Gene therapy has emerged as an effective way to enhance bone repair through delivering osteogenic growth factor, mainly bone morphogenetic proteins (BMPs). A good gene therapy regime consists optimal combination of three components: therapeutic gene or transgene, delivery vector and cellular vehicle. The aim of this study is to determine whether the response of cellular vehicle to the autocrine effect of therapeutic gene product can affect the performance of an ex vivo gene therapy strategy, and to investigate the possible underlining mechanism. We separated different populations of rat muscle-derived cells based on their ability to adhere to collagen type I, and then compared their response to BMP2 and BMP4 stimulation. These initial comparisons led to the selection of two distinguish populations (PP1 and PP6) of rat muscle derived cells: PP1 did not, but PP6 did respond to BMP2 and BMP4 by osteogenic differentiation, as evidence by the expression of an early osteogenic marker, alkaline phosphotase. PP1 and PP6 cells expressed similar level of BMP4 following transduction. When implanted into critical-calvarial defects, transduced PP1 cells expressing BMP4 healed the defect in all animal 7 weeks post implantation. In contrast, PP6 cells expressing BMP4, similar to control cells expressing LacZ, did not heal the defects in all animals even after 14 weeks post implantation. The inability of PP6 cells to heal the defect correlated to their lower rate of proliferation when compared to PP1 cells expressing BMP4 or PP6 cells expressing LacZ. The osteogenic differentiation of rat muscle derived cells correlates conversely with their proliferation potential under BMP4 stimulation. Thus, BMP4 protein directly inhibited proliferation of PP6 cells, but not PP1 cells. BMP4 also induced apoptosis of PP6 cells, but not PP1 cells. Thus, an effective bone gene therapy should use cellular vehicle, such as rat muscle-derived PP1 cells, that does not respond adversely to the autocrine effect of the therapeutic gene.

Dysregulated BMP4 Signaling in FOP Lymphocytes. L. Serrano de la Peña*, P. C. Billings*, E. M. Shore, F. S. Kaplan. Orthopaedic Surgery, University of Pennsylvania School of Medicine, Philadelphia, PA, USA.

Fibrodysplasia ossificans progressiva (FOP), a devastating disease of bone formation, is characterized by a process of heterotopic endochondral ossification which results in destruction and substitution of ligaments, tendons and skeletal muscle by bone. Bone morphogenetic proteins (BMPs), members of TGF-b superfamily of proteins, are potent osteogenic morphogens and are able to induce ectopic bone formation in animal models. Therefore, it was not surprising to find misregulation of BMP4 mRNA and protein in cultured lymphocytes and pre-osseous fibroproliferative lesional cells obtained from FOP patients. In order to examine downstream components of the BMP4 signaling pathway, we used fluorescence activated cell sorting analysis and observed that levels of BMP receptor type IA (BMPRIA) are 6 fold higher on the surface of FOP cultured lymphocytes compared with cells from unaffected individuals. These results are reproducible in uncultured lymphocytes from fresh peripheral blood. BMP4 downstream signal transmission was analyzed by immunoprecipitation and immuno-blots using antibodies against phosphorylated and unphosphorylated pathway targets. FOP cells exhibit basal hyperphosphorylation and ligand insensitivity of the BMP receptor complex relative to control cells. This insensitivity to exogenous BMP4 protein was confirmed when cells were treated with Noggin, a potent BMP4 antagonist. Following Noggin exposure, the level of BMPRIA phosphorylation remained constant in FOP cells, but decreased in normal cells, as expected. At least two distinct intracellular pathways mediate BMP signals to the nucleus. Although Smad-mediated signaling appears to be the major pathway for BMPs in many cell types, we find a predominant activation of P38 stress-activated protein kinase in lymphocytes. P38 protein, a member of the mitogen-activated protein kinase (MAPK) superfamily, shows the same pattern of chronic activation as BMPRIA in FOP lymphocytes but not in control cells. Our results suggest that FOP lymphocytes exhibit dysregulated BMP signaling, predominantly through the MAPK pathway.

BMP-2-induced Phosphatidylinositol 3 Kinase (PI 3-K) Regulates GATA-4 and MEF2 Ttranscription Factors During Cardiomyocyte Differentiation. N. Ghosh-Choudhury[1], S. L. Abboud[2], G. Ghosh Choudhury*[3]. [1]Pathology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, [2]Pathology, University of Texas Health Science Center, South Texas Veteran's Health Care System, San Antonio, TX, USA, [3]Medicine, University of Texas Health Science Center, GRECC, South Texas Veteran's Health Care System, San Antonio, TX, USA.

BMP-2 plays a pivotal role in cardiac development in mice. BMP-2 induces MEF2C and GATA-4, two critical transcription factors, which regulate cardiac development. In this study, we investigated the role of PI 3-K in cardiomyocyte differentiation using p19CL6 (CL6) cells as model. We used GATA-4 and specially MEF2 as the marker for cardiomyocyte differentiation. Incubation of CL6 cells with BMP-2 increased PI 3-K activity in PI 3-K and antiphosphotyrosine immunoprecipitates. BMP-2 stimulated GATA-4 and MEF-2 expression as determined by immunoblot analysis. Ly294002, a specific inhibitor of PI 3-K, significantly blocked BMP-2-induced expression of both transcription factors. To investigate the role of PI 3-K in MEF-2-dependent transcription, we performed gel mobility shift assay (GMSA) with nuclear extracts from BMP-2-treated CL6 cells using a ^{32}P-labeled DNA element, which recognizes this transcription factor. BMP-2 stimulated protein-DNA complex formation, which was significantly inhibited by 100-fold excess of cold oligonucleotide. Use of MEF2 antibody in supershift analysis showed the presence of this transcription factor in the DNA-protein complex. Ly294002 significantly reduced BMP-2-induced MEF-2-DNA complex formation. To investigate the transcriptional activity of MEF2 in BMP-2-induced cardiomyocyte differentiation, we used a reporter plasmid (MEF2LUC) in which the firefly luciferase gene is driven by 3 copies of the MEF2 DNA binding element. BMP-2 increased transcription of this reporter in CL6 cells. Ly294002 inhibited BMP-2-induced transcription of this reporter gene. Taken together these data demonstrate for the first time that PI 3-K regulates BMP-2-induced GATA-4 and MEF2 expression, two transcription factors necessary for cardiac development. Furthermore our data provide the first evidence that PI 3-K signaling modulates BMP-2-induced transcriptional activation of MEF2 during cardiomyocyte differentiation.

Local Bone Morphometry - A New Method to Assess Bone Failure. R. Müller, M. Stauber*. Institute for Biomedical Engineering, ETH and University of Zuerich, Zuerich, Switzerland.

Today, it is widely accepted that bone microarchitecture is a significant contributor to trabecular bone strength. Despite the progress in microstructural imaging over the last decade only few approaches have been presented expanding beyond classical 2D bone morphometry. Yet, it is very clear that bone microarchitecture cannot be explained without including direct 3D approaches. Especially, the ability to decompose the bone microarchitecture to extract individual structure features, such as trabecular rods and plates, show high potential to perform local bone morphometry. Local in that sense means that we are now able to quantify individual trabeculae with respect to their volume, thickness, orientation and type of structure. For the purpose of the project, we have scanned a total of 50 human vertebral bone samples (Ø8 mm x 10 mm) using µCT 40 imaging system (Scanco Medical, Switzerland) providing an isotropic resolution of 34 µm. After thresholding, a thinning procedure was applied to the 3D images yielding in a homotopic skeleton. The use of a topological classification algorithm allowed distinction of different point types in the skeleton enabling a complete decomposition of the skeleton in its rods and plates. We then used a dilatation algorithm to identify the volumetric extent of each trabecular rod and plate within the original structure. Subsequently, direct 3D morphometry was used to compute volume, thickness and structure type of each single element. In earlier experimental studies, we have found that bone failure can be predicted best using a “weakest link of the chain” approach. Local bone morphometry allowed identifying such “weak” trabeculae and therefore will improve our predictive power in the determination of bone strength and failure behavior. With upcoming in vivo high-resolution imaging systems, local bone morphometry is likely to become a standard tool not only for the assessment of bone quality in biopsies but also in the living.

Use of DXA, pQCT, Histomorphometry, and Micro-CT to Explore Bone Changes After Ovariectomy in Old Cynomolgus Monkeys. J. Legrand[1], C. Fisch[2], A. Bécret[2], S. de Jouffrey*[2], J. R. Claude*[3]. [1]Beaufour-Ipsen, Paris, France, [2]CIT, Evreux, France, [3]Faculty of Pharmacy, Paris, France.

The osteopenic, ovariectomized cynomolgus monkey is considered as a model of postmenopausal established osteoporosis in women and used for the assessment of the pre-clinical efficacy and safety of agents intended to prevent or treat this disease. We used dual X-ray absorptiometry (DXA), peripheral quantitative computed tomography (pQCT) and microcomputed tomography (micro-CT) in conjunction with histomorphometric analysis of undecalcified slices to explore changes in the bone structure that take place in vertebrae of old, ovariectomized cynomolgus monkeys. Mature female cynomolgus monkeys from Mauritius, approximately weighing 4 kg, were randomly allocated in two groups. Seven animals were ovariectomized (OVX) and thirteen were sham-operated (SHAM). Twenty months after surgery, bone mineral density (BMD) of the L2-L5 lumbar vertebral block and of the L4 lumbar vertebra were measured in vivo by DXA. The animals received dual bone labeling by alizarin complexone and were euthanized. After necropsy, the BMD of the L4 lumbar vertebra was measured ex vivo by DXA, and by pQCT. The L3 lumbar vertebrae were analyzed by high-resolution micro-CT. Undecalcified sections from the vertebral body of L4 vertebrae were Goldner stained and examined with a light microscope or left unstained and examined with a fluorescent microscope for the determination of histomorphometric parameters for both trabecular and cortical bone. The bone mineral density measurements of the L4 vertebrae obtained by DXA in vivo and ex vivo were highly correlated and were 9% statistically lower in OVX than in SHAM animals. The cortical and trabecular BMD levels measured by pQCT were also statistically 5 to 8% lower in OVX than in SHAM animals depending on the level of the slice. The cortical thickness was identical in both groups, but the cortical porosity was statistically 47% higher in OVX than in SHAM animals. The histomorphometric structural parameters of the trabecular bone did not statistically differ between groups, when measured by micro-CT or histomorphometry. These results suggest that the lower bone mineral density observed in OVX when compared to SHAM animals does not result from a decrease in bone volume but is the consequence of an increased bone remodeling, which induces an increase in cortical porosity and a secondary mineralization deficit.

Collagen Cross-Link Maturity and Crystallinity Indices Differ Markedly in Recombinant Congenic Mice Having Divergent Calculated Tissue Strength. R. D. Blank[1], M. Kaufman*[2], S. L. Bailey*[3], S. N. Coppersmith*[2], T. H. Baldini*[4], A. L. Boskey[5], P. Demant*[6], E. P. Paschalis[5]. [1]Medicine/Endocrinology, University of Wisconsin, Madison, WI, USA, [2]Physics, University of Wisconsin, Madison, WI, USA, [3]Physics, College of William & Mary, Williamsburg, VA, USA, [4]Biomechanics and Biomaterials, University of Colorado, Boulder, CO, USA, [5]Research Division, Hospital for Special Surgery, New York, NY, USA, [6]Genetics, Netherlands Cancer Institute, Amsterdam, Netherlands.

The structural strength of a bone can be partitioned into architectural and material components. In 3-point bending tests of 6 month old female humeri from the HcB/Dem recombinant congenic series, 2 strains differed markedly in calculated failure stress as summarized in the table. We used Fourier Transform Infrared Spectroscopic Imaging (FTIRI) to determine whether differences in collagen cross-link maturity, crystallinity, or spatial ordering could account for the large difference in calculated tissue strength between these 2 strains with similar mineral content. Cross-link maturity and crystallinity were assayed as the absorbance ratios at 1660:1690 cm^{-1} and 1030:1020 cm^{-1}, respectively. One-dimensional spatial correlation functions were estimated to compare the uniformity of the indices within fields. For HcB/8, the mean cross-link maturity index is 1.654 and the median is 1.641. The mean and median HcB/23 cross-link maturity indices are 1.273 and 1.365, respectively. The difference in cross link maturity is highly significant ($\chi^2 = 1968$, 9 df, $P < 10^{-15}$). For HcB/8, the mean and median crystallinity index are 0.950 and 0.974, respectively. In HcB/23, the corresponding values are 0.840 and 0.909. As for cross link maturity, the difference between the strains is highly significant ($\chi^2 = 400$, 6 df, $P < 10^{-15}$). Cross-link maturity and crystallinity are highly and similarly correlated in both strains, with correlation coeffecients of 0.751 for HcB/8 and 0.758 for HcB/23 ($P < 10^{-16}$ in both strains). We did not find evidence of significant differences between the strains' 1-dimensional spatial correlation functions. The high correlation between cross-link maturity and crystallinity reflects the interdependence of the protein and mineral elements of bone matrix. The data illustrate the usefulness of FTIRI to examine bone quality and relate it to biomechanical performance.

Anatomic and Biomechanical Performance of HcB/8 and HcB/23 Mice

Mouse Organ Culture Assay To Identify Bone Anabolic Agents. M. L. Jankowsky*, A. Houghton, R. W. Farmer*, M. Wos*, M. Petrey*, M. W. Lundy. Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Neonatal mice calvaria explants have been used to demonstrate the ability of PGE2 and PTH to increase bone resorption in vitro. Both these agents also increase bone formation and volume when administered parenterally to mice and rats. We investigated whether PGE2, PTH or BMP-2 could also increase bone formation in the mouse calvarial organ culture assay. Calvaria were removed from three-four day old mice, cut in half and incubated overnight in BGJ-b media. Media was changed and test agents added to each calvaria the next day, and three days later. Calvaria were removed on day 7, weighed, processed for paraffin embedding and sections obtained at 0.5 mm intervals. The effects of BMP2 on mineralized bone, osteoid, cellular matrix and cartilage were measured using a) point-count stereology (Cavalieri method) and analyzed using Fishers protected t-test, or b) semi-quantitative methods (graded 0 - 4 with 1 = normal) and analyzed using the Chi-square statistic. In a separate study, BMP2, PGE2 and PTH were evaluated using only the semi-quantitative method. PGE2, PTH and BMP2 all increased calvarial weight, but by increasing the amount of different tissues. PGE2 primarily increased the amount of osteoid, with minimal decreases in the amount of mineralized bone. PTH dramatically increased loss of the mineralized bone, but increased the amount of connective tissue containing osteoblast-like cells and matrix that often stained like osteoid but wasn't adjacent to mineralized bone. BMP2 increased cartilage, without increasing osteoid, as measured by both quantitative and semi-quantitative methods. In the tables below, significance is identified as *p < 0.05, **p < 0.01 or ***p < 0.005 compared to vehicle.

Study A: BMP2 Effects In Calvarial Organ Culture

Treatment (n)	Mineralized Bone	Osteoid	Connective Tissue	Cartilage
Quantitative point count analysis (mm^3)				
Vehicle (4)	0.3 ± 0.3	0.07 ± 0.04	1.0 ± 0.6	0.06 ± 0.07
BMP2-100 ng/ml (4)	0.3 ± 0.02	1.0 ± 0.02	1.2 ± 0.1	***1.3 ± 0.4
Semi-quantitative analysis (1=normal)				
Vehicle (4)	1.0 ± 0.0	2.0 ± 1.4	1.0 ± 0.0	0.5 ± 0.6
BMP2-100 ng/ml (4)	1.0 ± 0.0	2.0 ± 0.08	1.0 ± 0.0	*3.5 ± 0.6

Study B: Comparison of Treatments Using Semi-quantitative Analysis

Treatment (n)	Mineralized Bone	Osteoid	Connective Tissue	Cartilage
Vehicle (4)	1.0 ± 0.0	1.0 ± 0.0	1.0 ± 0.0	1.0 ± 0.0
BMP2-100 ng/ml (5)	1.0 ± 0.0	1.6 ±0.6	1.4 ± 0.6	*3.2 ± 0.5
PGE2-10^{-7} M (5)	0.8 ± 0.5	*2.2 ± 0.5	*2.2 ± 0.5	1.2 ± 0.5
PTH-10^{-11} M (6)	0.5 ± 0.6	*2.3 ± 0.8	1.5 ± 0.6	2.2 ± 1.5
PTH-10^{-7} M (5)	**0.0 ± 0.0	**0.0 ± 0.0	*3.2 ± 0.5	2.2 ± 1.1

In conclusion, this study demonstrated that PGE2 and PTH increase bone matrix formation in mouse calvarial organ culture, while BMP2 primarily increases cartilage.

Potential Use of a Hydroxyapatite-Collagen Composite in Orthopedics. M. E. L. Duarte[1], A. B. R. Linhares*[2], C. V. M. Rodrigues*[2], M. A. Mello[3], R. Borojevic*[1], M. Farina*[2]. [1]Dept. of Histology and Embriology and PABCAM/HUCFF, Universidade Federal do Rio de Janeiro, RJ, Brazil, [2]Dept. of Anatomy, Universidade Federal do Rio de Janeiro, RJ, Brazil, [3]Nebraska University, Omaha, NE, USA.

The number of materials proposed to be used as bone substitutes is constantly increasing. In dental and orthopedic surgery, the use of biomaterials is intended to replace the loss of mineralized tissue. Collagen has been used as a carrier for demineralized bone matrix (DBM) to improve the managing characteristics and preserve the osteoinductive potential of DBM. However, the biocompatibility of biomaterials is closely associated to cell behavior on contact with them and to cell adhesion to their surface. This study was aimed to examine the viability of culturing human osteoblasts on a hydroxyapatite-collagen composite prepared with cortical bovine bone and type I collagen (1:1). The biomaterial characteristics were determined by scanning electron microscopy (SEM) and X-ray diffraction (XRD). Osteoblasts were obtained from bone chips discarded after orthopedic procedures and plated ($7x10^4$ cells) on the hydroxyapatite-collagen composite surface. XRD results have shown that the bone powder was highly crystalline and composed mainly by hydroxyapatite (HA) particles (average diameter 295.13±112.62µm) with elongated geometries (shape factor 0.016 ± 0.009 and Feret diameter 73.67 ± 22.57). Collagen appeared mainly as locally oriented filaments or irregular networks adhered to bone particles. At day 4 after seeding, a small number of rounded shaped cells with few citoplasmatic projections

were observed on the composite surface. Cell morphology at this time point was suggestive of the beginning of the adhesion process to the composite. At day 11, cells displayed cuboidal morphology characteristic of osteoblasts and were strongly attached to the bone particles surface as well as to the collagen fibers. Cell distribution along the bulk of the composite seemed to follow the same pattern of distribution of the collagen fibers. These results suggest that the biomaterial used in this study, composed by bovine DBM and bovine collagen, was effective in the adhesion process and in the induction of human osteoblastic cell proliferation *in vitro*. Also it was apparent that the cells might have used the collagen fibers as tracks for migration, attachment and spreading throughout the composite surface.

Murine Calvarial Response in Vitro to IL-1 and PTH Measured with MicroCT. S. R. Stock[1], S. A. Foster*[2], L. A. Forman*[3], P. H. Stern[2]. [1]Institute for Bioengineering and Nanoscience in Advanced Medicine, Northwestern University, Chicago, IL, USA, [2]Molecular Pharmacology and Biological Chemistry, Northwestern University, Chicago, IL, USA, [3]Center for Comparative Medicine, Northwestern University, Chicago, IL, USA.

X-ray microCT, the high resolution variant of clinical CT, allows repeated in vitro observation of bone at spatial resolutions approaching 10 µm (laboratory) or 0.5 µm (synchrotron), and this approach permits the bone in the same specimen to be quantified before and after treatment. This study investigates how microCT (Scanco MicroCT-40) may be effectively employed in in vitro studies of mouse models of bone response to anabolic and other agents. Neonatal mouse calvaria, from individuals of the same litter, were incubated for 96 hours, and the response of control calvaria were compared with that of calvaria in media containing either IL-1 or PTH (all with N=3) using microCT and calcium release (calcein fluorescence titration). Data for 0.1 nM IL-1 treatment illustrate the approach; 3D renderings (constant threshold defining bone) show the 3D bone distribution for control (below left) and treated (below right) calvaria; the graph shows the corresponding calcium release. MicroCT renderings and calcium release show similar correlation for calvaria treated with different levels of PTH: little bone resorption or calcium release with controls, substantial resorption/release with 10 nM PTH and intermediate changes with 1 nM PTH. Bone volume from microCT correlated with the appearance of the renderings, but quantifying the pattern of bone loss in calvarial cultures will require different measures than are typically used in microarchitecture studies of trabecular bone.

Preparation of a Polymer Biomaterial (poly (2-Hydroxyethyl Methacrylate)) with an Inter-connected Macroporosity. An X-ray Microtomographic and Histomorphometric Study. R. Filmon*[1], F. Grizon*[1], C. Cincu*[2], M. F. Baslé*[1], M. Audran[1], D. Chappard[1]. [1]LHEA-GEROM, Angers, France, [2]Macromolar chemistry, University Polytehnika, Bucharest, Romania.

Poly (2-hydroxyethyl methacrylate) (pHEMA) is a polymer that has potentially wide biomedical applications: it is hydrophilic, biocompatible and has a hardness comparable to bone when bulk polymerized. Porous biomaterials allow increase bone integration specially when the pores are inter-connected. However, due to the hydrophylicity of the material, it is difficult to prepare large porous blocks that could be used as bone substitutes. We have used three types of water-soluble porogens (sugar fibers, sucrose crystals and urea beads) to prepare macroporous pHEMA. The porogens were embedded in the polymer by bulk co-polymerization at low temperature. They were dissolved by prolonged washing in saline. The different types of porous biomaterials were dried in an oven, and analyzed on a X-ray microtomograph. The polymer cubes obtained had a side measuring 1,5 mm length. 3D measurements of porosity were obtained in a referent space of 950 mm3. In addition, 2D sections were studied by image analysis with algorithms used to measure bone architecture (inter-connectivity indexes, star volumes, fractal dimension). Sucrose crystals, having a high volumetric mass, gave large pores, which were localized on the block sides. Urea beads and sugar fibers provided pores having the same star volume (resp. 2.65 ± 0.46 mm3 and 2.48 ± 0.52 mm3) but which differed by inter-connectivity index, fractal dimension and Euler-Poincaré's number. Urea beads caused non-connected porosity while sugar fibers created a dense and interconnected labyrinth within the polymer. Inter-connectivity was proved by doing a surface treatment of the pHEMA (carboxymethylation in water) followed by a von Kossà staining which detected the carboxylic groups. Carboxymethylated surfaces were observed on the sides of the blocks and on the opened or inter-connected pores. The disconnected pores were unstained. In the blocks prepared with sugar fibers, the surface of all the pores were carboxymethylated even in the very center of the blocks. Macroporous polymers can be prepared with water soluble porogens; X-ray microtomography appears a useful tool to measure porosity and inter-connectedness.

Quantitative Ultrasound in Bovine Cancellous Bone Does Not Predict Mechanical Damage. R. I. Price[1], T. T. Duong*[1], P. Davey*[1], B. Curtin*[1], R. Day*[2], E. Schwartz*[2], K. P. Singer*[3]. [1]Medical Technology & Physics, Sir Charles Gairdner Hospital, Perth, Australia, [2]Medical Physics, Royal Perth Hospital, Perth, Australia, [3]Department of Surgery, University of WA, Perth, Australia.

Reduced elastic modulus (E), arising from damage induced in human calcaneal cancellous bone by controlled compression, is not predicted by QUS variables Speed of Sound (SOS) or Broadband Ultrasound Attenuation (BUA) (Nicholson & Bouxsein, J Bone Miner Res 2000 15:2467); implying that QUS cannot detect onset of bone fragility in the absence of changes in architecture. The aim of this study was to impose similar mechanical conditioning on bovine cancellous specimens, known to have a higher BMD than the calcaneus, in order to examine whether changes in E were predicted by changes in QUS variables. Sixty cylindrical specimens (15 mm diameter and length) were extracted from bovine femoral condyles using an irrigated diamond coring drill, cleaned with graded alcohol and ether, dried, and hydrated with saline under vacuum. Specimens were randomised to 6 groups and subjected to mechanical testing (Instron 5566) as follows; (a) "preconditioning" phase, 14 compression cycles at 0.4% strain, with measurement of initial E (MPa); (b) "damage" phase (strain rate 0.0004 s-1) for each of 6 strain groups (0.4%, 1.0%, 1.2%, 1.5%, 2.0%, 2.2%); (c) "post-damage" phase, one cycle at 0.4% strain, measuring final E. Measurements were: (i) volumetric BMD (vBMD) using high resolution DXA; (ii) SOS and BUA (dB/MHz/cm) using custom apparatus; before and after mechanical conditioning. SOS was poorly correlated with the predicted "bar wave" velocity, v = SQRT(E/rho), where rho is apparent density (R2 = 0.054, $p<0.05$). vBMD was negatively correlated with BUA (R2=0.37, $p<0.001$) and positively with E (R2=0.13, $p<0.005$). The behaviour of BUA, in contrast to the calcaneus (Nicholson & Bouxsein, 2000) is consistent with its inverse parabolic dependence on BMD (Han S et al. Osteopor Int 1996 64:291) and the higher vBMD of bovine bone. SOS was correlated with vBMD (R2= 0.42, $p<0.001$). With increasing strain in the damage phase, E first fell from the baseline at 0.4% strain (-33.9+/-4.2[SEM]% for 1% strain, -59.0+/-5.3% for 1.20% strain), then rose (-19.0+/-8.1%, +6.9+/-14.1%, +4.35+/-13.6% for 1.5. 2.0 & 2.2% strains, respectively). There was no correlation between changes in E and changes in SOS or BUA, nor between changes in SOS and changes in BUA. It is concluded that the nonlinear response of the elastic modulus (E) in bovine cancellous bone to controlled, increasing strains is more complex than the equivalent response of E in the human calcaneus, but as in the latter case, changes in SOS and BUA do not predict changes in E induced by mechanical damage.

Cellular Alteration of Growth Plate Chondrocytes Affected by Mechanical Stress. N. Amizuka, Y. Seki*, S. Kenmotsu*, T. Sasaki, T. Maeda*. Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.

In order to elucidate the chondrocytic response to the mechanical stress, we have examined the morphological changes of growth plate chondrocytes under similar conditions to hypergravity or microgravity. Mouse tibial epiphyseal cartilage at 17-day-old fetal stage was extracted and then cultured in a continuous centrifuge (5 G) for 16 hours, or in rotation at 15 rpm for 16 hours, enabling putative hypergravity or microgravity, respectively. The stationary culture of the epiphyseal cartilage was employed for a control experiment. The centrifugal force and rotation for 16 hours had no effect on the size of the epiphyseal cartilage and on the expression of PTHrP and FGFR3 that are important for chondrocyte proliferation and differentiation. Although patches of actin filaments, identical to podosomes, were localized evenly along with the cell membranes of the proliferative chondrocytes in the control, chondrocytes affected with the centrifugal force developed the thick layer of actin filaments. Alternatively, chondrocytes in the rotation culture revealed less-developed and uneven distribution of actin filaments along with the cell membranes. Under an electron microscope, chondrocytes subjected to the rotation showed the flattened cell shapes and the ruffling of the cytoplasmic processes, whereas chondrocytes with various cell shapes often made contacts with each other, when affected by the centrifugal force. Thus, the centrifugal force or rotation appeared to distort the chondrocytic columns. In the intracolumnar transverse septa of the control cartilage, the longitudinal lines of electron-dense fibrils were associated with the short cytoplasmic processes of the normal chondrocytes, therefore, connecting adjacent chondrocytes. However, the longitudinal lines of the extracellular fibrils was hardly seen in both the centrifugal and rotation cultures. Thus, the altered distribution of actin filaments, irregular cell shape and the disappearance of longitudinal lines of extracellular fibrils suggest that the hypergravity and microgravity disturb the cell-to-matrix interaction between chondrocytes and peripheral cartilage matrix.

Pressure-responsive Synthesis of Cytokines by Humam Macrophages in vitro is Inhibited by Anti-TNF Blocking Antibody. C. E. Evans*[1], S. Mylchreest*[2], A. Mee*[3], J. L. Berry*[3], G. Andrew*[4]. [1]Laboratory Medicine Academic Group, University of Manchester, Manchester, United Kingdom, [2]Lmag, University of Manchester, Manchester, United Kingdom, [3]Medicine, University of Manchester, Manchester, United Kingdom, [4]Orthopaedic Surgery, Salford Royal Hospitals Trust, Salford, United Kingdom.

Previous studies showed that physical pressure stimulates cytokine synthesis by human macrophages in vitro in a time-dependent manner. This may be important in osteolysis around loosened joint replacements. This study examined whether blocking macrophage synthesis of TNFα affected synthesis of other cytokines. Monocytes were isolated from human buffy coats by adherence for 1 hour. Cell phenotype after overnight incubation exhibited macrophage markers CD68 & non-specific esterase. Macrophages were incubated with or without 0.05mg/ml blocking antibody to TNFα (AB) overnight (D0) or 7 days (D7), before pressurisation (5psi,1 hour, 2 secs on/off) in our unique pressure jig. Cultures were incubated for a further 23 hours. Control cultures were without AB or pressurisation. AB blocked endogenous TNFα synthesis & pressure stimulus did not overcome this block. Pressurised macrophages (noAB) synthesised more TNFα than controls. Pressurised macrophages synthesised more IL-6 at D0 & D7 than controls & incubation with AB abolished this increase. Levels of IL-1β were often undetectable but appeared to be reduced by incubation with AB. These results suggest that the increase in synthesis of bone-resorbing cytokines seen in pressurised macrophages is dependent upon initial synthesis of TNFα & that without TNFα, IL-1β & IL-6, which we previously showed attain maximum concentration 12 hours after TNFα, are not synthesised in response to pressure. This preliminary finding has implications for treatment of patients with loosened implants and supports the potential use of TNFα blocking antibodies as therapy in this situation.

	Days in vitro	TNFα	IL-1β	IL-6
+AB -Pressure	0	0.46(0.29)	0.73(0.30)	0.88(0.03)
+Pressure	0	1.2 4(0.07)	1.22(0.37)	1.89(0.71)
+AB +Pressure	0	0.48(0.20)	0.70(0.32)	0.88(0.16)
+AB -Pressure	7	0.14(0.17)	N.D.	0.75(0.11)
+Pressure	7	1.44 (0.25)	N.D.	1.78(0.31)
+AB +Pressure	7	0.26 (0.42)	N.D.	0.84(0.21)

Results are expressed as a ratio of test concentration (pg/ml)/control; "no effect' level is 1.0. Results are means of data from four separate experiments ±SD. "N.D.' = below minimum detectable level

Analysis of Mechanical Stress-induced Changes in Gene Expression Using Differential Display in Cultured Spinal Ligament Cells Derived from Patients with Ossification of the Posterior Longitudinal Ligaments. H. Ohishi*[1], K. Furukawa*[2], K. Ueyama*[1], S. Motomura*[2], S. Harata*[3], S. Toh*[1]. [1]Orthopaedic Surgery, Hirosaki University School of Medicine, Hirosaki, Japan, [2]Pharmacology, Hirosaki University School of Medicine, Hirosaki, Japan, [3]Aomori Prefectural Central Hospital, Aomori, Japan.

Ossification of the posterior longitudinal ligament (OPLL) of the spine is characterized by ectopic bone formation progressing in the spinal ligaments. When the posterior longitudinal ligament of the spine becomes ossified and enlarged, the spinal cord is compressed and myeloradiculopathy occurs. Mechanical stress which acts on the posterior ligaments or ligamentous enthesis of vertebral bodies is thought to be an important factor in the progression of OPLL. To investigate the mechanism of OPLL development, different gene expressions between cells derived from OPLL and non-OPLL patients (OPLL, non-OPLL cells) were identified by RT-PCR differential display technique. Five reproducible differences of the gene expression were detected and one clone had a DNA sequence with 95% homology to human prostacyclin synthase. Prostacyclin is a potent inhibitor of bone resorption and bone modeling and remodeling. To examine the effect of mechanical stress on the expression of prostacyclin synthase, OPLL and non-OPLL cells were subjected to uni-axial stretch (120% in length, 1Hz), and the relative levels of prostacyclin synthase and alkaline phosphatase mRNA on semiquantitative RT-PCR were investigated. In OPLL cells the expression of prostacyclin synthase and alkaline phosphatase were highly expressed at 6 hours, whereas no change was observed in non-OPLL cells. These results suggest that mechanical stress induces onset and progression of OPLL through the production of prostacyclin.

Application of Mechanical Stress Induces Integrin Signaling in Osteoblasts Cultured on RGD-grafted Surfaces. E. A. Cavalcanti-Adam[1], R. J. Composto*[2], E. Macarak*[3], I. M. Shapiro[4], C. S. Adams[4]. [1]University of Pennsylvania, Philadelphia, PA, USA, [2]Material Science and Engineering, University of Pennsylvania, Philadelphia, PA, USA, [3]School of Dental Medicine, University of Pennsylvania, Philadelphia, PA, USA, [4]Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA.

The objective of the investigation was to covalently link RGD peptides to a deformable silicone membrane and to use this substrate to test the hypothesis that mechanical deformation of the membrane is transduced through the integrin signaling pathway. MC3T3E1 cells were grown on silicone membranes grafted with a silane linker to RGDS- or RGES-(control) peptides. We found that RGDS enhanced osteoblast attachment. Cell attachment was integrin mediated. Thus, free RGD peptides as well as αVβ3 antibodies blocked the attachment of osteoblasts to these modified surfaces. Western blot analysis and immunohistochemistry indicated that the grafted RGD peptide upregulated αVβ3 integrin and focal adhesion kinase (FAK) expression; in contrast, the RGES surfaces caused minimal expression of these proteins. When osteoblasts were stretched by applying a dynamic equibiaxial strain to the RGD-surface, the expression of αVβ3 was further increased. Examination of FAK expression indicated that there was upregulation of the phosphorylated protein and that the extent of phosphorylation was dependent on the level of the applied strain. Bad, a protein downstream of FAK, was also modulated by strain application. Following mechanical stretch, phospho-Bad expression was elevated. These results clearly indicate that mechanical stress upregulates osteoblast survival signals. To ascertain if there was a concomitant down regulation of apoptosis, we measured the apoptotic sensitivity of mechanically stressed cells. We noted that serum deprivation killed significantly smaller numbers of mechanically stressed cells than non-stressed controls. It is concluded that the transduction of mechanical force by RGD-integrin interaction promotes bone cell survival, while at the same time inhibiting signals that promote osteoblast apoptosis.

Mechanical Stress-induced Tooth Movement model in Osteopontin-deficient mice. C. Chung*[1], M. Ishijima[1], M. Morinobu[1], S. Rittling*[2], K. Tsuji[1], K. Soma*[3], A. Nifuji[1], D. T. Denhardt*[2], M. Noda[1]. [1]Molecular Pharmacology, Tokyo Medical and Dental Univ., Tokyo, Japan, [2]Rutger Univ., Piscataway, NJ, USA, [3]Orthodontic Science, Tokyo Medical and Dental Univ., Tokyo, Japan.

When mechanical stress is applied to the tooth, tooth movement occurs in association with the remodeling of underlying alveolar bone. In rodent experimental tooth movement models we can observe bone resorption on the pressure side, and new bone apposition on the tension side according to the direction of the force applied. Osteopontin (OPN), a major noncollagenous bone matrix protein is known to be induced by mechanical stress especially in the pressure sides of experimental tooth movement model in vivo and to have a chemotactic effect on osteoclast precursors in vitro. Recent studies have also reported a difference not only in bone resorption but also in bone formation to mechanical stress in OPN-deficient mice. To elucidate the role of OPN in mechanical stress-induced tooth movement along with the alveolar bone remodeling, we have developed a mice tooth movement model using OPN-deficient mice. By anchoring TiNi closed coil spring to the maxillary incisors, light continuous force (2g, 10g) was applied to the maxillary right first molar for 1~3 weeks. The left side served as an untreated internal control. As days of force application increased, tooth movement and rotation of the treated first molar increased when measured by soft X-ray and micro CT scanning. Both WT and OPN deficient mice showed mesial tooth movement and mesio-palatal rotation of the treated molar compared to the control side. Surprisingly OPN deficiency did not result in a delay in tooth move-

ment, but showed an increased tooth movement as the activation duration proceeded from 1 week to 3 weeks. The periodontal ligament space surrounding the tooth was also measured by micro CT coronal sections of the distobuccal root of the treated molar. In the WT treated group the periodontal ligament space ratio of the tension side (distal periodontal ligament) to the pressure side (mesial periodontal ligament) was significantly greater compared to the KO group ($p<0.05$). Histological examinations of both WT and OPN deficient alveolar complex with treatment showed a reverse pattern in bone remodeling compared to the control. On the pressure side, there was clear presentation of TRAP positive osteoclasts, while in the tension side alkaline phosphatase positive new bone forming cells were observed. However there was no significant difference in TRAP and Alkaline phosphatase positive cells between the WT, OPN deficient group. This indicates OPN deficiency could be backed up by unknown compensating mechanisms for surrounding bone remodeling in the experimental tooth movement in mice

SU059

Osteopontin Deficiency Suppresses New Bone Formation in the Sutures Under Tensile Mechanical Stress in vivo. M. Morinobu[1], M. Ishijima[1], S. R. Rittling[2], K. Tsuji[1], H. Yamamoto*[3], A. Nifuji[1], D. T. Denhardt[2], M. Noda[1]. [1]Dept of Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Rutgers University, Piscataway, NJ, USA, [3]Ehime University, Matsuyama, Japan.

Mechanisms underlying mechanical stress-dependent control of bone remodeling are largely unknown. Mechanical stress enhances osteopontin (OPN) expression in osteoblasts, and OPN deficiency prevents unloading-induced reduction in bone formation (Journal of Exp. Med. 193:399, 2001). Thus, OPN could act as a transducer for mechanical stress. However, the function of OPN in bone formation under mechanical stress is not known. Therefore, we examined the role of OPN in bone formation under tensile mechanical stress in vivo in mice. Sagittal sutures of mice were subjected to expansion by orthodontic springs and bone formation was examined. One week expansion of the sutures resulted in bone formation in the edges of the parietal bones. RT-PCR analysis indicated increase in the levels of OPN mRNA expression in the cells in the wild type calvariae subjected to expansion. In addition, type I collagen mRNA was also expressed in the calvariae under the mechanical stimuli. Immunohistchemical analysis revealed highly abundant expression of OPN protein in the matrix of newly formed bone in the mechanically expanded sutures and on the inner edge of the parietal bone where stress was applied. Osteoblasts forming bone under tensile stress also exhibited high levels of OPN protein expression in the operated mice. In sham-operated mice (without expansion), OPN positive osteoblasts were also observed on the inner edges of parietal bone, however accumulation of OPN protein on the bone matrix was significantly less than expansion group. After the application of mechanical stress, OPN was expressed at low levels in fibroblastic cells in the fibrous interzone. On the primary matrix front, highly OPN positive-oval shaped transchondral cells were observed. Bone formation was clearly observed in the expanded suture area four weeks later in wild type mice. In contrast, reduction in such bone formation in the expanded suture area was observed in the OPN knockout mice. These observations revealed that OPN is required for bone formation under the tensile mechanical stress.

Skeletal Phenotype of Transgenic Mice Expressing the Beta-1 Integrin Cytoplasmic Tail In Osteoblasts. R. K. Globus[1], M. C. H. van der Meulen[2], C. Damsky*[3], J. B. Kim*[3], D. Amblard*[1], Y. Nishimura*[4], E. Almeida*[1], U. T. Iwaniec[5], T. J. Wronski[5]. [1]NASA Ames Research Center, Moffett Field, CA, USA, [2]Cornell University, Ithica, NY, USA, [3]UCSF, San Francisco, CA, USA, [4]NASA Ames Research Center, Moffett FIeld, CA, USA, [5]University of Florida, Gainesville, FL, USA.

To define the physiologic role of β1 integrin in bone formation and mechanical loading, transgenic mice were generated by expressing the cytoplasmic tail and transmembrane domain of β1 integrin under the control of the osteocalcin promoter. In cultured cells, this truncated fragment of β1 can act as a dominant negative. Previously, the matrix of calvariae was shown to be abnormal in transgenic (TG) compared to wildtype (WT) mice. In this study, we analyzed appendicular bone in TG and WT, male and female mice at 14, 35, 63, 90 and 365 days old (n=8-12/gp). To assess β1 integrin function in mechanical loading, a pilot study using hindlimb unloading by tail suspension was performed. 35d old TG and WT females were hindlimb unloaded for 4 wks (n=3-5). Body mass, bone mineral content, histomorphometric (distal femur) and biomechanical parameters were analyzed. Statistical significance ($P<.05$) was defined by ANOVA using the Tukey-Kramer post-hoc test. We confirmed transgene expression by immunoprecipitating then immunoblotting bone lysates using an antibody against the β1 tail. Body masses of TG mice at 63, 90 and 365d old were greater (16-25%) than WT. Some TG female mice at 365d appeared obese; mean abdominal fat mass was 415% greater in TG than WT mice. Tibiae were longer (5-7%) in TG than WT mice at 63 and 90d. Tibial mineral mass of 35d males was 7% lower in TG than WT mice, but at 63d was 21% higher. The % osteoblast surface in 35d TG mice was 20% higher than WT, and at 63d was 17% lower, while % osteoclast surface did not differ. In 365d mice, cancellous bone volume (125%) and endocortical mineral apposition rate (40%) were greater in TG than WT males but not females. In WT mice, hindlimb unloading caused a reduction in mineral mass of tibiae (-20%) and lumbar vertebrae (-22%) relative to normally loaded controls. Surprisingly, hindlimb unloading also caused a relative reduction (-13%) in humerus mass. The effects of hindlimb unloading on tibia and humerus mass were less obvious in TG than in WT mice. Since hindlimb unloading caused skeletal changes in both loaded and unloaded bones, systemic changes may contribute to bone responses observed using this animal model. In conclusion, transgene expression resulted in marked metabolic changes during growth and in the aged female. Our results demonstrate that expression of the β1 integrin cytoplasmic tail *in vivo* causes gender- and age-specific changes in select morphometric parameters, bone length, and bone mass.

Demonstration of MAP Kinase Activation in Response to Mechanical Stimulation in a Novel Rat Model of Fracture Healing. N. J. Hubbard*, S. K. Volkman*, S. A. Goldstein, M. R. Moalli. Orthopaedic Research Laboratories, University of Michigan, Ann Arbor, MI, USA.

The MAP Kinase family of threonine and serine kinases is activated in response to diverse extracellular stimuli, and various in vitro studies have demonstrated their responsiveness to mechanical strain. However, the signal transduction mechanisms which cells use to respond to the local strain environment during fracture healing are currently poorly characterized. We have developed the first in vivo model that enables the study of how mechanical stimulation influences the cellular and molecular processes that regulate fracture healing under normal, aged and osteopenic conditions. Using this model we examined the hypothesis that the stage of fracture healing, as well as the local strain environment determine the activation profile of MAPK. Mechanical load-induced MAPK activation was evaluated during the reparative and remodeling stages of fracture healing, which occur at either 8 days or 5 weeks post-operatively in this model, as determined by histological analysis. This study utilized young adult Fischer 344 female rats that received bilateral, 0.6mm, mid-diaphyseal femoral osteotomies. The osteotomies were stabilized with custom four pin external fixators that enabled normal cage activity post-operatively. At either 8 days or 5 weeks post-operatively, a uni-axial compressive load was applied to one fracture site, while the other fracture site was designated as the unloaded control. Due to the predominantly fibroblastic component of the 8 day reparative tissue, the mechanical stimulus was a displacement-controlled force, corresponding to a 15% strain of the fracture tissue. In contrast, due to increased consolidation in the 5 week tissue the mechanical stimulus was a load-controlled force, also corresponding to a 15% strain. Both experimental groups were loaded for 900 cycles at 1Hz. Specimens were harvested immediately after loading, snap frozen and prepared for immunoblot analysis using MAPK and phospho-specific MAPK antibodies. In the 8 day specimens MAPK activation was increased in loaded as compared to the unloaded tissue. Interestingly, MAPK activation was decreased in the loaded as compared to the unloaded tissue of the 5 week specimens. It appears that the viscoelastic nature of the undifferentiated, 8 day repair tissue may be dictating MAPK activation in response to mechanical stimulation. Immunolocalization studies are currently underway to identify the mechanoresponsive cellular phenotypes.

Use of Predominant Collagen Fiber Orientation for Interpreting Cortical Bone Loading History: Bending vs. Torsion. J. G. Skedros. Dept of Orthop Surg, U of UT, Salt Lake, UT, USA.

Habitual bending appears to be highly conserved in functional loading of appendicular long bones in terrestrial animals. In fact, empirical strain data demonstrate that bending produces the majority (>70%) of longitudinal strains occurring during controlled in vivo activity. Non-uniform patterns of predominant collagen fiber orientation (CFO) in cortical bone are highly correlated with the regional prevalence of tension and compression strain modes. Predominant CFO therefore appears to be highly sensitive and specific for interpreting loading history in a limb diaphysis when strain data are not available. Some bone regions, however, experience habitual torsion. While notable examples include the human femoral neck, and mid diaphyses of the sheep tibia, pigeon humerus, and turkey ulna, only the non-human bones have been verified with in vivo strain measurements. Due to the widely shifting neutral axis that occurs during torsional loading, non-uniform CFO patterns would not be expected in these regions. To test this hypothesis, transverse segments from mid diaphyses of 9 skeletally mature chicken femora were embedded in polymethyl methacrylate and examined for tissue adaptations. In vivo strain gauge studies have demonstrated that this region experiences prevalent torsion (Carrano and Biewener, 1999. J Morph). Undecalcified sections were milled to 100+/-5 microns and viewed under circularly polarized light. CFO is expressed as the mean graylevel in each microscopic field (approx. 2.3mm2) in the mid-cortical region of the cranial (Cr), caudal (Cd), medial (M), and lateral (L) cortices. Graylevels were quantified from pixel histograms obtained from digitized images. Embedded transverse sections from mid shafts of calcanei from a skeletally mature sheep and mule deer, and a horse radius, were used as "control" bones since strain gauge analyses have shown that they have a habitual tension/compression distribution. Results showed no statistically significant CFO differences between any of the chicken femora cortical regions, consistent with the hypothesis of the apparent absence of non-uniform regional CFO patterns in torsional loading. These results are consistent with recently reported findings in mid diaphyses of torsionally loaded mature sheep tibiae and turkey ulnae. It is suggested that the uniform CFO in the chicken femora actually represents adaptation for shear strains produced by torsion. CFO is also uniform in the neutral axes of the control bones where shear stains are prevalent. These observations suggest that predominant CFO is reliable for interpreting strain-mode-specific (tension, compression, shear) adaptations in bending and torsion.

SU063

Increased Dentin Matrix Protein (DMP1) Gene Expression in Osteocytes during Mechanical Loading of Bone. J. Gluhak-Heinrich[1], D. Pavlin*[1], L. F. Bonewald*[2], M. MacDougall*[3], S. E. Harris*[2]. [1]Orthodontoics, UTHSCSA, San Antonio, TX, USA, [2]Oral Biology, University of Missouri at Kansas City, School of Dentistry, Kansas City, MO, USA, [3]Pediatric Dentistry, UTHSCSA, San Antonio, TX, USA.

DMP1 protein has been shown to be expressed in early and mature osteocytes, specifically along their dendritic processes, which implies involvement in osteocyte function. Earlier *in vivo* studies proposed osteocytes to be mechanically responsive cells, but the role of DMP1 in this response is not known. The aim of this study was to examine the effect of mechanical loading on the expression of DMP1 mRNA in the mouse tooth movement model by *in situ* hybridization. The number of osteocytes expressing DMP1 mRNA was determined for various durations of loading between 6 hours to 7 days in 37 loaded and 33 control alveolar bone sites. Expression of DMP1 mRNA in osteocytes increased two-fold as early as 6 hours after loading. After 4 days of loading, DMP1 expression in osteocytes increased to a peak 3.7 fold in the bone formation sites and 3.5 fold in the resorption sites. Osteoblasts responded in the opposite manner, showing a transient 45% decrease of DMP1 mRNA in bone formation sites. A consistent decrease of DMP1 mRNA during the course of loading was observed in bone resorption sites, with maximum inhibition of 67% at day 2. In summary, increased expression in osteocytes and decreased expression in osteoblasts for DMP1 mRNA were observed for both resorption and formation sites. The response of DMP1 to mechanical loading was similar to that of osteopontin observed in our earlier study. These results support the hypothesis that DMP1 has an important role in the responses of osteocytes and osteoblasts to mechanical loading of bone *in vivo*.

SU064

Gravitational Force Alters Intracellular Signaling and Gene Transactivation. C. S. Ontiveros*[1], L. K. McCauley[2], L. R. McCabe[1]. [1]Physiology, Michigan State University, East Lansing, MI, USA, [2]Dept Perio/Prev/Geri, University of Michigan, Ann Arbor, MI, USA.

Changes in gravity affect the cellular and metabolic functions of osteoblasts. During spaceflight, microgravity conditions are thought to lead to decreased bone formation. Histology suggests that changes in osteoblast growth and mineralization are important contributors to this outcome but the specific mechanisms are unclear. Based on evidence demonstrating an important role for AP-1 in regulating growth and differentiation, our studies examined the influence of gravitational force on MAPK and downstream target transcription factor levels and activities in osteoblastic cells. Using a rotating cell culture system, MC3T3-E1 osteoblasts were exposed to simulated microgravity (24 h). To determine if transcriptional activities were influenced by gravitational force, osteoblasts were transfected with an AP-1 luciferase reporter plasmid and luciferase activity measured. Results indicated AP-1 transactivation was decreased under microgravity relative to normal gravity controls and constitutively active CMV reporters. To evaluate AP-1 binding nuclear extracts were obtained from cells cultured in simulated microgravity. AP-1 binding activity correlated with AP-1 transactivation. To evaluate the impact of microgravity on gene expression, AP-1 family members were evaluated by northern analysis to determine whether different AP-1 transcription factors were altered. Levels of cFos and cJun mRNA were decreased in a time dependent manner and correlated with decreases in AP-1 binding and transactivation. Because alteration of specific MAPK members directly influences AP-1 transactivation, intracellular signaling under microgravity was evaluated. Findings demonstrated significant differences in MAPK family member activities compared to normal gravity controls. Some MAPK activities were modulated in a time dependent manner. Next, we hypothesized that osteoblast responsiveness to extracellular cues could be altered under conditions of simulated microgravity. Cells were exposed to simulated microgravity or normal gravity and were treated with 10nM PTH. Interestingly, PTH mediated CRE transactivation was decreased under simulated microgravity when compared to untreated controls suggesting cells under microgravity are less sensitive to the actions of PTH. Taken together, our data demonstrates that alterations in gravitational force cause significant changes in basal and stimulated osteoblast signaling and gene transactivation. Understanding the molecular events leading to changes in signaling and transcription factor activation may facilitate the development of drugs to prevent bone loss.

Cathepsin K Deficiency in Pycnodysostosis Results in Accumulation of Non-digested Phagocytosed Collagen in Fibroblasts. V. Everts[1], W. Hou*[2], X. Rialland*[3], W. Tigchelaar*[1], P. Saftig*[4], D. Broemme*[2], B. D. Gelb*[2], W. Beertsen[5]. [1]Cell Biology, Academic Medical Centre, Amsterdam, Netherlands, [2]Human Genetics, Mount Sinai Hospital, New York, NY, USA, [3]Pediatrics, Centre Hospitalier Universitaire Angers, Angers, France, [4]Biochemistry, Christian-Albrechts University, Kiel, Germany, [5]Periodontology, Academic Centre for Dentistry, Amsterdam, Netherlands.

The rare osteosclerotic disease, pycnodysostosis, is characterized by decreased osteoclastic bone collagen degradation due to the absence of active cathepsin K. Although this enzyme is primarily expressed by osteoclasts, data indicate that it may also be present in other cells including fibroblasts. Since fibroblasts are known to degrade collagen intracellularly following phagocytosis, we analysed various soft connective tissues (periosteum, perichondrium, dermis, lamina propria of intestine, synovial membrane) from a 13-week-old human fetus with pycnodysostosis for changes in this pathway of collagen digestion. In addition, tissues (periosteum, perichondrium, dermis, synovial membrane) from cathepsin K-deficient and control mice were analysed. The tissues were fixed and processed for electron microscopic examination. Microscopic analysis of the human fetal tissues showed that cross-banded collagen fibrils had accumulated in lysosomal vacuoles of fibroblasts. The highest accumulation was found in connective tissues associated with bone or cartilage; lower amounts were found in the dermal and intestinal lamina propria. In studies of three children with pycnodysostosis (from whom only bone-associated tissues were available), a similar accumulation was seen in periosteal fibroblasts. In biopsies of controls, intracellular collagen was sporadically seen. In contrast to the findings in humans, in fibroblasts of murine cathepsin K-deficient tissues an accumulation of internalised collagen was not apparent. Our observations indicate that in humans with pycnodysostosis, but probably not in the mouse model mimicking this disease, the intracellular digestion of phagocytosed collagen by fibroblasts is inhibited. The data strongly suggest that in human fibroblasts cathepsin K is a crucial protease for this process. Murine fibroblasts may have other proteolytic activities that are expressed constitutively or up-regulated in response to a deficiency of cathepsin K. This may explain why cathepsin K-deficient mice lack some of the dysostotic features, which are prominent in patients with pycnodysostosis.

SU066

In Vivo Impairment of Collagenase Activity Does not Affect Bone Formation in Transgenic Mice Expressing Constitutively Active PTH/PTHrP receptors in Osteoblastic Cells. E. Schipani[1], R. Chiusaroli[2], A. Maier*[1], M. C. Knight*[1], M. Byrne*[3], M. Inada[3], L. Calvi[1], Y. Wang[3], R. Baron[2], S. M. Krane[3]. [1]Endocrine Unit, MGH-Harvard Medical School, Boston, MA, USA, [2]Cell Bio & Orthopedics, Yale University, New Haven, CT, USA, [3]Ciid, MGH-Harvard Medical School, Boston, MA, USA.

Expression of a constitutively active PTH/PTHrP receptor in vivo in cells of osteoblast lineage (Cl2 transgenic mice) causes a dramatic increase in trabecular bone volume and trabecular bone formation, and, conversely, a significant decrease in periosteal mineral apposition rate. Collagenase-3 (MMP-13) is a known downstream target of PTH action. In order to investigate the role of collagenase cleavage in generating the Cl2 bone phenotype described above, we bred Cl2 transgenic animals with mice carrying a mutated col1a1 gene that encodes a protein resistant to digestion by collagenase-3 and other collagenases (rr mice). Adult tibias and parietal bones from 1-month old double mutant animals (Cl2/rr) and from control littermates were analyzed by histology, in situ hybridization and histomorphometry. Trabecular bone volume was higher in Cl2/rr than in Cl2 mice. This increase occurred despite no change in the rate of bone formation, which was equally high in the two animal models. The finding suggests therefore that resorption was impaired in the doubly mutant mice. Interestingly, osteoclast number was not significantly different in Cl2/rr and Cl2 mice. Periosteal mineral apposition rate was similar in the two mutant mice, and significantly lower than in wild type. Serum measurements of ionized calcium and PTH are in progress. In summary, impairment of collagenase activity enhances the increased bone deposition in transgenic mice that express a constitutively active PTH/PTHrP receptor in cells of the osteoblast lineage but does not significantly modify either trabecular bone formation or periosteal mineral apposition rate. Increases in trabecular bone volume in the double mutant mice therefore must result from a deficit in bone resorption.

SU067

Ameloblasts Highly Express Enamel Matrix Serine Proteinase 1 (EMSP1) at Late Stage in Amelogenesis. T. Suzawa, T. Katagiri, R. Kamijo. Biochemistry, School of Dentistry, Showa University, Tokyo, Japan.

Ameloblasts, derived from inner dental epitherial cells, are specialized cells responsible for calcified enamel formation. Mature enamel is the highest calcified tissue among hard tissues in mammals. In early stage of amelogenesis, immature enamel contains large amount of enamel matrix proteins secreted by ameloblasts. In late stage, however, mature enamel contains less amount of enamel proteins due to degradation and removal of the proteins by proteinases. In rodents, ameloblasts are continuously differentiated from an apical loop and further mature into early secretory cells and mature cells. Ameloblasts secrete not only enamel matrix proteins but also proteinases, but the regulatory mechanism is still not known. In order to elucidate the mechanism of amelogenesis, we examined the changes of the expression levels of enamel proteins and proteinases in ameloblast differentiation. An ameloblst-rich cell layer was prepared from a labial side of mandibular incisors of 7-day-old ddY mice. Then, it was divided into three parts; an early secretory, transitional and mature parts, respectively, from an apical loop edge to a gingival margin edge. RT-PCR and Northern blot were used to detect mRNAs of enamel matrix proteins (amelogenin, enamelin, ameloblastin and tafterin) and proteinases (enamelysin and enamel matrix serine proteinase 1 (EMSP1). Expression of amelogenin, enamelin and enamelysin were abundant in early secretory ameloblasts. There was no difference in the pattern of ameloblastin and tafterin expression. In contrast, EMSP1 was highly expressed in mature ameloblasts. Taking together, these results clearly indicate that expression levels of enamel matrix proteins and proteinases in ameloblasts are changed during their differentiation. These changes may be required for removal of enamel proteins at late stage of amelogenesis. It was also suggested that EMSP1 expression is a useful marker for mature ameloblasts.

SU068

Effects of Tetracyclines on Bone and Cartilage Loss in a Rat Model of Rheumatoid Arthritis. P. Pastoureau, N. Moulharat*, V. Renoux*, S. Gaufillier*, M. Sabatini*. Rheumatology Division, Institut de recherches Servier, Suresnes, France.

Inhibition of bone and cartilage degradation *in vitro* is a well-known non-antibiotic effect of tetracyclines (TCs). This is thought to depend on inhibition of matrix metalloproteinases (MMPs) at different levels, including mRNA expression, activation of the proforms, and activity of the mature enzymes. The aim of this study was to examine the effects of doxycycline (Dox), minocycline (Mino) and tetracycline (Tetra), on bone and cartilage degradation induced by inflammation in adjuvant polyarthritis (AP) in the rat. In a parallel assay, we also examined the effects of Dox and Mino on mRNA expression of collagenase (MMP-13) in articular cartilage of AP rats. AP was induced by injection of complete Freund adjuvant into the right hind paw of female Lewis rats. They were then allocated to 4 groups of 12 animals: vehicle (arthritic control), Dox, Mino and Tetra. One extra group was not injected and served as non arthritic control (n=12). Preventive oral treatment started on the day of induction and was continued for 21 days at the same dose of 100mg/kg twice a day, for the three compounds. Pathology was assessed by visual score and paw edema volume. At sacrifice, also measured were bone mineral content of the proximal femur (by DEXA) as well as GAG and OH-Pro content of patellar cartilage (by colorimetric assays) of the non-injected paw. Expression of MMP-13 was analyzed by RT-PCR of mRNA extracted from the tibial cartilage of the non-injected knee, followed by band densitometry. Treated groups were compared to arthritic control and the results, expressed as percent of inhibition of the pathology, are the following:

	Paw edema	BMC	GAG	OHpro	MMP-13 expression
Doxycycline	3 %	48 % ***	58 %	57 %	51 %
Minocycline	53 % ***	53 % ***	47 %	100 % ***	100 %
Tetracycline	3 %	52 % **	18 %	100 % *	not done

n = 12 /group *:p<0.05; **: p<0.01; ***:p<0.001.

The three TCs effectively inhibited bone loss. This effect does not seem to be secondary to anti-inflammatory action, since only Mino significantly decreased paw edema and pathological score. The inhibition of MMP-13 expression by Dox and Mino correlates with the degree of protection against collagen loss in cartilage. Even if we cannot exclude that a) other MMPs contribute to tissue loss and b) TCs inhibit MMPs also by other mechanisms, these results suggest that decrease of MMP expression is at least in part responsible for the protective effects of TCs. This study also confirms the therapeutic potential of TCs in rheumatic diseases.

SU069

Collagenase-3 is induced in human osteoblasts by the synergistic interaction of T cell derived TNF-α, TGF-β and IFN-γ. L. Rifas. Internal Medicine,Division of Bone & Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA.

Activated T cells secrete multiple osteoclastogenic cytokines which play major roles in the bone destruction associated with Rheumatoid Arthritis (RA). While the role of T cells in osteoclastogenesis has received much attention recently, the effect of T cells on osteoblast activity is poorly defined. In this study, we investigated the hypothesis that in chronic inflammation activated T cells contribute to enhanced bone turnover by regulating human osteoblast (hOB) collagenase-3 production, thus priming the bone for osteoclastic resorption. As a model for RA, we have used activated T cell conditioned medium (ACTTCM) which mimics the *in vivo* cytokine repertoire. We have previously reported (ASBMR 2001) that ACTTCM induces collagenase-3 in human osteoblasts (hOB). Analysis of ACTTCM by specific ELISAs revealed that IFN-γ (23553 ± 2439pg/ml), TGF-β (1142 ± 12pg/ml) and TNF-α (466 ± 8 pg/ml) were major constituents. These cytokines are important regulators of bone turnover and collagenase-3 production. In order to define the role of these three cytokines, hOB were treated with 25% ACTTCM in the presence and absence of neutralizing antibodies to TNF-α, TGF-β or IFN-γ and collagenase-3 measured by specific ELISA. Neutralizing antibodies to TGF-β decreased by 28%, and to IFN-γ approximately 20%, collagenase-3 induction. However, neutralizing antibodies to TNF-α inhibited collagenase-3 by 70%. In order to examine more fully the effect of these three major T cell cytokines on collagenase-3 production, hOB were exposed to recombinant cytokines at their levels present in 25% ACTTCM either individually or in combinations and collagenase-3 production assayed by a specific ELISA. hOB treated with IFN-γ, TNF-α or TGF-β alone or combinations of TNF-α with IFN-γ or IFN-γ and TGF-β did not produce significant amounts of collagenase-3. Combinations of TGF-β and TNF-α induced a small induction. However, when hOB were treated with all three cytokines, collagenase-3 was induced to a level of 10 fold over that induced by TNF-α + TGF-β and 100 fold over control or individual cytokine alone. Furthermore, the combination of all three cytokines induced collagenase-3 to 70% of the level induced by 25% ACTTCM. Taken together, these results demonstrate that in chronic inflammatory diseases such as RA, multiple factors working in concert are responsible for the bone loss observed.

Prolactin Dependant Expression of RANKL in Mammary Epithelial Cells. S. Srivastava[1], M. J. Mistry*[2], N. D. Horseman*[3]. [1]Mol. and Cellular Physiology, University of Cincinnati, Cincinnati, OH, USA, [2]Mol and Cellular Physiolgy, University of Cincinnati, Cincinnati, OH, USA, [3]Mol. and Cellular Physiolgy, University of Cincinnati, Cincinnati, OH, USA.

Prolactin (PRL) and its immediate target genes are essential for lactation and full development of breast. PRL regulates cyclinD1 expression by activating STAT (STAT 5a) pathway. Mice with disruptions in genes that encode Receptor Activator of NF-κB (RANK) or its ligand RANKL, share similar phenotypes with mice lacking genes that encode PRL, STAT5a or cyclinD1, suggesting that RANKL, RANK or osteoprotegerin (OPG, RANKL decoy receptor) may be direct targets of PRL action. To test this hypothesis, total RNA was extracted from prolactin treated or untreated cells from total mammary gland and from primary mammary epithelial cells (PMEC) and assayed for RANK, OPG and RANKL. We found that untreated and treated PMEC as well as total mammary gland preparation equally expressed the mRNA for RANK and OPG. However, only PRL treated expressed RANKL. Furthermore PRL knockout mice (PRL-/-) failed to express RANKL in mammary epithelial cells, whereas pituitary grafted mice restored RANKL expression in PRL -/- mice. To further confirm that PRL directly regulates the transcription activity of RANKL, we transiently co- transfected RANKL–Luciferase reporter with β-galactosidase reporter constructs in CHO cell line that constitutively express PRL receptor (CHO-D6). CHO-D6 cells treated with PRL induced RANKL reporter activity in a dose dependent manner with maximum induction of 3 fold over untreated controls, demonstrating that RANKL transcription is under the control of PRL. Since PRL expression is developmentally regulated, we examined RANKL expression in virgin, pregnant and lactating mice. We found RANKL mRNA is expressed from mid-pregnancy (day 16) until the end of pregnancy, whereas virgin (6 week) mice failed to express RANKL. In contrast, OPG and RANK were constitutively expressed in mammary gland in all the stages examined. Consistent with this fact PRL receptor knockout mice showed markedly decreased in osteoblast activity and bone formation as compared to wild type littermates (Endocrinology 140:96, 1999), suggesting that the PRL effect is systemic and not restricted to mammary epithelial cells. In summary, we report that mammary epithelial cells express RANK and OPG. In addition, RANKL expression is developmentally regulated. We are currently investigating the link between RANKL expression on mammary epithelial cells and malignancy of breast tumor that leads to bone metastasis.

Role of CREB Phosphorylation on the Expression of 25-Hydroxyvitamin D-1-alpha-Hydroxylase in Human Prostate Cells. L. Wang*, M. F. Holick, T. C. Chen. Vitamin D, Skin and Bone Research Laboratory, Endocrine Division, Boston University School of Medicine, Boston, MA, USA.

25-Hydroxyvitamin D-1α-hydroxylase (1α-OHase) is expressed in prostate cells. The expression suggests that local production of 1,25-dihydroxyvitamin D could provide an important cell growth regulatory mechanism. However, there is differential expression of 1α-OHase activity among the primary cultures of prostate cells derived from cancerous, benign prostatic hypertrophy and normal tissue, and among normal (PZHPV-7) and various cancer cell lines (PC-3, DU145). No activity was found in cancer cell line LNCaP. Using luciferase reporter gene assay, we further observed a step-wise decrease in the basal promoter activity in two truncated promoter fragments, AN2 (-1100bp) and AN5 (-394 bp), with the highest basal activities found in PZHPV-7 and with loss of promoter activity in LNCaP. In order to understand the mechanism underlying the differential promoter activities among different prostate cells, we investigated the possible role of phosphorylation of cyclic AMP response element binding protein (CREB) on the regulation of 1α-OHase promoter activity in prostate cells. First we compared the levels of CREB phosphorylation among PZHPV-7, DU145, PC-3 and LNCaP cells by western blot analysis using antibody against phosphorylated CREB. We observed that CREB was phosphorylated to a greater extent in PZHPV-7 and DU145 cells than in PC-3 cells. No significant phosphorylation of CREB was found in LNCaP cells. Next, we utilized various activators and inhibitors of protein kinase A (PKA), protein kinase C (PKC), mitogen-activated protein kinase (MAPK) and calcium/calmodulin-dependent protein kinase II (CaMKII) to determine which kinases might be involved in phosphorylating the CREB in PZHPV-7 cells. We demonstrated that forskolin (an activator of PKA) increased the AN2 basal promoter activity 50% ($p< 0.01$), whereas H-89 (an inhibitor of PKA) inhibited the basal and forskolin-stimulated AN2 promoter activity 40 ($p<0.01$) and 70% ($p<0.005$), respectively. We also showed that PD98059 (an inhibitor of MAPK) decreased the AN2 promoter activity 70% ($p< 0.001$). Phorbol 12-myristate 13-acetate (an activator of PKC), GF109203 (an inhibitor of PKC) and KN-93 (an inhibitor of CaMKII) had no effect on AN2 promoter activity in PZHPV-7 cells. Thus, our results suggest that differential phosphorylation of CREB through PKA and MAPK pathways may be involved in the regulation of 1α-OHase promoter activity.

SU072

Androgen Deprivation Causes Bone Loss and Increased Prostate Cancer Metastases to Bone: Prevention by Zoledronic Acid. S. S. Padalecki, M. R. Carreon*, B. Grubbs*, Y. Cui*, T. A. Guise. University of Texas Health Science Center/Institute for Drug Development, San Antonio, TX, USA.

Most patients with advanced prostate cancer have bone metastases. Androgen ablation, a standard treatment for prostate cancer, causes increased osteoclastic bone resorption and bone loss. Bone is a repository for growth factors, which are released as a consequence of osteoclastic bone resorption. As a result, the bones of hypogonadal men should be fertile environment for prostate cancer metastasis to bone. To test the hypothesis that increased osteoclastic bone resorption due to androgen deprivation causes a more fertile environment for bone metastases, we developed a mouse model of prostate cancer bone metastases which mimics the clinical situation of men rendered hypogonadal as a result of treatment for prostate cancer. Surgical castration of male athymic nude mice resulted in reduced trabecular bone volume and increased osteoclast numbers over a 4-week period compared with sham-operated controls. To investigate the role of androgen deprivation in predisposing men with prostate cancer to bone metastases, athymic male nude mice underwent orchiectomy or sham surgery 4 weeks prior to tumor inoculation with PC-3 prostate cancer cells via cardiac inoculation. Mice were treated daily with zoledronic acid or vehicle from the time of surgery. Radiographs, bone mineral density and bone histomorphometry were used to assess bone mass and tumor osteolysis. Hypogonadism resulted in lower bone mineral density compared with sham-controls and this was prevented by zoledronic acid. PC-3 bone metastases were increased in hypogonadal mice treated with vehicle compared to eugonadal controls by x-ray and histology. Zoledronic acid decreased bone metastases in hypogonadal PC-3-inoculated mice and increased survival. Zoledronic acid had no effect on soft tissue metastases. Histomorphometric analysis indicated that tumor area and bone destruction was lower in mice treated with zoledronic acid compared with controls. This work provides in vivo evidence that androgen deprivation therapy causes bone loss and may increase prostate cancer metastases to the skeleton. Treatment with zoledronic acid not only prevented bone loss due to androgen deprivation but also reduced prostate cancer metastases to bone in this model. These data support the hypothesis that increased bone resorption due to androgen deprivation may result in a more fertile environment for the development of bone metastases. Bone resorption inhibitors, such as bisphosphonates, may benefit hypogonadal men with advanced prostate cancer to prevent bone loss as well as skeletal metastases.

Biochemical and Radiological Assessment of Prostate Cancer Bone Metastases in SCID Mice. S. Peleg[1], D. D. Cody[1], N. Navone*[1], E. Johnson*[1], A. Ismail*[1], G. H. Posner*[2]. [1]The University of Texas, M. D. Anderson Cancer Center, Houston, TX, USA, [2]The Johns Hopkins University, Baltimore, MD, USA.

In man, prostate cancer metastasizes almost exclusively into the bone. The reactions that these malignant cells induce in bone are mixed osteolytic and osteosclerotic responses. We have used intrafemoral injections of two prostate cancer cell lines that induce, preferentially, either osteolytic (PC3) or osteosclerotic (MDA-PCA-2b) response and assessed tumor progression in the bone in the presence or absence of the non-calcemic vitamin D analog JK-1626-2. Injection of MDA-PCA-2b cells into the femur of male SCID mice resulted in the production of detectable serum PSA by 4 weeks after inoculation, which continued to increase after seven weeks. A daily injection of 4 mcg/kg or 10 mcg/kg of JK-1626-2 reduced serum PSA levels by 30% and 45%, respectively, suggesting inhibition of tumor progression by the analog. In spite of the daily administration of high doses of JK-1626-2 for over 7 weeks there was no increase in serum calcium in the analog-treated animals. There was a subtle evidence of change in the tumor-inoculated bones by 2D X-ray imaging, but 3D micro-computed tomography (micro-CT) clearly revealed both loss of trabecular bone and gain of cortical bone in the tumor-bearing femurs. In contrast, intrafemoral injection of the osteolytic prostate cancer cells, PC3, resulted in a rapid bone loss that was evident by x-ray imaging within 18 days. Daily injections of the analog JK-1626-2 (4 mcg/kg and 10 mcg/kg), increased the severity of the bone lesion in the tumor-inoculated femurs by 60%. Furthermore, 3D sample measurements of bone mineral density by micro-CT at the tibias below the tumor-bearing femurs revealed a significant bone loss in the analog-treated animals. This loss of bone was not evident on the contralateral side, suggesting that malignant cells spreading into the tibia below the tumor site induced osteolytic activity. Serum calcium levels in the vehicle-treated tumor-bearing group were slightly but significantly higher than serum calcium in age-matched normal male SCID mice. Interestingly, this increase in serum calcium was more prominent in the analog-treated tumor-bearing animals, findings that were consistent with the observed increases in osteolytic activity in the tumor-bearing bones of these animals. These results indicate that micro CT is a sensitive tool for qualitative and quantitative assessment of bone lesions at early stages of either osteolytic or osteosclerotic metastatic bone disease in mice. Our results also suggest that vitamin D analogs may be useful to treat osteosclerotic metastatic bone disease but may have an adverse effect on advanced osteolytic bone metastases.

Markers of Bone Turnover Do Not Predict Bone Metastases During Long-Term Follow-Up of Breast Cancer Patients. M. J. Seibel[1], M. Koeller*[2], B. Auler-van der Velden*[2], I. Diel[2], H. W. Woitge[1]. [1]University of Sydney, Sydney, Australia, [2]Univ. of Heidelberg, Heidelberg, Germany.

Markers of bone turnover are often elevated in breast cancer patients with bone metastases (BM). To test whether bone markers could be used as early indicators of developing BM, we prospectively followed 112 postmenopausal women operated for primary breast cancer. At the time of diagnosis/ study inclusion, none of the women had BM, other skeletal disease or bone active drugs. During follow-up (range 0.6 - 4 yrs., median 30 mo.), patients were seen every 3 months and timed blood/ urine specimens were obtained. Eleven patients developed BM (BM+) and each of these were matched to 4 women free of BM (BM-). The markers measured were serum (s) calcium, sTAP, sBAP, sOC, sPICP, urinary (u) PYD, uDPD, uNTX, sNTX, uCTX, sCTX. All analyses were done in single batches after study end. Results: At any given point in time (including baseline), marker levels in the BM+ group did not differ significantly from those in the BM- group. Marker levels at baseline did not predict the later development of BM (OR 0.14 -1.01, all NS). 93% of all changes in bone markers were below the least significant change, as defined in an independent group of similar patients. The remaining 7% of values could not be associated in a consistent pattern with the occurrence of BM. Conclusion: In patients with breast cancer, biochemical markers of bone turnover can not be used to predict or diagnose incident BM. This lack in diagnostic validity is mainly attributable to the high overall and long-term variability of the currently used bone markers.

Blockade of TGFβ Signaling in Prostate Cancer Cells Exacerbates Osteolytic Metastases. X. Sun, S. Kakonen, T. Oba, B. L. Hill, B. G. Grubbs*, S. Burns*, T. A. Guise, J. M. Chirgwin. Molecular Medicine, U Tx Hlth Sci Ctr, San Antonio, TX, USA.

PC3 prostate cancer cells express abundant PTHrP and cause osteolytic metastases in nude mice. PTHrP production by PC3 cells is increased 4-fold by TGFbeta. Thus, we hypothesized that blockade of TGFbeta signaling in PC3 cells would decrease osteolytic metastases, as was observed with MDA-MB-231 breast cancer cells. Three stable clones of PC3 expressing a dominant negative TGFbeta receptor construct were isolated. 1B2 & 2B2 showed decreased PTHrP production basally and in response to TGFbeta, while 2B4 had unchanged basal production and was stimulated only 1.8X. Growth rates were unchanged in vitro. In the left cardiac ventricle bone metastasis model, these 3 dominant negative clones caused more osteolytic metastases and reduced survival in tumor-bearing mice compared with controls. Mice receiving 2B2 cells survived ~75d ($p<0.0001$ vs empty vector, EV) and 1B2 & 2B4 groups survived ~150 days ($p<0.05$ vs EV), at which time >75% of EV-inoculated animals were still alive. To determine the mechanism for the increased osteolysis caused by the dominant-negative TGFbeta receptor clones, conditioned media +/- TGFbeta were analyzed for osteolytic factors. Dominant negative clones secreted less IL-11, VEGF, and PTHrP than control. These factors could not account for the results seen in vivo. Other factors with actions on bone cells or tumor growth were examined by RT-PCR +/-TGFbeta. Factor mRNAs unchanged by TGFbeta treatment and in clones vs control cells included: osteoprotegerin, RANK ligand, hepatocyte growth factor, tissue inhibitor of metalloproteinase-1, urinary plasminogen activator, plasminogen activator inhibitor-1, IL-18, and its binding protein. However, insulin-like growth factor binding protein (IGFBP) 3 was stimulated by TGFbeta in EV controls and its expression was decreased in the dominant negative receptor clones. IGFs, along with TGFbeta, are abundant components of bone matrix. When released by osteoclastic resorption, IGFs could stimulate tumor growth in bone. This stimulation would normally be limited by IGFBP3 secreted in response to TGFbeta. The effects of TGFbeta signaling blockade on bone metastases may differ between breast and prostate cancer models for 2 reasons: 1) PC3 prostate cells basally secrete very high amounts of PTHrP, even when TGFbeta signaling is blocked; these are higher than those secreted by MDA-MB-231 cells and may be sufficient to stimulate osteolysis. 2) TGFbeta signaling may control prostate cancer cell growth in bone through a paracrine mechanism involving bone-derived IGFs and tumor-produced IGFBPs.

SU076

Effects of RANKL on Breast Cancer Cell Lines. C. Hwang*[1], H. Chung[2], Y. Kang*[1], I. Moon*[1], C. Yim*[2], K. Han[2], H. Jang*[2], W. Park*[2], H. Yoon[2], I. Han[2]. [1]Laboratory of Endocrinology, Samsung Cheil Hospital and Women's Healthcare Center, Seoul, Republic of Korea, [2]Medicine, Samsung Cheil Hospital and Women's Healthcare Center, Seoul, Republic of Korea.

Breast cancer metastasis commonly induces osteolytic bone lesions. This osteolytic metastasis is mediated by the differentiation and activation of osteoclasts through upregulation of RANKL. Breast cancer cells with the capacity to stimulate osteoclastic bone resorption may enrich the bone microenvironment with growth factors that may alter behavior of tumor cells. Therefore, we investigated whether the locally increased RANKL can affect the invasion of breast cancer or have the influence on the change of gene expressions in breast cancer cells. In this study, we showed the NF-κB activation using electrophretic mobility shift assay in breast cancer cell lines (MCF-7 & MDA-MB-231) when they were incubated with soluble RANKL (1 ng/ml-100 ng/ml). Semi-quantitative RT-PCR showed that the expressions of PTHrP, TGFβ mRNA in ratio to internal standard GAPDH mRNA were elevated in RANKL-treated cells(MCF-7, MDA-MB-231) compared with control (respectively; $P<0.05$), but the levels of IL-1β, IL-6, TNF-α, OPG mRNA were not changed. For invasion analysis, we used matrigel invasion assay system. MDA-MB-231 cells supplemented with RANKL for 18 hr in 0.1% BSA/α-MEM dose-dependently showed the high invasiveness (control;16±5 vs 100 ng/ml of RNAKL;146±27). Zymography and RT-PCR analysis of MMP-2, MMP-9 which were correlated with cancer invasion were not changed. In conclusion, these results suggest that the locally increased RANKL in bone microenvironment may activate the invasiveness of breast cancers and enhance the expression of osteolytic factors in tumor cell.

SU077

The Localization of Macrophage and Lymphocytes in Bone Metastasized Lesions. T. Sasaki[1], K. Ono*[2], T. Akatsu*[2], N. Kugai*[2], T. Maeda*[1], N. Amizuka[1]. [1]Division of Oral Anatomy, Department of Oral Biological Science, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [2]Department of General Medicine, National Defense Medical College, Tokorozawa, Japan.

In order to elucidate the immune-response in bone-metastasis, 4 week-old normal female Balb/c mice were injected with mammary carcinoma cells which were derived from the same strain. After 2 weeks, the tumor-injected mice were fixed with paraformaldehyde solution and then decalcified with EDTA solution. The femurs and tibiae were employed for histochemical and electron microscopic analyses including tartrate resistant acid phosphatase (TRAPase), alkaline phosphatase (ALPase), F4/80 (recognizing macrophage/monocyte lineage), CD45R (recognizing lymphocyte lineage) and CD31 (recognizing endothelial cells). A tumor mass metastasized in the metaphysis showed central necrosis, active proliferation of cells and tumor-derived angiogenesis. ALPase-positive osteoblastic stromal cells surrounded the metastasized lesion. Many TRAPase-possitive osteoclasts were localized on the trabecular surfaces facing to the tumor lesion, associated with ALPase-positive osteblastic cells. In contrast, F4/80-positive macrophages accumulated around the metastasized tumor cells, and often invaded its inner portion. Unlike macrophages, CD45R-positive lymphocytes were located apart from the metastasized tumor lesion; they made contacts with neither the tumor cells nor osteoclasts. Under electron microscope, the macrophages around the tumor lesion showed frequent contacts with the tumor cells by their cytoplasmic processes, and some of them exhibited many secondary lysosomes. Taken together, macrophages but not CD45R-possitive lymphocytes appeared to recognize the metastasized tumor cells in order for the immune-response. Thus, this study suggests that the macrophages play a crucial role in the immune system against the bone-metastasized tumor cells.

SU078

Use of Serum Markers of Tumor Burden and Bone Resorption to Monitor Disease Progression in a Nude Mouse Model of Breast Cancer-Induced Osteolysis. R. NicAmhlaoibh*[1], J. Risteli[2], C. Holst-Hansen*[3], P. Qvist*[1], C. Christiansen[4], N. Brünner*[3], J. Delaissé[1], A. Heegaard[1]. [1]Nordic Bioscience A/S, Herlev, Denmark, [2]Department of Clinical Chemistry, University of Oulu, Oulu, Finland, [3]The Finsen Laboratory, Rigshospitalet, Copenhagen, Denmark, [4]CCBR, Ballerup, Denmark.

Sensitive biochemical markers of cancer-induced osteolytic disease progression and response to therapy are lacking in preclinical models. Using the Arguello model of breast cancer-induced osteolytic disease we have studied the serum levels of cancer markers and bone resorption markers to identify a suitable marker to supplement radiographical evidence of disease and quantitatively follow disease progression and response to therapy. We compared different biochemical markers of tumor burden and bone resorption in 4-week-old nude mice inoculated with a bone-seeking variant of the human MDA-231 breast cancer cell line. Though we have recently found the cytokeratin-associated tissue polypeptide antigen, TPA, to be a very suitable marker for quantification of the tumor burden in extracts of long bones from these mice, and although serum TPA is useful in the clinic to monitor breast cancer progression, human TPA was not detected at significant levels in the serum of mice inoculated with MDA-231 cells. Other human breast cancer serum markers (CA15-3, VEGF, M-CSF) expressed by the MDA-231 cells in vitro, were also not detectable in the serum of diseased mice. Bone resorption markers such as CTX, ICTP, and TRAP5b have been used in the clinic to monitor osteolytic disease progression in patients, and also in the present model their levels were marginally (CTX, ICTP) or significantly (TRAP5b) increased at the late stage of osteolytic disease; however, as expected the basal levels of these markers were high and age-sensitive. In addition, we inoculated the mice with an MDA-231 cell line transfected with E.coli beta-galactosidase (MDA-231/BAG). The concentration of beta-galactosidase in serum from mice with progressive osteolytic lesions was significantly correlated with area of osteolysis and levels of TPA in bone extracts. A particular advantage of beta-galactosidase as a serum marker compared to the bone resorption markers is the negligible basal levels due to its bacterial origin. In conclusion, serum E.coli beta-galactosidase is a useful quantitative serum marker of disease progression in this mouse model of human breast-cancer induced osteolytic lesions.

SU079

Transforming Growth Factor-β Stimulation of Collagenase-3 Expression in Human Breast Cancer Cells. N. Selvamurugan, Z. Fung*, N. C. Partridge. Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA.

TGF (transforming growth factor)-β1, a crucial molecule in metastatic bone cancer, stimulates collagenase-3 (matrix metalloproteinase-13) expression in the human breast cancer cell line, MDA-MB231. Cycloheximide inhibited this stimulation, indicating that *de novo* protein synthesis was essential for this response. In order to analyze the specific response elements involved for TGF-β-stimulated collagenase-3 promoter activity in MDA-MB231 cells, the collagenase-3 promoter constructs having mutations at either the RD/Cbfa or AP-1 sites were used and the effect on CAT activity was assessed in these cells. Mutation of either the distal RD/Cbfa or the proximal RD/Cbfa or the AP-1 sites was enough to cause a significant loss of TGF-β response for collagenase-3 promoter activity in the breast cancer cells. To define the contributions of transcription factors binding to the proximal RD/AP-1 site, gel mobility assays were performed. Proteins in both control and TGF-β-treated nuclear extracts were able to bind to the human collagenase-3 RD/AP-1 site, but significantly more protein-DNA complex was produced when extract from TGF-β-treated cells was used. Further analysis of the proximal RD/AP-1 site-protein complexes identified the presence of both Cbfa1/runx2 and AP-1 factors. The functional role of the RD and AP-1 sites and their transcription factors for TGF-β-stimulated collagenase-3 promoter activity in MDA-MB231 cells was determined by co- transfection of the collagenase-3 promoter construct with either an AML/ETO construct that lacks the transactivation domain of Cbfa/runx and acts as a dominant inhibitor of Cbfa/runx proteins or an antisense-Fra-1 construct. Overexpression of AML/ETO inhibited both the basal and the TGF-β effect suggesting the requirement of the RD/Cbfa site and its transcription factor, Cbfa/runx for collagenase-3 promoter activity. Co-transfection of antisense-Fra-1 plasmid inhibited both the basal and TGF-β-stimulated collagenase-3 promoter activity indicating that the inhibition of Fra-1 expression by antisense-Fra-1 may abolish AP-1 transactivation since Fra-1 forms a complex with c-Jun, JunB or JunD that is necessary for AP-1 transactivation. The specificity of TGF-β-signaling for collagenase-3 promoter activity in MDA-MB231 cells was also determined by co-transfection of the collagenase-3 promoter construct along with either a truncated TGF-β type II receptor or a dominant negative Smad3. Taken together, our results suggest that both the AP-1 and RD sites and their transcription factors along with Smad proteins may account for TGF-β stimulation of collagenase-3 promoter activity in MDA-MB231 cells.

SU080

Gender-specific Role of Endothelin-1 (ET-1) in Pathological Bone Remodeling. K. S. Mohammad[1], J. J. Yin*[1], B. G. Grubbs*[1], Y. Cui*[1], R. Padley*[2], T. A. Guise[1]. [1]Molecular Medicine, UTHSCSA, IDD, CTRC, San Antonio, TX, USA, [2]Abbott, Chicage, IL, USA.

ET-1, a vasoconstrictor, and a potent stimulator of osteoblast activity may play a causal role in osteoblastic metastases. Human breast cancer lines, ZR-75-1, MCF-7 and T47D, all secrete ET-1 and cause osteoblastic metastases in nude mice. Selective ET_A and non-selective $ET_{A/B}$ receptor antagonists, completely inhibited ET-1 and ZR-75-1-mediated new bone formation in mouse calvariae; ET_B antagonist had no effect. In nude mice, an ET_A receptor antagonist (ABT-627, 20mg/kg/day) significantly reduced ZR-75-1 osteoblastic metastases. The data suggest that tumors metastatic to bone cause osteoblastic responses by secreting ET-1, which activates ET_A receptors on osteoblasts. Since ET-1 is expressed in the bone microenvironment, we hypothesized that chronic ET_A receptor blockade would alter normal bone remodeling. We investigated the role of chronic ET_A receptor blockade on bone remodeling in sex steroid-deficient male and female C57 black mice since prostate cancer patients with bone metastases are treated with androgen deprivation therapy. 4 week-old mice underwent orchiectomy, ovariectomy or sham-operation at which time ABT-627 or vehicle was started. BMD was measured at total body, femur, tibia and spine over a 36 week period. Hypogonadal males had significantly lower BMD at all sites compared with intact mice. In hypogonadal males, ABT-627 treatment caused higher BMD at the femur, spine and total body vs. vehicle. In contrast, ABT-627 treatment caused lower BMD at the femur in eugonadal males. Hypogonadal females had lower BMD at the tibia compared with eugonadal controls. In hypogonadal females, ABT-627 treatment caused lower BMD at the femur and spine vs. control treatment. In contrast, eugonadal females treated with ABT-627 had significantly higher BMD at all sites vs. vehicle-treated. Histomorphometric analysis of trabecular bone volume at the femur was consistent with the BMD data in the female mice. In male mice, trabecular bone volume at the femur was consistent with BMD except in eugonadals, where no differences between ABT-627 and control were noted. Taken together, these data indicate that 1) the predominant role of ET-1 in bone remodeling appears to be in pathologic states such as those associated with metastatic bone disease; 2) chronic ET_A receptor blockade has gender-specific differential effects on bone remodeling which depend on the presence or absence of sex steroids. The implications of these findings are: 1) ET_A receptor blockade should benefit those patients with osteoblastic bone metastases and 2) ET_A receptor blockade should not result in bone loss when used to prevent osteoblastic bone metastases in hypogonadal men.

SU081

Prostate Specific Antigen and Human Kallikrein 2 Expression of Prostate Tumor Cells Correlates with the Osteoblastic Response in Prostate Cancer Bone Metastasis. M. P. Roudier[1], S. H. King*[1], S. M. Ott-Ralph[2], R. L. Vessella[1]. [1]Urology, University of Washington, Seattle, WA, USA, [2]Medicine, University of Washington, Seattle, WA, USA.

Prostate cancer (CaP) primarily metastasizes to lymph nodes and bones where it stimulates an osteoblastic response in contrast to other adenocarcinoma bone metastases that are osteolytic. One of the notable differences between CaP and the other adenocarcinomas is the secretion of prostate associated serine proteases such as prostate specific antigen (PSA), human kallikrein 2 (hK2) and prostin. PSA can activate at least 2 main components involved in the osteoblastic response, TGFbeta and IGF. HK2 and prostin can also activate PSA and the bone morphogenetic proteins. These facts provide the rationale to test if PSA and hK2 expression in CaP bone metastases correlates with bone volume. Forty metastatic bone biopsies from eleven androgen independent patients who died from CaP were analyzed for bone volume by histomorphometry using plastic-embedded Goldner's stained sections and the Osteomeasure system. PSA and hK2 were assessed by immunohistochemistry using an avidin-biotin-peroxidase method with antigen retrieval on the following plastic section. Overall expression of PSA and hK2 was low in 2 patients (less than 20% of tumor cells expressing PSA and hK2) and high in the other 9 (greater than 40% of tumor cells expressing PSA and hK2). Overall bone volume was high in 9 patients (mean BV/TV = 49) and low in 2 patients (mean BV/TV = 9). However there was a wide variation of both immunoreactivity of tumor cells and bone volume from one bone site to another in a given patient. Consequently, there was a moderate correlation between the percentage of tumor cells expressing PSA and bone volume (r = 0.5). There was a similar but inverted correlation between the percentage of tumor cells expressing hK2 and the percentage of eroded surface (r = - 0.5). We conclude that PSA and hK2 expression modulates the osteoblastic response in CaP bone metastases. However, further studies are needed to demonstrate that PSA and/or hK2 expression are directly involved with augmenting the osteoblastic response. This will be accomplished in part using our intra-tibia osseous xenograft models that demonstrate osteolytic, osteoblastic and mixed osteolytic/osteoblastic bone responses.

Histomorphometric Comparison of our Osteolytic PC3 and Osteoblastic LuCaP 23.1 Intra-osseous Mouse Models of Prostate Cancer Bone Metastases with Clinical Specimens. M. P. Roudier*[1], J. E. Quinn*[1], S. M. Ott-Ralph[2], E. Corey[1], R. L. Vessella[1]. [1]Urology, University of Washington, Seattle, WA, USA, [2]Medicine, University of Washington, Seattle, WA, USA.

Although prostate cancer (CaP) bone metastases are typically osteosclerotic, there is also experimental, histological and biochemical evidence of associated increased bone resorption. We have shown that both osteolytic and osteoblastic patterns can be observed in different bone sites of a given patient. To validate our LuCaP 23.1 osteoblastic and PC3 osteolytic intra-osseous mouse models, we compared their histomorphometric data to those of human CaP osteoblastic and osteolytic metastases. LuCaP 23.1 tumors were sampled at early, mid and late stages and after castration, monitored by serum PSA levels (n=8). PC-3 tumors were all sampled after 27 days (n=6). For comparison, we used 10 osteoblastic (mean BV/TV=53.2) and 10 osteolytic (mean BV/TV=9.47) metastatic biopsies taken from autopsies of patients who died from CaP. All bone samples were fixed in buffered formalin, dehydrated and embedded in methylmethacrylate. Analysis was performed on Goldner and TRAP stained sections using the Osteomeasure system. Bone and osteoid volumes, eroded and osteoblastic surfaces, osteoblast and osteoclast numbers were assessed at a magnification 2.5 x on a 9.73 mm^2 total surface in PC3 and LuCap 23.1; at magnification 10 x, on 9.73 mm^2 total surface in a subset of 4 late-stage LuCaP 23.1 and at magnification 10 x on 11.7 mm^2 total surface in human biopsies. The mouse tibial measurements were performed at the injection site including the tibial plateau as a consistent anatomic reference. LuCaP 23.1 showed an increasing osteoblastic pattern (mean BV/TV at late stage = 49.14) while PC-3 showed a consistent lytic pattern (mean BV/TV = 5.91). Statistically there was no significant difference between the mouse and human osteoblastic pattern for bone volume, osteoid volume and eroded surface (p=0.60, 0.39, 0.12 respectively). Similarly there was no difference between the mouse and human bone volume in the osteolytic pattern (p=0.11). In human and mouse osteoblastic lesions, osteoblast cells were not fully differentiated. In both osteolytic lesions, an overall low number of osteoclasts was observed.We conclude that our mouse intra-osseous models reproduce quite well the osteoblastic and osteolytic patterns observed in human CaP bone metastases and can be used to study the mechanisms of CaP bone metastasis.

SU083

Rat Model of Metastatic Bone Disease. B. A. Lechowska, L. C. Dare*, S. J. Hoffman, J. A. Vasko-Moser*, M. W. Lark, G. B. Stroup. Musculoskeletal Diseases, GlaxoSmithKline, King of Prussia, PA, USA.

The injection of human breast cancer cells (MDA-MB-231) into the left heart ventricle of nude mice results in tumor development in the long bones and the spine ultimately causing osteolytic bone lesions closely resembling the human condition of cancer metastasizing to bone. An attempt to develop a similar model in the rat was undertaken because systemic compound profiles are generally more favorable, sample collection (blood, urine) is easier, and bone mineral density (BMD) measurements, an invaluable tool in bone metastases studies, are less variable and also easier in the rat. Hsd:RH-rnu 9-week old female rats were injected with either vehicle or MDA-MB-231 cells at $5x10^5$ (0.5 ml) per rat. Digital x-ray images of the hind limbs were taken at baseline, week 2, 3, and 4. Areal BMD (aBMD) of the lumbar spine and proximal tibia were taken at baseline, week 3, and week 4. Blood was collected at term, [Ca^{++}] was measured and plasma was saved for Ctx analysis. Left tibiae and L3 were excised for pQCT (tibia only) and µCT analysis. Animals were sacrificed at week 4 or at time of onset of hind-limb paralysis. Lesions in long bones were detected in 42% of the inoculated animals as early as week 2 with a mean area of 5.0 mm^2. By week 3, 75% developed lesions with a mean area of 26.9mm^2. No further increase occurred during the fourth week. ABMD of the lumbar spine increased in both groups, but slower in inoculated animals (118% and 113% respectively at week 4). In the proximal tibia, a steady increase in aBMD was observed in vehicle animals (120%, 121% at weeks 3 and 4 respectively), while no change occurred in the other group (101%) during the first three weeks and then a dramatic increase to 125%. This increase in the MDA group between weeks 3 and 4 occurred because at that time only relatively healthy animals remained (most affected ones were euthanized during the previous week due to paralysis). Whole blood Ca^{++} was significantly (p<0.01) higher in inoculated animals (1.47mM) than in Vehicles (1.42mM). Plasma Ctx were slightly higher in inoculated animals (8.6 ng/ml) than in vehicles (7.4 ng/ml). PQCT analysis of the proximal tibia showed that both, total (668.3 mg/cm^3) and trabecular (275.8 mg/cm^3) BMD, was significantly lower in inoculated animals than in controls (728.2 and 343.7 mg/cm^3 respectively). A similar trend was shown by µCT analysis of the same limb. In conclusion, a model of metastatic bone disease has been adapted to the rat. A wider array of analytical tools as well as pharmacokinetic advantages offer a benefit over the mouse model of this disease. This should be a very useful model in evaluating effectiveness of antiresorptive therapies against development and/or growth of osteolytic bone metastases.

SU084

Comparison of Quantitative Heel Ultrasound with Dual Energy X-ray Absorptiometry in Discriminating Fractures in an Elderly Male Population. J. Thomas*[1], S. A. Steel[2], E. Howarth*[3], S. M. Doherty*[4]. [1]Metabolic Bone Disease Unit, Centre for Metabolic Bone Disease, Hull, United Kingdom, [2]Metabolic Bone disease Unit. HS Brocklehurst Building. 220-236 ANLABY ROAD, Centre for Metabolic Bone Disease., Hull, United Kingdom, [3]Medical statistics, Hull University, Hull, United Kingdom, [4]Metabolic bone disease unit, Centre For Metabolic Bone Disease, Hull, United Kingdom.

In this study we compare the ability of BUA of the heel and BMD by DXA of spine and hip to discriminate fractures in an elderly male population over 60 years of age in a UK elderly male population. All the men over the age of 60 years (n=383) in a local general practice of 5,000 were contacted and invited to participate in this study. The subjects were given an appointment to attend the hospital for DXA of lumbar spine, femoral neck (GE-Lunar Expert -XL) and BUA of the heel (McCue CUBA). We report on the BMD results of spine, hip and on BUA and SOS of the heel. We also report on the ability of DXA, BUA and SOS to discriminate fractures, using an unadjusted analysis. As the WHO criteria by BMD for osteopenia and osteoporosis apply only to females we applied a T-score threshold of -2.8 and a BUA threshold of <60 dBMHz-1 for osteoporosis. A total of 198 subjects (52% of the eligible population), aged 60-90 (mean 69) years attended for DXA and BUA. BUA of both heels was obtainable in 112 subjects (57%). BUA and SOS measurements were significantly higher for the right heel compared to the left. The mean (standard deviation) BMD of the spine was 1.29 (0.23) gm/cm2 and 0.96 (0.14) gm/cm2 for hip. Similarly the mean (standard deviation) BUA and SOS measurements for the right heel were 81.66 (16.32) dBMHz-1 and 1619.07 (45.10) m/sec respectively and for the left heel 78.69 (15.45) dBMHz-1 and 1613.25 (39.03) m/sec respectively. Of those attending, 95 subjects (48%) had sustained fractures in the past: 89 (94%) were adult fractures and 18 (19%) followed low trauma. A total of 2 low trauma fracture subjects were osteoporotic by DXA and 2 had BUA<60 dBMHz-1 (5 in this fracture group had a failed BUA). With the above threshold DXA and BUA defined 5.6% and 17.6% as osteoporotic respectively. BUA and SOS are better discriminators of fracture than BMD as BUA and SOS both explained 61% of the overall variation in the model when compared to DXA, which explained only 57% of the variation. At this stage, the basic discrimination between DXA, BUA and SOS is very small. The study is ongoing to determine whether there is greater discrimination between the three methods in predicting future fractures.

SU085

Can the Combination of Two BMD Measurements Ever Improve Fracture Discrimination? R. Patel, G. M. Blake, I. Fogelman. Radiological Sciences, Guy's, King's & St Thomas' School of Medicine, London, United Kingdom.

Intuitively the combination of two or more BMD measurements should improve our ability to identify patients at high risk of an osteoporotic fracture. However, a number of clinical studies have shown that in practice the gains obtained are only modest. We have investigated the effect of combining two BMD measurements using a bivariate gaussian model described by a correlation coefficient r between the two T-score values and individual relative risk values RR_1 and RR_2 for the two measurements. The area under the curve (AUC) for the ROC curve showing the percentage of fracture cases identified plotted against the percentage of the whole population was calculated for: (i) the T-scores of the individual measurements; (ii) the weighted mean T-score ≤ -2.5 (the conventional statistical approach); (iii) either T-score ≤ -2.5 (the conventional approach using the WHO criteria). For approach (ii), when $RR_1 = RR_2$ the two T-scores were weighted equally. When $RR_1 \neq RR_2$ the optimum weighting was used as predicted by the bivariate gaussian model. Results for RR values of 1.5, 2.0 and 2.5 and r = 0, 0.5 and 0.7 are shown in the Table.

		Single Site	Two Sites Weighted Mean T-score ≤ -2.5			Two Sites Either T-score ≤ -2.5		
RR_1	**RR_2**	**AUC**	**AUC**			**AUC**		
			r = 0	r = 0.5	r = 0.7	r = 0	r = 0.5	r = 0.7
1.5	**1.5**	61.3	65.7	63.0	62.2	63.6	62.3	61.8
2.0	**2.0**	68.8	75.6	71.4	70.2	72.4	70.4	69.7
2.5	**2.5**	74.1	82.0	77.3	75.9	78.4	76.0	75.2
1.5	**2.0**		71.5	68.9	68.8	68.5	66.8	66.4
1.5	**2.5**		76.0	74.1	74.1	72.4	70.7	70.4
2.0	**2.5**		79.1	75.0	74.2	75.7	73.5	72.8

The most important conclusion is that the greatest improvement in fracture discrimination is obtained when the two measurements are extremely poorly correlated and have comparable values for RR. While correlations of r = 0.5 seem poor, in practice there is little benefit from combining such measurements. Finally, consistently larger AUC values are obtained using the weighted mean T-score compared with the WHO approach.

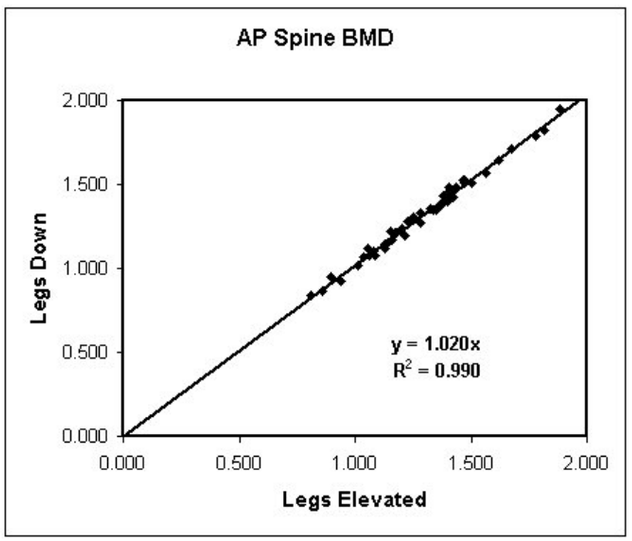
SU086

Effect of Patient Positioning Devices on Bone Density Measurements. R. H. Nord, D. L. Ergun, K. G. Faulkner. GE Medical Systems LUNAR, Madison, WI, USA.

DXA bone density measurements are widely used to assist in the detection of osteoporosis and other metabolic bone diseases, and to monitor change longitudinally following treatment. The typical bone density examination evaluates the lumbar spine and the proximal femora. It would be convenient if these scans could be acquired as a single procedure, without repositioning the patient between scans; however the traditional methods for spine and femur acquisitions require different positioning. This study determined the effect on bone density results of departing from traditional patient positioning, exploring the possibility of using the same positioning for both spine and femur acquisitions. 50 volunteer subjects were measured on a Lunar Prodigy densitometer from GE Medical Systems. Subjects included 37 women and 13 men, ages 24 to 83, widely varying in height and weight. Each subject was measured as follows: AP Spine: 2 scans with lower legs elevated in the standard manner, and 4 scans with legs extended straight out on the tabletop. Femur: 3 scans with feet in the standard positioner, and 3 scans with feet simply bound together, toes pointed straight up.

			slope	R sqr.
Spine	Legs Down vs Legs Elevated	L2-L4	1.020	0.990
Femur	Feet Together vs Standard Position	Neck	1.010	0.982
		Trochanter	0.973	0.984
		Total	0.991	0.994

Correlations were excellent between standard and non-standard positioning for all the scan regions investigated. All data sets were fit well by linear regression through the origin. Slopes of the regression lines were very close to unity.



Excellent correlations suggest that reference values acquired with standard positioning could be adjusted for use with alternate positioning, to obtain clinically similar T-score and Z-score values.

Disclosures: ***R.H. Nord****, GE Medical Systems LUNAR 3.*

Twenty-year Follow-up of Phalangeal Bone Density with Radiographic Photodensitometry and Radiographic Absorptiometry. S. Bonnick[1], N. DiMarco[1], K. Cohlmia*[1], L. Lewis*[1], J. Colvin*[1], L. Al-Dayeh*[2], X. Bi*[2]. [1]Texas Woman's University, Denton, TX, USA, [2]CompuMed Inc., Los Angeles, CA, USA.

Baseline and follow-up radiographic photodensitometry (RPD) films of the left hand of 319 individuals were re-analyzed using a modification of the Osteogram® radiographic absorptiometry (RA) technique. Associations between RA data and baseline and follow-up age were examined and models developed for the prediction of the follow-up RA bone mineral density (BMD) and the change in RA BMD. Between 1950 and 1965 approximately 3000 individuals underwent RPD studies. During a 19-month period in 1979 to 1981, 319 of these individuals (222 women and 95 men) underwent repeat RPD studies. Mean age at baseline was 20.1 years (3 to 79 years). At follow-up, mean age was 43.5 years (16 to 94 years). Mean length of follow-up was 22.5 years (13 to 28 years). A radiographic Look-Up-Table that maps RPD and RA wedge data was used to modify the analysis algorithm of the PC-based software Osteogram® (CompuMed, Inc., Los Angeles, CA). The customized Osteogram® RA technique was applied to RPD x-rays assessing BMD at the middle phalanges of the 2nd, 3rd, and 4th fingers. Mean (SD) baseline RPD and RA BMD was 0.22 (0.03) and 98.04 (16.00), respectively (r=0.397, p<0.01). Mean (SD) follow-up RPD and RA BMD was 0.20 (0.03) and 110.52 (13.63), respectively (r=0.621, p<0.01). The correlation for the change in RPD and RA bone density was 0.486, p<0.01. Pearson correlation coefficients for baseline and follow-up age and RA BMD values are shown in the table. All correlations were significant at p<0.01 (2 tailed).

	Baseline RA BMD	Follow-Up RA BMD	Change in RA BMD
Baseline Age	0.403	-0.657	-0.743
Follow-Up Age	0.444	-0.627	-0.748

Linear regression was performed using SPSS v10 with age and baseline RA BMD as predictors for the dependent variables of follow-up RA BMD and change in RA BMD.
Follow-up RA BMD = 91.014 - [(Baseline Age)(1.439)] + [(Baseline Age)^2 (1.109E-02)] + [(Baseline RA BMD)(0.413)]
Change in RA BMD = 91.014 - [(Baseline Age)(1.439)] + [(Baseline Age)^2 (1.109E-02)] - [(Baseline RA BMD)(0.587)]

Correlations of RPD and RA BMD were statistically significant and similar to that previously reported. RA BMD increased between measurements in individuals who were younger than age 49 at the time of both measurements and declined in individuals older than age 49 at the time of the second measurement.

Disclosures: ***S. Bonnick****, CompuMed Inc. 5; Merck & Co., Inc. 2, 5, 8.*

SU088

Low Bone Density Is a Major Risk Factor for Periprosthetic Bone Loss Following Total Hip Arthroplasty. G. M. Blake[1], A. I. A. Rahmy*[2], A. J. Tonino*[3], W. D. Tan*[2], I. Fogelman[1]. [1]Radiological Sciences, Guy's, King's & St Thomas' School of Medicine, London, United Kingdom, [2]Department of Nuclear Medicine, Atrium Medical Center, Heerlen, Netherlands, [3]Department of Orthopedic Surgery, Atrium Medical Center, Heerlen, Netherlands.

We report a study to investigate the relationship between periprosthestic bone loss following total hip arthroplasty (THA) and the preoperative BMD at the spine, femur and forearm. 51 patients (32F,19M) (mean age 63 y, range 46-75 y) undergoing THA were randomised to one of two cementless hip prostheses, either the Anatomic Benoist Girard (ABG) (Howmedica International, Rutherford, NJ) (n = 24) or the Mallory-Head Porous Hip (Biomet, Warsaw, IN) (n = 27). Preoperative DXA scans (Hologic QDR2000) were performed to measure BMD at the PA and lateral spine, the contralateral femur, and the non-dominant forearm. Postoperative DXA scans were performed to measure BMD in periprosthetic bone at 10 days (treated as baseline for the subsequent follow-up), 6 week, 3 month, 6 month, 1 y, 2 y and 3 y using the standard Gruen zone analysis and the total periprosthetic ROI. 48/51 patients completed the study at 3 y. Statistical analysis confirmed a highly significant relationship between periprosthetic bone loss at 6 month, 1 y, 2 y and 3 y expressed as percent from baseline and the preoperative BMD at the PA spine, trochanter, total hip and forearm. The Table shows the Students-t and p-values for the correlations with the total periprosthetic ROI at each time point. Weaker relationships were also seen for lateral spine, femoral neck and Wards triangle BMD for the 2 and 3 y data. The relationship remained statistically significant when data for the ABG and Mallory prostheses were analysed individually. In conclusion, low bone density at the spine, hip or forearm is a major risk factor for periprosthetic bone loss following THA.

Students t and p-values

	6 months	1 year	2 years	3 years
PA Spine	3.74 (< 0.001)	3.86 (< 0.001)	3.46 (0.001)	3.62 (0.001)
Femoral Neck	1.66 (0.104)	1.72 (0.093)	2.63 (0.012)	2.83 (0.007)
Trochanter	3.42 (0.001)	2.91 (0.006)	3.59 (0.001)	3.81 (< 0.001)
Total Hip	2.81 (0.007)	2.39 (0.021)	2.98 (0.005)	3.26 (0.002)
Ultradistal Forearm	3.20 (0.002)	3.16 (0.003)	3.13 (0.003)	4.35 (< 0.001)
Total Forearm	3.54 (0.001)	3.33 (0.002)	3.85 (< 0.001)	4.86 (< 0.001)

SU089

Retraction of an Overlying Fat Panniculus Is Indicated when Measuring Femur Bone Mass with DXA. D. Krueger[1], N. Vallarta-Ast[2], T. Kawahara-Baccus*[1], K. Elver*[3], N. Binkley[1]. [1]Institute on Aging, University of Wisconsin, Madison, WI, USA, [2]Radiology, Wm. S. Middleton VAMC, Madison, WI, USA, [3]Radiology, UW Health, Madison, WI, USA.

Dual energy x-ray absorptiometry (DXA) is currently the gold standard technique for osteoporosis diagnosis. However, DXA has limitations, including artifacts such as degenerative disease or metallic foreign bodies, which may confound results. It is possible that overlying fat folds may be a currently unappreciated confounder of proximal femur bone mineral density (BMD) measurement. As such, the aim of this study was to evaluate the effect of overlying fat on measured proximal femur BMD. Sixty-eight subjects (31 women/ 37 men) referred for routine BMD measurement at the Wm. S. Middleton VAMC were identified as having a fat fold within the DXA scan field by visual assessment of images obtained utilizing a GE Lunar Expert-XL densitometer. The mean ± SEM age, weight and body mass index (BMI) of these women was 64 ± 0.5 years, 207± 5.8 pounds and 36 ± 0.8; of the men 67 ± 0.6 years, 232 ± 7.0 pounds and 35 ± 0.8. Subsequent to their initial imaging, these 68 individuals were rescanned while retracting their fat panniculus away from the proximal femur scan area without other repositioning between scans. In 65% of the men, and 61% of the women, the femoral neck, total femur and/or trochanteric BMD differed by greater than the least significant change at our facility. In 14 of 68 subjects, the measured BMD differed by >10%. No pattern was observed to predict whether BMD would increase or decrease following fat retraction. Additionally, no relationship between BMI and change in BMD following fat retraction was demonstrated. To evaluate the reproducibility of BMD measurement with panniculus retraction, 25 patients were recruited for a precision study. The mean ± SEM age, weight and BMI of this group was 65 ± 0.7 years, 226 ± 5.2 pounds and 35.3 ± 0.8 respectively. Volunteers were scanned with their panniculus retracted, asked to stand from the table and had a second retracted scan performed. In this group, the total femur BMD least significant change (LSC) was 0.049 g/cm2, which compares favorably with our clinical total femur LSC of 0.033 g/cm2. In conclusion, overlying fat frequently alters BMD values obtained at the total proximal femur, femoral neck and trochanter. This impairs the ability to accurately diagnose low bone mass and monitor osteoporosis therapy in these patients. BMD precision with manual panniculus retraction is acceptable. As such, when fat overlays the proximal femur scan area, its retraction should be part of routine densitometric practice.

SU090

Lead in the Skeleton Interferes with Bone Mineral Density Measurements. E. Puzas[1], J. Campbell*[2], R. J. O'Keefe[1], E. M. Schwarz[1], R. N. Rosier[1]. [1]Orthopaedics, University of Rochester, Rochester, NY, USA, [2]Pediatrics, University of Rochester, Rochester, NY, USA.

Introduction: Two important pieces of data implicate the skeleton as a key tissue for the toxic effects of lead. They are; i) 95% of the body's lead burden resides in bone and ii) lead adversely affects bone cell metabolism. These findings would argue that lead-exposure may be an independent variable for low bone mineral density. In fact, however, no reports have documented osteoporosis (or osteopenia) in lead-exposed humans with DEXA. We believe this is due to a serious artifact created by lead in the measurement of bone density in humans. Methods: one mineral density of bovine bone containing added amounts of lead that mimic human levels was measured with DEXA and ultrasound (US). Also, the calcaneus of 18 human subjects with differing lead-exposure histories were measured with both DEXA and US. The DEXA measurements were performed on both Lunar and Hologic instruments. The ultrasound measurements were performed with a Lunar Achilles instrument. Results: The range of lead levels found in the bone of adult humans causes an artifactual increase in bone mineral density. The artifact ranges from a 4% (10 ug Pb/g bone) to 11% (100 ug Pb/g bone) overestimate of bone density. The overestimate occurred with instruments from both GE/Lunar and Hologic. Ultrasound measurements of the same samples showed no such increase. A ratio of an US measurement to a DEXA measurement at the calcaneus in patients (N=18) showed a statistically significant inverse relationship with blood lead levels. We have used this relationship to calculate a correction factor for bone mineral density based on historic lead-exposure. We believe this effect is due to attenuation of the x-ray beams by the high electron dense lead atoms according to principles of the photo-electric effect. Conclusion: A 4 - 11% overestimate of bone density can alter a patient's t-score by as much as 1.0. Thus, unless one knows the skeletal lead content of their patient, an accurate bone density cannot be determined. If this finding proves to be consistent throughout the population, then a large number of patients are under-treated for their low bone density.

Central DXA Reporting: What Do Clinicians Want? N. Binkley, D. Krueger, M. K. Drezner. University of Wisconsin, Madison, WI, USA.

Practicing clinicians reportedly prefer detailed bone densitometry interpretation. However, given the recent emphasis on physician education regarding osteoporosis diagnosis, this may no longer be the case. As such, a survey designed to assess clinician preferences regarding bone densitometry reports was conducted. On review of clinical requests, 212 health care providers were identified who had ordered at least one DXA scan at the University of Wisconsin from May through August 2001. All were requested by mail to evaluate potential elements of a central DXA report. Eleven possible components were listed on a one-page survey and providers were asked to indicate whether they would find each useful in their practice. The survey was anonymous, however different colors were utilized to allow determination of those providers who requested 1-4, 5-8, 9-12 and 13 or more DXA scans during the four-month interval to allow comparison of "low" and "high" users. Of the 212 surveys sent, 118 were returned (56%). There was no difference in response rate between high and low users. BMD values were requested by less than half (48%) of all responding clinicians and T-score by 82%. However, the overwhelming majority requested percentage of young normal and percentage of age-matched controls (91 and 88% respectively). Approximately 75% requested that DXA reports contain determination of need for therapy; interestingly, a similar percentage requested that reports include a recommendation for type of therapy. Enumeration of clinical risk factors for fracture was requested by 65% and fracture risk assessment by 81%. No difference in request for any component was present between the groups ordering 13 or more scans than those requesting 1-4. Twenty-seven responding providers did not request that reports include the T-score values; of these, 22 requested comparison with young normals, 25 with age-matched controls and 21 desired recommendation of need for therapy. In conclusion, a majority of clinicians requesting DXA scans continue to desire detailed reports including need for therapeutic intervention, therapy recommendations and fracture risk estimation. Furthermore, these data may imply that ~20% of health care providers ordering DXA scans may not be familiar with World Health Organization diagnostic criteria and National Osteoporosis Foundation treatment guidelines. A need for ongoing educational efforts persists.

Use of Densitometric Lateral Vertebral Assessment to Detect Prior Vertebral Compression Fracture. N. Binkley[1], K. G. Faulkner[2], T. Kawahara-Baccus*[1], D. Krueger[1], H. K. Genant[3], M. K. Drezner[1]. [1]University of Wisconsin, Madison, WI, USA, [2]GE Medical Systems, Lunar, Madison, WI, USA, [3]University of California, San Francisco, CA, USA.

Many vertebral fractures are clinically silent, but are associated with increased risk for subsequent osteoporotic fracture. A substantial number of these fractures are demonstrable using Instant Vertebral Assessment with Hologic densitometers[1]. Whether similar recognition is possible using dual-energy Lateral Vertebral Assessment (LVA) with GE Lunar densitometers remains uncertain. Thus, we evaluated the ability of LVA to detect prevalent vertebral fractures compared with conventional spine radiographs in postmenopausal women. In this ongoing study, dual-energy LVA and conventional thoracic and lumbar spine radiographs have been obtained in 32 postmenopausal women. Using an established visual semiquantitative system, vertebral fractures were visually identified individually by two non-radiologist physicians (NB & MKD) from printouts of LVA examinations. These results were compared to semiquantitative evaluations of the spinal radiographs by an expert radiologist (HKG). Study participant mean age ± SEM was 72.8 ± 0.9 (range 61-80) years; their mean lumbar spine BMD T-score was –2.0 ± 0.2 (range –3.9 - +2.7). Using LVA, 97% of the vertebrae from T-7 through L-4 were evaluable, although a majority of vertebrae from T-4 to T-6 were not adequately visualized for fracture assessment. In the evaluable vertebrae, prevalent fractures were identified in 13 vertebral bodies using LVA. Compared to spine radiographs, LVA exhibited a sensitivity of 62%, detecting 13 of 21 vertebral fractures observed on radiographs. Fractures which were undetected by LVA were either mild (grade 1) and/or located in the mid to upper thoracic spine. LVA correctly identified all moderate and severe (grade 2 and 3) vertebral fractures below T-7. On an individual basis, 19 of 32 patients had prior vertebral fractures identified on radiographs. Using LVA, 17 of these individuals were correctly classified as having existing fractures, while the two patients missed by LVA had grade 1 (mild) deformities. All patients without fracture by radiographs were correctly classified by LVA. In conclusion, the low radiation exposure dual-energy LVA technique on GE Lunar densitometers provides a rapid, convenient and economical way for non-radiologists to identify patients with, and without, vertebral fractures. LVA performance is comparable to published results using other DXA systems [1]. This capability should enhance care of osteoporotic patients and may offer an efficient screening technique for osteoporosis clinical trials.

Precision of Single versus Bilateral Hip Bone Mineral Density Scans. J. White*, S. S. Harris*, G. E. Dallal*, B. Dawson-Hughes. Calcium and Bone Metabolism Laboratory, USDA Human Nutrition Research Center on Aging at Tufts University, Boston, MA, USA.

Dual-energy X-ray absorptiometry (DXA) is a precise, fast, and noninvasive method to measure bone mineral density (BMD) and body composition. Software that integrates the results of bilateral DXA hip scans has recently become available. The present study was undertaken to determine and compare the precision of single (left) and bilateral hip BMD measurements and to assess the precision of spine and total body measurements made with a GE-Lunar Prodigy scanner. Six healthy, white postmenopausal women had DXA scans of the femoral neck (left and right), lumbar spine (L2-L4), and total body performed six times each on the same day with repositioning after each scan. Precision was better for the bilateral than for the single hip scans. Specifically, mean % coefficient of variation (%CV) in BMD for single and bilateral hip scans respectively were: 0.70% and 0.57% for the total hip (P=0.028), 1.37% and 0.88% for the trochanter (P=0.028), and 1.38% and 1.00% for the femoral neck (P=0.075). For both single and bilateral hip scans, mean %CV at the total hip was lower than that at the femoral neck and trochanter. Mean %CV was 0.99% for spine BMD (L2-L4), 0.65% for total body BMD, 1.04% for total body bone mineral content, 1.14% for total body fat tissue and 0.74% for total body nonfat soft tissue. In conclusion, precision of DXA hip BMD measurements is improved with bilateral hip scans compared with traditional single hip scans.

SU094

Results of a Follow-up Survey of an Osteoporosis Education and BMD Testing Program for Assisted Living and Skilled Nursing Residents. E. N. Schwartz[1], K. Baird*[1], T. W. Weiss*[2], Y. Chen[2]. [1]Foundation for Osteoporosis Research and Education, Oakland, CA, USA, [2]Outcomes Research, Merck & Co., Inc., West Point, PA, USA.

Osteoporosis remains a largely undiagnosed and untreated disease and its incidence is particularly high in the nursing home population. Here we report the results of follow-up contact with participants of an osteoporosis education and bone mineral density (BMD) testing program in residential communities and assisted living and extended care facilities in 2001. A technologist traveled to individual facilities to conduct BMD testing of the phalanges using an ALARA metriscan™ densitometer. Results were presented to each resident and were sent to their primary care physicians. A one-hour lecture on osteoporosis prevention was also provided to residents. Of the 2042 residents tested, a random sample of 1000 residents was contacted for a follow-up survey at 12 months. The total number of responses was 466 (response rate of 47%). After five responders, aged < 50 years, were excluded from the analysis, the final analysis sample was 461. Baseline demographics (age, gender, and ethnicity) were similar for responders and non-responders. The average age of responders was 78 (range 50, 97); 90% were female and 20% non-Caucasian (Asian 12%; Hispanic 3%; African-American 4%; other 1%). The average T-Score was -2.6 (range 0.97, -5.7); 65% had a T-Score ≤ -2.0 while 50% had a T-Score ≤ -2.5. Responders with T-Scores ≤ -2.0 were much more likely to follow-up with their provider, have follow-up diagnostic tests, have a baseline history of prior fracture after age 55 and have had a recommendation for pharmacologic treatment and/or calcium/vitamin D supplementation (table) since being screened. Osteoporosis testing and education programs that reach elderly residents of residential communities and assisted living and skilled nursing facilities may improve the level of care by increasing disease awareness and appropriate management and treatment.

	T-Score

Digital X-ray Radiogrammetry in Assessing Metacarpal Index and Bone Mineral Density in African-American Women. J. A. Shepherd[1], M. Meta[1], A. Rosholm[2], D. Goddard[3], M. Ovalle[4], Y. Sherrer[5], H. K. Genant[1]. [1]Radiology, University of California at San Francisco, San Francisco, CA, USA, [2]Spectra Pronosco A/S, Vedbaek, Denmark, [3]Osteoporosis Center, Brooklyn, NY, USA, [4]Evanston Northwestern Healthcare, Chicago, IL, USA, [5]Center for Rheumatology, Immunology, and Arthritis, Fort Lauderdale, FL, USA.

Bone mineral density (BMD) reference data of non-Caucasians is scarce. This study characterizes normal peripheral bone in African-American women using digital x-ray radiogrammetry and hand radiographs. We recruited 242 healthy African-American women between 20 and 80 years old at four different sites: San Francisco, CA, Fort Lauderdale, FL, Highland Park, IL, and Brooklyn, NY. Radiographs of the non-dominant hand were taken and analyzed using the X-posure System (Pronosco, Version 2. Denmark), a computer-based diagnostic tool that calculates bone status from an X-ray image of the hand. Bone mineral density and metacarpal index (MCI) of the second through fourth metacarpals were automatically calculated as weighted averages across the three bones. We calculated BMD and MCI Z-Scores (Z_{BMD} and Z_{MCI} respectively) from the African-American women BMD and MCI values and the manufacturer's age-matched North American Caucasian reference data. Five subjects were excluded because of either existing bone disease (2) or overexposed x-rays (3). The mean value of Z_{BMD} was 0.43 and of Z_{MCI} was –0.17. Both were significantly different from 0 with a p-value of less than 0.01. There was no statistically significant ($p<0.01$) relationship of either Z value to age, height, or weight. The paradoxical difference in signed between the average Z_{BMD} and Z_{MCI} was explained by an average increased cortical width of 6.5% for the African American women yet comparable cortical thickness. These relationships also held true for the subset of 100 African-American women from 20 to 39 years, the range typically used for T-score calculations. In conclusion, if African-American women are assessed with the Pronosco X-posure device and referenced to North American Caucasian data, it may be appropriate to adjust their T_{BMD} and Z_{BMD} values down by 0.43 and their T_{MCI} and Z_{MCI} values up by 0.17 to accurately reflect their bone status relative to their race-matched peers.

SU096

Urinary Excretion of Type I Collagen Alpha 1 Helical Peptide as a Marker of Bone Resorption in Mice. R. Brommage. Endocrinology, Lexicon Genetics, The Woodlands, TX, USA.

Measurements of the urinary excretion of N- and C-terminal telopeptides of Type I collagen provide a useful index of bone resorption in human studies. A new ELISA assay measuring peptides containing a fourteen amino acid region (620 to 633) within the triple helix of the alpha 1 chains of Type I collagen gives results similar to those obtained with N- and C-terminal telopeptides. Since human and mouse collagen sequences differ by only one amino acid in this region, this helical peptide assay may also be useful in studies of murine bone metabolism. The Quidel Helical Peptide ELISA was employed to explore the ability of this assay to reflect changes in bone resorption in mice. The single amino acid substitution (alanine for proline) did not affect the binding characteristics of mouse collagen peptides for the assay antibody since displacement curves for mouse urine and the human standard were parallel. Urinary creatinine levels, determined by an automated enzymatic assay, were used to normalize urinary helical peptide concentrations to urine volume. Urinary helical peptide excretion in male C57BL/6 mice declined 5-fold between 4 and 10 weeks of age, but remained constant between 10 and 16 weeks of age. This dramatic age-dependence reflects the decrease in bone modeling during the rapid growth phase of young mice. Male C57BL/6 mice treated every second day with subcutaneous injections of 1 mg/kg pamidronate to inhibit bone resorption excreted 38% to 44% less helical peptide in urine at 1, 2, 4 and 6 weeks after treatment initiation. Femur BMD, determined by PIXImus2 DEXA, was increased by 16% compared to vehicle-treated mice after 6 weeks of bisphosphonate treatment (75 vs 65 mg/cm^2). These findings indicate that analyses of the urinary excretion of helical peptide provide a valid index of bone resorption in mice.

SU097

Variability of Serum CTx Measurements in Healthy Male Adults. J. A. Guillemant*[1], C. Accarie*[2], S. E. Guillemant[3]. [1]Biochemistry, Faculté de Médecine Pitié-Salpêtrière, Paris, France, [2]Nutrition Hydrominérale, EPHE, Paris, France, [3]Biochemistry, Faculté de Médecine Pitié-Salpêtrière, EPHE, Paris, France.

Serum C-terminal cross-linked telopeptide (serum CTx) is considered as a sensitive index of bone resorption. In order to assess the utility of serum CTx in monitoring either the acute osteoclastic response to calcium load or the long-term response to therapy, the variability of measurements is to be taken into account. In study 1, fifteen young male adults (23.3 ± 1.2 y) were sampled five times between 07.30 and 08.00 at one week intervals. In study 2, twelve male sportsmen (30.7 ± 4.2 y) were sampled nine times between 08.30 and 09.30. Serum CTx was measured using one step immunoassay (Serum Cross-Laps ; Nordic Bioscience Diagnostics, Denmark). All samples from an individual were assayed in a single analytical batch and the same reference batch was used for the whole study. The within-subject CV (%), including both the analytical variation (CV # 5%) and the biological variation, and the critical difference (= 1.96 x 1.41 x within-subject CV%) were calculated. In study 1, the mean total within-subject CV was 14.2 (range 9-29) and the mean critical difference was 39 (range 25-80). In study 2, the mean total within-subject CV was 12.7 (range 7-19) and the mean critical difference was 35 (range 21-53). These values are substantially lower than those described by Hannon et al. (J Bone Miner Res 1998 ;13 :1124-1133) for urinary CTx in postmenopausal women and argue in favor of using serum CTx rather than urinary CTx for monitoring the effects of therapy . Nevertheless, it should be emphasized that our groups of subjects were very homogeneous and the conditions of sampling (time) very precise. Furthermore they had avoided all calcium-rich meal 12 hours before sampling. By the same token it could be noticed that the between-subject variation is larger (CV = 30%-40%) than the within-subjects variation which suggest that before monitoring the effects of therapy in a single patient its personal CTx variation could be previously measured in order to calculate its own individual critical difference.

SU098

Serum Osteoprotegerin (OPG): Relationship with Age and Dietary Improvement. S. Sankaralingam*[1], J. Cheung*[1], E. Prowse*[2], M. Frost*[2], K. Knapp*[2], I. Fogelman*[2], G. Hampson*[1]. [1]Chemical Pathology, St Thomas Hospital, London, United Kingdom, [2]Nuclear Medicine, Guy's Hospital, London, United Kingdom.

Osteoprotegerin negatively regulates bone resorption by preventing the binding of RANKL to RANK on osteoclasts thus inhibiting osteoclastic differentiation and activity. It is thought that improvement in nutrition may influence bone metabolism by modulating cytokine production. Nutritional intervention could therefore have a positive effect on OPG secretion. We developed and optimised an enzyme linked sandwich immunosorbant assay (ELISA) to measure OPG in serum. Intra and inter - assay CV were 9% and 12% respectively. We assessed circulating levels of OPG in 38 pre-menopausal women and 92 post-menopausal women with normal bone mineral density aged (mean [SEM] years) 36 [1.3] and 65 [1.0] respectively. We also investigated the effect of improvement in nutrition on serum OPG levels in 40 post-menopausal females aged ≥ 70 years with osteoporosis at the hip and a low body mass index (BMI) < 21kg/m2, randomised to two groups (n = 20 in each group). Group 1 received 1 gram of calcium and 800units of vitamin D and group 2 were given, in addition, dietary advice and nutritional supplement. Serial blood samples were taken at base line and at 1, 3, 6, 9 and 12 months following intervention. We observed a significant difference in serum OPG concentrations between pre and post- menopausal women (pre- menopausal 1.67 ng/ml [0.274], post -menopausal 2.54 ng/ml [0.09] $p < 0.0001$). Our results show a significant positive correlation of OPG with age ($r = 0.6$, $p < 0.0001$). There was a trend towards an increase in serum OPG level following intervention in group 2 compared to group1 (Mean [SEM] baseline group1 2.8 [0.147], group 2 2.6 [0.23], 1 month 2.7 [0.128], 2.9 [0.16], 3 months 2.7 [0.122], 3.0 [0.216], 6 months 2.8 [0.131], 3.1 [0.2] * $p < 0.05$, 9 months 2.7 [0.116], 3.1 [0.19]* $p < 0.05$ and 12 months 2.7 [0.10], 3.1 [0.28]. In conclusion, the increase in OPG levels in post menopausal women may be due to compensatory response to increased age related bone resorption. Our findings also support the theory that nutritional improvement may have a positive effect on bone metabolism by increasing OPG production.

SU099

Relationship Between Dental Panoramic Radiographic Findings and Biochemical Markers of Bone Turnover. A. Taguchi[1], M. Sanada*[2], E. A. Krall[3], T. Nakamoto*[1], M. Ohtsuka*[1], Y. Suei*[1], K. Tanimoto*[1], I. Kodama[2], M. Tsuda*[2], K. Ohama*[2]. [1]Oral and Maxillofacial Radiology, Hiroshima University, Hiroshima, Japan, [2]Obstetrics and Gynecology, Hiroshima University, Hiroshima, Japan, [3]Boston University, Boston, MA, USA.

Recent studies suggest mandibular inferior cortical shape and width on dental panoramic radiographs may be useful screening tools for low spine bone mineral density (BMD) or high risk of osteoporotic fracture. However, it is unknown if these measures are associated with bone turnover. We investigated relationships among dental panoramic radiographic findings, spine BMD and biochemical markers of bone turnover in 82 postmenopausal Japanese women aged 46 to 68 years (mean +/- SD, 54.7 +/- 4.9). None used medications that affect bone metabolism. Bone turnover was estimated by serum total alkaline phosphatase (ALP) and urinary N-telopeptide crosslinks of Type I collagen (NTx) corrected for creatinine (Cr). ALP data were missing for 6 patients. Mandibular inferior cortex shape (normal, mild/moderate erosion, severe erosion) and width were evaluated on dental panoramic radiographs. All findings were adjusted for years menopausal and body mass index (BMI). Distributions of spine BMD were 34 normal (T score>-1.0), 31 osteopenic (T -1.0 to -2.5) and 17 osteoporotic (T <-2.5) without spinal fracture. Degree of erosion was significantly related to NTx and ALP levels (Table). Similar NTx and ALP findings were seen among categories of spine BMD. The odds of low spine BMD in women with any cortical erosion were 3.8 (95% confidential interval=1.2 to 12.5). Women with osteoporosis had significantly less mandibular cortical width (mean +/- SE, 3.11 +/- 0.25 mm) than those with osteopenia (4.00 +/- 0.15 mm, P=0.003) or normal BMD (4.30 +/- 0.16 mm, P<0.001). NTx was not significantly correlated to mandibular cortical width but women in the lowest quartile of mandibular cortical width (<3.4 mm) had higher ALP levels (273 +/- 16 IU/L) than those in the upper three quartiles (236 +/- 9 IU/L, P<0.05). Our results suggest that mandibular inferior cortical shape on dental panoramic radiographs may be an indicator of bone turnover and spine BMD in postmenopausal women. Dentists may be able to refer postmenopausal women for bone densitometry by using panoramic radiographs taken for the diagnosis of dental lesions.

Means with matching symbols are significantly different: *P<0.001; #P<0.02; **P<0.01

Dental panoramic findings (n)	NTx (nmol BCE/mmol Cr)	ALP (IU/L)
Normal (47)	51.4+/-4.0*#	229+/-11**
Mild/moderate erosion (29)	77.9+/-5.1*	257+/-14
Severe erosion (6)	80.2+/-10.6#	318+/-28**

Hypovitaminosis D in Clinical Practice. P. J. Ryan. Osteoporosis Unit, Medway Maritime Hospital, Gillingham, Kent, United Kingdom.

Hypovitaminosis D is a common finding in the elderly and contributes to secondary hyperparathyroidism which is accepted as a major cause of bone loss in the elderly. The value of measuring 25OH Vitamin D in clinical practice is not established. Most patients with osteoporosis especially if elderly would usually be prescribed calcium and vitamin D supplementation as part of their management. This study examined the value of 25OH Vitamin D measurements in a specialised osteoporosis clinic setting. Measurements were made of 25OH Vitamin D, Parathormone, Calcium, Albumin and alkaline phosphatase in 218 patients of average age 61 years (SD15). Patients were investigated for vertebral fractures (22%), Osteoporosis on BMD (23%), Hip Fracture (7%), Wrist Fracture (7%), Other Fracture (13%), Steroid usage (10%), Malabsorption (6%), Renal Failure (3%), Epileptic Drugs (2%), Liver disease (2%), Other (5%). 65 % patients had a T score <-3.0 and Z score of <-1.5 at the lumbar spine or femoral neck. 118/218 (54%)had hypovitaminosis D (<40 nmol/l) and 41 (19%) severe hypovitaminosis D (<20 nmol/l). There was a trend to greater frequency of elevated parathormone measurements with lower 25 OH Vitamin D values. Low vitamin D levels were found across diagnostic categories and were identified in 88 % Hip fractures, 67 % Wrist fractures, 50 % Vertebral fractures, 52 % Other fractures and 46 % Low BMD. All patients had a normal serum calcium. There was no relationship between 25 OH Vitamin D and age. The study demonstrates a high frequency of hypovitaminosis D in a UK specialist bone clinic setting. Many patients were not elderly and the clear need for vitamin D therapy may not have been appreciated without vitamin D measurements.

Vitamin D and Parathormone values

25 OH Vitamin D	Mean age (years)	Normal Parathormone Nos (%)	Upper Tertile Parathormone Nos (%)	Elevated Parathormone Nos (%)
< 20 nmol/l	64	23 (59%)	8 (21%)	8 (20 %)
21-30 nmol/l	61	29 (66%)	7 (16 %)	8 (18 %)
31-40 nmol/l	64	24 (71%)	4 (12 %)	6 (17 %)
>40 nmol/l	58	86 (86%)	8 (8 %)	6 (6 %)

SU101

Evaluation of a Fully Automated Assay for Serum Procollagen Type I N-propeptide in Osteoporosis. P. Garnero[1], P. D. Delmas[2]. [1]Synarc, Inserm Unit 403, Lyon, France, [2]Inserm Unit 403, Lyon, France.

The aim of our study was to evaluate the performances of a new fully automated assay for serum PINP, a marker of bone formation. Serum PINP was measured with a two site immunoassay based on monoclonal antibodies raised against purified intact human PINP and detecting both intact mono and trimeric forms, but not fragments using an automated analyzer (Roche Diagnostics). Results were compared to those of the manual polyclonal based radioimmunoassay (Orion). Intra and inter assay CVs were below 2 % and 3%, respectively. Analytical dilution and recovery ranged from 94 to 118%. Serum PINP levels were stable for up to 24 hours at + 4°C or room temperature and after up to 4 freeze-thaw cycles. The median within person CV% assessed by 3 repeated measurements over 3 months in 15 untreated postmenopausal women was 8.8 %, resulting in a least significant change (LSC) of 17.6 %. In postmenopausal women, automated PINP highly correlated (n=50; r = 0.96, p<0.0001) with the manual RIA. PINP levels increased from a mean 46 ± 14 ng/mL in premenopausal women (n=44) to 63± 17 ng/ml in 33 healthy untreated postmenopausal women (+37 %, p<0.001). After 3 months of treatment with synthetic conjugated estrogens in 35 postmenopausal women, automated PINP decreased by 24% (p<0.0001), a decrease similar to that of PINP by RIA (- 26%, p<0.0001) whereas no significant change was observed with placebo. After 6 months of treatment with bisphosphonate in 31 postmenopausal women with osteoporosis, automated PINP decreased by an average of 55% (p<0.0001) and 30 patients (97%) showed a decrease larger than the LSC. We conclude that the automated assay for serum PINP is highly precise and is a sensitive indicator of the antiresorptive effects of bisphosphonate and estrogens. Because of its convenient use and high throughput this marker should be useful for the investigation of patients with osteoporosis.

SU102

Pronounced Heterogeneity in Long-Term Variability of Bone Turnover Markers in Patients with Breast Cancer. M. J. Seibel[1], M. Koeller*[2], B. Auler-van der Velden*[2], I. Diel[2], H. W. Woitge[1]. [1]University of Sydney, Sydney, Australia, [2]University of Heidelberg, Heidelberg, Germany.

Variability of bone marker measurements remains to be an issue of concern in the clinical application of these parameters. Most studies on marker variability have been performed in healthy subjects and over relatively short intervals of time. As part of a prospective diagnostic study, we evaluated the long-term variability of various bone markers in 113 postmenopausal women diagnosed with primary breast cancer. None of the patients had bone metastasis, other skeletal disease or bone active drugs. During follow-up (range 0.6 - 4.2 yrs., median 30 mo.), patients were seen every 3 months and timed blood/urine specimens were obtained. To minimise analytical variability, all analyses were performed after study end by the same technician, using well documented techniques and a single batch of reagents per analyte. The coefficient of variation was calculated as CV (%) =√Σ(CVi2)/n (CVi= SD/mean x 100; n= n of CVi). The least significant change (LSC) was then LSC (%)= Z x CV x √2. For a 95% confidence interval (LSC95), Z= 1.96. For a 80% confidence interval (LSC80), Z= 1.28. Results are shown in the table below.

.	sTAP	sBAP	sOC	sPICP	uDPD	uNTX	sNTX	uCTX	sCTX	sCa
CV	12.1	14.0	34.4	26.9	38.0	37.3	17.6	55.9	42.0	5.1
LSC 95	33,1	38,8	95,4	74,5	105,3	103,4	48,7	155	116,5	14
LSC 80	22	25,4	62,3	48,6	68,7	67,5	31,8	101,2	76,1	9,2

Conclusions: In this real life study of breast cancer patients, long-term variability varied greatly between markers. For certain markers (e.g. urnary and serum CTX), the LSC was considerably higher than previously reported.

SU103

Comparison of Serum Tartrate-resistant Acid Phosphatase 5b with Other Markers of Bone Turnover in Monitoring Alendronate Therapy. S. L. Alatalo*[1], K. K. Ivaska*[1], S. Cheng[2], H. Schmidt-Gayk[3], K. Uusi-Rasi*[4], A. Nenonen*[4], P. Kannus*[4], H. Sievänen[4], H. K. Väänänen[1], J. M. Halleen[1]. [1]Institute of Biomedicine, Department of Anatomy, University of Turku, Turku, Finland, [2]Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland, [3]Department of Endocrinology and Oncology, Laboratory group, Heidelberg, Germany, [4]The UKK Institute for Health Promotion Research, Tampere, Finland.

The purpose of this study was to compare the usefulness of serum tartrate-resistant acid phosphatase isoform 5b (TRACP 5b) with other markers of bone turnover in monitoring alendronate therapy. The subjects of this one-year double-blinded intervention trial were 164 healthy postmenopausal women who were within 5 years after onset of menopause and with no previous use of medication related to bone metabolism. The subjects were randomly assigned into two groups, one receiving 5 mg alendronate daily, and the other receiving placebo. All subjects received a daily supplement of calcium and vitamin D. The bone markers, including the resorption markers serum TRACP 5b, total urinary pyridinoline (PYR) and deoxypyridinoline (DPD), and the formation markers serum total osteocalcin (OC), bone-specific alkaline phosphatase (BAP) and procollagen I N-terminal propeptide (PINP) were assessed at baseline and at 3, 6 and 12 months after start of treatment. Bone mineral density (BMD) of the lumbar spine was measured at baseline and at 12 months. Compared with the placebo-group, BMD increased significantly more, and the

markers decreased significantly more in the alendronate-group ($p < 0.0001$ for each parameter). Least significant change (LSC) was determined for each marker based on their analytical and biological variability. Those subjects that showed a decrease of more than LSC were defined as responders for the treatment. Clinical specificity of each marker was determined as the percentage of non-responders in the placebo-group, and clinical sensitivity as the percentage of responders in the alendronate-group. The specificity and sensitivity, respectively, of the markers were: TRACP 5b 89,6% and 81,6%; DPD 90,9% and 60,5%; PYD 84,4% and 59,2%; BAP 93,3% and 55,3%; PINP 83,1% and 86,8%; OC 68,9% and 75,0%. When the specificity of each marker was multiplied with its sensitivity, the results were as follows: TRACP 5b 0,73; DPD 0,55; PYD 0,50; BAP 0,52; PINP 0,72; OC 0,52. The values were clearly higher for TRACP 5b and PINP, indicating that these two were the most specific and sensitive markers for monitoring alendronate treatment.

SU104

An Enzyme Immunoassay for Measurement of 1,25-Dihydroxyvitamin D. M. J. Gardner*, D. Laurie*, A. K. Barnes*, R. T. Duggan. IDS Ltd, Boldon, United Kingdom.

Measurement of 1,25-dihydroxyvitamin D (1,25D) is of clinical importance in determining the cause of disturbances of calcium metabolism such as in malignant hypercalcaemia, renal and parathyroid disease and vitamin D intoxication. Most 1,25D assays require significant technical expertise to perform because they use complex sample extraction procedures usually involving chromatography. Introduction of the IDS 1,25D RIA kit overcame this problem by using simple monoclonal antibody columns to perform immunoextraction of the 1,25D from serum. Extracted samples were reconstituted and then assayed by conventional RIA. We have used this technology to develop a non-isotopic enzyme immunoassay (EIA) with comparable performance to the RIA. Serum samples (500uL) were delipidated and 100uL of clarified sample added to immuno-capsules in duplicate, which were then rotated end over end for 90 min. Following washing to remove serum proteins, the 1,25D was eluted from the immuno-capsule (3 x 150uL ethanol), the solvent was evaporated under nitrogen and the residue reconstituted with assay buffer (100uL). Specific sheep anti-1,25D antibody (100uL) was added, the mixture vortexed and incubated for 15 min. The extract / antibody mixture (150uL) was added to an anti-sheep IgG coated micro-plate, incubated for 90 min (shaken); then 1,25D-Biotin conjugate (100uL) added and incubated for a further 60 min (shaken). The 1,25D-Biotin conjugate competes with the 1,25D for anti-1,25D antibody sites. After a wash, avidin peroxidase (200uL) was added, incubated for 30 min and washed. TMB substrate (200uL) was added and the colour developed for 30 min. After addition of 0.5M HCl (100uL) the absorbance was measured at 450nm. A calibration curve was prepared from the absorbance values for 1,25D buffer standards (8-500pM) using a 4-parameter curve fit. The sensitivity of the assay (mean minus 2SD of "0" calibrator) was less than 6pM. Intra-assay precision was 12.7%, 7.4% and 3.7% for serum controls (n=10) at 18pM, 62pM and 136pM respectively. Inter-assay precision was 14.4%, 8.1% and 6.3% for serum controls (n=6) at 19pM, 59pM and 129pM. Linearity was good with a mean for observed / expected of 119% for 8 samples diluted 1:2, 1:4 and 1:8 with the "0" calibrator. Recovery of spiked calibrator material for 8 samples calculated by observed incremental rise / expected rise was 86% at +25pM and 91% at +100pM. Correlation against the IDS RIA for 91 samples was: EIA = 1.08 x RIA + 2.3pM (R2=0.92). This technology provides a precise and sensitive non-isotopic assay for the measurement of 1,25D, which correlates well with the existing IDS RIA and can be completed within an 8-hour working day.

SU105

Comparison of Biochemical Markers of Bone Turnover in the Ovariectomized Sprague-Dawley Rat. J. Mayer*[1], A. M. Leyshon*[1], P. Qvist*[2], S. Y. Smith[1]. [1]CTBR, Montreal, PQ, Canada, [2]Nordic Bioscience Diagnostics A/S, Herlev, Denmark.

The purpose of this study was to compare RatLaps (C-telopeptide (CTx) of type I collagen), a marker of bone resorption, and N-mid osteocalcin (Rat-MID OC), a marker of bone formation, with free deoxypyridinoline (DPD, resorption marker), intact osteocalcin (OC) and total alkaline phosphatase (ALP, a surrogate formation marker), in a 2-week ovariectomized (OVX) rat model of osteoporosis. Three month-old virgin female rats were randomly assigned to 3 groups. Twenty animals underwent OVX of which 10 were given subcutaneous estradiol pellets (0.5 mg). Ten animals underwent surgery without removal of the ovaries (Sham controls). Blood and urine samples were collected from all animals following a 6-hour daytime fast (food and water deprivation) once prior to surgery and 7 and 14 days following surgery. Serum was harvested and analyzed for Rat-MID OC (NB Diagnostics, ELISA), intact OC (Biomedical Technologies RIA), total ALP (Hitachi 717 enzymatic assay) and CTx (NB Diagnostics RatLaps ELISA). Urine was analyzed for DPD (Immunodiagnostic System Ltd RIA) and CTx (NB Diagnostics RatLaps ELISA) (both corrected for creatinine). Rat-MID OC, intact OC and RatLaps (urine) were significantly increased for OVX controls compared to Sham controls 7 days post-surgery. Relative to baseline values, the percent change (increase) for OVX controls 7 days post-surgery was 39% for Rat MID OC and 78 and 76% for RatLaps serum and urine, respectively, far greater than the 14 to 18% increases observed with OC, ALP and DPD at this time-point. With the exception of DPD, all markers were significantly increased for OVX controls 14 days post-surgery, compared to Sham controls. At 14 days post-surgery RatLaps (serum and urine) showed greater than 2-fold increases for OVX controls relative to baseline levels. Estradiol was noted to effectively prevent the OVX-induced rise in all markers. The use of RatLaps (serum or urine bone resorption marker) and Rat MID OC (serum bone formation marker) permitted the early detection of the OVX-induced increase in bone turnover in this 2-week rat study and will provide sensitive tools for the rapid screening of potential anti-osteoporosis agents.

SU106

Prospective Follow-up Study of Biochemical Markers of Bone Metabolism for Diagnosis of Bone Metastases in Early Breast Cancer. S. Takahashi[1], M. Koizumi*[2], E. Ogata[3]. [1]Dep. of Medical Oncology, Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo, Japan, [2]Dep. of Radiology, Cancer Institute Hospital, Japanese foundation for Cancer Research, Tokyo, Japan, [3]Dep. of Internal Medicine, Cancer Institute Hopsital, Japanese foundation for Cancer Research, Tokyo, Japan.

We have previously shown that the bone metabolic markers, especially serum carboxy-terminal telopeptide of type 1 collagen (ICTP), were useful for diagnosis of bone metastases of breast cancer in a cross-sectional study. ICTP has been reported to derive from collagen degradation by matrix metalloproteases, and represent pathologic bone resorption such as bone metastases, not increase of physiologic bone resorption such as osteoporosis. Sensitivity and specificity of ICTP for diagnosis of bone metastases in our study was about 45% and 97%, respectively. But some reports showed that ICTP is also increased in patients without bone metastases. In this study we prospectively evaluated the efficacy of the bone metabolic markers for diagnosis of bone metastases in patients with early breast cancer. After operation, patients with high risk of bone metastases (stage III or n>3) were prospectively followed for at least 2 years or until bone metastases were detected, and bone metabolic markers were evaluated every 3 months. Urinary free deoxypyridinoline (fDPD, ELISA, Metrabiosystems), serum ICTP (RIA, Orion Diagnostica), procollagen type I C-terminal peptide (PICP, RIA, Orion Diagnostica) and bone-specific alkaline phosphatase (BAP, IMA, Metrabiosystems) were measured. 74 patients were recruited and followed so far. 7 patients have been diagnosed to have bone metastases with radiological diagnostic procedure. Sensitivity of bone metabolic markers at the time of diagnosis of bone metastases were: ICTP, 57%; BAP, 29%; fDPD, 71%; PICP, 29%. False positive rates (rates of patients without bone metastases who showed increase of the markers at least once) during the first year were high: ICTP, 50%; BAP, 42%; fDPD, 84%; PICP, 26%. But false positive rate of ICTP more than 1 year after operation decreased to 6%. In follow-up of patients with early breast cancer, bone metabolic markers seem not very useful for detecting bone metastasis within 1 year after operation, but ICTP might be useful thereafter.

SU107

High Remodeling Turnover in Venezuelan Osteoporotic Patients. G. S. Riera, Y. Cordero*, J. Ramos*, L. Marcano*. Medicine, UNILIME. Universidad de Carabobo, Valencia, Venezuela.

Bone mass is the result of a lifelong balance between bone formation and resorption, and in fact, most metabolic bone diseases including osteoporosis, are consequent to an unbalanced bone turnover. Osteoporotic syndromes are characterized by wide spectrum of bone turnover, ranging from accelerate to reduced remodeling rates. Higher rates of bone remodeling are in general associated to higher rate of bone loss and predict fractures. Biochemical Markers of Bone turnover were measured in 283 women. N-telopeptide: NTx, Osteomark, Ostex,Seattle,USA, Tartrate Resistant Acid Phosphatase: Hydrolysis of paranitrophenyl phosphate at 4.8 pH, Alkaline Phosphatase: Labtest. Roy Modified. Mean age was 57,93 ± 9.6 (30-85). BMD (T-score) at lumbar spine L2-L4 was – 2,36 and -1,6 at femoral neck. Previous fractures were present in 4,5%. Family history of osteoporosis was present in 8%, hypertension in 27.6% diabetes in 7.8%. Surgical menopause in 36.4% and HRT was taken by 35%. Mean values of bone markers were NTx 113,5±69 nMolBCE/mMolCreat, Tartrate Resistant Acid Phosphatase 9.79±3.2 and Alkaline Phosphatase 47.7±21. (Control premenopausal values in our lab are: NTx 40±15 nMolBCE/mMolCreat, TRAP 8.37±2.2 UI/l and AP 35±8.6 UI/l). Cut-off point for 2 and 3 SD above control mean were for NTX 70 and 85, for TRAP 12.77 and 14.9, and for AP 52.2 and 60.8. 62.2% or 55.8% of patient were classified as High Turnover, if the cut-off point is set at 2 or 3 SD above premenopausal mean of NTx. With TRAP values were 16.9% and 7.4% and with AP we found 31.8% and 18.0%. Conclusion. High Turnover osteoporosis (2 SD above the control mean) was present in 62.2% of our Venezuelan osteoporotic patients and 86.5% had resorption over the premenopausal mean according to N-telopeptide determination (NTx), this marker was able to identify more patients with high remodeling state than TRAP or Alkaline Phosphatase

SU108

Fracture Risk Assessment in a Primary Care Setting Using Point-of-Care Technology. S. Twaddle*, T. Mangion*, R. Chandra*, R. Leonard*, C. Moniz. Clinical Biochemistry, Kings College Hospital, London, United Kingdom.

Fracture risk assessment using DXA for community dwelling women over 65 requires different strategies from younger women since the prevalence of low trauma fractures and artefacts resulting in spurious BMDs are common in this age group. We offered an Osteoporosis Nurse led fracture risk assessment service to 755 women over 65 in one large primary care practice using a risk questionnaire, heel ultrasound (HUS) measurements and point-of-care bone biochemical markers. 328 (43%) attended a walk-in service and were classified as low risk (n=53), moderate risk (n=164) or high risk (n=111), based on a heel Stiffness Index T-score measured on a Lunar Achilles Solo machine, of > -1.0, between -1.0 to -2.5 or < -2.5, respectively. All were offered a clinical assessment but 182 were followed within 2 weeks with results of a self-administered fracture risk questionnaire, a point-of-care Crosslaps measurement using Osteosal $^{TM.}$. Subsequently, urine analysis for CTX (Crosslaps ^{TM}) was performed in batch mode in the laboratory at a later date. 44 (23%) had clinical osteoporosis and after excluding secondary causes were prescribed calcium and vitamin D alone or with anti-resorptives. 97 (53%) had no significant risk factors for fracturing and were given life-style advice. 44 (24%) were intermediate and were referred for DXA. Osteosal ^{TM} at baseline was of little value in decision making, but CrossLaps ^{TM} provided increased discriminatory power at a cut-off of 303 µg/mM creat, with 77% sensitivity and 65% specificity (vs 66% and 46% respectively for HUS alone) at a DXA T-score of -2.5. Osteosal ^{TM} correlated with Urinary-CTX (Crosslaps ^{TM}) at baseline and showed a significant reduction of -49% (95.9% CI -67 to -30, range -7 to -86%) in those taking anti-resorptive treatment after 3 months. Fracture prevention in primary care need effective strategies to identify and treat those with incident clinical osteoporosis (approximately 1 in 4 in our series), those who require DXA for management decision making and those who would benefit with life-style modification advice alone. Point-of-care technology such as peripheral bone scanning techniques and risk factor questionnaires can provide a means of making efficient use of resources for fracture risk assessment and bone biochemical markers for indicating bone turnover particularly when monitoring treatment response.

SU109

Urine and Plasma Bone Resorption Markers in Patients with Active Paget's Disease. B. H. Durham, J. J. Dutton*, W. D. Fraser. Bone Disease Unit, Dept of Clinical Chemistry, Royal Liverpool University Hospital, Liverpool, United Kingdom.

We have compared the concentrations of a urinary and a plasma marker of bone resorption in a cohort of elderly patients with active Paget's disease. The urinary marker was free deoxypyridinoline estimated using a HPLC method and normalised for creatinine [f DPD] and for plasma the beta form of the C terminal telopeptide of type 1 collagen [beta-CTX] analysed on the Elecsys automated platform using an ECLIA method [Roche Diagnostics, Germany]. The cohort consisted of 196 patients with Paget's disease who were not on any treatment [99 F, 97M] average age 70 years [range 56-84], the majority [99%]had total alkaline phosphatase [TAP] greater than an age related reference range, [mean 387 range 138-1629]. Blood and a 24hr urine was collected from each patient and the EDTA plasma and an aliquot of the urine was stored at -20oC until analysed. The correlation between f DPD [y] and beta-CTX[x] for all patients was y= 13.99x-0.53, r=0.80, for males y=13.58x -0.37, r=0.85 and for females y= 12.18x+0.38, r=0.77. The top of the reference ranges are 0.50 ng/ml for beta-CTX and 6.4 nmol/mmol Creat for fDPD. In our study 87/196 [44%] had both beta-CTX and fDPD concentrations greater than the top of the reference range , for beta-CTX alone 127/196[65%] and for fDPD 100/196[51%] were elevated. From the results in Paget's patients it appears that beta-CTX is elevated in a greater percentage than fDPD. Each test is reflecting a different component of the resorption process in patients with Paget's disease. The relatively lower elevation of beta-CTX and fDPD compared to TAP may be the result of alteration in beta to alpha CTX ratio and collagen crosslinking in newly formed collagen in Paget's disease.

SU110

Comparison of Changes in Serum Bone Markers for Various Osteoporosis Management Regimens. D. S. Ooi[1], A. B. Cranney[2], J. D. L. Gay[2]. [1]Pathology and Laboratory Medicine, Ottawa Hospital, Ottawa, ON, Canada, [2]Medicine, Ottawa Hospital, Ottawa, ON, Canada.

We (a) compared changes in serum bone-specific alkaline phosphatase (BSAP) and c-telopeptides (CTX) following treatment with raloxifene 60 mg daily (RAL), cyclical etidronate (ICE), alendronate 10 mg daily or 80 mg weekly (ALE) and risedronate 60 mg weekly (RIS), and (b) correlated changes in serum bone markers and bone mineral density (BMD). Serum bone markers were measured prior to and 2-36 months (median 12 months) following initiation or change in regimen in 118 patients attending a specialty clinic; 36 patients (32 females, 4 males) had corresponding BMD data. Serum BSAP was measured using Beckman Access Ostase and CTX by Roche Elecsys CrossLaps. BMD was measured by dual emission x-ray absorptiometry on a Lunar Expert. Median baseline and % change in BSAP and CTX, and % of patients showing either increase or decrease (of >20%) from baseline were:

Regimen (n)	BSAP (ug/L)	Change	% Incr, Decr	CTx (ug/L)	Change	% Incr, Decr
RAL (10)	9.4	+1%	44, 0	0.13	-8%	10, 40
ICE (11)	10.7	-3%	0, 27	0.17	-23%	27, 45
ALE (38)	10.1	-12%	26, 43	0.20	-41%	18, 40
RIS (6)	8.8	+7%	17, 33	0.09	-77%	17, 67
ICE to ALE (42)	9.4	-8%	10, 33	0.17	-43%	17, 46
ALE to RIS (6)	7.4	-19%	33, 50	0.14	-30%	0, 50

Correlations between decreases in BSAP and/or CTX and increases in BMD ($\geq$0.02 g/cm^2) in lumbar spine (LS) or femoral neck (FN) were not statistically significant. Patients with serum BSAP concentrations between 6 and 12 ug/L and CTX concentrations of $\leq$ 0.05 ug/L while on therapy were more likely to have increases in BMD, but did not achieve statistical significance. For CTX, LS increased in 67% vs 52% of patients, FN 42% vs 21%, for BSAP, LS increased in 67% vs 33%, FN 36% vs 25%. We conclude (a) CTX, a bone resorption marker, showed greater decreases with treatment than BSAP, a formation marker, and that the aminobisphosphonates effected the greatest decreases in CTX; (b) BSAP 6-12 ug/L and CTX $\leq$ 0.05 ug/L were more often associated with increases in BMD, however bone marker changes appear to be poorly predictive. This is consistent with the hypothesis that antiresorptives may effect fracture reduction through mechanisms other than increase in bone density such as reduction in bone turnover. In assessing patients on pharmacotherapy, bone markers should be used independently of BMD.

SU111

Is the Bone Marker Response Dependent on the Agent Used to Treat Osteoporosis. M. W. J. Davie, D. E. Powell*, M. Worsfold*, T. Jones*, H. Davies*, H. Williams*. Robert Jones & Agnes Hunt Orthopaedic Hospital, Oswestry, United Kingdom.

Response to osteoporosis therapy may be measured by bone markers or bone density (BMD). Diverse therapies may elicit different responses in different markers. We compared responses of NTX/Cr, DPD/Cr and lumbar spine BMD (L2-4) to treatment with bisphosphonates, HRT or calcium after one year of treatment and investigated whether any marker indicated response at 3 months. Results were expressed as the proportion of patients exceeding the Least Significant Change (LSC) i.e. in excess of the normal variation. Patients were identified by population screening, 145 Patients with osteoporosis (OP,T-score > -2.5) aged 71±6.8 yr treated with HRT (n=12), Bisphosphonates (n=75, 63% Didronel), calcium only (n=7) or not treated (n=48) were compared with non-osteoporotic (NOP) patients treated with bisphosphonates (n=10), HRT (n=3), calcium (n=11) or untreated (n=88). The decision to treat and the agent used were made by the patient's General Practitioner. Markers were measured pre-treatment and at 3, 6 and 12 months and for BMD pre-treatment and at 12 months. Since the distribution of the marker values was positively skewed, the data were log transformed. LSC was calculated from the variance of the values of the non-treated patients over the 4 readings for markers or 2 readings for BMD (LSC= 2.8 x sqrt(variance/mean)). Mann-Whitney was used to compare non-parametric data and Chi squared differences in proportions. Results are presented as mean ± SD. Age matched OP subjects had greater NTX/Cr values compared with NOP (82.4±53.4 vs 60.5±33.4 nM BCE/mM Cr, p<0.001) but similar DPD/Cr (6.69±2.66 vs 6.24±1.78 nM DPD/mM Cr, p=ns). The lower LSC was 60% for NTX and 60.3% for DPD. At month 12 70% of the bisphosphonate OP group responded using NTX, more than calcium (70% vs 29% p<0.05), but HRT showed no difference. The NOP group given bisphosphonate showed 80% exceeding LSC at 12 months (p<0.001). Using DPD/Cr only the HRT OP group showed more responding cf calcium after 12 months (42% vs 0%, p<0.05); in the NOP group there was no response. BMD response at 1yr showed only 33% of patients with OP exceeding LSC in the bisphosphonate group. NTX/Cr showed a response rate of 50% after 3 months in bisphosphonate treated subjects. NTX/Cr shows an earlier response, but even by 12months only 70% show a response to bisphosphonate. This response exceeds that seen with either DPD/Cr or BMD. HRT may however influence the production of DPD from matrix degradation more than NTX though whether this indicates a different effect on the osteoclast awaits elucidation. Bisphosphonates also reduce NTX/Cr in non-osteoporotic subjects suggesting an effect on osteoclasts in normal subjects.

SU112

Stability of C-telopeptides of Type I Collagen During Storage of Serum and Plasma Samples. P. Qvist[1], M. Munk*[1], C. H. Christiansen[2]. [1]Nordic Bioscience Diagnostics A/S, Herlev, Denmark, [2]Center for Clinical & Basic Research, Ballerup, Denmark.

It has recently been demonstrated that variability in bone resorption markers caused by circadian variation was reduced to a level similar to bone formation markers when blood sampling was performed in the morning after an overnight fast (S. Christgau, Clin Chem 46 (2000): 431). However, other pre-analytical parameters influencing variability should likewise be investigated, and the present study was performed to determine the effect of storage temperature on the stability of C-telopeptides of type I collagen (CTX) in serum and plasma. Blood samples from eight premenopausal women (age 27-43 years) and six men (age 28-60 years), were obtained from 8.00 to 10.00 am after an overnight fast. Serum and EDTA plasma were collected, aliquoted and stored at -20ºC, -80ºC, and -150ºC until testing. Circulating levels of C-telopeptides of type I collagen were determined by Serum CrossLaps® ELISA (Nordic Bioscience Diagnostics A/S). No decrease in CTX was observed at either temperature or sample matrix during this storage period as the mean recovery was in the range 98-106%. To further study the stability of CTX at elevated temperatures serum and EDTA plasma samples were obtained from healthy individuals, aliquoted and incubated at either 4ºC or 37ºC until testing. After seven days of incubation at 4ºC approx. 92% of CTX were recovered from serum samples, and after 60 days, 35 and 98% was recovered from serum and EDTA plasma samples, respectively. After incubation for 2 days at 37ºC, 45 and 94% was recovered from serum and EDTA plasma samples, respectively. After 14 days the recovery was 9 and 70%, respectively. These data demonstrate good recovery of CTX in serum samples stored frozen for extended time periods, and more than 90% of CTX could be recovered even after 7 days at 4ºC. Improved stability of CTX was observed in EDTA plasma samples with no detectable decrease even after two months at 4ºC. Therefore EDTA plasma samples might be a useful specimen for measurement of CTX due to the high analyte stability in this matrix. The practical implications of the improved stability of CTX in EDTA plasma samples need to be determined in routine clinical settings.

SU113

Bone Markers Predict Future BMD of Japanese Postmenopausal Osteoporotic Women with Hormone Replacement Therapy (HRT) or Bisphosphonate Treatment. O. Chaki, I. Gorai, K. Kurasawa*, K. Mochizuki*, Y. Arata*, H. Yoshikata*, R. Kikuchi, F. Hirahara*. Yokohama City University, Obstetrics and Gynecology, Yokohama, Japan.

Hormone replacement therapy (HRT) is essential for treating postmenopausal osteoporosis. But thereare some populations who had not received HRT because of complications (i.e.breast cancer, thrombosis etc.). In this study, we assessed the effects of HRT or Bisphosphonate on bone mass and turnover in postmenopausal osteoporotic Japanese population. Seventy one postmenopausal osteoporotic Japanesewomen (62.3+/-7.3 years) were enrolled into this study. Thirty one women were treated with HRT(conjugated estrogens 0.625mg/day, medroxyprogesterone acetate 2.5mg/day; HRT group), 19 women were treated with Etidronate(200mg/day for 2 weeks every 12 weeks; E group) and 21 women were with Alendronate(5mg/day). Lumbar spine bone mineral density(BMD) was determined at the start of the study(0 month) and every 6 months thereafter and biochemical indices, serum alkaline phosphatase(ALP), intact osteocalsin(IOC), urinary deoxypyridinoline(DPD), crosslinked N-telopeptide of type I collagen(NTx) and creatinine were measured at 0, 1, 3 and 6 months. BMD measurement was performed using dual energy X-ray absorptiometry(DXA, QDR2000, Hologic Comp.). There was no differences in each groups in age, years since menopause or BMI. Baseline lumbar spine BMD and biochemical indices did not show any substantial differences in among each groups. There were significant differences in percent changes of BMD(HRT group; 2.6+/-2.3%, E group; 4.0+/-1.5%, A group; 5.2+/-2.3%, A and E group vs. HRT group, $p<0.05$ at 6 months.). NTx and DPD significantly decreased at 3 months in each group from baseline ($p<0.03$). The magnitud of decreasewas grater in E and A group than HRT group(NTx: HRT;-34.1+/-11.5%, E;-38.7+/-10.5%, A;-46.4+/-9.5%). Furthermore, in A group, NTx and DPD significantly decreased at 1 month ($p<0.03$). In conclusion, 1) The bone spearing effect of Alendronate for treatment of postmenopausal osteoporosis appeared earlier and stronger than that of HRT or Etidronate. 2) Biochemical markers of bone resorption were clinically useful in the prediction of future BMD in HRT or Bisphosphonate treated women.

SU114

Assessment of Bone Formation- and Bone Resorption- Markers in Horses. B. Carstanjen[1], N. R. Hoyle*[2], A. Gabriel*[3], J. Detilleux*[4], H. Amory*[1], B. Remy*[5]. [1]Department of Large Animal Internal Medicine, University of Liege, Liege, Belgium, [2]Roche Diagnostics GmbH, Penzberg, Germany, [3]Department of Anatomy, University of Liege, Liege, Belgium, [4]Department of Quantitative Genetics, University of Liege, Liege, Belgium, [5]Department of Physiology of Reproduction, University of Liege, Liege, Belgium.

Various biochemical bone marker assays developed for serum or plasma samples are available in human medicine to monitor bone formation and bone resorption. Collagen breakdown products (β-CrossLaps; β-CTX) are used as indicator of bone collagen degradation and are detected in serum. The serum N-terminal extension peptide of type I procollagen (P1NP) is used as indicator of bone collagen formation. Serum osteocalcin (OC) is used as indicator of osteoblast activity. However, only few species specific assays are available in equine medicine. Aim of this study was to test fully automated ECLIAs for P1NP evaluation (Roche Diagnostics, Penzberg; Germany) and Serum β-CTX evaluation (Roche Diagnostics, Penzberg, Germany) for cross reactivity with horse serum. Additionally, to study the effect of age on bone formation and resorption in horses as determined by the human specific CTX- and P1NP- ECLIA and by a previously described equine specific OC RIA. Venous serum and EDTA plasma samples of 59 healthy horses, aged 1 to 35 years, were obtained between 9 am and 10 am. Horses were divided in 3 age groups. Group 1 (n=22) was composed of 1 to 4 years old horses, group 2 (n=21) of 4.5 to 15 years old horses and group 3 (n=16) was composed of older than 15 years old horses. Gender did not influence serum OC, plasma CTX and plasma P1NP values. Equine serum samples, serially diluted with equine serum free samples, were linear when analyzed with the P1NP- and CTX- ECLIA. Healthy horses showed plasma CTX values in the range from undetectable to 0.297 ng/ml. Plasma P1NP values ranged from undetectable to 3.891 ng/ml and serum OC values ranged from undetectable to 128.80 ng/ml. Group 1 showed highest plasma CTX ($p<0.01$) and serum OC ($p<0.01$) values compared to group 2 and 3. Group 2 showed highest plasma P1NP ($p<0.01$) values compared to group 1 and 3. In conclusion, commercially available human assays for CTX and P1NP quantification in serum/plasma may be a useful tool to monitor bone metabolism changes in horses. Age did influence serum/plasma bone marker concentrations in horses.

Synovial Fluid Analysis of Chlorinated-Peptides for the Early Diagnosis of Osteoarthritis. L. J. Nesti*, P. F. Sharkey*, S. Sastri*, M. J. Steinbeck. Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA.

Osteoarthritis is a severely debilitating and degenerative disease that is associated with marked pain and disability. Early detection and therapeutic intervention of arthritic joint diseases is crucial for successful management and treatment; however, there is currently no available biomarker with sufficient sensitivity and specificity for the early diagnosis of osteoarthritis (OA). In seeking to identify biomarkers that will aid in early detection and could be used to monitor the progression of cartilage destruction in OA, our lab has recently demonstrated that neutrophil and macrophage generated reactive oxygen species (ROS), specifically hypochlorous acid (HOCl) and chlorine gas (Cl_2), chlorinate collagen type II (col-II) obtained from human articular cartilage and increases its susceptibility to proteolytic degradation. Based on this unique reaction chemistry and Cl-product formation, we analyzed synovial fluid to determine the presence of Cl-peptides as a sign of cartilage destruction in early OA patients. In this study, we examined synovial fluid samples from 37 knees in 30 patients to identify and profile specific Cl-products that can be used to differentiate early stages of OA. We divided the samples into 3 groups using radiographic and clinical assessment: (1) Control, those patients with some type of acute knee injury with no history of OA and no radiographic evidence of OA; (2) Early OA, patients with a brief history of OA with either normal radiographs or mild arthritic changes seen on radiograph; and (3) Late OA, those patients with a longstanding history of OA and with radiograph evidence of OA. Using a proteomic approach, we identified all Cl-peptides in the synovial fluid samples with mass spectrometry and determined myeloperoxidase (MPO) levels, the enzyme responsible for $HOCl/Cl_2$ production, with a commercially available ELISA. This data was then compared with the OA classification groups. Patients in the control and advanced OA groups demonstrated little elevation in MPO levels and Cl-peptides were undetectable. Patients with early OA demonstrated significantly elevated levels of MPO and Cl-peptides were detected. This data suggests that the presence of Cl-peptides in synovial fluid may serve as a diagnostic marker for the detection of early OA.

Genetic Variations in Cortical and Cancellous Bone Loss Following Ovariectomy in Three Inbred Mouse Strains. C. Li*[1], M. B. Schaffler[1], H. T. Wolde-Semait*[1], C. Hernandez[1], J. Nadeau*[2], K. J. Jepsen[1]. [1]Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA, [2]Center for Computational Genomics, Case Western Reserve University, Cleveland, OH, USA.

The effects of genetic background on the magnitude and rate of post-menopausal bone loss are not fully understood. Inbred mice exhibit differences in bone formation rates during growth leading to variations in morphological and compositional bone traits of adult bone [1]. It is reasonable to expect that inbred mice will also exhibit differences in bone loss. We tested the hypothesis that three inbred mouse strains will show differences in the magnitude and timing of bone loss following ovariectomy. A total of 210 female mice from the C3H/HeJ ("high density"), C57BL/6J ("low density"), and A/J ("intermediate density") strains were examined. Mice were sham-operated or ovariectomized (OVX) at 16-weeks of age (n=10/strain/group) and sacrificed at 4, 8 and 16 weeks post-OVX. Differences in static and dynamic measures of cancellous bone loss in the distal femur were determined from standard histomorphometry of plastic embedded frontal sections. Differences in cortical bone mechanical properties were determined by loading femurs to failure in 4 point-bending. The results of the 4 and 8 week time points revealed significant differences in cortical and cancellous bone loss among the three inbred strains. The "intermediate density" A/J femurs showed no changes in either cortical or cancellous bone. The "low density" B6 femurs showed no change in cancellous bone mass but exhibited a 10% reduction in maximum load at 4 and 8 weeks post-OVX compared to age matched controls. The "high density" C3H mice exhibited a significant reduction (39%) in cancellous bone mass (%B.Ar/T.Ar) as early as 4 weeks post-OVX when compared to the age-matched sham group. This bone loss was accompanied by a 22% decrease in trabecular thickness (Tb.W) and number (Tb.N). The maximum load of C3H femurs was 7-12% lower at 4 and 8 weeks post-OVX compared to age matched controls indicating significant cortical bone changes. These results revealed significant differences in cortical and cancellous bone loss following OVX among three inbred mouse strains indicating that genetic background may play an important role in the magnitude and timing of OVX-induced bone loss. The results also revealed that OVX-induced bone loss was independent of initial "bone density" and that the genes which promote high peak bone mass may not protect against bone loss. Genetic Variations in the Structural Efficiency of Long Bones May Contribute to Variations in Mineralization Among Inbred Mouse Strains. C. Price*[1], C. Hernandez[1], J. Nadeau*[2], K. J. Jepsen[1]. [1]Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA, [2]Center for Computational Genomics, Case Western Reserve University, Cleveland, OH, USA.

Previous studies revealed that morphological variations between "high density" C3H/HeJ (C3H) femurs, "intermediate density" A/J femurs, and "low density" C57BL/6J (B6) femurs were evident as early as embryonic day E16.5 [1]. Certain aspects of these initial morphological variations were retained in adult femurs suggesting that genetic determinants of peak bone mass may occur early in life. Investigations of adult mouse long bones revealed that understanding the relationship between multiple bone traits was critical to understanding whole bone mechanical function [2]. While morphological variations between inbred strains have been reported [3,4], it remains unclear how the relationship between morphological and compositional traits changed during growth. To explain variations in adult bone traits, we examined how the relationship between morphological traits of A/J, B6, and C3H femurs changed during growth. Variations in post-natal bone morphology were determined by sacrificing 8-10 female A/J, B6, and C3H mice at 1, 4, 7, 14, 28, 56, 105, 182, and 365 days of age. Femoral cross-sectional area (amount of bone), polar moment of inertia (distribution of bone), and other geometric traits were determined from plastic sections. Moment of inertia increased with cortical area in a power law manner ($y=ax^b$) and all three strains showed a similar exponent, b, of 1.48 (A/J), 1.53 (B6), and 1.50 (C3H). However, morphological differences apparent at birth (day 1) lead to significant differences in the constant term, a. A/J and C3H exhibited nearly identical curves. B6 femurs exhibited a greater moment of inertia for a given area indicating that B6 femurs were structurally more efficient than A/J and C3H. The variation in structural efficiency may explain differences in mineralization observed between the 3 strains. The increased mineral content (i.e., increased tissue stiffness) of A/J and C3H femurs may represent an attempt to compensate for the reduced structural efficiency. The results revealed that the relationship between individual bone traits were defined early in life and that genetic background affected the relationship between these traits.

Double Heterozygosity for Osteogenesis Imperfecta (OI) and Cleidocranial Dysostosis (CCD): Altered Fibroblast Response to Phenol Red and Dexamethasone. Z. Zhang*[1], J. Korkko*[2], J. R. Shapiro[3]. [1]Medicine, Uniformed Services University, Bethesda, MD, USA, [2]Center for Gene Therapy, Tulane University, New Orleans, LA, USA, [3]Osteogenesis Imperfecta Program, Kennedy Krieger Institute, Baltimore, MD, USA.

The proband is a 28 year old Caucasian female who first fractured at age 1 year and later fractured her humeri, radii and femurs. Her clavicles are absent. Her father, grandmother and three uncles have OI. Her mother has CCD and neurofibromatosis. A brother has blue sclerae and cafe au lait lesions but no fractures. A second brother has OI, CCD and neurofibromatosis. Mutation analysis performed by conformation sensitive gel electrophoresis disclosed a COL1A1 IVS 14-2A>G present in the proband, her father and the OI-affected brother. A known CCD mutation, R 225Q (c.674G>A) was found in the mother and brother. We investigated the growth characterstics of the proband's dermal fibroblasts using MTS/PMS (Promega) which by 490 nm absorbance is proportional to the number of living cells in culture. Fibroblasts in passage 9-11, at a concentration of 1000/well, were cultured for 14 days in DMEM containing 10% FCS. Data is reported for day 3. Basal growth rate was decreased in proband cells compared to control ($p =<0.001$). Cells were cultured with estradiol, IGF-1, TGF-b1, basic FGF and in in phenol red (+) and phenol red (-) DMEM media. Basic FGF increased growth rates 8 to 10% ($p=<0.01$) in control and proband cells. Response to IGF-1 was positive, but not significantly different in control vs proband cells. TGF-b1 decreased growth rate 18% in both cell strains. Estradiol increased growth 9% to 12% in control and proband cells. Dexamethasone (10-7 M) increased growth 15% in control fibroblasts but not in proband cells. Phenol red (+) medium increased growth rate in control cells but not in proband cells. This is the first report of double heterozygosity for genes which are essential for normal fibroblast and osteoblast growth and differentiation. Fibroblasts containing a COL1A1 mutation show impaired growth rate responses to dexamethasone and phenol red. Phenol red contains lipophilic agents which has a stimulatory effect on cell growth acting through Na /K cationic channels. This suggests that cationic channels may modulate growth, and/or altered extracellular deposition of bone matrix proteins by OI fibroblasts.

Expression Profiling of Genes Involved in Osteoporosis using DNA Microarray. S. Kim[1], M. Kim*[2], J. Kim*[2], J. Choi[3], H. Shin*[4], E. Park*[5]. [1]Orthopedic Surgery, Kyungpook National University Hospital, Daegu, Republic of Korea, [2]Immunology, School of Medicine, Kyungpook National University, Daegu, Republic of Korea, [3]Biochemistry, School of Medicine, Kyungpook National University, Daegu, Republic of Korea, [4]Pathology, School of Dental Medicine, Kyungpook National University, Daegu, Republic of Korea, [5]Cell and Developmental Biology, Biomedical Research Institute, Kyungpook National University Hospital, Daegu, Republic of Korea.

Osteoporosis is a common and progressive skeletal disease primarily caused by genetic factors and hormonal imbalances. Alteration of gene expression caused by hormonal imbalances may be one of critical causes for osteoporosis. Although many genes have been implicated to play a role in osteoporosis, systematic studies are necessary to identify genes and to understand their roles in osteoporosis. In an effort to identify differentially expressed genes associated with osteoporosis, we utilized DNA microarray technology. Bone tissues were obtained from young woman of premenopause with high BMD and old woman of postmenopause with low BMD. RNA from cancellous bones was purified, reverse transcribed and labeled with either Cy3-dUTP (nonosteoporotic) or Cy5-dUTP (osteoporotic). Labeled probes were hybridized to the DNA chip containing 3,063 human mesenchymal cell derived genes (http://hair.knu.ac.kr). More than 2 fold in the ratio of Cy-3/Cy-5 was counted for positive signals. We identified 9 genes highly up-regulated in osteoporosis and 10 genes strongly down-regulated. Those up-regulated genes were cell signaling related genes such as IGFBP2 and endoglin, and transcription factors such as transforming growth factor beta inducible early growth response and nuclear factor related to kappa B binding protein. The down-regulated genes were progesterone membrane binding protein, signal transducer and activator of transcription 1, transcriptional adaptor3-like (PCAF histone acetylase complex). We also identified several genes that were not found in GenBank.These results suggest that osteoporosis is followed by fluctuations of expression of genes and the genes identified in this study may play a critical role in osteoporosis in vivo.

SU120

Phenotypic Differences in Bone Morphometry of Inbred Mice with High and Low Bone Density are Gender and Site Specific. D. J. Adams*[1], J. D. Delaney*[2], M. S. Moreau*[1], D. W. Rowe[2]. [1]Orthopaedic Surgery, University of Connecticut Health Center, Farmington, CT, USA, [2]Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA.

Inbred strains of female mice exhibiting relatively high (C3H/HeJ) and low (C57BL/6J) bone density have been employed recently to study the genetic regulation of bone mass, structure, and integrity. Female C3H mice demonstrate thicker, more highly mineralized femoral cortical bone than female B6 mice, but substantially less trabecular bone in their vertebrae and proximal femur. The objective of this study was to examine gender differences in cortical and trabecular bone architecture within femora of these two inbred strains as well as the outbred strain CD1. Femora were harvested from male and female inbred (C3H and B6) and outbred (CD1) 4-month old mice (38 mice, 6-7 per group). Cortical and trabecular morphometry were measured at mid-diaphysis and within the distal metaphysis, respectively, from images generated via X-ray computed microtomography. Cortical cross-sectional area, thickness, maximum area moment of inertia, and polar moment of inertia were significantly lower in femora from females than in males for B6 and CD1 mice ($p < 0.05$), but not for C3H mice. Flexural section modulus, a measure of geometrical bending strength, was lower in females than in males for all three strains, although only marginally significant for CD1 ($p = 0.057$). Despite substantial differences in cortical cross-sectional area and thickness, section modulus was the same in female C3H and B6 femora; however, section modulus was significantly lower in B6 males than C3H males ($p = 0.04$). Trabecular volume fraction was significantly lower ($p = 0.004$) in femora from B6 females than in B6 males ($10.7 \pm 0.8\%$ vs. $28.1 \pm 8.4\%$), and significantly higher ($p = 0.01$) in C3H females than in C3H males ($33.5 \pm 4.2\%$ vs. $21.8 \pm 7.4\%$). Femoral trabeculae in B6 females were thinner ($p = 0.008$), fewer in number ($p = 0.002$), and less connected ($p = 0.006$) than in males, whereas the trabeculae in C3H females were significantly thicker than in males ($p = 0.03$). Unlike cortical bone geometry, differences in trabecular bone morphometry between male B6 and C3H mice were minimal, including a small increase in the number of trabeculae ($p = 0.004$) that were otherwise of equal average thickness and not consequential in altering volume fraction ($p = 0.2$). Trabecular number, thickness, connectivity, and volume were substantially lower in B6 females than C3H females ($p < 0.005$). These data demonstrate that phenotypic differences in bone morphometry typically associated with C3H and B6 mice are gender and site specific.

