BMI, serum osteocalcin was negatively correlated with HbA1C, FPG and 2hPBG (P<0.05), and positively correlated with fasting C peptide (FC-P), 2h C peptide (2hC-P) and HOMA-β (P<0.05). In male, after adjustment for age and BMI, serum osteocalcin was negatively correlated with 2hPBG (P<0.05), and positively correlated

with FC-P, 2hC-P and HOMA-β (P<0.05). In female, after adjustment for age and BMI, serum osteocalcin was negatively correlated with HbA1C, FPG (P<0.05). Multivariable liner regression analysis showed that serum osteocalcin was the independent related factor in influencing HOMA-β and HOMA-IR in male, and it was also the independent related factor in influencing HOMA-IR in all subjects (P<0.05).

In T2DM, osteocalcin was negatively associated with glucose, implying osteocalcin could lower blood glucose. And osteocalcin was positively associated with FC-P, 2hC-P and HOMA-β, supporting the idea that osteocalcin might improve glucose control through promoting insulin secretion of pancreatic islet.

MO0439

Trabecular Bone Assessment in Type 2 Diabetes Mellitus. Mishaela Rubin*[1], Ankit Shah[1], Chiyuan Zhang[1], Serge Cremers[1], Elzbieta Dworakowski[1], Laura Beth Anderson[1], Didier Hans[2], Shonni Silverberg[1]. [1]Columbia University, USA, [2]Lausanne University Hospital, Switzerland

Type 2 diabetes mellitus (T2D) is associated with increased fracture risk despite greater bone mineral density (BMD). The reason for this paradox is not fully understood. Trabecular bone score (TBS) provides information independent of BMD by extracting variations in the spine DXA image, with more heterogeneity giving a lower score. TBS was recently shown to reflect skeletal fragility in T2D (Leslie et al JBMR 2013). We sought to confirm and extend these data by assessing the association of TBS with trabecular heterogeneity by high resolution pQCT (HRpQCT) and with changes in biochemical markers of bone turnover (BTM) in T2D. Postmenopausal T2D (n=14; duration T2D: 9 ± 2 yr; Hgb A1c: 9.3 ± 0.6%) and Controls (C; n=21; Hgb A1c: 5.6 ± 0.1%; p<0.001) of similar age (T2D: 58 ± 2 vs C: 58 ± 1 yr) and non-black race were compared. All had normal renal function and were on no bone-active medications or TZDs; 3 T2D and 4 Cs had prior fractures. TBS data were extracted from the Hologic DXA image using TBS iNsight software; HRpQCT data were obtained by XtremeCT (Scanco, Switzerland). Because weight was greater in T2D (T2D: 81 ± 5 vs C: 68 ± 3 kg; p=0.02), general linear models were used to compare T2D and Cs with the effect of weight removed. BMD by DXA did not differ at the spine, hip or forearm. Despite similar lumbar spine BMD (T2D: 0.920 ±0.03 vs C: 0.938 ± 0.03 gm/cm^2; p=0.68), TBS was significantly lower in T2D (T2D: 1.146 ± 0.04 vs C: 1.270 ± 0.02; p=0.01). Consistent with this, trabecular heterogeneity (SD of 1/Tb Number) at the tibia was greater in T2D (T2D: 0.397 ± 0.05 vs C: 0.259 ± 0.04; p=0.05). Other HRpQCT parameters did not differ. Weight adjusted biochemical indices showed that T2D had lower 25(OH)D (T2D: 18.2 ± 5 vs. C: 33.9 ± 4 ng/ml; p=0.02) and P1NP (T2D: 45.6 ± 3 vs. C: 63.2 ± 7 ng/ml; p=0.06) levels, but higher BAP (T2D: 50.6 ± 4 vs C: 34.7 ± 3 U/l; p=0.003). Osteocalcin, TRAP-5b and sCTx did not differ. In T2D, TBS correlated inversely with BAP (r=-0.69, p=0.04), while TBS was not associated with BTM in Cs. In summary, while BMD does not differ from controls in T2D, TBS is worse and is consistent with the greater trabecular heterogeneity seen on HRpQCT. The lower TBS may be associated with a defect in mineralization, as suggested by the low 25(OH)D and high BAP. Despite normal DXA measurements, these data suggest that abnormalities in trabecular bone could contribute to the observed increase in fracture risk in T2D.

Severe alterations in cortical and trabecular bone microarchitecture in lung transplant recipients. Alexander Valentinitsch*, Lukas Fischer, Matthew DiFranco, Claudia Schueller-Weidekamm, Franz Kainberger, Georg Langs, Janina Patsch. Medical University of Vienna, Austria

Organ transplant recipients often suffer from impaired bone strength arising from a combination of pre-existing secondary osteoporosis and disease aggravation in the post-transplant phase caused by various factors such as immunosuppressive therapy. In lung transplant (LUTX) recipients, the post-transplant drug regimen is particularly intense and fracture rates are high. Although, low bone mineral density [1] and altered states of bone turnover [2] have been described after LUTX, bone microarchitecture status has not been investigated in depth. After recovery from surgery, 46 patients (female:n=28,male:n=18;age=43.9±13.7yrs), and 46 healthy, age, and gender-matched controls (Co) underwent high resolution peripheral quantitative computed tomography (HR-pQCT) of the ultradistal radius. Scans were analysed with the standard and cortical analysis software of the manufacturer, and a 3D texture-based clustering method for trabecular bone (TMAC)[3]. Based on 3D morphology, TMAC defined three types of trabecular bone: TMAC1 contained thick trabeculae with low intertrabecular spacing, TMAC2 was characterized by trabeculae of intermediate morphometric quality, and TMAC3 was defined as regions with thinner, inhomogeneous trabeculae. Paired t-tests were used to compare mean differences between LuTX and Co. Compared with healthy women, female LUTX patients had higher cortical porosity (+51.5%,p=0.034), cortical pore diameter (+10.9%,p=0.009), diameter heterogeneity (+18.3%,p=0.021) and a higher volume fraction of morphologically poor trabecular bone (TMAC3; +41%,p=0.05). Compared with healthy men, male LUTX patients had lower cortical thickness (-18.9%,p=0.003), trabecular bone density (-23.3%,p=0.001), trabecular thickness (-14.4%,p=0.003), and trabecular number (-13%,p=0.028). TMAC3 was higher (+86.3%, p=0.02) and TMAC2 lower (-21.2%, p=0.001) than in healthy men. Our results indicate that cortical integrity and trabecular bone microarchitecture are both severely impaired in lung transplant recipients. Although, the morphologic pattern seems to vary with gender, men and women are affected by significant deficits in peripheral bone microarchitecture. Thinning and porosity of cortical bone might thus be crucial factors leading to disproportionally high risk of fragility fractures in lung transplant recipients. MO0441

Vitamin D Supplementation Decreases The Occurrence Of Acute Phase Response Following Intravenous Bisphosphonate Treatment In Paget's Disease Of Bone. Daniela Merlotti*[1], Luigi Gennari[1], Beatrice Franci[2], Barbara Lucani[2], Stella Campagna[2], Laura Cresti[2], Konstantinos Stolakis[2], Stefano Rotatori[2], Ranuccio Nuti[1]. [1]University of Siena, Italy, [2]Dept. Medicine Surgery & Neurosciences, University of Siena, Italy

Acute phase reaction (APR) is the most frequent side effect following the infusion of intravenous nitrogen-containing bisphosphonates (N-BPs), occurring in up to 40% of cases at the first infusion. A recent observation in postmenopausal women treated with N-BPs for osteoporosis evidenced a negative association between 25(OH)D levels and the development of APR, likely due to immuno-modulatory effects of vitamin D on gdTcells. However, this association remains to be demonstrated in patients with Paget's disease of bone (PDB). Moreover whether vitamin D supplementation is able to prevent the occurrence of APR has not yet been demonstrated. We initially performed a retrospective analysis of 205 consecutive patients treated with intravenous N-BPs (neridronic acid 200mg or zoledronic acid 5mg) for PDB. Overall APR occurred in 31% of cases and was more frequent in previously untreated patients (43%). Neither gender nor disease severity nor use of other drugs (i.e. statins or nonsteroidal anti-inflammatory drugs) apart previous N-BP treatment was associated with the occurrence of APR. Consistent with the previous report in osteoporotic women, 25(OH)D levels at the time of treatment were lower in PDB cases with APR than in patients who did not experience APR after infusion (16.4±7 vs 28.6 ±3 ng/ml, p<0.0001). Following this observation we performed a prospective study in 30 patients at the time of PDB diagnosis. Hypovitaminosis D was common in this cohort

of patients (mean 18.0±5 ng/ml; with 63% of cases below 20 ng/ml). All patients received oral vitamin D3 (7000 UI/week) for 60 days before N-BPs infusion with either zoledronic acid 5mg (16 pts) or neridronic acid 200mg (14 pts). Moreover a single oral dose of 25000 UI was given at baseline to all patients with 25(OH)D levels below 20 ng/ml. All adverse events occurring within the first week of the administration of the 2 N-BPs were listed. Of interest, APR occurred in 2/16 (12.5%) patients treated with zoledronic acid and 1/14 (7%) patients treated with neridronic acid (overall incidence rate 10%). In 2 of these cases 25(OH)D levels at the time of infusion were within the normal range (30.7 and 33.0 ng/ml) while in the third case remained below the range (18.8 ng/ml). These results suggest that APR following N-BPs infusion for PDB is a common event particularly in patients with hypovitaminosis D and that vitamin D supplementation prior bisphosphonate infusion is able to reduce the occurrence of this complication.

MO0442

Zoledronic Acid (ZA) Therapy in the Treatment of Patients with Paget's Disease of Bone (PD) Resistant to Prior Bisphosphonate Therapy or with an Unsustained Response of One Year or Less. Joseph Tucci*. Boston University School of Medicine, USA

The primary objective of this investigator initiated study supported by Novartis Pharmaceuticals was to evaluate the effect of (ZA) in patients previously treated with other bisphosphonates (etidronate, pamidronate, alendronate, risedronate) who had failed to respond or had remissions of ≤12 months. Patients included 7 males and 7 females who were 64-90 years of age. Three had been treated with intravenous pamidronate, 2 with risedronate, and 9 with 2, 3 or 4 bisphosphonates. Screening tests included chemistry profile, CBC, and serum PTH and 25-OHD. Serum alkaline phosphatase (SAP) and urine NTx creatinine ratios were measured before infusion of ZA and at 3,6,9, and 12 months, and thereafter at 4 monthly intervals for at least 3 years or until the offset of effect. Serum calcium was measured at baseline and 10-12 days after the infusion of ZA. At baseline, SAP ranged from 141-1009 U/L (normal 25-100). In all but 1 of 14 patients, SAP fell to normal following ZA. ZA effected remissions in 5 patients who had not had remissions with prior bisphosphonates and effected a more prolonged remission in the other 8 patients. Five patients withdrew from the study while in remission for 12,20,36,36, and 48 months. One patient was in remission at 24 months when she died following a stroke. One patient has remained in remission for 48 months and 2 others for 60 months. Normalization of SAP occurred in 1-9 months. Reactivation of (PD) occurred in one patient at 12 months who had previously failed to respond to alendronate and risedronate and in 3 patients at 24,36, and 40 months. ZA failed to induce a remission in 1 of the 14 patients despite a 74% decrease in SAP and failed to induce a remission followed a 2nd infusion. Serum calcium remained within normal limits 10-12 days after therapy in all but 2 asymptomatic patients in whom levels fell to 8 and 7.9 mg/dl. There were no other adverse clinical or biochemical effects that occurred during the 3 or more years of observation. In summary, ZA therapy was effective in 13 of 14 patients with PD in inducing remissions in 5 patients who had not had remissions with prior bisphosphonate therapy and in inducing more prolonged remissions in those who previously had remissions of ≤12 months. Our experience with 1 patient in whom a remission was not induced despite 2 courses of therapy is evidence of a continuing therapeutic challenge for some patients with a more resistant form of PD.

MO0443

Dexamethasone Affects GR and GILZ Expression in Mesenchymal Stem Cells from Osteonecrosis Patients. Azeb Haile[1], Dongqing Wang[1], Aaron Johnson[2], Robert Pivec[3], Michael Mont[3], Lynne Jones*[4]. [1]Johns Hopkins University, USA, [2]University of Maryland, USA, [3]Sinai Hospital of Baltimore, USA, [4]Johns Hopkins University School of Medicine, USA

Purpose: High dose corticosteroid therapy is a major risk factor for osteonecrosis. The aim of this study was to test whether bone marrow stromal cells (MSCs) from osteonecrosis patients respond differently to dexamethasone than MSCs from healthy controls regarding protein expression of the GR (glucocorticoid receptor) and GILZ (the glucocorticoid induced leucine zipper) proteins.

Methods: IRB approval and informed consent were obtained. hMSCs were isolated from bone marrow aspirates from 10 osteonecrosis patients (5 men, 5 women) undergoing total hip arthroplasty. The mean age was 43 years (range, 23-57). Comorbidities included corticosteroids (n=3), sickle cell disease (n=4), and other (n=3). Bone marrow aspirates (3-8ml) were collected in tubes containing 25U/ml heparin. Cells from 2 healthy donors were obtained from Texas A&M Health Science Center. Cells at passage 3 were cultured until 80% confluent. Dexamethasone was added at concentrations ranging from 10^{-8}-10^{-6}M and cells incubated for 48 hrs. GR and GILZ were detected from cell lysates using Western blots (Fig1).

Results: No significant differences were noted between the baseline levels (no dex) of GR and GILZ between the ON patient and control cells. However, the mean baseline level was the highest for the corticosteroid-associated patients for both proteins. GR levels decreased when the MSCs were exposed to dexamethasone (Fig2) ($p<.05$); the response of GR was similar for patient and control cells. The response of GILZ to dexamethasone was more variable between patients. Dexamethasone treatment resulted in increased expression of GILZ for 7/10 ON patients and control cells (#2) (Fig3). This increase was significant for the osteonecrosis patients for all doses ($p<.05$), especially for the non-steroid patients ($p<.02$).

Conclusions: Following corticosteroid treatment, protein expression of GR decreased while expression of GILZ increased. Wang et al. identified GILZ as a target gene for GR (1), and Shi et al. reported an antagonistic relationship between GILZ and GC-induced adipocytes differentiation (2). Studying the effect of corticosteroids on the expression and post-translational modification of the multiple hGR isoforms will help define the molecular mechanisms of corticosteroid-associated bone diseases and the inter-patient variability in corticosteroid responses that exist.

MO0444

Estrogen-mimicking isoflavone Genistein prevents the bone loss due to hypoxia in a rat model of Obstructive Sleep Apnea-Hypopnea Syndrome. Lige Song*[1], Yun Zhou[2], Xiao Liang[3]. [1]Tongji Hospital, Tongji University School of Medicine, Peoples Republic of China, [2]Dept.of Endocrinology, Tongji Hospital, Tongji University School of Medicine, China, [3]School of Basic Medical Sciences, Fudan University, China

The incidences of Obstructive Sleep Apnea-Hypopnea Syndrome (OSAHS) have been on rise in general population, in part, due to increasing obesity. The incidences are 2-fold higher in postmenopausal women, further exacerbating their risk of osteoporosis and fractures. Anoxia and other systemic complications of OSAHS including oxidative stress and metabolic abnormalities have been shown to cause detrimental effect on osteoblast proliferation and differentiation and also increase osteocalsts activity. In this study, we investigate whether an estrogen-mimicking isoflavone, Genistein, could reverse the decreased bone mass by intermittent hypopnea in ovariectomied rat. To mimic OSAHS, rats were housed in hypoxia chambers infused with nitrogen and normal air alternatively every 15 seconds, 8 hours per day, 5 days per week for 5 weeks. The air circulation was controlled by a time-lapse solenoid valve such that an oxygen concentration of 1% was maintained as assessed by a digital oxygen meter. The ovariectomied (OVX) rats had a significantly decreased vertebral bone mineral density (BMD) as compared to control rats (0.2546 ± 0.010 vs. 0.2684 ± 0.013, n=8, $p<0.05$). The simulated OSAHS in addition to ovariectomy (OVX + OSAHS) further significantly decreased the BMD compared to OVX alone rats (0.2454 ± 0.0173, n=8, $p<0.05$). Treatment with Genistein of the OVX + OSAHS rats significantly improved the BMD as compared to OVX + OSAHS group alone (0.2588 ± 0.012, n=8, $p<0.05$). Bone histomorphometry revealed a significant decrease in percentage trabecular area (Tb.Ar) in OVX as compared to controls (29.32 ± 6.98 vs. 31.14 ± 5.98, n=8, $p<0.05$). Tb.Ar was further decreased in OVX + OSAHS rats (28.41 ± 7.90, n=8, $p<0.05$) but was normalized in Genistein treated OVX + OSAHS rats (29.15 ± 6.89, n=8, $p>0.05$) as compared to OVX alone rats. Similar significant trends were observed in the measurement of trabecular thickness and trabecular spacing. Mechanical strength of the bone, as assessed by 3-point bending of femur, was not significantly changed in OVX vs control rats; although, it was significantly decreased in OVX + OSAHS rats compared to OVX alone (116.47 ± 15.32 vs. 126.57 ± 13.35, n=8, $p<0.05$). Genistein treatment of the OVX + OSAHS rats restored the mechanical strength of the femur to the level of OVX and control rats (124.81 ± 22.58, n=8, $p>0.05$). Taken together, this data suggest that the estrogen-mimicking action of Genestein can prevent OSAHS-induced bone loss in postmenopausal women.

Sex Steroid Hormones and Kyphosis in Older Men: The Osteoporotic Fractures in Men (MrOS) Study. Deborah Kado*[1], Mei-Hua Huang[2], Corinne McDaniels-Davidson[3], Gail Laughlin[4], Jane Cauley[5], Eric Orwoll[6], Nancy Lane[7], Marcia Stefanick[8], Elizabeth Barrett-Connor[1], Peggy Cawthon[9]. [1]University of California, San Diego, USA, [2]UCLA School of Medicine, USA, [3]SDSU/UCSD Joint Doctoral Program in Public Health (Epidemiology), USA, [4]UCSD, USA, [5]University of Pittsburgh Graduate School of Public Health, USA, [6]Oregon Health & Science University, USA, [7]University of California, Davis Medical Center, USA, [8]Stanford University, USA, [9]California Pacific Medical Center Research Institute, USA

In men, hyperkyphosis, or increased thoracic spine curvature, tends to progress with age and is associated with poor physical and pulmonary function, injurious falls, and premature mortality. Although closely associated with osteoporosis, only 1/3 of older persons with the worst degrees of kyphosis have underlying vertebral fractures. Rodent models of kyphosis suggest a link between sex steroid hormones and hyperkyphosis. To test the hypothesis that low sex steroid hormone levels are associated with kyphosis, we studied 996 men from the Osteoporosis Fractures in Men Study (MrOS) aged 65 – 99 years (mean age 72.9) who had baseline measures of total and bioavailable testosterone, total and bioavailable estradiol, sex hormone binding globulin (SHBG) and Cobb angle of kyphosis (calculated from lateral spine x-rays). Using multivariable linear regression, we examined the correlation between each sex-steroid hormone and kyphosis. Men had an average kyphosis of 38° (SD = 11.3) and 4.2% had a prevalent vertebral fracture. All sex hormones were normally distributed. Men had a mean testosterone level of 423.7 ng/dL (SD = 160.4), mean bioavailable testosterone of 216.4 ng/dL (SD = 70.6), mean total estradiol of 18.1 pg/mL (SD = 6.3), mean bioavailable estradiol of 12.3 pg/mL (SD = 4.5), and mean SHBG of 48.9 nmol/L (SD =19.7). Adjusting for age and clinic site, only total and bioavailable estradiol were significantly associated with kyphosis. Further adjustment for body mass index, prevalent vertebral fracture, hip BMD and degenerative disc disease did not materially change the results (see Table – each row represents a different fully adjusted model).

We considered additional potential confounders that included co-morbidities and health behaviors such as physical activity, alcohol use, and smoking, but adjustment for these factors made no difference in our findings. Confirming reports from the animal literature in a large epidemiological study, we report that older men with higher levels of total and bioavailable estradiol tend to have less kyphosis than men with lower estradiol levels. Of the sex hormones, estrogen appears to be the most important factor in determining both bone density and degree of kyphosis in older men.

Hormones	Beta-estimate (per SD)	95% Confidence Interval	P value
Total Estradiol (pg/mL)	-1.14	-1.83, -0.45	0.001
Bioavailable Estradiol (pg/mL)	-1.19	-1.92, -0.46	0.006
Total Testosterone (ng/dL)	0.11	-0.59, 0.81	0.75
Bioavailable Testosterone (ng/dL)	-0.09	-0.82, 0.64	0.81
SHBG (nmol/L)	0.51	-0.20, 1.23	0.16

MO0446

The bone sparing effects of 2-methoxyestradiol are mediated via estrogen receptor alpha. Anna-Lena Eriksson*[1], Anna Wilhelmson[2], Johan Bourghardt-Fagman[2], Åsa Tivesten[2], Claes Ohlsson[3]. [1]University of Gothenburg, Sweden, [2]Wallenberg Laboratory for Cardiovascular Research at the Sahlgrenska Academy, Sweden, [3]Center for Bone & Arthritis Research at the Sahlgrenska Academy, Sweden

2-methoxyestradiol (2me2), a naturally occurring metabolite of 17β-estradiol (E2), exerts bone sparing effects in animal models. *In vitro*, 2me2 has a very low affinity for estrogen receptors (ERs). ERα (ESR1) is crucial for the bone sparing effect of estradiol. We here assessed the involvement of ESR1 in the bone sparing effects of 2me2 in an *in vivo* model.

Nine-week-old wild type and ESR1 knockout (ESR1 KO) mice were orchidectomized and treated for 28 days with 6.66μg of 2me2 per day, or with placebo. Bone parameters were assessed using peripheral quantitative computed tomography (pQCT) and μCT.

2me2 preserved trabecular and cortical bone in WT mice. Trabecular vBMD was $64 \pm 20\%$ and trabecular BV/TV was $60 \pm 20\%$ higher in the metaphyseal region of the femur in the group treated with 2me2, compared with the placebo group ($p<0.01$). This was due to an increase in trabecular number ($41 \pm 10\%$, $p<0.01$) as well as trabecular thickness ($13 \pm 4\%$, $p<0.01$). In the ESR1 KO mice, treatment with 2me2 had no effect on trabecular bone (vBMD $5 \pm 5\%$, and BV/TV $6 \pm 18\%$ increase in the treatment group compared with the placebo group, non-significant)

Cortical bone mineral content in the diaphyseal region of the femur was $31 \pm 3\%$ higher in the 2me2 treatment group compared with placebo ($p < 0.001$). This was due to a $23 \pm 3\%$ larger cortical area and a $7 \pm 1\%$ higher cortical vBMD ($p<0.001$) compared with placebo. Cortical bone was not affected by 2me2 treatment in the ESR1KO mice (Cortical bone mineral content $2 \pm 2\%$ increase in the treatment group compared with the placebo group, non-significant).

In conclusion, our data show that the bone sparing effects of 2me2 on both trabecular and cortical bone parameters are mediated via ESR1. 2me2 may exert these bone sparing effects directly via ESR1 but given the low affinity of 2me2 for ESR1 this seems less likely. Alternatively, 2me2 might have been back transformed to E2, which in turn binds to ESR1. Further research is needed to clarify the mechanism underlying the ERα mediated bone-sparing effects of 2me2.

MO0447

Dietary vitamin D is reflected in a dose-response manner in circulating 25-hydroxyvitamin D and its C-3 alpha epimer as well as the 24,25 dihydroxyvitamin D metabolite in adult Sprague-Dawley rats. Christina Bianchini*[1], Hope Weiler[2]. [1]McGill University, Canada, [2]McGill University, USA

The C-3 α epimer (3-epi-25(OH)D) of 25-hydroxyvitamin D (25(OH)D) is present in high concentrations in infant serum samples and commonly present in adult serum. However the source the epimer and biological function in vivo remain unknown. The objectives were to: (1) establish a dose-response of 25(OH)D in response to increasing dietary cholecalciferol (2) describe the dose-response of other vitamin D metabolites including 24,25(OH)2D3 and 3-epi-25(OH)D (3) determine the biological response of bone to varied cholecalciferol and 3-epi-25(OH)D supplementation. Adult Sprague Dawley rats (12 weeks, n=36 female n=36 male) were randomized to: control AIN93-Mdiet (1 IU vitamin D3/g food) or experimental diets for 8 weeks: cholecalciferol 2 and 4 IU/g food, 3-epi-25(OH)D at 0.5 and 1 IU/g food and a 25(OH)D group (0.5 IU/g food) reference group. Body weights and food consumption were measured weekly. Blood samples were collected at as well as whole body dual-energy X-ray absorptiometry (DXA) at beginning, mid-point and end of study and in vivo micro-computed tomography (μCT) was performed at baseline and end of study. Vitamin D metabolites; 25(OH)D3, 24,25(OH)2D3, 3-epi-25(OH)D were quantified using liquid chromatography tandem mass spectrometry. Differences were tested using a mixed model ANOVA with post-hoc testing and Bonferroni adjustment. There were no significant differences among groups for weight or dietary intake throughout the

study. Plasma 25(OH)D followed a clear dose-response as did the 3-epi-25(OH)D and 24,25(OH)2D in response to increasing intake of cholecalciferol (Table). No significant differences were detected in bone mineral density among diet groups based on DXA and in vivo μCT scanning after post-hoc adjustments for multiple comparisons. These data are to our knowledge the first to describe several key vitamin D metabolites that respond in a positive dose-response manner to dietary vitamin D when provided at and up to four times above the recommendation for rodents. The Institute of Medicine recently set the target for 25(OH)D at 20 ng/ml for bone health in humans. Our data demonstrate that the AIN-93M control diet for rodents was not sufficient to achieve a 25(OH)D concentration of 20 ng/mL as measured using gold-standard LC-MS/MS. Longer-term studies are required to confirm the response of bone to higher intakes of vitamin D and the biological generation of 3-epi 25(OH)D.

Metabolites (ng/ml)	Diets					
	Control	2 IU Cholecalciferol	4 IU Cholecalciferol	0.5 IU 25(OH)D	0.5 IU 3-epi-25(OH)D	1 IU 3-epi-25(OH)D

MO0448

Ethnic and racial disparities in innate and adaptive immunity following vitamin D supplementation. Philip Liu*[1], Rachel Reyes[2], Andy Hur[3], Brandon Rafison[2], John Adams[1], Robert Modlin[2], Peter Joyce[2]. [1]Univeristy of California, Los Angeles, USA, [2]UCLA, USA, [3]Andy Hur, USA

A role for vitamin D and its metabolites in the human immune response has become increasingly clear via laboratory experiments. However, little is known regarding the levels of circulating 25-hydroxyvitmain D (25D) needed to facilitate the immune response in humans. We have previously demonstrated that innate (Toll-like receptor 2.1) and adaptive (IFN-γ) immune signals converge on a common vitamin D-dependent antimicrobial pathway in the human macrophage resulting in i) upregulation of the CYP27B1-hydroxylase, ii) conversion of prohormone 25D to the active metabolite 1,25-dihydroxyvitamin D (1,25D), iii) activation of the vitamin D receptor (VDR), iv) induction of antimicrobial peptides, cathelicidin (CAMP) and human beta defensin 4 (DEFB4), and v) antimicrobial activity. While increasing $25D_3$ levels of deficient sera during macrophage activation *in vitro* resulted in recapitulation of the antimicrobial response, it is unclear if modulation of 25D levels *in vivo* will have the same effect. To address this, we measured expression of CAMP and CYP27B1 from primary cultures of human monocyte-derived macrophages, preconditioned with sera from 25D deficient subjects before and after vitamin D repletion *in vivo*, then stimulated with TLR2/1 ligand or IFN-γ *in vitro*. Serum was collected prospectively and tested from 11 African American black, 34 Hispanic/Latino and 25 non-Hispanic white individuals who were vitamin D-insufficient/deficient (8-29ng/ml) and treated with 500,000 IU vitamin D_3. The total serum 25D levels of all individuals increased significantly by an average of 2.5 fold following vitamin D_3 treatment, with a 3.3 fold, 3.0 fold and 1.8 fold in the African American black, Hispanic/Latino and non-Hispanic white groups respectively. However, induction levels of CAMP via TLR2/1 or IFN-γ activation correlated with conditioning serum 25D levels only in the non-Hispanic white group (R=0.489, P<0.002 and R=0.501, P<0.002., respectively). In contrast, induction levels of CAMP via TLR2/1 or IFN-γ correlated with co-induction of CYP27B1 only in the Hispanic/Latino group (R=0.357, P<0.005 and R 0.419, P<0.001, respectively). These results demonstrate an ethnic/racial disparity in response to vitamin D supplementation and suggest that host genetics should be given consideration when determining the total 25D levels needed to reconstitute vitamin D-dependent immune responses.

MO0449

Expression of Cardiovascular System-Related Genes in Vitamin D Receptor Knockout Mice. Toshio Okano*, Naoko Tsugawa. Kobe Pharmaceutical University, Japan

Introduction: 1α,25-Dihydroxyvitamin D_3 (1α,25-D_3) is thought to play an important role in controlling cardiovascular functions. In human studies, vitamin D deficiency has been shown to increase myocardial contractility and fibrosis. In animal studies, vitamin D deficiency has been reported to induce hypertension and cardiac hypertrophy. The well-known function of 1α,25-D_3 is to maintain calcium homeostasis and to promote bone mineralization. However, apart from these classical actions, vitamin D has potent non-calcemic actions such as anti-proliferative, differentiation-inducing and immune-modulatory actions. To determine whether cardiovascular abnormalities caused by vitamin D deficiency are dependent or independent of calcium metabolism, we examined the expression of cardiovascular system-related genes in vitamin D receptor knockout (VDR-KO) mice fed a normal diet or a rescue diet to normalize serum calcium levels. Methods: Wild-type (WT) and VDR-KO littermates were divided into two groups, respectively. After weaning they were fed a normal diet or a rescue diet (2% Ca, 1.25% Pi, and 20% lactose) for 7 weeks before sacrifice. Serum calcium levels were measured. The mRNA levels of atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP), α-actin, α- or β-myosin heavy chain (α- or β-MHC) of the hearts and aorta were measured by real-time PCR. In WT and VDR-KO mice fed a normal diet or a rescue diet for 32 weeks after weaning, blood pressure (BP) was measured using a noninvasive computerized tail-cuff system. Results: The mRNA expression of ANP, BNP, α-actin, α-MHC, and β-MHC in the hearts and the mRNA expression of ANP in the aorta of VDR-KO mice fed a normal diet were significantly lower than those of WT mice. On the other hand, there was no significant difference in the mRNA expression levels of the above cardiovascular parameters between WT and VDR-KO mice fed a rescue diet. VDR-KO mice fed a normal diet for 32 weeks after weaning exhibited significantly higher systolic BP, diastolic BP, and mean BP compared with WT mice fed a normal diet for 32 weeks after weaning. However, there was no significant difference between the WT and VDR-KO mice fed a rescue diet for 32 weeks after weaning. Conclusion: Although vitamin D deficiency is a risk factor for cardiovascular abnormalities, the decreased ANP, BNP, and MHCs expression in the heart resulting in hypertension may be largely due to an impaired calcium homeostasis caused by vitamin D deficiency.

MO0450

Higher levels of $25(OH)D_2$ and $1,25(OH)_2D_2$ are associated with lower levels of $25(OH)D_3$ and $1,25(OH)_2D_3$ in older men. Christine Swanson*[1], Carrie Nielson[1], Smriti Shrestha[1], Steven Cummings[2], Elizabeth Barrett-Connor[3], Ivo Jans[4], Steven Boonen[5], Roger Bouillon[6], Dirk Vanderschueren[7], Eric Orwoll[1]. [1]Oregon Health & Science University, USA, [2]San Francisco Coordinating Center, USA, [3]University of California, San Diego, USA, [4]KU Leuven Labs, Belgium, [5]Center for Metabolic Bone Disease & Division of Geriatric Medicine, Bel, [6]Katholieke Universiteit Leuven, Belgium, [7]Catholic University of Leuven, Belgium

Vitamin D_2 has commonly been used as a supplement in the US, but the associations of serum vitamin D_2 with other vitamin D metabolites are unclear.

Sensitive, specific liquid chromatography-tandem mass spectrometry methods were used to measure vitamin D_3 and D_2 metabolites in archived serum (collected 2000-01) from 679 community dwelling men aged > 65 yrs randomly selected from those enrolled in the MrOS Study (>99% with GFR>30). The limit of quantification was 4 ng/ml for $25(OH)D_2$, 2 ng/ml for $25(OH)D_3$, 4.3 pg/ml for $1,25(OH)_2D_2$ and 6 pg/ml for $1,25(OH)_2D_3$. Spearman correlations were used to examine the associations among vitamin D metabolites. Supplement use was identified using a questionnaire at baseline.

$25(OH)D_2$ and $1,25(OH)_2D_2$ were detectable in 189 (28%) and 149 (26%) of the men respectively; 141 (21%) had detectable levels of both D_2 metabolites. 57.9% of the men reported using vitamin D supplements at baseline and they more often had detectable levels of $25(OH)D_2$ than those that did not report supplement use (43.6% vs. 2.5%). $25(OH)D_3$ was detectable in all (range 3.13 – 55.8 ng/mL); the median total 25OHD level was 25 ng/mL (range 3-56ng/mL). In the original 679 men, levels of total 25OHD were correlated with total $1,25(OH)_2D$ (r = 0.39, p<0.0001). Among the 141 men who had detectable levels of all metabolites (Table 1), $25(OH)D_2$ and $25(OH)D_3$ were strongly correlated with $1,25(OH)_2D_2$ & $1,25(OH)_2D_3$, respectively. However, men with higher levels of $25(OH)D_2$ had lower levels of $25(OH)D_3$ and $1,25(OH)_2D_3$ (Table 1), but higher $1,25(OH)_2D_2$ levels were not associated with lower levels of $1,25(OH)_2D_3$ (r =-0.043, p=0.61). Whereas higher $25(OH)D_3$ was associated with higher total $1,25(OH)_2D$, men with higher $25(OH)D_2$ tended to have lower total $1,25(OH)_2D$ levels.

Measures of vitamin D metabolites in a large cohort of men reveal that $25(OH)D_2$, a form of vitamin D derived exclusively from food and medical supplements, is associated with increased $1,25(OH)_2D_2$ levels, but decreased levels of both $25(OH)D_3$ and $1,25(OH)_2D_3$. The cause of the decrease in D_3 metabolite levels in the presence of D_2 is unclear, but may involve effects on 25-, 1α-, or 24,25- vitamin D hydroxylases. From a population perspective it appears that vitamin D_2 supplementation may reduce vitamin D_3 availability. The reasons for these relationships need further investigation and may have implications for the role of various forms of vitamin D supplementation.

Unadjusted correlations among vitamin D metabolite levels among 141 men with measurable levels of all metabolites

	Total 25OHD	$25(OH)D_2$	Total $1,25(OH)_2D$	$1,25(OH)_2D_2$	$1,25(OH)_2D_3$
$25(OH)D_2$	0.20	-0.26	-0.14	0.59	-0.32
p-value	<0.02	0.002	0.09	<0.001	<0.001

Inhibition of Methicillin-resistant Staphylococcus aureus (MRSA)-induced cytokines mRNA synthesis in human bone marrow derived mesenchymal stem cells (hMSCs) by 1,25-dihydroxyvitamin D3. Aparna Maiti*[1], William Jiranek[2]. [1]Virginia Commonwealth University, USA, [2]Department of Orthopaedic Surgery, Virginia Commonwealth University School of Medicine, USA

Staphylococci, particularly *Staphylococcus aureus* are the predominant cause of bone infection worldwide. Toll like receptors (TLRs) are an important segments of host response to bacterial infection and are expressed by a variety of immune and non-immune cells. Human mesenchymal stem cells (hMSCs) are multipotent cells found in many tissues of our body, can differentiate into stromal tissue such as bone. MSCs are known to expresses TLRs to recognize pathogenic particle and play important role in defense mechanism. 1,25-dihydroxyvitamin D_3 [$1,25(OH)_2D_3$] has direct effects on immunity modulated by vitamin D receptor (VDR) present in immune cells. Binding of ligand-activated VDR to its responsive element induces expression of antimicrobial peptides. The aim of this study was to explore the anti-inflammatory mechanism of 1,25-dihydroxyvitamin D_3 [$1,25(OH)_2D_3$] to inhibit *Staphylococcus aureus* infection mediated TLRs activation and downstream cytokine production in hMSCs via direct inhibition of transcription factor nuclear factor-?B (NF-?B) and affect global level of histone H3 lysine 9 trimethylation (H3K9me3) mark for transcriptional repression. Our data revealed that methicillin-resistant *Staphylococcus aureus* (MRSA)-infection predominantly induces TLRs 1-2, and 6 expressions in human MSCs as detected by qRT-PCR. MRSA-mediated TLR ligands reduced osteoblast differentiation and increase hMSCs proliferation, which indicated that *Staphylococcus aureus* as TLR ligands disrupted the multipotency function of hMSCs. 1,25-dihydroxyvitamin D_3 treatment followed by MRSA treatment inhibit nuclear translocation of p65-NF?B and reduced cytokines (IL-6, IL-8, and TNFα) mRNA levels along with NR4A2 in hMSCs. Finally, $1,25(OH)_2D3$ activated VDR restores the global level of H3K9me3 to repress MRSA-stimulated inflammatory cytokine IL-8 expression.

Local production of 1,25-dihdydroxyvitamin D3 in breast tumors of the pYMT mouse model regulates lipid metabolism as determined by imaging mass spectrometry and gene array analysis. Ami Grunbaum*[1], Jiarong Li[1], Richard Kremer[2], Pierre Chaurand[3]. [1]McGill University, Canada, [2]McGill University, Royal Victoria Hospital, Canada, [3]University of Montreal, Canada

Introduction: Mounting evidence suggests important protective roles for vitamin D in malignancies. Exploring the hypothesis that local production of 1,25-dihdydroxyvitamin D3 is protective, we are studying mouse breast cancer models in which localized deficiency has been induced by conditionally knocking out mammary expression of 1-alpha-hydroxylase. MALDI imaging mass spectrometry (I-MS) is becoming a method of choice to characterize the molecular content of biological tissues. Employing a systems biology approach, we are using I-MS in combination with gene microarray analysis of KEGG pathways of lipid biosynthesis to compare the lipid composition of breast tumors in 1-alpha-hydroxylase ablated (knockout) versus functional 1-alpha-hydroxylase (wildtype) mice.

Methods: Wildtype & knockout mouse (pYMT strain) breast tumors were harvested. Profiling and imaging MS of the tumors were performed by MALDI MS. To identify differentially expressed signals, spectra from each tissue section were compared by PCA & ANOVA. Lipids were identified by comparing accurate mass measurements with the LIPIDMAPS database and confirming by MS/MS. For gene analysis, tumors were analyzed by DNA microarray. Differentially expressed genes involved in lipid metabolism were mapped onto KEGG pathways of lipid biosynthesis.

Results: In a proof of principle pilot study, we have identified differences in lipid profiles of knockout compared to wildtype mouse breast tumors. Several classes of differentially expressed lipids were demonstrated, including phosphatidylinositol, phosphatidylethanolamine & phosphatidylcholine. Validation of our preliminary findings will require study of a larger well defined tissue cohort and comparison with an independent platform.

Initial analysis of our gene array data demonstrated up-regulation of several enzymes involved in sulfatide formation (serine palmitoyl transferase, galactosyl ceramide transferase) and down-regulation of sulfatide degrading enzymes (aryl sulfatase, cerebroside sulfatase). Further analysis by focussed PCR analysis of lipid pathways will improve the sensitivity and specificity of these findings.

Discussion: Currently, there is a lack of information concerning the role of lipids in cancer progression. Studies such as this will help in the discovery of lipid biomarkers to assist in the classification, diagnosis & prognosis of similar tumors. It will also enable the elucidation of metabolic pathways & potential therapeutic targets.

Local Synthesis of 1,25D Promotes Osteocyte Maturation. Andrew Turner*[1], Maarten Hanrath[2], Gerald Atkins[3], Paul Anderson[1], Howard Morris[4]. [1]Musculoskeletal Biology Research, University of South Australia, Australia, [2]University of Utrecht, Netherlands, [3]University of Adelaide, Australia, [4]SA Pathology, Australia

The local synthesis of active vitamin D (1,25D) by the enzyme CYP27B1 within osteoblasts has been previously shown to act in an autocrine manner to regulate cell proliferation and differentiation. Thus, in the current study we focused on the local metabolism of 1,25D within osteocyte-like cells. To do so we utilized the mouse cell lines MC3T3-E1, MLO-A5 and MLO-Y4 which represent increasingly mature stages of the osteoblast/osteocyte lineage, and are capable of further differentiation in culture. Our data confirm that expression of Cyp27b1 mRNA is a feature of the osteoblast lineage as cells transition to an osteocyte phenotype. Furthermore, osteocyte-like cells supplemented with 25D produce detectable levels of 1,25D in the media, sufficient to induce Cyp24A1 mRNA in all 3 cell lines studied. MC3T3-E1 cells, cultured for up to 4 weeks in osteogenic media, expressed low levels of FGF-23 mRNA under basal conditions, but expression was elevated 10-fold in the presence of 100nM 25D. Similarly, chronic 25D supplementation (100nM) increased osteocalcin (Ocn) mRNA by approximately 50% in cultures at Day 21 ($P<0.05$), however this effect was reversed in more mature cultures (44% decrease in Ocn mRNA at Day 28) suggesting that the role of locally synthesized 1,25D on activities such as mineralization may depend on the stage of maturation. Consistent with this observation, 25D exposure upregulated Ocn, Col-I and Alk Phos mRNA in MLO-A5 pre-osteocyte cells, but decreased Ocn and Phex in more mature MLO-Y4 osteocyte cells. This repression of Ocn and Phex by 25D in MLO-Y4 cells was exacerbated by transfection with a plasmid vector that increased transcription of a human Cyp27b1 transgene. Taken together, our findings suggest that the local synthesis of 1,25D within osteocytes promotes the maturation of less mature cells, and may regulate osteocyte gene expression and function in temporally dependent manner.

Lower Vitamin D Status is More Common among Saudi Adults with Type 1 Diabetes Mellitus than Non-Diabetics. Nasser Al-Daghri*. King Saud University, Saudi Arabia

Objectives: To determine vitamin D status among Saudi individuals with type 1 diabetes mellitus (T1DM) adults.

Methods: A group of 60 Saudi adults with T1DM and Diabetes Clinics, and 60 healthy controls. We measured serum 25-hydroxy vitamin D (25OHD), calcium Cholesterol, Glucose, HDL, Triglyceride in those patients, and compared the results between T1DM group and control subjects.

Results: Both T1DM and healthy groups has vitamin D deficiency. The mean levels of 25OHD were significantly lower in the T1DM adults compared to the controls (28.1 ± 1.4 nmol/l versus 33.4 ± 1.6 nmol/l). In the T1DM adults, 66.7% were mildly, 31.7% were moderately, and 3.3% were severely vitamin D deficient as compared with 41.7% (mildly), 31.7% (moderately), and 5% (severely) in the control group. Overall, 100% of the T1DM children, and 78% of the healthy children were vitamin D deficient.

Conclusion: Prevalence of vitamin D deficiency in diabetic adults is relatively high. Therefore, screening for vitamin D deficiency and supplementation of adults with low vitamin D levels should be warranted.

The Effect of Vitamin D Supplementation on Metabolic Phenotypes in Thais with Prediabetes. Hataikarn Nimitphong*, Rattanapan Samittarucksa, Sunee Saetung, Nuttapimon Bhirommuang, Laor Chailurkit, Boonsong Ongphiphadhanakul. Medicine department, Ramathibodi Hospital, Mahidol University, Thailand

Background: There have been inconsistent data about the benefit of vitamin D supplementation in cardiometabolic phenotypes. Moreover, reports regarding the issue in Asian populations are scant. In the present study, we investigated the effect of vitamin D supplementation for 3 months on anthropometric and glucose homeostasis measures in Thai adults with impaired fasting glucose (IFG) and/or impaired glucose tolerance (IGT).

Methods: Forty-seven IFG and/or IGT subjects completed the study. Subjects were randomized into 3 groups; control (n=18), vitamin D_2 weekly (n=19) or vitamin D_3 weekly (n=10). To raise total 25-hydroxyvatamin D [25(OH)D] levels to comparable levels with vitamin D_2 or D_3, vitamin D_2 20,000 IU or D_3 15,000 IU weekly were used. Anthropometric variables were obtained at baseline and at 3 months. Oral glucose tolerance test was performed at baseline and at 3 months. Total serum 25(OH)D, $25(OH)D_3$ and $25(OH)D_2$ were measured by LC-MS/MS. Insulin resistance (HOMA-IR) and insulin secretion index (HOMA%B) were calculated by the homeostasis model assessment.

Results: Total 25(OH)D levels significantly increased from baseline in both the vitamin D_2 and the vitamin D_3 groups; (D_2: Δ total 25(OH)D =12.8±3.6 ng/mL, $p <$ 0.01, D_3 13.1 ±4.1 ng/mL, $p = 0.05$) while there was no change in the control group (table 1). D_3 supplementation raised $25(OH)D_3$ significantly (+13.7 ± 4.9 ng/mL, $p <0.001$) while D_2 increased $25(OH)D_2$ levels (+25.9 ± 4.2 ng/mL, $p <0.01$) but with a decrease in $25(OH)D_3$ (−13.1 ± 3.1 ng/mL, $p <0.01$). Subjects were then classified into 2 groups, i.e., control and D_2 or D_3 supplementations. After 3 months of vitamin D supplementation, body weight (BW), waist circumference (WC) and systolic blood pressure (SBP) significantly decreased (table 2). HOMA-IR (p=0.09) and body mass index (BMI, p=0.06) also tended to decrease (table 2). Using robust regression analysis to examine the differences in changes in metabolic phenotypes after D_2 as compared to D_3, it was found that the use of D_3 was associated with a larger decrease in WC (coefficient = -3.5, $p < 0.001$) independent of the change in total 25(OH)D and baseline BMI. No difference between D_2 and D_3 was observed for other metabolic measures.

Conclusion: Weekly supplementations of vitamin D_2 (20,000 IU) or vitamin D_3 (15,000 IU) improve metabolic phenotypes in subjects with prediabetes. D_3 supplementation may decrease waist circumference more than D_2 supplementation.

MO0456

The vitamin D receptor is required for activation of the canonical Wnt and Hedgehog signaling pathways in keratinocytes. Thomas Lisse*[1], Hilary Luderer[2], Francesca Gori[3], Marie Demay[1]. [1]Massachusetts General Hospital & Harvard Medical School, USA, [2]Massachusetts General Hospital, USA, [3]Harvard School of Dental Medicine, Massachusetts General Hospital, USA

Alopecia (hair loss) in vitamin D receptor (VDR) knockout mice is due to impaired cyclic regeneration of the hair cycle, however the molecular basis for this phenotype remains unclear. Initiation of a new hair cycle requires activation of the canonical Wnt (cWnt) signaling pathway, leading to induction of Hedgehog signaling. Previous studies demonstrated that the VDR interacts with Lef1, an effector of the cWnt signaling pathway. To determine if the VDR is required for induction of cWnt and Hedgehog target genes, wild type (WT) and *vdr*$^{-/-}$ primary keratinocytes (KCs) were treated with Wnt3a conditioned media (cm) or a Hedgehog agonist (SAG, smoothened agonist). Gene expression was evaluated via rt-qPCR. In WT KCs, *Axin2* and *Gli1* transcript levels were induced 4.1±0.8 and 4.7±2.3 fold, respectively, three hours post Wnt3a-cm treatment compared to control-cm. Induction of *Axin2* and *Gli1* after three hours of Wnt3a-cm was impaired in *vdr*$^{-/-}$ KCs (2.3±0.2 and 1.8±0.4 respectively; p=0.001 and 0.03 vs. WT KCs), demonstrating abnormalities in early cWnt responses in *vdr*$^{-/-}$ cells. SAG treatment (50nM, 6hrs) induced expression of *Gli1* (2.7±0.6) in WT, but not *vdr*$^{-/-}$ KCs. Chromatin immunoprecipitation (ChIP) analyses were performed to evaluate VDR occupancy of the regulatory regions of the *Gli1* and *Axin2* genes. In WT KCs, the VDR was enriched 4.4±1.0 fold on *Gli1* sequences and 2.5±0.4 fold on *Axin2* regulatory regions. VDR was not enriched in these regions in *lef1*$^{-/-}$ KCs. However, the VDR was enriched at the *osteocalcin* (OC) vitamin D response element in both WT and *lef1*$^{-/-}$ KCs (2.4±0.3 and 2.9±1.2, respectively). These data demonstrate that the VDR is required for optimal induction of cWnt and Hedgehog target genes in primary keratinocytes. Furthermore, they demonstrate that absence of Lef1 impairs occupancy of the VDR at regulatory regions in cWnt and Hedgehog target genes, but does not impair interactions of the VDR with a classic VDRE. These studies suggest that impaired Lef1/VDR interactions are the molecular basis for impaired induction of cWnt and Hedgehog target genes during initiation of post-morphogenic hair cycles in *vdr*$^{-/-}$ mice.

MO0457

Vitamin D and Interferon beta Cooperate to Suppress Inflammatory Cytokines and to Ameliorate Disease Severity in Experimental Autoimmune Encephalomyelitis, the Murine Model of Multiple Sclerosis. Tanushree Samanta*[1], Robert Axtell[2], Sneha Joshi[1], Puneet Dhawan[1], Cheng Sun[1], Lawrence Steinman[2], Sylvia Christakos[1]. [1]University of Medicine & Dentistry & New Jersey - New Jersey Medical School, USA, [2]Stanford School of Medicine, Stanford University, USA

There is a high prevalence of vitamin D deficiency in multiple sclerosis (MS) patients and early maintenance of vitamin D sufficiency is associated with decreased risk of MS. However the immunosuppressive activity of vitamin D in MS has not been clearly defined. Interferon beta is the most popular first line treatment of MS but only reduces relapse rate by 30%. Therefore clinical trials using vitamin D or $1,25(OH)_2D_3$ analogs in combination with interferon beta would be a first consideration. In this study we examined the mechanisms by which vitamin D protects against neuroinflammation and whether vitamin D and interferon beta act synergistically to attenuate experimental autoimmune encephalomyelitis (EAE), the murine model of MS. In vivo treatment of mice with ongoing EAE with $1,25(OH)_2D_3$ was found to reverse paralysis and reduce IL-17 secreting CD4+T cells in the periphery and the central nervous system. The mechanism of $1,25(OH)_2D_3$ suppression of IL-17 was found to be transcriptional and to involve blocking of NFAT, recruitment of histone deacetylase, sequestration of Runx1 by the vitamin D receptor and induction of Foxp3. In addition, $1,25(OH)_2D_3$ was found to synergize with interferon beta to reduce IL-17 expression and transcription. Synergistic effects between interferon beta and $1,25(OH)_2D_3$ were also observed in inhibition of GMCSF and interferon gamma expression. Mice fed high dose vitamin D (20,000 IU/kg diet) were found to have significantly reduced EAE compared to mice fed the control diet (1,500 IU/kg). The combination of high dose dietary vitamin D and interferon beta (10,000 U every other day from 9 to day 17) was more effective than either high dietary vitamin D alone or interferon beta alone in ameliorating disease severity in mice with ongoing EAE. Although previous studies have shown that $1,25(OH)_2D_3$ can prevent EAE, this is the first study demonstrating that high dose of the hormone precursor, vitamin D, can cooperate with interferon beta to ameloriate disease severity in mice with ongoing EAE. From these studies we conclude that vitamin D and interferon beta have cooperative immunomodulatory effects and cooperate to diminish paralysis in ongoing EAE. These findings result in new concepts with regard to the mechanisms involved in the interaction of the vitamin D endocrine system and the immune system and provide a rationale for trials combining vitamin D and interferon beta.

A Novel Factor Derived From Resorbing Bone *In Vitro* Potently Stimulates C-Fos Expression In Breast Cancer Cells. Jane Dillon*[1], Peter Wilson[1], Alison Gartland[2], Robert Hipskind[3], James Gallagher[1]. [1]University of Liverpool, United Kingdom, [2]The Mellanby Centre for Bone Research, The University of Sheffield, United Kingdom, [3]Institut de Génétique Moléculaire de Montpellier, France

Metastasis to bone is a devastating development in cancer. When tumour cells disseminate to the skeleton, cancer becomes effectively incurable. Several factors found within bone are known to promote the growth of cancer cells but the complex interplay of host and tumour cells in the bone microenvironment remains to be elucidated. The overall aim of this project was to discover factors released during bone resorption that stimulate breast cancer cells. The specific objectives were to identify factors in conditioned medium from bone resorbing cultures that stimulate the key transcription factor, c-fos, as a biomarker of the metastatic activation of breast cancer cells.

Human osteoclasts were cultured on bone or dentine slices. The conditioned medium was harvested and added to cultures of Hs578T and T47D breast cancer cells which had been stably transfected with c-fos luciferase reporter gene constructs.

Conditioned medium from bone resorbing cultures produced a dose dependent induction in c-fos activity at dilutions 1:125 to 1:5. The stimulating activity correlated with the extent of resorption in the cultures from which it was isolated. There was a greater than 3 fold stimulation of c-fos with resorption conditioned medium, an effect larger than any other factors tested including dilutions of fetal calf serum, and candidate molecules. For example there was no induction of c-fos with TGFbeta or IGF1. EGF gave a significant stimulation up to 2 fold at doses between 20 and 200 ng/ml. PTHrP and purinergic receptor agonists also gave a stimulation but much lower than resorption conditioned medium. The activity could not be replicated by extracts of bone or dentine matrix or by conditioned medium from osteoclasts cultured on plastic. Collectively, these data strongly suggest that a previously unrecognised factor or cocktail of factors, in resorption conditioned medium was responsible for the induction of c-fos in the cell lines. Experiments are ongoing to identify the molecular entities contributing to the activating factor.In conclusion, we have identified a novel factor(s) derived from resorbing bone in vitro, which potently stimulates c-fos expression in breast cancer cells. The specific characteristics and potency of this factor(s) indicate that it cannot be ascribed to any of the known candidate molecules suggested to promote bone metastasis. This factor may provide a useful biomarker and a potential therapeutic target to prevent metastasis to bone.

Development of a 3D In Vitro Co-Culture System to Model Bone Metastatic Prostate Cancer. Eliza Fong*[1], Olyver Yau[1], Nora Navone[2], Xinqiao Jia[3], Daniel Harrington[1], Mary Farach-Carson[1]. [1]Rice University, USA, [2]The University of Texas MD Anderson Cancer Center, USA, [3]University of Delaware, USA

Tumors originating in the prostate metastasize to bone and presence of skeletal lesions greatly reduces patient survival. Understanding survival and growth mechanisms used by metastatic prostate tumors (PCa) in the bone marrow microenvironment is key to the discovery of novel therapeutics targeting PCa in bone. However, study of cell-cell and cell-extracellular matrix (ECM) interactions is impeded by a lack of clinically relevant preclinical models. Xenograft tumor models, while valuable, lack some critical features of human tumors growing in bone. We developed an *in vitro* model of bone metastatic PCa to recapitulate the heterotypic cell-cell adhesion events that occur between bone marrow stromal cells (BMSC) and PCa cells engrafted in bone. A challenge is that PCa cells and BMSCs, cultured independently, grow best in hydrogels with different compositional and mechanical properties. Hyaluronan (HA) is a major component of bone marrow ECM, and HA hydrogels reflect the low modulus environment of the tissue. Having previously shown the ability of HA hydrogels to support PCa cell growth, we next sought to develop a system to co-culture both cell-types using a 3D HA-gelatin hydrogel system that could simulate cellular interactions in bone.

We evaluated if HA-gelatin hydrogels could support the growth of HS-27a cells, a human cell line representing structural marrow cells. Using bright-field microscopy (Fig. 1A), phalloidin staining (Fig. 1B) and evaluation of DNA content as an index of proliferation, HS-27a cell numbers remained static in hydrogels for about 10 days, after which cellularity increased, and was accompanied by formation of a reticular network in the 3D matrix, reminiscent of the architecture of bone marrow stroma. When co-cultured with BMSC, bone metastatic PCa cells seeded onto these stromal cell constructs actively adhered to the reticular network of stromal cells, highlighting the potential of this model to study homing mechanisms of PCa (Fig. 1C and D). Subsequent work developed a bilayered HA-based system to model the interface between PCa and the bone marrow stroma. This system consists of stacked layers of 6-mm discs of HA-gelatin hydrogels, one optimized for encapsulating BMSC and the other PCa cells. Preliminary studies indicate this system can support primary bone marrow cells as well as PCa cells directly seeded from xenografts. This engineered 3D system provides a novel tool to study bone metastatic PCa in a controlled, biomimetic system, overcoming some limitations of current models.

Ectopic expression of twist-1 in breast cancer cells promotes bone metastasis formation. Martine Croset[1], Delphine Goehrig[1], Stephane Ansieau[2], Alain Puisieux[2], Philippe A.R. Clezardin*[3]. [1]INSERM, UMR1033, France, [2]INSERM, UMR 1052, France, [3]INSERM & University of Lyon, France

The basic helix-loop-helix transcription factor Twist-1 induces epithelial-mesenchymal transition and/or escape to the oncogenic-induced failsafe program, facilitating the intravasation of breast cancer cells in the systemic circulation and their dissemination to the lungs. Twist-1 is also expressed in breast cancer cells that disseminate in the bone marrow. Its involvement in breast cancer bone metastasis formation is however unknown. To address this question, we chose the human osteotropic MDA-MB-231/B02 breast cancer cell line which is devoid of Twist-1. MDA-MB-231/B02 cells were stably transfected with a Tet-inducible vector encoding for Twist-1, whose expression was specifically repressed in the presence of doxycycline (dox). Transfectants expressing Twist-1 or mock-transfectants were injected into the tail artery of immunodeficient mice. Radiographic analysis on day 32 after tumor cell injection revealed that the extent of osteolytic lesions in hind limbs of animals bearing Twist-1 tumors was increased, being 50% larger than that of animals bearing mock-transfected tumors. This difference was accompanied with a sharp reduction of the BV/TV ratio (indicating a higher bone destruction) and a 2-fold increase in the TuV/STV ratio (a measure of the skeletal tumor burden) compared with mice bearing mock-transfected tumors, as determined by histomorphometric examination. Twist-1 did not influence osteoclast-mediated bone destruction, as judged by the TRAP staining of osteoclasts at the bone/tumor interface in legs from animals bearing mock- or Twist1-expressing tumors. Importantly, the stimulatory effect of tumor-derived Twist-1 on bone metastasis formation was abolished in dox-fed animals, indicating that Twist-1 was responsible for enhanced in-vivo skeletal tumor growth. When breast cancer transfectants were injected orthotopically in female mice, Twist-1 expression induced a rapid tumor take compared with animals bearing mock-transfected tumors, whereas tumors grew at a similar rate, irrespective of Twist-1. Additionally, enhanced tumor take in animals bearing Twist-1 tumors was abrogated in dox-fed animals. In vitro, Twist-1 ectopic expression did not affect tumor cell proliferation and survival, nor their mesenchymal phenotype. By contrast, it promoted tumor cell invasion and enhanced microRNA-10b expression, a pro-invasive factor. Thus, our results strongly suggest that Twist-1 expression in breast cancer cells promotes bone metastasis formation.

Estrogen Depletion by Ovariectomy or Aromatase Inhibitors Increase Breast Cancer Bone Metastases in Female Nude Mice. Ahmed Harhash*[1], Wende Kozlow[2], Chris McKenna[2], Holly Davis[2], Maria Niewolna[3], Khalid Mohammad[3], Theresa Guise[3]. [1]Indiana University- School of Medicine, USA, [2]University of Virginia, USA, [3]Indiana University, USA

Treatment of estrogen receptor positive breast cancer consists of blocking the estrogen receptor by Tamoxifen or decreasing estrogen production with aromatase inhibitors (AIs).The use of AIs was reported to accelerate bone loss and cause osteoporosis in postmenopausal women. We hypothesize that estrogen depletion generates a high bone turnover state, creating the fertile soil for the metastases to grow.

To study the effect of estrogen depletion on bone metastases, 4 week old athymic nude mice were randomized to ovariectomy (OVX) or sham surgery. 10 weeks after surgery, OVX mice had lower BMD at lumber spine ($P<0.0001$) and proximal tibia ($P<0.0001$). Mice were then inoculated (intra-cardiac) with MDA-MB-231 breast cancer cells. 4 weeks after inoculation, OVX mice developed more bone metastases than sham mice as assessed by histology ($P=0.06$). To determine if AIs have the same effect on bone metastases, fourweek old nude mice were randomized to receive daily letrozole or vehicle. Four weeks after treatment,mice were inoculated with MDA-MB-231 cells and treatment was continued. Letrozole-treated mice had more osteolytic lesions on x-ray ($P=0.06$), on histological analysis of the hind limbs, bone metastases tended to increase in Letrozole-treated mice.

To determine if letrozole efficiently depletes estrogen, we compared the degree of bone loss and the change in uterine weight in vehicle- treated OVX mice to letrozole-treated OVX mice. BMD was followed for 28 weeks by DXA. Letrozole-treated OVX mice had lower BMD compared to vehicle-treated OVX mice at the lumber spine ($P<0.0001$), proximal tibia ($P<0.0001$) and distal Femur ($P<0.0001$). Bone marrow culture showed that letrozole-treated OVX mice had higher number of colony forming unit (CFU)-osteoblast ($P=0.0002$), CFU-fibroblast($P<0.0001$) and tartrate resistant acid phosphatase (TRAP)+ multinucleated cells ($P=0.0012$) compared to vehicle-treated OVX mice.Our results show that OVX and letrozole together are necessary to completely deplete estrogen production in athymic nude mice. Combining both approaches is necessary to achieve complete estrogen depletion and to efficiently study the effect of estrogen depletion on the development of breast cancer bone metastases. This model will replicate the clinical situation of treatment for hormone-dependent breast cancer.

Integrin αvβ3 and CD44 Pathways support osteoclastogenesis via a Runx2/Smad 5/Receptor Activator of NF-κB Ligand signaling axis in metastatic prostate cancer (PC3) cells. Aditi Gupta*[1], Meenakshi Chellaiah[2]. [1]University of Maryland, Baltimore, USA, [2]University of Maryland, Dental School, USA

Background:Skeletal complications such as bone loss and pathological fractures are developed as a result of androgen deprivation therapy and bone metastases in prostate cancer patients. Increased bone resorption by osteoclasts leads to bone loss. We have previously demonstrated that prostate cancer cells secrete receptor activator of NF-kB ligand (RANKL), a protein essential for osteoclast differentiation and activation. However, the mechanism(s) by which RANKL is produced remains to be determined. The objective of this study is to gain insight into the molecular mechanisms of RANKL expression by metastatic prostate cancer cells.

Results: We show here that phosphorylation of Smad 5 by integrin αvb3 and RUNX2 by CD44 signaling regulates the expression of RANKL in prostate cancer cells (PC3) derived from bone metastasis. Intranuclear targeting of RUNX2 is mediated by phosphorylation of Smad 5. Inhibition of Smad 5 phosphorylation by an inhibitor to αv reduced not only the nuclear localization of RUNX2 but also RANKL expression. Similarly knockdown of CD44 or RUNX2 by SiRNA attenuated the expression of RANKL. As a result, conditioned media from these cells failed to support osteoclast differentiation in vitro. Immunohistochemistry analysis of tissue microarray sections containing primary prostatic tumor (grade2-4) detected predominant localization of RUNX2 and phosphorylated Smad 5 in the nuclei. Immunoblotting analysis of nuclear lysates of prostate tumor tissue corroborates above observation.

Conclusions: In summary, we show here that CD44 signaling regulates phosphorylation of RUNX2. Localization of RUNX2 in the nucleus requires phosphorylation of Smad-5 by integrin αvb3 signaling. Our results suggest the possible integration of two different pathways in the expression of RANKL. These observations imply a novel mechanistic insight into the role of these proteins in bone loss when prostate cancer present in bone metastases.

MO0463

Osteocytes promote prostate cancer bone growth. Joseph Sottnik*, Honglia Zhang, Evan Keller. University of Michigan, USA

Purpose: Osteocytes are the most abundant cell type in mineralized bone. Prostate, breast, and lung cancers frequently metastasize to bone. However, the role that osteocytes play in the development of bone metastases is unknown. In the presence of physical stimuli, osteocytes are known to produce HGF, IGF1, and VEGF, a potentially potent tumor promoting cocktail. The goal of this study is to determine if soluble factors produced by osteocytes can promote tumor activity.

Methods: Conditioned media (CM) was prepared from MLO-Y4 osteocyte-like cells and MC3T3 osteoblast cells. Viability of prostate, breast, and lung cancer cell lines in the presence of CM was measured using resazurin. Further investigation was performed using the CM on prostate carcinoma (PCa) cell lines. Apoptosis and cell cycle analysis were performed using flow cytometry and western blot. Invasion and migration towards CM using modified Boyden chamber assays were performed. Western blotting was used to determine activation of signaling pathways and alterations in phenotypic markers. Immunofluorescence was used to evaluate cell-cell interactions between MLO-Y4 or primary murine osteocytes and tumor cells *in vitro*.

Results: Incubation with osteocyte CM significantly increased viability in multiple cancer cell lines compared to incubation with control or osteoblast derived CM. No difference in apoptosis was observed across multiple assays. Increased proliferation of PCa cells, as measured by cell cycle and western blotting, was observed. Osteocyte CM led to a significant increase in the migration and invasion of PCa cells. Upregulation of proteins characteristic of EMT and promotion of a mesenchymal phenotype were observed. MLO-Y4 and primary osteocytes were found to form functional cell-cell interactions with PCa.

Conclusions: Osteocytes were found to significantly promote PCa proliferation, migration, invasion, and a mesenchymal phenotype compared to osteoblasts. These observations provide evidence that osteocytes are pro-metastatic. Exploration of osteocyte-tumor interactions will provide insight to the bone microenvironment and may produce novel targets for therapeutic development.

MO0464

Association of QCT bone mineral density and bone structure with vertebral fractures in patients with multiple myeloma. Jan Borggrefe*[1], Sarah Giravent[2], Asmus Wulff[3], Jaime Peña[2], Felix Thomsen[2], Martin Heller[3], Claus-C Glueer[2]. [1]Institut und Poliklinik für Diagnostische Radiologie, Uniklinik Köln, Germany, Germany, [2]Christian-Albrechts-Universtät zu Kiel, Germany, [3]UK-SH Campus Kiel, Germany

In patients with multiple myeloma (MM) computed tomography is used for staging and to detect pathological fractures. We investigated the association of prevalent vertebral fractures in MM patients with Quantitative Computed Tomography (QCT) based bone mineral density (BMD) and structure.

We evaluated a cohort of 123 MM patients (50 women, 73 men) from the OLYMP CT study who underwent low-dose whole body CT in clinical routine. The CT scans were acquired with 1.5 mm slice thickness, 120 kVp and appr. 100 mAs with INTable Calibration Pad (Image Analysis, KY). We analyzed vertebrae T11 and T12 excluding those with focal osteolytic changes. An in-house QCT software (Structural*Insight*) was used for BMD and structural analyses, including trabecular separation (Tb.Sp), bone volume fraction (BV/TV), trabecular number (Tb.N), trabecular thickness (Tb.Th), and cortical thickness (Ct.Th). Given the limited spatial resolution a prescript app. for *apparent* was used. Vertebral fractures were diagnosed by two radiologists in consensus based on Genant-criteria. Multivariate logistic regression models were calculated and t-test were performed for differences between subgroups.45% of the patients had prevalent vertebral fractures. Patients with and without fractures were comparable in age (65 vs. 63 years, $p > 0.3$). Comparing men and women, BMD and structural variables were similar, except for Tb.N. which was lower in women ($p = 0.03$). Trabecular BMD in patients with fractures of 168 ± 6.0 mg/cc (mean $\pm$SEM) was lower than in non fracture cases with 189 ± 6.6 mg/cc ($p = 0.023$). In age-adjusted logistic regression the OR per SD was 1.6 (1.1, 2.3) for BMD 1.7 (1.1, 2.6) for app.BV/TV, 2.0 (1.4, 3.0) for app.Tb.Sp and 2.1(1.4, 3.2) for app.Tb.N. No significant differences were observed for app.Tb.Th or app.Ct.Th. In multivariate models combining BMD and structural variables, app.Tb.Sp and app.Tb.N remained significant after adjusting for age and BMD. Cortical parameters did not provide significant predictive value for fracture events.

Low-dose whole body QCT investigation of MM patients permits the investigation of bone fragility status in clinical settings. Despite limitations of image resolution bone rarefication with an 8% reduction of app.Tb.N could be detected. This may reflect lytic processes not yet apparent visually which would provide added value for staging of MM disease.

Cells of the Osteoblast lineage Hinder Acute Leukemia Progression in Murine Models: therapeutic implications. Maria Krevvata*[1], Barbara Silva[1], J. Sanil Manavalan[1], Aris Economides[2], Julie Teruya-Feldstein[3], Govind Bhagat[1], Ellin Berman[3], Stavroula Kousteni[1]. [1]Columbia University Medical Center, USA, [2]Regeneron Pharmaceuticals, Inc., USA, [3]Memorial Sloan-Kettering Cancer Center, USA

It is now appreciated that trabecular bone formation and establishment of hematopoiesis within the marrow are intimately coordinated. Osteoblasts influence homing of hematopoietic stem cells (HSCs) and are implicated in HSC lineage determination and expansion. In turn, deregulation of hematopoiesis is associated with hematological malignancies, which may in part be mediated by the microenvironment. The implication of cells of the osteoblast lineage in hematological disease recently came to light when deletion of the RNA processing *Dicer1* in osteoblast progenitors in mice induced myelodysplasia, a pre-leukemic condition in humans. We hypothesized that osteoblasts directly influence the fate of leukemic blasts. Consistent with this idea we found through genetic means that depletion of osteoblasts in syngeneic mouse models of acute myeloid or lymphoid leukemia increased circulating blasts and tumor engraftment in the bone marrow and liver or spleen leading to higher tumor burden and shorter survival. Myeloid activity was increased in the marrow and was coupled with a reduction in B-lymphopoiesis and compromised erythropoiesis suggesting that hematopoietic lineage progression was altered. In parallel studies in wild type mice, injection of the myelomonocytic leukemia cell line WEHI-3B or the lymphoblastic EL4 cells resulted in rapid, within 2 weeks, marked decrease in bone volume which was solely due to a decrease in the number of osteoblasts. Given this finding, we examined whether the course of leukemia could be ameliorated in mice by increasing their osteoblast numbers. Treatment of mice with acute myeloid or lymphoblastic leukemia with a pharmacological inhibitor for the synthesis of duodenal serotonin, a hormone suppressing osteoblast numbers, inhibited loss of osteoblasts in both models of leukemia. Mirroring the observations in mice lacking osteoblasts, maintenance of the osteoblast pool allowed for recovery of normal marrow function, hindered tumor burden and increased survival. Importantly, tumor burden inversely correlated with osteoblast numbers. Leukemia prevention was specifically due to maintenance of osteoblasts since selective inhibition of serotonin receptors in leukemia blasts did not affect leukemia progression in any of the two models. These results suggest that osteoblasts play a fundamental role in propagating leukemia in the bone marrow and that manipulating osteoblast numbers or function may be a potential target to treat leukemia.

Increased Expression of TAF12 in Myeloma Cells and the Bone Microenvironment Enhances Tumor Cell Growth and Osteoclast Formation. Noriyoshi Kurihara[1], Jumpei Teramachi[2], Yukiko Kitagawa*[1], John Chirgwin[1], G. David Roodman[1]. [1]Indiana University, USA, [2]The University of Tokushima, USA

Vitamin D (Vit.D) plays multiple roles in normal and malignant cellular function, including cell differentiation and proliferation, and is a key regulator bone homeostasis. Low Vit.D may play a role in the progression of lung cancer, breast cancer and prostate cancer as well as lymphoma and melanoma. However, the role of Vit.D in myeloma (MM) is much less clear. Vit.D insufficiency or deficiency has been documented in the majority of MM patients, but it is unclear if it affects disease activity. We previously found OCL precursors from patients with Paget's bone disease (PD) were hypersensitive to Vit.D and formed OCLs at physiologic concentrations of 1,25-(OH)2D3 (1,25-D3) rather than the pharmacologic concentrations of 1,25-D3 normally required for OCL formation. This enhanced sensitivity to 1,25-D3 was due to increased expression of a VDR co-activator, TAF12, a member of the TFIID transcription complex induced by IL-6. Since IL-6 levels also are increased in MM, we tested MM cells and marrow stromal cells (BMSC) for TAF12 expression. BMSC and CD138+ primary cells from MM patients expressed increased TAF12 levels compared to BMSC and CD138+ plasma cells from normal donors. MM cell lines (MM1.S, ANBL6, JJN3 and RPMI8266) expressed increased levels of VDR and TAF12 and were hyper-responsive to 1,25-D3. TNFα and IL-6 increased TAF12 expression in MM cells and BMSC. The increased TAF12 levels enhanced RANKL, VEGF, DKK1 and α4β1 integrin expression by CD138+ primary MM cells and MM cell lines in response to 10-10M 1,25-D3 and enhanced adhesive interactions between MM cells and BMSC to increase MM cell growth. To confirm the capacity of TAF12 to increase RANKL expression by MM cells in response to 1,25-D3, we made a stable TAF12 anti-sense JJN3 cell (AS-TAF12-JJN3). AS-TAF12-JJN3 cells had markedly decreased RANKL production, VDR content and CYP24A1 accumulation in response to 1,25-D3. Co-culture of JJN3 cells with BMSC treated with 1,25-D3 induced increased MM cell adhesion to BMSC that enhanced MM cell growth. In contrast, co-culture of BMSC with AS-TAF12-JJN3 cells resulted in decreased MM cell adhesion and growth. Further, 1,25-D3 treatment of human OCL precursors co-cultured with JJN3 cells, but not AS-TAF12-JJN3 cells, induced OCL formation which was blocked by OPG. These results suggest that increased expression of TAF12 in myeloma cells and their microenvironment allows low concentrations of 1,25-D3 to enhance tumor cell growth and osteoclast formation.

Multiple Myeloma Cells Suppress Osteoblastogenesis by Upregulating Gfi1 via Activation of the ER Stress Transducer IRE1α. Feng-Ming Wang*[1], Hong-Jiao Ouyang[2], Deborah Galson[3], G. David Roodman[1]. [1]Indiana University, USA, [2]University of Pittsburgh, USA, [3]University of Pittsburgh School of Medicine, USA

Osteoblast suppression induced by myeloma cells is a major factor in the morbidity and mortality of multiple myeloma bone disease. Gfi1 is an important *Runx2* transcription repressor responsible for the osteoblast suppression induced by multiple myeloma cells. However, it remains unclear how *Gfi1* is upregulated by myeloma cells. In this study, we report that *Gfi1* is an endoplasmic reticulum (ER) stress response gene. Co-culture of myeloma cells with the pre-osteoblastic cell line MC3T3-E1 subclone 4 (MC4) induced the transcription of *Gfi1* along with the known ER stress target genes, *Grp78, Gadd34, Chop, Edem1*, in the MC4 cells. Similarly, treatment of MC4 cells with the ER stress stimulators tunicamycin and thapsigargin increased *Gfi1* mRNA and protein via transcriptional regulation. Consistent with this, inhibition of the endoribonuclease activity of the ER stress transducer Ire1α by 3-Ethoxy-5,6-dibromosalicylaldehyde strongly attenuated the induction of *Gfi1* in MC4 cells. The induction of *Gfi1* by ER stress did not occur in *Ire1α* deficient mouse embryonic fibroblasts (MEFs). Tunicamycin and thapsigargin treatment of *Xbp1* deficient MEFs revealed that Ire1α-mediated upregulation of *Gfi1* is only partly dependent on the known Ire1α endoribonuclease target Xbp1s. Further, over-expression of wild-type IRE1α induced *Gfi1* mRNA in NIH3T3 cells, whereas endoribonuclease deficient-IRE1α (K907A) and kinase deficient-IRE1α (K599A) did not, and the induction was predominantly dependent on the endoribonuclease activity. Finally, knockdown of *Ire1α* in MC4 cells by either siRNA transfection or shRNA lentivirus transduction prevented ER stressor and myeloma cell upregulation of *Gfi1*, and also prevented myeloma cell induced suppression of *Runx2* and osteoblast differentiation. These data suggest that ER stress upregulates *Gfi1* mRNA via activation of IRE1α in bone marrow stromal cells exposed to myeloma cells, resulting in osteoblast suppression. Therefore, the endoribonuclease activity of IRE1α in stromal cells may be a potential therapeutic target for reversing the protracted inhibition of osteoblast differentiation in multiple myeloma.

MO0468

Osteoclasts from Multiple Myeloma Patients Are Highly Angiogenic. Rebecca Silbermann*[1], Dan Zhou[1], Wei Zhao[1], Courtney Tate[2], Wayne Blosser[2], Lisa Wyss[3], Louis Stancato[2], G. David Roodman[4]. [1]Indiana University School of Medicine, USA, [2]Eli Lilly & Company, USA, [3]Advanced Testing Laboratories, USA, [4]Indiana University, USA

Multiple myeloma (MM) bone disease is marked by increased osteoclast (OCL) formation and enhanced angiogenesis. Increased microvessel density in the MM bone marrow microenvironment (BMM) correlates with disease progression, and the apposition of OCL and endothelial cells in the BMM suggests that osteoclastogenesis and angiogenesis are linked. While MM cell, stromal cell, and endothelial cell interactions are known to produce angiogenic factors, OCL-conditioned media (CM) is also highly angiogenic, and the role of OCL themselves in MM angiogenesis has not been studied. We hypothesize that the angiogenic capacity of MM patient OCLs differs from healthy donor OCLs, and that MM OCL express different amounts of known angiogenic factors.

We cultured non-adherent bone marrow mononuclear cells from MM patients and healthy donors to induce OCL formation in the presence of mCSF and RANKL for 21 days. Purified, mature OCL populations were incubated in serum free media for 24 hrs. CM and OCL RNA were isolated and tested for angiogenic activity and expression of angiogenic genes. CM from healthy donor OCL and MM OCL significantly and dose-dependently increased human umbilical vein cell proliferation after 72 hrs. Endothelial cell cord formation was tested with adipose-derived stem cell / endothelial colony-forming cell co-cultures treated with each OCL-CM. Vascular networks were visualized with CD31 staining. Imaging and analysis were performed with the cord formation algorithm on the Thermo Fisher® ArrayScan® VTI. Both MM patient OCL-CM and healthy donor OCL-CM significantly increased cord formation, with dose-dependent increases in total tube area and connected tube area as compared with control. Direct comparison of MM patient OCL-CM with healthy donor OCL-CM, normalized for total protein concentration in the OCL cultures, demonstrated increased total tube area and connected tube area in the MM OCL-CM treated samples. Angiogenic gene expression in the MM and healthy donor OCL was compared using the Human Angiogenesis *Profiler* RT^2 PCR array. 30 of 84 genes screened had a 2 - 20 fold increased expression in the MM sample compared to the healthy donor. Highly expressed genes include ANG, CXCL12, PDGFB, and VEGFA.

These findings demonstrate that MM patient-derived OCL-CM is more angiogenic than healthy donor OCL-CM, and suggest that OCL may be major contributors to the increased angiogenesis seen in MM, in addition to their role in tumor growth and bone destruction.

Suppression of Osteoblastogenesis in Human MSCs Co-cultured with Human Multiple Myeloma Cells. Wei Zhang*[1], James Peterson[1], Moustapha Kassem[2], Matthew Drake[3]. [1]Mayo Clinic, USA, [2]Odense University Hospital, Denmark, [3]College of Medicine, Mayo Clinic, USA

Multiple myeloma (MM) is a malignancy of terminally differentiated clonal plasma cells. MM cells grow within the bone marrow (BM) cavity in close proximity to mesenchymal stem cells (MSCs), a dynamic population of self-renewing multipotent progenitor cells capable of osteoblastic differentiation. As most MM patients suffer from lytic bone destruction unmatched by bone formation, the interactions between MM cells and MSCs within the BM is likely crucial for MM bone disease.

To evaluate how MM cells impact MSC differentiation along the osteoblast (OB) lineage, we developed an *in-vitro* system in which the immortalized human MSC line hMSC-TERT was co-cultured in a transwell system separated by a 0.4 μm filter from the human MM cell lines RPMI8226 or U266. As a negative control, hMSC-TERT cells were co-cultured with hMSC-TERT cells. Following hMSC-TERT cell pre-differentiation with ascorbate and BGP for three days, MM cells were introduced and co-culture initiated. As expected, co-culture significantly reduced both AP activity and matrix mineralization in the hMSCs. Quantitative PCR results revealed that compared to control, hMSC-MM cell co-culture markedly suppressed the expression (by QPCR, n = 4-6, all $P < 0.01$) of OB differentiation marker genes in the hMSCs. Specifically, mRNA levels for AP decreased by 72-88%, col1α1 by 34-80%, and osteonectin by 54-81%. In contrast, hMSC expression of DKK1, a Wnt/beta-catenin pathway inhibitor with a well-recognized role in the pathogenesis of MM bone disease, was significantly increased by 52-100% ($P < 0.01$). Whole transcriptome sequencing is currently underway to evaluate for other hMSC genes impacted by co-culture. Given a recently described role for MSCs in regulating MM cell growth (J Clin Invest 123:1542, 2013), we also examined the effect of MSCs on proliferation markers in the MM cells. Consistent with these findings, MSC-MM cell co-culture markedly suppressed mRNA levels for cyclins A2 by 61-85%, B1 by 58-81%, and B2 by 55-84% (all $P < 0.01$) and Ki67 (-84% in RPMI 8226, $P < 0.01$; -36% in U266, $P = 0.057$).

In summary, using a co-culture system to simulate human MM cell/hMSC interactions, we found that MM cells significantly inhibited hMSC differentiation along the osteoblastic lineage; reciprocally, hMSCs suppressed MM cell proliferation gene expression. Future studies using this novel co-culture system will seek to understand the complex MM cell/hMSC interactions which underlie MM bone disease *in vivo.*

MO0470

Tumor-initiating Stem Cells are Regulated by α-CaMKII-induced VEGF in Human Osteosarcoma. Paul Daft*, Joan Cadillac, Majd Zayzafoon. The University of Alabama At Birmingham, USA

Osteosarcoma (OS) is among the most frequently occurring primary bone tumors, primarily affecting adolescents and young adults. Chemoresistance and disease recurrence are major challenges in the clinical management of OS and are thought to be caused by a small subpopulation of tumor-initiating stem cells (TISCs). Human OS TISCs are characterized by their expression of surface antigens $CD117^+$ and $Stro\text{-}1^+$, and the stem cell regulating transcription factors Sox2, Nanog, and Oct4. These OS TISCs are known to express high levels of receptors for vascular endothelial growth factor (VEGF). We have previously demonstrated that alpha-Ca^{2+}/Calmodulin kinase two (α-CaMKII) regulates VEGF and its autocrine signaling functions in human OS. Here, we examine whether OS TISCs are regulated by α-CaMKII-induced VEGF. Using fluorescence-activated cell sorting, we discovered that the pharmacological inhibition of α-CaMKII or VEGF in 143B OS cells by tamoxifen (1 μM) or bevacizumab (1 μM), respectively, decreases the population of $CD117^+$ and $Stro\text{-}1^+$ TISCs, and the gene expression (60%) and protein levels (80%) of Sox2, NANOG, and Oct4. Additionally, we developed a novel preclinical xenograft mouse model to examine the recurrence and metastasis of human OS. 143B OS cells were intratibially injected into mice, and tumors were allowed to grow for 2 weeks. Hind limbs-containing tumors were then amputated, and mice were confirmed to be tumor free by bioluminescent imaging 7 days post-surgery. Mice were randomized into four treatment groups: saline, tamoxifen (500μg/kg/day), and/or bevacizumab (5μg/kg twice weekly) and monitored monthly by bioluminescent imaging for the development of metastasis. The incidence of pulmonary metastasis/recurrence in saline treated mice was 100% two months after amputation. However, the incidence decreased to 38% in bevacizumab-treated mice, 12% in tamoxifen-treated mice, and 0% when both drugs were used. The levels of the TISCs subpopulation in pulmonary metastasis were determined by immunohistochemistry for Sox2, NANOG, and Oct4. We show that the number of TISCs were significantly increased in the recurrent metastatic pulmonary tumors when compared to primary amputated tumors. Furthermore, we show that treatment with tamoxifen and/or bevacizumab significantly decreases the number of TISCs when compared with saline treated mice. Taken together, our results demonstrate that α-CaMKII-induced VEGF controls the levels of TISCs both *in vitro* and *in vivo*.

A new *in vivo* methodology for quantifying intramuscular adipose tissue (IMAT) in the lower leg of women to define the relationship with BMD, strength, physical function and lifestyle variables. Janet Pritchard*[1], Sarah Karampatos[2], Karen Beattie[1], Lora Giangregorio[3], Stephanie Atkinson[1], Hertzel Gerstein[4], Zubin Punthakee[4], Jonathan Adachi[5], Alexandra Papaioannou[6]. [1]McMaster University, Canada, [2]Hamilton Health Sciences McMaster University, Canada, [3]University of Waterloo, Canada, [4]McMaster University, Canada, [5]St. Joseph's Hospital, Canada, [6]Hamilton Health Sciences, Canada

Introduction: Bone loss with age is linked to sarcopenia, defined as the aging-associated loss in muscle mass, strength and physical function. Muscle-bone interaction may also be influenced by fat infiltration of the muscle, known as intramuscular adipose tissue (IMAT). The primary aim of this study was to develop a reliable, non-invasive method of quantifying IMAT in the lower leg. The secondary aim was to determine the relationship between the amount of IMAT in the lower leg and BMD, strength, physical function, and other lifestyle variables.

Methods: This study included 28 postmenopausal women ⩾ 65 years of age with type 2 diabetes and 29 postmenopausal women without type 2 diabetes (control). All women were recruited from a diabetes outpatient clinic at Hamilton Health Sciences or the community. A 1-Tesla peripheral magnetic resonance imaging (MRI) system (OrthOne, GE) and fast spin echo sequence was used to acquire 10 sequential T1-weighted axial images of the non-dominant lower leg at the 66% site. Images were segmented with Slice-O-matic (Tomovision) using a threshold-based region growing technique to quantify IMAT area in each slice. The average cross-sectional area was calculated for each participant.19 participants' scans were analyzed in duplicate to assess intra-rater reliability, reported using root mean square coefficient of variation (RMSCV%) and type 2,1 intraclass correlation coefficient (ICC). Pearson correlation coefficients examined the relationships between IMAT and other variables.

Results: The relative intra-rater reproducibility of quantifying IMAT was good, with RMSCV% of 4.3% and ICC of 0.996 (95% confidence interval, 0.990-0.998). IMAT was related to lumbar spine and femoral neck BMD, timed-up-and-go result, grip strength, BMI, obesity, presence of type 2 diabetes, number of years since type 2 diabetes diagnosis, hip or knee OA and use of walking aid (Table 1).

Conclusion: This reliable method for measuring IMAT in the lower leg could be used in future studies to assess the interaction between muscle and bone quality. The positive relationship between BMD and amount of IMAT may be due to an interaction between BMI and IMAT, and skeletal loading. Lifestyle interventions may reduce the amount of IMAT and improve physical function and strength outcomes.

Table 1. Relationships between IMAT and BMD, strength, physical function and lifestyle variables.

	Pearson r	p-value
Lumbar spine BMD	0.273	0.042*
Femoral neck BMD	0.394	0.001*
Timed-up-and-go result	0.439	<0.001*
Grip strength	-0.268	0.048*

Elevated Levels of Circulating Sclerostin in Hypophosphatemic Rickets. Telma Oliveira*[1], Francis Glorieux[2], Frank Rauch[3]. [1]Bone & Mineral Unit, Division of Endocrinology-UNIFESP, Bra, [2]Shriners Hospital for Children & McGill University, Canada, [3]Shriners Hospital for Children, Montreal, Canada

Background: Sclerostin is an antagonist of the Wnt signaling pathway and thereby is involved in the control of bone formation activity. The role of sclerostin in heritable metabolic bone disorders has not been studied in detail.

Objective: The objective of the study was to evaluate serum sclerostin levels in patients with osteogenesis imperfecta (OI) and X-linked hypophosphatemic rickets (XLH), and analyze the relationship of circulating sclerostin concentrations with bone mineral density and biomarkers of bone metabolism.

Materials and Methods: Serum sclerostin was quantified in 152 individuals, including 31 patients with XLH (14.7 ± 7.6 yr), 12 patients with OI type VI (26.8 ± 23.3 yr), 79 patients with other OI types (12.6 ± 4.8 yr) and 30 healthy subjects (20.8 ± 16.1 yr).

Results: Circulating sclerostin levels were higher in the XLH group (31.4 ± 17.8 pmol/l) than in healthy controls (22.6 ± 9.6 pmol/l ($p = 0.03$). Serum sclerostin levels were significantly higher in subjects with XLH than in OI subjects (21.84 ± 11.8 pmol/l), $p = 0.002$. In the XLH cohort, serum sclerostin levels were positively associated with the bone resorption marker serum NTX ($r = 0.84$) and with lumbar spine areal bone mineral density z-scores ($r = 0.71$; $p < 0.001$ in each case). Sclerostin levels were higher in boys (9 patients) with XLH than in girls (22 patients) 49.9 ± 18.7 vs. 23.9 ± 10.7 pmol/l, $p = 0.003$. Within the OI group, there was no significant difference in sclerostin levels between patients receiving bisphosphonates (n=31) and patients (n=45) who had never received bisphosphonates (21.2 ± 12.5 vs. 23.2 ± 12.7 pmol/l, $p = 0.48$).

Conclusion: Serum sclerostin levels are increased in XLH, a disorder with high bone mass. This can be interpreted as a mechanism that slows down bone formation and thus prevents a further increase in bone mass.

LB-SA03

Longitudinal modelling of fat and bone mass between aged 10 and 18 in a large cohort of boys: The Reciprocal Relationships between Bone Mass and Fat Mass. Adrian Sayers*[1], Emma Clark[1], J.H. Tobias[2], Kate Tilling[1], Fiona Steele[1]. [1]University of Bristol, United Kingdom, [2]Avon Orthopaedic Centre, United Kingdom

Introduction: Fat mass and bone mass are highly correlated, and to accurately study the dynamic relationships between these tissues across time, multiple measures in large numbers of people are required. We have investigated the relationship between fat mass and bone mass using longitudinal data from 9102 DXA scans in 2724 boys, aged 10 to 18 years, from the population-based cohort ALSPAC, the Avon Longitudinal Study of Parents and Children.

Methods: Fat mass and bone mass were measured using DXA at 5 time points: aged 10, 12, 14, 15.5 and 18 years. Bi-variate dynamic models were used to simultaneously assess the associations between fat and bone across the time points, and their associations with the previous measurements of bone and fat. Analyses were

standardised and adjusted for birth weight, crown heel length and maternal social economic status. For clarity, results are reported as regression coefficients, δ, with 95% confidence intervals where 0 equals no predictive ability and 1 indicates perfect prediction. These coefficients reflect the average predictive ability of the measurement across all time points.

Results: Measurements of fat at the previous time point were highly predictive of fat at the subsequent time point [$\delta_{fat,fat}$=0.97 (95%CI:0.96, 0.98), p<0.0001]. However, for bone the association was weaker [$\delta_{bone,bone}$ =0.72 (95%CI:0.70, 0.73) , p<0.0001]. There was a positive prospective association between fat and subsequent bone mass [$\delta_{bone,fat}$=0.043 (95%CI:0.019, 0.068) , p<0.0001] and also a positive prospective association between bone and subsequent fat mass [$\delta_{fat,bone}$ =0.046 (95%CI:0.032, 0.051), p<0.0001].

Conclusion: As expected there was a strong association between fat and previous fat, whereas the association between bone and previous bone was weaker. This suggests an important role of environmental influences on gain in bone mass across adolescence. Also, as expected, we report a positive prospective association between fat and bone. Uniquely, we also show a positive prospective association between bone and fat, of a similar strength to that seen between fat and bone, suggesting increased bone formation also results in increased in fat mass. This may be due to a direct effect of bone cells on adipose cells, or reflect the shared mechanisms of gain in bone and fat mass, perhaps because of their common mesenchymal origins. This study highlights new avenues for research in population cohorts.

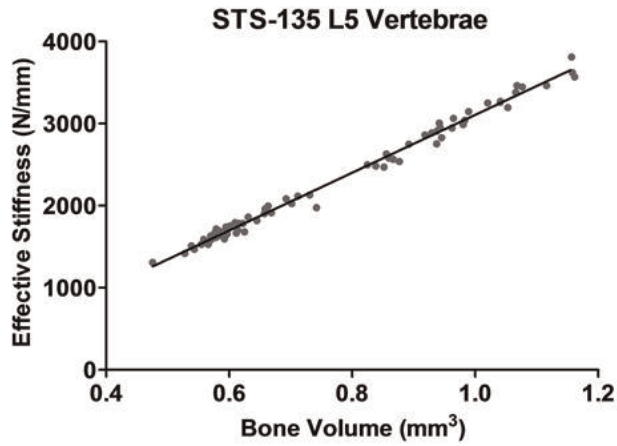
Effects of Spaceflight on the "Non-Weight Bearing" L5 Vertebra Measured by Finite Element Analysis in Mice Flown on Space Shuttle Flight STS-135. Elizabeth Marshall*[1], Lindsay Sullivan[2], Eric Livingston[3], Andrea Hanson[4], Travis Pruitt[5], Louis Stodieck[6], Laura Bowman[2], Rachel Ellman[7], Jordan Spatz[8], Chris Paszty[9], Mary Bouxsein[7], Virginia Ferguson[6], Ted Bateman[10], Anthony Lau[2]. [1]Meredith College, USA, [2]University of North Carolina at Chapel Hill, USA, [3]University of North Carolina, USA, [4]Wyle, USA, [5]Clemson University, USA, [6]University of Colorado, USA, [7]Beth Israel Deaconess Medical Center, USA, [8]Harvard-MIT Division of Health Sciences & Technology (HST), USA, [9]Amgen, Inc., USA, [10]Univesity of North Carolina, USA

Skeletal unloading during spaceflight reduces bone volume and bone mineral density. How this loss translates to functional changes in strength and stiffness in the lumbar vertebrae is not well described. This study uses finite element modeling (FEM) of "non-weight bearing" L5 vertebrae in mice flown on STS-135 to assess the relationship between bone volume and bone stiffness from spaceflight and sclerostin antibody (Scl-Ab).

Thirty mice were flown on Space Shuttle Flight STS-135 for 13-days (FL). Half of the mice were treated with vehicle (n=15) and half were treated with a Scl-Ab (n=15). Corresponding ground control (GC) groups were similarly treated. Subject specific FE models were meshed from microCT, isolating a 1.50 mm tall segment of the L5 vertebral body starting at the superior endplate, excluding the pedicles. A downward displacement of 7.5 µm was applied to the superior face of the vertebral body to assess stiffness and structural efficiency (stiffness per amount of bone volume).