SU121

Linkage Disequilibrium Mapping of Disease Genes with High Allele Frequency and Unknown Mode of Inheritance. G. Gong. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Morton, the founder of LOD score linkage analysis, has shown that segregation analysis is unreliable for finding susceptibility genes, which can be identified only by allelic association (linkage disequilibrium) with candidate loci. Recently, Altmül et al. have shown that true linkage is hard to find in mapping complex trait loci with family-based analyses, the future of genetic studies on complex traits such as osteoporosis lies in association analysis. Linkage disequilibrium mapping has been used for mapping rare but not common diseases. As a first step, we investigated whether linkage disequilibrium mapping can be performed under certain conditions seen in common diseases: high disease allele frequency and unknown mode of inheritance. Let n be the total number of subjects who are sampled randomly from the general population, n_D be the number of subjects with the disease, and a, b and c be the numbers of subjects with the disease and marker genotype A_1A_1, A_1A_2 and A_2A_2, respectively. Let p_1 and p_2 be the frequencies of marker allele 1 and 2, respectively, θ be recombination fraction between marker and disease loci, and t be the number of generations passed since the introduction of the mutation. We divide the number of heterozygotes b into two components, m and $(b - m)$. Let $a : m = (b - m) : c$. Thus, $m^2 - bm + ac = 0$, and m is known. Let $n_{DA1} = a + m$. We demonstrated that $(1 - \theta)^t = (n_{DA1} - p_1 n_D)/(p_2 n_D)$. We showed that this equation applies to diseases with high allele frequency. We further showed that this equation applies to diseases with dominant, co-dominant, overdominant, recessive or unknown inheritances. We propose that t be estimated with the ethnic groups in which an association is found: $t = 2{,}050$, when an association found in Asians and Caucasians, or $t = 5{,}000$ when an association is found in Africans and Asians/Caucasians. Here, t is racial divergence time in terms of number of generations. Previously, to find a disease-candidate gene allelic association has been the sole purpose and the end of study

without knowing where the susceptibility genes are exactly located. We show here that association studies become a real mapping tool to locate mutations or DNA sequence variations responsible for common diseases such as osteoporosis.

SU122

Identification of Five Genetic Markers in Mice that Influence Femoral Size and Shape. S. K. Volkman*[1], A. T. Galecki*[2], D. T. Burke*[3], M. R. Paczas*[1], M. R. Moalli[1], R. A. Miller*[4], S. A. Goldstein[1]. [1]Orthopaedic Research Laboratory, University of Michigan, Ann Arbor, MI, USA, [2]Institute of Gerontology, University of Michigan, Ann Arbor, MI, USA, [3]Human Genetics Department, University of Michigan, Ann Arbor, MI, USA, [4]Department of Pathology and Geriatrics Center, University of Michigan, Ann Arbor, MI, USA.

Skeletal fragility has been identified as a factor in more than one million fractures in the United States per year. These fractures are responsible for significant disability and death, and cost the nation more than an estimated ten billion dollars annually. The risk of fracture depends on many factors, including the amount, structural orientation and mechanical integrity of bone, but the extent to which these factors, and their effects on fragility, are regulated by genetic controls is unknown. Previous studies have shown that genetic background affects bone characteristics, particularly bone mineral density, in both mouse and human populations. Much less in known, however, about the specific genetic effect on bone size, shape and mechanical integrity. The purpose of this study was to investigate the genetic determinants of geometric properties of cortical bone in mice. This study utilized 294 female UM-HET3 mice, produced as the progeny of (BALB/cJ x C57BL/6J)F1 females and (C3H/HeJ x DBA/2J)F1 males. This breeding scheme produces a genetically heterogeneous mouse population that can be considered a very large sibship, in that each animal inherits 25% of its genes from each of the same four inbred grandparental strains. The mice were genotyped at 87 polymorphic loci using PCR-based methods and an ALFexpress automated sequence analyzer (Pharmacia, Piscataway, NJ). Animals were humanely euthanized at 18 months of age, at which time right femurs were removed and dissected free of soft tissue. Geometric traits of the femoral cortical bone were assessed with micro-computed tomography. Two genetic markers (D2Mit58 and D3Mit62) were associated with femoral cross-sectional area and cortical thickness, which describe bone size; one marker (D12Mit46) was linked with traits describing bone shape; and two markers (D11Mit83 and D15Mit171) were associated with both size and shape. Our results indicate that the genetic influence on cortical bone geometry is complex and that femoral size and shape may be influenced by different, though overlapping, groups of polymorphic loci.

SU123

Confirmation of Linkage of 17q23 to Bone Size Variation. F. H. Xu, H. Shen, Y. J. Liu, Y. Z. Liu, Q. Y. Huang, H. Y. Deng*, L. J. Zhao, T. Conway*, K. M. Davies, R. R. Recker, H. W. Deng. Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA.

Osteoporosis is a major public health problem in the world. Bone size is an important independent determinant of osteoporotic fractures. We conducted a whole-genome linkage scan with 635 individuals from 53 pedigrees to identify genomic regions that may contain QTLs underlying variation in bone area (measured by DEXA). Several genomic regions were identified. To confirm the previous results, we performed an expansion study with both increased samples and denser microsatellite markers within the previously localized regions. Seventy-nine pedigrees were used in this study with 1,816 subjects. The pedigree size ranges from 3 to 423, with a mean (SE) of 23.5 (5.6). A total of 74,498 relatives pairs that are informative for linkage analysis exist in our sample, among which are 3,393 sibling pairs, 316 grandparent-grandchild pairs, and 10,060 first cousin pairs. We genotyped a new set of microsatellite markers which distributed within previously identified genomic regions, with the average inter-marker distance narrowed to ~5cM. Adjusting for age, sex and other significant covariates, we conducted two- and multipoint linkage analysis using software package SOLAR. Some genomic regions previously identified were replicated in this expansion study. For examples, the genomic region 17q23 showed a MLS (maximum LOD score) of 1.18 (p=0.009) for wrist (ultra distal) bone size. Considering that the strength of evidence required for replication of a previously found linkage is different from that in a whole-genome linkage analysis, our results strongly support that the above genomic region may harbor a QTL affecting bone size variation. This study represents our effort in identifying genes and associated etiology for osteoporosis using various important phenotypes and may be one of the first few linkage confirmation studies for complex traits in bone genetic studies.

SU124

A Confirmation Study for Quantitative-Trait Loci for BMD-Related Obesity Phenotypes. Y. J. Liu, F. H. Xu, H. Shen, Y. Z. Liu, Q. Y. Huang, H. Y. Deng, L. J. Zhao, T. Conway, K. M. Davies, R. R. Recker, H. W. Deng. Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA.

Bone mineral density (BMD) is a major determinant of osteoporosis. The important indices of obesity such as body mass index (BMI), percentage fat mass (PFM), and body fat mass (FM) are significantly related with BMD. Therefore, study of the determination of obesity phenotypes may shed light on the nature of the determination of osteoporosis. We conducted a whole-genome linkage scan for QTLs for obesity phenotypes. Several genomic regions that may contain obesity-related QTLs were identified. To confirm the previous results, we performed an extension study with both increased samples and denser microsatellite markers within the previously localized regions. The pedigrees used in the study were expanded from 53 to 79, with subjects increased from 630 to 1816. The pedigree size ranges from 3 to 423, with a mean (SE) of 23.5 (5.6). A total of 74,498 relatives pairs that are informative for linkage analysis are included in our sample, among which are 3393 sibling pairs, 316 grandparent-grandchild pairs, and 10,060 first cousin pairs. We genotyped a new set of microsatellite markers which distributed within previously identified genomic regions, with the average genomic distance narrowed to ~5cM. Adjusting for age, sex and other significant covariates, we conducted two- and multipoint linkage analysis using software package SOLAR. Some genomic regions previously identified were replicated in this extension study. For examples, for BMI, on genomic region 1p36, a LOD score of 2.14 (p=0.0008) is achieved near marker D1S468 in twopoint analysis and a MLS of 1.38 (p=0.006) is achieved at the terminal end of short arm on chromosome 1 in multipoint analysis. Considering that the strength of evidence required for replication of a previously found linkage is different from that in a whole-genome linkage analysis, our results strongly support that the above genomic regions may harbor QTLs affecting obesity phenotypes. This study may be one of the first few linkage confirmation studies for complex trait genetic studies. Identification of determinants underlying the variation of phenotypes correlated with BMD such as obesity related phenotypes, should shed light on the determination of susceptibility to osteoporosis.

SU125

Second Stage of Genome Scan for QTLs Influencing BMD Variation. Q. Y. Huang, F. H. Xu, H. Shen, Y. J. Liu, Y. Z. Liu, H. Y. Deng*, L. J. Zhao, V. Dvornyk, K. M. Davies, R. R. Recker, H. W. Deng. Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA.

Osteoporosis is a common complex disorder with high social and economic costs. Low bone mineral density (BMD) is a major risk factor for osteoporosis. To identify genomic regions harboring QTLs (quantitative trait loci) contributing to BMD variation, we performed a two-stage genome screen. The first stage involved genotyping of a sample of 53 pedigrees (635 individuals) using 400 microsatellite markers spaced at approximately 10 cM intervals throughout the genome. Genomic regions with multipoint and/or two-point LOD greater than 1.5 were observed in chromosome regions 4q31-32, 7p22, 12q24, 13q33-34, 15p11 for spine BMD, 10q26, 12q13, 17p11 for hip BMD, and 3p26, 4q32, 9p22-24, 17p13 for wrist BMD. In the second stage, 60 microsatellite markers with a mean spacing of about 5 cM were genotyped in these regions in an expanded sample of 79 pedigrees that contain 1,816 subjects. The sample contains a total of 74,498 relative pairs that are informative for linkage analyses, among which there are 3,393 sibling pairs, 316 grandparent-grandchild pairs, and 10,060 first cousin pairs. Each pedigree was ascertained through a proband with extreme BMD at the hip or spine. BMD at the spine (L1-4), hip (the femoral neck, trochanter and intertrochanteric region) and wrist (the ultra-distal region) was measured by DEXA, and was adjusted for age, sex, height, and weight. Two-point and multipoint linkage analyses were performed for each BMD site using a variance component method that is implemented in the computer package SOLAR. Several regions achieved LOD scores in excess of 1 in the second stage follow-up study, in chromosome regions of 10q26, 7p22, 12q13, and 13q33-34. Our strongest evidence for linkage was on 10q26, where we obtained a peak multipoint LOD score (MLS) of 1.65 at 170 cM from peter for hip BMD. Genomic regions homologous to human 10q26 have previously been implicated in mice for BMD (Klein et al. 1998; Beamer et al. 2001). A potential candidate gene was identified in this region. In addition, a multipoint LOD score of 1.62 for spine BMD were achieved on chromosome 7. Further analyses are being conducted. Considering that the LOD score criteria of linkage confirmation for specific genomic regions are different from those in the first-stage whole genome scan, our results provide tentative evidence of confirmation of linkage of several genomic regions to BMD variation. To our knowledge, this is the largest linkage confirmation study in the bone genetics field.

SU126

A Confirmation and Extension Study for Linkage to an Important Complex Trait Related to Osteoporotic Fractures- Height. Y. Z. Liu, H. Y. Deng, J. R. Long, Y. Y. Zhang, S. B. Lu, F. H. Xu, H. Shen, Y. J. Liu, Q. Y. Huang, L. J. Zhao, T. Conway, R. R. Recker, H. W. Deng. Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA.

Height is an important complex anthropometric character with high genetic determination (its heritability is more than 50%). It is highly correlated with susceptibility to osteoporotic fracture. Studies of height variation will help identify and understand risk factors underlying susceptibility to osteoporotic fractures. We performed a whole genome scan on 671 subjects from 53 pedigrees. Several genomic regions were suggested to contain QTLs underlying height variation, which included 5q31 (144cM from pter of chromosome 5), 8p22 (16cM from pter of chromosome 8), 17q25 (114cM from pter of chromosome 17), Xp22 (10.1cM from pter of chromosome X), and Xq25 (139.4cM from pter of chromosome X). Based on these results, we performed a confirmation and extension study employing 12 new microsatellite markers concentrating in the above five genomic regions in a expanded sample of 79 pedigrees containing 1,816 subjects. The 79 pedigrees vary in size from 3 to 423 individuals, with a mean of 23.5(SE=5.6). These pedigrees contain 74,498 relative pairs informative for linkage analysis, among which, there are 3,393 sib pairs. Linkage analysis on sex- and age-adjusted height was conducted with SOLAR using a variance component method. We have finished two-point linkage analysis for the markers on the 3 autosomes. Confirmation linkage signals were detected around 146.1 cM from the pter of chromosome 5 (p=0.018) and around 105.7cM from the pter of chromosome 17 (p=0.029). Our preliminary analyses seem to confirm the linkage findings of our previous whole genome scan. Further analysis and experiment will be performed to fine-map the confirmed genomic regions and to identify positional candidate genes for testing for height variation. This study represents our extensive effort beyond initial whole genome linkage scan studies to identify factors underlying the variation of traits related to osteoporotic fractures.

SU127

Linkage Studies of RANK, RANKL and OPG in the Control of Bone Mineral Density. L. J. Miles*[1], E. L. Duncan[1], A. M. Crane*[1], J. A. H. Wass[2], M. A. Brown*[1]. [1]Spondyloarthritis and Bone Disease, Oxford University, Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, [2]Metabolic Bone Unit, Nuffield Orthopaedic Centre, Oxford, United Kingdom.

RANKL is a tumour necrosis factor ligand family member which together with its receptor, RANK, and its soluble secreted decoy receptor, OPG, comprise an important and novel cytokine system whose interactions regulate osteoclast formation, fusion, activation, survival and apoptosis. Whether genetic polymorphisms of the genes encoding these factors influence bone mineral density in the general population is unknown. To test this hypothesis, we studied 814 family members (330 men, 484 women) belonging to 164 families recruited with probands with extreme low BMD (t-score <-2.5, z-score <-2.0 at either the lumbar spine or femoral neck) from the outpatient services of the Nuffield Orthopaedic Centre, Oxford, UK. Seventeen microsatellite markers lying close to or within the genes of interest were chosen from publicly available databases, and resultant PCR fragments were run on ABI 3700 capillary electrophoresis genotyping machines. Quantitative trait linkage analysis in general pedigrees was then performed using SOLAR [1], controlling for the covariates age, height, gender and ascertainment effects. In agreement with our previously reported findings, weak linkage was observed between the region encompassing RANKL and femoral neck BMD (peak LOD score 0.53), but no significant linkage was observed at any other locus. We are currently studying these genes further for association using SNPs, within the genes themselves, identified by a combination of database searches, denaturing high performance liquid chromatography, and direct sequencing. Preliminary results of these studies will be presented at the meeting.

SU128

Lessons From Segregation Analysis for the Ascertainment of Families for Mapping of Osteoporosis Genes. E. L. Duncan[1], L. R. Cardon*[1], J. A. H. Wass[2], M. A. Brown*[1]. [1]Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, [2]Metabolic Bone Unit, Nuffield Orthopaedic Centre, Oxford, United Kingdom.

Theoretical studies suggest that families ascertained through probands with extreme trait values have greater power to detect quantitative trait loci. To test this hypothesis, we examined the genetic profile of 150 families with 768 individuals recruited with probands with extreme low bone mineral density (BMD, t-score <-2.5, z-score <-2.0). Complex segregation analysis was performed using the Pedigree Analysis Package (1). BMD measured at either the lumbar spine (LS, L1-4) or total hip was expressed either as raw values (g/cm2), or as t-scores or z-scores obtained from the Hologic normative database. Covariates assessed included age, height, gender and menopausal status (premenopausal, early postmenopausal (within 5 years of the menopause), and late postmenopausal (greater than 5 years from the menopause). In all models a major gene effect was observed in addition to a residual polygenic effect. Total heritability ranged at the spine from 0.36 to 0.57, and at the hip from 0.43 to 0.63. Comparing the use of t-scores, z-scores or raw BMD, in all cases heritability was equivalent to or higher when raw BMD was studied. Residual correlation between BMD and age and gender was observed when t- and z-scores were studied. These observations suggest that differences exist between the Hologic database and the population from which these families were drawn, and suggest that maximum power in genetic studies will be achieved by using raw BMD data adjusted for gender and age, rather than using data normalised using external normative databases. We have previously reported that in these families in all male-male comparisions there is greater correlation of the LS BMD than hip, and in female-female comparisons, there is greater hip BMD correlation than LS. This finding remains true for parent-offspring correlations when menopausal status is taken into account. Mother-daughter pairs are more similar at the hip than other parent-offspring pairs (0.45 vs 0.12-0.21, p=0.006), whereas father-son (0.29 vs 0.20-0.24) but not mother-daughter pairs were more similar at the LS. Father-daughter and mother-son pairs were always less correlated than father-son and mother-daughter pairs, supporting a gender specific effect independent of menopause status. This study confirms that whilst osteoporosis is predominantly determined by genes with individually small effects, by studying families drawn from the extremes of the population distribution, a significant major gene effect can be observed.

Identification of Genetic Loci that Influences Osteoclastogenesis or Bone Mineral Density in BXD RI Strains of Mice. L. Zhang*[1], X. Xu*[2], H. Hsu*[2], T. R. Nagy*[3], N. Said-Al-Naief*[1], K. J. Ho*[1], P. Yang*[2], J. Li*[3], H. Zhang*[2], J. M. McDonald[1], J. D. Mountz*[2]. [1]Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, [2]Medicine, University of Alabama at Birmingham, Birmingham, AL, USA, [3]Nutrition Science, University of Alabama at Birmingham, Birmingham, AL, USA.

In the present study, C57BL/6 X DBA/2 (BXD) recombinant inbred (RI) BXD strains of mice and their progenitor B6 and D2 strains were utilized to determine the genetic influence on osteoclasts and bone mineral density (BMD) in young (4 mo-old) and aged (13-mo- old) mice. TRAP staining and digital imaging analysis of femur and vertebrae, and in vitro analysis of osteoclastogenesis from bone marrow, showed that there was a significant increase in osteoclast numbers in young D2 compared to young B6 mice. BMD values obtained by dual-energy X-ray absorptiometry showed that there was a significant decrease in BMD in aged mice compared to young mice but there was no difference between B6 and D2 mice. Analysis of in vitro osteoclast differentiation activity and BMD in numerous BXD RI strains showed that there was a genetically dependant strain distribution pattern of these two variables. Nonetheless, there was low correlation between these two variables, suggesting regulation by at least two independent genes. The BMD values from 18 strains of BXD mice were used for Quantitative Trait Loci (QTL) analysis. The genetic locus influencing bone mineral density in BXD mice at 4 month of age was mapped to mouse chromosome 4 (D4Mit186) with a likelihood ratio statistics (LRS) reaching a linkage suggestive value of 18.4 (p = 0.00002). The in vitro osteoclast differentiation values from 11 strains of BXD mice were used for QTL analysis. The genetic locus influencing osteoclastogenesis in BXD mice at 4 month of age was mapped to mouse chromosome 19 (D19Nds1) with a LRS reaching a linkage suggestive value of 13.3 (p = 0.00026). These results suggest that in these mice there are two separated sets of genes that independently regulate osteoclastogenesis and BMD respectively.

SU130

Genotype-by-Sex and Environment-by-Sex Interactions Influence Variation in Serum Bone-Specific Alkaline Phosphatase Levels in Pedigreed Baboons. L. M. Havill, M. C. Mahaney, J. Rogers*. Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA.

While more than 77% of the 10.1 million people in the U.S. with osteoporosis are women, the contributions of genotype-by-sex (G×S) interactions to sex differences in BMD and other osteoporosis risk factors have not been studied. To address this question, we conducted a statistical genetic analysis of serum concentrations of bone specific alkaline phosphatase (BSAP), a highly specific marker of osteoblast function that is elevated in persons with conditions, like osteoporosis, characterized by excessive bone turnover and/or rapid bone loss. We assayed BSAP in frozen serum from 692 pedigreed baboons using a commercially available ELISA kit. Using a maximum likelihood variance decomposition approach, we treated sex as an environmental milieu in which genes influencing BSAP levels are expressed. We modeled the genetic covariance in BSAP between all relative pairs conditional on their sex so that the covariance is the product of the kinship, the genetic correlation between the trait levels in two sexes, and the genetic standard deviations in two sexes. Sex-specific maximum likelihood estimates of residual heritability for BSAP were greater for females than for males (h^2 = 0.44 vs. h^2 = 0.26, respectively), but likelihood ratio tests revealed only a marginally significant difference in sex-specific genetic variances (p = 0.057). In contrast, the between-sex genetic correlation (ρ_G = 0.43) was significantly less than 1 (p = 0.037), and the difference in sex-specific environmental variances was highly significant (p = 0.00006). These results represent the first evidence for the influence of G×S interactions on variation in an osteoporosis risk factor. While the overall contribution of genes to the total phenotypic variance in BSAP may not differ significantly by sex in these baboons, the diminished between-sex genetic correlation implies that different genes influence BSAP levels in the two sexes. Equally interesting, the highly significant differences in environmental variances suggests that unmeasured factors -- including those from the internal, biological environments of the two sexes -- account for a greater proportion of the BSAP variation in females than in males.

SU131

Genotype-by-Age Interactions Influence Normal Quantitative Variation in Spinal BMD in Pedigreed Baboons. M. C. Mahaney, L. M. Havill, L. Almasy*, J. Rogers*. Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA.

The association of decreased bone mineral density (BMD) and increased fracture risk with advancing age are hallmarks of osteoporosis, but the contributions of genotype-by-age (G×A) interactions to variation in BMD have not been investigated directly. To address this question, we conducted statistical genetic analyses of spinal BMD in a nonhuman primate model for age-related changes and pathology in bone in which we previously had estimated heritability and localized QTLs for this trait. We used maximum likelihood variance decomposition methods to analyze data on areal BMD (aBMD, g/cm^2) obtained by DEXA from two projections (anterior-posterior and lateral) at three thoraco-lumbar vertebrae in 692 pedigreed baboons. We modeled G×A interaction for aBMD by defining the additive genetic component of the variance as a function of age. We also modeled the genetic correlation between relative pairs at different ages as an exponential decay function across age values. Through numerical maximization, we simultaneously estimated these two G×A interaction terms plus the mean effects of sex, body weight, crown-rump length, and spinal arthritis severity on each measure of spinal aBMD. Likelihood ratio tests revealed evidence for G×A interaction for arithmetic mean thoraco-lumbar aBMD from both the anterior-posterior (A-P) and lateral (LAT) projections. For both A-P and LAT mean aBMD measures, we observed significant decreases in genetic variance with increasing age (p = 0.000783 and p = 0.002432, respectively). For the mean of LAT aBMD, the genetic correlation between aBMD at different ages differed significantly from 1.0 (p = 0.028). Analyses of aBMD at the three individual vertebral sites scanned from both the A-P and LAT projections, yielded results in complete concordance with those obtained from analyses of the means for each projection. The first observation implies that the magnitude of the effect of genes contributing to variation in aBMD changes with age. The second observation implies that different genes may influence variation in aBMD at different ages in these baboons. These results are consistent with observations by others of possible age-specific genetic effects on BMD in analyses of cohorts with different mean ages. They also may help explain, in part, apparent discrepancies between the results of genetic studies conducted by different researchers with data from subject populations exhibiting dissimilar age profiles.

SU132

Relation of Polymorphism of the COL1A2 and Estrogen Receptor α Gene to the Acquisition of Bone Mass in Prepubertal Finnish Girls. M. M. Suuriniemi*[1], A. Mahonen[2], V. Kovanen*[1], M. Alen*[3], J. Heino*[1], H. Kröger[2], F. Tylavsky[4], S. Cheng[1]. [1]University of Jyväskylä, Jyväskylä, Finland, [2]University of Kuopio, Kuopio, Finland, [3]PEURUNKA-Medical Rehabilitation Centre, Jyväskylä, Finland, [4]Univ of Tennessee, Memphis, TN, USA.

Genetic factors are strongly involved in bone metabolism. The purpose of this study was to evaluate the associations between polymorphism in candidate genes known to be involved in bone metabolism in adult population [COL1A2/PvuII site, estrogen receptor α (ERα)/ PvuII site, vitamin D receptor (VDR)/FokI and TaqI sites, and insulin-like growth factor (IGF)/dinucleotide repeat] and the acquisition of bone mass in prepubertal girls during two-year period. The subjects were 10-12-year-old girls (n=91) with Tanner stage I-II, who participated in an intervention study (the CALEX-study). Genotyping of the four genetic polymorphic sites was performed. Bone mineral content (BMC) and areal bone mineral density (aBMD) of the total body, total femur, and lumbar spine (L2-L4) were measured using dual-energy X-ray absorptiometry (DXA, Prodigy, Lunar). Our results showed that Tanner stage, height, weight, calcium/vitamin D consumption, and physical activity did not differ significantly among girls with different genotypes. The polymorphism of the VDR and IGF gene was not significantly associated with changes (%) of bone mass at different bone sites. The 24-months-change of total femur BMD differed with respect to the PvuII alleles of COL1A2 gene (p=0.031), the PP genotype group achieving the greatest increase in bone mineral density. The 24-months-change of total body and total femur BMC differed with respect to the ERα PvuII alleles (p=0.049 and p=0.046, respectively). There was also a tendency toward greater increase of all bone properties in girls with the PP genotype (both COL1A2 and ERα). In the case of the ERα polymorphism there was a clear gene dosage effect, while the COL1A2 polymorphism showed a homozygote preference. There was no association between the COL1A2 and ERα polymorphism. Our study indicates that the polymorphisms of the COL1A2 and ERα genes are associated with the increase in bone mass during prepubertal and pubertal phases. This may provide valuable knowledge for identifying girls who are at risk for osteoporotic fractures later in life.

SU133

Testing of Association and /or Linkage for the Estrogen Receptor-α Gene with Peak Bone Mass in US Caucasian Nuclear Families. L. J. Zhao, H. Shen, L. Elze*, R. R. Recker, H. W. Deng. Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA.

Decades of studies on bone have suggested numerous candidate genes that may regulate bone mineral density (BMD). Among these genes, one that has been studied frequently is the estrogen receptor alpha (ER-α) gene. However, the results of traditional linkage or association studies of the ER-α gene have largely been inconsistent and controversial. The purpose of this study is to test association and /or linkage of the ER-α gene with bone mineral density (BMD) in Caucasian nuclear families. We genotyped two polymorphic markers (Pvu II and Xba I) inside the ER-α gene for 636 individuals from 157 nuclear families with children generally aged 20-50. All these subjects are healthy Caucasians from Midwest of USA. By using the computer program QTDT, we tested for association alone, for linkage alone and for both linkage and association (TDT) between these two polymorphism markers with bone mineral density by specifying a recombination rate between these two markers as 0.0000005. All the raw BMD were adjusted by significant covariates, which include age, sex, weight and height. At the spine, we found marginally significant results for both association and linkage (TDT) between the two markers (Pvu II and Xba I) of ER-α gene and peak BMD (p = 0.0744 for Pvu II and p = 0.0516 for Xba I). In addition, marginally significant results have been observed for the test of linkage between the two markers and spine BMD (p < 0.10), for the test of association between the marker Xba I and Mid-radius BMD (p < 0.10). No population stratification was detected in our sample. We also conducted regular ANOVA test for the phenotype distribution among the genotypes in parents of the nuclear families. ANOVA test revealed that there are significant association between the Pvu II (p = 0.002) and Xba I (p = 0.013) markers and the mid-radius BMD. In conclusion, our preliminary results suggest that the ER-α gene may be one of the genetic factors underlying peak BMD variation in US Caucasians.

SU134

Differentiation of Caucasian and Asian Populations at Six Candidate Loci for Bone Mineral Density. J. R. Long, V. Dvornyk, H. Shen, L. J. Zhao, Y. Y. Zhang, H. W. Deng. Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA.

Bone mineral density (BMD) is a characteristic parameter for osteoporosis. It has strong genetic determination and several candidate genes have been studied for their association with BMD within populations of the same ethnicity. We comparatively studied two populations, Chinese and Caucasian, for polymorphism of seven markers of six genes that have been shown to be associated with BMD (Table). 804 and 327 random individuals were recruited in Hunan, China and Omaha, NE, USA, respectively. The Chinese population had significantly lower (p<0.01) total observed heterozygosity (H_o) over all the loci studied and H_o at CASR, AHSG, and PTH loci individually. The populations also manifested striking differences (p<0.01) in the frequencies of alleles and genotypes at all the studied loci, except the ER-*Pvu*II. In the Caucasian population, the overall distribution of the Sp1 alleles (s being the risk allele) was similar to that previously reported for the Caucasians (SS 67%, Ss 28% and ss 5%), while in the Chinese population 78% SS and only 1% ss genotypes were detected. The contrasting genotypic population structure was also observed for the CASR locus. Our data demonstrate that Asian populations have different genotype and allele frequency structure at some BMD candidate gene loci from that in Caucasians. The results have implications for evolutionary differentiation of genetic architecture of complex traits in various human populations, for differential genetic mechanism underlying the racial difference of the risk to osteoporosis, and for some inconsistent results in identifying genes underlying osteoporosis in various populations.

Dinucleotide Repeat (CA) Polymorphisms of the IL-6, TNFR2, and CT Genes and BMD. Y. Y. Zhang, Q. Y. Huang, H. Shen, H. Y. Deng, T. Conway, R. R. Recker, H. W. Deng. Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA.

Genetic factors play an important role in determining bone mass. In view of the reported associations between osteoporosis and polymorphisms of the interleukin-6 (IL-6), tumor necrosis factor receptor 2 (TNFR2), and calcitonin (CT) genes, an association study was performed between dinucleotide repeat (CA) polymorphisms at the IL-6, TNFR2, CT genes and BMD in 175 Caucasian nuclear families with 665 subjects. BMD at the spine (L1-4), hip (the femoral neck, trochanter and intertrochanteric region) and wrist (mid region) were measured by DEXA, and were adjusted for age, sex, weight, and height. The QTDT program was employed for analyses. For the IL-6 gene, nine alleles were observed in this population. The allele 8 (130bp) showed strongest association with the spine BMD (p=0.0006) and hip BMD (p=0.048). The alleles 3 (120bp) and 9 (132bp) showed weak association with spine BMD (p=0.0788) and hip BMD (p=0.096), respectively. The allele 2 (118bp) and 7 (128bp) are associated with wrist BMD (p=0.052 and 0.047, respectively). However, population stratification is observed for the alleles 3 (p=0.084) and 6 (p=0.07). For the TNFR2 gene, eight alleles were present in our sample, of which allele 3 (266bp) and allele 8 (276bp) were associated with wrist BMD (p=0.043 and 0.0245, respectively), allele 5 (270bp) with hip BMD (p=0.0669). Allele 1 (260bp) and 5 (270bp) are associated with spine BMD (p=0.0879 and 0.0637, respectively). However, population stratification is observed in allele 5 (p=0.0175) and allele 6 (p=0.098). For the CT gene, we detected six alleles, and only allele 4 (122bp) is weakly associated with hip BMD (p=0.08). Our data are consistent with earlier findings that IL-6 and TNFR2 gene polymorphisms are associated with spine and/or hip BMD. Further studies for linkage and identification of the causative mutation are warranted.

SU136

Osteoprotegerin (OPG) Serum Levels and OPG Polymorphism in Children with Polyarticular Juvenile Idiopathic Arthritis. L. Masi[1], L. Becherini*[1], E. Piscitelli*[1], S. Benvenuti*[2], G. Simonini*[3], F. Falcini*[3], A. Falchetti*[1], A. Tanini[1], R. Imbriaco*[1], M. Brandi[1]. [1]Department of Internal Medicine, University of Florence, Florence, Italy, [2]Department of Clinical Physipathology, University of Florence, Florence, Italy, [3]Department of Pediatrics, University of Florence, Florence, Italy.

Osteoporosis is a common manifestation in children with polyarticular juvenile idiopathic arthritis (JIA). The identification of OPG contributed to a new molecular and cellular concept of osteoclast biology. OPG inhibits differentiation of osteoclasts and it is important for protection of cartilage damage, a critical and irreversible step in the pathogenesis of arthritis. In addition, OPG gene may be a candidate gene in the regulation of bone mass. We have evaluated the levels of serum OPG in a group of 84 (66 female and 18 male) affected by JIA and 21 (11 female and 10 male) controls. The relationship between serum OPG and some disease parameters (PCR, VES and X-ray detectable erosions) was also evaluated. Moreover, a polymorphism of OPG gene was correlated with bone mass in these subjects. Serum OPG was measured using an ELISA method. OPG polymorphism was evaluated by PCR reaction of genomic DNA and digestion of the product by Fok I enzyme. Bone status was evaluated using DXA at the lumbar spine level. We observed that patients affected by JIA had significantly higher levels of serum OPG (60.19±25.9 vs. 39.56±11 pg/ml; p=0.002). In children affected by JIA patients under steroid therapy showed higher serum OPG levels in comparison with patients without therapy (63.19±25 vs. 43.81±20 pg/ml; p=0.001). No significant correlation was found between serum OPG and PCR, VES, and duration of the disease. However, patients with X-ray detectable erosions showed significantly higher OPG levels (72±22 vs. 50±18; p=0.007). CC genotype (76.4%) for the OPG gene was prevalent in the total population and the most frequent in normal children. TC genotype was the most represented in JIA patients (Chi2 test:8.9; df=2; p=0.006). Applying ANCOVA analysis and LSD test to evaluate the L-BMD differences among the OPG genotypes, we observed that patients with CC genotype had a L-BMD 9.4 % higher in comparison with TC genotype subjects (p=0.04). Finally, no significant differences in levels of serum OPG were found between the three genotypes. In conclusion, the increase of serum OPG in patients affected by JIA with erosions could reflect a compensatory response to degeneration of bone and cartilage and circulating OPG levels could predict disease activity but not bone mass changes. Conversely, OPG gene polymorphism may represent marker in the identification of JIA patient with higher risk of bone mass loss.

SU137

Lack of Association of Cdx Polymorphism with Bone Mineral Density in Korean Postmenopausal Women. S. Kim*[1], S. Kim*[1], Y. Rhee*[1], S. Li*[1], J. Jahng[2], S. Lim[1]. [1]Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea, [2]Orthopaedic Surgery, College of Medicine, Yonsei University, Seoul, Republic of Korea.

The caudal-related homeodomain Cdx-2 played an important role in the intestine-specific transcription of the human vitamin D receptor (VDR) gene. In other previous study, the polymorphism was identified in the core sequence 5'-ATAAAAACTTA-3' in the Cdx-2 binding site in the VDR gene promoter (Cdx-polymorphism). The objectives of this study were to investigate the relationship between Cdx polymorphism and bone mineral density (BMD) in Korean postmenopausal women. Cdx polymorphism was analyzed in 108 Korean postmenopausal women by direct DNA sequence analysis. BMD at the lumbar spine and proximal femur were assessed by dual energy X-ray absorptiometry. Among 108 postmenopausal women, 20 showed genotype A/A (adenine at -3731 nucleotides relative to the transcription start site of human VDR gene 5-ATAAAAACTTAT), 41 showed genotype G/G (guanine at -3731 nucleotide, 5'-GTAAAAACTTAT-3') and 47 showed genotype A/G (heterozygote). The osteoporotic group consisted of 77 women with primary osteoporosis (mean age, 60 ± 5.4 years ; mean Z score at the lumbar spine,-1.80±0.64). There was no difference in prevalence of Cdx polymorphism between the osteoporotic patients and normal control (p=0.293). BMD of the lumbar spine was 0.816± 0.171 g/cm2 in subjects with the AA genotype, 0.900± 0.233 g/cm2 in subjects with the A/G genotype, 1.016± 0.204 g/cm2 in subjects with the GG genotype (p=not significant). There was no significant association between Cdx polymorphism and Z score values of lumbar spine and proximal femur BMD. These data indicate that there are no significant effects of Cdx polymorphism on BMD in Korean postmenopausal women. Our data do not support the idea that Cdx polymorphism has an impact on the bone mass of postmenopausal women.

SU138

Evaluation of Estrogen Receptor Gene and Calcium Sensor Gene Polymorphisms in Patients with Primary Osteoarthritis. I. Szombati*[1], G. Poór[1], A. Tabak*[2], P. Temesvari*[1], P. Lakatos*[2]. [1]National Institute of Rheumatology and Physiotherapy, Budapest, Hungary, [2]1st.Dept.Of Medicine, Semmelweis University, Budapest, Hungary.

The importance of estrogen receptor (ER) gene polymorphism in the pathogenesis of osteoporosis has been well known for years. Recently, several studies were carried out focusing on the calcium sensor gene polymorphism in patients with osteoporosis. A hypothetical relationship has also been suggested between genetic variability of these genes and primary osteoarthritis (OA); however, there are no supporting data available in this field. The present study aimed to examine the theoretical connection between ER gene PvuII and XbaI and CaSR gene A986S polymorphisms and primary osteoarthritis. The authors investigated 44 patients with radiologically and clinically severe osteoarthritis (OA group, mean age: 66.1± 11.4 (SD) years, BMI: 27.8±3.5 kg/m2) and 140 control healthy subjects (C group, aged 55.5 ±5.3 years p<0.001, BMI±4.1 kg/ m2, p7 NS). The genetic evaluation was carried out in all OA cases and in the C group. In the OA group, the ER gene Pp allele was found in 36/41 (87.8 %) cases, the PP allel in 5/41 (12.2%) cases while pp allel was absent in this population. In the C group, significantly (p<0.0001) different results were found: Pp allele in 46/91 (505%), PP in 29/91 (31.9 %), pp in 16/91 (17.6%) cases were detected. The ER gene XbaI genotype frequency in the OA group was the following: Xx: 39/41 (95.1%), XX 2/41 (4.9%), and xx allel was not found in this group. Frequency of the XbaI allele in the healthy control group was significantly different (p= 0.0003): Xx 54/90 (59,3%), XX :16/90 (17.6%), xx: 21/90 (23%). The CaSR gene's alleles frequency in the OA group was: AS: 38/42 (90,5%), AA: 1/42 (2,4%), SS: 3/42 (7.1%). These frequencies were significantly different from the controls: AS: 32 /113 (28.3%), AA: 80/13 (70.8%), SS 1/ 13 (0.9%) (p< 0.0001). There were significant differences between the OA and C group in the studied alleles of the ER and CaSR genes. The authors did not find ER gene xx and pp alleles in patients with osteoarthritis. These findings may suggest that genetic susceptibility might significantly contribute to the developement of osteoarthritis.

SU139

Estrogen-Related Polymorphisms and Their Possible Association with Adult Height, Body Mass Index and Serum Cholesterol. A. L. Eriksson*[1], S. Skrtic*[1], T. Hedner*[2], C. Ohlsson[1]. [1]Div. Endocrinology, Dept. Internal Medicine and Dept. Clinical Pharmacology, Gothenburg, Sweden, [2]Dept. Clinical Pharmacology, Gothenburg, Sweden.

Clinical as well as experimental studies have demonstrated that estrogen is of importance for the regulation of skeletal growth, fat mass and serum cholesterol. We have previously shown that estrogen receptor-α (ERα) deficient mice have a disturbed longitudinal bone growth, are obese and have increased serum cholesterol. The aim of the present study was to investigate if ERα (PvuII) and/or aromatase (A/G, exon 3 of CYP 19) polymorphisms are associated with adult height, body mass index (BMI) or serum cholesterol in a large well-defined clinical cohort. From a subpopulation of the CAPPP cohort (a large hypertension trial conducted in Sweden and Finland) including 364 men and 129 women (age 29-66, mean 56,9), DNA was extracted from the leukocytes. PCR amplification was performed on the regions of interest and the patients were then genotyped with the DASH-technique (Dynamic Allele Specific Hybridisation). The ERα PvuII -polymorphism was not associated with any of the investigated parameters. The aromatase (A/G, exon 3 of CYP 19) polymorphism was associated with serum cholesterol (AA 6,69±0,15, AG 6,32± 0,10 GG 6,26±0,13 mmol/L, p=0,02) while no significant association was found with adult height or BMI. In conclusion, the aromatase (A/G, exon 3 of CYP 19) polymorphism is associated with serum cholesterol as demonstrated by increased levels of cholesterol in the AA-genotype compared with the other genotypes.

SU140

A Single Nucleotide Polymorphism of Interleukin-1-receptor-associated kinase Associate with Bone Mineral Densities of Adult Women. R. Ishida*[1], Y. Ezura[1], H. Yoshida*[2], H. Iwasaki*[1], T. Suzuki*[2], T. Hosoi*[3], S. Inoue[4], M. Shiraki*[5], H. Ito*[6], M. Emi*[1]. [1]Molecular Biology, Institute of Gerontology, Nippon Medical School, Kawasaki, Japan, [2]Dept. Epidemiology, Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, [3]Internal Medicine, Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan, [4]Geriatric Medicine, University of Tokyo, Tokyo, Japan, [5]Research Institute and Practice for Involutional Diseases, Nagano, Japan, [6]Orthopedics, Nippon Medical School, Tokyo, Japan.

Osteoporosis is a multi-factorial common disease, for which combination of genetic factors regulating bone mineral density (BMD) or bone geometry is assumed in pathogenesis. Interleukin-1 (IL-1) is one of the most potent bone-resorbing factors affecting bone mineral status, and a number of factors acting downstream pathways have been reported to influence bone turnover. In the current study, we focused on IRAK1, an important effecter of IL-1 receptor signaling cascade, by analyzing a correlation between two functional polymorphisms and bone mineral densities (BMD) adjusted by age and body mass index. First, significant correlation between IRAK1+587T/C and adjusted BMD (r=0.21, p=0.0017) was observed in 226 postmenopausal women living in a rural area of northern district of Japan. Consistent correlation was observed in independent subject group with 126 postmenopausal women living in the city area of eastern Japan (r=0.23, p=0.011). Furthermore, the correlation was consistent among randomly selected 21 subjects from outpatient clinic of osteoporosis (r=0.43, p=0.054). There was complete linkage disequilibrium between IRAK1+587T/C and IRAK1+1595C/T in our subjects. Although both IRAK1+587T/C and IRAK1+1595C/T result in amino acid change, functional importance of IRAK1+1595C/T is more likely because it resides in the alternatively spliced sequence of IRAK1b that was shown to have prolonged activation of IL-1 signaling in cultured cells. A significant and consistent correlation between genotypes of IRAK1+1595C/T and adjusted BMD both in general postmenopausal women and in patients indicate a widespread involvement of genetic variance of IRAK1 in bone turnover rate in women, which result in the onset of osteoporosis. Possible involvement of genetic variance in IRAK1 gene may explain, at least in part, the pathogenesis of postmenopausal osteoporosis and may contribute to establish a suitable treatment designs and plans for prevention of the disease.

SU141

The Relationship Between Quantitative Calcaneal Ultrasound and Estrogen Receptor Gene Polymorphism in Korean Premenopausal Women. D. Chung[1], D. Cho*[1], H. Kang*[1], M. Chung*[1], J. Park*[2]. [1]Department of Internal Medicine, Chonnam National University Medical School, Gwangju, Republic of Korea, [2]Department of Forensic Medicine, Chonnam National University Medical School, Gwangju, Republic of Korea.

Peak bone mineral density attained during adulthood is a major determinant of the risk for osteoporosis in later life, and it is largely determined by genetic factors. Quantitative calcaneal ultrasound (QUS) has a significant heritable component, and it is a noninvasive method of estimating bone mineral density (BMD) and bone quality. Estrogen is important for attainment of peak bone mass. In this study, we examined the relationship between the PvuII and XbaI polymorphisms in the estrogen receptor (ER) gene and QUS values at the calcaneus in 69 premenopausal healthy Korean women (mean age; 23.0±6.5years). Genotyping for ER polymorphisms was performed using polymerase chain reaction and RFLP methods. The presence of polymorphic sites at the estrogen receptor gene locus were denoted by p and x, whereas absence of these sites were P and X, respectively. Broadband ultrasound attenuation(BUA) and speed of sound (SOS) were measured at the calcaneus and stiffness index(SI) combining both factors were calculated using Achilles+ (Lunar, Madison, WI, U.S.A.). The frequency distribution of ER genotypes were; PP, 8(11.6%), Pp, 37(53.6%), and pp, 24(34.8%), XX, 3(4.3%), Xx, 23(33.3%), and xx, 43(62.3%). When PvuII and XbaI-RFLPs were combined, the frequencies were as follows; ppxx, 24(34.8%), Ppxx, 18(26.1%), PpXx, 19(27.5%), PPxx, 1(1.4%), PPXx, 4(5.8%), PPXX, 3(4.3%). Subjects with PP and XX genotypes tended to have higher stiffness indices than with pp and xx genotypes, but there were no statistical significances (PP, 91.9±12.6, Pp, 86.0±13.6, pp, 81.9±10.8, XX, 91.2±21.2, Xx, 86.2±14.2, xx, 84.3±11.4). These results suggest that ER gene polymorphisms may not be associated with QUS values at the calcaneus in Korean premenopausal women. However, the number of subjects were too small, further study will be needed with larger sample sizes.

SU142

Influence of Genetic Polymorphisms in VDR and COLIA1 Genes on the Risk of Osteoporotic Fractures in Aged Men. D. Álvarez-Hernández*, M. Naves*, I. Santamaría*, J. B. Díaz-López*, A. Rodríguez-Rebollar*, C. Gómez, J. B. Cannata. Servicio de Metabolismo Óseo y Mineral, Hospital Central de Asturias, Oviedo, Spain.

In the last decade, the likely effect of genetic markers related with the appearance and evolution of osteoporosis has been studied mainly in women, with no categorical results. The aim of this study was to assess the influence of genetic polymorphisms of the VDR and COLIA1 genes on the risk of osteoporotic fractures in men. The study population comprised 156 men, aged 64±9 (50-86), randomly recruited for the *EVOS Study*. They underwent several biochemical markers tests and bone mineral density measurements. Prevalent vertebral fractures and incident non-vertebral fractures were identified (the former, at the beginning of the study and the latter during a period of 10 years), as well as several genetic polymorphisms. According to the Genant classification, all fractures ≥2 were considered prevalent vertebral fractures. The analyzed genetic polymorphisms were located on restriction sites *Bsm*I (*B,b*), *Apa*I (*A,a*) and *Taq*I (*T,t*) in the VDR and Sp1 (*S,s*) in the COLIA1. *Bsm*I and *Taq*I polymorphisms did not show differences between fractured and non-fractured men, neither in the prevalent vertebral fractures nor in the incident non-vertebral fractures. *Apa*I polymorphism showed a slight statistical trend. The *aa* genotype would have a smaller prevalence of vertebral fractures [4% (1/25)], than the *Aa* and *AA* genotypes [14.7% (16/109)], p=0.179. These results were similar when the incident non-vertebral fractures were included. Statistical analysis of COLIA1 polymorphism and fractures (prevalent vertebral and incident non-vertebral) are shown in the table. The percentage of fractures was significantly higher in the *ss* genotype, with relative risk RR=7.64 and confidence interval CI=2.02-28.8 with respect to the other group, *S-*. This risk increased when incident non-vertebral fractures were included (RR=8.56, CI=2.32-31.5).

	PREVALENT VERTEBRAL FRACTURES	PREVALENT VERTEBRAL FRACTURES + INCIDENT NON-VERTEBRAL FRACTURES
GENOTYPE	**FRACTURE FREQUENCY***	**FRACTURE FREQUENCY****
S-	9.8% (12/122)	12.3% (15/122)
ss	45.5% (5/11)	54.5% (6/11)

* p= 0.003 and ** p=0.001

Results from COLIA1 polymorphism did not improve when data from other polymorphisms were added. Additionally, there were no significant differences either in lumbar or in femoral neck densitometry for any genetic polymorphism analyzed. These results show that in men, ss genotype of COLIA1 polymorphism could be the best osteoporotic fracture risk genetic predictor, independently of bone mass values.

SU143

A Common Polymorphism in the Methylenetetrahydrofolate Reductase (MTHFR) Gene Is Associated with Quantitative Ultrasound in Those with Low Plasma Folate. R. R. McLean[1], D. Karasik[1], J. Selhub*[2], K. L. Tucker[2], J. M. Ordovas*[2], S. Friso*[2], L. A. Cupples*[3], P. F. Jacques*[2], D. P. Kiel[1]. [1]Heb Rehab Ctr for Aged and Harvard Med Sch Div on Aging, Boston, MA, USA, [2]USDA Hum Res Ctr, Tufts Univ, Boston, MA, USA, [3]Biostat Dept, BU Sch of Public Health, Boston, MA, USA.

Our previously reported genome search in the Framingham Study using a quantitative ultrasound (QUS) phenotype found suggestive linkage on chromosome 1pter-1p36.3. This region contains several candidate genes for bone status, including the MTHFR gene. MTHFR catalyzes the conversion of 5,10-methylenetetrahydrofolate to 5-methyltetrahydrofolate, which is used for homocysteine methylation to methionine. Studies show that the homozygous form (TT) of the MTHFR C677T polymorphism (alanine-to-valine substitution) is associated with increased plasma homocysteine levels in individuals with inadequate plasma folate. Thus, we examined whether the C677T MTHFR polymorphism is associated with QUS and if it differs by folate status. We evaluated broadband ultrasound attenuation [BUA (dB/MHz)] of the calcaneus, using the SAHARA Bone Sonometer (Hologic), in 1745 men and women (mean age 60, range 32-86) who were members of the Framingham Offspring Study (1996-2001). Participants were genotyped for C677T alleles using standard PCR, digestion with HinfI, and then electrophoretic resolution of fragments to generate genotypes. Genotype frequencies in our sample were 40%, 46% and 14% for CC, CT, and TT, respectively. Plasma folate was measured using an automated chemiluminescence method. Because the homozygous mutation (TT) was of particular interest, participants were classified into two groups: 1) CC+CT and 2) TT. We used analysis of covariance to compare mean BUA between the two groups and tested for an interaction between C677T group and folate. We controlled for gender, age, BMI, smoking, physical activity, alcohol, calcium, and vitamin D intakes, and estrogen use in women. We found no difference in mean BUA between the two C677T groups [Least square means (LSM): CC+CT=75.6, TT=74.7, p=0.4]. Our test for interaction between C677T group and plasma folate was borderline statistically significant at the p=0.07 level. In the CC+CT group, there was no difference in mean BUA between the 71% of persons with high plasma folate (≥4 ng/ml) and the 29% with low folate (<4 ng/ml) (LSM: high=75.6, low=74.7, p=0.4). However, the TT individuals with low folate (61%) had significantly lower mean BUA (LSM: high=78.4, low=73.3, p=0.03). Our findings support the hypothesis that the association between a common mutation in the MTHFR gene and BUA is dependent upon folate status. Further understanding of the underlying mechanisms for these findings in bone is warranted.

SU144

Development of Genetic Screening Assays for Osteoporosis. D. Greene*, K. Walker*, S. Cayabyab*. Human Genetics, Roche Molecular Systems, Alameda, CA, USA.

Osteoporosis is a common chronic disease that is estimated to result in fractures for one out of every two women over the age of 50 and one out of every 8 men. It is a disease that has been increasing worldwide. There are ways to prevent and treat osteoporosis but it has proven difficult to predict who is most at risk for the disease. Given that the heritability for osteoporosis is estimated to be between 65 and 85%, there is tremendous potential to develop a genetic test that would predict disease. Such a test could be used to identify a subset of patients for more intensive screening (DEXA, qC/T) or in conjunction with such radiographic modalities provide a better estimate of risk and thus provide opportunities for earlier pharmacological intervention. The identification of clinically relevant genetic markers requires three major interacting areas of research - 1: candidate genes culled from basic research in bone physiology, from linkage and family studies, and from animal models, 2: large scale population based association studies to assess the effect of variations in these genes on disease and 3: genotyping platforms to efficiently genotype several thousand samples for several hundred possible variants. At Roche Molecular Systems we have developed several genotyping platforms and strategies for genotyping multiple samples for multiple markers. Phenotypes and candidate genes are selected from the research literature - ranging from basic research into bone physiology to linkage and family studies of osteoporosis. Genes are also selected based on genetic research in experimental animals. SNPs in these genes are taken from public databases and from our in house SNP discovery program. Selected SNPs are tested via real time PCR (or kinetic thermal cycling) in individuals and in pools of individuals. These tests provide information as to whether an association may be present and whether it should be pursued further. The SNPs that appear most promising are then put into an immobilized probe linear array assay. These assays, where a multiplex PCR product is hybridized to immobilized probes on nylon membranes, are used to interrogate up to 100 targets simultaneously. The simultaneous genotyping of many candidate SNPs can be achieved quickly and inexpensively.

SU145

Regulatory Polymorphisms of the COLIA1 Gene and Susceptibility to Fracture. F. E. A. McGuigan[1], T. L. Stewart*[1], S. C. Main*[1], N. Garcia-Giralt*[2], A. Diez-Perez*[3], D. Grinberg*[2], S. H. Ralston[1]. [1]Medicine & Therapeutics, University of Aberdeen, Aberdeen, United Kingdom, [2]Genetics, Universitat de Barcelona, Barcelona, Spain, [3]URFOA-IMIM, Hospital del Mar, Universitat de Barcelona, Barcelona, Spain.

Previously we have shown that the Sp1 binding site in the first intron of the COLIA1 gene is important for regulation of the gene. Alterations in this site result in allele-specific differences in transcription of the gene leading to reduced mineralisation and bone strength in some patients. Recently, two novel polymorphisms have been identified in the upstream promoter region of the COLIA1 gene at positions -1663 (T insertion/deletion) and -1997 (G/T substitution). This region of the promoter is known to play an important role in the regulation of COLIA1 expression. In a Spanish study of postmenopausal women, these polymorphisms showed a significant association with BMD. They were also found to be in linkage disequilibrium with the Sp1 polymorphism and all three polymorphisms interacted to predict BMD. The aim of our investigation was to further investigate the role of the promoter and Sp1 polymorphisms in the pathogenesis of osteoporosis using a case-control study of 149 postmenopausal Scottish women with and without vertebral fractures. There was no significant association between -1997 G/T and fracture (p=0.7). There was a non-significant trend towards association between -1663 DelT and fracture, with over-representation of the T7/T7 genotype in fracture cases (p=0.25). We found a significant association between the Sp1 polymorphisms and fracture, with over representation of the G/T and T/T genotypes in fracture cases (p=0.04). Haplotype analysis showed evidence of strong LD between all three polymorphisms (-1997G/T and -1663DelT, (p=0.008) for -1997 G/T and Sp1, (p=0.0081) and for -1663DelT and Sp1, (p<0.0001). Association analysis also showed a highly significant association between Sp1 / -1663 DelT haplotype and fracture, such that individuals carrying -1663T7 and Sp1 "T" alleles were greatly over-represented in the fracture cases (OR 6.1 [2.6-14.1]). In conclusion, this study confirms the allelic association between COLIA1 promoter polymorphisms and fracture and LD between the promoter and Sp1 polymorphisms. Further work is necessary to confirm the relationship between these polymorphisms and COLIA1 gene regulation.

SU146

Allelic Variation at the Insulin-Like Growth Factor I Receptor (IGF1R): Associations With Body Size and Bone Mass in Men. J. M. Zmuda[1], J. A. Cauley[1], M. E. Danielson[1], R. E. Ferrell*[2]. [1]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Human Genetics, University of Pittsburgh, Pittsburgh, PA, USA.

Height is a highly heritable trait, but very little is known about the genetic regulation of height. Insulin-like growth factor I (IGF-I) is a major determinant of linear bone growth and skeletal mass, and IGF-I action is mediated via the IGF-I receptor. In the present study, we tested the hypothesis that common allelic variation at the IGF-I receptor (IGF1R) locus is associated with measures of height and bone mass in 330 community-dwelling Caucasian men (age 66±7 yrs, mean±SD; range, 51-84 yr). BMD was measured at the hip and whole body with dual energy X-ray absorptiometry (Hologic QDR). Men were genotyped for a synonymous G-to-A single nucleotide substitution in exon 16 of the IGF1R gene. We found a significant monotonic increase in reported height at age 25 yr with increasing copies of the A allele (Table). Men with the A/A genotype were 3.2 cm or 0.5 standard deviations taller than men with the G/G genotype (P<0.01), and IGF1R genotype explained 3.2% of the total phenotypic variation in height. Similar results were observed for current standing height measured in the clinic with a stadiometer. In contrast, there was no significant association between this IGF1R polymorphism and femoral neck BMC, area or BMD. We found similar results for femoral neck BMAD, an estimate of volumetric density, and whole body BMD, and similar results after adjusting for age, weight and height (not shown). We conclude that allelic variation at the insulin-like growth factor I receptor locus may contribute in part to the genetic control of linear bone growth among men.

Table. Association between IGF1R Genotype, Height and BMD in Men.

	IGF1R Genotype			
	G/G	G/A	A/A	P (ANOVA)
No. of Men	113	166	51	
Height at age 25 yr (cm)	175.4 (6.3)	176.9 (6.0)	178.6 (4.6)	.005
Current Height (cm)	172.4 (6.8)	174.1 (6.1)	175.2 (5.0)	.016
FN BMD (g/cm^2)	.76 (.13)	.77 (.12)	.79 (.14)	.455

Values are mean (SD).

Vitamin D Response Element In TNF-alpha Promoter. I. Hakim*[1], Z. Bar-Shavit[2]. [1]Exerimental Medicine, Hebrew University, Jerusalem, Israel, [2]Experimental Medicine, Hebrew University, Jerusalem, Israel.

1,25-Dihydroxyvitamin D3 (VD) has been shown to modulate the synthesis and release of the cytokine TNF-alpha. We examine here if the increased abundance of TNF-alpha mRNA observed following VD treatment is due to increased transcript stability and/or synthesis. Analyses of RNA extracted from murine bone marrow derived macrophages (BMMs) revealed no change in TNF-alpha transcript stability in response to VD treatment. Next, we analyzed the promoter region (1.2 kb) of the TNF-alpha gene for potential vitamin D response elements (VDREs), and identified six sequences which could potentially serve as VDREs. The different core binding sites were spaced by one to six nucleotides (DR1-6, respectivily). To determine whether these potential VDREs are functional, we performed gel shift assays (EMSAs) with nuclear proteins obtained from BMMs. Similar to most characterized VDREs, the DR3-type VDRE (located 1008 to 994 base pairs upstream to transcription initiation) was found to be the most effective. The binding activity to this DR3 was ligand-dependent: an induction was observed following BMMs treatment with VD; while no induction was observed with 9-cis-retinoic acid, this retinoid further enhanced the activity of VD when added together. The specificity of the binding was demonstrated by the effective competition of unlabeled DR3 and of previously characterized VDREs found in the mouse osteopontin or in the rat osteocalcin promoters. A mutataed VDRE sequence from the osteocalcin promoter failed to compete with the DR3. The other potential VDREs found in the cytokine promoter exhibited various degrees of competition. We observed super-shift of the BMMs nuclear extract-DR3 complex in the presence of either antibodies to vitamin D receptor (VDR) or to retinoid X receptor (RXR). Our data suggest that VD increases TNF-alpha transcript abundance in BMMs via a transcriptional mechanism. The receptor complex interacting with the VDRE found in the promoter of the cytokine gene is probably composed of VDR-RXR heterodimer.

SU148

Microarray Analysis of mRNA Gene Expression of the Age-Related Delay in Fracture Healing in Rats. R. A. Meyer, B. R. Desai*, M. H. Meyer. Department of Orthopaedic Surgery, Carolinas Medical Center, Charlotte, NC, USA.

Genes active in the control of fracture healing are not well understood. Young rats heal fractures in four weeks while six-month-old rats require 10 weeks. Thus, genes regulating this process may be identified by their longer up-regulation in adult rats compared to that of young rats. To examine this, 6- and 26-week-old female Sprague-Dawley rats were subjected to mid-diaphyseal femoral fracture with intramedullary fixation. The fracture callus was collected at 0, 1, 2, 4, or 6 weeks after fracture. RNA was extracted and pooled between animals to create one sample for each time point for each age for a total of 10 arrays. cRNA was prepared and hybridized to Affymetrix U34A GeneChip arrays. Of the 8,700 genes on each array, 5,200 genes were scored as absent, and 3,300 as present. Of these, 1,155 were significantly up-regulated, and 927 were significantly down-regulated at 2 weeks after fracture in the adult rats. Up-regulated genes included cytokine and matrix genes for both cartilage and bone. Down-regulated genes included genes related to blood cell synthesis. The hematopoietic marrow may have been displaced by callus. Down-regulated genes also included mitochondrial genes. This may have been caused by the disruption to the local blood supply resulting in an increased anaerobic metabolism in the fracture callus. The data from genes previously studied by RT-PCR (Meyer *et al*., Bone 28: S205, 2001) were similar to the microarray data. Most genes with significantly altered mRNA expression had not been previously identified as participating in fracture healing. Cluster analysis was done with the self-organizing map (SOM) algorithm of the Data Mining Tool (Affymetrix). Clusters were identified with genes more strongly up-regulated in the adult rats than in the younger rats. This suggested partial resistance in the adults and the need for higher levels of expression to effect healing. Other clusters identified genes up-regulated by fracture in the young rats but not in the adults. This suggested loss of function in the adult that may also delay healing. In conclusion, skeletal fracture led to changes in RNA expression in many genes, most of which were not known to participate in the healing process. Cluster analysis revealed differential expression between the two ages that may have contributed to the slowing of the healing process in the adult animals.

SU149

Diverse Effects of Pleiotrophin on Bone Morphogenetic Protein-2 Induced Ectopic Osteogenesis. Y. Sato*[1], H. Takita*[2], N. Ohata*[1], M. Tamura[2], Y. Kuboki*[2]. [1]Department of Oral Functional Science,Graduate School of Dental Medicine, Hokkaido University, Sapporo, Japan, [2]Department of Oral Health Science,Graduate School of Dental Medicine, Hokkaido University, Sapporo, Japan.

Elucidation of molecular mechanisms controlling osteogenesis and growth factors in their processes has been one of the major subjects in bone biology. Pleiotrophin (PTN) is a heparin-binding, developmentaly regulated protein which found in brain, uterus, bone and cartilage. Recently bindings of N-syndecan and RPTP beta/zeta of the transmembrane receptor by PTN has been reported to enhance a migratory response in osteoblasts. We have already isolated PTN from bovine bone and have shown that it stimulated osteoblastic growth and differentiation (Biochem Biophys Res Commun, 186, 1288-1293, 1992). Further details of the function of PTN in bone tissue, however, have not been fully clarified. In this study, we examined the effects of PTN on bone morphogenetic protein (BMP)-induced ectopic osteogenesis. Recommbinant human BMP (rhBMP)-2 (1.2 µg) was combined with a carrier of fibrous glass membrane that had been established as an effective carrier. Various amounts of the purified bovine PTN or rhPTN were added to the rhBMP-2/carrier composites and implanted rats subcutaneously. The amount of bone induced in the system was increased with the addition of 10 µg of purified PTN or rhPTN. Alternatively, the amount of bone decreased with the addition of 50 or 100 µg of purified PTN dose-dependently, as judged by the alkaline phosphatase activity and calcium contents in the retrieved implants. Moreover, soft X-ray examination and histological analyses of the implants revealed that the addition of 10 µg of purified PTN or rhPTN induced more newly bone compared to the control. These findings demonstrated that PTN regulates BMP-induced ectopic osteogenesis and the PTN may be involved the regulation of osteoblastic differentiation and function in bone matrix.

SU150

Differential Mechanisms of IL-6 Induction by PTH and TNFα in Osteoblasts. J. Dai, X. Chen*, E. M. Greenfield. Orthopaedics, Case Western Reserve University, Cleveland, OH, USA.

We have previously shown that PTH and TNFα induce IL-6 mRNA expression and IL-6 protein secretion in MC3T3-E1 cells with distinct kinetics. Thus, while both PTH and TNFα induce IL-6 mRNA and protein rapidly, the effects of PTH are transient and the effects of TNFα are sustained for at least 24 hours. As a result, TNFα induces accumulation of 5-10 fold more IL-6 protein than does PTH after exposure for 24 hours. We have now extended these finding by showing that RANKL mRNA is induced by PTH and TNFα with kinetics similar to that of IL-6 mRNA. We have also further confirmed the relationship between IL-6 mRNA expression and IL-6 protein secretion by examining the effect of PTH in combination with IBMX. As expected, 10 nM PTH plus 100 μM IBMX induces high levels of cAMP (3-5 pmol/2 cm^2 well vs. 0.5-1 pmol/2 cm^2 well) for the duration of the experiment (4 hours). In contrast, IL-6 mRNA and protein are still induced transiently by PTH plus IBMX; however, IL-6 mRNA and protein are potently induced for 2 hours rather than for 1 hour as is observed in response to PTH alone. This increased secretion of IL-6 protein results in a 4-fold increase in the amount of IL-6 that accumulates in the culture media (169 pg/ml vs. 44 pg/ml, $p<0.0001$). Other investigators have shown that stimulation of IL-6 mRNA expression and protein secretion in osteoblasts after 24 hours of exposure to TNFα depends on activation of p38 MAPK. We therefore tested whether the effects of p38 occur during the early, rapid phase and/or the later, sustained phase of IL-6 induction by TNFα. We found that 1-10 μM SB202190, a specific p38 inhibitor, dose dependently blocks induction of IL-6 protein during both the rapid (0-6 hours) and sustained phases (12-24 hours). In contrast, the inactive analogue, SB202474, had much less effect on either phase of IL-6 induction by TNFα. Taken together, our results further characterize the differential mechanisms by which PTH and TNFα induce IL-6 expression in osteoblasts.

SU151

Lactoferrin Is a Potent Osteoblast/Chondrocyte Growth Factor, Inhibits Osteoclastogenesis, and Is Anabolic to Bone *In Vivo*. J. Cornish[1], K. E. Callon[1], T. Banovic*[1], U. Bava*[1], M. Watson*[1], Q. Chen*[1], K. Palmano*[2], N. W. Haggarty*[2], A. B. Grey[1], I. R. Reid[1]. [1]Medicine, University of Auckland, Auckland, New Zealand, [2]New Zealand Dairy Research Institute, Palmerston North, New Zealand.

Lactoferrin is an 80kD iron-binding glycoprotein present in breast milk, epithelial secretions, and the secondary granules of neutrophils. It circulates at 2–7 μg/ml, and has multiple postulated biological roles, including regulation of iron metabolism, immune function and embryonic development. We have demonstrated lactoferrin to be an anabolic factor in bone. *In vitro*, lactoferrin stimulates the proliferation of primary fetal rat osteoblasts, osteoblast-like cell lines and primary ovine chondrocytes at concentrations above 0.1 μg/ml. The magnitude of this effect exceeds that observed in response to other skeletal growth factors such as IGF-1 and TGFβ. DNA synthesis is also stimulated in murine neonatal calvarial organ culture, likely reflecting the proliferation of cells of the osteoblast lineage. Iron-depleted lactoferrin is considerably less potent as an osteoblast mitogen than iron-loaded lactoferrin. Lactoferrin is also a potent osteoblast survival factor. In TUNEL and DNA fragmentation assays, lactoferrin decreased apoptosis induced by serum withdrawal by up to 70%. Lactoferrin activates MAP kinase signaling in osteoblasts in a dose-dependent manner at concentrations of 1-100μg/ml. Lactoferrin also has powerful effects on osteoclastogenesis, decreasing osteoclast development at concentrations >1 μg/ml in a murine bone marrow culture system. However, lactoferrin did not alter bone resorption in calvarial organ culture, suggesting that it does not influence mature osteoclast function. *In vivo*, local injection of lactoferrin in adult mice resulted in increased calvarial bone growth, with significant increases in bone area and dynamic histomorphometric indices of bone formation after only 5 injections. Taken together, these data demonstrate that the naturally-occurring glycoprotein lactoferrin is anabolic to bone *in vivo*, an effect which is consequent upon its potent proliferative and anti-apoptotic actions in osteoblasts, and its ability to inhibit osteoclastogenesis. Lactoferrin may therefore have a physiological role in bone growth, and a potential therapeutic role in osteoporosis.

SU152

A Functional Role for Heat Shock Factors in the Transcriptional Regulation of Human RANK Ligand Gene Expression in Stromal/Osteoblast Cells. J. L. Roccisana*, M. Koide, G. D. Roodman, S. V. Reddy. Medicine, University of Pittsburgh, Pittsburgh, PA, USA.

RANK ligand (RANKL) is a critical osteoclastogenic factor that is expressed on stromal cells and osteoblasts. Most resorption stimuli induce osteoclast formation by modulating RANKL gene expression in stromal/osteoblast cells. In addition, cellular stress has been implicated in osteoclastogenesis. However, it is unclear how these stimuli modulate RANKL gene expression in the bone microenvironment. To characterize the transcriptional control of human RANKL gene expression in stromal/osteoblast cells, we PCR amplified and cloned a 2 kb 5'-flanking sequence of the RANKL gene, using normal human osteoblast derived genomic DNA as a template. Sequence analysis identified the presence of several potential Heat Shock Factor (HSF) responsive elements (HSE) in the human RANKL gene promoter region. Co-expression of HSF-1 or HSF-2 with the RANKL gene promoter-luciferase reporter plasmid in human osteoblastic cells demonstrated a 2-fold and 4.5-fold increase in promoter activity respectively. RT-PCR analysis for HSF-1 and 2 mRNA expression in human bone marrow cells, stromal cells (SAKA) and MG-63 osteoblast cells detected only HSF-2 expression. Expression levels of Heat Shock Proteins (HSP) mRNAs, which modulate HSF activation, were then analyzed. RT-PCR analysis demonstrated HSP-70 and HSP-90 mRNA expression in human bone marrow cells, a normal marrow stromal cell line (SAKA) and MG-63 cells. In contrast, HSP-27 mRNA was not expressed in bone marrow mononuclear cells. However, low levels of HSP-27 mRNA were detected in SAKA cells and osteoblastic cells. These data suggest that activation of HSF may play an important role in modulating RANKL gene expression in stromal/osteoblast cells.

SU153

Effects of IL-1beta and LPS on CTGF Expression in Mouse-derived Odontoblast-like Cells, MDPC-23. W. Sonoyama*, T. Kuboki*, T. Fujisawa*, T. Eguchi*, J. Uehara*, H. Yatani*, M. Takigawa. Okayama University Graduate School of Medicine and Dentistry, Okayama, Japan.

Dental caries is an infection disease that eventually leads to pulp inflammation. To protect the pulp tissue from severe inflammation, acceleration of the dentine matrix formation by odontoblasts takes place toward the pulp cavity. We have previously reported that connective tissue growth factor (CTGF) was up-regulated during reparative dentinogenesis in rat molars pulp. However, the up-regulation mechanisms of this factor are still unknown. The purpose of this study was to investigate the effects of interleukin-1beta (IL-1beta) and Escherichia coli lipopolysaccharide (LPS) on CTGF gene expression in odontoblast-like cells in vitro. MDPC-23, mouse-derived odontoblast-like cells were used in this study (Hanks et al., Connect Tissue Res, 1998). The cells were cultured in alpha-MEM supplemented with 10 % FBS until confluent. Total RNA was isolated from MDPC cells cultured for 12 and 24 hours with IL-1beta (0.1 ng/ml), or LPS (5 microg/ml) in alpha-MEM without FBS. Changes in CTGF and TGF-beta1 genes expression were examined by RT-PCR using each primer set by an unsaturated cycle number of amplification. The amounts of RT-PCR products were compared to that of 18S rRNA, and relative expression ratios were obtained. Next, the cells were cultured with recombinant CTGF (rCTGF, 50 ng/ml) for up to 3 days, and MTT assay was performed to examine the cell proliferation. Then, the cells were cultured under condition for mineralization (with ascorbic acid and beta-glycerophosphate) with or without rCTGF (50 ng/ml), and alkaline phosphatase (ALPase) activity was monitored according to the method described by Bassey et al. (1946) with some modifications. Interestingly, the MDPC-23 cells were expressing CTGF and TGF-beta1 genes. IL-1beta stimulation accelerated the CTGF gene expression to 1.2 and 1.7 times 12 and 24 hours after the stimulation, respectively. On the other hand, the TGF-beta1 gene expression was decreased to 0.4 times after 24 hours from IL-1beta stimulation. LPS stimulation increased the CTGF gene expression to 1.3 times, and decreased TGF-beta1 gene expression to 0.5 times after 24 hours. However, rCTGF had no obvious effects on proliferation and ALPase activity. These results indicate that the odontoblast-like (MDPC-23) cells are expressing CTGF and TGF-beta, and also indicated that both IL-1beta and LPS increased CTGF gene expression and decreased TGF-beta1 gene expression in the odontoblast-like cells within one-day period after stimulation.

Relationship Between Bone Density and Circulating Leptin Levels in Dietary Restricted Male Rhesus Monkeys. R. J. Colman[1], N. Binkley[2], R. Weindruch*[2]. [1]Primate Research Center, University of Wisconsin, Madison, WI, USA, [2]Department of Medicine, University of Wisconsin, Madison, WI, USA.

There is increasing evidence that leptin, the circulating hormone product of the obese gene, is more than an energy-regulating, body fat-related hormone. It has been implicated in reproduction, endocrine function, angiogenesis, hemopoieses, immune function, and brain development . Moreover, studies have long shown that obesity protects against osteoporosis and both bone mass and peripheral leptin concentration are related to body fat mass. More recently, studies have revealed a relationship between leptin and bone mass independent of body fat mass. As part of a long-term, multidimensional study of the effects of moderate (30%) dietary restriction (which retards the aging process in laboratory rodents) on aging, we explored the relationship between bone density and circulating leptin concentration in adult male rhesus monkeys (Macaca mulatta). At the time of data collection animals were between 13.9 and 20.0 years of age (mean = 15.5 years, sem = 0.4) and had been dietary restricted for 72 months. Animals were divided into control (C, n=14) and restricted (R, n=12), and analyzed for body composition and bone density (of the total body and lumbar spine) by dual-energy x-ray absorptiometry (DXA), and had fasting plasma drawn for leptin analysis. Plasma leptin concentration was 71% lower ($p<0.0001$), and body fat mass 78% lower ($p<0.0001$) in R compared to C animals. Additionally, total body ($p<0.02$) and lumbar spine ($p<0.0005$) BMD were lower in R compared to C animals. Stepwise multiple regression analysis revealed circulating leptin concentration to be a better predictor than body fat for both total body and lumbar spine BMD in C animals. However, circulating leptin concentration was not related to BMD in R animals. The lower body fat, circulating leptin concentration, and BMD associated with dietary restriction is as found previously. However the stronger relationship of leptin concentration than fat mass with BMD in the C animals, with no relationship between leptin and BMD in the R animals is a new finding. Further elucidation of the mechanism(s) involved in these differing relationships may prove informative in understanding the relationship of leptin to bone mass.

SU155

Endothelin-1 Modulates the Expression of Vascular Endothelial Growth Factor Associated with Osteoprogenitor Proliferation and Differentiation. C. J. H. Veillette*, H. P. von Schroeder. Surgery, University of Toronto, Toronto, ON, Canada.

Endothelin-1 (ET-1), a peptide produced by vascular endothelial cells (VECs), is implicated in the signaling between VECs, osteoblasts, and osteoclasts in bone development, remodeling and repair. Vascular endothelial growth factor (VEGF) also plays an important signaling role in these intercellular interactions and osteoblast derived VEGF has been implicated in various paracrine functions including osteoblast differentiation, osteoclast formation and angiogenesis. The goals of the present study were to determine the effect of ET-1 on the mRNA expression and protein production of VEGF isoforms during osteoprogenitor cell proliferation and differentiation in osteoblastic cells derived from fetal rat calvariae. Primary fetal rat calvaria (FRC) cells were seeded at a density of 4000 cells/cm^2 and cultured in the presence or absence of ET-1 (10^{-8}M) with each medium change for up to 18 days. Four, 7, 10, 14 and 18 days after plating, RNA was isolated and reversed transcribed into cDNA. Equal amounts of cDNA from each sample were subjected to PCR using specific primers to amplify the splice variants of rat VEGF-A. VEGF-A protein in the conditioned medium was analyzed using an ELISA. In addition, FRC cells from 7 or 14-days of culture were incubated in serum-free medium with or without ET-1 for up to 36 hours prior to harvesting total RNA and conditioned medium. RT-PCR and ELISA assessed the time and dose dependent responses to ET-1 on VEGF mRNA expression and protein production, respectively. Three VEGF mRNA isoforms were identified in osteoblastic cell populations from FRC cells, corresponding to VEGF120, 165 and 188 isoforms. The predominate isoforms, VEGF 120 and 165, were expressed highest at day 4 and day 18 with a decrease in expression at day 10. ET-1 markedly down-regulated VEGF expression and sustained the down-regulation in long-term cultures over time (ANOVA $p<0.001$). ET-1 inhibited VEGF mRNA expression by up to 2 fold by 3 hours after incubation in 7- and 14- day FRC cells. VEGF-A protein secretion was inhibited by ET-1 in a dose-dependent manner; with a maximal effect at 10^{-7} M. ET-1 (10^{-8}M) inhibited VEGF protein secretion after 24 hours by 5.8 fold ($p<0.01$) and 2.8 fold ($p<0.01$) in 7- and 14- day FRC cells, respectively. Our results show that ET-1 may play an important role in the regulation of osteoblast-derived VEGF and limit the paracrine actions of VEGF on endothelial cells, osteoblasts and osteoclasts during bone remodeling.

Mechanisms of Calcium Signaling in Human Bone Marrow-Derived Stromal Cells. N. R. Jorgensen[1], S. C. Teilmann*[1], Z. Henriksen*[1], R. Civitelli[2], O. H. Sorensen[1], T. H. Steinberg*[2]. [1]Osteoporosis Research Clinic, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark, [2]Washington University School of Medicine, St. Louis, MO, USA.

In vitro, bone cells propagate intercellular calcium waves (ICW) in response to mechanical stimuli. We have previously demonstrated that osteoblastic cells can propagate these waves by two different mechanisms. One is by autocrine action of ATP on purinergic P2Y receptors and occurs in the osteoblastic cell line UMR 106-01, while the other is dependent on gap junctional communication mediated by connexin 43 (Cx43), and occurs in another osteoblastic cell line, ROS 17/2.8. In human bone marrow-derived stromal cells (BMSC) both mechanisms occur, as these cells express both the gap junctional protein Cx43 and P2Y receptors. In the current studies we investigated the mechanism for the propagation of gap junction-mediated ICW in BMSC. Calcium concentration measurements were performed using video imaging and the Ca^{2+} indicator dye fura-2. ICW were elicited by mechanically stimulating single BMSC in monolayers, which caused fast ICW that spread to many cells. Adding ATP or UTP to the medium elicited calcium transients and also desensitized cells so that mechanical stimulation no longer caused a fast ATP-mediated ICW. Instead, mechanical stimulus caused a slower gap junction-dependent calcium wave that spread to only a few cells, as seen in ROS cells. These ICW required influx of extracellular calcium, but not release of calcium stores, and did not occur after plasma membrane depolarization by addition of extracellular potassium. In addition, low micromolar concentrations of the L-type voltage-gated calcium channel antagonist nifedipine totally blocked the propagation of ICW. To confirm that gap jucntion-dependent ICW in osteoblastic cells are mediated by L-type calcium channels, we performed similar experiments in UMR cells that had been transfected to express Cx43 (UMR/Cx43). After desensitization of P2 receptors, parent UMR cells do not propagate ICW, but UMR/Cx43 cells propagated slow calcium waves which were again inhibited by 1 uM nifedipine. Thus, BMSC propagate intercellular calcium signals in response to mechanical stimuli. These waves are propagated from cell to cell either by autocrine action of ATP on P2 receptors or by Cx43-mediated gap junctional communication and activation of L-type voltage gated calcium channels. These studies highlight the role of L-type calcium channels in the coordination of calcium responses among osteoblasts, and suggest that modulation of channel activity might influence bone turnover.

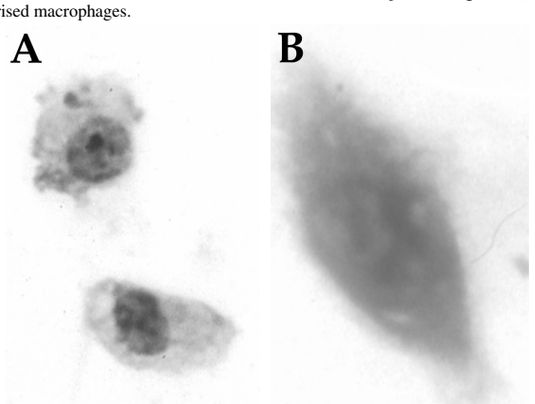
Fluid Shear of Very Low Magnitude Stimulates Growth and Improves Anchorage of Human Osteoblastic Cells *in Vitro*. C. Kasperk[1], B. Bundschuh*[1], U. Sommer*[1], B. Schweizer*[2], A. Lieder*[1], L. van den Heuvel*[1], S. Soezeri-Ludwig*[1], M. Holl*[1], P. Nawroth*[1], I. Boercsoek*[1], U. M. Liegibel*[1]. [1]Dept. of Medicine, Ruprecht-Karls-University, Heidelberg, Germany, [2]Institute of Applied Mathematics, Ruprecht-Karls-University, Heidelberg, Germany.

Mechanical loading of bone is crucial for the maintenance of normal bone architecture and may be transmitted to osteoblasts via shear stress by interstitial fluid flow. We applied very small fluid shear stress (1-63 µPa for 10-48 h) to primary human osteoblastic cells (HOC) *in vitro* to characterize proteins involved in translating physical force of low magnitude into a cellular response. The impact of very small fluid shear stress on bone cell metabolism may be of physiological significance in situations with pulsating fluid flow within the Havers‘ channels caused by blood pressure waves within the Havers‘ arteries. Very low shear stress by interstitial fluid shifts also occurs when the hydrostatic pressure within the blood vessels is disturbed by changes of the body position in space or by changes of bone perfusion. We demonstrate that fluid shear of very low magnitude significantly stimulated proliferation of HOC when stress was applied intermittently. Despite stimulating HOC proliferation, very low shear stress also increased differentiated cellular properties such as ALP activity, fibronectin (FN) and fibronectin receptor (FNR) production. TGFβ1+2 neutralizing antibodies and the presence of indomethacine inhibited the mitogenic action of fluid shear on HOC and the positive effects on differentiated functions. Furthermore, TGFβ1+2 dose-dependently increased the production of PGE_2, FN and FNR in HOC cultures. Therefore, the growth factor TGFβ is a physical stress responsive cytokine, regulating HOC proliferation and increasing the production of FN and FNR. In conclusion, fluid shear of very low magnitude possibly induced by arterial pulse waves in enclosed bone compartments or by centrifugal forces enhances osteoblastic proliferation and anchorage of bone cells within the bone matrix.

SU158

Pressure Induces 25-Hydroxyvitamin D 1-Alpha-Hydroxylase Activity in Macrophages: Implications for Disease. J. L. Berry*[1], S. Mylchreest*[1], J. G Andrew*[2], C. E. Evans*[1], A. P. Mee[1]. [1]Manchester University, Manchester, United Kingdom, [2]Salford Royal Hospital's Trust, Salford, United Kingdom.

The active metabolite of vitamin D, 1,25 dihydroxyvitamin D3 (1,25D), plays an essential role in the maintenance of serum calcium homeostasis and bone remodelling. In addition to renal synthesis of 1,25D (due to the actions of the renal 1-alpha-hydroxylase (1OHase) on 25 hydroxyvitamin D3), 1,25D is also produced in extra-renal sites. Activated macrophages are the source of 1,25D in several diseases, including arthritis, sarcoidosis and tuberculosis. In studies to determine the role of macrophages in hip joint replacement implant loosening, we have previously shown that macrophages respond to physical pressure by secretion of a variety of cytokines (IL-1, IL-6, and TNFalpha) that are known to play a role in bone metabolism. We have now used the same pressure system to examine the expression of 1OHase in macrophages. Isolated human peripheral blood monocytes, cultured for 7 days, developed a macrophage phenotype (CD68 and non-specific esterase positive). Macrophages were subjected to 5psi for 1 hour in a custom-built pressure chamber. Cells were then fixed and analysed for 1OHase mRNA and protein expression by in situ hybridisation (ISH) and immunohistochemistry (IHC). Low levels of 1OHase mRNA and protein (Figure 1A) were seen in non-pressurised macrophages. However, an obvious increase in 1OHase levels was seen at both the mRNA and protein (Figure 1B) level in pressurised macrophages.



These results show that pressure can induce a dramatic increase in 1OHase expression in macrophages. This has obvious implications for disease states where accumulation of macrophages is associated with local bone remodelling phenomena, such as in joint replacement implant loosening and atherosclerosis.

SU159

The Effects of Different Exercise Modes on the Biomechanical Properties of Growing Bone in Rats. T. H. Huang*[1], R. S. Yang*[1], S. C. Lin*[1], S. S. Hsieh*[2], F. L. Chang*[2], S. H. Liu*[3]. [1]Department of Orthopaedics, National Taiwan University Hospital, Taipei, Taiwan Republic of China, [2]Department of Physical Education, National Taiwan Normal University, Taipei, Taiwan Republic of China, [3]Institute of Toxiology, National Taiwan University, Taipei, Taiwan Republic of China.

During exercising, weight bearing plays an important role in improving the properties of bone material. The effects of non-weight-bearing exercise on bone, such as swimming, are still a controversial issue. In the present study, we designed two typical exercise modes, running and swimming, to investigate their effects on the biomechanical properties of growing bone. Twenty-four rats were randomly assigned into two exercise groups, which were RUN (n=8) and SWIM (n=8), and a control group (CON, n=8). Training program began when the animals were 7 weeks old. During the 8 weeks training session, RUN rats were trained on a level treadmill and the running speed was progressively increased from 12m/min to 22m/min. On the other hand, SWIM rats swam with a weight equivalent to 2%

body weight attached to their tails. The training frequency was 5 days a week. During the training period, exercise groups showed a lower body weight gain. After the end of training session, all the animals were deeply anesthetized and then sacrificed. Femur and tibia were collected for biomechanical three-point-bending testing by using a material testing system (MTS-858). For eliminating the effects of exercise-induced lower body weight gain on bone, one-way analysis of covariance (1-way ANCOVA) was used to compare means among groups and body weight was set as the covariate. In tibial and femoral maximal bending load, two exercise groups were higher than CON group, and SWIM group even showed a significantly higher value in maximal bending load (p= .039) than CON group. However, two exercise groups were significantly lower in tibial yield bending load than CON group (p= .002). In bending stiffness, two exercise groups were lower than CON, though the statistical significance was not reach. Analysis of yield energy showed that two exercise groups were higher in both tibial (p= .031) and femoral (p < .001) yield energy. In conclusion, bone tissues of the two exercise groups showed stronger and more elastic biomaterial properties. Swimming exercise might provide less mechanical loading as weight-bearing exercise so that it usually shows a less effects on improvement of BMD or BMC. However, swimming exercise even show an impressively better maximal load and yield energy in tibia than running exercise in present study. Therefore, non-weight-bearing exercise might have its specially benefits on bone and further study would be valuable to clarify this controversial issue.

SU160

Functional Gap Junctions are Essential for Prostaglandin E_2 (PGE_2) Production by Osteocytes in Response to Mechanical Strain by a Process Independent of Intercellular Channels. X. Wang*[1], E. Sprague*[2], J. X. Jiang[1]. [1]Biochemistry, University of Texas Health Science Center, San Antonio, TX, USA, [2]Radiology, University of Texas Health Science Center, San Antonio, TX, USA.

Connexin 43 (Cx43), a gap junction protein, is highly expressed in osteocytes in bone as well as in the osteocyte-like cell line MLO-Y4 compared to osteoblasts. However, osteocytes are only in contact through their dendritic processes, an extremely small area compared to the total surface area of this cell. These two observations suggest that Cx43 may have other functions in addition to forming intercellular channels between dendritic processes of adjacent osteocytes. Our previous studies using MLO-Y4 cells have shown that shear stress induced by fluid flow increases functional intercellular gap junctions, Cx43 protein, and PGE_2. Furthermore, we have demonstrated that PGE_2 is an essential mediator between mechanical strain and gap junction intercellular communication. However, the importance and role of gap junctions in the production and release of PGE_2 in response to mechanical stress is unknown. In this study, MLO-Y4 cells were plated at various cell densities so that at the lowest densities no cells were physically in contact with adjacent cells thereby preventing the formation of intercellular gap junction channels. These cells were subjected to fluid flow treatment for 2 hrs at 16 dynes/cm^2 and conditioned media assayed for PGE_2. The MLO-Y4 cells with no or few intercellular channels produced significantly more PGE_2 per cell than those at higher density with greater cell to cell contact. PGE_2 production was exponentially increased at the lowest cell density of $1x10^3$ cells/cm^2, compared to the highest cell density of $1.1x10^5$cells/cm^2. β-glycyrrhetinic acid, a specific and reversible gap junction channel blocker that can also block hemichannels, significantly reduced PGE_2 production induced by fluid flow at all cell densities tested, especially cells at the lowest density. Our results suggest that functional gap junctions in the form of hemichannels, instead of intercellular channels, are likely to play an important role in regulating the release of PGE_2 from mechanically treated MLO-Y4 cells. Studies are being performed using Cx43-null MLO-Y4 cells generated using antisense to provide further insight into the potential function of Cx43-formed hemichannels in the response of osteocytes to mechanical stimulation.

Simulated Microgravity Suppresses Osteoblastogenesis and Decreases Osteoblast Function. M. Zayzafoon, J. M. McDonald. Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Space flight is known to induce bone loss of weight-bearing bones. This decrease in bone mass has been attributed to a decline in bone formation without a significant change in bone resorption. Despite numerous studies, the mechanism for this serious condition is still unknown. To determine the effect of microgravity on bone, we utilized the Rotary Cell Culture System (developed by NASA) to simulate microgravity. Calvaria from 5 day old mice were harvested and cultured for 7 days under simulated microgravity. Histologically, we demonstrate a 4-fold decrease in alkaline phosphatase activity and 6-fold decrease in the cortical bone thickness and mineralization in response to simulated microgravity. We also demonstrate that simulated microgravity significantly decreases the expression of alkaline phosphatase (ALP), collagen I and osteocalcin as determined by real time RT-PCR. These results were not due to an increase in osteoblast apoptosis as it is shown by TUNEL staining. To determine the effect of simulated microgravity on osteoblastogenesis we cultured human mesenchymal stem cells (hMSC) grown on plastic microcarrier beads for 7 days in microgravity under osteogenic conditions. A decrease in mineralization was observed with a significant decrease in ALP and collagen I expression. Our preliminary data demonstrate that microgravity decreases the transactivation of Core Binding Factor Alpha 1 (Cbfa1) without any change in its expression in hMSC. Ongoing studies to identify the exact role of Cbfa1 in MSC response to microgravity and the modulation of its target genes are being performed. In conclusion, here we show that osteoblastogenesis in human mesenchymal stem cells and mouse calvaria is decreased in response to microgravity. This results in a decrease in bone mineralization and modulation of osteoblast gene expression. This response is mediated in part by decrease in Cbfa1 activity. Results from this study will increase our understanding of bone biology under microgravity and may lead to developing novel strategies capable of preventing bone loss in future long-term space flights.

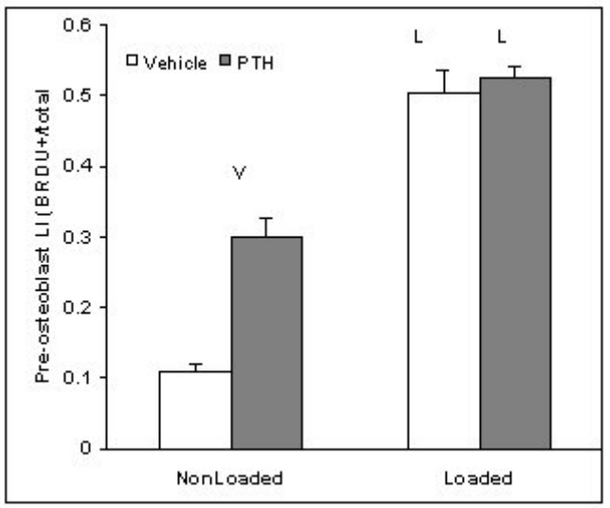
Mechanical Loading and PTH Stimulation of DNA Synthesis. J. A. Barry*, S. J. Tanner*, A. Peyton*, G. R. Haynatzki, D. M. Cullen. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Low bone mass that results in osteoporosis causes high morbidity and health care costs. Agents such as mechanical loads or exercise and PTH (parathyroid hormone) have the potential to stimulate bone growth. Although co-treatment with PTH can augment the effects of loading, the mechanism for this interaction is unknown. Our hypothesis was that short term treatment with PTH or loading increases bone cell DNA synthesis, and that combined the effects of loading and PTH are additive. Adult female Sprague-Dawley rats were divided into two injection groups of PTH (80ug/kg, n=4) or Vehicle (n=4). On days 0 and 1, each rat was injected subcutaneously and external loads were applied to the right tibia (35N, 36 cycles, 2 Hz). Bromodeoxyuridine (BRDU 40mg/kg) was administered every six hours throughout the 48-hour treatment period for a continuous label of DNA synthesis. Left (nonloaded) and right (loaded) tibiae were collected, decalcified, embedded in plastic, sectioned, and stained by immunohistochemistry. Differences were analyzed by GLM for repeated measures with significance at P<0.05. In nonloaded legs, PTH compared to vehicle treatment resulted in greater osteoblast and preosteoblast cell numbers and labeling indices. In the vehicle group, loaded legs were 2-3 fold greater than nonloaded legs for osteoblast and preosteoblast cell numbers. Similarly, labeling indices (# BrdU+/total # cells) for osteoblasts and preosteoblasts were 9 and 5 fold greater in loaded than nonloaded legs. There were no differences among loaded legs (PTH vs veh). When treatment was combined with loading, the PTH x Load effect on labeling index was smaller than the Vehicle x Load effects, due to the significant nonloaded leg PTH response. We conclude that individually, loading and PTH are anabolic stimuli for DNA synthesis. After 48 hrs at these loads and doses, the DNA synthesis response was greater for loading than PTH and when combined, PTH did not augment the loading effect. The effects of PTH and loading on preosteoblast DNA synthesis appear redundant.



SU163

Suppression of IL1-Stimulated mRNA Expression by Mechanical Shear in Chondrocytes. H. B. Sun*[1], Y. Liu*[2], H. Yokota[2]. [1]Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Biomedical Engineering, IUPUI, Indianapolis, IN, USA.

The specific aims of the current study were (i) to identify the genes whose IL1-stimulated expression in chondrocytes would be suppressed by mechanical shear, and (ii) to build a mathematical model for transcriptional regulation that would help understand the mechanism of suppression of the IL1-induced mRNA expression. A human chondrocyte cell line (C-28/I2) was used in this study and cells were grown under shear at 0-20 dyn/cm2 for 0 – 24 hours in the presence and absence of IL1. We focused on analyzing a family of matrix metalloproteinases (MMPs) together with the proteins expressed in extracellular matrix (ECM), since MMPs play the pivotal role in degeneration of ECM in response to proinflammatory cytokines. The semi-quantitative RT-PCR results show that the mRNA level of MMP-1, MMP-2 and MMP-13 was up-regulated by IL1, and that the elevated mRNA level was decreased by shear stress at 5 dyn/cm2. The effects of shear stress were examined not only at the transcriptional level but also at the proteolytic activity level. The fibril degradation assay using fluorescent substrates for MMPs revealed that collagenase and gelatinase activities were down-regulated by shear stress at 5 dyn/cm2. The shear responses of the family of MMPs in the chondrocyte cells in this study were similar, but not identical, to the shear responses in synovial cells. A higher shear stress was required to alter the expression of MMPs in C-28/I2 chondrocytes than the expression in MH7A synovial cells. The mathematical model for transcriptional regulation predicted involvement of transcription factor motifs such as AP1, AP2, NFkB, NFY, and PEA3 in shear responses as well as IL1 stimulation. The observed suppressive effects of shear stress on MMP expression and activities were additive to the stimulatory effects of IL1. Our study suggested that the molecular mechanism underlying the suppression of MMPs by mechanical shear might contribute to alleviating inflammatory reactions in joint tissue using a signal transduction pathway at least in part independent of IL1 induction.

SU164

Ontogenetic Development of the Ovine Calcaneus: A Model for Examining the Relative Contributions of Genetic, Epigenetic, and Extra-genetic Stimuli. J. G. Skedros, K. J. Hunt, C. L. Sybrowsky*. Dept of Orthop Surg, U of UT, Salt Lake, UT, USA.

Bone morphology may be largely constrained by genetic and epigenetic processes (e.g., via tissue interactions) that govern development along a given growth trajectory. We hypothesize that: 1) structural variations (e.g., trabecular orientation, cross-sectional shape), which dominate in early ontogeny, are primarily genetically/epigenetically derived, and 2) material (e.g., collagen fiber orientation (CFO)) and/or structural variations that appear later in development are primarily environmentally, or "extra-genetically" derived (e.g., as a response to strain transduction or microdamage formation). Because of its highly nonuniform morphologic organization, the ovine calcaneus appears to be a good model for examining mechanisms that mediate the modeling and remodeling processes that produce spatio-temporal developmental variations. Calcanei were obtained from 24 sheep (fetal - adult). In vivo strain data demonstrate that this bone receives relatively simple bending, with prevalent compression in the cranial and tension in the caudal cortex. Geometric measurements included: 1) cranial, caudal, medial, and lateral cortical thickness at 60% 'length', 2) maximum (Imax) and minimum (Imin) 2nd moments of inertia, and 3) cortical area (CA) and total area (TA). Lateral roentgenograms were analyzed for arched trabecular patterns, which may reflect tension/compression stress trajectories. Predominant CFO was determined using circularly polarized light in thin ultra-milled sections. Results showed that although CA/TA and Imax/Imin ratios increased linearly with bone length ($p<0.001$), significant cranial vs. caudal CFO and cortical thickness differences occurred only in the subadult and adult groups. Arched trabecular patterns were identified in fetal bones. The relatively early appearance of preferred trabecular orientation most likely represents programmed development. The 'delayed' temporal development of cross-sectional asymmetry and regional CFO anisotropy probably reflect influences of strain transduction. Mounting evidence suggests that the role of mechanotransduction, especially in the developing skeleton, is to provide the necessary threshold values required for implementation or maintenance of growth patterns that are mediated by modeling processes and guided principally by positional information. In contrast, we speculate that adaptations that are mediated by remodeling activities (e.g., non-uniform CFO patterns) may be more strongly influenced by strain transduction or byproducts of functional loading (e.g., regional or strain-mode-related differences and/or characteristics of microdamage).

SU165

Interactions between Estrogen and Mechanical Strain Effects on Osteoblasts Are not Influenced by Estrogen Receptor Type. T. Thomas[1], F. Lima*[1], M. Lafage-Proust[1], P. van der Saag[2], C. Alexandre[1], L. Vico[1]. [1]Inserm 9901, University Hospital of St-Etienne, Saint-Etienne, France, [2]Netherlands Institute for Developmental Biology, Utrecht, Netherlands.

Estrogens (E) and mechanical strain exert direct effects on osteoblast activity, with good evidence of interactions between their respective effects. Osteoblasts express both forms of estrogen receptors (ER) ERa and ERb, and previous studies have suggested a specific role for each receptor. Therefore, our working hypothesis was that the interactions between E and mechanical strain on osteoblast activity vary depending on which ER is preferentially activated. Using the human osteoblastic cells, U2Os, stably transfected either with ERa or ERb, we evaluated the effects of cyclical cell loading on a F-3000 Flexercell Strain Unit (1.5% elongation, 10 min/day), in presence of estradiol (E2) 10-8 M or not. The U2Os cell lines, either ERa or ERb transfected or the original U2Os cell line which does not express ER, were characterized by low alkaline phosphatase (AP) activity. They expressed all osteoblastic markers but osteocalcin because of a specific gene mutation. In both U2Os-ERa and U2Os-ERb cell lines, mechanical strain induced similar increases in AP activity and gene expression as measured by quantitative RT-PCR (Light Cycler, Roche), and a decrease in type I collagen gene expression. No change in proliferation rate was observed. Strain and E2 had a synergistic effect on AP activity as compared to each stimulus alone. Neither proliferation nor differentiation of the original U2Os cell line, was altered by strain or E2. In summary, the differences observed between the U2Os and the U2Os-ERa or -ERb cell lines are consistent with previous studies suggesting that ER play a critical role in mechanotransduction. However, these data do not support the hypothesis of differing roles for ERa and ERb in these defined experimental conditions. Understanding the mechanisms mediating interactions between estrogens and mechanical strain at the cellular level still requires further investigations.

SU166

Mechanically Related Changes in Gene Expression Using Real Time RT-PCR. M. E. Squire[1], L. R. Donahue*[2], M. Hadjiargyrou[1], C. Rubin[1], S. Judex[1]. [1]Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA.

Low level mechanical stimuli (<5 microstrain) can be anabolic to bone if induced at high frequencies (30-90 Hz). Conversely, removal of the normal mechanical environment can cause loss of bone tissue. We have recently demonstrated in BALB/cByJ mice that 10 minutes per day of whole body vibration at 45 Hz significantly increased trabecular bone formation rates in the proximal tibia by 34% while hind limb suspension (disuse) decreased bone formation rates by 48%. The identification of key molecular events behind this adaptive process may ultimately lead to the discovery of delivery targets and novel therapeutics for osteoporosis. Using reverse transcription polymerase chain reaction (RT-PCR), we previously characterized the expression of several candidate genes in response to both our anabolic and catabolic stimulus. Here, we tested whether real-time RT-PCR increases the sensitivity of detecting subtle changes in gene expression. Sixteen-week old female BALB/cByJ mice were randomly assigned to control, disuse (tail suspension), and mechanical stimulation groups (n=2 each). Mechanically stimulated mice were placed on a vibrating platform (0.25g, 45 Hz) for 10 min/d, 5 d/wk. After 4 days, RNA was extracted from the whole left tibiae (including bone marrow and cartilage). Real time RT-PCR quantified the expression of the genes coding for collagen type I (α1) and beta-2 microglobulin (beta-2). Mechanical stimulation up-regulated the relative expression (normalized to the housekeeping gene beta-2) of collagen type I by 30% +/- 4.4% (mean +/- SE) while disuse down-regulated the transcriptional levels by 40% +/- 4.8%. These results support our previous findings that collagen type I mRNA levels are rapidly reduced by mechanical unloading. The data also indicate that the expression of the most abundant protein in bone is increased after only 4 days of mechanical vibration, a result that we were unable to observe previously with conventional RT-PCR. Intriguingly, the relative changes in the expression of collagen type I as induced by low level mechanical vibration and disuse accurately reflected the relative changes in trabecular bone formation rates. In summary, this study indicates the superior sensitivity of real time RT-PCR in quantifying small changes in molecular expression levels of bone during the mechanically adaptive process. This sensitivity is currently being utilized for detecting subtle changes in the transcriptional level of genes critical for bone formation, resorption and maintenance.

SU167

Mechanical Properties of the Extracellular Matrix Regulate Fluid Shear-Induced Metabolism of Prostaglandins in Osteoblasts. S. M. Ponik, F. Pavalko. Cellular and Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN, USA.

Fluid shear stress (FSS) resulting from mechanical loading of bone in vivo is a potent stimulus for bone cell metabolism. In this study we tested the hypothesis that FSS-induced cell signaling may be regulated by changing the physical state of the extracellular matrix (ECM) or by modulating expression of integrin adhesion molecules, which link the actin cytoskeleton to the ECM. MC3T3-E1 osteoblasts were cultured on fibronectin or collagen that was adsorbed directly onto untreated glass slides or onto poly-L-lysine coated slides. Cells were allowed to rearrange the matrix for 16 hours and then were subjected to 90 minutes of laminar fluid shear. Following FSS, cells were incubated for 30-minutes during which released prostaglandins were allowed to accumulate in 1 ml of cell culture media. Prostaglandin-E_2 (PGE_2) released into the media was analyzed by enzymeimmunoassay. Integrin expression in cells grown on the different matrix proteins was evaluated by immunoprecipitation of biotin labeled cell surface proteins. Cells grown on either untreated glass or glass coated with fibronectin or collagen expressed both the α5 and αv integrin subunit at the cell surface. However, in response to FSS osteoblasts cultured on fibronectin and collagen released more PGE_2 then cells cultured on untreated glass. The α2 integrin subunit was expressed at the cell surface only in cells cultured on collagen, however, the FSS-induced PGE_2 release was not different between cells grown on fibronectin and collagen. This suggests that cells grown on fibronectin or collagen are more responsive to FSS than cells grown on uncoated glass. To further investigate the role of mechanical properties of the ECM in FSS-induced mechanotransduction, glass slides were first coated with poly-L-lysine prior to adsorption of fibronectin or collagen to immobilize the matrix and decrease the ability of osteoblasts to rearrange the ECM. Interestingly, FSS-induced PGE_2 release from osteoblasts cultured on poly-L-lysine-immobilized fibronectin or collagen was significantly decreased compared to cells cultured on fibronectin or collagen adsorbed to untreated glass. These data suggest that limiting the ability of osteoblasts to reorganize the ECM by immobilizing the ECM proteins decreases the cell's ability to respond to FSS.

SU168

Do Bones Have Memory? Glutamate Receptor Expression in Bone. K. M. Black*, B. L. Theriault*, G. I. Anderson. Pharmacology, Dalhousie, Halifax, NS, Canada.

Learning and memory involve both ionotropic and metabotropic glutamate receptors. Glutamate receptors have been identified in the bones of rat, rabbit, and mouse. Mechanical stimulation elicits changes in glutamate receptor expression. We postulate that glutamate receptors mediate mechanical stimulation to increase bone density in a manner analogous to their role in mediating CNS synaptic plasticity. Estrogen modulates glutamate receptor expression in the CNS: we suggest a similar role in postmenopausal osteoporosis. A mouse osteoclast model is being used to characterize the sensitivity of glutamate receptor expression to mechanical stimulation and estrogen levels. In some cultures, glutamate receptor expression has been seen to decrease or disappear during prolonged culture. To validate the use of our osteoclast culture model, we have verified the expression of the glutamate receptor subtypes and examined their sensitivity to mechanical strain. Bone marrow cells were flushed from the femora and tibiae of 7-week old female CD1 mice using a-minimal essential medium, 8 x 106 cells/35mm well were seeded onto collagen-I coated flexible silastic membranes and cultured for 7 days. Cells were mechanically stimulated (1 Hz, 900 cycles) on days 4, 5, and 6 of culture. The presence of glutamate receptor subunits in the cultured cells was analyzed using immunohistochemistry with mouse hippocampus slices as a positive control. After 7 days of culture, sufficient mature multinucleated osteoclasts differentiated from hematopoeitic progenitor cells to permit analysis. The expression of the following glutamate receptor subunits was confirmed in unstimulated multinucleated osteoclasts: NMDAR1, 2A, 2B, 2C; AMPAR1, 2/3, 4; mGluR1a and 5, but not mGluR2/3. The highest expression levels were observed for NMDAR2B and GluR4, suggesting that they play an enhanced role in the transduction of mechanical strain stimulus. Mechanical stimulation did not appear to alter the expression of NMDAR2B, AMPAR2/3, or AMPAR4, but caused decreases in NMDAR1, NMDAR2A, NMDAR2C, AMPAR1, mGluR1a, and mGluR5 expression. Additionally, we observed marked differences in the distribution of the different receptor subtypes: NMDA receptor subtypes 1, 2A, and 2C were mostly expressed in the periphery where podosomes form, further supporting their role mechanotransduction. We postulate that glutamate receptor subunit expression changes with mechanical stimulation and modulates osteoclast responsiveness to osteoblast glutamate signalling. We are currently tracking the mRNA levels of these immunocytochemically observed changes in glutamate receptor subtype expression induced by mechanical stimulation and the effects of varying estrogen levels in this model.

Hindlimb Unloading Decreases Osteoprogenitor Cell Number and Bone Formation in the Young Male Rat. N. Basso*, Y. Jia*, C. G. Bellows, J. N. M. Heersche. Faculty of Dentistry, University of Toronto, Toronto, ON, Canada.

Several lines of evidence indicate that the decrease in bone mass observed in humans and rats following space flight or mechanical unloading is primarily caused by a disruption in the development of cells of the osteoblast lineage. Using the NASA model of hindlimb unloading (HU) the effects of 14 days of HU on the number of fibroblastic colony forming units (CFU-F), alkaline phosphatase positive CFUs (CFU-AP), and osteoprogenitors (CFU-O) in cell populations isolated from the proximal femur (decreased loading), calvaria (increased pressure), and proximal humerus (normally loaded) of 6 week old male Fischer 344 rats (n=5) was investigated. Histomorphometry and *in situ* hybridization was performed on the proximal tibia to confirm previously reported changes in bone formation parameters following HU. Control rats were pair-fed. Cell populations were obtained from explant cultures and cultured for either 15 or 21 days in the presence of 10nM dexamethasone. The number of CFU-F in cell populations derived from HU and control rats for the 3 bone sites evaluated were similar. CFU-AP were decreased by 31% (19.2±1.7 vs. 13.3±1.2, $p<0.01$) in cells isolated from femur and increased 2-fold (18.7±1.0 vs. 38.7±1.5, $p<0.01$) in cells isolated from the calvaria of HU rats. CFU-O decreased by 77% (510.1±7.1 vs. 119.2±3.4, $p<0.01$) in cells isolated from femur and increased 1.4 fold (73.0±2.5 vs. 102.0±3.1, $p<0.01$) in cells isolated from the calvaria of HU rats. CFU-AP and CFU-O were not significantly different in cells isolated from humerus from either group. Histomorphometric analysis indicated that the major difference between HU rats and controls was a reduction in trabecular bone volume (BV/TV) which was decreased by 26% and 48% in primary and secondary spongiosa, respectively ($p<0.01$). There were also significant decreases in trabecular thickness (Tb.Th) and number (Tb.N), an increase in trabecular separation (Tb.Sp), and no difference in osteoclast number (Oc.N/BS) or surface (Oc.S/BS) in both regions examined. *In situ* hybridization analysis revealed a marked decrease in collagen mRNA content in the primary spongiosa of the proximal tibia of HU rats. In conclusion, cell culture studies illustrate that the number of osteoprogenitors and therefore osteogenic potential is decreased in cells isolated from the proximal femur, is increased in cells isolated from calvaria, and is not changed in the humerus as a result of HU. Histomorphometric evaluation indicates that in the proximal tibia HU results in a decrease in bone deposition in the primary and secondary spongiosa.

Inhibition of Fluid Shear-induced ATP Release in MC3T3-E1 Osteoblasts Depends Upon the Extracellular Matrix Proteins. D. C. Genetos[1], R. L. Duncan[2]. [1]Cellular and Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Orthopaedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA.

We have previously demonstrated that 12 dynes/cm^2 of fluid shear stress (FSS) applied to MC3T3-E1 osteoblasts produces a number of biochemical responses, including changes in intracellular calcium ($[Ca^{2+}]_i$) and gene expression. However, the mechanisms through which osteoblasts perceive and transduce mechanical signals into biochemical responses remain unclear. The expression in osteoblasts of ATP-activated P2 purinergic receptors that increase $[Ca^{2+}]_i$ may be one such mechanism We hypothesized that an additional osteoblastic response to FSS is the release of ATP. MC3T3-E1 cells were grown to confluence on either type I collagen- (10μg/cm^2) or fibronectin-coated slides (1μg/cm^2) and subjected to 12 dynes/cm^2 laminar flow. Fluid flow was applied in a parallel plate flow chamber using a flow loop to drive the flow medium through the channel of the flow chamber. Media samples were taken at various time points and ATP levels in the media were determined using an ATP-dependent luciferin/luciferase assay (Roche Biochemical) Static controls exhibited basal ATP release (7.0±0.5nM) that was increased to 27.8±1.6nM within 5 minutes of flow onset and remained elevated for the duration of flow. To determine if Ca^{2+} entry plays a role in ATP release in cells grown on either ECM, we pretreated the cells with either the mechanosensitive channel blocker gadolinium (Gd^{3+}, 10μM) or the L-type voltage-sensitive channel blocker nifedipine (5μM) prior to, and during, shear. Gd^{3+} failed to block ATP release in cells grown on either ECM. However, nifedipine significantly reduced shear-induced ATP release (5.6±2.1nM) in osteoblasts grown on type I collagen, but had no effect on cells grown on fibronectin. Interestingly, pre-treatment of osteoblasts with the chloride transport blocker DIDS (1mM) also significantly decreased ATP release in both static (0.47±0.2nM) and sheared (2.32±0.5nM) cells, independent of the ECM. These data indicate that ATP release is enhanced in osteoblasts subjected to FSS and can be dramatically blocked by the chloride transport inhibitor DIDS, possibly by blocking a mechanosensitive chloride channel that has been previously described in osteoblasts. While nifedipine failed to block ATP release from cells on fibronectin, shear-induced release was blocked to static control levels in cells grown on type I collagen. We have recently shown that inhibition of the L-type VSCC during mechanical loading of rat tibiae significantly reduced the bone formation rate in the loaded limb. The data presented here suggest a possible mechanism for this *in vivo* response

Modulation of NF-kB Translocation in Osteoblasts in Response to Shear is Mediated Via an ATP-dependent Pathway. D. J. Geist*[1], D. C. Genetos[2], R. L. Duncan[1]. [1]Orthopaedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Cellular and Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN, USA.

We have previously shown that Nuclear Factor-Kappa B (NF-kB) translocates to the nucleus in osteoblasts, subjected to fluid shear stress, within 1 hour. The focus of our present work is to elucidate the signaling mechanisms that influence the activation of NF-kB and the subsequent regulation of COX-2 and prostaglandin synthesis/signaling. MC3T3-E1 cells were grown to confluence in α-MEM media supplemented with 1% Pen/Strep and 10% FBS on fibronectin-coated glass microscope slides and subjected to 12 dynes/cm^2 of laminar flow. Fluid flow was applied in a parallel plate flow chamber using a flow loop with a constant hydrostatic pressure head that drives the media through the chamber in a constant laminar manner. The monolayer of MC3T3-E1 cells were flowed in α-MEM media with 0.2% FBS. Previous studies have demonstrated that the COX-2 gene contains a putative NF-kB binding site in its promoter. When we blocked IkB degradation with Nα-p-Tosyl-L-lysine chloromethyl ketone hydrochloride (TLCK), NF-kB translocation to the nucleus in response to fluid shear was prevented. Consequently COX-2 protein levels were reduced, compared to sheared controls, as shown in Western blot analysis. We have previously demonstrated that NF-kB translocation was dependent upon phospholipase C/IP_3 mediated intracellular Ca^{2+} release. A possible mechanism for PLC activation is via ATP binding to purinergic receptors. Inhibition of purinergic receptors with suramin, a general inhibitor of both P2Y and P2X receptor subtypes, prevented shear-induced NF-kB translocation. Previous reports have suggested that suramin may act to uncouple G-proteins. To ensure that NF-kB translocation is an ATP-mediated event we added apyrase, an enzyme that cleaves exogenous ATP into non-phosphorylated adenosine, to the flow media, and found that shear-induced NF-kB translocation was inhibited. To test whether other signaling mechanisms are involved in NF-kB translocation and COX-2 expression, we exposed cells to laminar flow in the presence of aminoguanidine, an inhibitor of both the constitutive and inducible forms of nitric oxide sythase (NOS). NF-kB translocation was not altered with aminoguanidine, indicating that this translocation was independent of nitric oxide (NO) signaling. These data indicate NF-kB translocation is modulated by shear-induced ATP release and that inhibition of NF-kB translocation reduced COX-2 production.

Dose Dependence of Bone Formation and Bone Remodeling Elucidated by Dynamic Fluid Flow Stimulation. Y. Qin[1], T. Kaplan*[2]. [1]Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, [2]SUNY Stony Brook, Stony Brook, NY, USA.

Introduction: Fluid flow that arises from the functional loading of bone tissue has been proposed to be a critical regulator of skeletal mass and morphology. To test this hypothesis, the bone adaptive response to a physiological fluid stimulus, driven by low magnitude, high frequency oscillations of intramedullary pressure (ImP) were examined, in which fluid pressures were achieved without deforming the bone tissue. Methods: The left ulnae of 12 adults, one-year-old male turkeys were functionally isolated via transverse epiphyseal osteotomies. An oscillatory sinusoidal fluid pressure was applied to the ulna with the magnitude of 15mmHg (n=4) (magnitude approximated to the normal marrow blood pressure), 76 mmHg (n=4) (close to 700 peak microstrain induced ImP) and 105 mmHg (n=4) (pressure close to impact loading) at 30 Hz, 10 min/day, for 4 weeks. The adaptive responses of bone were determined through morphometric measurement at the mid-diaphyses. The histomorphometry was analyzed by calculating total area adaptation of periosteal and endosteal new surface bone (NB) formation and intracortical porosity. Results: All animals subjected to fluid flow loading showed a maintenance or gain of total bone mass. While NB formation at the endosteal surface showed no significant difference among applied pressures at 15, 76 and 105 mmHg, it demonstrated dose sensitivity of NB formation at the periosteal surface. This resulted in an increase of NB as a result of an increase of loading pressure, i.e., 2.4±0.3% at 15 mmHg, 5.0±2.0% at 76 mmHg and 8.4±3.7% at 105 mmHg. Disuse induced approximately 3% intracortical porosity. These remodeling experiments have shown nonuniform spatial distribution at endosteal and periosteal surfaces. Interestingly, increasing ImP did not inhibit intracortical porosity rather it activated remodeling in the cortex. Discussion: These data confirmed that fluid flow could significantly elucidate adaptive response if applied at proper fluid pressure and frequency in a short loading duration. The results demonstrated that low magnitudes of ImP can initiate spatial fluid flow in bone and thus stimulate bone adaptive response. At high physiological magnitude, ImP can increase and improve this perfusion process through increasing fluid pressure. Within physiological range, new bone formation is proportional to applied fluid flow stimulation. While pressure applied exceeds the physiological intensity or in the pathologic range, it will trigger extensive remodeling process and even weaken the quality of bone.

Apoptosis Signal-Regulating Kinase 1 (ASK1) Knockout Mice Revealed Tail Suspension-Induced Bone Loss in C57B6 Background and Reduced Expression of Osterix Gene. H. Kondo*[1], M. Ishijima[1], R. Salingcarnboriboon*[1], M. Morinobu*[1], K. Tsuji1*[1], H. Ichijo*[2], A. Nifuji*[1], M. Noda*[1]. [1]Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Lab. of Cell Signaling, Tokyo Medical and Dental University, Tokyo, Japan.

The mechanisms of bone loss due to unloading have not been fully understood. Hindlimb suspension (HS) is one of the models of unloading-induced bone loss. We have shown that osteopontin deficiency suppresses bone loss due to HS in mice. However, signaling mechanism for unloading-induced bone loss is still not yet fully elucidated. ASK-1 is a MAPKKK, which is involved in stress-induced apoptosis via activation of p38 and JNK. The aim of this paper is to examine whether ASK-1 is involved in certain pathways of unloading-induced bone loss using ASK-1 knockout (ASK-1KO) mice subjected to HS for two weeks. Total of 25 male and 28 female wild and knock out mice with C57BL6 background, which was previously reported to be unresponsive to HS-induced bone loss, were used for the experiments. Micro-CT analysis indicated that basal levels of trabecular bone volume in the tibiae were similar between wild type and ASK-1 KO mice. Further analysis was conduced in four different regions designated as area1, 2, 3 and 4 , which werre within 210, 210/490, 490/770, and 770/2590 micrometer away from the growth plate respectively. In primary trabecular bone (designated as area 1), HS reduced bone volume similarly in wild type and ASK-1 KO male mice. In secondary trabecular bone, HS reduced bone volume in each of the are areas2,3 and 4 in ASK-1KO ($p<0.05$) but not significantly in wild type mice. Female mice did not show as high levels of bone volume as male and although similar tendency was observed in area2 in female, it was less clear. Urinary deoxypyridinoline excretion, mineralized nodule formation and osteolcast-like cell formation in bone marrow cultures were observed in both genotypes. RT-PCR analysis of bone marrow-derived RNA indicated that osterix mRNA levels were reduced by HS in wild type. Basal osterix mRNA levels were less in ASK-1KO than wild type ($p<0.05$). These data indicated that HS induced bone loss similarly in wild type and ASK-1KO mice with C57BL6 background in primary trabeculae while in secondary trabeculae HS reduced bone volume in ASK-1KO but less significantly in wild type mice.

Sex Steroids, Bone Mass And Markers of Bone Turnover Are Not Related to Stress Fractures in Women Runners. P. K. Korkia[1], O. M. Rutherford*[2]. [1]Sport, Exercise and Biomedical Sciences, University of Luton, Luton, United Kingdom, [2]Guy's, King's and St Thomas' School of Biomedical Sciences, King's College, London, United Kingdom.

The aim of this study was to investigate the role of oestradiol (E2) status, bone mass and bone turnover in runners with a history of a SF. Twenty eumenorrhoeic (EA) and 20 amenorrhoeic (AA) runners without SF and 9 EA and 7 AA with SF, and 10 sedentary controls (Con) were recruited. A lower limb SF had been diagnosed using an x-ray, bone isotope scan or equivalent within the previous two years. Oestradiol (E2), lutenising hormone (LH) and a bone formation marker (bone-specific alkaline phosphatase, BALP) were measured in serum. Bone resorption marker (N-telopeptide; NTx) and creatinine were measured from 24-hour urine samples. In menstruating subjects, samples were taken in the early follicular phase. Spine and tibia/fibula BMD was measured using DEXA (Lunar). The data was analysed using one-way Anova and logistic regression. Measures of serum E2 and LH confirmed that all AA runners were at the low end of normal range. The EA&SF had 40% and AA&SF 28% lower E2 values than their non-SF counterparts. Despite this, E2 was not found to be a significant predictor for SF. No significant differences were found in BMD between the SF and their non-SF menstrual counterparts. The AA had a significantly lower spine BMD compared to all other groups ($p<0.001$). No significant differences were seen in tibia/fibula BMD between any of the running groups, while in the Con were significantly lower after controlling for weight ($p=0.014$). No relationship was found between BMD and SF history. Compared to the Con, there were no significant differences in mean NTx levels in the SF or the non-SF groups. The AA and EA&SF had similar NTx levels and these were significantly greater than in the EA and AA&SF groups ($p<0.001$). Compared to the Con, BALP levels were significantly lower in EA and EA&SF ($p<0.001$) groups but not in the AA groups. The two AA groups had significantly greater BALP levels compared to the EA groups ($p<0.001$). The difference between the EA&SF and AA&SF remained for NTx and BALP after adjustment for the time lag between diagnosis of SF and time of the measurement. An uncoupling index, modified from Eastell et al (Osteoporosis Int.3:255-260,1993) was derived. According to this, resorption and formation was in balance in the EA, AA and Con. The EA&SF had increased resorption while in the AA&SF, formation exceeded resorption. Correction of bone markers for total body BMC did not change any of the conclusions. The results show that lowered E2, spine and tibia/fibula BMD were not related to SF in women runners. Bone turnover is altered in athletes with SF compared to controls and may be associated with reduced E2 status.

SU175

Eccentric Strength But Not Lower Leg Bone Mineral Density or Soft-tissue Composition Is Related to Stress Fractures in Women Runners. P. K. Korkia[1], O. M. Rutherford*[2]. [1]Sport, Exercise and Biomedical Sciences, University of Luton, Luton, United Kingdom, [2]King's College, Guy's, King's and St Thomas' School of Biomedical Sciences, London, United Kingdom.

The aim of the present study was to examine the relationship between tibia/fibula bone mineral density (BMD), bone area, soft-tissue mass and muscle strength in women endurance runners with a history of SF. Twenty eumenorrhoeic (EA), 20 amenorrhoeic (AA) and 9 EA and 7 AA runners with a unilateral lower limb SF were recruited. A lower limb SF had been diagnosed using an x-ray, bone isotope scan or equivalent within the previous two years. Bone mineral density, bone area, lean (muscle) and fat mass in tibia/fibula area were isolated from a total body BMD scan using DEXA (Lunar). Concentric and eccentric quadriceps (Q) and hamstrings (H) actions were measured using isokinetic dynamometry (KinCom 125AP) at 60 and 180 degrees per second (°/s) in a seated position. Concentric plantar flexion (PF), dorsi flexion (DF), inversion (IV) and eversion (EV) strength were measured at 60°/s in a supine position. All measurements of muscle force were done during the early follicular phase in menstruating subjects. For statistical analyses, one-way Anova, independent sample t-tests and logistic regressions were used. Because no significant bilateral or between-group differences were seen in muscle strength, tibia/fibula BMD, bone area, lean and fat mass in any of the groups, the groups were combined to runners with a lower limb SF (n=16) and those without a SF (n=58). There were no muscle strength differences between the affected and non-affected limbs, apart from eccentric Q action at 60°/s, which was weaker on the affected side ($p=0.004$). Group comparisons showed no significant differences in tibia/fibula BMD, bone area or lean and fat mass between the SF and non-SF groups. Similarly, no differences were found for muscle strength. We did find a weak negative link between SF and calf circumference ($p=0.065$) and for SF and the total soft-tissue mass around tibia/fibula ($p=0.062$), but not for fat or lean mass alone. Eccentric quadriceps strength at 180°/s was negatively related to SF ($p=0.027$) while eccentric H strength at 60°/s showed a weak positive relationship ($p=0.04$). The latter finding is somewhat puzzling, but may be reflective of a relative weakness of the quadriceps group in relation to the hamstrings in those with SF. In conclusion, soft-tissue bulk may be more important than actual soft-tissue composition in protecting the lower limb from a SF. The study suggests that eccentric strength around the knee joint, and especially the quadriceps group, may be of practical importance in protecting against SF.

SU176

Bone Sensitivity to Mechanical Loads with the Lrp5 HBM Mutation. D. M. Cullen[1], M. P. Akhter[1], D. Mace*[1], M. L. Johnson[1], P. Babij*[2], R. R. Recker[1]. [1]Osteoporosis Research Center, Creighton University, Omaha, NE, USA, [2]Wyeth Research, Andover, MA, USA.

In humans, the high bone mass (HBM) mutation in the Lrp5 gene results in larger, stronger bones than normal. We hypothesize that this mutation alters bone cell sensitivity to loading such that lower than normal strains stimulate bone adaptation. In this study we tested 4 month old, female HBM transgenic mice (Het) derived from C57BL/6tac mice (Wyeth Research) and their non-transgenic (NTG) littermates. The right tibiae of all mice (30/genotype) were loaded in four-point bending at either 5 or 6 N, 36 cycles, 2 Hz for 5 days. Calcein was injected on day 5 and 12, and tibiae collected on day 15. The loaded (right) and nonloaded (left) legs were measured by standard histomorphometry. Differences due to force, genotype, and leg (right vs. left) were assessed by GLM for repeated measures. Tibial cross-sectional area was greater in Het (1.43±0.21) than NTG (1.13±0.16) mice. Strain or bending is a primary stimulus for mechanical regulation and due to size differences, tibial strains for the same forces were calculated to be 60% greater in NTG tibiae than in Het tibiae. For both genotypes, loading at 5 and 6 N increased periosteal and endocortical formation in loaded compared to nonloaded legs. The load response (loaded-nonloaded) is shown below. Despite large differences in strain, there were no genotype differences for increased periosteal formation surface (FS) or bone formation rate (BFR) with loading. However, endocortical FS responses to loading were greater in Het than NTG mice. Within genotype, only endocortical responses showed significant differences due to applied force. While commonly at least 1000 με is required to initiate a slight bone response, similar strains created large formation responses in the HBM mice. We conclude that less strain is required to stimulate similar or larger bone responses in mice with the HBM mutation than in NTG controls. Increased sensitivity to loading in HBM mice needs to be confirmed over a greater range of strains and forces.

Variable[a]	NTG-5N	NTG-6N	Het-5N	Het-6N
Strain (με)	1721	2065	1083	1300
Peri FS (%)	39 (15)	35 (21)	46 (24)	40 (24)
Peri BFR (um/d)	945 (1010)	2403 (2353)	1506 (2291)	1649 (2438)
Endo FS (%) [b]	14 (15)	18 (18)	16 (18)	25 (19)
Endo BFR (um/d)	52 (18)	137 (126)	77 (91)	105 (148)

[a] Values represent the loading response (loaded-nonloaded (SD)) with loaded legs greater than nonloaded legs for all variables. P<0.001

[b] The loading effect increased with force and was greater in Het than NTG P<0. 01

Femora of Mice Lacking Myostatin Show Increased Trabecular Bone Density. M. Hamrick[1], G. Njus*[2], D. Ducharme*[2]. [1]Medical College of Georgia, Augusta, GA, USA, [2]Calhoun Research Laboratory, Akron, OH, USA.

Myostatin (GDF-8), a member of the transforming growth factor-β superfamily of secreted growth and differentiation factors, is a negative regulator of skeletal muscle growth. Myostatin-deficient animals show a marked increase in muscle mass compared to normals. We investigated the effects of increased muscle mass on bone modeling by examining cortical and trabecular bone strength and density in mice lacking myostatin function.

The experimental group used in this study included 12 female mice four months of age homozygous for the disrupted myostatin sequence whereas the control group consisted of 12 female wild-type mice also four months of age. The right femur of each mouse was cleaned of all soft tissue and examined using pQCT densitometry. Cross-sectional slices 1 mm thick were scanned at two different locations, the midshaft and the distal metaphysis. The midshaft is primarily cortical bone whereas the distal metaphysis has a high proportion of trabecular bone. The left femur of each individual was stored at -20ºC, thawed to room temperature, and the shaft loaded in four-point anteroposterior bending at a displacement rate of .10 mm/sec. Results show that the myostatin-deficient animals do not differ significantly from normals in bending stiffness (p=.89) or peak failure moment (p=.13). pQCT sections from the femur midshaft show that the myostatin knockouts have slightly (3%) greater cortical bone mineral density than normal mice but lower (10%) section modulus, which explains the similarity in peak failure moment between the two groups. pQCT sections from the distal metaphysis do, however, show that myostatin knockouts have over 20% greater trabecular bone density (p=.02) than normal mice. These data suggest that increased muscle mass resulting from myostatin deficiency may increase trabecular bone modeling in the limb skeleton.

The Freefall Impact Protocol: A Rodent Model to Assess the Effect of Impact on the Appendicular Skeleton. J. M. Welch*[1], C. M. Weaver[1], C. H. Turner[2]. [1]Foods and Nutrition, Purdue University, West Lafayette, IN, USA, [2]Indiana University Medical School, Indianapolis, IN, USA.

Impact exercise has been shown to have beneficial effects on the proximal femur of growing children. As a tool to further understand what changes this exercise promotes in weight-bearing bones, we developed an in vivo rat model in which rats are dropped from a specified height onto a hard surface. We tested 2 different falling heights and measured differences in the radius among treatment groups. Fischer 344 female rats (n=30), aged 4 weeks, were familiarized with exercise pens and daily handling. At 6 weeks they were randomly assigned to control (n=10) or 1 of 2 freefall groups (n=10 each). Animals assigned to the freefall groups were dropped from heights of either 30 cm or 60 cm. Rats were held horizontally above bare floor and, when released, landed on all four feet. Each rat was dropped every 11 seconds for 10 drops, 5 days a week, for 8 weeks. Additionally, all rats were allowed group exercise in pens 1.0 m in diameter, for the same amount of time daily, and consumed standard rat chow (1.0% Ca). No rat suffered injury or recognizable trauma as a result of this protocol. Upon completion of the 8 weeks of treatment, all rats were euthanized and their left radii removed. The radii were scanned by pQCT at 3 sites: 2.20 mm from the proximal end, midshaft, and 1.35 mm from the distal end. All tomographs were assessed for cross-sectional area (CSA) and volumetric bone mineral density (vBMD). Additionally, maximum and minimum second moments of area (I_{MAX} and I_{MIN}) were measured from the midshaft images. The data were analyzed by Tukey's Honestly Significant Difference Test for differences between groups ($p<0.05$). The vBMD at the proximal site (p=0.03; 5.2%) and distal site (p=0.01; 4.9%) increased over that of the controls in the 60 cm freefall group but not in the 30 cm group. No differences were found in vBMD at the midshaft. The CSA of the 60 cm group increased at both the proximal (p=0.001; 10.3%) and midshaft sites (p=0.002; 8.2%), but not at the distal site. No change in CSA was found in the 30 cm freefall group. Midshaft I_{MIN} increased in both the 30 cm (p=0.01; 18.1%) and 60 cm freefall groups (p=0.004; 21.4%), while I_{MAX} increased in only the 60 cm group (p=0.008; 14.9%). These results indicate that the freefall impact protocol provides a simple and effective new tool to stimulate a weight-bearing appendicular bone in growing rats. Responses in the radius were evident in rats subjected to the 30 cm drop height and improved in rats subjected to the 60 cm drop height.

SU179

Structural Changes in the Rat Humerus as a Result of Freefall Impact. J. M. Welch*[1], C. M. Weaver[1], C. H. Turner[2]. [1]Foods and Nutrition, Purdue University, West Lafayette, IN, USA, [2]Indiana University Medical School, Indianapolis, IN, USA.

Jumping can induce changes in the structure of children's bones. To further determine what structural changes occur as a result of impact loading, we subjected growing rats to a freefall impact protocol. F344 female rats, aged 6 weeks, were dropped 10 times per day, 5 days a week onto a hard surface. Rats in the freefall group (n=10) were dropped from 60 cm, while those in the controls (n=10) were not dropped. After 8 weeks the rats were euthanized and the left humeri removed. Each humerus was scanned by pQCT in 3 locations: (1) proximal site: 2.15 mm from the proximal end, (2) midshaft site, and (3) distal site: 1.15 mm from the distal end. At all sites the volumetric bone density (vBMD) of the total bone (vBMDtot), and both the cortical (vBMDcort) and trabecular (vBMDtrab) fractions were measured. The cross-sectional area of the whole bone (CSAtot), as well as its components, the cortical bone (CSAcort) and trabecular bone (CSAtrab), were also measured. Midshaft scans were analyzed for maximum and minimum second moments of area (I_{MAX} and I_{MIN}). The impact provided by 50 freefall impacts per week resulted in several structural changes in the humerus. At the midshaft, the bone gained CSAtot (p=0.003; 10.0%) due to increases in both the CSAcort (p=0.008; 13.6%) and CSAtrab (p=0.02; 10.5%). Additionally, changes in midshaft geometry were reflected in a greater I_{MIN} in the freefall group ($p<0.0001$; 34.1%). Midshaft I_{MAX} increased by 20.7% but this change was not significant due to variability within the groups. No difference was found in vBMD at the midshaft site. Both the proximal and distal ends of the humerus in the impact group increased in vBMD, with the proximal site reflecting greater changes than that of the distal. The proximal end increased in vBMDtot (p=0.0005; 5.6%) mostly due to an increase in vBMDtrab (p=0.02; 5.6%), while the change in the vBMD of the distal end was smaller (p=0.005; 3.3%), due to a lesser, and nonsignificant increase in both vBMDtrab (2.1%) and vBMDcort (1.5%). No changes were found in CSA at either end sites. These results indicate that the rat humerus gained structural strength in response to impact loading by increasing in all CSA fractions and I_{MIN} at the midshaft, and by responding in the proximal and distal ends by an increase in vBMDtot that was mostly due to an increase in trabecular density. The midshaft changes would attenuate the bending response to impact that is greatest at that site, while the greater trabecular density in the bone ends would result in a greater dissipation of the forces from the impact by distributing them into either more or thicker trabeculae.

SU180

Effect of Long-Term Impact-Loading on Mass, Size, and Estimated Strength of Humerus and Radius of Female Racquet-Sports Players: Aperipheral Quantitative Computed Tomography Study Between Young and Old Starters and Controls. S. Kontulainen*, H. Sievänen*, P. Kannus*, M. Pasanen*, I. Vuori*. UKK Institute, Tampere, Finland.

Bone characteristics were measured from 64 female players and 27 age-, height-, and weight-matched controls with pQCT and DXA. Players were divided into two groups according to the starting age of their tennis or squash training (either before or after menarche) in order to examine the possible differences in the loading-induced changes in bone structure and density. The used pQCT-variables were: bone mineral content (BMC); total cross-sectional area of bone (TotA); area of the marrow cavity (CavA) and that of the cortical bone (CoA); cortical wall thickness (CWT); volumetric density of the cortical bone (CoD) and trabecular bone (TrD); and bone strength index (BSI). BSI was compared to the DXA-derived areal bone mineral density (aBMD) to assess how well the latter represents the effect of mechanical loading on apparent bone strength. At the humeral shaft, the loaded arm's greater BMC (an average 19% gain in young starters and 9% in old starters), was due to a larger CoA (20% and 9%, respectively). The loaded humerus seemed to have grown periosteally (the CavA did not differ between the sites) leading to 26% and 11% gains in BSI in the young and old starters, respectively. CoD was equal between the arms (-1% difference in both player groups). The side-to-side difference in the young starters' BMC, CoA, TotA, CWT and BSI was 8% to 22% higher than that in the controls and 8% to 14% higher than that in the old starters. Old starters' BMC, CoA and BSI side-to-side difference was 6% to 7% greater than that in the controls was. The aBMD difference was 7% and 14% greater in young starters compared to that in the old starters and controls, respectively, whereas the difference between old starters and controls was 6%, in favour of the former. At the distal radius, the player groups differed from controls in the side-to-side BMC, TrD and aBMD differences only: the young starters' BMC difference was 9% greater, TrD and aBMD differences 5% greater than those in the controls, while the old starters' TrD and aBMD differences were both 7% greater than those in the controls. In summary, the structural adaptation of the humeral shaft to long-term loading seemed to be achieved through periosteal enlargement of the bone cortex and this adaptation was clearly greater if playing was started during the growing years. Exercise-induced cortical enlargement was not so clear at the distal radius, but the trabecular density seemed to been modified. DXA-based aBMD detected the intergroup differences but gave smaller estimates of the effect of exercise on the apparent bone strength at humeral shaft, especially in the young starters.

A Comparison of Cyclic and Rest-Inserted Loading. S. L. Poliachik*, N. Y. Moy*, S. C. Agans*, S. Srinivasan, T. S. Gross. Orthopaedics and Sports Medicine, University of Washington, Seattle, WA, USA.

Insertion of rest periods between each load cycle enables low magnitude loading to become osteogenic. To begin to optimize this stimuli, the current study sought to contrast the osteoblastic response induced by a protocol of strenuous cyclic loading to that achieved by lower magnitude, rest-inserted loading in growing mice. Loading was accomplished via non-invasive application of controlled loads to murine tibia. Sixteen C57Bl/6J mice (female, 16 wk) underwent a 2 week protocol where the right tibiae of the mice were dynamically loaded. Peak normal strains were estimated based upon application of beam theory to strain gage data collected from calibration mice. Animals were randomly assigned to 1 of 4 groups: 1) high magnitude repetitive loading of 100 cycles (peak mid-diaphysis strain of 1600με); 2) low magnitude rest-inserted loading of 10 cycles with 10s rest between cycles (550με peak strain); 3) medium magnitude rest-inserted loading of 10 cycles with 10s rest (1200με peak strain); and 4) medium magnitude rest-inserted loading of 10 cycles with 20s rest (1200με peak strain). Calcein was administered on day 3 and day 12, with the animals sacrificed on day 15. At the periosteal surface, unloaded contralateral control bones displayed minimal bone formation (0.04 ± 0.02 $\mu m^3/\mu m^2/d$). Low magnitude rest-inserted loading with 10s rest did not significantly increase bone formation compared to controls (0.01 ± 0.01 $\mu m^3/\mu m^2/d$, p=0.34). Rest-inserted loading at medium magnitude with 10s rest produced significant bone formation compared to control bones (0.20 ± 0.07 $\mu m^3/\mu m^2/d$, p=0.02). The bone formation for the medium magnitude rest-inserted loading group with 20s rest was similar to the 10s rest group (0.17 ± 0.13 $\mu m^3/\mu m^2/d$), and both medium magnitude rest-inserted groups exhibited greater bone formation than the high magnitude cyclic loading group (0.11 ± 0.07 $\mu m^3/\mu m^2/d$). We conclude that a rest-inserted protocol with only 10 cycles of daily loading induces periosteal bone formation comparable to 100 cycles at higher magnitude loads. One caveat is that the strains were applied in a non-physiologic orientation. If rest-inserted loading proves efficacious when applied in a physiologic orientation, its potential for extension to clinical trials would be greatly enhanced.

SU182

Effect of Physical Activity, Intensity and Length on Dimensions and Mineral Density of Apendicular Skeleton: Study on a Tennis Players Population. L. del Rio[1], P. Bassa*[1], R. Balius*[2], A. Ruiz Cotorro*[2], J. Parra*[2]. [1]Densitometria Osea, CETIR Centre Medic, Barcelona, Spain, [2]Fundacion Blume, Barcelona, Spain.

The aim of this study was to evaluate the effect of physical exercise on the regulation of size and bone density of limbs, as well as the degree of reversibility of such effects after a period with less exercise. **Method***: Bone mineral density measurements*: Global and regional analysis of bone mineral density (BMD) (g/cm2) were obtained using high-resolution DXA (GE-LUNAR, model EXPERT-XL) of both arms (on humerus, radius, ulna). *Osteometric measurements*: Total and sectorial measurements of projected length and width of both upper limb same bones were obtained. **Individuals**: A total population of 144 sportsmen volunteered, including 94 tennis players, which were in turn categorized according to age and physical activity as follows: 36 in growth period, 39 in young adults, 15 active veterans, 5 inactive veterans; the control group included, 50 sportsmen teenagers (24) and young adults (26) with symmetric exercise (martial arts and rowing). **Results**: Significant differences in BMD ($p<0.001$) and size (p: <0.001-005) were found in bones of dominant arm in comparison with non-dominant arm in the tennis players group, with being the region of interest in the upper humerus region the biggest one. Osteometric differences were greater in the projected width than in length, especially at humerus and ulna, and in segments richer in cortical bone. There were no differences in the control group nor the veterans inactive tennis players and the growth period group. **Conclusions**: This study confirmed the effect of physical activity on the regulation and mineralization of appendicular skeleton. Differences shown were small (non significant) in tennis players in growth period, and significant in young adults, with being related to exercise intensity and duration ($r=0.65$). Magnitude of these differences were greater in absorptiometry parameters than anthropometric ones, with the latter being kept in veterans players. Changes in BMD did not follow the same rule, since they were reversed with the lack of exercise.

SU183

The Role of $p57^{Kip2}$ Gene in Bone Metabolism. H. Amano[1], K. Suzuki[1], A. Nara*[2], K. Takahashi*[2], T. Tomita*[2], T. Urano[3], S. Inoue[3], S. Yamada*[1]. [1]Pharmacology, School of Dentistry, Showa Univ., Tokyo, Japan, [2]Biochemistry, School of Pharmaceutical Science, Showa Univ., Tokyo, Japan, [3]Geriatric Medicine, Faculty of Medicine, Tokyo Univ., Tokyo, Japan.

The cyclin-dependent kinase(CDK) inhibitor, $p57^{kip2}$ is a negative regulator of the cell cycle. Mice with a disruped $p57^{Kip2}$gene show cleft palate, endochondral bone ossification defects with incomplete differentiation of hypertrophic chondrocytes. We have also reported that the amount of $p57^{Kip2}$protein increased in rat osteoblasts treated with 1,25 vitamin D_3. However, the role of $p57^{Kip2}$ in bone metabolism is still unknown. In the present study osteoblasts derived from p57null(-/-) mutant calvaria showed increased the proliferation rate and higher alkaline phosphatase activity than that of wild type. In nodule formation assay, mineralization was siginificantly delayed in osteoblasts derived from -/- mice in the absence or presence of 1,25 vitamin D_3. Surprisingly, osteopontin mRNA expression was supressed by the addition of 1,25 vitamin D_3 . However -/-osteoblasts expressed the comparable amount of Vitamin D receptor mRNA to that of wild type. Moreover we have investigated the role of $p57^{kip2}$ on osteoclast formation. Osteoclast formation was also reduced in a co-culture system of -/-osteoblasts and wild type bone marrow cells in the presence of 1,25 vitamin D_3. Taken together, these results may suggest a possible involvement of p57 related to 1,25 vitamin D_3 signaling in the control of both osteoblast proliferation and osteoblast/osteoclast differentiation.

SU184

Increased Sensitivity of Osteoblast-like Cells Against Phosphate-induced Apoptosis Upon Pretreatment with Heparin. H. J. Hausser*, R. Brenner. Division for Biochemistry of Joint and Connective Tissue Diseases, University of Ulm, Ulm, Germany.

Long-term treatment with heparin has been associated with an increased risk of osteoporosis. While the mechanism(s) involved remain to be established, it can be hypothesized that heparin somehow interferes with the normal regulation of bone cells by heparin-binding growth factors. To shed some light on the pathogenesis of heparin-induced osteoporosis, we treated osteoblast-like cells (Saos-2) in monolayer cultures with different concentrations of heparin. After pretreating cells with 0.5 µg/ml heparin for 10 days, we observed a rapid loss of viable cells upon addition of ß-gylcerophosphate (10 mM). Cell death was due to apoptosis, as evidenced by positive TUNEL staining. Interestingly, RT-PCR analysis revealed that heparin treatment led to an increased expression of glypican-3. This glycosylphosphatidylinositol-anchored heparan sulfate proteoglycan which is mutated in Simpson-Golabi-Behmel Syndrome has been shown to induce apoptosis in a cell line-specific manner upon overexpression. Consistent with a possible involvement of this proteoglycan in the increased apoptosis-sensitivity of heparin-treated Saos-2 cells, preliminary data indicate that insulin-like growth factor 2 inhibts the ß-glycerophosphate-induced apoptosis. Our results support a model in which heparin-treatment leads to cellular changes which renders osteoblasts in the remodeling units more sensitive to apoptosis induced by phosphate liberated by active osteoclasts.

SU185

Transient versus Sustained Activation of Extracellular Signal Regulated Kinases (ERKs): A Potential Explanation for the Opposite Effects of Sex Steroids on Osteoblast and Osteoclast Apoptosis. J. R. Chen, S. Kousteni, L. Han, T. Bellido, R. S. Weinstein, C. A. O'Brien, R. L. Jilka, S. C. Manolagas. Division of Endocrinology and Metabolism, Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, U/sity of Arkansas for Medical Sciences, Little Rock, AR, USA.

Estrogens and androgens exert pro-apoptotic effects on osteoclasts but anti-apoptotic effects on osteoblasts, via nongenotropic mechanisms of action of their classical receptors. However, heretofore there is no mechanistic explanation for the diametrically opposite effects of these hormones on the life span of the two cell types. Based on evidence that estrogens or androgens exert their anti-apoptotic effects on osteoblasts via activation of both a Src/Shc/ERK and a PI3K signal transduction pathway, and downregulation of JNK, we have investigated here whether their pro-apoptotic actions on osteoclasts require similar signals. For this purpose osteoclasts were prepared from stromal-cell free cultures in the presence of MCS-F and soluble RANKL and were then pre-treated for 1 hour with either U012345 or PP1, specific inhibitors of ERK and Src phosphorylation, respectively. Cultures were maintained in the presence of 17β-estradiol (E_2) or dihydrotestosterone (DHT) for 24 hours and apoptosis was assayed by monitoring the nuclear morphology of TRAPase positive cells. Both U012345 and PP1 abrogated the pro-apoptotic effects of E_2 and DHT, indicating that as in the case of the anti-apoptotic effects of sex steroids on osteoblasts, their pro-apoptotic effects on osteoclasts are mediated through a Src/ERK signaling pathway. Nonetheless, Western blot analysis of ERK phosphorylation in osteoclasts revealed a dissimilar temporal pattern to that seen in osteoblasts. Indeed, in contrast to a rapid and transient phosphorylation of ERKs in osteoblasts, reaching a peak at 5 minutes and declining thereafter, in osteoclasts both E_2 and DHT induced the phosphorylation of ERKs within 15 min, and the extent of phosphorylation increased progressively thereafter for at least 24-hours. These results indicate that the opposite effects of estrogens and androgens on osteoblast and osteoclast survival are mediated via modulation of the same signaling pathways; and as shown elsewhere in this meeting result from a nongenotropic function of the classical receptors and an interchangeable ligand/receptor interaction in cells from females and males. However, sustained activation of ERKs in osteoclasts as opposed to transient activation of ERKs in osteoblasts may be responsible for the striking difference between stimulation of apoptosis in the former and attenuation of apoptosis in the latter cell type.

SU186

Prevention of Glucocorticoid-Induced Apoptosis in Osteocytes and Osteoblasts by Calbindin-D_{28k}. Y. Liu*[1], A. Porta*[1], R. Donnelly*[1], T. Bellido[2], S. Christakos[1]. [1]UMDNJ - New Jersey Medical School, Newark, NJ, USA, [2]Endo/Metab Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Health Care System,Univ. of Arkansas for Medical Sciences, Little Rock, AR, USA.

Recent studies have indicated that deleterious effects of glucocorticoids on bone involve increased apoptosis of osteocytes and osteoblasts. Since the calcium binding protein calbindin-D_{28k} has antiapoptotic properties in different cell types and in response to a variety of insults, we investigated whether calbindin-D_{28k} could also protect against glucocorticoid-induced cell death in bone cells. Apoptosis was induced by addition of dexamethasone (dex) (10^{-6}M) for 6h to cells transiently transfected with pREP4 vector or vector containing the cDNA for calbindin-D_{28k} together with an expression vector for nuclear green fluorescent protein. Apoptosis was assessed by evaluating nuclear morphology of > 100 transfected (fluorescent) cells. Dex-induced nuclear fragmentation of MLOY-4 osteocytic cells transfected with pREP4 vector (4.0% versus 16.7% apoptotic cells, -dex and + dex respectively). However the proapoptotic effect of dex was blocked in cells transfected with calbindin-D_{28k} cDNA (5.7% apoptotic cells + dex; $p< 0.01$ compared to vector transfected cells + dex). Similar results were observed in UMR osteoblastic cells and in primary murine osteoblastic cells. Dex-induced apoptosis in bone cells was accompanied by an increase in caspase 3 activity. The presence of calbindin markedly attenuated the activity of caspase 3. In vitro assays indicated a concentration dependent inhibition of caspase 3 by calbindin-D_{28k} (0.09 µM - 1.8 µM, K_i =0.22 µM). Calbindin-D_{28k} was found to act as an inhibitor and to bind to caspase 3 but not to act as a substrate for caspase 3. Calbindin inhibits caspase 3 specifically since the activity of caspases 1, 2, 4, 5, 6, 7 and 8 was unaffected by calbindin. Tryptic peptides of calbindin were separated and purified using HPLC and a 6,800 mw fragment was found to be responsible for most of the caspase 3 inhibitory activity. Besides inhibition of caspase 3, the antiapoptotic effect of calbindin in response to dex was also reproducibly associated with an increase in the phosphorylation of extracellular signal regulated kinases 1 and 2 (ERK 1 and 2). Although the mechanism is not known, this finding suggests that calbindin inhibits glucocorticoid-induced apoptosis not only by direct inhibition of caspase 3 but also by activation of survival kinases such as ERKs. This study, which is the first to demonstrate the prevention of glucocorticoid induced bone cell death by calbindin-$D_{28k,}$ has important implications for the therapeutic intervention of glucocorticoid-induced osteoporosis.

SU187

Osteoprotegerin (OPG) Binds TNFα with 2-20 nM Affinity and Regulates TNFα-Induced Apoptosis. R. Bu, C. W. Borysenko*, Y. N. Li*, L. Cao, H. C. Blair. Biochemistry, Pathology and Physiology & Cell Biology, U Pittsburgh, Pittsburgh, PA, USA.

TNF-family proteins are pivotal in the equilibrium of osteoclast and osteoblast activity. Osteoblast apoptosis is driven by cytokines including TNFα, a homolog of RANKL, which drives osteoclast maturation. The decoy receptor OPG modulates two TNFs, RANKL and TRAIL, but other OPG interactions are undefined. Osteoblasts express RANKL and OPG, paradoxically, since OPG neutralizes RANKL. We hypothesized that OPG has additional TNF interactions. We examined effects of OPG apoptosis induced by TNFα using MG63 cells. At 3-10ng/ml, TNFα increased apoptosis in serum free media 10 fold at 2-4h. This was diminished to near control by OPG at 10-30 ng/ml, by annexin V binding or TUNEL. This suggested that OPG protects osteoblasts from TNFα-induced apoptosis. It was, however, unclear whether the mechanism involved reverse signalling by osteoprotegerin bound to RANKL, a transmembrane protein, or an interaction with TNFα. We compared binding of TNFα, RANKL, and TRAIL by immune precipitation and found that OPG binds all of these in PBS at physiological pH. Western blots confirmed specificity of antibodies, with no detectible cross-reaction even with 100 ng of alternate TNF or receptor proteins. Solid phase adsorption, surface plasmon resonance, and carbodiimide crosslinking were used to study these interactions further. Ethyl-3 (dimethylaminopropyl)carbodiimide (EDC) crosslinked human TNFα and OPG efficiently, demonstrating binding in solution, but preventing interaction when TNFa or OPG are crosslinked to dextran support by EDC. However, murine OPG was active after EDC-surface crosslinking for plasmon resonance (Biacore 3000) and showed TNFα binding with dissociation constants 2.4-18 nM. In ELISA, human OPG/TNFα affinity was 2.4-21 nM. Varying binding constants reflected differences with conditions including molar ratios in solution, pH (6.8-8.0), salt concentration, and temperature, which suggest complex physiological interactions. Human RANKL binds both human and mouse OPG-Fc after EDC crosslinking while neither TRAIL nor TNFα did, suggesting that the RANKL interaction involves different OPG sites than binding to TRAIL or TNFα. Numerous other interactions can be studied using plasmon resonance and results include that mouse and human TNFα form heterotrimers. This study suggests that interactions between TNF receptors and TNFs are likely to involve complex interactions including mixed complexes of receptors and heterotrimers of TNFs. Some interactions may be weak, and not of physiological importance, although puzzling interactions such as effects of RANKL on osteoblasts may involve mechanisms related to novel interaction of TNFs and TNF receptors.

SU188

Extra- and Intracytoplasmic Domains of Syndecan-2 Play Distinct Roles in the Control of Osteoblast Proliferation and Apoptosis. D. Modrowski, E. Hay*, S. Le Mee*, P. J. Marie. INSERM U349, Paris, France.

Syndecans are cell surface heparan sulfate proteoglycans that serve as co-receptors and modulate the actions of a large number of extracellular ligands. We previously showed that syndecan-2 (Synd2) modulates the mitogenic activity of GM-CSF in human osteoblastic cells. To further examine the role of Synd2 in osteoblasts we overexpressed Synd2 in MG63 human osteoblastic cells. Full-length Synd2 cDNA was cloned in the expression vector pEGFP-C1 (Synd2-pEGFP). Site-directed mutagenesis was used to obtain a cDNA coding for Synd2 without its carboxyterminal motif (ΔCterSynd2-pEGFP). The cDNA coding for Synd2 lacking for its intracytoplasmic domain (ΔCSynd2-pEGFP) was obtained by PCR. The three constructions or the empty vector (pEGFP) were transfected into MG63 cells for transient or stable expression. Overexpression was confirmed by RT-PCR and Western Blot analysis until 4 days after transfection. Overexpression of Synd2-GFP and ΔCterSynd2-GFP increased cell proliferation for 3 days following transfection when compared with control cells transfected with pEGFP. In contrast to Synd2, transient expression of Synd2 lacking the intracytoplasmic domain (ΔCSynd2-pEGFP) dramatically decreased cell proliferation. Selection with G418 allowed to obtain few clones stably expressing GFP or ΔCterSynd2-GFP, and many clones stably expressing ΔCSynd2-GFP. All clones of cells transfected with Synd2-pEGFP died after 15 days of selection, suggesting induction of apoptosis. We therefore examined whether Synd2 controls apoptosis in MG63 cells. Most Synd2-pEGFP transfected cells were found to be positive for TdT-mediated X-dUTP Nick End Labeling (TUNEL) performed after 11 days of antibiotic selection. In contrast, TUNEL was strikingly decreased in ΔCSynd2-GFP expressing cells compared with control cells or ΔCterSynd2-GFP expressing cells. Accordingly, DNA fragmentation determined on agarose gel was increased in cells that transiently expressed Synd2-GFP and decreased in ΔCSynd2-GFP cells, when compared with GFP or ΔCterSynd2-GFP cells. Consisting with these results, caspases-2 and -9 and effector caspases-3, -6, -7 activities were increased by 40, 57, and 45 %, respectively, in Synd2-GFP expressing cells compared with control cells. The results show that 1) Synd2 controls osteoblastic cell proliferation and apoptosis, 2) the proximal part of Synd2 cytoplasmic domain is required for osteoblastic cell proliferation and 3) overexpression of Synd2 induces apoptosis whereas Synd2 lacking its whole intracytoplasmic domain protects MG63 cells from apoptosis. Thus, extra- and intra-cytoplasmic domains Synd2 play distinct roles in the control of osteoblast proliferation and apoptosis.

SU189

Ionizing Radiation Increases Apoptotic Sensitivity and Cell Cycle Arrest in Cultured Osteoblasts. K. H. Szymczyk*, I. M. Shapiro, C. S. Adams. Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA.

While a great deal is known about the effects of ionizing radiation on soft tissue, little is known on its effects on the resident cells of bone. To test the hypothesis that radiation induces bone cells apoptosis, we exposed MC3T3-E1 osteoblast-like cells to gamma-radiation (1.8 to 60 Grays). Cell viability was assessed using the MTT assay. Twenty-four hours post-irradiation, a small decrease in cell viability was noted. TUNEL and TEM analysis revealed that the decrease in viability was not due to the induction of apoptosis. However, there was a dramatic increase in sensitivity to apoptogens. We noted that when irradiated osteoblasts were treated with physiologically relevant apoptogens and chemotherapeutic agents, the number of cells killed by each apoptogen was dependent on the radiation dose. Moreover, the apoptogens and radiation acted synergistically to enhance cell killing. Since the number of surviving cells is dependent on the rate of cell proliferation, we measured osteoblast proliferative response by flow cytometry. Flow cytometric analysis demonstrated that the irradiated osteoblasts underwent cell cycle arrest. In addition, Western blot analysis indicated that p21 and GADD 153 were both elevated in a dose-dependent manner; there was no evidence of p53 activation. It is concluded that irradiation has at two-fold effect on osteoblasts: an increase in apoptotic sensitivity and activation of cell cycle arrest. Studies are in progress to determine if these events occur concomitantly, or are independent of each other.

SU190

Osteoblast Shape, Cytoskeleton and Extracellular Interactions Altered by Hyperosmolarity. S. Botolin*, M. Zayzafoon, L. R. McCabe. Physiology, Michigan State University, East Lansing, MI, USA.

Diabetes mellitus is often accompanied with complications, including bone loss and increased fracture rate. This disease is marked by elevated blood glucose levels and hyperosmolarity. Changes in cell shape and cell volume are important in cell responsiveness and accommodation to a hyperosmotic environment. Therefore, we investigated MC3T3 osteoblast cell shape and expression of proteins involved in shape and volume regulation during acute and chronic hyperosmotic exposure. Exposure to hyperosmotic (320 mOsm) media resulted in significant osteoblast shrinkage. Specifically, osteoblasts developed a more satellite appearance that was clearly evident one hour following treatment. Consistent with this finding, modifications in proteins associated with cell shape were also found and were still evident with long term hyperosmotic exposure. Treatment of osteoblasts daily with media containing an additional 22 mM of glucose, mannitol or contrast dye resulted in an increase in the concentration of heat shock protein HSP27 and osmotic stress protein 94 (Osp94). The induction of these molecular chaperones/cytoskeleton stabilizers is likely a protective response of osteoblasts to chronic exposure to hyperosmotic stress. In addition, levels of connexin 43 and integrin beta 5 were also increased, suggesting that cell-cell and cell matrix interactions are also altered. Taken together, our findings demonstrate that exposure of osteoblasts to hyperglycemic/hyperosmotic conditions associated with poorly controlled diabetes can cause significant changes in osteoblast shape, cytoskeleton and extracellular interactions. Based on our previous findings we hypothesize that these changes contribute to altered osteoblast function.

CpG Methylation Around Transcription Start Site of RANKL Gene Controls Its Steady-State Expression. S. Kitazawa, R. Kitazawa. Division of Molecular Pathology, Department of Biomedical Informatics, Kobe University Graduate School of Medicine, Kobe, Japan.

Receptor activator of NF-kB ligand (RANKL) is a membrane-bound signal transducer requisite for differentiation and maintenance of osteoclasts. RANKL expression on stromal/osteoblasic cells is tightly regulated to maintain physiological serum calcium levels and bone mass. These stromal/osteoblasic cells, however, comprise a rather heterogeneous population ranging from immature mesenchymal cells to mature osteoblasts and also respond differently to bone resorptive stimuli. In the mouse coculture system, we also have demonstrated the passage-dependent difference of cultured mouse stromal cells in supporting osteoclastogenesis because of altered RANKL gene expression. To address the issue of what molecular mechanism gives the diversity of RANKL gene expression to stromal/osteoblastic cells, we characterized mouse and human RANKL gene promoters. The former promoter contains two CpG clustering regions: one around the transcription start site and the other downstream of the vitamin D response element (VDRE). The latter, on the other hand, containes one CpG clustering region around the transcription start site. Using earlier- and later-passage mouse ST2 cells, we analyzed the CpG methylation status by sodium bisulfite mapping and found that CpG loci around the transcription start site (-66/+246) were predominantly methylated in later-passage ST2 cells. Moreover, earlier- and later-passage ST2 cells transfected with a RANKL promoter construct showed the same steady-state level of luciferase activity and of the inducible effect of 1,25(OH)2D3. Furthermore, the introduction of methylation to the promoter construct silenced promoter activity. Taken together with the fact that DNA methyltransferase (Dnmt) 3b, a de novo DNA methylase, increases in both senescent and immortalized cells, our results suggest that CpG methylation around the transcription start site of the RANKL gene is an important development and a senescence-related epigenetic event, and that its heterogeneity might cause the diversity of the stromal/osteoblastic cells in RANKL gene expression.

SU192

PTH Induction of the Osteocalcin Gene: Requirement for an 82 bp Sequence in the Promoter and Involvement of Multiple Signaling Pathways. G. Xiao, D. Jiang*, R. T. Franceschi. Periodontics/Prevention/Geriatrics, The University of Michigan, Ann Arbor, MI, USA.

Parathyroid hormone (PTH) is an important peptide hormone regulator of bone formation and osteoblast activity. However, its mechanism of action in bone cells is largely unknown. The present study examined the mechanism of PTH regulation of the mouse osteocalcin gene in MC3T3-E1 preosteoblastic cells. PTH stimulated osteocalcin mRNA and promoter activity in a dose and time-dependent manner. Deletion of the promoter sequence from -1316 to -116 caused no change in PTH responsiveness while deletion from -116 to -34 led to complete loss of PTH stimulation. Interestingly, this promoter region does not contain the Runx2 binding site shown to be necessary for PTH responsiveness in other systems. Either H89 or PKI, two specific PKA inhibitors, blocked the PTH response. Forskolin alone, a PKA activator, stimulated OCN expression, but did not increase the PTH response. GF109203X, a specific PKC (protein kinase C) inhibitor, also abolished PTH stimulation. The PTH response is not blocked by U0126, a specific mitogen-activated protein kinase (MAPK) inhibitor. Thus, both PKA and PKC pathways are required for this regulation. Furthermore, phorbol 12-myristate 13-acetate (PMA), an activator of the PKC pathway, dramatically increased the PTH effect although it alone only slightly stimulated gene expression. Interestingly, this synergy was blocked not only by H89, GF109203X, but also by U0126, indicating that MAPK pathway is also required for this regulation. Collectively, these results indicate that PTH stimulation of OCN gene expression requires PKA, PKC, as well as MAPK signaling pathways.

SU193

Transcriptional Profiling of Human Osteoblast Differentiation. J. Billiard[1], R. Moran*[1], K. Gillis*[2], M. Chatterjee-Kishore*[2], E. Brown*[2], L. Sauter*[2], M. Whitley*[2], E. Wilson*[2], B. Komm[1], P. Bodine[1]. [1]Women's Health Research Institute, Wyeth Research, Collegeville, PA, USA, [2]Expression Profiling Sciences, Wyeth Research, Cambridge, MA, USA.

We have developed a collection of human conditionally immortalized cell lines in discrete stages of osteoblast (OB) differentiation. In the present study, we used four cell lines representing preosteoblasts, early and late mature OB, and preosteocytes to analyze changes in gene expression that occur during differentiation. Their respective phenotypes were confirmed by cell morphology and expression of appropriate osteoblastic markers. The mRNA samples from each cell line were subjected to gene chip analysis using the Affymetrix Hu6800 chip (7070 genes) and a custom chip enriched in bone and cartilage cDNAs (3378 genes). The experiment was performed twice on two sets of RNA. A 3-fold change in gene expression between preosteocytic and preosteoblastic stages was considered significant. Overall, 44 genes were found to consistently change in both experiments. Many of the differences reflect expected patterns and support the relevance of our results. These include down-regulation of osteoprotegerin, collagen type I and its processing enzyme, lysyl oxidase, as well as up-regulation of matrix metalloproteinase 1 and plasminogen activator. Other changes have not been reported and offer new insight into the OB differentiation process. Several genes regulating cell proliferation increased with differentiation, among them was the inhibitor of apoptosis, survivin, a member of TNF superfamily CD27L, and the metastasis-promoting S100A4 protein. Cell motility and migration promoting factors including autotaxin, midkine, and CTGF peaked in early and late mature OBs. We also saw changes in mRNAs involved in maintaining the cytoskeleton and extracellular matrix. Actin filament capping protein and α tubulin increased, whereas OB-cadherin and ankyrin decreased during differentiation. Our screen also identified several genes whose role in the differentiation process is uncertain. These include a small ras-related GTPase associated with diabetes that increased with differentiation, an HMG-box transcription factor, SOX4, that was down-regulated, and several components of the complement pathway that decreased with differentiation. The inhibitor of osteoclast formation, follistatin, also decreased with OB differentiation. In summary, this study provides a comprehensive profile of gene expression during human OB differentiation. Gene chip analysis is a powerful tool permitting us to associate genetic changes with OB physiology. With this information the role of the OB in the bone remodeling process will become more completely characterized.

Use of Human Genome Data to Identify a DNA Fragment that Completely Recapitulates the Hormone/Cytokine Regulation of the RANKL Gene: A Key Advance Toward Full Elucidation of its Molecular Control. Q. Fu, S. C. Manolagas, C. A. O'Brien. Div. of Endo/Metab, Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

PTH, $1,25(OH)_2D_3$, and the gp130 cytokines stimulate osteoclastogenesis and bone resorption primarily by upregulating the expression of RANKL in cells of the stromal/osteoblastic lineage. The mechanisms by which these agents stimulate RANKL expression remain poorly understood. Previous studies using murine RANKL promoter-luciferase constructs containing up to 7 kb of 5'-flanking region have produced inconsistent results with some studies finding a 2-fold stimulation by $1,25(OH)_2D_3$ while other studies find no stimulation by any osteoclastogenic agents. With the ultimate goal of identifying mechanisms involved in RANKL gene expression, we utilized the human genome sequence contig map to identify a bacterial artificial chromosome (BAC) containing a 200 kb fragment of human DNA encompassing the 40 kb RANKL gene flanked on both sides by more than 70 kb. The BAC harboring this fragment was obtained and modified by homologous recombination to contain a Neo cassette and used to stably transfect UAMS-32 cells which express endogenous RANKL in response to cAMP analogs, OSM, or $1,25(OH)_2D_3$. Several clones containing the full-length BAC, as assessed by Southern blot analysis with probes corresponding to regions near either end of the 200 kb fragment, were analyzed for basal and stimulated expression of the human RANKL gene by Northern blot using a human-specific RANKL probe. Seven of 7 clones expressed human RANKL mRNA which was upregulated by dibutyryl-cAMP, $1,25(OH)_2D_3$, or OSM by an average of 10-, 8-, or 4-fold, respectively. The level of basal human RANKL mRNA expression varied among the clones and was not correlated with gene copy number. Dibutyryl-cAMP stimulated transcription, as assessed by nuclear run-on, of both the human RANKL transgene and the endogenous murine RANKL gene. These results indicate that cis- and trans-acting regulators of the RANKL gene are sufficiently conserved between humans and mice such that the human gene can be appropriately expressed in murine cells. Further, cis-acting elements necessary for regulation by osteoclastogenic agents lie within 70 kb of the beginning or end of the human RANKL gene. However, these regions are not sufficient for position-independent or copy-number dependent expression. Identification of the cis-acting sequences necessary for regulation of this construct by osteoclastogenic agents in stromal/osteoblastic cells, and thereby the trans-acting factors that bind them, should provide novel targets for anti-resorptive therapy.

SU195

Overexpression of DLK (delta-like, EGF-like Homeotic Protein) Enhances the Adipogenic Differentiation but Maintain Osteoblastic Differentiation of Human Bone Marrow Stromal Cells. B. M. Abdallah*[1], C. Jensen*[2], G. Leslie*[2], T. Jensen*[3], M. Kassem[1]. [1]Endocrinology, University Hospital of Odense, Odense, Denmark, [2]Immunology, University of Southern Denmark, Odense, Denmark, [3]Genetics, University of Aarhus, Aarhus, Denmark.

The molecular mechanisms of human marrow stromal cells (mesenchymal stem cells, hMSC) differentiation into specific lineages are poorly understood. Dlk (delta-like, also known as pref-1, FA-1) belongs to a family of transmembrane proteins containing epidermal growth factor-like repeat motifs homologus to the notch/delta/serrate. Dlk is involved in the control of several cellular differentiation processes including adipogenesis and it has been reported to inhibit adipocyte differentioation of the preadipocyte 3T3-L1 cell line. As hMSC can differentiate into several cell lineages including adipocytes, the role of dlk in controlling the differentiation processes was examined. Gene expression of dlk was quantitated using a reverse-transcriptase polymerase chain reaction (RT-PCR) and Northern analysis. Normal hMSC obtained from different donors was shown to express constitutively dlk. Furthermore, dlk was expressed in human fetal osteoblast cell line (hFOB) as well as human fetal bones (gestation age 5, 8 and 12 weeks) but was down regulated in adult bone. Full-length DLK cDNA from human liver cDNA library was cloned and subsequently subcloned in a retroviral expression vector (GCsam) that was employed to stably transfect hMSC/TERT$^+$: a human telomerase-immortalized MSC line capable for differentiation into multiple cell types including osteoblasts and adipocytes (Simonsen et al, Nature Biotechnology, 2002 in press).The resultant cell line (hMSC-dlk$^+$) was shown to express high levels of dlk protein in the conditioned media (more than 1.2 μg/ml versus 0.2 μg/ml in control cells) as determined by ELISA and more than 90% of the cells expressed dlk as shown by immunostaining. In contrast to 3T3-L1 cell line, when MSC-dlk$^+$ cells were induced to adipocyte differentiation in a medium containing insulin, dexametasone, IBMX and BRL49653, they formed a larger number of adipocytes as determined by fluorescence-activated cell sorting (FACS) analysis and higher levels of gene expression of PPAR-γ2 and lipoprotein lipase (LPL) compared to control cells. In addition, MSC-dlk$^+$ maintained their osteoblast differentiation potential as estimated by gene expression of osteocalcin, collagen type I and alkaline phosphatase and cytochemical staining for alkaline phosphatase. Our data suggest that dlk signaling does not mediate the adipogenic commitment of hMSC, although dlk overexpression enhances the response of the hMSC to the adipogenic differentiation signals.

SU196

Vitamin D Induces Thrombomodulin Expression in Osteoblasts. A. L. M. Sutton*, D. R. Dowd*, P. N. MacDonald. Pharmacology, Case Western Reserve University, Cleveland, OH, USA.

Vitamin D is critical for the proper development and maintenance of the skeleton. 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) is the bioactive metabolite of vitamin D that functions through the vitamin D receptor (VDR), a member of the nuclear hormone receptor family. The $1,25(OH)_2D_3$-VDR complex acts on bone both indirectly, by regulating calcium and phosphate homeostasis, and directly by modulating osteoblast and osteoclast activity. In particular, vitamin D inhibits the proliferation and induces the differentiation of osteoblasts. To characterize novel genes regulated by $1,25(OH)_2D_3$ in MG-63 human osteoblastic cells, we utilized gene expression array analysis. This approach identified several genes that are highly induced following a 6-hour treatment with 10^{-8}M $1,25(OH)_2D_3$. One of these transcripts encodes thrombomodulin, a transmembrane anticoagulant protein. Northern blot analysis shows a time- and dose-dependent induction of thrombomodulin expression by vitamin D treatment in MG-63 cells. Thrombomodulin mRNA is undetectable without vitamin D treatment, but appears after three hours and steadily increases up to 24 hours of treatment with vitamin D. This up-regulation is specific for $1,25(OH)_2D_3$ since another vitamin D metabolite, $24,25(OH)_2D_3$, does not affect thrombomodulin expression. Additionally, cycloheximide treatment only minimally diminishes this response, suggesting that the vitamin D-induced increase in thrombomodulin mRNA does not require *de novo* protein synthesis. Thrombomodulin is a membrane protein known for its anticoagulant effects in the cardiovascular system. However, thrombomodulin is expressed in a variety of other tissues, including the lung, keratinocytes, and developing bone, suggesting that it may have other functions. Since vitamin D regulates cellular differentiation and thrombomodulin is expressed in the developing bone, we hypothesize that thrombomodulin may be involved in vitamin D-mediated differentiation of osteoblasts. Studies are currently underway to elucidate the function of thrombomodulin in osteoblasts and to map the promoter elements responsible for the vitamin D response.

SU197

Gene Expression Profiling Analysis of BMP-2 Induced Commitment Towards the Osteoblast Lineage. E. Balint[1], D. S. Lapointe*[2], H. Drissi*[1], A. J. van Wijnen[1], J. L. Stein*[1], J. B. Lian[1], G. S. Stein[1]. [1]Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA, [2]Information Services, University of Massachusetts Medical School, Worcester, MA, USA.

Runx-2 and BMP-2 are both required for osteogenic lineage commitment and differentiation. To identify gene regulatory mechanisms that drive osteoblast differentiation in response to BMP-2 and in relation to the induction of Runx-2, gene expression microarray analysis was performed. Total RNA was isolated from C2C12 cells at 1, 2, 8, 12 and 16 hours following BMP-2 treatment. Northern blot analysis confirmed suppression of myogenic genes and induction of osteoblast phenotypic genes with Runx-2 mRNA detected by 16 hours in two independent experiments. Gene expression profiling analysis was carried out using hierarchical clustering, SOM analysis and functional clustering. Approximately 900 out of the 13,000 genes showed a minimum change of 1.8-fold throughout the time course. About half of these genes are either activated or repressed during differentiation. Approximately 250 genes were continually upregulated, 450 were continually downregulated, while the remainder exhibited transient elevations during the BMP-2 time course. Functional groups with particular expression patterns including signaling proteins, growth factors, receptors and cell cycle regulators were identified. Among the genes in the functional clusters were known BMP-2 responsive genes, validating the experimental model. Within these clusters we also identified numerous genes with no known function in the bone environment. Consistent with the appearance of the osteoblast phenotype detected by Northern blot analysis, phenotypic, extracellular and cell adhesion proteins begin to exhibit changes in expression at about 8-12-16 hours. In contrast, a representative group of transcription factors (n=62) show sequential patterns of induction or inhibition throughout the time course. A subset (20%) of these transcription factors including both activators and repressors, are acutely induced in response to BMP-2 (1 hour). Subsequent waves of transcription factor induction/repression follows at 2, 8, 12 and 16 hours. The functional clustering method allows predicting functions of genes and EST's clustering together with known genes. Additionally, the functional gene clusters permit identification of common regulators for functionally related groups of genes that exhibit similar expression patterns. This global analysis of expressed genes provides insight to the understanding of the regulatory events that coordinate BMP-2 and Runx-2 activities in osteogenesis.

SU198

A Region of the hBMP-6 Promoter Contributing to Basal and Glucocorticoid-Mediated Effects. Y. Liu[1], G. A. Hair*[1], M. Viggeswarapu[1], M. Nellis*[2], L. Titus[3], S. Voorhees*[1], S. D. Boden[1]. [1]Orthopaedics, Emory University, Atlanta, GA, USA, [2]Atlanta Research and Education Foundation, Decatur, GA, USA, [3]Research, VA Medical Center, Decatur, GA, USA.

The glucocorticoid regulation of osteoblast differentiation is mediated by a 5-8 fold induction of BMP-6 mRNA and protein in secondary rat calvarial cell cultures. To determine the molecular mechanism by which BMP-6 is regulated, we constructed luciferase reporter vectors by inserting the previously characterized hBMP-6 promoter and its 5' flanking region into the pGL3-Basic vector. Transfection of sequential 5' and internal deletion constructs of the reporter vectors along with a GC receptor (GR) expression vector into HeLa cells revealed that the region –869 to –598 is important in mediating both basal and GC-inducible luciferase expression. GC induction was typically 2-3 fold. Luciferase activities of the constructs containing the region –869 to –598 were significantly higher than that of the proximal promoter(-90 to +12) alone. Accordingly, deletion of this region dramatically reduced both basal and GC-induced activities. However, sequence analysis of the region revealed no consensus glucocorticoid responsive element. Further segmentation of the region revealed that a construct containing the 5' end of this region (-869 to -780) retains significant luciferase activity. In order to determine segments of the –869 to –598 region important for transcription factor binding, DNase I footprinting and EMSAs were performed. The primary data demonstrated that nuclear extracts of Hela cells transfected with GR differentially bound to three DNA segments (5'end –869 to –780; midregion –779 to -714 and 3'end –713 to -598) depending on GC treatment. Glucocorticoids increased binding of the nuclear extracts to the 5' end, decreased binding to the 3'end, and did not affect binding to the midregion. We conclude that glucocorticoid can regulate BMP-6 expression at the transcriptional level probably through an indirect mechanism and the region –869 to -598 is critical for both basal and GC-regulated expression.

SU199

Gene Expression Profiles and Transcription Factors Involved in PTH Signaling in Osteoblasts Revealed by Microarray and Bioinformatics. L. Qin[1], P. Qiu*[2], L. Wang*[2], X. Li*[1], P. Tolias*[1], N. C. Partridge[1]. [1]Physiology and Biophysics, University of Medicine and Dentistry of NJ, Piscataway, NJ, USA, [2]Schering-Plough Research Institute, Kenilworth, NJ, USA.

PTH is a major mediator of bone remodeling and an essential regulator of calcium homeostasis having both anabolic and catabolic effects on bone. Prolonged exposure to PTH causes increased bone resorption. The molecular mechanism of PTH signaling in the osteoblast is still largely unknown. UMR 106-01, a rat osteosarcoma osteoblastic clonal cell line, is a model system to study the effects of PTH *in vitro*. The present study was designed to delineate genes and pathways that are regulated by PTH (10^{-8} M) using DNA microarray techniques and bioinformatics approaches. Total RNA, isolated from UMR 106-01 cells collected at 4, 12 and 24 h after treatment with or without 10^{-8} M PTH, was converted into cRNA and hybridized to an Affymetrix rat genomic microarray chip. After stringent filtering, 126 known genes and 30 unknown ESTs were found to have at least 2-fold expression changes in the PTH-treated samples. Most genes previously known to be regulated by PTH were also identified in this screening, such as MMP-13, IGFBP-5, fos, Nurr77, tPA, decorin, fibronectin etc. Real-time quantitative RT-PCR experiments confirmed that about 90% of the genes are indeed regulated by PTH in UMR 106-01 cells and about 50% in primary osteoblasts. Most of these genes belong to the following protein families: hormones, growth factors and their receptors; signal transduction pathway proteins; transcription factors; proteases; metabolic enzymes; structural and matrix proteins; transporters. Analysis of these genes identified several novel biological pathways regulated by PTH, including neurotrophic factor signaling, neurotransmitter signaling, growth factor and cytokine signaling, feedback regulation of signal transduction pathways and glucose metabolism. Next, we designed a computation method to identify the transcription factors involved in PTH signaling. Using human genome sequence, we found human orthologs for 73 genes from the 126 PTH-regulated genes and 61 genes' promoter start site were annotated. The promoter sequences from these genes were matched against a transcription factor database to identify transcription factors that have significantly higher numbers of binding sites within these promoter regions compared to random occurrences. Those transcription factors that are possibly involved in PTH signaling include AP-1, C/EBP, CREB, AP-2, AP-4, myc, SP1, FoxD3 etc. Our data demonstrate that PTH has profound effects on many aspects of osteoblasts through a limited set of transcription factors, suggesting a commonality of signaling pathways.

The Early Response Gene Epidermal Growth Factor Response Factor (ERF-1) Is Regulated by Parathyroid Hormone and Expressed in Osteoblastic Cells. S. Reppe*[1], O. K. Olstad*[1], J. E. Reseland*[2], E. Rian*[3], V. T. Gautvik*[1], G. J. Kjendlie*[1], K. M. Gautvik[1], R. Jemtland*[4]. [1]Department of Medical Biochemistry, University of Oslo, Oslo, Norway, [2]Institute for Nutrition Research, University of Oslo, Oslo, Norway, [3]Department of Immunology, The Norwegian Radium Hospital, Oslo, Norway, [4]Endocrine Section, Department of Medicine, The National University Hospital, Oslo, Norway.

We have recently identified ERF-1 as one of the genes that are up-regulated by human recombinant PTH(1-84) in human OHS osteoblast-like cells using cDNA expression arrays (Atlas). ERF-1 (also known as butyrate response factor (BRF1), TIS11b, or cMG1) is a member of the TIS11 gene family comprising early response genes that binds DNA through a highly conserved Cys3His binding motif. Northern blot analysis showed that ERF-1 mRNA was up-regulated 3-4 fold in OHS cells treated with hPTH(1-84) for 24h. hPTH(1-84) and hPTH(1-34) (10-9 - 10-10M), but not hPTH(3-84), increased ERF-1 mRNA expression in a time-dependent manner. Forskolin and 8-Br-cAMP duplicated the stimulation of ERF-1 mRNA levels by PTH, while protein kinase C activator TPA was without effect. H89, a protein kinase A (PKA) inhibitor, blunted the stimulatory effects of 8-Br-cAMP or hPTH(1-84) on ERF-1 mRNA expression in OHS cells during co-incubation. These data indicate that PTH increases ERF-1 mRNA levels via activated PTH/PTHrP receptors, where the cAMP-dependent adenylyl cyclase (AC) signaling pathway is important. ERF-1 is also expressed in various human and rodent clonal osteoblast-like cells and ERF-1 mRNA levels are enhanced by PTH(1-84) treatment in primary mouse calvarial osteoblasts cultured for 7d in osteogenic medium. In contrast, treatment of primary osteoblasts with recombinant bone morphogenetic protein 2 (BMP2) caused reduced ERF-1 mRNA levels relative to controls. The expression pattern of ERF1 in differentiating primary human osteoblasts is currently under investigation. This is, as far as we know, the first report to show that ERF-1 is part of the PTH response in osteoblasts via receptor-coupled activation of the cAMP/AC/PKA pathway.

SU201

Gene Expression Regulation During Osteoblast Differentiation of Mesenchymal Stem Cells by Microarray Analysis. W. T. Steegenga*, J. M. A. Hendriks*, W. Olijve, E. J. J. van Zoelen*. Applied Biology and Cell Biology, University of Nijmegen, Nijmegen, Netherlands.

Mesenchymal stem cells are the cells which can, upon receipt of the right triggers, differentiate into osteoblasts. Osteoblast differentiation is a multistep series of events modulated by an integrated cascade of gene expression. To search for new genes involved in the early and late phase of osteoblast differentiation on a large scale, microarray (MA) technology was employed. In a first MA experiment murine C2C12 mesenchymal progenitor cells were induced to differentiate into mature osteoblasts by treatment with bone morphogenetic protein 2 (BMP2). Analysis of the regulated transcripts showed the activation of a number of transcription factors not previously identified as regulators of osteoblast differentiation. We are currently analysing the effects of these genes on Cbfa1 transcription activation. In addition, by means of cluster analysis a large number of potential new late phase bone makers were identified. The bone specificity of the identified late response genes was determined by comparing BMP2-induced expression in C2C12 and MC3T3 osteoblasts with that in NIH3T3 fibroblasts. This resulted in the identification of 9 novel genes and ESTs that were specifically induced in osteoblasts, in addition to the well-known markers alkaline phosphatase and osteocalcin. Expression of three of these putative late phase bone markers was observed *in vivo* in developing bone by *in situ* hybridisation of E16.5 mouse embryos. In a second MA experiment we analysed gene expression regulation during 34 days of osteoblast differentiation of human mesenchymal stem cells on 15 different time points. Results will be presented showing the regulation of a number of well established bone markers and of many previously unidentified transcripts in different phases of the differentiation process. By means of hierarchical clustering, these genes can be grouped by similarities in their expression profiles, resulting in subsets of early, intermediate and late response genes, which are representative of the distinct stages of the osteoblast differentiation process. Analysis of the pathways leading to the regulation of the genes present in the independent clusters is under current investigation.