FEM of L5 vertebrae found a 20% decrease in stiffness and a 17% decrease in bone volume in the FL mice compared to the GC mice. Scl-Ab treatment resulted in increased stiffness by 75% and increased volume by 61% in the FL and increased stiffness by 65% and volume by 53% in the GC. Scl-Ab had a greater effect on bone volume and stiffness in both the FL and GC groups in comparison to the FE results of the proximal tibia or proximal femur ("weight bearing" bones) from the same mice. Bone structural efficiency changes were significant, but small compared to volume and stiffness, with a 4% decrease between GC and FL mice and a 9% increase and 8% increase respectively for the Scl-Ab treated FL and GC mice. Regardless, linear regression found a strong relationship between bone volume and stiffness of the L5 vertebrae among all test groups (P<0.01, R2=0.99). When examining the "weight-bearing" bones from the same mice, the changes in bone efficiency were larger between FL and GC, suggesting gravity has a greater effect on efficiency in "weight bearing" than in "non-weight bearing" vertebrae.

Regardless of treatment, bone volume was a good predictor of bone stiffness in the "non-weight bearing" L5 vertebrae, which was not observed in the "weight bearing" bones from the same mice. The unloading environment of microgravity caused a significant loss of L5 vertebrae stiffness in the vertebral body and treatment with Scl-Ab increased volume and stiffness in both FL and GC mice.



Regression shows linear relationship between bone volume and stiffness in L5 vertebrae (R2=0.992)

Passive Standing and Electrical Stimulation are Eligible Therapies for Preserving and Reverting the Loss of Bone Quality in Rats with Complete Spinal Cord Injury. Ariane Zamarioli[1], Daniel Maranho*[1], Francisco Jose De Paula[2], Leslie Morse[3], Ricardo Battaglino[4], Jose Volpon[1], Antonio Shimano[1]. [1]University of Sao Paulo, Brazil, [2]School of Medicine of Ribeirao Preto - USP, Brazil, [3]Harvard Medical School, USA, [4]The Forsyth Institute, USA

Objective: To assess the effects of passive standing (PS) and electrical stimulation (ES) on bone quality in rats with spinal cord injury (SCI).

Design: Seven-week-old male Wistar rats were divided into eight groups (n=7/group): (1) Sham33d; SCI33d; SCI+PS33d; SCI+ES33d; Sham63d; SCI63d; SCI+PS63d and SCI+ES63d. Complete SCI was generated by surgical transection of the cord at T10 level. ES and PS were performed 3days/week, 20minutes/day, for 30 days, whereas prevention was initiated three days after the surgery in the 33d groups and, treatment was started 33 days after SCI in the 63d groups. The following analyses were performed: biomechanical test, BMD analysis, H&E and Trap staining histology, microtrabecular quantification by Micro-CT in tibia, and serum markers for both formation (osteocalcin and OPG) and resorption (sclerostin and TRAP).

Results: SCI decreased bone quality in bones situated below injury level, which was more pronounced in long-term paraplegia (p<0.01). Thirty-three days of injury caused a reduction of 56% in mechanical strength, 72% in BMD, 61% in BV/TV, 50% in TbN, 60% in ConnDens, 20% in serum osteocalcin and 52% in serum OPG level. Whereas was observed an increase in serum levels of TRAP (47%), sclerostin (41%) and TbSp (133%), in comparison with SCI rats without treatment. These changes remained after 63 days of paraplegia, with some exacerbations as 67% in bone strength, 63% in TbN and 44% in osteocalcin. Regarding therapeutic modalities, both PS and ES preserved and reverted the bone loss following SCI (p<0.01) at varying degrees. PS increased BMD in 38%, bone mechanical strength in 48% (prevention) and in 96% (treatment), BV/TV in 40% (prevention) and in 75% (treatment), TbN in 100% (prevention) and in 117% (treatment), TbTh in 13%, ConnDens in 65% (prevention) and in 82% (treatment), osteocalcin in 75% (prevention) and in 176% (treatment) and OPG in 137%. Additionally, PS increased bone resorption in 43% (prevention) and in 63% (treatment) for TbSp and in 34% for sclerostin. ES also increased the bone quality of paraplegic rats, but to a lesser degree than PS; mechanical resistance in 35%, TbN and TbTh in 20%, osteocalcin in 40% and, decreased TbSp and TRAP in 22%.Conclusions*:* Passive standing and electrical stimulation have potential osteogenic effects as therapeutic modalities to both prevent and treat bone loss after spinal cord injury. Further investigation with the combination of both therapies may be performed.

Alterations to Cortical Bone Fatigue Life Depend on Bisphosphonate Type.
Garry Brock*[1], Anthony Ingraffea[1], Jennifer MacLeay[2], Adele Boskey[3], Marjolein Van Der Meulen[1]. [1]Cornell University, USA, [2]Colorado State University, USA, [3]Hospital for Special Surgery, USA

Bisphosphonates (BP) are commonly prescribed for treatment or prevention of osteoporosis. Through osteoclast inhibition, BP suppress bone remodeling, preventing repair of damaged and aged tissue. Alendronate (ALN) treatment has been associated with increased microdamage in vivo[1] and shorter fatigue life[2] in cortical bone in the laboratory. Here we examined the fatigue life of cortical bone tissue treated with different generation BP and a SERM. Fatigue was chosen because atypical femoral fractures manifest as stress fractures.

In two experiments[3], skeletally mature sheep (n=25) were fed a metabolic acidosis (MA) diet to induce osteopenia[4] and then treated with ALN (n=2), zoledronate (ZOL n=6), raloxifene (SERM n=2) or vehicle (n=3 or 6 Table 1). Beams of cortical bone were cut from the medial region of the femoral diaphysis and anhydrously polished to a final cross section of 2 x 2 x 25mm. Beams were loaded cyclically to failure in four-point bending to generate surface strains of 400 to 4000με. Modulus degradation and cycles to failure were measured. Tissue mineral density (TMD) was measured by microCT.

Cycles to failure was similar across all groups except ALN, for which fatigue life was approximately an order of magnitude shorter ($p<0.01$ Figure 1). Differences in mineralization did not explain fatigue life and were not significant. SERM (+21.3%) and ALN (+7.7%) TMD were increased over their MA control, ZOL (+1.0%) was not.

These results suggest that the fatigue life of cortical bone is not altered by ZOL and is diminished by ALN. ZOL is a third generation BP with greater binding affinity for bone than ALN. Reduced fatigue life with ALN but not ZOL suggests repeated dosing, oral intake or chemical composition alters fatigue behavior of cortical bone. This study is limited by the small sample sizes for ALN and SERM; however, shorter fatigue life with ALN treatment was demonstrated previously[2]. Overall this study suggests that fatigue life of BP-treated cortical bone depends on the specific BP despite similar biologic mechanisms of action.

Table 1: Groups in this study. Osteopenia[4] induced in sheep with MA diet and treated with vehicle, ALN, ZOL or SERM. Red line indicates sheep euthanasia.

Figure 1: Cycles to failure (log scale) for all groups. ALN fatigue life shorter compared to all groups. Whisker plots show individual data points. Red line = grand mean.

Nuclear Src Activity Functions to Suppress the Anabolic Response of Osteoblasts and Osteocytes to Fluid Shear Stress. Julia Hum*[1], Richard Day[1], Joseph Bidwell[1], Yingxiao Wang[2], Fredrick Pavalko[1]. [1]Indiana University School of Medicine, USA, [2]University of California San Diego, USA

Global deletion of Src kinase from mice results in increase bone mass. We tested the novel hypothesis that Src plays a previously unrecognized role in bone formation by regulating gene expression in osteoblasts and osteocytes, particularly in response to mechanical loading. Inhibition of Src activity using a pharmacologic inhibitor in MC3T3 osteoblasts and MLO-Y4 osteocytes led to an increase in expression of the anabolic bone gene osteocalcin. Mechanical stimulation of MC3T3 osteoblasts and MLO-Y4 osteocytes by fluid shear stress further enhanced expression of osteocalcin when Src activity was inhibited. Importantly, using a Src biosensor and nuclear fractionation, we report for the first time that Src activity in the nucleus increased in response to fluid shear stress. This study supports the idea that Src plays a nuclear role, suppressing expression of osteocalcin via a previously unrecognized function that limits the anabolic response of osteoblasts and osteocytes to fluid shear stress.

Ankle and forearm fractures are associated with similar low areal BMD and bone microstructural alterations in post-menopausal women. Emmanuel Biver*[1], Claire Durosier[1], Thierry Chevalley[2], François Herrmann[1], Serge Ferrari[1], René Rizzoli[1]. [1]Division of Bone Diseases, Geneva University Hospitals & Faculty of Medicine, Switzerland, [2]University Hospitals of Geneva Division of Bone Diseases, Switzerland

Ankle fractures are among the most common non-vertebral fractures. Previous studies have suggested that peripheral, but not axial areal(a) BMD predicted, though poorly, ankle fracture risk, in contrast to the well recognized association between forearm fractures and aBMD. Bone microstructure analysis may reveal alterations not captured by aBMD. To investigate the association between bone microstructure and ankle fractures, we determined distal radius cortical and trabecular bone microstructure by HRpQCT (XtremCT, Scanco Co, Bruttisellen, CH), together with aBMD by DXA, in 749 post-menopausal women aged 65.0 ± 1.4 ($x \pm SD$) years, with or without prevalent ankle or forearm fractures. Dietary protein and calcium intakes, and physical activity were evaluated by questionnaires.

Prevalent ankle and forearm fractures (having occurred after the age of 20) were found in 63 (8.0%) and 59 (7.8%) women, respectively. As compared with women without prevalent fracture, and after adjustment for height, weight, dietary intakes and physical activity, women with prevalent ankle fracture had lower aBMD (spine: -7.7%, $p<0.0001$; femoral neck: -6.4%, $p<0.001$; distal third radius: -4.1%, $p<0.01$), and lower distal radius total volumetric BMD (-10%, $p<0.001$), cortical thickness (-8.8%, $p<0.01$) and BV/TV (-13.2%, $p<0.001$). The corresponding values in women with prevalent forearm fracture were aBMD: -8.8%, $p<0.0001$; -6.8%, $p<0.001$; -3.4%, $p<0.025$; and distal radius microstructure: -16.3%, $p<0.0001$; -12.3%, $p<0.001$; -21.5%, $p<0.0001$. For 1 SD decrease, ORs for ankle and forearm fractures were 2.1 and 2.2 (both $p<0.0001$), 2.4 and 2.3 (both $p<0.001$), and 1.8 and 1.6 (both $p<0.01$) for spine, femoral neck and distal third radius aBMD, respectively. Similarly, ORs were 1.8 and 2.6 (both $p<0.001$), 1.6 and 1.7 (both $p<0.01$) and 1.8 and 2.9 (both $p<0.001$) for distal radius volumetric BMD, cortical thickness and BV/TV, respectively. There was no statistically significant difference in aBMD or bone microstructure values between women with prevalent ankle and forearm fracture.

These results highlight similar lower aBMD and bone microstructure values in postmenopausal women with prevalent ankle or forearm fracture. These alterations suggest that prevalent ankle fractures should be considered as a significant risk factor for subsequent fractures and taken into account in fracture risk assessment.

The role of FoxA factors in the onset and development of Osteoarthritis. Andreia Ionescu*[1], Lin Xu[2], Elena Kozhemyakina[1], Yefu Li[2], Andrew Lassar[1]. [1]Harvard Medical School, USA, [2]Harvard School of Dental Medicine, USA

We have recently identified FoxA transcription factors as key regulators of chondrocyte hypertrophy in the developing skeleton (Dev.Cell 22(5),2012).Therefore, we next asked whether the Fox A family is involved in the onset and development of osteoarthritis (OA) in the adult cartilage.To evaluate the expression of FoxA2 in postnatal articular cartilage, we employed a tamoxifen-inducible Cre driver knocked-into the 3' UTR of the FoxA2 gene. After crossing this mouse line into the ROSA26 reporter line, we observed that FoxA2 expression was highest in the knee and the femoral cap articular cartilage of one-month old animals, it precipitously declined at 3 months of age and remained at this low level through at least 1 year. To evaluate whether FoxA family members are necessary for cartilage degradation, we conditionally deleted FoxA2 in the articular cartilage of FoxA3 -/- mice, using a tamoxifen-inducible CRE recombinase driven by the Prg4 (Lubricin) regulatory sequences. Subsequently, we performed surgical destabilization of the medial meniscus on either the tamoxifen treated *Prg4CreERT2/+;FoxA2fl/fl;FoxA3-/-* mice or control *C57BL/6* animals. While the wild-type *C57BL/6* mice that have undergone surgery developed significant cartilage degradation (OARSI score 5.87 ± 0.12), the tamoxifen treated *Prg4CreERT2/+;FoxA2fl/fl;FoxA3/-* mice showed very little sign of articular cartilage damage (OARSI score 1.45 ± 0.26). I next asked whether overexpression of FoxA2 in murine articular cartilage cells is sufficient to accelerate cartilage degradation. To drive exogenous FoxA2 expression in articular chondrocytes, I have generated mice containing the FoxA2 transgene driven by a reiterated reverse tetracycline transactivator (rtTA) response element (*TREtight-FoxA2*). This transgenic animal was in turn mated to a mouse containing rtTA knocked into the ROSA 26 locus downstream of a "floxed" STOP transcription cassette. Tissue specific expression of rtTA was achieved with the tamoxifen-inducible *Prg4CreERT2* line.Control mice, lacking the FoxA2 transgene, that have undergone surgery developed mild symptoms of the disease (OARSI score 1.37 ± 0.33). In contrast, triple transgenic mice that have undergone surgery developed far more cartilage damage with more lesions on the articular cartilage (OARSI score 2.63 ± 0.43). These findings imply that the FoxA transcription factors are crucial regulators of osteoarthritis following surgically induced joint destabilization.

Detection and Partial Characterization of Bone Marrow Derived Cells in Periodontal Ligament. Masaru Kaku*, Asadullah Mohammad Edris, Megumi Kitami, Takako Ida, JM Rosales Rocabado, Katsumi Uoshima. Graduate School of Medical & Dental Science, Niigata University, Japan

It is well accepted that the substantial contribution of neural crest (NC) derived cells during the development of periodontal ligament (PDL). However the number of non-NC derived cells increases as PDL tissue development progresses. These observations suggest that non-NC cells are recruited to PDL from other cell sources during the tissue remodeling. Recent studies showed that bone marrow derived circulating mesenchymal stem cells (MSC) are found in peripheral blood vessels and are thought to contribute to tissue remodeling, especially to the tissues that undergo rapid remodeling. Considering the extremely high turnover rate of PDL tissue, it is possible that bone marrow derived MSCs reside in and contribute to the tissue maintenance of the PDL. The purpose of this study was to detect and partially characterize the bone marrow derived cells in developed PDL in vivo. Bone marrow stromal cells were collected from femur and tibia of Green Fluorescent Protein (GFP) rats (SD-Tg (CAG-EGFP)) and injected to the femur of the immuno-deficient rats (F344/NJcl-rnu). After 4 weeks of the GFP cell injection, tooth containing periodontal tissue, femur, skin, kidney and intestine were harvested, histology sections were prepared and subjected to immuno-histochemical analysis. GFP positive, femoral bone marrow derived cells were detected in PDL and the positive cell ratio was less than 0.1 %. The GFP positive cells have perivascular localization and some showed cluster like aggregate. While CD29, SSEA4, HNK1, αSMA and PDGFRβ positive cells were detected in PDL cells, only CD29 and SSEA4 positive cells were detected among GFP positive cells. The GFP positive cells were found not only in PDL, but also other mesenchymal tissues (i.e. cancerous bone surface of femur, connective tissue layer of skin, cortex of kidney and lamina propria of intestine). Our results clearly demonstrated that the GFP positive cells, which injected to femoral bone marrow cavity, were detected in PDL. The presence of GFP positive and MSC marker positive cells strongly indicates the supplementation of MSCs through the blood stream during the tissue remodeling of PDL. Furthermore, our observations strongly support the notion of circulating MSCs. Further studies are necessary to elucidate the significance of the bone marrow derived cells in PDL and mechanisms of delivery.

RANKL-Dependent and -Independent Mechanisms of Acute Calcemic Responses to PTH(1-34). Hila Bahar*[1], Akira Maeda[2], Monica Reyes[2], Thomas Dean[2], Ernestina Schipani[3], Paul Kostenuik[4], John Potts[2], Thomas Gardella[2]. [1]MGH & HMS, USA, [2]Massachusetts General Hospital, USA, [3]Indiana University School of Medicine, USA, [4]Amgen Inc., USA

Injection of Parathyroid Hormone (PTH) into animals or humans is well known to result in rapid (within 30 minutes) and robust (>10%) increases in blood ionized calcium (Ca^{++}) levels, but the molecular and cellular mechanisms underlying such an acute response are not fully understood. PTH regulates blood Ca levels largely by acting on both bone and kidney, but the PTH-induced increases in renal Ca reabsorption are likely to be too small and slow to account for the rapid calcemic responses observed with PTH injection. On the other hand, it is not clear whether an increase in the process of osteoclast (OC)-mediated bone resorption, which involves indirect activation of OCs by osteoblast/ocsteocyte-produced RANKL, could occur quickly enough to account for the rapid calcemic responses to PTH injection. To asses a possible role of RANKL-mediated activation of OCs in the acute calcemic response to PTH, we injected mice *iv* with PTH(1-34) (50 nmol/kg), either with or without the RANKL inhibitor, osteoprotegerin-Fc (OPG-Fc, 5 mg/kg), and assessed blood levels of Ca^{++} at times thereafter. We observed that the acute calcemic response to PTH(1-34) was markedly blunted by co-injection with OPG-Fc (PTH(1-34) vs. PTH(1-34)+OPG-Fc, $P<0.04$ and $P<0.000004$ at the 1 and 2 hour time points, respectively, n=6). These results suggest that at least some component of the mechanisms by which PTH induces a rapid calcemic response involves rapid activation of the RANKL/OC pathway of bone-resorption. We then assessed whether depletion of the OC cell populations would alter the calcemic response to PTH(1-34). To do this, we pre-treated mice for one week with OPG-Fc to block differentiation and activation of the OC pool, which is dependent on RANKL. Mice were thus injected *sc* with either vehicle (VEH) or OPG-Fc (5 mg/kg) on days 0, 3 and 6; then, on day seven, the mice were injected with either VEH or PTH(1-34) (50 nmol/kg) and acute calcemic responses were measured. Surprisingly, the acute calcemic response to PTH(1-34), assessed at 1 and 2 hours post-PTH injection, was not at all diminished in mice pre-treated with OPG-Fc, but rather was equivalent to that seen in the OPG-naive mice ($P>0.8$; n=8). There was a complete absence of TRAP-positive cells in the proximal tibia of the OPG-Fc-treated mice, versus an abundance of TRAP-positive cells in the VEH-pretreated controls. And, blood levels of TRAP-5b were significantly lower (85%) in the OPG-Fc-pre-treatment group, than in the VEH group ($P<0.001$), thus confirming that OPG-Fc pre-treatment strongly diminished OC cell function and numbers. The longer-term OPG-Fc treatment data thus suggest that PTH can act to mobilize Ca into blood via a heretofore unrecognized mechanism that is independent of RANKL and is induced or amplified by conditions that reduce or ablate OC populations. The possible roles of other cells types, such as osteocytes, in mediating this PTH-induced Ca mobilization need to be explored.

Identification of Small Molecule Activators and Inhibitors of the Mutated $G_s\alpha$ Responsible for Fibrous Dysplasia of Bone by High-Throughput Screening; Results from the Secondary Screen using the Rat Pituitary GH3 cell-line model. Nisan Bhattacharyya*[1], Marek Kucka[2], Lesley A. Mathews[3], Marc Ferrer[3], Michael Collins[4]. [1]Csdb Nidcr Nih, USA, [2]NICHD, NIH, USA, [3]NCATS, NIH, USA, [4]National Institutes of Health, USA

Missense mutations in the α-subunit of the G-protein, Gsα, are directly correlated with the occurrence of fibrous dysplasia of bone/McCune-Albright syndrome (FD/MAS), a disease that is defined by skeletal abnormalities and as well as various forms of hyperfunctioning endocrinopathies. The biochemical outcome of these mutations (R201H or R201C) is constitutively active Gsα leading to increased levels of cellular cAMP. Clinically these patients can elicit ligand-independent hypersecretion of hormones in endocrine cells, (e.g., increased growth hormone and prolactin secretion by the pituitary) and age-dependent apoptosis of bone cells. In order to identify both small molecule activators and inhibitors of the mutated Gsα, high-throughput screening (HTS) was performed by measuring cAMP levels in Chinese hamster ovary (CHO) cells stably expressing the wild-type or mutant Gsα proteins. Chemical libraries comprised of more than 3X105 compounds in multiple doses were used and a total of 101 inhibitory and 129 stimulatory compounds were identified. The aim of this study was to develop a hormone-based rat pituitary cell culture model that would be useful in the secondary screening and identifying small molecule modulators specific for the mutant Gsα protein.

Several stable cell lines that overexpress either the wild-type (WT) or gsp (R201C or R201H) were prepared in the GH3 cells. Cell-lines were selected based for equivalent Gsα protein expression levels and high or low cAMP levels. Cells were treated with various concentrations of agonists and antagonists including known adenylyl cyclase activators and inhibitors as the controls. Prolactin levels were measured after 4 hours of incubation using a radioimmunoassay method. Results from inhibitor studies indicated that 36% of the selected inhibitors could inhibit prolactin secretion in GH3 cells expressing the wild-type or mutant Gsα. In fact, there were at least 7 compounds that resulted in reduced prolactin levels (down to 50% or more) at 10 μM concentrations. Results also showed that there were at least 3 compounds that could specifically inhibit the prolactin levels only in the cells expressing the mutant Gsα. In addition, secondary screening results from activator studies indicated that there 8 compounds that could increase prolactin levels in both wild-type and mutant protein expressing cells.

In conclusion, this secondary screening system for gsp activity we has confirmed that '36% of molecules identified in the earlier screens have inhibitory activity and that 3 compounds have selective activity on mutant Gsα. Results also indicated that there 8 of the 129 compounds identified in the stimulator screen have stimulatory activity. These compounds will be tested further in preparation for the development of drugs for the treatment of FD/MAS and other gsp-mediated diseases.

BMP2 Regulates CXCL12 in Endosteal Cells and their Commitment to Osteoblastic Differentiation. Timothy Myers*[1], Lara Longobardi[2], Helen Willcockson[1], Alessandra Esposito[3], Billie Moats-Staats[3], Ping Ye[3], Tieshi Li[2], Joseph Temple[3], Anna Spagnoli[2]. [1]University of North Carolina, USA, [2]University of North Carolina at Chapel Hill, USA, [3]UNC, USA

We have reported that bone marrow mesenchymal stromal (MSC) transplanted into fracture mouse models improve healing and thus provide a potential therapy to treat fracture non-unions. BMP2 is a critical component of the fracture healing process as it is expressed immediately after injury and mice lacking BMP2 in mesenchyme limb progenitor cells lack callus formation. We have previously shown that BMP2-expressing transplanted MSC localize along the endosteum of fractured bones and proper homing of transplanted cells depends on the CXCR4-CXCL12 signaling axis. To determine the interplay of BMP2 and CXCL12 in an *in vitro* model we used RT-PCR analyses of isolated endosteal cells from hindlimb bones of mice to measure changes in CXCL12 expression and the potential for osteoblastic differentiation. We measured CXCL12 expression in wild type (WT) endosteal cells, osteoblasts and MSC and compared them to Prx1Cre-BMP2-deficient cells and found that cells lacking BMP2 produce more CXCL12. Next we tested endosteal cells for the ability to differentiate into osteoblasts and found that WT cells had increasing osteoblastic markers over 14 days whereas BMP2-deficient endosteal cells expressed only low levels of the same markers. To test the effect of MSC on endosteal cells, we co-cultured endosteal cells with WT MSC. We found that CXCL12 expression significantly decreased in endosteal cells. However, in endosteal cells plus BMP2-deficient MSC cultures, endosteal CXCL12 remained highly expressed, suggesting a role for BMP2 in the regulation of endosteal CXCL12. To test a direct effect, endosteal cells were treated with BMP2 upon which endosteal cells differentiated into osteoblasts as determined by increases in osteoblastic markers, while CXCL12 expression decreased. BMP2 treatment also induced a downregulation in several factors expressed by endosteal cells (SCF, HGF, PECAM, CD164). To recapitulate the circumstances in our fracture model, endosteal cells from BMP2-deficient mice were co-cultured alone, or with either WT, or BMP2-deficient MSC. WT MSC induced a decrease in CXCL12 expression along with increases in osteoblastic markers that was not seen in BMP2-deficient MSC. Thus, in endosteal cells, osteoblastic differentiation and CXCL12 expression are closely related and can be regulated by BMP2 and this downregulation of CXCL12 could be a key switch for the allowance of endosteal cells to undergo osteoblastic differentiation.

Putative Hematopoietic Progenitor Cells (HPCs) from Craniofacial Skeleton: Contrasting Long Bone Marrow Hematopoietic Stem/Progenitor Cells. Nan Jiang*[1], Jeremy Mao[2]. [1]USA, [2]PI, USA

Objective: Identify putative hematopoietic stem/progenitor cells (HSCs/HPCs) from craniofacial bones. Appendicular bone marrow is known to harbor two distinct stem-cell populations: hematopoietic stem cells (HSCs) and mesenchymal stem cells (MSCs). One of the fundamental hypotheses in stem cell biology is that MSCs, along with osteoblasts, form niches for HSCs in bone marrow. Whether craniofacial bones harbor HSCs is obscure.

Methods: Adult C57BL/6 mice were scarified to harvest mandibular bone-marrow contents and appendicular bones, the femur and tibia, as a positive control. Following established HSC isolation protocols, we subjected mandibular bone-marrow aspirates to centrifuging to form a density gradient. Mononucleated cells were aspirated from a thin cell-rich layer and subjected to Lin- selection by magnetic-activated cell sorting. Lin- cells were further sorted with CD34-, Sca1+ and c-kit+ antibodies by MoFlo, followed by additional characterization: colony-forming unit assay and flow cytometry. To appreciate whether mandibular marrow cells can be sustainably potentiated, cells were suspended in long-term culture media with 10-6 M hydrocortisone and cultured on irradiated bone marrow cells for 4 weeks at 33?C in 5% CO2. Upon 4-wk culture, cells were assayed and further isolated for clonogenic assay.

Results: A total of 1.5% Lin- cells from mandibular bone marrow were CD34-/low/c-Kit+ /Sca1+ cells (CD34-KSL cells) that represent a heterogeneous population of short-term repopulating HSCs, long-term repopulating HSCs and multi-potent progenitors. Mandibular CD34-KSL cells showed self-renewal over the tested 14 days and broad similarity to CD34-KSL cells isolated from appendicular bone

marrow of donor-matched mice. Interestingly, mandibular CD34-KSL cells differentiated into CFU-E/CFU-GM/CFU-GEMM, in contrast to BFU-E/ CFU-Pre B. Even following long-term culture, few mandibular bone marrow CD34-KSL cells differentiated into the lymphoid lineage, yielding only 0.5% CD45R/B220+ cells. Contrastingly, 57.2% CD45R/B220+ cells were isolated from appendicular bone marrow CD34-KSL cells following long-term culture.

Conclusion: The mandible harbors putative hematopoietic progenitor cells or CD34-KSL cells that show important differences from well-established HSC from appendicular bone marrow. Deficient lymphoid differentiation of mandibular HPCs suggests that appendicular HSCs may migrate to craniofacial bones and replenish the lymphoid lineage in the head.

Fra1 deletion in B cells regulates bone homeostasis. Aline Bozec*[1], Bettina Groetsch[2], Dirk Mielenz[2], Erwin Wagner[3], Georg Schett[4]. [1]Deu, [2]1Medizinische Klinik 3 Rheumatologie und Immunologie, Friedrich-Alexander-Universitat Erlangen-Nurnberg, Germany, [3]Research Institute of Molecular Pathology, Austria, [4]Friedrich-Alexander University Medical School, Germany

Bone is crucial to maintain haematopoiesis as bone marrow spaces allow the interaction of bone and immune cells that functionally influence each other. The AP1 transcription factor is known to be essential for bone homeostasis and immune cell maintenance. Notably, Fra-1 was shown to regulate bone homeostasis by controlling osteoblast activity and the immune system by regulating plasma cell formation.

In addition of enhanced basal level of IgG1 and auto-antibodies observed in B cell specific Fra1 deficient mice, bone microCT analyses revealed a decreased bone volume in these mutant mice. Moreover, the histomorphometrie analyses revealed that the bone loss in mice with B cell specific deletion of Fra-1 was due to increase in osteoclast size and number.

Furthermore *in vitro* wild-type osteoclast assays supplemented with serum from mice Fra-1 deficient in B cell or with supernatant from Fra-1 deficient B cell cultures showed an increase in osteoclast differentiation, suggesting that Fra-1 expression modified the B cell secretome, which is increasing osteoclastogenesis. Interestingly, this effect was dependent of the presence of IgG in the supplemented serum. Finally, purified IgG from Fra-1 mutant serum further increased the number of polynucleated osteoclasts.

These findings indicate that Fra-1 expression in B cells acts on IgG level and pattern, which plays an important role in bone homeostasis. The identification of the molecular pathway will certainly lead to novel insights into the cross-talk between osteoclasts and B cells.

Cortical and Trabecular Microarchitecture Impairment Correlates with Fibroblast Growth Factor-23 and Metabolic Acidosis in Men with Stages 3 and 4 of Chronic Kidney Disease. Francisco Paranhos Neto*[1], Guilherme Lima[2], Luciana Silva[2], Miguel Madeira[2], Inayá Lima[3], Maurilo Leite Junior[4], Carlos Gomes[4], Maria Lucia Farias[1]. [1]Federal University of Rio de Janeiro, Brazil, [2]Division of Endocrinology - University Hospital Clementino Fraga Filho, Federal University of Rio de Janeiro, Brazil, [3]Nuclear Instrumentation Laboratory, COPPE, Federal University of Rio de Janeiro, Brazil, [4]Division of Nephrology - University Hospital Clementino Fraga Filho, Federal University of Rio de Janeiro, Brazil

Chronic kidney disease (CKD) leads to disorders of mineral and bone metabolism described as CKD-Mineral and Bone Disorder (CKD-MBD). The discrepancies between the clinical picture, bone histomorphometry and bone densitometry raise doubts on the validity of this method in patients with CKD-MBD. High Resolution Peripheral Quantitative Computed Tomography (HR-pQCT) is a new and noninvasive method to assess bone microarchitecture that may help the evaluation of CKD-MBD. We investigated 46 men, 50 to 75 years, in stage 3 and 4 of CKD by HR-pQCT and correlated densities and structural parameters with biochemical changes. Patients on stage 4 exhibited a greater impairment of cortical and trabecular bone parameters, such as lower density and thickness associated with increased trabecular area and cortical perimeter, suggesting trabecularization of cortical bone. They also showed lower 25 hydroxyvitamin D [25(OH)D] and bicarbonate, and higher fibroblast growth factor 23 [FGF-23] and parathyroid hormone [PTH] serum levels. Estimated glomerular filtration rate [eGFR] correlated inversely with PTH and FGF-23 and positively with bicarbonate and 25(OH)D. FGF-23 correlated positively with PTH and negatively with 25(OH)D. PTH also correlated negatively with 25(OH)D. FGF-23 and metabolic acidosis were the only independent factors strongly associated with the bone impairment identified by HR-pQCT, suggesting the importance of these two biomarkers in the clinical management of these patients.

Keywords: HR-pQCT, CKD-MBD, metabolic acidosis, FGF-23, PTH, vitamin D, Renal Osteodistrophy

Cutaneous Skeletal Hypophosphatemic Syndrome: A new syndrome of FGF23 excess. Diana Ovejero*[1], Young Lim[2], Harald Jüppner[3], Michael Gottschalk[4], Cynthia Tifft[5], Rachel Gafni[6], Alison Boyce[7], Edward Cowen[8], Nisan Bhattacharyya[1], Lori Guthrie[1], William Gahl[5], Gretchen Golas[5], Keith Choate[2], Michael Collins[6]. [1]Skeletal Clinical Studies Unit, Craniofacial & Skeletal Disease Branch, National Institute of Dental & Craniofacial Research, National Institutes of Health, USA, [2]Department of Dermatology, Yale University School of Medicine, USA, [3]Pediatric Nephrology Unit & Endocrine Unit, Massachusetts General Hospital & Harvard Medical School, USA, [4]Pediatric Endocrinology, Rady Children's Hospital, San Diego & Departments of Pediatrics, University of California, USA, [5]NIH Undiagnosed Diseases Program, NIH Common Fund; Office of the Clinical Director, NHGRI, National Institutes of Health, USA, [6]National Institutes of Health, USA, [7]Children's National Medical Center, USA, [8]Dermatology Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, USA

Pathologically elevated levels of fibroblast growth factor-23 (FGF-23), a bone-derived hormone that exerts a pivotal role in phosphate homeostasis, cause renal phosphate wasting, hypophosphatemia, and impaired skeletal mineralization. Rarely, elevated FGF-23 levels and hypophosphatemic rickets are found in association with congenital mosaic cutaneous disorders, such as epidermal and large congenital melanocytic nevi. In such cases, concomitant segmental dysplastic skeletal lesions are always observed. Furthermore, these disorders are variably associated with abnormalities in other organs such as the eye, brain and vasculature. Given the broad spectrum of cutaneous and systemic finidings, we have designated this disorder cutaneous-skeletal hypophosphatemia syndrome (CSHS). The source of the excess FGF23 production is to date unknown. In this report we describe 5 such individuals, 4 of which were affected with epidermal nevus, and one with large congenital melanocytic nevi. All of them presented extensive skin surface area involvement present since birth. The foci of dysplastic bone exhibited a variable distribution but typically were localized at same side as the skin lesions and exhibited a predisposition for the appendicular skeleton. Blood tests revealed in all cases hypophosphatemia associated with elevated or inappropriately normal FGF-23 levels, renal phosphate wasting, normocalcemia and no apparent abnormalities in the parathyroid function. Radiographic imaging studies revealed generalized ricketic changes and unhealed fractures in untreated patients. Histologic examination of dysplastic bone revealed fibroblast-like spindle-shaped cells surrounded by a relatively dense collagen matrix, an appearance consistent with cells in the osteogenic lineage. In addition, a number of other pathologic lesions were inconsistently observed in other tissues. These findings were consistent with somatic mosaicism for mutations contributing to multisystem disease. When treated adequately with phosphate and calcitriol, ricketic changes healed. However, unlike previous reports, none of the patients in our series who underwent ablative treatment of skin lesions showed improvement in phosphate metabolism. Given the involvement of skin and bone, tissues of ectodermal and mesodermal origins respectively, CSHS could be explained by a mutation in an early common progenitor. The underlying molecular mechanisms that drive this syndrome remain to be elucidated, but due to the phenotypic and metabolic similarities in all our subjects, we can assume that there is a common pathway implicated in all of them. Moreover, we can also infer from these observations, that the altered molecular events responsible for these disorders, may be involved in physiological FGF-23 regulation.

Minimally invasive parathyroidectomy versus bilateral neck exploration for primary hyperparathyroidism: a systematic review and meta-analysis. Omar Kreidieh*[1], Ghada El-Hajj Fuleihan[2], Hala Ahmadieh[3], Elie Akl[3]. [1]Lebanon, [2]American University of Beirut-Medical Center, Lebanon, [3]American University of Beirut, Lebanon

Objective: Compare the effects of Minimally Invasive Parathyroidectomy (MIP) and Bilateral Neck Exploration (BNE) on selected patient-important outcomes, in patients with sporadic primary HPTH undergoing surgery for the first time.

Methods: MEDLINE and EMBASE databases were searched up to January 2013 in order to conduct a Cochrane systematic review and meta-analysis of randomized controlled trials comparing BNE to MIP for the treatment of sporadic primary hyperparathyroidism. Primary outcomes were short (6 months) and long term (5 years) success rates (eucalcemia), total incidence of perioperative adverse events, all cause mortality, Health Related Quality of Life (HRQL), duration of surgery, and cosmetic satisfaction.

Data Collection and Analysis: Two independent reviewers screened titles, abstracts, full texts, extracted data from selected studies, and assessed risk of bias, with oversight from two senior investigators. The GRADE methodology to assess the quality of evidence was used.

Results: 5 trials with 264 adult participants were included; data was not extractable for HRQL and cosmetic satisfaction. Success rate in the MIP compared to BNE showed a RR= 0.98 [0.94;1.02] at 6 months (moderate quality of evidence), and of 0.94 [0.83; 1.08] at 5 years (low quality of evidence). The duration of surgery from 3

studies was shorter in the MIP group, RR= -18.32 [-30.69,-5.94] minutes, and the RR for the total incidence of peri-operative adverse events from 4 studies was 0.31 [0.09;1.1]. Both outcomes had a very low quality of evidence. One study found no difference in HRQL at one month and 6 months, with very low quality evidence. Mortality could not be adequately assessed. In 5 studies, peri-operative symptomatic hypocalcemia was significantly lower at two days, RR=0.55 [0.31;0.96], but not at six months, RR=0.3 [0.01;7.23]. The standardized mean difference postoperative pain score at 48 hours from 2 studies was -0.7 [-1.69;0.28], and the relative risk of vocal cord paralysis was 1.88 [0.47;7.47]. There was no reported difference in bleeding in 2 studies, nor in infection rate in one study. The conversion rate from MIP to BNE was 20% in 3 studies.

Conclusion: MIP and BNE had comparable success rates. Peri-operative hypocalcemia and post-operative pain were lower in the MIP group, while vocal cord paralysis was lower, in BNE. Our findings call for larger, prospective, randomized trials.

Caloric Restriction during Growth, Serum Irisin and Bone Mass loss at Maturity. Vanessa Yingling, Tiffiny Butler*. Temple University, USA

Caloric restriction without malnourishment has maintained bone mass relative to bodyweight perhaps due to muscle mass maintenance. Muscle mass may increase bone mass due to loading or myokine secretion. Irisin is a myokine linked with bone mass maintenance mainly due to exercise. The long term effect of acute caloric restriction on bone mass at maturity remains elusive.

We set out to determine if 30% post pubertal food restriction during growth alters serum irisin and trabecular bone mass at maturity. Rats were assigned to groups: (n= 5-8), control (C), food restriction (FR), control recovery (RC), food restriction recovery (RFR), control ovariectomy (COVX) and food restricted ovariectomy (FROVX). A 6 week 30% food restriction protocol began at 65 days of age followed by a 10 week recovery period and then ovariectomy surgery (OVX) at 180 days of age. At sacrifice (108 days, 180 days and 227 days (47 days post OVX)) left femurs and L5 vertebrae were scanned using an ex vivo micro CT scanner. Serum assays for carboxy terminal collagen crosslinks (CTX), insulin like growth factor-1 (IGF-1) and irisin were performed. Student's t-tests determined significant differences between groups ($p< .05$). Linear regression was used to normalize percent trabecular bone volume (BV/TV) by body weight.

Normalized femur BV/TV was similar between groups. However, post OVX normalized vertebral trabecular BV/TV was greater in the FROVX group compared to COVX ($p<.05$). Lower serum CTX and IGF-1 were found in FR group following restriction. No differences in serum irisin were found between groups yet FR triceps surae muscle mass was lower than control ($p<.05$). During recovery, serum IGF-1 increased in RFR compared to RC with no difference in CTX or irisin ($p<.05$).

Food restriction during growth had no detrimental effect on BV/TV following 6 weeks of restriction and attenuated vertebral bone loss post OVX even though serum CTX levels were similar in COVX and FROVX groups. Lower resorption and formation resulting from restriction suggests a slowing of turnover. However during recovery serum IGF-1 increased resulting in a ''catch-up'' in trabecular BV/TV translating into bone loss attenuation following OVX. Irisin was similar between groups following restriction and recovery but FR animals had lower muscle mass on average suggesting more irisin per gram of muscle with restriction. No long term deficits in bone mass occur from caloric restriction during development.

Early Behaviors of Transplanted Cells and the Effect of HSP27 on the Cell Survival. Megumi Kitami*, Masaru Kaku, Takako Ida, JM Rosales, Kastumi Uoshima. Graduate School of Medical & Dental Science,Niigata University, Japan

The combination of growth factors, scaffolds and cell transplantation, so called tissue engineering triad has been proposed as the gold standard of the tissue regeneration. Nonetheless, seeking more effective and less invasive application will still open up a new vista of the regenerative therapies. For instance, in Niigata University Medical and Dental Hospital, cultured periosteal cell sheet have been used for transplantation as a clinical trial of bone augmentation. Even though more than 50 cases of the trials have been carried out and appeared to be effective enough clinically, biological backgrounds of the transplanted cell behaviors are still unclear and there might be more efficient way of applications. The purpose of this study was to evaluate the fate of transplanted cells and the application of HSP27, an anti-apoptotic protein to the transplanted cells to explore a new way of cell transplantation. Primary human osteoblasts were cultured on a temperature responsive culture dish (UpCell, CellSeed Tokyo, Japan). After 3 weeks of culture, cell/matrix sheet was transplanted to the calvarial subperiosteal pocket of F344/NJcl-rnu immuno-deficient rats. The transplants were harvested after 1, 3, 5 days, paraffin embedded samples were prepared and immuno-histochemical analysis were performed. Neoangiogenesis was observed at the surface of transplants at days 3, and it was observed at the center of transplants at day 5. TUNEL-positive apoptotic cells were found at the ratio of 4.5%, 14.5% and 4.7% at day 1, 3 and 5 respectively. While PCNA-positive cells were rarely found at day 1 and 3, it became detectable at day 5 and the positive cell ratio was 4.6%. These results indicate that part of transplanted cells dead due to apoptosis at the initial stage of the transplantation. Then, we try to reduce the number of dead transplanted cells by introducing an anti-apoptotic protein HSP27. An HSP27 expression vector, pCMV-SPORT6-mHSP27 was transfected to osteoblast-like cell line MC3T3-E1. The H_2O_2 induced apoptosis was partially rescued by the over expression of HSP27. The over expression of HSP27 did not affect the cell proliferation and mineralization ability of MC3T3-E1 cells. These results suggests that transplanted cell death could be rescued by the over expression of HSP27 without affecting the mineralization ability. Further study will warrant the establishment of more effective cell transplantation protocol for the bone augmentation.

Roles of Histone Demethylase PHF8 in Osteogenic Differentiationand Bone Regeneration. Qianqian Han*, Qisheng Tu, Lan Zhang, Yin Tang, Jake Jinkun Chen. Tufts University School of Dental Medicine, USA

Epigenetic regulation of gene expression is a central mechanism that governs cell stemness, determination, commitment, and differentiation. It has been recently found that PHF8, a major H4K20/H3K9 demethylase, plays a critical role in craniofacial and bone development (*Nature466*, 503-7, 2010). As a nuclear matrix protein, special AT-rich sequence-binding protein 2 (SATB2) is expressed in branchial arches and in cells of the osteoblast lineage, therefore required for bone development and formation. However, our previous understanding of the modulation of SATB2 impedes our further insight into this important osteogenic transcription factor. In this study, we hypothesize that PHF8 promotes osteoblastogenesis by epigenetically regulating the expression of master gene SATB2. We performed a series of studies including real time PCR, Western blot, gain- and loss- functions, chromatin immunoprecipitation (ChIP) assays and *in vivo* animal models. Our results showed that expression levels of PHF8 and SATB2 in preosteoblast MC3T3-E1 and bone marrow stem cells (BMSCs) increased simultaneously during osteogenic induction. Overexpressing PHF8 in BMSCs and MC3T3-E1 cells with wild type PHF8 upregulated the expression of SATB2, Runx2 and osterix, and bone matrix proteins. Conversely, knockdown of PHF8 reduced the expression of SATB2 and other bone marker genes. Furthermore, using ChIP assays, we found that PHF8 specifically bound to the transcription start site (TSS) of the *Satb2* promoter, and the expression of H3K9me1 at the TSS region of Satb2 decreased in PHF8 overexpressed group. Our *in vivo* results indicated that PHF8 promoted the bone regeneration in critical-sized defects in mouse calvarias. Taken together, our results suggest, for the first time, that PHF8 enhances osteogenic differentiation via regulation of the SATB2 expression pattern by modulating histone methylation states and subsequently converting its chromatin into a transcriptionally active conformation.PHF8/SATB2 mediated epigenetic regulatory axis further harnesses BMSCs differentiation and facilitates bone tissue formation and regeneration.

Anabolic Wnt-mTOR signaling enhances Integrated Stress Response via stimulation of Glutamine consumption. Courtney Karner*, Fanxin Long, Emel Esen. Washington University School of Medicine, USA

A defining feature of osteoblasts is their capacity to produce large amounts of extracellular matrix proteins. This increased capacity for protein synthesis is coupled with a heightened integrated stress response (ISR), commonly known as endoplasmic reticulum (ER) stress, in osteoblasts. Previous genetic studies have demonstrated the functional importance of ISR in normal bone formation in mice. However, whether ISR in osteoblasts is activated by unfolded proteins in the ER, or an alternative mechanism is not understood. Because Wnt proteins have emerged as potent inducers of bone formation, we have investigated the mechanism through which Wnt3a activates ISR during osteoblast differentiation in the mesenchymal progenitor ST2 cells. We find that Wnt3a induces ISR independent of Beta-catenin/Lef/TCF signaling, but critically dependent on mTORC1 activation that stimulates protein synthesis. Remarkably, however, inhibition of PERK, a critical activator of ISR in response to unfolded proteins in the ER, did not allay ISR induced by Wnt3a. In contrast, knockdown of GCN2, a kinase that is known to mediate ISR in response to amino acid deprivation, suppressed Wnt3a-induced ISR. Moreover, supplementation of glutamine, but not other amino acids, alleviated ISR in response to Wnt3a. Indeed, Wnt3a greatly stimulated glutamine consumption, at least partly due to the increase in anaplerosis to the tricarboxylic acid (TCA) cycle. Importantly, preventing glutamine anaplerosis alleviated ISR and osteoblast differentiation in response to Wnt3a. Thus, our results support a model in which Wnt signaling induces ISR necessary for osteoblast function through increased glutamine metabolism.

LB-SA23

Netrin1 is a critical autocrine factor for osteoclast differentiation. Aranzazu Mediero*[1], Bhama Ramkhelawon[2], Edward Purdue[3], Steven Goldring[4], Kathryn Moore[2], Bruce Cronstein[5]. [1]NYU SCHOOL OF MEDICINE, USA, [2]Leon H. Charney Division of Cardiology, Department of Medicine, NYU-Langone Medical Center, USA, [3]Caspary Research Building, Hospital for Special Surgery, USA, [4]Hospital for Special Surgery, USA, [5]NYU Medical School, USA

Netrins have been extensively studied for their role in axonal guidance during neural development. In addition, netrins are chemopulsants for a variety of non-neuronal cell types via binding to their receptors Unc5b and DCC. Although thought to suppress inflammation in several settings, netrin1, acting via Unc5b, inhibits macrophage migration directed by chemokines CCL2 and CCL19 to promote macrophage retention in and exacerbation of atherosclerotic plaque. We asked whether Netrin1 was expressed during osteoclast (OC) differentiation and whether it plays a role in OC differentiation.DXAscan and MicroCT analysis were performed on Netrin1 deficient mice (radiation chimeras) and wildtype (WT, radiation chimeras) littermates. OC differentiation was studied as M-CSF/RANKL-stimulated differentiation of murine bone marrow precursors to TRAP+/multinucleated cells, in the presence/absence of recombinant Netrin1 and Unc5b antibody. Netrin1, Unc5b and DCC expression were studied by RT-PCR and Western Blot in primary bone marrow-derived osteoclasts. Netrin1 immunostaining was performed in human tissue obtained following primary prosthesis implantation or after prosthesis revision. During OC differentiation cell-associated Netrin1 and Unc5b (but not DCC) protein expression increased by $30\pm2\%$ and $98\pm4\%$ respectively ($p<0.001$,n=4) and Netrin1 secretion increased by $66\pm2\%$ ($p<0.001$,n=4). Consistently, RANKL stimulates an increase in Netrin1 and Unc5b mRNA expression during OC differentiation (25 ± 4 and 3 ± 0.5 fold change respectively $p<0.001$,n=4). Moreover, in Netrin1-deficient marrow precursors OC differentiation was diminished by $65\pm2\%$ as compared to control ($p<0.001$,n=6), an effect reversed by addition of recombinant netrin1 to cultures ($121\pm5\%$ increased, $p<0.5$,n=4). An antibody to the netrin1 receptor Unc5b reduces OC formation by $57\pm6\%$ ($p<0.001$, =6) whereas an antibody to DCC had no effect on OC formation ($5\pm4\%$ reduction, p=NS vs. control,n=6). Finally, DXAscan and MicroCT analysis demonstrated an increase in bone mineral density (BMD), total volume (TV), bone volume (BV) and TV/BV in both cortical and trabecular bone in Netrin1 deficient mice when compared to WT ($p<0.01$ for all, n=5). Netrin1 immunostaining in human tissue biopsies reflect enhanced expression in tissue from implant revision when compared to primary implants.The chemorepulsant Netrin1 is required for osteoclast differentiation and stimulates OC differentiation by an autocrine mechanism. This finding suggests that Netrin1 may be a novel target to reduce OC-mediated bone resorption and to prevent joint prosthesis loosening.

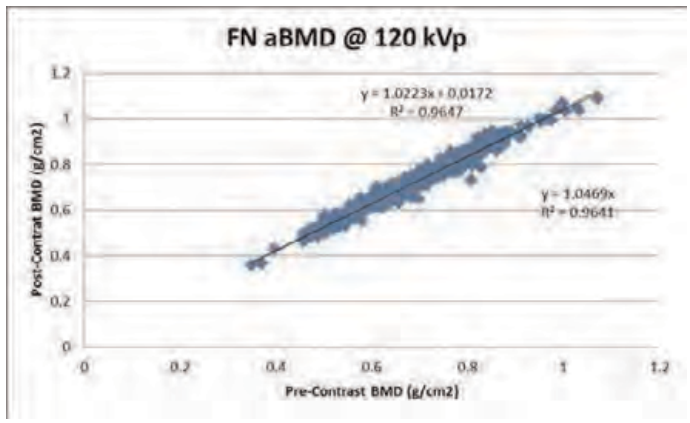
Direct Comparison of Pre- and Post-Contrast Enhanced Scans for Quantitative CT Bone Mineral Density Measurement at the Proximal Femur: Implications for Opportunistic Osteoporosis Screening. Alyssa Maciejewski[1], Timothy Ziemlewicz[1], Neil Binkley[2], Alan Brett*[3], Keenan Brown[3], Perry Pickhardt[1]. [1]University of Wisconsin School of Medicine & Public Health, USA, [2]University of Wisconsin, Madison, USA, [3]Mindways Software, Inc., USA

Objective(s): For patients undergoing routine contrast-enhanced MDCT exams, an opportunity exists for concurrent BMD screening without additional radiation exposure or patient time using quantitative CT (QCT) of the proximal femur. Previous studies have demonstrated equivalence between unenhanced CT and DXA for femoral neck BMD evaluation, but the impact of IV contrast requires further study. We investigated the effect of IV contrast enhancement on areal BMD measurement compared with the established DXA-equivalent pre-contrast QCT analysis (“CTXA”) at the hip.

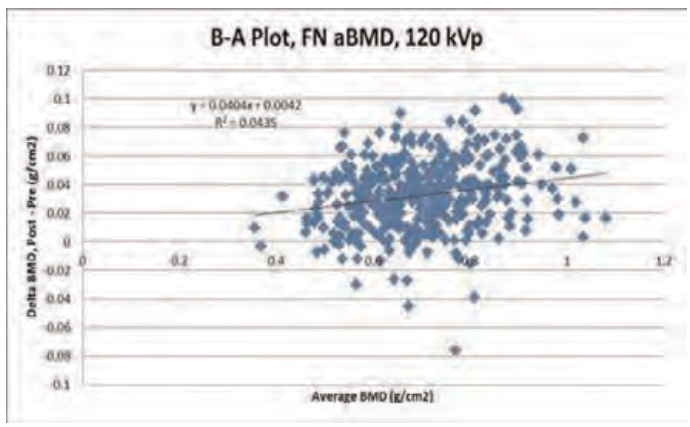
Methods: Our cohort included 410 male and female adults (mean age, 65.3 ± 10.0 years; range, 49-95 years) who had standard CT urography (CTU) at $120kV_p$ (GE Healthcare, Waukesha, WI) between Aug. 2011 and May 2013. CTU exams represent an ideal protocol for this assessment as both pre-and post-contrast series are obtained, and the split-bolus contrast-injection technique effectively combines dynamic and delayed phases, resulting in excreted contrast in the urinary bladder. Areal BMD (aBMD) in g/cm^2 of the femoral neck was measured on both pre-and post-contrast CT series using QCT Pro Version 5.1 (Mindways, Austin, TX) with asynchronous phantom calibration. Constant bias and multiplicative factor corrections for the post-contrast series were derived from the Bland-Altman plot linear regression slopes.

Results: Mean pre- and post-contrast aBMD of the femoral neck was 0.68 ± 0.12 and 0.71 ± 0.12 g/cm^2, respectively. Although the estimated slope of a correction was significantly different from zero ($p<0.0001$), the SD of the distribution of residuals (SEE) for a constant bias and a multiplicative model correction were very similar at 0.0232 and 0.0231, respectively.. The constant bias correction associated with contrast enhancement was 0.032 ± 0.023 g/cm^2 which corresponds to 0.29 ± 0.21 T-score units using the CTXA young normal aBMD reference SD of 0.111 g/cm^2. T-score categorization changed between pre- and post-contrast series in 63 (15.4%) of 410 patients prior to simple correction, compared with 35 (8.5%) patients after correction.

Conclusion: For the purposes of opportunistic osteoporosis screening at routine post-contrast abdominopelvic CT scans, a simple offset correction of -0.3 T-score units for femoral neck BMD assessment appears to be appropriate. This simple additive measure could greatly enhance osteoporosis screening since it can be applied regardless of the clinical indication for CT scanning.



Comparison of areal BMD for Pre- and Post-Contrast CT



Bland-Altman Plot of Pre and Post-Contrast Change in BMD

Large-scale Whole Genome Sequencing Study for Bone Mineral Density: the UK10K Consortium. Hou-Feng Zheng*[1], Vincenzo Forgetta[1], Scott Wilson[2], Nicholas Timpson[3], Nicole Soranzo[4], Tim Spector[5], Brent Richards[1]. [1]McGill University, Canada, [2]University of Western Australia, Australia, [3]Bristol University, Canada, [4]Sanger institute, Canada, [5]King’s College London, United Kingdom

Aim: To identify genetic variants, including rare variants, associated with bone mineral density (BMD), we performed an association study using whole genome sequencing data within UK10K Consortium (http://www.uk10k.org/).

Methods: 3781 samples from TwinsUK (discovery study) and ALSPAC were whole genome sequenced in Sanger Institute. The haplotypes of sequenced individuals were then imputed into an additional 3896 TwinsUK GWAS samples (replication study), which are independent of the sequenced samples. We tested the association of TwinsUK samples at lumbar spine (L1-L4) (LS), femoral neck (FN) and forearm BMD separately in these two datasets. The phenotypes were standardized adjusting for age, age^2, weight and sex where appropriate. We undertook single variant tests, as well as a collapsing test of coding variants, with GEMMA and skatMeta, respectively. We then meta-analyzed the association results from the sequenced and imputed TwinsUK datasets. We set significant and suggestive thresholds for single variant test at $5x10^{-8}$, and $5x10^{-6}$, and set significance threshold for collapsing tests at $2.5x10^{-6}$ (0.05 over ~20,000 genes across the genome).

Results: In the single variant test meta-analysis of data from the discovery and replication studies for forearm BMD, 143 variants from *WNT16* locus were significant, and another 125 variants were suggestive. For LS and FN BMD, we identified 156 (including 11 *LRP5* variants) and 125 suggestive variants. In the skatMeta analysis of coding variants, we identified *WNT16* and *HSPB1* to be strongly associated with forearm BMD, however, when we excluded common variants (MAF>5%) in gene region, *WNT16* was no longer significant, suggesting common missense variants in *WNT16* drove the association signal. Nine rare coding variants in *HSPB1* were collapsed and had an association P-value of $9.8x10^{-7}$, and this association was largely driven by rs28708645 (MAF= 0.005, $P=9.4x10^{-8}$). We also identified 3 genes (including *LRP5*) and 11 genes for LS and FN BMD, respectively.

Conclusion: In this whole genome sequencing data analysis for BMD, we identified a novel, rare missense variant in a non-canonical *HSPB1* transcript (ENST00000447574) as an important genetic determinant of forearm BMD, and confirmed the association of variants in *WNT16* and *LRP5* with forearm and LS BMD, respectively, and highlighted other novel loci and genes. These variants will soon undergo replication in 44,057 additional samples.

Associations of Serum Sclerostin and Polymorphisms in the *SOST* Gene with Bone Mineral Density and Markers of Bone Metabolism in Postmenopausal Chinese Women. Jin-Wei He*, Zhen-Lin Zhang. Shanghai Sixth People's Hospital affiliated with Shanghai Jiao Tong University, China

Objective: The aims of this study were to (1) evaluate the associations of serum sclerostin with bone mineral density (BMD) and markers of bone metabolism in postmenopausal Chinese women; (2) observe the relationships between the single nucleotide polymorphisms (SNPs) of the *SOST* gene with serum sclerostin, BMD and markers of bone metabolism.

Design: A cross-sectional study was conducted in 703 postmenopausal Chinese women (aged 50-94.5 years). Ten tagging SNPs (rs1234612, rs1513670, rs1634330, rs1708635, rs2023794, rs7220711, rs74252774, rs851057, rs851058, and rs865429) of the *SOST* gene were genotyped. Serum sclerostin and markers of bone metabolism were measured, including serum intact parathyroid hormone, 25(OH)D, procollagen type 1 Nterminal propeptide (PINP) and β-CrossLaps of type I collagen containing cross-linked C-telopeptide (β-CTX). BMD of the lumbar spine and proximal femur were measured by dual-energy X-ray absorptiometry.

Results: Serum sclerostin was positively correlated with BMD at lumbar spine, femoral neck, total hip and serum 25(OH)D (all $P<0.01$) but negatively correlated with β-CTX ($P<0.01$). The significance between BMD at lumbar spine, hip,serum β-CTX and serum sclerostin persisted even after adjustment for age, BMI and serum 25(OH)D (all $P<0.01$). But it exhibited no correlation with age and serum P1NP. SNPs (rs1513670, rs851057, rs851058, rs1708635 and rs1634330) in the SOST gene were significantly associated with serum P1NP. We failed to identify a significant association between the SNPs, haplotypes of *SOST* with BMD,serum sclerostin and other markers of bone metabolism.Conclusion: Our results suggested that serum sclerostin was positively correlated with BMD at lumbar spine, femoral neck, total hip, serum 25(OH)D and negatively correlated with serum β-CTX. Five SNPs in the *SOST* gene were associated with serum P1NP. Genetic polymorphisms in *SOST* may not be a major contributor to serum sclerostin or BMD in postmenopausal Chinese women.

Bone Marrow Adiposity is associated with Non-vertebral Fractures in Women. Luai Ahmed[1], Rajesh Shigdel[2], Ragnar Joakimsen[3], Petter Eldevik[3], Erik Fink Eriksen[4], Jacqueline Center[5], Roger Zebaze[6], Ashild Bjornerem*[7]. [1]Faculty of Health Sciences, University of Tromsø, Norway, [2]University of Tromso, Norway, [3]University Hospital of North Norway, Norway, [4]Oslo University Hospital, Norway, [5]Garvan Institute of Medical Research, Australia, [6]Austin Health, University of Melbourne, Australia, [7]University of Tromsø, Norway

The relationship between fat and bone is complex, but an increasing body of evidence suggests that increased marrow adiposity may signal a switch in stem cell differentiation towards adipogenesis and may be linked to bone loss. We therefore wanted to study whether marrow adiposity was associated with fracture risk.

In a nested case-control study in Tromsø, Norway, 162 postmenopausal women aged 54-94 years with fractures (hip, humerus and forearm) and 221 controls, had bone marrow fat proportion quantified as the proportion within the total bone with attenuation below that of water in QCT images of the subtrochanteric femur using StrAx 1.0 software. Femoral neck (FN) BMD was assessed using DXA. For the analysis we used linear and logistic regression analyses adjusted for age, height and weight.

Marrow adiposity increased by 0.20 and 0.29 SD for each SD increase in age and height, and by 0.14 and 0.48 SD for each SD decrease in weight and FN aBMD, respectively (all $p<0.01$). Women with fractures exhibited a higher proportion of marrow fat than controls; 31.2% (SEM 0.5) vs. 27.5% (SEM 0.4), $p<0.001$. Marrow adiposity was associated with fractures independently of FN aBMD, with OR of 1.55 (95% CI 1.17-2.04) for each SD increase in marrow adiposity, while each SD decrease in FN aBMD had OR of 1.72 (95% CI 1.26-2.33). Marrow adiposity significantly contributed to the variance in fracture risk (increment of R^2 was 0.02, $p=0.001$).

Our study suggests that marrow adiposity is an independent risk factor for bone loss and fracture.

Hyponatremia is associated with higher odds for fracture in hospitalized patient. Hussein Rajab*, Louis Loutrell. Medical University of South Carolina, USA

Backgrownd and Significance: Mild hyponatremia is the most common electrolye imbalance in older population, and has traditonally been considered begnign, but it may be associated with gait and attention deficit and an increased risk of fall. The association of mild hyponatremia and bone fracture is still unknown. Analysis of hospitalized patients records was conducted to evaluate the impact of hyponatremia on fracture risk.

Design: This study analyzed 145111 patient records from state of New Jerssey hopitlization records in 2010 using ICD 9 codes. Discharge diagnosis that might contriubute to hyponatremia, e.g., SIADH, CHF, hypothyroidism, pneumonia, liver cirrhosis, also, diagnosis that amight be assoicated with increase risk of fall and fracture, e.g., confusion, hypotension, osteoprosis, seizure, and gait abnormalities, were invistigated.

Results: Total records were 145111. Hyponatremia were present in 46409 (31%) patients . Out of these patients, mean age was 67 years, 25346 (54%) were female. 2258 (4.8%) had fracture, 3440 (7.4%) had osteoprosis, and 2835 (6.1%) had fall. Only 126 patients were diagnosed with SIADH according to the ICD9 codes. Hyponatremia were present in 70 % of those with versus 30 % of those with out a confirmed fracture ($P < 0.001$). On Multivariate logistic regression analysis controlling for age, sex, history of HTN, osteoprosis, confusion, pneumonia, hypothyroidisim, CHF, hyponatremia Na $<$ 135 versus Na $>$or= 135 mmol/L remained significantly and independently associated with fracture occurrence ($P < 0.01$).

Conclusion: Elderly patients with unsteady gait and/or confusion should be checked for the presence of mild hyponatremia and if present it should not be ignored. Hyponatremia can impair cognitive function and result in unsteady gait and falls. It can also produce bone impairment through osteo-porosis (due to increased bone resorption in order to mobilize sodium from the bone) or altered bone quality(through decreased bone microfracture repair). In elderly patients who take medications that cause hyponatremia, namely diuretics, antidepressants, and anticonvulsants. These medications should be avoided or carefully monitored. Patients with unsteady gait and/or confusion should be checked for the presence of mild hypona-tremia (Na $<$135 mEq/L) and if present, it should be treated.

Safety and Tolerability of BA058 Transdermal, a Novel Analog of hPTHrP Delivered via a Microneedle Patch: Results of a Phase 2 Clinical Trial. Louis Brenner*[1], Kris Hansen[2], Marcie Clarkin[3], Kyle Haraldsen[4], Bente Juel Riis[5], Michael Bolognese[6], Paul Miller[7]. [1]USA, [2]3M Drug Delivery Systems, USA, [3]Radius Health Inc., USA, [4]Radius Health, USA, [5]Nordic Bioscience, Denmark, [6]Bethesda Health Research, USA, [7]Colorado Center for Bone Research, USA

BA058 is a novel synthetic analog of hPTHrP (1-34) currently being developed as an osteo-anabolic therapy for the treatment of postmenopausal osteoporosis (PMO). Daily BA058 subcutaneous (SC) injection has produced promising safety and efficacy results thus far in Phase 1 and Phase 2 studies, and is completing treatment in a Phase 3 fracture prevention study. There is evidence of poor adherence and persistence with current osteo-anabolic agents available for the treatment of osteoporosis in clinical practice, with daily compliance in the Forteo® pivotal study ranging from 79 to 83%. Non-persistence and underuse may reduce the drugs' effectiveness, placing patients at increased risk of fractures with resultant negative outcomes. Thus, there is a significant need for an alternative to injection for delivery of osteo-anabolic agents that improves patient convenience and compliance. To achieve this, we have piloted the use of a microneedle patch (3M) for BA058 transdermal (TD) delivery. This was a randomized, double-blind, placebo controlled Phase 2 study of BA058 TD in healthy postmenopausal women with osteoporosis, conducted in 9 centers in the US (NCT#01674621) and EU. 250 subjects were enrolled and randomized to daily treatment with BA058 TD 50 µg, 100 µg, 150 µg, or TD placebo, or BA058 SC 80 µg for 24 weeks. At baseline, the mean age of the randomized subjects was 66.5 years and the mean t-score for spine and total hip were -2.33 and -1.47, respectively. Thirty-nine percent of randomized subjects had a history of fracture. A total of 32 (12.8%) subjects dropped out of the study, 27 (13.5%) who were randomized to the TD group and 5 (10%) who were randomized to the SC group. Compliance, based on subject diary reports and defined as the total number of administered daily doses/the total number of days on study * 100, for completed subjects was 99% in the TD groups. There were 12 serious adverse events (SAEs) reported in 9 subjects (3.6%); none of these events were considered to be related to study drug or route of administration. In conclusion, BA058 TD was well tolerated in this study population, with an SAE profile consistent with medical events in postmenopausal women. The BA058 TD compliance rate was on average higher than previous clinical trial experience with injectable osteo-anabolic drug delivery. The results of this study indicate that BA058 TD offers the potential of a new transdermal administration option for the osteo-anabolic treatment of PMO.

The Effects of Oral Bisphosphonate Therapy on the Peripheral Skeleton in Postmenopausal Osteoporosis: The TRIO Study. Richard Eastell*[1], Margaret Paggiosi[1], Nicola Peel[2], Eugene McCloskey[1], Jennifer Walsh[1]. [1]University of Sheffield, United Kingdom, [2]Sheffield Teaching Hospitals, United Kingdom

Clinical trials of bisphosphonate therapy have usually examined changes in bone within central skeletal regions; few have assessed their effects on the peripheral skeleton.

We conducted a randomised, open-label, parallel, controlled trial of three bisphosphonates, orally administered at their licensed dose for two years, and examined their effects on the peripheral skeleton using multiple modes of measurement (NCT00666627). We studied 172 postmenopausal women (ages 53-84 years) who had either a BMD T-score of <-2.5 at the spine and/or total hip (stratum 1), or a BMD T-score of <-1.0 plus a previous low trauma fracture (stratum 2). Eligible participants were randomised to one of three treatment groups, either (i) alendronate 70 mg once a week, (ii) risedronate 35 mg once a week, or (iii) ibandronate 150 mg once a month; all were prescribed calcium (1200 mg) and vitamin D (800 IU) supplements over the two year study period. We also recruited 226 premenopausal women (ages 33-40 years) as controls, and studied them for up to 2 years.

Central skeletal assessments included DXA of the lumbar spine and total hip (Hologic Discovery A). Within the peripheral skeleton, we measured forearm and total body BMD using DXA, calcaneus BMD using DXL, radius and tibia total BMD (4% and 33% sites) using pQCT, finger BMD using radiographic absorptiometry (RA), and ultrasound variables of the fingers and calcaneus using QUS. Mixed model ANOVA was used to evaluate the effects of treatment by visit and any interaction of BMD change with treatment, using the ibandronate group as reference.

Measurements remained stable in the premenopausal controls over 2 years (Table 1). By 2 years, oral bisphosphonates resulted in significant increases ($p<0.05$) in BMD within the central skeleton and a few, but not all, of the sites in the peripheral skeleton. Responses were observed by DXA (total body BMD), by DXL (calcaneus BMD), by pQCT (33% total forearm BMD) and by QUS (QUS-2 BUA). There were treatment interactions in BMD change at the lumbar spine and total body (table).

Thus, we found that the calcaneus was the only site in the peripheral skeleton where changes similar to those found in the central skeleton occurred. This may help

to explain why the most striking effect of oral bisphosphonates is on fracture risk reduction within the central skeleton.

Table 1. Change in BMD over two years in response to 3 oral bisphosphonates

Site	Ibandronate (n=57)	Alendronate (n=57)	Risedronate (n=58)	Time effect, p-value	Controls (n=226)

Effects of a New Conjugate Drug in a Rat Model of Postmenopausal Osteoporosis. Careesa Liu*[1], Robert Young[2], Marc Grynpas[3]. [1]University of Toronto, Canada, [2]Simon Fraser University, Canada, [3]Samuel Lunenfeld Research Instituteof Mount Sinai Hospital, Canada

Prostaglandin E_2 (PGE_2) promotes bone formation in vivo, but has significant side effects when administered systemically. Since PGE_2 acts on bone via the EP4 receptor, we use a specific EP4 agonist (EP4a) to promote bone formation. Moreover, because bisphosphonates such as alendronate (ALN) target bone mineral, our approach reversibly conjugates ALN with EP4a via a linker (LK), such that the bone-binding property of ALN allows EP4a to be directly delivered to bone sites upon systemic administration of the ALN-LK-EP4a conjugate. Hydrolytic enzymes in the bone environment then gradually cleave the links to free both EP4a and LK, allowing EP4a to promote bone formation while leaving ALN bound to bone.

We investigated the in-vivo effects of ALN-LK-EP4a in a curative experiment, in which 3-month-old female Sprague-Dawley rats were ovariectomized (OVX), allowed to lose bone for 6 weeks, then treated for 6 weeks (n=9-12/group). Treatment consisted of conjugate in low dose (CL, 5mg/kg IV weekly) and high dose (CH, 25mg/kg IV week 1, 15mg/kg weeks 2, 4, 6), co-dosed unconjugated EP4a and ALN-LK (EA, 2.5mg/kg each IV weekly), vehicle for OVX (OV, IV weekly) and sham-operated rats (SV, subcutaneous daily), and PGE_2 (PG, 4mg/kg subcutaneous daily).

Histomorphometric analysis of the proximal tibial metaphysis shows that osteoid volume is dose-dependently increased under conjugate treatment. In addition, while CL exhibited increased MS/BS (35%), MAR (69%), and BFR/BS (131%) compared to OV, EA was decreased compared to CL. Micro-computed tomography (microCT) shows conjugate-induced dose-dependent increase in vertebral trabecular BV/TV with concomitant increase in Tb.N, and CL led to 63% recovery of OVX-induced bone loss while CH exceeded sham levels. Trabecular vBMD is dose-dependently increased, and the vertebral load-bearing ability under compression is improved but the material strength was unchanged.

MicroCT of the femoral shaft shows that conjugate treatment led to dose-dependent increase in both endocortical woven bone formation and cortical porosity. However, CH resulted in excessive remodeling that occluded the marrow cavity and increased the cortical porosity by 30X compared to OV. This enhanced the load-bearing ability but compromised the material strength.

These results indicate that conjugate treatment dose-dependently promotes bone formation and restores OVX-induced bone loss, with conjugation of the two components being crucial to the anabolic effect.

Co-Administered 1,25-D Enhances the Direct Effect of Amino Acids on Total Transepithelial Calcium (Ca) Transport In Vitro. Jessica Bihuniak*[1], Jane Kerstetter[1], Karl Insogna[2]. [1]University of Connecticut, USA, [2]Yale University School of Medicine, USA

Nutrient-nutrient interactions that influence intestinal Ca transport are not well categorized. 1,25-dihydroxyvitamin D3, (1,25-D) is known to augment transcellular Ca transport. Increasing dietary protein in humans and rats has been shown to increase intestinal Ca absorption without affecting rates of bone formation or resorption. To examine the interaction between 1,25-D and dietary protein on gut Ca absorption, Caco-2 Bbe cells, a model of intestinal epithelia, were cultured in transwells for 25-26 days. At Time 0, Ca-45 was added to the upper chamber in the presence of: transport buffer (TB, control), a mixture of amino acids (AA) in TB at a final concentration twice that of normal growth media (2XAA), 100 nM 1,25-D or a combination of 2XAA and 100 nM 1,25-D. Total transepithelial Ca transport was estimated as the amount of Ca-45 appearing in the basolateral buffer at 6 hrs, expressed as a percentage of the total Ca-45 applied to the upper chamber at Time 0. For the two experimental conditions employing 1,25-D, the hormone was added 24 hrs before the study was begun, and continued for the subsequent 6 hrs. The osmolalities of all treatments were equivalent. A one-way ANOVA followed by Tukey's multiple comparisons was used to evaluate differences in Ca-45 flux.

As expected, treatment with 1,25-D increased transepithelial Ca flux (2.1 ± 0.2 vs. 4.1 ± 0.6%; 2-fold increase; $P \leq 0.05$), indicating that this model responds normally to vitamin D. Exposing Caco-2 cells to 2XAA for 6-hrs resulted in 6.3-fold and 3.2-fold increases in Ca flux compared to control and 1,25-D treatments, respectively ($P \leq 0.0001$). Combination treatment with 2XAA and 1,25-D induced a significantly greater increase in Ca flux than either 2XAA alone (1.3-fold increase compared to 2XAA; $P \leq 0.01$) or 1,25-D alone (4.2-fold increase compared to 1,25-D; $P \leq 0.0001$).

These data provide evidence for a direct effect of AA on transepithelial Ca flux. The observation that the effects of AA and 1,25-D on Ca transport are at least additive, supports a salutary interaction between these two nutrients. Whether 1,25-D and AA exert the majority of their effects via similar or different Ca absorption pathways remains to be determined.

Our data are consistent with a previous in vivo study that showed an enhanced effect of 1,25-D and L-lysine on Ca absorption in rats (Wasserman et al., J Nutr, 1957; 62:367-76).

LB-SA33

Teriparatide increases bone formation and bone mineral density in adult women with anorexia nervosa. Pouneh Fazeli*[1], Irene Wang[2], Karen Miller[2], Joel Finkelstein[2], Mary Bouxsein[3], Anne Klibanski[1]. [1]Massachusetts General Hospital & Harvard Medical School, USA, [2]Massachusetts General Hospital, USA, [3]Beth Israel Deaconess Medical Center, USA

Anorexia nervosa (AN) is a psychiatric disorder characterized by self-induced starvation and low weight. Predominantly affecting women, the lifetime prevalence of AN approaches 2.2%. Bone loss is a major medical co-morbidity associated with AN, with nearly 90% of women with AN having bone mineral density (BMD) values more than one-standard deviation below an age-comparable mean. Importantly, AN is associated with a seven-fold increased risk of fracture, but there are no approved therapies for the low bone mass in these patients. Because bone formation is reduced in patients with AN, treatment with teriparatide [(hPTH-1-34), TPT], a potent anabolic agent, would appear to be a logical approach. However, TPT-induced bone formation requires local IGF-I synthesis, and IGF-I synthesis in response to growth hormone is reduced in patients with AN. Thus, to determine the effect of TPT on bone turnover and BMD in patients with AN, we randomized 21 women (mean age +/- SD: 47.0 +/- 7.9 yrs) who met DSM IV weight and psychiatric criteria for AN, to receive TPT (20 μg SC daily, n=10) or placebo (PBO) (n=11) for 6 months. We measured BMD of the spine and hip by dual energy x-ray absorptiometry and serum P1NP and CTX at baseline and six months. At baseline, both groups were of comparable BMI and BMD measurements of the spine and hip were similar (Table 1). CTX levels were also similar in both groups whereas P1NP levels were higher in TPT vs PBO (TPT: 63.0 +/- 24.6 ng/mL vs PBO: 37.4 +/- 20.8 ng/mL, p=0.02) (Table 1).

After six months of treatment, BMD increased significantly more with TPT than with PBO at the PA spine: (TPT vs PBO: 6.0 +/- 4.4% vs 0.2 +/- 2.3%, $p<0.01$) and lateral spine (TPT vs PBO: 10.5 +/- 7.8% vs -0.6 +/- 3.3%, $p<0.01$). The results remained significant after controlling for changes in weight and baseline P1NP level. Changes in FN (p=0.4) and total hip (p=0.8) BMD were similar in both groups. P1NP levels increased significantly more with TPT than with PBO (TPT vs PBO: 158 +/- 125% vs 8 +/- 35%, $p<0.01$) whereas changes in CTX levels in the two groups were comparable (p=0.3). TPT was well tolerated by all subjects.

In conclusion, six months of treatment with TPT selectively increases osteoblast activity in adult women with AN, which leads to significant increases in PA and lateral spine BMD. Further studies are needed to determine whether longer term treatment with TPT will increase BMD at other skeletal sites such as the proximal femur.

	Teriparatide (n=10)	Placebo (n=11)	*p*-value
BMI (kg/m²)	17.6 ± 1.3	16.6 ± 1.2	0.08
BMD of PA spine (g/cm²)	0.77 ± 0.08	0.81 ± 0.11	0.28
PA spine T-score	-2.6 ± 0.7	-2.1 ± 1.0	0.29
BMD of lateral spine (g/cm²)	0.53 ± 0.09	0.57 ± 0.05	0.22
Lateral spine T-score	-3.5 ± 1.1	-3.0 ± 0.6	0.24
BMD of total hip (g/cm²)	0.71 ± 0.14	0.69 ± 0.05	0.72
Total hip T-score	-1.9 ± 1.1	-2.0 ± 0.5	0.60
BMD of femoral neck (g/cm²)	0.60 ± 0.11	0.60 ± 0.05	0.70
Femoral neck T-score	-2.3 ± 1.0	-2.3 ± 0.5	0.57

Effects of 1α,25-Dihydroxyvitamin D3 on subcellular localization, VDR/RXRα interaction by Fluorescent resonance energy transfer (FRET) and nuclear mobility of RXRα by Fluorescent loss after photobleaching (FLIP). Sylvester Jusu*[1], John Presley[2], Loan Nguyen-Yamamoto[3], Benoit Ochetti[2], Richard Kremer[3]. [1]Canada, [2]McGill University, Canada, [3]McGill University, Royal Victoria Hospital, Canada

The Human Retinoid X receptor alpha (hRXRα) plays a critical role in DNA binding and transcriptional activity through its heterodimeric association with several members of the nuclear receptor superfamily including the human vitamin D receptor (hVDR). Several cancer cell lines have been shown to be resistant to the growth inhibitory action of 1,25(OH) $_2D_3$, the biologically active metabolite of vitamin D3. In the malignant HPK1*Aras* cells 10-100 fold higher concentrations of $1,25(OH)_2D_3$ are required than the non-malignant normal HPK1A cells to achieve comparable inhibition of cell growth. We previously showed that hRXRα phosphorylation on serine 260 was responsible for this resistance.

To obtain insight into the effects of hRXRα phosphorylation on the hVDR/hRXRα complex physiological function in living cells, we studied subcellular localization, hVDR- hRXRα interaction and nuclear mobility of GFP-tagged hVDR or hRXRα wt and the non-phosphorylatable hRXRα ala260 mutant in the presence of either 1, 25(OH) $_2D_3$, the MEK inhibitor UO126 or a combination of UO126 and 1, $25(OH)_2D_3$.

We show, through transfection of hVDR and hRXRα tagged constructs, that subcellular localization of both hVDR and hRXRα are localized to the nucleus in 1, 25(OH) $_2D_3$ treated HPK1A cells and HPK1Aras cells treated with UO126 or following transfection of the non- phosphorylatable hRXRα ala260 mutant.

Also, we demonstrate using FRET that hVDR and hRXRα interact in the absence of the ligand in both HPK1A and HPK1Aras cell lines. However, ligand addition increases their interaction in HPK1A cell but only in HPK1Aras cells treated with either UO126 or transfected with the non- phosphorylatable hRXRα ala260 mutant. This clearly demonstrates that heterodimerization of the hVDR / hRXRα complex and interaction in HPK1Aras cells can be improved and possibly reversed with the use of a non-phosphorylatable hRXRα ala260 mutant which completely abolishes hRXRα phosphorylation and restores the function of $1,25(OH)_2D_3$.

Lastly, we demonstrate using FLIP that the half time of dissociation of the receptor in the nucleus and residence time of the receptor within the nuclear compartments are significantly increased in HPK1Aras cells transfected with the non-phosphorylatable hRXRα ala260 mutant suggesting that binding of the hVDR/hRXRα complex to chromatin and therefore effective gene transcription or repression can be achieved with HPK1Aras cells transfected with non-phosphorylatable hRXRα ala260 mutant.

Validation of The University of Connecticut Osteonecrosis Numerical Scale (UCONNS) for Risk Assessment of Osteonecrosis of the Jaws. Regina Landesberg*, Yana Stolyarov, Lisa Marie Di Pasquale, James Grady, Daniel Wakefield, Pamela Taxel. University of Connecticut Health Center, USA

Purpose: Osteonecrosis of the jaws (ONJ) is defined by exposed bone that fails to heal in 6 to 8 weeks. The ability to predict which patients will develop ONJ has remained elusive and the pathophysiology of ONJ remains ill-defined; a number of clinical risk factors have been implicated. Based on the current literature, we have developed an instrument to assess and risk-stratify co-morbidities that are critical for the development of ONJ, the UCONNS. This report describes an initial retrospective validation of this tool.

Methods: Information on 14 patients with documented ONJ was derived from a retrospective chart review of patients seen at UCHC OMFS Clinic. Information on 16 patients without documented ONJ, but who have cancer (breast, prostate, multiple myeloma, lung, ovarian) and/or were receiving bone-modifying medications was drawn from the UCHC Cancer Center. Data were extracted from medical records. These data included: Bone-modifying agents (including total accumulated dose), steroids, chemotherapy and immunomodulators, oral health and surgical procedures, medical conditions and co-morbidities. The UCONNS groups patients into three categories of risk for the development of ONJ; minimal (<10), moderate (10-15) and significant (>16). The group means for the UCONNS scores were compared using two group t-tests. The distribution of categorical variables was compared among the groups using exact chi-squared tests due to the small sample size. We used a two-sided alpha level of significance of 0.05 to assess statistical significance.

Results: The mean UCONNS score for the ONJ group was 23 +/- 8 and the mean score for the non-ONJ group was 14 +/- 4. Statistically significant risk factors ($p<0.05$) for ONJ included poor dental hygiene status, the presence of active oral infection, surgical procedures, and oral and/or IV steroid use within the past 12 months. The total bone-modifying agent use was significantly greater in the ONJ population (p=0.002); however, the cumulative dosage of zoledronic acid approached significance (p=0.07). The results of t-tests showed that the total UCONNS score was a sensitive predictor of ONJ status among at-risk patients. While the individual variables including medical co-morbidities (other than steroids) and smoking did not show significance, this may reflect the small sample size and distribution of these conditions. Future analysis on a larger population including benign conditions is warranted and may identify other critical risk factors for ONJ.

Hedgehog Signaling Regulates Expression of Cholesterol Biosynthetic Genes in Osteoarthritis. Shabana Ali*[1], Benjamin Alman[2], Heather Whetstone[2]. [1]Canada, [2]The Hospital for Sick Children, Canada

Osteoarthritis (OA) is a common degenerative disease of the joint that is characterized by degradation and calcification of articular cartilage, osteophyte formation, and subchondral bone changes. We previously found that Hedgehog (Hh) signaling is activated in human OA and murine models of OA. Since Hh signaling regulates Gli-mediated gene expression, we investigated whether the expression of Hh target genes in chondrocytes promotes OA pathogenesis by disrupting normal chondrocyte behavior. To identify Hedgehog target genes, microarray analyses were performed to detect changes in gene expression when the Hh pathway was inhibited in human OA cartilage samples. Results from the Affymetrix Human Gene 1.0 ST microarray were analyzed for differentially expressed genes, and were validated by real-time PCR. Using Ingenuity® Pathway analysis, several genes known to be involved in sterol homeostasis were found to be upregulated with Hh inhibition. To determine the function of these genes in OA, mice with cartilage-specific cholesterol accumulation were generated. Compared to wildtype littermates, these mice display skeletal dysplasia, including shortened bones and delayed development of the secondary ossification centre. With aging or surgically induced joint instability, these mice also developed typical phenotypic features of OA. They express markers that are associated with OA, such as type X collagen. Genetic manipulation of Hedgehog signaling in these mice suggests that Hh signaling is modulating the phenotype by regulating sterol homeostasis. Therefore Hh signaling regulates genes which modulate sterol biosynthesis and through this mechanism Hh activation drives cartilage degeneration. These data suggest that cholesterol dysregulation predisposes to OA, and provide support for pharmacologic correction of intra-articular sterol imbalance as a novel treatment for osteoarthritis.

Prepubertal calcium supplementation alters the timing of adolescent skeletal growth and mineral accretion in boys. Kate Ward*[1], Tim J Cole[2], Yankuba Sawo[3], Ann Laskey[1], Ann Prentice[1]. [1]MRC Human Nutrition Research, United Kingdom, [2]MRC Centre of Epidemology for Child Health, United Kingdom, [3]MRC Keneba, Gambia

In rural Gambian prepubertal children with low mean daily calcium intakes (300mg/day) we reported positive effects, sustained for at least a year, on bone mineral content (BMC) after 12 months supplementation with calcium carbonate to international levels [1,2]. This group has been followed up regularly until the end of height growth. Results showed that boys in the calcium group (Ca) reached peak height velocity earlier and were taller in mid-adolescence, but stopped growing earlier and were shorter than the placebo (P) group[3] . Our aim was to determine whether the supplementation also altered the timing and rate of skeletal growth and mineral accretion.

80 prepubertal boys (8.0-11.9 years (y)) who participated in the RCT (1000mgCa/day, 5 days/week for 1 y) have been studied longitudinally for 13 years. DXA scans and anthropometry were performed 1y and 2y post-supplement and biennially thereafter. Outcomes were whole body (WB), spine and total hip BMC (g) and bone area (BA, cm^2), and lean mass. Within-individual changes over time and the effects of supplementation on the longitudinal profiles were analysed by the Superimposition by Translation and Rotation method (SITAR)[4]. Results are presented as mean differences ± SEM (months[mo]).

For the whole group mean age at peak velocity was: WBBMC=17.6y, WBBA=16.6y and lean mass=16.1y. Peak WBBA velocity preceded peak WBBMC velocity by 1.02 years ($p<0.0001$). This pattern of growth was similar to those reported in populations with moderate-high calcium intakes, but the ages of peak BMC and BA velocity were delayed in Gambian subjects.

As with height, Ca entered the skeletal growth spurt earlier than the P group, Ca-P peak accrual: WBBMC (6.8 ± 3.4mo, p=0.04), WBBA (6.1 ± 3.1mo, p=0.05), lean mass (4.4 ± 2.4mo, p=0.07). Similar BA results were found for spine (5.8 ± 3.1mo, p=0.06) and total hip (5.6 ± 3.0mo, p=0.07) but they did not reach statistical significance. There were no differences in the velocity of accrual of adult BMC or BA between the groups.

In conclusion, 12 mo of prepubertal calcium supplementation in Gambian boys with a low calcium intake increased BMC in the short-term and advanced the timing of the adolescent skeletal growth spurt. However, it was not associated with a sustained increase in BMC or bone size in young adult men.

LB-SU03

Effects of Low-Magnitude High-Frequency Vibration on Bone Density, Bone Resorption and Muscular Strength in Ambulant Children Affected by Duchenne Muscular Dystrophy. Maria Luisa Bianchi*[1], Silvia Vai[1], Lucia Morandi[2], Giovanni Baranello[2], Barbara Pasanisi[2], Clinton Rubin[3]. [1]Istituto Auxologico Italiano IRCCS, Italy, [2]Fondazione Istituto Neurologico C. Besta IRCCS, Italy, [3]State University of New York at Stony Brook, USA

Some recent studies have demonstrated that low-magnitude high-frequency vibration (LMHFV) may increase bone density (BMD) or decrease bone loss in primary osteoporosis in adults and secondary osteoporosis in disabling conditions (e.g. cerebral palsy) in children.

This is the first prospective double-blind randomized placebo-controlled study to investigate the impact of LMHFV on BMD and muscular strength in children affected by Duchenne muscular dystrophy (DMD). We enrolled 21 ambulant children with DMD (mean age 9.3 $\pm$ 3.9 years). For at least 6 months before the study, all children were treated with glucocorticoids and calcifediol (0.7 mcg/kg/die), and took 100% of calcium RDA. The children were randomly assigned to either active LMHFV devices (delivering 0.3g, 30Hz; N=11, among them 2 brothers) or placebo devices (factory-transformed to produce no vibration; N=10). Children were instructed to use the platforms for 10 minutes a day for 1 year.

At baseline, bone age was evaluated (X-rays). At baseline, 6 and 12 months all children underwent auxological and neurological evaluation: muscular strength (measured by myometer at lower and upper limbs); BMD (by DXA): at spine (BMAD), hip, total body less head; auxological parameters: weight, height, Tanner stage; lab tests: calcium, phosphate, parathyroid hormone, 25-OH vitamin D, 1,25(OH)2 D; bone turnover markers: bone alkaline phosphatase (BSAP), osteocalcin, C- and N-terminal telopeptides (CTx, NTx).

Compliance was 79% (active group) and 75% (placebo group), and all children tolerated the treatment well. BMD significantly increased vs. baseline only in the active group (spine BMAD +7.9% $p<0.02$; TB +6.8% $p<0.02$; femoral neck +9.8% $p<0.01$). There was no change or a decrease in the placebo group (spine BMAD -2.9%, TB -3.9%, femoral neck -4.8%). Muscular strength did not change significantly in both groups.

25-OH D was within normal range in all children, as well as calcium, phosphate, PTH. Bone markers evaluation showed an increase in formation markers (BSAP and osteocalcin) and a significant reduction in resorption markers (CTx -12.3%, NTx -16.9%, $p<0.05$ vs. baseline for both) in the active group. An increase in resorption markers was observed in the placebo group (CTx +8.7%, NTx +10.6%, $p<0.05$ vs. baseline for both).

These data suggest that LMHFV can effectively improve BMD and bone turnover in ambulant DMD children, notwithstanding disease progression and chronic steroid use.

LB-SU04

Mechanical Properties of Cancellous Bone from Normal, Osteoporotic and Treated Sheep. Gavriel Feuer*[1], Subrata Saha[2], James Bennett[3]. [1]USA, [2]State University of New York Downstate Medical Center, USA, [3]SUNY Downstate, USA

The purpose of the current study was to assess efficacy of a synthetic bone mineral (SBM) made of magnesium, zinc, and calcium phosphate with and without fluoride that could be used to prevent and treat osteoporosis. Twenty eight sheep were randomly allocated into one of four groups. Osteoporosis was induced in three of the four groups using a combination of ovariectomy (OVX), corticosteroid injections, and a low mineral diet. One group underwent a sham operation and served as a control for the study.

The sheep were sacrificed after 8 months. Cancellous bone cores (7.9 mm diameter, 2.8 mm thickness) were prepared from the distal end of the right femurs and their wet density was measured. A shear punch test was performed separately on the midpoint of the three distal samples. A load-deflection curve was generated for each slice and the shear stress of each sample was calculated by dividing the peak load by the shear area. The peak load, shear stress, stiffness, and density of the distal three samples for each core were averaged. Statistical analysis was performed using analysis of variance (ANOVA) to compare the means for each treatment group with Tukey adjustment for multiple comparisons.

The mean peak load of all the samples was 104.2 $\pm$ 34.1 N, the shear stress was 3.7 $\pm$ 1.6 MPa, the stiffness was 976.3 $\pm$ 378.7 N/mm, and the density was 1.148 $\pm$ 0.030 g/cc. As shown in Fig. 1 there was a significant increase in shear stress, peak load, stiffness and density between the SBM (F+) treated group and the OVX group. There was also a significant increase in shear stress, peak load and density between the SBM (+F) treated group and the sham operated group.

The current study showed a significant difference among the four treatment groups regarding the peak load, shear stress, stiffness, and density of the cancellous bone. There was a statistically significant improvement in the peak load, shear stress, and density when comparing the SBM (+F) group with the ovariectomized and sham-operated groups. In addition, there was a statistically significant improvement in the stiffness when comparing the SBM (+F) group with the ovariectomized group. These results suggest that although there was no significant difference between the SBM (+F) group and the SBM (-F) group, the SBM (+F) tended to be more effective at preventing loss of cancellous bone strength in osteoporosis.

Precision of Bone Mineral Density Calculation Utilizing Single X-Ray Absorptiometry (SEXA) versus Dual X-ray Absorptiometry (DEXA) in-vitro. Chester Lowe*[1], Li Sun[2], Jianhua Li[3], Yan Chen[1]. [1]KUB Technologies, Inc, USA, [2]Mt Sinai School of Medicine, USA, [3]Tount Sinai School of Medicine, USA

Abstract: Precision of Bone Mineral Density Calculation Utilizing Single X-Ray Absorptiometry (SEXA) versus Dual X-ray Absorptiometry (DEXA) in-vitro.

OBJECTIVE: To evaluate the precision of mouse bone mineral density (BMD) measurements by Brand P dual-energy X-ray absorptiometry (DEXA) versus Kubtec DIGICOM BMD single-energy absorptiometry(SEXA) in vitro.

METHODS: (1) The coefficients of variation (CV) for BMD measurements at various skeletal

regions were repeatedly determined by DEXA and SEXA in a preliminary study of mice weighing between 17.4 grams – 38.5 grams were analyzed on both machines. (2) Identical Regions of Interest, L3-L5, both sides of femurs and tibias, were visualized and the BMD calculated on both the SEXA and DEXA machines. And (3) resultant calculations were compared.

RESULTS: (1) The CVs of the preliminary BMD measurements in different regions of mice weighing between 17.4 grams to 38.5 grams by SEXA calculations versus the DEXA calculations were as follows, 135.52% for lumbar vertebra (L3-L5), 122.3% for left femur, 139.5% for right femur, 141% for left tibia, and 149.9% right tibia, respectively. (2) The BMD values in the 5 preliminary mice were (57.9 +/- 10.7 SEXA; 42.9 +/- 4.9 DEXA) mg/cm2 in lumbar vertebra (L4-6), (89.2 +/- 10.7 SEXA; 72.9 +/- 7.5 DEXA) mg/cm2 in left femur and (88.3 +/- 11.1 SEXA; 63.3+/- 8.3 DEXA;) mg/cm2 in right femur, (67.7 +/- 5.0 SEXA; 48.0 +/- 5.0 DEXA) mg/cm2 in left tibia and (65.2+/- 8.8 SEXA; 43.5+/- 4.5 DEXA;) mg/cm2 in right tibia, respectively., (3) The BMD values calculated and recorded were consistent between the SEXA and DEXA unit on the ROIs selected with variations between the 2 techniques being accounted for by the higher resolution and the 16-bit output of the SEXA detector versus the lower resolution and 8-bit output of the DEXA unit.

CONCLUSION: Measurement of MOUSE BMD in vitro by the Kubtec DIGICOM BMD SEXA is a useful method, it can produce repeatable results, and it can reflect the changes in mouse bone masses with good precision and as accurately as can Brand P utilizing DEXA.