SU202

Cell-cell Interaction Mediated by Cadherin-11 Selectively Enhances the Mesenchymal Tissue Formation. I. Kii*, A. Kudo. Life science, Tokyo Institute of Technology, Yokohama, Japan.

Cell-cell interaction is an essential event for tissue formation, however, the role of cell-cell adhesion in cell differentiation and tissue formation is unclear. Cadherins form the adherence junction and adhere cells. Recently, it has been suggested that cadherin has abilities to differentiate cells and form several tissues through its adhesion in the embryonic stem cell-derived teratomas; E-cadherin promotes the epithelial tissue formation, and N-cadherin promotes the bone, cartilage and neuroepithilium formation. The osteoblasts were reported to express N-cadherin and cadherin-11, and N-cadherin was indispensable for osteoblasts to induce the alkaline phosphatase activity and form the nodule structures. The targeted disruption of cadherin-11 leads to loss of bone density. Here, we demonstrate that cadherin-11 is widely expressed in the mesenchymal tissues, and cell-cell adhesion mediated by cadherin-11 is responsible for the mesenchymal tissue formation. We examined the localization of cadherin-11 proteins and RNAs in tissues. The immunohistochemical analysis of paraffin sections of the E16.5 mouse embryo head revealed that cadherin-11 proteins were localized in the mesenchymal tissues: osteoblasts, muscle cells, chondrocytes, stromal cells, and vascular pericytes or smooth muscle cells. Whole mount RNA in situ hybridization analysis of the mouse skulls in the stage of E15.5-E18.5 indicated that cadherin-11 was expressed conspicuously in the sutural mesenchyme and pre-osteoblastic cells. To search the function of cadherin-11 in the osteoblastogenesis, the calvarial development of cadherin-11-/- neonatal mice was investigated. Cadherin-11-/- neonatal mice had an ectopic island ossification in the metopic sutural mesenchyme by the side of nasal bone, while the ectopic island ossification was scarcely observed in +/+ neonatal mice, and the smaller one was observed in +/- neonatal mice. These results suggest that cadherin-11 participates in the formation or maintenance of the sutural mesenchyme. Next, we examined the role of cadherin-11 in cell differentiation. The cadherin-11 overexpressed embryonic stem cells were implanted subcutaniously, and teratomas were formed. HE staining showed that the teratomas derived from cadherin-11 overexpressed ES cells produced higher amounts of bone, cartilage and muscle tissues than those from control embryonic stem cells to which the empty vector was introduced. These results demonstrate that cadherin-11 selectively enhanced the mesenchymal tissue formation. In conclusion, cell-cell interaction mediated by cadherin-11 is responsible for the enhancement and maintenance of the mesenchymal tissues containing bone and cartilage.

SU203

Interleukin-6 and Interleukin-11 Modulate Osteoblast Differentiation and RANKL Expression via Activation of JAK-STAT Signal Transduction Pathway. C. Shih, J. F. Shyu. Biology and Anatomy, National Defense Medical Center, Taipei, Taiwan Republic of China.

Interleukin (IL)-6 and IL-11 are members of IL-6 type cytokines which play important roles in normal and abnormal bone remodeling (e.g. postmenopausal osteoporosis) via regulation of cell proliferation and differentiation. IL-6 and IL-11 enhance formation and function of osteoclast via stromal/osteoblastic cells. So far, the effects of IL-6 and IL-11 on Janus kinase (JAK)/signal transducer and activator of transcription (STAT) signal transduction pathway and receptor activator of NF-kB ligand (RANKL) in bone cells are still not well known. The purposes of this study were to investigate 1)which of the JAK/STAT family members or MAP kinase are involved in mediating actions of IL-6 and IL-11 and 2)the relationshop between the activation of IL-6 and IL-11 signal pathways and the biological effects of IL-6 and IL-11 in primary osteoblasts and MG-63 cells. Osteoblasts ($4x10^5$/10 cm Petri dish) were grown to confluence, incubated in low serum (0.5%) and stimulated with different concentrations of IL-6 or IL-11. Cell were lysed in lysis buffer. Lysates were centrifugated and immunoprecipitated with the appropriate antibodies (JAK1/JAK2/TYK2/STAT1/ STAT3/MAPK). Tyrosine phosphorylation was determined by anti-phosphotyrosine Western blotting. Effect of IL-6 or IL-11 (10, 100 or 1000 U/ml) on RANKL expression and osteoblast differentiation were assessed by Western blotting and alkaline phosphatase (ALP) activity assay. Both JAK1 and JAK2 were tyrosine phosphorylated with IL-6 while only JAK1 was tyrosine phosphorylated with IL-11. Moreover, with IL-6 or IL-11, both STAT1 and STAT3 were tyrosine phosphorylated and translocated to the nucleus. Both IL-6 and IL-11 caused a dose-related increases in RANKL expression and stimulated ALP expression in osteoblasts. In conclusion, IL-6 and IL-11 modulate osteoblast differentiation and RANKL expression via the activation of specific members of JAK-STAT pathways.

Expression of Phospholipid Receptors and a Phospholipid Phosphatase in Osteoblast Cells. B. L. Hill, C. Xu*, K. E. Callon, J. Cornish, A. Grey. Medicine, University of Auckland, Auckland, New Zealand.

The naturally occurring phospholipids lysophosphatidic acid (LPA) and sphingosine-1-phosphate (S1P) induce mitogenic and anti-apoptotic responses in a variety of cells. Previously we have described these effects, and characterized the intracellular signaling pathways which subserve them in primary rat osteoblasts and the rat osteoblast cell line UMR-106 treated with either LPA or S1P. The proliferative and anti-apoptotic actions of each phospholipid in osteoblastic cells were sensitive to the Gi protein inhibitor pertussis toxin, implying the involvement of G protein-coupled receptors. In this study we report the expression of specific cell membrane bound receptors for LPA and S1P and a cell membrane associated phospholipid phosphatase in osteoblastic cells. The edg family of G-protein coupled receptors comprise those that bind LPA with high affinity (edg 2, 4 and 7) and those that bind S1P (edg 1, 3, 5, 6 and 8). Both primary rat osteoblasts and UMR-106 cells express the S1P receptors edg 1 and 5 as assessed by RT-PCR but do not express edg 3, 6 or 8. Immunohistochemical analysis of whole fixed primary rat osteoblasts confirmed the presence of edg 1 protein on the surface of these cells. The LPA receptor edg 2 was identified by RT-PCR in primary rat osteoblasts and UMR-106 cells. Membrane-associated phospholipid phosphatases (LPP-1 and LPP-3) are believed to regulate the availability of LPA and S1P for binding to the edg receptors. RT-PCR analysis of primary rat osteoblasts and UMR-106 cells indicates expression of LPP-1 by these cells. We conclude that the mitogenic and anti-apoptotic actions of LPA and S1P on primary rat osteoblasts and the rat cell line UMR-106 are via the interaction of these ligands with their specific edg receptors which are expressed in an osteoblast specific manner. The interaction of LPA and S1P with these receptors is likely to be further regulated by the presence of phospholipid phosphatase on the surface of these cells.

The P55 TNF Receptor Mediates TNF Inhibition of Osteoblast Differentiation. L. Gilbert*, A. Brantley*, J. Rubin, M. S. Nanes. Division of Endocrinology, Department of Medicine, Emory University and VAMC, Atlanta, GA, USA.

Tumor necrosis factor-α contributes to the pathophysiology of osteoporosis by stimulating bone resorption and inhibiting new bone formation. We have previously shown that TNF is a potent inhibitor of osteoblast differentiation from their pluripotent precursor cells in fetal calvaria, marrow stroma, or in clonal MC3T3-E1 pre-osteoblast cells (Gilbert et al Endocrinology 141:3956 2000). TNF action is mediated by structurally homologous cell surface receptors, p55 and p75, that differ in function. The identity of the TNF receptor type expressed by pre-osteoblasts is unknown since these cells are studied in a mixed culture system. To determine which TNF receptor mediates inhibitory effects on the differentiation of osteoblasts, the effect of TNF was studied in marrow stromal cells obtained from mice genetically deficient in one or both TNF receptors and in control mice matched for the C57BL/6 genetic background. These mice have been reported to be born at the expected Mendelian frequency and to have no overt phenotype. Progression of stromal cells toward the osteoblast phenotype was assessed by monitoring the formation of a mineralizable matrix using the von Kossa stain and by measurement of the secretion of the osteoblast-specific matrix protein osteocalcin. Marrow stromal cells were cultured for 14 days in alpha-MEM supplemented with 10% fetal calf serum, ascorbate, and β-glycerophosphate. Post-confluent control cultures formed mineralized nodules by day 8 and secreted osteocalcin. Treatment of wild type cultures with TNF (10ng/ml) from days 1-14 or 2-14 completely inhibited the formation of mineralized nodules. TNF-treated cells remained viable. In cultures derived from either $p55^{-/-}$ or $p55^{-/-}p75^{-/-}$ mice, TNF treatment had no effect on osteoblast differentiation. Both $p55^{-/-}$ and $p55^{-/-}p75^{-/-}$ cultures appeared indistinguishable from their respective controls whether or not treated with TNF. Osteocalcin levels were (mean±SEM ng/ml): wild type control, 207±6; wild type TNF treated, 2.1±0; p55-/-p75-/- control, 188±8; p55-/-p75-/- TNF treated, 155±33.6; p55-/- control, 192±25.3; p55-/- TNF treated, 215±4. These results support the requirement for the p55 TNF receptor as a mediator of TNF inhibition of osteoblast differentiation.

Perfusion Culture System Improves Osteogenesis of Rat Bone Marrow-Derived Osteoblastic Cells in Porous Ceramic Materials. Y. Wang*[1], T. Uemura[1], J. Dong[1], H. Kojima[1], T. Tateishi[2]. [1]Tissue Engineering Research Center (TERC), National Institutes of Advanced Industrial Science and Technology (AIST), Tsukuba, Ibaraki, Japan, [2]Biomedical Engineering Laboratory, University of Tokyo, Tokyo, Japan.

Perfusion culture has showed benefits to many cell types in three-dimensional (3D) culture. In this study, we made an attempt to increase bone formation in composites of BMO and β-tricalcium phosphate (β-TCP) by perfusion culture method. For *in vitro* test, BMO/β-TCP composites were cultured in perfusion container (Minucells and Minutissue, Bad Abbach, Germany) with fresh medium delivered at a rate of 2 ml/hr by the peristaltic pump to the perfusion container. ALP activity and osteocalcin (OCN) contents of composites were measured at the end of 1, 2, 3 and 4 weeks of subculture. For *in vivo* test, after subculture for 2 weeks as described above, the composites were implanted into syngeneic rats subcutaneously. These implants were harvested at 4 or 8 weeks after implantation. Then the samples underwent biochemical analysis of alkaline phosphatase (ALP) activity, OCN and histological analysis. ALP activities and OCN contents in the composites of perfusion group were obviously higher than that of the control group both *in vitro* and *in vivo*. Light microscopy and SEM revealed more active bone formation in BMO/β-TCP composites at 4 weeks and 8 weeks after implantation. These data show that application of perfusion culture system during subculture of BMO in porous ceramic scaffold is beneficial to their osteogenesis activity. After differentiation culture *in vitro* by perfusion culture system, the activity of the osteoblastic cells and the consequent bone formation *in vivo* can be significantly enhanced. These results suggest the described perfusion culture system is a valuable and convenient tool for applications in tissue engineering, especially in the generation of artificial bone tissue.

Melatonin Promotes the Osteoblastic Differentiation and Bone Formation. R. Tokuyama*[1], K. Satomura[1], S. Tobiume*[1], K. Yamanouchi*[2], K. Kume*[1], E. Kitaoka*[1], S. Nishisho*[1], N. Masuda*[1], Y. Hibi*[1], M. Nagayama*[1]. [1]First Department of Oral and Maxillofacial Surgery, School of Dentistry, The University of Tokushima, Tokushima, Japan, [2]Department of Dentistry and Oral Surgery, Tokushima Red Cross Hospital, Tokushima, Japan.

Melatonin is the major hormone secreted by the pineal gland, and its levels are synchronized by environmental light. A number of recent studies demonstrated that melatonin regulated a variety of physiological processes including control of circadian rhythms, regulation of reproductive function, regulation of temperature, sexual development and immune system. Moreover, melatonin is known to influence the release of growth hormone and cortisol in human. These findings suggest that melatonin may have an influence on skeletal growth and bone formation. However, little is known about the influence of melatonin on osteoblasts or bone formation. This study was performed to determine whether melatonin could regulate the proliferation and differentiation of human osteoblasts *in vitro* and mouse bone formation *in vivo*. Reverse transcription-polymerase chain reaction and Western blotting analysis showed that human osteoblasts expressed melatonin 1a receptor and that its expression levels decreased gradually with age of hosts. Melatonin stimulated the proliferation of human osteoblasts in a dose-dependent manner at the concentrations between 50 and 200 μM. In addition, alkaline phosphatase activity of human osteoblasts was enhanced by melatonin at concentrations equal to and more than 10 μM. Melatonin also promotes the expression of mRNA for bone-related genes such as type I collagen, osteopontin, bone sialoprotein and osteocalcin in a dose-dependent manner at concentrations ranging from 1 to 200 μM. Moreover, melatonin stimulated the mineralized matrix formation *in vitro* at the concentration as low as 100 μM. To evaluate the effect of melatonin on bone formation *in vivo*, melatonin was intraperitoneally administered to mice at a dose of 100 mg/kg of body weight. Histological analysis using the labeling with tetracycline and calcein revealed that the volume of newly formed bone of femora increased by the treatment with melatonin. Taken together, these results suggest the possibility that melatonin plays a potential physiological role in bone formation and skeletal growth.

SU208

Tachykinins Stimulate Bone Formation by Rat Calvarial Osteoblasts via the Neurokinin-1 Receptor. T. Goto[1], E. Fukuhara*[2], K. Kometani*[3], S. Kobayashi*[1]. [1]Oral Anatomy, Kyushu Dental College, Kitakyushu, Japan, [2]Oral Surgery, Kyushu Dental College, Kitakyushu, Japan, [3]Orthodontics, Kyushu Dental College, Kitakyushu, Japan.

Tachykinins are neuropeptides that work as neurotransmitters and neuromodulators, and are found throughout the body. Substance P (SP), neurokinin A (NKA), and neurokinin B (NKB) are the major subtypes of tachykinins, and their receptors (neurokinin (NK) -1, -2, and -3 receptors) form the three receptor subtypes. To identify the role of tachykinins in bone formation, we investigated the expression of NK1-Rs in osteoblasts and the effects of SP, NKA, and NKB on bone formation by rat calvarial osteoblasts. Rat calvarial osteoblasts were isolated from the calvariae of three-day-old Wistar rats, and cultured for three weeks in alpha-MEM containing 10% serum, ascorbic acid, dexamethasone, and beta-glycerophosphate. We examined NK1-R expression using RT-PCR, and the binding of fluo-SP to cultured osteoblasts. The effects of SP, NKA, and NKB were investigated by adding these neuropeptides to the culture medium. Furthermore, the effects of blocking these peptides by using SP and NK1-R antagonists were examined. NK1-R mRNA expression and fluo-SP binding were found in 16-day cultured osteoblasts, but not in 8-day cultured osteoblasts or osteoblastic cells ROS. A significant increase in bone formation by cultured osteoblasts was observed with the addition of 10(-7) – 10(-6) M SP or 10(-11) – 10(-9) M NKB, but not NKA. These increases in bone formation with the addition of SP or NKB were inhibited by the addition of SP or NK1-R antagonists. The results indicate that SP and NKB stimulate bone formation by osteoblasts at the late stage of bone formation via NK1-Rs, and that this process is dependent on the expression of NK1-Rs in osteoblasts. These findings suggest that neuropeptides secreted from sensory neurons modulate bone formation following expression of their receptors.

SU209

The Effect of Connective Tissue Growth Factor (CTGF) on Differentiation and Adhesion of MC3T3-E1 Osteoblast-like Cells. R. A. Kanaan*[1], P. Ebrahimpour*[1], S. L. Smock*[2], T. A. Owen[2], S. N. Popoff[1], F. F. Safadi[1]. [1]Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA, [2]Cardiovascular and Metabolic Diseases, Pfizer Global R&D, Groton, CT, USA.

Connective tissue growth factor (CTGF) is a secreted, extracellular matrix-associated signaling protein that regulates diverse cellular functions including adhesion, proliferation and differentiation. We recently showed that osteoblasts *in situ* express CTGF during active growth of the skeleton as well as during fracture repair. Primary osteoblast cultures demonstrated a bimodal pattern of CTGF expression being relatively high during the period of proliferation and reaching peak levels during the period of mineralization. Furthermore, blocking the activity of the endogenous CTGF produced and secreted in these cultures using an anti-CTGF antibody caused a dramatic dose-dependent inhibition of nodule formation and mineralization. In this study, we first examined the effect of CTGF overexpression on osteoblast differentiation by transient transfection of MC3T3-E1 cells with a CMV-CTGF construct. CTGF over-expression resulted in significant increases in alkaline phosphatase activity and calcium deposition (mineralization) compared to control cultures that were treated with transfection reagent alone or transfected with an empty vector. Other studies have shown that specific integrins serve as receptors for CTGF on fibroblasts and endothelial cells. We examined whether MC3T3-E1 cells can adhere to an immobilized CTGF substrate and determined whether specific integrins are involved in this adhesive interaction. MC3T3-E1 cells were plated into culture wells pre-coated with increasing concentrations of recombinant CTGF (rCTGF) with 1% BSA serving as a control substrate. MC3T3-E1 cells adhered to the rCTGF wells in a dose-dependent manner with maximal adherence in wells coated with 5 μg/ml. We then examined whether specific integrins mediate this adhesive interaction by pre-incubating the MC3T3-E1 cells with a panel of anti-integrin antibodies including anti-αvβ3, -αIIbβ3, and -αvβ5. The anti-αvβ5 antibody decreased cell adhesion by 70%, while other antibodies, such as the anti-αvβ3 antibody, had no effect on cell adhesion. These data suggest that the integrin αvβ5 acts as a receptor for CTGF on MC3T3-E1 cells. The induction of distinct signaling pathways mediated by a CTGF/integrin interaction may provide a molecular basis for at least some of the effects of CTGF on osteoblast differentiation.

SU210

Crosstalk between Vitamin C and Vitamin D Signals on the Differentiation of Human Osteoblast-like (MG-63) Cells. R. Hata[1], S. Takamizawa*[2], Y. Maehata*[2], K. Izukuri*[2], Y. Kato*[2], K. Imai*[3], H. Senoo*[3], S. Sato*[4], A. Kimura*[5]. [1]Department of Biochemistry and Molecular Biology, Bioventure Research, Kanagawa Dental College, Yokosuka, Japan, [2]Department of Biochemistry and Molecular Biology, Kanagawa Dental College, Yokosuka, Japan, [3]Department of Anatomy, Akita University School of Medicine, Akita, Japan, [4]Department of Orthodontics, Kanagawa Dental College, Yokosuka, Japan, [5]Department of Molecular Pathology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan.

In order to investigate mechanisms of human osteoblast differentiation, we employed culture system of MG-63, human osteosarcoma derived cells. The cells were cultured in Dulbecco's modified Eagle's medium with various additives. When the medium was supplemented with L-ascorbic acid 2-phosphate (Asc 2-P, 0.25 to 10 mM), a long-acting vitamin C derivative, growth of the cells was stimulated in the early phase of the culture. Relative rate of collagen synthesis of the cells and alkaline phosphatase (Alk-Pase) activity, a marker for osteoblast differentiation were also increased. The stimulative effects of Asc 2-P on the growth and Alk-Pase activity were attenuated by the co-presence of 0.25 mM azetidine 2-carboxylic acid or 0.2 mM ethyl dihydroxybenzoate, inhibitors for collagen synthesis, suggesting these stimulative effects are dependent on collagen synthesis. Comparison of levels in mRNAs obtained from two culture conditions, cultures in the absence and presence of Asc 2-P, by a gene chip method, indicated that increases in messenger RNA for type III collagen chain is responsible for the increase in collagen synthesis. Addition of 1-alpha, 25-dihydroxycholecalciferol (active vitamin D3, 10 to 100 nM) in the culture medium suppressed growth of the cells but stimulated Alk-Pase activity. Co-presence of Asc 2-P and active vitamin D3 showed synergistic action on the Alk-Pase activity but relatively less effect on the growth of the cells. These data indicate that the presence of crosstalk between vitamin C and vitamin D signals on the expression of Alk-Pase activity, a marker for osteoblast differentiation.

SU211

Effect of Acyl-CoA Binding Protein on Bone Cell Differentiation. H. Si*[1], H. Kim*[1], J. Kim*[1], Y. Kim*[1], Y. Jung*[1], S. Lee*[2], S. Kim[3], H. Ryoo[4], S. Mandrup*[5], R. Park*[1], I. Kim[1], J. Choi[1]. [1]Biochemistry, Kyungpook Natl. Univ. School of Medicine, Daegu, Republic of Korea, [2]Advanced Materials Division, Korea Research Institute of Chemical Technology, Daejeon, Republic of Korea, [3]Orthopedics, Kyungpook Natl. Univ. School of Medicine, Daegu, Republic of Korea, [4]Oral Biochemistry, Kyungpook Natl. Univ. School of Dentistry, Daegu, Republic of Korea, [5]Molecular Biology, Odense University, Odense, Denmark.

Dietary fatty acid has been known as a modulator of the onset and progression of various diseases such as osteoporosis, osteoarthritis, diabetes, obesity and hypertension. The acyl-CoA binding protein(ACBP), intracellular acyl-CoA pool former and transporter of acyl-CoA thioesters, is ubiquitously expressed 10 kDa protein and its gene expression is upregulated during adipogenic differentiation. However, the ACBP function in bone cells remains unknown. The biological activity of ACBP on bone cells was determined by Northern blot analysis, RT-PCR and stable transfection experiment using chondrocyte and osteoblast differentiation models. The expression of ACBP mRNA was the highest at proliferation stage and down regulated at matrix maturation stage and increased again at differentiation stage but less than that of proliferation stage during ATDC5 chondrocyte differentiation. However, the expression of ACBP mRNA was gradually decreased during MC3T3-E1 osteoblast differentiation. To know the loss of function effect, ATDC5 and MC3T3-E1 cells were stably transfected with ACBP antisense or control empty expression vectors. The antisense ATDC5 cells, which expressed ACBP antisense mRNA, showed higher alkaline phosphatase activity and gene expression of osteonectin, type II collagen, and type X collagen than those of control cells. These results indicate that suppression of ACBP gene expression stimulates chondrocyte differentiation. However, the expression of antisense ACBP mRNA in MC3T3-E1 cells showed the inhibition of osteoblastic differentiation. The antisense MC3T3-E1 cells showed lower alkaline phosphatase activity than that of control cells during osteoblast differentiation. Taken together, suppression of ACBP gene expression stimulates chondrocyte differentiation but inhibits osteoblast differentiation. This implicates that lipid metabolism is important in bone cell differentiation.

Differential Growth Factor Regulation of Bone Formation by Human Osteoprogenitor Cells *in vitro*. L. R. Chaudhary[1], A. M. Hofmeister*[2], K. A. Hruska[1]. [1]Pediatrics, Washington University School of Medicine, St. Louis, MO, USA, [2]Earth & Planetary Sciences, Washington University, St. Louis, MO, USA.

The osteogenic factors BMP-7, PDGF-BB, FGF-2 and dexamethasone (Dex) regulate the recruitment of osteoprogenitor cells, their proliferation and differentiation into mature osteoblasts, and play important roles in bone formation. However, their mechanisms of action on osteoprogenitor cell growth, differentiation, and bone mineralization remain unclear. Here, we examined the effects of various osteogenic agents on these parameters with Dex serving as a positive control. Human bone marrow stromal cells were plated in 6-well culture plates ($1x10^5$ cells/well) and treated with BMP-7 (40 ng/ml), PDGF-BB (20 ng/ml), FGF-2 (20 ng/ml), FGF-2 plus BMP-7, or Dex (10^{-7} M) for 28 days in the α -MEM medium containing 10% FBS, 10 mM β -glycerophosphate and 50 μg/ml ascorbic acid. The medium was changed twice weekly with respective treatments. BMP-7 regulated the entire osteoblast differentiation program. It decreased osteoprogenitor proliferation, and stimulated CBFA1 expression, cuboidal morphology, alkaline phosphatase (ALKP) levels and Alizarin Red S positive nodule formation which was shown by Fourier Transform Infrared (FTIR) spectroscopy to be due to hydroxyapatite (HA) deposition into a type I collagen matrix. Dex treated cells appeared elongated and fibroblast like compared to BMP-7 treated cells and BMP-7 effects exceeded those of Dex on the other parameters such as ALKP levels and cell morphology. FGF-2 did not stimulate ALKP, CBFA1 and cell morphology was distorted. PDGF-BB stimulated cell proliferation and had little or no effect on CBFA1, ALKP activity and biomineralization. Alizarin Red S staining of cells indicated that BMP-7, Dex and FGF-2 enhanced calcium mineral deposition, but Alizarin Red S stains all calcium mineral deposits. FTIR spectroscopic analysis of BMP-7 and Dex treated samples demonstrated the formation of HA similar to human bone but no HA formation was observed in control, PDGF-BB and FGF-2 treated samples. Although FGF-2 stimulated a dystrophic calcium mineral deposition. When FGF-2 and BMP-7 were added together, BMP-7 stimulation of ALKP and HA formation was inhibited. Our results demonstrate that BMP-7 has stimulatory effects on the osteoblast differentiation program leading to increased bone formation. The other factors were active at discrete parts of the program and were dystrophic or inhibitory, if present at the wrong stage of osteoblast differentiation.

hMSCs-Host Interactions in Ectopic Bone Formation. R. A. Dodds*[1], M. Jennings*[1], R. Young*[1], L. Kostura*[1], W. S. Zhou*[2], L. F. Cooper[2]. [1]Osiris Therapeutics, Baltimore, MD, USA, [2]University of NC, Chapel Hill, NC, USA.

In the absence of any stimulation, mesenchymal stem cells (MSCs) remain undifferentiated in culture. Upon attachment to an HA/TCP matrix, the MSC differentiates along the osteoblast (MSC-Ob) lineage and when implanted contributes to ectopic bone formation *in vivo*. The goal of this study was to determine the contribution of host-specific osteoinductive signals associated with osteogenesis supported by HA/TCP adherent MSCs. To achieve this goal, human (h) MSCs adherent to HA/TCP matrices (60/40 fibronectin coated) were subcutaneously implanted in the dorsum of SCID mice for 3-21 days (d), and osteogenesis evaluated at the tissue and molecular level by cytochemistry, immunohistochemistry and RT-PCR. Matrices were loaded with 1.5 x 10^6 hMSC, h-skin fibroblasts (Fb), or were cell free (Cf). Serial sections were reacted for alkaline phosphatase (AP), TRAP, non-specific esterase (monocytes, monos) and expression of h-specific antigen Ok^a. RNA isolated from explants was amplified (Taq polymerase) using species-specific primers for mouse (m) and human (h) BMP2, BMP6, BSP, CD14 (monos) and GAPDH mRNAs. Reactions were evaluated by transillumination of ethidium bromide stained gels. AP activity was evident in human Obs (Ok^a positive) as early as 3d. MSC-Ob differentiation (diff) increased at 14d, and was extensive by 21d. Bone formation apparent at 14d and 21d was associated with both OK^a positive (h-Obs) and Ok^a negative host cells. MSC-Ob diff was absent in the Fb loaded and Cf controls. Monos were evident at the periphery of the matrices in all groups, at all time points. Initial MSC-Ob diff (3-7d) preceded osteoclast (Ocs) diff; by 14-21d TRAP positive Ocs (mono- derived) were observed adherent to the HA/TCP. This association of Ocs with Ob diff is indicative of subsequent coupling between human Obs and mouse Ocs, and osteogenesis. Ocs were not observed in the matrices loaded with Fb or the Cf controls. Thus, Oc diff within the matrices was directly associated with hMSCs. Host-specific m-BMP2 was noted at all time points in all groups; m-BMP6 was expressed 7-21d. The early expression of m-BMP2 and 6 paralleled the expression of m-CD14 mRNA in all groups. At 3d, h-BMP2 and -6 expression was not observed but progressively increased thereafter, peaking at 21d. h-BSP expression was detected at 14d and 21d, paralleling the histological appearance of bone in hMSC containing matrices. From this data, we propose that the expression of m-BMP2 indicates the contribution of host osteoinductive signals at the HA/TCP matrix. When adherent hMSCs were present diff along the Ob lineage occurred, highlighting the importance of providing responsive cells within controlled host tissues to promote bone repair.

Effects of Cyclooxygenase-2 Gene Disruption on Osteoblastic Cell Growth. Z. Xu*, S. Choudhary*, C. B. Alander, L. G. Raisz, C. C. Pilbeam. Medicine, University of Connecticut Health Center, Farmington, CT, USA.

To study the role of cyclooxygenase-2 (COX-2) in osteoblastic function, we used primary calvarial osteoblasts derived from COX-2 wild type (+/+) and knockout (-/-) mice obtained by mating C57Bl/6x129 COX-2 heterozygote (+/-) mice. Calvariae from 5-8 wk old COX-2 +/+ and -/- mice were sequentially enzymatically digested; cell populations 2-5 were pooled, grown to confluence for 7-8 d and replated for experiments at 5000/cm^2. Similar to previous results in bone marrow stromal cell cultures, alkaline phosphatase (AP) activity was decreased in COX-2-/- cultures relative to COX-2+/+ cultures at 1-2 wk. Differences in AP activity were reversed by adding NS-398 (10^{-7} M), a selective inhibitor of COX-2 activity, to COX-2+/+ cultures or treating COX-2-/- cultures with PGE_2 (10^{-6} M). To determine if differences between COX-2+/+ and -/- cultures were due to differences in cell growth, cells were resuspended and counted by Coulter counter. COX-2-/- cultures had 1.8-fold more cells at day 5 of culture and 2.2-fold more cells at day 7 than COX-2+/+ cultures. Differences could not be accounted for by non-adherent cells since the percent floating cells was the same in COX-2+/+ and -/- cultures at day 5. Culture of COX-2+/+ cells with NS-398 (10^{-7} M) increased cell numbers on days 5 and 7 by 92-95%. Culture of COX-2-/- cells with PGE_2 (10^{-6} M) decreased cell numbers on days 5 and 7 by 57-79%. Measurement of viable cell number using the XTT assay (based on mitochondrial activity) showed 1.5-fold more viable cells in COX-2-/- cultures than in COX-2+/+ cultures at day 7 of culture. To examine differences in DNA synthesis, we measured the incorporation of ^{3}H-thymidine (TdR) during a 2 h pulse on day 4 of culture. TdR normalized to cell number was significantly increased in COX-2-/- cultures relative to COX-2+/+ cultures in 3 separate experiments, with the mean increase being 1.8-fold. In these 3 experiments, some cultures were serum deprived for 24 h to synchronize cells and then given medium with fresh serum (10% FCS) to stimulate cell growth. 48 h after addition of serum cell number had increased 2.7-fold cells in COX-2-/- cultures and 1.8-fold in COX-2+/+ cultures; TdR normalized to cell number was 1.7-fold greater in COX-2-/- cultures. To examine resistance to cell death, we measured the change in viable cell number with the XTT assay following 24 h of serum deprivation on day 4 of culture. COX-2+/+ cell number did not change, while COX-2-/- cell number fell by 77%. We conclude that absence of COX-2 in calvarial osteoblastic cultures decreases early markers of osteoblastic differentiation, increases cell number as a result of enhanced cell proliferation, and may decrease resistance to stress-induced cell death.

SU215

Site-Specific *In Vivo* Response to Osteogenic Induction by Human Bone Marrow Stromal Stem Cells of Different Embryonic Origins. S. O. Akintoye*[1], S. Shi*[1], J. Brahim*[2], M. T. Collins*[1], P. G. Robey[1]. [1]Craniofacial and Skeletal Diseases Branch, National Institute of Dental and Craniofacial Research/National Institutes of Health, Bethesda, MD, USA, [2]Clinical Research Core, National Institute of Dental and Craniofacial Research/National Institutes of Health, Bethesda, MD, USA.

The bone marrow contains a combination of different cell types that secrete various connective tissue components. Because of the osteogenic potential of bone marrow stromal compartment, injection of autologous bone marrow into surgical defect is commonly used to generate bone. Although the craniofacial bones (CF) develop embryologically from neural crest cells while the axial and appendicular bones develop from mesoderm, it is still unclear if there exists site-specific genetic and phenotypic differences in human bone marrow stromal stem cells (hBMSSCs) from these sites. The aim of this study was to investigate differences in bone formation by hBMSSCs of different embryonic origins. Bone marrow samples from CF (specifically, maxilla and mandible), and iliac crest (IC) were obtained from a normal adult female volunteer. hBMSSCs were established in culture using α-MEM (minimum essential medium) containing 20% fetal bovine serum supplemented with or without osteogenic inducers: dexamethasone (10^{-8} M) and ascorbic phosphate (10^{-4} M). Differentiation capacity of the cells was characterized *in vivo* by transplantation of 2 $x10^6$ cells attached to ceramic particles (hydroxyapatite/tricalcium phosphate) into the subcutis of immunocompromised mice. Six populations of cells (IC, maxilla and mandible hBMSSCs with and without osteogenic inducers) were transplanted in duplicates and harvested at different time points: 4, 6, 10 and 12 weeks. Each transplant was fixed, decalcified and hematoxylin/eosin stained sections were prepared for histological analysis. Bone formation was scored using an established system. Without osteogenic inducers, CF formed more bone than IC at each time point. When stimulated by osteogenic inducers, IC was more sensitive than CF by forming bone 2 weeks earlier, and more bone quantitatively. Interestingly bone formed by CF were isolated islands with less hematopoietic marrow compared with IC bone that was more compact and contained more hematopoietic marrow. To our knowledge this is the first time hBMSSCs of different embryonic origins are being compared from the same donor. Further understanding of these site specific differences is needed as it may have an impact on selection of graft materials to repair osseous defects.

SU216

Unfractionated Heparin Enhances IL-11-Induced STAT3 Activation And Leads To Increased Osteoclastogenesis *in vitro*. K. J. Walton*, J. M. Duncan*, M. K. G. Butcher*, P. Deschamps*, S. G. Shaughnessy. Pathology and Molecular Medicine, McMaster University, Hamilton, ON, Canada.

We have previously demonstrated that long-term heparin treatment causes cancellous bone loss in rats due in part to an increase in the number of osteoclasts lining the trabecular bone surface. In the present study, we investigated this phenomenon by examining the ability of heparin to synergistically enhance IL-11-induced osteoclast formation. Treatment of murine calvaria and bone marrow cells with IL-11 was found to induce the formation of tartrate resistant acid phosphatase positive ($TRAP^+$) multinucleated cells (MNCs) in a dose dependent fashion. No effect was seen when co-cultures were treated with heparin alone. However, when co-cultures were treated with both IL-11 and heparin, IL-11's ability to induce $TRAP^+$ MNC formation was enhanced 6-fold. In an attempt to resolve the mechanism responsible for this effect, we examined the ability of heparin to influence IL-11 signaling using murine calvaria cells. Heparin was found to enhance both IL-11-induced STAT3-DNA complex formation and transactivation, without altering either STAT3 tyrosine or serine phosphorylation. Heparin was also found to enhance IL-11's ability to induce the expression of both receptor activator of NF-κβ ligand (RANKL) and glycoprotein (gp)130. When taken together, these findings suggest a plausible mechanism by which heparin may cause increased osteoclastogenesis and therefore bone loss when administered long-term.

SU217

Modulation of the Purinergic Ca2+ Signaling Pathway in Osteoblasts by Olpadronate: Evidence on the Existence of a Bisphosphonate Receptor. G. Santillan*[1], S. Katz*[1], G. Stockman*[1], R. L. Boland*[1], E. Roldan*[2]. [1]Biologia, Bioquimica & Farmacia, Universidad Nacional del Sur, Bahia Blanca, Argentina, [2]Gador S.A., Buenos Aires, Argentina.

We have observed before that in rat osteoblasts (ROS 17/2.8 cells) both olpadronate (OPD) and its R1-aminosubstituted derivative IG-9402 interact with the purinergic calcium signaling pathway, rapidly modulating cytosolic Ca2+ levels by a mechanism implying activation of the PLC/IP3 pathway, release of Ca2+ from IP3-sensitive intracellular stores and influx of extracellular Ca2+. In the present work we have further characterized this interaction. Spectrofluorimetric measurements in Fura-2-loaded ROS 17/2.8 cells showed that stimulation with ATP (5 - 50 μM) in the absence of external Ca2+ induced a fast and transient cytosolic Ca2+ rise. When calcium was added to the medium, Ca2+ influx from the outside through voltage-dependent (VDCC) and store-operated calcium (SOC) channels was observed. Addition of OPD (0.1 - 1 μM) after ATP treatment inhibited Ca2+ entry in the presence of 5μM nifedipine and 5μM verapamil but not in the absence of the VDCC inhibitors. These results suggest that OPD blocks ATP induced calcium influx through SOC but not VDCC channels, acting at the mechanisms which couple inner store depletion and Ca2+ entry. Also, previous radioligand binding studies using [H3]OPD revealed the presence in ROS 17/2.8 cells of a saturable and high affinity binding site for OPD (Kd = 1 μM) which was partially competed by IG-9402 (Kd = 1.5 μM) but not at all by purinergic agonists. We have now observed that etidronate and alendronate compete too for binding to this site (Kd = 2 - 2.5 μM). These results reinforces the notion about the existence of a membrane receptor for bisphosphonates. Such putative receptor may serve as epicenter from which their message is decoded into transmembrane signaling pathways triggering the appropriate cellular response.

SU218

MSP-RON Signalling in Human Osteoblasts Requires Cell Adhesion and Lipid Raft Iintegrity. C. Camerino*[1], M. Santoro*[2], G. Colaianni*[1], G. Mori*[1], G. Gaudino*[2], A. Zallone[1]. [1]Department of Human Anatomy and Histology, University of Bari, Bari, Italy, [2]Department of Medical Science, University of Oriental Piedmont, Novara, Italy.

Ron is a receptor tyrosine kinase that mediates the biological effects of Macrophage Stimulating Protein (MSP). Ron expression has been analyzed in vivo during mouse embryogenesis showing a specific pattern of expression during the development of epithelial, bone and neuroectodermal tissues. We previously evaluated the role of MSP on human Osteoblasts (OBs) demonstrating that this factor plays a role in the differentiative and antiapoptotic pathways of these cells, activating Ca^{2+} mediated signals and triggering different intracellular events mediated by MAPK, AKT and $p70^{S6K}$. Growth, differentiation and survival of anchorage-dependent cells are regulated through signals generated by adhesion to extracellular matrix (ECM). We investigated the role of ECM in the signal pathways activated by MSP. Using Anti-Phosphotyrosine antibodies the phosphorilation state of Ron has been analyzed. In OBs cultured in adhesion condition, binding of MSP to RON induced a rapid phosphorilation of RON 150 kDa β-chain albeit a basal state of phosphorilation was also visible in unstimulated cells. We than speculated if the basal Ron phosphorilation could be due to the adhesion to the ECM that OBs physiologically produce. Indeed in OBs cultured in non adhering conditions, Ron phosphorilation was visible only after MSP stimulation while in unstimulated OBs we can not detect any RON phosphorilated form. Interestingly in non adhering OBs, MSP stimulation failed to activate MAPK and AKT that were activated only in OBs cultured in adhesion condition. These data show that ECM adhesion can lead to RON oligomerization and transphosphorilation, which causes an increase in RON kinase activity above the basal level that initiates the autophosphorilation, however only binding of MSP to RON can turn on the signals responsible for the activation of intracellular pathways like MAPK and AKT. In further experiments we have evidenced that MSP mediated signals require lipid raft integrity. Indeed analyzing the effects of MSP on OBs by single cell fluorometry we detected an intracellular Ca^{2+} increase that was abolished by pretreating the cells with the lipid raft inhibitor methyl-β-cyclodextrin. Similarly in methyl-β-cyclodextrin pre-treated OBs, MSP failed to activate MAPK, AKT and $p70^{S6K}$ that resulted clearly visible in OBs stimulated with MSP but not treated with methyl-β-cyclodextrin.

SU219

ERK Activation is Necessary for RANKL Expression Induced by High Extracellular Calcium. Y. Kim*, S. Kim*, G. Kim, J. Baek. Dept of Pharmacology and Dental Therapeutics, College of Dentistry Seoul National University, Seoul, Republic of Korea.

High extracellular calcium has been implicated in the regulation of osteoclastic bone resorption but the exact mechanism has not been thoroughly elucidated. High extracellular calcium has been shown to stimulate the expression of RANKL, known to be an essential factor for osteoclastogenesis, in osteoblastic cells. In this study, we explored whether the MAP kinase pathway is involved in the regulation of RANKL expression by high extracelluar calcium in mouse calvarial osteoblastic cells. As previously reported, high extracellular calcium induced the RANKL expression in mouse calvarial osteoblastic cells. PD98059, an inhibitor of MEK, an upstream activator of ERK (p44/42), inhibited the RANKL expression induced by high calcium but the inhibition was not complete. U0126, a potent specific inhibitor of MEK, reduced the RANKL induction by high calcium in a dose-dependent manner and completely abrogated at 20 μM. In addition, high extracellular calcium stimulated ERK phosphorylation after 5 min and the ERK activation was maintained after 30 min of high calcium treatment. These results indicate that ERK pathway plays a role in regulating RANKL expression by high extracellular calcium.

SU220

Role of a RGD-peptide in Signalling Pathways in Human Bone Marrow Stromal Cells. S. Pallu*[1], R. Bareille*[2], A. Jonczyk*[3], M. Dard*[4], J. Amedee[2]. [1]INSERM U 443, Bordeaux, France, [2]INSERM U443, Bordeaux, France, [3]Merck Clinical Research, Darmstadt, Germany, [4]Merck Biomaterial GmbH, Darmstadt, Germany.

Osseointegration of bone substitutes can be considerably helped if the implants are cellularized with autologous osteoblastic cells before implantation. Moreover, design of materials with pro-adhesive properties towards osteogenic cells constitutes one of our objectives. Modification of materials by grafting RGD-containing peptides is based on the affinity of integrins to extracellular matrix proteins including in their sequence the RGD sequence. Among the different sequences, the best result in terms of adhesion, has been obtained with a cyclic peptide (cyclo-DFKRG). Here we assessed the function of tyrosine kinase activities (PTK) and the phosphorylation of p125 FAK and MAPK (p42, p44) which could affect cell proliferation, cell differentiation. Human bone marrow stromal cells have been cultured for 15, 30, 60, 90 min in IMDM alone onto different coatings: cyclo-DFKRG (100μM), poly-L-Lysine (PLL) (5%), fibronectin (FN) (10μg/ml) and plastic culture dishes. Total proteins were extracted using a RIPA buffer containing protease and phosphatase inhibitors. PTK activities contained in cell extracts are determined by using a kit provided from PROMEGA. Phosphorylation of p125FAK and MAPK (p42, p44) have been determined by Western blotting using specific antibodies against these proteins and using a monoclonal anti-phosphotyrosine. Products have been quantified using NIH 1.62 and the ratio PY20/p125FAK; PY20/p44; PY20/p42 have been normalized using a-tubulin as control. Culture onto cyclic RGD-peptides induces an increase of PTK activities which reached a maximum after 30 min of culture. Unspecific adhesion as confered by poly-L-Lysine induces a basal PTK activities, contrary to the specific adhesion confered by fibronectin coatings but to a lesser extent than RGD-surfaces. In the same way, adhesion to cyclo DFKRG promotes tyrosine phosphorylation of the p125FAK and MAPK (p42, p44) after 15 to 30 min of cell seeding and then decreased. Fibronectin coatings induce a similar kinetic of phosphorylation according to the engagement of integrins upon adhesion but with a lower extent. Unspecific adhesion confered by poly-L-Lysine induces the lowest level of phosphorylation of these proteins. In conclusion, adhesion of HBMSC onto this cyclic RGD induces activation of several intracellular signal transduction molecules which could be responsible of the stimulation of osteocalcin expression showed by competitive RT-PCR analysis, and to an increase of matrix mineralization. This peptide seems to be a good candidate to modify biomaterials and then to increase its osseointegration.

Parathyroid Hormone Induces the Nuclear Orphan Receptor NOR-1 in Osteoblasts Primarily through cAMP-PKA Signaling. F. Q. Pirih*, L. Pham*, J. M. Nervina, S. Tetradis. School of Dentistry, UCLA, Los Angeles, CA, USA.

Parathyroid hormone (PTH) regulates osteoblast function by initiating a cascade of gene expression. First to undergo changes in their expression are the primary response genes, whose expression is rapid, transient, and critical for the subsequent molecular events that generate PTH's osteotropic effects. Identifying PTH-induced primary response genes and understanding the molecular signals mediating their function are of fundamental importance in unveiling the mechanisms by which PTH regulates bone metabolism. Among PTH-induced primary response genes are Nurr1 and Nur77, members of the NGFI-B nuclear orphan receptor family. A third NGFI-B gene, NOR-1, is induced in the brain, but to date has not been shown to be regulated in osteoblasts. We report here that PTH induced NOR-1 mRNA in primary mouse osteoblasts (MOB cells) and cultured mouse calvariae mainly through the cAMP-protein kinase A (PKA) signaling pathway. PTH rapidly and transiently induced NOR-1 mRNA levels in MOB cells, with maximal induction at 2 h with 10 nM hormone. PTH binds to the PTHR1 receptor, which is coupled to the PKA, protein kinase C (PKC) and calcium pathways. To determine which pathway(s) mediate PTH-induced NOR-1 induced expression, MOB cells were treated with 10 μM forskolin (FSK, PKA activator), 1 μM phorbol ester (PMA, PKC activator) and 1 μM ionomycin (IO, calcium ionophore). FSK strongly induced NOR-1 mRNA levels, while PMA and IO showed a weaker induction of NOR-1 mRNA levels. In addition, 10 nM PTH (3-34), which does not activate the PKA pathway but activates PKC and calcium pathways, did not induce NOR-1 mRNA levels. Selective pathway inhibitors were tested to further delineate the relative importance of each pathway in mediating PTH-induced NOR-1 expression. A 30 min pretreatment with 30 μM H89 to block PKA inhibited PTH- and FSK-induced NOR-1 mRNA. Overnight pretreatment with 1 μM PMA to deplete PKC did not affect PTH-induced NOR-1 mRNA, but did inhibit PMA-induced NOR-1 mRNA. Finally, PTH induced NOR-1 mRNA maximally at 1 h in cultured neonatal mouse calvariae. Taken together these data indicate that PTH induced NOR-1 mRNA primarily through the cAMP-PKA pathway. PTH-regulated induction of all members of the NGFI-B nuclear orphan receptor family suggests that these genes play an important role in the immediate response of osteoblasts to PTH, with implications for the overall effect of PTH on bone metabolism.

SU222

Parathyroid Hormone Induces NFIL3/E4BP4 Gene Expression in Bone. I. C. Ozkurt*, S. Tetradis. School of Dentistry, University of California at Los Angeles, Los Angeles, CA, USA.

Following binding to its receptor parathyroid hormone (PTH) activates the cAMP/protein kinase A (PKA), protein kinase C (PKC) and calcium signaling pathways and subsequently induces transcription of several osteoblastic primary response genes. Products of primary response genes, subsequently, initiate the cascade of molecular events that mediate osteoblast response to PTH and play a pivotal role in the effects of PTH on bone metabolism. We have performed representational difference analysis and identified the Nuclear Factor regulated by IL-3 (NFIL3)/ adenovirus E4 promoter Binding Protein (E4BP4) as a PTH induced primary gene in osteoblasts. NFIL3/E4BP4 is a basic leucine zipper (bZIP) transcription factor, binds DNA as a dimer and acts either as transcriptional repressor or activator. Osseous localization and PTH induction of NFIL3/E4BP4 have not been reported previously. The objectives of our studies were to characterize the PTH induction of NFIL3/E4BP4 gene expression and to identify the presence of NFIL3/E4BP4 protein in the nucleus where it presumably regulates downstream gene expression. For all our experiments we utilized primary osteoblasts (MOb) derived from 7-day old mouse calvariae. PTH strongly increased NFIL3/E4BP4 mRNA levels MOb cells and in mouse calvariae organ cultures with maximal induction at 2 hours and at 10 nM. Pretreatment with cycloheximide (CHX) superinduced, while pretreatment with actinomycin D inhibited, the PTH induction of NFIL3/E4BP4 mRNA levels. To detect levels of nuclear NFIL3/E4BP4 protein, electrophoretic mobility shift assays (EMSAs) were performed utilizing nuclear extracts from PTH treated MOb cells and a consensus NFIL3/E4BP4 response element (NF3RE) as a probe. PTH induced binding to the NF3RE that peaked at four hours and declined thereafter. A recombinant NFIL3/E4BP4 protein showed a similar binding to the NF3RE. When two mutant NF3REs were used the PTH-induced binding and the binding of recombinant NFIL3/E4BP4 were strongly reduced. CHX significantly reduced the PTH-induced NF3RE binding suggesting that it contains newly synthesized proteins. Finally NFIL3/E4BP4 antibodies supershifted the PTH-induced NF3RE binding complexes suggesting that they contained the NFIL3/E4BP4 protein. In conclusion, PTH induces NFIL3/E4BP4 gene expression in primary osteoblasts and organ cultures. Furthermore, PTH induces specific binding to a consensus NF3RE that contains newly synthesized proteins and is recognized by an NFIL3/E4BP4 antibody. NFIL3/E4BP4 induction could mediate PTH regulation of downstream osteoblastic genes.

SU223

PTHrP Actions in Differentiated Osteoblasts: The Role of the MAPK Pathway. C. Chen*, A. J. Koh*, L. K. McCauley. Perio/Prev/Geriatrics, University of Michigan, Ann Arbor, MI, USA.

Parathyroid hormone-related protein (PTHrP) regulates proliferation and differentiation of osteoblastic cells via binding to the parathyroid hormone receptor (PTH1R). The PKA pathway governs a majority of the effects induced by PTHrP on osteoblasts, but recent evidence also implicates the mitogen-activated protein kinase (MAPK) pathway. To evaluate the role of MAPK in PTHrP-mediated gene expression and regulation of apoptosis, northern analysis, western analysis and cell viability assays were performed. MC3T3-E1 cells were induced to differentiate, pre-treated with U0126 (a MEK inhibitor) for 2h, then treated with PTHrP for different time points. Osteocalcin gene expression was downregulated at 48h by U0126 (7-fold), PTHrP (11-fold), and the combination of U0126 and PTHrP (20-fold). Bone sialoprotein gene expression was downregulated at 48h by U0126 (1.3-fold), PTHrP (1.5-fold) and the combination (3-fold). In contrast, PTHrP downregulated PTH1R gene expression at 48h, but U0126 had no effect and in combination did not alter the PTHrP downregulation. PTHrP induced c-fos gene expression (1h) but U0126 had no effect alone and did not alter the PTHrP induction. Interestingly, U0126 blocked the PTHrP stimulation of fra-2 (2h) and IL-6 (2h) gene expression. We have previously shown that PTHrP induces apoptosis (6h) in differentiated MC3T3-E1 cells and further that PTHrP rapidly decreases phosphorlyation of AKT (an inhibitor of apoptosis in the phosphorylated state). Here, we investigated the role of MAPK and found that a 2h pre-treatment with U0126 before PTHrP treatment partially blocked the pro-apoptotic effect of PTHrP. However, western blot analysis revealed that U0126 had no effect on the PTHrP decrease in phosphorylation of AKT. This suggests that the MAPK pathway is partially responsible for PTHrP mediated apoptosis, but that inhibition of MAPK does not alter the PTHrP effect on AKT phosphorylation. In addition, these data indicate that inactivation of the MAPK pathway by U0126 shows differential regulation of PTHrP stimulated AP-1 members (effecting fra-2 but not c-fos), reduces PTHrP stimulated IL-6 and synergistically downregulates certain osteoblastic markers (BSP, OCN) associated with differentiation. These data confer that the MAPK pathway plays an important role in the actions of PTHrP and suggest that gene expression and apoptosis are regulated by PTHrP via multiple pathways in differentiated osteoblasts.

SU224

Evidence that Activation of Phospholipase D is an Early Event in Downstream Signaling by PTH in UMR-106 Osteoblasts. J. M. Radeff*[1], A. T. K. Singh[1], D. A. Dossing*[1], S. Sebti*[2], P. H. Stern[1]. [1]Molecular Pharmacology and Biological Chemistry, Northwestern University, Chicago, IL, USA, [2]H. Lee Moffitt Cancer Center, University of South Florida, Tampa, FL, USA.

Parathyroid hormone (PTH) activates multiple signaling pathways in osteoblasts, although the precise mechanisms and/or cross-talk between these pathways have not been clearly established. In the current study, we have investigated connections between PTH actions on phospholipase D (PLD), protein kinase C (PKC), expression of the interleukin-6 (IL-6) promoter and receptor activator of NFkB ligand (RANKL) in UMR-106 osteoblastic cells. We have also investigated the potential influence of AC/cAMP/PKA on these pathways. a) Hydrolysis of membrane phospholipids by PLD generates phosphatidic acid, which is converted to diacylglycerol (DAG), a direct activator of PKC, by phosphatidic acid phosphatase. Propranolol was used to inhibit phosphatidic acid phosphohydrolase, demonstrated by an increase in PA and a decrease in DAG. Propranolol prevented the PTH-stimulated membrane translocation (visualized by immunofluorescence) of PKCα and attenuated IL-6 promoter expression, suggesting that PLD pathways contribute to these downstream responses. In contrast, the direct stimulation of PKCα translocation by phorbol dibutyrate, which would not require PLD, was not inhibited by propranolol. b) PTH stimulated membrane translocation of RhoA, but not other small G proteins (RhoB, Rac1, Cdc-42). Dominant negative RhoA (Rho19N), a geranyl geranyl transferase inhibitor (GGTI-2166) and a Rho kinase inhibitor all prevented PLD activity and PKCα translocation by PTH. GGTI-2166 and the Rho kinase inhibitor did not affect phorbol dibutyrate-stimulated PKCα translocation. GGTI-2166 and Rho kinase inhibition also attenuated PTH-stimulated IL-6 promoter expression. c) Although PTH stimulates IL-6 and RANKL expression through both PKC and PKA pathways, forskolin and IBMX failed to promote PKCα translocation. PTH-stimulated PKC translocation was unaffected by the PKA antagonist PKI. These findings establish a pathway from RhoA and Rho kinase to PLD-generated DAG that stimulates PKCα translocation, leading to IL-6 expression. In addition, the AC/cAMP/PKA pathway does not appear to influence these events.

Ultrastructural Changes in Cathepsin K Deficient Osteoclasts. R. Kiviranta[1], K. Ivaska*[2], J. Risteli[3], H. K. Väänänen[2], E. Vuorio[1], T. Laitala-Leinonen[2]. [1]Department of Medical Biochemistry and Molecular Biology, University of Turku, Turku, Finland, [2]Department of Anatomy, University of Turku, Turku, Finland, [3]Department of Clinical Chemistry, University of Oulu, Oulu, Finland.

Bone resorption is a multi-step process performed by osteoclasts. Cathepsin K is a major protease in resorption of bone matrix molecules. Recent reports indicate that cathepsin K deficient mice develop severe osteopetrosis of long bones due to their inability to degrade organic bone matrix. The aim of our study was to evaluate the cell biological changes in cathepsin K deficient osteoclasts. We chose to generate our own cathepsin K (Ctsk) knockout mice by replacing exons 2 to 5 of the gene with a neomycin resistance gene in embryonal stem cells. Chimeric mice were mated with C57Bl/6J females to get outbred heterozygous Ctsk+/- mice. These mice were subsequently mated to obtain wild type (wt), heterozygous (Ctsk+/-) and homozygous (Ctsk-/-) mice for the inactivated cathepsin K allele. Peripheral quantitative computed tomography (pQCT) was used to confirm the previously published osteopetrotic phenotype at the age of 8 weeks. To study bone resorption in vitro, primary wt and Ctsk-/- osteoclasts were cultured on bovine cortical bone slices for 3 to 4 days. The culture media were analyzed for bone degradation products. Immunofluorescence analysis of various osteoclast and bone matrix proteins was performed to study the morphology of Ctsk deficient osteoclasts. pQCT measurements showed increased bone mineral density in the long bones of Ctsk-/- mice and extensive trabeculation of bone marrow spaces. The amount of medium C-terminal telopeptide of type I collagen (ICTP), degradation products of C-terminal telopeptides of type I collagen (CTX) and bone derived osteocalcin fragments were significantly decreased in the Ctsk-/- cultures. Cathepsin K immunostainings confirmed that Ctsk-/- osteoclasts did not express any detectable cathepsin K protein. Large vesicles containing type I collagen were found in Ctsk-/- osteoclasts while no type I collagen was detected inside the wt cells. Phalloidin staining revealed that a majority of the actin rings were abnormally thick in these osteoclasts, and in most of the cells the actin ring was either partially or totally disrupted into podosomal structures. Also the ruffled border and sealing zone were disorganized. The inner vinculin ring was absent from the vicinity of the disrupted actin structures. This data suggests that the ingestion of large amounts of undegraded type I collagen arrests the bone resorption in Ctsk-/- osteoclasts and leads to disassembly of the sealing zone. Thus cathepsin K deficiency severely impairs osteoclast function.

SU226

Bone Resorption in Osteoclasts Overexpressing Cathepsin K. J. Morko*[1], K. Ivaska*[2], M. Mulari*[2], S. Ylönen*[2], H. K. Väänänen[2], E. Vuorio[1], T. Laitala-Leinonen[2]. [1]Department of Medical Biochemistry and Molecular Biology, University of Turku, Turku, Finland, [2]Department of Anatomy, University of Turku, Turku, Finland.

Bone resorption cycle is a multistep process including osteoclast attachment, polarization, resorption and detachment. The polarization for resorption includes many cytoskeletal changes and formation of distinct plasma membrane domains, namely ruffled border, sealing zone, basal membrane and functional secretory domain. Subsequent resorption includes both the solubilization of crystalline hydroxyapatite and the degradation of demineralized organic matrix. Cathepsin K, a lysosomal cysteine proteinase, has been proposed to be a major proteinase in this degradation process. We have recently developed a transgenic mouse model overexpressing cathepsin K. The present study was designed to study how cathepsin K overexpression affects bone resorption in cultured osteoclasts. Two-day old mice homozygous for the transgene locus and nontransgenic controls were used as a source of osteoclasts, which were cultured on bovine cortical bone slices. Cathepsin K and its transcripts were studied by Western and Northern analyzes, respectively. Other osteoclastic and bone matrix proteins were studied by immunofluorescence stainings. Resorption was analyzed from bone slices, and pits were visualized by field emission scanning electron microscopy. Levels of released degradation products of bone proteins were measured from culture media. Northern and Western analyzes confirmed the overexpression of cathepsin K. Confocal microscopy demonstrated localization of excess cathepsin K near the ruffled border and in numerous intracellular vesicles throughout the osteoclast cytoplasm. These vesicles were positive for Rab7 or Rab9 GTPases indicating that the transport of cathepsin K inside the osteoclasts occurred in

specific endo- and exocytic vesicles. Also the amount of carbonic anhydrase II was slightly increased indicating an enhanced production of protons required for enhanced demineralization. The amount of cathepsin K in the resorption front was increased, and the amounts of type I collagen and osteocalcin in the resorption pits were decreased indicating enhanced degradation of organic bone matrix. This was confirmed with bone slice and culture medium analyzes, where the number of resorption pits, the resorbed area, and the amounts of released degradation products of bone proteins were increased. The current data demonstrates that excessive cathepsin K production leads to increased bone resorption characterized by an enhanced membrane trafficking.

SU227

Osteoblasts Render Osteoclastic Bone Resorption Sensitive to Matrix Metalloproteinase Inhibitors. J. Delaissé, M. T. Engsig*, T. L. Andersen*, K. Henriksen*, T. Kirkegaard*, M. Ovejero*, M. A. Karsdal, C. Christiansen, N. T. Foged*. Nordic Bioscience A/S / CCBR, Herlev, Denmark.

A variety of experiments performed on cultured bone explants have demonstrated that both cysteine proteinases, including cathepsin K, and matrix metalloproteinases (MMP) are rate limiting for osteoclastic bone resorption. However, pit formation by purified osteoclasts is decreased only in the presence of cysteine proteinase inhibitors, not in the presence of MMP inhibitors. Furthermore, the resorption of bone explants from mice lacking the different osteoclastic MMPs is not decreased compared with that of wild types. We thus hypothesized that the MMP responsible for the MMP inhibitor sensitivity of resorbing bone explants is not of osteoclast origin, but instead, may originate from osteoblasts. In order to test this hypothesis, we performed the pit assay with rabbit osteoclasts in the presence of osteoblastic MC3T3 cells at increasing cell densities, thereby mimicking the osteoblastic cell layer lining native bone surfaces. In the absence of osteoblasts, the MMP inhibitors GM6001 and BB94 did not inhibit pit formation. In the presence of osteoblasts, however, pit formation was inhibited by the MMP inhibitors, and the sensitivity to MMP inhibitors increased with increasing cell densities, reaching comparable levels as for bone explant cultures. Next, we investigated systematically the mRNA and protein expressions of MMP-1, -2, -3, -9, -10, -11, -12, -13, and -14 in bone explants, and found a unique localization pattern of MMP-13: the mRNA is highly expressed in mononucleated cells next to resorbing osteoclasts, whereas the protein is not only at the level of these cells, but also further away at the level of osteoclasts, and is particularly abundant in the osteoclastic resorption zone, as assessed in adjacent sections with 5 different antibodies against MMP-13. Finally, we also found that MMP-13 levels are increased in the bones of mice receiving a calcium deficient diet and showing upregulated bone resorption; MMP-13 levels return to normal upon replenishment with a normal diet and normalization of bone resorption to control levels. A key role of MMP-13 in bone resorption is also shown by the decreased resorption of bone explants from mice lacking MMP-13, compared to wild types (S. Krane, J. Bone Min. Res., 161, S149). In conclusion, these data show the type of proteinases involved in bone resorption may depend on the cellular environment of the osteoclast. More specifically, an osteoblastic proteinase of the MMP family, most likely MMP-13, controls osteoclastic bone resorption. MMPs represent thus an additional category of osteoblastic gene products controlling osteoclastic bone resorption.

SU228

Bone in Transgenic Mice Overexpressing Tartrate-resistant Acid Phosphatase (AcP5, TRAP). S. J. Jones[1], A. Boyde[1], A. R. Hayman[2], T. M. Cox*[3]. [1]Department of Anatomy and Developmental Biology, University College London, London, United Kingdom, [2]Division of Molecular and Cellular Biology, School of Clinical Veterinary Science, Bristol, United Kingdom, [3]Dept of Medicine, University of Cambridge, Cambridge, United Kingdom.

Transgenic mice overexpressing tartrate-resistant acid phosphatase (AcP5) were reported to have less trabecular bone than their wildtype, but the mice were examined only as neonates (1). The present study reports on older animals. Wildtype and transgenic mice with either threefold or eightfold overexpression of AcP5 were culled at 10-11 weeks, or at 18 months or 22-23 months. Femurs and tibiae-fibulae, fixed in 70% ethanol, were either embedded in PMMA or opened longitudinally to expose the marrow cavity and cleaned with Tergazyme (Alconox, New York, NY). The embedded specimens were cut and micromilled. All specimens were coated with carbon for SEM using backscattered electrons (BSE). Forelimbs from the older animals were also examined by Piximus DEXA (Lunar). SEM @ 10-11 weeks: male and female femurs of each of the three genotypes showed less than 2% difference in lengths, and internal and external diameters of the bones and extent of trabeculation in distal femur were equal. There was no evidence for increased bone turnover in the transgenic compared with the wildtype mice. SEM @ 18 or 22/23 months: no trabeculae remained in the marrow cavity at either 18 or 22/23 months in any genotype, and the sizes of the bones were similar. Endosteal resorption pits in the bones from mice overexpressing AcP5 did not differ from those in the wildtypes in appearance or distribution, nor were the internal or external diameters of the bones larger. No differences were found from quantitative BSE SEM analysis in either age group. No differences in BMC and BMD were detected by DEXA. There are no differences between the wild type, the 3X and the 8X overexpression phenotypes at the ages examined. The present findings can be explained by assuming that the rate limiting step in osteoclastic bone resorption of mature lamellar bone tissue is that of the acid induced demineralisation prior to organic matrix degradation employing proteolytic enzymes (2). Although lack of AcP5 results in disruption of endochondral ossification and some impairment of resorption leading to a mild osteopetrosis (3), having more AcP5 does not increase bone resorption, because enough is sufficient.

Acid Phosphatase and Oxygen Radical-Generating Activities of Type 5 Tartrate-resistant Acid Phosphatase Are Functionally Independent. S. L. Alatalo*[1], H. Kaija*[2], H. Ylipahkala*[1], Y. Lindqvist*[3], G. Schneider*[3], P. Vihko*[2], H. K. Väänänen[1], J. M. Halleen[1]. [1]Institute of Biomedicine, Department of Anatomy, University of Turku, Turku, Finland, [2]Biocenter Oulu, Research Center for Molecular Endocrinology, University of Oulu, Oulu, Finland, [3]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden.

Type 5 tartrate-resistant acid phosphatase (TRACP) is an enzyme with unknown biological function that is expressed by bone-resorbing osteoclasts and activated macrophages. Active site of the enzyme contains a binuclear iron center with two irons, one of which is redox-active. In addition to its acid phosphatase (AcP) activity TRACP is also capable of generating reactive oxygen species (ROS) in vitro. Both activities require the redox-active iron in the active site. We have studied the two activities using wild-type and mutated forms of recombinant rat TRACP. Single amino acid mutations were generated by site-directed mutagenesis targeted to the amino acids predicted to be important for the AcP activity. The mutated amino acids were either in the substrate-binding pocket of the enzyme or in the alternative glycosylation sites, but not in the amino acids coordinating the two iron atoms in the active site. The AcP activity was determined using 4-NPP as substrate, and ROS activity either by monitoring the formation of malondialdehyde acetal from degradation products of deoxyribose or by detecting the fluorescence of 7-hydroxycoumarin-3-carboxylic acid (7-OHCCA) after hydroxyl radical attack. The pH-optimum of wild-type recombinant rat TRACP was 4.5 for the AcP activity and 6.5 for the ROS generating activity. All the mutated TRACP enzymes had significantly decreased AcP activity compared to the wild-type enzyme, while the ROS generating activity was decreased, not affected or increased. The changes in the AcP and ROS generating activities did not correlate with each other in individual mutants. These results suggest that not only the substrate availability and specificity, but also the pH of the environment may regulate the function of TRACP. We conclude that the two activities of TRACP may have independent mechanisms and function in different cell types and different intracellular compartments.

SU230

Interleukin-12 Induces Apoptosis of Bone Marrow Cells in Tumor Necrosis Factor-alpha Mediated Osteoclastogenesis. H. Kitaura[1], N. Nagata*[1], M. Tatamiya*[1], N. Yoshida*[1], K. Nakayama*[2]. [1]Department of Orthodontics, School of Dentistry, Nagasaki University, Nagasaki, Japan, [2]Department of Oral Microbiology, School of Dentistry, Nagasaki University, Nagasaki, Japan.

In recent years, much importance has been attached to the relationship between cytokines and bone metabolism. Although RANKL is an essential cytokine for inducing the differentiation of osteoclasts, it has recently been found that the differentiation of osteoclasts is also induced by TNF-alpha. Few studies have clarified the relationship between bone metabolism and Interleukin-12 (IL-12) that plays an important role in immunity. In this study, we investigated the effects of IL-12 on TNF-alpha-mediated osteoclastgenesis. Whole bone marrow cells collected from ddY mice were cultured in the medium containing M-CSF and TNF-alpha with or without IL-12. When bone marrow cells were cultured in the medium without IL-12, a number of osteoclast-like cells were formed. On the other hand, when they were cultured with IL-12, the number of adherent cells decreased in a dose-dependent manner. We found morphological changes such as cell atrophy, and nuclear and cellular fragmentation, and biological changes such as DNA fragmentation in the adherent cells treated with IL-12, indicating apoptosis of these cells. Direct effects of IL-12 on TNF-alpha-inducing osteoclastgenesis were determined using M-CSF dependent bone marrow macrophage (M-BMM) as an osteoclasts precursor (preOC). Apoptotic effects such as cell atrophy were not observed in M-BMM, suggesting that apoptosis would not be induced by a direct effect of IL-12 on preOC, but by a factor formed by IL-12-treated non-preOC cells in whole bone marrow cells. The IL-12-mediated apoptosis was markedly inhibited when bone marrow cells were treated with anti-FasL antibody. FACS analysis revealed that TNF- alpha up-regulated Fas expression on the surface of adherent cells in bone marrow cells culture in the presence of M-CSF, whereas IL-12 could not express Fas in the cells. IL-12 induced FasL on the surface of non-adherent cells in bone marrow cells culture, whereas TNF-alpha could not express FasL in the cells. Taken together, it was found that presence of both IL-12 and TNF-alpha was indispensable for apoptosis in this culture system and the apoptosis was induced by Fas/FasL interaction between adherent and non-adherent cells in bone marrow cells. In summary, we found in this study that a combination of IL-12 and TNF-alpha induced apoptosis of bone marrow cells and that the apoptosis may be caused by interaction of TNF-alpha-induced Fas on the adherent cells and IL-12-induced FasL on the non-adherent cells.

SU231

Human Osteoclasts Secrete TNF-α and IL-6 in Response to IL-1α Stimulation. T. R. Fuson*, R. J. S. Galvin. Gene Regulation, Lilly Research Labs, Indianapolis, IN, USA.

Soluble factors within the bone microenvironment influence osteoclast differentiation and function; however, the role of osteoclasts as autocrine regulators of osteoclast differentiation or resorption has not been well studied. Since IL-1 induces cytokine secretion in numerous cell types and is a critical regulator of osteoclastic bone resorption, we evaluated the effects of IL-1α on IL-6 and TNF-α secretion from cultured human osteoclasts. Delta cultures [suspension culture of cells (1 x 10^6 cells/ml in a T-150 flask) in Iscoves DMEM containing 25% heat-inactivated FBS, 1% antibiotic/antimycotic solution, 20 ng/ml rhIL-3, 20 ng/ml rhGM-CSF, and 10 ng/ml stem cell factor] of human umbilical cord blood cells (purchased from BioWhittaker) served as the source of osteoclast progenitor cells. After 6-16 days in Delta culture, the suspension cells (CD33+) were collected and osteoclast differentiation was induced with rhRANKL and rhM-CSF. The cells were seeded at 2.5 x 10^5 cells/cm^2 in DMEM containing 10% charcoal-stripped FBS, 1% antibiotic/antimycotic, rhRANKL (50 ng/ml) and rhM-CSF (50 ng/ml). After 7 days, large numbers of TRAP-positive multinucleated cells were observed. These *in vitro* generated osteoclasts formed resorption lacunae when cultured on bovine cortical bone slices. The ability of these osteoclasts to secrete IL-6 and TNF-α was evaluated in cells cultured on plastic. The cells were pre-cultured in medium containing 1 mg/ml BSA or 10% FBS (1.5-4 h), and then treated with rhIL-1α (10-100 ng/ml) for 5, 18, 24 or 28 h in the appropriate medium. The medium concentrations of IL-6 and TNF-α were evaluated using a Human Cytokine Linco*plex* Kit (Linco Research Inc.). IL-1α increased the IL-6 concentration a minimum of four-fold following an 18-24 h treatment. A significant increase in IL-6 release to the medium was observed following 5 h of treatment. IL-1α also increased the release of TNF-α into the medium (4-70 fold) following 18-24 h of treatment. Similar results were observed in cultures treated in the presence of FBS or BSA. These results support previous immunohistochemistry studies which demonstrated that human osteoclasts express IL-6 and TNF-α, and suggest that rhIL-1α regulates IL-6 and TNF-α release from human osteoclasts. Furthermore, IL-6 and TNF-α may serve as autocrine regulators of osteoclast differentiation and/or function.

Regulation of Mouse Osteoprotegerin Gene Expression by Steroid Hormones. T. Kondo*, R. Kitazawa, S. Maeda*, S. Kitazawa. Division of Molecular Pathology, Kobe University Graduate School of Medicine, Kobe, Japan.

Glucocorticoid-induced osteoporosis is a common and serious complication of systemic glucocorticoid use. It is generally accepted that glucocorticoids increase bone resorption *in vitro* as well as *in vivo*. In cocultures of ST2 cells and bone marrow macrophages, 1,25 dihydroxyvitamin D_3 supports osteoclastogenesis, and dexamethasone (Dex) administration synergistically stimulates it. To explore the precise mechanism whereby Dex stimulates osteoclastogenesis, we analysed the effect of Dex on cis-acting elements of the mouse osteoprotegerin (OPG) and the receptor activator of NF-κB ligand (RANKL) gene. The 5'-flanking region of the mouse OPG gene was cloned, and a series of deletion constructs ligated with a pGL3-Basic vector plasmid (Luc -116, Luc -697, Luc -1125, Luc -1487) were transfected into ST2 cells and subjected to luciferase assay. Transfected cells were treated with Dex (10^{-7}M) for 48h to assess its effect on the OPG promoter activity. Mirroring Northern blot analysis, Dex reduced the promoter activity of Luc -1487 to 50%. Electrophoretic gel motility shift assay (EMSA) carried out to determine protein-DNA binding on the putative AP-1 binding site (-293/-287, TGACTGA) showed specific binding to the putative AP-1 site and the supershift with an anti c-Jun antibody; the mutation of the putative AP-1 site (TGACTGA to CTCCCTC) nullified the protein-DNA binding. A construct containing the mutated AP-1 binding site (Luc -1487m) showed reduced promoter activity. Moreover, the Luc -1487m construct was resistant to Dex-driven suppression. To assess the inhibitory effect of Dex on the OPG gene at the protein level, the amount of OPG protein secreted by ST2 cells into the culture medium was measured by sandwich enzyme-linked immunosorbent assay (ELISA). The production of OPG protein decreased significantly by the 48-hour treatment with Dex, suggesting that Dex negatively regulates OPG partly by transrepressing OPG promoter activity through the AP-1 site and partly through a posttranscriptional modification process. On the other hand, Dex upregulated RANKL promoter activity to 130%, although only a nominal increase of mRNA was observed by Northern blot analysis. We speculate therefore that glucocorticoids per se promote osteoclastogenesis mostly by inhibiting OPG and partly by concurrently stimulating RANKL reciprocally, thereby enhancing bone resorption.

Expression of Osteoblast Differentiation Factor in Mature Osteoclasts. N. Udagawa[1], K. Itoh*[2], X. T. Li*[3], H. Ozawa[3], N. Takahashi[3]. [1]Biochemistry, Matsumoto Dental University, Nagano, Japan, [2]Biochemistry, Showa University, Tokyo, Japan, [3]Institute for Dental Science, Matsumoto Dental University, Nagano, Japan.

Previous morphological experiments suggest that osteoclastic bone resorption induces bone synthesis by osteoblasts. This indicates that bone resorption is coupled with bone formation by an unknown factor (coupling factor). The discovery of RANKL elucidates the precise mechanism of osteoclast differentiation and mature osteoclast function regulated by osteoblasts. In this study, we explored the possibility that mature osteoclasts express a factor which induces differentiation of osteoblasts. Osteoclast preparation obtained from cocultures of mouse bone marrow cells and osteoblasts on collagen-gel-coated dish were spot-cultured for 5 h in the center of a single culture well. Then, osteoblastic cells in the spot-culture were removed completely by trypsin-EDTA to purify osteoclasts on the center of the culture well. Mouse stromal cells, MC3T3-G2/PA6, ST2 and C3H10T1/2, all of which are negative for alkaline phosphatase (ALP, a marker enzyme of osteoblasts), were uniformly plated over the culture well. The spot cocultures were performed for 3 days, then fixed and double-stained for tartrate-resistant acid phosphatase (TRAP, a marker enzyme of osteoclasts) and ALP. ALP-positive cells appeared inside or just around the colony of TRAP-positive osteoclasts. No ALP-positive cells were observed outside the colony of osteoclasts. Treatment of the spot coculture with a soluble form of the extracellular domain of BMP receptor type IA (sBMPR-IA) or calcitonin did not inhibit the induction of ALP-positive cells When the contact between stromal cells and osteoclasts was inhibited by a membrane filter, no ALP-positive cells were formed in the spot coculture. ROSA26 transgenic mice express β-galactosidase in various tissues including hematopoietic cells. When osteoclasts obtained ROSA26 mice were spot-cocultured with stromal cells, osteoclasts were positive for β-galactosidase but ALP-positive cells were not, indicating that the osteoclast preparation does not contain progenitors of ALP-positive cells. These results suggest that mature osteoclasts express a membrane-bound factor which induces differentiation of immature stromal cells into ALP-positive osteoblasts.

Suramin Interacts with RANK and Inhibits RANKL-Induced Osteoclastogenesis. A. Regmi*, T. R. Fuson*, X. Yang*, J. S. Kays*, C. M. Moxham*, E. R. Zartler*, S. Chandrasekhar, R. J. S. Galvin. Lilly Research Labs, Eli Lilly and Company, Indianapolis, IN, USA.

Suramin, a naphthalene trisulfonic acid derivative, has been shown to exhibit numerous activities related to disruption of protein-protein interactions. For example, it has been shown to uncouple G-proteins from their receptors, inhibit cell-surface binding to EGF and PDGF, and dissociate trimeric human TNF-α. With respect to bone, suramin has been reported to inhibit osteoclastic resorption in organ culture and in a rodent model of hypercalcemia. Since RANKL is a member of the TNF- α family of proteins and is essential for osteoclast differentiation and function, we evaluated the effects of suramin on RANKL-induced osteoclast differentiation. Mouse spleen cell cultures were treated with rhRANKL (1.5 nM), mouse M-CSF (2.0 nM) and suramin (0, 1, 3, 10, 30, 100, 300 and 1000 μM) for six days. Osteoclast formation in the presence or absence of suramin was determined by quantification of tartarate-resistant acid phosphatase (TRAP), a marker for osteoclasts. Suramin inhibited osteoclast formation in a concentration dependent manner (IC_{50} = 207 μM). Since RANKL mediated osteoclast activation involves the IkB/NF-kB pathway, we next evaluated the effects of suramin on RANKL-induced signaling. Suramin (100 μM) inhibited rhRANKL (5 nM)-induced IkB-phosphorylation (at 15 min by Western analysis) in spleen-derived pre-osteoclasts and differentiated osteoclasts. To distinguish whether the effects of suramin are on RANK/RANKL binding or on post-receptor mechanism, suramin was also evaluated in a binding assay using rhRANKL (0.1 nM) and rhRANK/Fc chimera (0.2 nM). In this assay, a 40% reduction in rhRANKL binding was observed in the presence of 1 mM suramin. The effects of suramin on binding interactions were also evaluated by surface plasmon resonance technology and Nuclear Magnetic Resonace (NMR). Using a Bioacore 3000 for analysis, suramin was found to interact with immobilized rhRANK/Fc chimera in a concentration dependent manner and this interaction was two-fold greater for rhRANK/Fc compared to IgG_1 Fc. Suramin binding to rhRANK/Fc, but not IgG_1 Fc, was also demonstrated by saturation transfer difference NMR Spectroscopy. Binding of suramin to rhRANKL was barely detectable (at least an order of magnitude weaker than rhRANK/Fc). In the presence of equimolar amounts of RANKL and rhRANK/Fc, suramin still bound, presumably to the rhRANK/Fc. There was no indication of any perturbation in the binding to rhRANK/Fc in the presence of RANKL. In conclusion, suramin appears to inhibit RANKL induced osteoclastogeneis by binding to RANK and blocking the ability of RANKL to induce second messenger signaling.

Antisense Oligonucleotide-Mediated Blockade of RANK Inhibits Osteoclast Formation and Enhances Apoptosis in Murine Bone Marrow-Derived Osteoclasts. K. J. Myers*, X. Li*, J. Finger*. Antisense Drug Discovery, Isis Pharmaceuticals, Carlsbad, CA, USA.

RANK is a cell surface receptor expressed on osteoclast precursor cells and mature osteoclasts. RANKL is expressed and secreted from osteoblasts, and engagement of RANK by RANKL is essential for both the differentiation and full functional activity of osteoclasts. We have developed a second generation antisense oligonucleotide specific for mouse RANK mRNA. Isis 181071 was selected from a panel of 48 RANK-specific antisense oligonucleotides as producing the most potent dose-dependent reduction of RANK mRNA, with a 400 nM dose typically inhibiting 80-90% of RANK mRNA expression in undifferentiated RAW 264.7 cells. Isis 181071 also displayed dose-dependent inhibition of RANK mRNA in primary mouse bone marrow-derived osteoclasts and osteoclast precursor cells from bone marrow. Several different control oligonucleotides were without effect at reducing RANK mRNA in RAW cells and primary cells. Isis 181071 potently inhibited TRAP+ multinucleated cell formation from osteoclast precursor cells. This effect was most pronounced when the oligonucleotide was transfected into pre-osteoclasts rather than more differentiated cells, which had already begun to show evidence of polykaryon formation. Isis 181071 was also effective at accelerating apoptosis in mature osteoclasts. This was seen with enhanced caspase-3 activity in RANK antisense-treated cells as well as changes in nuclear morphology visualized by fluorescent microscopy. RANK antisense thus inhibits osteoclast activity through effects on both cell differentiation and also by stimulating apoptosis. These results are consistent with previous reports demonstrating a critical role for RANK in osteoclastogenesis and osteoclast survival.

Involvement of RANKL in Osteolytic Loosening of the Prosthesis After Total Hip Replacement. M. Horiki, T. Nakase, A. Myoui, T. Nishii*, N. Sugano*, H. Yoshikawa. Dept of Orthopeadic surgery, Osaka University Graduate School of Medicine, Suita, Japan.

Loosening of the implant is one of the major late complications of joint replacement surgery. Mechanisms of osteolysis have been extensively studied from a histological perspective, and osteoclasts have been shown to play an important role in osteolysis. However, specific molecules involved in this condition yet to be fully elucidated. A potent factor for osteoclastogenesis was recently identified and found to be identical to the ligand for receptor activator of NF-kB, RANKL. Together with M-CSF, RANKL has been shown to support differentiation and maturation of osteoclasts in vitro using mouse, rat, or human cells. Mice with a disrupted RANKL gene exhibited an osteopetrotic phenotype, suggesting RANKL plays an essential role in osteoclastic bone resorption . To investigate the expression and localization of RANKL, a recently purified potent regulator of osteoclastogenesis, in osteolytic loosening. . These recent findings led us to hypothesize that RANKL is involved in osteolysis around artificial implants. We examined fibrogranulomatous tissue interposed between the loosened implant and the host bone by immunohistochemistry and Reverse transcript polymerase chain reaction (RT-PCR). The fibrous tissues obtained seven samples from four patients (5 samples obtained from femurs, 2 samples obtained from acetabulums) during revision surgery. Firstly, we examined expression of RANKL mRNA using the fibrogranulomatous tissue obtained from patients. In all samples, we detected RANKL mRNA by RT-PCR as single bands at the expected molecular weight for human RANKL. Secondly, we examined these tissues by the histologicaly. These tissues were contained numerous macrophage-like mononuclear cells and multinucleated giant cells. Some of these cells contained numerous metal particles and polyetylene particles. In the immunohistochemical demonstrated that RANKL was localized in fibroblast-like cells (positive for PH) negative for CD68 and tartrate-resistant acid phosphatase (TRAP), and in round mononuclear cells and multinucleated giant cells, both of which were positive for CD68 and TRAP. RANKL was expressed by three distinctive types of cells, CD68/TRAP-positive mononuclear histiocytic cells, CD68/TRAP-positive multinuclear giant cells, and PH-positive fibroblastic cells. These cells may contribute to activated osteolysis by acting as bone resorbing effector cells, as well as by supporting osteoclastogenesis via RANKL. And these cells may be activated by particles. The present findings indicate that RANKL may be involved in osteolysis associated with prosthetic loosening.

TNF-α Downregulates Human Copper-Zinc Superoxide Dismutase Promoter in U-937 Human Promonocytic Cells. V. Afonso*, P. Collin*, A. Lomri. INSERM U349, Paris 10, France.

Proinflammatory cytokines such as TNF-α and IL-1ß; are known modulators of bone remodeling in vitro and in vivo. These cytokines induce the production of nitric oxide (NO) in various cell types, including osteoblasts and osteoclasts and NO has recently been implicated in the regulation of bone resorption and formation. In contrast, superoxide dismutase enzymes (SODs) protect cells from the deleterious effects of reactive oxygen species by scavenging superoxide radicals. Although cytosolic copper-zinc SOD (Cu/Zn-SOD-1) activity has been found modified in some specific situations including hematopoietic cell differentiation, aging and some tumor cells, It has been reported that TNF-α had no effect on SOD-1 expression. In order to determine if TNF-α effects involve Cu/Zn-SOD-1, transient transfection of promoter-reporter gene constructs and RT-PCR analysis were carried out in U-937 human promonocytic cells. We first examined endogenous Cu/Zn-SOD-1 mRNA, protein and activity levels by semiquantitative RT-PCR, Western blot and enzymatic analyses in human osteoblastic and U-937 cell lines. Both human osteoblastic and U-937 cell lines expressed high levels of Cu/Zn-SOD-1 mRNA, protein and activity in basal conditions. Constructs -1499 to -71 displayed basal promoter activity as well as TNF-α repression. In contrast deletion of the regulatory sequences immediately upstream of the TATAA box resulted in total lost of the luciferase activity. TNF-α-inhibited Cu/Zn-SOD-1 promoter activity by 77% ($p<0.01$) after 24 h of treatment and this effect was more pronounced after 48 h (90%, $p<0.01$). It is noteworthy that both basal and TNF-α-inhibited promoter activities gradually decreased following the progressive deletion of 5'-regulatory flanking sequences, indicating the existence of several cis-acting positive regulatory sequences spread along 1.5 kb of the Cu/Zn-SOD-1 promoter proximal region. Both basal and TNF-α-inhibitory elements were mapped to -71 and -29 region of the Cu/Zn-SOD-1 promoter. Sequence analysis of this fragment revealed the presence of different putative transcription factor binding sites (Sp-1, Egr-1, WT1, Krox-20, NF-IL6). In agreement with the transfection results, endogenous SOD-1 mRNA was suppressed by TNF-α (-41%) after 24 h. Our results underline the importance of cytosolic Cu/Zn-SOD as anti-cytotoxic and anti-inflammatory mediator in the osseous microenvironment and might explain partly the observed deficiency of bone formation in inflammatory sites.

SU238

Effects of T Cells on Osteoclast Formation in vitro Depend on the Method of Activation. N. Wyzga*[1], S. Varghese[2], S. Wikel*[3], F. A. Sylvester*[1]. [1]Connecticut Children's Medical Center, Hartford, CT, USA, [2]Saint Francis Hospital and Medical Center, Hartford, CT, USA, [3]University of Connecticut Health Center, Farmington, CT, USA.

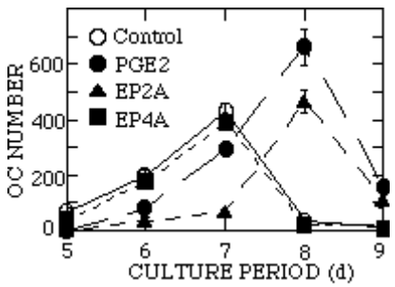
T cells are possible regulators of bone mass in chronic inflammatory diseases. Some investigators reported that activation of T lymphocytes results in RANKL-mediated increase in osteoclastogenesis, while others showed that activation leads to interferon-gamma (IFN-γ)-mediated inhibition of osteoclast formation. Because these studies were performed using different methods of T cell activation, we hypothesized that the method of activation determines their effect on osteoclastogenesis in vitro. T cells were harvested from spleen of 5-week-old male C57BL/6J mice using CD90(Thy1.2) magnetic beads. Activation of T cells was performed using anti-CD3e and CD28 antibodies (Antibodies), concanavalin A (Con A), phytohemagglutinin (PHA), and Staphylococcal enterotoxin A (SEA). T cell purity was >90% by flow cytometry. Conditioned media were collected after 4 days, and IFN-γ and RANKL concentrations were determined by ELISA. For osteoclast studies, RAW 264.7 cells (50,000/well) were cultured in α-MEM, containing 10% conditioned media and RANKL at 20 ng/mL. After 5 days, osteoclasts were detected by TRAP staining and a resorption assay. The percent resorbed surface correlated directly with the number of TRAP-positive cells (not shown). The table below summarizes the concentrations of IFN-γ and RANKL in conditioned media and the effects from different methods of activation on osteoclastogenesis (ND = non detectable). As shown, there was an inverse relationship between the concentration of INF-γ and osteoclastogenesis. Adding similar concentrations of IFN-γ to RAW 264.7 cells reproduced this effect. Pre-incubation of conditioned media with an anti-IFN-γ neutralizing antibody restored osteoclastogenesis. We conclude that the effects of T cells on osteoclastogenesis in vitro depend on the method of activation. IFN-γ is a potent inhibitor of osteoclastogenesis that counteracts the effects of RANKL, which may have implications in vivo in chronic inflammatory diseases.

Method	IFN-γ (pg/mL)n = 3	RANKL (pg/mL)n = 2	Osteoclasts
Resting T-cells	ND	ND	+
Antibodies	441,914 ± 2,737	1,068 ± 18	-
Con A	2,282 ± 1,157	7 ± 0.9	+/-
PHA	9 ± 3.4	31 ± 1.9	+
SEA	3,646 ± 969	170 ± 4	-

SU239

Biphasic Effects of Prostaglandin E2 on Osteoclast Formation from Spleen Cells. K. Ono[1], T. Akatsu[2], N. Kugai*[2], C. C. Pilbeam[1], L. G. Raisz[1]. [1]Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]General Medicine, National Defense Medical College, Tokorozawa, Japan.

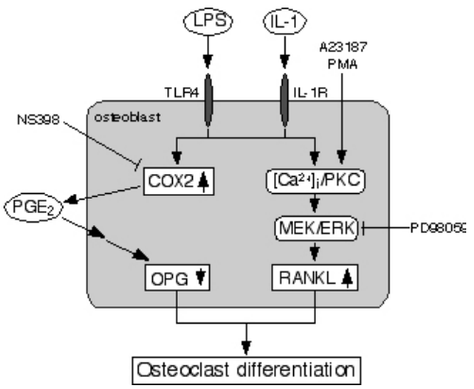
Prostaglandin E2 (PGE2) is a potent stimulator of osteoclast (OC) formation through receptor activator of nuclear factor-kB ligand (RANKL) in stromal/osteoblastic cells. PGE2 can also increase OC formation in spleen cells cultured with RANKL and macrophage-colony stimulating factor (M-CSF) in the absence of stromal/osteoblastic cells. In this study, we examined the time course for the effects of PGE2 and selective PGE2 receptor agonists on OC formation in spleen cell cultures treated with RANKL and M-CSF. Spleen cells from C57BL/6 mice were cultured in αMEM containing 10% FCS at 5 x 10^5 cells/well in a 24-well plate (1.0 ml/well) with 10 nM M-CSF and 10 nM RANKL. Cells were cultured with or without 1 μM PGE2, EP2 agonist (EP2A, ONO-AE1-259) or EP4 agonist (EP4A, ONO-AE1-329) for 5-9 d. At the end of culture, adherent cells were stained for tartrate resistant acid phosphatase (TRAP). TRAP-positive cells containing 3 or more nuclei were counted as OC. As shown in the figure, control cultures with only RANKL and M-CSF formed OC at 5 d with the peak at 7 d and subsequently declined. Treatment with PGE2 initially inhibited OC formation but at 8 d there was a significantly greater number of OC than in control cultures at 7 d. EP2A showed an initial inhibition and late peak parallel to PGE2 but with lower OC number. EP4A had no significant effect on OC number compared to control cultures. In a separate experiment OC were counted at 8 d after continuous, 0-4 d or 4-8 d treatment with PGE2, EP2A or EP4A. OC number was less than 2 in a control cultures, cultures treated for 4-8 d with PGE2 or EP2A and all cultures treated with EP4A. 0-4 and 0-8 d treatment with PGE2 or EP2A showed similar significant increases in OC number. We conclude that the effect of PGE2 on OC formation in spleen cell cultures in the presence of M-CSF and RANKL is mediated by the EP2 receptor and consists of an initial inhibition followed by a stimulation of OC formation. These effects are established during the first 4 d of treatment. We speculate that activation of the EP2 receptor produces a transient inhibition of replication of OC precursors followed by an increase in formation and/or survival of mature OC.



SU240

Lipopolysaccharide Stimulates Osteoclast Formation via RANKL Expression Independent of PGE2 Production. K. Suda*[1], N. Udagawa[2], M. Takami[1], K. Itoh*[1], J. Woo[3], N. Takahashi[4], K. Nagai*[3]. [1]Biochemistry, School of Dentistry, Showa University, Tokyo, Japan, [2]Biochemistry, Matsumoto Dental University, Shiojiri, Japan, [3]Biological Chemistry, Chubu University, Kasugai, Japan, [4]Institute of Dental Science, Matsumoto Dental University, Shiojiri, Japan.

The mechanism of osteoclast formation induced by lipopolysaccharide (LPS) was studied in cocultures of mouse osteoblasts and bone marrow cells. LPS stimulated osteoclast formation and prostaglandin E2 (PGE2) production in the coculture, both of which were inhibited by NS398, an inhibitor of cyclooxgenase-2. LPS stimulated receptor activator of NF-kB ligand (RANKL) mRNA expression, and inhibited osteoprotegerin (OPG) mRNA expression in osteoblasts. NS398 inhibited only down-regulation of LPS-induced OPG mRNA expression, suggesting that LPS-stimulated PGE2 production is important for the down-regulation of OPG in the coculture. Indeed, NS398 failed to inhibit LPS-induced osteoclast formation completely in the coculture with OPG knockout mouse-derived osteoblasts. Among several signal inhibitors examined, calcium/protein kinase C (PKC) inhibitors and PD98059 [an extracellular signal-regulated kinase (ERK) inhibitor] suppressed LPS-induced RANKL mRNA expression in osteoblasts. LPS stimulated phosphorylation of mitogen-activated protein kinase (MAPK) /ERK kinase (MEK), and that of ERK in osteoblasts. LPS-induced phosphorylation of ERK was inhibited by calcium/PKC inhibitors. A23187 (an ionophore) and phorbol-12-myristate-13-acetate (PMA: a PKC activator) but not PGE2 stimulated phosphorylation of ERK in osteoblasts. PD98059, an inhibitor of MEK/ERK, blocked osteoclast formation but not PGE2 production in cocultures treated with LPS. In addition, both PD98059 and NS398 inhibited osteoclast formation induced by interleukin 1 (IL-1) in the coculture, but only PD98059 suppressed IL-1-induced RANKL mRNA expression in osteoblasts. These results suggest that LPS and IL-1 promote osteoclastogenesis through two parallel events: one is enhancement of RANKL expression through calcium/PKC signals followed by MEK/ERK signals, and the other is suppression of OPG production mediated by PGE2.



SU241

Bacteral CpG-DNA and Viral Double-stranded RNA Stimulate Osteoclast Formation Through the Induction of RANKL in Osteoblasts. K. Suda*[1], M. Takami[1], N. Udagawa[2], K. Itoh*[1], T. Suzawa[1], J. Woo[3], K. Nagai*[3], N. Takahashi[4]. [1]Biochemistry, Showa University, Tokyo, Japan, [2]Biochemistry, Matsumoto Dental University, Nagano, Japan, [3]Biological Chemistry, Chubu University, Aichi, Japan, [4]Institute for Dental Science, Matsumoto Dental University, Nagano, Japan.

Lipopolysaccharide (LPS), a major constituent of Gram-negative bacteria, is proposed to be a potent stimulator of bone loss in inflammatory diseases such as periodontitis and osteomyelitis. Toll-like receptor 4 (TLR4) has been identified as the signal transducing receptor for LPS. Bacterial DNA, which is enriched in unmethylated CpG motifs, is shown to activate innate immune system. Virus-derived double-stranded RNA (dsRNA), which is produced by viruses during their replication, is also known to induce antimicrobial immune responses. Recent studies have shown that TLR9 and TLR3 are the receptors of CpG DNA and dsRNA, respectively. In this study, roles of bacterial CpG DNA and viral dsRNA in osteoclastic bone resorption were examined, in comparison with those of LPS. (1) RT-PCR analysis showed that primary osteoblasts expressed mRNA of TLR9 and TLR3 as well as TLR4. In contrast, osteoclasts expressed mRNA of TLR4 but not that of TLR9 and TLR3. (2) CpG DNA , polyinosine-polycytidylic acid [poly(I:C), a synthetic analogue of dsRNA] and LPS stimulated the formation of TRAP-positive osteoclasts in cocultures of mouse osteoblasts and bone marrow cells in a dose-dependent manners. GpC DNA (an inactive form DNA) failed to induce TRAP-positive cell formation in the coculture. TRAP-positive cells induced by CpG DNA, poly(I:C) or LPS formed resorption pits on dentine slices. Osteoprotegerin, a decoy receptor of RANKL, completely inhibited osteoclast formation in the cocultures treated with the bacterial and viral products. (3) RT-PCR showed that osteoblasts expressed RANKL mRNA in response to CpG DNA, poly(I:C) or LPS. RANKL mRNA was not induced by GpC DNA in osteoblasts. (4) When osteoblasts were removed from the coculture, almost all the TRAP-positive osteoclasts died within 48 h. LPS supported the survival of purified osteoclasts, but CpG DNA and poly(I:C) did not. Thus, unlike LPS, bacterial CpG-DNA and vial dsRNA failed to act directly on osteoclasts to induce bone-resorbing activity. However, like LPS, CpG-DNA and dsRNA stimulated RANKL expression in osteoblasts, which results in induction of osteoclast formation. These results suggest that together with LPS, bacterial CpG-DNA and viral dsRNA play important roles in osteoclastic bone resorption in inflammatory diseases.

SU242

Signals Mediated by p38 MAP Kinase Are Involved in Differentiation but not Function of Osteoclast Precursors. X. T. Li*[1], N. Udagawa[2], K. Itoh*[3], K. Suda*[3], N. Sato*[2], N. Takahashi[1]. [1]Institute for Dental Science, Matsumoto Dental University, Nagano, Japan, [2]Biochemistry, Matsumoto Dental University, Nagano, Japan, [3]Biochemistry, Showa University, Tokyo, Japan.

[Backgrounds] We previously reported that SB203580, an inhibitor of p38 MAP kinase, inhibited differentiation of bone marrow macrophages (BMMϕ) into osteoclasts in cultures treated with RANKL and M-CSF. However, SB203580 failed to inhibit pit-forming activity of osteoclasts induced by RANKL. Phosphorylation of p38 MAP kinase was induced by RANKL and LPS in BMMϕ but not in osteoclasts. In this study, we further investigated the role of p38 MAP kinase in the differentiation and function of BMMϕ. **[Methods]** BMMϕ were prepared from bon marrow cultures treated with M-CSF for 3 days. osteoclasts were prepared from co-cultures of osteoblasts and bone marrow cells. Activation of JNK, ERK, and p38 MAP kinase was determined by Western blotting in BMMϕ and osteoclasts in response to LPS. Activation of NF-κB was determined by evaluating the degradation of IκB. Production of pro-inflammatory cytokines such as IL-1, TNFα, and IL-6 in BMMϕ and osteoclasts in response to LPS was determined by ELISA. Phagocytic activity of BMMϕ and osteoclasts were determined by the incorporation of latex beads in the presence or absence of SB203580. **[Results]** (1) LPS induced activation of JNK, ERK, and NF-κB in BMMϕ as well as in osteoclasts. LPS stimulated phosphorylation of MAP kinase kinase 3/6 and ATF2, upstream and downstream signals of p38 MAP kinase, respectively, in BMMϕ but not in osteoclasts. (2) LPS stimulated production of IL-1, TNFα, and IL-6 in BMMϕ but not in osteoclasts. SB203580 failed to inhibit the production of these cytokines in BMMϕ treated with LPS. (3) BMMϕ but not osteoclasts showed vigorous phagocytic activity in the presence of M-CSF. SB203580 failed to inhibit the phagocytic activity of BMMϕ. **[Discussion]** SB203580 has been shown to inhibit differentiation of monocytes into dendritic cells induced by GM-CSF and LPS. These results suggest that p38 MAP kinase mediated signals are essentially involved in the differentiation of monocytes/macrophages not only into osteoclasts but also into dendritic cells. In contrast, p38 MAP kinase was not important for macrophage function such as cytokine production and phagocytosis. Signals of upstream and downstream of p38 MAP kinase were completely inactivated in osteoclasts. This phenomenon may be explained by the fact that osteoclast are terminally differentiated cells.

SU243

Osteoclast Progenitors Stimulated by TGF-beta or by RANKL Differ in their Sensitivity to Osteoclastogenesis Inhibitors. J. M. W. Quinn[1], K. D. Häusler*[1], C. Gange*[1], H. Zhou[1], J. S. Rubin*[2], T. J. Martin[1], M. T. Gillespie[1]. [1]St. Vincent's Institute of Medical Research, Fitzroy, Victoria, Australia, [2]NCI, NIH, Bethesda, MD, USA.

Osteoclast formation in vivo and in vitro results from stimulation of hematopoietic progenitor cells by M-CSF and RANKL. This differentiation proceeds in stages in vitro. After initial proliferation, calcitonin receptor and tartrate resistant acid phosphatase are apparent after day 3 of culture while multinucleation and bone resorption are evident after day 5. However, TGFbeta can substitute for RANKL in the initial phases. We previously noted that, in RANKL-dependent osteoclastogenesis assays, inhibitors such as IL-4 and osteoclast inhibitor lectin (OCIL) also act early in the culture period with little effect if added after day 2. We therefore investigated whether inducing the early stage of osteoclast differentiation by TGF-beta rather than RANKL results in a different sensitivity of the osteoclast progenitors to inhibitory factors. M-CSF-stimulated murine bone marrow cells treated with recombinant RANKL (rRANKL; 100ng/ml) for seven days resulted in 3.0±0.3 osteoclasts/ mm2. In contrast osteoclast formation did not occur when rRANKL was added to cells for days 3 to 7 of the culture period, i.e. rRANKL was omitted for days 0 to 3. With TGFbeta 5ng/ml stimulation for days 0 to 3 followed by rRANKL stimulation from days 3 to 7, 3.1±0.3 osteoclasts/ mm2 formed. A similar priming effect was noted with TNF-alpha (day 0 to 3)/rRANKL sequential stimulation (0.5±0.1 osteoclasts/ mm2). We then investigated the action of IL-4, GM-CSF, OCIL and RANKL-binding proteins osteoprotegerin (OPG-Fc), soluble RANK-Fc and secreted frizzled-related protein-1 (sFRP-1). In cultures stimulated only by rRANKL (days 0 to 7) all of these factors blocked osteoclast formation when added for the first three days of culture. However, in TGF-beta-primed cultures only IL-4, GM-CSF and sFRP-1 blocked osteoclast formation while OCIL, OPG-Fc and RANK-Fc had no effect. These results suggest that OCIL, OPG-Fc and RANK-Fc inhibitory action depend on the presence of rRANKL (presumably, in the case of OPG-Fc and RANK-Fc, by sequestering it) or on responses elicited by rRANKL. In contrast, IL-4, GM-CSF and sFRP-1 exerted a rRANKL-independent action. Thus, the sequence of stimuli to which progenitors are exposed may determine their sensitivity to particular inhibitors, an important consideration in investigating anti-osteolytic agents. The in vitro methods we employed may also provide insights into mechanisms of inhibitor action.

Function of Transcriptional Regulator, OCZF Expressed in Osteoclasts. A. Kukita[1], T. Kukita[2], T. Shobuike*[1], M. M. Rahman*[1], T. Nakamura*[1], O. Kohashi*[1]. [1]Microbiology, Saga Medical School, Saga, Japan, [2]Oral Cellular Molecular Biology, Faculty of Dental Science, Kyushu University, Fukuoka, Japan.

Osteoclast-derived zinc finger (OCZF) gene, which we isolated from osteoclast specific cDNA library, encodes a transcriptional regulatory factor. OCZF protein belongs to a member of POZ Zn finger proteins and has homology in POZ domain with other transcription factors including PLZF which has an important role in monocyte differentiation. In situ hybridization analysis with POZ domain of OCZF as a probe, OCZF mRNA was specifically present in the osteoclasts of rats developed adjuvant induced arthritis. We then examined OCZF expression by RT-PCR analysis using a mouse macrophage cell RAW264 subclone RAW-D which has high potential to differentiate into osteoclasts. RAW-D cell alone expressed OCZF at very low level but treatment of the RAW-D cells with sRANKL for 2 days increased the level of OCZF mRNA. The analysis with polyclonal antibody against OCZF protein also showed that OCZF protein was present in the nuclei of the multinucleated cells of RAW-D cells induced by sRANKL. We then infected RAW-D cells with retroviruses expressing OCZF and OCZF-EGFP fusion proteins. The cells that survived selection were expanded and were shown to express increased levels of OCZF protein by western blotting. These cells proliferated very slowly in comparison with RAW-D cells infected with parental retrovirus. In addition, the adhesive property of the cells expressing OCZF was altered and the aggregation of the cells was occurred. Because other POZ Zn finger transcriptional regulators are involved in the regulation of cell cycle, we then examined the effect of OCZF on transactivation of the cell cycle inhibitors such as $p21^{WAF1}$ and $p27^{KIP1}$ using these inhibitors promoter luciferase plasmids by transient transfection in RAW-D and NIH3T3 cells. We found that OCZF stimulated the transactivation of these plasmids. These results suggest that OCZF is involved in the downstream of RANKL signaling and inhibits growth of the cells by stimulating the expression of cell-cycle inhibitors in differentiated state.

SU245

CD44 Is Not Required for the Development of Bone Marrow Cells Into Actively Resorbing Multinucleated Osteoclasts. T. J. de Vries*[1], T. Schoenmaker*[1], R. van der Neut*[2], W. Beertsen*[3], S. T. Pals*[2], V. Everts[1]. [1]Dept. of Periodontology, ACTA, Dept. of Cell Biology and Histology, AMC, Amsterdam, Netherlands, [2]Dept. of Pathology, AMC, Amsterdam, Netherlands, [3]Periodontology, ACTA, Amsterdam, Netherlands.

Purpose: The role of CD44 in osteoclastogenesis was investigated. *Methods:* Genetically engineered mice were used that express (1) only the standard form of CD44 (CD44s), (2) a splice variant containing variable exons v3-v10 (CD44v3-v10), a splice variant containing variable exons v4-v10 (CD44v4-v10), or (4) no CD44 at all (CD44 k.o.). Bone marrow cells from these mice and wild type mice were cultured in the presence of M-CSF and RANKL to induce osteoclast differentiation. *Results:* Higher numbers of multinucleated TRAP-positive cells were observed in CD44 k.o. cultures, whereas no differences were observed between the other genotypes and wild type controls. Bone resorption was similar for all 5 genotypes. Since wild-type bone marrow only expressed the standard form of CD44 during osteoclastogenesis, further comparisons were performed between wild type and CD44 k.o. mice. Characterization of osteoclasts generated from wild type and CD44 k.o. mice revealed comparable mRNA levels of osteoclast related genes TRAP, cathepsin K and carbonic anhydrase II. The expression of calcitonin receptor proved to be higher in CD44 k.o. cultures. The possibility of a CD44 redundant fusion mechanism was studied by comparing the mRNA levels of proteins involved in macrophage fusion MFR, CD47 and $P2Z/P2X_7$. No difference in expression was observed between the CD44 k.o. and wild type cultures. We further studied the osteoclastogenic potential of wild type and CD44 k.o. marrow in the presence of CD44 blocking antibodies and agents which can compete with CD44 function chondroitin sulphate A and B. All agents used had similar effects on both genotypes, indicating that these effects are CD44 independent. *Conclusions:* Our data clearly demonstrate CD44 is not involved in differentiation of osteoclasts from bone marrow cells. This process differs from the formation of osteoclasts from splenocytes and macrophages, where a requirement for CD44 has been described. recombinant murine RANKL was kindly provided by Amgen Inc, Thousand Oaks, California, U.S.A.

Lactoferrin Delays Acquisition of the Osteoclast Phenotype. F. Lorget*[1], J. Clough*[1], M. Oliveira*[1], R. Mentaverri*[2], M. Daury*[1], M. Brazier[2], E. A. Offord*[1]. [1]Nutrition, Nestle Research Center, Lausanne 26, Switzerland, [2]Laboratory of Clinical Pharmacy, School of Pharmacy, Amiens, France.

Lactoferrin (LF) is an iron-binding protein found in exocrine secretions of mammals and released from neutrophil granules during inflammation. LF has potent antioxidant and antimicrobial properties due to its iron-chelating ability. In addition, it inhibits activation of macrophages in response to bacterial lipopolysaccharide (LPS) by an iron-independent mechanism. LF interferes with the interaction of LPS with its macrophage cell surface receptor (CD14), and also binds to soluble CD14 found in serum. Binding of LPS to CD14 activates several cytoplasmic kinases resulting in the activation of transcription factors, mainly AP-1 and NFkB. CD14 is expressed on osteoclast precursors derived from cells of the mononuclear-phagocytic lineage. We were therefore interested to know if lactoferrin could influence the bone resorbing process. We first investigated its effect on human osteoclast differentiation. The current experiments were carried out with bovine LF (bLF), which is commercially available and gives comparable bioactivity to human lactoferrin. Blood samples were obtained from healthy male donors less than 60 y. Peripheral blood mononuclear cells (PBMC) or selected CD14 positive cells were differentiated into osteoclasts in the presence of RANKL (25 ng/ml) and M-CSF (30 ng/ml). The osteoclast phenotype was assessed by (i) mRNA expression of calcitonin receptor (CTR) using semi-quantitative PCR and (ii) immunofluorescence labeling for calcitonin and vitronectin receptors (CTR and VNR) and actin ring formation. Bone resorbing ability was evaluated by measuring the resorbed area according to stereological principles. In some PBMC cultures, collagen breakdown products were analyzed by ELISA (CrossLaps™ for culture, Nordic Bioscience A/S). Bovine LF (1 to 100 µg/ml) dramatically stimulated the proliferation of selected CD14 postive cells undergoing osteoclast differentiation. In both CD14 selected and PBMC cells, the number of multinucleated CTR positive cells as well as bone resorbing activity were reduced in the early stages of culture (7 - 14 days) but not in the later stage (at 21 days). Taken together these results suggest that bLF delays acquisition of the osteoclast phenotype. This observation is of particular relevance to inflammatory bone disease, where inflammation and bone loss coexist.

SU247

Modulation of Osteoclastogenesis through Functional Adrenomedullin Receptors Expressed on Osteoclast Precursors, that Is partly Related to Osteoclast Differentiation Antigen. T. Kukita[1], A. Kukita[2], K. Tou*[3], T. Iijima*[3]. [1]Oral Cellular & Molecular Biology, Faculty of Dental Science, Kyushu University, Fukuoka, Japan, [2]Microbiology, Saga Medical School, Saga, Japan, [3]Oral Anatomy & Cell Biology, Faculty of Dental Science, Kyushu University, Fukuoka, Japan.

Fine regulation of osteoclastogenesis is mediated through cell surface molecules expressed on osteoclast precursors. Lines of evidence suggest that peptides regulating the vascular system modulate osteoclast differentiation and function. Adrenomedullin (AM), a member of the calcitonin family peptides, is a potent vasodilator and was shown to be mitogenic to fetal rat osteoblasts. We have previously found a unique cell surface antigen (Kat1-antigen) expressed in rat osteoclasts and their mononuclear precursors, which is involved in the functional regulation of the calcitonin receptor (CTR). Cross-linking of the cell surface antigen by use of the anti-Kat1-antigen monoclonal antibody (mAb Kat1) stimulated osteoclastogenesis under conditions exposed to calcitonin. Here we searched candidates for the natural ligand of the Kat1-antigen. Among factors we have examined, only AM provoked a significant stimulation in osteoclastogenesis in the presence of calcitonin but not in its absence in rat bone marrow culture system. This stimulatory effect mediated by AM was blocked by the addition of the mAb Kat1. ^{125}I-AM binding experiments including autoradiographic studies demonstrated that mononuclear precursors of osteoclasts expressed functional AM receptor and the specific binding of ^{125}I-AM was significantly inhibited by the addition of the mAb Kat1, suggesting a close relationship of the Kat1-Ag with the functional AM receptors expressed on mononuclear osteoclast precursors. Modulation of osteoclastogenesis through AM receptors expressed in osteoclast precursors is supposed to be important in the fine regulation of osteoclast formation.

Optimal Conditions for Generation of Active Human Osteoclasts In Vitro: Cell Source, Time, and pH. S. Filke, A. F. Schilling, J. M. Rueger, M. Amling. Trauma Surgery, Hamburg University School of Medicine, Hamburg, Germany.

Studying human osteoclast in vitro may lead to major advances in our understanding of osteoclast biology and is of paramount importance to gain insights in osteoclast associated human diseases. We have recently described an in vitro culture system to generate human osteoclasts (OCL) in which human mononuclear cells from either the peripheral blood (PBMC) or the bone marrow (BMMC) differentiate in the presence of M-CSF and RANKL but in the absence of any other supportive cells. Here we modified this human system to improve culture conditions for optimal osteoclast yield and osteoclast function. First we aimed at improving the source of osteoclast precursors. Having demonstrated that PBMC are as potent as BMMC in generating osteoclasts, we show here that 'buffy coats', the generally discarded left over which contains the mononuclear cell fraction when packed red-blood cells are produced, are an ideal cell source for osteoclast cultures. Then we characterized the time course of osteoclast development and function. In human cultures mononuclear cells start to fuse at day 5, and osteoclasts finish their morphological development and express osteoclast associated markers (e.g. TRAP, vitronectin receptor, calcitonin receptor) at day 14. In contrast functional activity only starts at this time with the first resorption pits of single osteoclasts being detected at day 21. Full functional activity of >80% of the osteoclasts formed is detected at day 28. Thus for differentiation assays the read out can be done after 2 weeks of culture, while pit assays for assessment of functional activity require 4 weeks of culture. Finally, we reasoned that an acid milieu might favor osteoclast differentiation and function as pH changes in the microenvironment have been reported for several diseases associated with local bone resorption (e.g. rheumatoid arthritis, implant loosening). Therefore cultures were performed at six different pH values ranging from pH 6.5 to pH 7.5. After 2 weeks the number of TRAP-positive multinucleated OCLs per high power field (magnification 400x) was 3.1 at pH 6.5; 3.4 at pH 6.8; 5.7 at pH 6.9; 5.5 at pH 7.1; 1.6 at pH 7.3; and 1.4 at pH 7.5 (experiments performed in quadruplicate; high power fields per culture n=40). Thus osteoclast development is significantly favored by moderate acid culture conditions with a pH between 6.9 and 7.1 ($p<0.005$).

Signaling via Gap Junctions Is Important for the Fusion of Human Osteoclasts In Vitro. A. F. Schilling, S. Filke, J. M. Rueger, M. Amling. Trauma Surgery, Hamburg University School of Medicine, Hamburg, Germany.

Precursors of human osteoclasts only start to fuse in vitro at a cell density that allows direct cell-cell contact. This observation led us to reason that cell-cell communication via gap junctions might play a role in the fusion process of human osteoclast precursors. To experimentally test this hypothesis, we first analyzed the expression of connexin 43, a gap junctional hemi-channel, known to be present on rat osteoclasts. Immunolabeling with specific antibodies revealed that connexin 43 is indeed highly expressed by human osteoclast precursors. To further test the functional role of this channel in the process of osteoclast fusion we blocked its activity by heptanol, a known inhibitor of gap junctional communication. Therefore we used an established in vitro culture system to generate human osteoclasts and administered heptanol (at 3 different concentrations) to these cultures in daily intervals. After 4 weeks of culture cells were fixed and labeled for TRAP, a typical marker of osteoclasts. TRAP positive multinuclear cells were counted as osteoclasts and TRAP positive mononuclear cells were counted as unfused osteoclast precursors. Indeed in treated cultures inhibition of gap junctional communication by heptanol led to a significant reduction (>50%) of multinuclear TRAP positive osteoclasts. Consequently also in vitro dentin resorption as assessed in a pit assay was significantly decreased. In contrast the number of TRAP positive mononuclear cells was not affected or even increase by the treatment with heptanol, ruling out the possibility that the decrease in multinucleated osteoclasts was due to toxic effects. These observations indicate that cell-cell signaling via gap junctions plays an important role in the fusion of mononuclear osteoclast precursors to multinuclear osteoclasts in the human culture system.

TGF-beta Affects the Rate of Formation and Phenotype of Human Osteoclasts Derived from Mobilized CD34$^+$ Cells. M. Wang*, H. Loughrey. SignalGene Inc., Montreal, PQ, Canada.

Human peripheral blood mononuclear cells (PBMC) are a well-established source of osteoclast progenitors. Several groups have shown that various combinations of cytokines induce formation of multi-nucleated tartrate-resistant acid phosphatase (TRAP) positive osteoclasts. These cells were functionally active as shown by bone resorption assays. We were interested in determining whether TGF-beta would enhance the rate of formation of human osteoclasts from mobilized CD34$^+$ cells in a fashion similar to that reported for mouse osteoclasts (1, 2). After adherence selection, human CD34$^+$ cells were treated for up to 11 days with M-CSF and sRANKL, and either with or without TGF-beta. On days 7 and 11 cultures were stained for TRAP and mRNA levels of TRAP and Calcitonin receptor (CTR) were assessed by RT-PCR. With only M-CSF and sRANKL present, TRAP+ multinucleated cells appeared around day 7 ultimately yielding a homogenous mature osteoclast population with increasing numbers detected on day 11. When cells were grown in M-CSF, sRANKL *and* TGF-beta, the rate of formation of osteoclasts was significantly higher than that observed without TGF-beta present. Moreover, two phenotypes were detected on days 7 and 11 in the presence of TGF-beta, in contrast to the homogeneous nature of the mature osteoclast population observed in its absence. The first and most predominant phenotype was the typical TRAP+ multi-nucleated osteoclast. The second phenotype had the appearance of tight cell aggregates that were TRAP positive. RT-PCR studies showed that under both culture conditions TRAP mRNA levels increased over time. However CTR mRNA was detected on day 11 in cells cultured with only M-CSF and sRANKL, but not in those cultured with added TGF-beta at either time point. Thus it is possible that osteoclasts generated in the presence of TGF-beta may not be functionally active. Future work is aimed at determining the nature of TRAP+ cell aggregates and characterizing the bone resorption ability of osteoclasts derived by culturing with TGF-beta.

Elucidating Differences Between Large and Small Osteoclasts Using the RAW 264.7 Mouse Macrophage Cell Line as a Model System. M. F. Manolson[1], K. Li*[1], H. P. von Schroeder*[2], S. Shorey*[1], D. Chandra*[1], J. N. M. Heersche[1]. [1]Faculty of Dentistry, University of Toronto, Toronto, ON, Canada, [2]University Health Network, University of Toronto, Toronto, ON, Canada.

Increased bone resorption in several bone diseases (e.g. rheumatoid arthritis, Paget's disease, multiple myeloma, periodontal disease) is associated with an increase in the size of osteoclasts in the affected areas, suggesting that an increase in osteoclast size may be related to increased resorptive activity. We found that, as a population, large osteoclasts are more effective resorbers than small osteoclasts, the reason for this being that the proportion of large osteoclasts that are resorbing is much greater than the proportion of small osteoclasts that are resorbing [1, 2]. This could explain why in disease states where there are more large osteoclasts, there is also much more bone resorbed. Our goal is to understand the molecular mechanisms that lead to the differences in resorptive activity between large and small osteoclasts. *In situ* hybridization on cultured rabbit long bone osteoclasts indicates that both the receptor for MCSF, *c-fms*, and the 100 kDa V-ATPase subunit, a3, are both expressed about 2.5 fold higher in large (≥10 nuclei) compared to small (≤5 nuclei) osteoclasts. To look for novel factors using genomic and/or proteomic approaches, we are extending this study by isolating RNA and protein from populations of large and small osteoclasts differentiated from the RAW 264.7 mouse macrophage (RAW) cell line. By titrating the concentration of recombinant soluble Receptor Activator of NFkB (sRANKL), and adjusting the time of incubation and frequency of media changes, two conditions have been established that maximally enrich for populations containing either large (≥10 nuclei) or small (≤5 nuclei) osteoclasts. Using protein isolated from these two populations, preliminary immunoblot studies have shown that cathepsin K and matrix metalloproteinase 9 are expressed at higher levels in large vs small osteoclasts. RNA isolated from large and small osteoclasts are currently being used to screen mouse and human cDNA microarrays to look for additional changes in gene expression. Thus, results using authentic rabbit osteoclasts and osteoclasts differentiated from RAW cells support the view the large osteoclasts differ from small osteoclasts in activation mechanisms, proton transport, and matrix degradation activity. The goal of this work is to selective inhibit the most active osteoclasts, eliminating excessive resorption related to disease while maintaining normal remodeling activity.

Microarray Expression Profiling of Osteoclast-Like Cells Differentiated with Lipopolysaccharide. H. Saleh*[1], N. Walsh*[1], T. Ravasi*[1], C. Wells*[1], Y. Okazaki*[2], P. Carninci*[2], Y. Hayashizaki*[2], D. A. Hume*[1], A. I. Cassady[1]. [1]Institute for Molecular Bioscience, CRC for Chronic Inflammatory Diseases, University of Queensland, Brisbane QLD, Australia, [2]Genome Research Science Centre, Yokohama, Japan.

Osteoclasts are large multinucleated cells of hematopoietic origin that function specifically to resorb bone. The differentiation of osteoclast progenitor cells into mature osteoclasts in vivo, is tightly regulated by bone-forming osteoblasts through the action of M-CSF and RANKL. The substitution of RANKL with bacterial lipopolysaccharide (LPS) has been shown to induce the differentiation of osteoclast progenitor cells in vitro into osteoclast-like cells (OCL). In pathological conditions, such as periodontal disease, LPS induces elevated osteoclast differentiation and bone resorption. Our aim in this study was to identify novel genes regulated by LPS during this process. We have used RIKEN 40,000 element mouse cDNA microarrays to establish the gene expression profile of LPS-differentiated mouse bone marrow OCL (LPS-OCL) and compared this with mouse co-culture derived osteoclast-like cells (OCL), and mouse bone marrow-derived macrophages (BMM) . We have identified gene clusters that are: (i) highly up-regulated in OCL as compared to BMM and LPS-OCL; (ii) LPS-inducible genes; (iii) down-regulated by LPS relative to BMM and OCL; (iv) shared by OCL and LPS-OCL. Amongst these genes are known osteoclast marker genes as well as many novel genes that have not also been associated with the three different cell populations. Shared osteoclast marker genes with relatively lower level in LPS-OCL implies that LPS-OCL represent "differentiating osteoclasts" under pathological conditions. This cell population has shown more intensive TRAP staining compared to BMM. On the other hand, co-culture derived osteoclast may physiologically represent more mature osteoclasts. We are characterising differentially expressed genes in OCL and LPS-OCL in order to identify novel regulators of osteoclast differentiation and function. These results will help to define our basic understanding of osteoclast differentiation based on the two models of osteoclast-like cells.

Radicicol Stimulates Osteoclast Differentiation at Low Concentrations. Z. Lee, W. Chung*, H. Kim*. National Research Laboratory for Bone Metabolism, Chosun University, Gwangju, Republic of Korea.

Radicicol, the pharmacological agent that has been shown to exert effects on several enzymes, has been reported to suppress osteoclast function by inhibiting the nonreceptor tyrosine kinase Src. We have examined the effect of radicicol on osteoclast differentiation. At high concentrations (0.1~5 μg/ml) radicicol inhibited formation of multinuclear tratrate-resistant acid phosphatase (TRAP)-positive osteoclasts from mouse bone marrow cells induced by RANKL. This inhibition was due to cytotoxicity. However at low concentrations (10 ng/ml) radicicol significantly enhanced osteoclast differentiation in both bone marrow cell and Raw264.7 cell cultures. As the increase in osteoclast differentiation was similar between cells treated only during the second half of culture period and those treated during the whole period, the effects of radicicol appeared to be after the formation of osteoclst precursors. This effect was accompanied by increased expression of β3 integrin, which was detected by both RT-PCR and FACS analyses. The low concentrations of radicicol also enhanced cell cycle arrest induced by RANKL, which appeared to be mediated by induction of p27 but not that of p21. Radicicol also resulted in a sustained ERK activation at the concentration that enhanced osteoclast formation. Our findings indicate that the pharmacological agent radicicol have diverse effects on osteoclasts depending on treatment concentrations.

Estrogen Inhibits PTH-Stimulated Osteoclastogenesis through Prevention of PTH-Induced Osteoprotegerin Downregulation in Mouse Marrow Stromal Cells. B. LIU[1], J. Wang*[1], H. Yu*[1], P. Chung*[1], F. Bringhurst[2]. [1]Oral Pathology, National Taiwan University Hospital, and School of Dentistry, National Taiwan University, Taipei, Taiwan Republic of China, [2]Endocrine Unit, Massachusetts General Hospital, and Harvard Medical School, Boston, MA, USA.

Osteoprotegerin (OPG), as a decoy receptor, is well known to inhibit osteoclastogenesis by preventing RANKL from binding to RANK. Recently, we have demonstrated that osteoprotegerin (OPG) is essential for estrogens antagonism of PTH-induced osteoclast formation in a mouse marrow stromal cell (MS1) and spleen cell coculture (Endocrinology 143:627-635, 2002). Although substantial evidence indicates that osteotropic factors such as PTH and estrogen regulate OPG expression in bone cells, its mechanism is not com-

pletely understood yet. In order to determine how OPG expression in PTH-stimulated MS1 cells is regulated by estrogen, we analyzed the effect of estrogen on OPG mRNA expression and protein secretion using semi-quantitative reverse transcript (RT)-PCR and enzyme linked immunoassay (ELISA). MS1 cells was pre-treated with rPTH-(1-34) (10-7 M) for 24 hours then stimulated with various concentrations of 17-beta estradiol (E2) ranging from 10-11 M to 10-8 M. The results indicated that PTH-pretreatment inhibited OPG expression while 24-hour treatment of MS1 cells with E2 significantly increased the OPG mRNA expression with the maximal effect at 10-8 M of E2. Time course studies demonstrated that E2 effect on stimulating OPG expression was detectable at 8 hour after treatment and reached a peak at 24 hour. The ELISA studies demonstrated that PTH-pretreatment inhibited MS1 cell OPG secretion whereas E2-treatment reversed the inhibition in a concentration-dependent manner. Simultaneous treatment of MS1 cells with a pure estrogen receptor antagonist, ICI 182,780, completely abolished the stimulatory effect of E2 on OPG production. Our results suggest that the mechanisms by which E2 inhibits PTH-stimulated osteoclast formation in the mouse coculture model are mediated in part by specifically preventing PTH-induced OPG downregulation.

SU255

Estradiol Down Regulates β3 Integrin Expression on Differentiating and Mature Human Osteoclasts. D. Saintier*, M. C. de Vernejoul, M. E. Cohen-Solal. INSERM U349, Paris, France.

Osteoporosis is related to estrogen deficiency, which induces increased bone resorption. We have previously shown that estradiol inhibits directly osteoclast differentiation and activity from human osteoclast progenitors in vitro. Osteoclast activity is dependent of β3 integrin for osteoclast attachment and further bone resorption. The aim of our study was to evaluate β3 integrin mRNA and protein expressions during human osteoclast differentiation and the effects of estradiol. Human peripheral blood mononuclear cells (PBMC) were allowed to differentiate into osteoclasts in the presence of 10%FCS (C), M-CSF (25ng/ml) and RANK-L (30ng/ml) (C+) for 18 days. Cells were also treated with 10^{-8}M estradiol (E2) or raloxifene (Rlx) from D1 to D18 to assess the effect on osteoclast precursors, from D12 to D18 for the effect on osteoclast differentiating cells, from D18 to D21 on mature osteoclasts. mRNA expression was investigated using nested RT-PCR in cells in 5 samples using Polymerase II as internal standard. Treatment with M-CSF and RANK-L (C+) increased the mRNA expression of β3 integrin compared with control cells (C) at each culture time. Already after 12 days of culture, E2 or Rlx decrease RNA expression of β3. Such a decrease was observed after 18 days of culture when steroids were added at D1 or D12 (for D1-D18: 0.6±0.2 AU for E2, 0.7±0.1 AU for Rlx; for D12-D18: 0.8±0.2 AU for E2, 0.9±0.2 AU for Rlx) compared with C+ (1.8±0.6 AU). When steroids were added to mature osteoclasts from D18 to D21, β3 integrin mRNA was also down regulated (0.6±0.2 AU for E2, 0.3±0.1 AU for Rlx) compared with controls (0.8±0.3 AU). The expression of β3 integrin was also evaluated using immunofluocytochemistry and western blot. The percent of cells labeled with β3 integrin antibody was increased with M-CSF and RANK-L and with culture time suggesting increased expression with osteoclast differentiation. The effect of E2 and Rlx added for 18 days was further assessed using western blot analysis: β3 integrin expression was significantly decreased with E2 (0.7±0.2 AU) and Rlx (0.7±0.3 AU) compared with C+ (1.3±0.6 AU). In conclusion, these data show a decreased β3 expression with E2 or Rlx. They also suggest that the direct inhibitory action of estradiol on bone resorption may be mediated through a down regulation of β3 integrin, which may affect osteoclast attachment.

SU256

Estrogen Receptor α Expression Increases with Osteoclast Differentiation but Is not Regulated by Estradiol and RANK-L. D. Saintier*[1], M. A. Burde*[1], J. M. Rey*[2], T. Maudelonde*[2], M. C. de Vernejoul[1], M. E. Cohen-Solal[1]. [1]Hopital lariboisiere, INSERM U349, Paris, France, [2]hopital A. de Villeneuve, laboratoire de biologie cellulaire, Montpellier, France.

Estrogen is a potent anti-resorbing hormone, which decreases osteoclast differentiation. Both estrogen receptors α (ERα) and β (ERβ) have been shown to be involved in bone loss of ovariectomized mice. Human osteoblasts express both ERα and ERβ. Presence of both ERs in human osteoclasts remains controversial, as well as the regulation by estradiol. Our aim was to study the regulation of ERs and RANK during osteoclast differentiation and estradiol treatment. Human peripheral blood mononuclear cells (PBMC) were cultured in red phenol-free DMEM,10% FCS in the absence (C) or the presence of M-CSF (25ng/ml) and RANK-L (30ng/ml) (C+) for 18 days in 9 samples. 10^{-8}M estradiol (E2) or raloxifene (Rlx) were added from day 1 to day 18. Bone resorption pits of dentine slices were evaluated at day 18. No pits were observed in C cultures. Compared with controls (C+), E2 and Rlx decrease total area of resorption pits (4.7 ±1.3 vs 3±0.9 and 2.3±0.75 respectively, $p<0.05$). mRNA expression of ERs was studied by competitive RT-PCR using HPRT as internal control in cells after Day1 (D1), Day 12 (D12) or Day 18 (D18) of culture. We found no expression of ERβ in our cells at any time and at any culture conditions and in presence of positive controls (SaOS3). In contrast, ERα was detected at all time. In control cultured cells (C), ERα expression was enhanced throughout the time of culture : 0.26±0.12 at D1, 0.32±0.10 at D12 and 0.84±0.15, $p<0.05$. Cells cultured with M-CSF and RANK-L (C+) had an identical increased ERα expression : 0.26±0.12 at D1, 0.53±0.10 at D12, 0.81±0.16 at D18, $p<0.05$, suggesting an increase of ERα expression with monocyte differentiation independent of RANK-L. Expression of ERα was also tested in the presence of E2 and Rlx. At day 12, E2 and Rlx do not regulate ERα expression (0.45±0.09 and 0.41±0.15 respectively) compared with C+ (0.53 ±0.10). No regulation was observed either at D18 (0.74±0.19 for E2, 0.41±0.12 for Rlx, p=NS). Moreover, the regulation of RANK during osteoclast differentiation and under estradiol was assessed by RT-PCR. We found that RANK expression was not regulated by RANK-L and estradiol in human differentiating osteoclasts. In conclusion, ERα expression increased with monocyte differentiation, but RANK-L and estradiol do not regulate RANK and ERα . These results may provide new insights in the mechanism of action of estradiol and pathogenesis of bone loss.

Secreted Frizzled-related Protein (sFRP-1) Inhibits TNFalpha- or RANKL-Dependent Osteoclast Formation. K. D. Häusler*[1], J. M. W. Quinn[1], N. J. Horwood[1], J. Ellis*[2], C. Lengel*[2], T. J. Martin[1], J. S. Rubin*[2], M. T. Gillespie[1]. [1]St. Vincent's Institute of Medical Research, Melbourne, Australia, [2]National Cancer Institute, NIH, Bethesda, MD, USA.

Wnt signaling is crucial in the processes of organogenesis and limb development, and in cancer metastasis. Moreover, Wnt signaling is crucial for osteoblast differentiation, apoptosis and the development of bone mass exemplified by the point mutations or genetic loss of LRP5, a co-receptor for Frizzled (Fz) family of proteins. Fz proteins can be antagonised by secreted frizzled-related proteins of which there are five members. The sFRPs contain a cysteine rich domain (CRD) with identity to the CRD of Fz proteins, and can bind to Wnt proteins to modulate their activity. We have found that sFRPs are expressed by the osteoblast and that these influence osteoclast formation. Neutralizing antibodies against sFRP-1 enhanced TRAP positive mononuclear and multinuclear osteoclast formation in cocultures of murine osteoblasts with spleen cells treated with PGE2 (10-7M) and 1,25 (OH)2 vitamin D3 (10-8M). Recombinant sFRP-1, or the CRD of sFRP-1, or sFRP-3 was able to dose dependently inhibit RANKL-dependent osteoclast formation in either osteoblast / spleen cocultures, RANKL+M-CSF-treated splenic or bone marrow cultures, or in RANKL-treated RAW264.7 cell cultures. In RANKL-independent osteoclast formation assays using RAW264.7 cells treated with TNFa +TGFb, sFRP-1 also blocked osteoclast formation while OPG did not affect osteoclast formation. The action of sFRP-1 to limit RANKL- or TNFa-induced osteoclast formation may be explained in part by the observation that recombinant sFRP-1 binds specifically to RANKL in an ELISA format. This finding raised the possibility that sFRP-1 limits osteoclast formation by binding directly to these TNF family members, and suggested that sFRP-1 may act as a decoy receptor potentially with dual specificity for RANKL and TNFa. However, a second mechanism is likely. In bone marrow cultures in which TGFb was present during the first three days and RANKL present only during the last three days of culture, sFRP-1 and OPG had different actions when added with TGFb. sFRP-1 inhibited osteoclast formation, while OPG did not effect osteoclast formation. Combined, these findings suggest that sFRP-1 (and possibly sFRP-3) may affect osteoclast formation by binding to TNFa or RANKL as well as through direct action upon hematopoietic cells, presumably interrupting Wnt signaling.

SU258

Mass Spectrometric Proteome Analysis of RANKL-induced Protein Expression in Osteoclast Differentiation. E. Lee*[1], Y. Jin*[1], R. Hwang*[1], Y. Rhee*[2], S. Lim*[2]. [1]Internal Medicine, College of Medicine, Brain Korea 21 Project for Medical Sciences, Yonsei University, Seoul, Republic of Korea, [2]Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea.

Osteoclasts are highly specified multinucleated bone resorbing cells known as part of the mononuclear phagocyte system. Cytokines macrophage colony stimulating factor (M-CSF) and the receptor activator of NFκB ligand (RANKL) induce differentiation of bone marrow hematopoietic precursor cells and umbilical cord blood cells into bone-resorbing osteoclasts without any requirement for stromal cells. RANKL is a type II membrane protein of the TNF family and plays a critical role in the regulation of osteoclastogenesis. Our aim was to identify and characterize the proteins induced by RANKL that are structurally and functionally undefined. In this study, we attempted to investigate the difference, using proteomics technique, of expression pattern between RANKL-induced cells and those not induced. Briefly, the cells were isolated from bone marrow of mouse femur and tibiae and human umbilical cord blood, respectively, and then were cultured in complete α-MEM media overnight. Next day, the non-adherent cells were removed, and only the adherent cells were further cultured in the presence of M-CSF. After 2 days, the cells were treated with RANKL for 6hr, 24hr, and 72hr respectively. And the obtained cells were subjected to protein purification and subsequent two-dimensional electrophoresis. After visualization of protein spots either by Coomassie or silver nitrate, digital gel images obtained by scanner were analyzed by PDQuest software (Bio-rad, USA) and the results were confirmed visually. The 2D protein pattern of the cells treated with only M-CSF was compared with those treated together with RANKL. As a result, Of thousands of proteins visualized, 32 proteins were increased over three times in amount. Concomitantly, 13 proteins were decreased. Up to now, we identified 26 protein spots using peptide mass spectrometry method by matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS). Furthermore, to confirm the change of the protein level, we will carry out western blot using specific antibody and differential display polymerase chain reaction. These resulting protein targets offer insights into the mechanisms of osteoclastogenesis in human and mouse and further provide opportunities to find out markers to facilitate early diagnosis of osteoporosis.

SU259

TGF-β Promotes Human Osteoclast Resorption by Increasing Proliferation of Precursors and Down Regulating Their Fusion Through p38 and p44/42 MAP Kinases. M. A. Karsdal*[1], T. Kirkegaard*[1], P. Rasmussen*[1], M. S. Fjording*[2], J. Nielsen*[1], M. Ovejero*[1], H. Lou*[1], M. Stahlhut*[1], P. Boissy*[1], N. T. Foged*[1], P. Qvist*[1], C. Christiansen*[3], K. L. Nielsen*[1], J. Delaissé*[1]. [1]Nordic Bioscience, Herlev, Denmark, [2]LEO Pharmaceuticals, Ballerup, Denmark, [3]Center for Clinical and Basic Research, Ballerup, Denmark.

Although RANK-L is essential for osteoclast formation, factors such as TGF-β are potent modulators of osteoclastogenic stimuli. These secondary stimuli are obviously important for both physiological and pathophysiological bone turnover, and are key points for understanding osteoclast biology. Using cultures of human osteoclasts differentiated from blood monocytes, we have investigated the direct effects of TGF-β on proliferation, fusion, resorption and signalling pathway of osteoclasts and their precursors. Human monocytes were isolated from peripheral blood, and cultured for 3 days with M-CSF. Hereafter, cells were washed extensively, detached by trypsin treatment and re-seeded either on bone slices or plastic and cultured with 25 ng/ml RANK-L and M-CSF for up to 28 days. When TGF-β was added directly after re-seeding for the first 14 days of culture, bone resorption at day 28 was dose-dependently affected in a biphasic curve, and reached a maximum corresponding to a 100% increase at 0.12 ng/ml. Both cell number and TRAP activity were increased to the same extent as resorption. Furthermore, as assessed morphologically, cell fusion was decreased by 50% in the presence of TGF-β. Conversely, TGF-β function blocking antibodies increased cell fusion. However, when TGF-β was present during the entire culture period (Day 1-28), we did not observe stimulatory effects on cell proliferation and resorption, clearly indicating context dependent effects of TGF-β during the different stages of osteoclastogenesis. To further investigate the time dependent effect of TGF-β, we analysed the signal transduction pattern induced by TGF-β in precursor and mature osteoclasts. Interestingly, p38 MAP kinase was activated only in precursor cells, whereas p44/42 and other kinases were activated in both precursor and mature osteoclasts. Furthermore, an inhibitor of p38 MAP kinase (SB203580 10μM) significantly inhibited TRAP activity in osteoclast precursors. These data clearly demonstrate that the presence of TGF-β at a given concentration and at a specific stage of osteoclastogenesis, dramatically influences several steps of this process, i.e. cell proliferation, TRAP expression, fusion, and modulates strongly the bone resorptive activity itself. Furthermore TGF-β acts directly on osteoclast precursors, through stage-specific activation of p38 MAP kinase.

SU260

Mutation of Tyrosine 559 in c-Fms to Phenylalanine Impairs Bone Resorption by Reducing Akt and ERK Phosphorylation. S. Takeshita[1], X. Feng[2], F. P. Ross[1], S. L. Teitelbaum[1]. [1]Pathology, Washington University, St. Louis, MO, USA, [2]Pathology, University of Alabama, Birmingham, AL, USA.

The intracellular signals by which c-fms, the M-CSF receptor, regulates osteoclast (OC) formation and function are unknown. We addressed this issue by retrovirally transducing primary OC precursors, namely bone marrow macrophages (BMMs), with a chimeric cDNA, EpoR/c-fms, containing the extracellular domain of erythropoietin receptor (EpoR) linked to the transmembrane and cytoplasmic domains of c-fms. Transduced cells treated with RANKL and either Epo or M-CSF generate similar OC numbers and bone resorptive capacity. We next transduced EpoR/c-fms cDNAs containing six individual tyrosine (Y) to phenylalanine (F) residues in the cytoplasmic tail (559, 697, 706, 721, 807 and 921) into BMMs and treated the cells with RANKL and either M-CSF or Epo. Cells expressing the c-fms mutations Y559F and Y807F exhibit decreased proliferation, measured by MTT activity and BrdU incorporation, and differentiation, assessed by TRAP solution assay. To determine the role of each mutation on OC function, BMMs bearing wild type and mutant chimeras were treated with M-CSF and RANKL to generate pre-OCs, which were replated on dentin slices. Fresh medium, containing RANKL and either M-CSF or Epo was added, and resorption assessed by Coomassie brilliant blue stain. Cells bearing EpoR/c-fms, with Y559 mutated to F, but not those expressing Y807F, are virtually incapable of resorptive activity, while the remaining four mutants fail to alter OC formation or function. We next examined c-fms-mediated Akt and ERK phosphorylation in BMMs and OCs. Thus, we expressed all individual Y mutations and treated serum- and cytokine-starved cells with Epo or M-CSF. While Akt is activated by the cytokines in both cell types, ERKs are activated only in BMMs. Y559F in the c-fms cytoplasmic domain arrests activation of both Akt and ERKs in BMMs and Akt in OCs. In contrast, Y807F inhibits Akt in BMMs, but has minimal effects in OCs. The kinase inhibitors LY294002 (PI3-kinase, PI3-K) and PP2 (c-Src family) dose-dependently dampen BMM proliferation and mirror the c-fms mutation Y559F, by blocking Akt and ERK activation. In summary residue Y559 in c-fms transmits signals in BMMs, activating both the PI3-K and c-Src pathways. In contrast, c-fms Y807 has limited capacity to signal. Thus, we have detailed, for the first time, Y residues in the c-fms tail which signal in authentic OC precursors. Y559 and Y807 are indispensable for osteoclastogenesis. In contrast, while Y559 is required for the resorptive function of OCs through phosphorylation of Akt and ERKs, Y807 is dispensable.

SU261

The Transcription Factor MITF is a Substrate for the p38 MAP Kinase. K. C. Mansky, M. C. Ostrowski. Molecular Genetics, Ohio State University, Columbus, OH, USA.

The severe osteopetrotic phenotype in microphthalmia (mi) mutant mice is caused by a defect in the terminal differentiation of osteoclasts. Immature mononuclear osteoclasts are present in the mi/mi mice, but these do not fuse or form ruffled borders. Thus the products of the MITF gene, the basic helix-loop-helix zipper (bHLHzip) factor MITF, and the closely related bHLHzip factors TFE3, TFEC and TFEB may be critical regulators of terminal differentiation in this cell type. Because MITF appears to be important for differentiation of osteoclasts, we are interested in understanding extracellular signals that positively regulate the activity of MITF and its partners. One partner of MITF in osteoclasts is PU.1, an ets family factor whose expression is restricted to hematopoietic cells. PU.1 expression is necessary for differentiation of a number of cell types, including osteoclasts. Our lab has previously shown that MITF and PU.1 physically and functionally interact. The RANK receptor a member of the tumor necrosis factor receptor family mediates an essential signal to osteoclast progenitors for their differentiation into osteoclasts. In cells treated with RANKL, p38 mitogen activated protein kinase activity is upregulated. Previously we have shown that there is a p38 phosphorylation site at serine residue 307 in the C-terminal region of MITF. Using a phospho-specific antibody, we were able to show that MITF was phosphorylated at the p38 site upon RANKL stimulation of bone marrow cells. The sustained phosphorylation of MITF correlated with a sustained phosphorylation of p38 MAP kinase and an increase in tartrate resistant acid phosphatase (TRAP) gene expression as measured by Real Time PCR. Activated p38 immunoprecipitated from RAW 264.7 cells and p38 alpha synthesized in vitro were able to phosphorylate MITF but were not able to phosphorylate MITF containing point mutation at serine residue 307. p38 MAP kinase can bind to C-terminal region of MITF (amino acids 217 to 419) and using site directed mutagenesis we are more precisely trying to map the p38 binding site in MITF. To determine the biological significance of the MITF p38 phosphorylation mutant, retroviral vectors containing MITF with the mutation at serine 307 are being used to try and rescue mi/mi osteoclasts. Lastly we have found in transient transfections that MITF co-transfected with a constitutively active MKK6, an upstream activator of p38 MAP kinase, leads to increased functional interaction between MITF and PU.1 and are currently trying to detemine if MITF phosphorylated at seine residue 307 leads to an increase in the physical interaction between MITF and PU.1.

SU262

c-Cbl, but not Cbl-b, Requires Src Phosphorylation to Interact with the p85 Subunit of PI3Kinase. G. DeBlasi, A. Sanjay, T. Miyazaki, W. C. Horne, R. Baron. Yale University, New Haven, CT, USA.

Osteoclasts (OCs) from osteopetrotic Src-/- mice are deficient in both cell migration and bone resorption, and exhibit cytoskeletal changes with altered podosomes and focal adhesions. Engagement of the vitronectin receptor activates Src and Pyk2, a FAK family member present in podosomes, and induces the formation of a tri-molecular complex of Src, Pyk2, and c-Cbl. OCs from c-Cbl-/- mice also exhibit defective migration. c-Cbl interacts with several downstream proteins, including PI3K, whose activity is also required for normal OC function. PI3K is known to bind to c-Cbl via its p85 subunit, a molecular interaction that appears to be necessary for effective translocation of PI3K to the cell membrane. Although recombinant p85-SH3 domains bind c-Cbl, the interaction between c-Cbl and p85 is dependent on phosphorylation of c-Cbl at Y731, suggesting that there is either an additional SH2-mediated interaction between c-Cbl and p85, or that a phosphorylation-dependent conformational change allows the SH3-mediated interaction and thereby the translocation of PI3K to the cell membrane to take place. Our goal was, therefore, to characterize both the molecular nature of the interaction between Cbl family members and the p85 subunit of PI3K, and the role of Src-dependent phosphorylation in these interactions. Mutation of c-Cbl Y731, a known target of Src kinase, to Phe prevents the association of c-Cbl and p85, as does mutation of the Src SH3 binding site on c-Cbl. These results suggest that the interaction of p85 and c-Cbl requires Src binding to and phosphorylating c-Cbl. Indeed, transfection with kinase-dead Src decreased the c-Cbl/p85 interaction in a dose-dependent manner. Given that c-Cbl is a member of a family of proteins and that Cbl-b is also highly expressed in OCs, possibly explaining the mild phenotype in c-Cbl-/- mice, we then determined whether Cbl-b would also interact with PI3K and whether the interaction was governed by the same constraints. In contrast to c-Cbl, over-expression of kinase-dead Src had no effect on the interaction between p85 and Cbl-b. Although highly homologous to c-Cbl, Cbl-b lacks a Tyr residue in a motif homologous to c-Cbl Y731, possibly explaining the independence from Src phosphorylation. This suggests that c-Cbl and Cbl-b bind p85 at different sites and that binding of PI3K to the two Cbl proteins may be regulated differently. In conclusion, the phosphorylation of c-Cbl Y731 by activated Src kinase is necessary for an SH3-mediated interaction with the p85 subunit of PI3K, whereas interaction between Cbl-b and PI3K is independent of Src activity. These differences in Src dependence might explain, at least in part, the phenotypic differences seen in c-Cbl-/- vs Cbl-b-/- mice.

SU263

The Protein-Tyrosine Phosphatase (PTP) Activity of PTP-Oc Is Essential for Both the Differentiation of U937 Cells into Osteoclasts and their Apoptosis. M. Amoui*, S. M. Suhr*, D. J. Baylink, K. H. W. Lau. Musculoskeletal Disease Center, Jerry L. Pettis Mem VAMC, Loma Linda, CA, USA.

Cells of monocyte-macrophage hematopoietic lineage differentiate into osteoclasts. Our past work indicates that once activated, osteoclasts rapidly undergo apoptosis. We also found that the osteoclastic PTP, PTP-oc, is involved in osteoclastic bone resorption. In the present study, we sought to test the hypothesis that the PTP activity of PTP-oc is essential for 1) the differentiation of osteoclasts and 2) their subsequent apoptosis. To test this hypothesis, we evaluated if overexpression of the wild type (wt) and dominant-negative (dn) PTP-oc in human promyelomonocytic U937 cells would affect their differentiation into active osteoclasts and their subsequent apoptosis. The wt PTP-oc expression construct was prepared by inserting the full-length PTP-oc cDNA in frame into our recently developed transposon-based expression vector. The dn PTP-oc construct was constructed by site-directed mutagenesis in which the catalytic cys-325 was mutated to ser. U937 cells were transfected with the wt, the dn PTP-oc, or the empty expression vector to obtain sta-

bly overexpressing cell clones. To test the effect of overexpression of wt or dn PTP-oc on osteoclast differentiation, we have developed a method in which U937 cells were induced by sequential TPA and $1,25(OH)_2D_3$ treatments to form osteoclast-like cells that resorb bone *in vitro*. This treatment converted 29±5% of the vector alone control cells into osteoclast-like cells. The same treatment converted 91±4% (P<0.001) of the U937 cells that were stably overexpressing the wt PTP-oc, but only 14±4% (P<0.001) of the dn PTP-oc stable U937 cell clones formed osteoclast-like cells. To assess the effect of overexpression of wt and dn PTP-oc on the apoptosis, we measured the relative percentage of apoptotic cells in cell pools that stably overexpressed either the wt or the dn PTP-oc by FACS analysis using an apoptotic assay kit and also by a DNA Laddering-based apoptotic assay. About 7-9% of the vector-transduced control cell pools were apoptotic. In contrast, the percentage of apoptotic cells in the cell pools that stably overexpressed the wt PTP-oc was >60% (P<0.001). The percentage of apoptotic cells in cells that stably overexpressed the dn PTP-oc (7-11%) was not significantly different from the control. On the basis of these findings, we conclude that the PTP-oc is a key osteoclastic enzyme which is required not only to promote osteoclast resorption by promoting osteoclast maturation but also to limit the extent of bone resorption by promoting osteoclast apoptosis. We suspect that these two processes can be independently regulated because PTP-oc is an upstream enzyme.

Glucocorticoid Cooperates With NFAT to Activate the Calcitonin Receptor in Osteoclasts. L. Peng*[1], C. Laplace*[1], S. R. Goldring[1], K. Matsuo*[2], D. L. Galson[1]. [1]NEB Bone & Joint Institute, Dept. of Medicine, Beth Israel Deaconess Medical Center & Harvard Medical School, Boston, MA, USA, [2]Dept. of Microbiology, Keio University School of Medicine, Tokyo, Japan.

During osteoclast differentiation, the calcitonin receptor (CTR) is transcriptionally activated. The osteoclast-specific murine CTR P3 promoter has previously been shown to be responsive to NFATs (Nuclear Factor of Activated T cells) which are activated by calcium signaling. Cotransfection of the –319/+61 P3-reporter (which contains 5 NFAT sites) and a constitutively active NFAT (ΔNFAT3; contains a deletion of the NFAT3 regulatory domain, leading to calcium-signaling independent nuclear localization) into uninduced RAW264.7 cells greatly increased P3-reporter activity above constitutive levels. Sequential 5' deletion of the P3 promoter demonstrated that NFAT sites 1-4 are sufficient for full activity, and that sequential loss of sites 2-4 resulted in a stepwise loss of NFAT-responsiveness. Therefore, we examined the individual and cooperative roles of each site by analyzing individual site-specific mutations of each of the NFAT sites within the –178, –148 and –118 P3 deletions. Although all the sites contribute to maximum ΔNFAT3 activation of P3, it is clear that site 2 (–97 to –93) is absolutely required, no matter how many other sites are present. Site 1 (+17 to +21) is the next most important site, followed in decreasing importance by site 3 (–130 to –126), and then site 4 (–157 to –153). Treatment of osteoclasts with the glucocorticoid dexamethasone (Dex) increases the expression of CTR protein and mRNA. Dex treatment of the P3 5' deletion series demonstrated that P3 is induced, in the absence of ΔNFAT3, by 20-to-40 fold, with the highest induction level observed with the –118 P3-reporter. This implies that the Dex-responsive element in the mCTR-P3 promoter lies between –118 and +61. There is a putative GRE binding site between –40 and –55. However, our results indicate that mutation of NFAT site 2 ablates 90% of the Dex responsiveness, regardless of the number of NFAT sites present. Interestingly, while NFAT site 2 is required for the P3 promoter to respond to cotransfection with ΔNFAT3 in the absence of Dex, P3 constructs with a mutated site 2 regain some responsiveness to ΔNFAT3 in the presence of Dex (~ 7-fold above Dex alone). Additionally, the Dex responsiveness of site 2 mutants is increased by ΔNFAT3. This indicates that the glucocorticoid receptor (GR) and NFAT cooperate to activate the CTR gene through NFAT site 2. This is the first report of GR cooperating with, rather than inhibiting, NFAT action. The precise nature of the Dex-GR interaction with the CTR gene and the mechanism of its cooperation with NFAT remain to be elucidated.

SU265

Functional Assessment Of Specific Gelsolin Peptide Domains In Osteoclast Actin Assembly and Motility. R. S. Biswas[1], D. S. Yuen*[1], K. A. Hruska*[2], M. A. Chellaiah*[1]. [1]Dept. of OCBS, University of Maryland, Baltimore, MD, USA, [2]Department of Pediatrics, Washington University, School of Medicine, St. Louis, MO, USA.

Gelsolin is a critical protein in osteoclast podosome assembly. Gelsolin deficient osteoclasts are devoid of podosomes, hypomotile and partially disabled in bone resorption. A multimolecular signal generating complex assembles on gelsolin in podosomes based on phosphatidyl inositol trisphosphate (PIP3) generated by associated PI 3-kinase and protein-lipid-protein interactions. The complex contains PI 3-kinase, c-Src, and other proteins based on these type of interactions with gelsolin. The primary amino acid sequence of gelsolin consists of six domains. The actin binding sites and activities of gelsolin are correlated with its six repeated (S1-S6) segments. The S1 and S2 domains of gelsolin each contain a phosphoinositides (PI) binding site, and recently, a third site in the C-terminal part of gelsolin was identified. The different segments of gelsolin were cloned in-frame into a bacterial expression vector, pTat-HA, to produce Tat-HA fusion proteins. The proteins were purified and transduced into mouse osteoclasts to study the role of actin- and PI- binding sites on actin assembly. Osteoclasts transduced with full length gelsolin, the N-, and C-terminal actin binding domains, and the PI binding domains, demonstrated an increase in F-actin content. After transduction osteoclasts were immunostained with anti-HA to detect the transduced protein and rhodamine phalloidin to detect F-actin. Osteoclasts transduced with full length and NH-terminal segments of gelsolin demonstrated dot-like structures similar to podosome structures which were stimulated in number by OPN. These osteoclasts were bone resorption competent and responded to stimuli. Thus, the transduced gelsolin or the NH-terminal segment functioned like gelsolin. Transduction of PIP2 binding domains produced larger patches enriched in transduced protein and F-actin, and these cells were bone resorptive disabled in response to stimuli. Thus, the transduced PI binding domain peptides did not function in podosome assembly but accumulated phosphoinositides producing a dominant negative effect of blocking stimulated assembly of the signal generating complex and bone resorption. Our results demonstrate that the PI binding sites in S1 and S2 domains, as well as in COOH- terminal gelsolin have effects on actin dynamics and motility of osteoclasts, and that separating PI binding from actin binding produces a diminished bone resorption in response to stimuli. Thus, gelsolin is an attractive osteoclast target which can be approached by affecting high order phosphoinositide binding.

SU266

A Novel Osteoclast-Specific *cis*-Acting Element Controls Expression of a Mouse Cathepsin K Gene. Y. P. Li, W. Deng*, K. Shimizu*, W. Chen*. The Forsyth Institute, Harvard School of Dental Medicine, Boston, MA, USA.

The osteoclasts, the bone resorbing cells, play a key role both in normal bone remodeling and in the skeletal osteopenia of arthritis, osteoporosis, periodontal disease and certain malignancies. Despite some recent insights from the effects of the targeted deletion of the *c-fos*, *PU.1* and *NF-κB* transcription factor genes on osteoclast differentiation, the mechanisms by which transcription factors control the process of osteoclast differentiation have not been identified. The cathepsin K gene is expressed at high levels only in differentiated osteoclasts. Therefore, it is an excellent marker with which to study the mechanisms of osteoclast-specific gene expression. The purpose of this study was to characterize the *cis*-acting elements required for osteoclast-specific expression of the cathepsin K gene. We reported we have found a novel critical *cis*-element in cathepsin K promoter. The *cis*-acting element required for osteoclast-specific expression has been located in the 5' flanking region of the gene. Osteoclast specific expression of 1.4 kb mouse cathepsin k promoter-CAT construct was verified by comparing CAT activity in osteoclast-like cell (i.e. differentiated MOCP-5 cells) with that in pre-osteoclast cells (MOCP-5) and that in non-osteoclastic cells (e.g. ROS 17/2.8, COS7, and C3H10T1/2 cell lines). In transfected MOCP-5 cells, cathepsin K promoter activity was up regulated about 50 folds by RANKL (OPGL). The deletion and point mutation transfection studies of cathepsin K promoter-CAT constructs defined the core of cis-acting element. Mutation of the core sequence of the *cis*-acting element in cathepsin K promoter resulted in loss of response to RANKL stimulation. The core sequence we defined does not correspond to the binding site of any known transcription factors. Competition-Gel Shift, Super-Gel Shift and DNase1 Footprinting assays revealed a DNA binding protein that bound the *cis*-acting element. Most interestingly, the binding protein was present in osteoclast-like cells, but absent from other non-osteoclastic cell lineage lines and mouse tissues. Therefore, our results suggested that we have characterized a novel *cis*-acting element that was bound by a unknown transcription factor that is restricted to the osteoclastic cell lineage and regulate osteoclast-specific expression of the cathepsin K gene possible through RANKL pathway.

SU267

Trp Channels Regulate Osteoclast Calcium Sensing. B. D. Bennett, K. A. Hruska. Pediatrics, Washington University School of Medicine, St. Louis, MO, USA.

Handling of extracellular calcium, [Ca2+]e, by osteoclasts is important due to the large amount of Ca2+ liberated as these cells resorb bone. Influx of bone derived Ca2+ into osteoclasts may impact the ability of OCs to resorb bone by regulating intracellular Ca2+ pools linked to Ca2+ extrusion. We have hypothesized that [Ca2+]e evoked rises in intracellular calcium, [Ca2+]i , is mediated in part by transient receptor potential channels (trpC) and we have demonstrated that phospholipase C (PLC) activation in OCs is coupled to [Ca2+]e and Ca2+ influx through trpC. We have demonstrated endogenous expression of trp channels in RAW 264.7 macrophage and authentic mouse osteoclasts. Normally PLC activation occurs downstream of heterotrimeric G-protein coupled receptors. To demonstrate that trp channels mediate receptor operated calcium influx in OCs we compared UTP-evoked [Ca2+]i rises in OCs and OCs overexpressing trpC3 and trpC6. UTP stimulation of the G-protein coupled P2Y receptor led to Ca2+ influx that was enhanced in trp3 and trp6 overexpressors, and [Ca2+]e stimulated [Ca2+]i increases were increased by trpC3 and trpC6 overexpression. [Ca2+]e-induced [Ca2+]i rises were inhibited by a trp channel dominant negative construct. Our results demonstrate a role for endogenous trp channel regulation of calcium sensing. To assess the potential role of trp channels in regulating OC handling of the extracellular Ca2+ by intracellular stores, the effect of trp overexpression on Ca2+ loading in intracellular calcium stores was determined. Release of intracellular Ca2+ stores, either by SERCA inhibition or stimulation of intracellular release channels, was increased with trp6 overexpression. Thus, trp regulates Ca2+ content in OC stores. We conclude that trp channels in OCs may form an important feedforward calcium signaling pathway that reports the extracellular Ca2+ load to intracellular stores and may regulate transcytosis of Ca2+ through stored Ca2+.

SU268

p38 MAP-kinase Mediates Glucose-Dependent Transcriptional Regulation of Osteoclast H^+-ATPase Expression. K. I. Larsen[1], L. V. Ponomareva*[2], W. Wang*[2], M. L. Falany*[1], J. P. Williams[2]. [1]Department of Pathology, University of Alabama, Birmingham, AL, USA, [2]Department of Internal Medicine, University of Kentucky, Lexington, KY, USA.

Bone resorption is glucose concentration-dependent and osteoclasts secrete acid via a vacuolar H^+-ATPase heavily expressed in the ruffled membrane. Mechanisms regulating glucose-dependent increases in bone resorption have not been identified. Glucose activates p38 MAP-kinase in other cells and since MAP kinases activate transcription factors, we hypothesized one mechanism mediating glucose-stimulated bone resorption may be increased expression of the H^+-ATPase. Glucose activates osteoclast p38 MAP-kinase in a time-dependent manner as determined by Western analysis with phospho-specific p38 antibody while total p38 levels are unchanged. The $K_{0.5}$ for glucose dependent activation of p38 MAP-kinase is ~2 mM, activation is maximal at 30 minutes and are returning to basal levels by 60 minutes. H^+-ATPase expression increases in a glucose concentration-dependent manner as determined by Western and Northern analysis. The specific inhibitor of p38 MAP-kinase, SB203580, inhibited glucose transport in osteoclasts, as well as glucose concentration-dependent increases in bone resorption and H^+-ATPase A and B subunits. H^+-ATPase expression is transcriptionally regulated since actinomycin D inhibits glucose stimulated increases in mRNA with no effect on G3PDH mRNA. We conclude that glucose transcriptionally regulates osteoclast H^+-ATPase expression by a mechanism likely to involve p38 MAP-kinase.

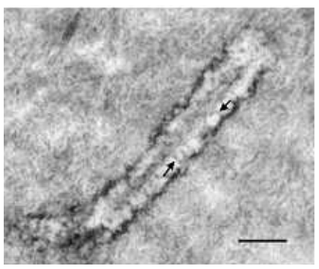
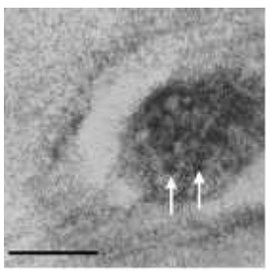
Ultrastructure of Osteocyte Process. L. You*[1], S. Weinbaum*[2], S. Cowin*[2], M. Schaffler[3]. [1]Mechanical Engineering, Stanford, Stanford, CA, USA, [2]Mechanical Engineering, City University of New York, New York, NY, USA, [3]Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA.

Osteocytes are believed to be the mechanical sensor cells in bone. One potential mechanism for the mechanosensing process is that osteocytes directly sense the deformation of the substrate to which they are attached. However, tissue level strains in whole bone are typically < 0.2 percent (1), yet many in vitro experiments show that dynamic substrate strains must be at least an order of magnitude larger for intracellular biochemical responses to occur (2, 3). Recently, a novel model was developed (4), which provides a new potential mechanism by which mechanical loading induced fluid flow in lacuno-canalicular system under routine physical activity can produce very large deformations on osteocyte processes that are at least one order of magnitude larger than bone tissue deformations. There are two key assumptions necessary for the model: 1) the presence of the transverse elements bridging the pericellular space surrounding the osteocyte process, which interact with the fluid flow and lead to the outward hoop tension on the process; 2) and the presence of bundled F-actin in the osteocyte processes, which resist the outward hoop deflection. However, morphological data to support these assumptions are scant. In the current studies, 1) transverse tethering elements were observed in the pericellular space surrounding the osteocyte process (Fig. 1),



and 2) close packed microfilaments were observed in the center of the cell process (Fig. 2).



Therefore, the current study provides strong evidence that the fundamental microstructural features needed for local mechanical amplification to function exist in and around osteocytes.

Serotonin Potentiates PTH-induced Collagenase-3 Activity in Osteoblasts and Stimulates Adenylyl Cyclase Activity in Osteocytes. M. M. Bliziotes[1], A. Eshleman*[2], X. Zhang[3], K. M. Wiren[4]. [1]Medicine, Oregon Health and Science University/Portland VAMC, Portland, OR, USA, [2]Pharmacology and Physiology, Oregon Health and Science University/Portland VAMC, Portland, OR, USA, [3]Behavioral Neurosciences, Oregon Health and Science University, Portland, OR, USA, [4]Behavioral Neurosciences, Oregon Health and Science University/Portland VAMC, Portland, OR, USA.

The neurotransmitter serotonin (5-HT) regulates osteoblast signaling pathways. We have demonstrated that 5-HT receptors and 5-HT transporter (5-HTT) are expressed in osteoblasts, and 5-HT increases AP-1 transcription factor activity. 5-HT regulates nitric oxide release by mechanically stimulated osteoblasts. The 5-HT2B receptor is expressed in osteocytes. We demonstrate that 5-HT potentiates the PTH-induced collagenase-3 activity in osteoblasts, and regulates osteocyte cAMP signaling. The clonal osteoblastic cell line UMR 106-01 was transfected with a CAT reporter construct containing the rat collagenase-3 promoter region including the minimal PTH-responsive sequences. Transfected cells were treated with 1 μM 5-HT for 6 hr, then PTH (100 nM) was added for an additional 24 hr. CAT activity was determined on cell lysates. The clonal osteocytic cell line MLO-Y4 was analyzed for the presence of 5-HT receptors by immunblot, and 5-HT transporter expression was analyzed by [^{3}H]5-HT competition uptake and [^{125}I]RTI-55 competition binding experiments. Cyclic AMP levels were determined following 60 min or 6 hr of 1 μM 5-HT treatment, followed by 10 min or 24 hr of 100 nM b(1-34)PTH, respectively. PTH treatment of UMR 106-01 cells induced a 5-fold increase in collagenase-3 promoter activity; 5-HT alone showed no effect. 5-HT potentiated the PTH response by 40%. MLO-Y4 cells express the 5-HT2A, 2B, and 2C receptors. MLO-Y4 cells express the 5-HTT, but not the dopamine or norepinephrine transporters. The Km for 5-HT uptake was 290±100 nM and the Vmax was 6.41±0.41 pmol/mg protein/min. 1 μM 5-HT for 60 min increased cAMP levels in MLO-Y4 cells by 60%, while 24 hr treatment increased levels by 2-fold. The effects were potentiated by PTH. We conclude: 1) 5-HT potentiates the PTH-induced collagenase-3 promoter activity in osteoblasts; this effect may occur by inhibition of a repressor, such as jun-B, which is upregulated by PTH; 2) 5-HT 2A, 2B and 2C receptors are expressed in osteocytes, as is the 5-HTT; 3) 5-HT is positively coupled to adenlylyl cyclase in osteocytes. Thus, 5-HT may have an important role in regulating matrix metalloproteinase activity in osteoblasts, and activates a signaling pathway in osteocytes which has been implicated in protection from apoptosis.

Pulsed Electromagnetic Fields Affect Phenotype and Connexin 43 Protein Expression in MLO-Y4 Osteocyte-like Cells and ROS 17/2.8 Osteoblast-like Cells. C. H. Lohmann[1], Z. Schwartz[2], Y. Liu*[2], Z. Li[3], S. A. Albert*[2], B. J. Simon[4], V. L. Sylvia[2], D. D. Dean[2], L. F. Bonewald[5], H. J. Donahue[3], B. D. Boyan[2]. [1]Orthopaedics, University of Hamburg-Eppendorf, Hamburg, Germany, [2]Orthopaedics, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, [3]Orthopaedics, Pennsylvania State University, College of Medicine, Hershey, PA, USA, [4]EBI, L.P., Parsippany, NJ, USA, [5]Oral Biology, University of Missouri, Kansas City, MO, USA.

Osteocytes, the predominant cell type in bone, are postulated to be responsible for sensing mechanical and electrical stimuli, and transducing signals via gap junctions. Osteocytes respond to fluid flow-induced shear by increasing connexin 43 (Cx43) levels, suggesting that they might be sensitive to physical stimuli like low frequency electromagnetic fields (EMF). Others have shown that preconfluent cultures of immature osteoblasts exhibit decreased intercellular communication in response to EMF but no change in Cx43. In the present study we examined if pulsed EMF (PEMF) (0-16 gauss; 15 Hz) modulates physiological responses of terminally differentiated osteocyte-like MLO-Y4 cells or of well-differentiated osteoblast-like ROS 17/2.8 cells. PEMF was applied to confluent cultures for 8 hrs/day for 1, 2, or 4 days for the MLO-Y4 cells and continuously for 1, 2, or 3 days for the ROS 17/2.8 cells. In MLO-Y4 cell cultures, PEMF increased alkaline phosphatase activity but had no effect on cell number or osteocalcin. TGF-β1 and PGE_2 were increased, while NO^{2-} production was differentially affected, depending on treatment time. After 1 day, NO^{2-} production was decreased; after 2 days it was unchanged; and after 4 days it was increased. PEMF's effect on TGF-β1 was via a prostaglandin-dependent mechanism involving Cox-1 but not Cox-2. In ROS 17/2.8 cells, PEMF didn't affect cell number, osteocalcin mRNA or osteocalcin protein. PEMF reduced Cx43 protein in both cells. Longer exposures also decreased Cx43 mRNA. This indicates that cells in the osteoblast lineage, including well-differentiated osteoblast-like ROS 17/2.8 cells and terminally-differentiated osteocyte-like MLO-Y4 cells, respond to PEMF with changes in local factor production and reduced Cx43, suggesting decreased gap junctional signaling. At least some of the effects of PEMF are due to increased prostaglandin production. Differences in cell response to PEMF may be cell-specific as well as signal-specific.

Prostaglandin E_2 Receptor (EP_2) Is Responsible for Increased Intercellular Communication Between Osteocyte-like Cells in Response to Mechanical Strain. B. Cheng*[1], S. Gu*[1], X. Wang*[1], E. Sprague*[2], L. F. Bonewald[3], J. X. Jiang*[1]. [1]Biochemistry, University of Texas Health Science Center, San Antonio, TX, USA, [2]Radiology, University of Texas Health Science Center, San Antonio, TX, USA, [3]Oral Biology, School of Dentistry, University of Missouri, Kansas City, KS, USA.

Osteocytes embedded in the matrix of bone are thought to be mechanosensory cells that translate strain into signals to initiate or regulate bone remodeling. We have previously shown that fluid flow shear stress dramatically induces prostaglandin release and COX-2 mRNA expression in osteocyte-like MLO-Y4 cells, and that prostaglandin E_2 (PGE_2) released by these cells functions in an autocrine manner to modulate gap junction function and connexin 43 (Cx43) expression. In this report, we examined the expression of the subtypes of PGE_2 receptors and potential signaling mechanisms in response to mechanical stimulation. Expression of PGE_2 receptor EP_2 was increased in response to treatment by fluid flow, while EP_1, EP_3, and EP_4 were unchanged. RT-PCR and Northern blot analyses showed that EP_2 receptor mRNA levels were elevated 30 min and further elevated 24 hrs after 2-hours of fluid flow treatment at 16 dynes/cm^2. Application of PGE_2 or conditioned medium from fluid-flow treated cells directly to untreated MLO-Y4 cells stimulated the expression of the EP_2 receptor in a similar fashion to fluid flow. The EP_2 receptor antagonist AH6809 suppressed the effects of all three, suggesting that EP_2 is the functional receptor that responds to fluid flow and to autocrine PGE_2. Conditioned medium from fluid flow treated MLO-Y4 cells and exogenously added PGE_2 stimulated cAMP production and protein kinase A (PKA) activity in untreated MLO-Y4 cells suggesting that PGE_2 released by mechanically stimulated cells is responsible for upregulation of cAMP and PKA. The adenylate cyclase activators, 8Br-cAMP and forskolin, also stimulated cAMP production and PKA activity, suggesting that cAMP activated PKA. The PKA inhibitor H89 blocked the activation of PKA by 8Br-cAMP and forskolin. Both 8Br-cAMP and forskolin enhanced intercellular connectivity, the number of functional gap junctions, and Cx43 protein expression. The increase in Cx43 in response to PGE_2 was attenuated by AH6809 suggesting that the EP_2 receptor mediates the effects of autocrine PGE_2 in the osteocytic response to fluid flow induced shear stress. Hence, the EP_2 receptor, cAMP and PKA are critical components of the biochemical signalling cascade between mechanical strain and gap junction-mediated communication between osteocytes.

A Potential Role for Osteocytes in Recruiting Osteoclast Precursors to Targeted Bone Sites. S. Ko, S. E. Harris, M. Dallas*, L. F. Bonewald. Oral Biology, University of Missouri-Kansas City, Kansas City, MO, USA.

The mechanism whereby osteoclasts are attracted to specific areas of bone for targeted removal are unknown. It has been hypothesized that the osteocyte, whether unstrained as in immobilization or overstrained as in pathological overload, can send signals indicating which bone should be removed. Osteoclast precursors must be recruited to the site of resorption and must undergo proliferation before fusion and activation. In this study, MLO-Y4 cells were used as a model for osteocytes and RAW264.7 and MOCP-5 were used as models for osteoclast precursors. It has been shown previously that MLO-Y4 cells express RANKL and support osteoclast formation and activation. In addition, these cells and their conditioned media (CM) stimulate proliferation and increase colony size of both RAW 264.7 and MOCP-5 cells. This capacity of MLO-Y4 cells was shown to be due to M-CSF, as anti-M-CSF antibody at 18 μg/ml completely blocked proliferation. MLO-Y4 cells produce large amounts of M-CSF, a factor known to be necessary for osteoclast formation. MLO-Y4 cells and CM are chemotactic for osteoclast precursor cell lines. Transwell membranes (polycarbonate, 8 μm pores) were used in which MLO-Y4 cells or CM were placed in the bottom well and the osteoclast precursor cell lines seeded into the transwell at $5x10^4$ cells per well. MLO-Y4 cells or CM alone increased transmigration of both RAW 264.7 and MOCP-5 cells at 6 hrs. To determine the factor(s) responsible, gene array analysis of MLO-Y4 cells was used. We found 4 factors elevated in MLO-Y4 cells compared to 2T3 osteoblasts, that had previously been described as chemotaxis factors. Two chemokines, MCP-3 and MIP-2α have been described to be chemotactic for monocytes and neutrophils, but their effect on osteoclast precursors was not known. TGF-β and VEGF were also elevated, and are known to induce osteoclast chemotaxis. TGF-β increased transmigration of both osteoclast precursor cell lines, whereas VEGF had no effect. Surprisingly, MCP-3 increased RAW 264.7 cell transmigration, but had no effect on MOCP-5 cells. This suggests that these cell lines may represent different types of precursors or different stages of osteoclast differentiation. Studies using neutralizing antibodies are underway to determine which cytokine(s) made by MLO-Y4 are responsible for osteoclast precursor chemotaxis and if MIP-2α is chemotactic for the osteoclast precursors.

SU274

Neuronal NOS (nNOS) Is Expressed in Human Osteocytes: Multiple Pathways of NO Regulation? A. Caballero[1], V. Das-Gupta*[2], N. Loveridge*[1], A. Pitsillides[2], J. Reeve[1]. [1]University of Cambridge, Cambridge, United Kingdom, [2]Royal Veterinary College, London, United Kingdom.

Until now, eNOS was considered to be the predominant osteocytic NOS isoform in bone and we previously studied the distribution of eNOS protein expression in the human femoral neck because of its possible involvement in the response to load. Studies in rat and human fracture callus have shown that nNOS mRNA is expressed sometime after fracture but no study has yet immunolocalised nNOS in human bone. In this study, we have analysed the density and distribution of both eNOS+ve and nNOS+ve osteocytes in the ilium. Ten micron frozen sections were cut from transiliac biopsies from 8 female osteoporotic patients (range=56-80 y) and incubated overnight in antiserum for eNOS and nNOS followed by peroxidase/VIP substrate detection. We used two separate eNOS antisera directed against different epitopes in the c-terminus. For nNOS three different antisera were used, two binding to different c-terminal epitopes and one binding to a n-terminal epitope. Sections were then incubated in propidium iodide or methyl green to detect all osteocytes. The density (no/mm2 bone) of eNOS and nNOS positive osteocytes and the distances from the nearest bone surface were determined by image analysis (NIH image). The percentage of osteocytes positive for nNOS was higher than that for eNOS (cortical: nNOS 84.04%, eNOS 61.78% $p<0.05$; cancellous: nNOS 82.33%, eNOS 65.21% $p<0.05$). When examined in each BMU the maximum and minimum distances of the eNOS+ve and nNOS+ve osteocytes from bone surface, there was no signicant difference between eNOS+ve and nNOS+ve osteocyte distributions. Only one eNOS antibody was able to detect eNOS epitopes in osteocytes. All three nNOS antibodies detected nNOS epitopes in osteocytes but those directed against the c-terminus had higher detection rates. The present of nNOS protein in osteoblasts and osteocytes was confirmed by western analysis. In conclusion, the nNOS isoform appears present in osteocytes and seems to be more prevalent than the eNOS isoform. The possibility exits that, as with the skeletal muscle, nNOS might contribute to regulating the local blood supply which we showed previously correlates with the corrected mineralisation rate of osteoid.

SU275

Prevalence of Osteoporosis in Rural Postmenopausal Women. J. M. Lappe, K. M. Davies, G. Haynatzki, D. Travers-Gustafson*, R. R. Recker. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Women living in farming communities may be perceived as having low risk of osteoporosis since they typically have had more weight bearing activity, well-balanced diets, and sunlight exposure than urban women. In fact, studies consistently show that fracture rates are higher in urban than in rural populations. Also, rural women have less access to DXA measurements. Thus, there is a risk that rural women will be overlooked in the Healthy People 2010 goal to reduce the proportion of adults with osteoporosis. The purpose of this analysis is to estimate the prevalence of osteoporosis in a population sample of rural women. The analysis was conducted on data from 1180 women randomly selected from the population of healthy postmenopausal women over 55 years of age in a nine-county farming area of Nebraska.

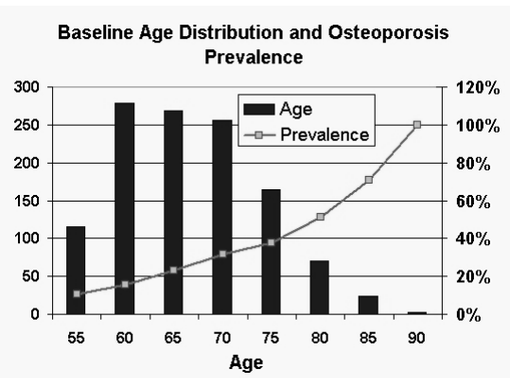
Baseline Characteristics

	Mean±SD
Age (yrs)	66.7±7.3
Age at menopause (yrs)	47.3±7.0
Body mass index wt/ht^2	29.0±5.6
Hip BMD (gm/cm^2)	0.862±0.14
Spine BMD (gm/cm^2)	0.944±0.16

Participants were enrolled into an intervention study of vitamin D and calcium. DXA scans and spine radiographs were obtained at baseline. For this analysis, osteoporosis is defined as hip or spine t-score <2.5 or presence of spine fracture on radiographs.

Osteoporosis Criteria	**n**
Hip or spine t-score<2.5	150
Spine fracture	100
t-score <2.5 and fracture	52

Analyses indicated that 26% of this population sample has osteoporosis. This compares with recent estimates by the National Osteoporosis Foundation that 20% of women age 50+ in Nebraska have osteoporosis and with NHANES III estimates that 13-18% of U.S. women over 50 are affected. These findings suggest that the prevalence of osteoporosis is currently underestimated in rural women and underscores the importance of targeting them in prevention and detection programs.



SU276

Racial Differences in the Effect of Early Milk Consumption on Postmenopausal Bone Mineral Density. A. R. Opotowsky*, J. P. Bilezikian. Medicine, Columbia University, New York, NY, USA.

Early milk consumption has been found to influence bone mineral density positively throughout life. Previous studies leading to this finding focused on white women; no data exist to support the view that black women also gain an equivalent benefit from early milk consumption. We hypothesized that there may be a racial difference in the effect of early milk consumption on postmenopausal hip bone mineral density (BMD). Using data from the Third National Health and Nutrition Examination Survey (NHANES III), we analyzed the relationship between reported childhood and teenage milk consumption and current femoral BMD among postmenopausal non-Hispanic white (NHW, n=1,711) and black (NHB, n=742) women. Among NHW women, controlling for age and body mass index (BMI), childhood and teenage milk consumption were positively associated with BMD at two of four sites and all four sites respectively. Early milk consumption, however, was not significantly associated with BMD at any site among NHB women. In fact, NHB women who consumed at least one glass of milk per week as children or teenagers had non-significantly lower BMD than their counterparts who consumed less than one glass of milk per week early in life (Table 1). To test the hypothesis that race modifies the effect of early milk intake on postmenopausal BMD, we evaluated the significance of the interaction between race and historical milk consumption in the overall population. The interaction between race and teenage milk consumption was significant at all sites, while the interaction between race and childhood milk consumption was significant at all sites except the femoral neck. Removing from the analysis subjects previously diagnosed with osteoporosis or who had sustained a hip fracture did little to alter the results. These findings neither challenge the importance of adequate calcium intake for the attainment of peak bone mass, nor demonstrate a detrimental effect of early milk consumption on bone health among black women. They do, however, reveal racial differences in the effect of early milk consumption on postmenopausal BMD. These observations underscore the need to be cautious about extrapolating nutritional relationships seen within one population to another.

Table 1: Effect of teenage milk intake on BMD by race, controlling for age and BMI

	White women		Black women	
	Coefficient	P value	Coefficient	P value
Femoral neck	0.023	0.005	-0.0184	0.22
Intertrochanter	0.032	0.006	-0.016	0.2
Trochanter	0.027	0.002	-0.0114	0.24
Total hip	0.03	0.002	-0.012	0.27

SU277

Environmental and Biologic Factors as Determinants of Peak Bone Mass in a Biracial Cohort. S. Y. S. Kimm[1], N. W. Glynn*[1], H. J. Kalkwarf[2], S. R. Daniels*[3]. [1]Family Medicine, University of Pittsburgh, Pittsburgh, PA, USA, [2]General & Community Pediatrics, Children's Hospital Medical Center, Cincinnati, OH, USA, [3]Cardiology, Children's Hospital Medical Center, Cincinnati, OH, USA.