Sequential *in vivo* tracking of osteogenic stem/progenitor cells during fracture repair. Dongsu Park*[1], Charles Lin[1], David Scadden[2]. [1]Massachusetts General Hospital, USA, [2]Center for Regenerative Medicine, Massachusetts General Hospital, USA

Bone is highly regenerative following injury but the existence of osteogenic stem/progenitor cells have long been hypothesized and in vivo demonstration of such cells has only recently been attained. In particular, their in vivo identity and dynamics are not clearly understood. We recently defined that osteogenic stem/progenitor cells (OSPCs) can be genetically marked by transient activation of the myxovirus resistance-1 (*Mx1*) promoter. Here, we demonstrate in vivo characteristics of endogenous osteogenic stem/progenitor cells and their progeny in bone repair. Using osteo-lineage cell tracing models and intravital imaging of induced microfractures in calvarial bone, we found the relocation of endogenous OSPCs to fracture sites during the first few days after injury. Sequential in vivo imaging of OSPCs in the fracture site revealed that OSPCs increase in number and differentiate into bone forming osteoblasts. Notably, *Mx1* and *nestin* (a known MSC marker) double-labeled mice showed that Mx1+nestin- OSPCs rather than Mx1+nestin+ cells are the source of new osteoblasts during fracture healing in vivo. Our findings further define in vivo identification of skeletal stem/progenitor cells with physiological role in bone remodeling and regeneration and may offer a means of investigating the role of stem cells and their molecular regulators for bone repair.

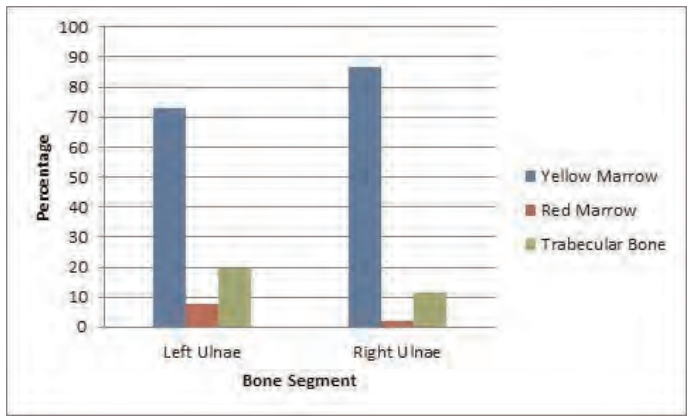
Mechanical Loading on Turkey Trabecular Bone Marrow Morphology. Quintin Eng*[1], Minyi Hu[1], Yi-Xian Qin[2]. [1]Stony Brook, USA, [2]State University of New York at Stony Brook, USA

Mechanical stimuli play an important role as a regulatory signal which allows the skeleton to recognize changes to its functional environment. Loading casues active bone remodeling by stimulating skeletal cells include osteoblasts, osteoclasts, osteocytes and osteoprogenitors. It would be vital to quantify the effects of mechanical stimuli on bone marrow. Medulla ossium rubra (red marrow), typically consists of mainly hematopoietic tissue; while medulla ossium flava (yellow marrow), mainly consists of adipocytic tissue. Red marrow is most prevalent at a young age and as time progresses; red marrow is converted to yellow marrow. Yellow marrow makes up the majority of bone marrow stroma, which contains mesenchymal stem cells (MSCs). Studying the effect of functional isolation with mechanical stimuli on bone marrow would give great insight into ways to promote bone growth. It was hypothesized that functionally isolated mechanically loaded bone can result in a higher red marrow content and lower yellow marrow content than normal functional bone.

An adult, one year old, skeletally mature male turkey's left ulnae was functionally isolated and mechanically loaded. Functional isolation and mechanical loading was achieved via two steel pins placed through drilled holes and a specially designed fluid loading device, performed by Dr. Yi-Xian Qin. The turkey was fed with a normal diet for one month and allowed to recover post-surgery then euthanized. Left and right ulnae were collected and proximal trabecular bones were then fixed in 70% ethyl alcohol before being embedded in paraffin. Microtone sections of 5 micron thick were collected. Each section was then stained with hematoxylin and eosin before photographed at a magnification of 10x using a Zeiss microscope. Image resolution was approximately one micron/pixel. ImageJ was used to analyze the images.

Analysis showed that sections of the loaded left ulnae contained a lower percentage of yellow bone marrow and higher red marrow content than the right ulnae. The amount of yellow marrow contained in loaded bone is lower than in unloaded bone. Yellow marrow contains MSCs which can differentiate into osteoblasts under functional loading; and leads to bone growth. A direct study of the number of osteoblasts and osteoclasts in functionally loaded and disuse bones would give important insight into ways of preventing and treating bone diseases such as osteoporosis and osteopenia.



Left vs. Right Ulnae

Reference Point Indentation Improves the DeXA-Derived BMD Prediction of Femoral Neck Strength. Adam Abraham*, Avi Agarwalla, Simon Tang. Washington University in St Lous, USA

Bone mineral density (BMD), as measured by DeXA, is the clinical gold standard for assessing fracture risk. BMD however is rather limited when diagnosing fragility in disorders involving diminished quality of the bone matrix. Reference point indentation (RPI), a novel tool for the direct minimally-invasive measure of bone material quality, discriminates between fracture vs non-fracture patients in BMD-matched cohorts, suggesting that bone quality is altered in fracture patients. Yet it is unknown whether RPI can assess the relative fracture risk, and whether the combined use of RPI-derived measures of bone quality and DeXA-derived BMD can more robustly predict the relative risk of fractures. Therefore, we aimed to determine the efficacy of RPI at discerning fracture risk and bone strength across the aging post-menopausal population.

Contralateral intact lower limbs from fourteen (ages: 58-97; 28 legs) fresh female cadavers were obtained from the Washington Univ. Femoral neck (FN) and total hip (TH) BMD were acquired using a clinical DeXA system (Hologic). RPI (BioDent Hfc) was performed *in situ* at the tibia mid-diaphysis for each leg through the skin and other surrounding soft tissues (15 sites/limb), and the parameter indentation distance increase (IDI) was averaged for each leg. Femoral neck strength was assessed by potting the proximal femur in PMMA and compressively loaded at the femoral head to failure at adduction 12° using an Instron 5866. Linear correlations were examined between the predictors BMD and IDI and response variables fracture load and work-to-failure.

BMD ranged from 0.39-0.94g/cm^2. FN and TH BMD were linearly correlated with failure load (FN:R^2=0.51, p<0.001; TH: R^2=0.55, p<0.001) and work-to-fracture (FN:R^2=0.35, p=0.002; TH: R^2=0.35, p=0.001). IDI was also linearly correlated with failure load (R^2=0.48, p<0.001) and work-to-fracture (R^2=0.36, p<0.001). More importantly, a multivariate model using TH-BMD and IDI yielded a significant improvement over the univariate correlations for both failure load (R^2=0.67, p<0.001) and work-to-fracture (R^2=0.47, p<0.001).

For the first time, we show that bone quality measured at the tibia by RPI can independently discern the relative risk of femoral neck fracture by predicting bone strength, and RPI may provide valueable clinical insights. Because fracture resistance is a culmination of both bone quantity and bone quality, utilizing both BMD and IDI may improve fracture risk assessment.

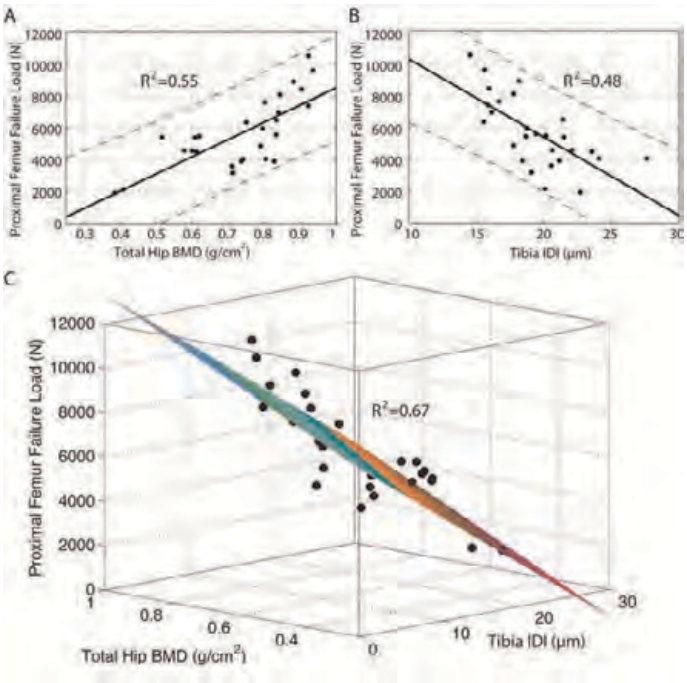

Fig 1: (A,B) BMD and IDI Predict FN Strength. (C) BMD and IDI combined better predicts FN Strength

Cortical thickness and elastic modulus of trabecular bone assessed by a novel ultrasonic bone densitometry are associated with vertebral fracture in type2 diabetes. Takashi Mishima*[1], Koka Motoyama[1], Kae Hamamoto[1], Shinsuke Yamada[1], Nagato Kuriyama[2], Yasuo Imanishi[3], Masanori Emoto[1], Yoshiyuki Watanabe[2], Masaaki Inaba[1]. [1]Department of Metabolism, Endocrinology, & Molecular Medicine, Osaka City University Graduate School of Medicine, Japan, [2]Department of Neurology, Kyoto Prefectural University of Medicine, Japan, [3]Osaka City University Graduate School of Medicine, Japan

In patients with type 2 diabetes, bone fracture is one of well-recognized complications. Accumulated epidemiological studies have shown that patients with type 2 diabetes exhibited the higher bone fracture rate despite their bone mineral density. Further assessments of bone quality are required. Recently, an ultrasonic wave propagation phenomenon described as Biot's theory that focuses on two longitudinal waves (fast and slow waves) has been actively studied and adopted for the assessment of bone strength. The LD-100® system (Oyo Electric, Kyoto, Japan) is a newly developed ultrasonic bone densitometry based on the waves, which can non-invasively evaluate trabecular bone density, cortical thickness, and elastic modulus of trabecular bone. Cortical thickness and elastic modulus of trabecular bone are highly co-relate with grip strength suggesting these two parameters are valid as well as bone mineral density.We studied the associations of cortical thickness and elastic modulus of trabecular bone by LD-100® system with vertebral fractures in 174 type 2 diabetic patients. In the population of GFR≥60 ml/min/1.73m^2, elastic modulus of trabecular bone exhibited significant decrease in the fracture group despite bone mineral density did not. In the population of GFR<60 ml/min/1.73m^2, not only BMD but also cortical thickness and elastic modulus of trabecular bone were significantly decreased in the fracture group. Multivariate logistic regression model showed cortical thickness and elastic modulus of trabecular bone were independent risk factor for vertebral fractures despite bone mineral density was not.

In conclusion, cortical thickness and elastic module of trabecular bone evaluated by a novel ultrasonic bone densitometry were associated with bone fragility in type2 diabetes.

mTOR Promotes Embryonic Skeletal Growth through Stimulation of Protein Synthesis. Jianquan Chen*[1], Jeffrey Arbeit[2], Fanxin Long[3]. [1]Washington University, USA, [2]Department of Surgery, Washington University School of Medicine, USA, [3]Washington University School of Medicine, USA

Mammalian target of rapamycin (mTOR), an evolutionarily conserved serine/threonine kinase, integrates nutritional status and growth signals to regulate cell behavior via two separate protein complexes mTORC1 and mTORC2, each with distinct downstream effectors. To investigate the role of mTOR signaling during mouse embryonic skeletal development, we employed the Cre-LoxP technology to delete either mTOR, or the mTORC1-specific Raptor, or the mTORC2-specific Rictor, in the limb skeletogenous mesenchyme with Prx1-Cre. We find that *Prx1-Cre; mTOR$^{f/f}$* newborns exhibited normal limb skeletal patterning, but severe diminution of the limbs. Histological analyses revealed that at birth the mutant limbs remained a fully cartilaginous element, completely lacking a marrow cavity that is normally evident at this stage. In addition, approximately 50% of the mutants exhibited exencephaly. Interestingly, *Prx1-Cre;Raptor$^{f/f}$* embryos exhibited skeletal phenotypes resembling those of *Prx1-Cre; mTOR$^{f/f}$* embryos. In contrast, *Prx1-Cre; Rictor$^{f/f}$* embryos exhibited slightly shorter and narrower limbs than the control littermates, but they appeared otherwise normal. At the cellular level, loss of either mTOR or Raptor didn't affect chondrocyte survival or proliferation, but diminished the size of chondrocytes and the amount of cartilage matrix proteins. Direct measurement of protein synthesis rate reveals a notable deficit in chondrocytes with disrupted mTORC1 signaling. Thus, mTOR signaling through mTORC1 stimulates protein synthesis by chondrocytes to ensure the proper growth of the embryonic skeleton.

Runx1 and Runx3 are downstream effectors of Nanog in the promoted osteogenic differentiation of mesenchymal cells. Toru Ogasawara*[1], Tadahito Saito[2], Shinsuke Ohba[1], Takahiro Abe[3], Yoshiyuki Yonehara[2], Tsuyoshi Takato[3]. [1]The University of Tokyo, Japan, [2]Nihon University School of Dentistry, Department of Oral & Maxillofacial Surgery, Japan, [3]Department of Oral & Maxillofacial Surgery, Graduate School of Medicine, The University of Tokyo, Japan

The roles of transcription factors in the maintenance of stem cell pluripotency are important and as yet unknown. We previously reported that transcription factor Nanog, which maintains the self-renewal of embryonic stem (ES) cells, promotes the osteogenic differentiation of mouse mesenchymal cell line C3H10T1/2 cells through a genome reprogramming process (J. Cell. Physiol. 228:163-71, 2013). In the present study, in order to clarify the mechanism underlying the pluripotency of stem cells and to develop a novel approach to bone regenerative medicine, we tried to discover the downstream effectors of Nanog in the promoted osteogenic differentiation of mesenchymal cells. To this end, we performed a DNA microarray analysis between C3H10T1/2 cells constitutively expressing GFP and those expressing Nanog cultured with rhBMP-2. By forced Nanog expression, the expression levels of about 1000 genes showed a more than twofold increase (log2Ratio>1) or decrease (log2Ratio<0.5). We selected several of the upregulated genes (Runx1, Runx3, Sox4, Zfp235, Klf13, etc.) as candidates that could regulate the osteogenic differentiation of mesenchymal cells as downstream effectors of Nanog. Among these genes, we here focused on Runx1 and Runx3 in consideration of both the log2 Ratio (Runx1: 3.45; Runx3: 1.61) and findings gathered from the literature. Real-time quantitative RT-PCR analyses confirmed that there were dramatic upregulations of both Runx1 and Runx3 in Nanog-expressing cells compared with the levels in GFP-expressing cells. Next, to investigate the functional relevance of Runx1 or Runx3 to the osteogenic differentiation promoted by Nanog, we knocked down Runx1 or Runx3 mRNA in Nanog-expressing cells through small RNA interference (siRNA). Real-time quantitative RT-PCR analyses revealed that the expression levels of type I collagen mRNA were inhibited by both siRunx1 and siRunx3, though those of osteocalcin were not affected. These results indicate that Runx1 and Runx3 are the downstream effectors of Nanog, especially in the early and intermediate osteogenic differentiation of mesenchymal cells.

FGF23 is a Naturally Phosphorylated Protein: FAM20C-mediated phosphorylation of Ser212 in human FGF23. Iris Lindberg[1], Kevin Li*[1], David Clark[1], Austin Yang[1], Lynda Bonewald[2]. [1]University of Maryland Medical School, USA, [2]University of Missouri - Kansas City, USA

Levels of serum phosphate are controlled by the peptide hormone FGF23, secreted from bone osteocytes. Elevated FGF23 has been shown to be responsible for hypophosphatemia and to play a role in cardiovascular outcomes in CKD. The posttranslational processing of this peptide hormone includes multi-site O-glycosylation, known to affect intracellular inactivation by proprotein convertases. The FGF23 protein also contains several casein kinase consensus sequences (S-X-D/E). It has

recently been shown that SIBLING proteins are phosphorylated at these consensus serines by the novel Golgi secretory kinase FAM20C. In this study, we asked whether FGF23 is also a substrate for secretory phosphorylation. We found that HEK cells transfected with plasmids encoding FGF23 and FAM20C, but not an inactive kinase mutant, were able to incorporate radiolabeled phosphate into immunoprecipitable 29 kDa FGF23 as well as into a 14 kDa C-terminal FGF23 fragment. Further work in the IDG-SW3 osteocyte model cell line showed that these cells are able to generate phosphate-labeled FGF23 and fragments in the absence of kinase transfection, suggesting endogenous FAM20C expression. Serine-to-alanine site-directed mutagenesis of four consensus sites was used to localize the site of phosphorylation to Ser212 (numbering according to wild-type human protein, including initiating methionine), though trace amounts of phosphorylation persisted in the Ser212Ala mutant. Since FAM20C is ubiquitously expressed, we asked whether commercially available recombinant FGF23, produced in NSO cells, is also phosphorylated. LC-coupled mass spectroscopy indicated the presence of phosphate at the homologous serine in recombinant R&D mouse FGF23. In support, a phosphopeptide-specific antibody raised against this site reacted preferentially with FGF23 secreted by FAM20C co-transfected HEK cells.

In conclusion, we have shown that FGF23 is naturally phosphorylated on the C-terminal fragment at Ser212 in a bone cell line; further, since FAM20C is widely expressed, it is likely that all commercially available recombinant FGF23 is also at least partially phosphorylated. The C-terminus of FGF23 is known to be involved in the interaction of Klotho with the FGF23 receptor; phosphorylation may play a role in this ternary interaction.

Role of Morphogenetic Proteins - FGF-23 and Klotho in the Vascular Calcification in Patients with Chronic Kidney Disease. Alexandra Plotnikova*[1], Ludmila Milovanova[2], Yurii Milovanov[3], Sergey Moisseyev[3], Lydia Kozlovskaya[4], Nikolay Mukhin[5], Daria Kryukova[6]. [1]PhD Student, investigator, Russia, [2]PhD, researcher, Russia, [3]M.D., PhD, supervisor of the research, Russia, [4]Professor, M.D., Russia, [5]Professor, M.D., the Head of Department, Russia, [6]PhD student, Russia

The aim of the study was to examine the relationship between changes in FGF-23/ Klotho levels in serum and diffuse arterial calcification in the patients with different stages of Chronic Kidney Disease (CKD).Materials and Methods: 70 patients with CKD 1-5D stage were included in the study: 41-with chronic glomerulonephritis, 22-tubulointerstitial nephritis and 7-hypertensive nephrosclerosis (30 men and 40 women, aged 20-65 years, mean age at enrollment was 41 $\pm$ 6,7 years). Serum FGF-23 levels (Human FGF-23 ELISA kit using monoclonal antibodies to the full FGF-23 molecule) and Klotho (Human alpha-Kl ELISA using anti-Klotho antibodies) were studied in these patients. The state of blood flow in the heart and large vessels (Doppler ultrasound), pulse wave velocity, calcifications presence (echocardiography) and vascular wall functional ability were studied. Results:In hypertensive CKD patients (n = 49), the degree of increasing Blood Pressure (BP) correlated positively with FGF-23 serum levels (r = 0,452; p <0,01) and inversely with Klotho levels (r = -0,687; p <0,01). In addition, in hypertensive patients (n = 49) was found the feedback between enhanced serum FGF-23 levels, reduced serum Klotho levels with increased left ventricular mass index (r=0,552; p<0,01 and r = -0,587 ; p <0,01). We also established the strong straight relationship of FGF-23 serum levels [r =0,492;p<0,01] and the reverse relationship of Klotho serum levels [r= -0,537; p<0,01] with the peripheral vascular resistance indices. In these patients increased FGF-23 levels and reduced Klotho levels have been associated with a higher frequency of calcification identification in the heart and large arteries [r=0,625;p<0,01 and r= -0,584;p<0.01].These correlations were strongest in the hypertensive patients who failed to achieve adequate blood pressure correction (n= 27). The patients who was a success to achieve and maintain target blood pressure level (120-130 mm Hg) had higher Klotho levels [r=0,509;p <0,01] and less pronounced degree of myocardial remodeling then those having uncorrected hypertension .This effect was more expressed in the patients who took nephroprotective means - angiotensin converting enzyme inhibitors or angiotensin receptor blockers for the hypertension correction. Conclusion.It was found the clear link between increased serum FGF-23 and decreased Klotho levels as increasing CKD severity, and diffuse arterial calcification, independent of traditional risk factors.

Molecular insights into the RANKL-RANK interface using human protein expression models. Subhajit Das*[1], Janice Bramham[2], Angela Duthie[1], Julie Crockett[1]. [1]University of Aberdeen, United Kingdom, [2]University of Edinburgh, United Kingdom

The interaction of Receptor Activator of NFκB ligand (RANKL) with its cognate receptor RANK is crucial for osteoclast formation. The recent discovery of mutations in RANK that are associated with rare forms of osteopetrosis confirmed previous in vitro and mouse-model studies. We studied eight of these mutations within human RANK to gain mechanistic insights into the regulation of RANK signalling.

We investigated the role of the PreLigand Assembly Domain (PLAD or 'IVVY' motif) within the cytoplasmic region of RANK in rare cases of osteopetrosis. Immunoprecipitation showed that, by contrast to wild-type RANK, the absence of PLAD in two truncated, mutant RANK proteins (W434X and G280X) prevented ligand-independent but not ligand-dependent oligomerisation and, in the W434X mutant with an intact TRAF6 binding domain, NFκB signalling was normal. Hence, unlike other TNF receptors, removal of PLAD did not interfere with ligand-induced trimerisation and subsequent NFκB signalling, demonstrating that therapeutic targeting of PLAD in prevention of osteoporosis may not be as effective as previously proposed.

The structural importance of the four extracellular, cysteine-rich domains (CRD1-4) in RANK was highlighted in the crystal structure of the mouse RANK-RANKL complex. We studied six disease-associated, point mutations within this region of human RANK. Recombinant, wild-type and mutant his-tagged RANK proteins (residues 26-210) were expressed in mammalian cells and purified by Ni^{2+}-affinity, followed by size-exclusion chromatography. Surface plasmon resonance analysis confirmed the very high affinity interaction between human RANKL and wild-type RANK (K_d<1 nM). RANKL showed slightly weaker binding to four mutants (A134V, D148V and R170G in CRD3; and C175R in CRD4) and no binding at all to two mutants, G53R (in CRD1) and R129C (in the linker between CRD2 and CRD3), indicating the crucial role of the latter two amino acids; the equivalent residues in mouse RANK have previously been shown to significantly interfere with RANKL-RANK interaction. This study shows, for the first time, the effect of disease-associated mutations in RANK on the biophysical interaction of human RANK protein with human RANKL and highlights CRD1 and CRD3 as having crucial roles in the RANKL-RANK interaction.

Taken together, this work provides novel insights into factors influencing RANKL-RANK interaction and signalling, which will be important for the future development of osteoporosis drugs.

Activin Expression During Osteoblastic Mice Embryonic Stem Cell Differentiation Induced by Bone Morphogenetic Protein. Bruno Camargos*[1], Aroldo Camargos[2], Fernando Reis[3], Rubens Tavares[3]. [1]Hospital Mater Dei, Brazil, [2]Menthor, Brazil, [3]Co-Menthor, Brazil

Embryonic stem cells (ESC) respond to molecular signals. Differentiation protocols of ESC into osteoblasts have been used successfully. Most protocols use bone morphogenetic protein (BMP) to induce osteoblast differentiation *in vitro*. Activin A is a growth factor that interacts with BMP and afects osteoblast proliferation and bone remodeling. Activin A may act through negative feedback on terminal osteoblastic differentiation stages. OBJECTIVE: evaluate Activin A expression during osteoblastic differentiation induced by BMP. MATERIAL / METHODS: a protocol for ESC differentiation into osteoblasts described by Kawaguchi was adapted. The cell culture in hanging drop method was substituted by suspension culture. Real time polimerase chain reaction (PCR) of cell indifferentiation markers (Oct-4, Nanog), osteoblastic differentiation markers (Osteocalcin, Runx2, Bone Specific Phospahtase) and Activin A were performed on key steps of the protocol. Immunocitochemistry targeted to Activin A documented it's expression along the differentiation process. RESULTS: the protocol adapted favoured osteoblastic differentiation. Bone markers and Activin A expression increased as the osteoblast differentiation protocol went through it's terminal stages compared to the indifferentiated cell samples. CONCLUSION: cell cultured in suspension demonstrated similar results to the hanging drop method originally described by Kawaguchi. Bone differentiation markers and Activin A expression increased during an osteoblastic differentiation protocol adapted.

Osteoclastogenesis And Bone Degradation In Aseptic Loosening And Implant-Associated Infection. Ulrike Dapunt*[1], Felix Lasitschka[2], Matthias Gaida[2], Thomas Giese[3], Gertrud Maria Hänsch[3]. [1]Resident for Orthopaedic Surgery, Germany, [2]Heidelberg University, Department for Pathology, Germany, [3]Heidelberg University, Department for Immunology, Germany

Aim Although total joint replacements are a successful orthopaedic intervention, loosening of implants remains a severe complication of this procedure.Loosening can be the result of persistent local bacterial infection, or can be ''aseptic'' and caused by mechanical failure. Aim of this study was to investigate underlying cellular and molecular mechanisms, particularly with regard to the inflammatory response and the generation of osteoclasts.Materials and Methods From patients requiring surgery due to an implant-associated infection or because of aseptic loosening, tissue samples were taken directly from osteolytic sites and for comparison from adjacent sites, distant sites and from muscle. The tissue samples were evaluated a) histologically for cellular infiltrates and b) by RT-PCR for the presence of infiltrating cells, inflammation-related cytokines, and the osteoclast-typical gene cathepsin K. Results In aseptic loosening, high expression of cathepsin K and MMP-9 were found at sites with marked osteolysis. At these sites also proinflammatory cytokines (MCP-1, MRP14 and MIP2α) were highly expressed. Importantly, the expression of these parameters gradually decreased from sites of osteolysis to adjacent tissue, to distant tissue and further on to muscle tissue.The cellular infiltrate consisted mainly of mononuclear cells. In patients with infection, there was the high expression of IL-8, exceeding that seen in the aseptic patients by 10 to 20 fold. IL-8 was found at sites of osteolysis, but expression was even more pronounced in adjacent and distant tissues.To address the question of the possible source of IL-8, biopsies of patients with infection were examined. Infiltrating cells were positive for IL-8, but surprisingly the majority of IL-8 was seen in the tissue around blood vessels.Conclusion Aseptic loosening is associated with osteoclast generation, a prominent monocytic infiltrate, and occurs independently of the RANK/RANKL system, which is reported to be the main inductor of osteoclasts in diseases like rheumatoid arthritis or periodontitis. High expression of IL-8 is a hallmark of bacterial infection, and because it can induce osteoclasts, it is feasible that it provides the link between infection and bone resorption.Apparently, the endothelium is an important source of IL-8, which might be crucial for the recruitment of immune cells and thus for progression of the inflammatory response which is characteristic for implant-associated infections.

Pro-Resolving Mediators in the Bone Microenvironment Drive Macrophage Efferocytosis of Apoptotic Osteoblasts. Laurie McCauley*[1], Jesmond Dalli[2], Amy Koh[1], Nan Chiang[2], Charles Serhan[2]. [1]University of Michigan School of Dentistry, USA, [2]Brigham & Woman's Hospital, USA

Osteal macrophages reside in the bone marrow in sites of bone modeling and remodeling. Specialized pro-resolving mediators (SPMs) of inflammation promote wound healing via facilitating the specific phagocytosis of apoptotic cells by macrophages (termed efferocytosis). Little is known relative to the composition, regulation, and function of lipid mediators in the bone marrow. This study identified the profile of SPMs in the bone marrow and elucidated a novel role for resolvins in osteal macrophage efferocytosis. The profile of lipid mediators in the bone marrow and spleen was determined by mass spectroscopy. Metabololipidomic profiling revealed increased levels of the pro-resolving mediators resolvin D2 (RvD2), RvE1, and leukotriene B4 (LXB4) in the bone marrow versus the spleen. Parathyroid hormone (PTH) was administered via a single injection to mice, bone marrow harvested two hours later, and metabololipidomic profiling performed. PTH treatment resulted in significantly increased RvD1 and RvD2 levels in murine bone marrow versus controls. In ex vivo studies utilizing confocal microscopy and videography, primary murine bone marrow macrophages efferocytosed labeled apoptotic MC3T3-E1 osteoblasts in a temporal manner. Efferocytosis assays were performed using peripheral human blood mononuclear cells (PBMCs) induced to differentate to macrophages with the addition of M-CSF. Macrophages were treated with a dose response of RvD1 and RvD2, followed by incubation with apoptotic human osteoblastic cells (hFOB). There was a significant increase in efferocytosis in macrophage cultures treated with RvD1 (100pM-10nM) and RvD2 (100pM-100nM). These findings highlight a unique profile of specialized pro-resolving mediators in the bone marrow. PTH increased select SPMs including RvD1 and RvD2, both of which significantly increased macrophage efferocytosis of apoptotic osteoblasts. This work identifies a new resolution circuit in bone that is responsive to PTH and facilitates clearance of apoptotic cells.

Effects of endurance training on bone formation in a rat model of chronic kidney disease (CKD) related growth retardation. Daniel Landau*[1], Maayan Guterman[1], Ariel Troib[1], Ralph Rabkin[2], Yael Segev[1]. [1]Ben Gurion University, Israel, [2]Stanford University, USA

Objectives: CKD in children is associated with suppressed body growth. We have recently reported on suppressed epiphyseal growth plate (EGP) growth hormone receptor (GHR) signaling and reduced local IGF-I in a rat model of CKD related growth retardation. Physical activity has been previously shown to increase expression of IGF-I signaling in muscles of rats with CKD, but the effects of this intervention on bone tissue have not been investigated yet. The purpose of this study was to examine the effects of endurance training on CKD related bone disease.

Methods: Twenty-day old / 50g male rats underwent a 2 step subtotal nephrectomy (CKD) or sham surgeries (C). The animals were divided into 2 running (treadmill, 20 m/min, 0.5 hr/day, 5 days/wk) groups: control (Cr) and CKD (CKDr) and 2 non running groups: C and CKD. Food delivery was equal for all groups. The intervention lasted 4 weeks.

Results: Growth retardation (both longitudinal and weight gain) was well noticed in CKD Vs C. Exercise caused an increase in longitudinal growth and tibial length in Cr Vs C rats. However, CKDr rats did not grow better than CKD. CKDr rats consumed less food than CKD but grew to the same extent, hinting for better food efficiency. Total EGP width was increased in CKD Vs C, mostly at the expense of the hypertrophic zone. This effect was suppressed in CKDr Vs CKD. EGP cells were better organized in CKDr and showed less necrotic areas than CKD. Type II collagen was increased in CKD and decreased in CKDr. IGF-I mRNA and immunostainable IGF-I were increased in CKDr Vs CKD.

Conclusions: Endurance training did not rescue CKD somatic growth retardation, but longitudinal bone formation was better organized, associated with increased EGP IGF-I, supporting its positive role in bone health.

Intracortical remodeling to meet mineral demands in X-Linked Hypophosphatemia (XLH). Carolyn Macica*[1], Richard Feinn[2], Steven Tommasini[3]. [1]Frank H. Netter School of Medicine Quinnipiac University, USA, [2]Frank H. Netter, M.D., School of Medicine at Quinnipiac University, USA, [3]Yale School of Medicine, USA

Hyp mice, a murine model of XLH, display increased porosity of cortical bone. However the etiology of changes in porosity is unknown. In addition, it is unclear how Hyp mice accommodate the increased mineral demands of pregnancy and lactation. As vitamin D biosynthesis is impaired in Hyp mice, and the highest density of mineral is in mature cortical bone, we hypothesized that mineral demand is met by intracortical remodeling, similar to that described in post-menopausal osteoporotic bone. Histochemical examination of Hyp cortical bone by von Kossa staining revealed that most intracortical pores were actually halos of demineralized bone, independent of osteocyte lacunae. Moreover, the central region of each halo stained positive for vascular markers. We therefore analyzed the femoral diaphysis by three-dimensional analysis using high resolution micro-CT (resolution = 1.55μm). Compared to C57BL6 controls, Hyp mice had a higher percentage of intracortical porosity (8.8% vs. 1.1%) due in part to a 9-fold increase in the percent volume of blood vessels (8.4% vs. 0.9%). This resulted in a 5-fold increase in intracortical surface area. Further, the percent volume of blood vessels and intracortical surface area increased in lactating Hyp compared to non-lactating Hyp controls. Taken together, these data suggest that so-called trabecularization of cortical bone serves as a means to create new bone resorption surfaces in the face of limited mineral availability. Consistent with this hypothesis is the finding of elevated type I collagen matrix degrading enzyme MMP-13 immunoreactivity and osteoclast activity detected by TRAP staining. We further characterized the matrix composition of cortical bone using FTIR analysis. Compared to C57BL6 controls, Hyp cortical bone had similar collagen cross-linking (2.77+0.14 vs. 2.83+0.14), significantly lower mineral/protein ratio (4.59+0.37 vs. 5.54+0.52, $p<0.05$), and significantly higher carbonate ion substitution (0.029+0.002 vs. 0.023+0.001, $p<.001$). Increased incorporation of carbonate into the hydroxyapatite lattice increases mineral matrix solubility and dissolution rate, making it possible to adsorb bone more readily. These data may provide insight into the mechanism of intracortical remodeling observed in osteoporosis and may have important implications in maintaining phosphate levels in the clinical management of XLH in adulthood during periods of high mineral demand.

The Role of Pigment Epithelium Derived Factor in Osteoblast Differentiation. Hadil Al-Jallad*[1], Frank Rauch[2], Marc McKee[3], Pierre Moffatt[4]. [1]Shriners Hospital for Children, McGill University, Canada, [2]Shriners Hospital for Children, Montreal, Canada, [3]McGill University, Canada, [4]Shriners Hospital for Children, Canada

Pigment epithelium derived factor (PEDF) is a secreted protein that is essential for bone metabolism. Absence of PEDF leads to osteogenesis imperfecta type VI, a severe heritable bone fragility disorder that is characterized by a mineralization defect in the presence of normal mineral metabolism. However, the precise role of PEDF in osteoblasts is unknown. In the present study, we therefore assessed the effects of PEDF knockdown and overexpression in the MC3T3-E1/M4 that we used as our *in vitro* model to study osteoblast differentiation. In PEDF deficient cells, collagen deposition was reduced and accompanied with delayed mineralization. Conversely, in PEDF overexpressing cells collagen deposition was significantly increased, with accelerated mineralization. PEDF deficient cells had 5- to 7-fold lower expression of osteoblast differentiation markers (tissue non specific alkaline phosphatase, osteopontin, osteocalcin, osterix/Sp7) and mineralization markers (Enpp1, Ank, Phex), whereas PEDF overexpression was associated with a significant up-regulation in the same markers. We conclude that lack of PEDF in osteoblasts primarily leads to an osteoblast differentiation problem, followed by delayed and decreased mineralization.

Dlk1/FA1 Negatively Regulates Insulin-induced Osteoblast Differentiation and Osteocalcin Production In Mice. Basem Abdallah*[1], Moustapha Kassem[2]. [1]Odense University Hospital, University of South Denmark, Denmark, [2]Odense University Hospital, Denmark

Dlk1/FA1 (Delta like 1/ fetal antigen 1) is a known inhibitor of adipocyte differentiation and its increasing level of expression was shown to induce insulin resistance in mice. We have recently identified Dlk1/FA1 as a novel regulator of bone remodelling that function to inhibit bone formation and stimulate bone resorption. To study the potential involvement of Dlk1/FA1 in mediating the link between bone and energy metabolism, we investigated the regulatory role of Dlk1/FA1 in insulin signalling in osteoblasts using calvaria culture osteoblasts (OB) derived from osteoblast-specific-*Dlk1* over-expressing mice (Col1-Dlk1) and *dlk1*-deficient mice. Treatment of primary OB with insulin showed to inhibit dlk1 mRNA expression in a dose dependent manner during osteoblast differentiation. Insulin-induced osteogenesis was blocked in Dlk1-overexpressing calvaria cells (Dlk1-OB), while it was significantly stimulated in the absence of Dlk1/FA1 expression by *Dlk1*-/- OB. Studying the mechanism underlying the inhibitory effect of Dlk1/FA1 on insulin signalling in osteoblast by western blot analysis revealed the impairment of insulin-induced Akt phosphorylation in Dlk1-OB as compared to wild type OB or *Dlk*-/- OB. In addition, 70% of the insulin-signalling associated genes were significantly down-regulated in insulin-stimulated Dlk1-OB compared to WT-OB as assessed by supper-array pathway analysis. Interestingly, Dlk1/FA1 overexpression in OB significantly upregulated the expression of Twist1/2, (Runx2 inhibitor) in association with the down-regulation of runx-2 expression and its target osteocalcin gene in response to insulin stimulation. Consequently, the serum levels of osteocalcin were markedly reduced by 38.6% in Col1-Dlk1 mice as compared to wild type control mice. In conclusion, our data demonstrated Dlk1/FA1 as a downstream target of insulin signalling molecule that negatively regulates insulin-induced osteogenesis and osteocalcin production by suppressing Akt-dependent pathway and inhibiting Runx2 expression. Thus, Dlk1/FA1 is a novel factor that might function to regulate the link between bone, fat and energy metabolism.

Fate of Implanted Stem Cells in Tissue Engineered Bone. Donna Jones*[1], David Turer[2], Jesse Taylor[3]. [1]USA, [2]University of Michigan, USA, [3]Hospital of the University of Pennsylvania, USA

Bone tissue engineering typically provides a source of cells, the fate of which is not well understood. This study utilizes *gfp* labeled, adipose-derived stem cells (ASCs) in varying concentrations (null, $1x10^4$, $x10^6$ and $x10^8$ cells/mL). ASCs were harvested from globally expressing donor rats, expanded and transferred to cellulose sponge and placed with xenograft bone chips (4x2x2 mm) inside a pedicled, periosteal pouch elevated from the tibia of Lewis rats. Implants were left *in vivo* for four weeks, imaged with μCT, harvested, histologically examined and tested for *gfp* expression. All constructs grew new bone, but those with added cells grew significantly more than controls, regardless of initial cell concentration (Fig 1). The new bone was histologically healthy but less organized than cortical bone. *Gfp+* cells were visible in the three treatment groups and these were localized in the areas of new bone external to the xenograft chip and tibia (Fig 2). Biomechanical testing showed a loss of elasticity (Young's Modulous) and strength following implantation. Addition of stem cells did not affect elasticity or failure strength, although implantation altered both characteristics relative to both native bone and non-implanted chips (Fig 3). These data demonstrate that bone tissue engineering can be accomplished without added growth factors (e.g., bone morphogenic proteins), if done in the presence of periosteum (a bone morphogenic tissue). ASCs increased bone growth, but cell concentrations over $1x10^4$ provided no additional benefit.

The combination of Cortical Porosity and FRAX improves the Diagnostic Sensitivity for Non-Vertebral Fractures in Women. Rajesh Shigdel*[1], Luai Ahmed[2], Ragnar Joakimsen[3], Petter Eldevik[3], Erik Fink Eriksen[4], Roger Zebaze[5], Ashild Bjornerem[1]. [1]University of Tromso, Norway, [2]Faculty of Health Sciences, University of Tromsø, Norway, [3]University Hospital of North Norway, Norway, [4]Oslo University Hospital, Norway, [5]Austin Health, University of Melbourne, Australia

The Fracture Risk Assessment Tool (FRAX), developed by the World Health Organization, helps to determine which patients may need medical treatment for bone fragility. The algorithm calculates the 10-year probability of a major osteoporotic fracture based on easily obtained clinical risk factors including femoral neck aBMD and has performed well in some cohorts but not in others. However, microarchitecture, particular cortical porosity is important for bone strength, and may improve fracture risk assessment, but is not included in FRAX. We therefore hypothesized that women with fractures are better distinguished from controls by the combination of cortical porosity and FRAX, than by either factor alone.

In a nested case-control design, 183 postmenopausal women aged 54-94 years with fractures (hip, humerus and forearm) and 210 age-matched controls from the Tromsø Study, Norway, had their 10-year probability of a major osteoporotic fracture assessed using FRAX including femoral neck aBMD, and simultaneously their cortical porosity was quantified in computed tomography images of the subtrochanteric femoral site using StrAx 1.0 software. The fracture risk was calculated as odds ratio (OR) using logistic regression analysis, and fracture sensitivity using the area under receiver operator curve (AUC).

Women with fractures exhibited higher mean cortical porosity than controls [43.8% (SEM 0.4) versus 40.3% (SEM 0.3)], and higher mean FRAX scores than controls [20.8% (SEM 0.6) versus 12.4% (SEM 0.4)] (both $p < 0.001$). Each standard deviation (SD) increase in cortical porosity increased the risk of fracture with OR of 2.20 (95% CI 1.72-2.81) $p < 0.001$ and the AUC was 0.69 (95% CI 0.64-0.74). Each SD increase in FRAX score increased the risk of fracture with OR of 4.57 (95% CI 3.25-6.42) $p < 0.001$ and AUC was 0.81 (95% CI 0.77-0.86). However, when cortical porosity was combined with FRAX the AUC increased by 0.03 (95% CI 0.003-0.05), $p = 0.03$, and the AUC for this combination was 0.84 (95% CI 0.80-0.88).

We infer that in this independent general population, a combination of cortical porosity and FRAX improve the diagnostic sensitivity.

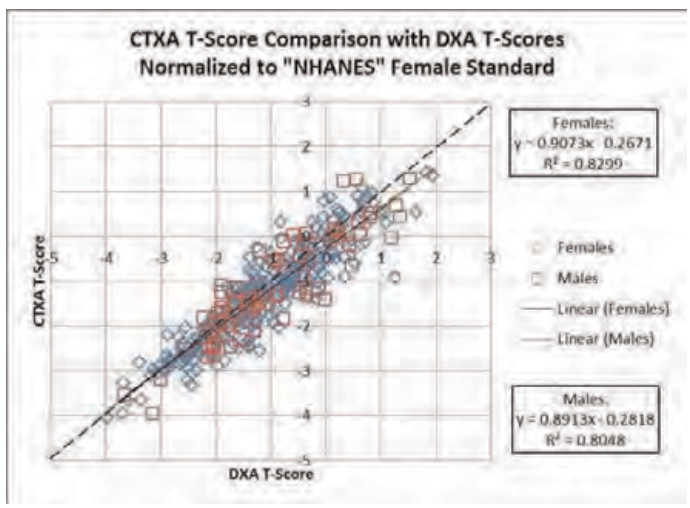
Comparison of DXA and Quantitative CT Bone Mineral Density Measurement using Contrast Enhanced Scans at the Proximal Femur: Implications for Opportunistic Osteoporosis Screening. Alyssa Maciejewski[1], Timothy Ziemlewicz[1], Neil Binkley[2], Alan Brett*[3], Keenan Brown[3], Perry Pickhardt[1]. [1]University of Wisconsin School of Medicine & Public Health, USA, [2]University of Wisconsin, Madison, USA, [3]Mindways Software, Inc., USA

Introduction: For patients undergoing routine contrast-enhanced MDCT examinations, an opportunity exists for concurrent osteoporosis screening without additional radiation exposure or patient time using proximal femur quantitative CT (QCT) "CTXA". Previous studies demonstrated equivalence between unenhanced CT and DXA for femoral neck BMD evaluation; and have suggested a small BMD bias correction for enhanced CT studies. We investigated the effect of IV contrast enhancement on femoral neck CTXA T-score measurement compared with DXA.

Method: This cohort included 78 male and 277 female adults (mean age, 59.7 ± 13.3 years; range, 21-90 years) who underwent standard contrast-enhanced CT assessment including the pelvis at $120kV_p$ (GE Healthcare, Waukesha, WI) between November 2001 and December 2009. All subjects also had DXA BMD (GE Lunar, Madison, WI) assessment within 100 days of the CT study (mean 46 ± 30 days). DXA T-scores were calculated using the NHANES III female reference data. Areal BMD in g/cm^2 of the femoral neck was measured on the CT series using QCT Pro Version 5.1 (Mindways Software, Austin, TX) with asynchronous phantom calibration. QCT T-scores were derived using manufacturer's female reference data.

Results: Linear regression analysis showed good correlation between DXA and CTXA (R2 = 0.824 for both BMD and T-scores) and the SD of the distribution of residuals (SEE) was 0.063 g/cm^2 or 0.45 T-score units. A Bland-Altman plot of T-scores indicates no trend in differences between the two measurements and a small bias with DXA T-score +0.18 units higher than CTXA.

Conclusion: In this cohort, femoral neck T-scores obtained by CTXA and DXA are highly correlated. The SEE for BMD correlation compares favorably to that of a prior study comparing DXA and CTXA (0.053 g/cm^2) and may be higher due to variance in bias introduced by contrast enhancement in this study. The small bias between DXA and CTXA T-scores presented here may be due to differences in CT scanner calibration due to differences in CT table scan height and scanner type. In conclusion, for opportunistic osteoporosis screening at routine post-contrast abdominopelvic CT scans, CTXA produces T-scores similar to DXA. Femoral neck QCT BMD measurement is now included in the WHO FRAX® tool and this method could greatly enhance osteoporosis screening since it can be applied regardless of the clinical indication for CT scanning.



Post-contrast CTXA vs DXA femoral neck T-Scores

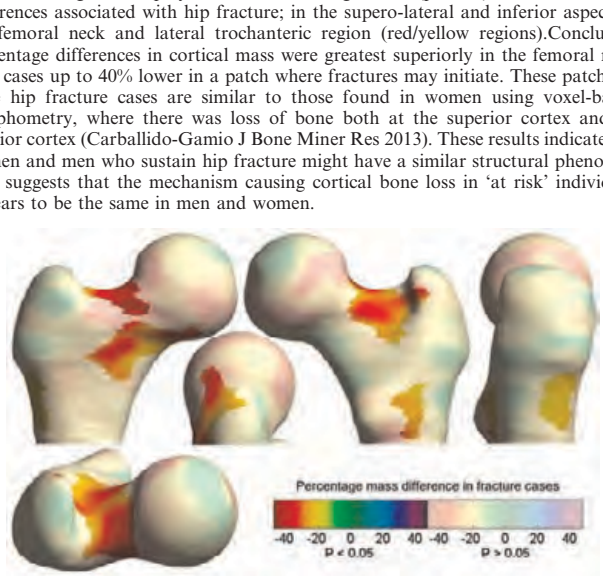
Cortical Bone Defects Associated with Hip Fractures in Men. Fjola Johannesdottir*[1], Graham Treece[1], Andrew Gee[1], Karen Blesic[1], Madhavi Vindlacheruvu[2], Simon Donell[3], Kenneth Poole[1]. [1]University of Cambridge, United Kingdom, [2]Cambridge University Hospitals NHS Foundation Trust, United Kingdom, [3]Norfolk & Norwich University Hospital NHS Foundation Trust, United Kingdom

Background: Studies have shown that women who sustain hip fracture have a structural phenotype. Quantitative computed tomography (QCT) measurements of cortical bone in conventional regions of interest (ROI's) are associated with hip fracture in both men and women, especially cortical thinning superiorly in the femoral neck. Therefore, we aimed to study if a phenotype could be identified among male hip fracture cases, using cortical bone mapping.

Design, Setting and Participants: Participants in this case-control study included 20 British men (mean age 79yr, SD: 8) with a hip fracture and 24 British healthy controls (mean age 69yr, SD: 10). The cortical bone mapping technique was applied to clinical CT scans to identify locations where cortical bone in hip fracture cases differed, on average, from controls. This method involves non-rigid registration to an average femur surface and statistical parametric mapping to identify ROI's where clusters of values differ significantly, using Stradwin and Surfstat software. For cases, the non-fractured hip was used. Model effects were group (case*control), age, weight, height, and shape. The results are presented as percentage differences in cortical bone mass between cases and controls with a scaled colour map on an average femur model.

Results: Figure 1 displays the locations of significant ($p<0.05$) cortical bone mass differences associated with hip fracture; in the supero-lateral and inferior aspects of the femoral neck and lateral trochanteric region (red/yellow regions).Conclusion: Percentage differences in cortical mass were greatest superiorly in the femoral neck, with cases up to 40% lower in a patch where fractures may initiate. These patches in male hip fracture cases are similar to those found in women using voxel-based-morphometry, where there was loss of bone both at the superior cortex and the inferior cortex (Carballido-Gamio J Bone Miner Res 2013). These results indicate that women and men who sustain hip fracture might have a similar structural phenotype. This suggests that the mechanism causing cortical bone loss in 'at risk' individuals appears to be the same in men and women.



Percentage difference in cortical mass between controls and fracture cases (negative=fracture case)

Time to Major Fracture in Younger Postmenopausal Women According to Age and BMD T-score: the Women's Health Initiative (WHI). Margaret Gourlay*[1], Robert Overman[1], Guillaume Filteau[1], Jason Fine[1], Kristine Ensrud[2], Carolyn Crandall[3], Catherine Womack[4], Margery L.S. Gass[5], Erin LeBlanc[6], John Robbins[7], Karen Johnson[8], Andrea Lacroix[9]. [1]University of North Carolina, USA, [2]Minneapolis VA Medical Center / University of Minnesota, USA, [3]University of California, Los Angeles, USA, [4]University of Tennessee, USA, [5]The North American Menopause Society, USA, [6]Kaiser Permanente NW, USA, [7]University of California, Davis Medical Center, USA, [8]University of Tennessee Health Science Center, USA, [9]Fred Hutchinson Cancer Research Center, USA

The optimal approach for BMD screening to identify younger postmenopausal women who might benefit from osteoporosis treatment has not been established. We studied 4068 postmenopausal women aged 50 to 64 years at baseline in the placebo groups of the Women's Health Initiative Hormone Therapy, Calcium/vitamin D or Dietary Clinical Trial (WHI-CT) or in the WHI Observational Study (WHI-OS). Eligible participants were without a history of major (hip or clinical vertebral) fracture or use of pharmacologic treatment for osteoporosis at baseline, and had at least one DXA BMD test with femoral neck, total hip and lumbar spine measurements. We conducted a competing risk analysis to estimate the time for 1% of women to experience a first major fracture according to age group and the lowest of femoral neck, total hip or lumbar spine BMD T-score at baseline (T-score >-1.50; T-score -1.50 to -2.49; T-score <=-2.50). Hologic 4500 densitometers were used to determine BMD at 1 to 7 visits, and T-scores were calculated using white female normative values. For women without osteoporosis (T-score >-2.50) at baseline, the competing risks were incident osteoporosis, initiation of an FDA–approved agent for the treatment of osteoporosis (bisphosphonate, calcitonin, raloxifene or teriparatide) and death. For women with osteoporosis (T-score <=-2.50) at baseline, the competing risks were initiation of treatment and death. Follow-up time ranged from 23 days to 18.6 (mean 14.0) years. Parametric cumulative incidence curves for the time to major fracture were estimated from log logistic cumulative incidence models for interval censored data adjusting for age, BMI, race/ethnicity, current smoking, current estrogen use, current use of oral glucocorticoids, self-reported rheumatoid arthritis, parent with hip fracture, and WHI-CT vs. OS participation. The adjusted estimated time for 1% to transition to major fracture ranged from 16.57 (8.47, 32.43) years for women aged 50 to 54 with baseline T-score >-1.50, to 5.44 (2.82, 10.47) years for women aged 60 to 64 with baseline T-score <=-2.50. Eight of 336 (2.4%) women with osteoporosis at baseline had a major fracture before initiation of treatment during the study period. Postmenopausal women without a history of major fracture or treatment who had their first BMD screening test between age 50 and 64 had a very low incidence of major fracture before age 65. Optimal timing of subsequent DXA screens requires further exploration.

Baseline age range (years)	Baseline T-score range	Event N/ Group N (%)	Time for 1% of participants to have a first hip or clinical vertebral fracture	
			Unadjusted years (95% CI)	Adjusted years (95% CI)*
50-54	> -1.50	2/799 (0.25)	27.01 (10.24, 47.80)	16.57 (8.47, 32.43)
	-1.50 to -2.49	2/233 (0.86)	11.76 (6.77, 20.44)	14.01 (7.65, 25.66)
	<=-2.50	2/38 (5.26)	7.56 (3.72, 15.44)	8.47 (4.00, 17.96)
55-59	> -1.50	6/889 (0.67)	19.47 (11.36, 33.32)	12.73 (6.68, 24.23)
	-1.50 to -2.49	3/391 (0.77)	8.48 (4.89, 14.70)	10.76 (6.00, 19.29)
	<=-2.50	3/104 (2.88)	5.46 (2.69, 11.10)	6.50 (3.16, 13.38)
60-64	> -1.50	7/880 (0.81)	14.62 (9.01, 23.73)	9.76 (5.36, 17.77)
	-1.50 to -2.49	12/554 (2.17)	6.37 (3.98, 10.24)	8.25 (4.80, 13.91)
	<=-2.50	3/194 (1.55)	4.10 (2.16, 7.78)	5.44 (2.82, 10.47)

*estimated time to mjr or clinical vertebral fracture, based on a competing risks quantile regression (Peng and Fine, 2009), adjusted for the sample averages of the other covariates in the model. For women with T-score <=-2.50 at baseline, data were adjusted for age, BMI, race/ethnicity, current smoking, current estrogen use, current use of oral glucocorticoids, self-reported rheumatoid arthritis, parent with hip fracture, and WHI-CT vs. OS participation. For women with T-score > -2.50 at baseline, data were adjusted for continuous BMD and age term

Predictors of non-vertebral fracture in older Chinese men and women: MrOS and Ms Os (Hong Kong). Timothy Kwok*. Hong Kong

Kwok T MD, Khoo CC MPhil, Leung J MSc, Woo J MD

Introduction - A prospective cohort study was performed to identify clinical risk factors of non-vertebral fractures in older Chinese men and women

Methods - 4000 community-dwelling Chinese men and women with average ages of 72.4 and 72.6 years were followed up for an average of 6.5 and 8.8 years respectively. At baseline, they were interviewed by a structured questionnaire, underwent clinical measurements including total hip BMD measurements by dual X ray absorptiometry (DXA). The incidence of non-vertebral fractures was ascertained by self report and electronic medical record, and confirmed by X ray. Stepwise Cox regression models were used to identify risk factors of non-vertebral and fragility fractures.

Results - The incidence rates of non-vertebral fractures were 10.3 and 20.5 per 1000 person years in men and women respectively. 81.2% and 99.0% of fractures were

fragility fractures in men and women respectively. The age adjusted Hazard ratio (HR) of total hip BMD for non-vertebral fractures was 1.43(95% CI 1.19-1.70) and 1.40 (1.25-1.58) per SD decrease in men and women respectively. In the multivariable stepwise Cox regression model for non-vertebral fractures with total hip BMD as covariate in men, age?80, history of fall in the past year, fracture at or after age of 50 years or chronic obstructive pulmonary disease, impaired visual depth perception, and low physical health related quality of life (SF12) were the significant factors. In women, the corresponding factors were fracture at or after age of 50 years, low visual acuity and slow narrow walking speed. ROC curve areas predicted by BMD increased when clinical risk factors were included, especially in men.

Conclusion - Clinical risk factors have additive value to hip BMD in predicting non-vertebral fractures in older Chinese people, especially in men.

Key Words: Fracture, bone; Asian continental ancestry group; Aged; Risk factors.

Long term effects of higher dietary calcium intake on vertebral fractures and severe abdominal aortic calcification in older Australians. Peter Ebeling[1], Dallas English[1], Caryl Nowson[2], Robin Daly[3], Belal Khan*[1]. [1]The University of Melbourne, Australia, [2]School of Exercise & Nutrition Sciences, Deakin University, Australia, [3]Centre for Physical Activity & Nutrition Research, Deakin University, Australia

Introduction: Higher dietary calcium intakes (DCI) prevent age-related bone loss; however, data on fracture prevention are equivocal. Evidence on the influence of DCI on the association between vertebral fractures and abdominal aortic calcification (AAC) is scant. Vertebral fractures and bone mineral density (BMD) may both be associated with AAC due to a common pathogenesis.

Aims and Methods: We assessed the long-term associations between DCI and prevalent vertebral fractures and AAC, measured by lateral thoraco-lumbar radiographs, and hip and spine BMD, by DXA, in 407 men and women, followed for a mean (SD) of 17.7 (1.1) years, randomly selected from a large prospective cohort study (MCCS). DCI was assessed using a food frequency questionnaire at entry (1990-1994). During follow-up (2010-2011), vertebral fractures were graded using the semiquantitative(SQ)-method and AAC was quantified using a 24-point score. Fasting serum lipids and serum 25-hydroxyvitamin D (25D) were also measured.

Results: The mean (SD) baseline age was 53 (5.4) years. 103 (29.8%) participants had 172 prevalent vertebral deformities between T5-L4, while 229 participants (66.2%) had prevalent AAC between L1-L4. Compared with the low DCI group (<500 mg/d), the risk of vertebral deformities was significantly lower (OR 0.46; 95% CI, 0.27-0.78) in the high DCI group (≥1300 mg/d), and there was a non-significant 50% decrease in the risk of AAC (OR 0.50; 95%CI, 0.23-1.08). When only moderate/severe vertebral fractures (OR 0.31; 95%CI 0.12-0.78) or severe AAC (OR 0.35; 95%CI, 0.13-0.94) were considered, the risk of both was significantly decreased with high DCI. High DCI tended to be associated with higher spine and hip BMD, but was only significantly related to higher femoral neck BMD in women ($\beta_{FemoralNeck}$ 0.04; 95%CI, 0.01-0.07). Tertiles of AAC were also positively associated with vertebral deformity grades (OR 1.44; 95%CI, 1.05-1.97) and inversely associated with whole body BMD (β -1.05; 95%CI, -1.98 - -0.11) independent of age, sex, serum 25D, cholesterol:HDL and lean mass:fat mass ratios.

Conclusion: Higher dietary calcium intake is associated with decreases in both vertebral fracture risk and severe abdominal aortic calcification, and maintenance of hip BMD in postmenopausal women. More severe abdominal aortic calcification was also associated with higher grade vertebral fractures and lower whole body BMD supporting the concept of a common pathogenesis.

Sexual Dimorphism in Sirtuin1 Regulation of Skeletal Aging. Rivka Dresner-Pollak*[1], Hanna Artsi[2], Einav Cohen-Kfir[3], Irina Gurt[2], Alon Bajayo[4], Teresita Bellido[5], Gal Ben Shalom[2]. [1]Hadassah-Hebrew University Medical Center, Israel, [2]Endocrinology & Metabolism Hadassah-Hebrew University Medical Center, Jerusalem Israel, Israel, [3]HEBREW UNIVERSITY Medicine Faculty, Israel, [4]Bone Laboratory Hadassah-Hebrew University Medical Center, Jerusalem Israel, Israel, [5]Indiana University School of Medicine, USA

Bone loss is an inevitable consequence of ageing. Recent advances in aging research identified the sirtuins as key regulators of the aging process and age-associated conditions. Others and we reported that Sirt1 deficiency results in decreased bone mass in mice (*Endocrinology* 152:4514-4524, 2011, *JBMR* 28:960-969, 2013). To understand the role of Sirt1 in skeletal aging we investigated the changes in structural and cellular phenotype in 129Sv Sirt1 haplo-insufficient mice (*Sirt1* $^{+/-}$) with aging.

μCT analysis of L4 and femur was performed in 1, 3, 5, 7 and 12 month-old female mice and up to 2 years in male mice. Gene and protein expression were determined. Osteocyte apoptosis was determined by Tunnel staining.

Reduced trabecular and cortical peak bone mass (-30% and -10% respectively) was found in the spine and femur of Sirt1$^{+/-}$ female but not in Sirt1$^{+/-}$ male mice. The rate of trabecular and cortical bone loss was similar in Sirt1$^{+/-}$ and WT mice of both genders. Femoral cortical porosity was 50% higher in the femurs of 7-month-old Sirt1$^{+/-}$ compared to WT female mice. No increased porosity was detected in the femurs of Sirt1$^{+/-}$ males. Consistent with these findings, trabecular and cortical osteocyte apoptosis was more than double in Sirt1$^{+/-}$ female mice accompanied by decreased DMP1 and increased sclerostin level.

Gene expression analysis of brown adipocyte markers revealed a marked reduction in PGC1α, Dio2, β3AR and PRDM16 in whole bone extracts obtained from 5-month-old Sirt1$^{+/-}$ female mice.

To explore the underlying mechanism of the sexual dimorphism, estrogen receptor alpha (ERα) and the androgen receptor (AR) were studied. Indeed, Sirt1 positively regulated ERα and negatively regulated AR in C3HT101/2 cells, primary bone marrow-derived mesenchymal and osteoclast cultures and in whole femoral extracts obtained from 6-8 week-old female and male mice.

To understand the relevance of these findings to skeletal aging, Sirt1 level was determined in whole femur extracts obtained from 3-and 12- month-old WT female mice and was found to decline by 50%.

Sirt1 regulates peak bone mass acquisition in 129Sv mice in a gender specific manner. Sirt1 regulates key cells in skeletal aging: the osteocyte, the longest lived cell in bone and the marrow adipocyte. The sexual dimorphism in skeletal effects of Sirt1 maybe explained but its opposite effects on ERα and AR expression in marrow mesnchymal stem cells, osteoblasts, osteoclasts and osteocytes.

Cheung[16], Suzanne Morin[17], Basel Masri[18], Cyrus Cooper[19], Sarah Morgan[20], Barbara Obermayer-Pietsch[21], Bente Langdahl[22], Rana Al Dabagh[23], K. Shawn Davison[24], Juliet Compston[25]. [1]McMaster University, Canada, [2]Dalhousie University, Canada, [3]University of Calgary, Canada, [4]Charité - Campus Benjamin Franklin, Germany, [5]University of Michigan School of Dentistry, USA, [6]The Permanente Medical Group, USA, [7]University of Auckland, Nzl, [8]New York Center for Orthognathic & Maxillofacial Surgery, USA, [9]Matsumoto Dental University, Japan, [10]University of California, Los Angeles, USA, [11]Mercy Health Osteoporosis & Bone Health Services, USA, [12]University of Florence, Italy, [13]University of Alberta, Canada, [14]Indiana University, USA, [15]University of Sheffield, United Kingdom, [16]University Health Network-University of Toronto, Canada, [17]McGill University, Canada, [18]Jordan Hospital, Jordan, [19]University of Southampton, United Kingdom, [20]University of Alabama at Birmingham, USA, [21]Medical university of Graz, Austria, [22]Aarhus University Hospital, Denmark, [23]University of Toronto, Canada, [24]University of Victoria, Canada, [25]University of Cambridge School of Clinical Medicine, United Kingdom

An International Osteonecrosis of the jaw (ONJ) Task Force was formed in 2012 and formalized key questions addressing the diagnosis and management of ONJ in oncology and osteoporosis patient populations. Following a comprehensive literature review with critical appraisal of the evidence, the questions were addressed and recommendations developed based on international consensus. ONJ is associated with high-dose intravenous bisphosphonate or denosumab therapy in oncology patients. The incidence of ONJ in the osteoporosis patient population has been estimated largely from surveys and retrospective studies at 0.001-0.01%. This may be only slightly higher than the background incidence of ONJ in the general population. ONJ has been described to occur in the absence of antiresorptive therapy (lingual mandibular sequestration and ulceration) in which case it appears to be a self- limited condition. The staging of ONJ now includes stage 0, an early stage of presentation without evidence of exposed bone, but with signs and symptoms of ONJ. Radiographic evidence of osteosclerosis or thickening of the lamina dura on plain films are features of stage 0 disease. It is not clear if all patients at stage 0 will necessarily progress to osteonecrosis and this requires more study. New insights into the pathophysiology of ONJ include effects of bisphosphonates on osteoclast inhibition and gamma delta T-cells in addition to local infection, inflammation and necrosis. Denosumab may contribute by inhibiting osteoclast function as well as possible effects on monocyte and macrophage function. Advances in imaging include cone beam CT enabling assessment of architecture with minimal radiation exposure in addition to MRI, bone scanning and PET. Good oral hygiene is key for prevention of ONJ. There is currently no evidence that withholding antiresorptive therapy reduces the risk of ONJ or the progression of the disease in osteoporosis patients. In those individuals at high risk for the development of ONJ, including oncology patients, antiresorptive therapy should be withheld following dental surgery until soft tissue closure with well epithelialized mucosa. Management of ONJ is challenging and is based on the stage, lesion size, comorbidities and contributing factors. Conservative therapy includes topical antibiotic mouth rinses and systemic antibiotic therapy. Localized surgical debridement is indicated in advanced nonresponsive disease with successful resolution in most cases.

Densitometry comparison after five years of therapy in patients with continuous bisphosphonates (BF) vs. sequential treatment: 3 years of bisphosphonates follow by 2 years of Strontium Ranelate (SrR). Carolina Pelegrin*[1], Malena Alvarellos[2], Maria Valeria Premrou[2], Laura Elena Maffei[2]. [1]Consultorios Asociados de Endocrinologia, Argentina, [2]coleague, Argentina

Introduction: Osteoporosis is a disease characterized by alteration of bone turnover with an increased bone resorption and decreased bone formation. The BP inhibits bone resorption and the SrR is a dual drug stimulating bone formation and inhibiting resorption.

Objectives: Evaluate densitometry response in patients (p) who had received five years of continued BP vs. patients who had received three years of BF treatment and then rotated to SrR.

Material and Methods: We retrospectively analyzed the medical histories of (p) treated at our center, evaluating densitometry changes in 4th and 5th year of BP treatment vs. SrR.

Results: We analyzed 79 women: 41 received continuous BP (74.1 ± 9 years), and 38 RS (70.2 ± 8.4).

Lumbar spine BMD (LS) to 3rd year in the SrR group 0.874 ± 0.116 36p , 0815 ± 37 BP group 0.088 (*p* 0.016). LS SrR group 4th year 0.861 ± 0.096 36 p and 0.876 ± 0.100 BP group (p 0.519).LS SrR group 5Th year in 30 p 0.901 ± 0.094 and 34 p BP group 0.868 ± 0.091(*p* 0.159).

Femoral neck BMD (FN) on 3rd year in 34 pat SrR group 0.666 ± 0.112 and 35 p BP group 0.719± 0.083 (*p* 0.03). FN on 4th year in 35 p SrR group 0,718 ± 0,100 and 34 p on po BP 0,716 ± 0,891 (*p* 0,926).FN on 5th year in 30 SrR p 0.739 ± 0.095 and 34 p on BP0.723 ± 0.084 (*p* 0.471).During 4th year of treatment improved 29 SrR p (82.8%) BMD increased 6.76 ± 4.92%, and 24 with BP (66.7%), increased 4.13 ± 2.64 (p 0,01).

We observed decrease in 6 SrR p (17.1%) and 12 with BP (33.3%) *p* 0.41.

This improvement was progressive with SrR after 5th year of treatment 26 p improved LS (89.7%) increased 8.90 ± 5.21 and 22 BP p (64.7%) increased 4.72 ± 3, 60 (*p* 0.003)

3 SrR p decreased (10.3%) vs. 12 BP p (35.3%) *p* 0020

After 5th years of treatment 24 SrR pat improved in FN (72.7%) inc 7,60± 8,31and 18 BP pat (52.9%) inc 2.61 ± 2 (p 0.009)

9 SrR pat decreased (27.3%) and 16 with BP (47.1%) After 5th year in FN 25 SrR pat (92.6%) inc 8.95 ± 9.5 and 22 with BP (64.7%) inc 2.71 ± 2.85 2 SrR pat decreased in FN(7.40%) and 12 with BP (35.3%)

Conclusions: Osteoporosis treatment is prolonged and it is often necessary rotate it to optimize the response or decrease adverse events. SrR showed a significant and progressive increase on BMD after BP administration in LS and FN, this response being higher than the continuous BP administration. Therefore we consider that BP-SrR sequential therapy is an attractive alternative in osteoporosis treatment.

Preosteoblasts are targets of hyperlipidemia-induced PTH resistance; a role of reactive oxygen species. Yin Tintut*[1], Xin Li[1], Jamie Garcia[1], Sidney Iriana[1], Jinxiu Lu[1], Ivo Kalajzic[2], David Rowe[2], Linda Demer[3]. [1]University of California, Los Angeles, USA, [2]University of Connecticut Health Center, USA, [3]David Geffen School of Medicine At University of California Los Angeles, USA

Lipid oxidation products initiate inflammatory reactions leading to pathogenesis of atherosclerosis. Evidence shows that they also contribute to bone loss by inhibiting differentiation and PTH receptor (PTH1R) expression in osteoblasts. We recently found that bone anabolic effects of PTH(1-34) are blunted in hyperlipidemic mice and that the PTH effects are restored by antioxidants. However, it is not clear which bone cell types are the targets of PTH(1-34) and/or inflammatory bioactive lipids. To investigate the effects of hyperlipidemia at the cellular level, hyperlipidemic *Ldlr*$^{-/-}$ mice were bred with Col3.6GFPtpz mice, in which preosteoblasts/osteoblasts carry a topaz fluorescent label, and with Col2.3GFPcyan mice, in which more mature osteoblasts/osteocytes carry a cyan fluorescent label. Daily PTH(1-34) treatment induced parameters of cortical bone growth, as expected, in Tpz-WT and Cyan-WT mice, but not in the Tpz-*Ldlr*$^{-/-}$ or Cyan-*Ldlr*$^{-/-}$ mice. Histological analyses of trabecular bone surfaces in femoral as well as calvarial bones showed that PTH(1-34) increased fluorescence intensity in WT-Tpz mice, but not in Tpz-*Ldlr*$^{-/-}$ mice. In contrast, PTH(1-34) did not alter fluorescence intensity in femoral cortical envelopes of either WT-Cyan or *Ldlr*$^{-/-}$-Cyan mice. To test the inhibitory mechanisms of bioactive lipids on PTH1R expression preosteoblasts, MC3T3-E1, were used. Treatment of cells with bioactive lipids induced intracellular oxidant stress and inhibited PTH1R expression, which was rescued by pretreatment with the antioxidant, Trolox. The inhibitory effects on expression of PTH1R as well as PTH-induced osteoblastic genes were mimicked by xanthine/xanthine oxidase, a known generator of reactive oxygen species. These findings suggest an important role of preosteoblasts as the target cells and downregulation of PTH receptor expression mediated by intracellular oxidant stress as the mechanisms in hyperlipidemia-induced PTH resistance.

Osteoporosis Knowledge, Self-Efficacy, and Health Beliefs among Chinese Men and Women with HIV. Evelyn Hsieh*[1], Liana Fraenkel[1], Elizabeth Bradley[2], Weibo Xia[3], Qu Cui[4], Karl Insogna[5], Taisheng Li[4]. [1]Yale School of Medicine, Section of Rheumatology, USA, [2]Yale School of Public Health, USA, [3]Peking Union Medical College Hospital, Department of Endocrinology, Peoples Republic of China, [4]Peking Union Medical College Hospital, Department of Infectious Diseases, China, [5]Yale University School of Medicine, USA

Prior studies demonstrate reduced bone density and increased rates of fracture among patients with HIV. Validated scales exist for measuring knowledge, self-efficacy for behavioral change, and health beliefs related to osteoporosis, but have not yet been applied to populations with HIV. Better understanding of these factors can help increase the effectiveness of osteoporosis interventions.

Subjects were drawn from a multi-center trial in China comparing 3 antiretroviral regimens. Volunteers completed a questionnaire with 6 sections including: 1. Fracture risk assessment, 2. International Physical Activity Questionnaire (IPAQ), 3. Calcium and vitamin D intake scale, 4. Osteoporosis Knowledge Test (OKT), 5. Osteoporosis Self-Efficacy Scale (OSES), and 6. Osteoporosis Health Beliefs Scale (OHBS). Demographic data were obtained from the parent study.

In total 245 subjects participated (182 men, 63 women). Median age (37 yrs), and average BMI (21.7 ± 0.2 kg/m2) were similar for both sexes. Men were more educated and more likely to report smoking (51.2 v. 5.3%, p=0.000) and alcohol use (26.7 v. 12.3%, p=0.030) than women. Calcium and vitamin D supplement use was low for both sexes (7.6 v. 12.0%, p=0.294; 9.4 v. 6.9%, p=0.789). Moderate physical activity level was most common (41.1 v. 44.6%, p=0.643). On average subjects reported consuming calcium and vitamin D rich foods less than once a week. OKT scores were low for both sexes, yet OSES scores reflected self-confidence regarding ability to adopt behavioral change (Table 1). Subjects felt neutral regarding personal susceptibility to and seriousness of an osteoporosis diagnosis. Perceived benefits of exercise and calcium intake were high for all subjects, however men perceived fewer barriers to exercise and calcium intake compared with women. Both sexes reported high health motivation scores (Table 1). Multiple regression analysis adjusted for age, sex and BMI showed that intake of calcium and vitamin D rich foods was directly correlated with OKT and OSES calcium score, whereas physical activity correlated with higher OSES exercise score and lower education level, but not with OKT exercise score.

Knowledge regarding osteoporosis is low among Chinese men and women with HIV, and women perceive more barriers to behavioral change than men. Calcium and vitamin D intake and physical activity levels have unique predictors. Understanding these associations may aid in the development of targeted behavioral interventions.

Test	Men (N=182)	Women (N=63)	*p-value*
Osteoporosis Knowledge Test [a]			
Exercise *mean ± SEM*	6.2 ± 0.3	6.0 ± 0.5	0.769
Calcium *mean ± SEM*	6.5 ± 0.3	6.5 ± 0.4	0.990
Osteoporosis Self-Efficacy Test [b]			
Exercise *median (IQR)*	66.7 (41.7-85)	76.7 (53.3-91.7)	0.789
Calcium *median (IQR)*	66.7 (43-80)	80 (55-95)	0.760
Osteoporosis Health Beliefs Scale [c]			
Perceived susceptibility *median (IQR)*	16 (12-18)	17 (13-19)	0.305
Perceived seriousness *median (IQR)*	18 (16-21)	18 (16-21)	0.545
Perceived benefits - exercise *median (IQR)*	24 (19.5-24)	22.5 (18-25)	0.313
Perceived benefits - calcium *median (IQR)*	22 (19-24)	22 (18-24)	0.544
Perceived barriers - exercise *median (IQR)*	16 (12-18)	18 (15-19)	0.010
Perceived Barriers - calcium *median (IQR)*	16 (13-18)	18 (14-19)	0.005
Health Motivation *median (IQR)*	23 (19-24)	23 (20-25)	0.656

a. Scale range: 0 (lowest) to 16 (highest)
b. Scale range: 0 (not at all confident) to 100 (very confident)
c. Scale range: 6 (strongly disagree) to 30 (strongly agree)

Macrophages support proliferation, invasion, and angiogenesis in thyroid cancer. Sun Wook Cho*[1], Sun Kyoung Han[2], Hyun Jin Sun[1], Ka Hee Yi[2], Young Joo Park[2]. [1]Department of Internal Medicine, National Medical Center, South Korea, [2]Department of Internal Medicine, Seoul National University College of Medicine, South Korea

Bone has an essential part in tumor progression by supplying numerous types of bone marrow cells to the tumor microenvironment. Among them, a subset of macrophages (tumor associated macrophages, TAMs) has been identified as having an important role in the progression of several human cancers. However, their characteristics and biological mechanisms still remain elusive. The purpose of this study was to determine the role of bone marrow-derived macrophages in thyroid cancer. First, we performed an in vitro experiment with a human thyroid cancer cell line (BHP10-3) and mouse primary bone marrow (BM) derived macrophages. Co-culture of BHP10-3 with the macrophages showed a significant increase in tumor cell survival and a decrease in cell apoptosis compared to a culture of BHP10-3 alone. Cell migration and invasion were enhanced in the BHP10-3/macrophage co-cultured group

compared to the BHP10-3 alone group. Furthermore, treatment with conditioned medium (CM) from the BHP10-3/macrophage co-culture group significantly enhanced tube formation potentials in human endothelial cells (HUVEC) compared to the control CM from the BHP10-3 alone group. Altogether, BM derived macrophages support tumor cell survival, invasion, and angiogenesis in vitro. Subsequently, we performed in vivo ectopic tumor implantation with nude mice. Co-transplantation of BHP10-3 and macrophages produced significantly bigger-sized tumors compared to the transplantation of BHP10-3 alone, which were attenuated by inducing the apoptosis of phagocytic cells by administrating clodronate liposomes. CD31 and VEGF-A gene expression correspondingly increased in tumors co-transplanted with macrophages compared to BHP10-3 cells transplanted alone. These changes were inhibited by the treatment of clodronate liposomes. Finally, to further characterize TMAs in thyroid cancer, macrophages (pre-stained with PKH26 dye) were sorted from tumor xenografts by flow cytometry, followed by gene expression analyses. Genes associated with alternatively activated macrophages (M2 type) (IL-10, IL-4, TGFβ, CD163), efferocytosis (clearance of apoptotic cells) (Scavenger receptor A, mannose receptor, Mer, Mer-6E) and angiogenesis (CD31, VEGF-A, MMP9) were up-regulated in macrophages from thyroid cancer xenografts compared to non-transplanted macrophages. In summary, BM derived macrophages promote tumor growth and angiogenesis in the thyroid cancer microenvironment through M2 polarization. These findings, herein, suggest a novel function of BM derived macrophages in a tumor microenvironment and a potential therapeutic target in human thyroid cancer.

T-type Voltage Sensitive Calcium Channel (T-VSCC) Is a Key Player in Load-Induced Bone Mechanotransduction and a Novel Target for Osteoarthritis Treatment. Padma Srinivasan*[1], Andris Kronbergs[2], Christopher Price[1], Liyun Wang[1], Randall Duncan[1], Catherine Kirn-Safran[1]. [1]University of Delaware, USA, [2]IU School of Medicine, USA

Involvement of subchondral bone in osteoarthritis (OA) is well established, as indicated by the presence of osteophytes and subchondral bone sclerosis in late OA patients. It is known that soluble metabolites released from mechanically stimulated osteoblasts enhance catabolic changes in the adjacent cartilage tissue.

In this study, we used a genetically-engineered mouse model carrying a null mutation for the pore forming subunit of the T-type voltage sensitive calcium channel (T-VSCC, also known as Cav3.2) to demonstrate that reduced mechanosensitivity in T-VSCC subchondral bone is chondroprotective. In addition, we show that T-VSCC is essential for the anabolic response of bone cells to load. Selective inhibition of T-VSCC in murine osteoblastic cells (MC3T3) prior to fluid shear stress (FSS ~3.5 dynes/cm^2 for 2 hours) significantly reduced the expression of genes such as cyclooxygenase 2 (*Cox2*) and osteopontin (*Spp1*) that are known to be initiators of a pro-inflammatory response and bone formation. Additionally, treatment of chondrocytes with conditioned media (CM) obtained from sheared MC3T3 cells induced expression of markers of hypertrophy. This early osteoarthritic response was nearly abolished when primary chondrocytes were treated with CM obtained from MC3T3 cells sheared in the presence of a specific inhibitor of T-VSCC. These results indicate that T-VSCC is upstream to the release of catabolic factors from osteoblasts and therefore can serve as a target for blocking subchondral bone-induced cartilage degeneration in OA.

To understand the link between T-VSCC and OA, we compared OA damage in T-VSCC knockout and control mice using a load-induced OA model (Fig.1A&B) modified from Poulet et al., 2011 [1]. OA histological scores obtained in knees subjected to the loading regimen shown below (Fig. 1C) indicate that T-VSCC knockout mice exhibit smaller OA damage than the wild-type age-matched controls. Together our data strongly support the idea that T-VSCC plays an important role in the joint response to injury related to posttraumatic OA. Ongoing studies will determine whether pharmaceutical blocking of T-VSCC may be used as a novel therapeutic approach for treating patients at risk to develop OA, such as young adults who suffer from abnormal joint loading due to previous joint injury.

Maturity-Sensitivity of Physical Activity on Skeletal Growth: A 15-year Mixed-Longitudinal Analysis. Brittney Bernardoni*[1], Tamara Scerpella[2], Jodi Dowthwaite[3], Quefeng Li[1], Sijian Wang[4]. [1]USA, [2]University of Wisconsin, USA, [3]SUNY Upstate Medical University;Syracuse University, USA

PURPOSE: To examine the maturity-sensitivity of physical activity on site-specific bone acquisition during growth; to quantify maintenance of skeletal benefits to early adulthood.

METHODS: Female gymnasts and non-gymnasts provided >15y of longitudinal data. Gymnasts were divided into 2 maturational activity exposure groups: PERI, quit gymnastics -1 to +1y peri-menarche (-0.1 ± 0.4 y); and POST, quit >1.75y post-menarche (4.1 ± 1.9 y). Subjects underwent annual whole body and regional (forearm, hip, lumbar spine) DXA scans; anthropometrics, gymnastics exposure (gym hrs), physical activity (PA) and maturity were assessed simultaneously. Multilevel modeling analyzed group differences in bone growth, controlling for bone size, age at menarche and non-gymnastics organized PA; data was centered at menarche (men age=0).

RESULTS: 56 subjects (n=33 NON, n=10 PERI, n=13 POST) provided growth data from men age -2y to +8y. Mean gym hrs for PERI and POST did not differ except during +1 to 2y (as PERI were quitting gymnastics). Height and lean mass means differed only for +6 to 7y, when NON were taller than POST ($p < 0.05$).

At both radius and femoral neck, gymnastics participation produced advantages in geometry, bone mineral content (BMC) and strength from men age -2 to 8y; advantages were maintained to young adulthood (5-80%, men age +8y). Distal radius metaphyseal area was increased in PERI vs. NON, with no additional benefit for POST. With continued exposure, POST gained additional metaphyseal and diaphyseal BMC (advantage vs. PERI, men age +2y=7-10%, $p<0.05$), and tended to improve diaphyseal area (advantage over PERI, men age +1y=3.5%, p=0.06; men age +2y=4.5%, p=0.09). These adaptations yielded large skeletal strength advantages for POST vs. NON at +7 to 8y: UD IBS=11% ($p<0.01$) and 1/3 Z=74% ($p<0.0001$). Proximal femur narrow neck (NN) strength adaptations were a product of smaller NN width and endosteal diameter, yielding advantages in cortical thickness (CT), BMC and buckling ratio. PERI had 8% greater CT vs. NON at men age +4y (p=0.037). Continued exposure gave POST even greater advantages at men age +4y (8% BMC, 13% CT, 13.5% BR, $p<0.001$) and +8y (5% BMC, 11% CT, 14.4% BR $p<0.05$). We did not identify maturity-specific loading effects at lumbar spine or total body.

CONCLUSIONS: Skeletal advantages to exercise during growth are site-specific and maturity-sensitive. Advantages persist to early adulthood, even with peri-menarcheal activity cessation.

Could casein kinase-2 interacting protein-1 (CKIP-1) be postulated as a molecular target for promoting aged fracture repair in females?. Jin Liu*[1], Baosheng Guo[1], Yixin He[1], Lei Dang[1], Xiaohua Pan[2], Lingqiang Zhang[3], Aiping Lu[1], Ge Zhang[1]. [1]Institute for Advancing Translational Medicine in Bone & Joint Diseases, School of Chinese Medicine, Hong Kong Baptist University, Hong Kong SAR, China, Hong Kong, [2]Jinan University & Hong Kong Baptist University Joint Laboratory of Innovative Drug Development, Institute of Biomedicine (Guangzhou); Department of Orthopedics in Second Hospital of Medical College (Shenzhen), Jinan University, China, China, [3]Beijing Institute of Radiation Medicine, State Key Laboratory of Proteomics, Beijing Proteome Research Center, Beijing, China, China

Aim: CKIP-1 plays an important role in regulating BMP signaling through interacting with Smurf1 to enhance Smad1/5 degradation and its gene-deficient mice exhibit accelerated osteogenesis (Lu et al., Nat Cell Biol, 2008). The purpose of this study was to not only compare the difference in CKIP-1 within female callus between aged and adult fractured patients/mice, but also investigate the relationship between CKIP-1 and angiogenesis/osteogenesis during fracture across adult and aged mice.

Materials and methods: Callus specimens from 19 female fractured patients (Table 1) undergoing surgery to treat malreduction were collected and randomly divided into the aged group (65–80 years; n=11) and adult group (40–50 years; n=8). The specimens were subjected to western blotting for quantifying protein expression of CKIP-1, Smurf1 and Smad1/5. Radiographic/clinical union time of the fracture site was recorded, respectively. Bilateral femur transverse fractures were created in 20 female 15-month-old mice (aged group) and 20 female 15-week-old mice (adult group). At post-fracture week 2 and 4, ten mice in each group were sacrificed and all the calluses from left femurs were subjected to western blotting for quantifying protein expression of CKIP-1, Smurf1 and Smad1/5. 3-D Micro-CT analysis was performed on the callus specimens from right femurs in both groups for evaluating callus neovascularization at post-fracture week 2 and callus mineralization at post-fracture week 4.

Results: There was higher CKIP-1 expression and lower Smad1/5 expression in female callus from aged patients/mice when compared to adult ones, whereas no significant difference was found in Smurf-1 expression between aged and adult groups in patients and mice (Figure 1). The time of radiographic/clinical union was delayed in aged patients when compared to that in adult ones (Left, Figure 2). Micro-CT-based angiography showed fewer and smaller blood vessels in aged mice at early stage when compared to those in the adult mice. Reconstructed calluses showed lower bridging mineralization tissues within the gap in aged mice than adult mice at the later stage (Right, Figure 2). The CKIP-1 expression level was negatively correlated with the vessel volume and the bone mineral content (Figure 3).

Conclusions: CKIP-1 could be further postulated as a molecular target for promoting fracture repair in aged females.Key words: CKIP-1; Aged fracture repair

LB-MO04

The interaction of force and repetition on bone and cartilage in an operant rat model of work-related musculoskeletal disorders. Vicky Massicotte*[1], Steven Popoff[2], Sean Gallagher[3], Jeffrey Driban[4], Ann Barr-Gillespie[5], Mary Barbe[2]. [1]Temple University, USA, [2]Temple University School of Medicine, USA, [3]Auburn University, USA, [4]Tufts Medical Center, USA, [5]Pacific University, USA

The relationship of musculoskeletal risk factors (force and repetition) on bone and cartilage was examined for the first time using an operant rat model of repetitive reaching and pulling. We examined changes in the distal radial metaphysis and articular cartilage occurring with performance of a handle-pulling task for 12 weeks at one of four repetition and force levels: 1) low repetition low force (LRLF), 2) high repetition low force (HRLF), 3) low repetition high force (LRHF), or 4) high repetition high force (HRHF). Rats performed one of these tasks for 12 wks, 2 hrs/day, in four 30 min sessions/day, with 1.5 hr breaks between sessions, 3 days/wk. Results were compared between task groups and to age-matched controls. MicroCT of the radial metaphysis showed a force x repetition interaction effect (2-way ANOVA: $p<0.0001$), with a significant decrease in trabecular bone volume (BV/TV) in the radial metaphysis of HRHF rats ($p<0.01$, compared to the other groups), while the HRLF rats showed a trend towards an increase in trabecular bone volume. Serum CTX, measured using ELISA, showed a force x repetition interaction effect (2-way ANOVA: $p=0.04$), with increased levels in HRHF rats ($p<0.01$, compared to the other groups). Serum osteocalcin showed a force x repetition interaction effect (2-way ANOVA: $p<0.0001$), with increased levels in LRHF and HRLF rats ($p=0.05$ compared to the other groups). In the distal radius articular cartilage, histological Mankin scoring showed a force x repetition interaction effect (2-way ANOVA: $p=0.002$), with increased pathology in 12-week HRHF rats ($p=0.05$, compared to the other groups). These pathological changes included loss of proteoglycan content (reduced Safranin O staining), altered tidemark regions and presence of subchondral cysts. Taken together, these results show a significant interaction between the critical musculoskeletal risk factors of force and repetition, consistent with a fatigue failure process in musculoskeletal tissues. This is demonstrated by the catabolic responses in the bone and cartilage of the distal radius in response to 12 weeks of HRHF loading. Thus, high force tasks exhibit a rapid escalation in risk for musculoskeletal disorders when combined with high repetition. In contrast, the distal radial bone demonstrated an anabolic response to 12 weeks of HRLF and LRHF loading, a finding that indicates that bone can adapt to these moderate demand tasks.

LB-MO05

Disuse sufficient to cause bone loss increases osteocytes' expression of sclerostin but has no effect on osteocyte RANKL. Peter Delisser*[1], Lee Meakin[1], Gabriel Galea[1], Lance Lanyon[2], Larry Suva[3], Joanna Price[1]. [1]University of Bristol, United Kingdom, [2]Royal Veterinary College, United Kingdom, [3]University of Arkansas for Medical Sciences, USA

The recent report[1] that, in mice at least, osteocytes are a major source of RANKL has led to the inference that it is by this means that these mechanically-responsive cells influence osteoclast recruitment, differentiation and activation in the processes of mechanically-related control of bone mass and architecture. This assumption appears to be supported by the finding that mice lacking RANKL do not show bone loss with tail suspension.

We attempted to relate changes in expression of RANKL and sclerostin in osteocytes with disuse-related bone loss associated in tibias of mice in limbs paralysed by unilateral sciatic neurectomy.

Seventeen week old female C57BL/6 mice underwent right sciatic neurectomy and left sham operation. They were sacrificed in groups; for qRT-PCR analysis for RANKL and SOST on day 3 (n=7) and day 14 (n=8), immunolocalisation of RANKL and sclerostin (n=4, day 4) and for microCT assessment of bone loss (n=8, day 21).

As expected, disuse as a consequence of sciatic neurectomy was associated with a significant loss of bone both in the proximal cancellous region (BV/TV -44.5%, $p<0.001$) and in the cortical compartment (-18.5% $p<0.001$ at 37% of their length from their proximal ends). Disuse had no effect on the periosteally enclosed area at this level (+2.7%, p=0.09), while cortical bone area was reduced (-11.6% $p<0.001$) and medullary area expanded (+29.3% $p<0.001$). The number of sclerostin immunopositive osteocytes was increased 4 days after neurectomy (+35.8% $p<0.01$) and osteocyte sclerostin mRNA expression elevated (+118% $p<0.05$) at day 14. In contrast, RANKL mRNA expression was unchanged between control and paralysed limbs at 3 and 14 days (+8.3%, p=0.76 and -21.2%, p=0.23). RANKL immunolocalisation was similarly unaffected (-0.2%, p=0.97 at 4 days).

These data support previous studies[2] showing that osteocytes respond to reduced loading in their surrounding matrix by increasing secretion of sclerostin.

The absence of any changes in RANKL with disuse suggests that RANKL is not involved in this resorption response, an observation that is incompatible with the view that RANKL derived from osteocytes is a necessary or universal influence in the recruitment, differentiation or activity of osteoclasts.

LB-MO06

Relationship between cortical bone porosity and mechanical properties in children with osteogenesis imperfecta : a preliminary study. Wafa Skalli*[1], Dominique Saletti[1], Clayton Adam[1], Vasiliki Vardakastani[1], Jean-Marc Allain[2], Pierre Mary[3]. [1]Arts et Métiers ParisTech, France, [2]Ecole Polytechnique, France, [3]Hôpital Armand Trousseau, France

Osteogenesis Imperfecta (OI) is a bone disease caused by abnormal type I collagen synthesis, resulting in increasing bone porosity and fragility. While subject specific biomechanical models could help in bone strength assessment for these patients, the necessary *in vivo* assessment of subject specific bone material properties is a major challenge, particularly for children. During surgery, very small bone fragments can be collected, allowing for mechanical testing at a mesoscopic (few millimeters) scale. In order to progress towards quantitative OI bone assessment in vivo, the aim of the current study is to search for correlations between cortical bone mechanical properties and microarchitecture.

Residual lower limb bone fragments were collected from 3 OI patients (age 3 to 7 years old, all under bisphosphonate treatment) after ethical committee approval and written consent. Fragments were wrapped in saline soaked gauze and fresh frozen at -18 ℃, then thawed at 6 ℃ and cut into parallelepiped samples. Depending on the initial fragment size, 1 to 3 samples per patient could be tested (total = 6), with dimensions varying from 5 to 7 mm in the longitudinal bone direction and from 1.3 to 4.3 mm in transverse directions. Compressive tests were performed at a strain rate of 0.1 $\%.s^{-1}$. Digital image correlation was used to quantify stress strain curves, Young modulus (E) and ultimate stress (σ_{max}). Specimens were then prepared for polarized light microscopy: fixation in 10% phosphate buffered formalin, dehydration, embedding in low viscosity resin, and milling to a thickness around 300 µm. Transmitted polarized light microscopy allowed characterization of collagen arrangement and pore size, and calculation of areal porosity.

Values for E and σ_{max} were highly variable, ranging respectively from 0.21 to 6.70 GPa (mean 2.89 GPa) and from 1.25 to 90.4 MPa (mean = 30.47 MPa). Mean areal porosity ranged from 9.2% to 14.5 %. Asymmetrical pores with dimensions often exceeding 100mm were observed. Strong correlations were found between porosity and both E ($r^2 = 0.9262$) and σ_{max} ($r^2 = 0.9598$).

These are preliminary results with only 6 samples. However for the first time, meso-scale mechanical properties of paediatric OI bone have been quantified, and a strong correlation found with porosity. The pore size often exceeds the resolution of existing in vivo pQCT technologies, which opens the way for in vivo quantification of OI bone and its subject specific modeling.

Cortical Porosity in Perimenopausal Female Patients with Fragility Fractures. Heinrich Resch*[1], Teresa Stanek[2], Janina Patsch[3], Afrodite Zendeli[4], Judith Haschka[5], Roland Kocijan[5], Christian Muschitz[6]. [1]Medical University Vienna, Austria, [2]The Vinforce Study Group KH Barmherzige Schwestern Vienna, Austria, [3]Medical University of Vienna, Austria, [4]The VINFORCE Study Group - St. Vincent Hospital - Medical Department II, Austria, [5]St. Vincent Hospital Vienna, Austria, [6]St. Vincent's Hospital, Austria

Objectives: There is increasing evidence that cortical bone loss producing porosity starts before menopause. The relatively slow loss of cortical bone volume, which is four-fold larger than trabecular bone volume accounts for 70 percent of all bone loss and the occurrence of peripheral fractures in younger age. Aim of this study was to investigate bone micro structure, i.e. cortical and trabecular structure in perimenopausal patients with atraumatic peripheral fractures.

Materials and Methods: We consecutively investigated 26 treatment naive female patients (23-59 yrs) with atraumatic peripheral fractures and T-scores being above the threshold of -2.5 SD at lumbar spine and hip. Structural parameters of cortical and trabecular compartments were analysed by HR-pQCT (Xtreme CT, SCANCO Medical, Switzerland) at the distal radius and the distal tibia. These data were compared to a control group consisting of 38 healthy female individuals in the same age range (23-60 yrs).

Results: BMD values at hip and spine measured by DXA were similar in both groups. Structural analysis showed significant differences between patients and the healthy group in cortical parameters, both for the radius and the tibia. At the radius patients had increased cortical pore volume (Ct.Po.V [mm^3]) (7.74 $\pm$ 4.97 vs 5.29 $\pm$ 3.78; $p < 0.01$), increased cortical pore diameter (Ct.Po.Dm [µm]) (0.17 $\pm$ 0.03 vs 0.15 $\pm$ 0.02; $p < 0.01$) and an increased distribution of cortical pore diameters (Ct.Po.Dm.SD [µm]) (0.07 $\pm$ 0.03 vs 0.06 $\pm$ 0.01; $p < 0.01$). At the tibia in addition to Ct.Po.V (61.15 $\pm$ 30.66 vs 37.33 $\pm$ 20.85; $p < 0.01$) also cortical porosity (Ct.Po [%]) (7 $\pm$4 vs 4 $\pm$ 3; $p < 0.01$) was increased. The most striking significance was found at the radius for the cortical pore diameter and at the tibia in the cortical pore volume . The trabecular indices were similar in patients and controls. The strongest correlations were found within the healthy group between cortical porosity and age at the tibia (r = 0.87) and the radius (r = 0.74). In the patient group there was a significant correlation at the tibia between age and Ct.Po (r= 0.66) and Ct.Po.V (r = 0.68).