Primary prevention of osteoporosis includes the achievement of maximal peak bone mass (PBM). Though calcium intake (Ca) and physical activity (PA) are said to affect PBM, their specific roles remain unclear due to a lack of prospectively collected data. We examined the impact of body composition, ethnicity, age of menarche, Ca, PA, smoking, contraceptive use, and pregnancy during the time of PBM accretion in 324 African American (AA) and 282 White (W) women seen annually since ages 9-10 yrs. Ca intake and PA levels were assessed by a validated 3-day food and activity diary. Habitual PA was assessed by a validated questionnaire. Daily Ca intake and PA levels were averaged over a 5 year period from ages 9 to 14. Current oral contraceptive (OC) and Depo-Provera/Norplant use, smoking status and "given birth before age 17" were ascertained. BMD and body composition were assessed at age 22±1 yrs by DXA of the whole body, lumbar spine, total hip and femoral neck. Separate multiple regression models were constructed for each bone site with all of the above as predictors. Lean body mass (LBM) was strongly correlated with BMD at all 4 sites with each kg associated with 0.006-0.008 g/cm^2 greater BMD, P<0.001. AA women had higher (P<0.001) BMD at all sites by 0.05 g/cm^2 (4.8%). Age of menarche was inversely (P<0.05) associated with BMD at all sites except the femoral neck (P=0.07). Each earlier year of menarche was associated with higher BMD by 0.016 g/cm^2 (1.5%) at the spine, 0.009 g/cm^2 (0.85%) at the total hip, and 0.007 g/cm^2 (0.6%) for the whole body. Race interaction with age of menarche was not significant, P>0.4. Ca intake was not (P>0.6) associated with BMD except at the total hip where there was a positive trend, P=0.096. Neither PA measure was associated (P>0.6) with BMD at any site. "Given birth" was marginally (P=0.06) associated with lower BMD at the femoral neck. Contraceptive use was not significant (P>0.25), but OC use showed a positive trend (P=0.1) at the total hip. Smoking was not (P>0.6) associated with BMD for any site. In summary, growth and rate of maturation had the greatest impact on PBM. Other factors, though suggestive for some, may not have sufficient impact to manifest as significant predictors. Though Ca and PA may affect PBM, their relative contributions in multivariate analyses where LBM is dominant may be masked due to the variability of their being self-reported measures. For their maximal effect to be shown, Ca and PA may also need to be evaluated in the context of other potentially mediating factors and other interactions.

SU278

The Effects of Milk Supplementation on Bone Accretion in Chinese Children. E. Lau[1], A. Chan[2], W. Lau*[2], H. Lynn[2]. [1]The Hong Kong Jockey Club Centre for Osteoporosis Care and Control, The Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China, [2]The Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China.

The calcium intake of Chinese children is amongst the lowest in the world, and supplementing the diet with calcium may be of tremendous public health significance in enhancing both mass. A randomized controlled clinical trial was conducted to study the effects of supplementing the diet of Chinese children with high calcium milk powder, on the rate of bone accretion. A total of 288 subjects (161 boys and 127 girls) aged 9-10 was randomized into 3 groups: supplementation by 80gm of milk powder containing 1300mg calcium, supplementation by 40gm of milk powder containing 650mg calcium, and no supplementation. Bone mineral density (BMD) was measured at the total body, total hip and the spine at baseline, 6 months, 12 months and 18 months. The percentage change in BMD between the 3 groups were compared by ANCOVA for repeated measures, adjusting for Tanner Staging.

Percentage change in BMD at 18 months

	Total Body	Total Hip	Spine
Boys			
80gm milk	4.1	10.6	10.7**
40gm milk	4.1	11.3	10.6
Control	3.0	9.9	9.0
Girls			
80gm milk	6.9	12.5	18.0
40gm milk	7.4	13.6*	16.4
Control	6.1	11.1	15.9

**P=0.01 and *P=0.06 by ANCOVA for repeated measures, as compared to the control group

Conclusion: There is a statistically non-significant trend that children whose diet is supplemented by milk have a higher gain in BMD.

SU279

High Prevalence of Vitamin D Insufficiency in the Elderly Population in Argentina. B. Oliveri, L. Plantalech, A. Bagur, A. Wittich*, G. Rovai*, E. Pusiol*, J. López Giovanelli*, G. Ponce*, A. Nieva*, A. Chaperón*, M. Ladizesky*, J. Somoza*, C. Casco, S. N. Zeni. Asociación Argentina de Osteología y Metabolismo Mineral, Buenos Aires, Argentina.

Vitamin D insufficiency is common in elderly populations (mainly in subjects living in homes for the elderly) and leads to secondary hyperparathyroidism, high bone resorption, bone loss and osteoporotic fractures. The aim of this study was to evaluate the nutritional status of vitamin D in elderly people living in their own homes in different cities in Argentina. 350 ambulatory subjects older than 65 years (X ± SD)(71.3± 5.2 years),(236 women and 114 men) from 7 cities in Argentina (between latitude 27ºS and 55ºS) were evaluated between the end of winter and beginning of spring (15th August-15th October). None of the subjects was receiving vitamin D or any medication that could affect mineral metabolism. They were grouped in 3 geographical regions: South Region (Bariloche: 41ºS, n=28; Comodoro Rivadavia: 45ºS, n=30; Ushuaia:55ºS, n=32); Mid-region (Buenos Aires 34ºS, n=168; Mendoza:33ºS, n=33) and North Region (Corrientes: 27ºS, n=30; Tucumán: 27ºS, n=30). Two patients were excluded because of primary hyperparathyroidism. Serum levels of calcium (Ca), creatinine (Cre) , bone alkaline phosphatase (BAP), 25(OH)D and mmPTH were measured. The results of 25(OH) D were analyzed as suggested by Mc Kenna (Osteoporosis Int 8, 1998): Deficiency(Def): <10 ng/ml; Insufficiency(Ins): >10-<20 ng/ml. The differences in 25(OH)D were the following: the South Region exhibited the lowest levels (p<0.0001vs North and Mid regions): 14.3± 5.6 ng/ml (Def:13%, Ins:75%), with the highest prevalence of deficiency in the southernmost city Ushuaia: 25%. The highest levels of 25(OH)D were observed in the North (p<0.03 vs Mid, p<0.0001vs South): 20.6 ± 7.4ng/ml (Def:2% Ins:50%). The Mid-region showed intermediate levels, between the South and North 17.8±8 ng/ml (Def:12% Ins:52%). Serum PTH and 25(OH)D were inversely related: r=-0.3, p<0.001). Serum levels of Ca(9.5±0.3mg/dl) BAP(61.0±19UI/l)and Cre(0.9±0.2mg/dl) were within normal limits with no significant differences among regions. Conclusion: The risk of insufficiency increases as latitude augments. The high prevalence of lower winter 25(OH) levels in this elderly urban population suggests the usefulness of vitamin D winter supplementation to reduce osteoporotic fractures.

SU280

Determinants of Circulating Levels of Vitamin D in Elderly People in Buenos Aires City, Argentina. L. Plantalech, B. Oliveri, H. Salerni*, J. Pozzo*, M. Ercolano*, M. Ladizesky*, C. Casco, S. N. Zeni, J. Somoza*, J. Fassi*, A. Bagur. Asociación Argentina de Osteología y Metabolismo Mineral, Buenos Aires, Argentina.

Elderly people, especially those living in overpopulated cities, are a susceptible population to hypovitaminosis D. The aim of this study was to investigate the winter serum level

of 25 OH vitamin D (25OHD) in 169 healthy people aged 71.5 ± 5.4 years (113 women and 56 men), living in Buenos Aires (34°S), and its relationship with exposure to sunlight, vitamin D (D) food (fish) intake, housing, clothing –use of beach-clothes such as short sleeves, shorts, etc– (using a questionnaire adapted from the EURONUT SENECA study), and socioeconomic status (determined by a test provided by the Asociación Argentina de Marketing). 25OHD was measured by Incstar RIA (ng/ml), none of the subjects received treatment with D. Results: Mean 25OHD was :17.5 ± 4.5ng/ml . Forty nine percent of the subjects had no exposure to sunlight; 63% of the study population consumed rich D food. The socioeconomic composition of the study population was: 15.3% high (H), 35.7% middle (M) and 49.0% low(L) level:. Serum 25OHD was higher in people with high exposure to sunlight vs. no exposure (23.3 ± 2.1 vs. 15.3 ± 0.1, p<0.001); who ate D food vs. zero intake (20.5 ± 1.7 vs. 15.2 ± 0.9,p<0.01) ; who lived in a house vs. apartment (19.2 ± 0.9 vs. 17.1 ± 1.3,p<0.05); who wore beach clothes in summer vs. long sleeves(20.9 ± 2.0 vs. 16.7 ± 0.7,p<0.01) and who had a high vs. low socioeconomic level (H: 20.7 ± 2.0 vs. L:.16.7 ± 0.7, p<0.05). A linear correlation was observed between 25OHD and exposure to sunlight (r:0.35, p<0.001). A multistep regression analysis showed that both D food intake and exposure to sunlight are predictors of levels of 25OHD (r2: 0.2, MSE:55.9, p<0.0001). Subjects in the high socioeconomic level had more exposure to sunlight (H: 5.5 ± 1.6 vs. M: 3.3 ± 0.6 vs. L: 1.4 ± 0.6 hours per week, p<0.03) and D food intake (H: 2.6 ± 0.2 vs. M: 1.7 ± 0.1 vs. L: 1.6 ± 0.1 time/week, p<0.0001) than those in the middle or low level. Conclusion: Hypovitaminosis D is found in a high percentage of our elderly population and is associated with low exposure during sunlight and poor D food consumption. It is the people with scant economic resources that are most affected by these factors.

SU281

Factors Related to Bone Health Among Canadian Chinese Immigrants Aged 45+. A. M. Cheung[1], R. Chaudhry*[2], K. Milstead*[2], C. Chan*[2], N. Diaz-Granados*[2], D. Lui-Yee*[2], M. Hamidi*[2], G. Chan*[3], L. Thompson*[4]. [1]Department of Medicine, University Health Network & University of Toronto, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]Yee Hong Community Centre, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada.

We conducted a community-based cross-sectional study to examine risk factors for osteoporosis and osteoporotic fractures among Chinese-Canadian immigrants aged 45 and older. Nine hundred and seventy-six (976) participants have been recruited to date through media announcements, health fairs, and community outreach through community centres, shopping centres, churches and libraries which predominantly serve the Chinese community in the Greater Toronto Area. We collected data on demographics, risk factors for osteoporosis and osteoporotic fractures, diet, physical activity, medication use, co-morbid conditions, fall and fracture history, and use of alternative and mainstream preventive health care. We also collected data on height and weight and measured heel bone density (BMD) using Sahara Qualitative Ultrasound (Hologic, Inc). Preliminary analyses were performed for the first 844 individuals recruited (589 women and 255 men, aged 45-95). Immigrants were mainly from Hong Kong (73%) & China (16%), with mean time in Canada of 12.8 years. Population characteristics included: mean age 59.9:63.4 (Female:Male); height 155.0:167.5 cm (F:M); weight 55.2:66.3 kgs (F:M). Dietary assessment showed that 88.5% of our participants consumed dairy products, with a median daily intake of 1.0 serving daily; 96% consumed soya products, median intake of 0.4 servings daily; 98.5% consumed dark green vegetables, median intake of 1.1 servings daily. A total of 167 falls were reported by 123 individuals (range 1-5 per person) in the three years prior to the interview. Of these reported falls, 68% occurred outdoors, 54% occurred during winter, and 23 fractures of various sites were reported. Mean heel BMD was 0.493:0.509 g/cm2 (F:M); mean t-score - 0.782:-0.907 (F:M). 3.9:3.2% (F:M) had t-score below or equal to -2.5, and 41.9:43.3% (F:M) had t-scores between -1 & -2.5. Compared to the North American Caucasian population (USDA, CSFII), this sample of Chinese-Canadian immigrants reported lower intake of dairy products but higher intake of dark green leafy vegetables. The BMD distribution of women and men in our study is similar to that reported in other North American studies (CAMOS, NHANES III). Further analyses are being performed to determine the relationship between the risk factors, BMD and osteoporotic fractures in the Chinese immigrant population recruited for our study.

Diagnosis of Vertebral Fracture by Instant Vertebral Assessment. J. Damiano*[1], S. Kolta[1], R. Porcher*[2], M. Dougados*[1], C. Roux[1]. [1]Rhumatologie, Hôpital Cochin, Paris, France, [2]Dbim, Hôpital Saint Louis, Paris, France.

Vertebral fractures are the hallmark of osteoporosis. They are independent risk factors for both vertebral and peripheral fractures. Instant Vertebral Assessment (IVA) is a radiographic method using dual energy X-ray absorptiometry (DXA) to assess vertebral deformities. We performed IVA of the spine from T4 to L5 (anteroposterior and lateral views) and BMD (g/cm²) measurement at the lumbar spine and left hip on a Delphi W device (Hologic, Waltham, MA) in 101 post menopausal patients (aged 70.6 ± 8.8 years). They also had lateral and anteroposterior X-rays of the thoracic and lumbar spine. Vertebral fracture was assessed independently by 2 investigators. Weighted kappa statistics vere calculated at the vertebral and the patient levels, adjusted for predefined confounding factors : scoliosis, osteoporosis (T score ≤ 2.5 at either spine or femur) and increased body mass index (BMI, Kg/m²). Sixty one patients had at least one vertebral fracture on X-rays. The percentage of vertebrae not legible was 1 % and 14 % on X-rays and IVA respectively. On IVA, T4 and T5 were not assessable in 42 % of patients. At the patient level, sensitivity and specificity of IVA, as compared to X-rays, were 80 % and 93 % respectively. Inter-reader agreement was good for X-rays (kappa score of 0.77) but moderate for IVA (kappa score of 0.53). At the vertebral level, sensitivity and specificity of IVA were 74% and 98%, and with a good inter-reader agreement (kappa scores of 0.85 and 0.62 for X-rays and IVA respectively). According to the prevalence of vertebral fracture in our sample, negative predictive value of IVA was 97.5% at the vertebral level and 85.3% at the patient level . Conversely, IVA also had a high positive value, 92% at the patient level. In post menopausal women, IVA may avoid unnecessary X-rays.

SU283

Long-Term Prediction of Fracture Incidence in Elderly Men and Women. K. P. Chang*, J. R. Center, T. V. Nguyen, J. A. Eisman. Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, NSW, Australia.

The Dubbo Osteoporosis Epidemiology Study is an ongoing longitudinal study of fracture incidence in men and women aged 60 and over. Fractures due to minimal trauma and non-pathological fractures were ascertained by reviewing all radiology reports from the two area radiology services over 12 years. From April 1989 to December 2000, 1055 symptomatic fractures were recorded in 807 persons over 39,357 person-years of observation. Fracture incidence was 3412 and 1632 per 100,000 person years for women and men respectively. The incidence of vertebral, proximal humerus, wrist, hip and pelvis fractures increased exponentially with age in both sexes, typical of osteoporotic fractures. As expected, the risk of subsequent fractures was increased by having any previous osteoporotic fracture; for example, 20% of men and 23% of women with hip and 35% of men and 25% of women with vertebral fractures sustained further fractures. Ankle, hand and foot fractures did not show an exponential age-related increase. However, these "non-osteoporotic" fractures were also predictive of future fractures, particularly in men, with 42% of men and 15% of women with ankle fractures having a subsequent fracture (relative risk: 15.8 [95% CI: 10.3 – 21.4] and 3.5 [95% CI: 0.9 to 7.9], men and women respectively). Similar but lesser increased risks were observed in men and women with prior hand and foot fractures. Although fracture incidence was greater in women than men for all but rib fractures, the female: male ratio decreased with age, particularly in the 80+ age group (e.g. hip 1.8:1, vertebral 1.4:1). Absolute fracture numbers peaked in the 70-79 age group for men (48% of all fractures in men) and in the 80-84 age group in women before declining, due to the smaller 'at risk' population. This is the first long-term study examining fracture incidence over 12 years. Ankle, hand, and foot fractures did not increase with age, but were strong predictors of subsequent osteoporotic fractures, especially in men. The data suggest that fractures traditionally thought not to be osteoporotic do indicate increased risk of future osteoporotic fractures. In addition, the fracture burden for society occurs in younger people than previously recognised, especially in men.

SU284

Incidence of Hip Fractures in Italian Males and Females Aged 45+ Years. P. Piscitelli*[1], S. Maggi*[2], R. Giorgino[3], G. Crepaldi[4]. [1]Epidemiology, Catholic University, Rome, Italy, [2]CNR Aging Center, Padova, Italy, [3]Procter&Gamble Health Care, Rome, Italy, [4]University of Padova, Padova, Italy.

No national-based data on the incidence rates of hip fracture in Italy have been published up to now. This study aims at assessing the incidence rates of hip fracture in Italian males and females aged 45+ years, using the National database available at the Department of Health. We identified codes 820.0 and 820.1 for cervical fractures, codes 820.2 and 820.3 for intertrochanteric fractures, codes 820.8, 820.9 and 821.1 for hip fractures at unknown sites. The most recent data available were for 1999. Census population data from the Italian National Institute of Statistics were used for calculating the incidence rates. The following table shows the rates (per 10,000) of cervical, intertrochanteric and all hip fractures in males and females, by age and sex.

Age	Cervical		Intertrochanteric		All		F:M ratio
	Males	Females	Males	Females	Males	Females	
45-64	1.6	2.9	1.7	1.6	3.6	4.9	**1.4**
65-74	6.1	15.3	6.5	12.3	13.6	30.2	**2.2**
75+	32.4	73.5	34.9	80.1	72.8	163.9	**2.3**

As expected, the incidence rates increase with age, in women the rates are more than double compared to males. We identified a total number of 17,777 hip fractures in men and 60,931 in women. The length of stay in hospital for cervical fractures increased from 14.9 days in the youngest group to 16.2 days in the eldest group in men and from 14.0 days to 17 days in women; for intertrochanteric fractures it ranged from 15.1 days in the youngest group to 16.2 days in the eldest group in men and increased from 14.6 days to 16.3 days in women. This is the first national assessment of hip fracture incidence rates in the Italian population. The rates are consistent with those observed in other Southern European countries. Inspite of the tremendous social impact of hip fracture, the perception of its frequency and severity remains still very low among the general population and also in the medical community, particularly if compared to other conditions considered "very severe", such as myocardial infarction (MI). The same government sources provide a figure of 57,569 MI in age matched men and 28,531 MI in age matched women, but the level of awareness for primary and secondary preventive interventions in this case is very high, while for osteoporotic fractures is virtually null.

SU285

Fractures History and Osteoporosis Drugs Usage: a Population-based National Study. S. Giannini[1], M. Bevilacqua*[2], G. Bianchi[3], S. Gonnelli[4], E. Palummeri*[5], M. Rossini*[6], R. Giorgino[7]. [1]Internal Medicine, University of Padova, Padova, Italy, [2]Endocrinology, Sacco General Hospital, Milano, Italy, [3]Rheumatology, Arenzano General Hospital, Arenzano, Italy, [4]Internal Medicine, University of Siena, Siena, Italy, [5]Geriatrics, Ospedale Galliera, Genova, Italy, [6]Osteoporosis center, Verona, Italy, [7]Procter & Gamble Health Care, Rome, Italy.

The ESOPO study is a national population based study to measure the prevalence of osteoporosis in the Italian general population. This research analyzed the pattern of osteoporosis drugs in subjects according to low trauma fractures history: 83 University and Hospital centers participated to the study. Subjects were randomly invited to participate to the study from 1,536 General Practitioners using their own Patients Directory. A total of 15,992 subjects (11,011 females aged 40-79 and 4,981 males aged 60-79 years) participated to the study. The current use of osteoporosis drugs (namely bisphosphonates, calcium, vitamin D, calcitonin or other drugs used for OP treatment) and HRT was noted. Low-trauma fractures which had occurred after the age of 50 was also recorded. Full data are available for 7,439 women and 4,606 men. The table below shows the age-adjusted proportion of female and male subjects according to fractures history and OP drugs current usage (*p<0.05 **p<0.01 ***p<0.001 vs. pts without fractures).

	Females		Males	
	With Fractures	Without Fractures	With Fractures	Without Fractures
Cases	1326	6133	783	3823
Any drug for OP	26.4%***	13.9%	3.1%**	1.9%
Bisphosphonates	12.7%***	5.6%	1.0%**	0.5%
Calcium	13.3%***	6.6%	2.0%**	0.8%
Vitamin D	10.6%***	4.4%	0.7%*	0.4%
Calcitonin	3.2%**	1.2%	0.4%	0.3%
Other drugs	1.6%	1.8%	0.1%	0.1%
HRT	10.1%	15%		
HRT > 1 year	5.5%	9.1%		

Patients with a history of fractures are more frequently treated with osteoporosis drugs, as predictable. Females are more likely to take a drug than men, which is probably due to higher historical knowledge on postmenopausal osteoporosis among Italian physicians. However, the study demonstrates that only 26% of women and 3% of men with a history of low trauma fractures are currently treated with any OP therapy. Bisphosphonates, calcium and vitamin D usage was higher in females than in males, but still very low: only 1out of 10 of women and 1 out of 100 men with fractures history are treated with bisphosphonates. The use of HRT is limited to early postmenopausal women and is unlinked to fractures history. This large study confirms that osteoporosis is clearly a mistreated disease in women; in men the use of bone active drugs is almost null. Health institutions involvement is mandatory for implementing educational programs to create both patients and physicians awareness on the "silent epidemic" disease.

SU286

Clinical Vertebral Fractures Are Associated with Hip, Rib, and Wrist Fractures in Postmenopausal Women: The Population Based ESOPO Study. O. Di Munno*[1], N. Malavolta*[2], M. Ferraris*[3], F. Silveri*[4], F. Trotta*[5], R. Pellerito*[6], M. Muratore*[7], R. Giorgino[8]. [1]Rheumatology, University of Pisa, Pisa, Italy, [2]S.Orsola Hospital, Bologna, Italy, [3]Rheumatology, S.Andrea Hospital, Vercelli, Italy, [4]Rheumatology, Murri Hospital, Iesi AN, Italy, [5]Rheumatology, S.Anna Hospital, Ferrara, Italy, [6]Rheumatology, Mauriziano Hospital, Torino, Italy, [7]Rheumatology, General Hospital, S.Cesario di Lecce, Italy, [8]Procter & Gamble Health care, Rome, Italy.

The ESOPO study was a national population based study aimed at measuring the prevalence of osteoporosis in the Italian general female population. This research assessed the relationship between the history of clinical vertebral fractures and other osteoporosis related fractures in postmenopausal women. Eighty-three University and Hospital centers located over 18 out of 21 Italian peninsular and insular regions participated to the study. Subjects were randomly invited to participate from 1,536 General Practitioners through their own Patients Directory by a specific randomization protocol: reasons of decline were accurately recorded. Eleven thousands-eleven females aged 40-79 were enrolled for the study. The history of clinical vertebral, hip, rib, wrist and other low-trauma fractures (humerus, pelvis, clavicle, leg) occurred after the age of 50 was recorded. The table below shows the proportion (±SEM) of 7,457 women with and without previous clinical vertebral fractures who had also reported a history either hip, wrist, rib or other low trauma fractures.

	With vertebral fx	Controls	p value	OR	95% C.I.
Cases	146	7313			
Hip fractures	4.1%±1.6%	0.8%±0.1%	0.0003	4.85	2.1-11.4
Rib fractures	15.1%±3.0%	1.8%±0.2%	<0.0001	9.7	5.6-15.8
Wrist fractures	18.5%±3.2%	5.0%±0.2%	<0.0001	4.3	2.8-6.7
Other fractures	17.8%±3.2%	10.2%±0.3%	0.0044	1.9	1.2-2.9

Almost 2% of the study subjects reported a history of clinical vertebral fractures after the age of 50. A very significantly higher number of them reported a history of either hip, rib, wrist or other low-trauma fractures when compared to controls. In particular rib fractures were showed to be very strongly associated with spine fractures by a nearly 10-fold OR increase. This study confirms the high frequency of osteoporotic fractures recurrence in the same subject: rib fractures risk should be taken frequently into account in subjects with osteoporosis. Finally the current spine-hip fracture paradigm should be shifted to a larger spine-hip-wrist-rib fractures circle.

SU287

Underestimation of Vertebral Deformity Prevalence: How Can We Improve Accuracy? N. Napoli*[1], S. Bucchieri*[1], L. Sutera*[1], D. Avila*[1], C. Sferrazza*[1], R. Giorgino[2], G. B. Rini*[1]. [1]Bone Metabolic Disease Unit Dept. II Internal Medicine, Policlinico Giaccone, Palermo, Italy, [2]Procter & Gamble Health care, Rome, Italy.

The prevalence of vertebral deformity is significantly underestimated due to the low frequency of symptoms and mostly the poor attention paid by clinicians and radiologists in the radiographic recognition of vertebral deformity. This study was aimed at measuring the proportion of false negative results for vertebral deformity assessment in an Osteoporosis workout setting based in an University center. Since October 2001 to March 2002 we analyzed 193 consecutive subjects(177 women and 16 men) who referred to the Bone Densitometry unit: all subjects had undergone a X-ray exam of thoracic and lumbar spine in external general radiology centers in the previous 3 months. The presence of vertebral deformity was either not reported or negative in all the original reports. Each film was centrally digitized: T4-L4 vertebral heights ratio was measured from a single physician by a dedicated morphometry software (Spine-X Analyzer, CAM Diagnostics, Milan, Italy). The system is based on a 6-point based recognition of the 3 vertebral heights: the intra-observer CV has been measured, ranging from 2.2% for lumbar to 3.1% for thoracic bodies. The full procedure takes from 5' to 12'. All X-ray films were then blindly evaluated by an expert skeletal radiologist in the University for a visual direct assessment of vertebral body heights. The presence of at least one vertebral deformity was observed in 164 out 188 (87%) of study subjects whose films could be measured by digital computerized morphometry (DCM) and in 124 out 186 (77%) of cases visual manual assessment (VMA) could evaluate. The presence of at least 1 vertebral deformity was concordantly shown by DCM and VMA in 85% of cases: 70% of the subjects showed multiple vertebral deformities according to digital analysis, 57% according to visual assessment. The following table shows the distribution of subjects according to the number of vertebral deformities as measured by DCM and VMA.

N. of vertebral deformities	DCM	%	VMA	%
0	24	12.8%	42	22.6%
1	34	18.1%	38	20.4%
2	36	19.1%	46	24.7%
3	35	18.6%	32	17.2%
4	24	12.8%	14	7.5%
5	16	8.5%	6	3.2%
6	12	6.4%	3	1.6%
7	5	2.7%	4	2.2%
8	2	1.1%	1	0.5%

Our data confirms that the prevalence of vertebral deformities is very largely underestimated in general practice: we propose the use of an easy-to-use computerized morphometry method on digitized films which was shown to dramatically improve diagnostic accuracy.

SU288

Smoking Is Associated with an Increased Fracture Risk in the General Population. L. Rejnmark, P. Vestergaard, L. Mosekilde. Dept. of Endocrinology and Metabolism, Aarhus Amtssygehus, Aarhus, Denmark.

In a cross-sectional design, we studied if smoking is associated with an increased fracture risk. A self-administered questionnaire was issued to 3,600 subjects (age 2-90 years) randomly selected from the general population. The questionnaire concerned prevalence of any fracture in the index subject and smoking habits along with gender, family fracture history, weight, height, age, and alcohol consumption. The adults completed the questionnaire themselves, while the parents completed the questionnaire on behalf of the children. 1637 (54.6%) adults, and 343 children (57.2%) responded. Current smokers had an increased prevalence of fractures compared to never smokers (OR=1.4, 95% CI: 1.1-1.8), while no

significant increase was present in previous smokers (OR=1.2, 95% CI: 0.9-1.6) after adjustment for potential confounders in a logistic regression model. Among potential confounder variables, both a maternal (OR=2.1, 95% CI: 1.6-2.6) and a paternal fracture (OR=1.4, 95% CI: 1.0-1.9) were associated with an increased fracture risk. Also increasing body mass index (OR=1.04, 95% CI: 1.01-1.06 per kg/m2) was associated with an increased fracture risk. Age, gender, and alcohol consumption were not associated with an increased fracture risk in this model. Thus, smoking is associated with an increased risk of any fracture even after adjustment for potential confounder variables. A family history of fracture is also a risk factor for sustaining a fracture.

SU289

Total Body Fat as a Predictor of Hip Fracture. G. El-Hajj Fuleihan[1], M. Badra*[2], A. Tayim*[2], M. Salamoun*[1], N. Afeiche*[2], O. Baddoura*[2], S. Boulos*[2], R. Haidar*[2], S. Lakkis*[2], R. Musharafieh*[2], A. Nsouli*[2], A. Taha*[2]. [1]Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon, [2]Orthopedics, American University of Beirut Medical Center, Beirut, Lebanon.

Osteoporosis is a major public health problem to-date, with hip fractures incurring a high human and economic toll. Several risk factors for hip fracture have been identified including BMD, age, BMI, height, hip axis length, direction and energy of fall. Hip protectors have been used as a mean to decrease energy of fall and therefore fractures. In this study we hypothesized that total body fat, an index of endogenous hip protection, is a risk factor for hip fractures. This project is part of an on-going institutional project evaluating the epidemiology of hip fractures in our tertiary referral center [JBMR 2001; 16(S1): M337]. As of the summer of 2000, all patients had total body fat measured. Total body BMC, total body fat, and BMD of the hip (contralateral side) were measured in 31 hip fracture patients (17 women,14 men) within one week of their fracture, and 19 controls (18 women,1man). A Lunar DPX-L densitometer was used for the first 8 subjects and a Hologic 4500 A for the last 24. A cross-calibration formula based on 72 subjects measured on both machines allowed calculation of mean total hip BMD and total hip T-scores using the manufacturer's database, expressed in terms of Hologic measurements. Osteoporosis was defined as a T-score<-2.5 using the NHANES database. Numbers expressed as mean (± SD).

Variable	Hip fxs,N=31	Controls,N=19
Age yrs	76(9)	70(6)*
BMI kg/m2	26(3)	31(4)*
Height cms	162(9)	153(8)*
BMD Total hip Hologic gm/cm2	0.65(0.14)	0.73(0.14)*
Total hip T-score NHANES	-2.6(1)	-1.8(1)*
Total body fat kgs	23.2(9.4)	31.1(6.5)*
Total body fat %	34(9)	42(4)*

* p<0.05 hip fractures vs control

BMD in hip fracture patients was significantly lower than controls, identical to Western standards (1-2), and identical in both genders. Significant correlates of hip fractures were age, BMI, height, BMD, total body fat, % body fat, hearing capability and mental status. In conclusion, in addition to confirming known predictors of hip fracture in our population, this is to our knowledge the first study demonstrating that body fat is a predictor of hip fractures. Body fat a known predictor of BMD, may also be a predictor of hip fractures due to mechanical (padding) factors, in addition to recognized hormonal reasons namely increasing circulating estrogen levels, and therefore BMD.

Strain Dependent Effects on Bone Fracture Healing in Mice. M. B. Manigrasso*, J. P. O'Connor. Orthopaedics, UMDNJ-New Jersey Medical School, Newark, NJ, USA.

Mice are an optimal mammalian model in which to study genetic and molecular processes that govern osteoporosis and the bone fractures that accompany osteoporosis. Variations in bone mineral density (BMD) have been defined for different inbred strains of mice indicating that genetic differences between inbred mouse strains controls BMD. The purpose of this study was to determine if BMD correlates with fracture healing capacity. To perform this study, a mouse femur fracture model was developed to measure the torsional mechanical properties of healing fractures. Initial experiments involved defining the normal radiographic, histological, and mechanical properties of the healing femur fractures in an outbred mouse strain (ICR). Based upon these initial experiments, three inbred mouse strains with defined BMDs were tested for their ability to heal femur fractures. The three inbred strains tested were C3H (high BMD), DBA/2 (moderate BMD), and C57BL/6 (low BMD). Fracture healing was followed in the inbred mouse strains by weekly radiography and torsional mechanical testing at 4 weeks post-fracture. Only 8-week old female mice were used. Radiography of the fracture calluses clearly indicated that C3H mice formed a larger and more X-ray dense callus than the C57BL/6 mice. The size and X-ray density of the fracture calluses formed by the DBA/2 mice were in between that of the C3H and C57BL/6 mice. These observations appeared to correlate increased fracture callus X-ray density and increased fracture callus size with increased BMD. Fractured femurs and the animals' contralateral unfractured femurs were mechanically tested at 4 weeks post-fracture (C3H: n = 12; DBA/2: n = 16; and C57BL/6: n = 7). Initial experiments with outbred ICR mice showed that fracture bridging occurs between 3 and 4 weeks after fracture. Therefore, fractured femurs from the inbred mouse strains were assayed at 4 weeks post-fracture to measure the initial mechanical properties of the healing callus. Bone and callus dimensions were measured prior to testing. Peak torque and angle at failure were obtained for each femur from its torque-angle deflection curve. From these values, torsional rigidity, shear stress, and shear modulus were calculated based upon a hollow-ellipse model of callus geometry. It was found that the absolute and relative mechanical properties of the DBA/2 fractured femurs were better than those obtained from the C3H and C57BL/6 mice. For instance, the fractured femur shear modulus for the DBA/2 mice (2.1 ± 1.3 GPa) was significantly different from that of the C3H (1.29 ± 0.58 GPa; p = 0.03) and C57BL/6 (0.78 ± 0.57 GPa; p = 0.003) mouse femurs. These results indicate that BMD is not a predictor of fracture healing capacity.

SU291

Morphometric X-ray Absorptiometry In Colles' Fracture Patients. L. del Rio[1], E. Kanterewicz*[2], A. Yáñez*[2], A. Diez[3]. [1]Densitometria Osea, CETIR Centre Medic, Barcelona, Spain, [2]Hospital de Vic, Vic, Spain, [3]Medicina Interna, Hospital del Mar, Barcelona, Spain.

Vertebral morphometry by DXA (MXA) is a research tool developed to evaluate the presence of vertebral deformities although its clinical utility is still limited. OBJECTIVE: The goals of this study were : 1) to know the prevalence of vertebral deformities by MXA in women with Colles' fracture; 2) to determine the correlations between MXA findings and BMD. METHODS: In an incident case-control study, 58 women (mean age 65.8 yrs) with a recent Colles' fracture and 83 population-based control women (mean age 58.7 yrs) were enrolled. Both BMD and MXA were performed by DXA (Lunar Expert). Anterior, middle and posterior heights were measured and wedge (Ha/Hp) and mid-wedge (Hm/Hp) ratios were calculated. A vertebral deformity was defined when at least one ratio fell 3 SD below the reference mean of that ratio at any vertebral level. RESULTS: Mean age of cases was 65,8 yrs and in controls 58,7 (p<0.05). Osteoporosis (T-score <-2.5 SD) was found at lumbar spine in 47% of cases vs 20% of controls (p<0.001) and at total hip in 19% vs 6% (p<0.005). Morphometric vertebral deformities were associated with older age (p<0.05) and were found in 19% of cases against 11% of controls (non-significant). Cases had a lower mid-wedge ratio than controls at each vertebral level (p<0.05) while wedge ratio results were more heterogeneous. When the sample was stratified by age, Colles' fracture show a trend to be associated with vertebral deformity only in the younger (<65 yrs) group. A low but significant coefficient of correlation was found between mid-wedge ratio and BMD mainly at hip level. CONCLUSIONS: A high prevalence of vertebral deformities is detected in Colles' fracture patients using MXA. There is a small positive correlations among MXA deformity ratios and BMD. Although older age is an important risk factor for the presence of vertebral deformities in the whole group, younger Colles' fracture patients showed more vertebral deformities than healthy controls of the same age range.

SU292

Relationship between Fractures of the Extremities and Bone Mineral Density: A 10-year Prospective Study. J. Finigan*[1], D. M. Greenfield*[2], N. F. A. Peel[1], A. Blumsohn[1], R. A. Hannon[1], R. Eastell[1]. [1]Bone Metabolism Group, University of Sheffield, Sheffield, United Kingdom, [2]University of Sheffield, Sheffield, United Kingdom.

Fractures of the feet, hands and skull have been considered to be unrelated to bone mineral density and so not characteristic of osteoporosis. We have carried out a 10-year prospective study of a group of 375 women who were ages 50 to 85 years at baseline. We measured bone mineral density at baseline by dual-energy x-ray absorptiometry (Lunar DPX), pyridinoline to creatinine ratio (PYD) by HPLC, tartrate-resistant acid phosphatase (TRACP) and bone alkaline phosphatase (bone ALP) by enzyme assay, and stiffness of the calcaneus at year 5 by quantitative ultrasound (Lunar Achilles). Details of incident non-vertebral fractures were ascertained from multiple sources including patient questionnaire and review of medical notes, and all were radiologically confirmed. The table shows the relative risk of fracture per standard deviation of bone measurement using a Cox Regression Model (with log transformation for bone markers). We divided the fractures into those of the extremities (hands, feet, skull) and the remaining non-extremity, non-vertebral fractures for comparison.

Measurement	Extremity (n=22)	Non-extremity (n=46)
Femoral neck BMD	2.01**	2.19***
Lumbar spine BMD	1.34	1.56**
Total body BMD	2.09***	1.87***
Achilles Stiffness	2.27**	1.56*
Urinary PYD	1.76**	1.32
Serum TRACP	1.84**	1.22
Serum bone ALP	1.58*	1.16

** p<0.01, *** p<0.001

The relative risks were significant for most measurements for extremity fracture and were of a similar magnitude to those for non-extremity fracture. Interestingly, the sites that best predicted extremity fractures were the total body (a site composed mainly of cortical bone, like the extremities) and the calcaneus (a site close to the foot fractures). The stronger prediction of bone markers for extremity fractures is unexplained. We conclude that fractures of the extremities should be considered to be related to low bone mineral density, and hence to osteoporosis.

SU293

The Radiographic Cleft in Dynamically Mobile Osteoporotic Vertebral Compression Fractures. F. E. McKiernan[1], T. Faciszewski*[2]. [1]Center for Bone Diseases, Marshfield Clinic, Marshfield, WI, USA, [2]Department of Orthopedic Spine Surgery, Marshfield Clinic, Marshfield, WI, USA.

Dynamic mobility refers to a change in configuration of a vertebral compression fracture (VCF) in different postures and implies the gross disruption of cortical and cancellous bone. The radiographic appearance of cortico-cancellous disruption is the intravertebral cleft. Considered a sign of vertebral osseous necrosis (Kummel's sign), clefts are not thought to occur in osteoporotic VCFs. Herein we describe the frequency, radiographic appearance and location of the intravertebral cleft in osteoporotic VCFs presenting for vertebroplasty (VP). Dynamic vertebral mobility was assessed by comparing preoperative standing lateral X-rays with preoperative supine, cross table-lateral X-rays of the index VCF. Dynamic vertebral mobility was defined as any change in fracture configuration apparent with unaided vision. Clefts appeared as intravertebral gas on plain X-ray or signal void on STIR sequence MR but were defined as low resistance, confluent reservoirs for polymethlymethacrylate (PMMA) at the time of VP. Fifty consecutive patients underwent 56 VP procedures to treat 82 VCFs. There were 33 (66%) women and 17 (34%) men. Twenty-four of 50 patients (48%) had intravertebral clefts. Thirty of their 82 VCFs (34%) had clefts. All 30 clefts occurred in mobile VCFs and no mobile VCF was without a cleft. No clefts were appreciated in fixed (non-mobile) VCFs ($p<0.001$). Twenty-two of 30 (73%) clefted fractures occurred at the thoraco-lumbar junction (T11-L1) but only 14 of 52 (27%) fixed fractures occurred at that site ($p< 0.001$). Clefts were appreciated in 4 of 29 (14%) of preoperative standing lateral X-rays, in 18 of 28 (64%) of supine cross-table X-rays and in 25 of 26 (96%) cases by MR. In one case the intravertebral cleft was only appreciated at the time of PMMA injection. Consistent with previous observations the content of the cleft (air or water) was variable and dependent upon time and position. PMMA fill patterns of clefted and non-clefted VCFs were distinct. This radiographic series documents that intravertebral clefts are frequent in osteoporotic VCFs presenting for VP. In many patients clefts can be appreciated on supine cross-table lateral X-rays but are almost always appreciated by MR. Clefts cluster at the thoracolumbar junction and appear to be necessary for dynamic mobility. The relationship between clefted, dynamically mobile VCFs and Kummel's disease needs reconsideration in light of these observations. Technical approaches to VP and clinical outcomes may differ between clefted and non-clefted VCFs.

SU294

The Management of Osteoporosis After Hip Fracture: Have We Improved Our Care? S. Bahl*, P. S. Coates, S. L. Greenspan. Endocrinology, University of Pittsburgh Medical Center, Pittsburgh, PA, USA.

Patients admitted for acute hip fracture are rarely recognized as having osteoporosis or managed appropriately despite the multiple available agents known to prevent fractures. To determine if physicians have improved the recognition and treatment of patients with acute hip fracture, we performed a retrospective analysis to identify the acute hip fractures admitted to the University of Pittsburgh Medical Center, a large tertiary care, academic institution, in the years 1995 and 2000. As a control group, age and sex matched patients with communnity acquired pneumonia were studied. We obtained the patients' demographic data, discharge medications and discharge diagnoses. There were 136 acute hip fractures in 1995 and 117 in the year 2000. Patients in 2000 were more likely to be diagnosed with osteoporosis (18% vs 4%, $p<0.02$), more likely to be discharged on calcium (17% vs 7%, $p<0.02$), and more likely to be discharged on antiresorptive therapy (15% vs 2%, $p<0.001$). Patients with a diagnosis in 2000 were older and more likely to receive antiresorptive agents than those without a diagnosis (29% vs 11%, $p<0.05$). None of the patients received a bone density scan while in the hospital. However in 2000, the patients admitted with pneumonia were just as likely to receive calcium, vitamin D, or antiresorptive agents at the time of discharge, as those with an acute hip fracture. In summary, although there was an improvement in the management of osteoporosis after acute hip fractures from 1995 to 2000, there was no difference in management of patients with hip fracture versus pneumonia in the year 2000. However patients with a "diagnosis" of osteoporosis were more likely to be discharged on appropriate therapeutic options. We conclude that patients identified with the diagnosis of osteoporosis after a fracture are more likely to receive effective management. Further studies are needed to determine the factors needed to target patients for appropriate diagnosis and therapy.

Patients with hip fracture and pneumonia

	Number	Calcium (%)	Vitamin D (%)	Antiresorptives (%)
All Hip Fracture (1995)	136	7	8	2
All Hip Fracture (2000)	117	17*	12	15**
Osteoporosis Diagnosed (2000)	21	24	19	29***
Osteoporosis Not Diagnosed (2000)	96	16	10	11
Pneumonia (2000)	120	20	18	10

*$p<0.02$ 1995 vs 2000 hip fracture patients
**$p<0.001$ 1995 vs 2000 hip fracture patients
***$p<0.05$ 2000 hip fracture patients: osteoporosis diagnosis vs no diagnosis

SU295

A 28 Month Audit of the Efficacy of the Fracture Liaison Service in Offering Secondary Prevention for Patients with Osteoporotic Fractures. A. R. McLellan, M. Fraser*. Medicine & Therapeutics, Western Infirmary, Glasgow, United Kingdom.

The Fracture Liaison Service(FLS), established in 1998, is the first service model of its kind in the world that delivers a comprehensive strategy of assessment (and treatment where appropriate) of osteoporosis for the secondary prevention of osteoporotic fractures to all women and men over 50years who present with 'low trauma' fractures. The FLS is effected by the Fracture Liaison Nurse (FLN), who liaises between secondary care bone metabolism services and the orthopaedic and accident & emergency units to deliver osteoporosis assessment and/or treatment for all appropriate outpatient and inpatient fracture cases. Initial contact with the FLN is designed to raise the patients' awareness of risk of osteoporosis and to apply protocols for the secondary prevention of fractures. For many that requires subsequent attendance at the FLN-DXA clinic, where the DXA result informs the selection of the most appropriate treatment. Other outcomes of the initial assessment by the FLN include a)starting 1000mg calcium carbonate+800I.U.vitaminD or b) review of compliance and use of existing antiresorptive treatments. In the first 28months, the FLS has assessed 3145 fracture cases (2538 women). Fracture sites by decreasing prevalence were wrist (n=992),hip (n=743),humerus (n=460), ankle (n=328), hand or foot (n=226), and at all other sites (n=396); women (age 73.4(SD11.8)yr accounted for between 73% (ankle) and 86% (wrist) of fractures. The table shows the prevalence of osteoporosis and osteopaenia (at lower of spine or total femur)(m/f) in 232m & 1151f who underwent DXA via the FLN-DXA clinic.

Prevalence of osteoporosis and osteopaenia (at spine or total femur)in 232m and 1151f.

Site	number m/f	% o'porosis	% o'paenia
Wrist	71 / 482	28% / 51%	42% / 33%
Hip	23 / 134	87% / 71%	13% / 28%
Humerus	47 / 156	43% / 49%	47% / 37%
Ankle	41 / 148	7%/ 30%	54% / 45%
Hand/foot	19 / 123	21% / 37%	42% / 40%
Other	31 / 108	29% / 52%	45% / 36%

At the 28 month audit of 3145 fracture cases who attended our hospital, overall 71% were assessed (by DXA) or were given treatment for secondary prevention; 10% were awaiting their assessment at the FLN-DXA clinic and 19% either refused assessment or did not attend. Corresponding data for wrist and hip fracture cases were: 67%, 11%, 22% and 84%, 6%, 10% respectively. The FLS is a highly effective model for delivering secondary prevention to inpatients and outpatients presenting to secondary care with incident osteoporotic fractures.

SU296

CANDOO: A Longitudinal Canadian Multi-Center Tertiary-Care Network for Observational Research in Osteoporosis and Osteopenia Using Standardized Clinical Practice Data: 11 Years Of Follow-Up. R. J. Sebaldt[1], J. D. Adachi[1], W. Olszynski[2], J. P. Brown[3], D. A. Hanley[4], R. G Josse[5], T. Murray[5], G. F. Stephenson[6], A. Petrie*[1], A. Mark*[1], C. H. Goldsmith*[7]. [1]Medicine, McMaster University, Hamilton, ON, Canada, [2]University of Saskatchewan, Saskatoon, SK, Canada, [3]Laval University, Ste-Foy, PQ, Canada, [4]University of Calgary, Calgary, AB, Canada, [5]University of Toronto, Toronto, ON, Canada, [6]Procter & Gamble Pharmaceuticals Canada, Inc., Toronto, ON, Canada, [7]McMaster University, Hamilton, ON, Canada.

The CANDOO Project (Canadian Database of Osteoporosis (OP) and Osteopenia) is a collaboration of OP specialists from across Canada for generating new knowledge about long-term outcomes of OP and its treatments and for validating clinical trial results in clinical practice. A comprehensive standardized clinical dataset appropriate to OP subspecialty practice was iteratively evolved by consensus. It has been collected by the CANDOO collaborators as integral part of the clinical care of new and follow-up patients since as early as March, 1990. Dataset updates accommodate new diagnostic and therapeutic options, and a self-administered OP-related quality of life questionnaire (mini-OQLQ) was added in 1995. Data are aggregated anonymously into a central database using standard operating procedures. The 7 collaborators, a biostatistician and a sponsor representative form the steering committee to monitor progress and plan data analyses and publications. By June 1, 2001, 9,855 patients were recorded (86% women (86% postmenopausal)), having at baseline: mean age 59 years, mean t-score at lumbar spine = -2.0, mean number of fractures = 1.3. 38,826 visits (assessments) were recorded, 74% of which were follow-up visits, with a median total patient follow-up of 3.0 years. 80% of patients were last seen within the past 2 years. Over the past 7 years, CANDOO data analyses and publications have confirmed the effectiveness of: (i) etidronate for treatment of corticosteroid-induced OP, (ii) etidronate and alendronate for treatment of male OP, (iii) addition of etidronate or alendronate to stable hormone replacement therapy for treatment of postmenopausal OP, (iv) mini-OQLQ for the demonstration of effect of vertebral and non-vertebral fractures on quality of life. We conclude that aggregate standardized longitudinal clinical practice data can provide valuable information about OP and treatment outcomes under clinical practice conditions.

Osteoporotic Fracture: Missed Opportunity for Intervention. L. Port*[1], J. R. Center[2], K. Henderson*[3], R. Cumming*[4], J. A. Eisman[2]. [1]Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, NSW 2010, Australia, [2]Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia, [3]Curtin University of Technology, Perth, Australia, [4]University of Sydney, Sydney, Australia.

As prior fracture is consistently associated with increased risk of subsequent fracture, subjects with a history of prior fracture represent a high risk group which could be targeted for intervention to reduce future fracture rates. This study aimed to investigate the relationship between hip fractures and treatment patterns following prior osteoporotic fracture. All patients admitted with hip fracture over a twelve month period to two teaching hospitals of the University of NSW, Sydney, Australia, were identified retrospectively from medical records. 380 hip fracture admissions were identified, with 35 exclusions not considered to be osteoporotic fractures or visiting from overseas at the time of fracture. Frequency of prior fractures and treatment status were recorded. Forty four per cent of the 249 women and 31% of the 96 men reported a prior fracture. These were prior hip fractures in 17% of the women and in 7% of the men. Among subjects with prior fractures, 18% of women and 7% of men were on any antiresorptive therapy (HRT, calcitriol or bisphosphonates). Even among those with a prior hip fracture, only 23% of women and none of the men were taking antiresorptive therapy. Calcium supplements were used in 12% of women and none of the men. In this study a high proportion of individuals suffering hip fractures had had prior "signal" fractures yet the majority of these were not receiving any therapy known to reduce the risk of further fractures. Even allowing for the approximate halving of fracture risk with potent antiresorptive therapy, these data indicate that the majority of high risk subjects with fractures do not receive therapy shown to reduce the risk of further fractures, including hip fractures.

SU298

Investigation of Prognostic Factors Relating 1-year Death and Lower Functional Status after Hip Fracture in Japanese Elderly Patients. H. Ishibashi*[1], S. Yamamoto*[1], H. Kawaguchi*[2], H. Fujita*[1], T. Suzuki*[3]. [1]Orthopedic Surgery, Tokyo Metropolitan Geriatric Medical Center, Tokyo, Japan, [2]University of Tokyo School of Medicine, Tokyo, Japan, [3]Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan.

[OBJECTIVE] Hip fracture has been reported to affect both a survival rate and functional status of the elderly patients. Although the treatment method of hip fracture is clinically established, the vital and functional prognosis of the fracture seems to remain unsatisfactory. To improve the prognosis, it is necessary to know what factors would influence it. The objective of this study is to investigate factors relating a 1-year death and lower functional status of elderly patients after hip fracture. [METHODS] The cases for this study were 370 patients (85.3 years old in average) who suffered hip fractures between January 1, 1999 and May 31, 2001. After investigating their vital status, we sent questionnaires in October 2001 to the survivors asking his/her functional status like BADL, IADL and mobility. Also, we gathered the perioperative information like age, gender, type of fracture, mental state, mobility before fracture, comorbidity, waiting period, operation time, volume of hemorrhage. We examined the statistical relationships of the results of the questionnaire and the patientsÅf background. [RESULTS] The ascertained numbers of survivors and deaths were 186 and 64, respectively. To calculate and analyze 1-year death, we extracted patients treated before October 31, 2000. Among them, 166 survivors and 33 deaths within 1 year after treatment were identified. Factors statistically relating 1-year death were male patients, higher age, trochanteric fracture, dementia, lower mobility before fracture, more comorbidity, heart disease and chronic lung disease. The lower functional status of the survivors was statistically correlated by such factors as higher age, dementia and lower mobility before fracture. [DISCUSSION] We should consider how to change the prognosis of this fracture for the better, as well as how to prevent and treat it. In this point, mobility is a good target, because it is one of the factors affecting both 1-year death and functional status and because it could be improved, for example, by the adequate acute-phase and long-term rehabilitation. [CONCLUSION] Investigation of patients after hip fracture revealed the factors relating to 1-year death after fracture and those relating to the lower functional status of the survivors.

SU299

Quality of Life in Postmenopausal Women with a History of Fracture of the Rib, Spine, Wrist, or Hip: Evidence from NORA. L. E. Wehren[1], E. Barrett-Connor[2], E. Barrett-Connor[3]. [1]University of Maryland, Baltimore, MD, USA, [2]University of California, San Diego, La Jolla, CA, USA, [3]University of California San Diego, La Jolla, CA, USA.

The disease burden of osteoporosis includes cost, mortality, and morbidity (functional limitation, loss of independence, pain, and impaired quality of life). Study of health-related quality of life (HRQoL) after fracture has focused on acute after-effects, or on the chronic effect of multiple vertebral fractures. Using data from the National Osteoporosis Risk Assessment (NORA), we examine whether women who report a history of fracture after age 45 of the rib, spine, wrist, or hip have impaired HRQoL as compared to women without this history, and whether deficits are fracture site-specific. HRQoL was measured at baseline using the Short Form-12 (SF-12) Health Survey in a randomly chosen subset of the NORA cohort. Using standard, validated scoring algorithms mean scores for physical (PCS) and mental (MCS) domains were calculated and compared between fractured and non-fractured groups. Linear regression was used to adjust for confounding effects of age. Of 87,060 participants with complete information, 9354 reported a history of fracture. Regardless of the site of the prior fracture, physical HRQoL was negatively affected in women with fracture history, and mental HRQoL was affected in women with a history of fracture of the spine or rib. After adjustment for age, fracture history is associated with lower mean scores in both domains. Prior fracture is associated with lower scores in both physical and mental domains of HRQoL, with greater effects seen in physical functioning. Spine and hip fracture produce the largest decrements. Estimates of the disease burden of osteoporosis may need to account for long-term effects of fracture. In addition, negative effects on HRQoL may directly or indirectly influence risk of future fracture.

Site of Prior Fracture	Physical Composite Score	Mental Composite Score
Spine (n = 970)	-6.85 (0.37)	-1.72 (0.31)
Wrist (n = 5229)	-0.66 (0.16)	-0.52 (0.14)
Rib (n = 3217)	-3.60 (0.20)	-1.68 (0.17)
Hip (n = 1135)	-5.34 (0.34)	-1.29 (0.28)
Any (n = 9354)	-2.43 (0.13)	-1.01 (0.10)

Older Men and Women with Kyphotic Posture are at Increased Risk for Mortality: The Rancho Bernardo Study. D. M. Kado[1], M. Huang*[1], E. Barrett-Connor*[2], G. A. Greendale*[1]. [1]Medicine, University of California, Los Angeles, CA, USA, [2]Medicine, University of California, San Diego, CA, USA.

Kyphotic posture is often assumed to be a consequence of vertebral fractures, although several studies report that only about ½ of those with the most severe kyphosis have evidence of spinal osteoporosis. Although vertebral fractures are associated with mortality, the association between kyphotic posture and all-cause mortality is unknown. To test whether older persons with kyphotic posture are at increased risk of subsequent death, we prospectively followed 1173 men and women, aged 50-98 (mean age 73.1 years) enrolled in the Rancho Bernardo Study. At the 1988-1992 clinic visit, kyphotic posture was measured with participants lying recumbent, as the distance from the occiput-to-table (units = 1.7 cm blocks, placed under participant's heads). Mortality was confirmed by review of death certificates after an average follow-up 4.2 years. Kyphotic posture, defined as ≥2 blocks, was present in 21.5% of the population. Cox proportional hazards models were used to assess the association between kyphotic posture and all-cause mortality. In age-adjusted models, persons requiring ≥2 blocks had a 1.75-fold increased risk of mortality compared with those requiring 1 or no blocks (95% C.I. = 1.32 - 2.31, $p < .0001$). After adjusting for potential confounders including age, sex, education, body mass index, spine bone density, clinical vertebral fracture, exercise, smoking, and alcohol use, persons with ≥2 blocks had a 1.49-fold increased risk of mortality (95% C.I. = 1.12 - 2.00, $p = .007$). We conclude that older persons with kyphotic posture have an increased risk of mortality that is independent of age, spine bone density, lifestyle factors, and clinical vertebral fracture. Our data suggest that kyphotic posture may be a clinical indicator of poor health outcomes.

Osteoporosis Coverage in Selected Women's Magazines and Newspapers, 1998-2001. L. S. Wallace[1], J. E. Ballard[2]. [1]Family Medicine, University of Tennessee Graduate School of Medicine, Knoxville, TN, USA, [2]Health and Kinesiology, University of Texas at Tyler, Tyler, TX, USA.

Mass media is an influential source of medical information and can shape health beliefs and prompt individual decision-making. The purpose of this review was to evaluate the accountability of osteoporosis information available in selected mass-circulating women's magazines (n=8) and a sample of newspapers (n=2) from 1998 through 2001. Osteoporosis articles (n=132) were assessed for sources of information used, incidence/prevalence statistics, risk factors and prevention measures. Expert sources were highlighted in the majority of articles (magazines: n=49, 84.5%; newspapers: n=59, 79.9%), while incidence/prevalence statistics were described in less than half of the articles (magazines: n=16, 27.6%; newspapers: n=32, 43.2%). Risk factors were discussed in 21 (36.2%) magazine and 33 (44.6%) newspaper articles, however much of the information presented was ambiguous and incomplete. Family history of osteoporosis, thin and/or small body frame, use of certain medications (e.g., corticosteroids, anti-convulsants), and Caucasian/Asian race were the most frequently cited non-modifiable risk factors. The most commonly discussed modifiable risk factors included: low dietary calcium consumption, sedentary lifestyle, cigarette smoking, and excessive alcohol consumption. Prevention measures were discussed in 54 (93.1%) magazine and 51 (68.9%) newspaper articles. Regular physical activity and adequate calcium intake were the most commonly discussed primary prevention measures. Of the secondary prevention measures cited, hormone replacement therapy and DEXA screening were the most common. Alendronate (Fosamax) and Raloxifene (Evista) were the most frequently mentioned tertiary measures. It appears that the reporting of osteoporosis in women's magazines and newspapers is not entirely balanced; thus, future coverage should provide greater detail when reporting risks and preventive measures.

SU302

Osteoporosis in Women with Anorexia Nervosa: Is there any Difference in Chinese Patients? S. Y. S. Wong*[1], S. Au*[1], L. Lee*[1], S. Lee*[2], E. M. C. Lau*[1]. [1]Jockey Club Centre for Osteoporosis Care and Control, Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China, [2]Department of Psychiatry, Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China.

Previous studies in Caucasians suggested that osteoporosis were frequent in women with anorexia nervosa (AN). To determine whether bone mass is reduced in Chinese patients with AN and to study the risk factors for low bone mass in AN patients, a case-control study was conducted. Bone mineral density (BMD) of the lumbar spine and the hip were measured by dual energy x-ray absorptiometry in 48 patients with AN. Z-scores were calculated by comparison with normative data obtained in the same population. For BMD of the spine, 55.1% had z-score higher than -1, thirty percent of patients had z-score between -1 and -2.49, and 14.3% of patients had z-score less than -2.5. For BMD at total hip, 53.1% of patients had z-score higher than -1, forty percent had z-score between -1 and -2.49 and 6.1% had z-score less than -2.5. In addition, 40.8% of patients had z-score between -1 and -2.49 and 14.3% had BMD z-score lower than -2.5 at either the spine or hip. Current body mass index (BMI) was the only factor found to be significantly associated with BMD at the hip and spine (<0.05) in AN patients. The following risk factors were not found to be significantly associated: duration of AN, lowest BMI, average calcium intake per day and average physical activity per week (p>0.05). It is concluded that Chinese patients with AN are at risk of low BMD. Body mass index was a significant predictor of reduced BMD in Chinese patients with AN.

SU303

Seasonal Variation in Bone Mass in Postmenopausal Women. K. Åkesson[1], P. Gerdhem*[1], H. Mallmin*[2], K. J. Obrant[1]. [1]Malmö University Hospital, Orthopedics, Malmö, Sweden, [2]Uppsala University Hospital, Orthopedics, Uppsala, Sweden.

There may be a seasonal variation in bone metabolism as judged from biochemical markers. Whether such a variation also has an impact on bone mass in postmenopausal and elderly women has yet to be resolved. We investigated seasonal variation in bone mass by cross-sectional designs in three large cohorts of women (n=3742) from two geographical regions in Sweden. One cohort was strictly population based (all 75 years old, n=1044) and two cohorts were patient based (age >54, mean age 67, n=1293 and mean age 69, n=1405). Each woman was assessed once and inclusion for the population-based sample was continuous throughout almost all days of the year, during three consecutive years. Bone mineral density (BMD) of the total body, hip (neck, ward, trochanter) and lumbar spine was determined by means of DEXA. For all three cohorts the BMD was similar in those assessed throughout the summer half year (April-September) compared to those assessed thoughout the winter half year (October-March). This absence of summer/winter difference was evident for all skeletal regions and remained after controlling for small differences in age and weight. On the other hand, when women who had been assessed during spring (January-June) were compared with women assessed during autumn (July-December) we found the BMD to be up to 5% higher during the spring in all skeletal regions in the population-based sample and 4% higher at the wards triangle and the trochanter in one of the patient-based samples but not in the other. After correcting for small differences in age and weight, women who had been assessed throughout the spring still had higher BMD compared with women assessed during autumn at the hip (neck, ward and trochanter) in the population-based sample and at the trochanter in one of the two patient-based samples. If the finding of a spring/autumn difference is true, a hypothetical explanation could be that an increased bone turnover including an initial high osteoclastic activity throughout autumn was triggered off by high vitamin-D levels in summer. In conclusion we firmly believe that we can state that there is no summer/winter variation in bone mass in postmenopausal women. On the other hand, and although our data are not conclusive, we found indications that BMD may be a few percent higher during the spring half year compared to the autumn half.

Can the SCORE^{tm} Algorithm Reduce the Need for Bone Densitometry? Results from the Danish Osteoporosis Prevention Study. N. Nissen*[1], P. Vestergaard[2], C. L. Tofteng*[3], O. Bärenholdt*[4], O. H. Sørensen[3], S. P. Nielsen[4], L. Mosekilde[2], B. Abrahamsen[1]. [1]Dept of Endocrinology M, Odense University Hospital, Odense, Denmark, [2]Dept of Endocrinology C, Aarhus University Hospital, Aarhus, Denmark, [3]Osteoporosis Research Clinic, Hvidovre, Denmark, [4]Dept of Clinical Physiology, Hilleroed, Denmark.

BMD can be measured quickly and safely, but identifying the appropriate subset of postmenopausal women for densitometry is notoriously difficult as most algorithms predict less than 20% of BMD. Recently, Lydick (Am J Man Care 1998; 4:37) proposed an algorithm (SCORE^{tm}) with high sensitivity and specificity for identifying women with low BMD. The purpose of the present study was to evaluate the performance of this algorithm as a prescreening tool in healthy Danish women with recent menopause. The study population consisted of 2016 healthy women, mean age 50.6 y (SD 2.8), recruited between 3 months and 2y after their last menstrual period. BMD at the spine, hip, forearm and whole body was measured using cross-calibrated Hologic QDR-1000 and -2000 densitometers. BMD was followed longitudinally for 5y. The population had a prevalence of osteopenia/osteoporosis of 34%/4.2% at the spine and 31%/1.3% at the total hip site. The data for SCORE calculation (*race, age, weight, estrogen use, fracture- and rheumatoid arthritis history*) was systematically recorded at the inclusion interview and subsequently retrieved from the study database. The cut-off for the algorithm was set at 6+ pts in accordance with the findings by Lydick et al. Diagnostic performance was as follows:

	Osteopenia(spine)	Osteopenia(hip)	Osteoporosis(spine)	Osteoporosis(hip)
Sens/Spec	66% / 57%	69% / 57%	80% / 50%	80% / 49%
PPV/NPV	44% / 76%	42% / 81%	7% / 98%	2% / 99%

Identifying participants with low BMD (T<-1) or osteoporosis (T<-2½). PPV positive predictive value, NPV negative predictive value).

The algorithm predicted 10% of the variation in BMD by linear regression analysis (p<0.001). 49% of the study population would not be referred to bone densitometry based on the SCORE result. Of these, 24% had spinal osteopenia. In a longitudinal assessment, 5.5% of those with SCORE <6 developed osteoporosis at the spine after 5y compared with 18.6% of those with SCORE 6+ (χ^2 p<0.001). In conclusion, the SCORE algorithm can predict part of the variation in BMD and development of osteoporosis. The algorithm might be useful for selecting patients for clinical trials but the discriminatory performance is too low to rule out osteopenia with confidence in clinical practice.

The Quality of the Most Recently Formed Osteoid is Altered in both High and Low Turnover Osteoporosis: Implications for Fracture Risk. A. L. Boskey[1], S. B. Doty*[1], E. DiCarlo[2], J. M. Lane[3], J. M. Lane[3], E. P. Paschalis[1]. [1]Research Division, Hospital for Special Surgery, New York, NY, USA, [2]Pathology, Hospital for Special Surgery, New York, NY, USA, [3]Orthopaedics, Hospital for Special Surgery, New York, NY, USA.

In the clinical setting bone mineral density (BMD), has been used as a predictor of fracture risk. But BMD is now recognized as not being the sole predictor of risk. Other factors including the structure and composition of the underlying matrix (mainly collagen) and mineral also contribute. To assess the distribution of collagen cross-links in trabecular bone at ~7um spatial resolution, Fourier transform infrared imaging was used, and the ratio of non-reducible (pyridinoline, (pyr)) and reducible (dehydro-dihydroxy-lysinonorleucine (deH-DHLNL)) cross-links in the collagen of not-previously demineralized stained thin sections of bone from human iliac crest biopsies that showed histomorphometric features of normal bone, low-turnover osteoporosis, and high-turnover osteoporosis (N = 9 per group; age range = 50-75 years old). Measurements were taken at various depths in the bone relative to formative or resorptive surfaces. Distinctive, but complex differences were found in the collagen cross-link ratios at the different depths in the different conditions with osteoporotic bone invariably exhibiting a statistically significant (p<0.01) higher pyr / deH-DHLNL ratio when compared to normals at anatomically equivalent microscopic loci. For example, the ratio 14um from the forming surface was 5.0+/- 0.5 in low turnover osteoporosis, 2.9+/- 0.6 in high turnover osteoporosis, and 0.89+/- 0.34 in controls. Thus even the most recently formed osteoporotic matrix is of different "quality" than normal. At 14um from the resorptive surface the high and low turnover values were similar to each other, but significantly different from controls. The ratio was 10+/- 0.5 in low turnover osteoporosis, 10.1+/- 0.6 in high turnover, and 4.2+/- 0.3 in controls. Because bone mechanical properties are determined in part by the collagen cross-link distribution, this study suggests the importance of such properties towards fracture risk.

SU306

The Role of Standardized Medical History Forms and Set Laboratory Panels in the Routine Diagnosis of Osteoporosis. A. Knauerhase*[1], D. Eska*[2], C. Zingler*[2], G. Tolkemitt*[3], R. Hampel*[2]. [1]Department of Internal Medicine, University of Rostock, Rostock, Germany, [2]University of Rostock, Rostock, Germany, [3]Radiological outpatient´s department, Rostock, Germany.

Is it possible to accurately predict osteoporosis by making use of a correlation between the results of bone density tests and the data collected on standardized medical history forms and/or the values measured in a set laboratory panel? The osteoporosis out-patient clinic at the University of Rostock analyzed the following parameters from 81 women and 59 men (avg. age 58.8, avg. BMI 25.1): height and height loss, weight, degree of pain and localization, previous or existing medical conditions, history of fractures in patient or patient´s mother, gynecological history, dietary factors, physical activity, intoxicants and medications. The laboratory values included serum and urine calcium, bone-specific alkaline phosphatase or osteocalcin, 25-OH Vitamin D, parathyroid hormone, creatinine, phosphate as well as AST and ALT. The bone density of each patient (lumbar spine) was measured with DXA (Hologic QDR 1000) or QCT. The statistical analysis was carried out using SPSS for Windows. For the group as a whole, the average T-score was -3,04 SD and the average bone density was 71,2 mg/cm3. Body weight showed a weak positive correlation with the T-score (r=0,2, p<0,05), whereas age correlated strongly negative to the QCT-value (r=-0,55, p<0,01). Patients without height loss had significantly higher T-scores than those with height loss (T-score -2,8 SD versus -3,2 SD, p=0,017). Patients with pain localized "everywhere" tended to have the lowest T-scores (-3,6 SD). Patients who had "no pain" had average T-scores of -3,1 SD, whereas Patients with "severe pain" had the lowest average T-scores (-4,4 SD). When considering fracture location, patients with either humerus or femur fractures showed the lowest bone densities (T-score -3,3 SD or 52,7 mg/cm3). Moderate alcohol consumption (up to 2 alcoholic drinks per day) tended to correlate to higher bone density when compared to absolute alcohol abstinence or alcohol abuse. Nonsmokers tended to have higher bone densities than smokers. Patients with higher milk consumption (>1l per day) tended to have higher bone densities (T-score -2,6 SD) than drinking no milk (T-score -3,1 SD). The rest of the parameters showed no correlation to bone density. Likewise, it was not possible to drawn a correlation between laboratory values and the results of the bone density test. Certain information concerning anthropometrical features or medical history can be of limited use in diagnosing osteoporosis, but laboratory panels contribute little.

SU307

Risk Stratification Among Caucasian Women with T-score Between -2.5 and -1.0: Results from the National Osteoporosis Risk Assessment. P. D. Miller[1], S. Barlas*[2], S. K. Brenneman*[2], T. A. Abbott[2], Y. Chen*[2], E. Barrett-Connor[3], E. S. Siris[4]. [1]Colorado Center for Bone Research, Lakewood, CO, USA, [2]Merck & Co., Inc., West Point, PA, USA, [3]University of California, San Diego, CA, USA, [4]Columbia University, New York, NY, USA.

Treatment intervention to reduce fractures has largely focused on women whose BMD T-score fall below -2.5. As a consequence, little management guidance is available to the clinician for women with BMD scores in the range -2.5 to -1.0, who are still at increased risk for fracture. Among Caucasian women in the NORA population (n=149,524), 38% (57,421) had baseline T-scores in the range -2.5 to -1.0 and accounted for 50% of the osteoporotic fractures reported during the first year of follow-up. The purpose of this study was to develop a classification algorithm that can be easily used to identify women with T-scores higher than -2.5 who are at the highest risk of fracture within 12 months of BMD testing. We used CART 4.0 (Breiman et al.) to build the optimum tree, taking into account the low incidence of fracture and unequal cost of misclassification (i.e. the cost of misclassification as low risk was set at greater than that for misclassification as high risk). Thirty-two risk factors identified in the literature and available in the NORA database were used to build the tree. The cross-validated optimum tree identified four risk factors including (in order of strength of association with fracture) prior fracture, T-score ≤ -1.8, self-rated health status (one question), and mobility. The algorithm is shown below after accounting for prior fracture, which demonstrated the highest risk for fracture.

High Risk definition for women with T-score -2.5 to -1.0 without prior fracture

If T-score £ -1.8; OR

If T-score > -1.8 AND health status is fair/poor; OR

If T-score > -1.8 AND health status is good/excellent AND mobility is poor.

The algorithm correctly identified most of the women with fractures in the "validation" sample at 82% sensitivity. 55% of the women with T-score > -2.5 were identified as high risk with an overall one-year risk for fracture of 2.4% (range 1.9 - 4.1). Women with prior fracture (first level of the algorithm) had a similar risk of fracture as those with T-score below -2.5 (4.1% and 4.3%, respectively). Women identified at higher risk were over 2 times more likely to have a fracture within one year than women not identified as high risk by the algorithm. A simple easy-to-use algorithm can improve identification of women with T-scores between -2.5 and -1.0 who are at least 2 times greater risk for fracture, and who may also have a risk similar to that of women with T-scores <-2.5.

The National Osteoporosis Foundation (NOF) Guidelines with Peripheral BMD Predict Fractures in Postmenopausal Women Across Ethnic Groups. E. Barrett-Connor[1], S. K. Brenneman[2], Y. Chen*[2], P. D. Miller[3], E. S. Siris[4]. [1]University of California, San Diego, CA, USA, [2]Merck & Co., Inc., West Point, PA, USA, [3]Colorado Center for Bone Research, Lakewood, CO, USA, [4]Columbia University, New York, NY, USA.

National Osteoporosis Foundation (NOF) recommends osteoporosis treatment in women who have T-score < -2.0 or < -1.5 with ≥ 1 risk factor for osteoporotic fracture. We examined the ability of peripheral BMD and four key NOF risk factors (prior fracture, weight < 127 pounds, family history of fracture, and smoking) to predict fracture risk in 5 ethnic groups, African-American, Caucasian, Hispanics, Asian, and Native American, using data from the National Osteoporosis Risk Assessment (NORA). Each participant had BMD measured at baseline at one peripheral site: heel (SXA or US), forearm (pDEXA), and finger (AccuDEXA). Fractures occurring in the subsequent year were identified by self-report. 163,979 women who had baseline BMD data and responded to the follow-up survey reported 2440 osteoporosis-related fractures (hip, rib, wrist/forearm and spine). Fracture rate per 1000 person years and relative risk for fracture by ethnic groups are shown below.

	African American	Caucasian	Hispanic	Asian	Native American
Total N	5841	146486	4411	1256	1281
Mean age (S.D.)	63.5 (8.9)	64.1 (9.0)	64.2 (9.1)	62.6 (8.7)	67.8 (9.5)
% Meeting NOF guidelines	11.7 %	22.6 %	26.8 %	32.8 %	31.1 %
Fx Rate: NOF (95% CI)	12.5 (5.2,19.9)	24.7 (23.2,26.2)	24.8 (17.0,32.5)	8.7 (1.1,16.2)	23.5 (10.4,36.6)
Fx Rate: Non-NOF (95% CI)	5.6 (3.8, 7.5)	8.8 (8.4, 9.3)	9.1 (6.3, 11.9)	3.5 (.07, 6.9)	9.7 (4.0, 15.5)
Relative Risk * (95% CI)	2.22 (1.1, 4.4)	2.79 (2.6, 3.0)	2.69 (1.7, 4.2)	2.33 (0.6, 8.7)	2.39 (1.1, 5.4)

* Based on Cox proportional hazards model adjusted for age

We conclude that low peripheral BMD and one or more of these NOF risk factors are effective in identifying women at increased risk for fracture in all ethnic groups.

Disclosures: ***E. Barrett-Connor****, Merck & Co., Inc. 2, 5.*

The Influence of Vitamin D Status on Bone and Muscle: The Inchianti Study. D. Maggio*[1], A. Cherubini*[1], R. Giorgino[2], F. Lauretani*[3], C. R. Russo*[3], U. Senin*[1], L. Ferrucci*[3]. [1]Geriatrics, University of Perugia, Perugia, Italy, [2]Procter&Gamble Health care, Rome, Italy, [3]Clinical Epidemiology, INRCA, Firenze, Italy.

The InCHIANTI study is a large population-based study performed in two Italian towns, located in the Chianti area near the city of Florence (Greve in Chianti and Bagno a Ripoli). The study population consisted of a random sample of the population aged of 65+ and a smaller sample of subjects who were randomly selected in each decade between 24 and 64 years. Aim of the study is to evaluate the relationship of vitamin D status with both bone density and muscle area at lower leg level. Peripheral Quantitative Computed Tomography at the right lower leg level was performed in each subject by a Stratec XCT 2000 device. The method allows the measurement of whole, trabecular, and cortical volumetric bone density (mg/cm^3) as well as muscle area (mm^2). 25 (OH)D was measured by RIA method with double antibody and serum intact 1-84 PTH was measured by IRMA method. Subjects aged 50+ were selected for this analysis. Data are available in 488 men and 627 women. The natural logarithm of vitamin D was used because the raw data were not normally distributed. 25 (OH)D levels were significantly associated with cortical bone volumetric density in females independent of age and body mass index (BMI) (β=14.1, SE 5.12; p<0.01) but not in men. 25 (OH)D levels were not associated either with cortical bone area or with trabecular bone volumetric density in either sex. Muscle area was associated with 25 (OH)D levels independent of age and BMI in both sexes (β=181.6, SE=82.2; p<0.05 in men; β=149.3, SE=61.4; p<0.02 in women). This study shows a positive association of vitamin D status with cortical bone density in women and with muscle area in both sexes.

SU310

Vitamin D Status in Old and Very Old Subjects: The Results of the Large Population-Based Italian Inchianti Study. A. Cherubini*[1], D. Maggio*[1], R. Giorgino[2], S. Bandinelli*[3], B. Bartali*[3], U. Senin*[1], L. Ferrucci*[3]. [1]Geriatrics, University of Perugia, Perugia, Italy, [2]Procter & Gamble Health care, Rome, Italy, [3]Clinical Epidemiology, INRCA, Firenze, Italy.

InCHIANTI is a study of the factors contributing to the decline of mobility in late life, which is performed in two Italian towns, located in the Chianti area near the city of Florence (Greve in Chianti and Bagno a Ripoli). The study population consisted of a random sample of the population aged of 65+ and a smaller sample of subjects who were randomly selected in each decade between 24 and 64 years. Each subject underwent a thorough clinical evaluation, a detailed interview (including a validated food frequency questionnaire), and a fasting blood drawing. This research is aimed at evaluating 25(OH)D and PTH levels in the InCHIANTI population. Serum 25 (OH)D was measured by RIA method with double antibody and serum intact 1-84 PTH was measured by IRMA method. Data are available in 564 men and 687 women. The following table shows mean ±SD levels of 25(OH)D and PTH by gender and age group.

	Males (n=564)			Females (n=687)		
Age (years)	N	25(OH)D [nmol/l]	PTH [pg/ml]	N	25(OH)D [nmol/l]	PTH [pg/ml]
<65	128	64.6±35.0	19.9±8.1	141	63.3±34.3	18.5±7.9
65-74	259	64.1±34.9	23.5±25.8	284	49.9±34.6	24.6±12.3
75-84	131	52.3±35.0	27.1±20.4	176	37.5±34.3	27.4±12.7
85+	46	35.7±22.6	35.6±28.3	86	31.8±31.8	38.1±30.3

In subjects aged 65+ years, 25(OH)D levels were negatively associated with age in both sexes (r=-0.32, p<0.0001 in males and r=-0.33, p<0.001 in females), while PTH levels were positively associated with age in both sexes (r=0.23, p<0.0001 in males and r=0.25, p<0.001 in females). The pattern of age related 25(OH)D decline was different between the 2 sex groups. 25(OH)D levels decrease was earlier in women, while the age-related decline of 25(OH) was more evident in the oldest age group in men. Moreover, 25(OH)D levels were significantly associated with Vitamin D dietary intake in women (r=0.09, p<0.05) but not in men (r=0.06, p=NS). In this population-based prospective study including a large sample of old and very old males and females, the analysis of baseline data reveals a sex-dependent pattern of age-related 25(OH)D decline. This suggests that different factors might influence vitamin D status in the two sexes.

SU311

A Longitudinal Study of Low Back Pain and Changes of Spinal Bone Mineral Density in Chinese Perimenopausal Women. S. C. Ho[1], S. Chan*[2], V. Yip*[3], A. Sham*[4], J. Woo*[5]. [1]Department of Community & Family Medicine, The Chinese University of Hong Kong, New Territories, Hong Kong Special Administrative Region of China, [2]CUHK, HK, Hong Kong Special Administrative Region of China, [3]The Polytechnic University, HK, Hong Kong Special Administrative Region of China, [4]Community & Family Medicine, CUHK, HK, Hong Kong Special Administrative Region of China, [5]Medicine & Therapeutics, CUHK, HK, Hong Kong Special Administrative Region of China.

We aim to present data on the association between the report of low back pain and changes of spinal bone mineral density (SBMD) in women undergoing menopausal transition. 438 Chinese women aged between 44 and 55y were recruited through random telephone digit dialing and from the University Family Medicne Clinic. Women on hormone replacement therapy or oophorectomy /hysterectomy were excluded. Women with scoliosis, prolapsed intravertebral disc, spine deformities, ankylosing spondylitis, or leg discrepancy were also excluded. A trained interviewer conducted structured face-to-face interviews. The data included the occurrence of LBP; socio-demographic, menopausal status and lifestyle variables. Women were classifed as pre-, or peri- or postmenopausal according to the WHO definitions of menopausal status. LBP was identified among women who experienced pain for more than one day during the past 12 months, in an area between the lower costal margins and the gluteal folds, with or without radiation into the leg, to below the knee. LBP caused by previous back surgery, cancer, vascular diseases or menstruation alone were excluded. We obtained BMD measurements at baseline, at 9 months (T1) and at 24 months (T2) with the use of dual energy x-ray densitometre (Hologic 4500A). The outcome variable was the percentage change of SBMD over the followup time. Women classified as perimenopausal at baseline or followup, or with a change of menopausal status during followup were categorized as going through menopausal transition. Among the 83 women going through menopausal transition from baseline to T1, and among the 104 women from baseline to T2, 32.5% and 40% respectively complained of LBP at baseline. The mean percentage changes of spinal BMD at T1 were 3.15 % (s.d. = 2.0), and 2.14 % (s.d. =3.12) among women with and without complaints of LBP. The mean spinal BMD changes at T2 were 6.27 % (s.d. = 3.42) and 5.67 % (s.d. = 4.33) respectively. The differences between the mean BMD changes at T1 reached statistical significance after adjustment for body fat. LBP may be a useful predictor of acute spinal bone loss in women going through menopausal transition. The relationship would warrant further investigation.

SU312

The Effect of Tobacco Smoking on Forearm Bone Density in Men and Women - the Nord-Trøndelag Health Study (HUNT), Norway. S. Forsmo[1], A. Langhammer*[1], L. Forsén*[2], B. Schei*[1]. [1]Dept. of Community Medicine and General Practice, Norwegian University of Science and Technology, Trondheim, Norway, [2]National Institute of Public Health, Oslo, Norway.

Smoking is known to be a risk factor of low bone mineral density and fractures. The fracture incidence in Norway is one of the highest in the world. About 30% of the adult population are current smokers. The purpose of this study was to analyse the association between tobacco smoking and forearm bone mineral density (BMD). In 1995-97 all inhabitants aged >19 years were invited to the HUNT study. The participants answered comprehensive questionnaires on demographics, life style, risk factors, symptoms and diseases. Among 92.000 invited subjects a 5 % sample was randomly selected for bone mineral density (BMD) measurement of the non-dominant forearm single X-ray absorptiometry (Osteometer DTX100). From the point of 8 mm distance between radius and ulna, the area 24 mm in proximal direction was identified as the distal area, whilst the area in distal direction to the endplate of radius was identified as the ultradistal site. The non-dominant arm was measured, provided no previous fracture in distal radius. Totally 71 % of the invited participated at the screening, but about 60% of the random sample participated in this substudy, A total of 2779 (1505 women and 1274 men) were eligible for analysis. Mean age for men and women, respectively, was 50.5 and 49.9 years (range 20-97). In men, 29.5% and 32.0% reported present or prior smoking, respectively. In women, 30.6% reported present and 20.3% prior smoking. The percentage of never smokers was highest in men 60 years of age. No difference in mean BMD between present, prior and never smokers was found neither in men nor women < 50 years of age. After the age of 50, BMD decrease was more accentuated in smokers. In bivariate linear regression, a strong statistically significant negative association between packyears of smoking and BMD was found in males (R2=4.0), but not in females. Adjusting for age and body weight, a statistically significant negative association was also found in women at both sites. In male smokers, 50 years or older, weight adjusted odds ratio of being in the lowest age specific BMD tertile, compared to never smokers, was 2.2 (95% CI: 1.4 - 3.5) at distal and 2.6 (95% CI: 1.5 - 3.8) at ultradistal radius. Corresponding OR in female smokers were 1.8 (95% CI: 1.2 - 2.7) and 1.5 (95% CI: 1.0 - 2.3). Adjusting for estrogen therapy and age at menopause did not change the outcome. This study shows that the effect of smoking on the skeleton in both men and women is found after the age of 50 and that the effect is possibly stronger in males.

SU313

Bone Mineral Density and Markers of Bone Remodeling in HIV Infected Patients According to the Treatment. C. Amiel*[1], A. Ostertag*[2], L. Slama*[1], C. Baudoin*[2], T. Nguyen*[1], E. Lajeunie*[3], W. Rozenbaum*[1], M. C. de Vernejoul[2]. [1]Service des Maladies Infectieuses et Tropicales, Hopital Tenon, Paris, France, [2]Hopital Lariboisiere, INSERM U349 et Service de Rhumatologie, Paris, France, [3]Laboratoire de Biologie Endocrinienne, Hopital Lariboisiere, Paris, France.

Osteoporosis has been reported in HIV-infected patients and has been suggested to be related to protease inhibitors treatments (PI). In order to assess this risk, and to investigate its putative link with treatments, we compared the bone density of HIV-infected men (HIV^+), who were treated either with PI(PI^+ n = 49) or without PI (PI^- n=51) or untreated (UT n=48). We included 81 males controls, HIV negative (HIV^-), recruited among hospital employees matched for age with the HIV^+ group (mean ± SD :40 ± 8 years). Bone mineral density adjusted on age (Z-score), was measured by DPX at the lumbar spine (LS) or the femoral neck (FN) using Lunar densitometer. Z-score was decreased in HIV^+ group, at the FN (HIV^+: -0.39± 1.05, HIV^-: 0.25± 0.87, p<0.001) and LS (HIV^+: -1.08± 1.21, HIV^-: -0.06± 1.26, p<0.001). Prevalence of osteoporosis at the LS was 11.5% among HIV^+ and 2.8% in HIV^- (p<0.01). Among HIV^+, the Z-score was not different according to duration of both the disease or the treatment but was correlated to BMI (r= 0.27 at LS and 0.35 at FN). The Z-score did not differ significantly between the treatment groups (at LS: UT: -0.82± 1.15, PI^-): -1.21± 1.41 PI^+: -1.21± 0.99, FN had similar result). UT patients had a lower duration of the disease (4.8± 5.0 years) than PI^+ and PI^-) (10.4± 4.5, p<0.01). BMI and viral load were identical among the 3 HIV^+ groups. After adjustment on age at HIV diagnosis, duration of the disease, BMI and BMI nadir, using multiple regression analysis, there was no significant difference between the 3 HIV^+ groups. Among PI^+ and PI^- groups, Z-score was not different according to the presence of lipodystrophy .
Markers of bone remodeling were measured in the 102 HIV^+ and 42 HIV^- subjects . HIV^+ patients had a decreased bone alkaline phosphatase (9+4 vs 12+4 ng/ml, p<0.01) and increased urinary crosslaps/Cr (3+2 vs 2+1, p<0.01) There was no important difference in the markers among the 3 HIV^+ groups and according to PI treatment. Cortisol was higher and leptin lower in HIV^+ compared to HIV^- subjects. In conclusion: There is a marked decrease in bone density in HIV infected patients that can lead to symptomatic osteoporosis. This osteoporosis is related to an imbalance with high bone resorption and decreased bone formation. Our transversal study does not show a deleterious role of the treatment but points to a decreased bone density before the start of treatment in HIV patients

SU314

Long-Term Effects of Serum Cholesterol over 34 Years on Bone Mineral Density (BMD) in Women and Men: The Framingham Osteoporosis Study. E. J. Samelson[1], L. A. Cupples*[2], M. T. Hannan[3], P. W. F. Wilson*[4], K. E. Broe*[1], Y. Q. Zhang*[4], D. Levy*[5], S. A. Williams*[6], V. Vaccarino*[7], D. P. Kiel[3]. [1]Hebrew Rehab Ctr, Boston, MA, USA, [2]BU Sch Pub Health, Boston, MA, USA, [3]Hebrew Rehab Ctr /Harv Med Sch, Boston, MA, USA, [4]BU Sch Med, Boston, MA, USA, [5]Framingham Study, Boston, MA, USA, [6]AstraZeneca, Wayne, PA, USA, [7]Emory Sch Med, Atlanta, GA, USA.

Low BMD is associated with increased risk of cardiovascular mortality and aortic calcification in postmenopausal women suggesting a possible role for cholesterol in the pathogenesis of both osteoporosis and atherosclerosis. No prospective studies have determined the effect of long-term cholesterol levels on BMD. The purpose of this study was to examine the relation between total serum cholesterol level (TCHOL), averaged over 34 years, and subsequent BMD in women and men in the Framingham Osteoporosis Study. Participants included 1162 cohort members (712 women, 450 men; mean age 76, range 67-98) who obtained hip (femoral neck), spine (L2-L4), and radial shaft BMD measurements using Lunar SP2 and DP3 in 1988-89. TCHOL and information on confounders were collected at study exams conducted every two years since cohort enrollment in 1948. For the present analyses, levels of TCHOL (mg/dL) were averaged over the 34 years of study follow-up prior to BMD measurement. Similar methods were used to obtain mean values of systolic blood pressure (SBP), smoking, alcohol, body mass index (BMI), and diabetes. In women, years of estrogen use were summed over the 34-year follow-up period. Women were also classified according to recent estrogen use (two years prior to BMD). Sex-specific linear regression modeled BMD as a function of TCHOL quartile, adjusted for age, BMI, smoking, alcohol, SBP, diabetes, and in women, duration and recency of estrogen use (Table). Women with higher TCHOL had lower femoral neck BMD than women in lower TCHOL quartiles; however, an inverse trend was not observed at other bone sites. Men with higher TCHOL had lower lumbar spine and radial shaft BMD than men in lower TCHOL quartiles, whereas no relation was observed between TCHOL and femoral neck BMD in men.

Adj. Mean BMD (g/cm^2) by TCHOL Quartile (Q1=Low, Q4=High)

	Q1	Q2	Q3	Q4	Trend, P	Q1	Q2	Q3	Q4	Trend, P
	Women					Men				
Femur	0.73	0.72	0.71	0.71	.07	0.87	0.86	0.90	0.86	.99
Spine	1.07	1.08	1.06	1.08	.96	1.37	1.33	1.35	1.30	.09
Radius	0.51	0.51	0.49	0.51	.61	0.73	0.72	0.72	0.70	.01

While there was some suggestion of an inverse association between TCHOL and BMD, the relation was not consistent for women and men or for all bone sites. In conclusion, cholesterol is not likely to be a significant contributor to the relation between BMD and coronary heart disease.

Relationship between Vitamin D, PTH and Bone Mineral Density in Postmenopausal Women. Preliminary Data. N. Malavolta[1], M. Frigato*[2], R. Mule'*[2], L. Pratelli*[3], S. Gnudi*[4]. [1]Dipartimento di Medicina Interna e dell'Invecchiamento, Azienda Ospedaliera di Bologna, Policlinico S.Orsola-Malpighi, Bologna, Italy, [2]Dipartimento di Medicina Interna e dell'Invecchiamento, Azienda Ospedaliera di Bologna Policlinico S.Orsola-Malpighi, Bologna, Italy, [3]Laboratorio di Patologia Clinica, Istituto Ortopedico Rizzoli, Bologna, Italy, [4]Medicina Interna, Istituto Ortopedico Rizzoli, Bologna, Italy.

To assess the relationship between vitamin D, bone mineral density (BMD) and parathiroid hormone in post-menopause, we studied 96 consecutive postmenopausal women (mean age 62.5±7.2) whose BMD (measured at spine and femoral neck), intact plasma parathiroid hormone (iPTH), serum 25-hydroxy-cholecalciferol (25HD) and serum 1,25 diydroxy-cholecalciferol (1,25DHD) were determined for clinical screening of osteoporosis. A clinical examination was carried out in all subjects to exclude patients with malignancy, long-term immobilization, major rheumatic diseases, chronic renal, hepatic or pulmonary diseases, Paget's disease of bone or long-term treatment with drugs known to affect bone (more than 6 months for estrogen, anabolic steroids, calcitonin or bisphosphonates, or more than 3 months for glucocorticoids or antiepileptic drugs). Mean values of examined parameters were 16.4±10.2 ng/ml for 25HD, 25.2 ± 8.0 pg/ml for 1,25DHD, 58.7±20.3 pg/ml for iPTH, 776.4±129.3 mg/cm² for spine BMD and 639.6±79.2 mg/cm² for femoral neck BMD. 25HD was found to correlate with age (R=0.30, p<0.004), iPTH (R=0.30, p<0.004) and spine BMD (R=0.31, p<0.002) but not with femoral neck BMD. 1,25DHD was not correlated with any of the considered parameters. iPTH was weakly correlated with age (R=0.20, p<0.050). Selecting a cut-off of 15 ng/ml of 25HD as indicative of vitamin insufficiency there was a lower spine BMD (p<0.017) and higher iPTH (p<0.035) in women having their 25(OH)D below the cut-off compared with those above it. There were not differences between groups about age, 1,25DHD and femoral neck BMD. Our data indicate that 25HD status is correlated with spine BMD and iPTH and should be enquired as risk factor for postmenopausal vertebral bone loss.

Recruitment of Middle-Aged Chinese-Canadian Immigrants for a Study of Bone Health. R. Chaudhry*[1], C. Chan*[1], N. Diaz-Granados*[1], K. Milstead*[1], D. Lui-Yee*[1], G. Chan*[2], A. Cheung[3]. [1]University Health Network, Toronto, ON, Canada, [2]Yee Hong Community Centre, Toronto, ON, Canada, [3]University Health Network & University of Toronto, Toronto, ON, Canada.

We have successfully recruited 976 Chinese-Canadian immigrants, men and women aged 45 and older, for a study of osteoporosis and osteoporotic fractures using convenience sampling methods. Participants were recruited through media announcements, health fairs, and community outreach through community centres, shopping centres, churches and libraries which predominantly serve the Chinese community in the Greater Toronto Area. In order to assess how representative our sample is of the general Chinese-Canadian population, we compared the characteristics of our cohort to that of the Chinese population in the 1998/99 National Population Health Survey (NPHS), a population-based Canadian survey, and the 1996 Census of Canada. The 1998/99 NPHS estimates that there are close to 300,000 men and women of Chinese ethnicity, aged 45 and older, living in Canada; this is similar to what is reported from the 1996 Census of Canada for visible minority Chinese in the same age group. Preliminary analyses were performed for the first 844 individuals recruited to our study (589 women and 255 men). The majority of participants recruited were from Hong Kong (73%) and China (16%), and the rest primarily from Taiwan and Vietnam. We compared our study population to only those individuals in the NPHS, age 45 or older, who responded that either their race or ethnicity was Chinese. The age distribution of women in our cohort is very similar to that of the NPHS (41% are aged 45-54, 24% are aged 55-64, and 35% are aged 65 and older). Males in study are, however, older (27% are aged 45-54, 24% are aged 55-64, and 49% are aged 65 and older). In terms of educational attainment, 43% of women and 60% of men in our study report some post-secondary education. This is a higher proportion than reported in the NPHS, 38% and 51% respectively. Seventy percent of women in our study are married, as compared to 63% in the NPHS, and 92% of men reported being married, as compared to 89% in the NPHS. The Chinese immigrant population recruited to our study through convenience sampling methods appear to be more highly educated than the general Chinese immigrant population in Canada. Women recruited to the study appear to be more representative of the Chinese immigrant population than the males recruited to our study. The NPHS captures data on health indicators, such as height, weight, self-reported health status, smoking, vision and hearing, as well as access to traditional and alternative preventive health care. Further analyses will be reported with respect to these characteristics.

SU317

Balance Characteristics Among Women with Osteoporosis. S. Jaglal[1], B. Maki*[2], G. Hawker[3]. [1]Rehabilitation Science, University of Toronto, Toronto, ON, Canada, [2]Centre for Studies in Aging, Toronto, ON, Canada, [3]Osteoporosis Research Program, Sunnybrook & Women's College Health Sciences Centre, Toronto, ON, Canada.

Persons with osteoporosis, are at increased risk for bone fractures caused by falls. These fractures occur because of a combination of injury and intrinsic bone fragility. In a previous study we determined that 39% of women attending a multidisciplinary osteoporosis clinic (n = 198) with BMD < -2.5 reported a fall in the previous year. Almost half of these patients were under the age of 60 years and did not have the majority of risk factors commonly associated with falling. Lynn et al (1997), suggested that patients with osteoporosis may have balance features that destabilize them, particularly those with kyphosis. We hypothesized, that balance and gait problems may be contributing to a high rate of falls in individuals with osteoporosis. In this preliminary study we tested, three groups of women, those without osteoporosis (n=11), those with osteoporosis who had no history of falls (n=11) and those with osteoporosis who had a history falls (n = 12) to determine their postural balance and gait characteristics, fear of falling and level of physical activity. The first series of balance tests assessed the control of postural sway during quiet, unperturbed stance (platform not moving) under three test conditions, eyes open or closed on a firm or soft surface and while doing a secondary task. To assess balance recovery mechanisms, the subjects performed tests while the platform randomly moved and were instructed to recover balance by taking a single step forward as rapidly as possible. Results: The controls were significantly younger (47.1 $\pm$ 8.3 yrs) than the osteoporotic patients (58.7 $\pm$ 7.2 yrs). Controls reported exercising more than the osteoporosis subjects at a strenuous level. There was no difference between the three groups in the unperturbed stance experiments. However, measures of balance recovery were significantly different for both antero-posterior sway (mean frequency) and medio-lateral sway (average speed) after controlling for age such that the osteoporosis patients who had fallen were significantly different from those who had not fallen and the controls. These comprehensive balance test results suggest that osteoporosis due to low BMD is not associated with poor balance but rather a previous history of falls. We also noted that the majority of falls in this group occurred outdoors whereas most of the literature on fall prevention targets indoor falls. Therefore a fall history noting location should be taken from patients with osteoporosis and appropriate fall prevention strategies should become part of the treatment protocol for this subgroup.

Bone Density Status of the Elderly in Taiwan - Results of the Nutrition and Health Survey in Taiwan, 1998-1999 by Quantitative Ultrasound Scan. Y. Lin[1], J. Chiu*[2], W. Pan*[1], M. Lin*[3]. [1]Inst. Biomed. Sci., Academia Sinica, Taipei, Taiwan Republic of China, [2]Fooyin Inst.of Technology, Kaohsiung County, Taiwan Republic of China, [3]City Health Dept., Kaohsiung, Taiwan Republic of China.

Osteoporosis has become a growing public health problem as the elderly population expands rapidly in Taiwan in recent decades. The Elderly Nutrition and Health Survey in Taiwan, 1998-1999 was carried out to evaluate the overall nutrition and health status of people aged 65 years and above. The survey was conducted using a multi-stage complex sampling scheme. Townships or city districts in Taiwan were classified into 13 strata. Bone density was measured at heel by quantitative ultrasound (QUS) bone densitometry (CUBA Clinical, McCue). Broadband ultrasound attenuation (BUA, in dB/MHz) was measured, and the corresponding T-score was calculated. 1227 males and 1170 females who had complete physical examination data with ultrasound bone scan were included in the current analysis. All variables were weighted to represent the elderly population in Taiwan. Subjects were grouped by age and gender. Compared to the reference group (65-69.99 y/o group for both genders), elderly women older than 75 y/o had significantly lower weight, BMI, and BUA, and were shorter in height. Men who were 75 y/o and older also had lower weight and BMI, but no significant difference in BUA was observed. Percent of women with BUA T-score in between -1 and -2.5, and below -2.5 significantly increased in those aged 75 y/o and older. Nearly 90% of the women aged 85 y/o and older were classified as having T-score lower than -2.5. In men the distribution of T-score did not change across these age groups. There was no association between the stratification effect and the risk of having low BUA T-score (T-score < -2.5) in either gender. Results of univariate logistic regression analyses showed that in men higher weight and BMI were protective (OR, or odds ratio=0.97 and 0.90, respectively, p<0.0001), whereas in women height was also positively associated with lower risk of having low BUA T-score (OR=0.93, p<0.0001) in addition to weight (OR=0.93, p<0.0001) and BMI (OR=0.87, p<0.0001). These protective effects remained after adjusted for age. Older age (OR=1.11, p<0.0001) as well as longer postmenopausal duration (OR=1.06, p=0.0004) increased the risk in females. The length of time period between menarche and menopause was not related to the status of having low BUA T-score. This is the first island-wide survey with the use of QUS technology as the screening tool to investigate the bone health status of the elderly in Taiwan. The results suggested that there is an overall problem of low bone density in the elderly, especially in women aged 75 years and older.

Body Composition and Serum Leptin Changes during Hormone Replacement Therapy: A Prospective Study. A. Arabi*[1], C. Roux[1], R. Porcher*[2], C. L. Benhamou[3], P. Garnero[4]. [1]Rhumatologie, Hôpital Cochin, Paris, France, [2]Hôpital Saint Louis, Paris, France, [3]ERIT M0101, Orleans, France, [4]SYNARC, INSERM U403, Lyon, France.

To elucidate the mechanisms underlying the effects of hormone replacement therapy (HRT) on body composition and bone mineral density (BMD), we assessed body composition, serum leptin levels, and the influence of these parameters and of their changes on bone density and bone turnover in 109 healthy postmenopausal women beginning either tibolone 2.5mg (n=29), tibolone 1.25 mg (n=42) or estradiol 2 mg plus norethisterone acetate 1mg (E2+NETA) (n=38), daily for 2 years. At baseline, 1 year, and 2 years, body composition and BMD of the total hip, femoral neck, lumbar spine L2-L4 and the total body were determined by dual energy X-ray absorptiometry (QDR 2000, Hologic), and android fat, gynoid fat, and android obesity index (AOI) were calculated. Serum levels of leptin, bone alkaline phosphatase, osteocalcin and the urinary excretion of type I collagen C-telopeptide (CTX) were measured at the same time points. At baseline, BMD at all sites, lean mass and gynoid fat correlated negatively, whereas android fat and AOI correlated positively, with years since menopause. BMD at all sites correlated with both fat mass and lean mass (r= 0.26, p=0.0066 and r= 0.42, p<10-4 at the total femur). Serum leptin levels correlated positively with total hip BMD: r= 0.26, p= 0.032, and negatively with osteocalcin: r=-0.24, p= 0.043, and CTX: r= -0.4, p= 0.0006.BMD increased at all sites with treatment in all groups with a higher increase of spine BMD in the E2+NETA group(p<10-4). Serum bone alkaline phosphatase, osteocalcin, and urinary CTX decreased by 27%, 36% and 51% respectively without difference between groups. Lean mass increased significantly in all groups (p<10-4), by a mean of 7%, 3% and 6% with tibolone 2.5mg, tibolone 1.25 mg and E2+NETA respectively; android fat and AOI decreased significantly in all groups (p<10-4 and p=0.0023 respectively). The increase in BMD at all sites correlated positively with changes of lean mass at 2 years. No significant changes in leptin levels and no correlation between changes in biochemical bone markers and changes in leptin levels at 2 years were found. In conclusion, 1- both fat mass and lean mass are related to BMD in postmenopausal women, the relation being strongest with lean mass, 2- high serum leptin level are associated with decreased bone turnover and increased hip bone mineral density, 3- serum leptin levels are not affected by HRT, 4- HRT reverses body composition changes occurring with menopause, 5- E2+NETA and tibolone have effects on lean mass which may play a mediating role in their effect on BMD.

SU320

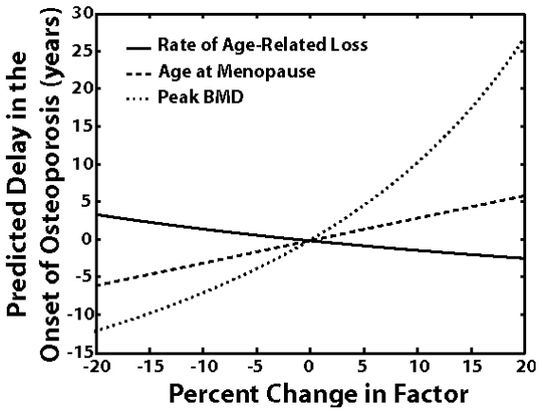
Serum RANK Ligand Levels and Bone Mineral Content in Hyperthyroidism. G. Speer*, Á. Tabák*, É. Bajnok*, I. Takács, Z. Nagy, P. Lakatos. 1st. Dept. of Medicine, Semmelweis University, Budapest, Hungary.

Thyroid hormone-stimulated bone loss is a clinically significant side effect of hyperthyroidism. Its pathomechanism has not yet been fully elucidated. RANKL (receptor activator of nuclear factor kb ligand) is an essential factor in the differentiation and function of osteoclast, produced by osteoblast. Increased production of RANKL has been shown to be associated with increased bone resorption. In the present study, we investigated the serum RANKL levels in hyperthyroidism as well as its relationship with bone mineral density (BMD) and bone quality assessed by bone sonography (QUS) in 40 healthy and 52 hyperthyroid women with osteoporosis. RANKL levels were detected by ELISA. BMD was measured at the lumbar spine and femoral neck using DEXA and at the midshaft radius using SPA method. Bone quality was estimated by QUS at the calcaneus (BUA). There was no difference in RANKL levels between healthy and hyperthyroid subjects. However, we found a significant (p=0.022) inverse correlation between serum RANKL levels (1.34±1.21, mean±SD, pmol/l) and BUA values when all subjects were pooled. The serum levels of RANKL did not correlate with BMD in either group. Our data raise the possibility that RANKL might play a role in the determination of bone quality.

SU321

Quantifying the Relative Influence of Peak BMD, Age-Related Bone Loss and Menopause on the Development of Osteoporosis. C. J. Hernandez[1], G. S. Beaupré[2], R. Marcus[3], D. R. Carter[2]. [1]Orthopaedics Department, Mt. Sinai School of Medicine, New York, NY, USA, [2]RR&D Center, VA Palo Alto Health Care System, Palo Alto, CA, Mechanical Engineering Dept., Stanford University, Stanford, CA, USA, [3]Eli Lilly and Company, Indianapolis, IN, USA.

Because osteoporosis is defined in terms of bone mineral density (BMD), any factor that influences BMD also influences the development of osteoporosis. Factors that determine a woman's BMD include the rate of loss she experiences as she ages (age-related loss), bone loss at menopause and peak BMD. Understanding the relative influence of each of these factors may help identify important preventive treatments and provide new ways to identify women at risk for osteoporosis. In this analysis we utilize a computer model of the bone remodeling process to predict the relative influences of peak BMD, age-related bone loss and menopause on the development of osteoporosis. Bone loss caused by aging is simulated by reducing the focal bone balance so that less bone is formed than is resorbed at each remodeling site. Increases in bone turnover at menopause are based on declines in serum estradiol observed clinically. The delay in the development of osteoporosis (defined as BMD <2.5 S.D. from the young adult mean) caused by modifying peak BMD, age-related bone loss or the age at menopause is quantified. The results suggest that peak BMD has the most influence on when osteoporosis develops. A 10% increase in peak BMD from the population average delays osteoporosis by 10 years while the same change in the age at menopause or the rate of age related bone loss is predicted to delay osteoporosis by approximately 2-3 years (see figure).



Because peak BMD is determined primarily during growth and maturation our analysis suggests that bone mass in early adulthood may be a more important risk factor for the development of osteoporosis than rates of bone loss later in life. This model is different from previous simulations of bone loss throughout adulthood (Ross et al. 1988 Bone 9:337-347) because it details the bone remodeling process that is responsible for changing bone mass. The bone remodeling description allows the model to describe how multiple factors might magnify or reduce bone loss caused by each other. Further work with this model would be required to predict fracture risk or Remaining Lifetime Fracture Probability.

SU322

Serum OPG Levels and Bone Mineral Content in Healthy, Postmenopausal Osteoporotic and Hyperthyroid Subject. Z. Nagy, Á. Tabák*, É. Bajnok*, I. Takács, G. Speer*, P. Lakatos. 1st Department of Internal Medicine, Semmelweis University, Budapest, Hungary.

Osteoprotegerin (OPG) a member of tumor necrosis factor receptor superfamily. OPG-deficient mice develop severe osteoporosis whereas administration of recombinant OPG to rats results in increased bone mineral density (BMD). Thus,OPG may be important in the aetiology and treatment of osteoporosis in humans. In the present study, we investigated serum OPG in human subjects as well as its relationship with bone mineral density (BMD) and serum beta-crosslaps in 83 healthy, 87 osteoporotic women and 89 hyperthyroid women with osteoporosis. OPG levels were detected by ELISA. BMD was measured at the lumbar spine and femoral neck using DEXA and the midshaft radius using SPA method. There was no difference in OPG levels between healthy, osteoporotic and hyperthyroid subjects.The serum levels of OPG did not correlate with the age, height, BMD and the beta-crosslaps levels in either group. Our data do nat support a passibility that serum OPG might reflect changes in bone metabolism.

SU323

Bone Mineral Density (BMD) of the Dominant and Non-dominant Hip in Postmenopausal Women. R. A. Brownbill, L. G. Tamborini, J. Z. Ilich. School of Allied Health, University of Connecticut, Storrs, CT, USA.

The universal testing sites for osteoporosis are bone density measurements in spine and hip. Recently, a software for successive measurements of both hips was developed, however it is not clear whether both hips need to be tested. The purpose of this study was to determine whether there is a difference in BMD between dominant and non-dominant hip and whether one of them correlates better with other skeletal sites. We also examined whether past physical activity and walking speed affected differently BMD of each hip. Participants were 123 Caucasian women, age 68.9±6.9 years (mean±SD), all healthy and not taking medications known to affect bone. BMD of both hips (in the regions of neck, Ward's, trochanter, and shaft), the total body, spine, and forearm was measured by DPX-MD densitometer. Past activity was assessed by the Allied Dunbar Fitness Survey for older adults and the 8-meter normal- and brisk-pace walking speed was assessed in a straight hallway. Subjects were also divided based on their past activity and walking speed, and subgroup analyses were performed. Pearson r and t-tests were used in analyses. Results showed no statistical difference in any of the measured regions in two hips. Mean % difference for neck, Ward's, shaft, trochanter, and total hip was 0.2, 1.6, 1.3, 1.5, and 0.7, respectively. Non-dominant hip correlated better than dominant and better than average of two with all skeletal sites except spine. In the non-dominant hip, r ranged from 0.502 (with forearm) to 0.793 (with total body) and in the dominant hip from 0.417 (with forearm) to 0.770 (with total body), all p values <0.05. Subjects with higher walking speed had higher neck BMD in the non-dominant hip (p<0.05). There was no difference between BMD in two hips regarding the levels of past activity. Although two hips had similar BMD, the non-dominant hip correlated better with other skeletal sites. We conclude that it might be sufficient to measure BMD in only non-dominant hip.

SU324

A Mid-Region Fragment of Human Parathyroid Hormone (hPTH 28-48) Has no Anabolic Action in Older Mice In Vivo. A. Iida-Klein[1], S. S. Lu[1], K. Yokoyama*[1], D. W. Dempster[1], J. Nieves[2], R. Lindsay[2]. [1]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

During early skeletal development in fetal or neonatal rodents, PTH (28-48) has been shown to stimulate creatine kinase activity and to increase the cortical width of the tibia. However, it has not yet been defined whether PTH (28-48) exhibits a similar anabolic action on the mature murine skeleton. To compare the effects of PTH (28-48) to that of PTH (1-34) in older mice, female C57BL/6 mice at 22 weeks were treated with PTH (28-48) 90 mcg/kg/day (n=9), PTH (1-34) 80 mcg/kg/day (n=9) or vehicle (n=8) 5 days a week (s.c.) for 3 weeks and their bone mineral density (BMD) measured in vivo weekly by dual energy X-ray absorptiometry (DXA). The rate of bone gain at each skeletal site for the initial 3 weeks was calculated by linear regression. From 22 weeks of age, most control animals increased BMD with a mean rate of 0.315, 0.364 and 0.333 mg/cm2/week in the tibia, femur and total body, respectively. In the lumbar vertebrae, however, control animals lost bone (mean -0.131 mg/cm2/week, n=8) between 22 and 25 weeks, suggesting bone loss begins at this site prior to this age. PTH (1-34) increased the rate of initial bone gain by 4-fold ($p<0.01$), 5.7-fold ($p<0.0001$) and 2.9-fold ($p<0.005$) in the tibia, femur and total body bone, respectively, and induced a significant bone gain in the lumbar vertebrae (mean rate changed from -0.131 to +1.605 mg/cm2/week, $p<0.05$). However, PTH (28-48) did not show any anabolic actions on BMD at any sites during 3weeks of treatment with a mean rate of 0.314, 0.386, 0.293 and 0.572 mg/cm2/week for the tibia, femur, total body and lumbar vertebrae, respectively. The appearance of the anabolic action of PTH (1-34) at the long bone sites was somewhat delayed in the older mice as compared to younger mice. These data suggest that the skeletons of mature mice retain responsiveness to the anabolic effect of PTH (1-34), but with age the anabolic activity of PTH (28-48) is lost and a higher dose or longer treatment may be required for the latter being anabolic.

SU325

Age Is a Major Correlation Factor Affecting In Vivo Murine Bone Mineral Density (BMD) for the Longitudinal Studies. K. Yokoyama*[1], S. S. Lu[1], J. Nieves[2], D. W. Dempster[3], R. Lindsay[2], A. Iida-Klein[1]. [1]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, USA, [3]Regional Bone Center, Helen Hayes Hopsital, West Haverstraw, NY, USA.

Age and body weight (body size) are important factors, which directly or indirectly affect bone mineral density (BMD) for the longitudinal studies of mouse skeleton, in addition to the experimental conditions such as estrogen-deficiency or treatment with anabolic agents. Although murine models have been intensively utilized for the study of bone metabolism, the database for in vivo murine BMD in normal bone physiology is currently very limited. The present study analyzes in vivo BMD data to determine the factors affecting BMD in mice within one strain. From a total of 136 C57BL/6 female mice between 10 and 23 weeks of age, a total of 532 dual energy X-ray absorptiometry (DXA) scans were analyzed at 4 different skeletal sites (femur, tibia, lumbar spine and total body bone) in correlation to their age and body weight. There are 6 groups analyzed:1) intact mice treated with vehicle (C, n=111), 2) intact mice treated with PTH(1-34) 40 mcg/kg/day (s.c.) 5 days a week for 1 to 7 weeks (P, n=113), 3) sham-operated mice with vehicle (SC, n=78), 4) sham mice treated with PTH (SC, n=80), 5) ovariectomized (Ovx) mice with vehicle (OC, n=76) and 6) Ovx mice with PTH (OP, n= 74). In intact control mice between 10 and 17 weeks, BMD correlated positively with age at all skeletal sites (r = 0.6790, 0.6910, 0.6660 and 0.4283, for total body, femur, tibia and lumbar spine, respectively). The majority of this relationship was related to the continued increase in size of the animals, and body weight was the other important determinant of BMD (r = 0.5828, 0.5052, 0.5438 and 0.4094 for total body, femur, tibia and lumbar spine, respectively). Ovx eliminated the increase in bone density with age in the tibia (r = 0.1600) and lumbar spine (r = -0.1600), and attenuated the relationship in the femur (r = 0.3775) and total body (r = 0.4555). The relationship between body weight and BMD was also reduced by Ovx. Treatment with PTH enhanced the positive relationship between BMD and age at all sites, and in both intact younger animals as well as after Ovx. The present data suggest that age is the most important factor affecting BMD at all sites particularly in younger intact mice, and that body weight may not be a good normalizing factor especially in older operated animals.

SU326

Both Androgen and Estrogen Signalings Contribute to the Maintenance of Bone Mass in Males: Analyses of Male Androgen Receptor Deficient Mice. H. Kawano[1], T. Sato*[2], T. Yamada*[2], T. Matsumoto*[2], H. Kawaguchi[1], S. Kato[2]. [1]Orthopaedics, Univ. of Tokyo, Japan, [2]IMCB, Univ. of Tokyo/ CREST, Japan.

Although testosterone (T), the main androgen, is known to be essential to maintain bone mass in males by the fact that orchidectomy causes bone loss both in animals and humans, the role of androgen signaling on bone in males remains unknown. This is because T activates not only androgen receptor (AR) as T itself or its metabolite dihydrotestosterone (DHT), but also estrogen receptors through aromatization into estradiol (E_2). We recently established an AR deficient mouse (ARKO) line and reported that male ARKO exhibits high turnover osteopenia. Since the T level was markedly decreased due to severe atrophy of genital organs in male ARKO as compared to male wild-type littermates (WT), the decrease in estrogen signaling possibly causes the osteopenia. The purpose of this study was to know the contributions of androgen and estrogen signalings on bone metabolism in males by analyzing ARKO with both disrupted androgen signaling and decreased estrogen signaling. WT and ARKO were orchidectomized (ORX) or sham operated at 3 weeks of age, and implanted subcutaneously with a slow releasing pellet of placebo, T, or DHT (10 mg / 60d). Plain X-ray and 3D-CT features, BMD, and histomorphometric parameters of long bones were compared among 8 experimental groups: WT, WT+ORX, WT+ORX+T, WT+ORX+DHT, ARKO, ARKO+ORX, ARKO+ORX+T, and ARKO+ORX+DHT (each n=8), at 8 weeks of age. WT+ORX, ARKO and ARKO+ORX all showed similar decreases in bone mass (about 15% lower in BMD and 75% lower in BV/TV) and increases in bone formation / resorption parameters than did WT, indicating that testis is the principal source of bone regulatory androgen. Although the serum T level was confirmed to be fully restored to the WT level in the two T implanted groups, bone mass and turnover of ARKO+ORX+T showed about the half restoration (8% lower in BMD and 43% lower in BV/TV than WT) while those of WT+ORX+T showed full restoration to the WT levels. The restored half in ARKO+ORX+T is due to the effect of E_2 converted from the implanted T, whereas the unrestored half indicates the direct effect of androgen through AR. Since the serum E_2 level did not differ between the two groups, bone regulatory E_2 seemed to be converted mainly *in situ* in skeletal tissues. Although ARKO+ORX+DHT showed no restoration of bone mass or turnover by DHT implantation, about half the restoration was seen in WT+ORX+DHT as in WT. This also indicates the contribution of androgen signaling because DHT is not converted to E_2. We therefore conclude that both androgen and estrogen signalings contribute to osteopenia in male ARKO, indicating the involvement of both signalings in the maintenance of bone mass in males.

SU327

Effects of Orchiectomy on Bone Turnover and Bone Mass in the Aged Sprague-Dawley Rat. N. Doyle*[1], J. Jolette*[1], J. Mayer*[1], P. Qvist*[2], R. G Erben[3], S. Y. Smith[1]. [1]CTBR, Montreal, PQ, Canada, [2]Nordic Bioscience Diagnostics A/S, Herlev, Denmark, [3]Ludwig Maximilians University, Munich, Germany.

The purpose of this study was to evaluate the effects of orchiectomy (ORX) on bone turnover measured by biochemical markers and on bone mass as measured by densitometry in the aged Sprague-Dawley rat. Eighteen (18) month-old male rats were randomly assigned to 2 groups by body weight. Thirteen animals underwent ORX and 13 animals underwent Sham surgery. Animals were monitored for 16 weeks. Bones were retained for histomorphometry. Blood and urine samples were collected from all animals following a 6-hour daytime fast pre-surgery and 14, 28, 56, 84 and 112 days following surgery. Serum was analyzed for Rat-MID osteocalcin (OC), total ALP and C-telopeptide (RatLaps). Urine was analyzed for free deoxypyridinoline (DPD) and RatLaps (both corrected for creatinine). Bone densitometry by DXA and pQCT was performed pre-surgery and at 8, 12 and 16 weeks after surgery. DXA scans were obtained for the whole body, femur and lumbar spine. Peripheral QCT scans were obtained at the proximal tibia metaphysis and diaphysis. Body weights were recorded biweekly and seminal vesicle and prostate weights were recorded at necropsy. Ten animals/group survived the four-month observation period. Body weight decreased post-surgery for both groups recovering to pre-surgery weight only for Shams. Seminal vesicle and prostate weights for the ORX group were 23% and 28%, respectively, of the Sham controls. Increases in DPD (x1.6 to 2) were observed at all time-points for the ORX group relative to baseline (and compared to Shams). Urine RatLaps was increased at days 14 and 28 (x1.8) with levels declining to Sham levels thereafter. Increases in OC were noted from day 28 reaching a plateau by day 84 (x2 relative to baseline). Serum RatLaps and ALP showed no consistent differences between groups. Sixteen weeks post-ORX, the distal femur showed the greatest change in BMD measured by DXA with a 15% decrease relative to baseline and 11% compared to Shams. Tibia metaphysis trabecular BMD (pQCT) was decreased 37% relative to baseline and 19% compared to Shams at 16 weeks. The greatest changes in BMD generally occurred during the first 8 weeks post-surgery. An increase in endosteal circumference and decrease in cortical thickness was observed at the diaphysis for the ORX group compared to baseline and Shams. There was no change in periosteal circumference following ORX. ORX in the aged rat induced high turnover osteopenia as measured by biochemical markers and bone densitometry. These data support the use of this androgen-deficient model to evaluate potential anti-osteoporosis agents.

SU328

Androgen Deprivation in Veterans with Prostate Cancer: Implications for Skeletal Health. M. E. Elliott[1], A. J. Wilcox*[2], M. L. Carnes*[3], R. Tobias*[1], H. Baade*[1], E. Stamos*[1], C. D. Counts*[1]. [1]School of Pharmacy, University of Wisconsin, Madison, WI, USA, [2]VA Medical Center, Madison, WI, USA, [3]Department of Medicine, University of Wisconsin Medical School, Madison, WI, USA.

Osteoporosis and fractures are well-recognized complications of androgen deprivation in patients with advanced prostate cancer, and bone loss in these individuals can be reduced by bisphosphonate therapy. The frequency with which skeletal health is assessed and treated in these patients is unclear, however. Accordingly, we have undertaken a retrospective survey of skeletal health assessment and its management in patients undergoing gonadotropin releasing hormone agonist-induced androgen deprivation for prostate cancer at a Veterans Affairs Medical Center (VAMC). Veterans with prostate cancer (but without bony metastases) and receiving leuprolide or goserelin were identified from pharmacy records for the years 1993 through 2001 and included in the study. Hypotheses were: (1) Fracture risk factors in addition to androgen deprivation would be found in most patients; (2) bone mass measurements or vitamin D status would be assessed in a minority; (3) only a minority would receive bisphosphonate therapy or have contraindications for such treatment. The work was approved by the appropriate institutional review boards of the University of Wisconsin and the Madison, Wisconsin VAMC. One hundred and eighty five veterans were identified according to study criteria and included in the project. The median length of androgen deprivation was 18 months (range 1-99). Seventy-six percent of men (95% confidence interval [CI] 70-82%) had other fracture risk factors (13% past history of fracture, 56% current or former tobacco use, 20% documentation of alcohol abuse, 32% body mass index <25 kg/m2, 8% long-term prednisone or antiepileptic drug use). Sixteen percent (CI 11-21%) had received a bone mass measurement, and 6% (CI 3-9%) were assessed for vitamin D status. Only ten percent of men (CI 6-14%) had contraindications to bisphosphonate therapy (swallowing difficulties or inadequate renal function), although only 16% (CI 11-21%) were receiving such therapy. Thus, only a small minority of men had their skeletal health or vitamin D status assessed, and few received specific therapy, despite absence of contraindications. We conclude that the skeletal status of male veterans receiving androgen deprivation for prostate cancer is not adequately evaluated nor treated. Education of clinicians and creation of algorithms may improve long-term care in these patients at high risk for fracture.

SU329

Cortical Bone Loss in Androgen-Deficient Aged Male Rats Is due to Increased Endocortical Bone Remodeling. N. Reim*, K. Stahr*, J. Eberle*, R. G. Erben. University of Munich, Institute of Animal Physiology, Munich, Germany.

Hypogonadism is considered to be one of the major risk factors for osteoporosis in men. However, the mechanisms of bone loss due to androgen deficiency are still unclear. Therefore, we sequentially investigated the effects of androgen deficiency on cortical bone in aged orchiectomized (ORX) rats. Hundred-seventy 13-month-old male Fischer-344 rats were either ORX or sham-operated. Following in vivo fluorochrome labeling, groups of 8 - 15 SHAM and ORX rats each were killed at 2 weeks and at 1, 2, 3, 4, 6, and 9 months postsurgery. As measured by peripheral quantitative computed tomography (pQCT) analysis, total bone mineral density and cortical thickness of the tibial shaft were decreased in ORX rats, beginning from 2 months postsurgery until the end of the study. A consistent decrease in volumetric cortical BMD was seen only beyond 6 months post-ORX. In good agreement with the pQCT data, histological analysis of bone cross-sections at the same bone site revealed cortical bone osteopenia by 2 months postsurgery and at all later time points. Androgen deficiency induced a sustained decrease in periosteal bone formation during the first 4 months post-ORX. Interestingly, this change was reversed at the end of the trial. However, although periosteal expansion of the tibial shaft tended to be slower in ORX rats compared with SHAM controls, the reduction in total cross-sectional area of the tibial shaft in ORX animals reached statistical significance only at 4 months postsurgery. The major mechanism for cortical bone loss in aged ORX rats was a progressive expansion of the marrow cavity, which was associated with an initial increase in endocortical eroded perimeter at 1 and 2 months postsurgery, followed by a sustained increase in endocortical bone formation until the end of the study. At the end of the study, endocortical bone surfaces showed clear evidence of increased bone remodeling in ORX rats, and resorption canals originating from the endocortical surface extended deeply into the underlying cortical bone. All these changes were prevented in aged ORX rats receiving testosterone supplementation. We conclude that androgen deficiency-induced cortical bone loss in aged, non-growing rats is mainly due to augmented endocortical bone remodeling.

SU330

Calciotropic Hormones and Bone Resorption Markers in Healthy Older Men. B. I. Gulanski[1], S. Rettinger*[2], A. L. Arnold*[2]. [1]Internal Medicine, Section of Endocrinology, VA Connecticut Healthcare System, West Haven, CT, USA, [2]Yale University School of Medicine, New Haven, CT, USA.

Osteoporotic fractures are important causes of death and disability in older men, however the mechanisms of age-related bone loss remain uncertain. Conflicting data exists regarding changes in biochemical markers of bone metabolism in older men, and the role of calciotropic hormones in age-related bone loss. We measured calciotropic hormones, gonadal steroids, interleukin-6 (IL-6), bone turnover markers, and bone mineral density (BMD) in healthy community-dwelling men over the age of 50 years without known secondary causes for bone loss and not taking medications known to affect bone metabolism. Seventeen healthy eugonadal subjects (mean age 68; range 50-90 years) were included in the analyses. The majority were Caucasian (94%). Thirty-six percent had either osteopenia or osteoporosis. Mid-molecule PTH values above the upper limit of normal were found in 5/17 (29%) subjects. 1,25 dihydroxyvitamin D (1,25OH2D) levels were widely variable, but all within the normal range. Elevated levels of urinary N-telopeptide (NTX) values were found in 4/17 (24%), however serum osteocalcin was elevated in only 1/17 (6%). The mean value of IL-6 was elevated at 6.3 (± 3.5) pg/ml and was above the normal range in the majority of subjects. Bivariate analyses revealed that PTH and 1,25 OH2D were strongly and significantly correlated with IL-6 (r=0.56 and 0.71 respectively; p values < 0.02) and NTX (r=0.69 and 0.81 respectively; p values <0.002). IL-6 was highly correlated with NTX (r=0.82; p<0.001) but not osteocalcin (r=0.04; p=NS). In conclusion, elevated levels of PTH and NTX were found in roughly one quarter of healthy eugonadal men over the age of 50 years. PTH and 1,25OH2D were strongly and significantly associated with IL-6 and urinary NTX.

SU331

Effects of Ribavirin in Combination with either Interferon alpha or Peginterferon alpha-2b on Calcium and Bone Metabolism in Patients with Chronic Hepatitis C. F. J. S. Fonteles*[1], J. B. A. Paixão*[2], H. S. M. Coelho*[2], M. L. Duarte[3], M. F. Farias[1]. [1]Div. Endocrinology, HUCFF, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, [2]Div. Gastroenterology, HUCFF, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, [3]Histology and Embriology / PABCAM, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.

Combination therapy of Ribavirin with Interferon alpha (R+IFN) is recommended for chronic virus C hepatitis, but a negative impact in calcium metabolism and in bone density has recently been reported. Peginterferon alpha-2b (PegINF) is a new analog, also used in combination with R, but there are no reports on the effects of R+PegIFN on calcium and bone metabolism. Twenty-one female and 16 male patients with chronic virus C hepatitis confirmed by PCR for HCV RNA, persistently elevated alanine amino-transferase and liver biopsy, were enrolled in a prospective study of the comparative effects of R+INF (n=18) and R+PegINF (n=19). All patients were HIV negative. Ribavirin was administered per os according to body weigh, 800-1200 mg/day, in association with either subcutaneous INF 3 million units 3 times a week or subcutaneous PegINF 1.5mcg/kg body weigh once a week. Bone density was evaluated at lumbar spine (LS) and femoral neck (FN) by DEXA, Lunar Coorp. at baseline. Serum calcium, phosphorus and intact PTH (IRMA from DSL, Diagnostic Corp., California) and urinary NTx (ELISA, Osteomark, Ostex International, Seattle, WA) were measured at baseline and after 3 months. Mann-Whitney test was used to compare the 2 groups, and Wilcoxon test was used to evaluate the early effects of therapy. Groups R+INF and R+PegINF did not differ at baseline considering age (50.3+/-5.6 and 46.4+/-10.7 yrs), median Z-scores at LS (-0.4 and -0.7) and FN (-0.4 both groups), serum Ca (8.9 and 9.15 mg/dL) and iPTH (55.5 and 56.9 pg/mL). After 3 months, a significant decrease in serum Ca (-2.7% , p=0.01) and a significant increase in serum iPTH (41,3% , p=0.02) were evident when all patients were considered together, but no difference was found between groups. Serum phosphorus did not change with both therapeutic schedules. Median urinary NTx tended to decrease, but the variation was not significant. Our results confirm the negative influence in calcium balance of Ribavirin in association with INF and also with PegINF, and raises the question whether the secondary elevation in serum iPTH may contribute to the bone loss described with the antiviral therapy

SU332

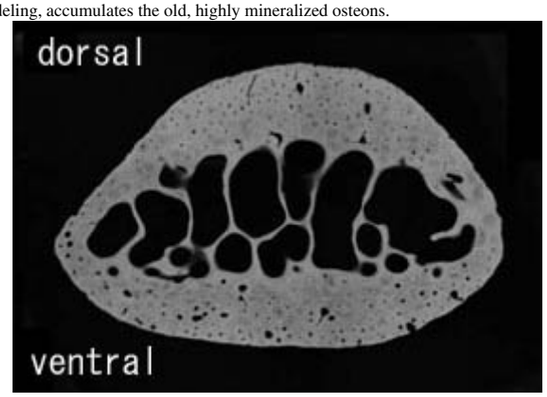
Mineralization Density Is Correlated with Activation Frequency in Women with Postmenopausal Osteoporosis. S. M. Ott. Medicine, University of Washington, Seattle, WA, USA.

In women with postmenopausal osteoporosis, the reduction in fracture rates after treatment with antiresorbing drugs is not directly related to the changes in bone density measured by radiographic techniques. Other aspects of bone (bone quality) such as bone turnover rate and mineralization density within bone metabolic units, could play a role in determining bone strength. This study examined the relationship between bone turnover and mineralization density in women with postmenopausal osteoporosis. Tetracycline-labelled iliac crest bone biopsies were obtained from 39 women with osteoporosis. Standard bone histomorphometric measurements were made, and mineralization density was determined using a backscattered electron micrograph imaging technique. Bone was scanned at 100x and 20 fields of trabecular bone were imaged per section. Image analysis was done using the NIH image program. The average mineralization density was calculated for each subject. The activation frequency showed a significant negative correlation with the mineralization density (r = 0.49, p=0.004). There was no relationship between mineralization density and formation period or mineral apposition rate, but a significant correlation with the mineralizing surface (r = 0.57, p = 0.0005). Thus, women with higher activation frequency had lower mineralization density. The activation frequency depends on the number of bone metabolic units and on the formation period (the duration of formation at any spot on the bone surface). The mineralization density appears to depend on the number of bone forming units rather than the duration of formation at each unit. An increased number of BMU's could lower mineralization density by replacing older, more mineralized bone with newer, less mineralized bone. Although this study documents a significant relationship between mineralization density and bone turnover in women with osteoporosis, it does not predict the optimum values of these aspects of bone quality.

SU333

Degree of Mineralization and Microdamage Accumulation in Cortacal Bone of Dog Rib. T. Mashiba*, S. Mori, Y. Cao*, J. Li*, S. Komatsubara*, J. Kawanishi*, T. Akiyama*, K. Miyamoto*, H. Norimatsu. Orthopedic Surgery, Kagawa Medical University, Kagawa, Japan.

This study was designed to evaluate the relationship between degree of secondary mineralization and microdamage accumulation in the cortical bone of dog rib. Left 9th rib was harvested from ten beagles aged 4 years old, stained en bloc with basic fuchsin and embedded in MMA. A 100 mcm-thick transverse section was cut for contact microradiograph (CMR) and microdamage analysis. Upon exposure for CMR, each rib section was arranged with calibration aluminum step wedge. An 8-bit gray scale digital image was taken from CMR using a microscope equipped with digital camera, then gray level of each osteon was quantified using NIH image software. Degree of mineralization was measured at X100 in cortical bone of ventral and dorsal side, separately. Microdamage measurement was performed using a same transverse section used for CMR, and the location of damage was examined. New, lower mineralized osteons were observed more frequently in ventral side of rib cortical bone than dorsal side. In contrast, old, highly mineralized osteons were found more frequently in dorsal side of rib cortex. Mean degree of mineralization was significantly higher in dorsal side than in ventral side. Microdamage was observed mainly in ventral side of rib cortical bone, where higher tensile stress is distributed in vivo. This suggests that increased production of microdamage initiate more number of intracortical remodeling as a damage repair process in ventral side, lead to increased population of new, lower mineralized osteons, whereas fewer damage production in dorsal side initiate less remodeling, accumulates the old, highly mineralized osteons.



SU334

Are Healthy Premenopausal Women with Asthma and Endometriosis "Normal"? M. F. Delaney[1], S. Hurwitz*[2], N. Glass*[1], M. Hornstein*[3], E. Israel*[4], M. S. LeBoff[1]. [1]Endocrine-Hypertension, Brigham and Women's Hospital, Boston, MA, USA, [2]Harvard Medical School, Boston, MA, USA, [3]Gynecology, Brigham and Women's Hospital, Boston, MA, USA, [4]Medicine, Brigham and Women's Hospital, Boston, MA, USA.

Study recruitment requires the enrollment of volunteers with the disease state to be studied, who are otherwise normal. The baseline screening evaluation may uncover unexpected results. The purpose of the study is to determine the prevalence of undiagnosed medical conditions in a volunteer population of young normal women, as assessed at baseline evaluation in two studies. We reviewed the records of 112 premenopausal women with mild asthma and 27 women with endometriosis (endo) recruited for IRB-approved studies at Brigham and Women's Hospital (BWH). All women were recruited from advertisements, mailings, and physician offices including asthma and gynecology clinics at BWH, Beth Israel Hospital, and affiliated practices. Women included were between the ages 18-46 with a mean of 34.8 yr in the asthma study and a mean of 32.6 yrs in the endo study. Evaluations considered abnormal included calcium intake <600mg/day, vitamin D (25D) ≤15 ng/ml, TSH <0.5 or >5 μU/ml, PTH >65 pg/ml, calcium <8.5 or >10,5 mg/dl, NTX >65 nmol/ BCE/mm, DHEAS <80 μg/mL, and BMI <18.5 or >25 kg/m^2. We included bone density measurements performed on QDR 2000 (Hologic, Waltham, Mass). We found that intact PTH and calcium were normal in both groups. In the asthma group, the mean lumbar spine (LS) Z score was +0.06 (SD 1.03) and total hip (TH) Z score was -0.04 (SD 0.85). The endo group mean LS Z score was -0.1 (SD 0.9) and TH Z score was 0 (SD 0.9). In summary, we found 12% of all normal healthy volunteers were vitamin D deficient, and 15-33% had high bone turnover by NTX, and 26% had a very low DHEAS levels. A low calcium intake was found in 17 of the endo group. Four percent of women had low BMI but we found 26-42% were overweight. In an otherwise healthy group of premenopausal women, these are surprising results. Premenopausal women with endometriosis and asthma and potentially other groups of healthy study participants may have alterations in skeletal homeostasis that are not clinically evident. To identify potential confounding variables on bone in subjects enrolled in clinical studies, a careful baseline evaluation to exclude secondary causes of bone loss should be performed even in the healthiest volunteers.

Abnormal value	Ca intake <600mg/d	25D ≤15	TSH <0.5	TSH >5	NTX >65	DHEAS <80	BMI <18.5	BMI >25
Asthma	0%	12%	0%	5%	15%	-----	4.5%	42%
Endo	17%	12%	8%	0%	33%	26%	4%	26%

SU335

Oral Bisphosphonates for Treatment of Osteoporosis in Elderly Patients with Impaired Renal Function. E. M. Lewiecki, L. A. Rudolph. New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA.

Background: Elderly patients with osteoporosis are commonly treated with oral bisphosphonates. These patients often have diminished muscle mass, resulting in a serum creatinine that underestimates impairment of renal function. Alendronate and risedronate, the two bisphosphonates approved in the USA for prevention and treatment of osteoporosis, are not recommended in patients with creatinine clearance < 35 ml/min or < 30 ml/min, respectively, due to lack of experience. Since creatinine clearance is not usually measured in clinical practice prior to starting bisphosphonate therapy, some patients with unrecognized impaired renal function may be receiving these medications. Objectives: This study was undertaken to test the hypothesis that some clinical practice patients with impaired renal function are being treated for osteoporosis with oral bisphosphonates, and that serious adverse consequences are unlikely to occur as a result. Methods: A retrospective chart review of female clinical practice patients, age 65 and over, treated with an oral bisphosphonate for osteoporosis or osteopenia during the period 4/7/97 to 7/31/01 was done. Creatinine clearance was estimated from age, body weight, and serum creatinine using the Cockcroft-Gault formula. Adverse outcomes were assessed. Results: 124 women met the inclusion criteria. Of these, 16 (12.9%) had an estimated creatinine clearance < 35 ml/min, and 11 (8.9%) had an estimated creatinine clearance < 30 ml/min. There were no serious adverse events attributed to bisphosphonate therapy in the patients with impaired renal function. Conclusion: Oral bisphosphonates were prescribed to elderly patients with previously unrecognized impaired renal function, without evidence of serious adverse consequences. This may be a common occurrence in clinical practice. Further investigation on the effects of bisphosphonates in patients with impaired renal function is suggested.

How Common Is Loss of Bone Mineral Density in Elderly Clinical Practice Patients Receiving Oral Bisphosphonate Therapy for Osteoporosis? E. M. Lewiecki, L. A. Rudolph. New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA.

Background: Bone mineral density (BMD) is often measured during bisphosphonate therapy for osteoporosis to monitor for therapeutic effect. Most patients in clinical trials of alendronate and risedronate have an increase or no change in BMD in response to treatment. It is uncertain that clinical practice patients can expect to have the same BMD response to therapy as clinical trial patients. Clinical practice patients may not be as compliant as patients in clinical trials, often have confounding co-morbidities, and may have unrecognized secondary causes of osteoporosis that could impair the therapeutic effect of bisphosphonates. Objectives: This study was undertaken to assess BMD response in elderly clinical practice patients being treated with oral bisphosphonates for osteoporosis. Methods: A retrospective chart review of female clinical practice patients, age 65 and over, treated with an oral bisphosphonate for osteoporosis or osteopenia during the period 4/7/97 to 7/31/01 was done. Subjects for clinical trials, patients referred for consultation, and patients who did not have at least one comparable follow-up DXA were excluded. Each comparable follow-up DXA was evaluated for the presence or absence of a statistically significant change in BMD of the spine or total hip at the 95% confidence level. Least significant change was calculated according to the guidelines of the International Society for Clinical Densitometry. Clinical assessment, confounding co-morbidities, and outcomes of those who lost BMD were reviewed. Results: There were 104 women who met the study criteria. Of these, 10 (9.6%) had a significant loss of BMD at the spine, total hip, or both skeletal sites over a period of at least one year. No patients admitted to non-compliance in drug taking. Laboratory and radiologic work-up of the bone-losers revealed 5 patients (4.8% of the total group, 50.0% of the bone losers) with previously unrecognized contributing factors of clinical significance- vitamin D deficiency, primary hyperparathyroidism, impaired renal function, iatrogenic hyperthyroidism, and cystic bone disease in the hips. Bone-losers typically had multiple co-morbidities and took numerous medications. Conclusion: About one in ten clinical practice patients on bisphosphonate therapy for osteoporosis showed significant bone loss. Evaluation of these bone-losers commonly uncovered previously unrecognized medical conditions that required changes in therapy.

Three-Years Treatment With Risedronate Does Not Alter Bone Mineral Crystallinity In Post-Menopausal Osteoporotic Subjects. E. P. Paschalis[1], R. Phipps[2]. [1]Hospital for Special Surgery, New York, NY, USA, [2]Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Factors such as bone microarchitecture and bone quality as well as bone mineral density (BMD) need to be considered when assessing fracture risk. It has previously been shown that 1- and 3-yr treatment of postmenopausal osteoporotic patients with risedronate reduces vertebral fractures and concomitantly preserves bone microarchitecture as well as increasing BMD. In the current analysis we examined the effects of 3-yr risedronate treatment on mineral crystallinity/maturity, a factor of bone quality, via Fourier transform infrared microscopic imaging (FTIRI). FTIRI allows analysis of bone mineral crystallinity and three-dimensional structures of collagen and other proteins in undemineralized thin tissue sections at the ultrastructural level (each image analyzes a 400 x 400 um^2 area with a spatial resolution of 7 um). Iliac crest biopsies were obtained from nine postmenopausal osteoporotic subjects at baseline and after 3-y treatment with risedronate, 5mg/day orally. The biopsies were embedded in methylmethacrylate, and the trabecular bone region was analyzed by FTIRI in ~4 um thick sections for determination of mineral crystallinity (bone mineral crystallite size in the crystallographic c-axis). Three images (each >2000 pixels)/ section were acquired. Crystallinity was compared before and after treatment for each subject (paired t-test). In the group overall (n=9), risedronate had no significant effect on mineral crystallinity of trabecular bone. Crystallinity before (C_b) and after (C_a) treatment was 0.993±0.104 and 0.924±0.060, respectively (mean ± standard deviation). In one subject however, crystallinity was significantly lower (P<0.01) after treatment (C_b=1.060±0.011 and C_a=0.897±0.015). There was no significant effect in the other 8 subjects. This lack of an increase in mineral crystallinity coupled with increased BMD and preservation of microarchitecture suggests that risedronate suppresses osteoclasts but not osteoblasts. These results contrast to the previously reported increase in mineral crystallinity seen with another bisphosphonate (ibandronate) and with hormonal replacement therapy, and suggest a unique mechanism of action for risedronate.

SU338

Risedronate Treatment of Established Primary and Secondary Osteoporosis in Men: 1-Year Results of a 3-Year Prospective Study. J. D. Ringe, A. Dorst*, H. Faber*, K. Ibach*, J. Preuss*. Medizinische Klinik IV, Klinikum Leverkusen, Akad. Lehrkrankenhaus der Univ. zu Köln, Leverkusen, Germany.

Although osteoporosis is more common in women, approximately one fourth of all hip fractures occur in men. The age-adjusted prevalence of vertebral deformities appears to be similar in men and women. Risedronate sodium has been shown to significantly increase bone mineral density and to reduce the risk of morphometric vertebral fractures in one year and the risk of clinical vertebral fractures after only 6 months of treatment in patients with postmenopausal osteoporosis. In the current study we examine the effects of risedronate on the mean change in lumbar spine, femoral neck and hip BMD in men with primary and secondary osteoporosis. Secondary endpoints include vertebral and non-vertebral fractures, pain, safety, and tolerability. This single center, open label, randomized prospective 3-yr clinical study with yearly examinations enrolled during the first year 102 male patients. They were randomized following their oral consent to receive either (group A) oral risedronate 5 mg daily (plus calcium 1000 mg and 800 IU Vit. D daily; n=51) or (group B) alfacalcidol 1 μg daily (plus calcium 500 mg daily; n=26) or (group C) calcium 1000 mg daily plus 800 IU vitamin D daily (n=25). In group A 19 of 51 patients and in group B+C 19 of 51 patients had secondary OP. In group A 26 of 51 patients and in group B+C 26 of 51 patients had a prevalent vertebral deformity. The patients are seen at baseline and at 12, 24 and 36 months. Bone mineral density (BMD), safety, and tolerability were compared. Spine x-rays are obtained at baseline and yearly thereafter. Men receiving risedronate showed a significant lumbar spine BMD increase of 4.2% compared with a increase of 0.7% in Group B+C patients (p<.0001). The change of total hip BMD was +2.32% in men treated with risedronate and –0.04% in group B+C after 1 year (p<.0001). The corresponding changes in femoral neck BMD were + 1.52% and –0.02% (p=0.0011). Both therapies were well tolerated. A significant reduction of back pain after one year was observed in patients receiving risedronate as compared to group B+C. After 1 year risedronate produced favorable effects on BMD consistent with the results from phase III trials in postmenopausal osteoporosis. The average increase rates were significantly higher than with alfacalcidol or plain vitamin D showing that risedronate is superior in the treatment of men with established primary or secondary osteoporosis. Year 2 and 3 investigations to determine positive long-term Risedronate effects in men with osteoporosis are currently performed.

SU339

Three Year Treatment Results with Alendronate vs. Alfacalcidol in Established Primary Osteoporosis in Men. J. D. Ringe[1], K. Dauhrer*[2], A. Dorst*[1], H. Faber*[1]. [1]Medizin Klinik IV, Leverkusen, Germany, [2]Merck, Sharp & Dohme, Munich, Germany.

Osteoporosis in men is an underdiagnosed and undertreated problem worldwide. Alendronate is the first bisphosphonate studied extensively in men. Our trial was a 3-year prospective, randomized, open-label, active-controlled, randomized clinical study comparing the effects of oral alendronate (ALN), 10 mg daily, and alfacalcidol (1α -D), 1 μ g daily, on bone mineral density (BMD), fracture events, height, back pain, safety and tolerability in 134 males with primary established osteoporosis. All men received 500 mg calcium daily. BMD was measured at the lumbar spine and femoral neck using dual-energy x-ray absorbtiometry (DXA). Spine x-rays were obtained at baseline and every 12 months thereafter, and were evaluated by a radiologist blinded to treatment assignment. At 3 years 1α -D-treated patients showed a significant mean 3.5% increase in lumbar spine BMD, compared with a mean increase of 11.5% in men receiving alendronate ($P < 0.0001$ between groups). The corresponding increases in femoral neck BMD were 2.3% and 5.8% for the alfacalcidol and alendronate groups, respectively ($P = 0.0015$ between groups). Over 3 years, new vertebral fractures occurred in 24.2% and 10.3% of the 1α -D and ALN patients, respectively ($P = 0.040$). ALN-treated patients also had a significantly lower height loss. There were no between-group differences in non-vertebral fractures or changes in back pain. Both therapies were well tolerated, with a compliance rate > 90 %. We conclude that although 1α -D has significant effects on BMD, ALN has greater effects on BMD and fracture efficacy.

One Year Treatment With Risedronate Preserves Trabecular Architecture. T. E. Dufresne*[1], P. E. Chmielewski*[1], B. Borah*[1], M. C. Prenger*[2]. [1]Procter & Gamble Pharmaceuticals, Mason, OH, USA, [2]Procter & Gamble Pharmaceuticlas, Mason, OH, USA.

Risedronate has been shown to reduce vertebral and nonvertebral fractures, including hip fractures in osteoporotic postmenopausal women. Morphometric vertebral fractures are reduced by up to 65% in just 1 year in postmenopausal osteoporotic women. Increases in BMD explain these changes only partially. Other factors such as bone turnover and bone architecture play an important role in the anti-fracture efficacy seen with antiresorptives. The objective of the present study was to determine the effect of risedronate treatment on trabecular architecture in postmenopausal women. Paired iliac crest biopsies (baseline and 1 year) from early postmenopausal women were analyzed using three dimensional microcomputed tomography (3D μCT). Women 6-60 months postmenopause were enrolled in a double blind, placebo-controlled study. The primary end point of this previous study was change in LS BMD at 1 year with risedronate treatment. The mean percentage change from baseline in LS BMD at 1 year was 1.4% in the risedronate group and -2.9% in the placebo group. Trabecular architecture degraded significantly in the placebo group (n=12 pairs) as evidenced by a 20% decrease in bone volume, a 13% decrease in direct trabecular number and an 86% increase in marrow star volume compared to baseline values. In the risedronate treated group (n=14 pairs), no significant changes were evident in any of these parameters from baseline. Compared to the risedronate group, the placebo group experienced decreases in BV/TV (p=0.032), trabecular thickness (p=0.061) and trabecular number (p=0.030) and increases in trabecular separation (p=0.019) and marrow star volume (p=0.016). In conclusion, risedronate preserves trabecular bone architecture in postmenopausal women in 1 year. This may contribute to the rapid fracture efficacy seen with risedronate.

SU341

Mineral Binding Affinities and Zeta Potentials of Bisphosphonates. G. H. Nancollas*[1], R. Tang*[1], S. Gulde*[1], F. H. Ebetino[2], R. J. Phipps[2], R. G. G. Russell[3]. [1]SUNY, Buffalo, NY, USA, [2]Procter & Gamble Pharmaceuticals, Mason, OH, USA, [3]University of Oxford, Oxford, United Kingdom.

Different interactions with bone may contribute to differences in pharmacokinetic behavior and in persistence of effect of individual bisphosphonates (BPs). We have previously shown that risedronate has lower kinetic binding affinity for bone mineral (hydroxyapatite or HAP, and octacalcium phosphate or OCP) than does alendronate. The purpose of the present study was to extend these observations to other bisphosphonates, and also to determine bisphosphonate effects on mineral surface phenomena such as zeta potential. BP effects on HAP and OCP crystal growth and dissolution were studied with the constant composition method at ionic strength 0.15 M, 37ºC. Adsorption affinity constants (K_L) were calculated from the kinetic results. Under conditions likely to simulate rate and extent of BP binding onto bone there were significant differences in K_L among the various BPs for HAP growth (pH 7.4, σ = 7) and OCP growth (pH 6.2) with rank order of Zol > Aln > Iban > Ris > Etid > Clod. Affinities were similar for mineral dissolution under conditions likely to prevail during osteoclastic resorption (HAP at pH 4.5 and OCP at pH 6.0). Effects of the various BPs on HAP and OCP growth and on zeta potentials are given below. Zeta potential, the electrical potential near the crystal surface, is a sensitive indicator of the adsorption of bisphosphonates onto the calcium phosphate. These data show that the crystal surface is modified by the adsorption of bisphosphonates with different molecular charges directly related to the proton dissociation of their functional groups. Differences in kinetic binding affinities may contribute to the apparent shorter terminal (bone) half life of risedronate, and to faster clinical off-responses seen with risedronate compared to alendronate and zoledronate.

			HAP Zeta Potential	
BP	K_L HAP Growth (L/mol)	K_L OCP Growth (L/mol)	pH 7.4	pH 5.0
Clodronate	7.20×10^5	2.08×10^6	--	--
Etidronate	1.19×10^6	4.0×10^6	--	+
Risedronate	2.19×10^6	5.3×10^6	--	+
Ibandronate	2.36×10^6	7.69×10^6	++	++
Alendronate	2.94×10^6	8.0×10^6	++	++
Zoledronate	3.47×10^6	1.47×10^7	+	++

SU342

Suppression of Bone Resorption was Restored within Two Months after Quarterly Intravenous Bolus Infusion of Ibandronate in Japanese Osteopenic Women without Vitamin D and Calcium Supplementation. A. Itabashi[1], K. Nemoto[1], M. Tsuboi*[2], N. Nakamichi*[2], H. Orimo[3]. [1]Clinical Laboratory Medicine, Saitama Medical School, Saitama, Japan, [2]NS Clinic, Tokyo, Japan, [3]Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan.

Lowered bioavailability due to food interaction and upper gastrointestinal problems of orally administered bisphosphonates led us to evaluate the efficacy of three monthly intravenous ibandronate injection therapy in postmenopausal osteopenic women. We conducted a phase I placebo-controlled dose-ranging study of intravenous ibandronate in Japan. Fifty otherwise healthy postmenopausal women, aged 60 to 75, with lumbar (L2-L4) BMD between -2.5SD and -1.5SD T-score were enrolled after written informed consent. They were randomly assigned to placebo, ibandronate (BM21.0955) 0.25, 0.5, 1, and 2 mg group (10 subjects for each) and the drug was administered intravenously as a bolus injection (2ml, 30 seconds). The injection was repeated after 13 weeks. No calcium nor vitamin D supplementation were given during the study period. Bone resorption markers (urinary DPD, CTx, NTx) rapidly decreased until 8 days, in a dose-dependent manner, then gradually recovered, returning to the baseline level at 2 months. The second administration showed exactly the same pattern. Osteocalcin and bone specific alkaline phosphatase did not change during the whole period (6 months). No significant gain of lumbar BMD was observed at 6 months. The treatment was well tolerated and no safety concerns were identified. These data suggest that more frequent dosing or higher doses may be necessary to attain an optimal magnitude in efficacy.

The Impact of Dropouts on the Efficacy of 5 mg Risedronate: An Assessment Based on an Imputation Analysis. J. D. Adachi[1], K. G. Siminoski[2], G. Cline*[3], J. P. Brown[4], A. B. Cranney[5], D. Goltzman[6], D. A. Hanley[7], A. B. Hodsman[8], R. G. Josse[9], D. L. Kendler[10], L. Ste-Marie[11], W. P. Olszynski[12], A. Tenenhouse[6], Z. Li*[3]. [1]McMaster University, Hamilton, ON, Canada, [2]University of Alberta, Alberta, AB, Canada, [3]Procter & Gamble Pharmaceuticals, Mason, OH, USA, [4]Laval University, Ste-Foy, PQ, Canada, [5]University of Ottawa, Ottawa, ON, Canada, [6]McGill University, Montreal, PQ, Canada, [7]University of Calgary, Calgary, AB, Canada, [8]Western University, London, ON, Canada, [9]Toronto University, Toronto, ON, Canada, [10]University of British Columbia, Vancouver, BC, Canada, [11]University of Montreal, Montreal, PQ, Canada, [12]University of Saskatchewan, Saskatoon, SK, Canada.

Risedronate 5 mg treatment has been demonstrated to reduce the risk of vertebral fractures by 61-65% within 1 year and by 41-49% within 3 years in two large placebo-controlled studies. In these two studies, the pre-specified statistical methods with time-to-event analysis for fracture data were able to include 85% of the maximum person-years. Therefore, about 15% of the person-years were missing due to dropouts. In this analysis, we attempted to assess the impact of dropouts on the efficacy of 5 mg risedronate. Namely, had these dropouts completed the study, what treatment efficacy would have been observed? A logistic regression model was used to determine the important risk factors for dropouts. We used multiple imputation analyses for each treatment group (placebo and risedronate 5.0 mg) with adjustment for important prognostic factors at baseline such as number of prevalent vertebral fractures, baseline BMD values and years since menopause. The treatment effect in fracture risk reduction was estimated based on the Cox's regression model.

	VERT-NA Risk Reduction (95% CI)		VERT-MN Risk Reduction (95% CI)	
	Original	Imputation	Original	Imputation
Yr 0-1	65% (38%, 81%)	68% (46%, 82%)	61% (32%, 78%)	63% (34%, 79%)
Yr 0-3	41% (18%, 57%)	46% (25%, 61%)	49% (27%, 64%)	52% (33%, 66%)

Our analysis indicated that the subjects with severe osteoporosis in the placebo group were more likely to drop out from the study than those subjects in the risedronate 5 mg group. Our imputation analysis suggested that estimates of fracture risk reduction were very robust to the dropouts. A numerically higher fracture risk reduction might have been observed had all subjects completed the three-year study. Therefore, if there was a bias that might have been introduced in the estimates of the anti-fracture efficacy due to dropouts, the bias was unlikely to be in favor of risedronate.

SU344

Treatment with Alendronate 70-mg Once Weekly† for 3 Months Decreases Biochemical Markers of Bone Turnover in Men with Osteoporosis. P. Miller[1], E. Orwoll[2], M. Czachur*[3], B. MacIntyre*[3], A. Leung[3]. [1]Colorado Center for Bone Research, Lakewood, CO, USA, [2]Oregon Health Sciences University, Portland, OR, USA, [3]Merck Research Laboratories, Rahway, NJ, USA.

This is a 3-month interim analysis of a 12-month, double-blind, randomized, multicenter, placebo (PBO)-controlled study to assess the efficacy of alendronate (ALN) 70-mg once weekly (OW) for the treatment of osteoporosis (OP) in men. The study randomized 167 men, aged 38 to 91 (mean 66.1) years, with idiopathic or hypogonadal OP (defined as lumbar spine or femoral neck [FN] BMD ≥ 2 SD below the normal mean or FN BMD ≥ 1 SD with a prior OP fracture). Fifty-eight received placebo, and 109 received ALN 70-mg OW. All patients received supplementation with open-label calcium (approximately 1000 mg) and vitamin D (approximately 400 IU) daily. No clinically meaningful differences were observed between the treatment groups for any of the baseline characteristics including age, race, weight, height, body mass index, gonadal status, bone-specific alkaline phosphatase (BSAP) or urinary N-telopeptides of type I collagen (NTx). Mean baseline BSAP was 13.6 ng/ml and urinary NTx was 32.8 pmol BCE/µmol creatinine. As shown below, treatment with ALN 70-mg OW for 3 months, significantly decreased urinary NTx and serum BSAP relative to PBO and baseline.

Bone Resorption Marker (urinary NTx) and Bone Formation Marker (serum BSAP) at Month 3

Treatment	N	BL	Mo 3	Percent Change from Baseline ††
Urinary NTx				
Placebo OW	53	33.70	34.66	4.3 (-5.9, 15.6)
ALN 70mg† OW	103	32.23	19.20	-41.4 *** (-46.1, -36.4)
Serum BSAP				
Placebo OW	53	13.21	12.21	-7.4*** (-11.1, -3.6)
ALN 70mg† OW	104	13.71	10.34	-23.5*** (-26.7, -20.1)

†† Transformed from Ln(fraction of baseline).

Within treatment test of mean = 0; ***:$p \leq 0.001$ versus baseline.

Between-treatment group comparison was significant for both NTx and BSAP ($p \leq 0.001$).

These results are consistent with those observed in a previous study of daily ALN 10-mg in 241 men with OP. The results of the primary efficacy analysis of the percent change from baseline in lumbar spine BMD after 12 months of treatment with ALN 70- mg OW will be available upon completion of the trial.

SU345

Once Weekly Alendronate Produces a Greater Decrease in Bone Resorption Than Does Daily Risedronate. D. Hosking[1], S. Adami[2], D. Felsenberg[3], J. Reginster[4], J. Cannata[5], M. Valimaki*[6], A. Santora[7], S. Suryawanshi*[7]. [1]Nottingham City Hospital, Nottingham, United Kingdom, [2]Ospedale Valeggio, Verona, Italy, [3]University Hospital, Berlin, Germany, [4]Chu de Liege, Liege, Belgium, [5]Hospital Central de Asturias, Asturias, Spain, [6]Helsinki University Central Hospital, Helsinki, Finland, [7]Merck Research Labs, Rahway, NJ, USA.

We report the results of the first head-to-head trial designed to compare the efficacy of alendronate and risedronate for the treatment of osteoporosis. The 3-month, randomized, double-blind, multicenter international study with double-blind extensions for an additional 9 months (12 months in total), enrolled 558 postmenopausal women. Patients were 60-90 years old (mean, 69), with osteoporosis defined by low BMD T-score (either lumbar spine or total hip/femoral neck ≤ -2.5, or ≤ -2.0 at both sites). The primary endpoint was 3-month change in urinary N-telopeptides of type 1 collagen / creatinine (NTx), a marker of bone resorption. Bone specific alkaline phosphatase, BMD (spine and hip), and safety evaluations will be completed after 12 months. Patients maintained a calcium intake of at least 1000 mg daily through food and/or calcium supplements. Patients were randomized into three treatment groups: alendronate 70mg* once weekly using standard am dosing; risedronate 5mg daily dosed 2 hours after a meal and at least 2 hr before the next; or matching placebo for each. Results are based on an intention-to-treat analysis of urinary NTx at Month 3.

Percent Change in Bone Resorption from Baseline at Month 3

	Placebo N= 105		Alendronate N=202		Risedronate N=210	
	Mean	Mean ±SE	Mean	Mean ±SE	Mean	Mean ±SE
Urinary NTx	-10.0*	(-13.8, -6.0)	-55.0***	(-56.7,-53.3)	-35.6***	(-37.7,-33.4)

*** p < 0.001; * p ≤ 0.05; Within-group test of mean percent change=0.
Tests for between treatment comparison of Alendronate Vs Risedronate, Alendronate Vs Placebo, and Risedronate Vs Placebo had p-values <0.001.

In this study, alendronate produced a 50% greater reduction in bone resorption than did risedronate. This difference may be due to the superior anti-resorptive efficacy of alendronate 70 mg once weekly, reduced bioavailability of risedronate resulting from post-meal dosing, or both.

SU346

Effect of Etidronate on Three-Dimensional Trabecular Structure of Ovariectomized or Immobilized Rats. A. Nishida[1], M. Ito[1], K. Hayashi*[1], T. Nakayama*[2], T. Tanaka*[2]. [1]Radiology, Nagasaki University, Nagasaki, Japan, [2]Sumitomo Pharmaceuticals Reserch Division, Osaka, Japan.

Etidronate (EHDP) has been reported to prevent bone loss caused by ovariectomy (OVX) or sciatic neurectomy (NX) in rats. The purpose of this study was to determine whether EHDP could prevent the deterioration of three dimensional trabecular structure caused by OVX or NX in rats. Eight-week-old female Lewis rats were subjected to OVX or NX or respective sham operation. They were divided into 6 groups with 10 animals in each group; OVX, its sham operation (sham-OVX), OVX+ EHDP treatment (OVX+E), NX, its sham operation (sham-NX), and NX+ EHDP treatment (NX+E). EHDP at 5 mg/kg or vehicle were injected subcutaneously five days a week from 2 weeks after surgery for 2 weeks. The proximal metaphysis of the tibia was scanned using micro-CT (μCT20, SCANCO Medical, Switzerland) craniocaudally for 150 slices with 13 micron-slice thickness. The region of interest of 50 slices under the growth plate-metaphyseal junction was defined as proximal portion, and 50 slices distal to the proximal portion was defined as distal portion. The proximal and distal portions were analyzed separately. Structural parameters such as bone volume fraction (BV/TV), trabecular number (Tb.N), trabecular thickness (Tb.Th), trabecular separation (Tb.Sp), trabecular bone pattern factor (TBPf), structure model index (SMI), and degree of anisotropy (DA) were assessed. The structural parameters changed in both OVX and NX compared with their respective sham groups. In proximal portion, there was no significant difference in BV/TV between EHDP treated groups and their respective sham groups, which indicates that EHDP prevented bone loss induced by both OVX and NX up to sham level. The greater effect of EHDP on trabecular structure appeared in OVX than in NX; structural parameters of OVX+E improved beyond the OVX-sham level such as SMI (p=0.0031) and TBPf (p=0.0079), while those of NX+E did not improve up to the NX-sham level, such as Tb.N (p=0.0274), Tb.Sp (p=0.0116), and SMI (p=0.0359). The DA significantly increased by OVX, while it decreased by NX. After the treatment with EHDP, DA decreased in both OVX and NX rats. In distal portion, all parameters of OVX+E and NX+E did not improve up to their respective sham groups. In conclusion, EHDP could prevent deterioration of trabecular structure caused by OVX and NX, however the effect of EHDP in NX rats was less than that in OVX rats. These results suggest that the external loading contribute to prevent deterioration of three-dimensional trabecular structure in the treatment with EHDP.

SU347

Effect of Minodronate (ONO-5920) in Adult Rats with Collagen-induced Arthritis. I. Yamane*, D. Yamasaki*, M. Enokida*, T. Okano, H. Hagino, R. Teshima*. Department of Orthopedic Surgery, Faculty of Medicine, Tottori University, Yonago, Japan.

[Purpose] Minodronate (ONO-5920), which contains an imidazol ring, is a newly synthesized third-generation bisphosphonate, and is said to have the most potent inhibitory activity against bone resorption. We investigated the effects of minodronate (ONO-5920), on bone mineral density (BMD), bone microstructure and bone metabolism in adult collagen-induced arthritis (CIA) rats using two different treatment schedules. [Methods] Seven-month-old female Sprague-Dawley rats were grouped into 4 groups: (1)control group (Cont); (2)CIA group (CIA+Veh); (3)CIA + therapeutic treatment group (CIA+The); (4)CIA + prophylactic treatment group (CIA+Pro). In therapeutic treatment, minodronate was orally administered from 2 weeks after sensitization. In prophylactic treatment, this agent was similarly administered from immediately after sensitization. Every 2 weeks until 8 weeks after sensitization, BMD in the proximal metaphysis of the tibia was measured using peripheral quantitative computed tomography (pQCT, XCT-960). After killing, serum osteocalcin (OC) and tartrate-resistant acid phosphatase (TRAP) were measured, and histomorphometric analysis was carried out in the secondary spongiosa of the proximal tibia. [Results] In CIA+Veh, cancellous BMD in the proximal metaphysis of the tibia was significantly decreased compared with that in Cont group. But bone loss in the proximal metaphysis of the tibia in CIA+Pro was inhibited during the experiment. In CIA+Veh, BV/TV and Tb.Th values were significantly lower and ES/BS, N.Oc/BS and BFR/BV values were significantly higher than those in Cont. At any parameters, there were no significant differences between in Cont and CIA+Pro. The value of OC was significantly higher in CIA+Veh than in Cont . The value of TRAP showed no significant difference among four groups. [Discussion] It was considered that minodronate potently inhibited increased osteoclast numbers and bone resorption with accelerated bone turnover related to arthritis, and was effective for inhibiting bone loss and maintaining microstructure of cancellous bone. [Conclusions] It was concluded that minodronate treatment prevented inflammation-induced secondary bone loss and deterioration of bone microstructure by reducing bone turnover related to arthritis to the normal level. In particular, prophylactic treatment was more useful than therapeutic treatment.

SU348

Osteogenesis Imperfecta: Continuous Increment of Bone Mass with Two Years of Cyclical Intravenous Pamidronate following Oral Therapy. C. Tau[1], C. Mautalen[2], O. Brunetto*[3], V. Alvarez*[1], M. Farenga*[1], M. Rubinstein*[4]. [1]Metabolismo Cálcico y Oseo, Endocrinología, Hospital de Pediatría Garrahan, Buenos Aires, Argentina, [2]Centro de Osteopatias, Buenos Aires, Argentina, [3]Endocrinologia, Hospital Pedro Elizalde, Buenos Aires, Argentina, [4]Laboratorio Central, Hospital de Pediatría Garrahan, Buenos Aires, Argentina.

Osteogenesis imperfecta (OI) is an hereditary disease characterized by bone fragility, frequent fractures and progressive skeletal deformities. Bisphosphonate administration improves the quality of life and decreases fractures in children with OI. The aim of this study was to analize the effect of 2 years of cyclical intravenous pamidronate (IV-APD) in 11 children (4F,7M) with OI type I, n=3; OI type III, n=3 and OI type IV, n=5, age (X ±SEM): 7.2±1.4 (range 1.6 to 19.7 y.o.). Every child received IV-APD (provided kindly by Gador Pharmaceutical)at 3-4 months intervals for 2 years, in cycles of 3 consecutive days, (dose 6.5±0.7 mg/kg/year (range 4.8-11.8) the 1st year and 6.8±0.8 (range 2.5-13.1) the 2nd year).Patients also received calcium 0.5 to 1 gr and vitamin D 400-800 IU/day. Prior to intravenous therapy, these patients have received 1 year of oral pamidronate (O-APD). Spine bone mineral density (BMD) was measured by DEXA. Knees X-rays were taken every 6 months. Average basal Height Z-Score (range 0.93 to -5.87) increased, but not significantly: -3.24±0.65 vs -2.85±0.74 the 1st year of IV-APD, and -2.95±0.76 the 2nd year. Basal BMD (0.35±0.04) increased significantly after 1 and 2 years of treatment (0.45±0.03, p<0.02, and 0.51±0.04 gr/cm2, p<0.005, respectively) and Z-Score BMD increased from -3.9±0.2 to -2.5±0.3 and -2.1±0.3, p<0.005, after one and 2 year of treatment respectively. There was an average annual BMD increase of 33±3% (range 1 to 82%) after the 1st and, 12±2% after the 2nd year of therapy. The patients had an annual BMD increase of 27±6% during previous oral therapy. Fractures, between 0.9 to 8/ year before therapy (3.1±0.6), decreased sharply with O-APD (1.4±0.4/year, p<0.02) and continued to diminish with IV-APD (1.2±0.3/year, 1st year, and 0.7±0.2, 2nd year, p<0.0005). As in normals, Z-Score BMD was positively correlated with height after 1 and 2 year of therapy (r: 0.68, p<0.02 and 0.73, p<0.01,respectively. X-rays showed dense lines under growth plates in most patients. Conclusion: Two years of intravenous cyclical pamidronate improved bone mass in children with Osteogenesis Imperfecta with a diminution of the number of fractures and better quality of life. Bone mass had a continuous increment even in patients who had previously augmented the BMD after oral APD.

SU349

Bisphosphonates Enhance Cancellous Bone's Mechanical Properties through Improvement of Three-dimensional Microarchitecture. M. Ding*[1], J. S. Day*[2], D. B. Burr[3], T. Mashiba*[3], T. Hirano*[3], H. Weinans[2], D. R. Sumner[4], I. Hvid*[1]. [1]Orthopaedic Research Lab, Aarhus University Hospital, Aarhus C, Denmark, [2]Orthopaedic Research Lab, Erasmus University Rotterdam, Rotterdam, Netherlands, [3]Departments of Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, [4]Departments of Anatomy and Orthopaedics, Rush Medical College, Chicago, IL, USA.

The aim of this study was to investigate the effects of one-year high dose (5-6 times the clinical dose) risedronate (0.5mg/kg/day) or alendronate (1.0mg/kg/day) on the three-dimensional (3-D) microarchitectural and mechanical properties of canine cancellous bone. We hypothesized that the administration of high dose bisphosphonates might significantly change vertebral cancellous bone microarchitecture in addition to increasing bone density and mechanical properties. A high-resolution micro-CT scanner was used to scan cubic specimens (5*5*5 mm3) produced from canine first lumbar vertebrae. Microarchitectural properties of the specimens were calculated directly from the 3-D datasets and the mechanical properties of the specimens were determined. Our data demonstrate significant changes in the cancellous bone microarchitecture after bisphosphonate treatment. The bisphosphonate-treated cancellous bone was typically plate-like, denser, with thicker and more trabeculae compared to those of the controls. Consistent with architectural changes, the Young's moduli of cancellous bone were greater in all three directions with the greatest in medial-lateral direction after bisphosphonate treatment. Our results suggest a bone remodelling-adaptation mechanism stimulated by bisphosphonates that maintains bone volume fraction and trabecular thickness, thus changes trabeculae towards more plate-like, and enhances mechanical properties. The secondary degree of anisotropy contributed significantly to the explained variance in bone strength, and the primary degree of anisotropy improved the explanation of variance for Young's modulus, i.e. 79-83% of strength variances or 83-91% of modulus variances could be explained by the combined anisotropy and bone volume fraction. These significant improvements of cancellous bone architecture provide a rationale for the clinical observation that fracture risk decreased by 50% in the first year of bisphosphonate therapy with only a 5% increase in bone mineral density. We conclude that bisphosphonates enhance mechanical properties and reduce fracture risk through improvement of architectural anisotropy of cancellous bone 3-D microarchitecture.

SU350

The Minipig Is a Good Model for Glucocorticoid-Induced Bone Loss and Shows Efficacy of Ibandronate Treatment for This Disorder. C. C. Glüer[1], K. E. Scholz-Ahrens*[2], W. Timm*[1], R. Barkmann[1], G. Delling*[3], F. Bauss*[4], J. Schrezenmeir*[2]. [1]Medical Physics, Dept. Diagn. Radiol., University Hospital Kiel, Kiel, Germany, [2]Institute of Physiology und Biochemistry of Nutrition, FDRC, Kiel, Germany, [3]Bone Pathology, University Hospital Eppendorf, Hamburg, Germany, [4]Roche Diagnostics GmbH Penzberg and Inst. of Pharmacol and Toxicol Heidelberg University, Mannheim, Germany.

Few large animal models for glucocorticoid (GC) induced osteoporosis have been established. We investigated whether the G÷ttingen Minipig shows trabecular bone loss under glucocorticoid treatment and whether such loss can be recovered by treatment with a bisphosphonate. As part of a larger study, 30 primiparous sows were allocated to 3 experimental groups when they were 15 months old: control group (CTR, n=10), GC treatment for 15 months (GC, n=9), and GC treatment for 15 month plus ibandronate (IBN) treatment for months 8-15 (GC+IBN, n=11). Animals were fed a semisynthetic diet until they were sacrificed. Groups GC and GC+IBN received prednisolon at a daily dose of 1mg/kg body weight for 8 weeks and thereafter 0.5 mg/kg body weight. IBN was administered subcutaneously and intermittently with an integral dose of 2.2mg/kg body weight spread over 22 weeks. Bone mineral density (BMD) of the lumbar spine was assessed in vivo by Quantitative Computed Tomography (QCT) before treatment, after 7 months and after 15 months in 23 animals. Data were analyzed by paired and unpaired t-tests and are given as %mean ± %SEM. BMD was stable in the control group (n=9) both during month 1-7 (-2.5%±2.5%, n.s.) and month 7-15 (-0.5%±1.2%, n.s.), while decreasing in the GC group (n=6) by -13.6%±1.9% (p<0.0005) in the first 7 months and increasing by 2.1%±1.2% (n.s.) in the remaining 8 months. In the IBN-treated group (n=8), the bone loss in the first 7 treatment-free months of -10.9%±1.8% (p<0.0001) was more than recovered by month 15 (+14.8%±1.2%, p<0.0001). During the 8 month treatment period, BMD changes in group GC+IBN were significantly larger by +12.6% (p<0.0001) and +12.7% (p<0.0001) compared to the 8-month changes in the GC group and the CTR group, respectively. Our results demonstrate that minipigs suffer from bone loss induced by GC and that this loss can be more than recovered by 8 month treatment with ibandronate. GC induced bone loss in minipigs can be efficiently monitored in vivo by QCT.

Not All Calcium Carbonate Supplements Are Equally Absorbable. R. P. Heaney, M. J. Barger-Lux. Creighton University, Omaha, NE, USA.

In the US, calcium supplements are regulated as foods and demonstration of bioequivalency is not required. There seems to be a general presumption of equivalent absorbability across different commercial products using the same calcium salt. This report presents an analysis of data from eight studies that examined the absorbability of calcium carbonate. Each study measured bioavailability of the calcium in a different pharmaceutical formulation of calcium carbonate. The absorbability of each product was compared to plain calcium carbonate that had been prepared without added pharmaceutical ingredients or formulation. The main outcome measures were fractional calcium absorption for products that were intrinsically labeled with a calcium isotope and absorptive calcemia (i.e., area under curve) for marketed products that could not be labeled intrinsically. Subjects were healthy women and men aged 20 to 66 who denied conditions or drugs known or suspected to affect absorptive function. The results showed that two of eight calcium carbonate supplements, one a swallowable and one a chewable tablet, exhibited absorbability comparable to that of plain calcium carbonate. The other six were substantially less bioavailable. The worst performer provided less than half of the calcium predicted for its load size. No product exhibited absorbability superior to plain calcium carbonate. We conclude that pharmaceutical formulation of calcium carbonate supplements has an appreciable effect on absorbability of their calcium. Clinical trials and individual treatment regimens using poorly available calcium sources will produce suboptimal benefits. The industry needs to study this issue and produce products with demonstrated bioequivalency.

Isolated Soy Isoflavones Prevent Bone Loss in the Hip in Postmenopausal Women. A. Vincent*[1], L. A. Fitzpatrick[2]. [1]Internal Medicine, Mayo Clinic, Rochester, MN, USA, [2]Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

Soy isoflavones have estrogen-like effects on target tissues. Clinical trials that examined the effect of isoflavones on bone density are limited by relatively short duration which is insufficient to detect changes in bone mineral density (BMD).This study investigated the effect of isolated soy isoflavone supplements on bone markers and BMD of the spine and hip. 70 healthy postmenopausal women (mean age 58.3 yr) were randomly assigned to placebo or 2 isolated soy isoflavone tablets containing 110 mg isoflavones for a period of 12 months. The products are commercially available as "Healthy Woman Soy Menopause" a proprietary, standardized tablet made from highly concentrated soy isoflavones and containing 320 mg of soy extract and 55 mg of isoflavone per tablet. Subjects were on an isoflavone poor diet for the entire study period.Groups were matched for age, height, weight and BMI at baseline. Bone markers were measured at baseline, 3 and 6 months. BMD was performed at baseline, 6 and 12 months. We report the results of bone markers in 70 subjects who completed the 6-month time point and BMD in 37 study subjects who completed the 12-month time point. The results were analyzed using the Wilcoxin rank sum test. Between groups, no differences were detected in median changes of serum NTx (p=0.3), Urine NTx (p=0.9), pyridinoline (p=0.12), deoxypyridinoline (p=0.24), bone alkaline phosphatase (p=0.6) or osteocalcin (p=0.4). Compared to placebo, subjects in the soy isoflavone group had smaller losses in hip BMD both at six months (p=0.024) and 12 months (p=0.01). Similarly, smaller non-significant losses of spine BMD were seen in the isoflavone group compared to placebo at 12 months. Serum estradiol and bioavailable estradiol increased in both groups from baseline to six months but the differences were not statistically significant. This is the first reported prospective randomized placebo-controlled trial to see changes in BMD from isolated isoflavones. Women in the isoflavone group had smaller decreases in bone density at the hip when compared to placebo at 6 and 12 months. Though a smaller decrease in bone density was also observed at the spine at 12 months in the isoflavone treated group differences were not statistically significant. This study suggests that isoflavones may preferentially effect cortical bone over cancellous bone. In conclusion soy isoflavone supplementation had a beneficial effect on hip BMD compared to placebo.

Gelatine Hydrolysate Suppresses High Bone Turnover in Pre-menopausal Women. T. Koike[1], Y. Kajiwara*[2], E. Yamashita*[2], Y. Ito*[1], K. Inui[1]. [1]Orthopaedic Surgery, Osaka City University Medical School, Osaka, Japan, [2]Nitta Gelatin Inc., Yao, Japan.

Gelatine has numerous applications, including the pharmaceutical, food and photographic industries. We have developed gelatine-hydrolysates, including the fermented products digested with a pineapple extract to facilitate the function of gelatine. Recently, it has been reported that the ingestion of gelatine has beneficial effects on bone mineral density (BMD) in mice. However, the effects of gelatine hydrolysates on bone metabolism in human have not been studied. This prospective, randomized clinical trial examined the effects of oral gelatine hydrolysates on BMD, biochemical markers of bone turnover, safety, and tolerability in 42 pre-menopausal healthy women. Women before the menopause received either gelatine-hydrolysate 10 g/day (n = 15, 41.3±4.8 years), fermented gelatine-hydrolysates 10 g/day (n = 15, 41.5±4.5 years), or nothing (n=12, 38.8±5.2 years). Urine and serum samples were collected at baseline and at 1, 4, and 8 weeks of administration. To assess bone resorption, we measured the urinary deoxypyridinoline and N-terminal cross-linking telopeptide of type I collagen (NTX), while serum bone alkaline phosphatase and osteocalcin were analysed to assess bone formation. Quantitative ultrasound (QUS) measurement at the calcaneus (A-1000plusII, Lunar) was performed at baseline and at the end of the study. There was no significant difference in bone metabolic markers and QUS values between groups at baseline. All participants who received gelatine products could take a dose every day through the study period and did not show any kinds of adverse events. Generally markers of bone resorption and formation and QUS values did not change in any groups. There were 9 women who showed irregular menstrual cycle and higher urinary NTX (>40 nMBCE/mMCr). Among those higher bone turnover women, urinary NTX decreased significantly only in the fermented gelatine hydrolysates-treated group. These data suggested that short-term (8 weeks) oral gelatine treatment (10 g daily) was well tolerated and might be effective in decreasing higher bone turnover in pre-menopausal women. Longer-term treatment with larger clinical populations is indicated to define more fully the potential efficacy and safety of gelatine therapy.

SU354

Carotts Consumption Prevents Bone Loss in Ovariectomized Rats. C. PUEL*, J. Mathey*, M. Horcajada*, B. Chanteranne*, M. Davicco*, P. Lebecque*, J. Barlet*, V. Coxam. Groupe ostéoporose, INRA, Saint-Genès Champanelle, France.

With increasing life expectancy the implications of osteoporosis are huge and this disease is major public health problem. Diets rich in fruits and vegetables are protective against chronic, degenerative disease. This action could be attributed to the presence of antioxidants like vitamin C, E or β carotene which inhibit free radical production and bone resorption in laboratory studies. The present investigation was carried out to assess the effects of fresh carrots on bone metabolism in ovariectomized (OVX) rats. Thirty 3 month-old Wistar rats were investigated. Twenty were OVX, while the 10 remaining were sham-operated as controls (SH). All the animals were fed a control synthetic diet for 90 days. 15% carrots were added to the diet given to half of the OVX (OVXC). Ovariectomy elicited a marked atrophy of the uterine horns (g) (OVX : 0.25 ± 0.06 ; OVXC : 0.14 ± 0.02 vs 0.61 ± 0.08 in SH ; $p<0.05$). Castration also induced a significant decrease in both total (g/cm2) (OVX : 0.2392 ± 0.0027 vs 0.2536 ± 0.0059 in SH ; $p<0.05$) and metaphyseal femoral mineral density) (OVX : 0.2432 ± 0.0044 vs 0.2617 ± 0.0067 in SH ; $p<0.05$), which was prevented by carrots consumption (OVXC : 0.2534 ± 0.0025 and 0.2561 ± 0.0023, respectively). In the same way, a higher femoral diameter (cm) (OVXC : 3.79 ± 0.03 vs 3.58 ± 0.05 in OVX, $p<0.05$) was associated with a trend towards an improved femoral strength. Moreover, on day 90, urinary deoxypyridinoline (DPD, nmol/mmol creatinine) excretion (a marker for bone resorption) was higher in OVX (99.51 ± 13.05) rats than in OVXC (72.70 ± 8.49) or in SH rats (75.98 ± 4.77). These results indicate that carrots consumption, inhibits ovarectomy-induced trabecular bone loss in rats, by slowing down resorption activity and increasing femoral diameter.

Serum Gla-type Osteocalcin as a Marker for Prediction of Effectiveness of Menatetrenone, a Vitamin K Analog, in Treatment of Glucocorticoid-induced Osteoporosis. I. Tanaka[1], H. Oshima[2]. [1]Department of Biofunctional Research, National Institue for Longevity Sciences, Obu, Japan, [2]Department of Laboratory Medicine, Fujita Health University, Toyoake, Japan.

[Objective] We have shown the effectiveness of menatetrenone, which is an analog of vitamin K and a co-factor for calcium deposition at bone formation, in treatment of glucocorticoid-induced osteoporosis. In this study, we try to clarify clinical usefullness of bone makers in prediction of the effectiveness in glucocorticoid-induced osteoporosis. [Subjects & Methods] Fifty nine patients (47 females and 12 males) with collagen diseases under corticosteroid treatment were enrolled in this prospective study. Subjects were 59 collagen disease patients under corticosteroid treatment. The new incidence of the vertebral compression fracture at two years after the start of corticosteroid therapy was evaluated about the 37 patients among those. The mean of age, daily corticosteroid dosage(prednisolone equivalent), and total corticosteorid dosage were 46 years old, 20.3mg/day, and 6.3g, respectively. Serum Glu type and Gla type osteocalcin (GluOC and GlaOC), and deoxypyridinoline in the urine (DPD) were measured by the ELISA methods. Vertebral compression fractures were evaluated with X-ray photography. [Results] 1) New vertebral compression fracture were revealed in 16 out of 59 cases (27%). 2) Among new corticosteroid(an average dosage of 37mg) medicated patients who were not used anti-osteoporosis agents, GluOC values decreased after four weeks (an average of 54% of pre-value). On the other hand, there was no significant change in GlaOC and DPD values at four weeks after the start of corticosteroid treatment . The use of anti-osteoporosis agents, such as etidronate or active vitamine D3, did not influence the values of the bone markers. 3) A significant negative correlation was found between daily corticosteroid dosages and GluOC values ($p< 0.05$). 4) In the cases who have fractures at the time of bone marker measurements, GluOC and GlaOC values showed significantly higher values ($p< 0.03$, $p<0.03$) compared to those with no fractures. 5) In patients treated with menatetrenone (n=12), GlaOC demonstrated higher values (15.5+/-3.1ng/ml) in 3 cases who had new fractures in the following 2 years than in 9 cases (7.0+/-4.1) having no fracture in that priod ($p<0.03$). [Conclusion] It is suggested that serum GluOC levels decreased in dosage dependent manner after treatment with corticosteroids, and menatetrenone effectively prevented vertebral fractures in patients with low serum GlaOC values.