Summary: In perimenopausal women cortical bone is more dismantled than trabecular bone especially at the tibia. This increase of cortical porosity may be an explanation for the higher susceptibility to peripheral fragility fractures in younger females.

XBP1S, a BMP2-inducible transcription factor, Accelerates Endochondral Bone Growth by activating GEP Growth Factor. Fengjin Guo*, Xiaofeng Han, Peng Zhang, Zhangyuan Xiong, Meiling Li, Fei Xia. Chongqing Medical University, Peoples Republic of China

In this study,we report that XBP1S is a key downstream molecule of BMP2,and it is required for BMP2-mediated chondrocyte differentiation.XBP1S is upregulated during chondrocyte differentiation and demonstrates the temporal and spatial expression pattern during skeletal development,the expression profile of XBP1S is closely linked to the entire chondrogenic period(Fig.1).Overexpression XBP1S stimulates chondrocyte differentiation in vitro and endochondral ossification ex vivo.XBP1S significantly stimulated chondrocyte hypertrophy,mineralization,and bone length(Fig.2).The result of genome-wide DNA chip analysis showed that approximately 50 genes were up-regulated(2-fold) by BMP2,including XBP1S.The realtime PCR results showed that XBP1S mRNA is up-regulated 3-fold by BMP2.Besides,reductions of the endogenous XBP1S by siXBP1S adenovirus sharply decrease chondrogenic responses induced by BMP2,including ColII,ColX,SOX9 and RUNX2 expression.These results support the concept that XBP1S is a BMP2-inducible transcription factor and required for BMP2-mediated chondrocyte differentiation(Fig.3).In addition,XBP1S activates granulin-epithelin precursor(GEP) growth factor and induces GEP expressions in the process of chondrogenesis(-Fig.4).We next investigated whether endogenous GEP is required for XBP1S-induced chondrocyte development.Realtime PCR result showed that Ad-XBP1S can not promote BMP2-induced ColII,ColX and RUNX2 expression in GEP-/- BMSC cells,however,after infection with Ad-GEP,Ad-XBP1S can increase the expression of ColII,ColX and RUNX2 induced by BMP2 in GEP-/- BMSC cells.It was indicated that Ad-XBP1S activates BMP2-induced chongenesis through GEP. Besides,the effect of XBP1S-induced chondrogenesis and endochondral bone formation largely abolished in GEP-/- BMSC cells,however,it can be largely corrected in the presence of Ad-XBP1S+Ad-GEP.XBP1S recovered the potent stimulating effect of chondrocyte differentiation,mineralization and endochondral bone growth in GEP null growth plates rescued by GEP(Fig.5).Taken together,endogenous GEP is required for XBP1S-stimulated chondrocyte hypertrophy,mineralization,and endochondral bone formation.

In a word,XBP1S acts as a new GEP regulator and increases GEP-stimulated endochondral bone formation:(1)Overexpression of XBP1S stimulates chondrogenesis in vitro and endochondral bone growth ex vivo;(2)XBP1S is a downstream molecule of BMP2 and is required for BMP2 stimulation of chondrogenesis;(3)XBP1S increases GEP expression in chondrogenesis and enhances chondrogenesis through GEP;(4)XBP1S accelerates the chondroinductive activity of GEP.

Effects of Dynamic Hydraulic Flow Loading on Articular Cartilage Alteration against Functional Disuse. Sarah Moy*[1], Yi-Xian Qin[2], Minyi Hu[3]. [1]USA, [2]State University of New York at Stony Brook, USA, [3]Stony Brook University, USA

Introduction: Osteoarthritis patients exhibit a decrease in articular cartilage and the remodeling of the subchondral bone and the calcified cartilage [1]. Since dynamic hydraulic flow loading has been shown to mitigate the loss of bone due to disuse [2], it would be interesting to see how it could affect the thickness of the articular cartilage, which plays a vital role in protecting load-bearing joints. Thus, the objective of this study was to determine the effects of dynamic hydraulic stimulation (DHS) on uncalcified and calcified cartilage thickness in a rat hindlimb suspension (HLS) functional disuse model.

Materials and Methods: Five-month old Sprague-Dawley rats were divided into five groups: 1) baseline control (n=1), 2) age-matched control (n=1), 3) hindlimb suspension (HLS, n=1), 4) HLS+static-loading (n=1), and 5) HLS+2Hz DHS (n=1). Dr. Minyi Hu conducted the daily DHS loading in the mid-tibial region for ''10 minutes on, 5 minutes off, 10 minutes on,'' 5 days per week for a total of 4 weeks. The tibiae were then removed from the rats and embedded in poly-methyl methacrylate (PMMA). To analyze the articular cartilage, the embedded tibiae were sectioned at 5 microns and stained with Safranin O/Fast Green [3]. The stained samples were analyzed using ImageJ to quantify the thickness of the uncalcified (stained as darker red) and calcified cartilage.

Results: The HLS group had a smaller amount of uncalcified cartilage than the baseline group, though, it had a slight increase in calcified cartilage. This could be due to the remodeling of the subchondral bone plate [1]. HLS+2Hz DHS showed a decrease in uncalcified cartilage and an increase in calcified cartilage. However, the results could be heavily influenced by the small sample size per group.

Conclusions: The study does not currently show significance in terms of the effects of DHS on the thickness of articular cartilage. However, it is still an ongoing project which will increase the number of samples per group to increase the statistical power.

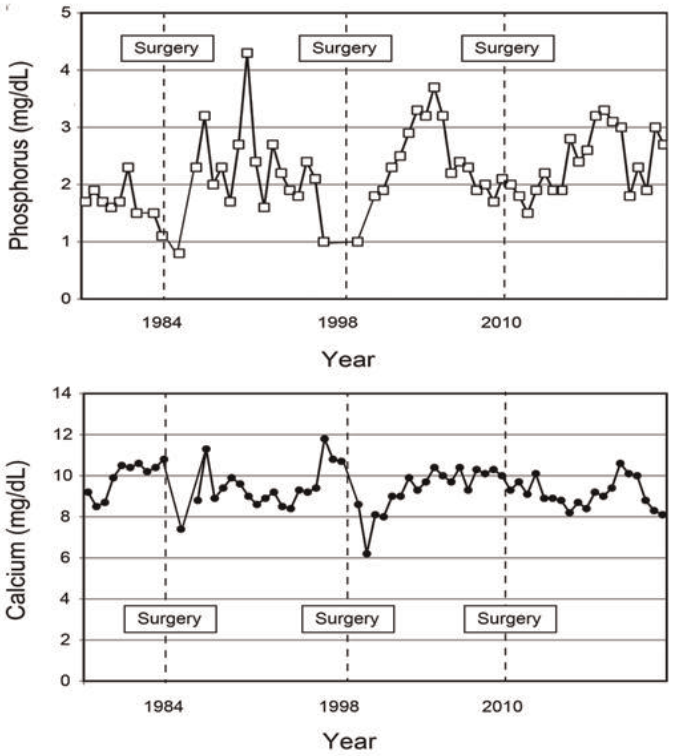
LB-MO10

Role of Parathyroid Function and Phosphate Regulation in a Patient with Tumor-Induced Osteomalacia (TIO). Daniel Cadena*[1], Zinnia San Juan[2], Alan Burshell[3]. [1]USA, [2]Subinvestigator, USA, [3]Ochsner Clinic Foundation, USA

Phosphate regulation is affected by intestinal and renal phosphate handling as well as changes in bone fluxes. Well-known regulators include parathyroid hormone (PTH) and vitamin D. In more recent years, phosphaturia-inducing peptides have been identified as playing a role in both hypophosphatemic and hyperphosphatemic disorders.

A 79-year-old woman followed since age 32, initially presented with muscle weakness, soreness, bone pains, hip and clavicular fractures from 1968 to 1977. Evaluation in 1968 revealed hypophosphatemia (1.4-1.8 mg/dL [normal 2.7-4.5 mg/dL]), phosphaturia (tubular reabsorption of phosphate of 33% [n: 85%]), normal serum calcium (9.2 mg/dL [n: 8.7-10.5 mg/dL]), and elevated alkaline phosphatase (23.2-34.8 KAU [n: 4-12 KAU]). She was treated for hypophosphatemic osteomalacia with increasing doses of phosphate and vitamin D supplements with minimal improvement in phosphorus levels and symptoms. She developed tertiary hyperparathyroidism (serum calcium 10.2-10.8 mg/dL). In 1984, a bone biopsy showed osteomalacia and osteitis fibrosa cystica. Tertiary hyperparathyroidism was treated with parathyroidectomy in 1984 and also in 1998 with subsequent development of hypoparathyroidims. Interestingly phosphate levels normalized with hypoparathyroidsm and declined with tertiary hyperparathyroidsm. In 2009, FGF23 was found to be elevated at 4,850 RU/mL (n: 0-180 RU/mL). In April 2010 knee radiographs revealed a tibial tumor. The biopsy revealed a phosphaturic mesenchymal tumor, and was positive for FGF 23 mRNA by reverse transcription polymerase chain reaction (RT-PCR). The tumor was resected in July 2010. After surgery, calcitriol and phosphorus supplements were resumed, and cinacalcet started. Laboratory results showed normal PTH, calcium, and phosphorus levels and FGF 23 decreased to nadir of 507 RU/mL.

This case illustrates that serum phosphate levels appear to be inversely proportional to the parathyroid hormone in a patient with elevated FGF23 levels and TIO. Tertiary hyperparathyroidism has been reported in TIO and other FGF23 mediated diseases and occurred twice in our patient. Phosphate levels were below normal with tertiary hyperparathyroidism and normalized with surgical hypoparathyroidism on two occasions. Cinacalcet and calcitriol together normalized serum phosphate levels and inhibited PTH secretion. Medical and surgical parathyroidectomy are treatments for TIO and normalize the serum phosphate.



Serum phosphorus and serum calcium levels during surgical interventions

***Asxl1* Plays an Important Role in Bone Remodeling by Regulating both Osteoblasto- and Osteoclasto-genesis Through Histone Modification.** Feng-Chun Yang, Peng Zhang*. Indiana University, USA

Epigenetic mechanisms play an important role in the tissue-specific regulation of gene expression. Histone methylation is one of the most important epigenetic modifications. However, whether histone methylation underlies the physiology and pathophysiology of bone remodeling is not well established. *Additional sex combs* like 1 (*Asxl1*) has been shown to play an important role in both activation and silencing of *Hox* genes through interacting and regulating multiple histone modifying enzymes. Importantly, *ASXL1* is mutated in patients with Bohring-Opitz syndrome (BOS), characterized by severe bone deformities and other developmental deficits. Here, using an *Asxl1*-targeted mouse models, we challenged if deleting *Asxl1* dysregulates critical genes controlling osteoblasto-/osteoclasto-genesis, and bone remodeling through altered histone modifications.

Using qPCR and *Asxl1:GFP* reporter knock-in mice, we found that *Asxl1* is highly expressed in all mesenchymal stem cells (MSC) and preosteoclasts (preOCLs). $Asxl1^{-/-}$ mice are runt and have significantly lower BMD and less trabecular bone volume than WT littermates. $Asxl1^{-/-}$ mice had markedly decreased number of marrow MSCs with skewed differentiation favoring adipocytes, while away from osteoblasts. In contrast, $Asxl1^{-/-}$ preOCLs had increased OCL differentiation and bone resorptive capacity. To delineate the gene expression changes, microarray was performed with MSCs and preOCLs of $Asxl1^{-/-}$ and WT mice. A number of differentially expressed genes in $Asxl1^{-/-}$ MSCs (*Runx2*, *Sp7, Bglap1*) and in $Asxl1^{-/-}$ preOCLs (*Nfatc1*, *Acp5*, *Ctsk*) are implicated in the regulation of osteoblasto-/osteoclasto-genesis, respectively. Wnt5a and receptor tyrosine kinase-like orphan receptor (Ror), key members of non-canonical Wnt/β-catenin signaling pathway, are upregulated in both MSCs and preOCLs derived from $Asxl1^{-/-}$ mice. Furthermore, *Asxl1* loss dramatically reduced the H3K4me3 levels in MSCs and preOCLs. In addition, ChIP-qPCR in WT and $Asxl1^{-/-}$ MSCs and preOCLs showed that the dysregulated gene expression correlated with specifically altered histone methylation patterns across selected gene loci.These results indicate that deletion of *Asxl1* dysregulates histone methylation states and gene expression in MSCs and preOCLs, which in turn alters their differentiation program, leading to bone developmental defects. These results demonstrate a pivotal role of histone methylation in bone homeostasis.

Type 2 receptor-level competition between BMP and Activin ligands regulates postnatal bone mass. Jonathan Lowery*, Giuseppe Intini, Laura Gamer, Karen Cox, Vicki Rosen. Harvard School of Dental Medicine, USA

Recent studies have demonstrated that postnatal bone mass is tightly controlled by the opposing actions of the canonical BMP (SMAD1/5/8) and Activin/TGFbeta (SMAD2/3) pathways: bone formation is increased by BMP signaling and decreased by Activin/TGFbeta signaling. However, the molecular mechanisms that allow these pathways to antagonize one another *in vivo* remain unclear. That the type 2 receptors for Activins (ACVR2A/B) also bind BMPs with high affinity led us to hypothesize that competition between BMPs and Activins at the type 2 receptor level plays a role in determining the balance of SMAD1/5/8 and SMAD2/3 activation *in vivo* and, in turn, regulates bone mass. Here we show that forcing all BMP and Activin signaling in bone cells to compete for ACVR2A/B by removing the BMP-specific type 2 receptor in *Bmpr2*-cKO mice leads to reduced Activin signaling in bone but has no effect on BMP signaling. *Bmpr2*--cKO mice have profoundly high bone mass by 2 months of age (>91% increase over littermates, $p<0.0001$) that is due to an increase in osteoblast (OB) activity and a higher bone formation rate (>101% over littermates, $p<0.02$) with no change in bone resorption. We confirmed the bone mass increase is due to reduced Activin signaling by systemically administering the ACVR2B-Fc receptor decoy, which has been demonstrated to sequester Activins and is currently under investigation as a clinical therapy. Five weeks of this treatment caused a >62% increase in bone mass in wild type mice ($p<0.007$) but had no effect on bone mass in *Bmpr2-cKO* mice, indicating that decreased SMAD2/3 signaling in these mice occurs at the level of pathway activation. Further, we identified MSC/osteoprogenitors as the cell type where receptor competition alters bone mass by comparing the phenotypes of mice lacking BMPR2 in OBs and osteocytes to those lacking BMPR2 in MSC/osteoprogenitors. Our findings suggest that increased utilization of ACVR2A/B by BMPs in osteoprogenitor cells comes at the expense of Activin signaling, providing the first mechanistic insight into the antagonism between SMAD1/5/8 and SMAD2/3 signaling in regulating postnatal bone mass. Our results are potentially informative to numerous human pathologies associated with changes in the balance of these two pathways, including pulmonary arterial hypertension, lung and kidney fibrosis, asthmatic airway remodeling, muscular dystrophy, osteosclerosis, and osteoporosis.

Inflammation and Bone in Early Pubertal Black and White Children. Paige Berger*[1], Emma Laing[1], Stuart Warden[2], Kathleen Hill Gallant[3], Dorothy Hausman[1], Ralph Tripp[1], George McCabe[3], Connie Weaver[4], Munro Peacock[5], Richard Lewis[1]. [1]The University of Georgia, USA, [2]Indiana University, USA, [3]Purdue University, USA, [4]Purdue University, Dept of Nutrition Science, USA, [5]Indiana University Medical Center, USA

Inflammation is thought to influence bone properties, yet few studies have examined the relationships between inflammatory markers and bone in humans. The purpose of this cross-sectional study was to investigate the associations between serum inflammatory markers and serum markers of bone metabolism and cortical bone in black and white boys and girls. Fasting blood samples were collected from 314 healthy, early pubertal children (n=155 male; n=164 black). Luminex xMAP technology was used with a Milliplex Map immunoassay to analyze samples for markers of inflammation believed to influence bone turnover (monocyte chemoattractant protein-1 [MCP-1], interleukin-6 [IL-6], tumor necrosis factor-alpha [TNF-alpha], and vascular endothelial growth factor [VEGF]). ELISA was used to measure serum osteocalcin (OC) and bone alkaline phosphatase, RIA for 25-hydroxycholecalciferol (25[OH]D) and 1,25-dihydroxycholecalciferol (1,25[OH]2D), IRMA for parathyroid hormone (PTH), and a clinical analyzer was used for calcium (Ca) and creatinine (Cr). Peripheral quantitative computed tomography (pQCT) was used to assess cortical bone of the tibial diaphysis. Bivariate and partial correlations controlling for race and percent body fat were conducted among outcome variables. MCP-1 was positively associated with 25(OH)D ($r=0.28$, $P<0.0001$) and negatively associated with OC ($r=-0.13$, $P=0.03$) and PTH ($r=-0.15$, $P=0.01$). MCP-1 was also negatively associated with pQCT-derived cortical volumetric bone mineral density ($r=-0.22$, $P=0.0003$), endosteal circumference ($r=-0.13$, $P=0.03$), and polar strength-strain index ($r=-0.14$, $P=0.03$). IL-6 was positively associated with OC only ($r=0.18$, $P=0.003$). When race was added as a covariate, these relationships were no longer significant. There were no significant correlations between TNF-alpha or VEGF and bone biomarkers or cortical bone measures. Given the lack of research in the area of inflammatory markers and bone in humans, these relationships warrant further exploration.

Mutations in the *SLCO2A1* gene and primary hypertrophic osteoarthropathy: a clinical and biochemical characterization. Zeng Zhang*, Zhen-Lin Zhang. Shanghai Jiao Tong University Affiliated Sixth People's Hospital, China

Context:We previously demonstrated that deficiency of the prostaglandin transporter (SLCO2A1) is a cause of primary hypertrophic osteoarthropathy (PHO). However, its clinical and metabolic characteristics have not been well defined.

Objective: The objective of the study was to expand this mutational spectrum to better delineate the SLCO2A1 deficiency phenotype and investigate the clinical and metabolic characteristics of a cohort of subjects with PHO.

Design, Setting, Patients, and Main Outcome Measure: Eleven affected individuals and their available healthy family members from nine unrelated Chinese families with PHO (seven of which were previously undescribed) were clinically studied. The *SLCO2A1* gene was screened and analyzed. Urinary levels of PGE_2 and PGE-M were measured using competitive enzyme-linked immunosorbent assays. The serum levels of total testosterone, estradiol, sex hormone-binding protein, luteinizing hormone (LH), follicle-stimulating hormone (FSH) and fasting gastrin were detected.

Results: Nine different *SLCO2A1* mutations were identified in affected individuals in the seven previously undescribed families, seven of which (Glu165X, Ala286GlnfsX35, Gln356AlafsX77, Gly369Asp, Gly379Glu, Glu465Lys, and c.861+2T>C) were novel. The urinary levels of PGE_2 and PGE-M were much higher in the SLCO2A1-de?cient individuals and decreased with age. There was no relationship between sex hormones and PGE_2 or PGE-M. There was no significant difference in the levels of fasting serum gastrin between PHO patients with watery diarrhea and their relatives.Conclusions: The present findings broaden the allelic spectrum of *SLCO2A1* mutations. The urinary levels of PGE_2 and PGE-M in the SLCO2A1-de?cient individuals decreased with age. The measurement of excreted PGE_2 and PGE-M may have implications in the differential diagnosis, treatment and follow-up of PHO.

Circulating α-Klotho Levels Are Inversely Correlated to FGF-23 in TumourInduced Osteomalacia. Paul Zeun*[1], Jonathan Tang[2], Christopher Washbourne[2], Isabelle Piec[1], Emily Fisher[3], William Fraser[2]. [1]Dr., United Kingdom, [2]University of East Anglia, United Kingdom, [3]Miss, United Kingdom

Tumour induced osteomalacia is characterised by high circulating levels of fibroblast growth factor 23 (FGF23) due to ectopic secretion from mesenchymal tumors. An abundance of FGF23 drives the hypophosphatemia and low 1,25-dihydroxy vitamin D levels characteristic of this condition. The single-pass trans-membrane protein α-klotho is integral for FGF23-mediated receptor activation and its downstream effects. In addition, α-klotho may have a phosphaturic effect independent of FGF-23. The regulation of α-klotho in the face of high circulating FGF23 is currently unknown.

We investigated the relationship between circulating FGF23 and α-klotho in patients with TIO. We identified 15 consecutive plasma FGF-23 requests in subjects with confirmed TIO for testing. FGF-23 was measured using Immutopics C-term ELISA kit and soluble α-klotho was measured using the IBL ELISA kit. The group consisted of 7 males and 8 females with an age of 53 ± 20 years (mean ± SD). Only one subject was not on treatment for TIO at the time of sampling. The average circulating levels of FGF23 and α-klotho were 286 ± 244 RU/ml and 644 ± 309 pg/ml respectively. There was an inverse correlation between FGF-23 and α-klotho (Pearson coefficient - 0.28). This inverse correlation may suggest that increasing levels of FGF23 in TIO down-regulate α-klotho expression in the kidney and parathyroid glands leading to reduced circulating levels of α-klotho. Given α-klotho's role in mediating FGF23 signalling and that α-klotho may be a phosphaturic factor in its own right; such an adaptive mechanism would help partially reduce the renal phosphate wasting seen in TIO.In summary there is an inverse correlation seen between circulating levels of FGF23 and α-klotho in TIO. This may suggest there is a down-regulation of α-klotho expression to limit the phosphate wasting and resultant hypophosphatemia that is seen in TIO.

Retinaldehyde (Rald) Increases Bone Mass by Repressing PPARγ, Increasing BMP2, and Stimulating Brown- like Adipogenesis: Implications for Treating Obesity and Osteoporosis. Shriram Nallamshetty*[1], Phuong Le[2], Hong Wang[1], Jorge Plutzky[1], Clifford Rosen[3]. [1]Brigham & Women's Hospital, USA, [2]Maine Medical Center Research Institute, USA, [3]Maine Medical Center, USA

New drugs to induce brown-like adipogenesis are being investigated for treating obesity and type 2 diabetes. However, a major off-target effect of such therapies (e.g. FGF-21, rosiglitazone, β3 agonists) is significant trabecular bone loss. Previously we showed that retinaldehyde (Rald), which is converted to retinoic acid by retinaldehyde dehydrogenase 1 (Aldh1a1), induces a thermogenic program in white adipose tissue (WAT) while increasing BMP2 expression in mesenchymal stromal cells (MSCs), thus promoting osteogenic differentiation. *Aldh1a1*$^{-/-}$ mice demonstrate high bone mass, resistance to diet-induced obesity, and ''browning'' of visceral fat *in vivo*. To understand Rald's unique effects on bone and fat, we examined: (1) *in vitro* actions of Rald and RAR/RXR modulators on osteoblast differentiation, and (2) *in vivo* effects of rosiglitazone (rosi) and a high fat diet (HFD) on bone mass, marrow adiposity, WAT, and BAT in Aldh1a1 deficiency. Rald (1 μM) induces alkaline phosphatase (ALP) in ST2 MSCs at day 2 even in the absence of ascorbic acid (AA) and beta glycerolphosphate (BGP). Furthermore, Rald's induction of ALP is blocked by an RAR but not an RXR antagonist. In contrast, Rald decreased ST2 MSC adipogenic differentiation by 80% through inhibitory effects on PPARγ and Cebpα expression. We next treated 18 week-old *Aldh1a1*$^{-/-}$ mice and WT B6 female mice with rosi (20 mg/kg/day for 12 weeks). Rosi increased visceral WAT in WT mice but not *Aldh1a1*$^{-/-}$ mice (50% reduction, $p<0.05$) with no effects on BAT. Similarly, when both strains were administered a HFD, there was a marked blunting in total body weight gain and fat accumulation in *Aldh1a1*$^{-/-}$ mice ($p<0.05$). *Aldh1a1*$^{-/-}$ mice challenged with rosi or HFD had significantly higher femoral BV/TV and less marrow adiposity than WT treated mice ($p<0.05$). Histomorphometry of the rosi-treated mice (n=5 per genotype) revealed an increase in Osteoblast number/Bone Area in the *Aldh1a1*$^{-/-}$ mice (WT: 45.84±16.54; *Aldh1a1*$^{-/-}$: 72.08±33.03; $p=0.15$) and a significant decrease in osteoclast number and OC surface/bone perimeter vs WT ($p<0.001$). In summary, Rald enhances osteogenesis *in vitro* and *in vivo*, reduces osteoclast activation *in vivo*, and protects against diet- induced obesity and rosi-induced marrow adiposity by impairing PPARγ transactivation. These findings support further studies of Rald and Aldh1a1 inhibition of Rald as potential therapies for obesity and osteoporosis.

Ras Signaling Increases the Number of Osteoprogenitor Cells leading to Increased Bone Mass. Garyfallia Papaioannou*[1], Noriaki Ono[1], Simona Nedelcu[2], Jacqueline A Lees[2], Henry Kronenberg[1], Tatsuya Kobayashi[1]. [1]Massachusetts General Hospital, USA, [2]Koch Institute for Integrative Cancer Research, Massachusetts Institute of Technology, USA

Introduction: Ras signaling regulates cellular processes such as proliferation, differentiation and survival. However, its role in bone-lineage cells has not been fully understood. To determine the role of Ras signaling in bone-lineage cells in different differentiation stages, we overactivated the Ras signaling in mature osteoblasts, preosteoblasts and precursor cells of bone lineage using a tamoxifen-inducible, Cre-dependent overexpression system (CreERt). Methods : Mice harboring an expression construct containing a constitutively active mutant Kras gene preceded by a floxed "stop" sequence were crossed with mice expressing CreERt driven by a 3.2 kb-long type I collagen (Col1), an Osterix (Osx), or a type II collagen (Col2) promoter. The activation of the mutant Kras gene was achieved by tamoxifen injection at embryonic day (E) 18.5. Bone samples were analyzed at several time points. To trace the cells expressing Kras oncogene, a fluorescent reporter expressed only after cre activation was also bred in. Cellular proliferation was assessed by the BrdU assay. Results: A short chase experiment using the Col2-CreERt and Cre reporter mice suggested that a small number of Col2-positive cells were present in the bone marrow of perinatal mice. When Kras oncogene was activated in Col2-positive cells at E18.5, mice showed increased trabecular bone and modest growth plate shortening at 3 weeks of age. The number of stromal cells in the primary and secondary spongiosa was substantially increased. The stromal cells were mostly positive for the fluorescent reporter, indicating that they were descendants of Col2-positive cells. These results suggest that Col2-positive cells in the bone marrow are osteoblast progenitors and that overactivation of Ras signaling directly increases their number, leading to an increase in bone mass. The BrdU assay showed increased stromal cell proliferation, suggesting that Ras signaling positively regulates proliferation of bone progenitor cells. In contrast, activation of Kras in Col1-positive mature osteoblasts at E 18.5 did not cause a significant increase in bone mass. Activation of Kras in Osx-positive cells at E18.5 resulted in a bone phenotype similar to but milder than that of the Col2CreERt: Kras mice. Conclusions: Ras signaling increases the number of descendants of Col2-positive osteoprogenitor cells in the bone marrow in early differentiation stages to increase bone mass.

Effects of Calcium-independent Phospholipase A_2 on Differentiation and Activity of Cortical Bone derived Osteoblasts. Bill Hancock*[1], Jason Ashley[2], Gregory Clines[2], Sasanka Ramanadham[2]. [1]University of Alabama, USA, [2]University of Alabama at Birmingham, USA

Arachidonic acid and arachidonate metabolites are recognized mediators of bone modeling. These mediators can be generated by Phospholipases A(2) (PLA(2)) which hydrolyze the sn-2 fatty acid substituent from phospholipids. Most cellular Arachidonic acid is esterified in this position within membrane glycerophospholipids. Previously generated knockout mice, lacking the group VIA PLA(2) (iPLA(2)beta), exhibit an enhanced, age-related decline in cortical bone thickness, trabecular bone volume, and bone mineralizing surfaces. These mice lose mineral apposition by 6-months of age and gain lipid droplets in their bone marrow. Our new studies have shown that, relative to WT cells, osteoblasts differentiated from cortical bone mesenchymal stem cells of knockout mice express lower levels of Runx2 and Alkaline Phosphatase mRNA. This correlates with decreased osteoblastogenesis and osteoblast activity. These differentiated osteoblasts also exhibit reduced mineralization as detected by Alizarin Red staining and quantification. This reduction can be rescued by the treatment of osteoblasts with prostaglandin E2, a common metabolite of Arachidonic acid produced by cyclooxygenase metabolism. Prostaglandin E2 is known to increase osteoblast replication and differentiation. Our studies indicate that reduced differentiation factors and reduced mineralization are induced by knockout of iPLA(2)beta; further demonstrating the role of iPLA(2)beta in mesenchymal stem cell fate and bone remodeling.

Post–Alendronate DXA Monitoring Strategy Based on 5-year Changes in BMD. Brian Mcnabb*[1], Eric Vittinghoff[2], Richard Eastell[3], Ann Schwartz[2], Douglas Bauer[2], Kristine Ensrud[4], Elizabeth Barrett-Connor[5], Dennis Black[2]. [1]San Francisco VA Medical Center, University of California, San Francisco, USA, [2]University of California, San Francisco, USA, [3]University of Sheffield, United Kingdom, [4]Minneapolis VA Medical Center / University of Minnesota, USA, [5]University of California, San Diego, USA

Context: Despite many women being candidates for therapy cessation after 5 years of alendronate, no information exists on how to monitor these women after therapy cessation.

Objective: To estimate the time until femoral neck BMD T-score (FNBMD-T) drops below -2.5 amongst women who have completed 5 years of alendronate therapy.

Design and Setting: Percent change in BMD over time functions were calculated using repeated measures models. These results were used to estimate the number of years until 10-50% of women with various baseline FNBMD-Ts crossed the prespecified FNBMD-T threshold of -2.5.

Participants: Four-hundred and four women who had received an average of 5.1 years of alendronate during the Fracture Intervention Trial (FIT) and were subsequently followed for 5 treatment-free years (on placebo) during the FIT Long Term Extension trial were used to derive functions for the percent change in BMD over time.

Results: Mean 5-year percent decline in BMD was 1.7% at the femoral neck and 3.6% at the total hip. The most rapid rate of bone loss occurred from baseline to year 2, with slower bone loss thereafter (test for this bone loss pattern versus linear bone loss pattern over 5-year period: $p = 0.0009$). For women with slightly higher BMD after stopping treatment, it took far longer for FNBMD-T to drop below -2.5. For example, for those with FNBMD-Ts of -2.1, it took over 5 years v. those with FNBMD-Ts of -2.3, it took 0.7 years for 20% of women to drop below -2.5.

Conclusions: When considering a retreatment threshold after alendronate discontinuation of FNBMD-T of -2.5, measuring BMD by DXA within 5 years of discontinuation is only likely to trigger a management change for women with FNBMD-T $<$ -2.1 at the time of discontinuation.

Table 1: Number of Years (95% CI)* Until 10 to 50% of Women with Femoral Neck T-scores of -2 to -2.4 Drop Below a T-score of -2.5, After 5 Years of Alendronate

Percentages of Patients	Starting T-Scores				
	-2	-2.1	-2.2	-2.3	-2.4
10%	4.9 (3.8 – > 5)	3.7 (2.2 – 4.2)	0.9 (0.5 – 2.1)	< 0.1 (N/A – 0.3)	--------
20%	--------	> 5 (4.4 – N/A)	4.2 (2.2 – 4.8)	0.7 (0.5 – 1.8)	-------
30%	--------	--------	> 5 (4.6 – N/A)	3.4 (1.1 – 4.7)	0.2 (0.1 – 0.5)
40%	--------	--------	--------	> 5 (3.5 – N/A)	0.9 (0.6 – 2.3)
50%	--------	--------	--------	--------	4.8 (1.1 – > 5)

Results are based on the mean and distribution of change in femoral neck BMD over time for women from the FLEX placebo group with femoral neck BMD T-scores +/- 0.25 T-scores from the starting T-score at baseline of the treatment-free period. Each 0.5 T-score window contains a mean of 117 women from the population of 404. The 95% CIs are derived from the bootstrapping method using 100 repetitions.
* Mean, lower, and upper bounds of 95% CI all > 5 or < 0.1 for blank entries.
Abbreviations: CI, Confidence Interval; BMD, bone mineral density; FLEX, Fracture Intervention Trial Long Term Extension trial.

The 2nd Generation of HR-pQCT: Progresses in Bone Microstructure Assessment with 61çm Voxel Size *In Vivo* Scans. Nicolas Vilayphiou*, Stefan Hämmerle, Bruno Koller. Scanco Medical AG, Switzerland

We developed in 2004 a novel high resolution peripheral quantitative tomography (HR-pQCT) scanner dedicated to bone microstructure assessment at the ultradistal radius and tibia. This 1st generation scanner, XtremeCT (XT1, Scanco Medical AG, Bruttisellen, Switzerland), proposes a 2.8min scan over a 9.02mm region, with 82µm voxel size for radiation 3µSv dose [Laib et. al – Bone 1999]. Movement artifacts are known to affect XT1 scans, notably at the radius. They impact dramatically the reproducibility of the measurements, and reduce the number of valid scans in longitudinal studies on bone fragility or osteoporosis treatment efficacy [Pialat et. al – Bone 2011].

We are developing a new HR-pQCT scanner (XtremeCT 2 - XT2) to address the movement artifacts issue. Hardware improvements allow for scan time shortening with no cost on image quality, with 2 different scan protocols over 10mm. The basic protocol was specified to be compatible with XT1: 1.5min scan, 91µm voxel size and 4µSv dose. The 2nd protocol has better resolution and is still affordable for patient scans: 61µm voxel size, 2min scan time and 5µSv dose.

A forearm phantom (Radiology Support Devices, Long Beach, CA) was scanned to compare results across the different scan protocols. XT1 scan was the reference to address compatibility between the two scanners, whereas XT2 scan at native 30µm voxel size served as a gold standard to address the accuracy of all measurements. Lower resolution scans (82 and 91µm) were analyzed with the standard evaluation used in XT1. High resolution scans (61 and 30µm) were completely analyzed with direct transformation methods. Results are presented for Trabecular density (Tb.vBMD), number (Tb.N), thickness (Tb.Th) and bone volume fraction (BV/TV).

The basic XT2 scan gave similar results on trabecular bone as on XT1 excepted for Tb.N where it is lower. Both low resolution scans overestimated Tb.N and under-sestimated Tb.Th. The 61µm scan was more accurate with Tb.N=1.11 and Tb.Th=241, compared to 1.01 and 247 obtained at 30 µm. All results are detailed in the Table.

Reduced scan time should lead to significant improvements regarding movement artifacts on *in vivo* scans. Also a new forearm cast will help to limit patient mobility. Overall, studies on bone deterioration or on osteoporosis treatment efficacy should all benefit from this new scanner. Especially as XtremeCT 2 will make possible 61µm scans for the 1st time in clinical research.

	Scan parameters			Trabecular microarchitecture			
Scanner	Voxel size [µm]	Dose [µSv]	Scan Time [min]	Tb.vBMD [mgHA/ccm]	BV/TV [%]	Tb.N [1/mm]	Tb.Th [µm]
XT 1	82	3	2.8	239	19.9*	1.58	126*
XT 2	91	4	1.5	222	18.5*	1.26	147*
XT 2	61	5	2.0	235	20.9	1.11	241

Adherence to Oral Bisphosphonates and the Risk of Subtrochanteric or Diaphyseal Femur Fractures among US Medicare Beneficiaries with Part D Coverage. John Wang*[1], Michael Ward[1], Timothy Bhattacharyya[1], Leighton Chan[2]. [1]Intramural Research Program, NIAMS/NIH, USA, [2]Rehabilitation Med Dept, Clinical Center, NIH, USA

Long-term use of oral bisphosphonates has been implicated in increased risks of atypical hip fractures located primarily in the subtrochanteric region of the diaphysis. We hypothesized that higher exposure to oral bisphosphonates was associated with an increase in the incidences of subtrochanteric or diaphyseal femur fractures. In this large national cohort study of Medicare fee-for-service female beneficiaries with at-least 24-month part D coverage from 2006-2010, we followed 522,287 new bisphosphonate users from their index prescription until a primary inpatient diagnosis of subtrochanteric/femur shaft (n=948) or typical hip (n=9,382) closed fracture, a switch to another bisphosphonate or different type of anti-osteoporosis medications, disenrollment, or end of the study. Adherence was measured as medication possession ratio (MPR: the proportion of days with prescription filled over days of follow-up), and classified according to: 1) MPR $<$ 1/3 as less compliant, 2) MPR$\geqslant$1/3 - $<$ 2/3 as compliant, and 3) MPR $\geqslant$ 2/3 as highly compliant. Survival analysis was used to determine the cumulative incidence of subtrochanteric/femur shaft fractures with typical hip fractures or mortality as a competing risk. There were dose-dependent increases in incidences of subtrochanteric/femur shaft fractures as the level of adherences increased (Figure, Gray's test, $p<0.0001$). Within the highly compliant group, the age-adjusted rate of subtrochanteric/femur shaft fractures increased from 56.7 per 100,000 person years in the first year to 175.1 in the fifth year, compared to an increase from 44.3 to 66.6 for the less compliant group during the same period. The adjusted hazard ratio for the highly compliant vs the less compliant was 1.23 (95% Confidence Interval: 1.06-1.43) overall, 1.09 (0.89-1.34) before and 2.09 (1.48-2.95) after 3 years of follow-up. Other risk factors included age, prior vertebral fractures, diabetes, inflammatory arthritis, comorbidity index, and statin use. These were also risk factors for typical hip fractures. However, age-adjusted incidence rates of typical hip fractures were significantly lower among highly compliant beneficiaries, compared to less compliant users (e.g., 873.8 vs 1,168.7 after four years, $p<0.03$). In conclusion, subtrochanteric/femur shaft fractures, unlike typical hip fractures, are positively associated with higher adherence to long-term ($\geqslant$ 3 years) prescription of oral bisphosphonates in the elderly female Medicare population.

A Frailty Index Predicts 10-Year Fracture Risk: Longitudinal Data from the Canadian Multicentre Osteoporosis Study (CaMos). Courtney Kennedy*[1], George Ioannidis[1], Lehana Thabane[1], Kenneth Rockwood[2], Jonathan Adachi[3], Susan Kirkland[2], Laura Pickard[1], Alexandra Papaioannou[4]. [1]McMaster University, Canada, [2]Dalhousie University, Canada, [3]St. Joseph's Hospital, Canada, [4]Hamilton Health Sciences, Canada

Purpose: Although the association between frailty and fractures is recognized, this relationship has not been well quantified across a frailty continuum. A Frailty Index is a continuous measure which considers the degree of frailty as proportional to the number of accumulated "health deficits" (symptoms, signs, diseases, and disabilities). This approach correlates well with other frailty measures and offers not only precision (i.e., the ability to differentiate different degrees of frailty), but also generalizability since the framework can be applied to most epidemiological data-sets. Using baseline data from the Canadian Multicentre Osteoporosis Study (CaMos), we created the 31-item CaMos Frailty Index and examined whether it was predictive of incident fractures over 10-years. Methods: CaMos is a prospective cohort study of 9423 randomly selected Canadians aged 25 years and older. Total CaMos Frailty Index scores were derived by summing the deficit score on individual variables (0=absent, 1=maximal expression of deficit) and dividing by the total number of variables (n=31), yielding a score between 0 and 1. We used a competing risk proportional sub-distribution hazards model to examine the association between baseline CaMos Frailty Index scores and 10-year fracture risk adjusting for age, sex, body mass index, education level, femoral neck t-score, and anti-resorptive therapy. Hazard Ratios (HR; *p-values*) are expressed for each 0.10 increase in baseline CaMos Frailty Index score [approximately one standard deviation (SD)]. Results: Our analysis cohort was CaMos participants 50 years and older (n=7753). At baseline, the mean age was 66.7 (SD 9.35) years, 71.8 % were women. The mean Frailty Index score was 0.14 (SD 0.11), ranging from 0 to 0.64. During a mean follow-up of 7.70 years (SD=3.17), 986 participants died before a fracture occurred and 1121 had a fracture. For every 0.10 increase in CaMos Frailty Index scores, the HR was 1.33 ($p=<0.001$) for hip fractures and 1.24 ($p=<0.001$) for all fractures (excluding face, cheek, skull, toe, finger). Conclusions: During the study period (up to ten-years of follow-up), for each 0.10 increase in baseline CaMos Frailty Index score, the risk of a hip fracture increased by 33% and all fractures by 24%. Irrespective of age and bone mineral density, the CaMos Frailty Index is an operational measure of frailty that was predictive of incident fractures.

Mouse models of telomere dysfunction phenocopy skeletal changes found in human age-related osteoporosis. Tracy Brennan*[1], Robert Pignolo[2], Kurt Hankenson[2]. [1]University of Pennsylvania School of Medicine, USA, [2]University of Pennsylvania, USA

A major challenge in the elderly is osteoporosis and the associated high risk of fracture. Telomere dysfunction is a cause of cellular senescence and telomere shortening occurs with age in cells from most human tissues, including bone. Telomere defects contribute to the pathogenesis of two progeroid disorders characterized by premature osteoporosis, Werner syndrome and dyskeratosis congenital, and it is hypothesized that telomere shortening contributes to aging of bone. Using mice with disrupted telomere maintenance molecules, including mutants in the Werner helicase ($Wrn^{-/-}$), telomerase ($Terc^{-/-}$) and $Wrn^{-/-}$ $Terc^{-/-}$ double mutants, we evaluated the skeletal phenotypes as models for human bone aging. Compared to young wild-type mice, micro-computerized tomography (µCT) analysis revealed that young $Terc^{-/-}$ and $Wrn^{-/-}Terc^{-/-}$ mice have decreased trabecular bone volume, trabecular number, trabecular thickness, as well as increased trabecular spacing. In cortical bone, young $Terc^{-/-}$ and $Wrn^{-/-}Terc^{-/-}$ mice have increased cortical thinning, and increased porosity relative to age-matched wild-type mice. These trabecular and cortical changes were accelerated with age in the $Terc^{-/-}$ and $Wrn^{-/-}Terc^{-/-}$ mice compared to older wild-type mice. Histological quantification of osteoblasts in aged mice showed a similar number of osteoblasts in all genotypes. However, analysis of kinetic parameters of bone formation showed a significant decrease in mineralization surface and mineral apposition rate in older $Terc^{-/-}$ and $Wrn^{-/-}Terc^{-/-}$ bone, suggesting that osteoblast dysfunction is a prominent feature of precocious aging in these mice. Except in the $Wrn^{-/-}$ single mutant, osteoclast number did not increase in any genotype. Young $Wrn^{-/-}Terc^{-/-}$ mice had a statistically significant increase in bone marrow fat content compared to young WT, which remained elevated in aged double mutants. Overall, the bone phenotype of $Wrn^{-/-}Terc^{-/-}$ mutant mice is largely accounted for by the contribution of telomerase deficit rather than absence of the Wrn helicase. Taken together, our results suggest that $Terc^{-/-}$ and $Wrn^{-/-}Terc^{-/-}$ mutants recapitulate the human bone aging phenotype and are useful models for studying age-related osteoporosis.

Eight Years of Denosumab Treatment in Postmenopausal Women With Osteoporosis: Results From the First Five Years of the FREEDOM Extension.

Socrates Papapoulos*[1], Kurt Lippuner[2], Christian Roux[3], Jesse Hall[4], David Kendler[5], E. Michael Lewiecki[6], Maria Luisa Brandi[7], Edward Czerwiński[8], Edward Franek[9], Péter Lakatos[10], Carlos Mautalen[11], Salvatore Minisola[12], Jean Yves Reginster[13], Soren Jensen[14], Nadia Daizadeh[4], Andrea Wang[4], Michelle Geller[4], Rachel B. Wagman[4], Henry G. Bone[15]. [1]Leiden University Medical Center, The Netherlands, [2]Bern University Hospital, Switzerland, [3]Paris Descartes University, France, [4]Amgen Inc., USA, [5]University of British Columbia, Vancouver, Canada, [6]New Mexico Clinical Research & Osteoporosis Center, USA, [7]University of Florence, Italy, [8]Krakow Medical Center, Poland, [9]Central Clinical Hospital MSWiA, Poland, [10]Semmelweis University, Hungary, [11]Centro de Osteopatias Medicas, Argentina, [12]Sapienza University, Italy, [13]University of Liège, Belgium, [14]CCBR, Denmark, [15]Michigan Bone & Mineral Clinic, USA

Purpose: Denosumab (DMAb) is an approved therapy for the treatment of postmenopausal women with osteoporosis at high/increased risk for fracture. The effects of DMAb treatment for up to 10 years are being evaluated in the 3-year FREEDOM study and its 7-year extension. Here we report the 5-year results from the extension, representing up to 8 years of continued DMAb treatment.

Methods: During the extension, all subjects received 60 mg DMAb Q6M and daily calcium and vitamin D. In this analysis, subjects in the long-term group received 8 years of DMAb (3 years in FREEDOM followed by 5 years in the extension); subjects in the cross-over group received 5 years of DMAb (3 years of placebo in FREEDOM and 5 years of DMAb in the extension).

Results: Of 3046 subjects who continued to participate in the extension at the time of this submission, 88% (2678; 1382 long-term, 1296 cross-over) of subjects have completed dosing at year 8. Bone mineral density (BMD) data showed continued mean increases from FREEDOM baseline for cumulative 8-year gains of 18.5% (lumbar spine) and 8.2% (total hip) in the long-term group and continued to increase in the cross-over group with cumulative 5-year gains of 13.8% (lumbar spine) and 4.8% (total hip) (all $P < 0.05$ compared with FREEDOM and extension baseline; Figure). Serum C-telopeptide (CTX) was rapidly and similarly reduced after each DMAb dose with the characteristic attenuation of effect at the end of the dosing period. Incidence of new vertebral and nonvertebral fracture continued to remain low throughout the extension; hip fracture incidence during year 8 was 0.2% and < 0.1% for the long-term and cross-over groups, respectively. Overall incidences of adverse events (AEs) and serious AEs were consistent with data reported previously in the extension study.

Conclusions: DMAb treatment for up to 8 years was associated with persistent reduction of bone turnover, continued increases in BMD, and low fracture incidence. Modeling-based bone formation in cynomolgus monkeys in the context of maximal reduction of remodeling may help explain these clinical observations (Ominsky ASBMR 2013 submitted abstract). The benefit/risk profile for DMAb remains favorable.

BPS804, an anti-sclerostin monoclonal antibody, improves disease biomarkers and markers of bone formation in patients with adult-onset hypophosphatasia (HPP).