SU356

Effect of a Diet Low in Cation-Anion Balance on Bone Mineral Density and Skeletal Fragility in Lumbar Vertebrae of Mature Ewes. J. F. Millets*[1], J. M. MacLeay*[2], A. S. Turner*[2], D. L. Wheeler[1]. [1]Mechanical Engineering, Colorado State University, Fort Collins, CO, USA, [2]Clinical Sciences, Colorado State University, Fort Collins, CO, USA.

There is a great need to develop and utilize a practical large animal model to investigate the pathogenesis of osteoporosis and lead to the development of new therapies for this disease. The objective of this study was to determine if significant loss of bone mineral density (BMD) and concurrent increases in skeletal fragility could be induced using a diet low in dietary cation-anion balance (LDCAB) compared to a normal hay diet with a moderate cation-anion balance (MDCAB). Twenty-four adult female sheep were divided into four treatment groups (n=6): No Ovariectomy (Ovx) with MDCAB diet (Control), Ovx with MDCAB (Ovx), No Ovx with LDCAB diet (LDCAB) and Ovx with LDCAB diet (Ovx-LDCAB). The MDCAB diet provided 300Meq/kg dry matter (DM) and the LDCAB diet - 350Meq/kg DM. Dual-Energy X-ray Absorbtiometry (DEXA) scans of the L5 vertebral bodies were taken in vivo at 0-months and 6-months (prior to euthanasia). Axial compression tests were performed on the L3 and L5 vertebral bodies, prepared to have plano-parallel surfaces following removal of dorsal elements, processes and endplates. Specimens were loaded cranially at a displacement rate of 5mm/min to a strain of 20%. Maximum strength and modulus was calculated from load/displacement data obtained during test. Statistical ANOVA and Duncan's comparison tests were performed with a level of significance of 0.05.

Summary of Mean Results

Group	Change in BMD (g/cm2)	Maximum Strength (MPa)	Modulus (MPa)
Control	0.03±0.09 a	60.69±7.09 a	2890.47±1837.40 a
Ovx	0.07±0.05 a	57.27±7.86 a	1865.50±456.38 b
LDCAB	0.08±0.09 a	53.56±8.47 ab	1676.48±482.37 b
Ovx-LDCAB	0.18±0.08 b	48.07±10.44 b	1655.32±452.06 b

Means with the same letter are not different at level of significance=0.05.

The Ovx-LDCAB group had significantly greater change in BMD and lower Maximum Strength than other three treatment groups. The modulus in the control group was significantly greater than other groups. The results of this study show that a LDCAB diet can induce significant decreases in BMD and skeletal fragility over a short period of time. This model shows considerable promise for use in the study of human postmenopausal or senile osteoporosis. Static and dynamic histomorphometry are currently under way to assess the LDCAB effect on bone metabolism.

Dried Plum Is Beneficial to Bone Health Without Gastrointestinal Side Effects. L. J. Hammond*[1], E. A. Lucas[1], D. A. Khalil[1], A. B. Arquitt[1], M. E. Payton*[2], B. J. Smith[1], B. H. Arjmandi[3]. [1]Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, [2]Statistics, Oklahoma State University, Stillwater, OK, USA, [3]Nutritional Sciences, Oklahoma State University, Stilwater, OK, USA.

The beneficial effect of dried plum on bone health has been demonstrated in both our animal (JANA, 4:50-56, 2001) and clinical studies (J Womens Health Gend Based Med., 11:61-68, 2002). Dried plum prevented the ovarian hormone deficiency-induced loss of bone mineral density (BMD) in rats as well as reversal of bone loss in osteopenic rats. In a recent clinical study, we demonstrated that three months of daily consumption of 100 g (10 to 12) dried plums significantly increased serum levels of insulin-like growth factor-1 (IGF-1) by 17% and bone specific alkaline phosphatase (BALP) by approximately 6%, suggesting that dried plum may exert positive effects on bone in postmenopausal women. An impediment to the incorporation of dried plums into the diet is due to perceived gastrointestinal side effects. This study investigated the effect of dried plum on bowel habits of postmenopausal women. Fifty-eight healthy postmenopausal women, randomly assigned to receive either dried apple or dried plums daily for 3 months, were asked to assess the bowel habits during the course of the study. Women were asked to fill out questionnaires at baseline, and each month thereafter. Participants were asked to rate consistency, strain, pain, and feeling of constipation based on a 7-point scale with 1 being the least. Reported below are the means ± SE for the dried plum regimen: There were no significant differences in bowel habits for women on either the dried apple or dried plum regimen. These results show that incorporating dried plums into the diet of postmenopausal women can positively affect bone health without the negative gastrointestinal side effects.

	Baseline	Month 1	Month 2	Month 3
Stool Frequency (per week)	11±1	11±1	11±1	12±1
Estimated Fecal Bulk (cups)	8.6±1.0	9.5±1.0	10.8±1.0	9.4±1.1
Consistency	3.4±0.2	3.2±0.2	3.1±0.2	3.0±0.2
Strain	2.6±0.2	2.5±0.2	2.3±0.2	2.1±0.2
Pain	1.5±0.2	1.8±0.2	1.6±0.2	1.5±0.2
Feeling of Constipation	2.0±0.2	2.1±0.2	1.8±0.2	1.8±0.2

The Combination of Vitamin E and Soy Protein Exerts Added Skeletal Benefits in an Aged Rat Model of Male Osteoporosis. D. A. Khalil[1], M. P. Akhter[2], S. Juma[1], E. A. Lucas[1], D. S. Galloway*[3], L. J. Hammond*[1], D. Soung[1], B. J. Smith[1], R. Recker[2], B. H. Arjmandi[1]. [1]Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, [2]Osteoporosis Research Center, Creighton University, Omaha, NE, USA, [3]Oklahoma Veterinary and Medical Teaching Hospital, Oklahoma State University, Stillwater, OK, USA.

Studies examining the effects of soy protein or supplemental vitamin E on bone report that these dietary agents may prevent bone loss in animal models of postmenopausal osteoporosis. This study examined the separate and combined effects of vitamin E and soy protein on prevention of bone loss in an aged rat model of male osteoporosis. Sixty, 13-month old F344 rats were randomized into 5 groups and either orchidectomized (ORX; 4 groups) or sham-operated (1 group). Rats were fed a casein- or soy protein-based diet with adequate (75 mg/kg diet) or supplemental vitamin E (750 mg/kg diet) for 180 days. Treatment effects on bone mineral density (BMD), bone mineral content (BMC), and urinary deoxypyridinoline excretion (Dpd) are presented below. Results suggest that the combination of vitamin E and a soy protein-based diet imparts synergistic effects on bone that are not observed with vitamin E or soy protein alone.

	Sham	ORX	ORX	ORX	ORX
Protein Source	Casein	Casein	Casein	Soy	Soy
Vitamin E	75	75	750	75	750
Change in Body BMD, g/cm^2	+0.0062^{ab} (0.0053)	-0.0066^{b} (0.0043)	-0.0095^{b} (0.0061)	-0.0024^{b} (0.0055)	+0.0160^{a} (0.0068)
Tibia BMC, g	0.4033^{a} (0.0071)	0.3552^{bc} (0.0056)	0.3357^{c} (0.0087)	0.3557^{bc} (0.0074)	0.3637^{b} (0.0100)
Tibia BMD, g/cm^2	0.1997^{a} (0.0019)	0.1855^{b} (0.0015)	0.1784^{c} (0.0023)	0.1873^{b} (0.0020)	0.1881^{b} (0.0027)
4th Lumbar BMC, g	0.1579^{a} (0.0031)	0.1265^{bc} (0.0025)	0.1212^{c} (0.0035)	0.1319^{b} (0.0033)	0.1338^{b} (0.0039)
4th Lumbar BMD, g/cm^2	0.2268^{a} (0.0028)	0.2101^{bc} (0.0022)	0.2050^{c} (0.0032)	0.2114^{bc} (0.0029)	0.2177^{b} (0.0036)
Urinary Dpd, nmol/mmol creatinine	71.2 (15.7)	117.5 (13.3)	119.2 (14.3)	97.3 (15.7)	104.1 (14.3)

Values are Mean (SE), n=12. For each parameter, means that do not share the same superscripted letters are significantly different ($P < 0.05$).

SU359

Soy Protein Increases The Bone Mineral Content in Ovariectomy-Induced Osteopenia in Aged Rats. L. Devareddy*[1], V. Hailey-Zitlin*[2], A. Ferris*[1], B. H. Arjmandi[1]. [1]Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, [2]Food Science and Human Nutrition, Clemson University, Clemson, SC, USA.

Soy protein has been reported to prevent bone loss in ovarian hormone deficiency. However, to what extent soy protein itself or its non-nutritive components, e.g. isoflavones and saponins, exert this bone protective effect requires further investigation. Another objective of this study was to investigate the effects of soy on bone of intact animals. To evaluate the bone protective ability of soy protein with or without its non-nutritive components in intact (sham) or ovariectomized (ovx) rats, 60 eight-month old female Sprague Dawley rats were divided into 3 ovx and 3 sham groups. Animals were fed either a casein- or soy protein-based diet for 90 days Treatment effects on bone mineral density (BMD) of the tibia are presented in table below.

Treatment	Protein Source	Tibial BMD
Sham	Casein	0.2010 ± 0.010 ^{a}
Ovx	Casein	0.1922 ± 0.006 ^{b}
Sham	Isoflavone-deplete soy	0.2037 ± 0.007 ^{a}
Ovx	Isoflavone-deplete soy	0.1974 ± 0.004 ^{ab}
Sham	Soy protein with isoflavones	0.2019 ± 0.006 ^{a}
Ovx	Soy protein with isoflavones	0.1954 ± 0.005 ^{ab}

Values are mean ± SD, n=10; Values with different superscripted letters are significantly different ($P < 0.05$).

Results of this study indicate that bone density of intact rats is unaffected by soy protein compared to casein and that soy protein irrespective of its non-nutritive components exerts bone protective effects in ovarian hormone deficiency.

SU360

Using a Population-Based Evidence-Based Disease Management Program to Prevent and Treat Osteoporosis in Postmenopausal Women. C. J. Metge*[1], C. K. Yuen[2], W. D. Leslie[2], M. Yogendran*[3], B. Kvern*[2], L. Manness*[4]. [1]Faculty of Pharmacy, University of Manitoba, Winnipeg, MB, Canada, [2]Faculty of Medicine, University of Manitoba, Winnipeg, MB, Canada, [3]Manitoba Centre for Health Policy, University of Manitoba, Winnipeg, MB, Canada, [4]Patient Health, Merck Frosst Canada Ltd., Winnipeg, MB, Canada.

A population-based use of an evidence-based disease management program to prevent and treat osteoporosis in post-menopausal women is currently being evaluated by the Maximizing Osteoporosis Management in Manitoba (MOMM) project. This public/private partnership between the University of Manitoba, Merck Frosst Canada Ltd. and Manitoba Health unites a broad coalition of health care stakeholders as active participants and co-investigators. Approximately 6000 Manitoba women at high risk of osteoporosis and/or fracture have been identified through the province-wide administration of a risk factor survey to a random sample of 40,000 women over 50 years of age. During its first year of data collection, MOMM has collected extensive demographic, diagnostic and therapeutic information on 8,681 women (22% response rate). From these, 5,945 women have been identified as being 'high-risk' for fracture and the focus of future interventions. In addition, another 8,018 women with a diagnosed hip fracture (1997/2001) identified through administrative claims files are also being followed for the appropriateness of their post-fracture interventions. The first step in designing population-based interventions is to identify gaps in care. By merging three different data sources [administrative claims, survey-based data and a clinical dataset (bone mineral density results)] this project is better informed about the gaps that need tackling in the designing of population-based interventions. The baseline analysis of data collected through the three data sources has been completed. Our findings to date have found that 53% of Manitoba women 50 years or older are at increased risk of fracture. The rate of clinical investigation for osteoporosis in Manitoba is less than 10% and less than 10% of women with a previous hip fracture are dispensed treatment for osteoporosis. Less than 9% of women at low risk of fracture are obtaining treatment. In conclusion, gaps in the treatment and prevention of osteoporosis in Manitoba women over 50 years of age have been identified. Data responsive interventions are in the conceptual stage and are based on these findings.

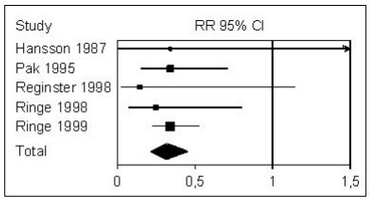
The Bone Turnover Related Concept for Treating Osteoporosis. M. A. Dambacher[1], M. Neff[2], H. Schwarz*[1], L. Qin*[3]. [1]University Clinic Balgrist, Zurich, Switzerland, [2]Center for Osteoporosis, Zurich, Switzerland, [3]Chinese University, Hong Kong, Hong Kong Special Administrative Region of China.

Purpose: To define a treating concept for osteoporosis related to findings in bone turnover. Methods: We performed measurements of trabecular bone density in patients in Zurich and Hong Kong with an identical device (hrpQCT, Densiscan, Scanco AG, Zürich-Bassersdorf). The reproducibility of this method in mixed populations is ± 0.3%. Results: In early-postmenopausal women the rate of bone loss in peripheral trabecular bone was 4.3% and in axial trabecular bone 4.7%/year (Ito). Approximatly 34% of these women were "fast-loser". In contrast, the proportion of fast-loser in women with very low bone mass (e.g. severe senile osteoporosis) is nearly 75%. "Fast-loser" is a patient losing more than 3%/year of trabecular bone mass in distal radius. The average loss of trabecular bone mass (early-postmenopausal women) in the fast-loser group (only 34%) was 7%/year and 1% in the slow (non) loser (66%). Conclusions: The bone turnover related concept for treating osteoporosis distinguishes between osteoanabolic and antiresorptive agents. Antiresorptive agents are in first line bisphosphonates, only fluorides are currently available as osteoanabolic agents. Although there is still discussion about the vertebral fracture reducing efficacy of fluoride, there is clear evidence, that the vertebral fracture rate is reduced in patients treated for at least two years with 15 to 20 mg F-equivalents /d. The data are shown in the figure. The results of these studies suggest the use of osteoanabolic agents early in the postmenopause where slow-loser situations are dominant and trabecular connectivity is still good. In contrast, antiresorptive agents should be used in severe osteoporosis where the proportion of fast-loser is high.



RR and 95% CI for new vertebral fractures in patients treated for 3-4 years with low-dose fluoride

SU362

Improving Management of Glucocorticoid Induced Osteoporosis: A Randomized Controlled Trial of Multifaceted Interactive Education. D. H. Solomon[1], J. N. Katz*[2], A. M. La Tourette*[1], J. Coblyn*[2]. [1]Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA, USA, [2]Rheumatology, Brigham and Women's Hospital, Boston, MA, USA.

Prior work suggests that most patients receive sub-optimal care of glucocorticoid-induced osteoporosis (GIOP).We conducted an RCT of multifaceted interactive education for rheumatologists aimed to improve management of GIOP for their patients with RA taking oral glucocorticoids (GCs). All rheumatologists practicing at one academic medical center were randomized to receive a three part educational intervention or not (control). The intervention included: 1) a 90-minute discussion of GIOP, current practices regarding GIOP at the medical center, and strategies for improving practice; 2) a confidential audit of each rheumatologist's practice with respect to GIOP; and 3) a 1 page handout on treatment for GIOP. We then examined the medical records of patients with RA taking GCs seen by the control or intervention rheumatologists. The structured chart abstraction focused on the 6 months prior to the intervention and the 6 months after. Of the 624 eligible patients identified with RA, 375 patients were taking GCs at their index visit and were included in this study. Patients seen by rheumatologists in the intervention and control groups were similar with respect to age, gender, menopausal status, rheumatoid factor status, duration of RA, proportion taking disease-modifying anti-rheumatic drugs, and rates of comorbid illnesses. Prior to the intervention, 9% of the intervention group underwent bone densitometry (DXA) as did 6% of the control group (P=0.2). Post-intervention DXA rates were 8% for the intervention group and 9% for the control group (P=0.9). Considering pre- and post-intervention periods together, 16% of the intervention group and 13% of the control group underwent DXA (P=0.4). With respect to treatment, prior to the intervention, the rates of prescription osteoporosis medication use (not including HRT) were 26% for the intervention group and 24% for the control group (P=0.5). After the intervention, 27% of the intervention group and 29% of the control group received non-HRT prescription treatment (P=0.8). When we consider pre- and post-intervention periods together, 28% of the intervention group and 30% of the control group received non-HRT prescription treatment (P=0.9). We tested a 3-part interactive educational program in the setting of an RCT and found no increase in rates of DXA and/or use of medications for osteoporosis. We hope that focus groups with these rheumatologists can help inform future interventions.

The DOMINO Project: To Improve the Compliance of Osteoporotic Patients with Periodic Feedback of Urinary CTX Values. O. Di Munno*[1], M. Mazzantini*[1], V. Braga*[2], S. Adami[2]. [1]Internal Medicine, Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Rheumatologic Rehabilitation, University of Verona, Valeggio sul Mincio (Verona), Italy.

It is well known that discontinuing drug therapy is common in clinical practice. This represents a relevant problem in chronic diseases such as osteoporosis (OP). Recent studies have shown that the compliance in clinical practice is much lower than that in controlled clinical trials. Nearly half of the women starting HRT stopped after a mean of 9 months (Ettinger B, 1996) and about one third of those given alendronate did so after a mean of 8 months (Ettinger B, 1998). Furthermore, many patients may not be compliant with dosing instructions, that are particularly strict in the case of bisphosphonates (BFs). In order to improve patient compliance the use of markers of bone resorption has been proposed. In osteoporotic patients treated with BFs urinary N- or C-telopeptides of type I collagen (uNTX, uCTX) measured by ELISA have been shown to be significantly reduced after 2-3 months. This short-term drop of uNTX or uCTX can predict also the long-term response to therapy in terms of BMD and possibly of fracture risk, thus giving (to both physician and patient) valuable information on treatment efficacy and (to physician) on patient compliance. Recently, a simple and quick diagnostic tool measuring uCTX has been developed (Osteosal™ , Instaquant™): this hand-held multi-path photometer, self-calibrating, generates T-score results of creatinine normalized uCTX, with high correlation with ELISA technique (r = 0.87), and thus it is an effective way to measure uCTX at the point-of-care. The Italian DOMINO project is aimed at testing the possibility to improve the compliance of osteoporotic subjects treated with antiresorptive drugs with a periodic feedback of uCTX values obtained with Osteosal™ and Instaquant™ . Four hundred and fifty physicians have been involved into this project, each enrolling between October 2001 and May 31st 2002 fifty postmenopausal osteoporotic women (total 22.250) planned for antiresorptive once-a-day therapy. The patients are being included into either of two arms: non-CTX arm, in which uCTX will not be measured; and CTX arm, in which uCTX will be measured at baseline, 3 and 6 months and the results will be discussed with the patient. All patients will receive an OP educational sheet together with a diary for the annotation of the days in which the drug has not been taken. Analysis of data collected from the first 700 patients of the CTX arm have shown that uCTX is significantly correlated to age (r = -0.09, p = 0.02), but not with lumbar BMD (r = -0.02, p = ns). Compliance will be assessed by counting the number of patients at control visits and days of therapy in both arms.

A Survey of Information Needs of Family Physicians for the Management of Osteoporosis. S. Jaglal[1], G. Hawker[2], L. Jaakkimainen*[3], J. Carroll*[3], W. McIsaac*[3], S. Cadarette[4], D. Davis*[5]. [1]Rehabilitation Science, University of Toronto, Toronto, ON, Canada, [2]Medicine, University of Toronto, Toronto, ON, Canada, [3]Family and Community Medicine, University of Toronto, Toronto, ON, Canada, [4]Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada, [5]Continuing Medical Education, University of Toronto, Toronto, ON, Canada.

A survey of a large sample of family physicians in Ontario, Canada was recently conducted as part of a larger study to identify knowledge gaps and barriers to managing osteoporosis in family practice. The mail questionnaire was developed based on the key issues and themes identified in a prior set of focus groups. The findings from these focus groups clearly indicated that the format of the current information available on the management of osteoporosis does not meet the needs of family physicians or their patients in addressing knowledge gaps. The survey was conducted to validate the findings of the focus groups and assist with the development of dissemination and implementation strategies. The survey was mailed to 1000 family physicians between May and June 2001. These physicians were obtained through a computer-generated random sample of active Ontario members of the College of Family Physicians of Canada (CFPC) stratified by urban/rural practice location and male/female physicians. A total of 505 physicians responded (n = 364 eligible surveys; n = 120 no longer practising family medicine and; n = 24 who never see postmenopausal women). Of the 364 eligible respondents; 50% were male, 77% practiced full-time, 35% rural, and 40% graduated more than 15 years ago. Overall, male/female and urban/rural information needs were similar. The majority of respondents (82%) were interested in a guideline/reminder tool for diagnosis and treatment and would like the following information provided on it: an indication of a patient's risk for fracture (97%), an indication of a patient's risk for osteoporosis (95%), a list of potential risk factors that should be considered (95%), and inclusion of a treatment algorithm based on bone densitometry results (95%). Family physicians indicated that the preferred formats were a laminated card (76%), a tear off sheet (63%) and a personal digital assistant program (19%). Preferred dissemination methods were direct mail (86%) and CME events (44%) or group modules (41%). As in the focus groups, patient education material was seen as lacking. The results of our survey also indicate that published guidelines in their present form are not being used. Based on our findings, we will be developing prototypes of tools that can assist family physicians with the management of osteoporosis and will test their implementation in a future study.

SU365

Low Prevalence of Osteoporosis Diagnosis and Treatment on Admission to Nursing Home. R. G. Crilly, M. Kloseck*. Division of Geriatric Medicine, University of Western Ontario, London, ON, Canada.

Osteoporosis is highly prevalent in the long-term care population but much under treated. The purpose of the present study was to ascertain how often osteoporosis appeared as a patient problem at the time of admission to the institution. Charts were randomly selected for review at three nursing homes (skilled nursing facilities). As indicators that osteoporosis might be present, the charts were searched for any mention of osteoporosis or osteoporosis-related fracture in the application form, in the admission history, in any associated documentation, in the medications being taken and in any test results in the chart, especially x-ray reports. Medications listed on the application documentation and those initially prescribed by the admitting physician were reviewed for any bone-active compounds. A total of 169 charts (47 male; 122 female; mean age 82 years + 9.56 S.D.) were audited. Only 13 (7.7%), 12 of which were female, came with a specific diagnosis of osteoporosis, two having had a recent hip fracture and six being on treatment (etidronate with calcium and vitamin D) including the two patients with a hip fracture. Of the 13, two, both with spinal fractures and one also with a hip fracture, had etidronate discontinued at admission. An additional 10 patients (8 female) were admitted with a diagnosis of a recent hip fracture but without a specific diagnosis of osteoporosis. None of these arrived on treatment and in none was treatment started. Etidronate was started in two additional patients who had neither a diagnosis of osteoporosis nor hip fracture. Additionally 11 patients without an osteoporosis diagnosis were on calcium and an additional patient was started on calcium at time of admission. No patient was on alendronate or calcitonin; two were on estrogen for unclear reasons, and a further two without osteoporosis and fractures were prescribed estrogen at admission. In no chart was there an extensive database suggesting that a systematic search for past information had taken place. This applied to all system and disease categories and not just to osteoporosis. This study confirms that few patients in nursing homes are on osteoporosis-related treatments despite the known high prevalence of osteoporosis in this population. A factor underlying this might be the paucity of information available to the admitting physician. However, even when patients arrived with the diagnosis of osteoporosis no additional treatment was begun. There seems to be little or no systematic effort to obtain further information after admission. It appears that the nursing home is part of a continuum of non-care for osteoporosis. An improved strategy for the recognition and treatment of osteoporosis in these patients is needed.

SU366

An Intervention that Educates Wrist Fracture Patients and Their Physicians Can Increase the Detection and Treatment of Osteoporosis – Interim Results of a Controlled Trial. S. R. Majumdar[1], B. H. Rowe*[2], D. Folk*[2], J. A. Johnson*[3], B. H. Holroyd*[2], D. W. Morrish*[1], C. H. Harley*[1], W. P. Maksymowych*[1], I. Steiner*[2], B. Wirzba*[1], D. A. Hanley[4], A. S. Russell*[1]. [1]Medicine, University of Alberta, Edmonton, AB, Canada, [2]Emergency Medicine, University of Alberta, Edmonton, AB, Canada, [3]Public Health Sciences, University of Alberta, Edmonton, AB, Canada, [4]Medicine, University of Calgary, Calgary, AB, Canada.

Fragility fractures of the wrist are the most common symptomatic fracture related to osteoporosis. However, only 10-20% of wrist fracture patients >50 years of age are investigated or treated for osteoporosis in the year post-fracture. The purpose of this study was to use a quality improvement intervention to increase detection and treatment of osteoporosis in older patients with fractures of the wrist treated in the Emergency Department (ED). The intervention included case-finding in the ED; patient counseling (written materials and phone calls about osteoporosis and the importance of follow-up); and primary care physician education (patient-specific one page guidelines recommending BMD testing and evidence-based treatment options, endorsed by local “opinion leaders”). The intervention was compared to usual care controls in a prospective, quasi-randomized, double-blind trial. Patients >50 years with a wrist fracture who were discharged home from the EDs of two large hospitals were eligible; patients already receiving osteoporosis treatment or who were unable/unwilling to give informed consent were excluded. Main outcomes were BMD testing and osteoporosis treatment within 6 months of fracture. Presented results are based on the first planned interim analysis. During the first year, 215 consecutive patients were screened, and 80 patients allocated to intervention (n=44) or control (n=36). Main reasons for exclusion were osteoporosis treatment (n=65) and admission to hospital (n=42). Study patients had a mean age of 67 years (range 50-92 years) and 78% were female. There were no significant differences in important clinical characteristics between intervention and control patients. Using intention-to-treat analyses, 52% of intervention patients had undergone BMD testing compared with only 8% of controls 6 months post-fracture (absolute increase 44%, p<0.001). Furthermore, 27% of intervention patients were started on osteoporosis treatment compared with only 6% of controls (absolute increase 21%, p=0.010). All treated patients were prescribed a bisphosphonate. We conclude that, compared with usual care, an ED-based intervention has the potential to significantly increase the rate of detection and treatment of osteoporosis in older patients with fractures of the wrist.

SU367

An Education Intervention Directed At Healthcare Providers and Patients Improves Attention to Osteoporosis in the Fracture Patient. C. Simonelli[1], J. Morancey*[1], L. Swanson*[1], K. Killeen*[1], T. W. Weiss*[2], Y. Chen[2]. [1]HealthEast, Woodbury, MN, USA, [2]Merck & Co., Inc., West Point, PA, USA.

A pilot project of 301 postmenopausal women hospitalized for a low impact fracture revealed low attention to osteoporosis (Pilot). At one year, only 10% had bone mineral density testing (BMD), 37% were using calcium, and 26% were on osteoporosis medication therapy. We hypothesized that an education program directed toward physicians and nurses and bedside education provided to the patient would increase osteoporosis diagnostic testing and treatment. Staff education was provided in the form of grand round lectures, presentations at staff meetings, mailings and brochures. A general guideline about osteoporosis was placed in the chart of all patients identified with fragility fracture. A geriatric nurse practitioner identified 186 consecutive patients who were hospitalized for low impact fractures during a 6-month period in 2000. Patients were counseled about nutrition, home safety and fall prevention and information about bone density testing and osteoporosis medication was discussed (Educ). Follow-up data were collected by telephone at 6 and 12-months. Results are shown at discharge (D/C) and follow-up. After education intervention, there was a significant increase in bone density testing, and calcium and vitamin D use that persisted through 12 months after intervention. While the use of osteoporosis medication increased, the increase was not statistically significant. This suggests that educational intervention directed at fracture patients and their healthcare providers may increase attention to osteoporosis in this high-risk population and improve quality of care.

Histomorphometric Evaluation of the Tibio-Fibular Junction after a Long-term Oral Administration of S12911 in Female Rats. V. Shen[1], C. Liu*[1], V. Marque*[2], I. Dupin-Roger*[2], D. Bazot*[3], I. Tupinon-Mathieu*[2]. [1]SkeleTech, Inc., Bothell, WA, USA, [2]Laboratoires Servier, Courbevoie, France, [3]Biologie Servier, Gidy, France.

S12911 (PROTOS®) is a new agent having shown its effectiveness in the treatment of postmenopausal osteoporosis. As the therapeutic use in humans may require prolonged administration, a long-term treatment study was performed in intact Fischer 344 rats. The bone effects at the cortical level were investigated. In this study, cortical bone histomorphometric parameters were measured at the tibiofibular junction of 118 female Fischer rats treated with 0, 225, 450 or 900mg/kg/d of S12911 for 104 weeks. Thirty-micron thick sections were prepared and surface stained with toluidine blue. Results are means ± SEM, ANOVA + Dunnett's test. The treatment with S12911 increased total bone area, cortical area, periosteal perimeter and cortical thickness. At 900mg/kg/d, total bone area, cortical bone area and periosteal bone perimeter were significantly higher than in the control group (+10, +13 and +5%, respectively). After 104 weeks of treatment, the marrow area and endosteal bone perimeter did not show any changes, or even a slight decrease, which is in keeping with the lack of changes seen in endosteal eroded surface. Conversely to what is found in young animals, there was a measurable amount of cortical porosity in a majority of animals. It was not related to treatment since the average percentage of cortical porosity remained the same. In conclusion, cortical bone is improved by a long-term S12911 treatment, as shown by histomorphometric measurements. This confirms previous densitometry and biomechanical findings reported in intact and ovariectomized rats. These results, in addition to those found for trabecular bone, demonstrate that S12911 possesses therapeutic potential by improving both cancellous and cortical bone.

SU369

Histomorphometric Evaluation of the Proximal Tibia Metaphysis after a Long-term Oral Administration of S12911 in Female Rats. V. Shen[1], B. Robin*[2], D. Bazot*[3], I. Tupinon-Mathieu*[2]. [1]SkeleTech, Inc., Bothell, WA, USA, [2]Laboratoires Servier, Courbevoie, France, [3]Biologie Servier, Gidy, France.

S12911 (PROTOS®) has been shown to reduce the risk of vertebral fracture in postmenopausal osteoporosis. As the therapeutic use of S12911 may require prolonged administration in humans, a long-term treatment study was performed in intact Fischer 344 rats. The long-term effect and safety of the treatment at the trabecular bone level were evaluated. In this study, trabecular bone histomorphometric parameters were measured at the tibia metaphysis of 119 female Fischer rats treated with either 0, 225, 450 or 900mg/kg/d of S12911 for 104 weeks. Five-micron thick sections were prepared and stained with von Kossa stain and McNeal counterstain. Results are expressed as means ± SEM, ANOVA+ Dunnett's statistical tests were performed. Long-term treatment with S12911 significantly and dose-dependently increased (+27 to +41%) cancellous bone volume (BV/TV). The increase in BV/TV was the result of increased trabecular thickness (Tb.Th) and number (Tb.N). Trabecular separation (Tb.Sp) was significantly and dose-dependently decreased at all tested doses. The bone tissue was mainly made of mineralized tissue since osteoid volume (OV/BV) and osteoid thickness (O.Th) were similar between all groups (treated or not). In all groups, O.Th was less than 1.5µm well within the range of physiological levels, indicating no toxicity of this long-term treatment. In conclusion, trabecular bone mass and architecture are improved by long-term S12911 treatment, as shown by histomorphometric measurements. This confirms previous densitometry and biomechanical findings reported in intact and ovariectomized rats. These results, in addition to those found for cortical bone, demonstrate that S12911 possesses therapeutic potential by improving both cancellous and cortical bone.

Bone Anabolic Effects of Subcutaneous Treatment with Basic Fibroblast Growth Factor in Ovariectomized Rats. U. T. Iwaniec, K. A. Magee*, N. G. Mitova-Caneva*, T. J. Wronski. Physiological Sciences, University of Florida, Gainesville, FL, USA.

Although basic fibroblast growth factor (bFGF) is a potent stimulator of bone formation when administered intravenously, less is known regarding the effects of this agent on bone following subcutaneous administration. Therefore, the purpose of this study was to characterize the skeletal response to subcutaneous injection of high doses of bFGF in ovariectomized (ovx) rats. Female Sprague Dawley rats were ovx or sham-operated at 3 months of age and left untreated for 2 months to establish cancellous osteopenia in the ovx group. Rats (7-10/group) were then injected sc with either vehicle or bFGF at a dose of 1 mg/kg/day for 21 days. Blood was drawn at necropsy for determination of hematocrit and serum calcium and phosphorus levels. Lumbar vertebrae were collected and processed undecalcified for quantitative bone histomorphometry. Data were analyzed with the Kruskal-Wallis test followed by a nonparametric posthoc test. The level of statistical significance was set at P<0.05. All data are reported as mean±SD. Treatment of ovx rats with bFGF for 21 days had no adverse effect on body weight, a general index of the health of the animals. At termination of treatment, vehicle-treated sham rats, vehicle-treated ovx rats, and bFGF-treated ovx rats weighed 339±22 g, 353±15 g, and 355±13 g, respectively. The levels of serum calcium and phosphorus were likewise not affected by sc administration of bFGF. However, treatment of ovx rats with bFGF resulted in substantially reduced hematocrit levels in comparison to treatment of ovx and sham rats with vehicle (24±5%, 40±3%, and 39±3%, respectively). Cancellous bone volume was lower in vehicle-treated ovx rats than in vehicle-treated sham rats (31±5% vs. 37±3%, respectively). Although treatment of ovx rats with bFGF had no effect on cancellous bone volume (32±5%) in comparison to treatment of ovx rats with vehicle, osteoid volume was markedly increased in the bFGF-treated animals (8±4% vs. <0.1%). In addition, treatment of ovx rats with bFGF resulted in a 4-fold increase in osteoblast surface and an 8-fold increase in osteoid surface in comparison to treatment of ovx rats with vehicle. Osteoclast surface, an index of bone resorption, was not affected by bFGF treatment. These findings indicate that administration of high doses of bFGF via subcutaneous injection markedly increases bone formation and may be a useful treatment for cancellous osteopenia in the estrogen-deplete skeleton.

Evidence That Sensitivity to Growth Hormone (GH) is Growth Period and Tissue Type-Dependent: Studies in GH Deficient (lit/lit) Mice. Y. Kasukawa, R. Guo*, D. J. Baylink, S. Mohan. J.L. Pettis VAMC, Loma Linda, CA, USA.

Based on past findings that the magnitude of GH effects on the activation of its intracellular signaling molecule, STAT-5, in liver is age-dependent, we proposed that the effect of GH to increase peak BMD is growth period dependent. To evaluate this hypothesis, the GH-deficient lit/lit mouse, which exhibits deficiency in both endocrine and local IGF-I actions, was used as a model. GH (4 mg/kg body wt./day) or vehicle was administered three times a day during the prepubertal and pubertal (day 7-34), pubertal (23-34), post pubertal (42-56) and adult (day 204-217) periods and their effects on the musculoskeletal system were evaluated by DEXA and pQCT. GH treatment during different periods significantly (P<0.001) increased total body BMC (47-90%), BMD (7-15%), bone area (37-62%) and lean body mass [LBM] (52-85%) and decreased % fat (27-56%) compared to vehicle. As indicated by the range in the brackets, the magnitude of change varied markedly depending on the treatment period. The net gains in total body BMC (5.8 mg/day) and BMD (0.3 mg/cm^2/day) were greatest when GH was administered between days 42-55 compared to other periods. Accordingly, net gain in femur total volumetric BMD (PQCT) was significantly greater (P<0.001) when GH was administered between days 42-55 compared to other growth periods, which was due to greater increase in cortical thickness during this period. The above time-dependent BMD changes imply that the critical metabolic pathways for GH responsiveness are maintained for only a short time during growth. In contrast to changes in BMD, the net loss in % body fat was greatest (-1.3%/day) when GH was administered between days 204-216 and least when GH was administered between days 7-35 (-0.15% day). To determine if GH-induced anabolic effects on musculoskeletal system are maintained after GH withdrawal, we performed DEXA measurements 3-7 weeks after stopping GH treatment. The increases in total body BMC, BMD and LBM but not the decrease in body fat were sustained after GH withdrawal. Summary: 1) GH treatment increased bone accretion and LBM but decreased % body fat in GH deficient mice. 2) The net change in bone accretion was greatest when GH was administered immediately after puberty while net change in % body fat was greatest when GH was administered during adult period. 3) Maintenance of GH-induced changes in target tissues after GH withdrawal was dependent on tissue type. Conclusions: 1) Sensitivity to GH in target tissues is growth period and tissue type-dependent. 2) Continuous GH-treatment is necessary to maintain body fat loss but not BMD gain (Supported by the Department of the Army [DAMD17-97-2-7016] but does not reflect the position/policy of the government).

Apomine, a Novel Bone Anabolic Agent, Stimulates Bone Formation and Is Hypocholesterolemic in a Mouse Model. Y. Guyon-Gellin*, P. Latin*, P. Villemin*, E. J. Niesor*. Biosciences and Pharmacology, Ilex Oncology Research, Versoix, Geneva, Switzerland.

Apomine is a novel bisphosphonate ester currently in phase II clinical trials. Previous studies have demonstrated that Apomine inhibits cholesterol synthesis *in vitro* and decreases cholesterol levels in various rodent and non-rodent species by increasing the rate of HMG-CoA reductase degradation. Furthermore, Apomine was shown to decrease HMG-CoA reductase mRNA in bone after oral administration in mice. Both statins and nitrogen-bisphosphonates such as risedronate, which inhibit different steps of the mevalonate-isoprenoid -cholesterol (MIC) synthetic pathway, affect bone formation in rodent models. Since the statins have been shown to display bone anabolic activity, Apomine (50, 100, and 200 mg/kg, in the diet) was tested for similar activity in a model of normal mice treated for a 5 weeks period. Changes in bone parameters were measured by pQCT in the right femur to assess the bone anabolic activity of Apomine. Apomine increased trabecular bone mineral content (BMC) by +15%, +33%, and +40% with 50, 100, and 200 mg/kg, respectively. Trabecular density was increased with a similar pattern. In the cortical femur, Apomine increased BMC by +10%, +22%, and +17%. Cortical thickness was increased by +8%, +14%, and +15%, and polar moment of inertia (PMI) was increased by +8%, +20%, and +21% at doses of 50, 100, and 200 mg/kg, respectively. Furthermore, Apomine decreased plasma cholesterol by -22% and -35% with 100mg/kg and 200 mg/kg, respectively. Risedronate (100 mg/kg, in the diet) was used as the reference drug to validate the mice model and was shown to increase trabecular BMC, cortical BMC, cortical thickness, and PMI without hypocholesterolemic activity. These results suggest that Apomine increases bone mass, improves indices of stiffness, and simultaneously lowers plasma cholesterol in mice after a 5 weeks oral administration period.

S12911 Treatment Maintains Bone Mineral Crystal Characteristics. S. Cazalbou*, C. Combes*, C. Rey*. Equipe PCP, ENSIACET, CIRIMAT UMR 5085, Toulouse, France.

S12911 (Protos®) is currently being developed as a treatment for osteoporosis. The aim of the present study was to analyze the effect of S12911 treatment on bone mineral characteristics and ionic exchanges at the mineral level. Female *Macaca fascicularis* monkeys were separated into 4 groups, receiving 0, 200, 500, and 1250 mg/kg/day of S12911 (strontium ranelate), respectively. At the end of 52 weeks of treatment, 4 animals were sacrificed in each group, and 2 animals were sacrificed after a 10 week reversibility period. The analysis of bone mineral crystals was performed on powdered samples of the humeral diaphysis and epiphysis using chemical measurements for the Ca, P, Sr, and CO_3 content, X-ray diffraction for determination of crystalline phases and mean size of crystals, and Fourier transform infrared (FTIR) spectroscopy for evaluation of fine structural characteristics. Furthermore, diaphysis

samples underwent an exchange test (bone powder added to a solution of $Ca(NO_3)_2$ for 30 min). Analysis of bone powders before and after exchange was carried out by the three techniques previously described and allowed to obtain a Sr exchange rate. S12911 treatment induced a dose-related increase in the bone Sr content. Preferential Sr uptake (around 2.5 fold) was observed in the epiphysis compared with the diaphysis. After the reversibility period, Sr release was greater in the epiphysis than in the diaphysis. These differences were due to higher bone turnover, higher mineral reactivity due to the amount of labile environment, and better contact with body fluids for the epiphysis than for the diaphysis. Similar Sr content ratios between epiphysis and diaphysis were found in all animals, indicating that Sr incorporation into the different tissues was strongly correlated. Bone Sr incorporation did not lead to any modification of the stoichiometry and crystal size. No modification of the amount of nonapatitic environments of PO_4, CO_3, and HPO_4 was noted by FTIR spectroscopy. The exchange test demonstrated a slight constant exchange rate of 9 to 12% Sr incorporated in the diaphysis. This rate was independent of the treatment dose and bone mineral Sr content, indicating that this easily bone exchangeable Sr was located in labile hydrated nonapatitic environments, on the crystal surface. After the reversibility period, this Sr exchange rate decreased. After the ionic exchanges test, no modification was noted in crystal characteristics. This data, which indicates that Sr incorporation is preferential into bones with high turnover and takes place partly on the crystal surface, demonstrates the safety of S12911 maintaining mineral crystal characteristics during and after treatment.

Differential Feedback Regulation of HMG-CoA Reductase mRNA in Bone and Liver: Studies with Apomine. M. Montjovent*, D. Masson*, P. Latin*, O. Maurhofer*, Y. Guyon-Gellin*, E. J. Niesor. Biosciences and Pharmacology, Ilex Oncology Research, Versoix, Geneva, Switzerland.

Apomine is a novel bisphosphonate ester that increases the rate of degradation of HMG-CoA reductase in the hepatoma (HepG2) and osteosarcoma (Saos-2) derived cell lines. Furthermore, *in vivo*, Apomine decreases plasma cholesterol and increases bone mineral content and density in mice. Preliminary *in vitro* experiments using microarray technology have shown that the expressions of different genes involved in cholesterol metabolism such as farnesyl diphosphate synthase, isopentenyl-diphosphate delta isomerase, and lanosterol synthase were strongly up-regulated by Apomine treatment of HepG2 cells. In contrast, their expressions did not change in Saos-2 cells, suggesting that liver and bone cells respond differently to inhibition of the mevalonate-isoprenoid-cholesterol (MIC) pathway. The hypothesis was then tested *in vivo* in tissues from mice treated with Apomine. Male mice were administered Apomine (100 mg/kg in diet) for 1, 2, and 3 days. HMG-CoA reductase mRNA was measured in livers and tibiae by quantitative RT-PCR. As expected from the hypocholesterolemic activity, HMG-CoA reductase mRNA was consistently increased in the liver (>100%). Surprisingly, in the same animals, HMG-CoA reductase mRNA was significantly decreased (from -19% to -51%) in bone tissues after 1, 2, and 3 days. The decreased expression of HMG-CoA reductase mRNA in bone was maintained in animals treated for a longer period (2 and 3 weeks), whereas HMG-CoA reductase mRNA in livers of the same animals was significantly increased (+117% to +131%). Thus, liver and bone tissues respond differently, and in an opposite manner, to the inhibition of the MIC pathway produced by Apomine. These results support the hypothesis that bone tissues might not be able to upregulate the MIC pathway and thus might be exquisitely sensitive to inhibitors of various steps of this pathway.

Pharmacological Profile of Apomine, a Bone Anabolic Drug that Induces HMGCoA reductase Degradation. E. J. Niesor[1], D. Masson*[1], M. Montjovent*[1], N. Lameloise*[1], Y. Guyon-Gellin*[1], S. Van Dijk[2], S. Weitman*[2], C. L. Bentzen[3]. [1]Biosciences and Pharmacology, Ilex Oncology Research, Versoix, Geneva, Switzerland, [2]Ilex Oncology, San Antonio, TX, USA, [3]Ilex Oncology Research, Versoix, Geneva, Switzerland.

The Mevalonate-Isoprenoid-Cholesterol (MIC) synthetic pathway plays an important role in the regulation of both osteoclastic bone resorption and osteoblastic bone formation as demonstrated by studies on the mechanism of action of nitrogen bisphosphonates and statins. Apomine a novel tetra-isopropyl bisphosphonate ester, under development, inhibits the MIC pathway in liver (HepG2) and osteoblast (Saos2) derived cells by the unique mechanism of increasing the rate of degradation of HMGCoA reductase. This activity is observed even in the presence of statins and in a statin-resistant cell line, LP-90 (IC50 10nM). Apomine, at hypocholesterolemic doses, was shown to increase bone formation in normal mice. No changes in plasma cholesterol were observed in mice treated with simvastatin or risedronate, which inhibit the MIC pathway at different steps, or by different mechanisms. *In vitro* and *in vivo* studies demonstrated that the inhibition of cholesterol synthesis produced by Apomine triggered the expected positive feedback on enzymes of the MIC pathway (ie HMGCoA red mRNA) in HepG2 cells and in liver tissue from treated animals. Surprisingly, this feedback was not observed in Saos2 cells incubated with Apomine and in bone from mice treated orally with Apomine. Apomine displays both antiproliferative and bone anabolic activities and prevents bone metastasis of breast cancer cell in mice receiving intracardiac injection of MDA-MB-231 cells. The potential bone anabolic activity of Apomine was investigated in Cynomolgus monkeys receiving 25mg/kg/day of Apomine orally for 3 weeks. The plasma marker of osteoblast activity, bone alkaline phosphatase (BAP), was increased by up to 24 % ($P<0.01$). As expected from results previously obtained with the antiresorptive bisphosphonic acids, SR-92D3, the chemically de-esterified derivative of Apomine decreased BAP in this animal model. The unique pharmacological profile and good tolerance of Apomine in preclinical and clinical studies suggest that Apomine may have the potential to become a drug of choice in the treatment on cancer associated bone pathologies and osteoporosis.

pQCT Analysis of the Anabolic Effects of a Group of Novel Small Peptides on Bone in Intact Adult Rats. G. B. Schneider[1], D. T. Bui*[2], K. J. Grecco*[2]. [1]Basic Medical Sciences, Northeastern Ohio Universities College of Medicine, Rootstown, OH, USA, [2]Division of Basic Medical Sciences, Northeastern Ohio Universities College of Medicine, Rootstown, OH, USA.

We have previously demonstrated that 14 amino acid peptide fragments, based on a human sequence from the third domain of the native serum protein, vitamin D binding protein (DBP) elicit anabolic effects on the skeleton. Intermittent systemic injections of the peptides to intact, newborn and adult rats resulted in significant increases in total bone density within two weeks of treatment. A single, local injection of the same 14 a.a. peptide generated new bone at the site of injection at one week (Schneider et. al., JBMR, 16:S231). In the current study we evaluated peptide fragments ranging in length from 3 - 13 a.a. from the same region of the DBP protein in intact adult rats. Female rats were given subcutaneous injections of saline or peptide (0.4ng/g body wt.) every other day for two weeks; two days after the final injections, the rats were euthanized and the femurs and tibias collected for analysis by peripheral quantatative computerized tomography (pQCT). Specific slices through the metaphysis and mid-shaft of each bone were analyzed from the scans. The proximal tibia metaphysis and midshaft slices were representative of the skeletal responses to the various peptide fragments. The efficacy of the peptide fragments was based on their effect on total bone density. Fragments 12, 11, 10, and 4 amino acids in length demonstrated highly significant ($p < 0.001$) increases in total bone density in the proximal tibia metaphysis. All of these peptides also illustrated the same trends with respect to the other parameters evaluated: increases in cortical/subcortical bone density, decreases in total surface area and decreases in periosteal and endosteal circumferences. The effective peptides also elicited significant increases in bone density of the midshaft, but the other trends were not as prevalent. Those peptide fragments that did not increase bone density did not illustrate any consistent trends with respect to the other parameters measured. The anabolic peptides appear to be increasing bone density and decreasing the diameter and cross-sectional area of the bone. None of the peptides affected bone length, which remained consistent with the saline controls. We hypothesize that the increased bone density may be reflecting better quality bone; the decrease in cross sectional surface area may be in response to this superior quality bone. Biomechanical testing of the bones treated with the effective peptides is planned to test this hypothesis.

SU377

Discovery of Novel Dual Action Src Kinase Inhibitors Demonstrating Anti-Resorptive and Bone Formation Activities In Vitro and In Vivo. L. Xing*[1], Y. Wang*[2], R. Sundaramoorthi*[2], T. Keenan*[2], C. Metcalf*[2], W. Shakespeare*[2], R. Bohacek*[2], M. R. van Schravendijk*[2], T. Yamashita[1], T. Sheu*[1], E. Puzas[1], D. Dalgarno[2], J. Iuliucci*[2], T. Sawyer[2], B. F. Boyce[1]. [1]University of Rochester, Rochester, NY, USA, [2]ARIAD Pharmaceuticals, Cambridge, MA, USA.

Src is a non-receptor tyrosine kinase required for osteoclast (ocl) activation and bone resorption. In addition to its required role in osteoclasts, Src also negatively regulates osteoblast (obl) function. Thus, it is a well-validated therapeutic target for prevention and treatment of postmenopausal osteoporosis and other diseases with bone loss. To this end, we used structure-based drug design to develop a series of novel, potent (low nM IC50s) non-peptide inhibitors of Src tyrosine kinase. These small-molecule Src tyrosine kinase inhibitors incorporate bone-targeting chemical moieties that confer them with high affinity for hydroxyapatite as well as cellular selectivities (ocl and obl). Furthermore, they exhibit significant selectivity (>100-1000 fold) to inhibit Src relative to a panel of more than 30 protein kinases. AP23588 is a promising lead compound from this series of bone-targeted Src tyrosine kinase inhibitors, which possess dual action properties (anti-resorptive and anabolic activities), including: 1) inhibition of ocl resorption in vitro (pit area and number reduced by 55-97% at 1 uM), effects comparable to alendronate; 2) inhibition of PTH-induced hypercalcemia (50-100% inhibition) and bone resorption in vivo; 3) dose-dependent stimulation of alkaline phosphatase activity and mineralized bone nodule formation of fetal rat calvarial cells 2-fold after 5 and 13d treatment, respectively; 4) increased expression of obl genes (cbfa-1 and osteocalcin) detected using real-time PCR and a luciferase reporter assay; and 5) increased periosteal obl numbers and new bone formation in vivo after its injection over the calvaria of normal mice. Our findings provide evidence that these specifically designed bone-targeted Src tyrosine kinase inhibitors prevent bone loss and stimulate bone formation. Thus, they have beneficial action in bone and promising utility for the prevention and treatment of osteoporosis.

Has Treatment for Osteoporosis Improved? D. H. Solomon[1], J. Finkelstein[2], H. Mogun*[1], J. Avorn*[1]. [1]Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA, USA, [2]Endocrine, Massachusetts General Hospital, Boston, MA, USA.

Several studies have found that under-diagnosis and under-treatment of osteoporosis is common. These have generally been small surveys conducted at a single clinic or hospital and have not examined trends over time. We examined the rates of osteoporosis treatment before and after hip or wrist fracture in older adults. In a very large continuously enrolled Medicare cohort that also partcipates in a state-run pharmaceutical benefits program, we studied all patients who had undergone a procedure for and/or received a diagnosis of hip or wrist fracture during the period 1995 - 1999. Information regarding filled prescriptions was assessed to determine the proportion of patients using a prescription osteoporosis medication (HRT, calcitonin, etidronate, alendronate, risedronate, raloxifene) in the six months before and after a fracture. During the five year study period, 14,889 persons sustained a hip fracture and 10,216 had a wrist fracture. 8.7% of subjects who experienced a hip fracture filled a prescription for an osteoporosis medication in the six months prior. This increased slightly to 9.5% after the hip fracture. For wrist fracture, 9.1% had filled a prescription in the six months before and 10.8% after the fracture. The frequency of treatment increased significantly over the study period. In 1995, 3.8% of persons with either hip or wrist fracture subsequently filled a prescription for an osteoporosis medication; in 1999, 15.2% filled a prescription (P for trend < 0.001). Patient factors found in adjusted models to be associated with use of a prescription for an osteoporosis medication after a hip fracture include: female gender (OR 4.7; 95% CI 3.3 - 6.7), white race (OR 2.3; 95% CI 1.3 - 4.1), prior fractures (1.2, 95% CI 1.1 - 1.5), fewer comorbid conditions (OR 1.2 ; 95% CI 1.0 - 1.4), and fewer hospitalizations in the prior year (OR 1.5; 95% CI 1.1 - 1.9). In this large community-based cohort, the proportion of persons receiving prescription osteoporosis treatment after hip or wrist fracture is sub-optimal. Trends suggest a slight improvement. Several factors are associated with filling osteoporosis prescriptions. These data can help in the design of quality improvement programs for the management of osteoporosis.

Risedronate Improves Quality of Life in Women with Osteoporosis After 6 Months: Results from a Prospective Cohort Study. J. Semler*[1], F. Raue[2], A. Grauer[3], S. Eggenweiler*[4]. [1]Immanuel Krankenhaus, Berlin, Germany, [2]Endocrine Practice, Heidelberg, Germany, [3]Procter & Gamble Pharmaceuticals, Geneva, Switzerland, [4]Procter & Gamble Pharmaceuticals, Weiterstadt, Germany.

The impairment of quality of life is an important consequence of osteoporosis. Risedronate has been shown to significantly reduce the risk of morphometric vertebral fractures in one year and the risk of clinical vertebral fractures after only 6 months of treatment in patients with postmenopausal osteoporosis. We conducted a large, prospective cohort study to confirm the efficacy and safety of risedronate 5mg/d therapy for the prevention or treatment of postmenopausal or glucocorticoid-induced osteoporosis. A total of 2739 office-based physicians in Germany enrolled 9188 patients into the study. We report here the results on changes in patients' quality of life during 6 months of risedronate treatment. Patients were asked to submit a completed quality of life questionnaire (short OQLQ)[1] before initiation and after 6 months of treatment. The questionnaire assessed 5 domains of quality of life (symptoms, physical function, activities of daily living, emotional function, leisure) with two questions per domain. A set of seven graded response options per domain was offered to the patients to record their answers. Median age of the patients in the trial was 68.7 years, 3342 (36.4%) of the patients had evidence of vertebral fractures at baseline. 4887 (53.2%) patients completed the first questionnaire, 6394 (69.6%) of the patients completed the second, a total 4413 (45.1%) patients completed both questionnaires and were therefore included in the quality of life analysis. After six months of treatment, there was a significant improvement in the overall quality of life (p<0.001, Wilcoxon-Rank test, two-sided), and in each of the domains individually (p<0.001, Wilcoxon-Rank test, two-sided). The results of this large cohort study show a significant improvement in quality of life parameters after only 6 month of risedronate treatment - the same time period in which a significant clinical vertebral fracture reduction has been demonstrated in clinical trials.

Bone Health Behaviors and Self-Efficacy: An Analysis Based on *Choices* FOR BETTER BONE HEALTH™. S. L. Silverman[1], D. T. Gold[2], M. K. Conditt*[3], B. E. Miller[3]. [1]Cedars-Sinai, Los Angeles, CA, USA, [2]Duke University, Durham, NC, USA, [3]Procter and Gamble, Mason, OH, USA.

Osteoporosis self-management is effective when women adhere to four bone health behaviors (taking medicine, taking calcium and vitamin D, exercising, and managing chronic pain). We studied the self-efficacy (belief that one can do the behavior) for each of these four bone health behaviors using baseline data from 72 ambulatory community dwelling women at four centers nationally participating in the beta and gamma tests of *Choices* FOR BETTER BONE HEALTH™ , an osteoporosis self-management program (mean age= 72.5 yrs ± 7.9). (1) We hypothesized that the belief that a woman could do any health behavior would be strongly correlated with her belief about a second health behavior. This was true for exercise and taking medication (r=0.27, p=0.02), exercise and managing pain (r=0.45, p=0.0001), taking CA/Vit D and taking medication (r=0.33,p=0.005) but was not seen for exercise and taking CA/Vit D (r=0.13, NS). (2) We hypothesized that psychosocial factors influence patients' beliefs that they can do bone health behaviors. Belief that one could cope with negative feelings was significantly correlated with beliefs that one could take medication (r=0.48, p<0.0001), exercise (r=0.27, p=0.02), take CA and Vit D (r=0.29, p=0.015) and manage pain (r=0.45, p<0.0001). (3) We hypothesized that those women who believed that osteoporosis was treatable would also believe that they could do each of the bone health behaviors. Believing that one could make one's bones healthier was significantly correlated with beliefs that one could exercise (r=0.55, p<0.0001), beliefs that one could manage pain (r=0.39, p=0.0036), beliefs that one could take meds (r=0.38, p=0.0005) and beliefs that one could take enough CA and Vit D (r=0.31, p=0.02). (4) In a subset of women (n=17) in the gamma test, we also studied the relationship between beliefs and self-report of the behavior. Correlations varied depending on the behavior: Calcium (r=0.77); Vit D (r=0.22); exercise (r=0.02); and managing pain (r=0.05).We conclude that: (1) Patients who believe they can do one bone health behavior believe they can do most other bone health behaviors,(2) psychosocial factors play an important role in adherence to bone health behaviors such as taking osteoporosis medication, (3) belief that osteoporosis is treatable is significantly correlated to beliefs about ability to do bone health behaviors, and (4) beliefs about a bone health behavior and the report of the performance of the behavior are not always highly correlated. Our study confirms the importance of self-efficacy beliefs in self-management of osteoporosis.

Differences and Similarities in Generic HRQoL of Osteoporosis and other Chronic Diseases in Postmenopausal Women in a Population Based Multicenter Study. M. G. Glüer*[1], D. M. Reid[2], C. C. Glüer[3], B. Stampa[4]. [1]Center for Biotechnology and Nutrition, Kiel, Germany, [2]University of Aberdeen, Aberdeen, United Kingdom, [3]University Hospital Kiel, Kiel, Germany, [4]Synarc A/S, Hamburg, Germany.

Although there are now data demonstrating the impact of osteoporosis on Health Related Quality of Life (HRQoL) these data are mostly derived from evaluation studies of osteoporosis specific questionnaires and pharmaceutical trials where patients are selected by distinct criteria. This is to our knowledge the first study that investigates these issues in a population based study (OPUS: Osteoporosis and Ultrasound study) with centers in Germany, Great Britain and France. We investigated in 2374 postmenopausal women (age range 55 to 79 years) self-reported disease and generic HRQoL, employing the SF12 and two items according to the Euroqol thermometer regarding health and HRQoL (0: dead to 100: best HRQoL). We categorized 5 major disorders (Osteoporosis: n=142, Angina Pectoris: n=107, Asthma: n=126, Cancer: n=97, Rheumatoid Arthritis (RA): n=76, total: n=548) according to self reported disease status. Women suffered from only one of the five selected disorders but may have had other health problems in addition. Patients with osteoporosis did not differ from patients with other disease groups in terms of the physical and mental function or with regard to overall Quality of Life and health perception. Except for the Mental Health domain of the SF12, HRQoL of osteoporotic patients was poorer than the rest of the sample ("Other', n=1782). This is particularly interesting because these groups are not necessarily entirely healthy but might suffer from chronic disease other than the five specified.

	SF12 physical	SF12 mental	Euroqol Health	Euroqol QOL
Osteoporosis	41.5±10.6 (n=133)	48.7±9.6 (n=133)	69.8±17.0 (n=137)	65.50±26.1 (n=136)
Cancer	44.6±9.3 (n=91)	51.3±8.9 (n= 91)	73.9±16.9 (n=94)	71.1±25.0 (n=95)
Asthma	42.2±11.0 (n=124)	48.1±10.2 (n=124)	70.7±18.8 (n=124)	69.8±23.4 (n=122)
Angina	41.0±10.5 (n=102)	48.6±10.2 (n=102)	68.9±18.8 (n=104)	67.2±25.8 (n=104)
RA	41.5±10.9 (n=73)	50.2±10.1 (n=73)	69.8±15.1 (n=74)	66.5±23.9 (n=73)
Other	45.7±10.1* (n=1750)	49.9±10.1 (n=1750)	74.1±16.8* (n=1782)	72.5±22.7* (n=1782)

* "Osteoporosis' vs. 'Other' p<0,05

Quality of Life is reduced in women with osteoporosis to a similar degree as in those with cancer, asthma, angina pectoris and RA. It is significantly lower than in study participants without these five disorders. These data need to be confirmed in an independent population database.

SU382

Parathyroid Hormone (PTH) and Alendronate in the Treatment of Osteoporosis: PaTH Trial Update. D. M. Black[1], C. M. Rosen[2], S. Greenspan[3], K. Ensrud[4], J. Bilezikian[5], T. Hue[1], J. McGowan[6]. [1]University of California San Francisco, San Francisco, CA, USA, [2]University of Maine, Bangor, ME, USA, [3]University of Pittsburgh, Pittsburgh, PA, USA, [4]University of Minnesota, Minneapolis, MN, USA, [5]Columbia University, New York, NY, USA, [6]National Institutes of Health, Bethesda, MD, USA.

The PaTH study's primary aim is to evaluate the efficacy of a rhPTH (1-84, 100 microgram/day) and alendronate (10 mg/day) combination therapy for osteoporosis on bone mineral density (BMD) and bone markers. PTH, an anabolic therapy, has been shown to increase BMD and prevent bone loss. PTH 1-34 has recently been shown to reduce fracture

risk. It is not known to what extent combination therapy of an anabolic agent with an anti-resorptive agent, such as alendronate, will be beneficial. Enrollment for PaTH was completed in September 2001. A total of 238 postmenopausal women with low BMD and a risk factor for subsequent fracture, were enrolled in a double-blind, randomized clinical trial, and will be followed for 2 years at 4 clinical centers in the U.S. The women were randomly assigned to 1 of 4 treatment groups: PTH alone, alendronate alone, PTH followed by alendronate and PTH concurrently with alendronate. PTH or its placebo is given only in the first year. The main endpoints include BMD measured by dual energy x-ray absorptiometry and biochemical markers of bone turnover. As of April 1, 2002, the median follow-time is 9 months and 94 (39%) have completed one year of treatment. The last patient will complete the first year in early September 2002. An analysis of the one-year data will be performed at that time and completed by January 2003. Adherence to protocol has been high. 81% of participants are still taking study injections and 88% are still taking study pills. About 97% are still participating in follow-up visits. In addition to the main study endpoints, we have instituted a number of ancillary studies including the effect of PTH/alendronate on spine and hip quantitative computed tomography (QCT) and ultrasound (Sahara). We are also studying the short-term effect of PTH/alendronate on serum calcium and on blood pressure. It is expected that this study will help to answer some of the important clinical questions about the optimal combination of PTH and anti-resorptive therapy.

SU383

Monthly Intravenous Pamidronate Is a Safe and Efficacious Treatment for Patients with Osteogenesis Imperfecta. I. Fujiwara[1], E. Ogawa*[1], Y. Igarashi*[2], K. Kojima*[1], Y. Katsushima*[1], K. Iinuma*[1]. [1]Pediatrics, Tohoku University School of Medicine, Sendai, Japan, [2]Igarashi Pediatric Clinic, Sendai, Japan.

Treatment with bisphosphonates are suggested to increase bone mineral density (BMD) and decrease fracture frequency in patients with osteogenesis imperfecta (OI). Effectiveness of intravenous (IV) pamidronate in cycles of 3 consecutive days with 3 to 4-month intervals is reported, though patients require hospitalization during the treatment. We show efficacy of monthly IV pamidronate at clinics for the period of 6 and 12 months for patients with OI type I/IV and OI type III, respectively. Fourteen patients with OI (7 with type I, 1 with type II, 5 with type III, 1 with type IV) were treated with monthly IV pamidronate (initial dose of 0.6 - 1.1 mg/kg) at the age from 1 month to 13 years (average 6 years and 9 months old). Pamidronate was administered at clinics except newborn patients. Lumbar bone mineral density (BMD) was measured by DXA and serum alkaline phosphatase (ALP) and urinary deoxypyridinoline (Dpyr) were analyzed before and after the treatment. Average fracture rate decreased from 5.3 to 1.1/year after IV pamidronate (p=0.037). Standard deviation (SD) scores of BMD for age significantly increased in both type I/IV (-3.38 to -2.18, p=0.018) and type III (-5.69 to -4.03, p=0.0002) after 6 and 12 months of treatment, respectively. BMD tended to sustain after cessation of the treatment, then they started to decline 12 months (type III) and 18 months (type I) after the therapy. Seven patients were re-treated because of significant decrease in BMD or increased fracture rate 14 to 103 (median 20) months after the cessation of the treatment. Dpyr showed a marked decline 1 week after the first treatment (43.7 % of baseline level [BL]), returned to the BL at 1 month in some patients, and stayed around 70 % of BL. ALP gradually decreased to 60 % of BL at 6 months after the treatment (p=0.026). Transient fever after the initial treatment in 6/14 and hypocalcemia in 2/14 were mild adverse effects observed. Respiratory distress deteriorated after pamidronate in a type II patient. Linear growth was not disturbed by the treatment in type I patients. These data suggested that monthly IV pamidronate at clinics is safe and effective for patients with OI who are without respiratory symptoms.

SU384

Identification of a Novel Splice Site Mutation in RUNX2 Gene causing Korean Cleidocranial dysplasia. H. Kim*[1], M. Hwang*[1], R. Park*[1], I. Kim[1], A. J. Van Wijnen[2], J. L. Stein[2], J. B. Lian[2], G. S. Stein[2], J. Choi[1]. [1]Biochemistry, Kyungpook Natl. Univ. School of Medicine, Daegu, Republic of Korea, [2]Cell Biology, Univ. of Massachusetts Medical School, Worcester, MA, USA.

Cleidocranial dysplasia (CCD) is an autosomal dominant disorder characterized by patent sutures and fontanelles, hypoplasia of clavicles, supernumerary teeth, short stature and other skeletal deficiencies. Haploinsufficiency of the RUNX2 gene results in a CCD. Each mutation of RUNX2 gene in CCD provides an opportunity to understand the pivotal role of RUNX2 gene during bone growth and development. In this study, we analyzed the coding region and 5'- and 3'-untranslated region of RUNX2 gene in five Korean CCD patients using PCR and direct sequencing. Clinical feature was taken by X-ray and photographs of the affected family members. The mutation of three different types was detected. One of them was a novel mutation and others were reported previously. First, we identified a novel exon1 splice donor site mutation (donor splice site GT → AT) at exon1- intron junction. Using RT- PCR, we found that this exon was skipped in affected patient. Second was a heterozygous C- to -T transition in exon7 leading to a translational stop codon in codon 391. Third, was missense mutation at arginine 225 (R225Q; CCG → CTG) in two patients. One case, we could not find any mutation in promoter (up to 755 bp from ATG translation start site), 5'-UTR, coding region and 3'-UTR. There was no difference in severity of phenotypes among patients with identified mutations. The novel splice donor site mutation will provide a useful window to understand how RUNX2 plays its role during bone growth and differentiation.

SU385

Bone Structure and Strength and Muscle-Bone Interactions in 15 Children with Osteogenesis Imperfecta (O.I.). A pQCT Study. E. J. A. Roldán[1], J. L. Ferretti[2], G. R. Cointry*[2], C. Tau[3]. [1]Dept. of Clinical Pharmacology, Gador SA, Buenos Aires, Argentina, [2]CEMFoC, Natl. Univ. of Rosario, Rosario, Argentina, [3]Dept. of Calcium Metabolism, Pediatric Hospital, Buenos Aires, Argentina.

This study analyzes the skeletal status and muscle-bone relationships in 5 boys and 10 girls aged 2-16 years with untreated type I (5), III (5) and IV O.I. (5) and 31 3-21-year controls. The cross-sectional bone area (CSA) and vBMD (attenuation threshold = .710 cm^{-1}), and the moments of resistance and Stress-Strength Indices (SSI's) for bending and torsion of the tibia, and the whole- and fat-free CSA's of the calf muscles were measured by pQCT (XCT-3000, Stratec) at the standard, 66% site of the leg. The vBMD, increasing with age in controls, remained around 900 g/cm^3 showing great dispersion in the O.I. children, corresponding the lowest values to type IV. Bone CSA and SSI's increased with age in controls an more slowly in type I O.I., remaining constantly low in types III-IV. The *"mass/accumulation" curves* between bone CSA (*y*) and vBMD (*x;* usually negative hyperboles) plotted higher for control than O.I. children, these showing no significant slope. Bone CSA and SSI's increased with mobility score, a variable affected by the O.I. type. Both bone CSA and SSI's increased in all groups with the fat-free muscle CSA, more in control than in O.I. children. The whole O.I. group showed single slopes with increasing values of both variables for types IV < III < I. The vBMD of all the O.I. children increased logarithmically with the muscle CSA's, reaching normal values at approximately 600 mm^3 of fat-free muscle CSA regardless of O.I. type. The fat-free/whole muscle CSA ratio decreased in the order: controls > type I O.I. > types III-IV O.I. Fracture incidence rate decreased exponentially with SSI's and mobility score in O.I. children of all types together. This shows that untreated O.I. children (specially types III and IV) are unable to improve compact vBMD, mass and strength with age, presumably because of both, mass/architecture and mineralization defects (low bone formation, enhanced intracortical porosity by disuse-mode remodeling) in proportion with muscle weakness. These effects could be associated with shifts in the mechanostat setpoints for triggering bone modeling and disuse-mode remodeling. Despite that pQCT determinations neglect the mineralization-unrelated, microstructural factors which are affected in O.I., the SSI's predicted adequately the fracture incidence in O.I. children.

Fracture Repair in Fibrous Dysplasia of Bone: Evidence for Local Segregation and Dynamic Selection of Disease Genotype. M. Riminucci[1], A. Corsi*[1], E. Ippolito*[2], P. Gehron Robey[3], P. Bianco[4]. [1]Medicina Sperimentale, Università dell'Aquila, L'Aquila, Italy, [2]Orthopedics, Universita Tor Vergata, Rome, Italy, [3]Nidcr, csdb, NIH, Bethesda, MD, USA, [4]Medicina Sperimentale e Patologia, Universita La Sapienza, Rome, Italy.

Fibrous dysplasia (FD) is a skeletal disease caused by postzygotic mutations of the Gs alpha gene and characterized by the growth of a pathologic osteogenic tissue at a single (monostotic) or multiple (polyostotic) skeletal sites. In long bones, FD is known to occur as medullary lesions, usually sparing the outer cortical bone. Pathological fractures represent a common complication of FD. We have investigated the repair process at four fracture sites in three patients with FD who underwent corrective surgery at 1, 3, 4 and 12 weeks after a long bone (femur and humerus) fracture. The histology was correlated to mutation analysis separately conducted for different histological components of the samples. The latter consisted in osteotomies depicting the intramedullary FD lesion, the subperiosteal repair reaction, and the periosteum, in an orderly spatial sequence. Reparative changes within the FD tissue proper consisted of an enhanced but dysplastic osteoid-formation activity, whereas reparative changes at subperiosteal sites were indistinguishable from normal ones. Histologically, the periosteal reaction consisted of formation of BSP-enriched lamellar bone deposited by morphologically normal osteoblasts, whereas the repair of fibrous dysplastic bone was noted for an excess deposition of BSP-deprived osteoid by morphologically abnormal osteoblasts. R201 mutations were demonstrated in all samples obtained from the FD lesions proper. In contrast, the disease genotype was not detectable (by DNA sequencing of the relevant PCR product) in the periosteum overlying the fracture, analyzed in 2/4 patients. In one of these, however, the mutation could be detected in the histologically normal subperiosteal bony callus (generated by periosteal cells), and in stromal cells isolated in culture from the callus. Our data show that a) the disease genotype is undetectable by standard methods in the periosteum overlying a mutation-positive FD lesion, indicating a spatial segregation of mutated cells across periosteum vs endosteum of the same bone region, b) proliferative events induced by a fracture, leading to the formation of a subperiosteal callus, positively select mutated cells, without necessarily leading to the deposition of FD bone. These data suggest that dynamic events of local selection of cells carrying the disease genotype are of critical importance in the pathophysiology of FD lesions and their complications.

SU387

Onset of Fibrous Dysplastic Lesions Is Related to the Skeletal Site of Involvement. J. S. Lee[1], N. Ziran*[2], C. Chen*[3], A. I. Leet[1], S. Wientroub[4], P. G. Robey[1], M. T. Collins[1]. [1]Craniofacial/Skeletal Diseases Branch, NIDCR/NIH, Bethesda, MD, USA, [2]Dept Orthopedic Surg, Univ of Rochester, Rochester, NY, USA, [3]Diag Rad/Nuc Med, NIH, Bethesda, MD, USA, [4]Dept of Ped Orthopedic Surg, Dana Children's Hosp, Tel Aviv, Israel.

Fibrous dyplasia of bone (FD) caused by post-zygotic activating mutations of GNAS1 is a slowly progressing skeletal condition. Years of follow-up are required to discern subtle changes in physical appearance. Additionally, unless a fracture in long bones or an expanding cyst associated with FD brings attention to the skeletal problem, detection of skeletal FD may be incidental and detected at a later age, especially in cases of monostotic FD. Thus, it is not clear when FD lesions occur, if a patient is born with lesions and if new lesions occur throughout life. Without question, FD lesions can expand to adjacent bones but understanding the onset of lesions may establish appropriate timing for medical therapy (before onset of lesions and skeletal deformity) or surgical therapy (after lesions stabilize; no new lesions develop). In a unique instance, the opportunity to evaluate patients for FD lesions at an early age occurs when patients are found to have precocious puberty (PP) in the setting of McCune-Albright syndrome (MAS). The aim of this study was to evaluate when and where FD lesions occur in patients with MAS. 9 female patients were included in this study. MAS was detected by onset of PP (menses or development of secondary sex characteristics before age 8); bone scans confirmed presence of FD. Serial bone scans were obtained for at least 4 years. The skeletal system was divided into craniofacial (CF) (8), axial (10), and extremity (18) sites. For the initial bone scan, mean chronological age was 4.7 (2.3-8.4); mean bone age was 7.5 (2.5-12.0). Average number of years between initial and latest bone scans was 11.3 (6.5-18.3). Average number of bone scans per patient was 4 (3-6 scans). In all cases, CF lesions were the earliest detected. When comparing the total number of lesions in the latest bone scans and the age at which the total number was reached, the number of CF lesions was established by the mean chronological age of 10.2 (3.6-20.1). The total number of extremity lesions was established by the mean chronological age of 13.4 (9.9-20.1). Total number of axial lesions was established by the mean chronological age of 15.1 (9.9-21.2). CF FD lesions appear earlier than in other regions, followed by those in extremities, and then in axial bones. In the context of MAS/PP, these results highlight the importance of early screening for skeletal lesions and initiation of appropriate therapy. This study also demonstrates the high occurrence of CF and axial lesions which had previously been considered infrequent.

Genetic Heterogeneity of Paget Disease of Bone in French-Canadian Families. S. Auger*[1], N. Laurin*[1], J. P. Brown[2], V. Raymond[1], J. Morissette*[1]. [1]Endocrinologie moléculaire et oncologique, Centre de recherche du Centre Hospitalier de l'Université Laval (CHUL), Quebec, PQ, Canada, [2]Groupe de recherche en maladies osseuses, Rhumatologie-immunologie, Centre de recherche du CHUL, Quebec, PQ, Canada.

Paget disease of bone is characterized by focal increases of the bone remodeling process. Genetic factors play a major role in the etiology of the disorder. Seven susceptibility loci have been mapped for the disease. Six are known as *PDB1* to *PDB6*. There is also one, as yet unnamed, locus at chromosome 18q23. We previously reported the mapping of 11 French-Canadian families affected by autosomal-dominant (AD) Paget disease to *PDB3* at 5q35-qter and the linkage of 2 other kindreds to *PDB4* at 5q31. We recently characterized the gene causing Paget disease at *PDB3* as Sequestosome1 (*SQSTM1/p62*). In the present study, we tested 10 additional pedigrees (104 individuals) for linkage at *PDB3*, *PDB4*, *PDB5* (2q36) and *PDB6* (10p13) using a total of 36 microsatellite markers. For linkage analysis, 25 subjects were considered affected, 10 unknown and 69 normal. Two-point and multipoint linkage analyses were performed assuming an AD mode of inheritance with incomplete penetrance. Two markers at *PDB3*, NL5 and D5S2073, showed positive two-point lodscores of 0.53 (θ=0.2) and 0.66 (θ=0.1), respectively. Parametric multipoint analysis, however, revealed lodscore values below -3 across the locus. For *PDB4*, two-point lodscore values below -2 were obtained for all 14 markers spanning 14 cM and multipoint analysis gave values below -4 over the region, showing evidence against linkage. For *PDB5* and *PDB6*, the summated two-point lodscore values were below -2 for 3 of 4 markers spanning 50 cM of each region. Multipoint lodscore values between -1 and -3 were obtained for both regions. These results did not support linkage of our families to any of these regions. When analyzed individually, a few families showed positive lodscore values to one or more region. In the majority of these kindreds, no haplotype cosegregated with the disease phenotype. Some families were too small to show evidence for or against linkage to any specific locus. As linkage to *PDB3* could not be excluded in some families, affected individuals of the 11 pedigrees were screened for mutations in the *SQSTM1/p62* coding region. No mutation segregating with the disease was detected in these families. Our study demonstrated that the *PDB5* and *PDB6* loci do not represent important loci for French-Canadian pagetic families who do not show linkage to *PDB3* or *PDB4*. These data therefore suggest that additional loci may be associated with Paget disease of bone in our population.

SU389

Role of TAF_{II}-17 in the Enhanced 1,25-Dihydroxyvitamin D_3 Responsivity of Osteoclast (OCL) Precursors from Paget's Disease. N. Kurihara[1], S. V. Reddy[1], J. Cornish[2], G. D. Roodman[1]. [1]Medicine, University of Pittsburgh, Pittsburgh, PA, USA, [2]Medicine, University of Auckland, Auckland, New Zealand.

We reported that bone marrow cells from patients with Paget's disease express measles virus nucleocapsid (MVNP) transcripts. Interestingly, expression of the MVNP gene in normal OCL precursors resulted in formation of OCL that shared many characteristics of OCL from Paget's patients (JCI 105, 607-614, 2000), including forming OCL at physiologic concentrations of 1,25-$(OH)_2D_3$, which were 1-2 logs less than required for normal OCL formation. Furthermore, MVNP transduced normal OCL precursors expressed high levels of TAF_{II}-17, a VDR binding peptide. Increased levels of TAF_{II}-17 were also present in pagetic OCL precursors. We hypothesized that the enhanced sensitivity of pagetic OCL precursors to 1,25-$(OH)_2D_3$ results from induction of a specific VDR co-activator by the MVNP gene. To test this hypothesis, RT-PCR analysis of MVNP transduced normal OCL precursors and pagetic bone marrow cells treated with 1,25$(OH)_2D_3$ was performed. TAF_{II}-17 mRNA was highly expressed in both of these cell types compared to other VDR co-activators (SRC-1, CBP/p300, DRIP-205). To determine if the increased levels of TAF_{II}-17 allowed formation of transcription complexes with the vitamin D receptor (VDR) at low concentration of 1,25-$(OH)_2D_3$, CFU-GM transfected with the MVNP cDNA or empty vector (EV) were treated with 10^{-10} to 10^{-8} M 1,25-$(OH)_2D_3$, and then used in GST-VDR pull down experiments. TAF_{II}-17 bound VDR in MVNP transduced cells at very low concentrations of 1,25-$(OH)_2D_3$ (10^{-10} M). In contrast, EV transduced cells required treatment with 10^{-8} M 1,25-$(OH)_2D_3$ for the TAF_{II}-17-VDR complexes to form. Furthermore, when CFU-GM transduced with the MVNP gene or EV were cultured for 14 days in the presence or absence, of a TAF_{II}-17 antisense oligodeoxynucleotide (AS-ODN) and treated with 10^{-11}-10^{-7} M 1,25-$(OH)_2D_3$ to induce OCL formation, AS-ODN decreased the amount of TAF_{II}-17 in MVNP transduced OCL precursors and inhibited OCL formation about 40%. Addition of mismatched AS-ODN to the cultures had no effect on OCL formation or TAF_{II}-17 expression levels. These data suggest that increased expression of TAF_{II}-17 may in part be responsible for the enhanced 1,25-$(OH)_2D_3$ responsivity of pagetic OCL precursors.

SU390

Serum Osteoprotegerin and Receptor Activator Nuclear Factor Ligand (RANKL) in Paget's Disease of Bone. L. Alvarez[1], N. Guañabens[1], P. Peris[2], I. Ros*[2], T. Ferró*[3], F. Pons*[4], X. Filella*[3], A. Monegal*[2], J. Muñoz-Gomez*[2], A. M. Ballesta*[3]. [1]Metabolic Bone Diseases Unit. IDIBAPS, Hospital Clinic, Barcelona, Spain, [2]Service of Rheumatology, Hospital Clinic, Barcelona, Spain, [3]Service of Biochemistry, Hospital Clinic, Barcelona, Spain, [4]Service of Nuclear Medicine, Hospital Clinic, Barcelona, Spain.

Osteoprotegerin (OPG) and receptor activator of nuclear factor k-B ligand (RANKL) have a crucial role in osteoclast formation and activity. However their contribution to the pathogenesis of Paget's disease, a bone disorder characterized by increased bone resorption and bone formation, is unknown. Aims: To evaluate serum OPG and RANKL in patients with Paget's disease of bone and their relationship to disease activity as well as the effect of bisphosphonate therapy on their values. Patients and methods: 31 patients (18 men and 13 women) aged 62.65 ± 2.01 years, with Paget's disease were included. Serum OPG, RANKL, bone alkaline phosphatase and procollagen type I N propeptide as well as urinary N-terminal cross-linking telopeptide of type I collagen were measured at baseline and at 1 month after discontinuation of therapy with tiludronate (400 mg/day/oral x 3 months). The activity of the disease was also evaluated at baseline by quantitative bone scintigraphy. The results were compared with those of a control group of similar age (61.64 ± 1.7 years) and gender (20 men and 19 women). Results: Patients with Paget's disease showed higher mean baseline OPG values compared with those of the control group (4.11 ± 0.39 vs 2.93 ± 0.11 pM/L, p=0.002). Serum OPG concentrations decreased significantly after treatment with tiludronate (3.488 ± 0.226 pM/L, p= 0.032). RANKL values were not significantly different from those of the control group (1.07 ± 0.2 vs 1.10 ± 0.15 pM/L, p=ns). Moreover, they did not change after therapy. No correlation was found between baseline OPG and RANKL levels and bone markers or quantitative scintigraphic indices. There were no differences in bone markers nor scintigraphic indices when patients were classified according to baseline OPG (> 4.1 pM/L vs < 4.1 pM/L) and RANKL (> 0.41 pM/L vs < 0.41 pM/L) values. Conclusions: Serum OPG increases in Paget's disease and decreases after treatment with tiludronate. Serum RANKL does not vary in Paget's disease. Both serum OPG and RANKL are unrelated to the activity of the disease. The increase in serum OPG may reflect a protective mechanism of the skeleton to compensate for increased bone resorption.

SU391

Large Phenotypic Variability of Paget Disease of Bone caused by the P392L Sequestosome1/p62 mutation. N. Laurin*[1], J. Morissette*[1], V. Raymond[1], J. P. Brown[2]. [1]Endocrinologie moléculaire et oncologique, Centre de recherche du Centre Hospitalier de l'Université Laval (CHUL), Quebec, PQ, Canada, [2]Groupe de recherche sur les maladies osseuses, Rhumatologie-Immunologie, Centre de recherche du Centre Hospitalier de l'Université Laval (CHUL), Quebec, PQ, Canada.

Paget disease of bone (PDB) is a common disorder characterized by focal and disorganized increases of bone turnover. Seven loci have been associated with this disorder. Last year, we reported the mapping of the third locus associated with the disorder, *PDB3,* at 5q35-qter. Using 24 French-Canadian families and 112 unrelated pagetic patients, we

recently identified the gene causing Paget disease at *PDB3* as sequestosome1 (*SQSTM1/p62*). A recurrent mutation in *SQSTM1/p62* (P392L) was detected in 11 pedigrees (46%) and 18 sporadic cases (16%). According to our data, the penetrance of this mutation reached 80 % for individuals 60 years old and over. The aim of this study was to assess genotype-phenotype analysis of the P393L mutation. The individual phenotype of 20 patients carrying the P392L mutation (all members of two extended families and including a homozygote) was evaluated. The severity of the disease was assessed by the age at onset, the levels of total serum alkaline phosphatase (SAP) and the bone involvement (number of sites and area of the skeleton affected by PDB calculated by the use of Rénier et al.'s index). A wide range of clinical severity was seen among individuals carrying the P392L mutation. The age at onset varied between 27 to 72 years old and one 77 year-old individual did not show any sign of the disease. The majority of patients from these two families were diagnosed in the scope of this study. The number of affected bones was between 1 to 31 for affected patients and the percentage of affected skeleton between 1 to 64%. These observations are not correlated with the current age or age at diagnosis. The homozygote was severely affected (age at diagnosis 46, 26 affected bones and 31% of the skeleton affected), however, his phenotype is comparable to at least five other family members who are heterozygote for the P392L mutation. The phenotypic expression was highly variable within these two families. However, all patients with the PDB phenotype had the P392L mutation. These observations suggest that there might be other important genetic (background) and/or environmental factors, such as a common viral infection (measles), that could contribute significantly to the variability in the severity of Paget disease of bone. We are currently evaluating the serologies for measles virus in these patients.

SU392

Normalization of Hypercalcemia with the Calcimimetic AMG 073 in a Patient with Metastatic Parathyroid Cancer. M. Peacock. School of Medicine, Indiana University, Indianapolis, IN, USA.

Management of metastatic parathyroid cancer and its associated hypercalcemia is challenging given its resistance to anti-cancer therapy. Progressive morbidity and eventual mortality often result from the hypercalcemia rather than the cancer. The calcimimetic AMG 073 has been shown to reduce serum PTH and normalize hypercalcemia in patients with primary hyperparathyroidism*. This report describes the use of AMG 073 to manage hypercalcemia in a patient with metastatic parathyroid cancer. A 57 year-old woman underwent total parathyroidectomy for parathyroid gland cancer 7 years prior to the study, and subsequently developed neck and lung metastases. Before treatment with AMG 073, serum calcium was 14.0 mg/dL, intact PTH was 785 pg/mL, and she had marked symptoms of hypercalcemia, including lassitude and drowsiness. The hypercalcemia did not resolve with local radiation or bisphosphonate therapy. AMG 073 30 mg bid was initiated, and the dose increased every 2 weeks to achieve a serum calcium ≤ 10.0 mg/dL. Serum calcium began to fall within 1 week of starting therapy and continued to fall as the dose was increased. Hypercalcemia normalized after 14 weeks at a dose of 70 mg tid. The patient was normocalcemic on this dose after 22 weeks (Table). Her symptoms resolved as serum calcium fell, and she returned to normal activities. Plasma PTH decreased from 785 pg/mL at baseline to 686 pg/mL at week 14, was 658 pg/mL at week 22, and 477 pg/mL at week 30. Serum alkaline phosphatase (sALP) decreased and serum phosphorus increased to normal with AMG 073 therapy.

(Normal ranges)	Calcium (8.4-10.3 mg/dL)	PTH (10-65 pg/mL)	Phosphorus (2.2-5.1 mg/dL)	sALP (31-115 U/L)
Baseline	14.0	785	2.2	330
Week 14	10.4	686	3.9	289
Week 22	9.5	658	Not done	Not done
Week 30	10.8	477	2.9	245

The calcimimetic AMG 073 was well-tolerated, reduced PTH, and was highly effective in normalizing hypercalcemia and controlling the associated symptoms in this patient with metastatic parathyroid cancer.

*Peacock M, et al. The calcimimetic AMG 073 reduces serum calcium in patients with primary hyperparathyroidism. *J Bone Miner Res* 2001; 16(Suppl 1): S163.

SU393

Expression of *GCMB* by Intrathymic PTH-secreting Adenomas Indicates Their Parathyroid Cell Origin. A. Maret*[1], C. Ding[1], S. S. Kadkol*[2], W. H. Westra*[2], M. A. Levine[1]. [1]Pediatric Endocrinology, Johns Hopkins University, Baltimore, MD, USA, [2]Pathology, Johns Hopkins University, Baltimore, MD, USA.

The *GCMA* and *GCMB* genes encode human orthologs of the *Drosophila* glial cells missing (gcm) gene. *GCMB* is uniquely expressed in developing and mature parathyroid cells and is critical for the development of the parathyroid glands in mice as well as in humans. Mice in which parathyroid glands have been surgically removed or genetically ablated (*Gcm2* knock out) have residual PTH production from a subset of thymic cells that co-express the *Pth*, *Casr,* and *Gcm1* genes. These findings suggest that intrathymic adenomas that produce PTH might be derived from thymic epithelial cells that express *GCMA*. The goal of the present study was to determine the cell-type origin of intrathymic parathyroid adenomas. We obtained paraffin-embedded thymic tissue from normal subjects of varying ages as well as 16 adult patients diagnosed with intrathymic parathyroid adenoma. A eutopic parathyroid adenoma served as a control. Total RNA was extracted from five 10-µm sections of each paraffin block using xylene and digestion with Proteinase K followed by phenol/chloroform extraction. After treatment with DNase I the yield of total RNA was estimated by RT-PCR of 18s ribosomal RNA. Exonic primers that span one intron were designed to amplify *GCMB* and *GCMA* mRNA by RT-PCR, yielding predicted fragments of 120-bp and 182-bp, respectively. RT-PCR analysis of normal human thymus from a fetus and subjects aged 7 days to 21 years showed expression of *GCMA* mRNA (40-60 cycles) but not *PTH* (60 cycles) mRNA or *GCMB* mRNA (60 cycles). All intrathymic parathyroid adenomas and the eutopic parathyroid adenoma revealed a 120 bp fragment for *GCMB* mRNA (41 cycles). No *GCMA* product was seen after the same number of PCR-cycles. The identity of the *GCMB* amplicons was confirmed by direct sequence analysis and slot blot analysis using an internal 21 bp *GCMB* oligonucleotide. In conclusion, our data show that normal human thymus expresses the *GCMA* gene, and that intrathymic parathyroid adenomata express *GCMB.* Thus, intrathymic parathyroid adenomas are not derived from thymic epithelial cells but rather from ectopic parathyroid cells that had likely migrated errantly during embryogenesis.

SU394

Vascular Stiffness Is Increased in Patients With Primary Hyperparathyroidism. M. R. Rubin, M. S. Maurer*, B. E. Diamond*, L. E. K. Coffin*, J. P. Bilezikian, S. J. Silverberg. Columbia University, College of P & S, New York, NY, USA.

When primary hyperparathyroidism (PHPT) was a more symptomatic disease, it was often associated with increased cardiovascular risk. As the clinical manifestations of the disease have changed to a milder, more asymptomatic disorder, investigation is shifting to more subtle cardiovascular abnormalities. It has been proposed that PHPT increases vascular calcification and stiffness and hence cardiovascular risk. Previous reports on vascular stiffness in PHPT are limited by confounding lipoprotein abnormalities and lack of anthropomorphic data. We measured arterial stiffness in 25 patients (Pts) with mild PHPT (serum calcium 10.6 ± 0.1 mg/dl, PTH 119 ± 19 pg/ml) and in 83 controls (Ctls). Arterial stiffness was measured mathematically with a non-invasive device (Sphygmocor, Australia) as the augmentation index (AI). AI increases as arteries stiffen, resulting in a heightened aortic systolic pressure and increased left ventricular afterload. Pts and Ctls were similar to each other in age and gender. We found no significant difference overall between the groups in AI (Pts 143 ± 4 %, Ctls 137 ± 3 %; p=NS). However, when variables altering vascular stiffness (obesity, height, hypertension, diabetes mellitus, atherosclerosis, and smoking) were controlled for, a significant difference was found (P<0.01 for model). In this model, AI was increased in Pts as compared with Ctls (P<0.05). The increase in AI was positively associated with higher PTH levels (R=+0.505; P=0.01) and negatively associated with radial BMD (R= -0.450; P<0 .05). There was no association between AI and serum or urinary calcium or markers of bone turnover. In summary, vascular stiffness is increased in patients with mild PHPT. The increase is associated with evidence of more active parathyroid disease (higher PTH, lower cortical BMD). It is not known whether increased AI is due to vascular calcification, to direct properties of PTH, or to other factors. The findings of increased vascular stiffness may have important implications for management decisions in asymptomatic PHPT.

SU395

Atypical Adenoma: A New Form of Parathyroid Neoplasia. M. R. Rubin[1], S. J. Silverberg[1], V. L. LiVolsi*[2], B. Bennett*[1], T. P. Jacobs[1], J. P. Bilezikian[1]. [1]Columbia University, New York, NY, USA, [2]University of Pennsylvania Health System, Philadelphia, PA, USA.

When primary hyperparathyroidism (PHPT) presents as a mild, asymptomatic disorder and not accompanied by indications for surgery, conservative monitoring is appropriate. When PHPT presents as a symptomatic disorder accompanied by indications for surgery, operative removal is appropriate. Rarely, some patients in this latter category have parathyroid carcinoma (PCA). It accounts for <1% of patients with PHPT and is cured only by surgery. It is important to determine which symptomatic cases of PHPT are likely to be cancerous. Clinical features which distinguish PCA from benign PHPT include markedly elevated levels of serum calcium and PTH and overt renal and skeletal involvement. Histologic features include capsular or vascular invasion to the thyroid or soft tissues, mitotic figures in tumor parenchymal cells, uniform sheets of cells separated by fibrous trabeculae and metastases. Recently, a new pathologic entity, "atypical adenoma" (AA), has been defined. AA is described by adherence to soft tissues of the neck or thyroid, mitoses, marked cytologic atypia, capsular entrapment and invasion (into but not through the capsule) and intratumoral fibrosis. The clinical features of AA have not yet been defined. We now report 7 patients (Pts) with active PHPT, in whom pre-operative suspicion for PCA was low, but who were all operative candidates. 3 patients were overtly symptomatic (kidney stone, n=1, fractures, n=2). Serum calcium was > 12 mg/dl in 4 of the 7 Pts; PTH was 247 ± 106 pg/ml (range: 74-876; nl: 10-65). Urinary calcium was 260 ± 60 mg/g Cr. All 4 women and 3 men (age: 60.1 ± 3.1 yr) were diagnosed at the time of surgery and initial histology as PCA with capsular invasion (n=3), or atypical cells with nuclear pleomorphism (n=4). However, after more detailed review, 4 samples were interpreted as AA, 1 patient had confirmed PCA and 2 had typical adenoma. There was no recurrent disease during 4 ± 3 years of follow up (range: 1-7), with normal serum calcium (9.3 ±0.2 mg/dl) and PTH (44.9 ±7.5 pg/ml). Bone density improved by approximately 10% (LS T-scores: -2.6 ±0.7 to -1.8 ±0.7; P=0.09). AA may represent a precursor lesion of PCA. However, in this small group, surgical cure of AA and PCA was associated with biochemical and BMD improvements similar to those seen with benign PHPT. In summary, in patients who have clinical features of more active PHPT than usual, but who are not suspected to have PCA, the possibility of PCA or this new pathologic entity, AA, should be considered.

SU396

The Relationship of Serum RANKL to Bone Resorption in States of Acute and Chronic Parathyroid Hormone Excess. I. A. Nakchbandi*[1], U. Masiukiewicz[1], M. Mitnick*[1], R. Lang*[2], B. Kinder*[1], K. L. Insogna[1]. [1]Yale University School of Medicine, New Haven, CT, USA, [2]Osteoporosis Center, Hamden, CT, USA.

It has been previously reported that both acute and chronic elevations in circulating PTH levels are associated with increased serum levels of IL-6 and its soluble receptor (IL-6sR). Blood levels of IL-6 and IL-6sR rise rapidly during short-term PTH infusions and are markedly elevated in patients with primary and secondary hyperparathyroidism. In these patients, both serum IL-6 and IL-6sR correlate with markers of bone resorption and in a recent longitudinal study of patients with primary hyperparathyroidism, serum IL-6sR correlated strongly with rates of femoral bone loss. Since it is now possible to measure serum RANKL and OPG in humans and since PTH regulates RANKL expression, we examined the relationship between serum RANKL/OPG and bone resorption in subjects infused with PTH and in patients with primary hyperparathyroidism. Thirteen postmenopausal women were infused with PTH for 36 hours. PTH induced slight increases in serum RANKL (0.9±0.1→1.3±0.1 pmol/L, nl<1.0) while OPG declined slightly (5.4±0.7→4.5±0.6 pmol/L) during the infusions. Serum RANKL was only weakly correlated with bone resorption markers (urine Dpd; r=0.2, p<0.05). In 29 patients with primary hyperparathyroidism, serum RANKL levels were more significantly elevated at 1.7±0.1 pmol/L while OPG remained within the normal range (5.6±0.3 pmol/L). The elevation in RANKL correlated with both urinary DPD and serum NTX (r=0.5, p<0.005 for DPD; r=0.4, p<0.05 for NTX). Serum RANKL also correlated with serum IL-6sR (r=0.55, p<0.005). Similarly to IL-6sR, RANKL correlated negatively with rates of bone loss at the total femur, r=-0.55, p<0.005. We conclude that circulating levels of RANKL are increased in states of chronic parathyroid hormone excess, and that in hyperparathyroidism, serum RANKL correlates with rates of bone loss at the total femur.

SU397

A Huge Lytic Bone Lesion Prior to and Following Parathyroid Adenoma Excision After 30 Years Follow-up. A. Halabe*[1], M. Harel*[2], D. Gonzalves*[3], M. Lorberboym*[4], G. Gvirtz*[3], R. Shor*[1]. [1]Internal Medicine and Metabolic Bone Diseases, Edith Wolfson Medical Centre, Tel Aviv Israel, Israel, [2]E.N.T., Edith Wolfson Medical Centre, Tel Aviv Israel, Israel, [3]Department of Radiology, Edith Wolfson Medical Centre, Tel Aviv Israel, Israel, [4]Department of Nuclear Medicine, Edith Wolfson Medical Centre, Tel Aviv Israel, Israel.

Bone involvement as a complication of primary hyperparathyroidism is rarely seen nowdays. We present an 82 years old patient who suffered from left kidney stones since 1970 because of primary hyperparathyroidism. The diagnosis was based on the presence of hypercalcemia, hypophosphatemia, lowTmP/GFR and elevated serum iPTH levels. In 1971 she underwent left uretherolithotomy followed one year later by left nephrectomy due to infected kidney stones. A cervical exploration was performed but no adenoma was found and two parathyroid glands were removed. Venous sampling was performed, indicating a venous gradient at the right lower pole of the thyroid gland. A second exploration was performed, and the right pole of the thyroid gland was removed where other normal parathyroid gland was found. Further investigations at N.I.H. included venous sampling, arteriography and a mediastinal exploration but no adenoma was found. She was treated with orally inorganic phosphates controlling her serum calcium around 10-11 mg/dL, 24h-urinary calcium excretion around 300 mg/24h and serum iPTH 100-200 pg/mL. Since 1993 there was a progressive increase in serum PTH up to 3000-4000 pg/mL. A parallel increase in serum alkaline phosphatase from normal up to 900 IU was also observed. Serum calcium 10.8 mg/dL, and creatinine 1.4-1.8 mg/dL remained stable. Two years ago the patient was reported to be bed-ridden for a period of three months, due to severe pain at the left hemipelvis and sacroiliac joint. CT and MRI showed a tremendous osteolytic lesion involving mainly the left sacroiliac joint. A cervical U.S. and MIBI scan showed a parathyroid adenoma located between the common carotid artery and jugular vein on the left side. A third neck exploration was done and a parathyroid adenoma was partially excised. Histological examination demonstrated "chief cell" parathyroid adenoma with fibrous tissue and no mitosis or malignant cells. Following surgery, the patient was given oral calcium 2.0 gr/day and alpha D_3 1.0 ucg/day for a period of 14-months. Serum calcium stabilized around 10.5 mg/dL, PTH levels declined to around 250-340 pg/dL and alkaline phosphatase returned to 250 IU. A repeated CT of the pelvis showed a significant improvement of the bone lesion. This case is unique because of the new bone lesion affecting mainly the sacroiliac joint with clinical and radiological evidence of improvement and the lengthy follow-up of thirty years.

SU398

Genotype-phenotype Relationship in Human Autosomal Recessive Osteopetrosis (arOP) Dependent on Mutations of the ATP6i Gene. A. Taranta, S. Migliaccio, I. Recchia*, M. Caniglia*, M. Luciani*, G. De Rossi*, C. Dionisi-Vici*, R. M. Pinto*, P. Francalanci*, R. Boldrini*, E. Lanino*, G. Dini*, G. Morreale*, D. Del Principe*, F. Cassini*, G. Palumbo*, S. H. Ralston, A. Villa*, P. Vezzoni*, A. Teti. Experimental Medicine, University of L'Aquila, L'Aquila, Italy.

The ATP6i gene encodes for the osteoclast specific a3 V-ATPase subunit and accounts for 50% of patients with arOP. Genotyping of four patients revealed three new allele mutations, also confirmed by RFLP analysis. Patients shared macrocephaly, growth retardation, impaired vision and generalized increase of bone mass. Massive and irregular primary spongiosa with unresorbed cartilage trabecular cores and fibrous tissue featured the bone biopsies. Significant numbers of hypo-functional, but morphological normal, osteoclasts were associated with the trabecular profiles, where shallow Howship lacunae were also observed. Abnormal obvious increase of active osteoblasts was noted, suggesting associated osteosclerosis pattern. Remarkably, patients shared high alkaline phosphatase activity, probably reflecting intense osteoblast activity. Hypocalcaemia was hypothesized to stimulate PTH release, as the PTH serum levels were elevated, and PTH was thought to determine increased osteoclasto- and likely osteoblasto-genesis. Abnormally intense TRAP activity was revealed in bone biopsies and in in vitro osteoclasts. TRAP activity returned to close normal levels in post-bone marrow transplant osteoclasts, suggesting their donor origin, also corroborated by positive outcome and improvement of osteosclerosis. An a3 subunit C terminus-targeted antibody failed to detect the a3 protein and the lymphocyte splice variant, TIRC7, by Western blot, as in our patients these proteins were predicted to be frame-shifted or truncated down-stream the mutations. Immuno-histo and -cytochemistry confirmed this occurrence, providing simple tools for early diagnosis. In vitro analysis of blood-born osteoclasts showed unremarkable cytoskeletal arrangement, podosome pattern, alphavbeta3 integrin, Pyk2 and c-Src distribution, confirming no morphological and/or adhesion/motility anomalies. In contrast, pit analysis demonstrated impaired, but still remarkable bone resorption activity, suggesting partial molecular complementation of the a3 subunit by alternative proton transport mechanisms, and providing a background for potential pharmacological targets to be investigated. In conclusion, we provided evidence suggesting common cellular and clinical features in patients harboring mutations in the ATP6i gene, and suggested potential tools for early diagnosis and pharmacological targeting for this severe disease.

SU399

IV Bisphosphonate Therapy in Children Under 36 months of Age with Osteogenesis Imperfecta. L. A. DiMeglio[1], L. Ford*[2], C. McClintock*[2], M. Peacock[2]. [1]Pediatric Endocrinology, Indiana University, Indianapolis, IN, USA, [2]Medicine, Indiana University, Indianapolis, IN, USA.

Bone mineral density (BMD) and fracture rates in children with osteogenesis imperfecta (OI) improve with oral and intravenous (IV) bisphosphonate therapy. There is limited data available on the efficacy of this therapy in very young children with OI. To examine this, we have instituted a prospective clinical trial of IV bisphosphonate in children under the age of 3. Children (n=8) received cycles of IV pamidronate, 1.5 mg/kg over 3 days every 2 months until the age of 2, then 2.25 mg/kg over 3 days every 3 months until the age of 3, then 3 mg/kg over 3 days over the age of 3. Three children received some infusions via a port or central venous line. The primary outcome was total body (TB) BMD, which was measured at 4-monthly intervals. Secondary outcomes included: biomarkers of bone turnover, fracture incidence, calcium biochemistry, anthropometric measures, dental anomalies, audiologic evaluations, assessment of quality of life, pain measures, and evaluations of gross motor function. Characteristics of 8 children (6 with type III (severe) OI and 2 with type I (mild) OI) are summarized in the table. (Rx = Treatment; ND = not done)

OI Type	Age at Start of Rx	Time of Rx/# of Infusions	Annualized % Change TB BMD	Fractures before/ during Rx
III	1 month	8 months/6	14%	15 / 1
III	2 months	6 months/4	3.2%	5 / 0
III	4 months	29 months/15	28%	9 / 5
III	4 months	6 months/4	33%	1 / 0
I	11 months	27 months/12	14%	2 / 0
III	15 months	14 months/7	-10%	14 / 7
III	32 months	3 months	ND	28 / 0
I	35 months	24 months	14%	3 / 0

The children have demonstrated an increase in BMD beyond expected for age and a decrease in markers of bone turnover on therapy. Radiographs showed discrete dense bands under growth plates corresponding to infusions. Other than fevers following the initial dose of IV bisphosphonate, no adverse effects of therapy have been noted. The children have maintained normal height/length and weight gain. These data confirm that IV bisphosphonate therapy is safe and effective for very young children with OI.

SU400

Abnormal Peri-Pubertal Growth and Development in Girls with Adolescent Idiopathic Scoliosis. W. T. K. Lee*[1], C. S. K. Cheung*[1], X. Guo[2], S. P. Tang*[1], J. C. Y. Cheng*[1]. [1]Orthopaedics & Traumatology, The Chinese University of Hong Kong, Shatin, Hong Kong Special Administrative Region of China, [2]Rehab. Sciences, Hong Kong Polytechnic University, Kln., Hong Kong Special Administrative Region of China.

Adolescent Idiopathic Scoliosis (AIS) is a 3-dimentional deformity of the spine affecting girls in majority between aged 9-16-y. Abnormal pattern of physical growth has been described in AIS patients. Sequential anthropometric development and its variation with pubertal maturation in AIS girls has not been reported. A cross-sectional study was conducted to examine the physical growth of AIS patients *vs.* age and maturity matched normal controls during peri-pubertal period of growth. 582 AIS girls aged 11-16-y and 206 age-matched healthy girls were recruited. Weight (Wt), height (Ht), body mass index (BMI), arm span, sitting height (SH) and Leg length (LL) were evaluated using standard methods. Tanner's staging (Breast stage, BS) was used to grade pubertal maturation. At pre-puberty, AIS girls had significantly shorter arm span, SH & LL than those of controls (Table 1). After the onset of puberty, the reverse relationship was observed. The differen-

tials of arm span and LL gradually increased *with significant differences* between the AIS and control group (Table 1). In addition, Wt and BMI of AIS were found significantly lower than those of controls from BS 2-4 (p= 0.05 - 0.01). Table 1. Percent change in body segments between AIS & Control group using independent t-test

Breast Stage (BS)	Ht	Arm span	LL
	% Difference from the Control group (P-value)		
1	- 4.7 % (0.03)	- 4.3 % (0.04)	- 6.0 % (0.002)
2	- 0.9 % (ns)	+ 1.7 % (0.029)	+ 1.7 % (0.049)
3	- 0.3 % (ns)	+ 1.3 % (0.039)	+ 1.5 % (0.018)
4	+ 1.4 % (0.013)	+ 3.3 % (<0.001)	+ 3.3 % (<0.001)
5	+ 3.9 % (0.003)	+ 5.1 % (0.001)	+ 6.2 % (0.002)

To conclude, body segments: Ht, arm span, SH and LL were significantly shorter in AIS before the onset of puberty. However, body segments of AIS grew significantly longer than those of controls after the onset of puberty, and the discrepancies became larger when the AIS became sexually matured. Results of this large-scale study indicates the presence of abnormal peripubertal anthropometric growth in AIS pointing to likely underlying abnormalities in the regulation of growth and maturation in AIS.

SU401

The Pharmacokinetics and Short-Term Safety of Alendronate in Children and Adolescents with Osteogenesis Imperfecta (OI) Type I. L. M. Ward[1], A. E. Denker*[2], A. G. Porras*[2], S. Shugarts*[2], R. Travers[1], C. Mao*[2], A. Dynder*[2], P. Deutsch*[2], F. H. Glorieux[1]. [1]Genetics Unit, Shriners Hospital for Children, Montreal, PQ, Canada, [2]Merck & Co., Inc., Whitehouse Station, NJ, USA.

Alendronate (ALN) has potential use as a weekly oral agent in pediatric patients with osteoporotic conditions. Our aim was to evaluate the pharmacokinetics and short-term safety of ALN in children with mild OI. Twenty-four children (4-16 yrs) with OI type I received ALN 125 µg IV and oral ALN in a two-period randomized crossover study, with doses separated by a two week washout. The oral dose was 35 mg for patients weighing < 40 kg, 70 mg for ≥ 40 kg. Urine was collected for 24 hrs to determine the total urinary excretion of ALN (TUE-ALN). Patients were monitored for 24 hrs following ALN dosing and phone contact was made 10-14 days after the second dose. Laboratory safety parameters were evaluated pre- and post-study. Twenty-four patients successfully completed the study. 13 subjects received the IV dose and 11 received the oral dose in the first period. The TUE-ALN (dose-adjusted to 1 mg) and bioavailability (%) were as follows:

Dose	LS† Mean TUE-ALN (µg)	SD‡	Bioavailability (%)	95% CI§ for Bioavailability
<40 kg, N=12				
35 mg PO	1.9	1.6	0.43	0.28, 0.64
125 µg IV	441.9	61.0		
≥40 kg, N=12				
70 mg PO	2.4	2.1	0.56	0.36, 0.87
125 µg IV	438.5	90.7		

Root Mean Squared Error = 0.444 (ANOVA model); †LS = Least-Squares (back-transformed from the log scale); ‡SD = Standard Deviation; §CI = Confidence Interval. Comparing adult data from historic studies with results from the pooled pediatric patients, there was no difference in the bioavailability (Geometric mean ratio (GMR) (pediatric/adult)=0.74, 95% CI 0.51,1.07) nor in the TUE-ALN following the IV dose (GMR=1.09, 95% CI 0.96,1.23). Eighteen of the 24 patients reported a total of 44 adverse experiences. All were mild or moderate in intensity, 80% (35/44) occurred within 48 hrs, 91% (40/44) lasted <24 hrs, and 75% (33/44) followed the oral dose. The most common side effects were headache (N=7), nausea (N=7), fever (N=5) and abdominal pain (N=6). Slight decreases were observed in the absolute lymphocyte count and serum alkaline phosphatase at post-study. In conclusion, the bioavailabilities of single oral doses of ALN 35 mg (for children < 40 kg) and 70 mg (for children ≥ 40 kg) were similar to each other and to adults in previous studies. In addition, the TUE-ALN following the IV dose was the same for younger and older children and no different compared to adults, suggesting similar percent distribution to bone regardless of age. The drug was generally well-tolerated.

SU402

Feet in a Family with Type I Osteogenesis Imperfecta (OI). J. Reese*[1], A. L. Burshell[2], W. Coleman*[3]. [1]Medical Student, Tulane University, New Orleans, LA, USA, [2]Section on Endocrinology, Ochsner Clinic Foundation, New Orleans, LA, USA, [3]Orthopedics, Ochsner Clinic Foundation, New Orleans, LA, USA.

Type I OI is the mildest type of OI and is caused by a quantitative defect in Type I collagen. The genetic defect in this large Acadian family is a single base pair substitution in COL1A1 causing one of the two proalpha1 chains not to be expressed. The affected family members have blue sclera, premature hearing loss, frequent childhood fractures, low BMD by DXA, increased flexibility and frequent foot complaints. Ten affected family members (5 women and 5 men) were compared to 16 non-affected non-family (9 women and 7 men) and 2 non-affected family members (1 woman, 1 man). Anteroposterior (AP) and lateral weight bearing X-rays were performed on each foot. Various angles and distances were drawn and measured by 2 observers. Data for each subject was averaged for each foot and observer's measurement, and OI feet compared to controls as well as published references. Lateral radiographs showed that the calcaneal inclination angle was significantly reduced in OI subjects. Additionally, the inferior calcaneal angle was decreased when compared to the 1st metatarsal declination angle, indicating rearfoot collapse. AP radiographs showed the following angles were significantly reduced in OI subjects compared to controls: calcaneus to midfoot, metatarsus adductus and the 2nd-5th intermetatarsal angle. The OI foot collapsed into pronation primarily in the sagittal plane. OI subjects often had a forefoot varus alignment, increased ankle dorsiflexion tested with the knee flexed, narrow foot width, and decreased metatarsal width. The feet of family members affected with OI demonstrate a unique combination of abnormalities. It seems probable that these changes are related to this family's known genetic abnormality of Type I collagen, which may adversely affect the bones, ligaments and tendons. It is unknown whether similar abnormalities are found in other genetic diseases of Type I collagen, including other families with Type I OI, Ehlers Danlos or osteoporosis.

SU403

Differential Diagnostics of Inherited Connective Tissue Diseases. V. Vyskocil. Department of Bone Disease, Charles University Hospital, Plzen, Czech Republic.

The authors followed 318 patients with connective tissue diseases from 1996 to 2001 (Marfan syndrome, Ehlers Danlos syndrome, osteogenesis imperfecta). The cause for that choice is genetic relationship of collagen defect. The studied groups consists of 52 patients with osteogenesis imperfecta OI, 82 children with Ehlers Danlos syndrome ED and 100 patients with Marfan syndrome MS and 84 with familiar joint hyperelasticity. As routine use of molecular genetic methods is impossible in an everyday practice the authors tried to apply the criteria combination for OI, MS and ED so that the validity of particular criteria could be evaluated and then used in diagnostic difficulties among the studied diseases. All 4 groups were examined by densitometry and also the markers of bone metabolism were evaluated (serum Ca, P, PTH, osteocalcin, PICP, telopeptid, in urine Ca, P, crosslinks). In the other 2 groups (ED, MS) the patients with decreased bone density were treated with calcium and vitamin D. Nevertheless the authors stated that in MS osteopenia would improve within 15-18 years even without therapy but in the 2 remaining groups (ED and OI) the treatment is necessary due to abnormal bone density. The present chest deformation was the indication for vital lung capacity measurements and FEV. The authors tried to evaluate the best clinical, radiograph, densitometric and biochemical criteria in diagnostic difficulties. **Conclusions:** In patients with OI the best criteria besides clinical findings were lower stature, asymmetry of the body and densitometry with decrease at least of 15 percent when compared with the other groups. That group has besides fractures the decrease of PICP and the highest levels of osteocalcin and crosslinks. The group of MS had no typical criterium in bone metabolism and densitometry when compared with OI and ED. For Marfan syndrome diagnostics the main criteria are metacarpophalangeal index, the index of arms´expansion to body height, positive ophthalmological findings and body dysproportion. At the same time pulmonary functions were worse in Marfan syndrom than in the groups with OI and ED. Ehlers Danlos syndrome had markedly increased osteocalcin besides basic diagnostic criteria and at the same time lower BMD of the forearm, close to patients with OI. Pes planus had no significance in all 3 groups. The answer to the treatment could be also the method of differential diagnosis in indistinct cases. The best reaction had patients with MS, lower increase of bone density had the patients with ED and the lowest one was in OI. The authors assume that the combination of different diagnostic methods is useful and could differentiate among those 3 groups of patients. Molecular genetics is the definite method in the unclear cases.

SU404

Vitamin D Status of Preterm Infants After Hospital Discharge. W. Koo, M. Hammami*. Pediatrics, Wayne State University, Hutzel Hospital, Detroit, MI, USA.

Preterm infants fed high calcium (Ca) and phosphorus (P) milk during hospitalization can maintain normal vitamin D status with low vitamin D intake. However, all preterm infants receive lower mineral milks after hospital discharge and it is not known whether this affects their vitamin D needs. We measured plasma 25 hydroxy-vitamin D (25 OHD) by radioimmunoassay, Ca and Mg by atomic absorption, and P by spectrophotometric method, at hospital discharge and at 4 and 12 months after hospital discharge, in preterm infants participated in a parallel, randomized, masked study fed milk formulas with either standard or enriched formulation. Ca, P and vitamin D contents per 100 kcal of the former were 73 mg, 56 mg and 60 IU, and for the latter were 105 mg, 62 mg, and 80 IU, respectively. None received additional vitamin D supplementation. Preliminary results from 42 preterm infants (gestational age 28.4 +/- 2.3 wks) showed plasma 25 OHD concentrations in infants fed standard formula were 30.5 +/- 9.8, 33.9 +/- 11.2 and 31.5 +/- 5.0 ng/mL, and in infants fed enriched formula were 23.0 +/- 8.1, 35.1 +/- 9.3 and 34.4 +/- 7.9 ng/mL, respectively. Plasma 25 OHD in the latter group increased with time but there were no significant differences between groups by repeated measures analysis. None of the infants had plasma 25 OHD < 10 ng/mL at baseline and none of the infants had plasma 25 OHD < 19 ng/mL on follow up. Plasma Ca, Mg and P were normal in all infants. We conclude that vitamin D contents in the infant formulas studied are sufficient to maintain normal vitamin D status in preterm infants after hospital discharge.

SU405

Hyperparathyroidism in a Patient with Pseudohypoparathyroidism Type Ib. K. A. Kennel*[1], J. A. van Heerden*[2], R. V. Lloyd*[3], B. L. Clarke[1]. [1]Division of Endocrinology, Mayo Clinic, Rochester, MN, USA, [2]Department of Surgery, Mayo Clinic, Rochester, MN, USA, [3]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN, USA.

A 51 year-old female with pseudohypoparathyroidism type Ib developed parathyroid hyperplasia and hypercalcemia. She was diagnosed at age 13 years after years of paresthesias, with hypocalcemia (5.5mg/dL), hyperphosphatemia (8.4mg/dL), increased parathyroid hormone (PTH), and mild osteitis fibrosa on bone biopsy. She had no features of AHO or family history of hypocalcemia. She was given calcium and vitamin D supplementation. Her symptoms resolved, and repeat bone biopsy showed healed osteitis fibrosa. Subsequently, her urine cyclic AMP (cAMP) was found unresponsive to exogenous PTH. Recently, her PTH levels increased dramatically above her baseline level, and her serum calcium became mildly elevated. Her serum calcium was 10.2 mg/dL (8.9-10.1), phosphorus 3.2 mg/dL, and PTH 21 pmol/L (1.0-5.2) on supplemental calcium 1800 mg, 1,25-dihydroxyvitamin D 0.25 mcg, and hydrochlorothiazide 25 mg each day. Baseline urine cAMP was 2.0 nmol/dL glomerular filtrate (1.3-3.7). Her bone mineral density was normal. Neck ultrasound revealed two enlarged inferior parathyroid glands. Parathyroid sestamibi scan confirmed focal uptake in these locations. At surgery, both the right and left inferior parathyroid glands were enlarged. The superior glands were of normal size and appearance. Baseline intraoperative PTH was 43.7 pmol/L. After her right inferior 720-mg gland was removed, her PTH decreased to 31 pmol/L. After her left inferior 130-mg gland was removed, her PTH decreased further to 6.9 pmol/L. Pathology review indicated parathyroid hyperplasia in both glands. Tissue tumor markers Ki-67 and p27 were absent. Her postoperative serum calcium decreased to 8.6 mg/dL, with a PTH nadir of 3.3 pmol/L. She began calcium 2400 mg and 1,25-dihydroxyvitamin D 0.50 mcg daily. By postoperative day three her calcium was normal at 9.2mg/dL. Two weeks later her serum calcium remained normal and her PTH had increased to 16.3 pmol/L (1.3-7.6), indicating function of her remaining parathyroid tissue. Her serum calcium has remained normal on these doses of supplemental calcium and 1,25-dihydroxyvitamin D over two years of follow-up. This patient demonstrates that hyperparathyroidism may occasionally develop in patients with pseudohypoparathyroidism Ib. PTH resistance in this disorder is due to decreased GNAS1 expression in the proximal renal tubules. The patient's documented osteitis fibrosa suggests she had partial skeletal responsiveness to PTH. Chronic stimulation by mild ionized hypocalcemia over many years may have resulted in her parathyroid gland hyperplasia.

Height and Weight Development During Long-Term Therapy with Cyclical Intravenous Pamidronate in Children and Adolescents with Osteogenesis ImperfectaTypes I, III and IV. L. M. Zeitlin*[1], F. Rauch[2], H. Plotkin[2], F. H. Glorieux[2]. [1]Genetic Unit, The Shriners Hospitals for Children, Canadial Hospital, Montreal, PQ, Canada, [2]Genetic Unit, The Shriners Hospitals for Children, Canadian Hospital, Montreal, PQ, Canada.

Treatment with pamidronate significantly improves the clinical course in children with osteogenesis imperfecta (OI). However, it is often feared that bisphosphonate therapy might affect longitudinal growth. In this study we analyzed the short-term (1-year) and long-term (4-year) growth effects of 2 to 4-monthly intravenous pamidronate treatment in children and adolescents (age 0.04-15.6 years at baseline) with moderate to severe OI types I, III and IV. At baseline, patients of all OI types were short for age. In the 116 patients who completed one year of therapy height z-scores increased significantly in OI-III (mean±SD, +0.3±0.8, p=0.04; n= 42), but did not change significantly in OI-I (n=29) and OI-IV (n=45). Weight z-scores increased significantly in OI-I (+0.2±0.4, p=0.01). Forty-one patients completed four years of therapy. Mean height z-scores increased significantly for OI-IV (+0.41±0.71; p=0.04; n=12), whereas non-significant trends were found for OI-I (+0.23±0.55; p=0.17; n= 14) and OI-III (+0.42±1.45; p=0.31; n=15). When height was expressed as a percentage of the result expected for untreated patients with the same OI type, long-term pamidronate therapy was associated with a height gain of +5% for OI-I (p=0.03), +11% for OI-III (p=0.01) and +12% for OI-IV (p=0.001). The mean weight of the pamidronate treated patients increased significantly when expressed as a percentage of the expected weight-for-height in untreated patients (OI-I, p=0.002; OI-III, p=0.02; OI-IV, p=0.05). This was due to a few patients with considerable weight gain, whereas most patients followed the curves of untreated patients. In conclusion, 4 years of cyclical intravenous pamidronate treatment led to a significant height gain in moderately to severely affected OI patients. Some children with OI gain weight excessively during pamidronate treatment, which should be closely monitored.

SU407

Bone Formation Following Ischemic Necrosis of the Femoral Head in a Piglet Model. W. Pritchard*, D. Pringle*, H. Kim. Shriners Hospitals for Children, Tampa, FL, USA.

Femoral head deformity after ischemic necrosis can lead to premature degenerative arthritis. Surgically induced femoral head necrosis in piglets was developed as an animal model to study pathogenesis of femoral head deformity. Revascularization begins 2 wks after infarction with later replacement of necrotic bone by fibrovascular tissue, compromising structural integrity of the bony epiphysis. Little is known about bone formation after ischemic necrosis including whether fibrovascular tissue that replaces necrotic bone contains precursor cells capable of osteoblastic differentiation. The purpose was to study bone formation in the piglet model of ischemic necrosis and to determine if fibrovascular tissue contains osteoblast precursors. Ischemic necrosis was induced in 24 piglets by placing a ligature around the femoral neck. Animals were sacrificed at 1,2,3,4,6 and 8 wks after surgery. Contralateral, non-operated sides were used as controls. After gross and radiographic assessments, paraffin sections were prepared for picrosirius,H and E,and immunohistochemistry. Enzyme-linked immunohistochemistry with monoclonal antibodies to markers of osteoblastic differentiation (osteopontin and osteonectin) were used. The infarcted heads deformed over time with resorption of necrotic trabeculae and replacement by fibrovascular tissue. Over the 8 wk period, 3 types of bone formation were observed: endochondral, appositional, and de novo intramembranous. These were observed within the femoral heads at different locations and times. First, endochondral ossification was observed at the periphery of the epiphysis where revascularization had taken place. This produced small centers of ossification. Second, appositional bone formation was observed surrounding some of necrotic trabeculae in bony epiphyses producing thickened trabeculae. Finally, intramembranous de novo bone formation was observed within dense fibrovascular tissue. Intramembranous bone formation was delayed and observed only at 8 wks when deformity was already severe. Immunoreactivity to monoclonal antibodies was observed in mesenchymal cells within fibrovascular tissue prior to intramembranous bone formation. Polarized light microscopy showed woven bone. This study showed bone formation following ischemia of femoral heads occurred through endochondral ossification, appositional formation on existing trabeculae, and de novo intramembranous ossification. Formation of new bone could prevent deformation of the femoral head following ischemia. Further studies are required to define factors that stimulate new bone formation in fibrovascular tissue which can be used therapeutically to prevent femoral head deformity.

SU408

Dietary Phosphate Restriction Therapy for Hypophosphatasia: Preliminary Observations. D. Wenkert[1], M. N. Podgornik*[1], S. P. Coburn*[2], L. M. Ryan*[3], S. Mumm[1], M. P. Whyte[1]. [1]Cntr Metab Bone Dis & Mol Res, Shriners Hosp Child, St. Louis, MO, USA, [2]Ft Wayne St Devel Cntr, Ft. Wayne, IN, USA, [3]Dept Rheumatol, Med Coll WI, Milwaukee, WI, USA.

Hypophosphatasia, an inborn error of metabolism characterized by insufficient alkaline phosphatase (ALP) activity, results from deactivating mutations in the TNSALP gene that encodes the tissue-nonspecific ALP isoenzyme. TNSALP normally functions as an ectoenzyme. Consequently in hypophosphatasia, three phosphocompounds accumulate extracellularly: phosphoethanolamine (PEA), inorganic pyrophosphate (PPi), and pyridoxal 5′-phosphate (PLP). Excess PPi, which inhibits hydroxyapatite crystal growth *in vitro*, could explain the associated rickets. Interestingly, patients with hypophosphatasia have high-normal or elevated circulating inorganic phosphate (Pi) levels due to increased renal reclamation of Pi (&σηψ; TmP/GFR). Recent studies indicate that Pi is an important competitive inhibitor of ALP activity *in vivo* as well as *in vitro*. Accordingly, reductions in extracellular Pi levels might substantially increase endogenous ecto- TNSALP activity in hypophosphatasia. To explore the impact of changes in extracellular Pi levels in hypophosphatasia, 10 affected children were randomized to 3-day regimes of either dietary Pi restriction (1/2 RDA), oral Pi supplementation (21-36 mg/kg/d), or oral vitamin B_6 (pyridoxine) challenge (1/3 mg/kg/d) to assess short-term changes in endogenous TNSALP substrate accumulation. Pyridoxine loading substantially increased the already elevated plasma PLP levels (2.5-4.8 fold), but did not alter urinary PPi levels. Perhaps this is because PLP represents only a small fraction of endogenous phosphocompounds. However, Pi supplementation increased urinary PPi and plasma PLP levels, consistent with relatively large amounts of Pi competitively inhibiting TNSALP endogenously. Dietary Pi restriction successfully lowered urine Pi in only 1 of 3 patients. In this girl, plasma PLP and urinary Pi as well as urinary PPi each decreased by about 50% (no consistent plasma PLP or urinary PPi changes were observed in the other 2 subjects). Our preliminary findings suggest that decreases in extracellular Pi levels may be helpful for hypophosphatasia. Perhaps dietary Pi binders will be an effective medical treatment.

SU409

Bone Mineral Density Assessed by DEXA does not Improve Spontaneously during Puberty in Girls with Untreated Mild Osteogenesis Imperfecta. D. Wenkert[1], M. N. Podgornik*[1], W. H. McAlister*[2], M. P. Whyte[1]. [1]Cntr Metab Bone Dis & Mol Res, Shriners Hosp Child, St. Louis, MO, USA, [2]Mallinckrodt Inst Radiol, Wash Univ Sch Med, St. Louis, MO, USA.

Osteogenesis imperfecta types I and IV are the relatively mild forms of this autosomal dominant, type I collagenopathy. Both types feature osteopenia with recurrent fractures. Blue sclera help to characterize type I disease. It is widely held that the severity of OI (fracture incidence) decreases at the time of puberty. To test this assumption, charts from 12 Caucasian girls with relatively mild OI who had never received pharmacologic therapy were reviewed. Nearly all patients had undergone 3 or more DEXAs (Hologic) between the ages of 10 and 20 years. Nine had type I OI, 3 had type IV OI. Changes in BMD Z-scores (matched by age) were assessed using Hologic software for L_1-L_4 and using a Pediatric Bone Mineral Density Applet (http://www-stat-class.stanford.edu/pediatric-bones/) for total hip and femoral neck. Changes were assessed for sequential determinations. Although fracture frequencies decreased, there was no significant trend for improvement in BMD Z-scores at any of these sites "across" puberty. Decreased fracture frequency in OI at the time of puberty could reflect changes in physical activity, enhanced bone quality, and/or better skeletal geometry, but we find no DEXA evidence for spontaneous improvement in BMD Z-scores.

SU410

Osteoporosis Pseudoglioma Syndrome Caused by a Novel, Homozygous, 2-Base Pair Deletion in The LRP5 Gene. S. Mumm, D. Wenkert, J. Hagen*, M. P. Whyte. Div Bone Miner Dis, Wash Univ Sc Med, Barnes-Jewish Hospt & Center for Metab Bone Dis and Mol Res, Shriners Hospt for Child, St. Louis, MO, USA.

Osteoporosis pseudoglioma syndrome (OPPG) is an autosomal recessive disorder caused by inactivating mutations in the gene which encodes the low density, lipoprotein receptor-related protein 5 (*LRP5*). Clinical features include early-onset blindness (described as retinal dysplasia within the first few months of life, or phthisis bulbi with calcifications and cataract formation diagnosed after 1 year of age), micro-ophthalmia, osteoporosis leading to fractures, wormian bones, hypotonia, and developmental delay. A 1-year-old Caucasian girl of aunt/nephew parentage was found by routine eye exam at 4 days-of-age to have no red reflex. Bilateral retina detachment with persistent fetal retinal vasculature were unexplained. Ophthalmologic surgery preserved light/dark perception. At age 11 months, bilateral distal femur fractures occurred during a fall. She was osteopenic. Our assessment showed microcephaly, micro-ophthalmia, hypotonia, and hyperextensibility of all joints. At age 12 months, after she came out of a spica cast, compression fractures of T_8 were noted. At 13 months compression fractures of T_{10}-T_{12}, L_1, L_2, and L_4 were also noted. Mutation analysis of *LRP5*, including sequencing of exons and intron/exon boundaries, revealed a homozygous 2-base pair deletion (3194_3195delAC) in exon 14. This would cause a frame shift at amino acid 1065 (D1065fs) and addition of 71 missense amino acids. OPPG reveals that *LPR5* acts significantly in bone accrual. In 2002, a single base pair change in exon 3 of *LPR5* was shown to cause a benign phenotype, autosomal dominant high-bone mass trait. Deactivating mutations in *LPR5* cause OPPG syndrome with 6 homozygous disease-causing frame shift and nonsense mutations in *LPR5*, as well as 6 heterozygous putative disease causing missense mutations. These mutations were found in a variety of exons but not exon 14. Our patient has a novel, homozygous, 2-base pair deletion in yet another region of *LPR5* which is, therefore, important for the normal functioning of the gene product.

SU411

Incadronate Disodium Delays and Inhibits Periarticular Bone Atrophy and Joint Destructon in Rat adjuvant-induced Arthritis. T. Akiyama*[1], S. Mori[1], T. Mashiba[1], H. Dobashi*[2], S. Komatsubara*[1], K. Miyamoto*[1], Y. Cao*[1], H. Norimatsu[1]. [1]Department of Orthopaedics, Kagawa Medical University, Kagawa, Japan, [2]Department of 1st. Internal Medicine, Kagawa Medical University, Kagawa, Japan.

Joint detruction of Rheumatoid Arthritis (RA) is accompanied by periarticular bone loss. Bisphosphonates have been used as agents for osteoporosis treatment. In this study we investigated whether bisphosphonate can prevent or delay joint destruction and periarticular bone loss in RA by using rat adjuvant-induced arthritis (AIA) model. Arthritis was induced by injecting 0.1mg of heat-killed Mycobacterium butyricum into the base of tail of female Lewis rats(7 weeks age). Bisphosphonate(incadronate disodium : YM-175, Yamanouchi Pharmaceutical Co., Ltd.) was also administered subcutaneously 3 times per week at a dose of 0.01, 0.1 mg/kg/day. Body weight and hindpaw volume were checked every week. 2 and 4 weeks later, rats were sacrificed and both hindpaws were excised. Joint destruction was evaluated radiologically and histologically. Radiography of ankle (tibiotarsal) joint and tarsal bones were taken by using soft X-ray system. Decalcified saggital sections were cut from ankle joint, stained with toluidine blue and tartrate-resistant acid phosphatase(TRAP). Destruction of articular cartilage and subchondral bone and osteoclasts infiltration were evaluated by using histomorphometry. In arthritic rats body weight decreased and hindpaws swelling was observed at 1 week and 3weeks. At 2 weeks, no changes were observed both ragiolodically and histologically. At 4 weeks, widespread and severe destruction was observed radiographically in tibio-tarsal joint and tarsal bone in arthritic control group, while bone destruction was mild in YM-175 treated groups. Histologically, severe destruction of articular cartilage , numerous osteoclasts infiltration and marked osteopenia of subchondral bone were found in arthritic control group, while these changes were suppressed dose-dependently in YM-175 treated groups. The results show that periarticular bone atrophy and joint destruction were reduced by administering YM-175. However, several destructive changes were observed even in YM-175 treated rats, suggesting that YM-175 suppressed joint destruction by delaying progression of arthritis, rather than preventing arthritis itself. In this study, it is concluded that YM-175 can delay periarticular bone atrophy and joint destruction in rat AIA dose-dependently, but can not prevent them completely.

SU412

Prognostic Value of Serum Bone markers and Hand Bone Densitometry in Very Early Arthritis: Preliminary Results of the VErA Study. A. Daragon*[1], O. Vittecoq*[1], M. Brazier*[2], O. Mejjad*[3], P. Fardellone*[4], K. Krzanowska*[3], P. Boumier*[4], C. Zarnitzky*[5], A. Phan Van*[6], A. Gayet*[3], J. F. Menard*[7], X. Le Loët*[1]. [1]Rheumatology, CHU & INSERM U519, Rouen, France, [2]Biochimie, CHU, Amiens, France, [3]Rheumatology, CHU, Rouen, France, [4]Rheumatology, CHU, Amiens, France, [5]Rheumatology, CHG, Le Havre, France, [6]Rheumatology, CHU, Tours, France, [7]Biostatistics, CHU, Rouen, France.

The aim of the study was to determine the prognostic value of serum bone markers and hand bone densitometry in very early arthritis. From a population-based recruitment, 165 patients with very early (median duration: 4.4 months [1-6 mo]) peripheral arthritis (swelling >= 2 joints for > 4 weeks) were studied. Patients were steroid and DMARDs naive. After a year, patients were classified as RA or non RA. Assessments were performed at entry (T1), after 9 (T2) and 12 (T3) months. Serum bone markers were C telopeptide (sCTX) by ELISA test, pyridinoline (Pyr) and deoxypyridinoline (Dpyr) by HPLC. Other investigation : hand bone densitometry (DEXA), hand and foot X rays. Prognosis was defined as the progression of radiological damage from T1 to T3 (van der Heijde modified Sharp's method). At T3, 42 patients had radiological progressive disease, and 123 no progressive disease. 121/165 patients fulfilled ACR criteria for RA (69% in non progressive group, 86% in progressive group, $p = 0.02$). At T1, no difference was found between progressive group and non progressive group, except for rheumatoid factors more frequent in progressive group ($p < 0,02$). Bone mineral density (BMD) of both hands decreased significantly from T1 to T3 in both groups. However, hand BMD decreased significantly more in the progressive group (- 4.5 % versus - 1.7 %, $p< 0.04$). Levels of sCTX, Pyr and Dpyr at T1 were correlated to the decrease of hand BMD from T1 to T3 ($p< 0.04$). At T1, hand BMD was not different between the 2 groups, but levels of sCTX, Pyr and Dpyr were significantly higher in the progressive group ($p < 0.02$). In patients with early arthritis, a structural bone damage progression after 12 months duration is associated to a decrease of hand BMD. Moreover, decrease of hand BMD and X Rays progression were correlated with levels of serum bone markers at entry. So, sCTX, Pyr and Dpyr could be good predictive factors of the severity of early arthritis assessed by structural damage.

SU413

Biomechanical Properties of the Femoral Head Following Ischemic Necrosis. D. P. Pringle*, T. J. Koob*, H. K. W. Kim. Shriners Hospital for Children, Tampa, FL, USA.

Ischemic necrosis can cause permanent deformity of the femoral head, which can lead to premature degenerative arthritis of the hip. Changes in the biomechanical properties following ischemic necrosis and its role in the pathogenesis of femoral head deformity have not been previously investigated. The purpose of this experiment was to determine the biomechanical properties of the femoral head following ischemic injury in an established animal model. A ligature was placed tightly around the right femoral neck of 18 piglets to disrupt the blood supply to the femoral head. The animals were sacrificed at 2, 4 and 8 weeks post operatively ($n = 6$). Sham operations were performed on 8 piglets, which were sacrificed at 2 and 8 weeks. The load bearing areas of the femoral heads were indented perpendicularly with a 4 mm spherical indenter to a depth of 0.5 mm. Resultant force and indentation depth were measured and indentation stiffness was computed from the force deformation curves. The results were correlated with radiographic and histologic parameters. The left (non-infarcted) femoral heads and sham-operated heads were tested and used as controls. The biomechanical indentation properties of the ischemic heads were significantly reduced in comparison to the controls at 2, 4, and 8 weeks post surgery ($p < 0.001$ at all time periods). At 2 weeks, the average indentation stiffness of the infarcted heads decreased 51% as compared to the controls. The bony epiphysis was necrotic and its growth was arrested, but the heads were not deformed. The average head quotient (height of bony epiphysis divided by the width) was 0.45 which was the same as controls. At 4 weeks, the average indentation stiffness was further decreased to 75%. Small areas of the femoral head had become revascularized. In these areas, necrotic bone had been resorbed and replaced with fibrovascular tissue. Mild head deformity was present (average head quotient was 0.41). At 8 weeks, indentation stiffness was reduced by an average of 74%, which was not significantly different than from the values of specimens obtained at 4 weeks post surgery. All infarcted heads were severely deformed (average head quotient was 0.23). Large areas of revascularization and bone resorption had occurred. In some areas new bone had been laid down but in an irregular manner. There was a significantly large loss of compressive stiffness of the femoral head at the early stage of ischemic necrosis which preceded any radiographic changes other than growth arrest of the bony epiphysis. Our results suggest that from the early stage of ischemic necrosis, the infarcted head is mechanically compromised and institution of load limiting treatment would be clinically beneficial.

SU414

Apoptosis at the Interfacial tissue of Failed Hip Arthroplasty. S. Kim*[1], J. Choi[2], K. Koo*[3], J. Kim*[4], H. Shin*[5], E. Park*[6], Y. Sohn*[7]. [1]Orthopedic Surgery, Kyungpook National University Hospital, Daegu, Republic of Korea, [2]Biochemistry, School of Medicine, Kyungpook National University, Daegu, Republic of Korea, [3]Pathology, School of Medicine, Kyungpook National University, Daegu, Republic of Korea, [4]Microbiology, School of Dental Medicine, Kyungpook National University, Daegu, Republic of Korea, [5]Pathology, School of Dental Medicine, Kyungpook National University, Daegu, Republic of Korea, [6]Cell and Developmental Biology, Biomedical Research Institute, Kyungpook National University Hospital, Daegu, Republic of Korea, [7]Orthopedic surgery, School of Medicine, Gyungsang National University, Jinju, Republic of Korea.

Periprosthetic osteolysis and subsequent loosening are major causes of failure after total hip arthroplasty. In the interface tissue from failed hip after replacement arthroplasty, macrophages express inducible nitric oxide synthase (iNOS) mRNA and iNOS immunoreactivity. Nitric oxide (NO) mediates programmed cell death (apoptosis) in various types of cells. We hypothesized that phagocytic cells in the tissue of aseptic loosening and osteolysis serve as local source of NO and other proapoptotic factors, which will cause DNA damage leading to apoptosis. To investigate this hypothesis, the interface tissues from 18 patients who underwent revision hip arthroplasty due to osteolysis and aseptic loosening were examined. Apoptotic cells were identified using terminal deoxyribonucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) staining. Immunohistochemistry analysis also displayed positive signals for iNOS, p53, Bax (pro-apoptotic signal), Bcl2 (anti-apoptotic siganal), and Ki-67 (proliferative index of cells) in revision hip arthroplasty. Of 18 interface tissues, 16 (89%) samples were positive for iNOS, p53, and Bax. In addition, 12 (67%) samples were positive for Bcl2 and Ki-67. All samples were positive for TUNEL staining. As control, 6 joint capsules were chosen as negative control and 6 herniated nucleosus pulposus materials were chosen as positive control. Of 6 joint capsules, only one (17%) was positive for iNOS, and Bax, respectively and three (50%) tested positive for TUNEL staining. Of six herniated nucleosus pulposus materials, four (67%) tested were positive for iNOS, three (50%) tested positive for Bax, one (17%) tested positive for Bcl2, one (17%) tested positive for Ki-67, and four (67%) tested positive for TUNEL staining. These results indicate that apoptosis inducing factors including nitric oxide, p53 and Bax might be important players in the pathogenesis of aseptic loosening and osteolysis of failed total hip arthroplasty.

SU415

Loss of Resistance to Vascular Invasion and Global Changes in Protein Synthesis with Increasing Severity of Osteoarthritis. J. O. Smith*, R. O. C. Oreffo, N. M. P. Clarke*, H. I. Roach. University Orthopaedics, University of Southampton, Southampton, United Kingdom.

The etiology of osteoarthritis (OA) remains unclear. To better understand the cellular basis, we compared the articular cartilage of human femoral heads from (1) 'controls' with non-OA cartilage, (2) OA samples with low degradation and (3) OA samples displaying high degradation. First, we tested the resistance to vascular invasion by placing pieces of cartilage onto the chorio-allantoic (CAM) membrane of chick embryos and culturing for 3-7 days. The vascular mesenchyme of the CAM will invade any tissue unless prevented by endogenous anti-angiogenic factors. 'Control' cartilage was resistant to vascular invasion, even when the angiogenic factor VEGF or the matrix-degrading enzyme MMP-9 were added to the tissue. In contrast, invasion took place in ~50% of OA samples. VEGF increased the incidence to 70% and MMP-9 further increased vascular invasion to 85% in low degradation and to 100% in high degradation samples. To further define the phenotype of OA chondrocytes, we studied their protein expression by immunocytochemistry. In contrast to 'control' chondrocytes, doublets or quadruplets of cells were present in the superficial layers of samples with low degradation. These chondrocytes had become activated (c-MYC positive) and expressed atypical proteins (e.g. VEGF and MMP-9), whereas single cells of the intermediate zone did not. At the border between the superficial and intermediate zone, we identified asymmetric cell divisions, i.e. divisions that define branch points in lineage commitment. This yielded one "osteoarthritic" chondrocyte (positive for c-MYC and VEGF/MMP-9) and one apoptotic cell. The "osteoarthritic" chondrocytes continued to divide and thus propagated the atypical phenotype so that chondrocytes in samples of severely degraded cartilage were present in clones of up to 32 cells with all cells expressing MMP-9/VEGF. We hypothesize that a global change in gene expression had taken place during the asymmetric cell division in which previously silenced genes, such as VEGF and MMP-9, were activated and constitutively expressed, possibly due to changes in the DNA methylation status of the promoter regions. These studies indicate that an early and significant characteristic of OA cartilage was loss of the normal resistance to vascular invasion and increased susceptibility to exogenous VEGF and MMP-9. In addition, global changes in protein expression occurred resulting in the constitutive expression of "osteoarthritic" chondrocytes (e.g. VEGF/MMP-9), contributing further to the progression of the disease. Delineation of the trigger for these changes has clear therapeutic implications.

SU416

Effect of $_{v}\beta_3$ Integrin Deletion on Inflammatory Arthritis. K. Aya[1], C. Pham*[2], K. Roth*[1], F. P. Ross[1], S. L. Teitelbaum[1]. [1]Pathology, Washington University School of Medicine, St. Louis, MO, USA, [2]Rheumatology, Washington University School of Medicine, St. Louis, MO, USA.

Periarticular osteolysis, reflecting accelerated osteoclast formation and function in face of inflammatory cytokines, is a disabling complication of rheumatoid arthritis.Thus, arrest of osteoclast function holds promise as a means of preventing bone loss in affected patients. The $\alpha_v\beta_3$ integrin is a particularly attractive target, in this regard, because not only is it the major integrin expressed by osteoclasts but is also abundant on stimulated endothelial cells. Thus $\alpha_v\beta_3$ is believed to play a role in neo-angiogenesis which may impact the inflammatory lesion as well as osteoclastogenesis. To determine if $\alpha_v\beta_3$ blockade holds promise as an inhibitor of the bone loss of rheumatoid arthritis we established an experimental paradigm of the disease, namely collage-induced arthritis (CIA) in $\alpha_v\beta_3$ deficient mice. Because the DBA1/J strain is most susceptible to CIA, β_3-/- C57BL6 mice were crossed to this background. The N2 β_3+/- mice whose leukocytes expressed the highest levels of the CIA susceptibility marker, I-A^q, were selected to breed N3. β_3-/- and β_3+/- littermates were injected, intradermally with 100 mg of bovine collagen type 2 (CII) in CFA containing heat-killed *Mycobacterium tuberculosis*. This was repeated 21 days later. The severity of arthritis in each paw was graded from 0 = normal to 3= severe. The sum of all four paws in each mouse was used as clinical score(CS). 2 weeks after the 2nd CII injection, CS in β_3+/-(9.7± 3.3) and β_3-/- (12 ±0) mice were similar as was the increase in hindpaw thickness (IHT) (β_3+/-, 0.76± 0.41; β_3-/-, 0.81± 0.27 mm). At three weeks, β_3+/- CS was 10.3± 2.4 and β_3-/- 12 ±0. IHT in both groups was also similar (β_3+/-, 0.85± 0.35; β_3-/-,0.59± 0.24 mm). All animals had radiographically detectable bony erosions, the severity of which was comparable in the mutant and control arthritic animals. Histological examination of hindpaws also revealed similar magnitudes of inflammation, cartilage damage, and bone erosion. Surprisingly, neo-angiogenesis was not decreased in inflamed joints of β_3-/- mice (PECAM-1(+) capillaries- β_3+/-, 429.2±45.3/mm^2; β_3-/-, 512.6± 78.0) (VEGFR2(+) capillaries- β_3+/-, 342.8±23.9; β_3-/-, 403.0± 78.2/mm^2). We have shown that high dose M-CSF normalizes β_3-/- osteoclast formation and function. In fact we find levels of the cytokine increased 10X by immunoblot, in arthritic paws. Thus, deletion of the $\alpha_v\beta_3$ integrin does not dampen inflammation or bone erosions in experimental rheumatoid arthritis. The aggressive bone resorption extant in these mutants may reflect normalization of β_3-/- osteoclasts by high ambient M-CSF.

SU417

Receptor Activator of the Nuclear Factor Kappa-B Ligand (RANKL) in Serum Is Related to Bone Density, Cartilage Breakdown and Inflammation in Early Active Rheumatoid Arthritis. P. Geusens[1], R. Landewé*[2], D. Chen*[3], C. Dunstan*[3], P. Garnero[4], S. van der Linden*[2], M. Boers*[5]. [1]Rheumatology, Maastricht University, Maastricht, Netherlands, [2]Maastricht University, Maastricht, Netherlands, [3]Amgen, Thousands Oaks, CA, USA, [4]INSERM, Lyon, France, [5]VU University Hospital, Amsterdam, Netherlands.

Bone involvement in rheumatoid arthritis (RA) is characterised by erosions in the joints, and periarticular and generalised bone loss. The final effector of this bone involvement is the osteoclast. As RANKL plays a central role in osteoclast activation, we studied the relation of serum RANKL to bone erosions, periarticular and generalised bone density at baseline in 119 patients with early active RA in the COBRA trial (Lancet 1997; 350:309, Arthritis & Rheumatism 2002; 46:347). Serum RANKL was measured by ELISA with two different monoclonal antibodies directed against the extracellular domain of human RANKL used for capture and detection. Serum RANKL values were logarithmically transformed. Bone mineral density (BMD) was measured in the spine and hip using DXA. Joint damage was scored using the Sharp-van der Heijde index. ESR, CRP and disease activity score (DAS) were used as markers of disease. C-telopeptide fragments of collagen type 1 (CTx-1) and CTx-2 were measured in urine and corrected for creatinine excretion. RANKL was negatively related to BMD in the hip (r=-0.226, p<0.05) and borderline to BMD in the spine (r=-0.188, p=0.07). No significant correlation was found with radiographic joint damage. RANKL was correlated with urinary CTx-2/creatinine (r=0.285, p<0.01) and CTx-1/creatinine (r=0.242, p<0.05). RANKL was related to CRP (r=0.355, p<0.001), ESR (r=0.255, p=0.01) and DAS (r=0.203, p<0.05). RANKL was higher in patients with rheumatoid factor (RF) than in patients without RF (p<0.001). We conclude that in patients with early active RA serum RANKL is related to periarticular BMD (in the hip) and to cartilage breakdown and borderline to generalised bone loss (in the spine). Serum RANKL is related to parameters of inflammation, and is higher in patients with RF. These results indicate that RANKL could play a central role in bone involvement of RA.

SU418

Estrogen Inhibits T Cell-Mediated Arthritis and RANK-Mediated Bone Resorption in Rats with SCW-Induced Arthritis. J. Chen, K. J. Downey*, J. L. Funk. Medicine, University of Arizona, Tucson, AZ, USA.

Streptococcal cell wall (SCW)-induced arthritis, an animal model of rheumatoid arthritis (RA), displays two stages of disease development, a chronic phase that is T cell-dependent and a separate acute phase that is not. Estrogen has previously been shown to inhibit collagen-induced arthritis, an animal model of RA that is also T cell-dependent. If the protective effect of estrogen in arthritis is T cell-mediated, we postulated that estrogen treatment in the SCW model would block the development of chronic arthritis, but not the T cell-independent acute phase. Additionally, we postulated that estrogen treatment would inhibit the bone loss that accompanies T cell-mediated arthritis. To test these hypotheses, a series of experiments were performed using 100g female Lewis rats treated with: (1) vehicle alone (control), (2) 17ß-estradiol (E2, 200-600µg/kg/d sc begun either 1 h or 4 d prior to SCW injection), (3) SCW (25mg/kg ip), or (4) SCW + E2. During the 36 d experiments, SCW-treated animals developed the usual acute phase of arthritis and subsequent nadir in joint swelling, followed by a persistent chronic phase of arthritis. Associated with the development of arthritis, bone mineral density (BMD) decreased in the femur (-19%) and lumbar spine (-13%) (GE Lunar PIXImus 2). Serum pyridinoline (Metra Biosystems), a marker of bone resorption, increased 62% in SCW animals, while osteocalcin (Biomedical Technologies), a marker of bone formation, was unchanged. Bone marrow cells, isolated from femurs and cultured with M-CSF and a RANK activating antibody, showed a 2-fold increase in osteoclast formation in SCW vs. control animals. Treatment of SCW animals with E2, even at doses as high as 600 µg/kg/d begun 4 days prior to SCW injection, did not prevent the acute phase of arthritis, as assessed by Arthritic Index, a standard measure of joint swelling. In contrast, during the chronic phase, E2 inhibited joint swelling by 46% ($p < 0.01$). E2 treatment, while having no effect on BMD in normal animals, inhibited SCW-induced bone loss by 47% and 61%, respectively, in the femur and spine ($p< 0.05$). E2 treatment also inhibited 50% of the increase in serum pyridinoline seen in SCW animals ($p< 0.05$), while having no effect on osteocalcin levels. Consistent with these results, evaluation of osteoclastogenesis in bone marrow cultures revealed a protective effect of E2 treatment in preventing 46% of the increase in RANK-mediated osteoclast formation seen in SCW animals ($p < 0.001$). These results suggest that estrogen treatment only inhibits T cell-dependent joint inflammation in animal models of RA. Moreover, estrogen treatment prevents arthritis-associated bone loss by blocking RANK-mediated bone resorption.

SU419

Synovial Fluid Concentrations of Leptin Increase in Knee Osteoarthritis. S. Juma[1], D. Soung[1], D. A. Khalil[1], C. Pasque*[2], B. H. Arjmandi[1]. [1]Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, [2]Orthopaedic Surgery and Rehabilitation, Oklahoma University Health Sciences Center, Oklahoma City, OK, USA.

A recent study has demonstrated that human chondrocytes express functional leptin receptors. This receptor is a member of the class I cytokine receptor family that mediates the effects of numerous different cytokines. In osteoarthritis (OA), the balance between cartilage synthesis and degradation is disrupted which, in part, may be due to increased production of pro-inflammatory cytokines and altered sensitivity to growth factors such as insulin-like growth factor-I (IGF-I). The present study explores the possible connection between synovial concentrations of leptin and IGF-I with the incidence of knee osteoarthritis (OA). Synovial fluid specimens were obtained from a total of thirty-four individuals (21 females and 13 males) with and without OA. Specimens were analyzed to determine leptin, IGF-I, and IGF-binding protein-3 (IGFBP-3) concentrations and were normalized to total protein.The synovial fluid levels of leptin, IGF-I, and IGFBP-3 concentrations were significantly higher in women with knee OA, but not in men. The elevated levels of leptin in synovial fluid of osteoarthritic individuals is suggestive of the loss or weakening of signaling pathways by which leptin interacts with chondrocytes to promote or maintain cartilage health. The functional roles of leptin and its receptors in cartilage metabolism in normal and osteoarthritic conditions need to be explored.

Synovial Fluid	F-NOA	F-OA	M-NOA	M-OA
Leptin (ng/mL)	7.89 ± 4.75	34.23 ± 5.54*	15.34 ± 4.12	23.95 ± 7.43
Normalized Leptin (ng/mg protein)	0.62 ± 0.15	2.42 ± 0.28*	1.70 ± 0.64	1.49 ± 0.34
IGF-I (pg/mL)	13.2 ± 5.3	52.5 ± 14.2*	51.8 ± 8.8	66.9 ± 10.4
Normalized IGF-I (pg/mg protein)	1.30 ± 0.24	3.20 ± 0.67*	3.60 ± 0.53	4.51 ± 1.19
IGFBP-3 (ng/mL)	5.0 ± 1.2	53.4 ± 4.0*	58.4 ± 16.9	74.6 ± 3.7

Oral Antiresorptive Therapy Prevents Bone Loss at the Lumbar Spine One Year After Liver Transplantation. P. M. Camacho[1], K. K. Islam*[2], M. I. Peralta*[1], S. D. Creech*[3], N. Bella*[1], F. A. Nabham*[4], G. W. Sizemore[1], D. H. Van Thiel*[2]. [1]Endocrinology and Metabolism, Loyola University of Chicago, Maywood, IL, USA, [2]Gastroenterology, Hepatology and Nutrition, Loyola University of Chicago, Maywood, IL, USA, [3]Oncology Institute, Loyola University of Chicago, Maywood, IL, USA, [4]Medicine, Loyola University of Chicago, Maywood, IL, USA.

Osteoporosis and fractures are known complications of liver transplantation. Previous studies have shown rapid declines in bone mineral density (BMD) in the lumbar spine (LS) and femoral neck (FN) in the post-transplantation period. There is a paucity of data on effective therapy for liver transplant-induced osteoporosis. One study evaluated intravenous pamidronate, and another small study compared calcitonin with etidronate sodium. There is no published study on the use of other oral antiresorptive therapy for prevention of liver transplantation-induced osteoporosis. We retrospectively evaluated pre and one year post-transplantation BMD's of 27 patients who underwent liver transplantation at Loyola University Medical Center from 1998-2000. 14 patients received oral antiresorptive therapy (**Tx group**), including alendronate (11), risedronate (2), estrogen (1). Combination therapy was used in 7/14 patients. 13 patients received no antiresorptive therapy (**no Tx group**). Patients with creatinine above 2 ug/dl, abnormal thyroid stimulating hormone or calcium levels before transplantation were excluded from the study. There were no differences in baseline characteristics (age, sex, weight, height, calcium and creatinine levels, pretransplant liver disease) between the groups. Pretransplant LS BMD was not statistically different but FN BMD was significantly lower in the Tx group (p=.048).

Comparison of Pre and One Year Post-transplant BMD Results

	No Tx Group		Tx Group	
	LS BMD	FN BMD	LS BMD	FN BMD
Baseline	1.234 ± .22	1.067 ± .17	1.147 ± .25	.929 ± .17
One year	1.190 ± .19 (p=.026)	.952 ± .18 (p=.008)	1.120 ± .26 (p=.552)	.844 ± .09 (p=.030)

BMD's are expressed as mean ± SD in gm/cm2. P values compare baseline and post-transplantation BMD using the Wilcoxon Signed-Rank test. At one year, the **no Tx** group had significant bone loss at the LS and FN. The **Tx** group preserved bone at the LS, but lost bone at the FN. Oral antiresorptive therapy appears to diminish bone loss at the lumbar spine one year after liver transplantation.

SU421

One Year Controlled Trial of Pamidronate in the Treatment of Severe Osteopenia After Long Term Renal Transplantation. C. Montilla*, E. Hernandez*, E. Alonzo*, R. Carlini*, A. Arminio*, P. Clesca*, E. Bellorin-Font*, J. R. Weisinger. Division of Nephrology, Hospital Universitario de Caracas, Caracas, Venezuela.

Bone loss, osteopenia and skeletal morbidity after renal transplantation have been well documented. Previous studies from our laboratory have demonstrated that bone alterations can persist many years after a successful renal transplant. Nevertheless, most of the therapeutic efforts have been directed toward the rapid bone loss occurring immediately after the transplant. For these reasons, we decided to conduct a prospective, randomized controlled study on the use of the bisphosphonate Pamidronate in long term male renal transplant patients with evidence of severe osteopenia or osteoporosis as assessed by dual X ray absorptiometry. Twenty-four patients were randomized to receive either oral Pamidronate (200 mg BID) or placebo. Lumbar spine (LS) and femoral neck (FN) bone mineral density (BMD) were similar in both groups at the start of the study. Both groups were similar in age (42.3 ± 6.1 and 37.3 ± 9.1 years), time after transplantation (6.8 ± 2.4 and 5.75 ± 1.91 years), and renal function (serum creatinine of 1.32±0.15 and 1.5±0.2 mg/dL). After one year of treatment, LS BMD increased significantly (6.6 %) in the Pamidronate group (0.927 ± 0.73 to 0.989 ± 0.093 g/cm^2, $p< 0.01$) with an important decrease in the T score (-2.58±0.82 to -2.10±0.87, $p< 0.05$). Similarly, no significant changes were observed in the LS BMD (0.919±0.08 to 0.944±0.09 g/cm^2, NS) or the T score (-2.63±0.65 to -2.44±0.7, NS) in the placebo group. No changes were observed in the femoral neck BMD in both the Pamidronate or placebo groups. Biochemical values including serum calcium, phosphorus and immunoreactive PTH were similar in both groups and did not change after treatment. There was a significant decrease in bone resorption markers (N-telopeptide of collagen cross-links) in the Pamidronate group with no change in the placebo treated patients. No significant side effects were observed in the Pamidronate group when compared to placebo. In summary, this study has shown an important improvement in bone mineral metabolism after 12 months on Pamidronate. The long-term effect of this drug remains to be clarified.

SU422

The Changes of Serum Growth Factor Levels Following Bone Marrow Transplantation: Impact on Bone Turnover Markers and Bone Mineral Density. M. I. Kang, K. H. Baek*, W. Y. Lee*, E. S. Oh*, K. W. Oh*, H. S. Kim*, J. H. Han*, K. W. Lee*, H. Y. Son*, S. K. Kang*, C. C. Kim*. Department of Internal Medicine, The Catholic University of Korea, College of Medicine, Seoul, Republic of Korea.

Loss of bone mass is usually detected after bone marrow transplantation(BMT), especially during the early post-transplant period. We recently reported that enhanced bone resorption following BMT is related to both the steroid dose and the increase in IL-6. We also suggested damage of marrow stromal microenvironment by myoablation partly explains impaired bone formation following BMT. It is well known that some growth factors play an important role in bone growth and osteogenesis. However, there has been no report in which the relationship between serum FGF-2 and IGF-I levels and BMD in human was studied. We have prospectively investigated 110 patients undergoing BMT and have analyzed 36 patients(32.4±1.3 years, 17 men and 19 women) who was measured DEXA before and 1 year after BMT. Serum calcium, phosphorus, creatinine, and biochemical markers of bone turnover were measured before BMT and 1, 2, 3, 4 and 12 wks, 6 Ms, and 1 yr after BMT. Serum FGF-2 and IGF-I levels were measured before BMT and 1, 3, and 12 wks after BMT. The mean bone loss in the lumbar spine and total proximal femur, calculated as the percent change from the baseline to the level at 1 yr was 5.2% ($p<0.05$) and 11.6% ($p<0.01$), respectively. The serum ICTP increased progressively until 4 weeks after BMT. Thereafter, it decreased gradually to reach basal values after 1 year. Serum osteocalcin decreased progressively until 3 wks after BMT. Then it increased transiently and finally returned to basal level at 1 yr. Serum FGF-2 and IGF-I also decreased progressively until 1 wks and 3 wks respectively, then increased to basal values at 3 Ms. There were positive correlation between the percent changes from the baseline BMD of lumbar spine and proximal femur BMD and baseline IGF-I level($r=0.50$, $p<0.05$, $r=0.51$, $p<0.05$). Significant correlation was also found between IGF-I and osteocalcin levels at 3 weeks after BMT. There was a strong positive correlation between the percent change of lumbar spine during post-BMT 1 yr and FGF-2 serum level at 3 wk ($r=0.75$, $p<0.01$), but not proximal femur. In conclusion, there was significant decline in the serum IGF-I and FGF-2 levels at immediate post-BMT period and it was related with decrease in bone formation and decrease of lumbar spine BMD during 1 year following BMT.

SU423

Testosterone Supplementation has Additional Benefits on Bone Metabolism in Cardiac Transplant Recipients Receiving Intravenous Bisphosphonate Treatment: A Prospective Study. A. Fahrleitner[1], G. Prenner*[2], K. H. Tscheliessnigg*[2], G. Leb*[1], C. J. Piswanger-Sölkner*[1], B. Obermayer-Pietsch*[1], H. P. Dimai[1], H. Dobnig[1]. [1]Endocrinology, Medizinische Universitätsklinik, Graz, Austria, [2]Transplantation, Universitätsklinik für Chirurgie, Karl-Franzens University, Graz, Graz, Austria.

Bisphosphonates (BP) are a promising therapeutic option in patients following solid organ transplantation. Hypogonadism is a frequent complication of immunsuppressive therapy. Aim of this study was to evaluate the effects of testosterone supplementation in addition to intermittent intravenous BP treatment on bone metabolism in patients following cardiac transplantation (CTX). Forty-one cardiac transplant recipients (mean age 56 +/- 9) were categorized as either eu- (n=18) or hypogonadal (n=23) based on their free testosterone levels. All patients were treated with 2mg ibandronate intravenously every three months in combination with 1200mg calcium and 800 IU vitamin D daily. Ten of the hypogonadal patients received additional testosterone supplementation (250 mg testosterone enanthate i.m. every 4 to 6 weeks). A laboratory analysis as well as a DXA measurement of the hip was performed at baseline and after 1 year of treatment. Baseline testosterone serum levels showed a positive correlation with bone mineral density (BMD) at the hip (Z-score [neck] and [trochanteric region]: $r=0.35$; $p=0.03$; Z-score [total hip]:$r=0.37$; $p=0.02$) and a negative correlation to the time elapsed since TX ($r= - 0.42$; $p=0.007$). Mean neck-BMD of hypogonadal men was 1 SD lower when compared to eugonadal men ($p<0.001$), whereas patient groups did not differ in age, cumulative prednisolone dosage, renal function, bALP, serum CTX, osteocalcin, iPTH or vitamin D3 levels. ;

	Baseline	delta BMD	delta BMD	CTX changes
	Z-score (neck)	delta Z-neck	delta Z-troch	delta sCTX
Eugonadal (n=18)	- 0.13 +/- 0.27	0.04 +/- 0.03	0.03 +/- 0.04	- 1023 +/- 515
Hypogonadal				
+testosterone (n=10)	-1.79 +/- 0.33*	+0.13 +/- 0.02*	+0.15 +/- 0.04*	- 2359 +/- 803*
-testosterone (n=13)	-1.21 +/- 0.33*	+0.03 +/- 0.02	+0.03 +/- 0.04	-524 +/- 402

*$p<0.05$ vs. baseline and eugonadal patients

A subanalysis of hypogonadal men with vs. hypogonadal men without testosterone supplementation revealed that significant reductions in bone turnover and gains in BMD were confined to testosterone-treated patients (see table).In summary, intermittent ibandronate therapy combined with calcium/vitamin D supplementation independent of gonadal status prevents bone loss in cardiac transplant recipients. Testosterone replaced hypogonadal men show an additional benefit in terms of slowing of bone turnover and increases in BMD.

SU424

The Growth Plate Under Immunosuppressive Therapy. C. P. Sanchez, Y. Z. He*. Pediatrics, UW Medical School, Madison, WI, USA.

Immunosuppressive agents necessary to maintain the renal allograft may affect linear growth in children. There is limited information on the effects of these agents on the growth plate cartilage. Thus, 51 weanling rats, 46± 4 grams, were randomly divided into the following treatment groups: Control (N=13) received saline, Pred (N=12) received prednisone at 3 mg/kg/dose, Rapa (N=13) received rapamycin at 2.5 mg/kg/dose, and CsA (N=13) received cyclosporine at 7 mg/kg/dose. The animals were evaluated after 14 days (N=24) and 28 days of treatment (N=27). All medications were given daily by gavage route at the same volume. Body weight and body length were obtained weekly. All animals were pair-fed to the Rapa group. To measure bone growth, tetracycline was given intraperitoneally 48 and 24 hours prior to sacrifice. Blood was collected for serum calcium (Ca), phosphorus (Phos), IGF-I and PTH at the time of sacrifice. The proximal tibia was obtained for growth plate histomorphometry. Gain in body weight was less in Rapa and Pred groups, 62± 6 and 66± 8 grams, compared to Control and CsA animals, 73± 7 and 77 ±3 grams, $p<0.003$, after 14 and 28 days of therapy. Gain in body length was much less in the Rapa animals, 7.6± 0.6 cm after 14 days and 13±1.2 cm after 28 days, compared to Control animals, 8.6± 0.5 and 16±0.6 cm, $p<0.006$. CsA animals had the largest increase in body length after 14 days of treatment, 9.3± 0.7 cm. Tibial length was shortest in the Rapa group, 3.0 ±0.05 and 3.4±0.09 cm, after 14 and 28 days, compared to Control, Pred and CsA groups, $p<0.05$. Serum Ca, Phos, IGF-I and PTH did not differ in all groups after 14 days of therapy, however, serum Ca, Phos, and PTH levels were lower in the Rapa group, 9.9± 0.1 mg/dl, 10± 0.4 mg/dl, and 31±21 pg/ml, respectively, after 28 days of treatment compared to the other groups, $p<0.05$. After 14 days of therapy, the width of the growth plate was widest in the Rapa animals, 675± 90 um, when compared to the Control, Pred and CsA groups, 499± 29, 498± 43 and 481± 42 um, $p<0.0001$. The area occupied by the hypertrophic chondrocytes was wider, 0.6± 0.02, and the proliferative chondrocytes smaller, 0.4 ±0.05, in the Rapa animals versus the other groups, 0.5 ±0.02, $p<0001$. Bone growth was greater after 14 days of treatment in the CsA treated animals, 312± 131 um/day, and lesser in the Pred animals, 120± 20 um/day, compared to the Control and Rapa animals, 154± 53 and 230± 159 um/day, $p<0.03$. After 28 days of treatment, however, the width of the growth plate and bone growth did not differ in all groups. Thus, rapamycin therapy may adversely affect the growth plate in the younger growing animals, but these changes may not be as evident in older animals. Further studies to evaluate changes in chondrocyte proliferation, chondrocyte hypertrophy and ossification during rapamycin therapy are needed.

SU425

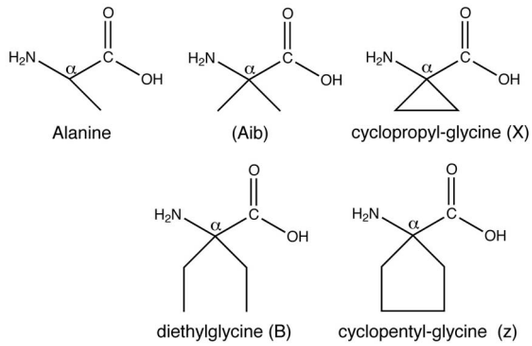
Response of Parathyroid Gland to Human Parathyroid Hormone (1-34) Infusion in Adult Growth Hormone Deficiency Before and During Growth Hormone Replacement. A. M. Ahmad*[1], J. Thomas*[1], M. Hopkins*[1], B. Durham*[2], H. White*[1], J. P. Vora*[1], W. D. Fraser*[2]. [1]Diabetes & Endocrinology, Royal Liverpool University Hospital, Liverpool, United Kingdom, [2]Clinical Chemistry, Royal Liverpool University Hospital, Liverpool, United Kingdom.

Alterations in both parathyroid gland sensitivity to changes in calcium concentration and end-organ response to the effects of PTH play a role in the development of osteoporosis. Since adult growth hormone deficiency (AGHD) is associated with increased prevalence of osteoporosis, we studied the effects of PTH (1-34) infusion on end-organ and parathyroid gland responsiveness. 6 patients with severe AGHD were recruited. All patients were admitted, prior to commencement of GH replacement (GHR), at 1300 h. Venous cannulae were inserted in each arm and ½ hourly blood sampling was commenced at 1400 h. hPTH (1-34) in normal saline was infused at a rate of 0.55 U/ kg/h over 24 h. PTH, calcium and albumin were measured on all samples. GHR was commenced after the baseline visit. The protocol was repeated at 3 and 12 months on GHR. The first 2 samples were averaged and demonstrated a significant increase in adjusted-calcium (ACa) concentration (mmol/L) at 3 and 12 months compared to baseline ($p<0.001$). A significant decrease in PTH (1-84) concentration (pmol/L) was observed at 3 and 12 months ($p<0.01$). Following hPTH (1-34) infusion, ACa concentration increased after 12 h in untreated AGHD patients, whereas, after 12 months on GHR, ACa concentration increased within 6 h. After 12 months on GHR, the percentage increase at 6 h was 3.2 ± 0.60% *vs.* 0.83 ± 0.66% in untreated AGHD patients ($p<0.05$) that remained significantly higher over the 24 h (17.8 ± 2.9% *vs.* 12.6 ± 2.2%, $p<0.05$). There was no significant difference in the maximum PTH (1-84) suppression between 0 (78.2%), 3 (77.3%) and 12 months (79.1%). There was a significant increase in the calcium set-point (the calcium concentration at which the rate of PTH secretion is one half of its maximal value) after 3 (2.50 ± 0.02, $p<0.05$) and 12 months (2.74 ± 0.02, $p<0.001$) compared to baseline (2.38 ± 0.03). We have demonstrated increased end-organ responsiveness to the effects of PTH resulting in a significant increase in calcium concentration in response to PTH (1-34) infusion, following GHR. These findings together with the significant increase in calcium set-point may explain the increase in basal calcium and decrease in PTH concentration following GHR. These results may help understand the mechanisms underlying the genesis of osteoporosis in AGHD.

SU426

Structurally Varied Conformationally Constrained Amino acids Substitutions at Positions 1 and 3 of PTH(1-14) Preserve or Enhance P1R Binding Affinity and cAMP-Signaling Potency. N. Shimizu, T. J. Gardella. Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

The structural basis by which the N-terminal residues of PTH contribute to the PTH receptor interaction process is unknown. Recently we found that PTH(1-14) analogs containing the α,α di-substituted amino acid, α-amino-isobutyric acid (Aib) at positions 1 and/or 3, have 10- to 100-fold higher affinities and cAMP signaling potencies than do their counterpart peptides containing alanine at these positions (Shimizu et al. 2001,JBC. 276 pp 49003). These enhancing effects could be due to new receptor contacts provided by the additional methyl group on Aib, or to the conformational constraints imposed by this residue on the peptide backbone, which favor α-helix. To examine these possibilities, we investigated whether other α,α-di-substituted amino acids distinct from Aib would also enhance affinity when introduced at positions 1 and/or 3 of [M]PTH(1-14) (M = $Ala^{1,3,12}$,Gln^{10},Har^{11},Trp^{14}). Three amino acids were chosen: diethylglycine (**B**), cyclopropylglycine (**X**) and cyclopentylglycine (**Z**):



In competition binding assays performed in an LLC-PK1-derived cell line (B28) that stably expresses the hPTH-1 receptor using ^{125}I-[$Aib^{1,3}$,Nle^{8},Tyr^{21},M]PTH(1-21) tracer, the affinities of the B3-, and Z3-containing analogs were comparable to that of [M]PTH(1-14) (IC_{50}s ~ 30 μM); the affinity of X3-containg analog was 14-fold lower than that of [M]PTH(1-14), and the affinities of the B1-, X1- and Z1-substituted peptides were 3- to 50-fold higher than that of [M]PTH(1-14), with the highest affinity exhibited by [Z^{1},M]PTH(1-14) (IC_{50} = 0.6 μM). The analog [Z^{1},Aib^{3},M]PTH(1-14) exhibited the highest binding affinity (IC_{50} = 100 nM) and cAMP potency {EC_{50} = 0.9 nM, compared to 200 nM for [M]PTH(1-14)} of any PTH(1-14) analog studied to date. The finding that several structurally distinct α,α-di-substituted amino acids improve affinity and potency when introduced at positions 1 and 3 of PTH(1-14) suggests that the enhancing effects of these substitutions are not due to specific sidechain contacts with the receptor, but, to the constraining effects that these residues have on the ligand's backbone conformation. The results are further consistent with the hypothesis that the amino-terminal domain of PTH is α-helical when bound to the activation domain of the P1R.

Role of Residue 19 in PTH(1-20) Analogs: Functional Evidence for Modulation of N-terminal alpha-helical Structure. N. Shimizu[1], J. C. Tsang*[1], J. T. Potts[1], A. Piserchio*[2], D. F. Mierke*[2], T. J. Gardella[1]. [1]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, [2]Department of Chemistry and Molecular Pharmacology, Brown University, Providence, RI, USA.

Previous data suggest that residue 19 in PTH and PTHrP (Glu and Arg, respectively) play important roles in binding to the PTH-1 receptor (P1R), but the molecular mechanisms remain unclear. We showed previously that, relative to Glu19, Arg19 increases PTH(1-34) affinity ~10-fold, but does not affect PTH(15-34) affinity, suggesting that the enhancing effect is mediated via the N-terminal portion of the ligand (Gardella et al. 1995 JBC 270 6584). More recently we showed that Aib substitutions at positions 1 and 3 in [M]PTH(1-14) (M = Ala1,3,12,Gln10,Har11,Trp14) increases affinity 10- to 100-fold and increases helicity, as judged by CD spectroscopy (Shimizu et al. 2001 JBC 76 49003). These observations led us to hypothesize that Arg19 and the Aib,1,3 substitutions improve affinity by the same mechanism: e.g. by stabilizing an N-terminal helix, and they would thus be redundant with each other. To test this, we prepared four [M]PTH(1-20) analogs that differed by having either Glu or Arg at position 19, and either Aib or Ala at positions 1 and 3, and we assessed their functional properties in an LLC-PK1-derived cell line (B28) that expresses the hP1R via stable transfection. In competition binding studies performed with 125I-[M,Y21]PTH(1-21) tracer radioligand, the apparent affinity of [R19,M]PTH(1-20) was 41-fold higher than that of [E19,M]PTH(1-20) (IC_{50} = 29±3 nM vs. 1,200±100 nM) whereas the affinity of [Aib1,3,R19,M]PTH(1-20) was only 9-fold higher than that of [Aib1,3,E19,M]PTH(1-20) (IC_{50}s = 7.7±1.7 nM vs. 72±28 nM). Effects on cAMP signaling potency were proportional to these effects on binding affinity, and parallel results were obtained in LLC-PK1 cells that express, via stable transfection, P1R-delNt, which lacks the amino-terminal extracellular domain. The overall results suggest that the enhancing effects of the Arg19 modification and that of the combined Aib1,3 modifications on affinity are largely redundant. Furthermore, in both cases, the effects are mediated via the juxtamembrane (J) region of the receptor. The data are thus consistent with the notion that the enhancing effects of both modifications (e.g. Aib1,3 and R19) are due to stabilization of α-helical structure in the N-terminal portion of the ligand, a conclusion supported by our initial NMR analyses. The preferred agonist structure for productive interaction with the J region of the P1R may thus be a helical segment comprised of PTH residues (1-20).

Gender Differences in the Response of Mouse Bone to Parathyroid Hormone. Y. Wang*[1], T. Sakata[1], B. P. Halloran[1], W. Beamer[2], C. Rosen[3], H. Z. ElAlieh*[1], S. Majumdar[4], D. D. Bikle[1]. [1]Endocrine Unit, University of California, Veterans Affairs Medical Center, San Francisco, CA, USA, [2]Jackson Laboratory, Bar Harbor, ME, USA, [3]St. Josephs Hospital, Bangor, ME, USA, [4]Department of Radiology, University of California, San Francisco, CA, USA.

Parathyroid hormone (PTH) possesses bi-directional actions, i.e. it is bone-catabolic and anabolic. Studies on the skeletal effects of PTH have seldom considered the effects of gender. Our study was designed to determine whether the response of mouse bone to PTH differed according to sex. As a first step, we analyzed gender differences on bone mass, and structural properties of 4 month control and PTH treated (80 μg/kg bw/day for 2 weeks) male and female mice using fat free weight (FFW), pQCT, μCT and bone histomorphometry. In control mice, FFW of tibia (FFW/BW), cortical bone thickness (C.Th), mean trabecular separation (Tb. Sp), and proximal tibia mineral were significantly less, while bone volume (BV), total bone volume (TV), BV/TV, connectivity density (Conn-Dens), and mean trabecular number (Tb. N) were significantly greater in male than in female mice. PTH significantly increased FFW/BW, periosteal bone formation rate (BFR) and mineral apposition rate (MAR) (30%, 60%, and 44%, respectively), while significantly decreasing BV (30%) in male mice compared with the control, but induced no significant changes in female mice. PTH increased Conn-Dens and decreased C. Th, and mean trabecular thickness (Tb.Th) in female mice, but decreased Conn-Dens and increased C.Th, and Tb.Th in male mice. We then analyzed the gender differences in bone marrow stromal cells (BMSC) from 6 week male and female mice treated with PTH (80 μg/kg BW/day for 1 week). PTH significantly decreased the osteogenic colony number, the total ALP activity on day 14, and the total mineralization on day 28 in BMSCs from female mice, but had less effect on these measurements in BMSCs from male mice. We then analyzed the mRNA levels of RANKL, OPG and bone formation markers in bone tissue (marrow removed) using real-time PCR. PTH increased mRNA levels of RANKL, α1-collagen, ALP, and osteocalcin in both female and male mice, but mRNA levels in female mice were higher than those in male mice. OPG mRNA levels were not affected by PTH in either sex. PTH decreased the mRNA level of IGF-1 in female, but increased it in male mice. Our results indicate that on balance PTH is anabolic on cortical bone but catabolic on trabecular bone in male mice, whereas the reverse trend is found in female mice. This may reflect the greater response to PTH of IGF-I gene expression (affecting primarily cortical bone) in males and/or the greater inhibition of BMSC formation and activity (affecting primarily trabecular bone) by PTH in the females.

SU429

PTH Transcriptionally Regulates ICER Expression via a cAMP-PKA Pathway in MC3T3-E1 Cells. Y. Huang[1], D. Battisti*[2], B. E. Kream[1]. [1]Department of Medicine-Endocrinology, U. Connecticut Health Center, Farmington, CT, USA, [2]Department of Orthodontics, U. Connecticut Health Center, Farmington, CT, USA.

Parathyroid hormone (PTH) regulates serum calcium levels in part by increasing osteoclastic bone resorption, which requires the secretion of several mediators from osteoblastic cells. PTH regulates the expression of many genes via a cAMP-PKA signaling pathway in osteoblasts, including inducible cAMP early repressor (ICER). ICER belongs to the CREM transcription factor family and is transcribed from an internal promoter (P2 promoter) of CREM gene. We previously showed that ICER mRNA is induced by PTH in calvarial organ cultures, in osteoblast cell cultures and in bone in vivo. To study the mechanism by which PTH induces ICER in osteoblastic MC3T3-E1 cells, a fragment of the CREM P2 promoter (-238/+14 bp) was linked to a luciferase reporter (CREMP2-Luc238). The CREM P2 promoter contains 4 CRE-like elements arranged in 2 distinct clusters (CRE1-2 and CRE3-4) that are separated by twelve nucleotides. Constructs with 5' serial deletions were generated to study the involvement of each CRE in the regulation of basal and cAMP inducible promoter activity. CREMP2-Luc constructs were stably transfected into MC3T3-E1 cells and two multi-clonal populations were obtained for each construct. The expression of CREMP2-Luc was measured as luciferase activity. CREMP2-Luc238 expression was induced by 10 nM PTH and 10 μM FSK; activity peaked at 4 h. To study the signaling pathway involved in CREMP2-Luc238 induction, stably transfected cells were treated with various signaling molecules for 4 h: 10 nM PTH(1-34), 10 μM FSK and 3 mM 8-bromo-cAMP significantly induced CREMP2-Luc238 to 205±35%, 494±68% and 369±81 % of control, respectively, whereas 100 nM PMA, 1 μM ionomycin and 100 nM PTH(3-34) were not effective. Deletion of CRE1-2 did not alter FSK inducibility compared to CREMP2-Luc238 (6.4±0.6 vs. 6.2±0.5 fold, respectively). Further deletion of CRE3 significantly reduced both basal activity and FSK inducibility. Electrophoresis mobility shift assays (EMSA) showed that CRE1-2 and CRE3-4 probes formed different protein/DNA binding patterns with nuclear extracts from MC3T3-E1 and primary mouse calvarial cells. These data suggest that the CREM P2 promoter is induced by PTH mainly via a cAMP-PKA signaling pathway. The CRE3 site plays a critical role in mediating the response to cAMP. Lastly, there is differential binding of transcription factors to the CRE clusters of the CREM P2 promoter.

SU430

Evaluation of Agonistic and Antagonistic Signaling Response of Analogs of PTH peptides (1-34), (3-34) and (7-34) in Saos-2 Cells Stably Expressing Multiple Copies of cAMP Response Element (CRE) Reporter System. B. M. BHAT, R. J. Murrills, V. E. Coleburn*, J. Yoon*, R. Rupert*, F. J. Bex. Bone Metabolism and Osteoporosis Group, Women's Health, Wyeth Research, Collegeville, PA, USA.

Several extensive peptide truncation and modification studies have led to a detailed understanding of the functional domains of PTH. These studies have revealed that N-terminal residues mediate mainly adenyl cyclase (AC)-PKA activation and C-terminal residues are involved in PLC-PKC activation. In addition, PTH (3-34), PTH (7-34) and PTHrp (7-34) bind to PTHR1 but act as partial agonists or potent antagonists in binding and cAMP assays. To evaluate the effect of these peptides further downstream in the signaling cascade and specifically on the cAMP response element (CRE), we generated stable Saos-2 cells expressing CRE elements to serve as bone anabolic and pathway specific reporter system. To amplify the signal, the integrated reporter system was designed to contain 15 copies of the CRE sequence upstream of a minimal promoter linked to a luciferase gene. In an overnight assay, PTH (1-34) induced strong CRE-luci expression that ranged between 10- 30 fold above controls with an EC50 of 1.24nM. In comparison, PTH (1-34) was also potent in Saos-2 membrane binding assay (0.3nM EC50) and in a Saos-2 cAMP induction assay (0.65nM EC50). This stable reporter cell line is responsive to other cAMP agonists including Forskolin, Isoproterenol, PGE2, PACAP, and VIP peptide. The specificity of the CRE-reporter system was further evaluated with truncated antagonistic peptides including hPTH (3-34), bPTH (7-34) and analogs with various amino acid substitutions. These studies revealed that at the CRE-activity level, hPTH (3-34) peptide was a more potent antagonist than bPTH (7-34), but it also has partial agonistic activity. Interestingly, bovine PTH (3-34) had substantially less agonistic activity than human PTH (3-34). The residues that are altered in the bovine peptide are Phe7Leu and Ser16Asn. In contrast to bPTH(3-34), bPTH (7-34) was a pure but less potent antagonist. Among four substituted analogs of bPTH/PTHrP (7-34), the Nle 8,18 analog showed the most ideal antagonistic profile; neither suppressing the basal CRE-activity nor showing any partial agonistic activity. These studies demonstrate a good correlation between CRE-related transcription with the known effects of PTH agonists and antagonists on binding and cAMP.

SU431

Molecular Cloning and Phylogenetic Comparison of the cDNAs Encoding the Tuberoinfundibular Peptide of 39 Residues (TIP39) in Several Vertebrate Species. I. A. Hansen*, S. Wortmann*, O. Jakob*, B. Allolio, E. Blind. Dept. of Medicine - Endocrinology, University of Wuerzburg, Wuerzburg, Germany.

The polypeptide TIP39 (tuberoinfundibular peptide of 39 residues), which has been isolated initially from bovine hypothalamus, is a potent activator of the PTH-2 receptor, whereas it acts as a high-affinity antagonist on the PTH-1 receptor. Starting from database search results we cloned the cDNAs coding for the TIP39 protein precursors from man *(homo sapiens)*, mouse *(mus musculus)*, rat *(rattus norvegicus)*, pufferfish *(takifugu rubripes)*, and zebrafish *(danio rerio)* by means of RT-PCR and RACE-PCR. The deduced TIP39 preprohormones have a similar structure consisting of a hydrophobic N-terminal signal peptide, an intercalated peptide followed by a dibasic cleavage site, and the actual TIP39 peptide. The length of the intercalated peptides varied between the various species e.g. 93 amino acids (aa) in zebrafish vs. 31 aa in man and mouse. TIP39 itself had an identical length in all analyzed species. The deduced aa sequences of the peptide TIP39 itself were found to be highly conserved: The sequence was 89% identical between man and mouse and still 55% and 59% identical between man and pufferfish or zebrafish, respectively; between pufferfish and zebrafish, the aa sequence was 87% identical. The relationship was similar for the Pre-Pro-TIP39 peptide, with a 79% identity between man and mouse, and a 60% identity within the fish species (pufferfish vs. zebrafish); the aa identity between mamalians (i.e. man, mouse) and fish (i.e. pufferfish, zebrafish) ranged only between 24% and 32%. Taken together, the presumed amino acid sequence of TIP39 is well conserved over a broad range of vertebrate species suggesting an important, but largely unknown, function of this peptide hormone. These cloned TIP39 cDNAs should allow us to further elucidate the function of this peptide by evaluating stage- and species-specific expression patterns using in-situ hybridization.

SU432

PTH Simulates PI3-Kinase and Its Down Effector AKT/PKB in Intestinal Cells. C. Gentili*, S. Morelli*, A. Russo de Boland*. Biologia, Bioquimica & Farmacia, Universidad Nacional del Sur, Bahia Blanca, Argentina.

Phosphoinositide 3-kinase (PI3K) is a lipid kinase which phosphorylates the D3 position of phosphoinositides and is known to be activated by a host of protein tyrosine kinases. PI3K plays an important role in mitogenesis in several cell systems. However, whether parathyroid hormone (PTH) affects the activity and functional roles of PI3K in intestinal cells remain to be determined. The objective of this study was to identify and characterize the PI3K pathway and its relation to other non-receptor tyrosine kinases in mediating PTH signal transduction in rat enterocytes. PTH dose- and time-dependently increased PI3K activity with a peak ocurring at 2 min. The tyrosine kinase inhibitor genistein, c-Src inhibitor PP1 and two structurally different inhibitors of PI3K, LY294002 and wortmannin, suppressed PI3K activity dependent on PTH. Co-immunoprecipitation analysis showed a constitutive association between c-Src and PI3K which was enhanced by PTH treatment, suggesting that the cytosolic tyrosine kinase forms an immunocomplex with PI3K probably via the N-SH2 domain of the p85α regulatory subunit. In response to PTH, tyrosine phosphorylation of p85α was enhanced, effect that was abolished by PP1, the inhibitor of c-Src kinase. PTH causes a rapid (0.5-5min) phosphorylation of Akt/PKB, effect that was abrogated by PI3K inhibitors, indicating that in rat enterocytes, PI3K is an upstream mediator of Akt/PKB activation by PTH. We report here that PI3K is also requiered for PTH activation of the mitogen-activated protein kinases ERK1 and ERK2, enzymes that regulate intestinal cell proliferation. Taken together, the present study demonstrate, for the first time, that PTH rapidly and transiently stimulates PI3K activity and its downeffector Akt/PKB in rat enterocytes playing c-Src kinase a central role in PTH-dependent PI3K activation and that PI3K signaling pathway contributes to PTH-mediated MAPK activation.

SU433

hPTH-(1-34) and hPTH-(1-31)NH_2 Prevent Phosphate from Killing MC3T3-E1 Preosteoblasts and HKRKB7 Pig Kidney Cells. C. M. Allen*[1], B. Chakravarthy*[1], P. Morley*[2], J. F. Whitfield[1], G. E. Willick*[1]. [1]Institute for Biological Sciences, National Research Council of Canada, Ottawa, ON, Canada, [2]Para TecH Therapeutics Inc., Ottawa, ON, Canada.

During the 1960's Whitfield et al (1) found that inorganic phosphate (Pi) dramatically enhanced x-radiation-induced apoptogenesis of human and rat lymphocytes. Almost 40 years later Meleti et al (2) reported that high concentrations of Pi are apoptogenic for osteoblasts. This suggests that BMU osteoblasts entering osteoclast excavations may face apoptosis-triggering Pi levels. But these osteoblasts may be protected from high Pi by signals from their PTHR1 receptors activated by their autocrine PTHrP. This was tested using MC3T3-E1 murine preosteoblasts and HKRK B7 porcine kidney epithelial cells (LLC-PK1 pig kidney cells expressing 10^6 human PTHR1 receptors/cell). As expected, raising the external Pi concentration between the basal 0.9 mM and 10.9 mM increasingly reduced the survival (as measured colorimetrically with the tetrazolium salt, MTT) of both MC3T3-E1 and HKRKB7 cells during the next 5 days. This killing action of Pi was prevented by adding 3mM PFA (phosphonoformic acid), a potent inhibitor of Pi uptake. While raising Pi to 7.9 mM in the MC3T3-E1 cells' α-MEM medium variably reduced the cells' survival by no less than 50%, this Pi killing was significantly reduced or prevented by adding 1-100 nM hPTH-(1-34) or hPTH-(1-31)NH_2 to the medium. For example, 7.9 mM Pi reduced MC3T3-E1 cell survival to 2.8±3.6% while 1nM hPTH-(1-31)NH_2 increased the survival to 44.0 ± 7.0%. A more detailed study of Pi killing and the effect of PTH on it was carried out with HKRKB7 cells. By 48 h after raising the Pi concentration in their DMEM medium to 10.9mM, for example, the apoptogenic caspase 3-like activity in the HKRKB7 cells had increased 15.7-fold and by 72 h the fraction of Hoechst 33258 fluorochrome-stained cells with apoptotic bodies had risen from 0% to 30%. As expected, PFA prevented the apoptogenic actions of 10.9 mM Pi as did 100nM hPTH-(1-34). In conclusion, it appears that PTHR1receptor signals can shield preosteoblasts and osteoblasts from any high Pi levels they might be exposed to in osteoclast excavations.

Continued Exposure to PTH Reduces Magnitude of Increased Bone c-fos Expression in vivo Compared to Once Daily PTH, But Does Not Change ex vivo Induction of Osteoclasts. J. Milas, N. Rao*, S. Murthy*, J. Pulcini*, X. Yu*, J. M. Hock. Anatomy & Cell Biology, Indiana University, Indianapolis, IN, USA.

Continued exposure to PTH is associated with the catabolic actions on bone; once daily (anabolic) PTH increases bone formation by stimulating osteoblast differentiation and inhibiting their apoptosis. Our aims were to determine if there were divergent effects of PTH regimen on expression of AP-1 family genes in vivo and bone resorption, and if continued exposure to PTH in vitro modified apoptosis of primary osteoprogenitors. Young C57Bl/6 male mice were treated for 5 days with vehicle or continuous hPTH 1-34 at 40 μg/kg as 6 injections within 6-8 hours/day (which reduces BMD after 12 days, Black et al, JBMR 1994) and terminated 30min after the last injection. Femur metaphyseal RNA was pooled for each group and expression of selected AP-1 genes evaluated by RNAse protection assay. Mice were given BrdUrd to label proliferating cells and calcein to label bone formation. In experiment 2, mice were treated with vehicle or hPTH 1-34 at 40 μg/kg either once daily (intermittent) or with 6 injections/day (continuous) for 6 days to ascertain comparative effects of regimens. Bone marrow and spleen cells were cultured for 7 days with RANKL and M-CSF to assess TRAP+ multinucleated cells (osteoclasts). In experiment 3, apoptosis was measured in cultured primary femur metaphyseal bone cells exposed to hPTH 1-34 at 0-10^{-10}M for 6h, 24h, 48h or 72h. In vivo, although continued exposure to PTH for 5 days was not long enough to decrease bone mass or alter bone shape, the catabolic response was initiated as urinary PYD/creatinine increased 1.4x and osteoclast number increased 1.5x. Immunohistochemistry showed an increase in BrdUrd+ fibroblasts and marrow fibrosis in the trabecular metaphysis of proximal tibia. Once daily and continuous PTH increased RNA expression of c-fos and junB, with little change in c-jun, junD or fra-2. Continuous PTH blunted the increase in c-fos expression by 3-fold. Ex vivo induction of osteoclasts by continuous or once daily PTH increased osteoclasts respectively by 2.2x or 3.6x in bone marrow and by 1.5x or 1.6x in spleen precursors. In vitro, continuous exposure to PTH inhibited apoptotic caspase activity by 60% at 48h and 30% at 72h. Inhibition of osteoprogenitor apoptosis and ex vivo induction of osteoclasts did not correlate with regimen-dependent differences in c-fos expression. Comparisons of catabolic and anabolic PTH regimens suggest that the magnitude of increase in c-fos expression may regulate stromal progenitor cell choice of fate as osteoblasts or fibroblasts.

Systemic Delivery of PTH Promotes Catabolic and Anabolic Responses in Tissue-Engineered Bone. A. Schneider, J. M. Taboas*, L. K. McCauley, P. H. Krebsbach. School of Dentistry, University of Michigan, Ann Arbor, MI, USA.

Remarkable advances have been made to stimulate bone growth via tissue-engineering strategies. Growth factors, scaffolds and gene therapy have all been used to optimize and support bone regeneration to mimic the native tissue structure and function. However, it remains unknown if tissue engineered bone recapitulates the biology of normal skeletal tissue in response to physiologic cues. Here, we present a tissue engineering strategy in which PTH actions on bone remodeling can be studied in vivo in a well-characterized ectopic bone organ. In this system, ossicles were formed by the differentiation of allogeneic transplanted murine bone marrow stromal cells seeded in gelatin scaffolds. Ectopic ossicles exposed to catabolic doses of PTH (1-34) contained a higher number of TRAP-positive osteoclastic cells per millimeter of bone (3.93 ± 0.7 (PTH) vs. 1.65 ± 0.3 (saline), p<0.01). Higher serum calcium levels were also observed in PTH-treated mice (p<0.02). In contrast, intermittent, low doses of PTH resulted in an anabolic response that significantly altered the ectopic bone microarchitecture. Microcomputed tomographic and histomorphometric analyses revealed a marked increase in percent bone volume (48.2 ± 2.0 % (PTH) vs. 30 ± 3.0 % (saline), p<0.01) and percent trabecular bone area (37.0 ± 7.4 % (PTH) vs. 14.1 ± 2.1 % (saline), p<0.05). No significant differences were observed in the number of osteocytes, cortical width and overall dimensions in ossicles from PTH-treated vs. control mice. Our findings demonstrate that cell-derived, tissue-engineered bone is truly responsive to physiologic stimuli. Catabolic doses of PTH induced an osteoclastic response, whereas anabolic doses of PTH promoted a significant increase in percent trabecular bone volume. These results suggest that systemic PTH may be used therapeutically to augment tissue-engineered bone. Furthermore, because multiple and distinct ossicles can be generated in a single animal, this system can be used to evaluate the effects of a variety of osteotropic agents. This versatile cell transplantation system may also be used to improve our understanding of bone physiology in health and disease and facilitate studies of the: (a) cellular and molecular mechanisms in skeletal regeneration, (b) cell-to-cell interactions in the bone marrow microenvironment and (c) efficacy of pharmacotherapeutic agents that modulate bone turnover in vivo.

SU436

Equine Parathyroid Chief Cells in Vitro: Secretion of Parathyroid Hormone (PTH), PTH and Calcium-Sensing Receptor mRNA Expression, and Effects of IL-1, IL-6 and TNF-alpha. R. E. Toribio*[1], C. W. Kohn*[2], C. C. Capen[1], S. E. Weisbrode[1], T. J. Rosol[1]. [1]Veterinary Biosciences, The Ohio State University, Columbus, OH, USA, [2]Veterinary Clinical Sciences, The Ohio State University, Columbus, OH, USA.

Parathyroid hormone (PTH) is secreted by the chief cells of the parathyroid gland in response to changes in extracellular ionized calcium (Ca^{2+}) concentration. *In vitro* studies on parathyroid cells have advanced our understanding of the physiology and pathophysiology of the parathyroid gland. Several conditions in the horses are associated with abnormal parathyroid gland function; for example, ionized hypocalcemia is present in 75% of horses with sepsis, and half of these horses have an abnormal parathyroid gland function. In the present study we measured PTH secretion, and PTH mRNA and calcium-sensing receptor (CaR) mRNA expression by equine parathyroid chief cell *in vitro*. We also evaluated the effects of interleukin (IL)-1ß, IL-6, and tumor necrosis factor (TNF)-alpha (cytokines known to be increased during sepsis in humans and animals) on PTH secretion, and PTH and CaR mRNA expression. The relationship between PTH and Ca^{2+} *in vitro* was inversely related and sigmoidal. PTH secretion in a low Ca^{2+} (0.8 m*M*) medium decreased from 100% (day 0) to 13% (day 30). PTH mRNA expression declined from 100% (day 0) to 43% (day 5), and to 25% (day 30). CaR mRNA decreased from 100% (day 0) to 31% (day 5), and to 16% (day 30). Chief cells exposed to high Ca^{2+} concentrations had a lower PTH mRNA expression (P<0.05) compared to low Ca^{2+} concentrations. Low and high Ca^{2+} concentrations had no effect on CaR mRNA expression. The inhibitory effect of high Ca^{2+} concentrations on PTH secretion also declined with increasing time in culture. By day 5, higher Ca^{2+} concentrations were required to inhibit PTH secretion and there was a shift (increase) of the Ca^{2+} set-point. After day 10 of culture, there was no significant difference in PTH secretion between low (0.8 m*M*) and high (2.0 m*M*) Ca^{2+} concentrations. IL-1ß (2000 pg/ml) decreased both PTH secretion (75%) and PTH mRNA expression (73%) (P<0.05). IL-1ß concentrations greater than 200 pg/ml resulted in significant (P<0.05) overexpression of CaR mRNA (up to 142%). The effects of IL-1ß were blocked by an IL-1 receptor antagonist (IL-1ra). IL-6 (5 and 10 ng/ml) decreased PTH secretion, but had no effect on PTH and CaR mRNA expression. TNF-alpha (1, 5, and 10 ng/ml) had no effect on PTH secretion, and PTH and CaR mRNA expression. In summary, the decreased responsiveness of parathyroid cells to Ca^{2+} from 0 to 30 days can be explained, in part, by the reduced CaR expression. IL-1 and IL-6 but not TNF-alpha may be important in influencing PTH secretion in the horse with sepsis.

SU437

PTH Analogues can be Defined by their Properties of Signal Transduction and Desensitization. R. W. Katz[1], Q. Sun*[2], E. Dworakowski*[2], S. Morris[3], J. P. Bilezikian[2]. [1]Oral Biology, Columbia University School of Dental and Oral Surgery, New York, NY, USA, [2]Medicine, Columbia University College of Physicians and Surgeons, New York, NY, USA, [3]Aventis Pharmaceuticals, Bridgewater, NJ, USA.

PTH and its biologically active fragments have anabolic effects on bone when administered in low dosage and intermittently. PTH activates osteoblasts through its receptor (PTH1R) and associated G proteins (GP). Deletion of the extreme amino terminal portion of the ligand abrogates receptor activation of adenylyl cyclase (AC) while phospholipase C (PLC) activation is tolerant to more drastic truncations at both amino and carboxyterminal ends of the molecule. Various PTH fragments may show differing effects on cells as a result of differential signal transduction and receptor desensitization, and this may explain their differing *in vivo* properties. Accordingly, we report differences in the properties of PTH (1-34), PTH (1-29) and a substituted PTH (1-21) in terms of AC activation and desensitization, and PLC activation. Maximal activation of AC by Saos-2 membrane homogenates was not different among the PTH peptide fragments. The respective K_as were different, with PTH (1-34) [1.49 x 10^{-8} M] almost four fold greater than PTH (1-21) [5.8 x 10^{-8} M], and almost ten fold greater than PTH (1-29) [1.32 x 10^{-7} M]. PLC activity was measured by inositol phosphate production in LLC-PK1 kidney cells expressing the rat PTH1 receptor. The three PTH peptides demonstrated a similar trend in IP production at 10^{-6} M [PTH (1-34) 5.2 +/- 0.3 fold, PTH (1-21) 3.7 +/- 0.2 fold and PTH (1-29) 2.2 +/- 0.1 fold]. Pretreatment of the Saos-2 cultures with PTH (1-34) at 5 x 10^{-8} M for 2 min suppressed AC activity by 71% but PTH (1-29) pretreatment suppressed activity by only 18% when the cell homogenates were subsequently challenged with PTH (1-34). However, at maximal concentrations PTH (1-34) and PTH (1-29) desensitized equivalently. The results of this study illustrate that fragments that are foreshortened at the carboxyterminal end of PTH (1-34) differed in their effects upon AC, PLC and receptor desensitization. These insights might help to design molecules in which biochemical behavior reflects *in vivo* properties.

SU438

An Amino-Terminal Form of PTH Different from hPTH(1-84) is Detected by a Cyclase-Activating PTH Assay Specific for hPTH(1-84). Clinical Evaluation. P. D'Amour[1], L. Rousseau*[1], J. H. Brossard[1], T. Cantor[2], P. Gao[2]. [1]Département de Médecine, Université de Montréal, Centre de recherche du CHUM, Hôpital Saint-Luc, Montréal, PQ, Canada, [2]Scantibodies Laboratory Inc., Santee, CA, USA.

Intact (I-) or Total (T-) PTH assays recognize PTH molecular forms other than hPTH(1-84), also called non-(1-84) PTH. They account for 15-20% of I-PTH immunoreactivity in normal individuals (NI) and for 40-50% in renal failure (RF) patients. A new Cyclase-Activating (CA) PTH assay has been demonstrated to react with hPTH(1-84) only and not with non-(1-84) PTH. In clinical samples, CA-PTH values are generally lower than I- or T-PTH values but this is not always the case. Furthermore, non-(1-84) PTH values evaluated by HPLC tend to be higher then similar values obtained from the difference between I- or T-PTH and CA-PTH. To investigate this phenomenon, we have analyzed sera from 6 NI, 5 patients with primary hyperparathyroidism (PHP) and 9 patients with terminal RF with both the CA- and T-PTH assays after HPLC separation with a new program which better separates hPTH(1-84) from non-(1-84) PTH. CA-PTH results were lower than T-PTH results in all NI (3.13±0.37 vs 2.29±0.33 pmol/L, p<0.01) but were higher in 3/5 patients with PHP, making the difference between the 2 assays minimal (25.7±26 vs 23.1±24.1 pmol/L, NS). In RF patients, the difference between the 2 assays was more marked and present in all patients (47±35 vs 33.3±26.1 pmol/L, p<0.01). Analysis of HPLC profiles indicated that the CA-PTH assay recognized a peak of PTH immunoreactivity migrating in front of hPTH(1-84) and different from the non-(1-84) peak recognized by the T-PTH assay. This peak represented 8.13±2.45% (range 4.7-12) of CA-PTH immunoreactivity in NI, 24.7±23.3% (range 9-63.3) in PHP patients and 22.2±7.3% (range 17.3-35) in RF patients. This peak of amino-terminal PTH was not recognized by the T-PTH assay suggesting structural modifications interfering with antibody recognition in the region 15-34. These results indicate circulating immunoheterogeneity of the amino-terminal region of PTH particularly in patients with primary and secondary hyperparathyroidism. They also complicate the evaluation of non-(1-84) PTH through the substaction of CA-PTH from T-PTH. More studies will be required to elucidate the exact structure of this new amino-terminal PTH molecule.

SU439

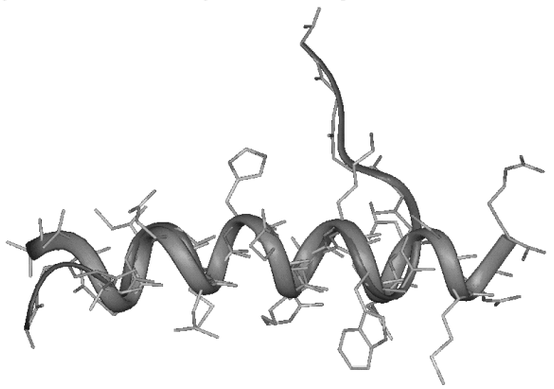
A Comparison of Two Assays Measuring Parathyroid Hormone (PTH) in Plasma in a Normal Population. J. P. Johannesson*, O. S. Indridason*, L. Franzson*, G. Sigurdsson. University Hospital, Reykjavik, Iceland.

Parathyroid hormone (PTH) is in its active form an 84 amino acid polypeptide, 1-84, but inactive fragments are also found in plasma, including 7-84. Most conventional assays measure not only the 1-84 form but also varying amounts of fragments depending on the assay used. A new method has been developed that is believed to measure only the 1-84 form. The purpose of this study was to compare one of the currently used assays to the new one in a large group of healthy individuals of different age. Data from an ongoing population based study of age related changes in calcium and bone metabolism was used. 456 individuals, 209 men and 247 women, age 40-85, from the Reykjavik area were selected. None of them used medications that affect bone metabolism. PTH was measured with two assays, one conventional (PTH elecsys, Roche) and the new one (PTH cap, Scantibodies). We assessed the correlation between the two with the Pearson correlation coefficient and the agreement with regards to normal and abnormal values with the Kappa statistic. We have also examined age related changes and correlation to kidney function. The Pearson correlation coefficient for the two assays was 0.787 (P<0.001) for women and 0.690 (P<0.001) for men. The Kappa statistic was 0.486 (P<0.001) for women and 0.283 (P<0.001) for men. PTH elecsys showed a statistically significant increase with age (P<0.01) but not PTH cap. PTH elecsys also showed a correlation to kidney function parameters (P<0.01) but PTH cap did not. We conclude that the two methods differed significantly in measuring PTH in a normal population. This difference can be explained to some extent by age related reduction in kidney function.

SU440

Residue 19 of Parathyroid Hormone: Structural Insight into the Role in Binding and Activation. A. Piserchio*[1], N. Shimizu[2], T. J. Gardella*[2], D. F. Mierke*[1]. [1]Department of Chemistry and Molecular Pharmacology, Brown University, Providence, RI, USA, [2]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

In the course of establishing a structure-activity relationship for parathyroid hormone (PTH) most attention has been placed on the so called activation domain (the N-terminus, residues 1-7 of the ligand) and the binding domain, consisting of the C-terminus of PTH. Recently an important role has been ascribed to residue 19 of PTH: PTH(1-20) analogs containing R19 are 10- to 100-fold more potent than those containing R19. Here the pharmacological findings are placed onto a structural framework. Using high-resolution NMR methods, two PTH(1-20) analogs, Aib[1]-V-Aib-E-I[5]-Q-L-M-H-Q[10]-Har-A-K-W-L[15]-N-S-M-R-R[20]-NH_2 and Aib[1]-V-Aib-E-I[5]-Q-L-M-H-Q[10]-Har-A-K-W-L[15]-N-S-M-E-R[20]-NH_2 have been structurally characterized in the presence of a lipid vesicle, used as a mimetic of the membrane environment of the PTH receptor. The charge reversal at position 19, E19 vs. R19, leads to distinct conformational differences in the C-terminus. The R19 containing analog is found to adopt a structure consisting of a stable, contiguous α-helix, from V2-R19. In contrast, the E19 containing analog is much less structured in the C-terminus, consisting of an α-helix from ca. V2-L15. These results clearly illustrate the importance of residue 19 in the stabilization of the helical nature of the ligand, an important feature for binding of reduced-size PTH analogs to the PTH1 receptor.



Superposition of the NM derived structures of the R19 (thick ribbon, side chains illustrated) and E19 (thin ribbon) containing PTH analogs.

The Effect of PTH(1-34) and PTH(2-38) on Mineralized Bone Nodule (MBN) Formation under Different Stage of Differentiation. Y. Lin*, L. J. F. Liu*, T. M. Murray, L. G. Rao. Calcium Research Lab, St. Michael Hospital, University of Toronto, Toronto, ON, Canada.

To investigate the effects of PTH(1-34) and PTH(2-38) on MBN formation at different stages of osteoblast differentiation, SaOS-2 cells were cultured under mineralizing conditions from day 1-18. The number and area of MBN were quantified in von Kossa-stained cells. A single 24 h treatment at day 2 with 10^{-8}M PTH(1-34), a fully effective PTH fragment, inhibited MBN area by 11.2%, while10^{-8}M PTH(2-38) had no effect. With 24 h of treatment at day 7, PTH(2-38), generally thought to be inactive, inhibited MBN area by 24.7%(10^{-8}M). With 6 h out of 48 h intermittent treatment from day 4 -18, PTH(2-38) inhibited MBN area by 20.0% (10^{-9} M) and 43.66% (10^{-8}M). No significant effect on MBN number was observed. However, PTH(1-34) 10^{-10}-10^{-8}M inhibited both MBN area and number at this condition. If PTH(2-38) was added from day 7-18, similar effects were observed. Nevertheless, from day 12-18, with 6 h out of 48 h intermittent treatment, 10^{-8}M PTH (2-38) did not have a significant effect on MBN formation, while, 10^{-8}M PTH(1-34) still inhibited MBN area by 45.3%. With continuous treatment from day 7-18, both fragments inhibited MBN area and number. PTH(1-34) 10^{-10}, 10^{-9} and 10^{-8}M inhibited MBN area by 8.2%, 75.4%, and 99.9%, while the inhibition rates were7.2%, 61.8%, and 99.8% for PTH(2-38). The least differences in effects between these two PTH fragments were observed in this condition compared to all the other conditions. PTH(1-34), at 10^{-10}, 10^{-9} and 10^{-8}M, when added at day 8 for 24 h, inhibited Alkaline Phosphatase(ALP) activity by 13.4%, 19.2% and 22.8%. PTH(2-38) did not affect ALP activity under this condition. PTH(1-34) 6 h out of 48 h intermittent treatment from day 8-16 also dramatically decreased ALP activity. However, PTH(2-38) did not affect ALP activity. PTH(2-38)'s effect on ALP activity was found in a longer treatment, and at the earlier stage of osteoblast development. At 10^{-8}M, continuous treatment from day 5-9 inhibited ALP activity by 30.4%. RT-PCR failed to show any significant change in ALP mRNA level after 1 h treatment of either fragment of PTH. Both PTH(1-34) and PTH(2-38) dramatically increased c-fos mRNA level. At 10^{-8}M, they increased c-fos mRNA by 286.6% and 214.8% after one hour treatment. These data suggested that in vitro, PTH(2-38) might have different effects on osteoblasts from that of PTH(1-34) in some stages of differentiation. Our results also showed that PTH fragments' potency on MBN was generally consistent with previous observations of reduced potency of PTH fragments lacking residue 1 on c-AMP activation. In addition, we observed that the PTH fragments' effects on MBN correlated well with their effects on up-regulating c-fos mRNA level.

PTH Stimulation of Mitogen-Activated Protein Kinases Does not Require PTH/PTHrP Receptor Phosphorylation and Internalization or Phospholipase C Activation. H. A. Tawfeek*, A. B. Abou-Samra. Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

Previous studies have demonstrated that binding of PTH and PTHrP to the PTH/PTHrP receptor regulates activity of the mitogen-activated protein (MAP) kinases. The cellular mechanisms underlying MAP kinase regulation by PTH are poorly understood. In the current study, we investigated the role of PTH/PTHrP receptor phosphorylation and internalization and stimulation of phospholipase C (PLC) in the activation of the extracellular signal regulated MAP kinases (Erk1/2). PTH normally stimulated Erk1/2 in two receptor mutants with impaired internalization, a phosphorylation-deficient PTH/PTHrP receptor (PD-PPR), in which 7 serine residues in the carboxy-terminal tail (CT) were mutated to alanine residues, and a tail-less PTH/PTHrP receptor (TL-PPR), in which the CT was truncated at residue 480. Immunoblot analysis revealed that MEK1/2 were also activated by PTH. Further, a specific MEK1/2 inhibitor blocked Erk1/2 activation by PTH; this suggests that MEK1/2 are involved in PTH activation of Erk1/2. To elucidate the role of PLC in PTH activation of Erk1/2, we examined Erk1/2 stimulation by PTH in a cell line expressing a mutant PTH/PTHrP receptor, DSEL, which is defective in PLC signaling. The DSEL mutant did not stimulate Erk1/2 suggesting that PLC stimulation is important for Erk1/2 activation. Alternatively, the DSEL mutant may be defective in signaling through another unknown pathway(s) that is important for PTH stimulation of Erk1/2. To distinguish the two possibilities, Erk1/2 activation by the PTH analog [Gly1,Arg19]hPTH(1-28), which does not stimulate PLC but normally stimulates cAMP accumulation, was examined. [Gly1,Arg19]hPTH(1-28) efficiently activated Erk1/2 in cell lines expressing wild type receptor. Taken together, these data suggest that PTH/PTHrP receptor internalization and stimulation of phospholipase C do not play a major role in PTH activation of Erk1/2. The data also demonstrate that MEK1/2 are involved in the process of PTH stimulation of Erk1/2.

Identification of Novel Contact Points between Residues in the Mid-Region of PTH(1-34) and the PTH1-Receptor: Refinement of the Model of the PTH--PTH1-Receptor Complex. A. Wittelsberger, M. Corich*, A. Barazza*, R. Yacobi, B. K. Lee*, M. Rosenblatt, J. M. Alexander, M. Chorev. Department of Bone and Mineral Metabolism, BIDMC-Harvard Medical School, Boston, MA, USA.

Parathyroid hormone (PTH) is the major hormone responsible for the regulation of calcium levels in blood and plays a role in bone remodeling. These activities are mediated through its cognate G-protein-coupled receptor, PTH1 Rc, a member of the class II family. Understanding the molecular mechanisms of ligand recognition and signal transduction by the PTH1 Rc may lead to the design of novel hormone analogs as drugs for the treatment of diseases such as osteoporosis, hypercalcemia of malignancy, and hyperparathyroidism. Using the benzophenone-based photoaffinity-crosslinking scanning approach, several contact points, mainly between positions in the N- and C-terminal helical segments of PTH(1-34) and the receptor, were identified previously. The emerging model of the ligand-receptor bimolecular interface includes single contacts between the N-terminal residue of the hormone and Met[425] in the ectopic portion of transmembrane helical domain 6, and between position 13 of the hormone and a site proximal to Arg[186] in the juxtamembrane portion of the N-extracellular domain (N-ECD) of the receptor, and several contact sites between residues at the C-terminal portion of PTH(1-34) and the amino terminal portion of the N-ECD of the receptor. It is very important for the upgrading of the existing model to elucidate additional contact sites between the receptor and residues in the mid-region of the hormone, i. e. in proximity to the putative hinge regions (positions 12 and 19). In this report, we present the design, biological characterization, and photoaffinity crosslinking studies of a series of novel PTH analogs containing the photoreactive *p*-benzoylphenylalanine (Bpa) residue in the mid-region of the hormone sequence, i.e. positions 11, 15, 18, and 21. Preliminary results obtained from restrictive digestion mapping and site-directed mutagenesis studies indicate that while the contact site for position 15 in the ligand lies in close proximity to the C-proximal end of the N-ECD the other positions in the ligand interact with additional extracellular domains of the receptor. Therefore, the novel contact points identified will enable the generation of an enhanced and refined model of the PTH--PTH1 Rc interactions that will be presented.

Regulation of Gap-Junctional Communication in Bone-Derived Cells by PTH Fragments with Different C Termini. G. D'Ippolito[1], P. Divieti[2], G. A. Howard[1], F. R. Bringhurst[2], P. C. Schiller*[1]. [1]GRECC/Research, VAMC and University of Miami School of Medicine, Miami, FL, USA, [2]Endocrinology, Mass General Hospital/Harvard Medical School, Boston, MA, USA.

Gap-junctional communication (GJC) plays a critical role in bone physiology. We have demonstrated that disturbance of GJC in osteoblasts results in down regulation of osteocalcin and bone sialoprotein gene expression and decreased hormonal responsiveness. Parathyroid hormone (PTH) can increase cell-to-cell GJC among bone cells, via activation of the type 1 PTH/PTHrP receptor (PTH1R). Long fragments of PTH, lacking the N-terminal portion of the hormone, are able to bind to a receptor distinct from the PTH1R and specific for the C-terminal region of PTH, the CPTH receptor (CPTHR). To assess if CPTHR activation is involved in cell-to-cell communication, we studied GJC in bone cells lacking PTH1R but expressing CPTHR. Quantification of GJC was determined utilizing a variation of the “two-dye” and “parachute” techniques in PTH1R-null osteoblastic (F1-14) and osteocytic (OC14) cell lines. After 8 days in culture dye transferred from loaded F1-14 to

F1-14 as well as to OC14 cells. Similarly, loaded OC14 transferred dye to OC14 as well as to F1-14 cells, demonstrating that PTH1R expression is not required for GJC. Subsequently we assessed whether PTH1R-null cells retain the capacity to form functional GJ channels with PTH1R-expressing cells. GJC was assayed between F1-14 or OC14 cells cultured for 8 days and MC3T3-E1 murine or ROS17/2.8 rat osteoblastic cells expressing functional PTH1R. Dye transferred from loaded MC3T3-E1 or ROS17/2.8 cells to PTH1R-null F1-14 as well as to OC14 cells. Similarly, loaded F1-14 or OC14 cells transferred dye to MC3T3-E1 or ROS17/2.8 cells. We then investigated whether PTH fragments, with different C termini, could modulate the extent of GJC among PTH1R-null bone cells and PTH1R-expressing osteoblastic cells. We quantitatively assayed GJC in the presence and absence of PTH (1-34) or PTH (1-84). Interestingly, PTH (1-84) significantly increased GJC among PTH1R-null cells, while PTH (1-34) had no effect in these cells. Moreover, PTH (1-84) increased GJC from loaded ROS 17/2.8 to OC14 or F1-14 cells; however, in this case PTH (1-34) had a stimulatory effect similar to that of PTH (1-84). Our results demonstrate that PTH1R-null cells not only form functional GJ channels among themselves but also with cells expressing PTH1R, and that activation of CPTHR not only increases GJC between PTH1R-null cells but also with PTH1R-expressing osteoblasts. Our data strongly suggest that CPTHR plays a critical role in regulating cell-to-cell communication and maintaining bone homeostasis independent of PHT1R.

Matabolic Acidosis Up-Regulates PTH/PTHrP Receptors in UMR 106-01 Osteoblast-Like Cells. E. A. Gonzalez[1], S. Disthabanchong*[2], K. J. Martin[3]. [1]Nephrology, Saint Louis University, Saint Louis, MO, USA, [2]Saint Louis University, Saint Louis, MO, USA, [3]Saint Louis University, St. Louis, MO, USA.

Metabolic acidosis results in skeletal demineralization by multiple mechanisms. One of these involves the inorganic phase of bone by which hydrogen ion is buffered by bone carbonate. In addition, the cellular components of bone also participate by the induction and repression of several skeletal genes. Previous studies have suggested that the action of parathyroid hormone (PTH), a major regulator of bone turnover, might be altered by acidosis. The present studies were designed to test directly, in vitro, whether acidosis altered the effects of PTH in UMR 106-01 osteoblast-like cells. Studies were conducted in confluent cultures of UMR 106-01 cells in MEM with 5% FBS at pH values varying from 7.4 to 7.1 by addition of HCl. After time periods of 4-48 hours, cells were tested for cyclic-AMP generation in response to PTH. PTH binding and PTH/PTHrP receptor mRNA levels were determined by radioligand binding assay and Northern analysis respectively. After 48 hours, decreases in pH from 7.4 to 7.1 resulted in a progressive increase in PTH-stimulated cyclic-AMP generation from 1978 +/- 294 to 4968 +/- 929 pmoles/culture/5 minutes($p < 0.05$). Basal cyclic-AMP concentrations were unchanged. PTH binding increased 1.5 to 2 fold. Competitive inhibition of radioligand binding revealed an increase in receptor number which was supported by upregulation of PTH/PTHrP receptor mRNA up to 2 fold from control levels. These findings demonstrate that metabolic acidosis stimulates the response to PTH in UMR 106-01 osteoblast-like cells by a mechanism that involves an increase in the levels of PTH/PTHrP receptor mRNA. Thus, the skeletal response to acidosis which includes an increase in bone resorption may result, at least in part, from an increase in PTH/PTHrP receptors leading to an enhanced effect of PTH on bone. This mechanism could contribute to the spectrum of skeletal abnormalities found in renal osteodystrophy.

The Putative Membrane Receptor for 1α,25(OH)$_2$-Vitamin D$_3$ Associated with Rapid Biological Responses Is Present in Chick Intestinal Caveolae. C. J. Olivera*[1], F. M. B. Silva*[2], J. E. Bishop[1], A. W. Norman[1]. [1]Univ. California, Riverside, CA, USA, [2]UFSC, Florianpolis, SC, Brazil.

The steroid hormone 1α,25(OH)$_2$-vitamin D$_3$ [125D] exerts its biological activity via distinct receptors that recognize different shapes of the conformationally flexible 125D. These include the nuclear vitamin D receptor (nVDR) associated with genomic responses and a putative membrane receptor (mVDR) linked to rapid, nongenotropic responses. We and others have previously shown that 125D elicits rapid responses including transcaltachia (rapid intestinal Ca^{2+} absorption) and activation of PKC and MAP-kinase in chick intestine. Here we report results from experiments using isolated caveolae (CV) membrane fractions from chronically vitamin D-deficient (-D) chick intestinal cells. CV are 50-100 nm plasma membrane invaginations that in some cells have been shown to be the site of localization of signal transduction molecules. Caveolin-1, a 21 kDa marker protein for CV membrane vesicles, was used for Western analysis to confirm the presence of this key protein in our intestinal CV fractions. Transmission electron microscopy of CV demonstrated the presence of membrane-isolated vesicles similar to those in cells known to possess CV. We have employed the CV fraction as a possible source of the mVDR and studied the *in vitro* saturable binding of [^{3}H]125D (0.05-15 nM) ± 100 fold excess nonradioactive 125D in our standard VDR steroid competition assay. We found that [^{3}H]125D consistently binds to the CV in a saturable fashion; the average KD is 2.0 nM ± 0.7 and the B_{max} is 35 ± 8 fmoles/mg protein; n = 8. Pretreatment of -D chicks with 6.5 nmoles of 125D 2 hrs before isolation of intestinal CV, followed by *in vitro* [^{3}H]125D binding studies, resulted in ~ 35% reduction in B_{max} (n = 3) with no change in KD. We conclude that *in vivo* occupancy of the CV mVDR significantly diminishes the number of binding sites available for *in vitro* CV binding of [^{3}H]125D. Only a low amount of [^{3}H]25(OH)D$_3$ (a measure of vitamin D binding protein contamination) and no [^{3}H]-24R,25(OH)$_2$D$_3$ bound to the CV, thus demonstrating the CV specificity of binding for [^{3}H]125D. Steroid competition assays using conformationally restricted analogs of 125D that are diagnostic for rapid or for genotropic responses indicated that both analog families can compete with [^{3}H]125D for binding to the CV fraction. Further, the process of rapid intestinal Ca^{2+} transport *in vivo* was found to modulate the extent of *in vitro* binding of [^{3}H]125D to CV. Collectively these experiments provide the first evidence for the existence of a binding protein, possibly the mVDR, for 1α,25(OH)$_2$-vitamin D$_3$ in caveolae fractions from chick intestine.

Evidence for Functional Cooperation between CCAAT/Enhancer-binding Protein Beta and the VDR/RXR Complex in the Regulation of 25-Hydroxyvitamin D$_3$ 24-Hydroxylase Transcription. P. Dhawan*[1], X. Peng*[1], M. Centrella*[2], T. L. McCarthy*[2], S. Christakos[1]. [1]Biochemistry and Molecular Biology, UMDNJ - New Jersey Medical School, Newark, NJ, USA, [2]Yale University Medical School, New Haven, CT, USA.

Relatively few 1,25dihydroxyvitamin D$_3$ (1,25(OH)$_2$D$_3$) regulated genes are known in target tissues maintaining calcium homeostasis. Using gene chip array we found that a gene in addition to 25-hydroxyvitamin D$_3$ 24-hydroxylase (24(OH)ase) and calbindin activated by a factor greater than 50% by 1,25(OH)$_2$D$_3$ in mouse kidney is CCAAT-enhancer-binding protein β (C/EBPβ), an important activator of transcription. Our findings were verified by Northern and Western blot analysis and induction of C/EBPβ by 1,25(OH)$_2$D$_3$ was observed in primary murine osteoblasts, in UMR osteoblastic cells as well as in mouse kidney. Results of Northern analysis indicated that the first significant induction of C/EBPβ mRNA by 1,25(OH)$_2$D$_3$ in UMR osteoblastic cells precedes the induction of 24(OH)ase mRNA (3h compared to 9h), consistent with a possible role of C/EBPβ as a mediator of the 1,25(OH)$_2$D$_3$ response of the 24(OH)ase gene. Since two putative C/EBPβ sites were noted in the 24(OH)ase promoter (at -964/-955 and at -395/-388), this possibility was tested in experiments in which COS-7 cells were transfected with the rat 24(OH)ase promoter (-1367/+74; VDREs at -258/-244 and -150/-136) and the human vitamin D receptor (hVDR) in the presence or absence of C/EBPβ. In dose response studies (0.125 - 5 μg C/EBPβ) we found that suboptimal 1,25(OH)$_2$D$_3$ induction of 24(OH)ase transcription could be enhanced a maximum of 20 fold by C/EBPβ. In the absence of 1,25(OH)$_2$D$_3$ the 24(OH)ase promoter failed to respond to C/EBPβ. C/EBPδ (but not C/EBPα) was also found to enhance the inductive action of 1,25(OH)$_2$D$_3$ on 24(OH)ase transcription. Deletion analysis indicated that enhancement of 1,25(OH)$_2$D$_3$ induced 24(OH)ase transcription by C/EBPβ was observed using the -671/+74 but not the -291/+74 rat 24(OH)ase promoter construct. The C/EBPβ site at -395/-389 (TTGGCAA) differs from the consensus by a single base and mutation of this site within the -671/+74 24(OH)ase promoter construct resulted in a marked attenuation of the response to C/EBPβ. Gel shift analysis indicated the ability of the C/EBPβ protein to interact with this element. These findings establish C/EBPβ as a novel 1,25(OH)$_2$D$_3$ target gene and indicate that C/EBPβ is a major transcriptional activator of the 24(OH)ase gene. In addition, from this study a fundamental role has been established for the first time for cooperative effects and cross talk between the C/EBP family of transcription factors and VDR in 1,25(OH)$_2$D$_3$ induced transcription.

SU448

Comparative Studies on 1α,25(OH)$_2$-vitamin D$_3$ Mediated Ion Channel Rapid Responses in Osteoblasts from Vitamin D Nuclear Receptor Knock-Out and Wild Type Mice. L. P. Zanello, H. L. Henry, J. E. Bishop, A. W. Norman. Univ. California, Riverside, CA, USA.

Osteoblasts are a major target for the steroid hormone 1α,25(OH)$_2$-vitamin D$_3$ [125D] where a primary outcome is a modulation of the bone remodeling process. 125D exerts its physiological effects through both genomic (modulation of gene expression via a nuclear 125D receptor [nVDR]) and rapid, non genomic (at the cell membrane level via a putative membrane receptor [mVDR]) mechanisms. To investigate whether the presence of a functional nVDR is required for a rapid 125D-mediated response(s), we studied the modulation by 125D of ion channel activities in osteoblasts isolated from nVDR knock-out (KO) and wild type (WT) mice calvaria. Whole-cell patch-clamp recordings were performed according to previous protocols (Zanello & Norman, 1997) on primary cultured KO and WT osteoblasts from (PCR) genotyped mice. KO osteoblasts were notably scarce in culture, while WT osteoblasts proliferated abundantly. Both cell types expressed inward and outward currents when subjected to depolarizing potentials between -40 and 80 mV from a holding potential of -50 mV. Our patch-clamp results demonstrated the existence of a 125D-inducible anionic current in the WT and KO osteoblasts, similar to a Cl^- current previously found in an osteoblast-like cell line (Zanello & Norman, 1997). Also a "background" capacitative current was consistently recorded in both WT and KO cells. Whole-cell capacitance measurements carried out in the presence of the hormone showed fluctuations in the range of 0.1-1 pF. This is equivalent to 10-100 _m^2 changes in plasma membrane surface when sampled at 1 sec intervals. We attributed these capacitance changes to the fusion of secretory granules to the cell surface, that is clearly seen with phase contrast microscopy of live cells. In parallel studies, bone tissue from both mice genotypes were separately subjected to mRNA microarray analysis to examine the expression of mRNAs coding for ion channels. There were qualitatively different ion channel profiles for each mouse genotype. More specifically, a Cl^- channel and a series of non-selective cation channels seemed to be preferentially expressed in KO osteoblasts, while mRNA levels for K^+, a capacitative Ca^{2+}, and L-type Ca^{2+} channels were notably below WT levels. We conclude that, as expected from the traditional understanding of 125D modulation of gene transcription, the absence of a functional nVDR in KO mice correlates well with changes in the expression of ion channel molecules (genomic effects). On the other hand, the existence of a 125D-sensitivite anionic current in both KO and WT osteoblasts suggest a common pathway for a rapid response which is independent from a nVDR.

SU449

Microarray Analysis of RNA from Tissues of Vitamin D Receptor Knock-Out and Wild Type Mice Treated with 1α,25(OH)$_2$D$_3$ or 24R,25(OH)$_2$D$_3$. H. L. Henry[1], M. Heim*[2], J. E. Bishop[1], R. Zielinski*[1], H. D. Shah*[1], C. Kwan*[1], I. Bendik*[2], W. Hunziker[2], A. W. Norman[1]. [1]Univ. California, Riverside, CA, USA, [2]Research and Development, Human Nutrition and Health, Roche Vitamins Ltd., Basel, Switzerland.

The vitamin D nuclear receptor null mouse (VDR-KO) offers the opportunity to probe possible VDR-independent responses of cells to the metabolites of vitamin D. We carried out GeneChip DNA microarray analysis of RNA from intestine, kidney and bone from VDR-KO and wild type (WT) mice. Three groups of mice fed a vitamin D deficient diet were given an IP dose of either 1α,25(OH)$_2$D$_3$ (250 ng) or 24R,25(OH)$_2$D$_3$ (500 ng) or vehicle (ethanol/propanediol, 1:1) 8 hours prior to tissue harvest. Total RNA from kidney, bone, and small intestine was isolated from each individual animal and biotin-labeled cRNA was synthesized for hybridization to mouse Affymetrix GeneChip arrays. Only sequences above a minimal level of expression (Average Difference > 150) were used for further analysis. The numbers of transcripts whose expression in vehicle-treated WT mice was at least two-fold greater than in vehicle-treated KO mice were 43, 20, and 98 for bone, intestine, and kidney, respectively. In a separate analysis of the VDR-KO data, 20 transcripts whose expression in bone was up-regulated at least two-fold over vehicle control by 24R,25(OH)$_2$D$_3$ but not by 1α,25(OH)$_2$D$_3$ in VDR-KO mice were identified. The same analysis in kidney and intestine yielded 11 transcripts in each tissue. All but 3 of the 20 24R,25(OH)$_2$D$_3$-regulated bone transcripts were also expressed in WT bone and nine of these were up-regulated by 24R,25(OH)$_2$D$_3$ in that tissue. Approximately half of the 20 transcripts were also expressed in either intestine or kidney, but only one was also up-regulated in one of these tissues (kidney). Of these 20 transcripts that are apparently up-regulated in bone by 24R,25(OH)$_2$D$_3$, 6 have been selected for further confirmatory analysis by RT-PCR. These include transcripts encoding HSP47, a molecular chaperone involved in collagen Type I synthesis, as well as proteins involved in apoptosis and protein phosphorylation. These studies provide evidence that 24R,25(OH)$_2$D$_3$ can alter the pattern of gene expression in a target tissue and confirms that the VDR-KO mouse is a useful model in which to examine elements of the vitamin D endocrine system in the absence of the 1α,25(OH)$_2$D$_3$-VDR complex.

SU450

Novel Interaction of the Vitamin D Receptor with a Mitochondrial Protein, Enoyl CoA Hydratase: Implications with Respect to Vitamin D Function. W. Lutz*[1], E. Frank*[1], M. R. Pittelkow*[2], D. Matern*[3], R. Rinaldo*[3], R. Kumar[1]. [1]Medicine and Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, [2]Dermatology, Mayo Clinic, Rochester, MN, USA, [3]Pathology and Laboratory Medicine, Mayo Clinic, Rochester, MN, USA.

The vitamin D receptor (VDR) interacts with co-activator and co-repressor proteins, and steroid hormone receptors to change gene expression. To assess whether the VDR interacts with other biologically relevant proteins, we used the yeast two-hybrid system to identify novel interacting proteins. The Gal4 yeast two-hybrid system was used to screen a kidney cDNA library. Saccharomyces cerevisiae, AH109 cells, were co-transformed with the pACT cDNA library vector and with the pGBKT7 vector expressing the VDR as a fusion protein with the Ga14 DNA-binding domain. Yeast transformants expressing a protein, which interacts with VDR were selected by nutrient auxotrophy and galactosidase activity. A transformant was obtained which expressed enoyl CoA hydratase, short, 1(ECHS1) (Accession # BC008906), a mitochondrial matrix enzyme, which catalyzes the hydration of 2-trans-enoyl CoA intermediates to L-3 hydroxy-acyl CoAs during mitochondrial beta-oxidation of fatty acids. To assess the function consequences of the interaction of the VDR and ECHS1 we compared fatty acid oxidation in primary cultures of skin fibroblasts derived from wild-type mice and VDR-null mutant mice. Beta-oxidation in fibroblasts was evaluated by measuring the concentration of acylcarnitines: C2, C3, C4, C6, C8, C10:1, C10, C12:1, C12, C14:1, C14, C16:1, and C16 in the culture medium by mass spectrometry. Concentrations of all acylcarnitines corrected for protein in the wells were lower in the culture medium from VDR null mutant mouse fibroblasts. The difference was statistically significant ($P < 0.05$) for C5, C8, C10, C14:1, and C16:1 acylcarnitines. As the steady state levels of acylcarnitines is inversely related to the rate of beta-oxidation these results suggest the interaction of VDR and ECHS1 reduces the activity of the enzyme. ECHS1 is encoded by a nuclear gene and is targeted to the mitochondrion by a leader sequence. As the VDR has not been reported to be present in mitochondria it is likely that the receptor and ECHS1 interact in the cytosolic compartment to alter ECHS1 activity by a yet to be defined mechanism. We show that the VDR interacts with enoyl CoA hydratase, a mitochondrial enzyme involved in the beta-oxidation of fatty acids. These results, in part, may explain previous observations in which vitamin D has been shown to alter mitochondrial function.

SU451

Nuclear Localization Sequence of NCoA-62/SKIP and its Colocalization with VDR. C. Zhang*, D. R. Dowd*, P. N. MacDonald. Pharmacology, Case Western Reserve University, Cleveland, OH, USA.

NCoA-62/SKIP is a novel coactivator protein in VDR-mediated transcription, and it functions by binding selectively to the VDR-RXR heterodimer in a ligand-enhanced manner. Little is known of the domains within the NCoA-62/SKIP protein that mediate its coactivator properties. In the present study, we identified a nuclear localization sequence (NLS) in the extreme COOH-terminus of NCoA-62/SKIP. FLAG-tagged NCoA-62/SKIP or a series of NCoA-62/SKIP deletion mutants were transiently expressed in COS7 cells, and the subcellular distribution of the proteins was examined with anti-FLAG antibodies and immunofluorescent microscopy. NCoA-62/SKIP WT showed strict nuclear staining, while NCoA-62/SKIP (1-530), lacking the last 6 amino acids in the COOH-terminus, showed exclusive cytoplasmic staining. These data suggested that residues 530-536 (KKRRKE) of NCoA-62/SKIP comprised a nuclear localization sequence. The sufficiency of the NLS of NCoA-62/SKIP was investigated by fusing this sequence to green fluorescent protein (GFP) at the COOH-terminus. GFP-NCoA (530-536) was located predominantly in nuclei, while GFP alone was equally distributed throughout the cells. To examine colocalization of NCoA-62/SKIP with VDR, we constructed HA-tagged VDR for immunostaining and confocal microscopy. HA-VDR was located predominantly in nuclei with a significant presence in cytoplasm in the absence of ligand. NCoA-62/SKIP WT colocalized with VDR in the nucleus. Importantly, coexpression of VDR transferred NCoA-62/SKIP (1-530) from cytoplasm to nucleus. These results indicate that 1) NCoA-62/SKIP is a nuclear protein; 2) an NLS consisting of 6 amino acids in the COOH-terminus is required and sufficient for nuclear-restricted expression of NCoA-62/SKIP; and 3) VDR expression targets NCoA-62/SKIP (1-530) to the nucleus through a physical interaction between VDR and NCoA-62/SKIP.

SU452

1α,25(OH)$_2$-vitamin D$_3$-Mediated Cross-talk from Rapid to Genomic Responses in Human Leukemic NB4 Cells as Studied by Microarray Analysis and Transfected Reporter Genes. A. W. Norman[1], J. E. Bishop[1], S. Ishizuka[2], H. L. Henry[1]. [1]Univ. California, Riverside, CA, USA, [2]Dept. Bone and Calcium Metabolism, Teijin Institute for Bio-Medical Research, Tokyo, Japan.

The steroid hormone 1α,25(OH)$_2$-vitamin D$_3$ [1α,25(OH)$_2$D$_3$] exerts its biological activity via distinct receptors that recognize different shapes of the conformationally flexible 1α,25(OH)$_2$D$_3$. These include the nuclear vitamin D receptor [nVDR; responsive to the 6-s-*trans* shape of 1α,25(OH)$_2$D$_3$] associated with genomic responses and a putative membrane receptor (mVDR) linked to rapid, nongenotropic responses [responsive to the 6-s-*cis* shape of 1α,25(OH)$_2$D$_3$]. We and others have previously shown that 1α,25(OH)$_2$D$_3$ elicits rapid responses in many cell types including the human leukemic NB4 cell line; these include activation and membrane translocation of PKC and activation of mitogen-activated protein kinase (MAP-kinase). Here we report results in NB4 cells from experiments addressing whether 1α,25(OH)$_2$D$_3$ mediated rapid responses cross-talk to modulate gene expression. We assessed the rapid response contributions to gene expression in the presence of either PD98059 (PD, an inhibitor of MAP-kinase that is known to phosphorylate transcription factors) or 1β,25(OH)$_2$D$_3$ [HL, an analog of 1α,25(OH)$_2$D$_3$ that is an inhibitor of 1α,25(OH)$_2$D$_3$ initiated rapid responses, with minimal effects on genomic responses]. NB4 cells were exposed to 10 nM 1α,25(OH)$_2$D$_3$ ± PD (10 μM for 3 hr) or 10 nM 1α,25(OH)$_2$D$_3$ ± HL (10 nM for 8 hr). Then the total RNA was isolated and biotin-labeled cRNA was synthesized for hybridization to human Affymetrix GeneChip arrays. Only sequences above a minimum level of expression were used for analysis. Of 44 genes that were up-regulated by 3 hr exposure to 1α,25(OH)$_2$D$_3$ (>2-6X), the presence of PD attenuated 20 of these genes (2-5X). Of 128 genes that were up-regulated by 8 hr exposure to 1α,25(OH)$_2$D$_3$ (>2-10X), 79 were attenuated by the presence of HL (13 > 4X; 20 > 3X; 23 > 2X). Comparable results were seen for 1α,25(OH)$_2$D$_3$ mediated down-related genes. In other experiments, NB4 cells were transiently transfected with an osteocalcin promoter [with a 1α,25(OH)$_2$D$_3$ response element, VDRE] linked to a growth hormone reporter and 24 hrs later the cells were exposed for 24 hr to 1α,25(OH)$_2$D$_3$ (10 nM) ± PD (5 μM). The expression of the osteocalcin reporter was inhibited in the presence of PD by 65% ± 7%. A similar result was obtained with the 1α,25(OH)$_2$D$_3$ responsive 25(OH)D$_3$-24-hydroxylase promoter. We conclude that by both microarray analysis or transfection of VDRE containing reporter genes there is evidence for 1α,25(OH)$_2$D$_3$ mediated rapid responses that modulate gene expression.

Comparative LC-MS/MS Based Metabolic Study of 1α,25(OH)$_2$D$_3$ and 20-methyl-1α,25(OH)$_2$D$_3$ Reveals Reduced Clearance through CYP24-catalyzed C24-oxidation. M. Kaufmann*, S. Masuda, G. Jones. Biochemistry, Queen's University, Kingston, ON, Canada.

CYP24-catalyzed metabolism of 1α,25(OH)$_2$D$_3$ through C24-oxidation results in the excretory form, calcitroic acid (CA). Increased biological activity of side chain substituted analogs of 1α,25(OH)$_2$D$_3$ arises partially from reduced CYP24-mediated target cell clearance, in addition to altered DBP and VDR affinity. The objective of this investigation was to compare the sites and rates of catabolism of 1α,25(OH)$_2$D$_3$ and a model analog, 20-CH$_3$-1α,25(OH)$_2$D$_3$ in human HPK1A-*ras* cells in a time (0-48h) and substrate concentration (100nM-10μM) dependent manner. Capacity of CYP24 to metabolize 1α,25(OH)$_2$D$_3$ and 20-CH$_3$-1α,25(OH)$_2$D$_3$ was assessed by substrate loss and *total* product formation using quantitative diode array [UV$_{265}$] and LC-MS/MS. Mass spectral characterization of metabolites was based upon molecular ions [MH$^+$], dehydration products, and sodium adducts. MS/MS spectra yielded a fragment ion [m/z=135] which formed the basis for highly sensitive and selective metabolite quantitation. 20-CH$_3$-1α,25(OH)$_2$D$_3$ was metabolized through analogous intermediates to 1α,25(OH)$_2$D$_3$ with a similar time-dependent metabolite distribution. At 4-8h time points of 1μM incubations, proximal pathway intermediates 1α,24,25(OH)$_3$D$_3$ [MH$^+$=433/+20-CH$_3$=447] and 24-oxo-1α,25(OH)$_2$D$_3$ [MH$^+$=431/445] predominated, whereas the terminal catabolites tetranor-1α,23(OH)$_2$D$_3$ [MH$^+$=361/375] and CA [MH$^+$=375/389] were the most prevalent at 48h. Analog metabolism differed by reduced production of 23-hydroxylated and side chain cleaved catabolites. Diminished production of 20-CH$_3$-24-oxo-1α,23,25(OH)$_3$D$_3$ over 24-oxo-1α,23,25(OH)$_3$D$_3$ [MH$^+$=461/447] was observed at high substrate concentrations [5-10μM, 24h] and at t=12-48h, 1μM. A similar trend for 20-CH$_3$-tetranor-1α,23(OH)$_2$D$_3$ over tetranor-1α,23(OH)$_2$D$_3$ was also observed at the 1μM time points. The terminal metabolite CA, was produced at t=12-48h, 1μM, and at high efficiency using low substrate concentrations (100-500nM, 24h). In contrast, 20-CH$_3$-CA was observed only at 1μM, 48h and in

lesser quantities than CA. 1α,23,25(OH)$_3$D$_3$ [MH$^+$=433] was observed to be a major product of 1α,25(OH)$_2$D$_3$ at 5-10μM, whereas no 20-CH$_3$ equivalent was found in analog incubations. We have revealed that 20-CH$_3$ substitution of 1α,25(OH)$_2$D$_3$ leads to altered metabolism through CYP24-catalyzed C24-oxidation, characterized by reduced 23-hydroxylation and conversion to water-soluble products. In conclusion, the finding of diminished metabolism of 20-CH$_3$-1α,25(OH)$_2$D$_3$ by CYP24 provides an explanation for increased biological activity for this, and perhaps other analogs.

SU454

Molecular Analysis of the Vitamin D Receptor Interactions with Highly Potent Vitamin D Analogues Using Site-Directed Mutagenesis. T. Okano[1], K. Nakagawa*[1], Y. Sowa*[1], K. Mikami*[2], N. Kubodera[3], K. Ozono[4]. [1]Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan, [2]Chemical Technology, Tokyo Institute of Technology, Tokyo, Japan, [3]Chugai Pharmaceutical Co., Ltd., Tokyo, Japan, [4]Developmental Medicine, Osaka University Graduate School of Medicine, Osaka, Japan.

The biologic effects of 1α,25-dihydroxyvitamin D$_3$ [1α,25-D$_3$] are believed to be mediated by the vitamin D receptor (VDR) that acts as a ligand-dependent transcription factor in the nucleus of target cells. Recently, the crystal structure of the human VDR ligand-binding domain (LBD) complexed to 1α,25-D$_3$ has been reported and it was revealed that the 1α-hydroxyl group forms two hydrogen bond with serine-237(H3) and arginine-274(H5), and the residues of lysine-264 and glutamic acid-420 form a salt bridge that stabilizes the conformation of the activation function domain 2 (AF-2) of the VDR. To examine the interactions of highly potent vitamin D analogues with the LBD, especially at the sites of H3, H5 and H12, point-mutations at Ser-237(Ser237Ala, S237A), Arg-274(R274A), and Lys-264(K264A) were generated in the hVDR expression plasmid (pSG5-hVDR) by site-directed mutagenesis using a PCR method. The mutant VDRs were evaluated for in vitro and in situ ligand-binding potency, ligand-dependent transcriptional activity in transfected MG-63 cells utilizing reporter constructs containing either rat 25-hydroxyvitamin D$_3$-24-hydroxylase or human osteocalcin gene promoter, in situ heterodimerization efficiency with retinoid X receptor a (RXRα) and in vitro VDR/RXRα/vitamin D response element (VDRE) complex formation efficiency in the presence or absence of the ligands. The results indicated that the relative binding affinities for 1α,25-D$_3$ were wild-type VDR (100%) = K264A (100%) > S237A (49%) > R274A (0%), while those for 20-epi-1α,25-D$_3$ were wild-type VDR (100%) > K264A (128%) > S237A (213%) > R274A (0%). The mutant VDRs all displayed significantly reduced transcriptional activities and VDR/RXRα heterodimer or VDR/RXRα/VDRE complex formation for 1α,25-D$_3$, while both S237A and K264A displayed similar biological potencies for 20-epi-1α,25-D$_3$ when compared with wild-type VDR. As expected, R274A was totally inactive. These results suggest that Arg-274 in the LBD of the VDR is essential for binding to both 1α,25-D$_3$ and 20-epi-1α,25-D$_3$ and play a vital role to transactivate vitamin D-target genes. In addition, the amino acid residues other than Ser-237 and Lys-264 in the LBD may be involved in the VDR binding of 20-epi-1α,25-D$_3$.

2,2-Dimethyl Analogues of 1alpha,25-Dihydroxyvitamin D3: The A-Ring Structure of the Ligands Differentiates Activity Profiles of the Natural Hormone. T. Fujishima*[1], A. Kittaka*[1], K. Yamaoka*[2], K. Takeyama[2], S. Kato[2], M. Kurihara*[3], H. Takayama[1]. [1]Faculty of Pharmaceutical Sciences, Teikyo University, Kanagawa, Japan, [2]Institute of Molecular and Cellular Biosciences, University of Tokyo, Tokyo, Japan, [3]National Institute of Health Sciences, Tokyo, Japan.

We have synthesized all possible A-ring stereoisomers of 2-methyl-1,25-dihydroxyvitamin D$_3$, demonstrating that the introduction of a simple methyl group to the A-ring of 1α,25-dihydroxyvitamin D$_3$ (**1**) yields the analogues with unique activity profiles. The eight 2-methyl analogues, which differ in stereochemistry of the methyl group on C2 and the hydroxyl groups on C1 and C3, exhibited cell differentiation- or apoptosis-inducing activity towards HL-60 cells, depending on the A-ring structure. In particular, 2α-methyl-1α,25-dihydroxyvitamin D$_3$ (**2a**) showed 4-fold higher affinity for bovine thymus VDR and 2-fold higher cell differentiation-inducing activity towards HL-60 cells in comparison with **1**, whereas 2β-methyl-1α,25-dihydroxyvitamin D$_3$ (**2b**) showed one-eighth of the affinity of **1**, with a weak apoptosis-inducing activity. In the present work, we have designed 2,2-dimethyl-1α,25-dihydroxyvittamin D$_3$ (**3**) as a hybrid analogue of **2a** and **2b** to investigate how these double methyl groups in the C2 position affect the activity profiles. Synthesis of all four possible stereoisomers of 2,2-dimethyl-1,25-dihydroxyvitamin D$_3$ was carried out by using a convergent method. The A-ring enyne synthon was obtained by a 9-step conversion of methyl hydroxypivalate in excellent yield. The bovine thymus VDR binding affinity of 2,2-dimethyl-1α,25-dihydroxyvittamin D$_3$ (**3**) was 3% of the affinity of **1**. The other three stereoisomers of **3**, which differ in stereochemistry of the hydroxyl groups on C1 and C3, showed rather weak potency. We preliminarily examined interaction of VDR with two coactivaters (SRC-1, TIF2) by the synthesized analogues in mammalian two hybrid assays. The natural hormone **1** induced interaction of VDR with two coactivaters (SRC-1, TIF2). In our preliminary results, the VDR that liganded with the methyl analogues appeared to possess a differentiated potency to recruit these coactivators depending on the A-ring structure. The 2α-methyl analogue (**2a**) induced rather strong interaction of VDR with SRC-1, whereas its 2-epimer, the 2β-methyl analogue (**2b**), showed a preference to TIF2. The 2,2-dimethyl analogue (**3**) exhibited a similar trend of the 2α-methyl analogue (**2a**). Molecular docking studies based upon the X-ray crystal structure of VDR suggested the importance of the 2-methyl substitution in a certain orientation. The detailed biological activities and molecular docking studies of the analogues will be presented.

SU456

The Novel 2alpha-Substituted 1alpha,25-Dihydroxyvitamin D3 Analogues as Superagonists: Evaluation of VDR-Binding and Remarkable Calcemic Activity. A. Kittaka*[1], Y. Suhara*[1], T. Shinki[2], T. Fujishima*[1], M. Kurihara*[3], H. Takayama[1]. [1]Faculty of Pharmaceutical Sciences, Teikyo University, Kanagawa, Japan, [2]School of Dentistry, Showa University, Tokyo, Japan, [3]National Institute of Health Sciences, Tokyo, Japan.

Stereocontrolled syntheses of 1α,25-dihydroxyvitamin D$_3$ (**1**) analogues with a 2α-substituent in three categories (**A** - **C**) have been accomplished in order to investigate the A-ring structure-activity relationships. The representative positive structural motifs at the 2α-position of **1** in VDR binding are the methyl group of the alkyl series (**A**), the 3-hydroxypropyl group in the ω-hydroxyalkyl series (**B**), and the 3-hydroxyalkoxyl group in the ω-hydroxyalkoxyl series (**C**). These analogues were systematically synthesized from the A-ring precursor enyne, derived from D-xylose or D-glucose, and the CD-ring bromoolefin part using Pd-catalyzed coupling reaction. Introduction of one of these positive motifs to the 2α-position of **1** showed ca. 2- to 4-fold higher binding affinity for bovine thymus VDR than that of the natural hormone. Biological activities of these analogues having similar length of the 2α-substituent in each category, i.e., propyl (C3) in **A**, 3-hydroxypropyl (O1C3) in **B**, or 3-hydroxypropoxyl (O2C3) in **C** were studied. In vivo analyses of Northern blot reveal increase in expression of CYP24 mRNA in rat intestine with C3, O1C3, and O2C3, as compared to **1**. The half-life of these analogues, especially O1C3 and O2C3, seems to be much longer than that of **1**; because expression of CYP24 mRNA maintains markedly higher level than that of **1** after 24 hrs. It is also interesting that calcemic activity of C3 in rat serum is almost the same level as **1**, even though VDR affinity of C3 is only 20% of the natural hormone. In the case of O1C3 and O2C3, remarkable calcemic activity continued even after 24 hrs. It would be due to high affinity for VDR and the long half-life of these analogues in rat serum. Some of synthetic analogues of **1** have been clinically used in the treatment of calcium and bone disease, secondary hyperparathyroidism, and skin disorder psoriasis. We believe our novel 2α-manipurated analogues would give important information in structure-activity relationships and contribute to elucidate the molecular mode of action.

SU457

Comparison of the Calcemic Actions of 1α(OH)D$_2$ and 1α(OH)D$_3$ and their Activated Metabolites. A. J. Brown[1], J. L. Finch[1], S. A. Strugnell[2], J. C. Knutson[2]. [1]Renal Division, Washington University, Saint Louis, MO, USA, [2]Bone Care International, Madison, WI, USA.

1α-Hydroxyvitamin D$_2$ (1α(OH)D$_2$ or doxercalciferol), a less calcemic analog than its vitamin D$_3$ counterpart 1α(OH)D$_3$ (alfacalcidol), is currently available for the treatment of secondary hyperparathyroidism in patients with renal failure. Both 1α(OH)D$_2$ and 1α(OH)D$_3$ are prohormones that must be activated to exert their actions. Although both are 25-hydroxylated *in vivo*, in animal and cell culture studies 1α(OH)D$_2$, but not 1α(OH)D$_3$, can be 24-hydroxylated to 1,24(OH)$_2$D$_2$, a metabolite that is much less calcemic than 1,25(OH)$_2$D$_2$ and 1,25(OH)$_2$D$_3$. In the present study, we have examined the calcemic activities of 1α(OH)D$_2$ and 1α(OH)D$_3$ and their dihydroxylated metabolites. 1α(OH)D$_2$ or 1α(OH)D$_3$ were administered IP (1.0 or 2.5 nmol/kg) to vitamin D-replete rats every other day for one week, and serum Ca and P were measured 24 hours after each injection. 1α(OH)D$_2$ was clearly less calcemic and phosphatemic than 1α(OH)D$_3$ even after a single injection. Metabolism and tissue distribution studies showed that in vitamin D-replete rats [^{3}H]1α(OH)D$_2$ was rapidly converted in vivo to both 1,25(OH)$_2$D$_2$ and 1,24(OH)$_2$D$_2$, but 1,25(OH)$_2$D$_2$ was the predominant metabolite both in the circulation and in the intestine and bone. The relative activities of 1α(OH)D$_2$ and 1α(OH)D$_3$ and their dihydroxy metabolites in stimulating intestinal calcium absorption and bone Ca mobilization were compared using vitamin D-deficient rats. The ED50s for stimulation of intestinal Ca absorption were similar for 1,25(OH)$_2$D$_3$ and 1,25(OH)$_2$D$_2$ (0.020 and 0.025 nmol/kg, respectively) but30 times higher for 1,24(OH)$_2$D$_2$ (0.70 nmol/kg). The ED50s for 1α(OH)D$_2$ and 1α(OH)D$_3$ were similar, but the amount of Ca absorption produced by 1α(OH)D$_2$ and 1α(OH)D$_3$ was markedly lower than that produced by the activated metabolites, and the amount of absorption produced by 1α(OH)D$_3$ was less than that produced by 1α(OH)D$_2$. 1α(OH)D$_2$ and 1α(OH)D$_3$ were equipotent in enhancing bone Ca mobilization as were 1,25(OH)$_2$D$_2$ and 1,25(OH)$_2$D$_3$. 1,24(OH)$_2$D$_2$ was less active than 1,25(OH)$_2$D$_3$ and 1,25(OH)$_2$D$_2$, but only at the lowest dose tested (0.01 nmol/kg). In summary, the strikingly disparate calcemic activities of 1α(OH)D$_2$ and 1α(OH)D$_3$ could not be readily explained by differences in their abilities to stimulate intestinal Ca absorption or bone Ca mobilization in vitamin D-deficient rats.

The Noncalcemic Vitamin D Analogue, EB1089, Downregulates Parathyroid Hormone-Related Protein (PTHrP) Gene Expression in the PC-3 Prostate Cancer Cell Line. V. A. Tovar Sepulveda*, M. Falzon*. Department of Pharmacology and Toxicology, and Sealy Center for Molecular Sciences, UTMB, Galveston, TX, USA.

Parathyroid hormone related protein (PTHrP) contributes to the pathogenesis and progression of prostate carcinoma and the tendency of this tumor to metastasize to bone. In previous studies we demonstrated that (1) PTHrP increases proliferation of the prostate cancer cell line PC-3 through both autocrine/paracrine and intracrine pathways, and (2) 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) downregulates PTHrP gene expression in PC-3 cells. $1,25(OH)_2D_3$ is hypercalcemic *in vivo,* and therefore cannot be used clinically. The present study was undertaken (1) to compare the effects of $1,25(OH)_2D_3$ and a noncalcemic analogue, EB1089, on PTHrP gene expression in PC-3 cells; (2) to analyze the mechanism via which $1,25(OH)_2D_3$ and EB1089 regulate PTHrP gene transcription in this cell line; and (3) to investigate whether the observed suppression of PTHrP gene expression has any effect on PC-3 cell growth. Both EB1089 and $1,25(OH)_2D_3$ downregulated steady-state PTHrP mRNA levels, as determined by Northern blot analysis. The two compounds also decreased secreted PTHrP levels, as determined by an immunoradiometric assay. The human PTHrP gene contains a negative vitamin D response element ($nVDRE_{PTHrP}$) analogous to the nVDRE within the human parathyroid hormone gene. Electrophoresis mobility shift assays (EMSAs) demonstrated that this $nVDRE_{PTHrP}$ interacts with the vitamin D receptor (VDR). Both $1,25(OH)_2D_3$ and EB1089 inhibited the reporter activity of a plasmid bearing the $nVDRE_{PTHrP}$ under the control of the SV-40 promoter, as determined by chloramphenicol acetyltransferase (CAT) assays. $1,25(OH)_2D_3$ and EB1089 also produced a significant, dose-dependent decrease in PC-3 cell growth, as determined by direct cell counting. These results suggest that EB1089 suppresses PTHrP gene expression in PC-3 cells by the same mechanism as $1,25(OH)_2D_3$. EB1089 may therefore prove to be therapeutically useful in the treatment of prostate cancer, since it lacks the undesirable hypercalcemic effect of $1,25(OH)_2D_3$.

SU459

CYP24-Null Keratinocytes Demonstrate that CYP24 Is Responsible for Activation and Inactivation of $1\alpha(OH)D_2$. S. Masuda[1], A. Arabian*[2], J. McCaig*[1], M. Kaufmann*[1], S. A. Strugnell*[3], J. C. Knutson*[3], R. St-Arnaud*[2], G. Jones[1]. [1]Biochemistry, Queen's University, Kingston, ON, Canada, [2]Genetics Unit, Shriners Hospital for Children, Montreal, PQ, Canada, [3]Bone Care International, Madison, WI, USA.

CYP24 is postulated to play an important role in the metabolic clearance of $25(OH)D_3$ and $1\alpha,25(OH)_2D_3$. Vitamin D prodrugs require side chain activation by enzymes in the liver and possibly other sites. Previous studies in human keratinocytes incubated with $1\alpha(OH)D_2$ have demonstrated the production of active metabolites and inactive catabolites in a dose- and time-dependent manner. This study examined whether CYP24 is responsible for this target cell activation/ inactivation. Keratinocytes isolated from CYP24 null mice, wild type, and heterozygotic mice were incubated with 50 nM [9,11-^{3}H]$1\alpha(OH)D_2$ and the metabolites characterized by HPLC. No metabolites of [^{3}H]$1\alpha(OH)D_2$ were generated with CYP24-null keratinocytes; most of the radioactivity remained as unchanged substrate. In contrast, wild type and heterozygotic keratinocytes completely converted [^{3}H]$1\alpha(OH)D_2$ into aqueous-soluble metabolites. Mammalian cells transiently transfected with CYP24 and incubated with [^{3}H]$1\alpha(OH)D_2$ produced a series of metabolites similar to those seen in keratinocytes, confirming the central metabolic role of CYP24 established with the mouse keratinocytes. To characterize further the entire set of CYP24-generated metabolites of $1\alpha(OH)D_2$, the human keratinocyte cell line, HPK1A-*ras,* was incubated with 10 μM $1\alpha(OH)D_2$ for 48 h, and the metabolites produced were identified by a combination of diode array and LC-MS detection. Surprisingly, the major metabolite found in the aqueous fraction did not correspond to calcitroic acid, the purported final product of both $1\alpha,25(OH)_2D_3$ and $1\alpha,25(OH)_2D_2$. Its molecular weight of 458 is consistent with the presence of a hydroxy group and a carboxyl group in the side chain. Lack of sensitivity to sodium meta-periodate oxidation indicated that the carboxylated position was C-26(27). The novel metabolite identified as $1\alpha,24\text{-}(OH)_2$, 26-carboxy D_2 is the presumed degradation product of $1\alpha(OH)D_2$, synthesized by CYP24 via successive 24-hydroxylation, 26-hydroxylation and further oxidation at C-26. These findings suggest that CYP24 has the capacity to both activate and inactivate prodrugs in target cells *in vivo* thereby offering the potential for treatment of hyperproliferative disorders such as psoriasis and skin cancer by topical administration of these compounds.

SU460

2-Methylene-19-Nor-(20S)-1,25-Dihydroxyvitamin D_3: A Potent Inducer of Osteoclast Formation through Actions on RANKL. H. Yamamoto, N. K. Shevde, O. Barmina*, L. Plum*, H. F. DeLuca, J. W. Pike. Biochemistry, University of Wisconsin- Madison, Madison, WI, USA.

The two carbon-modified vitamin D_3 analogue 2-methylene-19-nor-(20S)-1,25-dihydroxy-vitamin D_3 (2MD) is a highly potent selective vitamin D receptor modulator (SVDRM). Unlike 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) whose physiologic actions are homeostatic, recent studies indicate that 2MD is preferentially anabolic in vivo, leading to the formation of new bone in the rat at concentrations that do not induce hypercalcemia. Despite this, the analogue is a potent transcriptional regulator of osteoblast genes that either induce osteoclast formation (RANKL, OPG) or modulate their function (osteopontin), with peak activity two logs lower than that for $1,25(OH)_2D_3$. This results in the induction of osteoclast formation in either total bone marrow cultures or in coculture assays (ST2 osteoblast cells and either nonadherent hematopoeitic spleen precursors or RAW264.7 cells) at 10^{-10} M. These differences in potency between 2MD and $1,25(OH)_2D_3$ are also observed when the promoters for the human osteocalcin or the 24OHase genes are introduced as luciferase reporter constructs into MC3T3E1 cells and evaluated at concentrations from 10^{-12} to 10^{-7} M. In this context, however, the RANKL promoter (-965) is completely resistant to both ligands. Interestingly, the affinity of recombinant VDR for 2MD is identical to that for $1,25(OH)_2D_3$. We explored this discrepancy using cellular assays and molecular techniques including those involving protease digestion and mammalian two-hybrid interactions. Transcriptional dose response curves under reduced-serum or serum-free conditions for both $1,25(OH)_2D_3$ and 2MD revealed that ligand potency increased proportionately for both vitamin D compounds. This suggested that differences in analogue binding to either serum proteins or DBP were unlikely to explain the potency differences. Interestingly, digestion assays using limited trypsin digestion revealed no differences between $1,25(OH)_2D_3$ or 2MD in their ability to either protect VDR or to alter its pattern of digestion. Interaction technology, however, using the mammalian two-hybrid system revealed that association of VDR with both its RXRalpha partner as well as with the LXXLL domain of comodulator SRC-1 occurred at concentrations of 2MD that were two logs lower than that for $1,25(OH)_2D_3$. These studies suggest that in addition to its classification as a SVDRM, 2MD is a superagonist that stimulates transcription by enhancing interaction between the VDR and at least two protein partners that play key roles in vitamin D-dependent transcriptional activation.

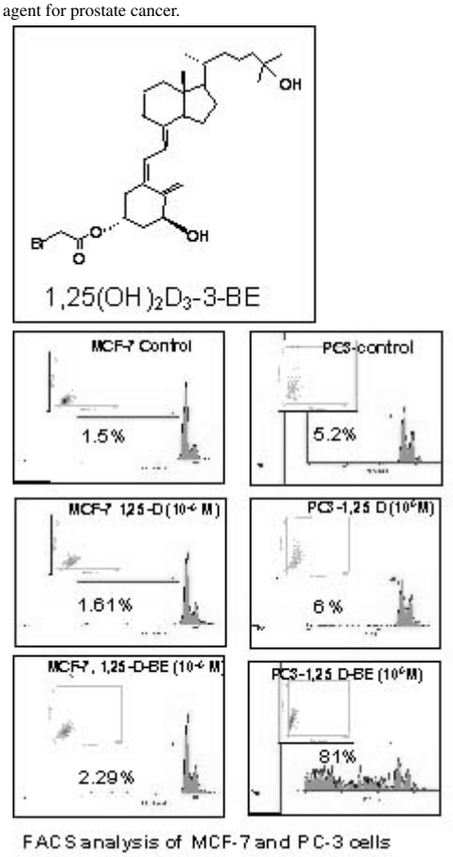
Cross-linking Analogs of Vitamin D for Prostate Cancer. N. Swamy*[1], R. Ray[2]. [1]Pediatrics, Brown University, Providence, RI, USA, [2]Medicine, Boston Unviersity School of Medicine, Boston, MA, USA.

1,25(OH)2D3 and its analogs are non-tissue specific due to the ubiquitous nature of VDR. Therefore, large doses of these compounds are required to harness any beneficial effect, causing hypercalcemia. Moreover, these analogs are antiproliferative, but not toxic to reduce tumor load. Ideally a vitamin D-related drug should be antiproliferaive and lethal to tumor cells at a dose that does not induce systemic toxicity. We have developed 1,25(OH)2D3-3-BE, a VDR-cross-linking analog and studied its growth-inhibitory effects in keratinocytes (skin cells), MCF-7 (breast cancer cells), LNCaP and PC-3 (prostate cancer cells), and PZ-HPV-7 (papillovirus immortalized normal prostate cells). We observed that 1,25(OH)2D3-3-BE had a stronger antiproliferative effect than 1,25(OH)2D3 in all the cells, but the effect was most pronounced in prostate cells. Furthermore, 1,25(OH)2D3-3-BE appeared to induce apoptosis in prostate cancer cells. FACS analysis of PC-3 and MCF-7 cells, treated with 10-6M of 1,25(OH)2D3-3-BE, revealed apoptosis (81% and 2% of PC-3 and MCF-7 cells respectively) while 1,25(OH)2D3-treated cells showed very little apoptotic effect. Our studies have shown that 1,25(OH)2D3-3-BE can be developed as a therapeutic agent for prostate cancer.



FACS analysis of MCF-7 and PC-3 cells treated With $1,25(OH)_2D_3$ or $1,25(OH)_2D_3$-3-BE

Changes in Vitamin D Status and Bone Mass in Primary Morbidly Obese Adolescents during Weight Reduction. H. Dao*[1], F. Oberlin[1], M. Frelut*[2], D. Porquet[3], G. Pérès*[4], P. Bourgeois*[1]. [1]Pitié-Salpêtrière Hospital, Rheumatology Department, Paris 13, France, [2]Robert Debré Hospital, Gastro-enterlogy Department, Paris, France, [3]Robert-Debré Hospital, Biochemical Laboratory, Paris, France, [4]Pitié-Salpêtrière Hospital, Sports Department, Paris 13, France.

Objective: The increasing prevalence of obesity in childhood and adolescence observed in many countries is currently a major public health concern. The aim of this study is to determine how the vitamin D statut and bone mass vary during weight loss in primary morbidly obese adolescents. Methods: 33 girls and 22 boys, aged 13.4+-3.6 year with BMI 34.6+-3.6 kg/m2 were included in a 7.5+-3.2 months multidisciplinary weight reduction programme including a slight caloric restriction and regular submaximal physical training. Vitamin D statut and bone mass were measured before and after weight loss. Results: Mean weight loss is 23.5+-8.9 kg ($p<0.0001$), growth is 2.7+-1.8 cm ($p<0.01$). Total BMC decreases less (253+-131 g, $p<0.0001$) than bone area (212+-14 cm2, $p<0.0001$) resulting in an increased BMD (0.003+-0.001 g/cm2, p=0.3). BMC Z scores remain higher than that in the reference population (2.7+-1.2 vs 2.5+-1.4 before and after weight loss respectively). Spinal BMC, bone area and BMD increases significantly in both sex ($p<0.001$) while femoral neck BMD only increases in boys ($p<0.01$). 25 OHD concentration increases significantly (12.7+-7.3 vs 16.5+-6.3µg/L, $p<0.003$) while PTH decreases but not significant (34.0+-11.9 vs 28.6+-7.0 pg/mL, p=0.083). 25 OHD <10 µg/L is 36 % before and 12 % after weight loss. The variation of plasmatic and urinary calcium and phophorus is not significant. There is a negative correlation between total BMC and 25 OHD before weight loss in both sex. Conclusion: Within limits of interpretation of DEXA, this multidisciplinary weight loss programme seems to maintain adequate bone mineralization and to improve vitamin D statut in the critical period period of puberty in primary morbidly obese adolescents.

M002

1,25$(OH)_2D_3$ Acts as a Bone Forming Agent in the Hormone Independent Senescence Accelerated Mouse (SAMP6) Model of Osteoporosis. G. Duque[1], N. Dion[2], V. Papavasiliou*[3], L. G. Ste. Marie[2], R. Kremer[3]. [1]Calcium Research Laboratory & Division of Geriatric Medicine, McGill University, Montreal, PQ, Canada, [2]Centre Hospitalier de l'Université de Montreal, Hôpital St. Luc, Montreal, PQ, Canada, [3]Calcium Research Laboratory, McGill University Health Centre, Montreal, PQ, Canada.

Senile osteoporosis is characterized by decreased bone formation rate with concomitant increased bone marrow adipogenesis and osteoblast apoptosis. The P6 strain of senescence-accelerated mice (SAM) is a model of senile osteoporosis with all of the above characteristics. Previous *in vitro* studies indicate that 1,25 dihydroxyvitamin D_3 (1,25 $(OH)_2D_3$) has opposite effects on bone cells by directly stimulating osteoblastic differentiation and mineralized matrix formation, while indirectly enhancing osteoclastic recruitment and differentiation through immature cells of the osteoblastic lineage. In this study, our aim was to determine the effect of 1,25 $(OH)_2D_3$ on bone mass and parameters of bone turnover in the SAMP6 model. Both male and female 4-months old SAMP6 (n=28) were infused continuously with 1,25 $(OH)_2D_3$ (18pmol/24h) or vehicle for a period of 6 weeks. Before and after the infusion period Dual Energy X-ray Absortiometry (DEXA) was performed and mice were then sacrificed. A significant increase in serum calcium levels was observed in the 1,25 $(OH)_2D_3$ treated group but both groups remained normocalcemic for the duration of the experiment. In 1,25 $(OH)_2D_3$ treated animals, histomorphometric analysis showed an anti-resorptive effect of 1,25 $(OH)_2D_3$ as well as a increase in bone formation demonstrated by higher bone volume and higher mineralization in treated bone with a difference of 20% as compared to the non-treated group. DEXA indicated a significant increase in both femora of +20% ($p< 0.001$) and spine bone mineral content of +40% ($p< 0.01$) in 1,25 $(OH)_2D_3$ treated animals as compared to pre-treatment levels. In contrast, non-treated animals indicated a significant decline in bone mineral content in femora (-5%, $p< 0.01$) and in spine (-8%, $p<0.002$) in the same period. Serum bone markers confirmed higher levels of osteoblastic activity in treated animals. Flushed bone marrow cells were separated and plated in osteoblastic differentiation media for a period of 3 weeks and then stained with Alizarin red. The number of bone forming colonies obtained from treated animals was significantly higher ($p< 0.001$) than those obtained from non-treated animals. In summary, our results demonstrate that 1,25 $(OH)_2D_3$ increases bone mass by stimulating bone formation in a mouse model of defective osteoblastogenesis, and suggest its potential usefulness as a therapeutic agent in senile osteoporosis.

M003

Calcium Supplementation Increases Height and Bone Mass of 16-18 Year Old Boys. A. Prentice[1], S. J. Stear*[1], F. Ginty[1], S. C. Jones*[1], L. Mills*[1], T. J. Cole*[2]. [1]MRC Human Nutrition Research, Cambridge, United Kingdom, [2]Department of Paediatric Epidemiology and Biostatistics, Institute of Child Health, London, United Kingdom.

The aim of the study was to investigate the impact of an increase in Ca intake on the growth and bone mineral status of adolescent boys. 150 boys aged 16-18 years were randomised, double-blind to receive 1000 mg Ca/d as the carbonate or a matching placebo for 12 mo (12.7±SD0.5 mo). The recruits were from sixth-form colleges in Cambridge, UK, had mean age 16.8±SD0.5 y and were 103% and 100% of the national average for weight and height at that age. Baseline Ca intake was 1198±SD448 mg/d, range (323-2395 mg/d). Randomisation was stratified according to physical activity level (less or greater than 9 h/wk sport, with or without participation in exercise sessions). Anthropometry and DXA of the whole-body, hip, lumbar spine and forearm (Hologic QDR 1000/w) were performed at baseline and at the end of the intervention. 143 subjects completed the study. Compliance with the calcium supplementation was 65±SD28%. Over the period of the study, the subjects grew in height, gained weight and experienced significant increases in bone mineral content (BMC), bone area (BA), bone mineral density (BMD) and size-adjusted bone mineral content (SA-BMC) at all scan sites. The calcium intervention resulted in a significantly greater BMC of the whole-body (1.3%, p=0.02), lumbar spine (2.5%, p=0.004) and hip (neck 2.1%, p=0.05, trochanter 4.6% p=0.007) but not the forearm. These effects were associated with significantly greater increments in statural height (0.4%, p=0.0004) and in BA at the lumbar spine (1.5%, p=0.003) and trochanter (3.6% p=0.009), but not at the whole-body and femoral neck. The differences in bone mineral were diminished but still evident when data were expressed as BMD but disappeared after size-adjustment, except at the femoral neck (SABMC 1.3%, p=0.05). No significant interaction was detected between the effect of the intervention and baseline Ca intake, tablet compliance or physical activity level. We conclude that calcium supplementation of these adolescent boys led to an increase in bone dimensions, including statural height, and that this resulted in a greater bone mass at the whole-body, spine and hip. Follow-up studies will determine whether this increase reflects a change in the tempo of bone growth in adolescence or represents an effect on skeletal size that persists into adulthood.

Exercise During Growth and Young Adulthood Is Followed by Fewer Fractures in Spite of Increased Bone Loss after Exercise Career. A. H. Gustavsson*[1], E. Giza*[2], P. Nordstrom[1], F. Nyquist*[2], C. Karlsson*[3], M. K. Karlsson*[2]. [1]Department of Surgical and Perioperative Sciences, Sports Medicine Unit, Umea, Sweden, [2]University Hospital MAS, Department of Orthopaedics, Malmo, Sweden, [3]Department of Orthopaedics, University Hospital MAS, Malmo, Sweden.

Exercise during growth is associated with increased peak bone mineral density (BMD). However, fragility fractures occur in old age. We asked: (i) are high peak BMD derived from exercise followed by increased bone loss with reduced activity? (ii) do former athletes have fewer fractures than controls? We measured femoral neck BMD in 55 active male ice hockey players, mean age 18 years (range 16-20) and 58 active male soccer players and weight lifters, mean age 24 years (range 16-35). Thirty-three ice hockey players and 37 soccer players and weight lifters retired during the 4-7 year prospective study. Sixty-three age- and gender- matched volunteers served as controls. We also compared the prevalence of fractures in 454 former soccer and ice hockey players mean age 69 years (range 50-92) and 908 age- and gender matched controls. Data is presented as mean ± SEM. The annual femoral neck BMD (g/cm2/year) loss was higher in both the retired ice hockey players (-0.020 ± 0.004, $p<0.001$) and the controls (-0.001 ± 0.004, $p<0.001$) than in the active ice hockey players (0.010 ± 0.004). The annual femoral neck BMD loss was higher in the retired soccer players (-0.022 ± 0.003) than both the controls (-0.009 ± 0.007, $p<0.05$), and the active soccer players (-0.009 ± 0.002, $p<0.01$). The active ice hockey players had higher BMD than both the controls ($p<0.01$) and the retired ice hockey players ($p<0.05$) and the active soccer players and weight lifters had higher BMD than both the controls ($p<0.01$) and the retired soccer players and weight lifters ($p<0.001$) at follow-up. The proportion of subjects with fractures was not lower in former soccer players than controls over all [111/454 (24.4%) versus 231/908 (25.4%); NS]; it was higher in the former soccer players when they were active and less than 35 years of age [81/454 (17.8 %) vs 127/908 (14.0 %); p = 0.06] and lower than controls in adulthood after the age of 35 years [39/454 (8.6 %) vs 112/908 (12.3 %), $p < 0.05$]. Additionally, the proportion of subjects with fragility fractures was lower in former athletes than controls [9/454 (2.0 %) vs 38/908 (4.2 %), $p < 0.05$]. The higher peak BMD attained by physical activity during growth is followed by increased bone loss with retirement. However, fracture rates are reduced in retired ice hockey and soccer players. It seems that exercise in men during growth may result in fewer fragility fractures later in life.

M005

Osteoporosis Prevention May Begin in Infancy. J. M. Eichenberger Gilmore*[1], J. C. Torner*[2], L. G. Snetselaar*[2], T. L. Burns*[3], E. E. Ziegler*[4], M. C. Willing[4], S. M. Levy*[1]. [1]Preventive and Community Dentistry, University of Iowa, Iowa City, IA, USA, [2]Epidemiology, University of Iowa, Iowa City, IA, USA, [3]Biostatistics, University of Iowa, Iowa City, IA, USA, [4]Pediatrics, University of Iowa, Iowa City, IA, USA.

Development of peak bone mass, a major determinant of osteoporotic risk, occurs primarily during childhood and adolescence. The goals of this project were to assess the influence of early infant feedings on subsequent bone development; and to help understand how early dietary and nutritional factors may relate to bone mass in early childhood. The study population is a cohort of healthy Iowa infants (n=469) recruited at birth. Parents of the infants returned mailed questionnaires and three-day diet diaries at 6 weeks, 3 months, and 6 months. Infant's diets were assessed and categorized by consumption of human milk (dichotomized "any" vs. "none"). The type of feeding and the nutrient content of the feedings was related to growth parameters and bone measurements of the same children at approximately 5 years of age. Linear multiple regression was used to examine the relationship between bone mineral content (BMC) and bone mineral density (BMD) and human milk consumption status. Overall, unadjusted univariate analysis revealed that at age 5 years, boys are taller than girls and have greater whole body, hip and lumbar spine BMC; and whole body and hip BMD ($p < 0.05$) despite similarities in body weight. Human milk consumers (dichotomized) had significantly greater BMC and BMD of the whole body, total hip, femoral neck, trochanter and Ward's triangle ($p < 0.05$) than non-consumers. Statistically significant differences in BMC adjusted for bone area (BA), height, weight and age; and BMD adjusted for height, weight and age were identified. In gender-stratified comparisons, the effect of human milk was evident in pairwise contrasts with diets devoid of human milk particularly among boys. Girls that consumed any human milk exhibited greater BMC and BMD of the Ward's triangle region of the hip ($p < 0.05$); whereas, boys that consumed any human milk exhibited greater whole body and total hip BMC and BMD. The results of this study support the hypothesis that bone mass as measured by BMC and BMD may be influenced by early diet, specifically human milk.

M006

Age Related Changes in Serum Osteoprotegerin Levels and Its Relationship with Biochemical Markers and Bone Mineral Density in a Population Based Sample. O. S. Indridason*, J. P. Johannesson*, L. Franzson*, G. Sigurdsson. University Hospital, Reykjavik, Iceland.

While osteoprotegerin (OPG) seems to be involved in the regulation of bone resorption and theoretically may protect against osteoporosis, its role in bone metabolism remains unclear. The purpose of this study was to examine age dependent changes in serum OPG levels and its relationship with bone mineral density and other markers of bone and mineral metabolism. We are conducting a randomised cohort study on age related changes in bone health in Icelandic subjects aged 40 to 85 years old. For the current study we used data from the first year of the study and excluded subjects who were taking medications affecting bone and mineral metabolism. OPG was measured with an ELISA (Biomedica, Austria). We divided the subjects into 5 age groups; ages 40 and 45, ages 50 and 55, ages 60 and 65, ages 70 and 75, and ages 80 and 85 years old. We used ANOVA to compare the groups with regard to OPG levels and Spearman´s correlation coefficient to assess relationship between OPG and other variables. We have studied 747 subjects to date. After exclusion, 456 subjects, 209 men and 247 women remained for the current analysis. There was a significant, almost linear increase in OPG levels with age; for women from 3.17±1.31 pmol/l in the youngest age group to 5.55±1.66 pmol/l in the oldest age group, and for men from 2.95±0.99 pmol/l in the youngest age group to 5.46±1.22 pmol/l in the oldest age group ($P<0.001$). For women, OPG showed an inverse correlation with BMD (r=-0.4, $P<0.001$) and oestradiol (r=-0.5, $P<0.001$), both of which decreased significantly with age. OPG showed positive correlation with age (r=0.5, $P<0.001$), tartrate resistant acid phsophatase (r=0.3, P=0.003), collagen crosslaps (r=0.35, $P<0.001$), alkaline phosphatase (r=0.32, $P<0.001$), ionised calcium (r=0.28, $P<0.001$), osteocalcin (r=0.36, $P<0.001$), and whole PTH (r=0.2, P=0.001). For men, the correlation between OPG and BMD was weaker than for women (r=-019, $P<0.007$) but also showed a positive correlation with age (r=0.6, $P<0.001$), sex-hormone binding globulin (r=0.38, P=0.001), alkaline phosphatase (r=0.37, $P<0.001$), and whole PTH (r=0.17, P=0.01). We conclude that OPG increases with age and correlates well with markers of bone resorption/turnover. While OPG levels are similar in men and women, the relationship between OPG and BMD is different between the sexes suggesting there may be gender related differences in the role it plays in bone metabolism. With more enrollment, allowing for multivariable analysis, we should be able to better to elucidate this role

M007

Skeletal Development and Calcium Requirements Are the Determinants of Serum PTH Level During Growth. N. E. Badenhop-Stevens*[1], J. D. Landoll*[1], L. A. Nagode*[2], S. L. Mobley*[1], E. Ha*[1], P. Goel*[3], B. Li*[3]. [1]Bone and Mineral Metabolism Laboratory, The Ohio State University, Columbus, OH, USA, [2]Veterinary Pathobiology, The Ohio State University, Columbus, OH, USA, [3]Statistics, The Ohio State University, Columbus, OH, USA.

The relationship between serum PTH and skeletal development has been examined in a cohort of young females, participants of a clinical trial with calcium (Ca) supplementation from childhood to young adulthood. 179 healthy Caucasian young females, age 10.8±0.8 y, in pubertal stage 2 and with Ca intake below threshold level (1480 mg/d) at baseline completed a 7-year long double-blind, placebo-controlled clinical trial (CT) with Ca citrate malate supplementation (Procter & Gamble Co.) of 1000 mg Ca/d. Anthropometry, bone mass measurements of the forearm & whole body by DXA (GE Lunar, DPX-L), nutritional and activity records were obtained every 6 months (m), while blood samples for Ca, PTH, and bone biomarkers were collected every 12 m. Hand X-rays for bone age and radiogrammetry were obtained at ages 11, 15, and 18 y. Serum intact PTH was measured by Nichols kits. Serum was stored in a freezer on -80oC and stability of the PTH was checked by repeated assay on the subsample (n=10) in 1994 and 2000, revealing agreement of 99.1%. Serum PTH levels among the control individuals accustomed to calcium intake of ~850 mg/day/7 years were much higher during the peak skeletal modeling phase of early puberty (~28 pg/ml) with the decline during skeletal consolidation phase (~24 pg/ml) as evidenced by the stabilization of the periosteal envelope of the metacarpal bones by age 15 and with minimal but continuous endosteal apposition of cortical bone by age ~18 y. The PTH values were much lower among the Ca supplemented individuals, however, the trend for the decline with growth was present in them as well. The results of this research indicate the presence of a "hungry bone" syndrome during rapid skeletal expansion when calcium requirements for skeletal development have not been met.As the bone consolidation phase proceeds, calcium requirement declines with concomitant decrease in serum PTH, presumably as a result of the increase in serum ionized Ca. The results of this research may have implications with regard to monitoring the adequacy of Ca nutrition during growth.

M008

Timing of Peak Bone Mass at Various Skeletal Regions of Interest in Young Females: Results of a Seven-Year Follow-up Study. J. D. Landoll*[1], N. E. Badenhop-Stevens*[1], P. Goel*[2], E. Ha*[1], S. L. Mobley*[1], B. Li*[2], V. Matkovic[1]. [1]Bone and Mineral Metabolism Laboratory, The Ohio State University, Columbus, OH, USA, [2]Statistics, The Ohio State University, Columbus, OH, USA.

Timing of peak bone mass at various skeletal regions of interest including the total body has been evaluated in a cohort (n=100) of healthy Caucasian females, participants of a clinical trial with Ca supplementation during growth. The data reported here are only for the control individuals who did not receive extra Ca supplementation and who maintained their baseline Ca intake of about 850 mg/d throughout the seven years of follow-up. Anthropometry and bone mass measurements of the whole body, proximal and distal forearm were done every 6 months from age 11 up to 18 years. Hip and spine measurements were done from age 15 to 18 and radiogrammetry measurements of the metacarpals were done at age 11, 15, and 18 years. Lunar DPX-L was used for bone mass measurements and Pronosco X-posure system was used to evaluate the geometry of the metacarpal bones. Young females reached a plateau in stature by about age 16 y. Periosteal bone expansion has been changing rapidly from age 11 up to 15 years (about 10%) with minimal but continuous apposition thereafter. Most of the bone mass at the other sites have been accumulating by the age of ~16 with continuous accretion at a slower rate thereafter. Bone mineral areal density measurements of the spine (from the whole body scan), femoral neck and trochanter reached a peak by the average age of 17 with a declining trend thereafter. The above results are in agreement with our previously reported cross-sectional data (JCI 93:799-808, 1994) and indicate that timing of peak bone mass is site specific. Understanding the reasons for the early decline in bone mineral density at the hip after reaching its peak may be quite important with regards to primary prevention of hip fractures. Further follow-up of the bone mass in the same cohort seems to be necessary to confirm the observed trends and to understand appropriately bone behavior with age.

M009

Randomized Trial of Physical Activity and Calcium Supplementationon BMC in 3-5 Year Old Healthy Children: The South Dakota Children's Health Study. B. Specker, T. Binkley*, J. Wermers*. EA Martin Program in Human Nutrition, South Dakota State University, Brookings, SD, USA.

Meta-analysis of adult exercise studies and an infant activity trial demonstrate a possible interaction between weight-bearing activity and calcium (Ca) intake. There are no reported studies specifically designed to test whether Ca intake modifies the bone response to activity. This randomized, placebo-controlled, 1-year trial of activity and Ca supplementation was conducted in 239 children aged 3 to 5 years. Children were randomly assigned to participate in either gross motor (GM) or fine motor (FM) activities for 30 min/d, 5d/wk for 12 mo. Within each activity group children were further randomized to receive either Ca (CA; Ca carbonate 1000 mg/d) or placebo (PLAC). Activity programs & supplements were administered and compliance recorded daily by study personnel at childcare centers. Total body BMC using DXA and measurements of the 20% distal tibia using pQCT were obtained at baseline & study completion. 3-d diet records & motion sensor readings were obtained at 0, 6 & 12 months. 178 children completed >38 wk of intervention and were present at the center >50%. Percent time in moderate + vigorous activity were similar at baseline, but higher in GM vs. FM at 6 & 12 mo (both, p=0.01). Total Ca intake was greater in CA vs. PLAC (1354±301 vs. 940±258 mg/d, $p<0.001$). Anthropometric and bone results were similar at baseline. Height increase was less in CA vs. PLAC (6.9±0.2 vs. 7.4±0.2 cm), but was not correlated with compliance within CA group and was not significant when total Ca quartiles were used. The main effects of activity & Ca were not significant for TB BMC or leg BMC. There was an interaction between activity & Ca on leg BMC (p=0.05). The difference in leg BMC gain between GM and FM was more pronounced in children receiving the CA vs. PLAC: among PLAC children there was a similar leg BMC gain in GM vs. FM, but among CA children those in GM had 9.7% greater increase in leg BMC than FM. A similar interaction was observed with activity & Ca quartiles. At study completion, children in GM group had greater periosteal and endosteal circumferences compared to FM ($p<0.05$). There were no differences in cortical thickness & area between PLAC and CA among FM children, but cortical thickness & area were lower in PLAC vs. CA among GM children (interaction, both $p<0.02$). In summary, Ca modifies the bone response to physical activity in young children such that high activity levels in the presence of low Ca may be detrimental to bone.

M010

Collagen-Phosphophoryn Sponge as a Scaffold for Bone Tissue Engineering. D. Iejima[1], T. Saito*[2], T. Uemura*[3], T. Tateishi*[4]. [1]AIST(National Institute of Advanced Industrial Science and Technology), TERC(Tissue Engineering Research Center), Tsukuba, Ibaraki, Japan, [2]Health Science Univ. Hokaido, Hokkaido, Japan, [3]TERC, AIST, Tsukuba, Ibaraki, Japan, [4]Univ. Tokyo, Tokyo, Japan.

Non-collagenous phosphoproteins that interact with type I collagen are thought to nucleate bone mineral into collagen network of mineralized tissues. Previously phosphophoryn cross-linked to collagen type I was reported to be an effective nucleator of apatite (Saito et al. Bone 21, 305 (1997); Saito et al. J.Bone Miner. Res. 13, 265 (1998)). On the other hand, free phosphophoryn molecules inhibit the apatite formation in vitro. On the basis of the above study, we expected that the collagen-phosphophoryn sponge could work as a good scaffold for bone tissue engineering and examined the in vivo bone formation in orthotopically transplanted collagen-phosphophoryn sponge and bone marrow osteoblasts composite in Fisher rats (bone defect model). Osteoblastic primary cells were obtained from the bone shaft of femorae of Fischer 344 male 7-weeks-old rats, according to the method of Maniatopoulos et al. The cell suspension of marrow cells was distributed through a T-75 flask with 15 ml of standard culture medium and incubated at 37oC in a humidified atmosphere containing 95% air and 5% CO2. When culture dishes become near confluent, after 10 days, they were treated with 0.1% trypsin and then concentrated by centrifuge to 106 cells/ml and subcultured onto the synthesized collagen-phosphophoryn sponge and collagen sponge(control). After 14 days culture with standard medium supplemented with 10nM dexamethasone, 10mM b-glycerophosphate, 50mg/ml ascorbic acid, the composites of collagen-phosphophoryn and osteoblastic cells and control composites were transplanted into bone defect sites with 2mm diameter hole of Fischer rats and then the wounds were sutured. The composites were harvested at 1,2,6,8 weeks after implantation, fixed with 4% paraformaldehide and 0.25% glutaraldehyde, decalcified, embedded in paraffin, and stained with hematoxirin and eosin. Results clearly showed that more bone formation was observed in collagen-phosphophoryn sponge and osteoblasts composites than control composites from 1 week to 8 weeks, suggesting that the collagen-phosphophoryn sponge is a good candidate as a scaffold for bone tissue engineering.

M011

BMP-2 Regulation of Calcification is Modulated by Substrate Microtopography. D. D. Dean[1], B. D. Boyan[1], L. F. Bonewald[2], E. P. Paschalis[3], C. H. Lohmann[4], J. Rosser*[2], D. L. Cochran*[5], Z. Schwartz[1], A. L. Boskey[3]. [1]Orthopaedics, The University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, [2]Oral Biology, University of Missouri, Kansas City, MO, USA, [3]Hospital for Special Surgery, New York City, NY, USA, [4]Orthopaedics, University of Hamburg-Eppendorf, Hamburg, Germany, [5]Periodontics, The University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Osteoblast physiology in monolayer culture is substrate-dependent; adhesion, differentiation and response to osteogenic agents are enhanced on titanium (Ti) surfaces with a micro-rough topography, while attachment and proliferation are decreased. Here, we tested the hypothesis that substrate microtopography modulates osteoblast physiology in multilayer cultures, and this is regulated by BMP-2 and dexamethasone (dex) in a surface-dependent manner. Fetal rat calvarial (FRC) cells were cultured on three Ti surfaces (PT, R_a=0.6 μm; SLA, R_a=4.0 μm; TPS, R_a=5.2 μm) and treated with rhBMP-2 or dex. At 14 d post-confluence, culture morphology was similar on all surfaces, including multi-layer nodule formation. Cell number decreased with increasing roughness in control and treated cultures, whereas cell layer alkaline phosphatase specific activity increased. BMP-2 caused a further increase in enzyme activity on all surfaces; dex increased activity on SLA and TPS. Von Kossa-positive nodule number and area were affected. Ca and P content in control cultures did not vary with surface roughness; BMP-2 and dex increased Ca on all surfaces; the greatest increase due to BMP-2 was on PT. Dex increased P on rough surfaces, while BMP-2 increased P on all surfaces. A 2:1 Ca/P weight ratio typical of biologic apatite was seen only in BMP-2-treated cultures on rough Ti, corresponding to FTIR imaging showing mineral associated with matrix. All other cultures exhibited dystrophic calcification. This shows that formation of apatite by FRC cells is regulated by both BMP-2 and substrate microtopography. Surface roughness enhanced physiological calcification and worked synergistically with BMP-2. These data suggest that during osteointegration, the implant surface modulates cell attachment, proliferation, differentiation and matrix calcification and that optimal surfaces can be designed for use clinically.

The Plasma Protein Fetuin/a2HS-glycoprotein Is a Physiologic Regulator of Bone Mineralization. P. Catala-Lehnen[1], C. Schäfer*[2], C. Mueldner*[1], M. Amling[1], J. Rueger*[1], W. Jahnen-Dechent*[2], T. Schinke[1]. [1]Trauma Surgery, University Hamburg, Hamburg, Germany, [2]IZKF Biomat, University Hospital Aachen, Aachen, Germany.

The plasma protein fetuin/a2HS-glycoprotein (hereafter refered to as Ahsg) is a major component of the bone extracellular matrix, although it is not expressed by osteoblasts. Ahsg inhibits apatite formation in vitro, and some Ahsg-deficient mice display ectopic calcification of soft tissues. These observations prompted us to ask the question whether Ahsg has an influence on bone mineralization. Therefore we analyzed Ahsg-deficient mice on a C57Bl/6 genetic background compared to their wildtype littermates (n=8 at the age of 4 months). Histomorphometric analysis revealed that Ahsg-deficient bones were indistinguishable from wildtype controls in terms of bone volume as well as osteoblast and osteoclast numbers. Despite the absence of a bone remodeling phenotype we found that Ahsg-deficient bones had improved biomechanical properties in a three-point bending assay (Force to failure was 20.44 +/- 5.03 in Ahsg-/- mice vs. 13.28 +/- 2.16 in wildtype controls, $p<0.001$). This is most likely explained by the fact that Ahsg-deficient bones have an increased bone mineral content (Ash weight as a percentage of dry weight was 59.7 +/- 4.7 vs. 53 +/- 2.76, $p<0.01$) which is consistent with the function of Ahsg as a systemic inhibitor of mineralization. We also found that the calcium to phosphate ratio in the ash of Ahsg-deficent bones was increased compared to wildtype controls (1.72 +/- 0.05 vs. 1.64 +/- 0.03, $p=0.07$) showing that Ahsg has an influence on bone mineral composition. Taken together, these data demonstrate for the first time that Ahsg is a physiologic regulator of bone mineralization. It is therefore the first non-hormonal plasma protein that has a major influence on bone strength. Our data also demonstrate that the biomechanical properties of bone are not solely dependent on bone volume or cortical thickness, but also on the composition of the mineral phase.

M013

Calcium Homeostasis: A Suggested Role for Bone Surface Proteins. R. V. Talmage*[1], G. E. Lester*[2], H. T. Mobley*[3], J. L. Matthews*[4]. [1]Orthopaedics, University of North Carolina, Chapel Hill, NC, USA, [2]National Institutes of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD, USA, [3]Biology, Kilgore College, Longview, TX, USA, [4]Baylor Medical Center, Dallas, TX, USA.

The purpose of this report is to ascribe to bone surface proteins a role in the maintenance of plasma calcium concentration. Presently, the functions of these proteins have been related primarily to bone formation though they also abound in mature bone. The unresolved aspects of plasma calcium control are the processes by which calcium is returned from bone to plasma in quantities sufficient to match that lost to bone surfaces by the established calcium gradient from ECF to bone mineral. Such processes must exist both in the presence and absence of parathyroid hormone (PTH). Recently a new hypothesis has been reported (J. Musculoskel. Neuronal. Interact. 1:121,2000) to explain this calcium movement. The hypothesis suggested the involvement of bone surface proteins as an intermediary step between bone mineral and the ionic calcium of the ECF. In this report, this potential step is studied further. A variety of non-collagenous proteins are found on the surfaces of bone mineral. One of these, osteocalcin, has been described by numerous investigators such as Hauschka. In "The Chemistry and Biology of Mineralized Tissues" (W.T. Butler, Ed, Ebsco Media Inc., Birmingham, Ala. 1985, pp. 149-158), he describes the ability of this protein to fit into the lattice work of hydroxyapatite. Based on this report, it is hypothesized that this and other proteins are able to transfer calcium directly from bone mineral onto the proteins. Subsequently, calcium complexed to these proteins equilibrates with the ionic calcium of the ECF bathing the bone surfaces. The net result is to transfer calcium from bone mineral to the ECF against a calcium gradient moving this ion the opposite direction. The control of plasma calcium levels can then be described as occurring in three continuous and competing steps. (1) The movement of calcium from ECF to bone mineral: (2) The continuous transfer of calcium from bone mineral to surface proteins: and (3) The continuous equilibration between calcium attached to these proteins and the ionic calcium in the ECF. This third step sets the ionic calcium concentration in the ECF. The bulk of this process is not PTH dependent. However, it is suggested that PTH sets a precise calcium concentration by its action on osteocytes and lining cells to determine the amount of calcium complexed to bone surface proteins that is available for equilibration with the ionic calcium of the surrounding ECF.

Association of Serum Osteoprotegerin Levels With the Severity of Coronary Artery Calcification. S. Jono*[1], Y. Ikari*[2], K. Hara*[2], A. Shioi[3], Y. Nishizawa[1]. [1]Department of Metabolism, Endocrinology and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan, [2]Division of Cardiology, Mitui Memorial Hospital, Tokyo, Japan, [3]Department of Cardiovascular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan.

Osteoprotegerin (OPG), a member of the tumor necrosis factor receptor family, has been identified as a regulator of bone resorption. It has been demonstrated that OPG is produced by a variety of tissues including the cardiovascular system as well as bone. OPG-deficient mice develop severe osteoporosis and medial arterial calcification of the aorta and renal arteries. OPG immunoreactivity was demonstrated in the normal blood vessels and in early atherosclerotic lesions. A recent clinical study suggests that there is a significant correlation between elevated serum OPG levels and cardiovascular mortality. It has been demonstrated that coronary artery calcium area correlates with histological coronary atherosclerotic plaque area. We examined whether serum OPG levels are associated with the severity of coronary artery calcification (CAC). This study involved 176 patients who underwent coronary angiography. The study group included 149 men and 27 women, with average age of 63 years. Coronary artery calcification was assessed by radiopacities within the vascular wall on coronary angiography and was classified as ND (not detected calcification), mild (focal radiopacities noted only during the cardiac cycle before contrast injection), moderate (diffuse radiopacities noted only during the cardiac cycle before contrast injection or focal radiopacities noted without cardiac motion), and severe (radiopacities noted only during the cardiac motion before contrast injection generally compromising both sides of the arterial lumen). Serum OPG levels were measured with enzyme-linked immunosorbent assay. Serum OPG levels are positively correlated with age, but other coronary risk factors showed no significant associations with serum OPG levels including male sex, hypertension, diabetes, hyperlipidemia and current smoking. Serum OPG levels were significantly greater in patients with CAC than in those without CAC. Moreover, as the severity of CAC increased, there was a significant increase in serum OPG levels. A similar association between serum OPG levels and the severity of coronary artery disease was found. Multivariate logistic regression analysis revealed that serum OPG levels were significantly associated with the presence of CAC. These data suggest that OPG may be involved in the progression of CAC, and that serum OPG may reflect certain stages of coronary artery calcification.

Overexpression of VEGF induces Bone Formation in the Cultured Bone Transplantation Model. T. Uemura[1], H. Kojima*[2], K. Matsumoto*[2], P. Wang*[3]. [1]TERC(Tissue Engineering Research Center), AIST (National Institute of Advanced Industrial Science and Technology), Tsukuba, Ibaraki, Japan, [2]Terc, AIST, Tsukuba, Ibaraki, Japan, [3]Univ. Tsukuba, Tsukuba, Ibaraki, Japan.

Angiogenesis is quite important for bone tissue regeneration, because formed blood vessels in bone supply oxygen and nutrients to osteoblasts to be differentiated to form new bone. In particular, cultured bone implantation using porous ceramics scaffolds, a kind of bone tissue engineering, needs enough blood vessel formations into central porous area, maintaining osteoblast activities. This is the first report successfully inducing bone formation and showing our application of adenoviral vector carrying angiogenic factor VEGF (vascular endothelial growth factor) for activating osteoblasts to transduce MSC (messenchymal stem cells) in a cultured bone transplantation model. For this purpose, we constructed the recombinant adenoviral vector carrying VEGF cDNA (Adv-VEGF) and confirmed that it worked well by analyzing the proliferation of Adv-VEGF infected HUVEC cells. Then the Adv-VEGF infected MSC / porous ceramic scaffold composite was implanted into subcutaneous sites and orthotropic sites of Fischer rats. In the rat bone defect model, much blood formation were observed at 10 days postimplantation. At three weeks postimplantation, more bone formation was observed in the Adv-VEGF infected group. At five weeks postimplantation, in addition to the induction of bone formation by virus infection, TRAP positive osteoclasts and invasion of bone marrow tissues were observed in the transplanted ceramics showing the remodeling of implanted ceramics. Overexpression of VEGF proved to be effective in inducing bone formation with remodeling in a cultured bone transplantation model.

S12911 Maintains Normal Matrix Mineralization Induced by Murine Calvaria Osteoblasts in vitro. A. Barbara*[1], P. Delannoy*[1], B. Robin*[2], P. J. Marie[1]. [1]INSERM U349, Paris, France, [2]Laboratoires SERVIER, Courbevoie, France.

There is growing evidence that S12911 administration increases bone mass and bone strength in normal and osteopenic animals as well as in humans. We previously reported that S12911, a compound containing two atoms of stable strontium, increases vertebral bone mass in rats by inhibiting bone resorption and stimulating bone formation without altering bone mineralization. We also showed that short term treatment with S12911 enhances osteoblastic cell recruitment and function in rat calvaria cultures. In order to ensure that S12911 does not alter matrix mineralization in long term culture, we analyzed the long term effects of S12911 on matrix mineralization using MC-3T3-E1 calvaria osteoblasts, a murine in vitro model of osteogenesis. Confluent MC-3T3-E1 cells were cultured for up to 14 days in the presence of ascorbic acid (25 µg/ml) and phosphate (3 mM) to induce matrix formation and osteogenesis. Matrix formation was determined by collagen synthesis measured by tritiated proline incorporation into the synthesized matrix. Matrix mineralization was quantified by measuring the number and surface of mineralized nodules using a digital image analyzer. Osteoblast function was determined by alkaline phosphatase (ALP) activity measured biochemically. Treatment with S12911 (1 mM) increased ALP on days 4 and 14 of culture. In this model, treatment with 1,25 (OH)2 vitamin D (1 nM) increased ALP activity on day 4, 8, 10, 12 and 14 of culture. Treatment with S12911 (1 mM) increased collagen synthesis on day 4, 8 and 10 of culture. In contrast, treatment with 1,25 (OH)2 vitamin D (1 nM) inhibited collagen synthesis at 4-14 days of culture. Long term treatment with S12911 (0.1-1 mM) did not alter matrix mineralization, as shown by the ratio of the surface of mineralized nodules to the number of mineralized nodules on day 14 of culture. Thus, long term treatment with S12911 modulates collagen synthesis and ALP activity in MC-3T3-E1 osteoblasts and does not alter matrix mineralization in this model, confirming that S12911 maintains normal bone matrix mineralization, as found in normal and osteopenic animals.

Human Aortic Valve Calcification is Accompanied by a Transition to an Osteoblast Phenotype. N. M. Rajamannan*[1], M. Subramanium*[2], D. Rickard*[2], S. Stock*[3], J. L. Donovan*[2], D. Fullerton*[3], T. Orszulak*[2], A. J. Tajik*[2], R. Bonow*[3], T. Spelsberg*[2]. [1]Cardiology, Northwestern University, Chicago, IL, USA, [2]Mayo Clinic, Rochester, MN, USA, [3]Northwestern University, Chicago, IL, USA.

Calcific aortic stenosis is the third most common cardiovascular disease in the USA. Despite the increasing prevalence the mechanism is poorly understood. We hypothesized that the mechanism for aortic valve calcification is similar to skeletal bone formation and that this process is mediated by osteoblast-like cells. To test this hypothesis we examined calcified human aortic valves replaced at surgery (N=22) and normal human valves removed at cardiac transplantation and sudden cardiac death (N=20). Electron microscopy and x-ray dispersive analysis were performed for ultrastructural analysis of the valves. MicroCT was performed to determine the 3 dimensional extent of mineralization. Immunohistochemistry was used to localize osteopontin protein. VonKossa, Goldner's stain and microradiography was performed to localize mineralization fronts. To analyze osteoblast and bone matrix markers, mRNA was isolated from calcified vs normal valves and RT-PCR was performed for a variety of osteoblast specific genes. The distribution of hydroxyapatite coincided with that of calcium as detected by a radiodense pattern using contact microradiography. Energy-dispersive electron microscopy analysis showed that the chemical composition of the calcified valve tissue was hydroxyapatite ($Ca_{10}(P0_4)_6(OH)_2$) interspersed in among the bundles of collagen, the major inorganic component of bone. Mirco-CT analysis identified the distribution of mineralization in the diseased areas. Osteopontin was present in the areas of mineralization by immunogold labeling and immunohistochemistry. RT-PCR of the mRNA from the calcified valves revealed increased levels of mRNA coding for osteopontin, bone sialoprotein, osteocalcin and osteoblast specific transcription factor Cbfa1. These markers indicate the presence of cells with an osteoblast-like phenotype involved in a calcification process analogous to bone formation. These markers were diminished in the normal valves. These findings support the concept that aortic valve calcification is not a random passive, degenerative process, but an active regulated process involving either a transformation of the human aortic valve fibroblast cell to an osteoblast-like phenotype or the recruitment of osteoblast precursor cells in the inflammed area.

Characterization of Mineralized, Honeycombed Sheets Made by MLO-A5 Cells and Comparison with Mineralized Nodules Made by Primary Osteoblasts. C. Barragan-Adjemian*[1], D. Eick*[1], V. Dusevich*[1], M. Dallas*[1], D. Nicolella*[2], L. F. Bonewald[1]. [1]Oral Biology, University of Missouri Kansas City, Kansas City, MO, USA, [2]Southwest Research Institute, San Antonio, TX, USA.

The differentiation and mineralization process of primary osteoblasts and several osteoblast cell lines has been thoroughly characterized. In these cells, proliferation is followed by matrix formation, then mineralization. Expression of various transcription factors and matrix proteins occurs over a 2-3 week time period that includes increases in collagen type 1 production, alkaline phosphatase during the matrix production state and osteocalcin increases with mineralization. Mineralization occurs within multi-layered cells known as nodules that are separated in culture by a non-characterized lawn of cells. The MLO-A5 cell line produces 70 times more osteocalcin than early primary osteoblasts, but similar amounts to mature, mineralizing osteoblasts. MLO-A5 cells mineralize in sheets, not nodules within 3-6 days. The Fourier Transformed Infrared spectroscopy of these *in vitro* cultures is very similar to spectra of rat calvaria. This cell line may represent a particular state in osteoblast differentiation, that of the mineralizing post-osteoblast, pre-osteocyte. These cultures were analyzed using Field Emission, Environmental Scanning Electron Microscopy, in dry mode, to yield secondary images of the culture topography. Honey-combed structures, reminiscent of newly forming trabecular bone, were revealed by using detection of backscattered electrons, a means of identifying mineralized from non-mineralized structures. The location and relative amount of calcium in these structures from 0 to 12 days was identified using Energy Dispersive X-ray Analysis. Cellular processes could be observed curving along the honeycomb structures, suggesting that the cell processes may direct formation of these structures. In non-mineralized areas, at very high magnification (150,000x), collagen bundles and fibers with potential nucleation sites were observed. Using atomic force microscopy to characterize these areas, un-mineralized collagen fibrils exhibiting the characteristic 69 nm banding were observed with clusters of mineral forming at specific locations along the fibrils. Studies are being performed to determine if fluid flow shear stress will modify these structures. These cells are proving to be a useful model to investigate the mechanisms of mineralization.

Bone Origin of the Serum Complex of Calcium, Phosphate, Fetuin, and Matrix Gla Protein: Biochemical Evidence for the Cancellous Bone Remodeling Compartment. P. A. Price, J. M. Caputo*, M. K. Williamson. Division of Biology, University of California, San Diego, La Jolla, CA, USA.

We previously described the discovery of a fetuin-MGP-mineral complex in the serum of rats treated with the bone active bisphosphonate etidronate, and showed that the appearance of this complex in serum correlates with the inhibition of bone mineralization by etidronate (JBC (2002)277:3926). The composition of this high molecular weight protein-mineral complex consists of about 18% mineral, 80% fetuin, and 2% matrix Gla protein (MGP) by weight, and the presence of the complex in serum 6h after an injection of 8mg etidronate/100g body weight elevates calcium by 1.8 fold (to 4.3mM), phosphate by 1.6 fold (to 5.6 mM), and MGP by 25 fold (to 12 µg/ml). In the present study we show that the inhibition of bone resorption by treatment with the hormone calcitonin, the cytokine osteoprotegerin, or the drug alendronate, completely inhibits the generation of the fetuin mineral complex in response to etidronate injection. These observations can best be explained by the bone remodeling compartment (BRC), a recently described cancellous bone compartment in which the concentrations of calcium and phosphate are determined directly by the combined actions of the osteoclast and the osteoblast (JBMR (2001)16:1575). When bone mineralization is acutely inhibited by etidronate, the BRC model predicts that the continuing action of osteoclasts will cause a sharp rise in the concentrations of calcium and phosphate in the aqueous solution of the BRC with the consequent spontaneous formation of calcium phosphate crystal nuclei whose growth could then be arrested by formation of a complex with fetuin. This possibility is supported by the observation that a similar fetuin-mineral complex indeed forms when calcium and phosphate are added to rat serum in vitro. When the inhibition of bone resorption by calcitonin, osteoprotegerin, or alendronate is combined with the acute inhibition of bone mineralization with etidronate, the BRC model correctly predicts that there will no longer be a sharp rise in calcium and phosphate, and therefore no longer be the formation of the fetuin mineral complex. There is evidence that the bone remodeling compartment is also a vascular compartment (JBMR (2001)16:1583), evidence which includes the presence of red blood cells within the compartment and the close association of the compartment with blood vessels. This vascular feature of the BRC could provide an explanation for the observations that the fetuin component of the fetuin-mineral complex is derived from plasma fetuin, and that the fetuin mineral complex appears in plasma within minutes of the inhibition of bone mineralization with etidronate.

M020

Gender – Specific Skeletal vs. Vascular Osteogenic Gene Regulatory Responses in LDL Receptor - Deficient Mice. J. S. Shao*, M. Bidder, A. P. Loewy*, C. Camillo*, M. Moon*, K. T. Bae*, C. F. Semenkovich*, D. A. Towler. Washington University, St. Louis, MO, USA.

Obesity is associated with higher bone mass; however, obesity is also a risk factor for type II diabetes, characterized by increased incidence of arterial calcific vasculopathy. Preliminary analyses of dystrophic human aortic valve specimens indicate that levels of osteopontin (OPN) and Msx2 mRNA track the extent of valve calcification. We identified the elaboration of this early osteogenic gene regulatory program in the calcifying aortas of LDL receptor (LDLR) deficient mice fed diets that induce diabetes with hypercholesterolemia. We wished to characterize effects of this diet -induced dysmetabolic state on orthotopic and heterotopic osteogenic gene regulatory programs, and potential interactions with responses to osteoanabolic agents such as PTH. Therefore 12 week old LDLR -/- mice (weight and gender matched) were fed mouse chow (less than 10 % calories as fat) or Harland Teklad TD 88137 (42% of calories as fat) for 6 weeks. Bone mineral content (BMC) quantified by DXA revealed higher baseline BMC values in males than in females ($p = 0.006$). High fat diets increased BMC in female (389 +/- 67 mg to 450 +/- 54 mg; $p = 0.06$), but not in male (463 + /- 25 mg vs. 450 + /- 27 mg) mice during this treatment period. By contrast, body fat was significantly increased only in male mice (13.0 +/- 1.4% vs. 20.3 +/- 1.3 %; $p = 0.04$). Real-time fluorescence RT-PCR was used to quantify osteogenic gene expression in total RNA isolated from single aortas and hindlimbs (n= 3 to 6 animals per treatment). In aorta, 2.7- fold increases in levels of Msx2 and Runx2 gene expression were observed, but only in male animals; osterix (Osx) was not induced (suppressed). This was associated with marked upregulation of aortic osteopontin (OPN) expression, but only in male animals. Conversely, in bone, Runx2 expression was induced 5-fold by high fat diets, but only in female animals; Osx mRNA increased ca. 2-fold in female bones, and Msx2 was unchanged. We next addressed whether PTH contributed to the regulation of osteogenic gene expression at orthotopic and heterotopic sites in male mice (exhibited robust vascular responses to diet). In 4 weeks, PTH (0.4 mpk s.c. daily) augmented BMC 23% in male LDLR -/- mice fed high fat diets (478 +/- 59 mg vs. 590 +/- 52 mg; $p = 0.01$). While PTH upregulated orthopic expression of Msx2 and OPN in the hindlimbs of male animals, it concomitantly suppressed aortic OPN and Msx2 mRNAs by > 50% ($p < 0.05$). Increases in body fat were not altered by PTH treatment, but glucose levels were lower. These data suggest that gender - specific metabolic signaling cascades differentially control osteogenic gene regulatory responses during orthotopic and heterotopic mineralization.

Neurotensin and Sortilin/Neurotensin Receptor-3 Promote Extra-Cellular Matrix Mineralization During Osteoblastic Differentiation of Mesenchymal Stem Cells. S. Maeda[1], T. Nobukuni*[2], K. Shimo-Onoda*[1], K. Hayashi*[1], K. Yone*[1], S. Komiya*[1], I. Inoue*[2]. [1]Department of Orthopedic Surgery, Faculty of Medicine, Kagoshima University, Kagoshima, Japan, [2]Division of Genetic Diagnosis, Institute for Medical Science, University of Tokyo, Tokyo, Japan.

Our aim was to understand the mechanisms which divide the fate of human mesenchymal stem cells (hMSCs) to osteoblasts or adipocytes, because it has been shown that bone volume loss associated with osteoporosis and aging is accompanied by a reduced osteoblastic bone formation and an increase in marrow adipose tissue. We compared gene expression profiles of hMSCs between osteoblastic and adipocytic differentiation 24 hours after stimulation using cDNA microarray to detect osteoblastic-specific up-regulated genes. The long-term, day 0 to 11 of differentiation induction, expression patterns of the screened genes were evaluated by quantitative real-time RT-PCR. The 10 genes were up-regulated during osteoblastic commitment, which included sortilin / neurotensin receptor-3. The over-expression of Sortilin using adenovirus vector in hMSCs resulted in acceleration of matrix mineralization during osteogenic differentiation. We tested the effect of lipoprotein lipase (LPL) on osteoblastic differentiation, because LPL had been reported to bind with sortilin and degraded from circulation in vitro. LPL inhibited osteoblastic mineralization in dose dependent manner. Interestingly, this LPL-mediated suppression of matrix calcification was rescued by sortilin-adenoviruses. Sortilin nor LPL had no impact on alkaline phosphatase(ALP) activity. These results and the evidence that LPL is bound on heparan-sulfate ptoteoglycans on the cell surface suggest that LPL has no effect on ostaoblastic differentiation itself of hMSCs but interfere mineralization of extra-cellular matrix by binding on proteoglycans. Sortilin may support mineralization by degrading LPL. Finally, the sortilin ligand neurotensin was tested for its ability to affect osteoblastic differentiation. Neurotensin RNA was up-regulated during early osteoblastic differentiation. Neurotensin promoted osteogenic mineralization, while showed little impact on ALP activity. Moreover, sortilin-adenoviruses enhanced the effect of neurotensin. Our results suggest that neuropeptide neurotensin and receptor sortilin do not affect osteoblast differentiation but may promote bone matrix calcification. Further studies including measuring bone volume of neurotensin knock-out mice or mice centrally injected with the peptide may clarify our hypothesis.

M022

Chondrocyte Differentiation Is Mediated by Inhibition of Cyclin-dependent Kinase 6 Expression as a Downstream Effector of p38 MAPK Pathway. T. Moro[1], T. Ogasawara[1], T. Shimoaka[1], H. Chikuda[1], S. Kamekura*[1], K. Nakamura[1], H. Okayama*[2], H. Kawaguchi[1]. [1]Orthopaedic Surgery, University of Tokyo, Tokyo, Japan, [2]Molecular Biochemistry, University of Tokyo, Tokyo, Japan.

Because cell cycle arrest at the G1 phase is a prerequisite for cell differentiation, cell cycle molecules such as cyclins, cyclin-dependent kinases (CDKs) and CDK inhibitors (CKIs) may possibly regulate not only proliferation but also differentiation of cells. To elucidate the regulation of chondrocyte differentiation by cell cycle molecules, this study investigated the involvement of these molecules in the differentiation of cultured mouse chondrogenic cell line ATDC5 in the presence of insulin. Initially, we analyzed the regulation of cell cycle molecules that are known to affect the G1 phase: cyclin D1, D2, D3, E, CDK2, 4, 6, and CKIs (p18, p21 & p27) during differentiation by Western and Northern blottings. In all of them, both protein and mRNA levels of CDK6 were markedly decreased at 12-24 h of culture and thereafter, while those of other cell cycle molecules did not change throughout the culture period up to 48 h. The protein degradation of CDK6 was not involved in this down-regulation because MG132, a potent proteasome inhibitor, did not reverse the protein level. When inhibitors of p38 MAPK, ERK-1/2 and PI3K: SB203580, PD98059 and LY294002, respectively, were added to the culture, only SB203580 blocked the decrease in the CDK6 protein level, indicating that the CDK inhibition is mediated by p38 MAPK pathway. In fact, p38 MAPK was confirmed by Western blotting to be phosphorylated in advance of the inhibition of CDK6 during differentiation of ATDC5 cells. To further investigate the contribution of CDK6 to chondrocyte differentiation, we established several stable clones of ATDC5 cells transfected with *cdk6* cDNA, and compared the differentiation among the high expressing clones, low expressing clones, and parental cells. All differentiation parameters: type II and type X collagen mRNA levels, alcian blue, alizarin red and alkaline phosphatase stainings, were markedly suppressed in high expressing clones compared with those in low expressing clones and parental cells, indicating that CDK6 expression causes the inhibition of ATDC5 differentiation. However, since cell proliferation determined by BrdU uptake and distribution pattern in the cell cycle phase determined by FACS were not different among the three groups, the inhibitory effect of CDK6 on chondrocyte differentiation was shown to be independent of its effect on the proliferation. We therefore conclude that CDK6 is a key molecule determining the differentiation rate as a downstream effector of p38 MAPK pathway in chondrocytes.

M023

Adenovirus Vector-mediated Alk Gene Transduction To Synovial Cells Induces Chondrogenic Differentiation. H. Seto*[1], H. Hiraoka*[1], M. Fujii*[2], T. Imamura*[2], K. Miyazono*[3], H. Kurosawa*[4], H. Oda*[1], K. Nakamura[1], S. Tanaka[1]. [1]Department of Orthopaedic Surgery, The University of Tokyo, Tokyo, Japan, [2]Department of Biochemistry, The Cancer Institute of the Japanese Foundation for Cancer Research, Tokyo, Japan, [3]Department of Molecular Pathology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [4]Department of Orthopaedic Surgery, Juntendo University, Tokyo, Japan.

We previously reported that the expression of constitutively active forms of bone morphogenetic protein (BMP) type I receptors (BMPR-IA and IB; BMPR-I group) and those of activin receptor–like kinase (ALK)-1 and ALK-2 (ALK-1 group) induced osteoblastic differentiation in mouse myoblast cell line C2C12. Chondrogenic differentiation of ATDC5 cells was induced by the receptors of the BMPR-I group but not by those of the ALK-1 group. Synovium is a thin tissue, which lines the nonarticular surfaces of diarthrodial joints. There is evidence that synovium contains cells with chondrogenic potential, and it was previously reported that synovial cells demonstrated chondrogenesis when treated with TGFβ1. In the present study, we demonstrated that adenovirus vector-mediated ALK-3 or 6 gene expression induced chondrogenic differentiation of synovial fibroblasts. Synovial tissues were obtained from synovial tissues of the knee joints of adult Japanese white rabbits or RA patients at the time of total knee arthroplasty under written informed consents. Synovial cells were isolated from the tissues by enzymatic digestion. After 3-5 passages, subcultured synovial cells are mainly composed of synovial fibroblasts with fibroblastic morphology and free from T cell or macrophage markers. The cells were then infected with adenovirus vectors carrying LacZ (control), HA-tagged constitutively active forms of ALK-3, 5, or 6 genes for 2 hours. Chondrogenic phenotypes of the cells were examined by Northern blotting or RT-PCR of type II,X collagen and aggrecan genes as well as Alcian blue staining. Expression of type I receptors in synovial fibroblasts was confirmed by Westen blotting with anti-HA antibody. After 3 days of infection, dramatic induction of type II and aggrecan genes were observed in rabbit and human synovial cells infected with ALK-3 or 6 virus, while no chondrogenic phenotypes were observed in LacZ or ALK-5-infected cells. Type X collagen expression or calcification was not observed in any types of cultures. These results suggest that adenovirus vector-mediated ALK-3 or 6 gene expression can induce chondrogenic differentiation of synovial fibroblasts, and that they are promising candidates for developing novel cell-based therapeutic approaches for postnatal articular cartilage repair.

The Healing Capacity of Cartilage in vitro. J. P. Petersen[1], W. Dömeland*[1], A. Ruecker*[1], K. Baumbach*[1], P. Adamietz*[2], J. M. Rueger*[1], N. M. Meenen*[1]. [1]Dept. of Trauma Surgery, Hamburg University School of Medicine, Hamburg, Germany, [2]Inst. of Med. Biochemistry and Molecular Biology, Hamburg University School of Medicine, Hamburg, Germany.

The capacity for self-repair of traumatic cartilage injuries is very poor. Lesions do not heal and usually lead to painful arthritis. Although this problem is known for more than 250 years, there is still no sufficient therapy for cartilage repair. One option for correction of chondral defects could be transplantation of tissue engineered cartilage. In this therapeutical option, cartilage generated by autologous chondrocytes in vitro is transplanted into the defect. Although the such generated tissue is biochemically well defined, the healing capacity of this cartilage is still unknown. Therefore, the aim of this study was to investigate the healing capacity of the in vitro tissue engineered cartilage. Cartilage was harvested from the articular surface of adult mini-pig knees. After the cells were isolated and multiplied in monolayer culture, they were seeded in alginate where they form cartilage with its typical extracellular matrix. This tissue engineered cartilage was lesioned with a scalpel and cultivated in medium supplemented with fetal calf serum and growth factors for 21 days. The cartilage was then analysed by histology, immunhistochemistry and by polarization-microscopy to assess the potential for self-repair. Macroscopical and histological analysis showed that the primary cut had healed homogenously. Polarization microscopy revealed that new collagen fibers cross the former cut and show a morphology typical for hyaline cartilage. Immunhistochemical analysis showed that collagen type II is expressed uniformly in the unlesioned cartilage as well as in the dissected area. This study shows that tissue engineered cartilage has the capacity for self repair in vitro, and that this reparation process not only produces scar tissue containing the typical cartilage formation.

M025

The Orphan Receptor, Estrogen Receptor Related Receptor Alpha, ERRa, Is Expressed by Chondrocytes and Reduced in Arthritis. E. Bonnelye[1], V. Kung[2], J. E. Aubin[2]. [1]Department of Molecular and Cell Biology, Ecole Normale Superieure de Lyon, Lyon, France, [2]Department of Anatomy and Cell Biology, University of Toronto, Toronto, ON, Canada.

The orphan estrogen receptor related receptor alpha, ERRa, has been shown to be expressed by osteoblasts and play a functional role in bone formation in the 21 d. fetal rat calvaria (RC) cell model in vitro. We now report that ERRa is also expressed by proliferating chondrocytes and perichondrial precursors but not in hypertrophic chondrocytes in fetal rat growth plate cartilage in vivo. In adult animals, growth plate chondrocytes including those of the hypertrophic zone are also intensely labeled as are articular chondrocytes. To determine whether ERRa expression changes during the chondrocyte developmental sequence, we used a rat chondrocytic cell line, RCJ3.1C518 (C5.18). ERRa mRNA was found by semi-quantitative RT-PCR to be highly expressed at all proliferation/differentiation/maturational stages of chondrocyte development and cartilage nodule formation in vitro. ERRa protein is also expressed at all stages but is highest in maturing and mature chondrocytes associated with cartilage nodules. Notably, ERRa is co-expressed with ERa and ERb in at least some chondrocytes in cartilage nodules. Given these observations, we blocked ERRa in differentiating C5.18 cell cultures using phosphorothioate-modified antisense oligonucleotides. While sense oligonucleotides had a small dose-independent effect, antisense oligonucleotides caused a striking dose-dependent decrease in cartilage nodule formation, i.e., 40% decrease at 1mM and 60% at 2mM. Inhibition of ERRa had effects during both the proliferation and differentiation developmental time windows. Since ERRa is highly expressed in articular chondrocytes, we asked whether ERRa expression levels change in chondrocytes in animal models of arthritis. We used semi-quantitative RT-PCR to assess ERRa levels in samples from a rat and a mouse model of collagen-induced arthritis. Strikingly, no significant change was observed in ERRa expression between control versus arthritic bone samples, but ERRa levels were significantly reduced in arthritic cartilagenous joints. Our findings show that ERRa is highly expressed in chondrocytes where it is co-expressed with ERa and ERb. They also indicate a critical role for ERRa in cartilage formation and integrity. These data suggest that ERRa may serve as a useful diagnostic tool in arthritis and that therapies based on manipulation to increase ERRa levels may be useful in a joint regenerative process.

Regulation of Chondrogenic Differentiation of ATDC5 Cells: A Role for Estrogens? M. Karperien[1], M. Steenvoorden*[2], J. Hoogendam*[2], C. Lowik[1], B. van der Eerden[2], j. Wit*[2]. [1]Endocrinology, LUMC, Leiden, Netherlands, [2]Pediatrics, LUMC, Leiden, Netherlands.

Sex-steroids have profound effects on longitudinal bone growth. They can exert direct effects on growth plate chondrocytes, due to the presence of ERa and ß mRNA and protein. The mechanism of action by which these receptors regulate growth and differentiation of chondrocytes are largely elusive. One possibility is that they influence the activity of the growth restraining PTHrP/IHh-feedback loop which is operational in the prenatal and postnatal growth plate. Indeed, ovariectomy of 3-weeks-old rats reduced PTH/PTHrP-receptor mRNA expression compared to sham as assessed by RT-PCR analysis of tibial growth plate preparations. To study the interactions between sex-steroids and the PTHrP/IHh-feedback loop in more detail, we have started to use the chondrogenic ATDC5 cell line. This cell line differentiates into mineralizing hypertrophic chondrocytes in monolayer in the presence of insulin. Hypertrophic differentiation is enhanced by the addition of BMP4 and can be inhibited by PTHrP. RT-PCR analysis identified the presence of ERa, but not ERß mRNA. In addition, expression of the IGFI-receptor and the Growth Hormone Receptor was found. The expression of ERa was not regulated by differentiation, nor by BMP4 or PTHrP-treatment. Hypertrophic differentiation of ATDC5 cells was dramatically accelerated by inducing cell aggregation when cells were cultured on bacterial dishes. Interestingly, under these culture conditions, insulin was not required for terminal chondrocyte differentiation. In fact collagen X mRNA expression was higher in aggregates cultured in the absence of insulin. However, in the presence of insulin aggregates were larger and their integrity was better maintained. Histological examination demonstrated the presence of alcian blue positive chondrocytes in the center of the aggregates. In addition, swollen cells with a hypertrophic appearance were identified both in the absence and the presence of insulin. The chondrocytes were surrounded by an outer layer of undifferentiated alcian blue negative cells mimicking a perichondrium. Culturing of ATDC5 cells as aggregates in the presence of estrogen reduced terminal chondrocyte differentiation as measured by a decreased mRNA expression of various late stage chondrocyte markers, such as collagen X. In conclusion, hypertrophic differentiation of ATDC5 cells can be accelerated by culturing the cells in aggregates. In addition, cell aggregation appears to be more important for hypertrophic differentiation than treatment with insulin. The ATDC5 cell line appears to be a suitable model to study interactions between sex-steroids and the PTHrP/IHh-feedback loop.

p38 Mitogen-Activated Protein Kinases in Chondrocyte Differentiation. L. Stanton*, S. Sabari*, F. Beier. Physiology, University of Western Ontario, London, ON, Canada.

Chondrocyte differentiation is an important part of bone development. Disturbance of the normal development of these cells can therefore lead to various diseases and conditions, such as osteoarthritis, hypochondrodysplasias and dwarfism. Thus, the activation and tight control of the signaling pathways controlling the physiology of these cells, is crucial. One signaling pathway that has been implicated in chondrogenesis and chondrocyte differentiation is the p38 MAPK signaling pathway. However, the precise role of p38 MAPK and the identity of p38 substrates and downstream transcription factors in the process of chondrocyte differentiation have not been described. We are studying the role of p38 in chondrocyte differentiation using mouse limb bud micromass cultures. Our results demonstrate expression of all four p38 MAP kinases during the chondrocyte differentiation program. We also show the temporal expression profile of these kinases in relation to various well-identified markers of chondrocyte maturation, thereby highlighting p38 MAPK expression at the various distinct stages of chondrocyte maturation. We will also present data on the biochemical roles of p38 in chondrocytes and p38 substrates involved in these processes. Understanding these pathways obviously provides greater insight into possible points of manipulation for disease treatments.

Retinoic acid Induces Expression of Osterix mRNA in Primary Cultures of Chondrocytes. K. Yagi[1], K. Tsuji[1], K. Shinomiya[2], A. Nifuji[1], M. Noda[1]. [1]Medical Research Institute, Tokyo medical and Dental University, Tokyo, Japan, [2]Tokyo Medical and Dental University, Tokyo, Japan.

During endochondral ossification, various local and systemic factors including cytokines and growth factors affect cellular events. Retinoic acid (RA) is one of such factors that regulate proliferation and differentiation of chondrocytes. It has been reported that RA suppressed expression of chondrocyte marker genes such as typeII collagen, aggrecan and Sox9 and that it induced the expression of osteocalcin, osteopontin(OPN) and Cbfa1 in chondrocytes. Thus RA is thought to act as a positive regulator of chondrocyte maturation and ossification. Osterix (Ostx) is a transcription factor that is essential for the bone formation and acts downstream to Cbfa1. We hypothesized that RA may act regulate the expression of Osterix. To elucidate the mechanism of the chondrocyte differentiation, we used the primary chondrocyte cultures derived from costochondral cells of newborn ICR mice. We examined the effects of bone morphogenic protein2 (BMP2), transforming growth factor (TGF)-β, basic fibroblast growth factor (FGF), dexamethasone, vitamin D, RA in the culture medium and evaluated the expression levels of Ostx and OPN mRNA. The expression of Ostx mRNA in chondrocyte cultures was upregulated in the presence of RA. Treatment with RA induced Ostx mRNA in a time-dependent manner. Treatment with BMP, dexamethsone, and vitamin D did not affect the expression of Ostx mRNA, therefore RA effects on Osterix gene expression was specific. RA and FGF, which regulate Ostx mRNA, induced OPN mRNA. FGF effect on OPN mRNA was dose-dependent and suppressed by the addition of U0126, MEK inhibitor. Since Ostx mRNA level was upregulated by RA and this response to RA was not observed at 24 hours but detected in 72 hours, some intermediate factors are involved in this signaling downstream of RA. Furthermore RA and bFGF induced OPN mRNA and bFGF signaling requires the MAPK cascade. In conclusion, RA induced the expression of Ostx mRNA in chondrocyte.

Function of the p21/p53 Pathway in Regulating Chondrocyte Apoptosis and Proliferation in Dwarf Mice. M. Hurley[1], G. Gronowicz*[1], D. Cassarino*[1], S. Clark*[1], N. Sims*[2], R. Baron*[2], M. Amling*[3], D. Brooks*[4], C. Wishcamper*[5], D. Lurie*[5], G. Proetzel*[6], J. D. Coffin[7]. [1]U. Connecticut HSC, Farmington, CT, USA, [2]School of Medicine, Yale Univ., New Haven, CT, USA, [3]Yale Univ., New Haven, CT, USA, [4]Univ. of Montana, Missoula, MT, USA, [5]Univ. of Montana, Missoula, MT, USA, [6]Scil Proteins, Halle, Germany, [7]Pharmaceutical Sciences, Univ. of Montana, Missoula, MT, USA.

Purpose: To characterize the regulatory mechanisms for FGF mediated dwarfism. Methods: Gene expression in TgFGF2 mice and NTg controls was examined using western blots or immunocytochemistry and in situ hybridization on sectioned bones. Results: Fibroblast growth factor-2 (FGF-2) overexpression in transgenic (TgFGF2) mice causes chondrodysplasia and dwarfism. Previous results suggest that excess FGF-2 could alter the chondrocyte transition from the stem cell population to the proliferative and hypertrophic phases, which is thought to involve programmed cell death in the hypertrophy zone. Cell proliferation and apoptosis assays on TgFGF2 and NTg mice reported here show that chondrocytes in TgFGF2 and NTg control mice proliferate at about the same rate, but the TgFGF2 chondrocytes undergo premature and rapid apoptosis causing premature chondrocyte drop-out in the TgFGF2 dwarf mice. Changes in collagen type II (col2), Collagen type X (col10) and Indian hedgehog (IHH) expression support this result. TgFGF2 mediated reductions in parathyroid hormone related peptide (PTHrP) and bcl-2 support a regulatory model where excess FGF2 decreases PTHrP, and down-regulates bcl-2 exposing growth plate chondrocytes in TgFGF2 mice to premature programmed cell death. Concomitant cell cycle regulation involves loss of p21waf expression in a p53 independent mechanism in the TgFGF2 mice. Conclusion: Even though p21waf is allowing entry into the cell cycle, there is not a significant increase in proliferation. Instead the cells enter apoptosis causing chondrocyte drop out in the proliferation and prehypertrophy zones. The mechanism for this is unclear. Overall, the FGF-2 regulatory model derived from TgFGF2 studies suggests that growth factors function to regulate overall stature and the relative proportions of the skeleton.

M030

Effects of Low Oxygen on Chondroinduction by Human Dermal Fibroblasts in 3-Dimensional Culture. S. Mizuno, J. Glowacki. Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA.

In developmental endochondral bone formation, mesenchymal cells condense without vascularity and as a result, cartilage is relatively hypoxic. Low oxygen (O2) has been shown as a potent regulatory factor for maintaining chondrogenesis in monolayer culture (Dev Bio 19:52,1969). Our hypothesis was that chondroinduction in vitro is enhanced by low O2 concentration. In previous studies, we developed a novel chondroinduction system [Exp Cell Res 227:89, 1996] consisting of human dermal fibroblasts (hDFs) cultured with demineralized bone powder (DBP) in a three-dimensional collagen sponge. We evaluated the effects of O2 concentration in perfused medium on matrix accumulation by chondroinduced hDFs. One million cells were seeded onto collagen sponges +/- DBP. A perfusion system was designed with a closed medium reservoir, gas exchange chamber, cylinder pump, and a glass column. As control, bovine articular chondrocytes (bACs) were enzymatically isolated and 3 million cells/sponge were injected into sponges. Sponges were incubated in culture dishes in DMEM/10%FBS for hDF or Ham's F12/10% FBS for bACs. After preincubation (under routine conditions) for 3 days, sponges were suspended in a glass column through which medium was perfused at either 2% O2 or atmospheric (AT) O2 concentration for an additional 5 or 7 days. As measures of chondroinduction and chondrogenecity, sponges were treated with 4 M guanidine and proteoglycan (PG) was precipitated with potassium acetate/alcohol. The accumulation of PG within the sponges was evaluated by ELISA with anti-keratan sulfate, anti-chondroitin 4-sulfate, anti-chondroitin monoclonal antibodies. After 7 days incubation with DBP, metachromatic matrix accumulated in all groups. The content of keratan sulfate in 2% O2 with perfusion (253 ± 39 ng/sponge) was 23% greater than AT O2 with perfusion (205 ± 12 ng/sponge, $P < 0.05$) and 20% greater than AT O2 without perfusion (211 ± 23 ng/sponge). The content of chondroitin 4-sulfate PG was similar in both perfused and non-perfused cultures at AT O2. Content of chondroitin 4-sulfate in 2% O2 with perfusion (167 ± 14 ng/sponge) was 18% greater than AT O2 with perfusion (141 ± 15 ng/sponge, $P < 0.05$) and 24% greater than AT O2 without perfusion (135 ± 27 ng/sponge, $P < 0.05$). In sum, chondrocyte matrix production was suppressed with perfusion and low O2 conditions enhanced chondroinductive and chondrogenic activity.

TNF-α Activation of the Apoptotic Cascade in Articular Chondrocytes Is Accompanied by Induction of Specific, Pro-Resorptive Factors, Metalloproteinases and Angiogenic Factors. T. Cho[1], W. Lehmann[2], C. M. Edgar[3], T. A. Einhorn[3], L. C. Gerstenfeld[3]. [1]Department of Orthopaedic Surgery, Seoul National University College of Medicine, Seoul, Republic of Korea, [2]Department of Trauma and Reconstructive Surgery, University of Hamburg, Hamburg, Germany, [3]Department of Orthopaedic Surgery, Boston University Medical Center, Boston, MA, USA.

TNF-α has been implicated in the progression of rheumatoid arthritis. Therapies that specifically block TNF-α activity have been shown to provide substantive diminishment in the symptoms of rheumatoid arthritis and slow the progression of joint degeneration. In the current studies, we demonstrate that TNF-α induces the expression of multiple mRNAs associated with the apoptotic cascade within murine articular chondrocytes. Furthermore, these mRNAs are directly dependent on the actions of TNF-α as mediated through its receptors, based on comparison of cells from wild type mice and TNF-α receptor deficient ($p55^{-/-}p75^{-/-}$) mice. The induction of the apoptotic cascade was accompanied by the increased expression of multiple factors involved in the regulation of skeletal tissue resorption and a number of specific metalloproteinases and angiogenic factors that promote vessel infiltration. The expression of specific mRNAs that showed quantitative changes from 2 to greater than 10 fold included iNOS, MMP3, VEGFi, VEGF D, VEGE and M-CSF. The dependence of the induction of these mRNAs on TNF-α was confirmed by comparison to the effects of TNF-α on the chondrocytes of receptor null mice. In summary, our findings demonstrate that TNF-α activates a complex array of factors within chondrocytes that contribute to the destruction of joint surfaces independent of its actions on synovial cells. These activities promote the apoptosis of the chondrocytes and the proteolytic destruction of cartilage extracellular matrix, while facilitating the activation of pro-resorptive cells and angiogenesis. Our findings provide a more comprehensive mechanistic understanding on why TNF-α blockade is so effective as a therapeutic in the treatment of rheumatoid arthritis.

M032

Hedgehog Signaling Enhances Expression of Osterix Gene in Chondrocytes. M. Takamoto[1], K. Tsuji[1], T. Komori[2], Y. Taketani*[3], A. Nifuji[1], M. Noda[1]. [1]Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Osaka University, Osaka, Japan, [3]University of Tokyo, Tokyo, Japan.

Hedgehog signaling is considered to play an important role in chondrogenesis. Indian hedgehog (Ihh), expressed in prehypertrophic zone of the growth plate, seems to regulate chondrocyte hypertrophy in a negative feedback loop with PTHrP. Ihh is needed for normal endochondral bone formation. However, downstream molecule of the hedgehog signaling is not fully understood. Osterix is a recently reported novel zinc finger-containing transcription factor, which is required for osteoblast differentiation and bone formation. In Osterix null mice, no bone formation is occurred. In this paper, we examined whether hedgehog signaling has any effect on the expression of Osterix gene. Chondrocytes were prepared from costal cartilage of the newborn mice. Then, chondroctytes were cultured in the presence or in the absence of hedgehog. RT-PCR was performed with Osterix primer. Osterix mRNA was expressed constitutively in these primary chondrocytes, and the expression level was enhanced in the presence of hedgehog signaling. These data indicated that osterix is the target of hedgehog signaling and may play a key role not only in the regulation of bone formation but also in chondrogenesis.

New Calcium Phosphate Scaffolds for Tissue Engineered Osteochondral Implants. Y. Larcher*[1], J. Hendry*[2], D. R. Sindrey[2], R. Hagg*[1]. [1]Millenium Biologix AG, Zurich, Switzerland, [2]Millenium Biologix Inc., Mississauga, ON, Canada.

Mosaicplasty and autologous chondrocyte implantation (ACI) are the most popular methods for repair of articular cartilage injuries. Donor site morbidity is a major concern of mosaicplasty whereas ACI is mainly limited by a relatively long rehabilitation time and its applicability for osteochondral injuries. Novel tissue engineering approaches using scaffolds with capacities to address bone and cartilage formation are believed to overcome existing hurdles. Skelite™ is a new porous calcium phosphate based biomaterial with unique biological activity, which has shown excellent results with respect to new bone formation in animal studies. The aim of this study was to investigate how this new osteoinductive biomaterial qualifies for *in vitro* engineering of osteochondral implants. Porcine articular chondrocytes were enzymatically harvested using a consecutive protease/bacterial collagenase digest. Isolated chondrocytes were seeded onto porous Skelite™ cylinders (7mm dia. x 5mm h). Such 3D high-density cell constructs were incubated in DMEM/F12 medium supplemented with 10% FBS, insulin and ascorbic acid for up to 4 wks. Ground polished sections were toluidine blue stained for assessment of the interface between cartilage and the biomaterial. The newly formed cartilage was further classified by collagen typing via SDS-PAGE and collagen-/proteoglycan quantification by means of H-Proline/DMB-assays. The chondrocytes formed physically palpable tissue with a seamless transition to the underlying Skelite™. The 1.5 mm layer of cartilaginous-like tissue was composed by numerous round to ovoid cells with a vacuolar cytoplasm and with a small round central nucleus, consistent with a chondrocytic phenotype. These cells were embedded in an abundant amorphous lightly metachromatic intercellular matrix having the histological hallmarks of hyaline cartilage. Collagen typing further confirmed that mainly cartilage specific collagen types II, IX and XI were formed when cultured up to 4 wks. Expectedly, due to the short culture period of 4 wks the tissue was still immature and contained only approximately 10-20% of total collagen or proteoglycan amount of native articular cartilage. The connection between biomaterial and cartilage was in all cases relatively tight, as *de novo* cartilage layers could not be removed by applying tensile forces using a forceps. We have demonstrated that Skelite™ not only is a proper scaffold for new bone formation but also supports the formation and attachment of cartilaginous tissue. Our results suggest that a Skelite™ cylinder seeded with chondrocytes could be a promising candidate as carrier matrix for cartilage repair therapy.

Molecular and *In Silico* Analysis of Novel DNAs Expressed During Chondroinduction of Human Dermal Fibroblasts. K. E. Yates. Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA.

Gene expression profiling has emerged as a means to infer biological mechanisms. Interpretation of differential gene expression patterns is confounded when limited information is available on genes of interest. Cloning of additional 5' and/or 3' sequence may be necessary to identify putative functions for novel genes. In this study, an *in silico* approach was combined with molecular techniques to characterize novel genes that are upregulated during postnatal chondroinduction of human dermal fibroblasts (hDFs) by demineralized bone. The purpose was to rapidly screen the novel sequences and prioritize them for further study. Upregulated genes were identified by representational difference analysis of genes expressed in chondroinduced and control hDFs. Novel sequences were defined as those for which a BLAST Sequence Similarity Search of the GenBank database (http://www.ncbi.nlm.nih.gov/Genbank/GenbankSearch.html) found no similar (>90% identity) human DNA sequence. Eleven of 100 clones analyzed were initially identified as novel. Gene expression of all 11 sequences were detected in human DFs, skin, and articular chondrocytes by RT-PCR. A subsequent BLAST search identified matches in GenBank for three human mRNAs and three human genomic clones (Table). Those sequences were aligned to the Human Genome Working Draft sequence using the BLAT algorithm (http://genome.ucsc.edu/cgi-bin/hgBlat?db=hg10) (Table). The Human Genome Browser (http://genome.ucsc.edu/cgi-bin/hgGateway) was used to view known and predicted mRNA sequences at the same genetic loci as the genomic clones. That analysis predicted sequence number 30 was a splice variant of alpha V integrin. Northern hybridization using seq. No. 30 as probe detected a transcript in hDFs similar in size (~8kb) to known alpha V integrin mRNAs. Of the 5 remaining novel sequences, 3 were fully aligned to the Human Genome Working Draft Sequence. Analysis of known and predicted mRNAs at the same genetic loci suggested that one of the novel sequences encodes a kinesin-related protein similar to the murine KIF26B protein. In summary, a putative function was assigned to 45% of DNA sequences initially identified as novel in chondroinduced hDFs. Coupling *in silico* with molecular biology tools expedites analysis of novel DNA sequences and selection of candidate genes for further study.

Identification of novel DNAs in chondroinduced hDFs by comparison to DNA sequence databases

Seq. No.	BLAST Result (GenBank Accession No.)	BLAT Result	Proposed Function

Expression of *Wnt* and *Frizzled* Genes During Postnatal Chondroinduction of Human Dermal Fibroblasts. K. E. Yates, S. Zhou*. Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA.

Wnt family proteins and their receptors, the Frizzled proteins (Fzd), modulate chondrogenesis during embryonic development. Expression of *wnt* genes may also regulate postnatal chondroblast differentiation and chondrogenesis. In previous studies, we used a novel *in vitro* collagen sponge culture system [1] to identify a pool of genes whose expression was altered in human dermal fibroblasts (hDFs) chondroinduced with demineralized bone powder (DBP) [2]. In this study, we identified *wnt5a* among those genes whose expression was increased (upregulated) in chondroinduced hDFs, and characterized expression of *wnt* and *fzd* genes during chondroinduction of postnatal fibroblasts. A clone containing the *wnt5a* 3' untranslated region was identified among a pool of genes upregulated in hDFs after 3 days of exposure to DBP. Northern hybridization using this clone as a probe detected several *wnt5a* mRNA transcripts (approximate sizes 1.9-, 4.6-, 6.8-, and 8.2-kb) in chondroinduced and control hDFs on day 3. An additional transcript (approximate size 9.0 kb) was transiently expressed only in chondroinduced hDFs. *In situ* hybridization using a probe for the *wnt5a* protein-coding region showed expression in hDFs in DBP/collagen sponges after 4 days, especially in those cells that surrounded the DBP. Expression of other *wnt* and *fzd* genes during chondroinduction (days 3, 7, 14, and 21) was characterized by semi-quantitative RT-PCR. *Wnt5b* mRNA was upregulated in chondroinduced hDFs 2.9-fold over control on day 3; a similar level of expression was observed in chondroinduced hDFs throughout the experiment. *Wnt10b* mRNA was upregulated in chondroinduced hDFs 2.6-fold over control on day 3, 4.8-fold on day 7, and declined thereafter. In contrast, transient suppression of *wnt2B/13* (42% of control) and *fzd7* (55% of control) mRNA levels were observed in chondroinduced hDFs on day 3. Expression levels of *wnt2, wnt3, wnt4,* and *wnt7b* and *fzd1, fzd2* and *fzd3* mRNAs were similar in control and chondroinduced hDFs at all timepoints. In summary, we found modulation of specific *wnt* and *fzd* gene expression during postnatal chondroinduction of dermal fibroblasts by demineralized bone. The results suggest the hypothesis that DBP-mediated changes in expression of Wnt and Fzd contribute to chondroblastic differentiation of postnatal fibroblasts.

Osteoblasts Express Multiple Forms of Laminins - Regulation with the Progression of Differentiation. V. Puche*[1], M. Clerget*[1], P. Rousselle*[2], L. Malaval[1]. [1]U403, INSERM, Lyon, France, [2]Umr 5086, ibcp, CNRS, Lyon, France.

Laminins (LNs) are trimeric molecules of the extracellular matrix which affect cell fate and activity. We have previously shown that LN-1 ($\alpha1\beta1\gamma1$) favors the attachment of osteoprogenitors to the substrate, suggesting a role for these molecules in osteogenesis and/or bone remodeling. Although LN chains are secreted by multiple cell types, only a few studies have focused on their expression by bone cells. To identify the isoforms of LN secreted by osteoblasts, we analysed their expression in a bone nodule forming model of *in vitro* osteogenesis, rat calvaria (RC) cell cultures. A cDNA bank of rat LN chains was generated by RT-PCR and used in Northern blot analysis. mRNA for subunits $\alpha4$, $\beta1$, $\beta2$ and $\gamma1$ were detected in RC cell cultures. The expression of $\beta1$ and $\gamma1$, which was confirmed by immunoprecipitation and Western blot, diminishes with culture time, i.e. the progression of osteogenesis. $\alpha4$ and $\beta2$ are not regulated with culture time but the expression of mRNA and protein is strongly inhibited by Dexamethasone (Dex). Bone nodules are clonal osteoblastic colonies, presenting a differentiation gradient from the periphery to the center. Immunofluorescence analysis of mature nodules shows a strong expression of $\alpha4$, $\beta1$ and $\beta2$, in particular by differentiated osteoblasts in the central part of the colonies. Interestingly, while $\gamma1$ is strongly expressed in peripheral proliferating preosteoblastic cells, labelling is absent in central cells, suggesting the expression of at least one other γ chain by mature osteoblasts. Immunoprecipitation after metabolic labelling with an anti-LN-1 polyclonal antiserum reveals the presence in RC cell cultures of several LN isoforms, whose number and level of expression are regulated with the progression of osteogenesis and under the action of Dex. Immunoprecipitations with specific antibodies show that most of these isoforms contain $\beta1$ and $\gamma1$, and that nidogen, another component of basal laminae, is present in RC cell cultures and is associated with some of the LN variants secreted. In summary, we have shown that multiple LN chains are expressed during osteogenesis *in vitro*, and differentially regulated at successive osteoblast differentiation stages and by Dex, which is a potent osteogenic agent in this model. Specifically, our data are compatible with the presence of LN-8 ($\alpha4\beta1\gamma1$) and/or LN-9 ($\alpha4\beta2\gamma1$) ; however, immunoprecipitation results indicate that other forms, some of which contain long α chains (which may be $\alpha1$, 2 and/or 5), are also secreted. Our data confirm the involvement in osteoblast biology of Laminins, an entirely new family on this scene.

Cellular Distribution and Protein Interactions of Na-dependent Phosphate Transporters in the Osteoclast. M. A. Khadeer*[1], Z. Tang*[1], H. S. Tenenhouse[2], N. Hernando*[3], M. V. Eiden*[4], A. Gupta[1]. [1]University of Maryland, Baltimore, Baltimore, MD, USA, [2]McGill University, Montreal, PQ, Canada, [3]Physiologisches Institut, Universität Zürich-Irchel, Zurich, Switzerland, [4]National Institutes of Mental Health, Bethesda, MD, USA.

We previously demonstrated that inhibition of Na-dependent phosphate transport in osteoclasts led to reduced ATP levels and diminished bone resorption. These findings suggested that Na/Pi cotransporters in the osteoclast plasma membrane provide Pi for ATP synthesis and that the osteoclast may utilize part of the Pi released from bone resorption for this purpose. The present study was undertaken to define the cellular localization of Na/Pi cotransporters in the mouse osteoclast and to identify the proteins with which they interact. Using glutathione S-transferase (GST) fusion constructs, we demonstrate that the type IIa Na/Pi cotransporter (Npt2) in osteoclast lysates interacts with the Na/H exchanger regulatory factor, NHERF-1, a PDZ protein that is essential for the regulation of various membrane transporters. In addition, NHERF-1 in osteoclast lysates interacts with a carboxy terminal Npt2 fragment fused to GST and to a lesser extent with the same Npt2 fragment lacking the PDZ-binding carboxy terminal amino acids TRL, consistent with the interaction of renal Npt2 with NHERF-1. Studies in osteoclasts transfected with green fluorescent protein-Npt2 constructs indicated that Npt2 colocalizes with NHERF-1 and actin at or near the plasma membrane of the osteoclast, and associates with ezrin, a linker protein associated with the actin cytoskeleton, likely via NHERF-1. Furthermore, we demonstrate by RT/PCR of osteoclast RNA and in situ hybridization that the type III Na/Pi cotransporter, PiT1, is also expressed in mouse osteoclasts. To examine the cellular distribution of PiT1, we infected mouse osteoclasts with a retroviral vector encoding PiT1 fused to a double HA epitope tag at the carboxy terminus. We show that PiT1 colocalizes with actin and is present on the basolateral membrane of the polarized osteoclast, similar to that previously reported for Npt2. Taken together our data suggest that association of Npt2 with NHERF-1, ezrin and actin, and of PiT1 with actin, may be responsible for membrane sorting and regulation of these Na/Pi cotransporters in the osteoclast.

Increased Collagen Degradation Is Associated with the Upregulation of Chondrocyte Differentiation Related Genes in Articular Cartilage Explants Induced by a Type II Collagen Peptide. E. V. Tchetina*. Joint Diseases Laboratory, Shriners Hospitals for Children, Montreal, PQ, Canada.

Articular cartilage degeneration in osteoarthritis (OA) involves excessive degradation of extracellular matrix (ECM), including type II collagen and aggrecan. It is also characterized by chondrocyte differentiation (hypertrophy).We hypothesised that destruction of the collagen network in OA is controlled by regulatory mechanisms of ECM resorption that govern chondrocyte terminal differentiation. In human and bovine articular cartilage explants the presence of a type II collagen peptide is capable of inducing collagenase cleavage of type II collagen, measured by ELISA. Examination by semi-quantitative RT-PCR of the expression profiles of genes involved in chondrocyte differentiation revealed

that the increase in collagen cleavage in human or bovine articular cartilage explants induced the collagen peptide was accompanied by the upregulation of terminal chondrocyte differentiation-related genes namely COL10A1, MMP-9, MMP-13, Indian hedgehog and TGFbeta1 as seen in the bovine growth plate. This was preceeded by the transient upregulation of the expression of bFGF and PTHrP. Upregulation of the cytokines IL-1alpha/beta and TNFalpha was also observed. Our results show that a cartilage collagen cleavage product can induce upregulation of the genes involved in chondrocyte terminal differentiation. This may contribute to the pathobiology of articular cartilage degradation in OA.

Microarray Analysis of Human Osteoblast and Cementum-derived Cell. M. Yamamoto[1], T. Nakamura[1], T. Yoshimoto*[1], W. J. Grzesik*[2], H. Sekiya[3], Y. Izumi*[1]. [1]Periodontology, Kagoshima University Dental School, Kagoshima, Japan, [2]Department of Periodontics, School of Dentistry, Dental Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, [3]First Department of Oral and Maxillofacial Surgery, School of Dental Medicine, Tsurumi University, Yokohama, Japan.

Teeth are connected to alveolar bone in jaws, with attachment apparatus composed of alveolar bone proper, periodontal ligament, and tooth cementum. Tooth cementum is generally thought to be closely related to bone. Heretofore, numerous previous studies using physiological, anatomical, histology, and biochemical techniques reveal the biological function and characteristics of cementum. However, specific molecular markers or characteristics of cementum are still to be identified. The purpose of this study was to analyze the differences in gene expression between human cementum-derived cell and normal human osteoblast using microarray technique. Radioisotope-labeled cDNA probes were reverse-transcribed with [α33P] dATP from total RNA extracted from cultured normal human osteoblast (NHOst, Clonetics, SanDiego,CA,USA), or human cementum-derived cell clone-10 (HCDC c10) which were isolated from teeth extracted on clinical demands. Side-by-side hybridizations with radioisotope-labeled cDNA probes onto 1176 genes membrane arrays allow the comparison of the expression pattern. Of the known 1176 spotted genes, 21 were unique to NHOst and 37 were distinctive to HCDC. To confirm the differential expression of genes between NHOst and HCDC c10, RT-PCR analyses were performed on 5 genes which were highly expressed in one of the two kind of cells. RT-PCR revealed that IGFBP2 was expressed highly in NHOst, and extremely low in HCDC c10. Further RT-PCR showed that IGFBP2 was expressed abundantly in matured NHOst, alveolar osteoblast and osteocyte isolated from human mandibles, and human osteosarcoma cell lime MG63. On the other hand, HCDC clone-12 did not express the IGFBP2 mRNA, similar to HCDC c10. In summary, these results indicate that IGFBP2 is one of the candidates for markers which are useful to distinguish between cementum-derived cells and other bone cells.

The Genetic Determinants of Bone Strength: Towards the Mapping of Candidate Genes for Bone Turnover. D. Jefferies*, R. Flemming*, C. Farquharson, D. Burt*, C. Whitehead*. Bone Biology Group, Roslin Institute, Edinburgh, United Kingdom.

Bone mineral density is a complex term that includes mineral content, size, trabecular complexity and shape. Bone strength is determined primarily by these variables. In order to characterise the molecular pathways involved in bone formation and resorption it is necessary to determine the genes that contribute to bone strength. Our approach has involved the selection of lines of chickens with high and low bone strength (high and low lines respectively). After 8 generations of bodyweight restricted selection on bone characteristics these lines have tibial breaking strengths that differ by 92% (303.7±12.5 v 157.9±10.9 Newtons: P<0.001), with no significant difference in bodyweight (1625.5±21.14 v 1706.8±36.8 grams). Measurements of mineral apposition rate (12.2±0.7 v 9.6±0.3 mm/day: P<0.001) and serum pyridinoline (0.39±0.03 v 0.46±0.021 pmol/ml: P<0.05) indicate that bone formation is increased and bone resorption is decreased in the high line compared to the low line. Tibial cortical thickness was also significantly greater in the high line (0.42±0.009 v 0.37±0.007 mm: P<0.001). Although the differences were not significant the number of osteoclasts per unit surface area of bone was lower in the high line (1063±101 v 1229±73 per sq. mm) and the serum concentration of carboxylated osteocalcin was higher (285±21.8 v 230±19.1 ng/ml) reinforcing the above trend. No differences were found in the levels of serum ionised or total calcium, or inorganic phosphate. We are currently using these two lines to discover candidate genes for bone strength using a dual approach: 1) Microarray analysis of gene expression in bone cells (osteoblasts and osteoclasts) of the high and low lines to characterise significant changes in gene expression between the lines. 2) QTL analysis of a classical F2 intercross to identify areas of the genome with significant QTL for bone strength. Genes that show significant differences in expression levels between the lines will be mapped initially using human/mouse/chicken comparative gene maps. Known properties of genes from available functional data will be used to prioritise the most likely candidate genes at each QTL. This dual approach will allow us to focus on a limited number of genes important for bone strength for further study.

M041

SFRP-1, a Wnt Antagonist, Is Expressed During Embryonic Development in Bone and Cartilage. J. B. Lian[1], B. Trevant*[1], J. Symons*[1], B. S. Komm[2], P. V. N. Bodine[2], G. S. Stein[1]. [1]Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA, [2]Women's Health Research Institute, Wyeth Research, Collegeville, PA, USA.

Members of the Wnt (wingless) family of secretory proteins have important regulatory roles throughout development in cell-fate determination and inductive tissue interactions, and are involved in many cell functions, including apoptosis. A set of secreted frizzled (FZ) related proteins (SFRPs) interact directly with Wnt factors to block ligand interaction with FZ receptors. Several studies have indicated that members of the Wnt, frizzled receptors, and SFRP families are expressed in osteoblasts and may regulate programmed cell death. Given the importance of apoptosis to regulation of bone development, we examined expression of SFRP-1 in a mouse model in which the beta-galactosidase gene replaced exon1. The LacZ protein, detected by beta-gal activity in whole embryos and cryosections, reflects in situ expression of the endogenous gene in its native context. Knockout of the SFRP-1 gene does not affect embryo development in homozygous mice. At 11.5 dpc beta-gal expression is observed in developing heart, brain, gut, and kidney, consistent with previous in situ hybridization studies and northern blot expression studies in normal mice. Taken together, these studies indicate that absence of functional SFRP-1 protein does not alter regulation of SFRP-1 expression. Beyond 15.5 dpc, beta-gal activity diminished, but was retained in these tissues. At this time, strong SFRP-1 expression becomes evident in connective tissue around developing ribs, but not in the safranin-O positive cartilage tissue forming the rib. From the 16.5-day embryo to the newborn, SFRP-1 is expressed in hyaline cartilage in limbs that have developed epiphyses. Beta-gal activity is observed selectively in regions undergoing joint formation, expansion, and reshaping. In limb bone, ribs, and calvariae, SFRP-1 expression is highest in the mineralizing bone tissue, overlapping alkaline phosphatase positive tissue. Our results support the following conclusions: 1) absence of SFRP-1 regulation of the Wnt pathway is likely compensated by other Wnt inhibitory proteins; 2) SFRP-1 is not expressed in all Wnt regulated developing tissues; and 3) SFRP-1 exhibits a selective expression pattern in the skeleton. We postulate that SFRP-1 is a component of the Wnt pathway operative in the developing skeleton and may be relevant to joint formation, shaping of the epiphyses, and regulating osteoblast populations.

Specific Osteoblast Cytosolic Proteins Bind and Stabilize Collagenase 3 RNA. S. Rydziel, A. M. Delany, E. Canalis. Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

Collagenase 3 (matrix metalloproteinase 13) degrades collagen fibrils and its activity is critical in the initiation of bone resorption. Glucocorticoid excess causes bone loss, and cortisol increases collagenase 3 synthesis in osteoblasts by increasing its mRNA stability. The collagenase 3 3' untranslated region (UTR) contains AU-rich elements that control transcript stability, and we used RNA electrophoretic mobility shift assay (REMSA) to demonstrate that cortisol increases the interaction of cytosolic proteins from fetal rat calvarial osteoblasts (Ob cells) with collagenase 3 AU-rich elements in the 3' UTR. In contrast, cortisol-dependent protein complexes were not formed with the coding region or the 5' UTR. Transient transfection of Ob cells with CMV-driven collagenase 3 constructs revealed decay of the recombinant transcripts following transcriptional arrest, and mRNA stabilization by cortisol. To confirm that the 3' UTR of collagenase 3, and specifically the AU-rich elements, were responsible for stabilization of its mRNA in osteoblasts, CMV-driven c-fos constructs, where the 3' UTR of the c-fos gene was exchanged with that of collagenase 3 gene, were created. Transient transfections of CMV-driven c-fos in Ob cells revealed a rapid decay ($t_{1/2} < 5$ min) of c-fos mRNA following transcriptional arrest, and stabilization when the 3' UTR was exchanged with that of the collagenase 3 gene ($t_{1/2} > 60$ min). Mutations of AU-rich elements in the collagenase 3 3' UTR sequence resulted in immediate destabilization of chimeric transcripts. Similarly, mutations of AU-rich elements in the 3' UTR of the collagenase gene resulted in immediate destabilization of transfected CMV-driven collagenase constructs, confirming that the AU-rich sequences determined collagenase 3 mRNA stability. A group of collagenase 3 RNA binding proteins was purified from cytosolic extracts of cortisol treated Ob cells by ultracentrifugation, ion exchange chromatography, RNA affinity chromatography, and polyacrylamide gel electrophoresis, and identified by mass spectroscopy. REMSA supershift assays using specific antibodies to each of these proteins demonstrated that vinculin and far upstream element (FUSE) binding protein 2 interacted with the AU-rich collagenase 3 3' UTR sequences. In conclusion, the 3' UTR of collagenase 3 regulates collagenase mRNA stability in osteoblasts. Interactions with cytoskeletal proteins, such as vinculin, and proteins that shuttle from nucleus to cytoplasm, such as FUSE binding protein 2, appear vital to the stability and targeting of transcripts to cytoskeletal polysomes.

Development of Bone-Derived Cell Lines from a Marine Teleost: Establishment of the First In Vitro Model System from Fish Suitable to Analyze Regulatory Pathways of Matrix Gla Protein and Osteocalcin Gene Expression. V. Laizé*, A. R. Pombinho*, M. L. Cancela. Ccmar, Universidade do Algarve, Faro, Portugal.