Lothar Seefried*[1], Jasmin Baumann[1], Sarah Hemsley[2], Shou-Ih Hu[3], Christine Halleux[2], Beate Kiese[4], Yue Huang[2], Steven Golieb[5], Simon Chivers[2], Marie-Anne Valentin[2], Babul Borah[3], Michaela Kneissel[6], Franz Jakob[7], Uwe Junker[2]. [1]Orthopedic Center for Musculoskeletal Research, Experimental & Clinical Osteology, Orthopedic Department, University of Würzburg, Germany, [2]Novartis Institutes for BioMedical Research, Switzerland, [3]Novartis Institutes for BioMedical Research Inc., USA, [4]Novartis Pharma AG, Switzerland, [5]Novartis Pharmaceuticals Corporation, USA, [6]Novartis Institutes for Biomedical Research, Che, [7]Orthopedic Center for Musculoskeletal Research, Experimental & Clinical Osteology, Orthopedic Department, University of Würzburg, Brettreichstraße 11, D-97074 Wuerzburg, Germany

Purpose: Previous case studies of adult-onset HPP patients treated with the bone anabolic molecule PTH1-34 (teriparatide, Forteo™) reported improvement in biochemical disease markers of HPP, bone pain, and accelerated fracture healing. Here, we report the tolerability, PK/PD and efficacy in a Phase 2A trial of the human anti-sclerostin monoclonal antibody BPS804 in patients with adult-onset HPP (ClinicalTrials.gov Identifier: NCT01406977).

Methods: Male and female patients age 18 to 75 years with clinical diagnosis of adult-onset HPP and confirmed *ALPL* genetic mutation were enrolled in this single center, open label trial. Patients received three escalating doses of BPS804 (5, 10, and 20 mg/kg i.v.) every two weeks and were followed for 3.6 months after the last dose. Primary endpoints were number of patients experiencing (serious) adverse events (AEs) and changes from baseline in the serum alkaline phosphatase (ALP) and bone-specific ALP (BSAP) enzymatic activity.

Results: Patients (N=8, mean age 47.8 years) had significantly below gender-matched normal levels of ALP and BSAP. Between days 2 to 29 after the 3rd infusion of BPS804, ALP and BSAP enzymatic activity increased vs. baseline by a mean of 37% (range 19-67%, $p<0.01$) and 30% (range 4-70%, $p<0.01$), respectively. BPS804 also increased bone biomarkers such as PINP, osteocalcin, and lumbar spine bone mineral density while it decreased CTX-1. BPS804 showed a typical PK profile for a human IgG2 lambda monoclonal antibody targeting a soluble ligand (T1/2 ~12 days), with no immunogenicity findings of clinical significance. One patient discontinued early from the study due to a serious AE deemed unrelated to BPS804. Most common AEs were affecting various organ systems (i.e., musculoskeletal and connective tissue, gastrointestinal, nervous system), were mild and transient in nature and mostly unrelated to study drug.Conclusions: BPS804 was generally well tolerated. BPS804 administration resulted in variable increases in ALP and BSAP activity and marked increases in bone formation biomarkers. As shown in this study, responsiveness to BPS804 treatment may vary considerably among adult-onset HPP patients. We hypothesize that osteoanabolic stimulation holds the potential as an effective treatment for bone loss, fragility fractures and fracture healing in genetically confirmed mild forms of HPP such as adult-onset HPP or odontohypophosphatasia, which has to be confirmed in larger clinical trials.

LB-MO28

Comparison of Atypical Femoral Fracture Patients on Long term Bisphosphonates with Controls matched for age and duration of bisphosphonate therapy.

Deeksha Mehta*[1], Nazia Shamsuddin[1], Zehava S. Rosenberg[1], Renata L. Vieira[1], Nirmal C. Tejwani[1], Kenneth A. Egol[1], james S. Babb[1], Valerie Peck[2]. [1]NYU Langone Medical center, USA, [2]NYU School of Medicine, USA

To define the risk factors for atypical femoral fracture patients on long term Bisphosphonate (BP) therapy by comparison with controls matched for age and duration of bisphosphonate therapy.

Methods: Approval was obtained from the IRB. We have previously reported data on 25 patients on long term BPs with atypical femoral fractures without a corresponding control group. We now conducted a retrospective chart analysis of 55 subjects with complete subtrochantric or diaphyseal femoral fractures of which 29 with all relevant data available were selected (a part of this group has been reported before). We selected 29 controls from a prospective asymptomatic database, matched for age and duration of BP use. All subjects studied were on alendronate. Relevant clinical and demographic data including age, gender, height, weight, duration of BP use and prior use of hormone replacement therapy (HRT) were collected. Laboratory and imaging data including calcium, 25-hydroxy vitamin D (25-OHD), alkaline phosphatase, intact parathyroid hormone (PTH), serum c-telopeptide (CTX), urine n-telopeptide (NTX) and bone mineral density (BMD) were obtained.

Results: The age range was 46-86 years and duration of BP was 8.7 years in control group and 9.62 years in patient group, respectively (p=0.318). The mean T-score at the femoral neck was -1.69 and -2.36 in the patient and control groups respectively, which was statistically significant (p=0.004). Similar trend in mean T-score was seen at total hip, -1.22 and -1.93 in patient and control groups, respectively (p=0.005). The bone turnover marker CTX was higher in patients vs. controls (251 vs. 154, respectively; p=0.038), which is an expected finding after a fracture. No statistically significant

differences were seen in 25-OHD, calcium, PTH, alkaline phosphatase, height and weight parameters or prior HRT use between the 2 groups.

Conclusion: Patients with atypical bisphosphonate femoral fractures when compared with controls matched for age and duration of BP therapy were shown to have higher bone mineral density, in the non-osteoporotic range. Hence, early or unnecessary initiation of BP in patients with hip BMD in the non-osteoporotic range or continued therapy in patients with hip BMD in the non-osteoporotic range can be a risk factor for atypical femoral fractures.

BA058, a Novel Human PTHrP Analog: Reverses Ovariectomy-Induced Bone Loss and Strength at the Lumbar Spine in Aged Cynomolgus Monkeys. Nancy Doyle[1], Aurore Varela[1], Susan Y. Smith[1], Robert Guldberg[2], Gary Hattersley*[3]. [1]Charles River Laboratories, Canada, [2]Georgia Institute of Technology, USA, [3]Radius, USA

BA058 is an analog of hPTHrP (1-34) undergoing clinical development for the treatment of osteoporosis. This study determined the effects of long-term (16 months) administration of BA058 on bone mineral density and strength in aged osteopenic, ovariectomized cynomolgus monkeys. Female cynomolgus monkeys, ⩾9 years of age, were randomly assigned to 5 groups based on whole body bone mineral content. Four groups of up to 16 animals were ovariectomized (OVX) and an additional group underwent Sham surgery. Treatment commenced after a 9-month bone depletion period. Animals received daily subcutaneously injection of either vehicle (Sham and OVX controls), or BA058 at 0.2, 1 or 5 µg/kg for 16 months. Lumbar vertebrae (L3 to L5) were retained for bone densitometry (DXA and pQCT) and biomechanical testing (vertebral body and core compression). As expected for osteopenic animals, decreases in BMD by DXA and pQCT (-19%) and bone strength parameters (yield load) were observed for lumbar vertebral cores (-30%) and vertebral body (-20%) in compression for OVX controls compared to intact Sham controls. Treatment with BA058 at 1 and 5 µg/kg/day resulted in complete reversal of the OVX-induced osteopenia at the lumbar spine with increased yield load of ~50% for the vertebral core and ~20% for the vertebral body compared to OVX controls. These changes were consistent with the increases in BMD of up to ~25%. At 1 and 5 µg/kg/day BA058 completely restored bone mass and bone strength (yield load) to values comparable to Sham control. At 0.2 µg/kg/day, there were partial gains in BMD and strength parameters. BA058 potentially offers important advantages as a new treatment for post-menopausal osteoporosis, including the ability to rapidly build new bone, sustain gains over time, and improve bone strength at clinically relevant sites.

LB-MO30

Continuous modeling-based bone formation: a novel mechanism that could explain the sustained increases in hip bone mineral density (BMD) with denosumab treatment. Michael Ominsky[1], Cesar Libanati[1], Rogely Waite Boyce[1], Paul Kostenuik[1], Roland Baron[2], Rachel Wagman[1], David Dempster*[3]. [1]Amgen Inc., USA, [2]Harvard School of Medicine & of Dental Medicine, USA, [3]Columbia University, USA

Denosumab administration in clinical studies is associated with continued increases in BMD and low fracture incidence through 8 years despite persistently low bone turnover markers and limited iliac crest tetracycline labeling[1]. We therefore hypothesized that, with persistently low bone remodeling, these BMD increases may result from a non-remodeling dependent mechanism to accrue bone matrix. To test this hypothesis, we examined the fluorochrome labeling pattern in proximal femur sections from ovariectomized (OVX) cynomolgus monkeys (cynos) treated with denosumab for 16 months.

Following OVX, mature 9+ year old cynos were treated with vehicle (n=20) or 25 mg/kg denosumab (n=14) QM for 16 months. Fluorochrome labels were administered at months 6, 12 and 16. Consistent with the potent anti-remodeling effect of this regimen (25x clinical dose), very low bone resorption and formation indices were observed histologically and by serum markers[2]. Despite these reductions, DXA BMD continued to rise at the femur neck in the denosumab group, from 5.9% at month 6 to 11.3% above baseline at month 16. Examination of proximal femur sections confirmed the low surface extent of label within the trabecular compartment of the denosumab group. In contrast, consistent and prominent labeling was observed in the cortex, primarily on both the superior endocortex (12 of 14 cynos) and the inferior periosteal surface (11 of 14 cynos), consistent with increasing cortical thickness. These regions typically contained multiple superimposed labels over smooth cement lines, often spanning months 6 to 16 (Figure), suggesting that modeling-based bone formation was continuous during denosumab administration.

Persistence of bone modeling on a background of maximal suppression of remodeling could explain the continued increases in BMD and mass observed with denosumab treatment. Importantly, this augmentation of bone mass occurred at biomechanically relevant sites on the superior and inferior aspects of the femur neck, and corresponded to significant increases in bone strength[3]. In conclusion, there is evidence in cynos that continual modeling-based bone formation occurs during denosumab therapy. This study provides the first histological evidence of a potential mechanism responsible for the clinical observations of continued BMD increases and low fracture rates with long-term denosumab administration in the FREEDOM Extension.

Co-treatment with *Fructus Ligustri Lucidi* and *Puerariae Radix* offsets their independent actions on bone/mineral metabolism in OVX rats. XL Dong[1], SS Cao[2], QG Gao[2], Haotian Feng*[3], Man-Sau Wong[1], Denney liya[4]. [1]Department of Applied Biology & Chemical Technology, The Hong Kong Polytechnic University, China, [2]The Hong Kong Polytechnic University, China, [3]Nestle Research Center Beijing, [4]Nestlé Research Centre, Switzerland

Accumulating evidences showed that *Fructus Ligustri Lucidi* (FLL) and *Puerariae Radix* (PR), two herbs long used in traditional Chinese medicine (TCM), could exert beneficial effects on bone and mineral metabolism individually. In this study, to further explore the potential of FLL and PR for bone protection, we aimed to evaluate therapeutic efficacies of cotreatment with FLL and PR on bone and mineral metabolism in ovariectomized (OVX) Sprague Dawley rats. Six-month-old OVX rats were used as postmenopausal osteoporotic models, and water extracts of PR and FLL were added to commercial diets individually or in combination and administrated to the OVX rats for 12 weeks. Bone properties, calcium and phosphorus absorption and bone biochemical markers were measured to investigate the potential interactions between the actions of PR and FLL on bone and mineral metabolism in OVX rats. PR treatment in this study did not significantly improve bone properties, but it greatly ameliorated the condition of secondary hyperparathyroidism induced by OVX in the animals. FLL significantly enhanced the intestinal Ca absorption rate and decreased the enlarged trabecular bone surface at the site of tibia metaphysics in OVX rats. However, the positive effects of FLL or PR alone on bone and mineral metabolism were diminished when OVX rats were co-treated with both FLL and PR. The results from the present study could provide insights for medical professionals to understand the potential negative impact of herb-herb interactions when combination of herbal mixtures is employed for the purpose of osteoporosis treatment & management.

Effect of Aromatase Inhibition on Bone Density and Bone Turnover in Healthy Postmenopausal Women: Results of the International Breast cancer Intervention Study II (IBIS-II). Richard Eastell*[1], Ivana Sestak[2], Fatma Gossiel[1], Rajesh Patel[3], Glen Blake[4], Robert Coleman[1], Anthony Howell[5], Mitch Dowsett[6], John Forbes[7], Shalini Singh[2], Jack Cuzick[2]. [1]University of Sheffield, United Kingdom, [2]Queen Mary University, United Kingdom, [3]Imperial College London, United Kingdom, [4]King's College London, United Kingdom, [5]Paterson Institute for Cancer Research, United Kingdom, [6]Institute of Cancer Research, United Kingdom, [7]University of Newcastle, Australia

Background: The inhibition of aromatase in postmenopausal women with breast cancer has been associated with an increase in fracture risk, and this effect may be mediated by an increase in bone turnover and in the rate of bone loss. It has been difficult to estimate the magnitude of the effect of aromatase inhibitors on bone because the control arm is usually women treated with tamoxifen and this is known to have effects on bone. Here, we compare the effect of aromatase inhibition on bone in the International Breast cancer Intervention Study (IBIS-II), which is a randomised, placebo-controlled trial of anastrozole versus placebo in postmenopausal women at increased risk of breast cancer.

Methods: Measurements of bone turnover markers for the bone sub-study have been completed for a sub-set of postmenopausal women from the bone study, which included 1410 postmenopausal women aged 40 to 70 years at increased risk of breast cancer. Women were stratified by T-score at baseline; if the spine and hip T-score were both equal or above -1.0, women were not offered any bisphosphonate (Stratum I), but advised to take calcium and vitamin D supplementation. Bone resorption by N-telopeptide of type I collagen (NTX) expressed as a ratio to creatinine (from a second morning void urine sample) were measured at baseline, 6 months and year 1, and for 289 women bone turnover marker results were available for all three time points. Lumbar spine and total hip BMD were measured by dual-energy x-ray absorptiometry (Hologic or GE Lunar) at baseline, 1 and 3 years.

Results: 289 postmenopausal women with normal BMD at baseline (T-score $\geq$-1.0) were included in this analysis (Anastrozole=142, Placebo=147). A median increase in NTX/Cr between baseline and year 1 of 20% was observed for anastrozole and a median decrease of 7% for placebo and the difference was statistically significant (P<0.0001). The median annual rate of bone loss was much greater at the total hip (-1.3% vs. -0.4%) and lumbar spine (-1.3% vs. -0.2%) for women receiving anastrozole compared to placebo (P<0.0001) (Table 1). The baseline NTX/Cr and the change in NTX/Cr between baseline and year 1 were not significantly related to the rate of bone loss.

Discussion: This is the first report of a large placebo-controlled trial investigating an aromatase inhibitor to show a significant bone loss in women taking anastrozole, which is likely due to an increase in bone resorption.

Table 1: Annual median changes (IQR) between baseline and year 1 for NTX/Cr and between baseline and year 3 for BMD in spine and total hip according to treatment allocation.

	Anastrozole (N=142)	Placebo (N=147)	Difference between baseline and year 1 (95% CI)
Annual change in NTX/Cr, nmol BCE/mmol Cr	8.9 (-3.1 to 21.8)	-1.9 (-11.7 to 10.2)	10.8 (5.4 to 16.2)
Annual change in spine BMD, %/year	-1.3 (-2.17 to -0.44)	-0.2 (-1.0 to 0.9)	-1.1 (-1.5 to -0.7)
Annual change in hip BMD, %/year	-1.3 (-1.8 to -0.6)	-0.4 (-1.3 to 0.3)	-0.8 (-1.2 to -0.5)

*NTX=N-Telopeptide x, Cr=Creatinine, BCE=Bone Collagen Equivalent, BMD=Bone Mineral Density

NFAM1 Signaling Modulates Osteoclast Differentiation in Paget 's Disease of Bone. Yuvaraj Sambandam*[1], Kumaran Sundaram[2], Sakamuri Reddy[2]. [1]Medical University of South Carolina, USA, [2]Charles P. Darby Children's Research Institute, USA

Paget's disease of bone (PDB) is a chronic focal skeletal disease that affects 2-3% of the population over 55 years of age. The primary abnormality in PDB is excess bone resorption by abnormal osteoclasts (OCLs) followed by abundant poor quality new bone formation. Recurrent mutations in SQSTM1/p62 ubiquitin associated domain (UBA) have been identified in PDB. Also, pagetic OCL contains paramyxoviral nuclear inclusions and nucleocapsid transcripts. We previously detected measles virus nucleocapsid protein (MVNP) transcripts in OCLs from patients with PDB. MVNP has been shown to induce pagetic phenotype in OCL. We showed that MVNP expression stimulates osteoclastogenesis by upregulating NFATc1, a critical transcription factor for OCL differentiation. We recently analyzed gene expression profiling by Agilent microarray and demonstrated MVNP significantly increased expression of several signaling molecules and cytokine/growth factors in normal human bone marrow derived preosteoclast cells. We thus identified MVNP upregulation (7-fold) of NFAT activating protein with ITAM motif 1 (NFAM1) expression. However, there is no change in NFAM1 expression in preosteoclast cells transfected with $p62^{WT}$ and $p62^{P392L}$. NFAM1 also known as CNAIP, is a ~30 kDa transmembrane glycoprotein that contains extracellular Ig domain and intracellular immunoreceptor tyrosine-based activation motif (ITAM) bearing region. We therefore hypothesize, that MVNP modulates NFAM1 signaling during pagetic OCL differentiation. Real-time PCR analysis showed that MVNP expression in human peripheral blood monocytes cells significantly increased (10-fold) NFAM1 mRNA expression without RANKL treatment. Cells transfected with a control empty vector (EV) and stimulated with RANKL showed a 3.0-fold increase in NFAM1 mRNA expression. Western blot analysis further confirmed that MVNP increased (4.8-fold) NFAM1 expression in these cells. NFAM1 has been shown to induce ITAM phosphorylation and Syk recruitment. Interestingly, MVNP expression resulted in increased ITAM phosphotyrosine activation (4.0-fold) and p-Syk (5.5-fold) levels in preosteoclast cells in the absence of RANKL. However, RANKL treatment alone increased ITAM activation (2.0-fold) and p-Syk (2.5-fold) levels in EV transfected preosteoclast cells. Furthermore, shRNA knockdown of NFAM1 suppresses MVNP induced NFATc1 expression in preosteoclast cells. Thus, our results suggest that NFAM1 modulates MVNP induced pagetic osteoclast development.

***CYP2R1* Gene Polymorphisms Are Associated With Variability In 25-Hydroxy Vitamin D Levels In The Elderly.** Asma Arabi*[1], Nathalie Khoueiry-Zgheib[2], Rami Mahfouz[3], Zainab Awada[2], Maya Rahme[1], Karim Firikh[1], Ghada El Hajj Fuleihan[1]. [1]Calcium Metabolism & Osteoporosis Program, American University of Beirut, Lebanon, [2]Department of Pharmacology & Toxicology, American University of Beirut, Lebanon, [3]Department of Pathology & Laboratory Medicine, American University of Beirut, Lebanon

Hypovitaminosis D is highly prevalent in the Middle East, although this region enjoys sunshine most days of the year. Genome wide association studies and candidate genes approaches have interrogated the role of genetic polymorphisms in the variability of 25 hydroxyvitamin D (25-OHD) levels in Western populations. The applicability of these studies to other races/populations is unclear.The cytochrome P450 2R1 (CYP2R1) plays a major role in the vitamin D hydroxylation in human. This study evaluated the association between variability in 25-OHD levels in Lebanese elderly and polymorphisms in 4 single nucleotides (SNP) of the CYP2R1 gene. Genotyping was performed for rs12794714, rs10741657, rs1562902, & rs10766197 SNPs in 250 subjects [109 men & 141 women] using Real-Time PCR. Blinded duplicate sample analyses were performed for all assays. Additional 10% of samples were repeated to verify reproducibility. Baseline 25-OHD levels were measured by chemiluminescent platform Liaison assay (DiaSorin).

The subjects' mean age was 71.0$\pm$4.7 yrs, mean BMI 30.0$\pm$4.5 kg/m^2 and mean 25-OHD level 18.4 $\pm$7.6 ng/ml. Genotype frequencies were in Hardy-Weinberg equilibrium.

There was a significant difference in 25-OHD levels between genotypes. For rs10741657 and rs1562902 SNPs, the mutant genotype had the highest 25-OHD levels compared to wild and heterozygous genotypes. Conversely, wild genotype had the highest 25-OHD levels for rs10766197 SNP [Table]. After adjustment for age, season, gender and BMI, mutant genotype had 25-OHD levels higher by 4.8 and by 4.3 ng/ml than wild genotype for rs10741657 SNP and for rs1562902 SNP respectively (p< 0.01). Conversely, for rs10766197 SNP, mutant and heterozygous genotypes had 25-OHD levels lower by 3.6 and by 2.7 ng/ml respectively compared to wild genotype (p< 0.01). Mutant genotype for rs12794714SNP had 25-OHD levels lower by 3 ng/ml compared to wild genotype (p=0.02) [Table]. Sub-group analyses by gender revealed comparable results for rs10741657 SNP in men and for rs1562902 and rs10766197 SNPs in women.

In conclusion, this study showed a significant difference in 25-OHD levels between CYP2R1 genotypes. This difference equates a daily supplementation of 200 to 400 IU vitamin D.

This study underscores possible genetic causes for the high prevalence of hypovitaminosis D in the Middle East. The impact on the response to vitamin D supplementation remains to be investigated.

Association between *CYP2R1* gene polymorphisms and OHD levels before & after adjustment for potential predictors

SNP/ Genotype (n)	25-OHD (ng/ml)**	p-value*	β (SE)[d]	p-value[d]

Control of Breast Cancer Growth and Dissemination By the Skeleton. Claire-Sophie Devignes*[1], Audrey Brenot[2], Amy-Jo Casbon[3], Audrey Devillers[1], Ying Yu[3], Zena Werb[3], Sylvain Provot[1]. [1]INSERM, France, [2]Washington University School of Medicine, USA, [3]UCSF, USA

Breast cancer is often associated with a poor prognosis largely due to its tendency to metastasize. Since Paget's ''seed and soil'' hypothesis from more than a century ago, it is known that bones constitute a very hospitable soil that attracts and allows breast cancer (BC) cells to thrive. Surprisingly, however, only a few studies have

addressed the role of the bone microenvironment in bone metastasis. We tested the possibility that osteoblasts (bone-making cells) could influence breast cancer metastasis to bone by inoculating a BC cell line (PyMT-FVB-Luc+ cells) either directly into the bloodstream, or into the mammary gland (fat pad) of syngeneic recipient mice presenting increased or decreased osteoblast numbers. Hypoxia and the Hypoxia inducible factor 1alpha (Hif-1alpha) play a fundamental role in bone development. Mice deficient for Hif-1alpha in osteoblasts (ΔHif-1alpha^{OB} mice, a Osx-Cre-mediated conditional knockout) present decreased number of osteoblasts and reduced bone mass. Conversely, mice deficient for von Hippel–Lindau (VHL, an E3 ubiquitin-ligase that targets Hif-1alpha for degradation) specifically in osteoblasts (ΔVHL^{OB} mice) present increased levels of Hif-1alpha protein in osteoblasts, and as a consequence, have a dramatic increase in osteoblast number and bone mass. Intracardiac injection of BC cells into these loss- or gain-of-function models reveals that osteoblasts directly or indirectly stimulate breast cancer metastasis to bone. Strikingly, our results also show that osteoblasts produce systemic changes, controlling breast cancer metastasis to several organs in addition to bones, as well as the growth of primary mammary tumors. Transplantation of BC cells in the mammary gland leads to larger primary tumors in ΔVHL^{OB} mice, and smaller tumors in ΔHif-1alpha^{OB} mice, compared to control mice. ΔVHL^{OB} mice also present increased disseminated tumors in multiple organs other than bones, both after tail vein (intravenous) and intracardiac injections of BC cells, or their transplantation in the mammary gland. Conversely, ΔHif-1alpha^{OB} mice present fewer disseminated tumors. Thus, osteoblasts can affect metastasis to distant tissues, well beyond the bone microenvironment. By providing the first evidence that the skeleton exerts a systemic control of breast cancer growth and dissemination, our study expands the biological importance of this organ, and our understanding of cancer biology.

ADULT BONE AND MINERAL WORKING GROUP

WG1

Normocalcemic Familial Hypocalciuric Hypercalcemia: Loss of Function Calcium Sensing Receptor (CASR) Mutation in a Patient with Noraml Serum Calcium. Marcio L Griebeler[1], Stefan K Grebe[2], Robert A Wermers[1]. [1]Division of Endocrinology, Diabetes, Nutrition and Metabolism; [2]Department of Laboratory Medicine and Pathology, Mayo College of Medicine, Mayo Clinic, Rochester, MN, USA.

Familial hypocalciuric hypercalcemia (FHH) [OMIM #145980] is a autosomal dominantly inherited lifelong condition caused by inactivating mutations in the calcium sensing receptor (CASR) gene leading to calcium-hyposensitivity which is manifested biochemically as chronic hypercalcemia, inappropriately elevated parathyroid hormone (PTH) and a low fractional excretion of filtered calcium.

CASE HISTORY: A 37-year-old female presented with proximal muscle weakness, fatigue and mental sluggishness which began 10 years ago. Two years prior to presentation she developed facial pain and was treated with prednisone for possible trigeminal neuralgia and subsequently had a tooth extracted. She had a history of ankle and forearm fractures as a child. Her family history was pertinent for hypercalcemia associated with an elevated PTH in her mother. Physical exam was unremarkable.

LABORATORY DATA: Normal blood work included the following: CBC, sodium, potassium, ESR, AST, ALT, alkaline phosphatase, TSH, and cortisol. Her serum calcium was generally high normal associated with an intermittently elevated PTH. Her most recent serum calciums were 9.7 mg/dl and 10.1 mg/dL, phosphorus 3.1 mg/dL, PTH 44 pg/mL, magnesium 2.2 mg/dl and 25-hydroxyvitamin D 24.5 ng/mL. Her 24 hour urinary calcium was 141 mg with a calcium-clearance to creatinine-clearance ratio of 0.01.

OTHER STUDIES: A parathyroid scan and ultrasound of the neck were nonlocalizing. CASR gene testing revealed a c.1606delG frameshift mutation (p.Glu536ArgfsX91) resulting in loss of normal protein function. She was also heterozygous for R990G, a mild activating mutation linked to an increased renal calcium excretion.

CONCLUSION: Compensatory activating mutations resulting in increased renal calcium excretion may mask the lifelong hypercalcemia that is expected in FHH and result in normocalcemic variants.

WG2

Treating Familial Hypocalciuric Hypocalcemia Type-3 (FHH3) with Cinacalcet. Malachi J McKenna[1], Tom FJ King[1], Ciara M McDonnell[2], McMyra O'Keane[1], Michelle Morrin[1], Mark T Kilbane[1]. [1]Metabolism Laboratory, St. Vincent's University Hospital, and National Children's Hospital, Tallaght, Dublin, Ireland.

FHH is a rare cause of hypercalcemia that typically presents with mild hypercalcemia, inappropriately low urinary calcium excretion and a normal parathyroid hormone (PTH) level. There are three genetically distinct types: FHH1 in about 65% of cases with loss of function mutations in calcium sensing receptor (CaSR) (chromosome 3q21.1); FHH2 with mutation in G Protein Alpha subunit 11 (Gα11) (chromosome 19p); and FHH3 with mutation in adaptor protein-2 δ sub-unit (AP2S1)(chromosome 19q13.3)1. In FHH3, missense mutations affect Arg15 that seems to impair CaSR internalization1.

AIM: We report two cases with different but recently recognized mutations in FHH3, both of whom were treated with Cinacalcet.

CASE 1: A 34 year old woman was referred with lethargy, generalized pains and headaches. Her three children have subsequently been diagnosed with hypercalcemia, and all have symptoms including severe learning difficulties. Sequencing analysis of AP2S1 codon_Q.Arg15 showed that she was heterozygous for c.43C>T (p.Arg15Cys). She had previously undergone exploratory neck surgery which had revealed four normal parathyroid glands with no evidence of an adenoma. Results were as follows: ionized calcium = 1.52 mmol/L (N: 1.19–1.35 mmol/L); PTH = 42.5 pg/mL (N: 15–65 pg/ml); 24-hour urine calcium = 2.3 mmol (N: <6 mmol/24hr); calcium:creatinine ratio = 0.06 mmol/μmol (N: 0.07–0.41 mmol/μmol); 1,25(OH)2D = 15.4 pg/mL (N: 10–64 pg/ml); PTHrp <1.4 pmol/L. Following commencement of Cinacalcet, there was a reduction in both ionized calcium (1.34 mmol/L) and PTH (21 pg/mL). Response has been sustained over 3 years.

CASE 2: A 24 year man old presented with fatigue and rib pains, and he suffered from autistic spectrum disorder. His father, one of his three siblings, and a fraternal cousin had hypercalcemia. Sequencing analysis of AP2S1 codon_Q.Arg15 showed that he was heterozygous for c.44G>A (p.Arg15His). Results were as follows: ionized calcium 1.53 mmol/L (N: 1.19–1.35 mmol/L); PTH 65.1 pg/mL (N: 15–65 pg/ml); 24-hour urine calcium 4.1 mmol (N: <7.5 mmol); urine calcium:creatinine ratio 0.01 mol/μmol (N: 0.07–0.41 mol/μmol). Tc99m-sestamibi scan did not reveal any evidence of parathyroid adenoma; 18-fluorodeoxyglucose positron emission computed tomography imaging showed no metabolic hyperactivity in the parathyroid glands, or any other soft tissues or bony skeleton. He was treated with Cinacalcet 30 mg twice daily. Ionized calcium fell to 1.2 mmol/L and PTH to 11.1 pg/mL. Symptoms of bone pain and fatigue improved, and he became less withdrawn.

CONCLUSION: Cinacalcet is effective as treatment of symptomatic FHH3 with significantly lower of ionized calcium and PTH levels and with a sustained response. It may improve associated behavioral aspects.

Fibrogenesis Imperfecta Ossium (FIO): Clinical Aspects to Global Gene Expression Profiling of Bone Tissue. Sanjay Kumar Bhadada[1], Vandana Dhiman[1], Akhilesh Kumar[1], Yashpal Gogate[1], Kumardeep Chaudhary[2], Sameer Aggarwal[1], Anil Bhansali[1], D.S. Rao[3]. [1]Postgraduate Institute of Medical Education and Research, Chandigarh (160012), India; [2]Senior Research Fellow, Bioinformatics Centre, CSIR-Institute of Microbial Technology, Chandigarh, India; [3]Chief of Bone and Mineral Research Laboratory, Henry Ford Hospital, Detroit, USA.

Fibrogenesis imperfecta ossium (FIO) is an uncommon, crippling, relentlessly progressive metabolic bone disease characterized by multiple pseudo-fractures. The molecular pathogenesis and treatment stratification of FIO is not clearly known. Hence, present study is designed to identify genes putatively involved in the pathogenesis of FIO based on their expression profile.

METHODS: Trans-iliac bone biopsy was done in patient with clinical characteristic of FIO. The differential gene expression, compared to healthy control was studied using global microarray (AffymetrixGenechip. Human Primview) and analyzed using Gene Spring GX 12.1 software. We explored the topological characteristics of differentially expressed genes in the context of the human interactome and analyzed for pathway annotations using reactome and NCBI Gene bank database

RESULT: Bone remodeling is interplay between osteoclastogenesis, mediated by osteoclasts and osteoblastognesis, mediated by osteoblasts. We observed down regulation of SPARC (which encodes osteonectin) and BGLAP (which encodes osteocalcin). Both osteonectin and osteocalcin play an important role in bone formation. One of the actions of IGF-1on bone formation is through increasing osteocalcin. The patient responded to growth hormone therapy, further emphasizing the role of BGLAP (which encodes osteocalcin). Mineralization defect and the clinical finding of pseudo-fractures can be explained by down regulation of genes involved in mineralization, namely SPP-1 (which encodes osteopontin) and BGLAP (which encodes osteocalcin). The upregulation of SOST gene adds 'fuel to the fire' by inhibition of Wnt signaling, important osteoblast activation pathway. We also found up regulation of OSTM-1 gene, involved in osteoclastogenesis. Similarly, we also observed increase in collagen expression but decrease in expression of signaling molecules (MMP, ICAM) involved in assembly of these collagens fibrils leading to defective collagen synthesis.

CONCLUSION: This study is the first systematic network and pathway analysis of candidate genes in FIO, providing abundant important information about gene interaction and regulation in this rare bone metabolic disorder. The use of gene-expression profiling improves the molecular classification of FIO. The results suggest potential functional components underlying the molecular mechanisms of FIO and, thus, facilitate generation of novel hypotheses in this disease.

WG4

Hypercalcemia and Pneumocystis Pneumonia After Liver Transplantation: A Case Report. E Cong and E Shane. Division of Endocrinology, Columbia University Medical Center, New York, NY, USA.

Pneumocystis jirovecii pneumonia (PCP) is a potentially life threatening opportunistic infection that manifests in immunocompromised patients, such as those infected with human immunodeficiency virus (HIV) or receiving immunosuppressive therapy after solid organ transplant[1,2]. Chemoprophylaxis is recommended for the first six to twelve months after organ transplant because the highest risk of PCP is during the first post-transplant year[3]. PCP-induced hypercalcemia is a rare phenomenon, with fewer than ten reported cases, all in renal transplant patients and patients with HIV or leukemia[4]. We report the first case of PCP-induced hypercalcemia arising as a complication in a patient following liver transplant.

CASE HISTORY: A 61 year old Caucasian gentleman presented to Columbia University Medical Center with two months of fevers, chills, night sweats, weight loss, dry cough and gradually worsening dyspnea on exertion. He also had oxygen desaturation on exertion and required supplemental oxygenation. His past medical history was remarkable for orthotopic liver transplant 1.5 years prior to admission for hepatitis C and hepatocellular carcinoma, primary ocular lymphoma diagnosed three years prior to admission and now in remission, chronic kidney disease, steroid-induced diabetes and moderate aortic stenosis. His outpatient medications included prednisone 5 mg, tacrolimus, mycophenolic acid, valcyclovir, insulin, metoprolol and amlodipine, vitamin D 1200 IU and calcium 1500mg. His diet included 600mg calcium (total intake 2100 mg daily).

LABORATORY DATA: Serum calcium 15.4 mg/dl [8.7–10.2], ionized calcium 1.85 mmol/L [1.12–1.32], creatinine 2.7 mg/dl (baseline 1.8–2.3), GFR 24 mL/min/1.73 m^2, phosphorous 4.1 mg/dl [2.5–4.3], parathyroid hormone 16 pg/ml [8–51], $1,25(OH)_2$vitamin D >220 pg/ml [15–75], 25-OHvitamin D 32 ng/ml [30–80], alkaline phosphatase 464 U/L [33–96] and PTHrP 16 pg/ml [14–27]. The patient had no prior history of hypercalcemia or hypervitaminosis D.

OTHER STUDIES: Chest imaging showed bilateral diffuse ground glass opacities in lower lobes and was negative for pulmonary embolism. MRI of the brain, abdomen and pelvis, bone scan and ophthalmology exam were negative for recurrent ocular lymphoma. Bronchoscopy was negative for malignant cells and mycobacterium tuberculosis, and revealed *pneumocystis* jirovecii organisms by methenamine silver stain.

TREATMENT: Serum calcium remained markedly elevated despite 3L IVF daily and IV furosemide 20–40mg daily for the first five days (see Graph). Bisphosphonates were not administered because GFR declined to 12 mL/min/1.73 m^2. On day six, prednisone was initiated at 40mg twice daily together with trimethoprim-sulfamethoxazole for presumptive PCP. On day ten, calcitonin 4 IU/kg SQ was given every twelve hours for a total of four doses. Hypercalcemia and hypervitaminosis D began to improve on day ten, with repeat labs on day fourteen showing a calcium of 10 mg/dl (corrected calcium 10.5 mg/dl) and $1,25(OH)_2$vitamin D of 19 pg/ml. Six months later, the patient is normocalcemic off prednisone, renal function has returned to baseline, PCP has not recurred and his ocular lymphoma remains in remission.

CONCLUSION: We present a case of a patient who presented 1.5 years after liver transplantation with severe hypercalcemia and PCP with extraordinarily high serum $1,25(OH)_2$vitamin D concentration that responded to therapy with steroids and antibiotics. This case report suggests that the mechanism of PCP-induced hypercalcemia is similar to that seen in granulomatous diseases such as sarcoidosis. In these disorders, hypercalcemia results via interferon-mediated expression of extrarenal 1α-hydroxylase activity in macrophages within granulomas[5]. This case also highlights that hypercalcemia may be a harbinger for development of PCP in immunosuppressed patients, and that expeditious workup and therapy for PCP and prednisone therapy effectively correct the hypercalcemia.

Osteoporotic Vertebral Fractures During Pregnancy: Be Aware of a Potential Underlying Genetic Cause. N Campos-Obando[1], L Oei[1], MEH Simon[2], MC Zillikens[1]. [1]Department of Internal Medicine, Erasmus Medical Center, Rotterdam; [2]Department of Clinical Genetics, Erasmus Medical Center, Rotterdam.

Although the baby growing in its mother's womb needs calcium for skeletal development, osteoporosis and fractures very rarely occur during pregnancy.

CASE HISTORY: A 27-year old woman in the 7th month of her first pregnancy contracted mid-thoracic back pain after lifting an object. The pain was attributed to her pregnancy, but remained post-partum. Her past medical history was uneventful, except for severely reduced vision of her left eye since birth. Family history revealed that her maternal grandmother had postmenopausal osteoporosis and her only brother had three fractures during childhood after minor trauma. Her height was 1.58 m, she had no blue sclerae or joint hyperlaxity.

LABORATORY DATA: Laboratory examination including serum calcium, phosphate, alkaline phosphatase, creatinine, bCTX, 25-hydroxyvitamin D and TSH was normal.

OTHER STUDIES: Multiple thoracic vertebral fractures were diagnosed on X-ray examination and DXA-scanning showed severe osteoporosis (T-score L2-L4: −5.7 SD, femur neck: −3.9 SD). DNA analyses revealed two compound heterozygous missense mutations in LRP5. Her mother carried one of the LRP5 mutations and was diagnosed with postmenopausal osteoporosis. Her brother, treated with cabergoline for a microprolactinoma, had osteopenia on DXA and carried the same LRP5 mutation.

TREATMENT: The patient was treated with risedronate for 2.5 years. BMD and back pain improved. She stopped bisphosphonate use 6 months before planning a second pregnancy.

CONCLUSION: Our patient was diagnosed with osteoporosis pseudoglioma syndrome/familial exudative vitreoretinopathy. Potentially underlying genetic causes should be considered in pregnancy-associated osteoporosis with implications for patients and relatives. More studies regarding osteoporosis treatment preceding conception are desirable.

Male Hypogonadism Impact in Bone Quality Assessed by Trabecular Bone Score (TBS). Mário Rui Mascarenhas[1-4], Ana Paula Barbosa[1-4], Ana Gonçalves[4], Vera Simões[2,3], David Santos Pinto[3], António Gouveia de Oliveira[5], Manuel Bicho[2], Didier Hans[6], Isabel do Carmo[1,4]. [1]Endocrine & Metabolic Diseases and [2]Center of Metabolism & Endocrinology, Genetic Lab. (FMUL); [3]CEDML – Clínica de Endocrinologia, Diabetes e Metabolismo de Lisboa, Lda.; [4]Endocrinology, Diabetes & Metabolism Department, University de Santa Maria Hospital, CHLN-EPE; [5]Biostatistic Department, FCMUNL, Lisboa, Portugal; [6]Center of Bone Diseases, Lausanne University Hospital, Lausanne, Switzerland.

OBJECTIVE: The high morbidity and mortality associated to osteoporotic fractures in men are important public health problems. Ageing and the tendency to fall are the main risk factors for reduced bone mineral density (BMD) in men. Male hypogonadism is a main secondary cause of low bone mass but the knowledge of bone microarchitecture is scant. The trabecular bone score (TBS) is determined from grey-level variation analysis of the AP spine DXA images using the experimental variogram concept to assess and qualify the bone microarchitecture.

AIMS: The purpose of this study is to compare the lumbar spine bone microarchitecture as estimated by TBS with the BMD at the L_1–L_4 as well as the correlation between spine TBS and BMD in hypogonadal and normal.

MATERIAL & METHODS: The BMD (g/cm^2) of the spine, proximal femur and distal forearm, as well as the total fat and lean body masses were measured by DXA in 108 hygogonadal (hypogonadal males group) and in 108 normal (control group) men. Site matched spine TBS was derived for each spine DXA scan (TBS iNsight software, Medimaps, France). Fasting blood was collected for LH, FSH, PRL, E2 and total testosterone measurements. The weight, height and BMI were also determined. Appropriate statistics were used with the significance level at $P<0.05$.

RESULTS: The mean age, weight and total body fat mass were identical, but the mean spine BMD, spine TBS and total body lean mass were significantly decreased in the hypogonadal men, as compared with the control group.

GROUP Technique	CONTROL	HYPOGONAL MEN	P
TBS L1-L4	1.350 (±0.1)	1.282 (±0.1)	0.0001
BMD L1-L4 g/cm²	1.074 (±0.2)	0.969 (±0.2)	0.0000
BMD HIP (total) g/cm²	1.067 (±0.1)	0.968 (±0.2)	0.0000

Significant negative correlation was found between the TBS and the age in the control group. A weak correlation between spine BMD and spine TBS was detected, validating this TBS is measuring different bone properties than BMD.

CONCLUSION: The study data show a significant decrease in both bone mass accessed by BMD and bone quality evaluated by TBS, thus suggesting an important negative impact in the bone strength in men with hypogonadism, which may be associated to an increased risk for osteoporotic fractures.

Conflict of Interest: Didier Hans is co-owner of the TBS patent and has corresponding ownership shares.

Acknowledgments: Medimaps (Medimaps, Bordeaux, France) and Radilan (Lisboa, Portugal) for the kind free access and use of the TBS iNsight software for this study

Hyperthyroidism in Young Women: Which Impact on Body Composition and Silent Vertebral Fractures Detected by VFA. Barbosa AP[1-4], Mascarenhas MR[1-4], Silva C[5], Távora I[5], Gonçalves A[4], Simões V[2,3], Bicho M[2], do Carmo I[1,4]. [1]Endocrinology University Clinic and [2]Metabolism and Endocrinology Center, Genetics Laboratory (FMUL); [3]CEDML - Endocrinology, Diabetes and Metabolism Clinic, Lda.; [4]Endocrinology, Diabetes and Metabolism Department, Santa Maria Hospital, CHLN-EPE; [5]Imagiology Department, Santa Maria Hospital, CHLN-EPE, Lisbon, Portugal.

Hyperthyroidism is a risk factor for reduced bone mineral density (BMD) as well as for osteoporotic fractures. Vertebral fractures are among the most frequent and are often silent. Only a third of them come to medical attention and up to 20% of patients with an incidental vertebral fracture experience a new one in the next year. Vertebral fracture assessment by dual-energy x-ray absorptiometry (VFA by DXA) is a radiological method of visualization of the spine, which confers more commodity for the patient and less radiation exposure than the conventional spine x-ray.

OBJECTIVE: To evaluate the BMD and the prevalence of silent vertebral fractures using VFA by DXA in patients with hyperthyroidism.

MATERIAL AND METHODS: In a group of 30 pre-menopausal women with hyperthyroidism, the body lean and fat masses (Kg) and the BMD (g/cm^2) at the lumbar spine (L_1–L_4), proximal femur, distal radius and whole body were evaluated by DXA (QDR Discovery, Hologic).

VFA was used to detect fractures and those were classified according to type (wedge, biconcave, crush) and severity (% of deformity) by Genant's semiquantitative method. Fast blood collection was also performed to measure the pituitary hormones levels. No patient was previously treated for hyperthyroidism, osteoporosis or low bone mass. The BMD was qualified by Z-score, according to the ISCD recommendations. Descriptive, Anova and regression analysis statistical tests were used.

RESULTS: The means (±SD) of the anthropometric data and of the BMD are described in table 1.

Table 1. The mean (±SD) anthropometric data, lean and fat body masses and the BMD at several skeletal sites.

Variables	Premenopausal women with hyperthyroidism *(n=30)*
Age *years*	40.8 *(±5.9)*
Height *m*	1.62 *(±0.05)*
BMI *kg/m²*	26.6 *(±4.6)*
Total body lean mass *kg*	40.7 *(±5.1)*
Total body fat mass *kg*	27.2 *(±8.1)*
BMD L_1-L_4 *g/cm²*	1.014 *(±0.1)*
BMD femoral neck *g/cm²*	0.812 *(±0.1)*
BMD distal radius *g/cm²*	0.696 *(±0.1)*
BMD whole body *g/cm²*	1.129 *(±0.1)*
Fractures *n (%)*	7 *(23.3%)*

BMD qualification: 1(3.3%)-osteoporosis, 9(30%)-reduced BMD and 20(66.7%)-normal BMD.

Significant relations were detected between total lean mass and femoral neck BMD. Regarding the vertebral fractures, we found 7 cases, 6 type wedge and 1 type crush, and all of them were grade 1.

CONCLUSION: The results of this study using VFA technology, may suggest that even in young women, the hyperthyroidism can originate reductions in the bone mineral density and also in the lean mass that can conjugate in the occurrence of asymptomatic vertebral fractures. These data also support the interest of VFA in the routine management of osteoporosis to detect precociously silent fractures and so, consider treatment as soon as possible.

SKELETAL FLUOROSIS DUE TO EXCESSIVE TEA DRINKING. Naveen Kakumanu, Saroj Palnitkar, Tarlsha Esridge, Robin Demuth, Sudhaker D Rao. Bone & Mineral Research Laboratory, Henry Ford Hospital, Detroit, MI, USA.

Skeletal fluorosis is prevalent in endemic areas of the world with high fluoride content in drinking water, but is rare in other parts of the world. Brewed tea is amongst the highest fluoride containing food products in the US.

CASE HISTORY: We describe a 47 year old woman who was referred to the Bone & Mineral Clinic for chronic diffuse bone pain and abnormal radiographs. She drank a pitcher of tea daily made from 100–150 tea bags for 17 years that she procured at the local dollar store. For the past 5 years she has developed pain in the lower back, arms, legs, and hips. Because of brittle teeth, her teeth were all extracted. Forearm radiographs demonstrated inter-osseous membrane calcifications, pathognomonic of skeletal fluorosis. Lumbar spine was uniformly osteosclerotic with rugger-jersey appearance, but without ligamentous calcifications.

LABORATORY DATA: Serum calcium (Ca) 9.6 mg/dl, creatinine 0.6 mg/dl, 25-hydroxyvitamin D 12 ng/ml, PTH 38 pg/ml, and fluoride level 0.43 mg/L (0.10 mg/L being the reporting limit). A 24-hour urine calcium was 112 mg/day.

OTHER STUDIES: BMD of the spine (L1–L4) was 2.244 g/cm2 (Z-score, +11.5), total hip 1.196 g/cm2 (Z-score, +2.5), femoral neck 1.05 g/cm2 (Z-score, +2.4), and forearm 0.772 g/cm2 (Z-score, +1.9). Bone histomorphometry showed slightly reduced cortical bone volume but increased cortical width. Calcellous bone volume and trabecular width were increased 1.5–2 fold. 3-D Micro-CT of the biopsy specimen showed low marrow space, and increased cortical and trabecular thickness. Bone formation could not be measured because of lack tetracycline labeling. However, osteoid indices were normal and there was no evidence of osteomalacia.

CONCLUSION: This case demonstrates an uncommon metabolic bone disease in the U.S. acquired from prolonged use of a common beverage. Other unusual features include: normal serum PTH, Ca, and alkaline phosphatase, despite vitamin D depletion and low Ca intake.. The skeleton accretes most of the fluoride burden and forms hydroxyl-fluoro-appetite. These crystals are more compact and stable than hydro-xyapatite and resist skeletal resorption resistant to PTH action; the latter leads to secondary hyperparathyroidism especially in endemic areas where vitamin D and calcium malnutrition is also endemic. The combination perpetuates further fluoride accumulation by increasing bone remodeling in the growing skeleton. Further insights and studies are needed to broaden our understanding of non-endemic skeletal fluorosis.