Recent studies on regulation of bone formation and mineralization in fish have been hampered due to lack of a well-characterized *in vitro* model system. Therefore, while numerous mammalian and avian cell lines, available for decades, have been successfully used for analysis of expression and regulation of genes from bone and cartilage, corresponding mechanisms in lower vertebrates have remained poorly understood. The purpose of this work was to develop bone-derived cell lines from fish origin capable of *in vitro* mineralization and suitable to characterize specific gene expression and regulation. Because of its economical and scientific importance, the teleost fish *Sparus aurata* has been chosen to initiate this work and vertebra-derived primary cell cultures were generated. Two of them (VSa13 and VSa16) were continuously kept in culture for over 100 passages and further characterized. Both cell types exhibited a fibroblast-like phenotype/slow growth when cultured at 22ºC in medium A, and a polygonal phenotype/rapid growth when cultured at 33ºC in medium B and were capable of inducing extracellular matrix mineralization when confluent as detected by von Kossa staining. Mineralization was observed in both cultures grown in medium B but no nodules could be detected when grown in medium A. Nature of the mineral deposits was investigated by X-ray diffraction and by measuring the quantity of calcium and phosphate associated with the matrix. The mineral structure of the deposits was similar to that of hydroxyapatite, a mineral present in mammalian and fish bones. Gene expression and regulation of *S. aurata* (Sa) Matrix Gla protein (MGP) and osteocalcin (BGP) were investigated in both cell types. SaBGP is expressed only in VSa16 cells and is up-regulated during mineralization. In contrast, SaMGP is expressed only in VSa13 cells, is up-regulated by increased extracellular calcium concentration and down-regulated during mineralization. Furthermore, SaMGP gene expression is regulated in VSa13 cells by different hormones, in a temporal and status of mineralized matrix-dependent manner. In this report we describe for the first time the establishment and initial characterization of two cell lines derived from vertebra of a marine teleost fish. Both are capable of mineralizing *in vitro* but they express osteocalcin and matrix Gla protein in a mutually exclusive manner and represent therefore a valuable tool for further studies on expression of genes involved in extracellular matrix mineralization.

M044

Medial Collateral Ligament Insertional Changes (μCT) After Anterior Cruciate Ligament Deficiency. J. M. LaMothe*, M. R. Doschak*, J. R. Matyas, R. C. Bray*, R. F. Zernicke. McCaig Centre for Joint Injury and Arthritis Research, University of Calgary, Calgary, AB, Canada.

The knee anterior cruciate ligament (ACL) has primary responsibility for preventing anterior-posterior translation of the tibia, and ACL disruption leads to increased knee instability. With ACL disruption, the medial collateral ligament (MCL) becomes critical in restraining knee movement, but no studies have investigated the potential influence of joint instability on MCL insertional changes after ACL loss. Loss of joint stability may lead to tissue deterioration affecting all tissues within the joint. Thus, we investigated changes in MCL insertional geometry following ACLX. Skeletally mature female New Zealand White rabbits were separated into two groups: ACLX (n=9) or normal age-matched controls (n=15). The ACLX group underwent unilateral transection of the right ACL followed by 6wk recovery, and the normal age-matched controls did not undergo surgery. Following 6wk recovery, rabbits were euthanized, and femurs were dissected. The medial femoral condyle was sectioned from the femur and scanned with micro computed tomography (μCT-Skyscan 1073). Two-dimensional images generated by scanning were quantified with standardized tracing methods and summated to extract MCL insert-related measurements (Scion image). The University of Calgary Animal Care Committee approved all procedures. There was no significant difference between ACLX and age-matched controls in volume of cortical bone containing the MCL insert. The percentage of cortical bone volume compared to a standardized bone volume surrounding the MCL insert was not significantly different between ACLX and normal controls. MCL insertional volume was significantly greater in the ACLX cohort ($p<0.04$). MCL cross-sectional area increased significantly after ACLX ($p<0.04$). After 6 wk, ACLX periarticular bone mineral density was significantly decreased ($p<0.05$). Thus, an increase in joint instability elicited concomitant changes in joint tissue morphology, and those changes may be associated with changes in joint loading and progression of post-traumatic osteoarthritis.

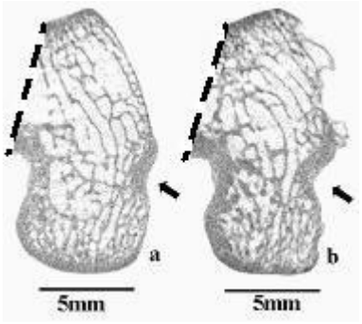

Figure 1. Transverse sections (μCT) of femoral medial condyles illustrating the MCL insert (arrow) in a normal control (a) and 6 wk ACLX (b) animal. Dashed lines denote a sagittal cut dividing distal medial and lateral condyles.

Overcoming the Immune Response to Permit Ex Vivo Gene Therapy for Spine Fusion Using Human Type 5 Adenovirus to Deliver LIM Mineralization Protein-1 (LMP-1) cDNA. M. Viggeswarapu[1], H. Kim*[1], S. D. Boden[1], G. A. Hair*[1], C. Oliver*[1], L. Titus[2]. [1]Orthopaedics, Emory University School of Medicine, Decatur, GA, USA, [2]Medicine, Veterans Affairs Medical Center, Decatur, GA, USA.

Cells transduced with human type 5 Adenovirus containing the osteoinductive LMP-1 cDNA (Ad5-LMP-1) can induce spine fusion in rabbits. Since up to 80% of the human population has been exposed to adenovirus, immune responses to the vector may limit this strategy in humans. Few studies have modeled previous adenoviral exposure and tested strategies to circumvent it. Our goals were: 1) To develop an animal model to simulate previous human adenoviral exposure; 2) To determine the impact of adenoviral pre-exposure on spine fusion induced with ex vivo Ad5-LMP-1; 3) To test strategies to overcome any potential immune response. Adult NZW rabbits were injected with 108 or 109 viral particles of Ad5-LacZ. At 4 weeks or 16 weeks after Ad5 injection, autologous buffy coats were prepared from peripheral blood and 4M cells/side were infected for 10 min with 4 plaque forming units/cell (MOI) Ad5-LMP-1. Cells were implanted on a collagen matrix for posterolateral lumbar arthrodesis. Non-immunized rabbits served as controls. Additional immunized rabbits underwent arthrodesis at 4 weeks with increased cell number (10M), viral dose (MOI=10), or both parameters increased. Rabbits were euthanized at 4 weeks and the spines were assessed by palpation and X-ray. A parallel study was performed in athymic rats using immunized rabbits for the donor cells. All non-immunized rabbits had solid spine fusions. None of the rabbits arthrodesed 4 weeks after Ad5 pre-exposure achieved fusion. At 4 weeks post Ad5 exposure, increasing the MOI to 10 did not overcome the immune response (0/3 fused), but increasing the cell number to 10M (2/3 fused) or increasing both cell number and MOI (3/3 fused) did overcome the immune effects. Delaying arthrodesis until 16 weeks after Ad5 exposure also overcame the immune response (3/3 fused) in rabbits pre-exposed to 108 vp. Similar results were seen in the athymic rat ectopic implant model, suggesting the immune effect was mediated by humoral antibodies rather than a T-cell response. In these studies two model systems were developed which simulate previous exposure to Ad5 and separate the cellular and humoral components of the response. There was a dose-dependent inhibition of spine fusion, probably due to inhibition of ex vivo Ad5-LMP-1 gene transfer to cells from animals previously exposed to Ad5. Data suggest the inhibition of AdV5 infection was due to neutralizing antibodies, rather than a T-cell-based response. Minor modifications in the gene transfer protocol overcame the immune response to allow ex vivo gene therapy

Expression of Small Leucine-rich Proteoglycan Genes During Mineralization by MC3T3-E1 Cells Cultured on Titanium Implant Material. T. Matsuura[1], S. Tsubaki*[1], T. Tsuzuki*[1], M. Yamauchi[2], H. Sato*[1]. [1]Oral Rehabilitation, Fukuoka Dental College, Fukuoka, Japan, [2]Dental Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA.

It is known that dental/orthopedic titanium implants create a unique microstructure at the bone-implant interface composed of a thin layer of collagen-free/proteoglycan-rich unmineralized matrices (20-50 nm) and a collagenous zone (100-500 nm). The presence of the former appears to be important for successful implants; however, the mechanisms of its formation are unknown. The objective of this study was to investigate the temporal mRNA expression patterns of small leucine-rich proteoglycans (SLRPs), i.e. decorin (DCN), fibromodulin (FM) and lumican (LM), and type I collagen (COL) during mineralization by MC3T3-E1 cells cultured on a titanium implant material (Ti) using a real-time PCR assay. The lysates of the cells cultured on Ti and plastic wells (Pl) for 10 to 50 days were used for calcium and mRNA quantification. The onset of calcium accumulation in the cultures on Ti (30/40 days) was significantly slower than that of Pl (20/30 days). The timings for high mRNA expression for alkaline phosphatase (ALP) and COL were also slower in the former when compared to the latter. However, as mineralization in the cultures proceeded, the temporal mRNA expression for SLRPs showed similar patterns between the two groups. In both cases, DCN mRNA increased up to two-fold, while FM mRNA diminished by almost 95 % at day 50. The latter pattern was similar to those of COL and ALP. The LM mRNA expression level remained essentially the same during mineralization. These results indicate that the temporal expression patterns of these SLRP genes in MC3T3-E1 cells are distinct from one another during mineralization on the Ti surface suggesting their specific roles in this process. The distinct temporal expression of these SLRP genes and their subsequent deposition in the extracellular matrix could be involved in the formation of the unique bone-implant interface structure.

M047

Proteolysis of Human Osteocalcin by MMP's and Cathepsin K. C. M. Gundberg[1], M. Clough*[1], J. S. Mort*[2]. [1]Orthopaedics and Rehabilitation, Yale University School of Medicine, New Haven, CT, USA, [2]Joint Diseases Laboratory, Shriners Hospital for Children, Montreal, PQ, Canada.

Circulating osteocalcin consists of the intact molecule and several smaller fragments. A large N-terminal-mid molecule fragment can be produced by tryptic activity in the circulation and during sample handling. The origin of other fragments is unknown. We have previously shown that the osteoblast can be a source of osteocalcin fragments while others report that fragments are released into the medium when osteoclasts are cultured on human bone slices. We therefore sought to determine if osteocalcin was a substrate for enzymes thought to be involved in the degradation and remodeling of bone matrix. Fully carboxylated (cHOC) or decarboxylated human osteocalcin (dcHOC) was incubated with MMP 1,

2, 3, 9, or 13 and Cathepsin K. An enzyme:substrate ratio of 1:100 (w:w) was used for all incubations. Cathepsin digestions were performed in 20 mM sodium acetate, 2 mM EDTA, 2 mM dithiothreitol, pH 5.0. MMP digestions were performed in 10 mM Tris, 0.2 mM NaCl, 10 mM CaCl2 , 0.05% Brij 35, pH 7.5. All digestions were carried out for 15 hours at 25 C and stopped with either trans-epoxysuccinyl-1-leucylamido-(4-guanidino) butane (E64) (cathepsin K) or 20 mM EDTA (MMP's). Digests were chromatographed on HPLC and peaks subjected to amino acid analysis. Electrospray mass spectrometry was performed to establish the sequence of fragments with potential tryptophan at the N- or C-terminus.There was limited digestion of cHOC by the MMP's whereas dcHOC was extensively fragmented. Cathepsin K degraded both cHOC and dcHOC, resulting notably in a large mid-molecular fragment generated from the carboxylated HOC(table).

Osteocalcin Fragments Produced

Enzymes	Carboxylated HOC	decarboxylated HOC
MMP1	1-4, 5-49	1-4, 5-49
MMP2	1-4, 5-49	1-4, 5-38, 45-49
MMP 3	1-4, 5-14; 42-49	1-4, 5-38, 42-49, 45-49
MMP8	limited (Minor amounts of 1-4, 6-39, 45-49	1-4, 6-39, 5-49, 42-49, 45-49
MMP9	none	1-4,6-39, 45-49
MMP 13	none	1-4,6-39, 45-49
Cathepsin K	1-4,6-39, 45-49	1-3,4-7, 8-17, 10-30, 31-34, 44-49

Even when uncarboxylated, the large mid-molecular fragment is not further degraded by MMPs. This region is in a highly structured section of the molecule and as a consequence may not be accessible to enzymatic cleavage. On the other hand, cathepsin K can cleave carboxylated OC to the large mid-fragment and further degrades it when it is uncarboxylated. The data suggest that a mid-molecular fragment may result from bone resorption. However, mid-molecular fragments may also result from proteolysis of uncarboxylated osteocalcin, which is made in a vitamin K-deficient state.

M048

Analysis of Osteocalcin Fragments Released from Osteoblasts and Osteoclasts in vitro. K. K. Ivaska*, H. Ylipahkala*, T. A. Hentunen, H. K. Väänänen. Institute of Biomedicine, Department of Anatomy, University of Turku, Turku, Finland.

Osteocalcin is the most abundant non-collagenous protein in bone matrix. It is produced by bone-forming osteoblasts and considered as a marker of bone formation both in serum and in cell culture. However, osteocalcin incorporated into bone matrix is also released during osteoclastic bone resorption. We have studied if osteocalcin immunoassays could thus be utilized to monitor both osteoblast and osteoclast cultures. Primary osteoblasts were induced from rat bone marrow cells and vitamin D3 was used to stimulate osteocalcin production. Primary osteoclasts were obtained from rat long bones and cultured on bovine bone slices. Parathyroid hormone (PTH) was used to stimulate resorption. In addition, human osteoclasts differentiated from peripheral blood mononuclear cells (PBMC) were used. Release of osteocalcin into medium during bone formation and bone resorption in vitro was evaluated with several in-house immunoassays for detection of different molecular forms of osteocalcin. For comparison, a commercial osteocalcin assay was used. The heterogeneity of osteocalcin released into medium was determined using reverse-phase HPLC. In bone formation assay, primary osteoblasts produced osteocalcin into culture medium after two weeks and osteocalcin synthesis was significantly upregulated by vitamin D3. All osteocalcin assays recognizing osteocalcin of rat origin were useful for monitoring the activity of rat osteoblasts. In bone resorption assay, primary rat osteoclasts as well as human PBMC-derived osteoclasts released detectable osteocalcin into medium. The amount of osteocalcin was increased in the presence of stimulators of resorption, e.g. PTH, and was decreased in the presence of inhibitors of resorption, e.g. bafilomycin A1 and a cysteine protease inhibitor E64. Osteocalcin level in the medium correlated with the concentration of well-characterized marker of bone resorption, C-terminal telopeptide of type I collagen (CTx), with r-value > 0.9. Several molecular forms of osteocalcin, including intact molecule, were identified in both osteoblast and osteoclast cultures. We conclude that detectable osteocalcin is released from bone matrix during bone resorption as well as it is synthesized by osteoblasts during bone formation. In addition to its conventional use as a marker of bone formation, osteocalcin could also be used as an index of bone resorption in rodent osteoclast and human PBMC-derived osteoclast cultures.

M049

Enhancement of Fibronectin- and Vitronectin-Adsorption to Polymer/ Hydroxyapatite Scaffolds Suppresses the Apoptosis of Osteoblasts. K. M. Woo*, G. Wei*, P. X. Ma*. Biologic & Materials Sciences, University of Michigan, Ann Arbor, MI, USA.

Bone fractures and damage are serious health problems, which result in about 450,000 surgical bone grafts every year in the United States alone. Bone tissue engineering is a promising new approach to replace damaged bones. In this approach, a scaffold (artificial extracelluar matrix) plays a pivotal role. The scaffold is a substrate for cells to attach to, serves as a template for tissue regeneration, and should finally be replaced by the cell-produced extracellular matrix. Bone is a specialized connective tissue for the mechanical support of the body, the protection of vital organs and reservoirs of several ions including calcium. To pursue these functions, bone has high rigidity and strength and is continually remodeled by the cells within it. Thus, an ideal scaffold for bone tissue engineering has mechanical strength, is biodegradable and serves as a three dimensional guide for cell growth and new bone formation. We developed highly porous biodegradable poly(lactic acid)/hydroxyapatite (PLLA/HAP) scaffolds, under the hypothesis that bone-mineral mimicking synthetic HAP could improve the mechanical strength and impart osteoconductivity to PLLA scaffolds. *In vitro* culture showed that better bone nodule formation in the PLLA/HAP scaffolds than in the PLLA scaffolds. We investigated the events leading to this feature and the underlying mechanism. Fifty percent of initially attached cells on the PLLA scaffolds were detached and showed apoptotic cell death within 24 h, while most cells on the PLLA/HAP scaffolds remained. To understand its underlying mechanisms, we examined the protein adsorption onto the scaffold materials. The PLLA/HAP scaffold adsorbed 40% higher and a different profile of serum proteins than the PLLA scaffold did. Serum fibronectin and vitronectin adsorbed with greater affinity to the PLLA/HAP scaffolds, and the pretreatment of the scaffolds with fibronectin and vitronectin increased the cell survival. These results indicate that our highly porous biodegradable PLLA/HAP scaffolds suppress the apoptotic cell death, and suggest that the enhancement of protein adsorption including fibronectin and vitronectin from serum plays an important role.

Uptake and Metabolism of the Cyclin-Dependent Kinase Inhibitor Flavopiridol in Cultured Mouse Osteoblasts: Implications on Therapy. O. Hoffmann[1], B. Hagenauer*[2], P. Haslmayer*[2], T. Thalhammer*[3], W. Jäger*[2]. [1]Pharmacology and Toxicology, University of Vienna, Vienna, Austria, [2]Pharmaceutical Chemistry, University of Vienna, Vienna, Austria, [3]Pathophysiology, University of Vienna, Vienna, Austria.

Flavopiridol (FP) is a novel cyclin-dependent kinase inhibitor currently undergoing clinical development for the treatment of cancer. In combination with doxorubicin it showed pronounced cytotoxicity against SaOs-2 human sarcoma cells lacking a functional retinoblastoma protein and it has been suggested that it would be a useful adjunct therapeutic agent. Although it is known that FP is extensively metabolized by UTP-glucuronosyltransferase (UGT1A9) to the 7-O-ß-glucopyranuronosyl-conjugate (FP-glu) in human liver, its metabolism in other tissues is still unknown. In particular, we focused on whether FP is metabolised in bone, where it might potentially inhibit bone metastatic lesions. Our strategy was to test FP effect, metabolism and transport in osteoblasts (OB). We observed that FP inhibited cellular growth of mouse calvarial OB cultured in αMEM+10% FBS, for 24h (IC50: 0.98µM). In addition, cellular uptake of FP was linear for up to 2h leading to the formation of FP-glu (K_M: 14.9±4.9µM; V_{max}: 0.29±0.036pmol/mg protein), which was rapidly excreted into the medium (K_M: 2.2µM; V_{max}: 2.8±0.36pmol/mg protein) indicating an active transport mechanism. To determine which transporter plays a role in OB, we tested genistein and verapamil, inhibitors of active transport by multi-drug resistance proteins (MRP) and P-glycoprotein (PgP), respectively. We found that 200µM genistein, but not verapamil significantly inhibited efflux by 39.1% and UGT1A9-mediated formation of FP-glu by 86.8%. Furthermore, genistein decreased uptake of FP by 51.4%, indicating that FP and FP-glu are substrates of MRPs rather than of PgPs. To confirm that FP and FP-glu are substrates of MRP1, we analyzed western blots of 5 x 10^6 cultured and FP treated OB and observed strong expression of MRP1 indicating that they are partial substrates of this transporter. These data demonstrate that FP undergoes slow extrahepatic glucuronidation in mouse OB and it diminishes OB proliferation, which may be particularly useful in the treatment of patients with cancers that induce sclerotic bone metastases.

M051

Differential Effects of Amino- and Non-Amino-Bisphosphonates on MMP-9 mRNA and Enzyme Protein Levels: Relevance for Soft and Hard Tissue Metastasis. J. Mandelin[1], H. Valleala*[2], R. Hanemaaijer*[3], S. Santavirta*[4], Y. T. Konttinen*[5]. [1]Institute of Biomedicine, University of Helsinki, Finland, [2]Department of Medicine, Helsinki University Hospital, Finland, [3]Gaubius Laboratory TNO-PG, Leiden, Netherlands, [4]Department of Orthopedics and Traumatology, Helsinki University Hospital, Finland, [5]Institute of Dentistry, University of Helsinki, Finland.

Bisphosphonates (BP) that closely resemble pyrophosphate, like the non-amino BP clodronate, are metabolically converted to nonhydrolysable analogues of ATP, which are able to inhibit ATP-dependent intracellular enzymes. In contrast, nitrogen-containing BPs (N-BP), like pamidronate, inhibit enzymes of the mevalonate pathway/ prevent the biosynthesis of isoprenoid compounds that are essential for the posttranslational modification of small GTPases. These two classes of BPs have differential effects on lipopolysaccharide (LPS)-stimulated, human monocyte-mediated cytokine synthesis and release. Furthermore, non-amino BP reduce skeletal metastasis in breast cancer, whereas N-BPs can increase the soft tissue metastasis. We therefore speculated that these two classes of BPs might have differential effects of MMP-9 production and secretion. ELISA measurements showed that MMP-9 concentrations in non- and LPS-stimulated monocyte culture supernatants at 24 hours were 14 ± 10 and 51 ± 44 ng x ml^{-1}, respectively. Pretreatment for 20-24 hours with clodronate suppressed LPS-stimulated MMP-9 secretion in a dose-dependent manner: inhibition at 30, 100, 300 and 1000 µM was 27 ± 20, 36 ± 11, 62 ± 12 and 87 ± 11, with p-values 0.078, 0.007, 0.002 and 0.0005, respectively. In contrast, N-BP pamidronate had a dual mode of action so that low 30 µM concentrations enhanced MMP-9 secretion to 146 ± 49%. Quantitative RT-PCR confirmed and extended these findings. MMP-9 mRNA levels were stable at various concentrations of clodronate, but again, N-BP had a dual mode of action: low 30 µM concentrations increased the MMP-9 mRNA levels almost 15-fold.Our findings demonstrate that bisphosphonates have a differential action on LPS-stimulated, human monocyte-mediated MMP-9 synthesis and secretion. Non-amino BP clodronate does not affect the MMP-9 mRNA levels, but inhibits MMP-9 synthesis and/or secretion at a post-transcriptional level in a dose-dependent manner. In contrast, N-BP pamidronate has a dual mode of action so that it enhances MMP-9 mRNA and enzyme protein levels at low doses. These findings may in part explain the differential clinical results on soft and hard tissue metastasis obtained with these two classes of BPs in experimental and clinical studies.

A Possible Functional Role of Cadherins to Prevent Osteosarcoma Metastasis. T. Kashima[1], K. Nakamura*[2], J. Kawaguchi*[3], A. Kudo[3], A. E. Grigoriadis[4]. [1]Department of Craniofacial Development, Guy's Hospital, King's College London, London, United Kingdom, [2]Department of Human Pathology, Graduate School of Medicine, University of Tokyo, Tokyo, Japan, [3]Department of Life Science, Tokyo Institute of Technology, Yokohama, Japan, [4]Department of Craniofacial development, Guy's hospital, King's college London, London, United Kingdom.

Osteosarcoma is characterized by aggressive pulmonary metastasis. However, the underlying molecular mechanisms of metastasis in osteosarcoma are still unclear. We have previously shown that N-cadherin (N-cad) and OB-cadherin/cadherin-11 (cad-11) are highly expressed in normal osteoblasts, but are anomalously expressed in human osteosarcomas. In this study, we examined the role of cadherins in osteosarcoma metastasis using an in vivo metastasis model of the mouse osteosarcoma cell line, Dunn, and its highly metastatic subline, LM8. RT-PCR and Western blot analyses demonstrated that Dunn and LM8 cells do not express appreciable levels of several members of the cadherin family, including N-cad and cad-11. We therefore introduced N-cad and cad-11 into LM8 cells and isolated stable subclones for further functional analyses. Immunoprecipitation assays demonstrated that all cadherin-overexpressing clones formed complexes with beta-catenin, whereas control transfectants did not. Overexpression of N-cad or cad-11 in LM8 cells resulted in an inhibitory effect on cell migration, using an in vitro migration assay on uncoated membranes. To clarify the role of N-cad and cad-11 in osteosarcoma metastasis in vivo, we inoculated overexpressing clones subcutaneously into C3H mice. After four weeks, analysis of the lung tissues revealed a reduced total lung weight in mice harboring cadherin-overexpressing cells. In addition, the number of lung metastases were also significantly reduced in all N-cad and one cad-11 transfectants. Measurement of the weight and volume of the primary tumors at the injection site demonstrated an overall inhibition of weight and size of tumors induced by N-cad- and cad-11-overexpressing cells as compared to mock-transfected cells. Western blot analysis of the primary tumors confirmed the expression of the transfected genes. Finally, we have begun to analyze the role of cadherins in osteosarcoma using transgenic mice overexpressing the c-fos proto-oncogene which develop osteosarcomas but do not form any lung metastases. Preliminary expression studies using Northern blot, in situ hybridization and immunohistochemistry analyses revealed that these tumors express both N-cad and cad-11, which is consistent with their inability to metastasize. Taken together, these observations suggest that the absence of N-cad and cad-11 function, i.e. cell-cell adhesion, is important in osteosarcoma metastasis.

NF-κB Over-expression Protects Growth Plate Chondrocytes from Ionizing Radiation-induced Apoptosis. M. J. D'Souza*[1], M. J. Zuscik[1], R. A. Eliseev*[2], T. E. Gunter*[2], E. M. Schwarz[1], J. E. Puzas[1], R. J. O'Keefe[1], R. N. Rosier[1]. [1]Orthopaedics, University of Rochester, Rochester, NY, USA, [2]Biochemistry and Biophysics, University of Rochester, Rochester, NY, USA.

The use of ionizing radiation as a modality to treat pediatric skeletal carcinomas is known to inhibit bone growth via damage to growth plate chondrocytes (GPCs). This is in contrast to articular chondrocytes (ACs), which display resistance to radiation damage via unknown molecular mechanisms. The purpose of this study was to identify these protective mechanisms/pathways in ACs and to determine if their activation in GPCs can confer radiation resistance. Since there is significant evidence suggesting that the transcription factor NF-κB acts in response to cell stress by suppressing the apoptotic program, we hypothesized that differential activity of this pathway in ACs and GPCs is responsible for the difference in radiation sensitivity of these cell models. To test this hypothesis, initial experiments were performed to compare the amount of basal NF-κB DNA binding and the amount of basal activation of an NF-κB responsive promoter/luciferase reporter (NF-κB-luc) in cultured chick GPCs and ACs. Supporting our hypothesis, gel shift assays using an NF-κB consensus oligo showed that nuclear extracts from ACs possessed 7-fold higher basal NF-κB DNA binding compared to GPCs. Furthermore, using cells transiently transfected with NF-κB-luc, basal promoter function was found to be 100-fold greater in ACs than in GPCs. Since basal NF-κB DNA binding/activation was found to be greater in ACs than in GPCs, we further tested our hypothesis by measuring the effect of ionizing radiation i) on activation of NF-κB-luc in ACs and GPCs, and ii) on activation of apoptosis in GPCs transiently transfected with p65 or the chicken homolog of NF-κB, c-rel. Suggesting that NF-κB was activated post-irradiation in ACs, a 3-fold stimulation of NF-κB-luc was detected following a 10 gray exposure. Conversely, activation of the reporter in GPCs was unaffected by this dose. Furthermore, the robust 15-fold induction of apoptosis by radiation in GPCs, as measured by caspase 3 activity, was reversed by transient transfection of the cells with either p65 or c-rel. This was compared to ACs which did not show caspase 3 activation following radiation, hypothetically due to their robust endogenous NF-κB activity. Collectively, these findings suggest that NF-κB signaling is a key radiation protective signal in ACs that can confer protection to GPCs in p65 and c-rel over-expressing models. We predict that future prophylactic strategies to avoid radiation-induced damage in the growth plate may involve activation of NF-κB signaling prior to radiation therapy.

Myeloma and Lytic Bone Disease: Interdependence of Tumor Growth and Osteoclast Activity. S. Yaccoby*, F. Zhan*, J. Shaughnessy*, B. Barlogie, J. Epstein*. Myeloma Institute for Research and Therapy, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Multiple myeloma is an incurable B cell neoplasia characterized by accumulation of monoclonal plasma cells. Myeloma tumor growth is restricted to the bone marrow, except in the most advanced stages of plasma cell leukemia. Myeloma growth is associated with severe osteolytic bone disease. We have established *in vivo* and *ex vivo* systems to study the reciprocal relationship between myeloma-induced osteoclastogenesis and tumor growth. *In vivo*, we have exploited the SCID-hu model, in which primary human myeloma cells grow exclusively in and interact with a human microenvironment (*Blood 92:2908, 1998; Blood 94:3576, 1999*), to demonstrate that in medullary, but not in extramedullary disease, survival and growth of myeloma cells depend on osteoclast activity (*BJH 116:278, 2002*). *Ex vivo,* purified myeloma cell-conditioned media from 12 patients increased migration of osteoclast precursors across a 5 μM pore size membrane 1.6-4.2 fold (p=0.001). In cocultures, myeloma cells increased 1.5-10.5 fold from 76±12 in control assays (p=0.002) the differentiation of osteoclast progenitors into mature, multinucleated, bone-resorbing osteoclasts in a stromal cell-free environment, via a RANKL-mediated mechanism. Mature osteoclasts reciprocated by maintaining the viability and proliferative activity of purified myeloma cells, determined by annexin V flow cytometry, BrdU labeling index, and [^{3}H]TdR incorporation, for as long as 50 days. In contrast, control cells cultured alone died rapidly. Quantitative oligonucleotide microarray analyses interrogating 12,000 genes showed ≥ 2 fold baseline changes in the expression of 95 common genes in myeloma cells recovered from 12 independent co-cultures. Similarly, 24 genes were changed in 10 osteoclast samples. Genes with altered expressions in the myeloma cells include oncogenes, chemokines, growth factors, and adhesion molecules, involved in tumor growth, metastases, osteoclastogenesis, and angiogenesis. Osteoclasts from myeloma patients and healthy donors yielded similar results. On hierarchical clustering with 150 myeloma patients, co-cultured myeloma cells fell into two distinct, medullary and extramedullary disease, clusters. The myeloma cell-osteoclast co-culture system that we have developed provides the opportunity to identify genes essential for myeloma cell survival, growth, and bone manifestations. These myeloma cell-osteoclast interactions and the genes involved could identify targets for novel therapeutic approaches for this devastating disease.

Immunofluorescence Co-localization Suggests a Shift in Complex from RANKL:OPG to RANKL:RANK During Osteosarcoma Tumorigenesis. A. M. Deshpande*[1], P. Bhatia[1], D. G. Ammerman*[1], T. Johnson-Pais*[2], D. M. Anderson*[3], K. K. Unni*[4], P. A. Meyers*[5], R. G. Gorlick*[5], R. J. Leach[6], M. F. Hansen[1]. [1]Center for Molecular Medicine, Univ. Connecticut Health Center, Farmington, CT, USA, [2]Dept. Pediatrics, Univ. Texas Health Science Center, San Antonio, TX, USA, [3]Immunex Corp., Seattle, WA, USA, [4]Dept. Pathology, Mayo Clinic, Rochester, MN, USA, [5]Dept. Pediatrics, Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [6]Dept. Cellular & Structural Biology, Univ. Texas Health Science Center, San Antonio, TX, USA.

Receptor activator of NFkB (RANK) and its associated ligand, RANKL, together with Osteoprotegerin (OPG) have been shown to be critical regulators of the bone remodeling process. OPG binds RANKL in normal resting cells/tissues to inhibit activation of RANK and subsequently its downstream pathways. Published data from cultured osteoblasts has shown that, during normal proliferation, the majority of RANKL is bound to OPG. RANK has also found to be expressed in normal osteoblasts at low, but detectable, levels. Previous studies have suggested that a RANK:RANKL interaction may have a stimulatory effect on osteoblasts. We were interested in determining if the normal pattern of RANKL:OPG interaction was altered during osteosarcoma tumorigenesis. Analysis of 49 primary osteosarcoma tumors and 4 tumor cell lines showed an increased expression of RANK while protein levels of RANKL and OPG remained comparable to those seen in the normal osteoblasts. Analysis of co-localization in the tumors showed an increase in co-localization of RANKL and RANK and a decrease in co-localization of RANKL and OPG consistent with a shift in complex formation from RANKL:OPG to RANKL:RANK. This shift in binding to the RANKL:RANK complex, within the tumor cell, has the potential to stimulate cell growth through an autocrine mechanism and may contribute to tumorigenic growth.

The Roles of Integrin $\alpha_v\beta_3$ and Osteopontin in Tumorigenicity of Human Melanoma Cells. M. A. Chellaiah[1], J. Strauss-Schoenberger*[2], K. A. Hruska[2]. [1]Department of OCBS, University of Maryland, Baltimore, MD, USA, [2]Department of Pediatrics, Washington University, School of Medicine, St Louis, MO, USA.

The M21-L cell line is a melanoma cell lacking expression of α_v and thus the $\alpha_v\beta_3$ integrin. We have used this cell line to define the role of α_v in protein association with the $\alpha_v\beta_3$ integrin. M21 cells were generated by overexpressing α_v cDNA in the M21-L cell line. We have reported that generation of cells lacking the α_v cytoplasmic domain (M21-L α_v1-995) resulted in the loss of $pp^{60c\text{-}src}$ association with the integrin, and failure of OPN activation of $pp^{60c\text{-}src}$ kinase. To further investigate the role of the α_v cytoplasmic domain in the integrin interaction with signaling proteins, three synthetic peptides corresponding to the cytoplasmic domain of α_v were constructed: α_v1- 986 to 994; α_v2-995 to 1003; α_v3-1004-1018. Peptides against the β_3 and β_1 cytoplasmic domains were used as controls. Peptides coupled to thiopropyl-sepharose beads were reacted with cell lysates made from

the various M21 cell lines. Proteins bound to the peptides were analyzed by Western analysis. The β-turn peptide of α_v corresponding to amino acids 995-1003 (α_v2) bound to several signaling and cytoskeletal proteins including: talin, paxillin, FAK, pp$^{60c\text{-}src}$, p130 cas and a few uncharacterized proteins. α_v1 and α_v3 did not exhibit lysate protein binding. Because osteopontin (OPN) expression has been implicated in the metastaic potential of melanoma and other tumors, a cDNA encoding full length human OPN was transfected into M21 cells (M21/HOPN). Lysates of these cells exhibited significant differences in the binding pattern of phosphoproteins with the cytoplasmic domain α_v2 peptide compared to M21 cell lysates. Thus, overexpression of an autocrine ligand of $\alpha_v\beta_3$ affected complex formation with the integrin and the signaling mechanisms activated. We then analyzed the impact of altered signaling on the tumorigenic potential of the M21 cell lines by subcutaneous injection of M21-L, M21, and M21/OPN cells. An increase in tumor size was observed in M21 cells as compared to M21-L and M21/OPN cells. The decrease in tumor growth when M21/OPN were injected indicates that the tumorigenic potential of $\alpha_v\beta_3$ is suppressed by over expression of OPN. The M21/OPN cells exhibited increased proliferation rates, cell adhesion, and motility *in vitro*, contrasting with the tumorigenicity data. We conclude that OPN is a unique ligand for $\alpha_v\beta_3$, and that its integrin activation potential produced differential signaling and diminished tumorgenicity in the nude mouse subcutaneous injection model.

Serum Levels of N-Terminal Propetide of Procollagen Type 1 (P1NP) in Patients with Multiple Myeloma or MGUS. K. Brenner*[1], J. Schuster*[1], A. Keck*[1], N. Hoyle*[2], R. Kyle*[3], H. Ludwig*[1], M. Pecherstorfer[1]. [1]I. Department of Medicine and Medical Oncology, Wilhelminenspital, Vienna, Austria, [2]Roche Diagnostics, Penzberg, Germany, [3]Department of Hematology and Internal Medicine, Mayo Clinic, Rochester, MN, USA.

Aim of the present study: To evaluate whether serum concentrations of P1NP differ between patients with multiple myeloma (MM) and those with monoclonal gammopathy of undetermined significance (MGUS). Patients and methods: 132 patients with newly diagnosed and untreated MM, and 111 patients with MGUS were included in the investigation. 38 individuals of the MGUS collective initially presented with MGUS but transformed into overt MM. 35 MGUS patients had had stable disease for at least two years, and a further 38 MGUS patients for at least 10 years. The median age of the population was 65 years and did not differ between the MM patients and the three groups of MGUS patients. P1NP was measured with an electrochemiluminescence immunoassay (Elecsys P1NP, Roche Diagnostics, Penzberg, Germany). Results: The median P1NP serum concentration was significantly higher in patients with MM (64.2 µg/L) than in patients with MGUS stable for 2 years (44.8 µg/L), stable for 10 years (50.4 µg/L) or in patients with initial MGUS later converting to MM (52.5 µg/L) (p< 0.0001). The three groups of MGUS patients did not differ with regard to P1NP levels. In MGUS patients whose disease converted to MM, the initial P1NP level (MGUS state) was a median 52.54 µg/L and, after disease progression (MM state), was 61.5 µg/L (p= 0.0575). Stratification of MM patients according to skeletal status (radiographic evidence of osteoporosis-like changes, lytic lesions, or normal radiographs) showed no differences in P1NP serum concentrations. P1NP did not correlate with age, ß2-microglobulin, the amount of monoclonal protein or serum creatinine levels. At a cut-off level of 64 µg/L, the sensitivity of P1NP in identifying MM was 50%, the specificity in excluding MGUS was 74%. Conclusions: P1NP serum levels, which are regarded as markers of bone formation, are higher in MM patients than in those with MGUS. The progression of MGUS to MM appears to be accompanied by an increase in PINP levels, which would reflect the enhanced bone turnover in this neoplastic disease. Due to the marked overlap of P1NP levels in patients with MGUS and with MM, this marker cannot be used to differentiate between the two plasma cell dyscrasias.

M058

p38 MAP Kinase Is Required For Bone Metastasis, But Not Locally Aggressive Growth, In A Mouse Model of Metastatic Breast Cancer. C. Suarez Cuervo*[1], K. W. Harris*[1], L. Kallman*[1], K. Väänänen[2], K. Selander*[1]. [1]Medicine, UAB, Birmingham, AL, USA, [2]Anatomy, University of Turku, Turku, Finland.

p38 belongs to the family of mitogen-activated protein kinases (MAPKs). p38 is frequently expressed in breast cancer. It is also abundantly expressed in the highly invasive MDA-MB-231 human breast cancer cells, where its activation was shown to be associated with vitronectin-induced urokinase plasminogen activator (uPA) production. This suggested to us that p38 may be important in bone metastasis. To test this hypothesis, we created MDA-MB-231 clones stably expressing dominant negative p38 (p38/AF clones). Unlike the control clones, the p38/AF clones did not up-regulate uPA when cultured on vitronectin. Basal and cytokine-induced levels of interleukin-6 and interleukin-11 were similar in control and p38/AF clones, as measured by ELISA-assays. We have previously shown that the local growth of the p38/AF clone exceeded that of the control clone in an orthotopic mouse model of breast cancer.To test the bone metastasis capacity of the p38/AF clones, a mouse model of breast cancer bone metastasis was utilized. Mice were inoculated with the p38/AF and control clones and bone metastases were allowed to form for 28 days. Histomorphometric analysis of the metastatic tumor area in the long bones of mice revealed that there were significantly less bone metastases in the mice that were inoculated with the p38/AF expressing cells (2.15 +/- 1.2 mm2, mean +/- sem, n=9, p<0.05), as compared to controls (11.9 +/- 2.9 mm2, n=10). In conclusion, expression of dominant negative p38 stimulated the locally aggressive growth of breast cancer in the orthotopic model. In contrast, p38 function was required for bone metastasis. Decreased bone metastasis was not mediated by a decrease in IL-6 or IL-11 production in the p38/AF clone, but may be related to decreased uPA production of these cells in the bone microenvironment.

M059

Opposing Effects of Osteoprotegerin on Bone Metastases: Activation of TGFβ Signaling in Breast Cancer Cells versus Inhibition of Osteolysis. S. M. Kakonen[1], T. Oba[2], B. G. Grubbs*[1], X. Sun[2], R. Sypniewska*[1], S. Burns*[2], T. A. Guise[1], J. M. Chirgwin[2]. [1]Molec Med, Univ Tx Hlth Sci Ctr, San Antonio, TX, USA, [2]Molec Med, Univ Tx Hlth Sci Ctr and VA Research Service, San Antonio, TX, USA.

Osteoprotegerin (Opg) is a secreted member of the TNF receptor gene family. It inhibits bone resorption by neutralizing RANK ligand but also protects tumor cells from apoptosis by neutralizing TRAIL. Previously we expressed full-length mouse Opg in the RANK ligand-negative MDA-MB-231 human breast cancer line, which causes osteolytic metastases, and tested 3 stable clones in an animal model. Clones expressing 24 or 60ng/ml Opg/10^5 cells/48h conferred a 25% survival advantage, compared to nude mice receiving cells expressing 0 or 150ng/ml Opg, by intracardiac inoculation. Opg was secreted by the cells throughout the animal experiment and effectively inhibited osteoclast formation since bone sections adjacent to Opg+ tumors showed significantly decreased [~4X] osteoclast number per mm of tumor-bone interface. Although Opg expression did not affect the growth rate of MDA-MB-231 cells in vitro, the majority of mice inoculated into the mammary fat pad with Opg+ cells (2x10^6) failed to develop tumors, compared to mice receiving empty vector (EV) control cells. The weak effects of Opg to decrease osteolytic metastases and the puzzling effects on growth in the mammary fat pad suggested that Opg may have autocrine regulatory effects on the tumor cells. We tested the effects of TGFβ on Opg+ clones since this factor plays a central role in the regulation of osteolytic metastases. Opg-expressing cell lines, but not controls, were growth inhibited 50% by TGFβ1. Conditioned media were assayed for concentrations of osteolytic factors. PTHrP was increased 3-5 fold both basally and in response to TGFβ in the 3 Opg+ clones compared to EV (p<0.001). The Opg+ clones showed significantly increased TGFβ induction of interleukin (IL)-11 (15-19X; p<0.001), while induction in EV controls was 4X. Compared to EV cells, the Opg+ clones basally secreted 5-10X more vascular endothelial growth factor, and up to 25ng/ml in response to TGFβ. In EV cells IL-6 was <30pg/ml and unresponsive to TGFβ. Basal and TGFβ-induced IL-6 (1.3-2.4X; p<0.01) were substantially increased in the Opg+ clones, reaching 200pg/ml. In summary, osteoprotegerin could promote breast cancer metastases to bone by sensitizing tumor cells to TGFβ, while at the same time opposing bone metastases by inhibiting RANK ligand-stimulated osteolysis. Enhancement by Opg of TGFβ signaling in breast cancer cells suggests that tumor cells may express an unknown receptor for Opg.

M060

Breast Cancer Cell Lines Selected from Bone Metastases Have Greater Metastatic Capacity and Express Increased Vascular Endothelial Growth Factor (VEGF), Interleukin-11 (IL-11), and Parathyroid Hormone-related Protein (PTHrP). S. M. Kakonen[1], Y. Kang*[2], M. R. Carreon*[1], M. Niewolna*[1], R. S. Kakonen*[3], J. M. Chirgwin[1], J. Massague*[2], T. A. Guise[1]. [1]Molec Med, Univ TX Hlth Sci Ctr, San Antonio, TX, USA, [2]Memorial Sloan-Kettering, New York, NY, USA, [3]IDD/CTRC, San Antonio, TX, USA.

Breast cancer frequently metastasizes to bone. Since PTHrP-neutralizing antibodies decrease but do not eliminate bone metastases it is likely that factors in addition to PTHrP contribute to the osteolysis. Possible factors include IL-11 and VEGF, since these stimulate osteoclastic bone resorption and, like PTHrP, their expression in MDA-MB-231 breast cancer cells is increased by TGFβ. We established multiple cell lines that have increased potential to metastasize to bone in a mouse model. We started with a variant of the MDA-MB-231 breast cancer line which had low capacity to cause bone metastases; only 1 of 10 nude mice inoculated into the left cardiac ventricle developed bone metastases over 12 weeks. We harvested bone metastases, established cell lines in culture and repassaged them by inoculation into the left cardiac ventricle of nude mice. We established cell lines from first, second and third passage bone metastases: 7 cell lines were identified which caused more bone metastases sooner than did the parental MDA-MB-231. The capacity of the cell lines to cause increased bone metastases was not due to an increased proliferation since growth at the mammary fat pad was not greater than that caused by parental MDA-MB-231. The production of osteolytic factors PTHrP, IL-11, and VEGF by the cell lines was determined in 48-hour conditioned media ±TGFβ by immunoassay. Basal PTHrP production was significantly increased in a majority of bone metastasis cell lines. The parental MDA-231 cells did not produce IL-11, but the cell lines extracted from bone metastases produced 40-240pg/ml/10^5 cells of IL-11. The lines also produced 2-4-fold more VEGF. TGFβ-induced PTHrP, IL-11 and VEGF were also higher in bone metastases cell lines, but the ratio TGFβ-induced to basal was similar to parental cells. In summary, cell lines extracted from bone metastases express higher levels of TGFβ-responsive osteolytic factors, IL-11, VEGF, and PTHrP, compared to the low-metastatic parental MDA-MB-231. Although the responsiveness to TGFβ is unchanged, the increased expression of these factors suggest that VEGF and IL-11, in addition to PTHrP, stimulate osteolytic bone metastases. TGFβ released as a consequence of bone resorption plays a central role in breast cancer metastases to bone. The data suggest that formation of metastases may involve selection in bone of tumor cells that have increased expression of TGFβ-responsive osteolytic genes.

M061

Three-dimensional Analysis of Trabecular Bone using Synchrotron Radiation Micro-CT in Bone Metastasis from Prostate Cancer. T. Sone[1], T. Tamada*[2], M. Fukunaga[1]. [1]Nuclear Medicine, Kawasaki Medical School, Kurashiki, Japan, [2]Radiology, Kawasaki Medical School, Kurashiki, Japan.

Prostate cancer frequently metastasizes to bone inducing osteosclerotic lesions. However, morphological details of bone metastasis of prostate cancer have not been clarified. The objective of this experiment was to investigate trabecular bone structure and degree of calcification in bone metastasis from prostate cancer using Synchrotron Radiation microcomputed tomography. Small cubes of lumbar vertebrae were excised post mortem, from the sites of metastasis, degenerative osteosclerosis, and the comparative sites of control subjects without skeletal lesion. Three dimensional imaging was performed by taking two dimensional radiographs as the specimens were rotated through 180' in 0.5' increments. The energy was set to 20KeV. The radiographs were reconstructed one slice at a time using a standard Fourier-filtered back projection algorithm. Each reconstructed slice was then stacked, providing data for 750^3 3D images with an isometric voxel size of 6 microns. The 3D images were segmented into bone and marrow fractions, and purified using a cluster labeling algorithm. The trabecular bone was then analyzed for mineral density and morphological parameters. Trabecular bone in metastatic lesions showed highly connected and isotropic network pattern compared with the control cancellous bone. Although the trabecular surface was markedly irregular, the mean trabecular thickness was similar to the control trabeculae. The mineral density of trabeculae in metastatic lesions ranged broader and its mean value was lower than the control. In contrast, trabecular bone in the degenerative sclerotic lesions showed the similar degree of anisotropy and connectivity compared with the control, whereas the trabecular thickness was increased. The mean mineral density shifted toward the higher value concomitantly with an increase of the lowest level of mineral density. The variations of these parameters would make it possible to distinguish significant characteristics, which are useful for understanding the pathophysiology of sclerotic metastasis of bone metastasis.

M062

Parathyroid Hormone Related Protein Neutralization Enhances All-transretonic Acid Induced Apoptosis in Prostate Cancer Cells. F. Asadi*[1], W. Zheng*[1], T. Rosol[2], S. C. Kukreja[1]. [1]Medicine, VA West Side Medical Center, Chicago, IL, USA, [2]Veterinary Pathobiology, Ohio State, Columbus, OH, USA.

In the advanced stages of prostate cancer, the tumor cells become androgen-unresponsive and resist apoptosis. The factors responsible for the increased cell survival in the androgen-resistant state are not known. We have previously demonstrated that PTHrp level is higher in androgen-unresponsive prostate cancer cells (C4-2 LnCaP) as compared to that in androgen-responsive prostate parent LnCaP cell line. In addition we demonstrated that treatment of these cells with PTHrP (1-34) prevented All-trans retinoic acid (tRA)-induced cell death and therefore it is possible that PTHrP contributes, at least partially, to the increased cell survival in the androgen-unresponsive cells. In the present studies, we examined the effects of PTHrP (1-36) neutralization on tRA-induced apoptosis and cell survival in three prostate cancer cell lines. The three cells lines we examined were: 1) androgen-responsive LnCaP-parent, 2) androgen-unresponsive subline C4-2 and 3) androgen- unresponsive and bone metastatic subline C4-2b. Cell survival was assessed by trypan blue exclusion and MTS proliferation assays. Cell apoptosis was examined by TUNEL assay. Baseline cell apoptosis was greater in the LnCaP cells as compared to that in the other two cell lines. Treatment with tRA 5uM resulted in a decrease in cell survival and an increase in apoptosis in all three cell lines. As previously demonstrated PTHrP (1-34) treatment protected against this tRA-induced apoptosis. Addition of PTHrP 1-36 antibodies resulted in a decrease in cell survival under basal conditions. Addition of PTHrP antibodies to the tRA-treated cells further reduced cell survival and increased apoptosis in all three cell lines.

Percent Apoptotic Cells

	LnCaP	C4-2	C4-2b

tRA+PTHrP Ab	88	76	81

FBS=Fetal Bovine Serum; Cont=Control; Ab=antibody

The studies demonstrate that endogenous PTHrP plays a role in increasing cell survival and inhibition of apoptosis and may be one of the factors involved in increased cell survival in androgen-resistant prostate cancer cells.

Radial Shaft Bone Density and Risk of Breast Cancer in White and African-American Women. D. A. Nelson[1], L. Darga*[1], R. K. Severson*[2]. [1]Internal Medicine, Wayne State University, Detroit, MI, USA, [2]Epidemiology, Karmanos Cancer Institute, Detroit, MI, USA.

We measured forearm bone mineral density (BMD) in 220 newly diagnosed breast cancer cases and 196 controls, ages 39-84 (mean = 56.3 + 10.8 years), 50.3% of whom were white and 49.7% African-American. BMD was measured by Norland pDEXA in the distal radius and the radial shaft. Z-scores (age, sex, and ethnicity specific) were calculated using the manufacturer's reference data. There was a significant difference in the radial shaft z-scores for breast cancer cases versus controls (0.45 +1.07 s.d. vs 0.19 + 1.08 s.d., p =0.015), but no significant group difference in the distal forearm (p=0.83). There were no significant ethnic differences in mean z-scores within the cases or controls. We investigated whether having above average radial shaft BMD (z-score > 0) was a significant predictor of breast cancer risk. Using logistic regression analysis with the z-score dichotomized as <=0 or >0, we found that the odds ratio for breast cancer is 1.98 for z-scores >0 (95% C.I. 1.32-2.97). We also evaluated the radial shaft z-score as a continuous variable in a logistic regression model, and the odds ratio for breast cancer associated with a one s.d. increase was 1.25 (95% C.I. 1.04-1.51). We also assessed the potential effect modification and confounding effects of menopause status, age group, body mass index, ever/never use of HRT, and duration of HRT. There were no significant interactions and no appreciable confounding effects of these variables on the relationship between BMD and breast cancer risk. We conclude that an above average radial shaft z-score is a significant risk for breast cancer in white and African-American women. The pDEXA method of BMD measurement is inexpensive, noninvasive, and portable, and can therefore be readily utilized in a clinical setting, with other risk factors, to evaluate breast cancer risk .

M064

Dihydrotestosterone (DHT) Induces Osteoprotegerin (OPG) Gene Expression in an Androgen Responsive Prostate Cancer Cell Line LNCaP. J. Zhang[1], Y. Lu*[2], X. Cao*[3], J. Dai[1], Z. Yao*[2], E. T. Keller[1]. [1]Pathology/ULAM, University of Michigan, Ann Arbor, MI, USA, [2]Department of Immunology, Tianjin Medical University, Tianjin, China, [3]Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Prostate cancers (CaP) are initially androgen dependent tumors that become androgen independent and metastasize to bone forming a mixture of osteoblastic and osteolytic lesions. CaP promotes the osteolytic component of metastases through receptor activator of NFkB ligand (RANKL). OPG is a soluble decoy receptor that inhibits RANKL activity. Accordingly, the goal of this study was to determine the regulation of OPG by androgens. We quantified OPG protein levels in cell culture supernatants using ELISA and OPG mRNA levels in cells using real time PCR of several CaP cell lines. The CaP cell lines included LNCaP (an androgen responsive cell line), C4-2B (an androgen non-responsive cell line derived from LNCaP cells), and PC-3 (an androgen non-responsive cell line). Both OPG protein and mRNA levels were greatest in PC-3, followed by C4-2B and least in LNCaP. Treatment of the LNCaP cells with DHT (0.1, 1, 10 and 100 nM) increased OPG protein and mRNA expression at 24 hours; whereas it had no effect in PC-3 and C4-2B cells. To determine if DHT increased OPG mRNA levels through induction of gene transcription, we transiently transfected LNCaP cells with the human OPG promoter (1.1 kb upstream of the 5' transcription initiation site) driving luciferase. DHT induced the promoter activity in a dose dependent manner (by 8 fold). To determine the cis-acting region on the OPG promoter through which DHT mediates its effect, we transiently transfected LNCaP cells with progressively-deleted OPG promoter-luciferase reporter constructs. Responsiveness to DHT was present with deletion of the promoter to -700; however, deletion of the fragment from -700 to -564 resulted in loss of all promoter activity. Taken together, these data demonstrate that DHT regulates OPG at the transcriptional levels. They also suggest that OPG expression is upregulated as CaP progresses and OPG may play an important role in pathophysiology of skeletal metastasis of CaP.

Extract from *Scutellaria baicalensis* Georgi (Huang Qin) Induces Prostate Cancer Cell Apoptosis and Diminishes the Tumor Growth in Murine Bone. Y. Lu*[1], Z. Yao*[1], Z. Zheng*[2], E. T. Keller[3], J. Dai[3], J. Zhang[3]. [1]Department of Immunology, Tianjin Medical University, Tianjin, China, [2]Department of Medicine, University of California-Irvine, Irvine, CA, USA, [3]Pathology/ULAM, University of Michigan, Ann Arbor, MI, USA.

Prostate cancer (CaP) frequently metastasizes to bone forming predominantly osteoblastic lesions with underlined osteolytic components. Because current therapies are generally ineffective in CaP skeletal metastases, patients seek alternative medicines such as herbal medicines, which have been used for many centuries in Asian countries. The purpose of this study was to identify Chinese herbal medicines that may be effective in CaP skeletal metastasis. We first screened 130 Chinese herbs (ethanol extracts) for anti-proliferation effects by non-radioactive cell proliferation assay in LNCaP and C4-2B CaP cells. (C4-2B cells, which form skeletal metastases, are derived from non-metastatic LNCaP cells). We found five extracts with anti-proliferation activity including extract from *Scutellaria baicalensis* Georgi (Huang Qin, HQ), which had the strongest effect. We next evaluated HQ's ability to induce apoptosis of LNCaP and C4-2B cells. HQ, in a dose-dependent manner, induced apoptosis of both cell lines based on DNA fragmentation and TUNEL assay. In addition, HQ induced apotosis-related gene caspase-3 and suppressed bcl-2 expressions in both cell lines. Therefore, we tested if HQ (1mg per mouse three times a week for 8 weeks intraperitoneally) could diminish establishment of skeletal metastases in mice. We injected C4-2B cells into tibia of SCID mice. The animals were randomized into two groups to receive either HQ or vehicle only (n=8/group). At 8 weeks post-tumor injection, mice were sacrificed and tumor establishment in the skeleton was determined using radiography, dual energy x-ray absorptiometry and histology. Radiographic and histological lesions were present in 7/8 vehicle-treated mice and in 6/8 HQ-treated mice. However, the radiographically- and histologically-determined areas of the tumors in the HQ-treated mice were approximately 47% that of the vehicle-treated animals. We conclude that HQ has efficacy for inducing CaP cells apoptosis in vitro and has the ability to diminish growth of CaP in murine bone.

Expression of RANK and RANKL Is Altered in Invasive Carcinoma and Bone Metastasis of Breast Cancer. P. Bhatia[1], M. Sanders*[2], M. F. Hansen*[1]. [1]Molecular Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]Pathology, University of Connecticut Health Center, Farmington, CT, USA.

Bone is the most common site of metastases by human breast cancer. Most breast cancers form osteolytic metastases, in contrast to tumors such as prostate cancer that form osteosclerotic metastases. Although some evidence suggests that formation of bone metastases by breast cancer cells is mediated by the increased osteoclastogenesis at the target site, a clear controversy exists whether formation of bone metastases is mediated by breast cancer cells directly or by stimulated osteoclasts. To test this we examined the expression of RANK and RANKL, two proteins critical to the bone remodeling signaling pathway, in invasive carcinoma of breast and bone metastases of breast. We observed increased expression of RANK and RANKL in the tumor cells from both the primary and metastatic lesions. Further, in the osteolytic metastases, breast tumor cells were seen directly in contact with the bone in the regions of osteolysis, without any osteoclasts in the vicinity. We suggest that overexpression of RANK and RANKL in breast cancer cells provides a growth advantage to the breast tumor cells, and the tumor cells appear to be directly responsible for the degradation of bone.

M067

Prevalence of Osteopenia and Osteoporosis by Central and Peripheral Bone Mineral Density in Men with Prostate Cancer during Androgen-Deprivation Therapy. J. M. Bruder, M. D. Welch*. Med/Endocrine, UTHSCSA, San Antonio, TX, USA.

Studies have shown that men with prostate cancer treated with androgen-deprivation therapy (ADT) have a lower bone mineral density (BMD) than age-matched controls. We and others have recently demonstrated a significant decrease in BMD after the first year of ADT. The loss of bone density, in some studies, was most pronounced in the radius. We wish to determine the prevalence of osteopenia and osteoporosis by central (spine and hip) and peripheral (radius) BMD in this group of men. We reviewed the charts of patients with prostate cancer seen in the Urology Tumor Clinic from 5/2001-9/2001 and identified 125 patients receiving ADT. Spine and hip BMD results were recorded in 89 patients. Fifty-four patients also had a BMD of the radius. In addition, 33 patients had serum concentrations of 25-hydroxyvitamin D (25-OHD), intact parathyroid hormone (iPTH), and 24-hour urine calcium and N-telopeptide (N-Tx) concentrations measured. The average age of the patients was 77 $\pm$ 7. The race included: 30.3% Hispanic, 58.4% Caucasian, and 9% African-American and 2.2% unknown. Twenty-four out of 89 patients with BMD determinations (26.9%) had osteoporosis of the hip or spine as determined by a T-score of <-2.5. Forty-five patients (50.6%) were designated as osteopenic (T score between -1.0 to -2.5) and 20 patients (22.5 %) were classified as normal. Forty-five of the 54 patients (83.3%) who also had a BMD of the radius measured were categorized as either osteopenia or osteoporosis. The results of the BMD of the radius changed the category of diagnosis (either from normal to osteopenia or osteopenia to osteoporosis) in 22 patients (40.7%). Furthermore, approximately half of the patients with the diagnosis of osteoporosis or osteopenia had an evaluation for secondary causes of osteoporosis. Three (8.8%) patients were classified as Vitamin D deficient with an absolute 25-OHD concentration less than or equal to 15 ng/ml. Fifteen patients (44.1%) had absolute 25-OHD concentration between 16 and 30 ng/ml and were considered insufficient in vitamin D. An elevated iPTH (>50 pg/ml) concentration was found in 11 patients (31.4%). In addition, urinary concentrations of N-Tx were elevated (>38) in 73.3%. The increase was most prevalent and pronounced in patients with osteoporosis (81.3%) compared to patients with osteopenia (64.3%). Men with prostate cancer treated with ADT show a high prevalence of osteopenia and osteoporosis by peripheral and central BMD measurements. The use of peripheral BMD appears to identify more patients with osteoporosis. This data suggest that the BMD of the radius should be obtained in men with prostate cancer receiving ADT in the evaluation of osteoporosis.

M068

The Involvement of LMP-1 in Prostate Cancer Metastasis to Bone. G. A. Hair*[1], L. Titus[2], S. D. Boden[1]. [1]Orthopaedics, Emory University, Atlanta, GA, USA, [2]Research, VA Medical Center, Decatur, GA, USA.

Bone metastases are a common complication in prostate cancer patients and can lead to extensive morbidity and increased mortality. Osteoblastic lesions are a common skeletal manifestation of neoplasia. Both Bone Morphogenetic Protein (BMP)-6 and -7 are involved in membranous bone formation. Their presence has been demonstrated in osteoblastic lesions associated with prostate cancer metastases. In osteoblast (OB) cultures, BMP-6 activity is mediated by several factors, including induction of the intracellular osteoinductive LIM Mineralization Protein-1 (LMP-1) and expression of BMP-7. LMP-1 overexpression is sufficient to induce OB differentiation in culture as well as bone formation in vivo. LMP-1 activity is mediated by the apparent induction of BMP-7 and –4. The goal of these studies was to correlate the effects of LMP-1 with those of BMP-6 and -7 in OB culture as a model for osteoblastic lesions occurring during prostate cancer metastasis to bone. Prostate cancer cells (LNCaP) were grown, and conditioned media (CM) harvested (Day 4 post-confluence) and examined for BMP-6 and –7 expression. Antisense oligodeoxynucleotides (AS-ODN) to BMP-6, BMP-7 or LMP-1 were added (Day 1 post-confluence; 4.0 μM) to inhibit expression of these proteins in LNCaP cells. CMs from untreated and AS-ODN-treated LNCaP cells were applied to multipotent C2C12 cultures to determine their ability to induce an OB phenotype (determined by changes in cell morphology and alkaline phosphatase expression). Here, we confirm that prostate cancer cells (LNCaP) appear to secrete both BMP-6 and –7. The AS-ODN inhibition of either BMP-6 or BMP-7 translation in LNCaP cultures inhibits the production of an osteoinductive CM. Constitutively high expression of the intracellular osteogenic protein LMP-1 is found in LNCaP cells. Furthermore, AS-ODN inhibition of LMP-1 in LNCaP cells inhibits production of an osteoinductive CM. Excess BMP-6 (100 ng/mL;Day 1) added to LNCaP cells cannot overcome LMP-1 AS-ODN inhibition and concomitant loss of osteoinductive activity of the CM whereas this inhibition can be overcome by the addition of suboptimal doses (50 ng/mL) of BMP-7. These data suggest a central role of LMP-1 not only in the differentiation of OBs in normal bone formation but also in producing osteogenic lesions in prostate cancer metastases to bone. These data also suggest a possible sequential relationship between the expression of BMP-6, LMP-1 and BMP-7. Understanding the relationship between BMP-6, BMP-7 and LMP-1 in prostate tumor-induced osteogenesis would have significant relevance in the clinical assessment and treatment of osteogenic lesions formed during prostate cancer metastases to bone.

The Proteasome Inhibitor PS-341 Inhibits the Growth of Metastatic Human Prostate Cancer in Bone. P. G. Whang*, R. C. Iglesias*, J. J. Gates*, J. R. Lieberman. Orthopaedic Surgery, UCLA School of Medicine, Los Angeles, CA, USA.

Proteasome inhibitors have been shown to suppress tumor growth by interfering with the NF-κB-mediated degradation of cell cycle regulatory proteins. The purpose of this study is to determine whether the proteasome inhibitor PS-341 inhibits the growth of human prostate cancer cells in a bone metastasis model. Suspensions consisting of $1x10^5$ human prostate cancer cells (PC-3) were injected into the left tibias of SCID mice. PS-341 (1.0 mg/kg) was administered i.v. twice a week according to the following protocols: Pretreatment (1 week of treatment before tibial injection until 4 weeks after); Treatment (4 weeks of treatment); Established Disease (4 weeks of treatment starting 4 weeks after tibial injection); Controls (4 weeks of saline injections). $1x10^6$ PC-3 cells were also injected subcutaneously into the left flanks of SCID mice in order to determine if there is a difference in the efficacy of PS-341 for the prevention of tumor formation in subcutaneous tissue versus bone. PS-341 (1.0 mg/kg) was administered i.v. twice a week as follows: S.C. Treatment (4 weeks of treatment); S.C. Established Disease (4 weeks of treatment once tumors became palpable). Tumor volume was recorded weekly until the time of sacrifice. All animals were euthanized at 8 weeks, at which time radiographs were obtained and both hindlimbs were harvested for histology. Radiographs of the control group demonstrated lytic lesions in bone, and histologic analysis revealed extensive cortical destruction and substantial tumor burden. According to a grading scale based upon the extent of cortical disruption (0 – normal, 1 – scalloping, 2 – 1 cortex disrupted, 3 – 2 cortices disrupted, 4 – complete destruction of the proximal tibia), all the treatment groups showed moderate improvement in the radiographic appearance of PC-3 lesions (Controls – 3.9, Pretreatment – 1.5, Treatment – 1.7, Established Disease – 1.9) with relative preservation of the proximal tibia. However, cortical disruption and tumor burden continued to be present on histologic sections. Administration of PS-341 prevented the formation of subcutaneous PC-3 tumors and decreased the volume of palpable subcutaneous tumors by 49.4%.These findings suggest that PS-341 may inhibit the growth of PC-3 tumors in bone but does not completely eradicate these cells. However, PS-341 does prevent the formation of subcutaneous PC-3 tumors. The attenuated antineoplastic effects of PS-341 against PC-3 tumors in bone may be a result of decreased vascularity and drug bioavailability compared to subcutaneous tissue. Further study is necessary to determine whether PS-341 may be a useful adjunct for the treatment of prostate cancer metastatic to bone.

Mechanisms of Anabolic Action of LNCaP Prostate Cancer Cells on Bone. R. S. Bhattacharyya*, P. H. Stern. Molecular Pharmacology and Biological Chemistry, Northwestern University, Chicago, IL, USA.

Bone metastases are a predominant consequence of late stage prostate cancer. These skeletal metastases tend to be osteoblastic and can promote irregular new bone formation. It has been hypothesized that a soluble factor(s), produced by the prostate cancer cells, is responsible for eliciting this anabolic effect on bone. Our studies have focused on the characterization of prostate cancer cell conditioned media (CM) responses on bone. We have utilized three different bone models, neonatal mouse calvarial bone tissue, MC3T3-E1 osteoblastic cells, and primary osteoblasts isolated from mouse calvaria. The cells or bone tissue were cultured for 24-72 hours and labeled during the final 2 hours of the culture period with ^{3}H-thymidine and ^{14}C-proline to assess cell proliferation and protein/collagen synthesis, respectively. Previous studies from our laboratory have demonstrated that diluted conditioned media (1/18X) from the LNCaP prostate cancer cells generate anabolic responses on ^{3}H-thymidine incorporation with smaller effects on ^{14}C-proline incorporation. The LNCaP CM treatments also produce stimulatory effects on both MC3T3-E1 cells and primary osteoblast cells, increasing both ^{3}H-thymidine and ^{14}C-proline incorporation to a greater extent than observed in the calvaria. In addition to the increase in osteoblast cell proliferation, in both calvarial bone tissue and MC3T3-E1 cells, LNCaP CM treatment elicits a stimulation of the MAP kinase pathway and an increase in the level of phosphorylated p42/44 MAP kinase protein expression. Inhibition of the MAP kinase pathway with the MEK inhibitor, PD98059, also decreases the LNCaP CM stimulated anabolic responses. The MAP kinase pathway has been shown to be involved in multiple proliferative pathways and growth factor responses. One of the many growth factors with proliferative effects on bone is insulin-like growth factor-I (IGF-I). IGF-I treatment stimulates both ^{3}H-thymidine and ^{14}C-proline incorporation in calvarial bone tissue and MC3T3-E1 osteoblastic cells. A neutralizing antibody to the IGF-I receptor blocked the stimulatory effects of LNCaP CM treatment on ^{3}H-thymidine and ^{14}C-proline incorporation in the MC3T3-E1 osteoblastic cells. These results suggest that the MAP kinase pathway and IGF-I may play a role in the effects of LNCaP prostate cancer cell CM on bone.

M071

Musculoskeletal Interactions In Obese, Hyperinsulinemic, Euglycemic Patients. M. R. Ulla[1], J. A. Sánchez*[1], M. Stivala*[2], F. Ghiglione*[2], R. Noriega*[1], G. Cointry*[2], J. L. Ferretti[2]. [1]CEOM, Córdoba, Argentina, [2]CEMFoC, Natl. Univ. of Rosario, Rosario, Argentina.

The aim of this study was to determine whether the metabolic disturbance caused by obesity-related, euglycemic hyperinsulinemia impairs the anthropometric and biomechanical relationships between bones and muscles as determined by the bone mechanostat. We have analyzed the relationships between the DEXA-assessed, whole-body BMC and lean and fat masses (LM, FM) in 30 men and 110 pre- and post-MP women with euglycemic hyperinsulinemia classified according to their fasting plasma insulin (FPI) levels, lower (i) or higher (I) than 15 uUI/ml; body-mass index values, lower (b) or higher (B) than 30, and Insulin Secretion Index (ISI; *Matsuda & DeFronzo 1999*) values, lower (s) or higher (S) than 2.8. The FPI correlated positively with LM and FM but not with BMC. Correlations between BMC and LM were parallel to those found in 300 normal age-matched controls for each group but showed lower intercepts for groups I, B, and S than i, b, and s. After adjusting logarithmically the BMC to a common, 18-kg FM value in order to compensate for the fat interaction with BMC determination, the groups I, B, and S showed significantly lesser intercepts than controls. Those differences were generally more significant for pre-MP women than for post-MP women or men. In these obese patients with fasting euglycemia, relative hyperinsulinemia may have increased FM. Assuming that LM reflects muscle mass, they would have also lowered the BMC/muscle proportion, perhaps reducing the mechanical influence of muscles on the skeleton. This could evidence the induction of a shift in the bone mechanostat setpoint (a typical, ~0.2% bone tissue strain under the maximal customary loads) to a higher level. In addition, the apparent estrogen dependence of the observed differences is congruent with the hypothesis that estrogens interact positively with that homeostatic system.

M072

pQCT Is a Precise and Accurate Tool for Skeletal Analysis of Mice In vivo. M. Priemel[1], C. Schmidt*[2], T. Kohler*[3], J. M. Rueger[1], R. Mueller[3], M. Amling[1], F. Eckstein[2]. [1]Trauma Surgery, Hamburg University School of Medicine, Hamburg, Germany, [2]Anatomy, Munich University, Munich, Germany, [3]Biomedical Engineering, Zurich University, Zurich, Switzerland.

Skeletal research relies extensively on animal models with particular focus on transgenic mice. The standard in characterization of a bone phenotype is histomorphometrical analysis of the skeleton. Micro CT provides additional three-dimensional structural information, but currently cannot be employed in living animals. In contrast peripheral quantitative computed tomography (pQCT) can be applied in anesthesized animals to follow bone changes longitudinally. However, its precision and accuracy in mouse bones has so far not been thoroughly studied. Therefore the specific aim of the current study was to determine the precision (reproducibility) and validity of pQCT in the tibia, femur, and lumbar spine of mice. We examined 27 animals (13 wildtype CL57BL6 mice and 14 leptin-deficient mice with a high trabecular bone volume fraction) at 6 months of age. Axial pQCT images of the tibia, femur and lumbar spine were acquired with a pQCT-M (Stratec, Germany) in quadruplicate. The same bones were subsequently analyzed by µCT imaging at a resolution of less than 10 µm and by histomorphometry after undecalcified embedding. The reproducibility of pQCT was best when analyzing 3 consecutive sections, the precision errors for BMC, area, and density being < 5% in the tibial metaphysis and spine, and < 2% in the femoral metaphysis. Precision errors were smaller at the shaft. The correlation between pQCT (trabecular density) and histomorphometry (BV/TV) was r = 0.89 at all three sites, when choosing small, central regions of interest. The correlation between pQCT and µCT (BV/TV) at the femur was r = 0.97 and that between histomorphometry and µCT r = 0.91. At the shaft, r was > 0.94 for total area, and cortical BMC between pQCT and µCT. Based on these data we conclude that pQCT is an excellent tool for analyzing the density of mouse bones in vivo, its distinct advantage being that living animals can be studied longitudinally.

M073

Precision of Orthopedic Scans Using the GE Lunar Prodigy. C. Simonelli[1], J. J. Monk*[1], H. S. Barden[2], K. G. Faulkner[2]. [1]HealthEast Clinics, Woodbury, MN, USA, [2]GE Medical Systems Lunar, Madison, WI, USA.

We evaluated the precision of bone mineral density (BMD) measurements from orthopedic scans using the Lunar Prodigy. Low precision error is important for measuring changes in periprosthetic bone density with confidence. Total hip replacement, a popular procedure for treating patients with hips damaged by disease or injury, alters the normal stresses applied to weight-bearing bone of the proximal femur. Subsequent redistribution of bone through remodeling, coupled with cell damage caused by wear debris shed from the implant, often results in substantial bone loss surrounding the implant and implant loosening. Both outcomes have a negative impact on prosthesis longevity and can cause difficulties for revision surgery. Dual-energy x-ray absorptiometry (DXA) precisely quantifies bone mineral density (BMD) adjacent to femoral prostheses *in vivo*, and is useful for measuring bone remodeling changes and bone loss longitudinally. Twenty-five subjects with total hip implants were studied. Orthopedic scans were performed twice with interim repositioning with the Lunar Prodigy, a narrow-angle, fan-beam densitometer (GE Medical Systems). Orthopedic analysis software positioned regions-of-interest at the seven Gruen zones around the implant to assess periprosthetic bone loss. Precision of Gruen zone BMD (Table 1) was calculated as the root mean square standard deviation.

Table 1. Precision of Gruen zone BMD measurements

Gruen Zone	Mean BMD (g/cm^2)	SD	%CV
1	1.24	0.03	2.7
2	2.11	0.03	1.6
3	2.21	0.03	1.5
4	2.08	0.03	1.3
5	2.12	0.04	1.7
6	1.83	0.04	2.0
7	1.22	0.04	3.2

Precision of 1% to 3% at all Gruen zones with the Lunar Prodigy was as good as or better than precision of 2% to 5% shown previously with pencil-beam systems [1,2]. Precision errors were considerably less than the BMD loss of 11% to 21% typically seen during the first six months following implantation [1], allowing rapid detection of bone loss in this at-risk population.

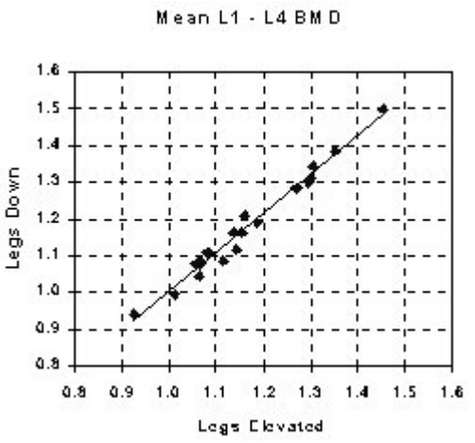
Comparison of Spine BMD Measurements from DXA With and Without Elevated Legs. C. Simonelli, J. J. Monk*. HealthEast Clinics, Woodbury, MN, USA.

Current procedure for measuring lumbar spine bone mineral density (BMD) using DXA requires the legs to be elevated. This position flattens the lower spine, with the intent of yielding more accurate and precise BMD values. In this study we wished to determine if elevating the legs has a significant impact on spine BMD accuracy and precision. Twenty subjects were scanned six times at the lumbar spine using the Lunar Prodigy (GE Medical Systems, Madison WI). Three scans were done using standard positioning, with the legs elevated by the spine block positioner supplied by the manufacturer. The other three scans were done without the spine positioner, with the legs flat on the scan table and feet secured with the dual femur positioner. Subjects were repositioned between scans. Spine BMD (L1-L4) was determined using the manufacturer recommended analysis procedure. L1-L4 BMD was compared using ANOVA to determine the potential influence of leg position. The root mean square precision error (%CV) was determined for the BMD values obtained in each position. There were no appreciable visual differences between the scans performed with the legs up or down. Disc spaces and vertebral bodies appeared identical, despite the positioning difference. There was a small, but statistically significant, difference of 1.1% in spine BMD (L1-L4) between positioner and no positioner values ($p < 0.001$). In 16 cases out of 20, the BMD was higher without the legs elevated. Precision was excellent in both positions, with CV of 0.96% with the positioner in place and 0.92% without positioner.

Table 1. Spine BMD and Precision for Subjects With and Without the Spine Positioner

	Mean L1-L4 BMD (g/cm^2)	SD (g/cm^2)	Precision %CV
Legs Elevated	1.174	0.011	0.96%
Legs Down	1.161	0.011	0.92%

Linear regression analysis (see graph below) confirmed that the BMD measurements with and without the leg positioner were highly correlated (r = 0.99), with slope near unity (1.06), an intercept close to zero (-0.06) and an SEE of 0.021 g/cm^2 or 1.8%. We conclude that elevating the legs has no clinically significant effect on spine BMD accuracy (1%) or precision. In subjects where elevating the legs is difficult, a measurement with the legs down can be used without a significant impact on measurement accuracy or precision.



Disclosures: ***C. Simonelli****, GE Medical Systems Lunar 2.*

Evaluation of Bone Mineral Density and Fat-Lean Distribution in Patients with Multiple Myeloma in Long Term Remission. S. Roux[1], C. Bergot*[2], J. P. Fermand*[3], J. Frija*[2], J. C. Brouet*[3], X. Mariette*[1]. [1]Rheumatology, Bicêtre Hospital, Le-Kremlin-Bicêtre, France, [2]Radiology, Saint-Louis Hospital, Paris, France, [3]Immuno-Hematology, Saint-Louis Hospital, Paris, France.

BMD evaluation could be of interest in the follow-up of MM patients, but few data have been published so far. In order to characterize the evolution of BMD in responder patients, BMD was evaluated in 44 MM patients (14F-30M, aged 35-65 years) in long term remission for at least 2 years (35.4±10.5 months) after high-dose chemotherapy and autologous transplantation (HDT) (n=38) or conventional chemotherapy (CC) (n=6) in a retrospective study. Patients never received bisphosphonates before or during the follow-up. All patients underwent a lumbar spine (LS) BMD (n=44) and a whole body (WB) BMD (n=35) before therapy and at least once in the remission period. BMD measurements were performed at interval of 1y (n=29), 2y (n=31) or 3 y (n=32). At baseline, mean LS BMD was 0.863±0,026 g/cm2, mean lumbar Z-score was -1.45 SD (-5 to 2.13). LS BMD increased from baseline by 5±1.8% (P<0.01), 9.3±1.7% (P<0.0001) and 14±1.9% (P<0.0001) at respectively 1y, 2y, and 3y. The number of osteoporotic patients (T-score <-2.5DS) decreased from 39% at baseline, to 28.5% at 1y, 22.5% at 2y and 18.5% at 3y. Compared to baseline, WB BMD decreased by -2.8±0.5% at 1y (P<0.0001), -2.6±0.7% at 2y (P<0.001) and -1.7±0.6% at 3y (P<0.01). When skeletal subregions on WB measurements were analyzed, axial BMD (lumbar and thoracic) increased and appendicular BMD (four limbs altogether) decreased from baseline in each group, with significant correlation between appendicular and WB BMD (r= 0.918), and LS and axial BMD (r= 0.823). Head BMD increased from baseline at 3y (P<0.0001). The pelvis BMD significantly decreased from baseline at 1y and the mean percentage change was -4.5±1% at 1y, -1.6±1% at 2y and -0.2±1.3% at 3y. While the lean compartment did not change, the mean percentage change of the fat compartment from baseline was -9.2 ± 8.4% at 1y, +8.5 ±7% at 2y and +28.4 ± 7.1% at 3y at the trunk, and -6.4 ± 5.5% at 1y, +4.8 ±4.9% at 2y and +17.1 ± 5% at 3y in peripheral areas. In conclusion, in MM patients in remission after HDT or CC, LS BMD progressively increased after a mean follow-up of 3 years. These patients never received bisphosphonates, so this increased was related to the anti-myeloma treatment per se. It is not surprising that the major effect on BMD was observed at the LS which is primarily composed of trabecular bone containing the bone marrow. In areas primarily composed of cortical bone (WB or pelvis), we observed a decrease of the BMD with values that tended to return to baseline at 3 y. Interestingly, a drastic increase of the fat content was also observed.

Assessment of Bone Mineral Density of the Calcaneus in Healthy and Osteoporotic Women by a New DXA Device. G. Martini, R. Valenti*, S. Giovani*, L. Gennari, S. Salvadori*, B. Galli*, R. Nuti. Metabolic Disease Unit, University of Siena, Siena, Italy.

Aim of the study was to analyze the reproducibility and the diagnostic capability of a new portable device (Calscan Dexa-t), able to measuring calcaneus bone mineral density (BMD). The technique is based on the concepts of dual-energy X-ray absorptiometry associated to the measure of heel thickness with laser beam. The population entered the study consists of fourty postmenopausal women (aged 47-82 years) and the following parameters were examined: lumbar spine (postero-anterior L2-L4) and total body-BMD (Lunar DPX), calcaneus imaging quantitative sonography (Lunar-Achilles), and calcaneus-BMD (Calcscan Dexa-t). On the basis of BMD T-score measured by DXA of L2-L4 and using -2.5 as cut-off, twenty women were classified as osteoporotic and twenty women were considered non osteoporotic (5 osteopenic and 15 normal, according to WHO classification). The short-term precision of Calscan was determined from three repeated measurements on the same subject. The coefficient of variation (CV), calculated by expressing the standard deviation as a percentage of the mean, was 2.4%. DXA-BMD of the calcaneus was significantly lower in osteoporotic patients in comparison to non osteoporotic subjects (0.273 g/cm^2 ± 0.40 vs 397 g/cm^2 ± 0.8, p<0.01) as well as DXA-BMC (1.4 g ± 0.2 vs 2.0 g ± 0.4, p<0.01), while no differences were appreciated as regards area and thickness. The diagnostic accuracy of Calscan has been assessed by comparing the agreement with BMD L2-L4 T-score: at Calscan, 16 on 20 osteoporotic women have a T-score <-2.5 and only 4 on 20 women without osteoporotic were misclassified. Sensitivity and specificity were 80% and 80%, respectively. Finally, heel-BMD showed high correlation with ultrasound stiffness (r=0.84), and total body-BMD (r=0.86); the relationship with L2-L4 BMD was lower (r=0.76), but highly significant. In conclusion, the new measuring device Calscan Dexa-t is easy to use; measurement time is relatively short so examinations are rapid; precision is sufficiently good; diagnostic capacity and relationhips with other sites of the skeleton or ultrasound device are excellent.

M077

Precision of Lumbar Spine and Femur BMD Measurements Using Hologic and GE Lunar Fan-Beam Bone Densitometers. S. B. Moody*, P. H. Bowen*. The Emory Clinic, Atlanta, GA, USA.

A low precision error is essential for serial bone density measurements, as skeletal changes associated with osteoporosis are only a few percent a year. Halving of the precision error reduces the time required to detect a statistically significant change in BMD by a factor of 2. In this study, we compared the precision of lumbar spine (L1-L4) and proximal femur BMD from two fan-beam densitometers, the Hologic QDR 4500 and the Lunar Prodigy. Thirty-one women were measured twice with the Lunar Prodigy (GE Medical Systems) and the QDR 4500 (Hologic) at the spine and left proximal femur with repositioning between each scan. Scans were acquired by an ISCD-certified technologist using the standard scan modes for each system: the Prodigy 30-second mode and the QDR 4500 60-second mode. Dual femur measurements that provide average BMD of the two femora were also acquired on the Prodigy. Precision was calculated as the root mean square standard deviation. Pooled precisions (variances) between the Prodigy and QDR 4500 measurements were compared with an F-test. Single femur Prodigy precision was superior to the QDR 4500, with statistically significant differences at all femoral regions (Table 1). Spine precision was comparable between the two systems.

Table 1. Precision of Prodigy and QDR 4500 Spine and Single Femur BMD Measurements

	PRODIGY (30 sec)	QDR 4500 (60 sec)	PRODIGY vs. QDR 4500
Region BMD (g/cm^2)	SD (%CV)	SD (%CV)	p
Femur Neck	0.010 (1.1%)	0.014 (1.8%)	0.03
Ward's	0.011 (1.4%)	0.025 (3.8%)	0.0001
Trochanter	0.007 (0.9%)	0.010 (1.4%)	0.03
Total Femur	0.006 (0.6%)	0.010 (1.2%)	0.002
Spine (L1-L4)	0.013 (1.1%)	0.012 (1.2%)	0.23

Single femur precision errors with the Prodigy 30-second mode were 30% to 60% lower than precision errors with the QDR 4500 60-second scan mode. The left/right average BMD of the Prodigy dual femur measurements further reduced precision error compared to single femur measurements (Table 2).

Table 2. Precision of Prodigy Single and Dual Femur BMD Measurements

Region	PRODIGY Single Femur %CV	PRODIGY Dual Femur %CV
Femur Neck	1.1%	0.7%
Ward's	1.4%	1.3%
Trochanter	0.9%	0.7%
Total Femur	0.6%	0.4%

We conclude that BMD changes from single femur measurements can be detected 30% to 60% faster with the Prodigy compared to the QDR 4500. Average BMD from the Prodigy dual femur scans can detect change 50% to 70% faster than single femur BMD from the QDR 4500.

Clinical Utility of Combining Calcaneal Bone Mass Measurement with Central DXA in Men. N. Vallarta-Ast[1], D. Krueger[2], N. Binkley[2]. [1]Radiology, Wm S Middleton VAMC, Madison, WI, USA, [2]University of Wisconsin, Madison, WI, USA.

Spinal degenerative disease often elevates measured bone mass in older men. However, peripheral bone mass measurement at the calcaneus is largely unaffected by such artifacts. The purpose of this study was to evalute the utility of calcaneal measurement to detect low bone mass in men. This ongoing study measured lumbar spine (LS), proximal femur (F), forearm (UDR) and calcaneus (Calc) BMD in 66 men age 55-86, referred for clinical DXA. GE Lunar instruments were utilized; Expert-XL (LS, F and UDR DXA), PIXI (Calc DXA) and Achilles Express (Calc ultrasound [US]). Ultrasound stiffness T-scores were derived utilizing the manufacturer's German normal male reference population. World Health Organization diagnostic criteria were arbitrarily applied to data from all instruments. The routine central site combination of LS plus F identified 30 men as osteoporotic; combining LS/F with any peripheral measurement increased ($p < .05$) the number of men identified as osteoporotic; LS/F/UDR = 36, LS/F/PIXI = 36, LS/F/US = 39. It was unexpected that the combination of LS/F with Calc US identified the greatest number, 39 (59%) of this group as osteoporotic. Twenty men had documented prior low trauma fracture; LS/F classified only 10 from this group as osteoporotic. Similar to results in the entire group, addition of US to LS/F diagnosed osteoporosis more frequently (16/20, $p = .03$) in the fracture subgroup than LS/F alone. In conclusion, it is widely accepted that application of WHO diagnostic criteria to calcaneal BMD measurement is inappropriate. However, these data suggest the WHO criteria remain appropriate when used in combination with central measurements. Specifically, combination of central and calcaneal BMD measurements increased osteoporosis classification in these men regardless of whether the calcaneus was measured with DXA or US. This likely reflects the limited utility of LS BMD measurement in this population due to the high prevalence of spinal degenerative disease. Given this situation, monitoring osteoporosis therapy at the calcaneus, a cancellous rich site, may be advantageous. Studies evaluating the feasibility of monitoring osteoporosis treatment at the calcaneus are indicated. The dichotomy of "central measurement" versus "peripheral measurement" may be impairing optimal osteoporosis care.

M079

Should One or More Vertebral Levels Be Used for Fracture Risk Assessment? D. L. Schneider, R. Bettencourt*, E. L. Barrett-Connor. University of California, San Diego, La Jolla, CA, USA.

Fracture risk assessment using dual energy X-ray absorptiometry has been based on 3 or 4 vertebral levels. However, one vertebral level has more bone area than the femoral neck. Is a single vertebral level as predictive of fracture as multiple levels? We examined the minimal number of vertebral levels and fracture risk in 978 community-dwelling ambulatory older women aged 43-97 years. At a 1992-1996 research clinic visit, a standard medical history including clinical fractures was obtained. Bone mineral density (BMD) was measured at the PA lumbar spine using two DXA machines (Hologic QDR 1000, L1-4, and 2000, L2-4). Lateral spine radiographs were read using the semiquantitative method for prevalent vertebral fractures. Osteoporosis was defined by the WHO criteria of T-score =< -2.5 using data from Hologic female normals for spine DXA. Twenty percent of women, mean age 72.2 years, reported clinical fractures and 12% had prevalent vertebral fractures. Results from the two DXA machines were similar. Approximately one in 5 women were identified as osteoporotic using the total spine BMD, and one in 3 women using the single lowest vertebral BMD. The proportion of clinical fractures and prevalent vertebral fractures were similar in women with osteoporosis identified by total or lowest spine BMD. There was no difference in risk of clinical fracture using total spine (OR, 1.68; CI 1.18-2.41) or lowest spine (OR, 1.73; CI 1.24-2.41) and vertebral fractures, total spine (OR, 2.11; CI 1.38-3.24) or lowest spine (OR, 2.18; CI 1.44-3.30). In summary, although fracture risk has been based on total spine BMD, lowest single vertebral BMD level provides a similar but not better predictor of fracture risk. Therefore, the minimum number of vertebra needed for fracture risk assessment is one.

M080

Preliminary Evaluation of the Lexxos 2D Digital DXA Scanner. K. M. Knapp, R. Patel, G. M. Blake, I. Fogelman. Osteoporosis Screening and Research Unit, Guy's Hospital, London, United Kingdom.

The Lexxos (DMS, Perols, France) is the first DXA scanner to utilise a 2D radiographic detector rather than the present convention of a fan beam. This enables faster acquisition times of approximately 2 seconds each for antero-posterior acquisition of the lumbar spine and proximal femur. The aim of this preliminary evaluation was to investigate the cross-calibration of the Lexxos with a Hologic QDR-4500W (Hologic, Bedford, MA), and to calculate the short-term in-vivo precision. A group of 33 patients had BMD measurements performed on both the Hologic and Lexxos scanners. A subgroup of 11 patients had two acquisitions each of the spine and hip performed with repositioning between acquisitions to measure in-vivo short-term precision. The agreement between the Lexxos and Hologic was calculated using linear regression, forcing the line through the origin. The short-term precision results were calculated using the RMS SD and CV% from the duplicate scans.

	n	R	SE(g/cm^2)	Slope
Spine	24	0.93	0.04	1.002
Femoral Neck	31	0.96	0.04	0.993
Total Hip	31	0.96	0.04	1.027

The RMSSD and CV% for the spine (n=9) was 0.02g/cm^2 and 1.8% respectively, for the femoral neck (n=11) was 0.01g/cm^2 and 1.4% and the total hip (n=11) was 0.02g/cm^2 and 1.8% respectively. The BMD values in the spine and hip demonstrate good agreement with the Hologic QDR-4500W. Further data is being obtained to evaluate the precision of the Lexxos scanner.

M081

The Influence of Bone Mineral Density (BMD) Testing on the Treatment of Osteoporosis (OP) in Two Canadian Non-Academic Community Centres. E. A. Papadimitropoulos[1], M. E. Hamel*[2], R. J. Sebaldt[2], J. D. Adachi[2], K. Siminoski[3], C. H. Goldsmith*[4]. [1]Research and Development, Eli Lilly Canada Inc., Scarborough, ON, Canada, [2]Rheumatology, McMaster University, Hamilton, ON, Canada, [3]Department of Radiology, University of Alberta, Edmonton, AB, Canada, [4]Statistics, McMaster University, Hamilton, ON, Canada.

A prospective cohort study with 3 month follow-up was conducted to characterize the patients that Canadian physicians are referring for BMD testing and to assess the impact of the results on subsequent treatment decisions and lifestyle changes. Testing was conducted in two Canadian non-academic centres, which included on-site and mobile dual-energy x-ray absorptiometry (DXA) units. Recruitment for the study consisted of successive patients who were referred for BMD measurements at each of the two BMD testing sites over a 3 month period. Patient questionnaires were used to collect data on demographics, risk factors, medications and lifestyle. The BMD results were used to divide patients into 3 groups; osteoporotic, osteopenic and normal BMD according to WHO criteria. Based on BMD results, 23% of patients were osteoporotic, 46% were osteopenic and 31% had normal BMD. There was a positive correlation between number of risk factors and reduction in BMD from normal values. Application of the Osteoporosis Society of Canada practice guidelines, the National Osteoporosis Foundation guidelines or the Osteoporosis Risk Assessment Instrument, respectively would have eliminated 45%, 13% and 43% of patients without OP that were referred for testing in our study and resulted in BMD testing for 53%, 85% and 78% of the patients with OP in our group. Following BMD testing, there was no significant change in patient-reported calcium intake or excerise, and 34% of patients felt that their knowledge of OP had increased. Three months after BMD testing, 60% of osteoporotic patients, 47% of osteopenic patients and 34% of patients with normal BMD were being treated with calcium, vitamin D or prescription medication. Risk factors and current guidelines are entirely satisfactory in screening patients for BMD referrals. The results of BMD tests influence treatment decisions in the primary care setting although in our cohort of patients did not appear to have a significant effect on patients' lifestyle choices nor result in a reported increase in knowledge about OP in a majority of patients.

Short Term DEXA Precision in Children Is Comparable to Precision in Adults. R. P. Green, J. Bartholic*, R. Civitelli. Washington University School of Medicine, St. Louis, MO, USA.

DEXA scans are increasingly being used to evaluate bone health in children at our institution, both for clinical and research purposes. Children may have more difficulty cooperating with positioning, which could result in increased study-to-study variability. Precision error (PE) provides an estimate of study-to-study variability and is used to assess the clinical significance of BMD changes. Therefore, we determined PE for pediatric patients using 15 healthy children, ranging in age 5-14 years. Each child completed three DEXA studies of AP and lateral spine (L-spine), total hip, and whole body (WB), using a Hologic QDR4500 scanner. All studies on each child were performed on the same day. The children left the table and returned for repeat scans. A single technician performed all the studies, including the adult AP spine and hip precision studies included for comparison. No assistance other then verbal instruction was provided to help the children remain still. PE for coefficient of variation (CV) and standard deviation (SD) were obtained using root-mean-square averages of each individual's CV and SD and are shown in the table. L-spine DEXA had a higher PE then any other site or projection. Because difficulty repositioning and maintaining position could contribute to greater variability in younger children, we used regression analysis to determine if there was a relationship between age and the SD or CV of each individual's repeated BMDs. No significant correlation was found at any site, with the exception of WB bone mineral content (BMC), where there was a positive correlation between age and an individual's SD (r^2=0.2797, slope=+1.68 gm/year, p=0.0427). However, no relationship was present between CVs of WB BMC measurements and age (r^2=0, slope=0, p=0.9936). These results indicate that in children between the ages of 5 and 14, DEXA studies at our institution have good precision, comparable to that of adult DEXA studies. Furthermore, younger children do not appear to have greater study-to-study variability, as might be expected if it were more difficult for them to cooperate with the study.

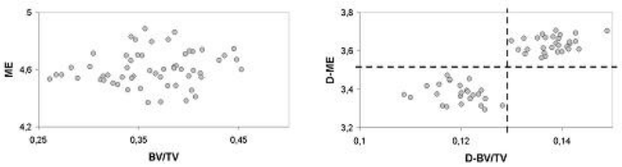
Adult and Pediatric Precision Results

Site	PE SD-Ped	PE CV-Ped	PE SD-Adult	PE CV-Adult
AP Spine BMD	0.0071 gm/cm^2	1.10 %	0.0099 gm/cm^2	0.90 %
L-Spine BMD	0.0222 gm/cm^2	3.89 %	ND	ND
Hip BMD	0.0094 gm/cm^2	1.19 %	0.0070 gm/cm^2	0.80%
WB BMD	0.0087 gm/cm^2	1.03 %	ND	ND
WB BMC	15.99 gm	1.05%	ND	ND

M083

Simulation of the Evolution of Trabecular Bone Structure from High Resolution Magnetic Resonance Imaging: A Preliminary Study Using "Distance to Topological Fracture". L. Pothuaud*, S. Majumdar. Magnetic Resonance Science Center, University of California, San Francisco, San Francisco, CA, USA.

Better knowledge of how a patient's bone is expected to evolve would be very useful for clinicians in increasing the accuracy of predicting risk of fracture in individual subjects. The aim of this work was to explore the utility of image analysis to simulate the evolution of trabecular bone structure. Fifty-seven normal postmenopausal women were recruited in our center following rigorous inclusion / exclusion criterion. High resolution Magnetic Resonance (MR) imaging was used to reconstruct a 3D image of trabecular bone of the ultra-distal radius. The imaging protocol was developed on a 1.5 Tesla clinical scanner, following optimized and standardized conditions, with an in-plane resolution of 156x156 microns2 and a slice thickness of 500 microns. The "apparent" trabecular bone structure was extracted from the gray level MR images by applying a global histogram-based threshold. Bone volume fraction (BV/TV), maximal entropy (ME), and Euler-Poincare characteristic (EPC) were evaluated following previously reported methods. 3D-Line Skeleton Graph Analysis (LSGA) technique was used to segment the 3D trabecular bone structure into elementary trabeculae. Next, a random trabecular deletion process was implemented to simulate bone changes. This process was performed until an ultimate 3D model with EPC = 0 was reached, characterizing the transition state between low-connectivity models and highly disconnected models (i.e., with several clusters of solid). The state reached by simulation and characterized by EPC = 0 was designated "topological fracture". The "distance to topological fracture" (DTF) was then characterized by the absolute differences D-BV/TV and D-ME between the initial structure and the TF model.



In this preliminary study, we hypothesized that the state EPC=0, reachable by image analysis and simulation, could be related to the bone fracture threshold. In a large group of normal subjects our DTF-based evaluation led to a clustering of the data into two well-separated classes (right). The other parameters used failed to yield such clustering (left). Further analysis will evaluate the meaning of DTF in terms of bone strength, and will determine its usefulness as a tool for predicting the risk of bone fracture in individual subjects.

M084

The Value of Percutaneous Transpedicular Trocar Biopsy for the Diagnosis of Vertebral Body Lesions. R. Kothe*[1], G. Möller[2]. [1]Dept. of Orthopaedics, Hamburg University School of Medicine, Hamburg, Germany, [2]Moosbergstrasse 10, D-64285 Darmstadt, Germany.

Despite the advances in imaging technology a spinal biopsy is often necessary for the diagnosis of vertebral body lesions. Recently, less invasive biopsy techniques using a needle or a trocar have gained increasing popularity. But there still is a lot of controversy if the obtained specimen allow an adequate histologic analysis. We evaluated the safety and accuracy of fluoroscopic guided percutaneous transpedicular trocar biopsies of the spine for the diagnosis of vertebral body lesions. 116 patients with different vertebral body lesions from T1 to S1 were evaluated in a prospective manner. Percutaneous transpedicular trocar biopsies were performed in mild general or local anesthesia. Under fluoroscopic lateral and a.p. C-arm control the specimens were obtained using a Jamshidi trocar with an internal diameter of 3.1 mm. The bone cores were divided in two halves. One was analyzed undecalcified in acrylat, the other decalcified in paraffin. In 112 out of 116 biopsies the quality of the specimen was assessed as good or excellent. No patient required a second biopsy because the obtained tissue was not sufficient. There were 38 malignancies, 32 cases of acute or chronic osteomyelitis, 20 isolated osteoporotic fractures, 3 hemangioma, 1 fibrous dysplasia and 1 chordoma. In 21 cases no pathology could be found. Two postoperative haematoma were the only complications in this series. Percutaneus transpedicular biopsy of the spine using a Jamshidi trocar can be performed safely and efficaciously under fluoroscopic guidance. The obtained specimens provide adequate bone cores for histologic examination with a high diagnostic yield, comparing well with open biopsies.

Biomechanical Examination of Cortical Bone Distribution in the Vertebral Body. H. Tsugeno*[1], B. Goto*[2], T. Fujita[2], M. Nakai*[1], M. Okamoto*[1], T. Yokoi*[1], S. Takata*[1], N. Nishida*[1], K. Ashida*[1], Y. Hosaki*[1], F. Mitsunobu*[1], Y. Shiratori*[3], Y. Tanizaki*[1]. [1]Misasa Medical Center, Okayama University, Tottori, Japan, [2]Calcium Research Institute, Kishiwada, Japan, [3]Department of Medicine and Medical Science, Okayama University Graduate School, Okayama, Japan.

Reductions of radial cortical bone volume and density in osteoporosis were reported by us using peripheral quantitative computed tomography (pQCT). In view of the technical limitations of equipment used in previous studies, which might lead to some inaccuracy in measuring the thin vertebral cortical bone, we used the more precise multi-slice CT Aquilion (Toshiba, Tokyo, Japan) to study deformity-free third lumber vertebra (L3) in 11 postmenopausal women (> 5 years after menopause, mean age; 67.3 years), including 6 patients with osteoporosis and 5 controls. Relative cortical volume (RCV), cortical bone mineral density (BMD) and trabecular BMD in the frontal part of the vertebral body (L3) were calculated. For comparison with those, RCV, cortical and trabecular BMD in the radius were simultaneously measured by pQCT (Stratec XCT960). Both RCV and cortical BMD showed the minimum value at sites close the top and bottom of the vertebral body, and the maximum value at the central part of the vertebral body. RCV, cortical and trabecular BMD in the center of the vertebral body showed significantly lower values (p=0.0039, p=0.0067, p=0.0039) in osteoporosis than those in the controls. RCV, cortical and trabecular BMD of the radius also showed significantly lower values (p=0.0002, p=0.0014, p=0.0047) in osteoporosis than those in the controls. Both cortical bone volume and density were low at sites close the top and bottom in the frontal part of the vertebral body, and these sites may coincide with the fragile part of the vertebral body. In patients with osteoporosis, both cortical bone volume and density in the vertebral body were reduced just like those in the radius.

3-D Synchrotron mCT Allows Unique Insight of Changes in Bone Quality. E. L. Rittman*[1], B. Borah*[2], T. E. Dufresne*[2], R. J. Phipps[2], J. P. Sacha*[1], S. M. Jorgensen*[1], R. T. Turner[1]. [1]Mayo Clinic, Rochester, MN, USA, [2]Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Incidence of bone fracture in people with osteoporosis has been shown to reduce markedly with bisphosphonate treatment. However, the role of bone turnover and its effects on the quality of trabecular bone is relatively unknown. Using a synchrotron CT source, we have developed a unique method to examine mineralization directly in 3-D and correlate it with the underlying trabecular structure. Our study involved micro-CT analysis of 10 pairs of iliac crest biopsies obtained from patients before and after treatment for three years with risedronate therapy. We scanned each biopsy at the Brookhaven National Laboratories' National Synchrotron Light Source X2B beam line micro-CT scanner. Using a novel off-axis rotation of the specimen, followed by a montaging of the full transverse profiles of the sinogram, up to an 8 mm diameter core could be examined without loss of information. Due to the high signal to noise and the monochromatic beam, this technique allows for high resolution (5 μm isotropic voxels) data where the younger less fully mineralized surfaces are clearly discernable from the older fully mineralized bone. Therefore, it is possible to visualize entire remodeled sites spanning broadly across the trabecular bone surface. Such precise delineation of remodeled surfaces is typically not possible with conventional Micro-CT technology, which is used primarily to analyze bone structure only. Preliminary results of histogram-based segmentation of the different density values in the specimens revealed that there was a significant reduction ($p < 0.05$) in less dense bone in the risedronate treated biopsies. This is consistent with previous histology and biomarker data associated with this study. The 3-D visualization of the trabecular surface after segmentation qualitatively confirms this reduction in the 3-year treatment group. This high resolution 3-D imaging method allows for the first time the examination of bone remodeling sites directly in 3-D on human biopsies treated with risedronate. This technique provides data consistent with established histology and will allow for correlation of changes in remodeling activity (size, depth, location) with the underlying trabecular structure (trabecular thickness, orientation, plates/rods, etc).

Comparison of Mechanical Response Tissue Analysis of the Ulna Bone with Quantitative Ultrasound and Dual Energy X-ray Absorptiometry. C. C. Djokoto*[1], S. D. Waldman*[2], M. D. Grynpas[3], A. M. Cheung[4]. [1]Institute of Biomaterials and Biomedical Engineering, University of Toronto, Toronto, ON, Canada, [2]Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada, [3]Institute of Biomaterials and Biomedical Engineering, University of Toronto and, Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada, [4]Department of Medicine, University Health Network and University of Toronto, Toronto, ON, Canada.

Mechanical response tissue analysis (MRTA) is a non-invasive technique used to determine the cross sectional bending stiffness (EI) of bone. Previous studies have examined the relationship between ulnar EI determined by MRTA, and bone mineral content (BMC) and bone mineral density (BMD) measured by dual energy x-ray absorptiometry (DEXA) at various anatomical sites. However, the speed of sound (SOS) in bone is related to both the elastic modulus and density, and should provide a better correlation with EI. In this study we correlated MRTA measurements of the ulna bone with quantitative ultrasound (QUS) of the ulna and DEXA measurements of the ulna, radius, hip and spine, to determine if EI correlates with other accepted modalities of bone measurement. A total of 56 healthy subjects (20 men and 36 women) between the ages of 18 and 83 were recruited. The response of the ulna to a low-frequency mechanical vibration was fitted to a 6-parameter model to determine EI. Axial SOS along the ulna bone was determined by QUS (Sunlight Omnisense), and BMC and BMD were determined by DEXA (Hologic QDR 4500A). The projected area of the DEXA ulna region of interest was used to estimate bone width, and BMD and SOS were combined to estimate the elastic modulus of the ulna. EI was found to correlate with DEXA projected area, BMC and BMD. No correlation was found between EI and SOS. EI was most strongly correlated with BMC measured at the site of the ulna bone corresponding to the location of the applied MRTA stimulus ($r = 0.773$, $p<0.001$). There was a weak but significant correlation between EI and estimated elastic modulus ($r = 0.548$, $p<0.001$). The correlations between EI and BMC or BMD are consistent with previous studies examining relationships between densitometry and MRTA. Although axial SOS measurements of the ulna bone alone did not correlate to EI, SOS combined with BMD did. We conclude that MRTA measurements reflect different qualities of bone than either QUS or DEXA alone. Future studies with larger cohorts are needed to further investigate the relationships between these three modalities of bone assessment.

M088

A Mathematical Model of Bone and Applications to Osteoporosis. G. H. Gunaratne[1], S. J. Wimalawansa[2]. [1]Department of Physics, University of Houston, Houston, TX, USA, [2]Department of Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ, USA.

Factors complicating the development of diagnostics for osteoporosis include the anisotropy of porous bone, fraction of trabecular mass, and trabecular thinning. It is extremely difficult to account for these factors and complex interactions between them in clinical studies or in experiments on ex-vivo bone samples. Mathematical models have been used successfully to extract such details in many physical systems. A corresponding analysis of bone can be used to establish the relative importance of mechanical factors that effect bone strength. This information can aid the design of suitable treatment options and help identify accurate non-invasive diagnostic tools. We introduce a mathematical model of a trabecular architecture (TA), which consists of a disordered network of fragile elastic struts. Features such as the preferential growth of regions under high strain (Wolff's Law) are included. Analysis of the model provides a surprising observation on load transmission; an incomplete network can only use a fraction of itself for stress propagation, and this fraction decreases with increasing loss of struts. As a consequence of this inefficiency, bone strength decreases non-linearly with BMD, and a new expression for it has been derived on the basis of our model. This expression was validated using previously published data on samples of human bone (Mosekilde et.al., Bone, 8, 79-85 (1987)). A new diagnostic (Γ) for the ultimate strength of a bone, that is constructed to express changes in the stress carrying backbone of a TA, is proposed. It is the ratio of linear responses of the network to static and periodic external strain, and predicts the ultimate strength of model networks accurately. Anti-resoptive therapies (e.g., bisphosphonates) induce a dramatic reduction of fracture incidence with modest increases of BMD. Analysis of the model system shows that preferential growth of bone at locations under high strain (Wolff's Law) is a possible explanation the reason underlying the efficacy of these agents. Furthermore, it is observed that the efficacy of bone growth is higher in weaker networks, suggesting that therapeutic intervention is more cost-effective in patients with established osteoporosis.

Fan-Beam Hip Axis Length Measurements Predict Hip Fracture. K. G. Faulkner[1], H. S. Barden[1], H. Bui*[1], P. K. Burke[2]. [1]GE Medical Systems Lunar, Madison, WI, USA, [2]Osteoporosis Diagnostic and Treatment Center, Richmond, VA, USA.

Previous studies have shown that a long hip axis length (HAL) is related to an increased risk for hip fracture, independent of age and bone density. However, most of these studies have been performed on older pencil beam densitometers, which are not subject to magnification effects. To evaluate whether fan-beam measurements of HAL are associated with hip fracture risk, we obtained dual-energy x-ray absorptiometry scans (Lunar Prodigy, GE Medical Systems) of the proximal femur on 980 white women aged 70 to 89 years. The Prodigy uses a multi-view fan beam to accurately measure length and area without the need for body size corrections. Measurements of HAL and femoral BMD (neck, upper neck, and total) of the 38 women with previous hip fracture were compared to the same measurements in 942 non-fractured controls of similar age. Results were compared using multiple logistic models, and odds-ratios (OR) were determined for hip fracture per standard deviation change in each measurement. There were no significant differences in age or height between fracture and control subjects. Hip fracture subjects weighed less and HAL was significantly longer in the hip fracture subjects compared to controls (Table 1). HAL was found to be correlated with height ($r = 0.48$, $p<0.001$) and weight ($r = 0.26$, $p<0.001$), but was unrelated to age ($r = 0.05$, $p=0.14$) or BMD ($r=0.03$, $p=0.36$). Each standard deviation (6mm) increase in HAL was associated with a 1.6-fold increase in the risk for hip fracture (OR 1.6, 95% CI 1.1-2.3). The relationship between hip axis length and fracture persisted after adjustment for age, femoral neck density, height, and weight (OR 1.5, 95% CI 1.02, 2.1). Decreasing femoral BMD at all measurement regions was also associated with an increase in hip fracture risk, consistent with previous studies (Table 1). We conclude that hip axis length measured with a multi-view fan beam DXA system predicts hip fractures in elderly Caucasian women, independent of age, height, weight, and bone mineral density. Results showed that HAL in subjects with hip fracture was significantly longer than HAL in subjects without hip fracture. All femur BMD variables were significantly lower in hip fracture subjects compared with subjects without hip fracture. Each standard deviation increase in HAL was associated with a 60% increase in hip fracture risk.

Table 1 (*p<0.05 and **p<0.01 compared to controls)

Measurement	Hip Fracture	Controls	OR per SD (95% CI)
Age (years)	77.5	76.2	NS
Height (cm)	159	158	NS
Weight (kg)	60.7*	64.1	NS
HAL (mm)	107.6**	104.9	1.6 (1.1-2.3)
Neck BMD (g/cm^2)	0.672**	0.747	2.4 (1.6-3.6)
Upper Neck BMD (g/cm^2)	0.519**	0.589	2.6 (1.7-4.2)
Total BMD (g/cm^2)	0.684**	0.787	2.4 (1.7-3.4)

M090

Analysis of Cortical Bone Parameters Extracted Automatically from Lumbar Vertebra CT Images. T. Nagaoka*[1], K. Kondo*[2], H. Honma*[1], K. Ogawa*[2], K. Sakurai[1]. [1]Kitasato University Graduate School of Medical Science, Kanagawa, Japan, [2]Housei University, Tokyo, Japan.

Various parameters were reported as predictive factors for fracture risk other than BMD (bone mineral density). Most of all resulted primarily from image-based analysis focused on the trabecular structure of vertebral bodies. For accurate prediction of fracture risk, we believe, parameters describing the characteristics of the cortical bone are also required. We acquired CT (computed tomography) images by a method similar to quantitative CT, and calculated parameters for cortical bone characteristics automatically from the CT images of lumbar vertebrae (8-bit intensity resolution) for 28 healthy females (50.6±7.5 years), 17 osteoporotic females without spinal compression fracture (69.6±6.2 years), and 11 osteoporotic females with fracture (73.2±3.2 years). In the cortical bone region including the vertebral body and pedicle, automatic extraction was first performed for the contour of the vertebral body by P-tile method, and then for the contour of cancellous bone within the vertebral body and the contour of the vertebral foramen by active contour models (snakes). The center of gravity in the vertebral foramen was then designated a reference point with the posterior of the spine at 0°, angle θ was measured counterclockwise. Three cortical bone regions were designated as an anterior region (AR, 150°-210°), lateral region (LR, 120°-150° and 210°-240°), and pedicle region (PR, 80°-110° and 250°-280°). Parameters based on intensity histograms for each region were the threshold creating a 4:6 ratio of low-intensity area to high-intensity area (T46), and the total frequency of intensity between 80 and 120 divided into four gradations (D80, D90, D100, D110). The maximum intensity value (peak value) along the radial direction was determined for every 1°, and the mean of the peak values within each region (Pmean), the maximum value (Pmax), and the minimum value (Pmin) were also used as parameters. Correlations between age and each parameter of healthy subjects were investigated. The results demonstrated stronger correlations for AR-Pmin, AR-T46, AR-D90, and LR-D80 than for BMD ($r = -0.75$). We deemed these parameters to indicate age-related changes in cortical bone, and we concluded that parameters related to regional cortical bone thickness and regional cortical bone density were extracted successfully. Values for AR-T46 and PR-T46 were also significantly lower in osteoporotic patients with fractures than in patients without fractures, and AR-D90 and PR-D80 values were conversely higher. The results suggest that these parameters are useful for fracture risk prediction.

M091

Analytic Model to Predict Mechanical Behavior of Skeletal Metastasis. A. Nazarian*[1], D. von Stechow[1], M. S. Cordio*[1], R. Mueller[2], B. D. Snyder[1]. [1]Orthopedic Biomechanics Lab, BIDMC, Harvard Medical School, Boston, MA, USA, [2]ETH, Zuerich, Switzerland.

Pathologic fractures occur in up to 30% of patients with skeletal metastases. We have developed a CT based structural analysis method to predict fracture risk based on the hypothesis that bone (normal or pathologic) follows the constitutive relationships established for rigid porous foams: i.e. the strength and modulus of bone depend on both bone tissue density (ρ_{tissue}) and the square of bone volume fraction (Vv_b). The ρ_{tissue} accounts for changes in mineralization, and Vv_b accounts for changes in morphology. However, this hypothesis has never been validated for metastatic bone, and the mechanical properties of skeletal metastases have not been previously described. After obtaining IRB approval and informed consent, 10 patients (7 male, 3 females, 57 ±15 years) underwent excisional biopsy of metastatic prostate, breast, lung, ovarian or colon cancer. The presence of metastatic cancer was confirmed histologically. The biopsy specimens were cored along the predominant trabecular orientation and cut into 24 cylinders. The ρ_{tissue} of each sample was measured using a pycnometer. Mechanical testing was performed using a novel micromechanical device coupled with micro-computed tomographic (μCT) imaging. Progressive step-wise compressive strains were applied to each sample. Each sample was imaged intact and again after the application of each strain step to visualize progressive deformation of the microstructure. The μCT image of each intact sample was divided into 5 equally segmented transaxial subregions and the volume fraction for each transaxial subregion calculated. A bivariate nonlinear regression model (Levenberg-Marquardt) of the form $E, \sigma = A\rho_{tissue}(Vv_b)^2+B$ was fit to the data. In all cases ρ_{tissue} was within the normal range of 1.6 to 2.2 g/cc. The μCT images demonstrated that sample failure occurred predominantly at the weakest subregion with minimum Vv_b. The model accounted for 78% and 88% of the variation in modulus and strength respectively using minimum Vv_b. These results establish a unifying principle that characterizes the mechanical behavior of metastatic bone tissue. In addition, ρ_{tissue} is unaffected by metastatic cancer, and the changes in the mechanical behavior of metastatic bone tissue are primarily caused by localized remodeling of trabecular architecture. This study validates the application of power law functions of bone density and volume fraction to derive the load carrying capacity of bone containing metastatic tumors. These findings suggest that bone itself can be viewed as a substrate undergoing remodeling by osteoclasts and osteoblasts in response to local and/or systemic modulators of their activity.

A New Staining Technique for Undecalcified Bone Sections that Enhances Visualization of Fluorochromes. D. Horn*, P. Rivas*, B. McCluskey*, G. R. Mundy, G. Gutierrez. OsteoScreen, LTD, San Antonio, TX, USA.

Bone histomorphometry (BHM) is an essential tool in basic and clinical research for the assessment of bone micro architecture. It is very useful in determining the cellular activity of the skeleton, since bone is constantly undergoing remodeling. BHM requires that the separate components of the tissue be differentially stained so they can be easily recognized and quantified. Either decalcified or undecalcified sections can be obtained for the analysis of mineralized bone and osteoid. It is also possible to determine not only the structural but also the dynamic changes occurring in bone. The extent and rate of bone formation are usually measured using ultraviolet microscopic analysis of fluorochrome labels in undecalcified sections. Until now however, these measurements have been performed on unstained slides, because the use of the commonly used stains, does not allow visualization of fluorescent dyes. Bone structure is very hard to visualize in unstained sections. For this reason, duplicate slides are usually employed, one stained slide for quantification of bone volume and other parameters, and one unstained slide for assessment of fluorochrome labeling. We have developed a new technique, which allows us to measure static and dynamic parameters using the same slide. We have used this approach in an experiment in which 4-month-old Sprague-Dawley female rats were labeled twice (six days apart) with calcein ip (15 mg/kg/day), and sacrificed 4 days after the last calcein administration. Tibias were excised, cleaned from soft tissue, and placed in 70% ethanol to be processed and embedded in methyl methacrylate. Proximal tibia sections (8 um thick) were obtained and placed directly into a 1% xylene orange solution at room temperature. After 5 minutes, slides were rinsed in DH_20, allowed to dry at room temperature and cover slipped. We were able to obtain very good staining of mineralized bone with xylene orange that allowed us to perform static and dynamic measurements in both cancellous and cortical bone using OsteoMeasure image analyzer linked to a fluorescent microscope. All these measurements were conducted on the same section, eliminating the need for duplication of slides and various staining techniques. Xylene orange has been used as a fluorochrome, but this is the first time that it has been shown to be effective as a staining agent without interfering with calcein labeling. Because this technique is very easy and gives uniform and reproducible results, we believe it is an excellent alternative to the Villanueva staining method, especially in cases where static and dynamic parameters need to be obtained as in models for osteoporosis and other metabolic bone diseases.

Outpatient percutaneous Bone Biopsy in a Rheumatology Practice - Methods, Patient Tolerance, and Impact on Disease Management. H. R. Barthel[1], A. Schulz*[2], B. Knoblauch*[2]. [1]Rheumatology Practice, Koenigstein, Germany, [2]Pathology, Justus-Liebig-University, Giessen, Germany.

Introduction: Bone marrow biopsy histology and histomorphometry are important tools in the diagnosis and management of metabolic bone and systemic inflammatory diseases. However, the invasive nature of the biopsy has hampered its widespread use. In addition, most often the procedures are done in inpatient settings only. We describe our experience in an outpatient rheumatology/internal medicine practice. During a time period of 2 years 17 bone biopsies were performed and their indications, tolerability, complications and impact on disease management were evaluated. All patients had full hematol., biochem., radiological, and Dexa or QCT bone density work ups before the bone biopsies were performed. Methods: In all patients the transiliac biopsy approach was chosen. Local infiltration anesthesia was applied to both sides of ileac crest. Biopsy was performed with an 8mm Bordier Trephine or an 1.5mm (11ga) Jamshidi needle at a position approx. 5-10cm dorsal and 3cm caudal of the spina iliaca anterior superior. No general anesthesia or sedation was used. After usage of the Bourdier trephine the skin incision was sutured, which was not necessary with Jamshidi needle technique. 2/3 of biopsies were performed to evaluate metabolic or osteoporotic bone diseases (mostly to evaluate elevated bone turnover by bone resorption markers despite bisphosphonate treatment) 1/3 of biopsies were done to evaluate bone marrow differentiation in syst. inflammatory conditions or to rule out marrow malignancies. Results: Bone biopsy was well tolerated with minimal pain perception by patients, in about 25% a second biopsy approach had to be performed through the same incision site to obtain an adequate specimen. Histol. evaluations obtained good to excellent specimen quality in all cases with adequacy of all core specimens obtained with the 1,5 mm Jamshidi in all cases; therefore this technique was used exclusively later. Although pat. were given pain meds to take home after the procedure less then half reported to have used them. Small hematomas occurred in all cases, to a subst. larger degree with the larger Bourdier Trephine. One (Bourdier) pat. complained of transient upper thigh numbness due to assumed cutaneous femoral nerve compression and needed evaluation with CT to rule out retroperitoneal hematoma. His symptoms subsided after 2 weeks. In about ¼ of cases disease management was changed after obtaining biopsy results. Conclusions: Transiliac bone biopsy can be performed with minimal risks in an outpatient setting. Results help in the management of patients with metabolic, osteoporotic, and inflammation mediated bone diseases.

Nuclear Magnetic Resonance Shows that a Decrease in Cortical Bone Mineralization Parallels an Increase in Osteoid Water. M. A. Fernandez-Seara*[1], S. L. Werhli*[2], M. Takahashi*[1], F. W. Wehrli[1]. [1]Radiology, University of Pennsylvania Medical Center, Philadelphia, PA, USA, [2]NMR Core Facility, Children Hospital, Philadelphia, PA, USA.

Bone strength strongly depends on bone matrix mineralization. Vose and Kubala first showed that an increase in ash of 7% increased static strength threefold. It is also known that an increase in mineral is accompanied by a decrease in osteoid water, since mineralization proceeds by water displacement while volume remains constant. Thus water content may potentially be used as a predictor of bone intrinsic strength. The purpose of this study was to investigate whether water content measured using non-destructive Nuclear Magnetic Resonance (NMR) techniques correlates with mineral content measured by gravimetric methods. Four rabbits (5-6 wk old) were fed a low phosphorus diet (0.09%) to induce hypomineralization of the skeleton. A second group of four rabbits received the same diet supplemented with sodium phosphate to normal phosphorus levels (0.5%). After 8 wks the animals were sacrificed and three cortical bone specimens were cut form the mid-shaft of the harvested tibiae, 2 of which were used to measure water and ash by gravimetric methods. The third one was used to measure water content by means of isotope exchange. Briefly, a proton NMR spectrum of the bone in air was obtained. Thereafter, the specimen was immersed in deuterium oxide and the deuterium-proton exchange was monitored by proton spectroscopy. After 8 hours, the bone was removed from the solution and a second spectrum was acquired in air. These data were used to calculate water content and to measure the diffusion coefficient of water in the bone matrix. In addition, bone volume was measured by MRI. Significant differences in water content measured by drying were observed between control (15.20 ± 0.08 wet weight %) and treatment (15.85 ± 0.07) groups (p=0.002). All treated animals had lower ash content than the controls (65.31 ± 0.11 vs. 67.06 ± 0.12 wet weight %, p=0.0001). Water measured by NMR was higher than the water measured by drying for both, but again significantly different between the control (18.66 ± 0.54 wet weight %) and treatment (21.42 ± 0.47) groups (p=0.02). Water volume fraction was increased in the treatment (40.47 ± 0.01 %) compared with the control group (36.30 ± 0.01 %), (p=0.03). There were significant negative correlations between ash and water measured by both techniques (drying: r2=0.88, p=0.002; NMR: r2=0.71, p=0.02). The results demonstrate a strong correlation between NMR-determined osteoid water and mineral content. Proton NMR has potential as a nondestructive method for indirect assessment of mineralization.

M095

Magnetic Resonance-Based Virtual Bone Biopsy Reveals Architectural Implications of Renal Osteodystrophy. F. W. Wehrli*[1], M. B. Leonard[2], B. R. Gomberg[3], P. K. Saha*[1]. [1]Radiology, University of Pennsylvania, Philadelphia, PA, USA, [2]The Children's Hospital of Philadelphia, Philadelphia, PA, USA, [3]University of Pennsylvania, Philadelphia, PA, USA.

Renal osteodystrophy (ROD) is caused by renal dysfunction that prevents the formation of the active form of vitamin D (calcitriol), leading secondary hyperparathyroidism. A key manifestation of ROD is abnormal bone turnover, accompanied by marrow fibrosis. High-turnover disease (osteitis fibrosa, OF) has been shown by histomorphometry to result in trabecular bone sclerosis and cortical thinning. Here we explore the potential role of the µ-MRI-based virtual bone biopsy (VBB) for quantifying trabecular and cortical bone properties. Localizer image-guided acquisition of transverse 3D MR images of the distal tibia (137x137x420mm3 voxel size) were processed to yield noise-less bone volume fraction maps from which, after subvoxel processing, grayscale images of 69x69x105 µm3 voxel size were obtained. Trabecular thickness was determined with a new method called 'fuzzy distance transform' which provides accurate measurements in the limited spatial resolution regime of in vivo µ-MRI. In addition, 2D spin-echo images were collected at the tibial mid-shaft for measurement of cortical bone parameters at 0.47 mm in-plane resolution and 2 mm slice thickness. Endo and periosteal boundaries were detected with a method based on tracing profiles diagonally across the tibia, from which cortical bone cross-sectional area (CCA) was determined. So far, 24 subjects have been studied but the data from only 17 subjects have been analyzed (10 patients and 7 gender/age matched controls, all African American). Patients had been on dialysis for 840±460 days. All patients except one had abnormally high PTH (672±364µg/l vs. a target level of 200µg/l in dialysis patients and a normal range of 10-65µg/l). The data revealed the following trends: Patients had increased trabecular thickness consistent with trabecular sclerosis, a sparser trabecular network, a thinned cortex, and increased bone area (the area encompassed by the periosteal boundary), the latter suggesting periosteal expansion. These effects were not statistically significant, presumably due to insufficient power at this stage of the study. However, the normalized CCA (CCA/bone area) was significantly smaller in the patients (p=0.05). The present preliminary data corroborate some of the structural features of secondary hyperparathyroidism and indicate that an entirely noninvasive image-based method, the MR-based VBB may have potential to characterize metabolic bone disease, obviating physical bone biopsy.

M096

Directional Measurement of Direct Thickness of Cancellous Bone. T. G. Morgan*, M. C. H. van der Meulen. Sibley School of Mechanical & Aerospace Engineering, Cornell University, Ithaca, NY, USA.

Determining the structure-function relationship for cancellous bone is important for understanding bone diseases, such as osteoporosis, as well as improving outcomes of prosthetic implant surgeries. Trabecular thickness (Tb.Th) is often used as a measure of the architecture of cancellous bone. However, Tb.Th is typically reported as a volume average and does not have any directionality. The goal of this study was to compare direct trabecular thickness measured throughout the volume and along the three primary directions of a cubic cancellous bone sample. A 4x4x4mm cube of cancellous bone from the distal femur of a New Zealand White rabbit was scanned on a micro-computed tomography system (EVS Corp, London ON) and reconstructed with 0.032mm isotropic voxels. The direct thickness (Hildebrand & Ruegsegger 1997) was calculated as the mean diameter of the spheres that fit within the trabecular structure. A single average value was measured for the entire structure, generating a volume-weighted direct thickness. Next the data were skeletonized, producing a one-voxel thick representation located at the midline of the trabecular structure. The nodes, where struts within the trabecular structure met, were removed and each strut's orientation was measured as the angle of a straight line connecting the two endpoints. Trabeculae lying within a 40 degree envelope of the three primary directions of the cube were identified. For each primary direction, the average direct thickness was determined for the individual trabecula identified. From the individual trabecular thicknesses, the overall mean and mean corresponding to each primary direction were determined. The measured direct thickness varied across the different measurement approaches. When the entire sample was considered, the average direct thickness was 0.177mm., and the mean thickness measured only from the trabeculae oriented along the three primary directions was 0.185mm. When the individual directions were considered, the average direct thickness measured in each of the directions was 0.181mm, 0.196mm, and 0.185mm. Measurement of directional direct thicknesses may provide a tool for measuring intraspecimen architecture variation and improve our understanding of the mechanical behavior of cancellous bone.

M097

Characterization of Changes in Trabecular Bone with Age and Disease. E. S. Mittra*[1], W. Lin*[1], B. Gruber[2], C. T. Rubin[1], Y. Qin[1]. [1]Biomedical Engineering, State University of New York, Stony Brook, NY, USA, [2]Allergy and Immunology, State University of New York, Stony Brook, NY, USA.

It is well known that changes in trabecular architecture occur with respect to age and disease and that these changes are related to fracture risk. This preliminary study seeks to elucidate which architectural parameters are most indicative of these properties. A 2 cm^3 section of trabecular bone was harvested from the calcanei of 4 cadavers chosen to be of similar, but advanced age. Physiologic orientation was maintained while harvesting such that the axes of the harvested cube were identical to *in vivo* anatomical axes. Mechanical property data was collected via compression testing and the specimens were subsequently scanned in a μCT machine. Table 1 shows the overall results. The bone volume fraction (BV/TV) gives a general picture of density and clearly identifies the osteopenic individual of the group.

Table . Selected micro-CT parameters showing overall trends.

Age / Sex	TV/BV	Conn. D.	DA	MIL
n/a / male	0.18	3.62	1.68	1.01
86 / female	0.14	4.23	1.64	1.07
85 / female	0.05	0.86	1.72	2.98
85 / female	0.14	5.20	1.58	0.98

The connectivity density (Conn. D.) was chosen to show a representative trend in μCT parameters, and was mimicked by other parameters such as trabecular thickness and trabecular spacing. The degree of anisotropy (DA) gives an indication of overall geometric heterogeneity and the most osteopenic bone had the largest value. In other words, the bone loss is occurring in a very specific manner with regard to geometry. The mean intercept length (MIL) values listed in the table correspond to the largest such values and show that the principal trabecular orientation of the osteopenic individual has a nearly 3-fold stronger effect in comparison to the nearest relatively non-osteopenic individual. An evaluation of the direction associated with these values show an average deviation from the superior-inferior axis of approximately 74º. This is thought to correspond to the physiologic loading direction during gait cycles. Micro-CT parameters seem to provide, therefore, a valuable tool to identify changes in trabecular architecture due to age or disease. In addition, our study provides a validation of the application of Wolff's law in that the principal trabecular orientation is maintained in the direction of principal loading (i.e., gait), and this effect is more pronounced in situations of bone loss.

M098

Computed Tomographic Microscopy in a Rabbit Model of Osteoarthritis. D. L. Batiste*[1], A. Kirkley*[2], S. Laverty*[3], N. L. Ford*[1], M. M. Thornton[4], D. W. Holdsworth[1]. [1]Imaging Research, John P. Robarts Research Institute, London, ON, Canada, [2]Department of Surgery, University of Western Ontario, London, ON, Canada, [3]Dept. de Sciences Cliniques, Universite de Montreal, St. Hyacinthe, PQ, Canada, [4]Enhanced Vision Systems, Corp., London, ON, Canada.

We are interested in the development of quantitative computed tomographic imaging techniques that can be used to study bone density and structure in animal models of osteoarthritis (OA). In this study, we investigate whether it is possible to use micro-computed tomography (micro-CT) to characterize a rabbit anterior cruciate ligament transection (ACLX) model of OA. We have imaged fresh excised tissue from skeletally mature New Zealand White rabbits, including both control animals and those that had undergone ACL transection 4, 8, or 12 weeks prior. All animal surgery was performed within the guidelines of the institutional animal care committee. Hindlimbs were harvested from control animals and imaged in saline, with the soft tissue intact. Specimens were imaged at 80 kVp on a micro-CT system system (Enhanced Vision Systems Corp., London Canada). During data acquisition, 262 digital x-ray projection images were obtained at 0.748 degree intervals. These images were then reconstructed to obtain a 2.5 x 2.5 x 2 cm3 volume of image data, with 0.085 mm isotropic voxel spacing. Example results are shown in the figure, where we compare sagittal sectional views of control (a) and ACLX (b) animals. Precision in the CT data is approximately 85 Hounsfield units, equivalent to about ±5% in bone density. The three-dimensional data format made it possible to characterize joint spacing and bone architecture. We found that joint spacing increased after ACLX, probably due to fluid accumulation. Also visible in the figure is the appearance of poorly mineralized osteophytes in the eight-week post-ACLX animals (arrow). Micro-CT has become a common tool during pre-clinical investigations of new treatments for osteoporosis, but this non-destructive technique is less commonly used during studies related to OA. In this study, we have demonstrated the potential viability of using quantitative high resolution micro-CT to characterize changes in bone architecture and bone density in a rabbit ACLX model of surgically induced osteoarthritis.

Bone Mineral Density at the Hip And Tibia and Speed of Sound at the Tibia in Spinal Cord Injured Individuals. L. M. Giangregorio*[1], C. E. Webber[2], S. M. Phillips*[1], A. L. Hicks*[1], N. McCartney*[1]. [1]Human Biodynamics, McMaster University, Hamilton, ON, Canada, [2]Nuclear Medicine, McMaster University, Hamilton, ON, Canada.

The aim of the present cross-sectional study was to evaluate the bone mineral density (BMD) at the hip and tibia, as well as the speed of sound (SOS) at the radius and mid-tibia in individuals with a spinal cord injury (SCI). The level of lesion ranged from C4 to T12, the average age of the participants was 32 years old, and average time post-injury was 10.2 years, with a range of 1.17 to 25 years. BMD at the hip was examined in 21 individuals (15 males, 6 females) using dual-energy x-ray absorptiometry (DXA), along with SOS measurements at the radius and mid-tibia with an ultrasonometer. In a sub-group of 14 individuals, tibia BMD was also measured using DXA. Using the WHO criteria for osteoporosis, 11 of 21 subjects were osteoporotic at the hip, 9 were osteopenic and 1 had normal hip BMD. In contrast, only one subject had a tibia SOS T-score of -2 and two subjects had T-scores between -1 and -2. Hip BMD and tibia SOS were moderately correlated ($r = 0.43$, $p0.05$). Hip BMD and tibia BMD were strongly correlated, however ($r = 0.69$, $p<0.005$). Radius SOS T-scores were 0.65 and 0.78 in males and females respectively, and were not correlated with any of the lower limb variables. Lower limb bone mass is reduced in spinal cord-injured individuals, but SOS at the mid-tibia is not. SOS may reflect bone properties other than bone density that may not be reduced in individuals with SCI.

Format of Ultrasound Report Influences Patient Compliance With Treatment and Understanding of Risk. L. Greenwald*[1], A. Bardwell*[2], P. Kushner*[3], J. Maliinak*[4], M. Lewicki[5], S. Silverman[6], M. Greenwald[1]. [1]Desert Medical Advances, Palm Desert, CA, USA, [2]Santa Fe, Santa Fe, NM, USA, [3]Long Beach, Long Beach, CA, USA, [4]La Mesa, La Mesa, CA, USA, [5]Osteoporosis Research, Albuquerque, NM, USA, [6]UCLA, Los Angeles, CA, USA.

A survey of 150 postmenopausal women with no prior bisphosphonate therapy is being conducted in the Southwestern U.S. Postmenopausal women were offered a free bone density with a Sahara ultrasound unit and asked to complete a questionnaire with their primary physician within 30 days. Entry criteria required a unique primary physician for each subject. The women were separated into subgroups above or below age 65 and this report is an interim analysis. For those over 65, the average age was 73 yrs(range 65-84)and insurers were managed care(50%), private(45%),and welfare(5%). Insurance type did not influence follow up with the primary physician. The subject and her physician received by random choice the results of the bone density as a traditional T score provided by Sahara or an absolute risk fracture report. Only 60% of women followed up with their doctor when given the traditional T score Sahara form (many wrote their test was "good' so they didn't need to follow up). Only 20% of these elderly women received a prescription for osteoporosis. In the other group, randomly assigned the absolute fracture report, 70% followed up with their doctor, 40% received a new osteoporosis prescription, and 95% filled the prescription. More women in this elderly group followed up with their doctor and a larger percentage received treatment prescriptions with the absolute fracture risk format for U/S ($p<0.07$). Most concerning was that only 22% of the women under age 65 (avg age 49) followed up with a physician with the traditional T score format. Many women may erroneously assume that there is no osteoporosis risk with the traditional T score U/S report.

M101

Can the WHO Criteria Be Applied to Multi-Site Axial Transmission Quantitative Ultrasound? K. M. Knapp[1], G. M. Blake[1], I. Yaniv[2], T. D. Spector[3], I. Fogelman[1]. [1]Osteoporosis Screening and Research Unit, Guy's Hospital, London, United Kingdom, [2]Sunlight Medical Ltd, Tel Aviv, Israel, [3]Twin Research and Genetic Epidemiology Unit, St Thomas' Hospital, London, United Kingdom.

The WHO criteria defines osteoporosis based on bone mineral measurement as 2.5 or more standard deviations below the young healthy adult mean at the hip, spine or radius. This criteria is widely used for the diagnosis of osteoporosis. However, the use of the WHO criteria may be inappropriate for the diagnosis of osteoporosis using other modalities such as QUS. A previous study by Weiss et al [1] found that different T-score cut-offs were required for SOS measurements of the phalanx, tibia and metatarsal to result in the same prevalence of osteoporosis as a T-score ≤ -2.5 for SOS at the radius. The aim of this study was to investigate the T-score thresholds for the diagnosis of osteoporosis from SOS measurements at the radius, tibia, phalanx and metatarsal compared to BMD measurements at the total hip. A group of 75 women aged 60-69, with no history of drugs or diseases known to affect bone metabolism, low trauma fractures or premature menopause/ prolonged amenorrhoea were recruited. SOS measurements were made at the phalanx, radius, tibia and metatarsal using the Sunlight Omnisense™ (Tel Aviv, Israel) and BMD measurements were made at the proximal femur using the Hologic QDR-4500a (Bedford, MA). The same method was applied as used by Weiss et al [1]. The prevalence of osteoporosis was calculated for BMD at the total hip for the age group 60-69 years. The equivalent T-score required to identify the same percentage of patients as osteoporotic for SOS measurement at the radius, tibia, phalanx and metatarsal was then calculated.

Site	n	Mean T-score	% prevalence	T-score threshold
Radius SOS	71	-1.00	5.6	-2.6
Tibia SOS	75	-1.15	17.3	-3.0
Phalanx SOS	52	-1.80	25.0	-3.0
Metatarsal SOS	49	-0.92	4.1	-2.2
Total Hip BMD	72	-0.60	4.2	-2.5

These results demonstrate that while a T-score cut-off of -2.5 is appropriate for use with Radius SOS, it is inappropriate for use with the other sites. Furthermore, differing T-score thresholds are required for the diagnosis of osteoporosis at different sites using the Sunlight Omnisense™ . Further research is required to verify these T-score thresholds using larger reference populations and possibly different methods for calculating the diagnostic thresholds.

Relationship Between Ultrasonic Backscatter and Trabecular Thickness in Human Calcaneus: Theory and Experiment. K. A. Wear*[1], A. Laib*[2]. [1]Food and Drug Administration, Rockville, MD, USA, [2]Scanco Medical AG, Bassersdorf, Switzerland.

Ultrasonic backscatter from calcaneus is a new diagnostic measurement that may complement existing measurements such as broadband ultrasonic attenuation (BUA), speed of sound (SOS), and bone mineral density (BMD). In addition, the study of scattering from bone elucidates mechanisms underlying attenuation (the combined result of absorption and scattering) and therefore may enhance diagnostic interpretation of BUA measurements. Previously, a model has been developed in which trabeculae are represented as cylinders that are narrow relative to the ultrasonic wavelength. This model predicts frequency dependence of backscatter from calcaneus in close agreement with measurements. Compared with other theoretical models for scattering from trabecular bone (that are also insightful and useful), the cylinder model is somewhat simplistic from a geometric standpoint. However, unlike the other models, it 1) does not require small variations in acoustic properties (material density and sound speed) between trabeculae and the embedding medium (in vivo: marrow or in vitro: water) and 2) allows for propagation within trabeculae of shear waves (which have been demonstrated to occur in cortical bone and therefore are likely to propagate in trabeculae). An approximate formula, derived from the cylinder model, has recently been developed to relate backscatter to four determinants: mean trabecular thickness (Tb.Th), mean trabecular spacing, trabecular mass density, and trabecular longitudinal sound speed. In the realm of expected values of these parameters for trabecular bone, the model predicts that backscatter is approximately proportional to Tb.Th to the nth power where n=2.9. Since volumetric BMD is expected to be proportional to Tb.Th to the power of 2 (rather than 2.9), there is hope that backscatter may convey some information regarding Tb.Th beyond that contained in BMD although recent empirical results, obtained in vitro with a moderate number of samples (Chaffai et al., Bone, 20, 229 - 37, 2002) suggest that this potential added information content is small. To experimentally test the approximate model, ultrasonic backscatter was measured on 43 human calcaneus samples in vitro. In addition, micro computed tomography (voxel size: 30 cubic microns) was performed in order to assess microarchitecture. A power law fit of backscatter coefficient versus Tb.Th produced an estimated exponent of n=2.8 with a 95 percent confidence interval of (1.7, 3.9). In conclusion, backscatter from human calcaneus provides potentially diagnostically useful information regarding mean trabecular thickness consistent with predictions from the cylinder model.

Measurements of Ultrasonic Backscattered Spectral Centroid Shift from Spine In Vivo – Methodology & Preliminary Results. K. A. Wear*[1], B. S. Garra*[2], M. C. Pinet*[2], S. Felker*[2], J. Mai*[2]. [1]Center for Devices and Radiological Health, Food and Drug Administration, Rockville, MD, USA, [2]Radiology Dept., University of Vermont, Burlington, VT, USA.

Previous reports have shown a good correlation between measurements of backscattered ultrasound and bone mineral density (BMD) in the calcaneus. Although measurements in calcaneus are useful, direct measurements in hip and spine would be more valuable since these sites are associated with the clinically most significant osteoporotic fractures. We have developed a technique to measure backscattered ultrasound from lumbar vertebrae using a commercial ultrasound scanner. The method relies on compression of the overlying abdominal tissue to a constant thickness to minimize measurement variability due to attenuation and diffraction effects. Since soft tissue may be approximated as an incompressible fluid, the tissue expands laterally in order to compensate for the longitudinal compression. Therefore attenuation due to overlying tissue between transducer and vertebra remains roughly constant. Radio frequency backscattered ultrasound data are acquired from L3 and/or L4 vertebral bodies using a GE-Vingmed System Five Ultrasound Scanner fitted with a 2.5 MHz phased array ultrasound probe. Data are acquired in both transverse and longitudinal planes after compressing the overlying tissue to a thickness of 3 cm. Correction for instrument gain settings and focusing/diffraction effects is achieved by use of data acquired from a tissue-mimicking calibration phantom (with attenuation coefficient matched to soft tissue) scanned immediately after the human subject using the same settings. The spectral centroid shift between the spine and phantom data is an index of ultrasonic attenuation within the spine. BMD was also measured using a GE-Lunar whole body DEXA system. From measurements from 11 vertebrae in 7 individuals, we have found a correlation coefficient of r = -0.61 between spectral centroid shift and BMD, with a slope of -0.16 MHz/(g/cm2). This negative correlation is expected as denser, more highly attenuating bone would be expected to produce greater downshifts in spectral centroid. In conclusion, 1) acquisition of ultrasonic backscatter data from human spine in vivo is feasible, and 2) spectral centroid shift exhibits a moderate negative correlation with BMD in accordance with expectrations.

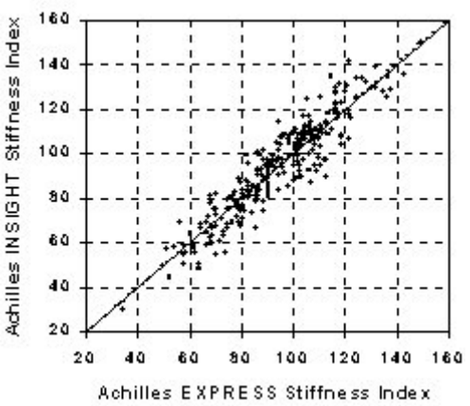
***In Vivo* QUS Performance of a Fixed-Array Bone Imaging Ultrasonometer.** W. K. Wacker*, R. F. Morris*, K. L. Morris*, G. F. Mitchelmore*, K. G Faulkner. GE Medical Systems Lunar, Madison, WI, USA.

The Lunar Achilles InSight (GE Medical Systems), a fourth-generation bone ultrasonometer, eliminates 'blind' measurement by displaying a real-time image of the heel prior to and during measurement. A Region-of-Measurement (ROM) circle is superimposed on the image to show the location of the ultrasound measurement. The image is produced using a 2-element coaxial transmit transducer and a 590-element two-dimensional array receiving transducer. Transmission bone ultrasonometry is increasingly accepted as a low cost, effective method to assess and manage osteoporotic patients. We compared the *in vivo* performance of the Achilles InSight to the performance of the Lunar Achilles Express (GE Medical Systems), a previous generation bone ultrasonometer. Measurements were performed on 253 subjects with a wide range of heel densities (Stiffness Index 35 to 149). Stiffness Index was highly correlated (r=0.93) between the two devices. Regression of Achilles InSight Stiffness Index values on Achilles Express values resulted in values for the slope (1.01) and intercept (-1.3) which were not significantly different from identity (α=0.05). We conclude that Stiffness Index values measured with Achilles InSight are equivalent to those measured with previous generation Lunar Achilles bone ultrasonometers.



M105

Quantitative Ultrasound for the Evaluation of Skeletal Growth in New-Borns. S. Gonnelli[1], A. Montagnani*[1], L. Gennari[1], C. Cepollaro*[1], S. Martini*[1], D. Merlotti*[1], M. Muraca*[2], S. Perrone*[2], G. Bonocore*[2], F. Bagnoli*[2], C. Gennari[1]. [1]Institute of Internal Medicine, University of Siena, Siena, Italy, [2]Institute of Neonatology, University of Siena, Siena, Italy.

One of the most debated issues in pediatric bone research is the optimal technique for determining bone status in growing children. Quantitative ultrasound (QUS), although being widely used in adults is, by far, scarcely employed in new-borns and in children. This study aimed to evaluate the usefulness of QUS in new-borns and the factors influencing QUS parameters. In 130 healthy new-borns (67 males and 63 females, gestational age range: 32.7-42.1 weeks) QUS parameters were assessed at distal metaphyses of humerus using Bone Profiler (IGEA, Italy), after an appropriate modification of caliper and software. In all subjects we evaluated: AD-SoS (m/s), the characterizing graphic trace parameters (SDy, FWA and BTT) and finally two new indices: SoS (m/s), that is the speed of sound calculated on the first peak and BTT_{1570} (µs), that is the interval time between the first peak of the ultrasound and when this reaches the speed of 1570 m/s. QUS measurements were also performed in all mothers (age range: 24-38 years) who also self-reported a calcium questionnaire. In 30 infants QUS were repeated also after 12 months. In the 130 new-borns we obtained the following results: 1749.8±34.1 m/s for AD-SoS; 879.8±2596.9 mV/µs² for SDy; 1.96±0.73 mV for FWA; 0.23±0.10 µs for BTT; 0.91±0.16 µs for BTT1570 and 1724.8±25.3 m/s for SoS. No differences were found in QUS parameters between the two sexes. Among QUS parameters only BTT and BTT_{1570} correlated with anthropometric indices, such as skull diameter (r=0.18, p<0.05; r=0.39; p<0.01, respectively), the weight (r= 0.20, p<0.05; r=0.37; p<0.01, respectively) and the height (r=0.20; p<0.05 only for BTT1570). The mothers showed a reduction of AD-SoS (T-score: –1.04±0.82), whereas the graphic trace parameters resulted normal as compared to normative data. No correlations were found between mothers and new-borns data. Children, who underwent a second measure after 12 months, showed a reduction of AD-SoS, SDy and FWA, whereas BTT significantly (p<0.001) increased. In conclusion, the present study pointed out that: Bone Profiler is able to perform QUS measurements in new-borns; among all QUS parameters BTT and BTT_{1570} showed the best correlation with anthropometric indices of new-borns; preliminary longitudinal data seem to suggest BTT as the best parameter to monitor the physiological bone growth in pediatric subjects. Therefore, QUS, for its technical characteristics (radiation-free, low cost, portability, rapid scan), offers promise as useful tool for widespread use in pediatrics.

M106

Correlation Between Cut-Off Value Determined by Using Quantitative Ultrasound and Threshold of Fracture in Japanese Women. K. Yoh*[1], K. Makita*[2], H. Kishimoto*[3], H. Ohta[4], I. Gorai[5], J. Hashimoto[6], Y. Nakatuka*[7], S. Yoshimoto*[8], S. Kamae*[9]. [1]Orthopedic Surgery, Hyogo College of Medicine, Nishinomiya, Japan, [2]Keio University, Tokyo, Japan, [3]Sanin Rosai Hosp., Yonago, Japan, [4]Tokyo Women's Univ., Tokyo, Japan, [5]Yokohama City Univ., Yokohama, Japan, [6]Osaka Univ., Osaka, Japan, [7]Osaka City Univ., Osaka, Japan, [8]Hyogo Chuo Hosp., Sanda, Japan, [9]Hyogo College of Medicine, Nishinomiya, Japan.

The aim of this study was to assess the ability of Quantitative Ultrasound (QUS) to identify woman with vertebral fracture. Recently, the QUS technique is becoming available around the world. To diagnosis osteoporosis by using QUS, the correlation between it and dual energy X-ray absorptiometry (DXA) as well as the ability to identify fracture risk needs to be investigated. For this reason, a total of 388 Japanese women, including patients with osteoporosis, were tested, after signing an informed consent. The speed of sound (SOS) of all subjects was measured at the right calcareous using QUS (FURUNO CM-100, Japan), and bone mineral density (BMD) was measured at the lumbar spine (L2-L4) using DXA (Norland: XR26/36, Hologic: QDR-2000 and Lunar: DPX). All subjects also underwent radiographic examination of the thoracic and lumbar spine with the criterion recommended by the Japanese Society for Bone Mineral Research. (This criterion: In the measurement of vertebral bodies, heights of the posterior margin (p), the central portion (c) and the anterior margin (a) of vertebral bodies, fracture and deformity is defined as a/p of less than -25% and c/p as well as c/a of less than –20%.) The result was divided into two categories: 107 women (mean age: 66.0 years) were without vertebral fracture and 281 women (mean age: 61.5 years) were with vertebral fracture. The average value of SOS was 1480m/s without vertebral fracture and 1493m/s with vertebral fracture, respectively. As a result of each sensitivity and specificity curve analysis on SOS, the intersection point was 1484m/s. This SOS value, 1484m/s, is almost the same as the cut-off value for diagnostic of osteoporosis of SOS, 1487m/s, derived from lumbar BMD using DXA. These data showed the high correlation between the cut-off values of SOS derived from with or without vertebral fracture and the cut-off value of SOS derived from diagnostic of osteoporosis based on DXA. In conclusion, SOS measurement can be used to diagnose osteoporosis as well as to predict fracture risk.

Quantitative Ultrasound Measurement at the Femur in Vitro: Feasibility Study, Precision and Relationship Between BUA And BMD. L. Akrout*[1], F. Padilla[1], C. Latremouille*[2], P. Laugier[1]. [1]Lip umr 7623, CNRS - Universite Paris 6, Paris, France, [2]Institut d'Anatomie, Anatomie Broussais Hotel-Dieu, Paris, France.

The goal of this paper is to demonstrate the feasibility of QUS measurements at the femur, and to present relationships between QUS and DXA at the femur. Measurements of broadband ultrasonic attenuation (BUA) represent an established means of skeletal status assessment in osteoporosis, and especially for the prediction of fracture risk at the femoral neck. Today, the preferred site of ultrasound measurement is the calcaneus (heel bone). However, the predictions might be improved if the measurements were performed directly at the site of fracture. Six human femur freshly removed from cadavers have been measured with a pair of 0.5 MHz focused transducers . 2D rectilinear scans were performed and the RF signals were recorded at each measurement point. An appropriate signal processing has been developed to find ROIs were the frequency-dependent attenuation was linear and to compute BUA (slope of the frequency dependent attenuation). 2D BUA images, 6*6 cm2, were obtained, centered on the femoral neck and the great trochanter. Roughly, 20 measurements with reposioning were performed on each sample to determine the reproducibility. The CVs were computed for 4 different ROIs, and were found to vary from 2 to 6% The mean BUA in a ROI centrally located in the great trochanter was compared with BMD (Hologic QDR 4500A) in a site-matched ROI. It resulted in a linear relationship with r^2 = 0.7. In a second step, slices with parallel faces of 2 cm thickness were cut along the sagital axis of two specimens. The same procedure of BUA measurement was followed on 7 ROIs for each slices. The corresponding CVs were found between 2 and 6% Comparison with BMD in site-matched ROIs resulted in a linear relationship with r^2 = 0.9. These data demonstrate in vitro the feasibility of QUS measurements at the femur with reasonable reproductibility. Although, it is not yet possible to conclude on the relationship between QUS and BMD at the femur due to the small number of specimens, our results suggest that BUA could be considered as a surrogate marker of BMD at the proximal femur, which is consistent with data previously shown at the calcaneus.

M108

Assessement of Trabecular Microstructure Using Ultrasonic Statistical Models of Trabecular Bone Microstructure. F. Jenson*, F. Padilla, P. Laugier. Lip umr 7623, CNRS - Universite Paris 6, Paris, France.

The goal of this study is to assess the mean trabecular thickness of trabeculae, in human cancellous bones from ultrasonic backscattering measurements. To address this inverse problem, we propose a model for the ultrasonic frequency-dependent backscatter coefficient in cancellous bone. A weak scattering model is used and the backscatter coefficient is expressed in terms of an autocorrelation function of the medium. The autocorrelation function describes the statistical properties of the fluctuations of the mechanical properties (i.e., density and compressibility) of cancellous bone specimens. Different autocorrelation functions (Gaussian, exponential and dense media) are used to compute the backscatter coefficient. Comparison is made with experimental data obtained on 19 human specimens of calcanei and for frequency ranging from 0.4 to 1.2 MHz. For each specimen a non-linear regression is performed to fit the theoretical predictions to ultrasonic experimental data and the mean trabecular thickness is estimated. Experimental data and modeled theoretical predictions are averaged over the 19 specimens. A good agreement between experimental data and predictions was found for both the magnitude and the frequency dependence of the backscatter coefficient. We also found a good agreement between the experimental mean trabecular thickness (Tb.Th=130±6.5 µm) derived from the analysis of 3D images of bone microarchitecture (very high resolution synchrotron radiation micro tomography) and theoretical predictions (Tb.Th-Gauss=140±10 µm, Tb.Th-exponential=153±12.5 µm and Tb.Th-dense=138±6.5 µm). These results open interesting prospects for the assessment of bone microarchitecture from ultrasonic backscattering measurements.

Assessment of Changes Occurring in Subchondral Bone during Rat Skeletal Maturation using 400 MHz Quantitative Ultrasound. B. Jaffre*[1], K. Raum*[2], J. Brandt*[3], A. Watrin*[4], A. Klemenz*[2], P. Netter*[4], P. Laugier[1], A. Saied[1]. [1]Lab. Imagerie Parametrique, CNRS-Paris 6 UMR 7623, Paris, France, [2]Inst. Med. Physics and Biophysics, Martin Luther University, Halle, Germany, [3]Orthoped. Clinic, Martin Luther University, Halle, Germany, [4]Lab. of Pharmacology, CNRS-UHP UMR 7561, Nancy, France.

High frequency scanning acoustic microscopy is referred to as an acoustic imaging system with a spatial resolution comparable to that of light microscopy. Usually it allows the qualitative characterization of acoustical properties at or close to the surface of flat samples. With the previously described Multi Layer Analysis (MLA) method it is furthermore possible to obtain quantitative acoustic information which can be related to mechanical and structural properties of the tissue under study. We have used this technique to investigate the age-related changes occurring in subchondral bone during rat skeletal maturation. Sixteen patellae of 8 immature (7 weeks old) and 8 mature (11 weeks old) rats were thawed in methanol, frozen in liquid nitrogen and cut in the sagittal plane of the patella using a high precision milling machine. Samples were then imaged in methanol at 400 MHz (3 µm spatial resolution) using an acoustic microscope (KSI SAM 2000). Acoustic impedance (Z) images of each sample were constructed using the local measurement of the reflection coefficient. Results were compared to histology. Qualitative analysis revealed that bone porosity decreases with age and the bone/cartilage interface gets more regular. The mean impedance of mature and immature samples were similar and around 5.0 ± 0.6 Mrayl. However in mature bone, two regions of different reflection coefficients could be distin-

guished on 6 samples out of 8: a region just beneath cartilage where the lower Z (4.5 ± 0.6 Mrayl) could be due to the less mineralized transitional zone between bone and cartilage; and a region of higher reflection coefficient (Z = 5.2 ± 0.7 Mrayl) and probably higher mineralization in the deeper and earlier formed bone. High resolution 400 MHz acoustic microscopy is sensitive to some changes occurring in subchondral bone during the maturation process. Qualitative images enable assessment of changes in bone structural organization and elastomechanical properties at a microscopic scale. Measurements of acoustic impedance are a new means to quantify the observed changes. The study of relationships between QUS microscopy and bulk properties will be the object of further works. QUS microscopy could therefore be a new method to investigate changes occurring in bone during the development of diseases like arthritis and osteoarthritis affecting bone and cartilage.

M110

Quantitative Ultrasound Before And After Heart Transplantation: A Cross-Sectional Study. C. Cepollaro*[1], S. Gonnelli[1], A. Montagnani*[1], M. Breschi*[1], C. Pondrelli*[1], D. Bruni*[1], M. Mangeri*[1], F. Diciolla*[2], M. Maccherini*[2], C. Gennari*[1]. [1]Institute of Internal Medicine, University of Siena, Siena, Italy, [2]Institute of Cardiac Surgery, University of Siena, Siena, Italy.

During the past 2 decades, heart transplantation (HTx) has evolved from an experimental procedure to an accepted life-extending therapy for patient with end-stage heart failure (ESHF). Patients with ESHF awaiting HTx tend to have reduced BMD related to cardiac cachexia with poor nutrition, prolonged physical inactivity and other factors. After HTx, glucocorticoid and immunosuppressive therapy could produce further bone loss. Although DXA is the most used technique for assessing BMD, quantitative ultrasound (QUS) has been explored as an alternative for the assessment of skeletal status. This study aimed to evaluate bone status, by DXA and QUS, before and after HTx. We recruited 30 patients (25 males and 5 females, mean age 55.7±9.0) with ESHF awaiting HTx and 62 patients (48 males and 14 females, mean age 57.3±9.1) who had undergone HTx 12-24 months before. Patients on treatment with bone antiresorptive drugs were excluded. In all patients and in 92 age and sex-matched healthy controls, we performed DXA (Hologic QDR 4500) at lumbar spine (BMD-LS) and at femur (total: BMD-T, neck: BMD-N, trochanter: BMD-Tr, inter-trochanter: BMD-Itr, Ward's triangle: BMD-W) and QUS parameters at calcaneus (speed of sound: SOS, broadband ultrasound attenuation: BUA and Stiffness) by Achilles plus, and at phalanxes (amplitude dependent speed of sound: AD-SoS) by Bone Profiler (Igea, Italy). The T-score values for DXA were: -1.5 for BMD-LS, -1.0 for BMD-T, -1.6 for BMD-N, -1.0 for BMD-Tr, -0.9 for BMD-Itr, -2.0 for BMD-W in the ESHF group and respectively of -1.7, -1.3, -1.9, -1.2, -1.2 and -2.3 in the HTx group. Considering QUS parameters, in the ESHF group, SOS, BUA, Stiffness and AD-SoS showed T-score values respectively of -2.0, -2.2, -2.7 and -1.9; while in the HTx group, the T-score values resulted -2.3, -2.6, -3.0 and -2.2 respectively for SOS, BUA, Stiffness and AD-SoS. In both ESHF and HTx patients, all DXA and QUS parameters resulted significantly lower than incontrols. Instead, the differences in DXA and QUS between ESHF and HTx did not reach the statistical significance. We can conclude that: QUS parameters at calcaneus and at phalanxes, similarly to DXA, are significantly reduced in ESHF; trabecular bone seems to be more affected than cortical bone. QUS, namely at calcaneus, may be a useful tool to assess bone status in heart transplants recipients also in view of some technical advantages, (radiation-free, portability, low cost). However, further longitudinal studies are needed to confirm its usefulness in the management of HTx patients.

M111

Comparison of Ultrasonic Measurements versus DXA in the Course of Osteoporosis Prevention at the Department of Traumatology, University of Vienna Medical School, Austria. N. A. Zobor*[1], M. Greitbauer*[1], D. Mueller*[2], P. Pietschmann*[3], V. Vecsei*[1]. [1]Dept. of Traumatology, University of Vienna, Medical School, Vienna, Austria, [2]University of Vienna, Medical School, Vienna, Austria, [3]Dept. of Pathophysiology, University of Vienna, Medical School, Vienna, Austria.

The purpose of the investigation: comparison of ultrasonic versus DXA measurement in patients who already have suffered a fracture. Method: The bone density was measured in the patients who were of 55 years or older, and have suffered a fracture. The measurements were performed with ultrasonic (on the phalanx, radius and tibia) and by DXA (on the lumbar spine and hip), respectively. From each kind of measurement the worst result was taken for statistical analysis and the patient was treated according to it. Results: In our collective 44 patients could be measured in both ways. The mean age was 76.1 years and we had 87% women and 13% men. According to the DXA measurements 83% of them had osteoporosis and 17% osteopenia, while the ultrasonic measurements showed in 79.4% osteoporosis and 20.6% osteopenia. When comparing the ultrasonic with DXA, the measurements of the phalanx and radius were in 85.7% in good agreement with the DXA results, while on the basis of the tibia measurements only 16% had osteoporosis and 26% osteopenia, and the rest 58% was judged as healthy. Conclusion: In contrast to tibia measurements, in elderly patients with recent fractures ultrasound results at the phalanx and the radius show good agreement with DXA-values.

M112

Concordance of Heel Quantitative Ultrasound and Central DXA in Patients Taking Different Forms of Glucocorticoids. V. I. Petkov*, M. T. Tran*, M. I. Williams*, C. T. McMurtry, R. A. Adler. Endocrinology, McGuire Veterans Affairs Medical Center, Richmond, VA, USA.

Quantitative ultrasound (QUS) may provide information about bone quality not reflected in DXA measurements. The mechanism of bone loss in glucocorticoid-induced osteoporosis differs from most other forms of osteoporosis, as demonstrated by histomorphometry. The goal of this study was to determine if such differences can also be found in the relationship of QUS measurements to central DXA in patients exposed to various glucocorticoid (GC) treatments. We analyzed data from 2 prospective studies conducted in subspecialty clinics at a single Veterans Affairs Medical Center. The participants filled out a questionnaire, which included questions on GC therapy (oral and local), had QUS of the heel (Hologic Sahara), and underwent central DXA (Hologic 4500) within a month. Subjects were divided into 4 groups based on questionnaire responses: ever or currently on oral GC (50%), only intra-articular GC (21%), ever or currently on inhaled GC (16%), and never had GC therapy (13%). ANOVA was used to determine differences between groups and ANCOVA to account for possible confounding by other variables. The relationships among QUS measurements and central DXA (spine, total hip, and femoral neck) in each of the treatment groups were examined. A total of 189 subjects had heel QUS [Speed of sound (SOS), Broadband ultrasonic attenuation (BUA), Quantitative ultrasonic index/Stiffness (QUI), Bone mineral density (BMD), and T-score] and central DXA. The mean (SD) age was 62 (13.6). Nine subjects were women; 2/3 were white men. Mean T-scores were: spine -0.19 (1.8), total hip -0.56 (1.10), femoral neck -1.15 (1.07), and heel -0.57 (1.24). When analyzed by GC treatment group, no significant differences in the QUS measurements were found. However, subjects treated with oral GC had significantly lower spine BMD than those treated with local injectable GC (mean difference from ANCOVA model 7.4%). The correlations among the QUS parameters and DXA at the spine, hip, and femoral neck were similar across the four groups, with one exception. In subjects exposed to oral GC, the correlation of heel SOS with femoral neck or total hip BMD was much less than that of the other heel measurements, suggesting that SOS assessed a characteristic of bone not reflected in the DXA measurements. In patients with pulmonary or rheumatologic disorders, heel QUS and central DXA are generally concordant to a degree reported in other populations. Only the SOS measurement in the oral GC subjects seemed to differ from other QUS parameters. Studies are underway to better quantitate exposure to GC in order to further refine our findings.

M113

Can Heel Ultrasound Bone Mineral Density Plus a Questionnaire Predict Osteoporosis in Rheumatology Patients? M. T. Tran*, V. I. Petkov*, C. Holt*, M. I. Williams*, R. A. Adler. Endocrinology, McGuire Veterans Affairs Medical Center, Richmond, VA, USA.

Rheumatology Clinic patients often need glucocorticoid therapy, and any musculoskeletal disorder that decreases physical activity may be a risk factor for osteoporosis. Ideally patients would be screened with central BMD by dual energy x-ray absorptiometry (DXA). To find a cheaper alternative, we determined whether the combination of heel ultrasound (QUS) BMD and a short questionnaire about risk factors could identify patients at risk for osteoporosis, defined by low central BMD by DXA. Rheumatology Clinic patients completed a simple questionnaire and had heel QUS. Within 1 month, spine, total hip, and femoral neck BMD were tested by DXA. Subjects having previous BMD tests were excluded, including many patients with inflammatory joint disorders. A total of 102 men and 13 women (72 white, 39 black, and 4 other) completed the questionnaire, 111 underwent heel QUS, and 105 had a DXA. Of those with DXA, 21 had a spine, total hip, or femoral neck T-score $\leq$ -2.0. Only 9 patients were taking oral corticosteroids at screening, 31 had a rheumatoid arthritis, and 49 had osteoarthritis. Simple linear regression showed that central DXA correlated significantly with weight and BMI (body mass index) and with all heel QUS parameters. No significant relationships were found between total questionnaire score and any BMD measurement. By stepwise multiple regression analysis, weight, heel BMD, family history of osteoporosis, and race were found to be significant predictors of BMD in the total hip (42% of variance). Similar models for both femoral neck and spine BMD explained less than one-third of variance. Using a DXA T-score of -2 to define central bone loss, a heel T-score of -1 provided a sensitivity of 81%, specificity 71%, positive predictive value of 17%, and negative predictive value of 94%. ROC curve analyses indicated that heel T-score and weight generated a larger area under the curve (0.850, 95% CI [0.756, 0.94]) than did either characteristic alone. In conclusion, heel QUS predicted central BMD in patients enrolled in a Rheumatology Clinic. Though total questionnaire score did not improve predictability, several specific risk factors such as weight, age, race, and family history of osteoporosis did contribute. Thus, heel ultrasound BMD with or without a short questionnaire moderately predicts central BMD in a patient population of primarily white men with degenerative joint disorders and in lesser numbers, rheumatoid arthritis not on glucocorticoids.

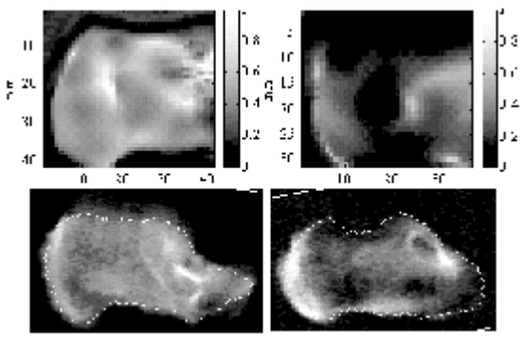
M114

Assessment of Bone Quantity and Quality in Human Cadaver Calcaneus Using Scanning Confocal Ultrasound and DEXA Measurements. Y. Qin[1], Y. Xia*[2], W. Lin*[2], A. Chadha*[2], B. Gruber[2], C. Rubin[2]. [1]Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, [2]SUNY Stony Brook, Stony Brook, NY, USA.

Advents in ultrasound (US) provide a unique method for evaluating bone strength. Using a developing scanning confocal acoustic diagnostic (SCAD) system, we have tested the feasibility of US assessment for bone quality in the real body region. Measurements were performed on 19 human cadaver calcanei age from 66 to 97 years old. The right foot of each cadaver was tested either by confocal scan mode or by plane wave, non-scan mode. The scanning region converged in the middle of the median plane of the calcanei, covering an approximate 40x40 mm2 with 1 mm resolution. The signals transmitted through the bone were processed to calculate broadband ultrasound attenuation (BUA, dB/MHz), the ultrasound energy attenuation (ATT, dB), and the ultrasound velocity (UV, m/sec). A 15x15 grid region of interest (ROI) was chosen. For both scan and non-scan modes, the obtained US properties (ATT, BUA, UV) were correlated with the bone mineral density (BMD, mg/cm2) measured by DEXA (Hologic 4500A, Bedford, MA). A calculated bone BMD data array was generated by combining BUA and UV data for predicting bone density. SCAD generated UV and BUA images demonstrated resolution compatible to X-ray and MR images (Fig)[Top: SCAD BUA, normal (left) and osteoporotic (right); Bottom: corresponding DEXA). Strong correlations were found between BMD and BUA and between BMD and US estimated index (Table. 1). Correlations between BMD and US parameter were significantly improved by using scan mode and selected ROI as compared to non-scan mode, yielding correlations between BMD and scanning US parameters as R=0.43 (ATT), R=0.82 (BUA), R=0.52 (UV) and R=0.86 (scan US est. BMD), as compared non-scan US parameters, R=0.33 (ATT), R=0.66 (BUA), R=0.24 (UV), and R=0.81 (est. BMD). These results suggest that SCAD is feasible for in vivo bone quality mapping. A well-developed system may result in a unique tool for assessing bone quality.

Table 1

Ultrasound Measurement	Scan Mode	Non-scan mode
Parameter	Mean (SD)	Mean (SD)
ATT (dB)	33.1 (8.8)	34.9 (12.1)
BUA (dB/MHz)	55.3 (15.8)	47.7 (19.4)
UV (m/s)	1506 (40)	1554 (47)
BMD (mg/cm2)	0.403 (0.156)	0.403 (0.156)
Est. BMD (mg/cm2)	0.428 (0.141)	0.420 (0.123)



M115

Quantitative Ultrasound of the Heel Does Not Predict Bone Density at the Femoral Neck More Accurately Than Simple Clinical Indices in Postmenopausal Caucasian Women. E. A. Mossman*, N. C. Grinnell*, L. Cole*, K. L. Osborn*, M. R. McClung. Oregon Osteoporosis Center, Portland, OR, USA.

Physicians are confronted with a wide and poorly defined array of clinical diagnostic features upon which to base referral for BMD testing. With the high cost of the DXA procedure to consider and a growing number of aging women potentially at risk, the use of an effective screening tool could significantly reduce the number of patients unnecessarily referred for DXA testing. Quantitative ultrasound sonography (QUS) testing and similar methods of assessing bone at peripheral sites in the skeleton may represent a potential tool with which to select patients for DXA testing. Several index scoring systems based on readily available clinical factors are also available at present, including the Simple Calculated Osteoporosis Risk Estimation (SCORE), the Osteoporosis Risk Assessment Instrument (ORAI), and the Osteoporosis Self-Assessment Tool (OST). These indices may represent attractive alternatives to QUS testing as screening methods for DXA. We compared the performance of these indices with QUS in predicting low DXA bone density at the hip. Femoral neck DXA T-scores ≤ -2 and -2.5 were used as outcome thresholds. Values for each index were calculated using clinical data from the electronic medical records of 656 patients referred for bone density testing at our clinic who had received both DXA (Lunar Prodigy) and QUS (Lunar Achilles) tests. Subjects were postmenopausal Caucasian women with no evidence of DJD, who were not taking oral steroids, anti-resorptive therapy other than estrogen, or anti-seizure medications at the time of the visit. The performance of the screening alternatives in predicting low hip bone density is shown in the table below.

	DXA T-Score ≤-2			DXA T-Score ≤-2.5		
Predictor	Sensitivity	Specificity	Area under ROC curve (95% CI)	Sensitivity	Specificity	Area under ROC curve (95% CI)
QUS	87.8%*	54.6%*	0.802 (0.764-0.841)	92.9%*	49.7%*	0.852 (0.809-0.895)
SCORE†	95.9%	35.0%	0.788 (0.749-0.827)	97.1%	31.1%	0.831 (0.782-0.880)
ORAI	91.2%	43.8%	0.756 (0.713-0.800)	97.1%	39.9%	0.817 (0.769-0.864)
OST	71.4%	66.2%	0.776 (0.736-0.815)	81.4%	62.5%	0.822 (0.774-0.871)

* At threshold QUS T-Score of –1 or lower † n=654 for SCORE analysis

In this referral-based population of postmenopausal Caucasian women, QUS did not predict low DXA bone density at the hip significantly better than any of the three clinical indices. Area under the ROC curve was similar among all 4 diagnostic schemes for both outcome thresholds. The OST index uses only weight and age to predict the likelihood of low bone density, and performed similar overall to QUS testing. Given that the clinical indices are simple, free, and require only clinical data that is likely already collected at the visit, the benefit of QUS screening as a means of selecting patients for DXA tests is dubious.

M116

Effect of the TGF β T869C and the CYP19 TTTA Repeat Polymorphisms on Bone Mineral Density and Prevalent Fracture in Elderly Women. R. L. Prince[1], I. M. Dick[1], A. Devine[1], S. S. Dhaliwal*[2], S. Li*[2], S. Wilton*[3]. [1]Department of Medicine and the Western Australian Institute for Medical Research, University of Western Australia, Perth, Australia, [2]Endocrinology and Diabetes, Sir Charles Gairdner Hospital, Perth, Australia, [3]Australian Neuromuscular Research Institute, University of Western Australia, Perth, Australia.

Osteoporosis is a common disease of bone that is strongly genetically determined. In a population based study of 1337 caucasian women over the age of 70, we have examined genetic polymorphisms in two candidate genes that may influence bone mineral density (BMD) and fracture, the TGF β T869C polymorphism in codon 10 and the Aromatase (Cyp19) tetranucleotide repeat in intron 4. The TGF β C allele was observed in 50.0% of the subjects and was associated with reduced hip BMD at all sites (2.8% total hip, 2.4% femoral neck, 2.6% intertrochanter, 3.4% trochanter) compared to the TGF β TT genotype. The TGF β C allele was also associated with a reduction in the calcaneal quantitative ultrasound (QUS) parameters BUA, SOS and stiffness of 0.87%, 0.26% and 2.4% compared to the TGF β TT genotype. A Cyp19 (TTTA)n > 12 was observed in 63.1% of the subjects and was associated with reduced hip BMD (1.9% total hip, 1.7% femoral neck, 2.0% intertrochanter, 2.3% trochanter) but was not associated with a reduction in calcaneal quantitative ultrasound . After adjustment for weight in an ANOVA model, the effect of the TGF β C allele was no longer significant except at the trochanter but the QUS parameters remained unchanged. The Cyp19 (TTTA)n > 12 effect on BMD remained significant after adjustment for weight.

Odds Ratios for Osteoporosis and Prevalent Fracture

	TGFβ c allele	Cyp19 (TTTA)n>12
O.R. for osteoporosis	2.18 (1.21-3.91	1.63 (0.89-2.99)
O.R. for prevalent fracture	1.37 (1.02-1.85)	1.02 (0.74-1.08)

As indicated above, a TGF β C allele was associated with an increase in osteoporosis (T score < 2.5 S.D. below premenopausal mean) and prevalent fracture. Despite its effect on hip BMD a Cyp19 (TTTA)n > 12 was not associated with osteoporosis or fracture. After adjustment for BMD and QUS stiffness, the association of the TGF β C allele with prevalent fracture was no longer statistically significant (O.R. 1.42, 95% C.I. 0.99-2.0), indicating the association between a reduction in BMD and stifness with fracture. However, the disparate effects of the TGF β C allele and Cyp19 (TTTA)n > 12 on fracture, despite similar effects on BMD in the same population, indicate that the TGF β C allele may be associated with BMD independent, in addition to effects that are dependent on BMD .

M117

The Relationship between Vitamin D Receptor Gene Polymorphisms and the Effect of Hormone Replacement Therapy on Bone Mineral Density in Postmenopausal Korean Women. J. Kim, J. Kim*, S. Kim*, Y. Choi*, S. Moon*, J. Lee*. Department of Obstetrics & Gynecology, Seoul National University Hospital, Seoul, Republic of Korea.

The objective of this study was to investigate whether vitamin D receptor (VDR) gene polymorphisms are associated with the effect of hormone replacement therapy (HRT) on bone mineral density (BMD) in postmenopausal Korean women. The BsmI, ApaI, and TaqI polymorphisms were analyzed by restriction fragment length polymorphism, and poly (A) polymorphism by GeneScan and direct DNA sequencing in 303 postmenopausal Korean women who received HRT for 1 year. HRT was administered by sequential regi-

men of conjugated equine estrogen and medroxyprogesterone acetate. Serum bone alkaline phosphatase (BAP), CrossLaps (CTX), osteocalcin and 1,25 $(OH)_2$ vitamin D_3 levels were measured by immunoassay and BMD at the lumbar spine and femoral neck by dual energy X-ray absorptiometry before and after HRT of 1 year. The BsmI and TaqI polymorphisms were significantly associated with annual percentage change in BMD at the lumbar spine. The bb and TT genotype showed a significantly lower percentage change in BMD of lumbar spine than the Bb and Tt genotype. The bb genotype was more prevalent in HRT-nonresponders (women who lose more than 3 % of bone mass per year) than in HRT-responders, while the Bb gentype was more prevalent in HRT-responders, but the TaqI polymorphism was not distributed differently among HRT-responders and HRT-nonresponders. Combining the BsmI and TaqI genotype reflected only the differences caused by the BsmI polymorphism. No significant association between annual percentage changes in BMD at all skeletal site studied and the ApaI or poly (A) polymorphism was observed. There were no significant differences in the annual percentage changes in 1,25 (OH)2 vitamin D3 or biochemical markers such as osteocalcin, BAP and CTX, among any of the genotypes analyzed. In conclusion, the VDR BsmI polymorphism is associated with the effect of HRT on BMD at the lumbar spine in Korean women.

M118

The Association Study Between the Change in Bone Mineral Density and Serum Estradiol, SHBG Levels and HLA DR2 Type After One Year of HRT. K. Han*[1], I. Moon*[2], H. Choi*[1], C. Yim*[1], H. Chung*[1], H. Yoon*[1], I. Han*[1]. [1]Department of Internal Medicine, Samsungcheil Hospital, School of Medicine, Sungkyunkwan University, Seoul, Republic of Korea, [2]Endocrine Laboratory, Samsungcheil Hospital, Seoul, Republic of Korea.

Estogen acts to prevent osteoporosis by regulating the production of cytokines, including IL-1, IL-6, and TNF. Some studies have shown that the ability to secrete cytokines at the lymphocyte is related to the HLA class II type, and thus, in DR2 type, this finding may be related to the presence of nonresponder group to minor stimulus. This study aims to investigate the relationship between the change in BMD after HRT and the serum sex hormone levels and HLA DR type. The study subjects were 117 women who had received at least one continuous year of HRT, and their mean age at baseline and mean age of menopause were 52.3±4.7 and 47.7±4.7, respectively. To verify the HLA DR2 type, the DR2 specific region in chromosome 6 was selected as a primer, amplified by PCR and observed for the presence of the band. The serum E2 levels at baseline, 3 months, and 1 yr after HRT were 6.3 pg/ml (5.1-8.4), 38.0 (20-60.3), and 41.0 (21.0-60.8) (median IQR), respectively, and the serum SHBG levels increased to 75.0 nmol/l (54.0-104.5), 149.0 (102.8-189.0), and 152.0 (124.0-182.0), respectively. The BMD of spine and femur increased by 3.6% and 1.7% in one year, and the nonresponder group in the spine was 15.4%. The change in spine BMD also was significantly associated with the change in serum E2 and E2/SHBG ratio after HRT, and the correlation coefficients were 0.26 (p=0.01) and 0.27 (p=0.005), respectively. The prevalence of HLA DR2 type was 21.7%, and there were no significant associations between HLA DR2 and clinical parameters. HLA DR2 type did not show significant correlation with baseline BMD and the change in BMD after HRT. However, the baseline deoxypyridinoline level was significantly higher in the HLA DR2 positive group at 8.9±2.6 nmol/mmol Cr compared to the HLA DR negative group at 7.7±1.9. Although not statistically significant, baseline osteocalcin level in the HLA DR2 group also had a tendency to be higher. In conclusion, after HRT, there was no statistically significant correlation between the change in BMD and the serum sex hormone level and the HLA DR2 type, but the HLA DR2 was associated with bone turnover markers and with the rapid bone loss group. This observation is incompatible with the previous reports that HLA DR2 type is associated with the non-responder group to cytokine production, and thus, further in vitro studies need to be conducted to verify these findings in Korean women.

M119

Polymorphisms in the Promoter of the Osteoprotegerin Gene are associated with reduced Perimenopausal Bone Mass. B. L. Langdahl[1], P. Vestergaard[1], B. Abrahamsen[2], C. L. Tofteng[3], N. Kolthoff[4], L. Mosekilde[1]. [1]Endocrinology and Metabolism, Aarhus University Hospital, Aarhus C, Denmark, [2]Endocrinology, Odense University Hospital, Odense C, Denmark, [3]Endocrinology, Hvidovre Hospital, Hvidovre, Denmark, [4]Clinical Physiology, Hillerød Sygehus, Hillerød, Denmark.

Osteoprotegerin (OPG) is a soluble receptor for RANKL and is therefore a competitive inhibitor of osteoclast differentiation and activity. We have previously examined the OPG gene for polymorphisms and found 12 of which 5 were informative. In a case-control study we demonstrated that the rare alleles of the A^{163}-G (G) and T^{245}-G (G) polymorphisms are associated with increased risk of osteoporotic vertebral fractures. In this study we examined the effect of the five polymorphisms: A^{163}-G, T^{245}-G, T^{950}-C, G^{1181}-C and A^{6890}-C on perimenopausal bone mass and early postmenopausal bone loss in 2016 normal women. A^{163}-G: Women with the rare genotypes AG or GG (28.2%) had lower BMD at the lumbar spine (LS): 1.013± 0.131 g/cm^2 versus 1.031± 0.139 g/cm^2 (p<0.05). Perimenopausal bone loss was not affected and BMD(LS) 5 years after menopause was 0.949± 0.144 g/cm^2 in women with AG or GG genotypes versus 0.971± 0.142 g/cm^2 in women with AA genotype (p<0.05). In women treated with HRT, the relative difference between the genotypes was also preserved after 5 years. No significant differences were found at the hip. T^{245}-G: are in strong linkage disequilibrium with A^{163}-G. Women with the rare genotypes TG or GG (9.1%) had reduced BMD(LS): 0.999± 0.134 g/cm^{2}compared with 1.030± 0.137 g/cm^2 (p<0.02). The perimenopausal bone loss tended to be higher in women with TG or GG genotypes: 6.7% versus 5.5% after 5 years (p=0.11) and BMD(LS) after 5 years was 0.932± 0.136 g/cm^2 in women with TG or GG genotypes compared with 0.969± 0.143 g/cm^2 in the women with TT genotypes (p<0.05). Women with different genotypes responded similarly to HRT and the relative difference between the genotypes was preserved after 5 years treatment. No significant differences were found at the hip. None of the other polymorphisms had any effects on perimenopausal bone mass or early postmenopausal bone loss. In conclusion: Two polymorphisms in the promoter of the OPG gene: A^{163}-G and T^{245}-G are in strong linkage disequilibrium. The rare genotypes are significantly associated with reduced perimenopausal bone mass at the lumbar spine. The difference in bone mass was preserved 5 years after menopause independent of whether the women received HRT or not.

M120

Investigation of the Association of dinucleotide Repeats within the Calcitonin and Interleukin 6 Receptor Genes with Low Bone Mineral Density in the Irish Population. C. M. Silke*[1], F. Wynne*[2], K. Quane*[2], M. Daly*[1], F. Shanahan*[2], M. G. Molloy[1], F. Drummond*[2]. [1]Rheumatology, Cork University Hospital, Cork, Ireland, [2]Medicine, Cork University Hospital, Cork, Ireland.

Low bone mineral density (BMD) is a major risk factor for the development of osteoporosis. It is estimated that between 60-80% of variance in BMD is attributable to heredity. Segregation studies have shown that BMD is under the influence of more than one gene. Interleukin 6 (IL6) stimulates osteoclast development and increases bone resorption leading to osteoporosis. Calcitonin (CT) is a calcium-regulating hormone that lowers the calcium level in serum by inhibiting bone resorption. In this study the possible association between dinucleotide (CA) repeat polymorphisms at the IL6 Receptor (IL6R) and the CT locus in 127 postmenopausal Irish women was investigated (mean age 61.31±8.12 years). Participants were recruited from the bone density unit in the Cork University Hospital. IL6R and CT polymorphisms were amplified by PCR and analysed on an ABI 310 Genetic analyzer using genescan software. Regression analysis was used to identify possible confounding factors with BMD at the lumbar spine (LS) and femoral neck (FN) using SPSS v10.0. Significant covariates with BMD identified from stepwise linear regression analysis were used to adjust BMD. Association of these polymorphisms with low BMD was investigated by analysis of variance (ANOVA). Eleven IL6R alleles were found in this population. The most frequent was A1 (151 base pairs) occurring at a frequency of 0.38. This is in contrast with a Japanese population where the frequency for this allele was 0.01. Thus, there appears to be a marked difference between these two racial groups. Nine alleles were found for CT with the most frequent being B5 (121 base pairs). BMD at the LS was adjusted for age and weight, and at the FN was adjusted for age, weight and height. BMD measurements at the FN and LS were compared amongst individuals according to whether they had 0, 1 or 2 copies of A1 (IL6R) or B5 (CT). No association was observed between BMD at the FN or LS and the IL6R A1 allele (p =0.56, p = 0.62, respectively). Similarly, association was not found between the CT B5 allele and BMD at the LS (p=0.35) or the FN (p=0.54), in this population. This is in contrast to a Japanese study which observed significant association between BMD and genetic variations at the CT locus. There was no interaction observed between these genotypes and BMD at either skeletal site when the population was divided into those aged above and below 60 years. We are currently increasing the number of women participating in order to increase the statistical power of our study.

M121

Body Mass Index and Circulating Testosterone Modulate the Effect of Aromatase Gene Polymorphism on Bone in Elderly Men. L. Gennari[1], L. Becherini*[2], D. Merlotti*[3], L. Masi[2], B. Lucani*[3], S. Gonnelli[3], A. Falchetti*[2], N. Dal Canto*[3], R. Nuti[1], C. Gennari[3], M. L. Brandi[2]. [1]Metabolic Disease Unit, University of Siena, Siena, Italy, [2]Department of Internal Medicine, University of Florence, Florence, Italy, [3]Institute of Internal Medicine, University of Siena, Siena, Italy.

Predictors of osteoporosis in men are not clearly defined. Evidence suggest that conversion of testicular androgens into estrogen plays a dominant role in determining bone mineral density (BMD) in men. Recently we demonstrated that a TTTA repeat polymorphism in the CYP19 gene was associated with differences in aromatase activity and lumbar BMD values in elderly males and females. In the present study we longitudinally tested the role of this CYP19 polymorphism on bone loss at different skeletal sites and on vertebral fracture risk in 300 elderly men. Femoral and lumbar BMD (DEXA), bone ultrasound parameters (calcaneous and phalanx), estradiol (E), testosterone (T), sex hormone binding globulin, and bone turnover markers (urinary CTX and serum bone specific alkaline phosphatase) were evaluated for each man at baseline and after 3 years. Six different allelic variants containing respectively 7,8,9,10,11 and 12 TTTA repeats were detected. Circulating E levels positively correlated with body mass index (BMI), T, and the number of TTTA repeats and were significantly higher in subjects with a high repeat genotype (TTTA>9) than in those with a low repeat genotype (TTTA<9). Moreover, men with a low repeat genotype showed higher rates of bone loss at the lumbar spine and Ward's triangle than those with a high repeat genotype. Interestingly an association between CYP19 polymorphism and vertebral fracture risk was observed with a lower incidence of fractures in the high repeat group (RR = 0.20). Finally, a significant interaction with BMI and T was observed. Differences in baseline BMD, bone turnover markers and rates of bone loss between low and high TTTA repeat genotypes were higher when analysis was restricted to subjects with a normal BMI, while progressively decreased in magnitude when overweight or obese men were considered. A similar increased CYP19 genotype effect was observed in subjects with T levels below the median. Taken all together, these results show a major role of CYP19 repeat polymorphism in determining trabecular bone loss and vertebral fracture risk in elderly men and suggest that the CYP19 genetic effect on bone is modulated by circulating androgens and by the amount of body fat.

M122

Intronic Polymorphisms of the Estrogen Receptor Beta Gene Are Associated with Bone Mineral Density: The Framingham Study. D. Karasik[1], A. M. Shearman*[2], L. A. Cupples*[3], K. Gruenthal*[2], D. E. Housman*[2], D. P. Kiel[1]. [1]Hebrew Rehab Ctr for Aged, Harvard School of Medicine, Boston, MA, USA, [2]Ctr for Cancer Research, MIT, Boston, MA, USA, [3]Biostat Dept, BU Sch of Public Health, Boston, MA, USA.

Estrogen exerts its physiological role on bone metabolism via two estrogen-activated transcription factors: estrogen receptor (ER) α and the more recently characterized ERβ. Unlike ERα, few studies have examined variation in the ERβ gene for association with bone mineral density (BMD) and none in large populations that include men as well as women. A single study (Ogawa et al., 2000) has shown association of an ERβ CA repeat polymorphism allele with lumbar BMD in postmenopausal women. Several studies, however, including our own, have reported modest evidence of linkage between BMD and the ERβ region on chromosome 14. The aim of this study was to assess whether silent polymorphisms in ERβ are associated with BMD in men and women. We studied 723 men and 795 women (mean age 60 yrs, range 29-86) from the Offspring Cohort of the Framingham Study. BMD was measured at the femur (neck, trochanter, Ward's area) and lumbar spine (L2-L4) sites. DNA samples were genotyped for three intronic polymorphisms: the previously studied CA repeat and two single nucleotide polymorphisms (SNPs) selected from the National Center for Biotechnology Information SNP database. BMD were adjusted for covariates including age, height, weight, calcium, vitamin D, smoking, alcohol, physical activity, and years since menopause and estrogen therapy in females. For the highly polymorphic CA repeat we subdivided the 15 alleles into two classes at the median number of repeats: small alleles had less than 22 CA repeats, and the remainder were defined as large alleles. In women, but not men, there was a significant association of the CA repeat genotype with Ward's BMD only; women 'homozygous' for the short allele displayed lower BMD than 'heterozygotes' or 'homozygotes' for the large allele (ANOVA p = 0.03 for Ward's BMD). Of the two SNPs, one was very rare and had no significant association with BMD. The second SNP showed an association with BMD at all 4 sites in men (ANOVA p = 0.028 for femoral neck, p = 0.005 for trochanter, p = 0.016 for Ward's area, p = 0.021 for lumbar spine) but not in women (all p>0.1). In conclusion, we identified association of an ERβ CA repeat polymorphism with BMD (Ward's area) in women. The CA repeat had previously given evidence of association with BMD (lumbar spine) in Japanese women. In addition, we have observed significant association of another ERβ polymorphism with BMD (at four sites) in men from the Framingham Study. Variation in the ERβ gene may potentially play a role in BMD and deserves further study.

M123

Polymorphism Analysis of LDL Receptor-Related Protein 5 (LRP5). K. M. Allen[1], A. Anisowicz*[1], M. G. FitzGerald*[2], P. Van Eerdewegh*[1], R. D. Little*[1], T. Keith*[1], R. R. Recker[3], M. L. Johnson[3]. [1]Human Genetics, Genome Therapeutics Corp., Waltham, MA, USA, [2]GenomeVision Services, Genome Therapeutics Corp, Waltham, MA, USA, [3]Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Mutations in LRP5 have been associated with two extreme bone mineral density (BMD) phenotypes mapped to chromosome 11q13; High Bone Mass (HBM) and osteoporosis pseudoglioma syndrome (OPPG). We previously reported that a single point mutation resulting in a glycine to valine amino acid change (G171V) was responsible for the autosomal dominant high bone mass trait in the HBM kindred and resulted in no clinical bone abnormalities (Little et al. AJHG 70:11, 2002). OPPG, in contrast, is an autosomal recessive disorder characterized by premature osteoporosis that leads to bone fracture and deformities as well as juvenile-onset blindness. Frameshift or nonsense mutations were detected in affected offspring from 9 OPPG families and putative disease-causing missense mutations were detected in another 3 OPPG families. Carriers of the OPPG alleles also had reduced BMD suggesting that OPPG LRP5 mutations can have dominant as well as recessive effects (Gong et al. Cell 107:513, 2001). The occurrence of LRP5 mutations associated with changes in BMD in these two disorders suggests that other allelic forms of LRP5 may contribute to a spectrum of bone density phenotypes. For example, a QTL contributing to normal variation in BMD also maps to 11q12-3 further suggesting that LRP5 may play a role in determining BMD in the normal population (Koller et al. JBMR 13:1903, 1998). To identify polymorphisms in LRP5 that can be tested for their association with BMD we have sequenced the entire coding region (23 exons) as well as intron-exon boundaries in the HBM kindred and in 20 sporadic individuals with elevated BMD (combined hip and spine Z score > 4) as well as 8 random individuals. We observed a total of 42 single nucleotide polymorphisms (SNPs) including 6 missense, 11 silent, and 25 intronic mutations. The HBM G171V was found only in the affected individuals of the HBM kindred. Further analysis is needed to determine if 3 silent mutations identified in the sporadic cases are associated with elevated BMD, since silent mutations can potentially be related to phenotypic variability by influencing splicing accuracy or efficiency. In conclusion, to facilitate the analysis of LRP5 in broader populations, we have identified both coding and intronic SNPs in LRP5 as well as designed primers and PCR protocols for sequencing all exons. Association between polymorphisms in LRP5 and normal variations in BMD and/or segregation with Mendelian forms of extreme BMD could have broad implications in the diagnosis and treatment of osteoporosis.

M124

Testing of Association and/or Linkage for Five Candidate Genes with Peak BMD in US Caucasian Nuclear Families. H. Shen, L. J. Zhao, J. R. Long, Y. Y. Zhang, L. Elze, R. R. Recker, H. W. Deng. Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA.

Bone mineral density (BMD) plays an important role in determination of osteoporosis. Studies have shown 50-90% of population variation in BMD is under genetic control. Candidate-gene approach is one of the two major approaches for searching genes that influence BMD. However, traditional linkage or association studies on several candidate genes yield inconsistent and controversial results. Transmission disequilibrium test (TDT) is a robust and powerful approach for testing both linkage and association. It is significant only in the presence of both linkage and association. Here, we studied 636 individuals from 157 nuclear families, in which 62 families have one child, 43 with 2 children and 34 with 3 children, the rest nuclear families have 4 or more children. There are a total of 257 sib pairs in the sample. All these subjects were genotyped with six polymorphic RFLP markers for five candidate genes [*BstU I* inside the Transforming growth factor β1 (TGF), *BsaH I* inside the Calcium-Sensing Receptor (CASR), *Msc I* inside the Collagen type 1 α 1 (COL1A1), *Sac I* and *Nla III* inside the α_2 HS-glycoprotein (AHSG), and *Rsa I* inside the Osteoprotegerin (OPG)]. Spine, hip and mid-radius BMD of all subjects were measured by DEXA. By using the program QTDT, we performed tests for linkage alone, association alone, then for both linkage and association (TDT) between the BMD and the genotypes of these candidate genes. Age, height, weight and sex were adjusted as covariates. For the spine BMD, at the *Sac I* of the AHSG gene, we found marginally significant evidence for association ($p < 0.07$), and for both linkage and association by the TDT ($p < 0.10$). Marginally significant results were also found for association for spine BMD at BsaHI inside CASR gene ($p < 0.10$) and *Msc I* inside the COL1A1 gene ($p < 0.09$). Other unspecified results are generally not significant or only marginally significant. Further extension studies with more nuclear families will be performed to confirm or verify the preliminary results in this study.

M125

Studies of Linkage and/or Association of Estrogen Receptor-α (ER-α), Vitamin D Receptor (VDR) and AHSG Genes with Peak BMD in Chinese Nuclear Families. Y. J. Qin*[1], Q. R. Huang[1], Q. Zhou*[1], J. H. Lu*[1], J. W. He*[1], H. W. Deng[2]. [1]Center for Preventing and Treating Osteoporosis, Shanghai Sixth People's Hospital, Shanghai, China, [2]Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA.

Variation of bone mineral Density (BMD) is mainly regulated by genetic factors. Extensive molecular genetics studies have been performed to search for genes underlying BMD variation; however, few studies were performed in Chinese populations. In our previous study among 150 Chinese nuclear families (Qin, 2001), results suggested that the BMD at spine and hip may be modulated by vitamin D receptor (*Apa I*) and estrogen receptor-α (*Pvu II and Xba I*) genotypes. Those results require confirmation with larger samples which may confer reasonable statistical power to test relatively robustly for the importance (linkage and/or association) of these candidate genes to BMD. According to theoretical statistical power analyses, ~400 nuclear families are required for the transmission disequilibrium test (TDT) to detect the presence of both association and linkage for a gene responsible for about 10% of the bone mass variation. In this study, a total of 402 Chinese nuclear families with 1263 subjects with children aged between 25-40 were recruited in the present study. All subjects were genotyped by PCR-RFLP at polymorphic sites of *Apa I* inside the VDR gene, *Pvu II* and *Xba I* inside the ER-α gene and *Sac I* inside the AHSG (α_2 HS-glycoprotein) gene. BMD were measured at lumbar spine (L1-L4) and hip (femoral neck, trochanter, intertrochanteric region). Raw BMD values were adjusted by age, sex, height, and weight as covariates. Using the program QTDT, we detected significant results for association ($p < 0.05$) between spine BMD and ER-α *Xba I* genotypes, but we also detected population stratification for ER-α *Xba I* with spine BMD. Therefore, this association result should be interpreted with caution. For BMD at the hip, at the two markers (*Pvu II* and *Xba I*) inside the ER-α gene, significant ($p < 0.05$) results were generally found for linkage testing and for the testing of both linkage and association (TDT). No significant effect of the VDR and AHSG genotypes on spine or hip BMD was detected. In conclusion, this study indicates the ER-α gene may act as a QTL underlying BMD variation in Chinese population, but VDR and AHSG genotypes were not shown as significant for BMD in our Chinese sample.

M126

Tests of Linkage and /or Association of Genes for COL1A1, PTH, BGP and IL-6 with Peak BMD in a Large Sample of Chinese Han Nuclear Families. X. H. Liu*[1], S. F. Lei*[1], X. G. Zhou*[1], X. Y. Mo*[1], Z. K. Cao*[1], M. Y. Liu*[1], Y. J. Qin*[2], Q. R. Huang[2], Q. Zhou*[2], H. Shen[3], H. W. Deng[3]. [1]College of Life Sciences, HuNan Normal University, Changsha, China, [2]Center for Preventing and Treating Osteoporosis, Shanghai Sixth People's Hospital, Shanghai, China, [3]Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA.

Numerous molecular genetic studies have been performed to search genes underlying bone mineral density (BMD) variation. However, few such studies were performed in Chinese populations. In this study, we tested linkage alone, association alone, and linkage and association of the genes for Collagen type 1 alpha 1 (COL1A1), parathyroid hormone (PTH), osteocalcin (BGP) and interleukin 6 (IL-6) with BMD in 1,263 subjects from 402 Chinese Han nuclear families with children aged 25-40. Among these nuclear families, 349 have 1 child, 50 have two children and 3 have 3 children. The RFLP genotypes of COL1A1 (*Msc I*), PTH (*BstB I*), BGP (*Hind III*) and IL-6 (*BsrbI*) in each individual were

determined by PCR-RFLP procedures. For the raw BMD of the spine (L1-L4) and hip (femoral neck, trochanter, intertrochanteric region and Ward's triangle), adjusting for significant covariates of age, sex, height and weight, we performed tests for linkage alone, association alone, and then for both linkage and association using the program QTDT. Associations were found between the COL1A1 marker with the BMD at trochanter (p = 0.01) and Ward's triangle (p = 0.04). Evidences for population stratification were also found between the COL1A1 (*MscI*) with BMD at these two sites. Similar results were detected for association and population stratification between the COL1A1 genotypes with the spine BMD and the combined (femoral neck, trochanter and intertrochanteric region) total hip BMD. Population admixture may interfere with the detection of genetic effects of candidate genes for complex traits. Hence, the significant association results should be interpreted with caution. We also found marginally significant results for linkage alone (p < 0.09), and for linkage and association (p < 0.10) for the marker *Bsrb I* inside the IL-6 gene for the trochanter BMD. Other unspecified results are generally not significant. Compared with earlier studies in non-Chinese populations, our results may suggest population heterogeneity for the genetic effects at candidate genes across populations of various ethnic groups.

M127

Overexpression of FGF2 Protein Isoforms in Osteoblasts: Effects on Proliferation and Differentiation. L. Xiao*[1], P. Liu[2], T. Sobue[1], J. Coffin[3], M. M. Hurley[1]. [1]Medicine, Univ of CT Hlth Ctr, Farmington, CT, USA, [2]Genetics, Univ of CT Hlth Ctr, Farmington, CT, USA, [3]Pharmaceutical Sciences, Univ of Montana, Missoula, MN, USA.

Fibroblast growth factor-2 (FGF2) regulates bone remodeling in vitro and in vivo. There are 3 nuclear isoforms of 22, 23, and 24 kDa and a low molecular wt (LMW) 18 kDa FGF2 protein that is exported from cells. The effect of each isoform on OB function has not been elucidated. To examine the effects of FGF2 isoforms on OB function, a set of expression vectors, called Col3.6-FGF2 isoforms-IRES-GFPsaph, were built by replacing a CAT fragment in previously made Col3.6-CAT-IRES-GFPsaph with individual human FGF2 isoform cDNA between Afe I and Sca I sites. These expression vectors are capable of concurrently overexpressing individual isoforms and GFPsaph from a single bicistronic mRNA. These vectors also harbor a neomycin selection gene. The expression vectors were stably transfected into ROS 17/2.8 cells and the transfected cells were then selected with G418 for a month. Expression of GFP reporter gene in transfectants was detected under fluorescent microscopy. Expression of each FGF2 isoform transgene was demonstrated by Western blot analysis. ROS 17/2.8 cells expressed rodent endogenous FGF2 protein isoforms of 17.5, 19, and 21 kDa, whereas FGF2 transfected cell lines overexpressed the specific human FGF2 isoforms encoded by the respective transgene. To assess the effects of overexpression of different FGF2 isoforms, we compared cell number in ROS17/2.8 cells stably transfected with control (Col3.6-IRES-GFP saph) vs each of the Col3.6-FGF-IRES-GFPsaph constructs. Cells were plated at 5000 cells/well in 96 well dishes in F-12 medium containing G418, (200 μg/ml) and either 1 or 10% FCS. After 96 h cells were harvested and viable cell number was measured by the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) proliferation assay. In the presence of either 1 or 10% serum, cell number was increased between 28% and 45% in cells harboring the different FGF2 transgenes. To examine OB gene expression and differentiation, ROS 17/2.8 cells were cultured with ascorbic acid and beta-glycerophosphate for 14 days. Northern analysis showed similar expression of Col1a1 or Alkaline phosphatase (ALP) mRNA and similar ALP staining in all cell lines. However, osteocalcin (OC) mRNA expression was 48% higher in cells overexpressing the LMW 18 kDa protein. In summary, overexpression of all isoforms of FGF2 protein increased viable cell number in the presence of low or high concentrations of serum. Overexpression of 18 kDa FGF2 increased OC mRNA, a marker of differentiated OBs. We conclude that differential expression of FGF2 proteins may be important in modulating OB function.

M128

FGF-23 Is a Novel Regulator of Mineral Homeostasis with Unique Properties Controlling Vitamin D Metabolism and Phosphate Reabsorption. T. Shimada*[1], T. Muto*[1], H. Hasegawa*[1], Y. Yamazaki*[1], Y. Takeuchi[2], T. Fujita*[2], S. Fukumoto[3], T. Yamashita[1]. [1]Pharmaceutical Research Labs, KIRIN Brewery Co., Ltd., Takasaki, Japan, [2]Department of Medicine, University of Tokyo School of Medicine, Tokyo, Japan, [3]Department of Laboratory Medicine, University of Tokyo Hospital, Tokyo, Japan.

FGF-23 was identified as a causative factor of tumor-induced osteomalacia. Missesnse mutations in FGF-23 gene were also found to be associated with autosomal dominant hypophosphatemic rickets. Previous reports indicated that FGF-23 can induce hypophosphatemia with increased renal phosphate excretion, inappropriately low serum 1,25-dihydroxyvitamin D [1,25$(OH)_2$D] level and rickets/osteomalacia in vivo. However, it is still unclear how FGF-23 causes these abnormal phosphate and vitamin D metabolism. In the present study, we analyzed acute effects of FGF-23 injection on serial changes of biochemical parameters and expressions of key molecules regulating serum phosphate and 1,25$(OH)_2$D levels. Purified full-length recombinant FGF-23 (5 μg/head) was administered into BALB/c mice intravenously. Reduction of serum phosphate level was first observed after 8 hours. Western blot analysis revealed that the expression of type IIa sodium phosphate cotransporter (NPT2a) was simultaneously decreased. However, changes of serum Ca and PTH levels were not observed. Serum concentration of 1,25$(OH)_2$D was significantly diminished already at 3 hours after the injection. Maximum reduction of 1,25$(OH)_2$D was observed from 8 to 13 hours. Northern blot analysis demonstrated that the administration of FGF-23 reduced the expression of 25-hydroxyvitamin D-1α-hydroxylase (1αOHase) and enhanced the expression of 25-hydroxyvitamin D-24-hydroxylase (24OHase) in kidneys. Because these effects on key enzymes in vitamin D metabolism were observed within 1 hour after the FGF-23 administration, FGF-23 seemed to regulate the expression of these enzymes directly. Such changes of enzyme expression have not been reported in other hormonal factors except for 1,25$(OH)_2$D. In summary, administration of FGF-23 caused rapid suppression of 1αOHase and induction of 24OHase expression, followed by decrease of serum 1,25$(OH)_2$D prior to reduced expression of NPT2a and hypophosphatemia. Although it is not evident at the moment whether reduced expression of NPT2a and hypophosphatemia are mediated by decreased 1,25$(OH)_2$D level, these results indicate that FGF-23 is a novel regulator of mineral homeostasis with unique properties controlling vitamin D metabolism and phosphate reabsorption.

M129

FGF2-stimulated Osteopontin Gene Expression Is Mediated by AP1 Through the Activation of ERK Pathway. H. Kim*[1], H. Park*[1], J. Choi[2], S. Kim*[3], H. Kim[4], H. Ryoo[1]. [1]Biochemistry, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea, [2]Biochemistry, School of Medicine, Kyungpook National University, Daegu, Republic of Korea, [3]Skeletal Genome Research Center, Kyungpook National University, Daegu, Republic of Korea, [4]Pediatric Dentistry, Kyungpook National University, Daegu, Republic of Korea.

Craniosynostosis, characterized by the premature closure of cranial suture, is a congenital disease that is resulted from precocious osteoblast differentiation around suture area. Most of the diseases are resulted from mutations of the fibroblast growth factor receptors, which reflects that FGF/FGFR signaling is indispensable for the osteoblast differentiation. Our previous report showed that osteopontin is an early marker of osteoblast differentiation and strongly expressed in calvarial bones during development. FGF2-soaked bead treatment on osteogenic fronts of mouse calvaria accelerated suture closure and osteopontin gene expression was strongly induced around beads. Specific aim of the present study is illumination of the regulation mechanism of osteopontin by FGF signaling. FGF2-stimulated osteopontin expression required the new protein synthesis. We suspected AP1 in this regulation since FGF2 induced immediately and temporally all the components of AP1 family in osteoblastic cells. Also, EMSA and site directed mutagenesis of AP1 binding site showed that the binding between AP1 and its cis-acting element was crucial for osteopontin induction by FGF signaling. Blocking of ERK pathway by PD98059 completely and specifically abrogated FGF2-induced AP1 gene expression while other MAP kinase or PKC blocker could not. Consistently, the Erk blocking also completely abrogated osteopontin expression around FGF2 beads in mouse calvaria organ culture. Taken together, FGF2-induced osteopontin gene expression is controlled by newly synthesized AP1 transcription factor whose expression is specifically regulated by ERK pathway.

M130

Phenotypic Characterization of Bones of Transgenic Mice Overexpressing Fibroblast Growth Factor-2. T. Sobue[1], L. Xiao[1], Y. Okada[2], Y. Tanaka[2], M. Ito[3], N. Okimoto[2], T. Nakamura[2], J. D. Coffin[4], M. M. Hurley[1]. [1]Univ. of Connecticut Health Ctr, Farmington, CT, USA, [2]Univ. of Occupational & Environmental Health, Kitakyushu, Japan, [3]Univ. of Nagasaki, Nagasaki, Japan, [4]Univ. of Montana, Missoula, MT, USA.

Basic fibroblast growth factor (FGF2) is an important regulator of bone formation and resorption as well as a potent mitogen for osteoblasts. We previously reported that non targeted overexpression of FGF-2 cDNA linked to the phosphoglycerate kinase promoter in transgenic (TgFGF2) mice enhanced apoptosis of chondrocytes in the prehypertrophy zone, premature closure of the growth plate and shortening of bone length of femurs and humeri. In this study, we assessed the effect of overexpression of FGF-2 on bone structure in vivo in TgFGF2 mice harboring the human FGF-2 coding sequence. Hemizygous TgFGF2 males were mated with non-transgenic (NTg) FVB/N females to produce litters of hemizygous TgFGF2 and NTg mice. FGF2 protein levels were assayed by ELISA and were higher in epiphysial bones of TgFGF2 mice age 4 to 230 days old. Structural parameters of trabecular bone were determined by micro-computerized tomography (μCT) of the distal femurs from 1, 3 and 6 months old mice. In 1 month old female TgFGF2 mice, there was a 32% decrease in trabecular bone volume (BV/TV) compared with NTg mice. Trabecular separation (Tb.Sp) was significantly increased compared with NTg mice (0.11 ± 0.01 vs. 0.08 ± 0.01 mm; p<0.01). Trabecular number (Tb.N) and Trabecular thickness (Tb.Th) were not significantly altered. In 3 months old female TgFGF2 mice, BV/TV (13.0 ± 4.3 vs 21.4 ± 0.8 %; p<0.01), Tb.N (4.39 ± 0.43 vs 5.02 ± 0.33 mm-1; p<0.05) and Tb.Th (51.3 ± 5.1 vs. 58.4 ± 4.2 μm; p<0.05) were all significantly reduced compared with NTg mice. In 6 months old male TgFGF2 mice, there were significant reductions in BV/TV (6.6 ± 2.0 vs. 9.7 ± 2.6 %; p<0.05) and Tb.N (1.50 ± 0.35 vs. 2.24 ± 0.51 mm-1; p<0.05). Tb.Sp (0.65 ± 0.14 vs. 0.43 ± 0.11 mm; p<0.05) was significantly increased compared with NTg mice. Bone mineral density (BMD) measured by Piximus DEXA in femurs from 4 week old female mice showed a significant decrease in Tg FGF2 compared with NTg (37.9 ± 1.9 vs. 46.5 ± 2.3 mg/cm2; p<0.05). In summary, FGF2 overexpression in Tg mice decreased bone mass and BMD in both male and female mice. This is consistent with FGF2 overexpression functioning as a negative regulator of bone growth in this animal model. FGF2 mediated apoptosis and chondrocyte drop out could cause decreased deposition of cartilage and matrix; because bone spicules appear to be diminished and disorganized at the epiphysial growth plate in TgFGF2 mice. Defects in osteoblast growth and differentiation combined with chondrocyte deficiencies, likely result in decreased bone density.

M131

ERK Activation in Wounded Osteoblasts Is Mediated by Basic Fibroblast Growth Factor. R. Landesberg, A. B. Burke*, S. Thomas*, R. W. Katz. Columbia University, NY, NY, USA.

The immediate signal transduction response of osteoblasts to acute trauma is poorly characterized. We previously described an in vitro model for osteoblast trauma to investigate the molecular mechanisms of wound healing in bone. Following disruption of a confluent monolayer, "wounded" osteoblasts demonstrated a rapid and transient activation of ERK 1/2. The p38 or SAPK/JNK pathways were not activated by wounding. We hypothesize that growth factors such as bFGF are rapidly released from the cells or surrounding matrix in response to wounding. Previously, we demonstrated that ERK 1/2 could be activated by the media from wounded osteoblasts suggesting that ERK activation was mediated by a soluble factor. In the present report we show evidence that one factor responsible for the activation of ERK 1/2 is basic fibroblast growth factor (bFGF). The osteoblast cell line IRC 10/30 myc 1 was grown to confluence in 100 mm dishes, serum starved, and then wounded. Sham treated dishes served as a control. The media was saved following incubation and concentrated by ultrafiltration through a 3,000 dalton molecular weight cut-off membrane. Equal amounts of concentrated media were analyzed by immunoblotting for bFGF. Experiments were performed with varying concentrations of suramin (an inhibitor of heparin binding growth factors) added to the media one hour prior to wounding. In some experiments dishes of confluent cells were serum starved for six hours in the presence of bFGF (10 ng/ml) or Epidermal Growth Factor (EGF, 50 ng/ml). Following pretreatment the plates received either fresh growth factor or were wounded as described. Phosphorylated ERK 1/2 was assayed by western blot analysis. Media from wounded cells demonstrated increased amounts of bFGF when compared to sham treated dishes. When conditioned media from wounded cells was added to confluent IRC cells, activated ERK 1/2 levels were slightly below that noted in the wounded dishes themselves. This effect was destroyed by boiling and suppressed by the addition of suramin. Finally, the upregulation of phosphorylated ERK 1/2, seen in response to exogenous bFGF or to wounding, was significantly abrogated by pretreatment with bFGF, but not EGF. The data suggest that bFGF is a significant component of the soluble factor(s) responsible for ERK 1/2 activation in wounded osteoblasts.

Role of Insulin-like Growth Factors and Fibroblast Growth Factor-2 in TGF-ß Mediated Regulation of Endochondral Bone Formation. A. Mukherjee*, J. Alvarez*, R. Serra*. Molecular and Cellular Physiology, University of Cincinnati, Cincinnati, OH, USA.

Transforming growth factor-ß1 (TGF-ß1) is known to regulate chondrocyte proliferation and hypertrophic differentiation by a perichondrium dependent mechanism, suggesting the involvement of other factors in the process. To begin to determine which additional factors are involved, we studied the effect of Insulin-like Growth Factors (IGF-I, IGF-II) and and Fibroblast Growth actor-2 (FGF2) on metatarsal organ culture. An increase in chondrocyte proliferation and hypertrophic differentiation was observed after treatment with IGF-I. A similar effect was seen after the perichondrium was stripped from the metatarsals suggesting IGF-I acts directly on the chondrocytes. IGF-II added to the metatarsal organ culture also resulted in an increase in BrdU incorporation in the chondrocytes. Furthermore, the treatment of organ cultures with TGF-ß1 down regulated the beta subunit of the IGF-I receptor as determined by immunoprecipitation and immunoblot assays. FGF-2 treatment of the organ cultures resulted in a decrease in bone elongation and hypertrophic differentiation as well as a decrease in BrdU incorporation into chondrocytes and an increase in BrdU incorporation in perichondrial cells, similar to treatment with TGF-ß1. Unlike TGF-ß1, a similar effect was seen with FGF2 after the perichondrium was stripped suggesting FGF2 acts directly on chondrocytes. TGF-ß1 treatment upregulated the FGF receptor 3 expression as determined by immunoprecipitation and immunoblot assays. The data suggest IGF-I stimulates while FGF-2inhibits proliferation and hypertrophic differentiation during bone formation by acting directly on the chondrocytes. Furthermore TGF- ß is involved in the regulation of the IGF receptor and FGF receptor 3, suggesting the possibility of interaction between these three signaling cascades in overall bone development.

Basic Fibroblast Growth Factor has Rapid Bone Anabolic Effects in Ovariectomized Rats. R. A. Power, U. T. Iwaniec, K. A. Magee*, N. G Mitova-Caneva*, T. J. Wronski. Physiological Sciences, University of Florida, Gainesville, FL, USA.

Basic fibroblast growth factor (bFGF) has a strong bone anabolic effect in intact and ovariectomized (OVX) rats. TGFβ and IGF-I may mediate this effect, as osteoblastic immunostaining for TGFβ and gene expression for IGF-I have been reported to be significantly increased in intact and OVX rats treated with bFGF for 1-2 weeks. The purpose of this study was to examine the early effects of bFGF therapy, *in vivo*, on bone formation and gene expression in OVX rats. Animals were OVX at 3 months of age, and maintained untreated for 3 months. At 6 months of age, one group of OVX rats (BSL OVX) and one group of sham-operated rats (BSL SHAM) were euthanized. Additional OVX groups were treated IV with bFGF (Chiron Corp., CA) at a daily dose of 200 µg/kg and euthanized at 1, 2, 3, 6, and 10 days. An additional group of OVX rats was treated IV with vehicle daily for 10 days, then euthanized. At necropsy, lumbar vertebrae were collected for cancellous bone histomorphometry and RNA isolation. RNase protection assays were performed to quantify mRNAs encoding $TGF\beta_1$ and IGF-I. All values listed below are mean±SD. Osteoblast surface (Ob.S/BS; %) and osteoid surface (OS/BS; %) were significantly higher at 1d (12.3±4.5; 10.5±4.0), 2d (17.8±10.8; 15.6±9.9), 3d (21.3±6.5; 18.9 ±6.0), and 6d (21.2±6.5; 27.4±8.0) in bFGF-treated OVX rats than in BSL SHAM (1.4±0.6; 1.3±0.6) and BSL OVX (5.2±2.4; 4.6±2.1) rats; values for Ob.S/BS and OS/BS were significantly higher at 3d and 6d than at 1d. Ob.S/BS and OS/BS were also significantly higher in OVX rats treated with bFGF (25.2±7.8; 26.8±9.8) for 10 days than in OVX rats treated with vehicle (9.3±5.4; 7.8±4.5). Osteoclast surface (Oc.S/BS; %) was significantly higher in BSL OVX rats (0.8±0.2) and at 1d (0.7±0.4) and 2d (0.5±0.4) in bFGF-treated OVX rats than in BSL SHAM rats (0.2±0.1). However, Oc.S/BS was significantly lower at 3d (0.3±0.1) and 6d (0.4±0.2) in bFGF-treated OVX rats than in BSL OVX rats. Oc.S/BS was also significantly lower in OVX rats treated with bFGF for 10 days (0.3±0.3) than in OVX rats treated with vehicle (0.9±0.3). mRNA levels for $TGF\beta_1$ and IGF-I were not significantly different between BSL OVX rats and bFGF-treated OVX rats at 3d. However, mRNA levels for these growth factors were higher in OVX rats treated with bFGF for 10 days than in vehicle-treated OVX rats. The results of this study indicate that the bone anabolic effects of bFGF in OVX rats begin as early as 24 hours post-treatment and increase with time. The growth factors $TGF\beta_1$ and IGF-I do not appear to be associated with initiation of the bone anabolic response to bFGF, but may be necessary to sustain this response.

M134

Basic Fibroblast Growth Factor Stimulates RANKL and Inhibits OPG in Human Bone Marrow Stromal Cells and Microvascular Endothelial Cells via Prostaglandin Independent Pathways. P. Collin-Osdoby, L. Rothe, P. Osdoby. Department of Biology, Washington University, St. Louis, MO, USA.

RANKL is the key signal required for the full development, activation, and survival of resorptive osteoclasts (OC), and its actions are neutralized by binding to OPG. Various osteotropic signals regulate RANKL and OPG expression by osteoblasts (OB) or bone marrow stromal cells (BMSC), thereby influencing OC formation and function. Recently, we showed that human microvascular endothelial cells (HMVEC) also expressed RANKL and OPG, and that inflammatory cytokines (IL-1, TNF) upregulated RANKL/OPG in HMVEC to cause an increase in HMVEC-mediated human OC formation and bone resorption. Basic FGF is an important angiogenic and bone remodeling factor that indirectly stimulates OC recruitment, development and activity in vivo and in vitro. High bFGF levels are linked to excessive vascularity and OC-mediated bone destruction in inflammatory conditions. Therefore, we investigated if bFGF may regulate RANKL or OPG expression in HBMSC or HMVEC to indirectly promote OC formation and bone resorption. HBMSC exposed to bFGF (1 nM, 24 h) exhibited increased RANKL mRNA expression and decreased OPG mRNA levels, leading to a 2-fold rise in the ratio of RANKL/OPG. In HMVEC, bFGF (10 nM, 6 h) also increased RANKL mRNA expression relative to that of OPG, however to a somewhat lesser extent than in HBMSC. In contrast to bFGF, IL-1 (1 nM, 24 h) increased both RANKL and OPG in HMVEC, while it raised RANKL and decreased OPG mRNA expression in HBMSC. To learn whether bFGF upregulated RANKL/OPG expression via an induction of prostaglandins, COX-2 mRNA expression was examined in HBMSC and HMVEC. Whereas IL-1 (1 nM, 24 h) strongly increased COX-2 mRNA expression in HBMSC and did not alter it in HMVEC, bFGF decreased COX-2 mRNA expression in HMVEC and did not alter it in HBMSC. Therefore, the regulation of RANKL and OPG by bFGF in HBMSC or HMVEC may occur via prostaglandin-independent MAPK activation pathways. We conclude that bFGF regulates RANKL and OPG in both HBMSC and HMVEC, via non-prostaglandin mediated mechanisms. Thus, the ability of bFGF to stimulate the expression of RANKL relative to OPG in stromal and vascular endothelial cells present in an inflamed site may contribute to the pathological role of bFGF in promoting OC recruitment, development and bone destruction in inflammatory conditions such as rheumatoid arthritis.

M135

Tgf-ß2 Regulates Fgf2 Signaling and Activity. J. T. Rawlins*, J. R. Sayne*, L. A. Opperman. Biomedical Sciences, Texas A&M University System Health Science Center, Dallas, TX, USA.

FGFR mutations have been linked to premature cranial suture obliteration (craniosynostosis) in humans. In animal models, both Fgf2 and Tgf-ß2 induce cranial suture obliteration, while Tgf-ß2 neutralizing antibodies rescue from obliteration sutures destined to fuse. This study was designed to determine the nature of potential Tgf-ß2 and Fgf2 interactions in regulating coronal suture patency. E19 fetal rat calvaria were cultured serum-free, plus or minus Fgf2 and neutralizing antibodies to Tgf-ß2. Calvaria were harvested and prepared for histological analysis and average suture width determined using digital image capture and Metamorph software. Addition of Fgf2 significantly narrowed coronal suture width, while removal of Tgf-ß2 activity by addition of Tgf-ß2 neutralizing antibodies had no effect on suture width. Addition of Fgf2 and Tgf-ß2 neutralizing antibodies together resulted in wide open sutures, preventing the suture-narrowing effects of Fgf2. Tgf-ß2 has been shown to inhibit Twist expression in sutures, and Twist is a negative regulator of Fgfr expression. Since Tgf-ß2 downregulates Fgfr2 expression in sutures, it is hypothesized that removal of Tgf-ß2 activity results in upregulated Twist expression, followed by down-regulated Fgfr expression and reduced Fgf2 signaling. This is seen morphologically as rescue of Fgf2 treated sutures from obliteration. Studies currently underway are determining if there is a link between Tgf-ß2 regulation of Twist and Fgfr2 expression.

M136

Impaired Fracture Healing in the Absence of TNF-α Signaling. L. C. Gerstenfeld[1], T. Cho[2], T. Kon*[3], T. Aizawa*[4], A. Tsay*[1], G. L. Barnes[1], D. T. Graves*[5], T. A. Einhorn[1]. [1]Department of Orthopaedic Surgery, Boston University Medical Center, Boston, MA, USA, [2]Department of Orthopaedic Surgery, Seoul National University College of Medicine, Seoul, Republic of Korea, [3]Department of Orthopaedic Surgery, Chiba University School of Medicine, Chiba, Japan, [4]Department of Orthopaedic Surgery, Toshoku University School of Medicine, Aiba-ku, Japan, [5]Department of Oral Biology, Boston University School of Dental Medicine, Boston, MA, USA.

Tumor necrosis factor-alpha (TNF-α) is both a major inflammatory factor that is induced during an innate immune response to injury and contributes to the regulatory processes of normal bone resorption. The role of TNF-α during fracture healing was examined in wild type and TNF-α receptor ($p55^{-/-}/p75^{-/-}$) deficient mice. These results demonstrate that TNF-α is a primary regulatory cytokine in postnatal endochondral bone formation and that it plays multiple roles in this process. In the absence of TNF-α signaling, chondrogenic differentiation was delayed by 2 to 4 days but subsequently proceeded at an elevated rate. Endochondral tissue resorption was delayed two to three weeks in the TNF-α receptor ($p55^{-/-}/p75^{-/-}$) deficient mice compared to wild type animals. Functional studies demonstrated that TNF-α mediated both chondrocyte apoptosis and expression of pro-resorptive cytokines that control endochondral tissue remodeling by chondroclasts and/or osteoclasts. While the TNF-α receptor ablated animals showed no overt developmental alterations of their skeletons, these results demonstrated that TNF-α plays an important role in promoting postnatal fracture repair. Our findings indicate that TNF-α signaling is required for normal fracture healing, and they identify essential mechanisms that regulate fracture repair.

Infection with Chlamydia Pneumoniae Stops Development of Peak Bone Density in Growing Male Mice and Is Associated with Increased Levels of Resorptive Cytokines. P. R. Nordström[1], A. H. Gustavsson*[2], O. Nilsson*[3], S. Bergström*[3], A. Waldenström*[4]. [1]Department of Surgical and Perioperative Sciences, Sports Medicine Unit, Umea, Sweden, [2]Department of surgical and perioperative sciences, Sports Medicine Unit, Umeå, Sweden, [3]Department of Clinical Microbiology, Microbiology, Umeå, Sweden, [4]Department of Public Health and Clinical Medicine, Cardiology division, Umeå, Sweden.

Estrogen status, physical activity, and body weight are some of the important determinants of bone density. However, together these factors only explain a small part of the variation in bone density. Infection with Chlamydia pneumoniae (TWAR) is sometimes associated with chronic infections in humans. We investigated whether infection with TWAR in still growing male c57BL/6 mice was associated with decreased peak bone density. Nineteen mice were infected by nasal inoculation with a TWAR containing suspension at ten weeks of age, and 20 mice were sham infected and served as controls. Bone density (mg/mm3) of the distal femur, proximal tibia, and femur diaphysis was measured before and after 16 days of infection using pQCT. Compared to sham infected mice, the infected mice increased significantly less in total bone density of the distal femur (0.4% vs. 9.4%, p=0.01), proximal tibia (-1.6% vs. 9.7%, p=0.001), and cortical bone density of the femur diaphysis (2.7% vs. 5.4%, p=0.006). The relative bone loss was seen in cortical and subcortical bone rather in trabecular bone. The levels of interleukin-6 (56 vs. 39 pg/mL, p=0.02) and interleukin-1b (11 vs. 0 pg/mL, p=0.003) were increased in serum of infected mice. Also levels of osteocalcin (228 vs. 50 pg/mL, p<0.001) were increased in the infected mice. There was no significant difference in weight gain (p=0.53) when comparing infected and sham infected mice. In conclusion, infection with TWAR results in decreased peak bone density and is associated with increased levels of bone resorptive cytokines in male mice.

Modulation of Transcription by Glucose-dependent Insulinotropic Peptide in MG-63 Osteoblastic-like Cells Evaluated by Gene Chip Analysis. Q. Zhong*[1], K. H. Ding*[1], L. Ruan*[1], P. Sridhar*[1], A. Mulloy[2], R. Bollag*[1], C. M. Isales[2]. [1]Institute of Molecular Medicine and Genetics, Medical College of Gerogia, Augusta, GA, USA, [2]Department of Medicine, Medical College of Georgia and the Augusta VAH, Augusta, GA, USA.

Previous reports from our laboratory have demonstrated that Glucose-dependent Insulinotropic Peptide (GIP) increases bone formation both in vivo and in vitro. In view of our results demonstating multiple effects of GIP on osteoblastic proliferation and differentiation we wished to examine the genes activated by GIP in the osteoblastic-like cell line MG-63 using gene microarrays. MG-63 cells were stimulated with the appropiate agonist for 2 hours. GIP 0.1 nM increased 98 genes by at least two fold, the largest change being a 22 fold increase in the gene for the human helix-loop helix protein (Id2). GIP 1 nM increased 119 genes the largest change being a 24.9 fold increase in the expression of mRNA for Fas. GIP 10nM increased the expression of 187 genes and GIP 100nM increased the expression of 415 genes. In contrast PTH 10nM increased the expression of 17 genes the largest change being a 5.5 fold increase in the expression of GLI-Krupple related protein and 1,25 dihydroxyvitamin D 1μM increased the expression of 130 genes. In summary, GIP, is a potent activator of gene expression in osteoblastic-like cells and highlights the potency of this agent as a modulator of osteoblatic cell function.

M139

Effect of Glucose-dependent Insulinotropic Peptide on 3H-Thymidine Incorporation in Osteoblastic-like Cells and its Interaction with other Hormones. K. H. Ding*[1], Q. Zhong*[1], D. Xie*[1], J. Xu*[1], R. Bollag*[1], C. M. Isales[2]. [1]Institute of Molecular Medicine and Genetics, Medical College of Gerogia, Augusta, GA, USA, [2]Department of Medicine, Medical College of Georgia and the Augusta VAH, Augusta, GA, USA.

Glucose-dependent insulinotropic peptide (GIP) has been reported to have an anabolic effect on bone formation. Since GIP likely serves as a hormonal link between nutrient ingestion and bone formation we wished to investigate whether there were any additive or synergistic interactions between GIP and other nutritionally related hormones on osteoblastic cell proliferation. GIP, amylin, insulin and 1,25 dihyroxyvitamin D all significantly stimulated 3H thymidine incorporation into MG 63 osteoblatic-like cells: Control: 10,698+523; GIP 10nM: 14,769+551; Amylin 10nM: 14,333+1748; Amylin 100nM: 14,742+1246; Insulin 10nM: 17,143 +1180; Insulin 100nM: 14,684+877: 1,25 dihydroxyvitamin D 10nM: 16,201+993; 1,25 dihydroxyvitamin D 100nM:17,308+1622 (CPM Mean+SEM). IGF-1 had no effect on thymidine incorporation; IGF-1 10nM: 10,706+158; IGF-1 50nM: 10,097+429 CPM+SEM. If GIP 10nM was added in conjunction to IGF-1 there was now a statistically significant effect on thymidine incorporation: IGF-1 10nM+ GIP 10nM: 14,684+1938; IGF-1 50nM +GIP 10nM: 12,789+426 CPM+SEM. However, concurrent administration of GIP and either amylin, insulin, 1,25 dihyroxyvitamin D or IGF-1 had no statistically significant additive or synergistic effect over addition of GIP by itself. In summary, GIP, amylin, insulin and 1,25 dihyroxyvitamin D all stimulate 3H thymidine incorporation into MG 63 osteoblastic-like cells. However, GIP does not synergize with these other hormones in potentiating the effect of GIP by itself.

M140

Mechanisms for Inflammatory Bone Loss: Catabolic Effects of Chemokines MIP-1α and RANTES via Coordinated Actions on Osteoblasts and Osteoclasts. X. Yu, Y. Huang*, P. Collin-Osdoby, P. Osdoby. Department of Biology, Washington University, St. Louis, MO, USA.

Bone remodeling by osteoclasts (OC) and osteoblasts (OB) is regulated by osteotropic hormones, growth factors, cytokines, and chemokines. Certain chemokines are locally increased at sites of inflammatory bone loss where they function to recruit and activate cells. Recently, OB and OC were also shown to release chemokines at inflammatory sites. Because little is known about chemokine effects on bone metabolism, we analyzed chemokine receptor expression and actions in murine OB, OC, and their precursors. CCR1, CCR3 and CCR5 receptors were detected by multi-probe RPA in mouse OB (generated from newborn mouse calvaria or bone marrow stromal cells) and OC (RANKL differentiated from murine RAW 264.7 or bone marrow cells). CCR1 increased during OB differentiation, beginning at day 6, and was maximal at day 15-18 when ALP activity and mineralization were increased. CCR1 also rose during OC differentiation from RAW or murine bone marrow cells. Thus, we examined if CCR1 ligands (MIP-1α, RANTES, or MCP-3) regulated OB or OC development or function. When OB were differentiated for 3, 9, 15, or 21 days before 48 h treatment with MIP-1α, RANTES or MCP-3, ALP activity was decreased and MMP-2 activity increased by MIP-1α or RANTES with maximal effects at day 15 when CCR1 levels peaked. Because ALP increases in OB differentiation in association with mineralized bone matrix synthesis, while MMP-2 is a matrix-degrading protease, these results suggest that MIP-1α and RANTES exert catabolic effects on OB-mediated bone remodeling. Relative to OC, MIP-1α, RANTES or MCP-3 induced pre-OC (RAW cell) chemotaxis, and MIP-1α increased mature OC (RAW-OC) motility. None of the chemokines affected OC bone pit resorption. Thus, CCR1 may stimulate OC recruitment by inducing pre-OC chemotaxis and mature OC motility, actions that could locally elevate bone resorption. OB and OC also released CCR1 ligands. MIP-1α and RANTES secretion increased in OB differentiation, and were further raised by IL-1 or TNF (maximal at day 9-15 when CCR1 peaked). MIP-1α release was higher (10-60x), and RANTES lower (10-100x), from pre-OC or OC than OB. IL-1 or TNF did not affect RANTES, and only slightly increased MIP-1α release from pre-OC. Thus, OB may be a main source of RANTES in basal or inflammatory conditions, whereas MIP-1α is produced by OB, pre-OC or OC and increased by inflammatory cytokines mainly in OB and pre-OC. These chemokine levels are in the range that exhibit biological actions on OB and OC. Therefore, CCR1 chemokines may exert catabolic effects on bone metabolism via their coordinated autocrine and paracrine actions on OB, OC, and their precursor cells in inflammatory conditions.

M141

Regulation of IL-6 and gp130 Expression by VIP, PACAP-38, Secretin and Glucagon in Mouse Calvarial Osteoblasts. E. Persson*, U. H. Lerner. Oral Cell Biology, Odont. Inst., Umea, Sweden.

Signaling molecules in skeletal nerve fibers have been shown to regulate bone cell activities. The effects of the neuropeptide vasoactive intestinal peptide (VIP) are likely to be due to direct effects on bone cells since osteoclasts and osteoblasts express different VIP receptor subtypes [Ransjö et al. BBRC 274:400, 2000; Lundberg et al. Endocrinology 142:339, 2001]. In the present study, we have investigated the effects of VIP, pituitary adenylate cyclase-activating peptide 38 (PACAP-38), secretin and glucagon, all belonging to the same superfamily of peptides, and the potent bone resorption stimulator IL-1β, on the expression in osteoblasts of IL-6 and the IL-6 intracellular signal-transducing unit glycoprotein 130 (gp130). Mouse calvarial osteoblasts were isolated and incubated in the absence and presence of VIP, PACAP-38, secretin, glucagon and IL-1β for 48 hrs, followed by culture media collection for IL-6 ELISA analysis. In addition, RNA isolation was performed to study the effects of VIP, PACAP-38 and secretin on the mRNA expression of IL-6 and gp130 by using semi-quantitative RT-PCR analysis. The RT-PCR analysis showed that VIP and PACAP-38 both stimulated the mRNA expression of IL-6, whereas secretin had no effect. The results were consistent with the IL-6 ELISA demonstrating that both VIP and PACAP-38 stimulated IL-6 synthesis in a dose-dependent manner, whereas secretin and glucagon had no effect. Furthermore, IL-1β stimulated IL-6 synthesis dose-dependently and the effect was synergistically potentiated by VIP. Both VIP and PACAP-38 decreased the mRNA levels for the IL-6 signal transduction unit gp130, whereas secretin had no effect. These results together indicate that VIP-2 receptors on the osteoblasts mediate the signals affecting IL-6 and gp130, which is in line with the previous findings that osteoblasts express VIP-2 receptors but not VIP-1 receptors. Since osteoclast activity and formation requires the concerted action of several signalling molecules expressed by osteoblast/stromal cells and preosteoclasts/osteoclasts, the importance of the effects of VIP, PACAP-38, secretin and glucagon on IL-6 and gp130 on bone resorption requires further studies. The data further supports the view that neuro-osteogenic interactions are important in bone metabolism and further indicates the possibility of neuro-immune interactions in bone.

M142

The IL-6/IL-6 Soluble Receptor Cytokine System Plays a Role in Mediating PTH-Induced Soluble RANKL Release. M. Mitnick, B. Sun, S. McCarthy*, K. Insogna. Yale University, New Haven, CT, USA.

Recent studies indicate that the interleukin-6/interleukin-6 soluble receptor (IL-6/IL-6sR) cytokine system plays a role in mediating the resorptive actions of PTH. The resorptive response to PTH is markedly attenuated in animals pretreated with neutralizing antibody to IL-6, a finding also observed in IL-6 knock-out animals. RANKL transcript expression is induced by PTH and RANKL is also thought to be critical for mediating the resorbing effects of this hormone. The relationship between the IL-6/IL-6sR and RANKL/OPG cytokine systems is unclear. We therefore infused rats with PTH or vehicle for 5 days and serially measured circulating levels of IL-6/IL-6sR and RANKL/OPG. IL-6 rose significantly within 24 hrs (8.3 pg/ml vs. 4.5 pg/ml, PTH vs. vehicle-infused animals) and was 4-fold elevated at the end of 5 days (21.9 pg/ml vs. 4 pg/ml). Serum RANKL levels did not rise significantly until 72 hrs of infusion (163 vs. 73 pg/ml) but were nearly 5-fold elevated at day 5 (429 vs. 91 pg/ml). This temporal relationship suggested the possibility that IL-6/IL-6sR might play a role in mediating the release of RANKL into the circulation. We therefore examined the effect of neutralizing IL-6 in vivo on PTH-induced changes in circulating RANKL levels. In mice infused with PTH for 5 days, serum RANKL was 2-fold elevated compared to vehicle infused animals. (172±14 vs. 84±15 pg/ml, $p<0.5$). In mice pretreated with neutralizing antibody to IL-6 there was a significant attenuation in the PTH induced increase in serum RANKL (107±5 vs. 142±10 pg/ml, neutralizing antisera vs. control anitbody, $p<0.005$). Serum levels of RANKL were dramatically lower in PTH infused IL-6 knock-out animals than in the wild-type littermates (41±5 vs. 103±8 pg/ml, $p<0.05$) and similar to the value in vehicle infused wild-type animals. To determine whether these changes were also observed at the cellular level, primary human and murine osteoblasts as well as a hepatocyte cell line (HepG-2 cells) were treated with either a control antibody or a neutralizing antibody to IL-6 in the presence of either PTH or vehicle. Neutralizing IL-6 in vitro significantly attenuated the PTH-induced release of RANKL into the culture media. RANKL release was reduced by 50%-60% in the osteoblast cultures and by 40% in the hepatocyte cultures ($p<0.005$ for each). We conclude that the IL-6/IL-6sR cytokine system participates in PTH induced release of soluble RANKL both in vitro and in vivo. The precise mechanism by which this occurs remains unclear but suggests that interdiction of the IL-6/IL-6sR cytokine system may impair PTH-induced resorption in part by diminishing expression of soluble RANKL.

M143

T cells Are Critical Mediators of IL-7 Induced Bone Loss In Vivo. G. Toraldo, C. Roggia, W. P. Qian,*, R. Pacifici, M. N. Weitzmann. Bone and Mineral Diseases, Barnes-Jewish Hospital and Washington University, St. Louis, MO, USA.

Interleukin-7 (IL-7), a powerful lymphopoietic cytokine, is known to induce bone loss in vivo. Recent studies have suggested that IL-7 induces bone loss by stimulating the proliferation of B220+ cells, a population capable of acting as early osteoclast (OC) precursors. However, how IL-7 leads to differentiation of precursors into mature OCs remains unknown. We previously reported that in vitro, IL-7 upregulated T cell derived osteoclastogenic cytokines including Receptor Activator of NFkB Ligand (RANKL). To demonstrate the importance of T cells to the bone wasting effect of IL-7 in vivo we have now examined IL-7 induced bone loss in T cell deficient athymic nude mice. We show that T cell replete mice undergo significant bone loss following IL-7 administration, concurrent with induction of RANKL and TNFalpha (TNF) secretion by splenic T cells. In contrast, T cell deficient nude mice were resistant to IL-7 induced bone loss, and showed no detectable increase in either RANKL or TNF, despite an upregulation of B220+ cells. Importantly, T cell adoptive transfer into nude mice, restored IL-7 induced bone loss, and RANKL and TNF secretion, providing a clear demonstration that T cells are essential mediators of IL-7 induced bone loss in vivo.

The Relationship Between Growth Factor mRNA and Protein Levels in Human Bone. M. H. Bünger*[1], T. Andersen*[1], L. Sørensen*[2], H. Oxlund*[3], M. Lind*[1], E. F. Eriksen[2], C. Bünger*[1], B. Langdahl[2]. [1]Orthopaedic Research Lab., Aarhus University Hospital, Aarhus C, Denmark, [2]Medical Endocrinology Dept. C, Aarhus University Hospital, Aarhus C, Denmark, [3]Department of Anatomy, Aarhus University, Aarhus C, Denmark.

mRNA expression is used for determination of bone cell activity or response to various agents. Few have been concerned whether a measured mRNA expression is followed by a corresponding protein production and thereby effect. We investigated the relation between mRNA and protein levels in human bone. 62 spinal surgery patients (38 males and 24 females, mean age 45, range 13-78) were included. An 8 mm bone biopsy was taken from the posterior iliac crest prior to graft harvesting. 20 of the patients had blood samples taken prior to surgery. RNA isolation was performed using Trizol®-technique. Proteins were isolated by precipitation with acetone and re-dissolved in demineralised water by sonication. mRNA for TGF-β1, IGF-I and II, BMP-2 and 7, FGF-b and LMP-1 were measured by semiquantitative RT-PCR using b-actin as internal standard. Proteins measured were IGF-II(measured as free + bound IGF-II), TGF-β1, both using ELISA kits, and Collagen 1. Collagen 1 content was calculated after further isolation and measurement of hydroxyproline. Protein values were adjusted for the total protein content(measured with the Lowry method). OPG, PINP, IL-6, sCTX concentrations in the serum samples were measured using ELISA kits. PTH, Calcium, Alkaline Phosphatase and Osteocalcin were measured by the clinical chemistry department at the hospital. All values were log-transformed before calculation of the Pearson correlation coefficient. No correlation between mRNA and adjusted protein levels were found for neither IGF-II nor TGF-β1. A positive correlation between TGF-β1 protein levels and mRNA levels for LMP-1 (0.300, $p<0.038$) was found. mRNA levels for IGF-I correlated negatively to TGF-β1 protein levels (-0.353, $p<0.011$). mRNA levels for TGF-β1 and IGF-I were found to correlate negatively to Collagen 1 content in the biopsy (-0.331, $p<0.020$ and -0.530, $p<0.0005$ respectively). BMP-2 mRNA levels were found to correlate negatively to sCTX and IL-6 levels in serum (-0.495, $p<0.026$ and -0.515, $p<0.024$ respectively). TGF-β1 mRNA levels were found to correlate negatively to PINP (-0.423, $p<0.063$) but positively to PTH (0.437, $p<0.054$). These results suggest that mRNA expression in human bone does not directly reflect the concentration of the corresponding protein. Correlations between mRNA and concentrations of other proteins than the corresponding were observed. Surprisingly a connection between mRNA levels for the transcription factor LMP-1 and TGF-β1 protein levels were observed.

M146

The Novel Hormone, Preptin, Is Another Bone-Active Product Of The Pancreatic β-Cell. J. Cornish[1], K. E. Callon[1], U. Bava*[1], A. B. Grey[1], X. Xu*[1], C. M. Buchanan*[2], G. J. S. Cooper*[2], I. R. Reid[1]. [1]Medicine, University of Auckland, Auckland, New Zealand, [2]School of Biological Sciences, University of Auckland, Auckland, New Zealand.

Several hormones that regulate nutritional status also impact on bone metabolism. Preptin is a recently isolated 34-amino acid peptide hormone that is co-secreted with insulin and amylin from the pancreatic β-cells. Preptin corresponds to Asp^{69} - Leu^{102} of proIGF-II. We have assessed preptin's activities on bone. Preptin, like insulin and amylin, dose-dependently stimulates the proliferation (cell number and DNA synthesis), of primary fetal rat osteoblasts and osteoblast-like cell lines at periphysiological concentrations ($>10^{-11}$M). In addition, thymidine incorporation is stimulated in murine neonatal calvarial organ culture, likely reflecting the proliferation of cells from the osteoblast lineage. Preptin does not affect bone resorption in this model. The mitogenic effect of preptin on osteoblasts appears to be dependent upon signaling via p42/44 MAP kinases. Preptin induces phosphorylation of p42/p44 MAP kinases in osteoblastic cells in a dose-dependent manner (10^{-8} -10^{-10} M), as assessed by immunoblotting. The proliferative effects of preptin on primary osteoblasts were blocked when the cells were pre-treated with either of the MAP kinase kinase inhibitors PD-98059 or U-0126. We also assessed preptin's effects on primary osteoblast apoptosis induced by serum deprivation. Apoptotic cells were detected by light microscopy using a modified TUNEL assay. Preptin had anti-apoptotic effects, at 10^{-8} M with treatment/control ratio of 0.78 ± 0.08. In conclusion, preptin is a novel bone-active factor secreted from the pancreatic β-cell that may act in concert with the other β-cell hormones, insulin and amylin, to stimulate bone formation in hyperinsulinemic states, such as obesity. These findings may also be relevant to the high bone mass observed in patients with chronic hepatitis who secrete high levels of proIGF-II.

M147

GH Stimulates Differentiation of Osteochondral Precursor Cells in a Rat Osteotomy Model. M. Huening[1], T. Lindner*[1], H. J. Bail*[1], A. Flyvbjerg*[2], N. P. Haas*[1], M. Raschke*[1]. [1]Trauma and Reconstructive Surgery, Charité, Berlin, Germany, [2]Endocrinology, Komunehospital, Aarhus, Denmark.

GH is an important regulator of cartilage and bone formation which also stimulates bone healing. Purpose of the study was to characterize the cell populations directly involved in the healing process. A total of 48 adult, female SD rats underwent osteotomy of the left femur resulting in an 0,3 mm gap which was subsequently stabilized by a monolateral external fixator. Group I: 3 mg rh-GH subcutaneously /kg body weight /day; Group II: vehicle. 1, 2 and 3 weeks after surgery bones of each group (n=8) were collected, immediately formalin-fixed, decalcified with EDTA and embedded in paraffin. Serial sections were cut and stained alcian-blue. To evaluate the histological stage of healing 3 stains of each animal were scored. Single points were given when bone formation was observed in certain fields of the gap region. To visualize cellular gene expression in situ hybridization was performed on serial sections using Digoxigenin-labelled RNA-probes of extracellular matrix proteins (ECMP). Probes were transcribed from cDNA-clones of mouse type-I collagen (COL1), mouse type-II collagen (COL2), rat osteopontin (OPN) and rat osteocalcin (OC). Histologically Group I animals reached a significant higher score after 1 and 2 weeks. Also gene expression was markedly different between the two groups. After 1 week osteochondral progenitor cells could be detected in the osteotomy gap which were characterized by simultaneous COL1 and COL2 expression. Group I animals showed significantly more such cells.After 2 and 3 weeks COL1-signals were mainly located in deeper layers of the woven bone. In group I a stronger gene expression was noted. At these time points COL2-mRNA was localized in chondrocytes of cartilaginous callus with group II animals showing more of these cells. OC was expressed primarily by mature osteoblasts in the deeper layers of woven bone in both groups at later time points. OPN was mainly observed in osteoblasts and hypertrophic chondrocytes at the ossification front with more signals in group I animals after 1 and 2 weeks. To our knowledge this is the first study demonstrating the influence of GH on ECMP gene expression in bone regeneration. It appeared that gene expression patterns were markedly changed, especially osteochondral progenitor cells were detected more frequently in the early phase. Moreover cartilage formation seemed to be suppressed after 2 and 3 weeks in this model. We conclude that GH may exert its stimulatory effect by promoting the differentiation of precursor cells into osteogenic cells.

Effect of IGF-I Haploinsufficiency on Growth and Bone Mineral Density in Outbred Male and Female Mice. J. He[1], H. W. Woitge[1], C. J. Rosen[2], L. R. B. Donahue[3], B. E. Kream[1]. [1]Department of Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]Maine Center for Osteoporosis Research and Education, St. Joseph Hospital, Bangor, ME, USA, [3]Jackson Laboratory, Bar Harbor, ME, USA.

Insulin-like growth factor I (IGF-I) is a key regulator of prenatal and postnatal growth in mice. Many in vitro culture models show that IGF-I is an anabolic growth factor for bone formation, and some human studies demonstrate a positive correlation between serum IGF-I levels and bone mass. An important question is whether IGF-I is a determinant of bone mass throughout life. Mice with a disruption of both Igf1 alleles display a high degree of perinatal lethality in all background strains examined, a feature that precludes a detailed study of their phenotype at various stages of postnatal life. Therefore, as an experimental model, we have chosen to study the influence of IGF-I haploinsufficiency on growth and bone mass in heterozygous Igf1 null (HET) mice, in which one Igf1 allele has been disrupted by the deletion of exon 3 using targeted mutagenesis. These mice are amenable to study as they are healthy and breed normally. In the present study, cohorts of male and female wild-type (WT) and HET mice in the outbred CD-1 background were derived from WT-HET breeding pairs and sacrificed at 1, 2, 4, and 8 months of age. In these initial studies, the number of mice in each group ranged from 6-20. The following measurements were made: body weight, femur length, femoral bone mineral density (BMD) by dual-energy X-ray absorptiometry (DEXA), and serum IGF-I levels by radioimmunoassay. At 1 month, female HET mice had reduced body size, femur length, BMD and serum IGF-I levels compared to female WT mice. Male mice did not show a significant genotype effect at this age, except for serum IGF-I levels; however, male mice showed a tendency toward reduced body size, femur length and BMD. At 2 months, both male and female HET mice had reduced body size, BMD and serum IGF-I levels (femur length was not measured). At 4 and 8 months, male HET mice had reduced body size, femur length, BMD and serum IGF-I levels; female HET mice showed similar changes, but serum IGF-I levels were not significantly different from WT. At 8 months, WT mice showed a significant gender effect: despite their lower body size, female mice had higher femoral BMD and femur length compared to males. In summary, IGF-I haploinsufficiency in outbred male and female mice resulted in reduced body size, femur length, serum IGF-I levels and areal BMD at most ages. Outbred Igf1 heterozygous null mice will provide a useful model to reveal whether IGF-I is a determinant of bone mass during postnatal life.

Evidence that Human Osteoblasts/Skin Fibroblasts Produce an Inhibitor of IGFBP-4 Protease/Pregnancy-associated Plasma Protein-A (PAPP-A). C. Sexton*, S. Mohan, T. Boykin*, S. Kapur*, D. J. Baylink, X. Qin. J.L. Pettis VAMC, Loma Linda, CA, USA.

IGFs play a pivotal role in regulating osteoblast proliferation, differentiation, and apoptosis *in vitro* and bone metabolism *in vivo*. IGFBP-4, the most abundant IGFBP produced by human osteoblasts (hOBs), counter-regulates the activity of IGFs. Importantly, previous studies demonstrated that the effective concentration of the IGFBP-4 in hOB culture is subject to regulation by an IGF-dependent IGFBP-4 protease now known as PAPP-A. Based on the findings that the activity of other proteases are precisely regulated by specific protease inhibitors, and that treatment of hOBs or human skin fibroblasts (hSFBs) with a PKC activator (TPA) resulted in a loss of IGFBP-4 proteolytic activity, we predict that cells which produce PAPP-A may also produce a specific inhibitor of PAPP-A. To test this hypothesis, we determined whether or not the TPA-induced loss of IGFBP-4 proteolytic activity in both hOB and hSFB cultures is mediated through induction of a PAPP-A inhibitor. Treatment of hOBs and hSFBs with 100 nM TPA for 48 hr essentially abolished the IGFBP-4 proteolytic activity in the CM without a profound effect on PAPP-A levels. Addition of excess IGF-II to TPA CM failed to restore the IGFBP-4 proteolytic activity. Addition of TPA CM to control CM dose dependently inhibited IGFBP-4 proteolysis. Moreover, IGFBP-4 proteolysis by control CM was inhibited by PAPP-A immunodepleted CM. The magnitude of inhibition by PAPP-A-depleted TPA CM was greater than that of the PAPP-A-depleted control CM. These data strongly suggest that both hOBs and hSFBs produce a PAPP-A inhibitor which is further up-regulated by activation of the PKC pathway. Since PAPP-A, when covalently linked to proMBP, exhibited a >100 fold reduced IGFBP-4 protease activity compared with the PAPP-A homodimer, we sought to determine if the loss of PAPP-A activity is due to the formation of PAPP-A/proMBP complex. Under non-reducing conditions, PAPP-A/proMBP complex in human pregnancy serum, but not the PAPP-A from either hOB control CM or TPA CM, reacted with proMBP antibody. Additional experiments involving evaluation of the inhibitor activity of proMBP-depleted TPA CM are in progress to determine if the loss of PAPP-A activity in TPA CM is due to non-covalent interaction of PAPP-A with proMBP. In conclusion, these studies demonstrate that: 1) TPA treatment reduced IGFBP-4 proteolysis through induction of a PAPP-A inhibitor rather than reduction of PAPP-A synthesis; and 2) PAPP-A inhibitor may play an important role in regulating the effective concentrations of IGFBP-4 via inhibition of the activity PAPP-A in osteoblasts.

Mathematical Model Predicts that Directed, Random and Pathologically Accelerated Bone Remodeling Are Determined by Osteoclast Autocrine Factors. S. V. Komarova*[1], R. J. Smith*[2], L. M. Wahl*[2]. [1]CIHR Group in Skeletal Development and Remodeling, The University of Western Ontario, London, ON, Canada, [2]Department of Applied Mathematics, The University of Western Ontario, London, ON, Canada.

Bone remodeling involves resorption by osteoclasts, followed by formation of new bone by osteoblasts. Significant contributions to the regulation of bone remodeling derive from interactions between cells of the osteoblastic and osteoclastic lineages. However, experimental approaches to test these interactions are limited. In this study, we employed mathematical modeling to investigate the regulation of bone remodeling. We constructed a model describing the interactions between osteoblasts and osteoclasts and consequent cell population dynamics at a single site of bone remodeling. We included in the model the ability of osteoblasts and osteoclasts to interact with each other (via paracrine factors) as well as their ability to produce factors affecting themselves (autocrine factors). Changes in bone mass were calculated from the difference between rates of formation and resorption, which were proportional to the number of active osteoblasts and osteoclasts, respectively. We investigated how changes in the effectiveness of autocrine and paracrine factors influenced the stability and dynamic behavior of the system. The region of stability for our model included stable nodes, stable foci and centers. Stable nodes, characterized by an individual event of bone remodeling initiated by external stimulus, represented directed bone remodeling. Stable foci and centers, exhibiting intrinsically regulated oscillations, corresponded to random bone remodeling. In addition, unstable behavior resembling pathological bone remodeling seen in Paget's disease was observed. Changes in the effectiveness of osteoclast autocrine factors switched the system among these three different types of behavior. The osteoclast autocrine factor could correspond to a local factor such as TGFβ. The ability of this factor to change the dynamic behavior of the system demonstrated in our model could account for the conflicting observations regarding the effects of TGFβ on bone remodeling. In summary, the mathematical model revealed that interactions between osteoblasts and osteoclasts result in complex system behavior, which cannot be deduced from studies of each cell type alone. The behavior of the system was most sensitive to changes in the osteoclast autocrine factors. The model will be useful in future studies assessing the impact of cytokines and growth factors on the overall process of bone remodeling.

Activations of p42/44 MAPK and JNK by TGF-β Negatively Regulate Smad3-induced ALP Activity and Mineralization in MC3T3-E1 Cells. H. Sowa*, H. Kaji, T. Yamaguchi, T. Sugimoto, K. Chihara*. Endocrinology and Metabolism, Kobe University Graduate School of Medicine, Kobe, Japan.

TGF-β inhibits alkaline phosphatase (ALP) activity and mineralization in mouse osteoblastic MC3T3-E1 cells (MC), while its local administration stimulates bone formation in vivo. We recently demonstrated that Smad3, a critical component of the TGF-β signaling pathway, promotes ALP activity and mineralization in MC (JBMR, in press). Recently, Smad3-knockout mouse showed decreased bone mineral density, indicating that Smad3 plays an important role in the regulation of bone formation. However, why the effects of TGF-β and Smad3 on ALP activity and mineralization are different remains unknown. The purpose of the present study is to clarify the roles of mitogen activated protein kinase (MAPK) in TGF-β- and Smad3-pathways in osteoblast. TGF-β activated p42/44 MAPK, p38 MAPK and c-Jun N-terminal kinase (JNK) in MC. Specific inhibitors of p42/44 MAPK activation (PD98059 and U0126), as well as JNK inhibitors (curcumin and dicumarol) antagonized the inhibitory effects of TGF-β on ALP activity and mineralization, while specific inhibitor of p38 MAPK (SB203580) did not affect them. PD98059 and curcumin promoted Smad3-induced ALP activity and mineralization, while SB203580 inhibited them. In the luciferase reporter assay using 3TP-lux with specific Smad3-responsive element, PD98059 and curcumin enhanced TGF-β - and Smad3-induced transcriptional activity. On the other hand, TGF-β -induced production of type I collagen was antagonized by curcumin, but not by PD98059. The present study indicates that activations of P42/44 MAPK and JNK byTGF-β negatively regulate Smad3-induced ALP activity and mineralization in osteoblast. We propose that Smad3 is a molecule responsible for bone formation, and the local combined administration of Smad3 and inhibitors of p42/44 MAPK might be a novel therapeutic strategy for the stimulation of bone formation.

The Role of Angiogenesis in Distraction Ostogenesis of the Mouse Tibia. R. S. Carvalho*[1], T. Einhorn*[1], C. M. Edgar[1], W. Lehmann*[2], D. M. Pacicca[1], L. C. Gerstenfeld[1]. [1]Orthopedics, Boston University School of Medicine, Boston, MA, USA, [2]Department of Trauma and Reconstructive Surgery, University Clinic Hamburg-Eppendorf, Harburg, Germany.

Distraction osteogenesis is a commonly used technique for limb lengthening. However, the basic mechanisms by which it promotes new bone formation are not well understood. A feature of this process is the observation of robust vascularization of repair tissue both proceeding and during the regenerative process. Therefore, the aim of this study was to investigate the role of angiogenesis in bone regeneration during distraction. In order to test this hypothesis and examine the molecular mechanisms that regulate bone formation we have developed a murine model of distraction osteogenesis. The tibias of Balbc mice 8 to 12 weeks old were fitted with a 6 mm track distractor originally designed for intra-oral bone distraction. Mice were divided into three groups of 6 to 8 animals each for the following experimental phases; 1) latency of 7 days post surgery before the onset of distraction, 2) active distraction of 10 days and 3) post distraction consolidation of 14 days. The rate of distraction was 0.3 mm (2X 0.15mm/day). Samples were processed for standard histology or total RNA was extracted. Micro-arrays containing 96 cDNA fragments from genes associated with the angiogenic process were assayed. In addition, arrays containing more than 20 cDNA fragments from genes encoding signals for proteins with metaloproteinase (MMPs) activity were also used. Finally, the expression of bone extracellular matrix proteins (ECM) and bone morphogenic proteins (BMPs) was studied by ribonuclease protection assays. Validation of this model by histology was evidenced by the induction of new bone formation in the distraction gap with successful bone lengthening. The molecular analysis results indicated that a number of angiogenic and MMP genes were selectively induced during the three separate phases of the distraction protocol. Some of these genes include fibronectin, Hif1A, gelat A and B, SPARC, osteopontin, cyclophilinA, PEDF, VEGFA, TGFb1, endostatin, FGF receptor3, angiopoietin2, MMP2, MMP8, MMP9, MMP13 and MMP14. The expression of ECM genes showed that osteopontin and bone sialoprotein were significantly increased during distraction and expressions of BMP1, BMP3, BMP4, BMP5 and BMP6 were also stimulated. These initial studies start to show the temporal and spatial expression of the angiogenic signals that drive new bone formation during distraction. These experiments represent the first step in defining the molecular mechanisms that regulate bone formation during distraction osteogenesis while testing the functional role of angiogenic regulators in this process.

TGF-β3 Regulation of KC Chemokine Expression in Mouse Mesenchymal C3H10T1/2 and Pre-Osteoblast MC3T3-E1 Cells. D. S. Bischoff*[1], J. H. Zhu*[2], N. S. Makhijani*[1], D. T. Yamaguchi[1]. [1]Research Service, VA Greater Los Angeles Healthcare System, Los Angeles, CA, USA, [2]Research Service, VA Greater Los Angeles Healthcare System, Sepulveda, CA, USA.

Fracture healing is a complex process involving several coordinated steps including hemostasis, inflammation at the fracture site, recruitment and proliferation of mesenchymal cells, cartilage formation followed by replacement of cartilage with bone, and finally bone remodeling. Healing events are mediated by a variety of growth factors and cytokines including members of the TGF-β family. The role of these cytokines is to attract mesenchymal cells to the fracture site that can undergo proliferation and differentiation to form bone. IL-8, a member of the CXC chemokine family is a potent neutrophil chemotactic cytokine. Recently it has become apparent that neither the mouse or rat genome contains a gene that encodes IL-8, although, the genomes do have genes for other CXC chemokines that may be structurally similar to IL-8. Two of these genes, the platelet-derived growth factor-induced KC protein and the macrophage inflammatory protein-2 (MIP-2), have homology to IL-8 and may be functionally equivalent to IL-8 in the mouse. It was found that IL-8-like immunoreactivity was present in the mesenchymal-like cells, macrophages, monocytes, osteoblasts, and pre-chondrocytes in the fracture callus in both young and old rat histologic sections using a polyclonal antibody generated against human IL-8. The role of TGF-β3 on expression of the KC gene in C3H10T1/2, a mouse pluropotent mesenchymal cell line, and MC3T3-E1, a mouse pre-osteoblastic cell line was also explored. RNA was isolated from undifferentiated C3H10T1/2 and MC3T3-E1 cells grown in the absence of ascorbic acid (AA) and β-glycerophosphate (βGP) and treated with 2 ng/ml of TGF-β3 for 0, 3, 6, and 24h. Time points were also taken for all-*trans* retinoic acid (ATRA)-differentiated C3H10T1/2 cells and for MC3T3-E1 cells grown in the presence of AA and βGP at 14 days in culture. Initial northern results for TGF-β3 suggest that KC gene expression is stimulated beginning at 3h post-treatment in ATRA-differentiated C3H10T1/2 cells but not until 24h in undifferentiated cells. KC is also expressed at low levels in MC3T3-E1 cells cultured in the presence or absence of AA and βGP, although, this expression is not stimulated by TGF-β3 treatment. Conclusions: 1) Chemokine IL-8-like immunoreactivity is found in mesenchymal-like cells among other cell types in the fracture callus of old and young rats; 2) KC gene (structurally related murine equivalent to IL-8) is upregulated in the mesenchymal C3H10T1/2 cell line by TGF-β3, and although expressed in MC3T3-E1 cells, is not regulated by TGF-β3 in this cell line.

M154

TGF-β Isoforms Stimulate Chemotaxis But Not Cell Proliferation in the Pluripotent Mesenchymal Stem Cell Line C3H10T1/2. N. S. Makhijani*, D. S. Bischoff*, D. T. Yamaguchi. Research Service, VA Greater Los Angeles Healthcare System, Los Angeles, CA, USA.

Transforming growth factor-β (TGF-β) has been implicated in the promotion of bone repair. Three isoforms of TGF-β, TGF-β1, -β2, and -β3 are expressed in fracture healing, however their specific roles in the repair process are unknown. Proliferation of mesenchymal precursors of chondrogenic and osteogenic cells and migration of these precursors to repair sites are important early steps in bone repair. Differential actions of the TGF-β isoforms on early events of bone repair were explored in the pluripotent mesenchymal precursor cell line, C3H10T1/2. Cell migration or chemotaxis was determined using a modified Boyden chamber in response to concentrations of each isoform from 1 picogram/ml to 1 nanogram/ml while proliferation was assessed by radiolabeled thymidine incorporation and cell counts at concentrations from 0.1 picogram/ml to 10 nanograms/ml. Both TGF-β1 and -β2 demonstrated a similar dose-dependent chemotactic stimulation of C3H10T1/2 cells with maximum chemotaxis demonstrated at 0.1 nanograms/ml of peptide. However, maximal chemotactic response to TGF-β3 occured at 1 picogram/ml with lesser effects at higher concentrations. Twenty-four hour incubation with 3H-thymidine showed that TGF-β2 at concentrations of 0.1 and 1 nanogram/ml significantly enhanced 3H-thymidine incorporation. However, the 3H-thymidine incorporation studies implying cell division were not borne out by cell counts. While it appeared that TGF-β3 was mildly stimulatory for cell proliferation, statistical analysis did not demonstrate significance. Conclusions: 1) while all three TGF-β isoforms stimulate chemotaxis of C3H10T1/2 cells, TGF-β3 appears to be more potent at the lowest concentration tested while the other two isoforms were more potent at higher concentrations; 2) TGF-β isoforms do not appear to stimulate cell proliferation in C3H10T1/2 cells; 3) 3H-thymidine incorporation may not accurately reflect cell proliferation in this cell line.

M155

Cross-talk Between TGFβ Signaling and PPARγ2 Controls the Fate of Mesenchymal Bone Marrow Progenitors. B. Lecka-Czernik, C. Cousins*. Geriatrics, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Both adipocytes and osteoblasts are derived from a common mesenchymal progenitor and their differentiation is inversely related. The cytokine TGFβ1 controls osteoblast and inhibits adipocyte formation, whereas the transcription factor PPARγ2 plays a critical role in suppressing the osteoblast and inducing the adipocyte phenotype. We have investigated how these opposing activities of TGFβ and PPARγ2 interact with each other and how they contribute to the control of the phenotype of marrow cells. We found that the effect of TGFβ1 on marrow adipocyte differentiation includes the inhibition of PPARγ2 gene expression, which is normally induced during adipogenesis through the autoregulatory mechanism. The PPARγ2 promoter fragment contains a Smad-binding element SBE1 that binds predominantly Smad6 and Smad7, TGFβ signaling proteins. Thus, the effect of TGFβ1 on the regulation of PPARγ2 expression occurs on the transcriptional level and may involve a SBE1 *cis*-acting element. To determine whether, additional TGFβ-mediated mechanisms play a role in the inhibition of the adipocyte phenotype, we used U-33/γ2 cells that were stably transfected with a PPARγ2 expression construct and constitutively express PPARγ2 protein on a level comparable to that seen in marrow adipocytes. We found that TGFβ1 inhibits adipocyte differentiation of these cells by inhibiting the pro-adipocytic activity of PPARγ2 activated with rosiglitazone. This suggests that, in addition to controlling PPARγ2 gene expression, TGFβ1 also controls the activity of PPARγ2 protein. The inhibition of PPARγ2 activity does not require *de novo* protein synthesis. Additionally, we found that the interaction between PPARγ2 protein and the TGFβ1-signaling pathway has a reciprocal character, since PPARγ2 inhibits Smad6 and Smad7 gene expression and modulates the inhibitory effect of TGFβ1 on alkaline phosphatase activity. This effect requires activation of PPARγ2 by rosiglitazone and is not seen in the presence of the PPARγ antagonist GW9662, or in U-33/c cells that do not express PPARγ2. As reported recently, Smad3 may modulate the activity of several transcription factors, among them Runx2/Cbfa1 and PPARγ1, another PPARγ isoform, by physical interaction with these proteins. We postulate that a similar interaction may occur between Smad3 and PPARγ2, resulting in the inhibitory effect of TGFβ1 on the pro-adipocytic activity of PPARγ2 on the one hand, and PPARγ2 inhibitory effect on the TGFβ1 signaling pathway on the other. This possibility is currently under investigation.

Transforming Growth Factor-β1 Selectively Activates p38 Mitogen-activated Protein Kinase and NF-κB upon RANK Stimulation. S. J. Park*, E. J. Chang*, J. S. Ko, H. M. Kim. College of Dentistry and IBEC, Seoul National University, Seoul, Republic of Korea.

Although transforming growth factor-β1 (TGF-β1) is involved in osteoclast differentiation, the intracellular signaling mechanism by which TGF-β1 participates in osteoclastogenesis is still unclear. In this study, we compared the effects of pre-treated with or without TGF-β1 in early stage of osteoclastogenesis to clarify how TGF-β1 regulates RANKL-induced osteoclast differentiation. We pre-treated murine bone marrow cells with TGF-β1 and then stimulate RANK with RANKL after withdrawal of TGF-β1. TRAP-positive multinucleated cell formation was increased by pre-treatment of TGF-β1 in presence of low concentration of RANKL. Treatment of pre-osteoclasts with SB203580 apparently inhibited RANKL-induced osteoclast differentiation in case of the pre-treatment of TGF-β1. Further investigation showed that TGF-β1 reversed the inhibitory effect of SB203580 in RANKL-induced osteoclastogenesis. In contrast, ERK MAPK inhibitor or PI3-kinase inhibitor did not significantly change the effect of TGF-β1. To elucidate the molecular basis of TGF-β involvement in RANK signaling, we observed the effects of TGF-β1 on RANK-derived MAP kinase pathway. Pretreatment of TGF-β1 selectively triggered activation of NF-κB as well as p38 MAPK but not ERK and JNK MAPK upon RANK stimulation. These results indicate that TGF-β1 modulates RANK-derived p38 and NF-κB activation, resulting in promoting osteoclast differentiation.

Bone Morphogenetic Protein Gene Expression Patterns are Altered by Physiological and Pharmacological Regulators of Bone Metabolism. M. Zhang*, A. Maran, G. L. Evans*, A. M. Kennedy*, R. T. Turner. Orthopedic Research, Mayo Clinic, Rochester, MN, USA.

The Bone Morphogenetic Proteins (BMPs), which belong to the transforming growth factor-ß (TGF-ß) super family, have been implicated in bone formation during development, bone regeneration and in the induction of bone formation, as well as non bone related functions. Very few studies have investigated the role of BMPs in normal bone turnover and disease. In this report, we describe the changes in BMP gene expression in rat long bones in the presence of various regulators of bone turnover. BMP expression (BMP 1-7) was measured in the proximal tibial metaphysis by RNAse protection assay. Acute exposure to an estrogen in ovariectomized rats resulted in the down regulation of mRNA levels for several BMP (BMP 1, -2, -3, -4, and -7) family members. Growth hormone selectively increased BMP-1 in hypophysectomized rats while intermittent administration of PTH increased mRNA levels for BMP-1 and -7. Acute (24 hr) exposure to ethanol, an important risk factor for osteoporosis, had no effect but a long-term (2 month) treatment led to an increase in BMP-2 and BMP-4 mRNA levels. Also, alcohol prevented the PTH-induced increase in mRNA levels for BMP-1 and -7. No changes in BMP expression was observed following either hindlimb unloading or spaceflight. These findings demonstrate that BMP expression is influenced by selected physiological and pharmacological regulators of bone turnover in an effector specific pattern. These findings suggest that BMPs may play a role in mediating the skeletal response to some of the most important regulators of bone metabolism.

Lysophospholipids Activate Latent TGF-beta1 and Release Active TGF-beta1 from Extracellular Matrices Produced by Growth Plate Chondrocytes. Z. Schwartz, I. Gay*, V. L. Sylvia, D. D. Dean, B. D. Boyan. Orthopaedics, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Costochondral growth plate chondrocytes produce and store latent TGF-β1 in their extracellular matrix. Several mechanisms allow for the spatial and temporal control of the release of latent TGF-β1 from the matrix and its activation. Activation of matrix vesicle (MV) phospholipase A_2 (PLA_2) by $1\alpha,25(OH)_2D_3$ releases MMP-3 from the organelles, resulting in latent TGF-β1 activation. Here, we tested the hypothesis that lysophospholipids, which are produced by the action of PLA_2, participate in this process. Small latent recombinant human TGF-β1 was incubated with lysophosphatidylcholine (LPC) or lysophosphatidylethanolamine (LPE) [0.6 to 600 μg/ml] and the production of active TGF-β1 measured by ELISA. LPC and LPE caused a biphasic activation of latent TGF-β1, with maximum activation seen in samples treated with 2 μg/ml. Active TGF-β1 was released at incubation times of 9-360 minutes with a peak at 180 minutes. PC and PE, but not choline, also activated latent TGF-β1. However, the effect was much less than that achieved using lysoderivatives of these phospholipids. We verified that the product of the activation was functional TGF-β1 by assessing its ability to enhance [^{3}H]-thymidine incorporation by growth plate chondrocytes. The reaction product significantly enhanced proliferation whereas neither LPC nor LPE was able to do so. Extracellular matrices produced by growth zone (GC) and resting zone (RC) chondrocytes were also incubated with LPC or LPE. Both LPC and LPE stimulated the release of TGF-β1 from the cell free extracellular matrices. Addition of LPC and LPE to GC chondrocyte cultures caused an increase in PKC specific activity of intact cells and matrix vesicles produced by the cells. No increase was observed in plasma membranes, suggesting that the effect was targeted to the extracellular organelles. Moreover, there was a synergistic increase in PKC in cultures co-treated with $1\alpha,25(OH)_2D_3$. In contrast, LPC and LPE inhibited PKC activity in RC cell cultures and partially inhibited the stimulatory effect of $24R,25(OH)_2D_3$. These results suggest that LPC and LPE have an important role in chondrocyte regulation, both directly on MV PKC activity, which is cell maturation dependent, and indirectly by activation of latent TGF-β1 in the matrix.

M159

The Presence of Bone Morphogenetic Proteins (BMPs) in Megakaryocytes and Platelets. J. B. Sipe*, C. A. Waits*, B. Skikne*, M. Imkie*, R. Dhanyamraju*, H. C. Anderson. University of Kansas Medical Center, Kansas City, KS, USA.

Platelets contain various growth factors implicated in the process of bone remodeling and repair, such as Transforming Growth Factor-β (TGF-β), Platelet Derived Growth Factor (PDGF) and Epidermal Growth Factor (EGF), and have been cited as having the ability to induce new bone formation. Recently, we have identified Bone Morphogenetic Proteins (BMPs) 1 through 6 within human fetal megakaryocytes, cells which give rise to platelets, by immunohistochemistry. The possibility of platelets containing BMPs, contributing to their osteoinductive potential, was the focus of this study. Human platelets were isolated from serum, washed and lysed with a buffer containing 2% sodium dodecylsulfate (SDS), to give a lysate of pure platelet proteins. Immunoblotting (Western blotting) technique was performed to identify BMP-2 and BMP-4 within the lysate, using a polyclonal goat-anti-human BMP-2 antibody (Santa Cruz) and a monoclonal mouse-anti-human BMP-4 antibody (NovoCastra), respectively. The proteins were detected using a chemiluminescent detection kit (Amersham-Pharmacia biotech). The use of Western blotting technique revealed the presence of BMP-2 and BMP-4 in isolated human platelets. These findings demonstrate the presence of significant amounts of BMP-2 and BMP-4 in platelets, which may account for their role in bone formation and repair.

M160

Effect of TGFß2 and BMP-3 on Chondrocyte Dedifferentiation in an In Vitro Aggregate Model. B. Han*[1], B. W. Tang*[1], F. Cordoba*[1], M. E. Nimni*[1], B. S. Strates[2]. [1]Departments of Surgery, Biochemistry and Orthopaedics, Keck School of Medicine, University of Southern California, Los Angeles, CA, USA, [2]Departments of Orthopaedics and Rehabilitation, College of Medicine, University of Florida, Gainesville, FL, USA.

Using animal implantation models, we have shown that rhTGFß2 and rhBMP-3, members of the TGFß1 superfamily, are capable of inducing new bone and cartilage formation. To test the hypothesis that chondrocytes are targets of growth factors, we employed an aggregate cell culture system to show that growth factors regulate chondrocyte dedifferentiation. Briefly, cells were obtained from articular cartilage by collagenase digestion (Worthington Biochemicals, Lake Wood, NJ) in monolayer culture using FBS/DMEM + 10-7 dexamethasone after trypsinization. Cells were centrifuged and pellets exposed to various growth factor concentrations, media changed every 4 days, cell aggregates removed at intervals up to 21 days and frozen at -80ºC in OTC medium. Five μm Cryostat sections were fixed in 10% buffered formalin, stained with Alcian blue or fixed in 100% methanol and reacted with type II collagen antibody (Chemicon, Temecula, CA), incubated at 1:40 dilution and fluorescence developed with a second antibody (FITC conujugated goat anti-rabbit IgG). Cells also were homogenized and electrophoresed (SDS-PAGE 4-7%) for Western blots. Chondrocyte progenies from 5th monolayer cultures, without growth factor added, formed a multilayer matrix-rich substratum expressing type II collagen. Addition of rhTGFß2 (0-5 μg) enhanced Alcian blue positive proteoglycan expression in a dose-response manner and expression in a dose-response manner and expression of type II collagen immunohistochemically and by Western blot. Addition of rhBMP-3 at low concentrations also enhanced type II collagen expression that was inhibited at high concentrations. Addition of both growth factors had no synergistic effect. These data indicate that chondrocytes are potential targets of growth factors and may be involved in the regulation of cartilage formation and its repair process.

M161

TGF-β Stimulates Chondrogenesis and Inhibits Adipogenesis of Human Marrow Stromal Cells (hMSCs) *in vitro*: The Role of Wnt-mediated Signaling via LRP5. S. Zhou[1], K. Eid*[2], J. Glowacki[3]. [1]Department of Orthopedic Surgery, Brigham & Women's Hospital & Harvard Medical School, Boston, MA, USA, [2]Department of Orthopedic Surgery, Brigham & Women's Hospital, Boston, MA, USA, [3]Department of Orthopedic Surgery, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA.

The decrease in bone volume associated with osteoporosis and age-related osteopenia is accompanied by an increase in marrow adipose tissue. Recent data indicates that Wnt-mediated signaling via LRP5 (LDL receptor-related protein 5) affects bone mass. Wnt signaling inhibits adipogenesis, and stimulates chondrogenesis and/or osteogenesis. TGF-β was reported to enhance chondrogenic/osteogenic differentiation and depress adipogenic differentiation. TGF-β and Wnt signaling pathways can synergistically activate target genes. We tested the hypothesis that TGF-β promotes chondrogenesis and inhibits adipogenesis in human marrow stromal cells, and one of its pathways is Wnt-mediated signals via LRP5. Human bone marrow was obtained from a 58-year-old woman. Adherent stromal cells were expanded and seeded in 3D collagen sponges or were plated in 2D monolayer culture. All cultures included 100 nM dexamethasone with or without 10 ng/ml human TGF-β1 for 35 days. RT-PCR analysis showed that TGF-β up-regulated aggrecan and collagen type II and down-regulated lipoprotein lipase. This was evidence that TGF-β promotes chondrogenesis and inhibits adipogenesis of human marrow stromal cells, but the mechanism was unknown. To investigate the mechanism, we used a human stromal cell line, KM101. KM101 cells were cultured in 2D in phenol red-free α-MEM supplemented with 10% HI-FBS until they reached 80% confluence. The medium was replaced with fresh medium supplemented with 1% charcoal/dextran stripped FBS. After 2 days, when cells were quiescent, 1-5 ng/ml of human TGF-β1 was added to the culture medium. RNA was isolated 6 hours after stimulation. As revealed by RT-PCR, TGF-β up-regulated LRP5, Wnt4, Wnt5a, and Wnt7a, down-regulated Wnt5b, and had no affect on Wnt2, 3, 7b, 10b, 13 and 14 gene expression in KM101 cells. Our results showed TGF-β enhancement of chondrogenesis and inhibition of adipogenesis of hMSCs. TGF-β's regulation of LRP5 and Wnts implies that Wnt-mediated signaling via LRP5 has a role in the effects of TGF-β in chondrogenesis and adipogenesis, either independently or cooperatively with TGF-β signaling pathways.

M162

Relationship Between Hip Bone Density and Calcaneal Stiffness Index Responses to Resistance Training. D. A. Bemben, M. G. Bemben*, S. A. Brickman*. Health and Sport Sciences, University of Oklahoma, Norman, OK, USA.

The purpose of this study was to determine whether changes in total hip BMD in response to resistance training could be detected by changes in calcaneal stiffness index (SI) in older men (n=13) and women (n=18). The 40 week training programs involved 3 sets of 12 isotonic resistance exercises using Cybex® equipment performed 2-3 days/week at either low (40% 1 repetition maximum) or high (80% 1 repetition maximum) intensities. Dual Energy X-Ray Absorptiometry (Lunar DPX-IQ, software version 4.7b) was used to measure BMD of the left proximal femur at baseline, 20 weeks and 40 weeks of training. One the same day as the bone scans, the Achilles+ Ultrasonometer (Lunar Corporation) was used to obtain the SI of the left os calcis. There were no significant (p>.05) gender differences in total hip BMD or calcaneal SI at baseline. There was a significant (p=.001) training effect and a trend (p=.06) for a gender x training effect for calcaneal SI as men increased about 4% from baseline to 40 weeks (82.6±4.7 to 86.2±5.1) while women increased 1% (81.5±4.1 to 82.3±4.0). Total hip BMD increased significantly (p<.05) from baseline to 40 weeks of training for both genders. There were moderate positive correlations (r=.69 to .74, p<.05) between calcaneal SI and total hip BMD at baseline, 20 and 40 weeks of training. However, a low negative correlation (r=-.15, p>.05) was found between calcaneal SI and total hip BMD percent changes from baseline to 40 weeks, indicating that the direction of the total hip BMD response was not matched by the direction of the calcaneal SI response. In conclusion, calcaneal SI and total hip BMD improved in response to resistance training, but the relative changes in calcaneal SI and total hip BMD were not related. Thus, calcaneal SI may not be a valid indicator of the total hip BMD response to an exercise intervention.

M163

Effects of a Mutation in the Lrp5 Gene on Bone Biomechanical Properties. M. P. Akhter[1], D. M. Cullen[1], D. J. Wells*[1], M. L. Johnson[1], P. Babij*[2], G. R. Haynatzki[1], R. R. Recker[1]. [1]Medicine, Creighton University, Omaha, NE, USA, [2]Wyeth Research, Andover, MA, USA.

Identification of the high bone mass (HBM) mutation in the Lrp5 gene has allowed investigators to examine the role of Lrp5 in signaling pathways for bone adaptation to mechanical load. We report the biomechanical strength and mass data in bones from HBM transgenic (HET) mice and their non-transgenic (NTG) littermates. A total of 120 mice (17 wk old, male and female) equally divided into transgenic (HET) and non-transgenic littermates (NTG) were used. Left femurs and ulnae were collected and frozen at -20 C in saline solution for subsequent biomechanical testing. Before testing, femur (FEM) mid shaft anterior-posterior (A-P) widths were measured. Femur shafts were subjected to 3-point bending tests with the lower supports 5mm apart and touching the posterior surface. After testing the femoral shaft, the femoral necks (FN) were tested in bending. All tests were performed using an Instron 5543 at a rate of 3mm/min. Load-displacement curves were analyzed for structural strength properties that included 1) ultimate load (ULT); 2) yield load (YLD); and 3) Stiffness (STIF). Ulnae bone ash weights were measured using standard bone ash technique. Genetic and gender differences in all the measured variables were tested using ANOVA at a significance level of P<0.05. The structural strength properties of both the femur shaft and neck were greater in transgenic (HET) mice as compared to the control (NTG) mice (Table). Femoral shaft anterior-posterior widths in HET mice were also greater than that in the NTG mice. In addition, bone ash content was greater in HET mice than in NTG mice. Femoral neck (FN) stiffness in males were greater than in the corresponding female mice (Table). These data suggest that the HET mice have a larger sized and structurally stronger skeleton. For example, in HET mice the greater size (A-P width) of the femurs resulted in greater structural strength at the femoral shaft and same could be true at the femoral neck site. In addition, greater bone ash weight suggest that HET mice have larger sized ulnae as compared to the NTG mice.

Indomethacin Suppresses the Bone Adaptation Response to Mechanical Loading in C57BL/6J Mice. M. P. Akhter, D. M. Cullen, D. J. Wells*, D. L. Mace*, R. R. Recker. Medicine, Creighton University, Omaha, NE, USA.

The bone adaptation mechanism involves a prostaglandin mediated pathway. C57BL/6J (B6) mice have shown a strong bone adaptation response to changes in the loading environment (mechanical stimulus or disuse in tibiae). This project investigated the prostaglandin pathway for bone adaptation to loading in B6 mice through indomethacin treatment to inhibit prostaglandin synthesis. Two groups of mice (n=12/group, 4 mo. old, female, C57BL/6J) were subjected to tibial loading using a four-point bending device at a schedule of 36 cycle per loading session for 3 weeks. Mice were either treated with 2mg/kg of indomethacin or saline (placebo). Indomethacin or placebo was given 3 hours prior to a loading (5N bending load inducing a range of 1500-1600με) session on Monday, Wednesday, and Friday. Standard histomorphometric techniques were used to quantify the net (right leg loaded– left leg nonloaded) loading related bone adaptation response. The load related response was measured in terms of periosteal formation surface (**FS**=(0.5sL+dL+WoS)/ BS), woven bone area (**WoAr**), and bone formation rate (**BFR**). The differences between the placebo and indomethacin treatment in nonloaded legs and in the loading response (loaded-nonloaded) on all the measured variables were compared using one-way ANOVA at a significance level of P<0.05. There were no differences in the nonloaded left leg between placebo and indomethacin treatment. However, the mice treated with indomethacin had a smaller load related bone adaptation response as compared to the placebo treated mice. The increases in FS, WoAr, and BFR were lower in the indomethacin treated mice as compared to the placebo group. Although indomethacin treatment decreased the load related bone formation response it did not eliminate the response completely. These results are similar to those seen in rats exposed to four-point bending. Sensitivity to indomethacin provides an insight into the possible role of PGE_2 in the bone adaptation pathway. These data suggest that the B6 mouse is an excellent model to study the pathways and mechanisms involved in PGE related mechano-transduction signals that are involved in initiating the bone adaptation response to a unique mechanical stimulus.

Effects of 40 Weeks of Resistance Training on Bone Mineral Density in Older Men and Women. M. G. Bemben*, D. A. Bemben, S. A. Brickman*. Health and Sport Sciences, University of Oklahoma, Norman, OK, USA.

The purpose of this study was to examine the effects of 40 weeks of resistance training on the bone mineral density (BMD) of men (n=49) and women (n=78), aged 60-71 years. The training programs involved 3 sets of 12 isotonic resistance exercises (5 upper body, 7 lower body) using Cybex® equipment performed 2-3 days/week at either low (40% 1 rep-

etition maximum) or high (80% 1 repetition maximum) intensities. Muscular strength was assessed at baseline and at 5 week intervals to determine the rate of progression. Dual Energy X-Ray Absorptiometry (Lunar DPX-IQ, software version 4.7b) was used to measure BMD at the AP lumbar spine (L2-L4), the proximal femur, and for the total body at baseline, 20 weeks and 40 weeks of training. Men had significantly ($p<.05$) higher BMD than women for the trochanter, total hip and total body sites. Both men and women experienced significant ($p<.01$) increases in the trochanter, total hip and spine BMD sites from baseline to 40 weeks of training. There was a significant ($p<.05$) training effect and a trend ($p=.06$) for a gender x training effect for the total body BMD with men tending to decrease from baseline to 20 weeks, while the women increased total body BMD from 20 to 40 weeks of training. There were no significant differences between the low and high intensity programs for effects on BMD. In conclusion, resistance training significantly improved spine and hip BMD in both men and women, and total body BMD in women. The intensity of the exercise did not influence the BMD responses.

BMD Responses to Resistance Training

BMD Site (g/cm^2)	Men (n=49) Baseline	Men 40 Weeks	Women (n=78) Baseline	Women 40 Weeks

M166

Remobilization Restores Bone Mass But Not Microarchitecture After Long-term Disuse in Old Adult Dogs. C. Li*, D. Laudier*, M. B. Schaffler. Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA.

Disuse results in not only a dramatic loss of bone mass, but also changes in bone architecture. In cancellous bone, these changes result from a combination of thinning, perforation and ultimately complete loss of trabecular elements. Bone mass that is lost during immobilization can substantially recover with restoration of loading. However, whether bone architecture can recover after long-term disuse is unknown. In the current study, we examined both the bone mass and microarchitectural bases of cancellous bone recovery from long-term disuse osteoporosis. Right forelimbs of 5-7 years old retired breeder Beagle dogs (N=32) were immobilized (IM) for either 3 or 6 months periods, at which time animals were either sacrificed (3IM or 6IM), or remobilized (RM = allowed to resume normal weight-bearing) for an additional 12 months (3IM-12RM and 6IM-12RM). Nonimmobilized age-matched animals were served as control. Changes of cancellous bone were examined using histomorphometry on sections from distal metacarpal metaphyses. At 3 months after IM, there was a marked reduction (-38%) of cancellous bone mass (%Tb.Ar/T.Ar), resulting from a significant decrease in trabecular thickness (Tb.Wi, -45%) and trabecular number (Tb.N, -17%). Bone formation (L.Pm/B.Pm, MAR and BFR/B.Pm), bone turnover (Ac.F) and resorption (E.Pm/B.Pm) were significantly higher in 3IM group compared to control group; these latter results indicate that disuse bone loss at this long-term period is a "high turnover" type process. After 6 months of IM, there was no further decrease in Tb.Wi, but a continued decline in Tb.N. At this time, bone turnover slowed to near control level; however, bone resorption remained elevated. In both 3IM-12RM and 6IM-12RM groups, bone mass was restored to the control level, indicating that bone mass can recover even in older animals. This recovery occurred through thickening of the existing trabeculae. However, bone microarchitecture did not recover from long-term disuse osteoporosis. Trabecular number remained lower in both 3IM-12RM (-12%, $p<0.09$) and 6IM-12RM (-23%, $p<0.002$) groups when compared to the control group. These data indicate that bone mass can recover from long-term disuse osteoporosis, but microarchitectural changes are unreversible. This failure to restore bone microarchitecture may have important implications for determining whether bone can recover adequate mechanical integrity after recovery from osteoporosis.

M167

Attenuation of Disuse Bone Loss by Estrogen and Raloxifene in Mature Male Rats. S. A. Bloomfield[1], M. R. Allen[1], C. Nolan*[2], C. L. Smith[2]. [1]Health & Kinesiology, Texas A&M University, College Station, TX, USA, [2]Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX, USA.

Decreased mechanical usage as experienced during spaceflight, bedrest, and hindlimb unloading (HU) induces loss of bone mass and dramatic reductions in bone formation. Serum testosterone and testes weight is reduced in male rats subjected to HU. Humans and rats with testosterone (TES) and/or aromatase deficiencies experience bone loss, which may be attenuated by 17-β estradiol (E_2) treatment. The objective of this study was to assess the ability of E_2 and the selective estrogen receptor modulator raloxifene (RAL) to minimize deleterious effects of 28 d HU in male rats. Mature adult Sprague-Dawley (6-mo-old) rats were implanted with time-release pellets (Innovative Research of America; Sarasota, FL) containing vehicle (VEH), E_2 (12 μg/d), or RAL (535 μg/d) and were randomly assigned to one of 4 groups: cage-control activity + VEH (CON-VEH; n=12), HU+VEH (n=11), HU+ E_2 (n=10), or HU+RAL (n=12). Peripheral quantitative computed tomography scans (pQCT; Stratec XCT Research M) for bone mineral density (BMD) and geometry were taken *in vivo* at the proximal tibial metaphysis on days 0 and 28; *ex vivo* scans were performed at the distal femur, and proximal and mid-shaft humerus. Serum estradiol, LH, and FSH were measured by RIA. A large reduction in testes mass (-65%) was observed in HU+VEH vs. CON-VEH rats; this reduction was magnified by E_2 treatment, but unaffected by RAL. Serum LH and FSH were elevated by HU, but significantly depressed by E_2 to levels even below those in CON-VEH rats, whereas RAL had little effect on either. Both E_2 and RAL attenuated loss of endocortical bone at the metaphysis in both tibia and femur, reducing the increase in marrow area observed in HU+VEH rats by 50% and 13%, respectively. In the normally loaded humeral metaphysis, HU+ E_2 rats gained bone at the endocortical surface and had an increase in cancellous BMD. RAL prevented and E_2 attenuated the 5% decrease in cancellous BMD in the proximal tibia observed in HU+VEH rats. In conclusion, RAL attenuated loss of endocortical and cancellous bone at metaphyses of unloaded long bones without the deleterious endocrine effects produced by E_2 treatment in these male rats. Hence, RAL may prove useful in attenuating disuse-induced bone loss in males and should be investigated further.

Hip Section Modulus, A Measure of Bending Resistance, Is More Strongly Related To Physical Activity Than BMD. S. Kaptoge[1], N. Dalzell*[1], R. Jakes*[2], N. Wareham*[2], K. Khaw*[3], T. J. Beck[4], N. Loveridge[1], J. Reeve[1]. [1]Department of Medicine, Cambridge University, Cambridge, United Kingdom, [2]Institute of Public Health, Cambridge University, Cambridge, United Kingdom, [3]Clinical Gerontology Unit, Cambridge University, Cambridge, United Kingdom, [4]Department of Radiology, The Johns Hopkins University School of Medicine, Baltimore, MD, USA.

We hypothesized that measures of physical activity would have a closer relationship with section modulus (SM), an indicator of bending resistance, than with BMD because physical activity might expand the bony envelope which reduces BMD. 423 men and 436 women mean age 72yrs (SD=3) were recruited from a prospective population based-cohort study to a study of hip bone loss. Hip BMD was measured on two occasions 2-5 years apart (mean 2.7, DXA - Hologic 1000W). Hip structural analysis (HSA) software was used to calculate structural indices and BMD from the DXA scans on three narrow regions: the narrow neck (NN), intertrochanter (IT) and shaft (S). A physical activity and lifestyle questionnaire was administered at baseline. Multivariate repeated measures analysis of variance was used to model the association between these variables and SM, periosteal diameter (PD) and BMD (4 conventional Hologic regions and 3 narrow regions). In all regions in both genders, body weight was positively associated with SM, PD and BMD ($P<.0001$). Periosteal diameter in 5 of 6 regions, both genders, was associated with lifetime physical activity ($P<0.019$). There was a significant decline of BMD with age at the NN and S regions in women ($P<0.022$) but not SM, or PD which increased. In women, previous fracture history was associated with having lower values of BMD and SM (except for NN, $P<0.017$). Section modulus was positively associated in women with hrs/week recreation (NN, P=0.004), heavy physical activity (NN, P=0.002) and stair climbing (S, P=0.027) whereas NN BMD was the only BMD associate of physical activity in women (P=0.016). In men, section modulus was positively associated with heavy activity (IT and S, $P<0.005$) and moderate activity (IT, P=0.012) while BMD was positively associated with moderate activity (IT and S, $P<0.032$). In conclusion, proximal femur diameter is associated positively with life-long physical activity. If this is mediated through a loading related effect on periosteal expansion, BMD may be an unsatisfactory outcome measure in physical activity studies since it is inversely related to projected bone area. SM in contrast was associated with several measures of recent physical activity.

M169

Site-Specific Effects of Physical Activity and Body Weight on Bone Strength and Geometry: Findings from the Penn State Young Women's Health Study. M. A. Petit[1], T. J. Beck[2], T. L. Oreskovic[2], K. Uusi-Rasi[2], C. Bently*[1], H. Lin*[1], L. Tom[1]. [1]Health Evaluation Sciences, Penn State University, Hershey, PA, USA, [2]Radiology, Johns Hopkins University, Baltimore, MD, USA.

Both body weight and physical activity are known to influence BMD, however little is known about their effects on bone strength and geometry. To explore the effects of these two different types of skeletal loading, we examined proximal femur bone geometry and strength at age 21 using data from the longitudinal Penn State Young Women's Health Study. Participants were enrolled in the study from age 12 and measurements made annually for 10 years. Proximal femur scans at age 21 were analyzed using a hip structural analysis program to assess BMD, subperiosteal width, bone axial strength (cross-sectional area, CSA) and bone bending strength (section modulus, Z) at the femoral neck and femoral shaft regions. Height and weight were measured by standard procedures and body composition taken from DXA total body scans. Data were analyzed in two ways: i) by activity tertile based sports-exercise scores (by questionnaire) from ages 12-18 (inactive n = 19; normal active n = 19; high active n= 20); and ii) by weight tertiles (light n = 20; medium n = 20; heavy n = 18). BMD and bone structural variables at age 21 were compared between groups before and after adjusting for covariates using analysis of covariance. After controlling for body size and lean mass, exercise group differences between the upper and lower tertiles at the femoral neck remained significant for BMD (+10%), section modulus (+12.2%), CSA (+10.2%) and cortical thickness (+10.7%), but not for subperiosteal width. At the femoral shaft, differences remained significant only for BMD (+8.0%) and CSA (+6.5%). When data were divided into weight tertiles differences were significant for all unadjusted variables. However, after adjusting for height and activity, differences decreased and became non-significant at the femoral neck. In the femoral shaft region, differences remained significant with the heaviest girls having greater bone axial strength (CSA +9.1%) and cortical thickness (+15%), but no difference in Z or bone width. Together, these results suggest that loading from high body weight is more likely to influence the long bone axial strength (CSA), while loading from sports-exercise may exert greater benefit to femoral neck bone bending strength (Z).

Patterns of Femoral Neck Bone Loss in Spinal Cord Injury and Spaceflight. J. R. Shapiro[1], T. J. Beck[2], A. LeBlanc[3], V. Schneider[4], B. Mustapha*[5], L. Shakelford*[6], T. Oreskovic*[2], P. Ballard*[5], C. Ruff*[2], J. Toerge*[5], J. Caminis[7]. [1]Uniformed Services University, Bethesda, MD, USA, [2]Johns Hopkins University, Baltimore, MD, USA, [3]Baylor College of Medicine, Houston, TX, USA, [4]NASA, Washington, DC, USA, [5]National Rehabilitation Hospital, Washington, DC, USA, [6]Johnson Space Center, Clearlake, TX, USA, [7]Novartis Pharmaceutical, East Hanover, NJ, USA.

Spaceflight and spinal cord injury (SCI) cause lower limb disuse. SCI is proposed as a model for spaceflight bone loss. Hip DXA scans (Hologic QDR1000) were obtained within 10 weeks of acute SCI and at 3-6 months follow-up in 9 paraplegic and tetraplegic subjects enrolled in a blinded placebo controlled trial of an intravenous bisphosphonate. DXA data were also analysed using the Hip Structure Analysis (HSA) program that measures BMD and geometric properties in narrow regions across the proximal femur. Rates of change were computed as the percent change from baseline or pre-flight/time to follow-up or post-flight for SCI or Cosmonauts.Rates of change in bone parameters at the femoral neck are shown in the figure for pooled SCI and Cosmonauts. BMD, cross-sectional area (CSA), cortical thickness and section modulus (Z) each decrease while buckling ratio (BR) increases and width changes are non-significant in both SCI and microgravity. Rates of change are much greater among cosmonauts although the difference is at least partially due to lack of change expected in some treated SCI subjects. This alteration in geometric properties underlies a decrease in section modulus and an increase in calculated BR that may be associated with increased fracture risk. Conclusions: 1) Bone loss parameters in the femur shaft are similar in SCI and after prolonged spaceflight. 2) Decreased periosteal bone expansion in the presence of endocortical bone resorption suggests a common mechanism operating in both situations. 3) SCI is an appropriate surrogate for modeling the effects of microgravity on bone.

Use of Transgenic Mice Harboring a Collagen Reporter that Reflects Osteoblastic Activity and Responds to Isometric Loading of Long Bone and Spine. J. D. Delaney*, D. Adams*, D. W. Rowe. University of Connecticut Health Center, Farmington, CT, USA.

Bone remodeling reflects the recruitment and regulation of osteo-progenitor cells to preosteoblasts, osteoblasts and osteocytes. Transgenic mice expressing a chloramphenicol acetyl transferase (CAT) marker gene under the control of the rat 3.6 kb COL1A1 promoter (pOBCol3.6) have been previously used as a surrogate marker of the osteoblastic lineage. These mice provide a rather simple and sensitive metric of an activated osteoblastic lineage within intact bone. Our goal is to develop a standardized form of skeletal loading of otherwise mobile mice that is independent of gravity and the volition of the subject. An orbital shaker (Model C10, New Brunswick Scientific) was adapted to contain 16 compartments to exercise the mice uniformly but separately. To determine a rotational force that would elicit a sustainable osteogenic response, 10-12 month old CD-1 mice heterozygous for pOBCol3.6CAT were divided into four groups (n = 6). They were taken through a conditioning phase in which the rotational speed was gradually increased as the mice adapted by "clutching" the stage ultimately achieving a maximum of 250 RPM for 30 minutes a day. The mice were harvested after 1, 2 and 3 weeks of the maximal exercise and compared to control animals who spent 30 min/day in the cages without rotational stimulation. The fact that the mice in all groups lost body weight, femoral trabecular bone volume by µCT (controls 9.29% ± 1.17 and exercised 2.38% ± 0.37%) and failed to increase CAT activity suggested that this vigorous protocol was catabolic for the mice. A second experiment used 8 month old mice that were exercised at 60, 120 and 180 RPM for 30 min every over day (q.o.d.). Relative to control mice, no response in CAT activity was observed in the 60 or 120 RPM group but the femurs from the 180-RPM displayed a four-fold induction of CAT activity after only one week of exercise that returned to a baseline at 2 weeks. Micro-CT data indicated that trabecular bone volume was not being depleted over the course of the experiment, (controls = 13.6% ± 9.0%; 1 week = 14.1% ± 4.5%; 2 weeks = 13.4% ± 8.0%; and 3 weeks = 16.1% ± 9.9%). A third experiment utilizing 5-6 month old mice and the 180 RPM/qod protocol demonstrated a statistically significant (25%) increase in CAT activity in the long bones at 3,7,and 11 days of exercise while the spine samples showed a two-fold increase in CAT activity by 11 days of exercise (all significant to $p < 0.05$). Thus the model does appear to induce new osteogenic activity in which trabecular bone of the spine is particularly responsive. Currently mice transgenic for ColGFP marker genes are being subjected to this protocol to visualize the cellular response to mechanical loading.

M172

Bone and Muscle Recovery after 28 Days of Hindlimb Unloading in Mature Male Rats. M. R. Allen[1], H. A. Hogan[2], S. A. Bloomfield[1]. [1]Health and Kinesiology, Texas A&M University, College Station, TX, USA, [2]Mechanical Engineering, Texas A&M University, College Station, TX, USA.

The purpose of this study was to investigate the response of bone and muscle to hindlimb unloading (HU) and subsequent reambulation. Our working hypothesis was that both tissues would experience significant decrements in mass/strength after 28 days of HU, but that muscle would recover more fully and quickly upon return to cage activity (after 7 & 14 days). Fourteen skeletally mature male Sprague-Dawley rats (6-mo-old) were randomly divided into four groups: baseline control (BC, n=5), 28d HU (HU, n=3), 28d HU + 7d recovery (7REC, n=3) and 28d HU + 14d recovery (14REC, n=3). The results to date are from the first phase of a long-term multi-year study. Longitudinal in-vivo measurements were made using peripheral quantitative computed tomography (pQCT) for bone mineral density (BMD) and cross-sectional geometry of the proximal metaphyseal and mid-diaphyseal tibia on day 0, after 28d HU, and at sacrifice. Hindlimb plantar flexor muscle mass and in-vivo peak isometric torque were obtained on the day of sacrifice. Body mass and plantar flexor muscle mass were lower ($p < 0.05$) in HU compared to BC. Body mass returned to control values in both 7REC and 14REC while muscle mass significantly increased compared to HU but remained lower than BC. Maximum isometric torque was reduced by 15% in HU compared to BC with full recovery for 14REC. Combining data from all unloaded animals after 28d HU (n=9), total and trabecular BMD decreased by 6.5% and 11.8% , respectively, in the proximal tibia metaphysis compared to 0-day values. After 7d of recovery, total and trabecular BMD were non-significantly reduced (-1.6% and -4%, respectively) compared to values after 28d HU, while 14REC also tended to have lower total BMD (-3%) compared to 28d HU. Trabecular BMD of 14REC animals showed a trend of higher values (+6.8%) compared to HU values but lower relative to 0-day values. There were no changes at the mid-diaphysis with respect to BMD or geometry in any group over time. The results confirm that muscle, a very plastic tissue, recovered its unloading-induced force loss after 14d of cage activity, but bone did not. Interestingly, muscle mass did not recover fully, which suggests some alteration in contractile properties of the muscle fibers. Both total and trabecular BMD of the proximal tibia metaphysis were dramatically reduced by HU and failed to recover after 14d of cage activity. These results tend to support the hypothesis, but further work is needed to define the trends more conclusively and to assess if and when BMD returns to baseline values. A large and/or persisting mismatch between bone and muscle strength could very well place the bone at an increased risk of fracture.

M173

The Effects of Nitric Oxide and Titanium Particulate Debris on RANKL Expression and Secretion in Osteoblast . J. T. Ninomiya, M. J. Sytsma*, J. A. Struve. Department of Orthopaedic Surgery, Medical College of Wisconsin, Milwaukee, WI, USA.

Particulate wear debris generated from total joint implants is known to incite the production of a host of pro-inflammatory cytokines and other proteins, ultimately leading to loosening and failure. Recently, the proteins RANKL and its soluble decoy receptor OPG have been shown to have a critical role in the formation of osteolysis. The short-lived free radical nitric oxide (NO) is synthesized in response to specific cytokines and plays a role in the bone remodeling process and we hypothesized that nitric oxide alters osteoclast maturation in response to particulate debris through the regulation of RANKL gene expression and secretion. The roles of NO and titanium particle stimulation on the gene expression and secretion of both RANKL and OPG were investigated in murine osteoblastic MC3T3-E1 cells. Titanium particles in the presence or absence of the nitric oxide donor PAPA NONOate were added to osteoblasts, while controls consisted of unstimulated cells in the absence of particles or NO. Total cellular RNA was isolated and RT- PCR was performed using specific primers for RANKL and OPG, with the results normalized to actin. The effects of particles and NO on osteoclast maturation were assessed using osteoblast whole cell lysates which were collected following incubation. Samples of the cell lysates were added to a murine bone marrow osteoclast maturation assay, and multinuclear TRAP+ cells were counted under light microscopy. Both particulate debris and NO donors alone and in combination increased the gene expression of RANKL, which peaked at 12 hours. However, the combination of titanium particles and NO displayed a significantly higher induction of RANKL transcripts than did titanium or NO alone. In addition, at 12 hours RANKL transcripts demonstrated a significantly higher induction compared to OPG, its soluble decoy receptor, in all three experimental groups. The TRAP assay demonstrated that lysates from MC3T3 E1 cells exposed to titanium for 48, 72, and 96 hours caused a significant increase in the number of TRAP+ cells (osteoclasts) generated from murine bone marrow cultures when compared to lysates from cells that were not exposed to titanium. Also, the addition of an anti-RANKL antibody to a culture containing recombinant RANKL showed a significant decrease in TRAP+ cells when compared to the RANKL protein alone. Our data demonstrate that NO and titanium alone and in combination significantly increase the ratio of RANKL:OPG, resulting in increased osteoclastogenesis. These findings provide important insight into the mechanisms of implant loosening and suggest that nitric oxide modulates bone resorption through a RANKL dependent mechanism.

M174

Influence of Human Osteoblasts on Hematopoietic Stem Cells: Analysis in Coculture on a Synthetic Biphasic Calcium Phosphate Ceramic. N. M. Rochet*[1], N. Tieulie*[2], L. Ollier*[2], A. Loubat*[2], J. M. Bouler*[3], G. Daculsi*[3], G. F. Carle*[1], B. Rossi*[2]. [1]UMR CNRS-UNSA 6549, Nice, France, [2]INSERM U364, Nice, France, [3]INSERM EMI99-03, Nantes, France.

Very little is known about the relationship between bone cells and hematopoietic stem cells (HSC). It has been suggested that human osteoblastic cells could participate to the

survival and/or self-renewal of the CD34 positive hematopoietic stem cells. Using a biphasic calcium phosphate ceramic (BCP), we have studied the influence of normal human osteoblasts on the proliferation and differentiation of CD34 positive cells purified from cord blood, in coculture experiments. This macroporous biomaterial is composed of 60% hydroxyapatite and 40% beta-tricalcium phosphate and has been widely used as a bone substitute in human and rodents. This BCP ceramic mimics partially the three-dimensional structure and the chemical composition of cancellous bone. After one to three weeks of coculture, the hematopoietic cells were counted, analysed morphologically and clonogenic assays were performed to enumerate the CFU-GEMM (Colony Forming Unit - Granular Erythroid Monocyte Megacaryocyte), BFU-E (Burst Forming Unit - Erythroblast) and CFU-GM (CFU - Granular Monocyte). We have demonstrated that human osteoblasts seeded on BCP induce the rapid differentiation of hematopoietic stem cells into both granular and monocyte/macrophage pathways. These results are clearly different from those obtained after coculture on plastic. Indeed, during the first week of coculture on plastic, human osteoblasts induce the proliferation of very immature hematopoietic progenitors (CFU-GEMM). Starting on the second week, we have observed the specific differentiation of these CFU-GEMM into the granular pathway. Using RT-PCR and RNase protection assay, we have shown that the cytokine expression profile of human osteoblasts cultured on BCP is different from that observed on plastic. This finding could explain, as least in part, the differential effects observed on HSC when cocultured on those different surfaces. Additional results suggest that the biomaterial by itself might play a direct role in the differentiation of HSC. In conclusion, we have shown that the nature of the culture substratum must be taken into account when studying the influence of osteoblasts on HSC. Our results suggest that rather than self-renewal, osteoblasts in contact with BCP support the differentiation of HSC in the granular and monocytic pathways leading to osteoclast precursors.

M175

Osteoclasts Produce Inhibitors of Osteoblast Differentiation. J. M. Owens, K. McDermott*, J. Li, J. Wozney, H. Seeherman. Musculoskeletal Sciences, Wyeth Research, Cambridge, MA, USA.

Significant bone formation has been reported in a recombinant human bone morphogenetic protein-2 (rhBMP-2)-stimulated, non-human primate core defect model of intraosseous bone induction, (Seeherman et al ORS, 1998 and 2000). In this animal model, rhBMP-2 treatment induced unexpected, significant, transient bone resorption during the first 2 weeks post-implant, followed by dramatic bone formation present at 4 weeks. Histological analyses revealed that trabecular bone adjacent to the rhBMP-2 implant, was surrounded by numerous osteoclasts resorbing bone. Interestingly, bone surfaces in the rhBMP-2 treated core defects contained only a few osteoblasts during the first 2 weeks post-implant. These findings prompted the hypothesis that activated osteoclasts secrete certain factor(s) that inhibit osteoblastic differentiation. Using the mouse osteoclast-like myeloma cell line RAW264.7 and a mouse osteoblastic cell line (MLB13MYC clone 14, Rosen et al 1994, JBMR 9:1759), we investigated possible roles for osteoclasts in regulating the differentiation of osteoblasts. RAW264.7 cells were treated with 100ng/ml RANKL for 7 days to induce osteoclastic cells (TRAP positive, bone resorbing cells). Fresh medium containing RANKL was added at days 3, 5 and 7. Conditioned medium (CM) samples were collected at time of medium change and transferred onto monolayers of Clone 14 osteoblastic cells. Addition of CM from RAW cells treated with RANKL for 5 to 7 days resulted in significant (up to 80%) inhibition of alkaline phosphatase (alk phos) expression. RANKL at 100ng/ml did not inhibit alk phos expression in Clone 14 cells. Using a similar system, it has recently been shown by others that platelet-derived growth factor (PDGF) is the major inhibitory factor of osteoblastogenesis (JBMR 17:257-265, 2002), where anti PDGF antibody almost completely reversed the inhibitory actions of the CM. In the present study, however, treatment with 2µg/ml PDGF antibody, which completely blocks PDGF-stimulated 3H-thymidine incorporation by NR6R-3T3 fibroblasts, only partially (16%) reversed the inhibitory actions of the CM. This suggests that osteoclasts secrete more than one factor that regulates osteoblast formation and activity and that PDGF may not be the major factor. Our in vitro findings provide further evidence that the induction of numerous osteoclasts in our in vivo model of intraosseous bone formation, may be responsible for the delayed osteoblastic response to rhBMP-2, by their secretion of factor(s) which directly or indirectly suppress osteoblastogenesis.

Decreased Osteoblast Function in RANK-/- Mice. L. Xing[1], E. M. Schwarz[1], R. J. O'Keefe[1], W. C. Dougall[2], B. F. Boyce[1]. [1]University of Rochester, Rochester, NY, USA, [2]Immunex, Inc., Seattle, WA, USA.

A RANKL GST fusion protein was shown last year to stimulate bone formation in vivo and in vitro, suggesting that RANKL/RANK signaling may play a regulatory role in osteoblast (obl) function. To further study this possibility, we examined obl parameters in bones from wild-type (wt) and RANK-/- mice. In both calvarial and long bone sections, RANK-/- mice at three ages (8-day, 3-weeks, and 3-month) have: 1) decreased mineral apposition rate (0.65+/-0.14 um/day vs 1.4+/-0.5 in wt mice) and bone formation rate (0.40+/-0.12 um3/um2/day vs 1.0+/-0.25 in wt mice); 2) decreased obl number (2.9+/-0.5 obls/mm bone surface vs 4.4+/-0.2 in wt mice); 3) flat and irregularly-shaped obls; but 4) normal matrix mineralization (with von Kossa staining) and obl alkaline phosphatase (ALP) staining, despite low blood calcium and high PTH values. Thus, although bone matrix volume is markedly increased in the RANK-/- mice due to osteopetrosis, their obl activity is reduced and the mice do not have osteomalacia. To investigate if the activity of RANK-/- obls is also decreased in vitro, calvarial obl from wt or RANK-/- mice were cultured with or without BMP2. ALP activity and mineralized nodule formation (basal or in response to BMP2) were similar in cultures from wt and RANK-/- mice, and treatment of calvarial osteoblasts with RANKL had no effect on ALP activity. To study the response of RANK-/- obls in vivo to a known stimulator of bone formation, FGF (4 ug/day for 3 days) was injected over the calvariae of RANK-/- mice and their wt littermates. RANK-/- mice formed more new bone after FGF administration than wt mice [51+/-13 new bone (% pre-existing bone) vs 25+/-3% in wt mice]. Because RANK-/- mice have increased blood PTH levels, we hypothesized that continuous PTH treatment would inhibit wt obl function in vitro. We found that PTH (0.1 and 1ug/ml) inhibited both ALP and nodule formation in FRC cells. Our findings indicate that the absence of RANK signaling is associated with reduced basal obl activity in vivo, but not in vitro or in response to BMP2 treatment in vitro, and importantly, they have an increased response to FGF in vivo. This suggests that the reduced obl phenotype in RANK-/- mice may be secondary to a circulating inhibitor, possibly PTH, and that RANK signaling may not be a major direct regulator of obl function.

M177

Effects of PTH on RANK-L and OPG Gene Expression During Osteoblast Differentiation. J. C. Huang[1], T. Sakata[2], M. Bencsik*[2], B. Halloran[2], D. D. Bikle[2], R. A. Nissenson[2]. [1]Growth and Development, University of California San Francisco, San Francisco, CA, USA, [2]Endocrine Research Unit, University of California Veterans Affairs Medical Center, San Francisco, CA, USA.

RANK-L is a critical factor in the induction of osteoclastogenesis. Its decoy receptor OPG is an inhibitory factor that negatively regulates this process. The ratio of the expression of these two proteins is a major determinant of bone turnover. Despite the physiological importance of these genes, the mechanisms by which their expression is regulated by factors that control bone turnover remain incompletely understood. Both genes are expressed in cells of the osteoblast lineage, but the precise relationship between the state of osteoblast differentiation and RANK-L and OPG expression is not clearly defined. In the present study, mouse bone marrow stromal cells isolated from 3-month old male C57Bl/6 mice were cultured for 28 days in the presence of ascorbic acid and beta-glycerophosphate. At specific time intervals (Day 7, 14, 21, and 28), the cells were acutely stimulated with bPTH(1-34) (100 ng/ml, 2 hrs) followed immediately by RNA extraction. Levels of mRNA encoding RANK-L, OPG, alpha-1(Type I) collagen [alpha-1 col] and alkaline phosphatase [Alk. PO4] (early bone markers), and osteocalcin [OC] (late bone marker) were assessed by quantitative real-time RT-PCR. The freshly isolated stromal cells followed a predictable pattern of differentiation, with alpha-1 col and Alk. PO4 expression peaking at 14 day, whereas the osteocalcin gene was maximally expressed after 21 days in culture. OPG reached maximal expression at Day 14 (2.5-fold over Day 7 levels) before tapering off. Conversely, RANK-L established an increased pattern of expression as differentiation occurred, reaching maximum at Day 28 of cell culture. Stimulation with acute PTH caused an inhibition of OPG expression but induced a significant increase in RANK-L expression (relative to control) at the latter stages of cellular differentiation (Days 21 & 28). Acute treatment with PTH did not detectably alter the expression of any of the bone marker genes. By contrast, chronic exposure of cells to PTH (100 ng/ml) starting at the beginning of the culture period resulted in a dramatic decrease in the expression of all of the bone markers, indicating a PTH-induced block in osteoblast differentiation. We conclude: 1) in this model system, maximal sensitivity of the RANK-L gene to PTH occurs relatively late in the process of osteoblast differentiation; and 2) chronic exposure of pre-osteoblasts to PTH can prevent the progression to mature osteoblasts.

M178

Ovariectomy Increases Stromal Cell M-CSF Production via Selection and Expansion of Stromal Cell Lineages Exhibiting Increased Casein Kinase 2 Activity and Resistance to TNF Induced Apoptosis. Y. Gao[1], W. Qian*[1], T. Gianluca*[1], C. Simone[1], N. M. Weitzmann[2], S. Oscar[1]. [1]Division of Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA, [2]Division of Bone and Mineral Diseases, Washington University School of Medicine, St. louis, MO, USA.

The increase in TNF induced by ovariectomy (ovx) leads to the selection of bone marrow stromal cells (SCs) with the capacity of producing high levels of M-CSF. The resulting increase in M-CSF level is a key mechanism by which ovx induces bone loss. Ovx SCs exhibit increased casein kinase 2 (CK2) activity which leads to enhanced M-CSF transcription through CK2-induced Egr-1 phosphorylation. Since CK2 is a constitutively active kinase, the ovx induced increase in CK2 activity results from selection and expansion of SCs with intrinsic high CK2 activity. However the mechanism of this selection is unknown. We found that the high levels of TNF characteristic of ovx mice induces apoptosis of SCs with low CK2 activity and low M-CSF production, but not of SCs with high CK2 activity and high M-CSF production. In contrast, SCs with both low and high CK2 activity survive exposure to the lower levels of TNF of sham mice. Furthermore, the specific CK2 inhibitor emodin blocked CK2 activity and abolished the ability of ovx SCs to resist TNF induced apoptosis. Thus, ovx induces the survival and the expansion of SCs with high CK2 activity and high M-CSF production through selective TNF induced apoptosis of SCs with low CK2 activity. Since NFkB, a CK2 substrate, blunts TNF induced apoptosis, we investigated if CK2 blocks TNF induced SC apoptosis by inducing NFkB. We found NFkB activity to be about 2 fold higher in ovx SCs than sham SCs, both unstimulated and TNF stimulated. Ovx SCs possess high levels of the NFkB subunits p50 and p52 while sham SCs have low or undetectable levels of these proteins. In addition, TNF treatment greatly enhanced the expression of p50 and p52 proteins in sham but not in ovx SCs. Thus, the NFkB p50 and p52 are maximally expressed in unstimulated ovx SCs. Conversely, IKBalpha was more abundant in sham than in ovx SCs. Together, these findings demonstrate that ovx upregulates NFkB activity by downregulation of its inhibitor IKBalpha. Furthermore, the CK2 inhibitor emodin blocked TNF induced NFkB activation, confirming that ovx upregulates NFkB through CK2. In summary, the data suggest that elevated levels of CK2 in ovx SCs protect these cells from TNF induced apoptosis by enhancing the anti-apoptotic factor NFkB activity. As a result, the increase in TNF caused by ovx allows the selection of SCs with high M-CSF production and high osteoclastogenic activity.

M179

Protein Kinase C alpha/estrogen Receptor alpha Interaction in Osteoblasts during Differentiation. M. Brama*, M. Longo*, M. Marino*, K. S. Korach*, W. C. Wetsel*, R. Scandurra*, R. Baron, A. Teti, S. Migliaccio. Experimental Medicine, University of L'Aquila, L'Aquila, Italy.

In osteoblast-like cells undergoing confluence-induced differentiation, calcium-dependent protein kinase C (PKC) activity increases, while estrogen receptor alpha (ERalpha) binding and responsiveness to estrogens decrease. We tested the hypothesis that the underlying molecular mechanism requires physical interactions between ERalpha and PKC isoforms. Anti-ERalpha and anti-PKCalpha immunoprecipitates were obtained from rat primary osteoblasts at different confluence conditions, and tested for the presence of PKC isoforms and ERalpha. PKCalpha was found to co-immunoprecipitate with ERalpha both in sub- and post-confluent cells, but to a much greater extent in the latter, where higher levels of the differentiation marker alkaline phosphatase were expressed. All of our anti-ERalpha immunoprecipitates contained a single PKCalpha post-translational variant, *i.e.* its well-known 40 KDa cleavage product PKM alpha, encompassing the catalytic site, with barely detectable amounts of uncleaved protein. Interestingly, only the 66 KDa ERalpha variant was present in input lysates from sub-confluent cells, whereas its newly described 46 KDa splice variant became detectable solely upon differentiation. In rat osteosarcoma cells ROS.SMER #14, stably transfected with ERalpha, we found no significant variation of co-immunoprecipitable PKCalpha levels. In these cells, full-length ERalpha was found to be greatly reduced at post-confluence, but its 46 KDa isoform was unchanged. Both 80 and 40 KDa forms of PKCalpha were readily detectable, but, again, the former was nearly absent in anti-ERalpha immunoprecipitates. As shown by our previous results, c-Src plays an important role in confluence-induced differentiation in osteoblastic cells, and has been found to interact with PKC isoforms. Thus, we analysed c-Src expression and activity in our cells. We observed a significant and transient increase of c-Src expression and kinase activity, which preceded maximal PKC activation. PKCalpha from differentiated osteoblasts induced c-Src phosphorylation *in vitro*. In contrast, c-Src was unable to phosphorylate PKCalpha, although tyrosine phosphorylation was apparent in this PKC isoenzyme and increased in differentiated cells. These data suggest close interactions between PKCalpha, c-Src and ERalpha in osteoblastic cells, which may be crucial for the differentiation process and the related decrease in estrogen responsiveness.

Modulation of Human Estrogen Feceptor alpha *F* Promoter Activity by a Protein Kinase C-dependent Mechanism in Differentiated Osteoblast-like Cells. M. Longo*, V. De Luca*, S. Denger*, G. F. Caselli*, F. Gannon*, A. Teti, S. Migliaccio. Experimental Medicine, University of L'Aquila, L'Aquila, Italy.

The gene for human estrogen receptor alpha (ERalpha) gives raise to six different mRNAs driven, in a tissue-specific manner, by six different promoters (*A* to *F*) and translated into a single protein. The *F* promoter has been described as specifically active in bone cells, but its modulation has not yet been clarified. To elucidate the role of ERalpha promoters in bone physiology and their regulation, we stably transfected human osteoblast-like cells negative for ER (SAOS-2) with expression vectors carrying human *A*, *B*, and *F* ERalpha promoter sequences upstream of the luciferase reporter gene. No luciferase activity was detected in cells containing promoters *A* and *B* relative to cells transfected with empty vectors. In contrast, high basal luciferase activity was found in two clones carrying the *F* promoter. Our previous results have evidenced significant modulations in ERalpha levels and activity, as well as close interactions between ERalpha and PKC isoforms, upon confluence-induced osteoblast differentiation. Thus, we analyzed *F* promoter activity at post-confluence and its possible dependence on PKC isoforms expression and/or activity. *F* promoter activity was evaluated in sub-confluent and post-confluent cells, and found to be constantly up-regulated in the latter. A two/three-fold higher luciferase activity was detectable 24 hr after confluence, with no significant increase up to 96 hr. Again, no such increase could be evidenced in cells carrying the *A* and *B* promoters. Overnight treatment of post-confluent cells with 10^{-7} M 12-O-tetradecanoylphorbol-13-acetate (TPA) nearly abolished PKCalpha protein expression and resulted in a significant decrease of *F* promoter activity, which strongly suggests a PKC-dependent up-regulation of the promoter upon differentiation. We also observed that in sub-confluent cells identical TPA treatment induced a slight increase of *F* promoter activity. In cells treated with calphostin *C*, a compound inhibiting the activity, but not the expression, of most PKCs, no variation in luciferase activity relative to untreated counterparts was observed. In addition, we observed an unchanged Fos family member expression, but a modulated phorphorylation pattern on c-Jun N-terminal serines (63 and 73) in sub- vs. post-confluent cells, either untreated or TPA-treated, suggesting differential confluence-dependent regulation on the AP1-site harboured in the *F* promoter. Collectively, these data strongly suggest tight relationship between intact PKC pathways and *F* promoter regulation, possibly involving kinase activity-dependent and -independent PKC functions.

M181

Potassium Calcium-dependant BK Channel: A Potential Membrane Target of Estrogens and SERMs in Human Osteoblasts. V. Breuil*[1], G. Romey*[2], L. Euller-Ziegler[3], B. Rossi*[1], H. Schmid-Antomarchi*[1]. [1]U 364, INSERM, Nice, France, [2]Institut de Pharmacologie Moléculaire et Cellulaire, CNRS, Nice, France, [3]Rheumatology, University Hospital L'Archet, Nice, France.

Estrogens, and more recently SERMs (Selective Estrogen Receptor Modulators), have been recognized for their positive effects on bone. However, their mechanisms of actions is still only partially resolved. Although it generally is accepted that estrogens act at genomic level by binding to intracellular estrogen receptor, they trigger nongenomic effects mediated by plasma membrane receptor. One of these is to increase activity of BK channel in many cells types (smooth muscle and vascular endothelium), but as never been reported in bone. BK channels are composed of a (encoded by Slo gene) and b subunits. The a subunit forms the K+-selective pore, while b subunits influence the pharmacology, kinetics, and voltage/calcium sensitivity of BK channel. b1 and b4 subunits have been reported to mediate estrogen effects on BK channel. In this study, we show that primary human osteoblasts, and 3 cells lines of human osteosarcoma (MG63, SaOs2, CAL72) express the Slo protein (Western-Blot). Using RT-PCR, we observe in all these cells the expression of the 4 b subunits (b1, b2, b3, b4). In electrophysiology analysis, we observe the typical calcium-induced potassium current of high conductance of BK channel. As expected, b1 subunit expression induce Charybdotoxine and Iberiotoxine (classical inhibitors of BK channel) resistance of BK channel. We investigate the effects of 17b estradiol and Tamoxifen (a SERM) on BK channel activity. In outside-out configuration, 17b estradiol (1-10mM) increase BK channel opening (Npo) in 20% of the cases ; however, we observe no effect in inside-out configuration, suggesting that the target of this effect is located at the extracellular side of the membrane. Interestingly, Tamoxifen (1mM) increase the BK channel activity in 100% of the cases. Our data indicate that estrogen and SERMs can modulate BK channel activity, sheading a new light on nongenomic effects of estrogens and opening new ways for therapeutic development.

M182

Bone Marrow Stromal Cells Express Two Distinct Splice Variants of ER-α that are Regulated by Estrogen. A. Sanyal, B. L. Riggs, T. C. Spelsberg, S. Khosla. Mayo Clinic, Rochester, MN, USA.

The expression of ER-α in reproductive and non-reproductive tissues (such as bone) is regulated by a complex set of promotors. Moreover, splice variants of ER-α appear to be present in different tissues. In addition to the mRNA giving rise to the conventional, full-length, 66 kD receptor, the most common ER-α variant described to date is a 46 kD receptor lacking the AF-1 domain, which arises through alternate splicing of the parent ER-α transcript. While this variant retains responsiveness to estrogen in some tissues, in other tissues it is unresponsive to estrogen and appears to function in a dominant negative manner, at least for actions requiring the AF-1 domain. Since osteoblast differentiation is clearly regulated by estrogen, we sought in the present study to define the ER-α splice variants and their regulation by estrogen in the mouse bone marrow stromal cell line, ST-2, which can be induced to differentiate into mature osteoblasts. By Western blot analysis, ST-2 cells expressed both the 66 and 46 kD forms of ER-α . By analysis of the expressed mRNAs using primers specific for the distinct splice variants giving rise to the two proteins, we also found that ST-2 cells contained the mRNAs for both the 66 kD as well as the truncated, 46 kD receptor. Using primers specific for each of the five 5'-untranslated exons, we found that ST-2 cells utilized only the promoters upstream of exons F and C (in contrast to most reproductive tissues, which utilize promoters upstream of virtually all the five exons). Interestingly, search of the Celera mouse genome database revealed that the exon F promoter contained both an ERE half-site and a consensus AP-1 sequence, suggesting that this promoter may be regulated by estrogen. Consistent with this, estradiol (10^{-8} M) treatment of ST-2 cells markedly diminished levels of the 66 kD ER-α protein (by 78%) as well as the 46 kD variant protein (by 86%). Analysis of the mRNAs revealed that, in ST-2 cells, the mRNA encoding the 46 kD variant arises exclusively via the estrogen responsive, F-promoter, whereas the 66 kD mRNA arises from both the F and C promoters, with only the transcript arising from the F promoter being suppressed by estrogen. In summary, these findings indicate that: (1) bone marrow stromal cells express at least two variants of ER-α; (2) promoter usage in these cells is much more restricted than in classical reproductive tissues; and (3) estrogen downregulates the ER-α message and protein in these cells through effects on one of the two promoters utilized by these cells. These findings have potential implications for understanding the mechanisms by which bone may regulate sensitivity to estrogen under conditions of widely varying estrogen levels, as occur during the estrus or menstrual cycles.

M183

Demonstration of Aromatase Activity in Rodent Bone. U. I. Moedder*, B. L. Riggs, S. Khosla. Mayo Clinic, Rochester, MN, USA.

The aromatization of C19 precursor steroids to estrogens in extragonadal sites such as the breast, vasculature, brain, and bone has been amply demonstrated in higher primates. However, it is generally believed that in rodents, aromatase is present only in the reproductive tissues and in the brain. It has been suggested that the local aromatization of androgens to estrogens may play an important role in regulating bone metabolism (Simpson et al. TEM 11:184, 2000). Since mouse and rat models are used extensively for studies on sex steroid action on the skeleton, the issue of whether C19 steroids can be locally aromatized in bone to estrogens in rodents is clearly important to definitively resolve. Thus, we used a well characterized aromatization assay which measures the conversion of ^{3}H-androstenedione to estrone (Ackerman et al. JCEM 53:412, 1981) to assess aromatase activity in the femurs and tibias from 6 month old mice. Aromatase activity in mouse bone was clearly

detectable (2.28 fmol/h/g bone). Moreover, the specific aromatase inhibitor, 4-hydroxyandrostenedione, markedly reduced aromatase activity in the mouse bone samples to 0.21 fmol/h/g bone, attesting to the specificity of the assay in assessing aromatase activity. Having established the presence of aromatase activity in mouse bone, we next hypothesized that ovariectomy would increase aromatase activity in bone, perhaps as a "protective" local mechanism. However, comparison of both aromatase activity and mRNA levels (by reverse transcriptase polymerase chain reaction) in bones from sham operated versus ovariectomized mice and rats (n = 3 per group) assessed 9-14 days following surgery failed to detect any differences. These findings were confirmed in *in vitro* studies using ROS 17/2.8 cells in which treatment with estradiol (10^{-7} M) had no effect on aromatase mRNA expression. In conclusion, our studies demonstrate that rodent bone does express measurable aromatase activity, but this does not appear to be regulated *in vivo* or *in vitro* by estrogen. While species differences may exist between primates and rodents in terms of the contribution of local aromatization of androgens to estrogens towards skeletal homeostasis, our findings do suggest that rodent models can be used to address this issue.

M184

Raloxifene Stimulates Osteoprotegerin and Inhibits Interleukin-6 Production by Estrogen-Responsive Human Trabecular Osteoblasts. V. Viereck[1], C. Grundker*[1], S. Blaschke*[2], H. Siggelkow[3], K. Frosch*[4], G. Emons*[1], L. C. Hofbauer[5]. [1]Dept Gynecology, Goettingen, Germany, [2]Div Nephrol/Rheumatology, Goettingen, Germany, [3]Div Gastroent/Endocrinology, Goettingen, Germany, [4]Dept Trauma Surgery, Goettingen, Germany, [5]Div Gastroent/Endocrinology, Marburg, Germany.

The selective estrogen receptor modulator (SERM) raloxifene suppresses bone loss and inhibits osteoporotic fractures in postmenopausal women. Its protective skeletal effects following activation of estrogen receptors (ER) are thought to be mediated through paracrine factors that are produced by osteoblastic lineage cells and act on osteoclastic lineage cells. Receptor activator of nuclear factor-kB ligand (RANKL) is an essential factor for osteoclast formation and activation, and enhances bone resorption, while osteoprotegerin (OPG) which is produced by osteoblastic cells neutralizes RANKL, thus preventing bone resorption. Recently, 17b-estradiol and phyto-estrogens were found to stimulate OPG mRNA levels and protein secretion in a human osteoblastic cell line through activation of the ER-a. In this study, we assessed the effects of raloxifene on OPG mRNA steady state levels (by semiquantitative RT-PCR and Northern analysis) and protein production (by ELISA) in primary human trabecular osteoblasts (hOB) which predominantly expressed ER-a. Raloxifene enhanced both ER-a and ER-b gene expression, and induced the gene expression for the estrogen target gene, progesterone receptor by three-fold, respectively. Moreover, raloxifene increased OPG mRNA levels and protein secretion by hOB cells by to two- to four-fold in a dose- and time-dependent fashion with a maximum effect at 10-7 M and following exposure for 48 to 72 h ($P < 0.001$). Co-treatment with the pure ER antagonist ICI 182,780 completely abrogated the stimulatory effects of raloxifene on OPG protein secretion, indicating that the stimulatory effects of raloxifene were specifically mediated through the ER. Analysis of cellular markers of osteoblastic differentiation revealed that raloxifene enhanced type I collagen secretion and alkaline phosphatase activity by three-fold and two-fold, respectively ($P < 0.001$). In addition, raloxifene also inhibited gene expression and protein secretion of the bone resorbing cytokine interleukin (IL)-6 by 25 to 40%, respectively ($P < 0.001$). In conclusion, our data suggest that raloxifene is capable of stimulating OPG production and inhibiting IL-6 production by human osteoblasts, thus favouring an anti-resorptive cytokine milieu. Since OPG production increases with osteoblastic cell maturation, enhancement of OPG by raloxifene could be related to its stimulatory effects on osteoblastic differentiation.

Estradiol and Genistein Stimulate Calcium Deposition and Alkaline Phosphatase Activity in BMP-4 Pretreated MC3T3-E1 Cells. M. Gros-van Hest, A. van Helvoort*, I. Schoenmakers*. Department of Condition and Disease Specific Research, Numico Research B.V., Wageningen, Netherlands.

Estradiol and isoflavones were reported to increase BMD *in-vivo*.To investigate whether the increased BMD can be ascribed to a stimulatory effect of these components on bone formation, the pre-osteoblastic cell line MC3T3-E1 was employed. These cells were pretreated with BMP-4, since BMP-4 was suggested to enhance osteoblastic maturation (Xiao et al., 2002). MC3T3-E1 cells were cultured in phenol red free alpha-MEM supplemented with 10% non-charcoal stripped FCS and ascorbic acid with or without BMP-4 for 3 days. Thereafter, cells were exposed to 17ß-estradiol (E-7M) or genistein (E-6M) in phenol red free alpha-MEM supplemented with 10% charcoal stripped FCS, ascorbic acid and ß-glycerophosphate for 4-11 days. Alkaline phosphatase activity, DNA and calcium depositions were determined. In the absence of BMP-4, 17ß-estradiol slightly, but significantly increased alkaline phosphatase activity and calcium deposition. Cells only formed mineralized bone nodules when pretreated with BMP-4. Preteatment with BMP-4 significantly increased alkaline phosphatase activity and calcium depositions, which could be further stimulated by 17ß-estradiol and genistein. These data suggest that estrogenic components stimulate BMP-4 induced bone formation. This *in-vitro* model is estrogen sensitive, which makes it a valid model to identify estrogenic components stimulating bone formation.

Molecular Mechanisms of Action of the Soy Phytoestrogen Genistein: Emerging Role for its Effects via PPARγ. Z. Dang, S. E. Papapoulos, C. W. G. Lowik. Department of Endocrinology and Metabolic Diseases, Leiden University Medical Center, Leiden, Netherlands.

Interest in soy phytoestrogens for maintenance of health including bone has exploded. However, the molecular mechanisms of action are poorly understood, which frustrates their applications. We used the principal soy phytoestrogen genistein as a model compound to study the molecular mechanisms of action. First, a dose response of genistein showed that osteogenesis in KS483 cells, mouse and human bone marrow cells was stimulated by genistein below 1 μ M but inhibited by micromolar concentrations based on changes in ALP activity, nodule formation, calcium deposition and mRNA expression of Cbfa1, PTH/PTHrP receptor and osteocalcin. In constast, adipogenesis was inhibited by genistein below 1 μ M but stimulated by micromolar concentrations based on changes of adipocyte numbers and mRNA expression of PPARγ 2, aP2 and LPL. The effects of genistein were ER-mediated below 1 μ M but non-ER-mediated in the micromolar range. Second, genistein in the micromolar range binds directly to and activates PPARγ . Concurrently, it inhibited p44 and p42 MAPK activity, leading to stimulation of PPARγ activity. These data indicate that genistein could dully activate PPARγ . Third, cotransfection of PPARγ 2 with ERE-luc into KS483 cells exposed to genistein downregulated its estrogenic transcriptional activity. Our data indicate that activation of PPARγ by genistein in the micromolar range resulted in its antiestrogenic effects. Likewise, cotransfection of ERα or ERβ into KS483 cells exposed to genistein resulted in a decrease of PPRE-luc reporter activity. These findings strongly suggest that biological effects of genistein are concentration dependent and are the result of the balance between activated ERs and PPARγ . Finally, PGC-1 is a common coactivator for PPARγ and ERα in KS483 cells. Interestingly, mRNA expression of ERα , PPARγ 2 and PGC-1 was all downregulated by 1 μ M genistein but upregulated by 25 μ M genistein after 11 days of culture. To test whether there is competition between PPARγ and ERα for PGC-1, we cotransfected ERα or PPARγ 2 or PGC-1 with ERE-luc or PPRE-luc constructs into KS483 cells exposed to genistein. Our results indicate that this is probably not the case. In summary, we define, for the first time, PPARγ as a new target for genistein. Moreover, the biological effects of genistein are determined by the balance between activated ERs and PPARγ , which is concentration dependent. Our findings could have significant physiological implications and can explain diverse action of genistein in different tissues in a way analogus to that of selective estrogen receptor modulators (SERMs).

M187

Development of Inducible Estrogen Receptor-alpha and –beta Osteoblastic Cell Lines to Examine Differential Estrogen Regulation. D. G. Monroe[1], S. A. Johnsen*[1], B. J. Getz*[1], S. Khosla[2], B. L. Riggs[2], T. C. Spelsberg[1]. [1]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, [2]Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

Estrogen (i.e. 17-β-estradiol; E2) plays pivotal roles in the function and maintenance of the skeleton, including in the bone-forming osteoblasts (OBs). The functions of E2 are largely mediated through two distinct estrogen receptor isoforms, ERα and ERβ, both of which are coexpressed in OBs. Following E2 binding, the ER can either homodimerize or heterodimerize and regulate gene expression through direct DNA binding of specific elements (i.e. estrogen response elements or EREs) or through indirect DNA binding (i.e. AP1 elements). Although numerous genes are known targets of the ERs in various tissues, little information exists regarding the differential regulation of gene transcription by ERα or ERβ homodimers or the ERα/β heterodimer in OBs. Therefore, to determine whether ERα and ERβ homo- and hetero-dimers can differentially regulate genes in OBs, we developed doxycycline (Dox)-inducible ERα and ERβ stable lines in the U2-OS osteosarcoma model system. Determination of receptor concentrations within these lines using a biopsy nuclear binding assay demonstrated that the ERα (U2OS-ERα) and ERβ (U2OS-ERβ) lines express approximately 8700 and 7300 functional receptors per nucleus, respectively, when treated with Dox. Treatment of the U2OS-ERα and U2OS-ERβ lines with 50 ng/ml Dox and 10 nM E2 resulted in induction of the progesterone receptor (PR) mRNA as analyzed by semi-quantitative RT-PCR, in agreement with previous reports from our laboratory. The induction of PR transcript, and of other genes under study, demonstrates that our ER stable lines function normally to regulate endogenous gene expression. One of these genes, osterix (Osx), is required for the development of mature OBs and is involved in osteoblastic differentiation. Any E2 regulation of the Osx transcript would be of utmost interest. Interestingly, RT-PCR analysis in the U2OS-ERα and U2OS-ERβ lines demonstrated an apparent isoform-specific E2 regulation of Osx. To complement these studies, an ERα/β cell line is being produced in which a constitutive ERα gene is introduced into the U2OS-ERβ line. Treatment of the cells with Dox would trigger the induction of the ERβ gene and therefore result in the formation of ERα/β heterodimers. Current studies involve further analysis of the E2 regulation of Osx gene expression and comparison of the patterns of other E2 regulated genes using microarray analysis in the U2OS-ERα, U2OS-ERβ, and U2OS-ERα/β cell lines. The data generated from these experiments will allow us to identify those genes uniquely regulated by the various ER dimers.

Study of The Aromatase Cytochrome P-450 Gene (CYP19) Promoter Usage in Osteoblasts Cells. A. Enjuanes*[1], N. Garcia-Giralt*[2], D. Grinberg*[2], S. Balcells*[2], A. Supervia*[1], M. Bustamante*[2], L. Mellibovsky*[1], X. Nogues*[1], A. Diez-Perez[1]. [1]Urfoa, IMIM (Institut Municipal d´Investigació Mèdica), Barcelona, Spain, [2]Departament de Genètica, Universitat de Barcelona, Barcelona, Spain.

P-450Arom catalizes the conversion of androgens into estrogens and its presence in bone cells has been documented. Given the incomplete understanding of CYP19 gene regulation in osteoblast cells, we have undertaken a detailed study on the promoter usage of CYP19 gene in a cultured human osteoblast cell line. Several plasmids containing the following CYP19-promoter regions upstream of a luciferase reporter gene were constructed: pA) I.4 promoter region (pr); pB) I.4 pr and exon I.4; pC) I.3 pr; pD) I.3 pr and exon I.3; pE) promoter II, exon I.3, I.3 pr and exon I.6; and pF) promoter II and exon I.3. MG-63 cells were grown in Dulbecco×s modified Eagle medium (DMEM) supplemented with 10% fetal calf serum (FCS). CYP19 promoter vectors and pSVB-Gal control vector were co-transfected in MG-63 cells at 70 % confluency in DMEM without FCS using FuGene Reagent. Six hours after transfection, MG-63 cells were incubated in DMEM without FCS for 24 hours with alternative treatments. One day later, cells were lysed and chemiluminescent assays were performed to mesure luciferase and β-galactosidase activities. Both transfection experiments and chemiluminescent assays were duplicated at each experimental step.Results:

	pA	pB	pC	pD	pE	pF
10% FCS	0.27 (±0.15)	0.39 (±0.14)	0.24 (±0.02)	0.50 (±0.10)	0.36 (±0.03)	0.30 (±0.15)
DEX 100nM	1.71 (±0.35)	2.62 (±0.53)	1.35 (±0.35)	1.34 (±0.16)	1.20 (±0.23)	1.41 (±0.18)
VitD 100nM	1.61 (±0.14)	1.04 (±0.13)	1.63 (±0.14)	2.08 (±0.47)	1.65 (±0.23)	1.28 (±0.48)
VitD + DEX 100nM	2.19 (±0.55)	2.08 (±0.90)	1.69 (±0.13)	1.38 (±0.17)	1.80 (±0.14)	1.69 (±0.20)
17β-estradiol	1.03 (±0.13)	0.63 (±0.10)	0.83 (±0.24)	0.96 (±0.17)	0.85 (±0.40)	1.10 (±0.13)
Testosterone	1.20 (±0.21)	0.77 (±0.09)	0.97 (±0.33)	1.00 (±0.14)	1.00 (±0.37)	1.01 (±0.11)

Values correspond to luciferase activities (normalized by β-galactosidase) expressed respect a reference value of 1 for the basal condition (BSA 0.1%). Mean (sd)

In MG-63 cells, I.4 pr plus exon I.4 mediate the stimulation by DEX, and exon I.4 seems to be important for this stimulation. In contrast, exon I.4 seems to negatively affect the VitD stimulation. Pr I.3 plus exon I.3 mediate the stimulation by VitD and the exon I.3 seems to be relevant for this stimulation. In all cases, FCS inhibit basal expression whereas, 17β-estradiol and testosterone seem to have no effect on these promoters.

M189

Reduced Mineralization by Sera from Women with High Bone Mineral Density: Evidence for Estradiol Control of Mineralization. M. van Driel*, E. M. Colin*, C. J. Buurman*, M. Koedam*, H. A. P. Pols, J. P. T. van Leeuwen. Internal Medicine, Erasmus MC, Rotterdam, Netherlands.

Both a reduced quantity and quality of bone increase the risk for osteoporotic fractures. The elasticity of bone and its resistance to fracture is related to the degree of mineralization. When mineralization reaches too high levels, bone has a decreasing ability to absorb impact energy, becomes more stiff and brittle and more susceptible to fractures. In the present study we analyzed whether there are differences in mineralization between serum from postmenopausal women with a very low or high bone mineral density (BMD). For this purpose sera of 21 women with a femoral neck BMD within the lowest quintile (<0.75 g/cm^2) and sera of 29 women within the highest quintile (≥0.92 g/cm^2) were tested. Hormones and serum/urine markers of bone metabolism were measured. Human fetal osteoblast (SV-HFO) cells, that proceed through different stages of differentiation in culture, including extracellular matrix formation and mineralization, were cultured in medium supplemented with the various sera for 21 days. Mineralization and alkaline phosphatase activity (AP) were measured at 21 days of differentiation. Mineralization was significantly higher in sera of the low BMD group compared to sera of the high BMD group (0.18 ± 0.04 nmol/μ g DNA vs. 0.15 ± 0.04 nmol/μ g DNA, p = 0.02), while at day 21 no difference in induction of AP was observed. There were no differences in serum 1,25-dihydroxyvitamin D_3 and PTH levels between the two groups. Serum 17β -estradiol (E2) levels were significantly lower in women with a low BMD compared to women with a high BMD (17.0 ± 4.6 pmol/l vs. 45.4 ± 6.9 pmol/l, $p < 0.01$). A possible role for E2 was further analyzed by testing the effect of various concentrations E2 on mineralization and AP at multiple time-points during culture. E2 treatment resulted in a 10-20% reduction in calcium deposited during the whole culture period, with most pronounced effects at later time points (days 19-21). In addition, E2 reduced AP activity by 10-20%, with most pronounced effects in the period preceding the peak activity of AP (days 7-14). No effects of E2 on total amount of DNA were observed. In conclusion, serum from postmenopausal women with a high BMD and high E2 level results in a reduced mineralization, which is supported by the direct inhibition of mineralization by E2. Besides the known role in controlling bone turnover via regulation of osteoclast function, on basis of the current data a new role for estradiol can be postulated: control of the extent or set-point of mineralization, which potentially contributes to the quality of bone.

Cloning and Characterisation of the Human Cbfa 1/Runx2 Promoter. S. Gutzwiller*[1], V. Geoffroy*[2], B. Fournier*[1]. [1]Bone Metabolism Unit, Novartis Pharma AG, Basel, Switzerland, [2]Inserm u349, Hôpital Lariboisière, Paris, France.

Runx2 is a transcription factor belonging to the runt domain family, which has been shown to be essential for osteoblast differentiation. Runx2 deficient mice develop to term, their skeleton is characterized by a complete absence of intramembranous and endochondral bone, a consequence of the maturational arrest of hypertrophic chondrocytes and osteoblasts. Three isoforms of the Runx2 gene have been identified that differ in their N-terminal sequence. The Runx2/Osf2 isoform has a novel N-terminus and has been detected exclusively in bone and prostate. Very little is known about the structure of the human Runx2 promoter region to explain this intriguing tissue restricted expression. Therefore we decided to clone the human Runx2 promoter region. Here, we report the cloning of a 12Kb promoter region of the human Runx2 from a PAC library, and the subcloning of 5.3Kb of this region into a luciferase reporter vector. We investigated the activity of the human Runx2 promoter in different cell types and found that its activity is greater in mature osteoblastic cells compared to chondrocytic, pre-osteoblastic, and fibroblastic cells. We studied the regulation of this promoter with two hormones essential for bone metabolism such as PTH (1-34) and 1,25 Dihydroxyvitamin D3. PTH (1-34) was not able to modulate Runx2 promoter activity. In contrast, 1,25 Dihydroxyvitamin D3 dose dependently repressed the promoter activity with a maximum inhibition of 50%. Some transcription factors have been suspected to act upstream of Runx2, these hypotheses were mainly based on in vitro data often coupled with observation of skeletal abnormalities in animal models where these genes were deleted. Very little information is available on the ability of these factors to directly modulate Runx2. We studied the effect of some of these proposed genes on the activity of the human Runx2 promoter. We showed that the homeobox gene Msx2 decreased the activity of the human Runx2 promoter. The Ets1 and 2 transcription factors had no effect on the activity of this promoter despite the presence of perfect consensus site on this promoter. In conclusion, we have identified negative regulators of the human Runx2 promoter activity. The positive regulators of Runx2 remain to be identified.

The Effects of Near Infrared and Visible Light on RANKL and OPG Gene Expression and Secretion in Osteoblasts. J. T. Ninomiya[1], G. S. Takenishi*[1], J. A. Struve[1], E. V. Buchmann*[2], H. T. Whelan*[2]. [1]Department of Orthopaedic Surgery, Medical College of Wisconsin, Milwaukee, WI, USA, [2]Department of Pediatric Neurology, Medical College of Wisconsin, Milwaukee, WI, USA.

The effects of light on wound healing has become an exciting area of research interest, since light emitting diodes (LED) in the near infrared and visible range have been shown to promote rapid healing of ulcers and other skin lesions. We therefore hypothesized that exposure to near infrared (IR) light would have similar effects on bone, promoting enhanced bone turnover. Therefore, we chose to evaluate the effects of LED light on the gene expression and secretion of RANKL and osteoprotegerin, two modulators of osteoclast maturation and ultimately bone resorption. Murine osteoblast MC3T3-E1 osteoblastic cells were stimulated with LED light at specific wavelength and energy densities until confluent. Three stimulatory wavelengths (670, 728, and 880 nm) and energy densities (4 J & 8 J) were utilized. PTH was added as a positive control following the final LED exposure, and after 12 hours of further incubation total RNA was collected. The effects of LED light on the gene expression of RANKL, OPG, and IL-6 were determined by RT-PCR, and were compared to actin controls. A functional osteoclast maturation assay was performed using bone marrow cells extracted from mouse femurs. The effects of whole cell lysates on the maturation of osteoclast precursors were determined by counting the number of TRAP positive multinucleate cells in each sample. Osteoblasts demonstrated wavelength and energy specific responses to LED light. Specifically, exposure to 880 nm at 4 J increased RANKL gene expression and decreased OPG gene expression. The osteoclast maturation assay results confirmed that LED exposure increased RANKL secretion in osteoblast cells, resulting in enhanced maturation of osteoclast precursors. Additionally, the number of multinucleate osteoclast cells was significantly greater in the samples stimulated with LED light alone compared to unstimulated controls. Our studies suggest that near IR and visible light may play an important role in the regulation of bone resorption through alteration of the gene expression and secretion of RANKL and OPG. These studies have important implications in the management of osteoporosis, fracture healing, orthopaedic implant loosening, and the prevention of bone loss due to prolonged space flight.

p300 Requires Runx2/Cbfa1 and the Vitamin D3 Receptor to Regulate Bone Specific Osteocalcin Expression but not its Intrinsic Histone Acetyl Transferase Activity. A. Villagra*[1], J. Sierra*[1], J. Olate*[1], A. van Wijnen[2], J. Lian[2], G. Stein[2], J. Stein[2], M. Montecino[1]. [1]Department of Molecular Biology, University of Concepcion, Concepcion, Chile, [2]Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA.

p300 is a multifunctional transcriptional co-activator that serves as an adaptor for several transcription factors including nuclear steroid hormone receptors. p300 contains an intrinsic histone acetyltransferase (HAT) activity that may be critical for promoting steroid-dependent transcriptional activation. Therefore we addressed p300 control of basal and vitamin D3-enhanced activity of the bone-specific osteocalcin (OC) promoter. In osteoblastic cells, OC gene transcription is principally regulated by the Runx2/Cbfa1 transcription factor and is stimulated in response to vitamin D3 by the Vitamin D3 receptor complex. We find that transient overexpression of p300 results in a significant dose-dependent increase of basal and vitamin D3-stimulated OC gene promoter activity. This stimula-

tory effect requires intact Runx2/Cbfa1 binding sites as well as the Vitamin D responsive element (VDRE). In addition, by co-immunoprecipitation we show that the endogenous Runx2/Cbfa1 and p300 proteins are components of the same complexes within osteoblastic cells under physiological concentrations. The stimulatory effect of p300 on the OC promoter is independent of its intrinsic HAT activity, as a HAT-deficient p300 mutant protein up-regulates expression and cooperates with P/CAF to the same extent as the wild type p300. Based on these results, we propose that within the OC promoter context, p300 interacts with key transcriptional regulators of this phenotype-restricted gene and connects factors bound to distal and proximal promoter sequences.

M193

Translational Regulation of RUNX2 Isoforms: Type-I mRNA Is Translated by Internal Ribosomal Entry Site Mechanism While Type-II mRNA Translation Is Cap-dependent. N. Elango*, Y. Li*, S. Elango*, M. S. Katz. Dept Medicine, Univ Texas Hlth Sci Center and GRECC, VAMC, San Antonio, TX, USA.

RUNX2, a transcription factor implicated in the regulation of osteoblast differentiation and gene expression, is expressed as two isoforms. The two isoforms, type-I and type-II, are encoded by two different mRNAs with distinct 5' untranslated regions (UTRs) (type-I: 1015 nucleotides and type-II: 210 nucleotides). We recently showed that both RUNX2 mRNAs are expressed but dormant in osteoblast precursors and nonosteoblastic cells, and that the expression of both isoforms is regulated at the translational level. In this study we investigated whether the two 5' UTRs function as translational regulators. In vitro transcribed luciferase mRNA containing type-II 5' UTR was translated efficiently in rabbit reticulocyte lysate, whereas luciferase mRNA with type-I 5' UTR was not. In contrast, in transient transfection experiments using clonal osteoblastic cells (UMR-106), translation of luciferase reporter containing type-I 5' UTR was 6 times that of reporter with type-II 5' UTR. Most eukaryotic mRNAs are translated by a cap-dependent ribosome scanning mechanism and are efficiently translated in vitro. The type-I 5' UTR is long and GC-rich, and thus capable of forming stable secondary structures inhibitory to cap-dependent translation. Accordingly, we reasoned that the translation of type-I 5' UTR containing RNA observed in UMR-106 cells might be mediated by an alternative mechanism involving an internal ribosomal entry site (IRES). To investigate this possibility, we performed dicistronic mRNA translation assays using expression vectors containing CAT as the first cistron followed by type-I 5' UTR upstream of luciferase (second cistron); dicistronic constructs in which type-I 5' UTR was replaced by 5' UTRs of β-globin (known to be translated by the cap-dependent mechanism), type-II RUNX2, and luciferase (pGL3-Promoter) mRNAs were used as controls. When UMR-106 cells were transfected with the dicistronic constructs, luciferase activity was detected only in cells transfected with the construct containing type-I 5' UTR. From these results we conclude that translation of type-I RUNX2 mRNA is mediated by an IRES element whereas translation of type-II mRNA is cap-dependent. Interestingly, 40 nucleotides long stem-loop and unstructured sequences inserted near the 5' terminus of the type-I 5' UTR decreased reporter translation by 75% and 90%, respectively. Thus the structural integrity of the type-I 5' UTR appears to be essential for the activity of the IRES element. Translational control of RUNX2 mRNAs by alternate 5' UTR dependent mechanisms may play a role in the regulation of osteoblast differentiation.

M194

Functional Integration of Runx2 and BMP2 Responsive Regulatory Signals at Transcriptionally Active Subnuclear Sites in Osseous and Non-Osseous Cells. S. K. Zaidi, A. J. Sullivan*, A. J. van Wijnen, J. L. Stein*, J. B. Lian, G. S. Stein. Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA.

Runx2/Cbfa1 controls osteogenic lineage commitment and is a transcriptional effector of BMP2 responsive Smad signaling. Genetic defects in the Runx2 and Smad pathways interfere with normal development. The *in situ* localization of Runx2 and Smad proteins must impact the mechanisms by which these proteins function together in gene regulation. To address the significance of the Smad interaction with Runx2 at subnuclear domains, we examined the organization of Runx2-Smad complexes in the nucleus of osseous and non-osseous cells. In response to TGFβ/BMP, Smad enters the nucleus, but does not associate with the nuclear matrix in non-osseous cells lacking Runx2. In osteoblasts, Runx2 recruits either TGFβ responsive Smads 2/3 or the BMP2 related Smads 1/5 to Runx2 subnuclear foci. We show that Smad-Runx2 complexes are associated *in situ* with the nuclear matrix and this association requires the intranuclear targeting signal of Runx2. The convergence of Smad and Runx2 proteins at these sites supports transcription as reflected by BrUTP labeling and functional cooperativity between the proteins. A specific point mutation that abrogates targeting to the nuclear matrix, retains interaction with Smads, but reduces transcriptional activity on a TGFβ responsive promoter. We conclude that the integration of Runx2 and Smad-related signals, which is critical for normal skeletal development, is mediated by *in situ* interactions at specific foci within the nucleus.

M195

Transcriptional Induction of the Osteocalcin Gene During Osteoblast Differentiation Involves Acetylation of Histones H3 and H4. J. Shen*[1], J. B. Lian[1], M. A. Montecino[2], G. S. Stein[1], J. L. Stein*[1], A. J. van Wijnen[1]. [1]Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA, [2]Departamento de Biologia Molecular, Universidad de Concepcion, Concepcion, Chile.

The remodeling of chromatin is required for tissue-specific gene activation to permit interactions of transcription factors and co-regulators with their cognate elements. Here, we investigate the chromatin mediated mechanisms by which the bone-specific osteocalcin gene is transcriptionally activated during cessation of cell growth in ROS 17/2.8 osteosarcoma cells and during normal osteoblast differentiation. Acetylation of histones H3 and H4 at the osteocalcin (OC) gene promoter was assayed during the proliferative and post-proliferative stages of cell growth by using chromatin immunoprecipitation (ChIP) assays with antibodies that recognize different acetylated forms of histones H3 or H4. The results show that the promoter and coding regions of the OC gene contain very low levels of acetylated histones H3 and H4 during the proliferative period of osteoblast differentiation when the OC gene is inactive. However, in mature osteoblasts and confluent ROS 17/2.8 cells, in which the OC gene is actively transcribed, histone H3 and H4 acetylation is observed in the initial 1.1 kbp of the OC gene promoter and the coding region. Histone acetylation at the RUNX2 (CBFA1) locus, which is expressed throughout osteoblast differentiation, is not altered post-proliferatively. We conclude that acetylation of histones H3 and H4 is functionally coupled to the chromatin remodeling events that mediate the developmental induction of OC gene transcription in bone cells.

M196

Regulation of Bone Sialoprotein Gene Expression by the Homeodomain Proteins Msx2 and Dlx5. G. L. Barnes[1], K. Hebert*[1], M. Q. Hassan*[2], A. van Wijen[2], M. F. Young[3], J. B. Lian[2], G. S. Stein[2], L. C. Gerstenfeld[1]. [1]Department of Orthopaedic Surgery, Boston University Medical Center, Boston, MA, USA, [2]Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA, [3]Craniofacial and Skeletal Diseases Branch, National Institute of Dental Research, NIH, Bethesda, MD, USA.

Bone Sialoprotein (BSP), a phosphorylated and sulfated RGD containing glycoprotein, represents one of the major non-collagenous, extracellular matrix proteins of bone. The expression of BSP is primarily restricted to the mineralized tissues of the skeleton, specifically hypertrophic chondrocytes and osteoblasts. While the restricted nature of BSP expression is well characterized, the molecular regulation of BSP restricted expression remains poorly understood. Recent studies have demonstrated that a homeodomain binding element in the murine BSP promoter is required for the osteoblast-selective expression of BSP and that this element was capable of binding to Dlx5. We have reported similar findings demonstrating that a putative homeodomain element is required for selective expression of both the avian and human BSP promoters in either hypertrophic chondrocytes or osteoblasts. However, our studies do not support the conclusion that Dlx5 acts through direct DNA-binding at this cis-acting element. Furthermore, our results do not support the conclusion that Dlx5 directly modulates BSP expression. Instead, our studies demonstrate that Msx2 represses BSP expression and that Dlx5 acts by antagonizing this repression. Furthermore, our data support the conclusion that the regulation of BSP by Dlx5/Msx2 is not dependent on direct DNA binding at either of the previously described putative homeodomain binding elements in the BSP promoter. This study represents the first report of the regulation of BSP by Msx2 and suggests that the mechanism of regulation of BSP by the combination of Dlx5 and Msx2 factors occurs through a mechanism independent of direct DNA binding similar to that previously described for the osteocalcin gene.

M197

Detection of Jab1-Smad4 Interaction by Both Biochemical Method and AFM. M. Wan[1], W. Hou*[2], X. Shi[1], X. Cao[1]. [1]Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, [2]Biomedical Engineering, CBSE, University of Alabama at Birmingham, Birmingham, AL, USA.

The AP-1 proteins are a family of transcription factors, members of which are essential for bone and cartilage development. Jab1, the Jun activating binding protein, specifically stabilizes complexes of c-Jun or JunD with AP-1 sites, increasing the specificity of target gene activation by AP-1 proteins. Jab1 mRNA expression has been detected in both osteoblast MC3T3-E1 cells and isolated mouse calvaria. Thus Jab1 may represent an important regulator of gene transcription during bone development. Smad4 is the common mediator in the TGF-β/BMP signaling pathway. Previously, we found that Jab1 antagonizes TGF-β function by inducing degradation of Smad4. In this study, we examined the specific interaction of Jab1 with Smad4 in yeast, in vitro, in mammalian cells and by atomic force microscope (AFM). We demonstrated that Jab1 interacts with Smad4, not with Smad1, Smad3, Smad6, or Smad7 in both yeast two-hybrid and pull-down assays. We also performed immunoprecipitation assays. Jab1 was co-immunoprecipitated with Smad4 in 293T cells when both proteins were overexpressed. In addition, we demonstrated that endogenous Jab1 interacts with Smad4 in Mv1Lu cells. More importantly, we could directly view the images of the interaction between these two proteins by AFM. AFM has been recently employed to study the adhesive strength and mechanics of various biomolecular binding interactions, including protein-protein interactions. These measurements rely on measurement of the deflection of an AFM cantilever with a known force constant during retraction of a sample surface from an appropriately modified AFM tip. We demonstrated that both Jab1 and Smad4 alone were present in trimer under AFM. They developed into a ring-shaped hexamer complex when they were mixed together about five minutes later, indicating these two proteins interact with each other and rapidly form a complex. Jab1 is also known as subunit 5(CSN5) in COP9 signalosome regulatory complex (CSN). It is critical to know whether CSN complex is involved in the interaction with Smad4 in vivo. Our result indicates that the complex of CSN may not involved in the interaction with Smad4 by immunoprecipitation assays. In summary, the interaction of Jab1 with Smad4 may provide some novel mechanisms by which Jab1 regulates osteoblast differentiation and bone formation, and may help us find another potential therapeutical approach for bone related diseases.

M198

Homeodomain Protein Interactions at the Bone-Specific Osteocalcin Promoter Regulate Transcription During Osteoblast Differentiation. M. Q. Hassan*, J. Pratap, S. Gutierrez*, A. Javed, J. L. Stein*, A. J. van Wijnen, G. S. Stein, J. B. Lian. Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA.

Developmental expression of the osteocalcin (OC) gene is tightly regulated during osteoblast differentiation. The rat -1.7 OC-CAT transgene is expressed in 13.5 day embryos when the homeodomain(HD) proteins, Msx-2 and Dlx-5 are highly expressed. However, in vitro studies have shown that HD proteins contribute to suppression of OC transcription. In this study, we examined activity of the multipartite OC Box which binds both HD and non-HD proteins. To focus on the mechanism of transcriptional regulation by the OC Box, we constructed a series of point mutations spanning twelve nucleotides of the core OC Box. We identified two mutations, one that selectively abrogated binding of HD complexes, but retained the non HD protein-DNA interaction (mCC1), and the other lost binding of all interacting complexes (J2). In transfection assays in multiple cell types, the CC1 mutant expressed higher than WT, while expression of the J2 mutant was decreased, indicating that both enhancer and repression complexes at the OC Box contribute to basal transcription. To further define activity at the OC Box during osteoblast differentiation, we assayed nuclear extracts from primary rat osteoblasts at three stages of maturation (proliferation, matrix maturation, and mineralization). Modifications in the protein-DNA complexes at the OC Box were observed at each stage of differentiation, further indicating selective binding by distinct classes of factors in relation to OC gene expression. The OC Box is in close proximity to C/EBP and Runx2 enhancer elements. To address the interaction of homeodomain proteins with other regulatory elements, we examined in the ROS 17/2.8 cell line the consequences of Msx-2 and Dlx-5 expression on OC promoter-constructs in which either the C/EBP or Runx site was mutated. As expected, basal activity of the two mutant constructs was significantly decreased from wild type. However, expression of the homeodomain proteins increased basal activity two-fold in constructs carrying the C/EBP or Runx site mutations. These findings suggest promoter context dependent crosstalk among enhancer and repressor domains. Taken together, our results show that the OC Box contributes to regulation of OC transcription and its activity is influenced by neighboring enhancer elements that may contribute to suppression of activity at the OC Box through multimeric regulatory complexes.

M199

Histone Deacetylase (HDAC) 3 Interacts with Runx2 (Cbfa1, AML-3) and Represses Runx2-induced Transcription of the Osteocalcin Promoter. T. M. Schroeder*[1], X. Li*[2], J. J. Westendorf[2]. [1]Biochemistry, Molecular Biology and Biophysics Graduate Program, University of Minnesota, Minneapolis, MN, USA, [2]Orthopaedic Surgery and Cancer Center, University of Minnesota, Minneapolis, MN, USA.

Runx2 (Cbfa1. AML-3) is required for bone formation and cooperates with several oncogenes to induce T cell lymphomas. Runx2 binds the DNA sequence TGPuGGPu to either activate or repress transcription of numerous osteoblast-specific genes. We are interested in defining the molecular mechanisms by which Runx2 represses transcription. We previously demonstrated that Runx factors recruit histone deacetylase containing complexes to regulate tissue-specific gene expression. Histone deacetylases (HDACs) regulate transcription by removing acetyl groups from lysine residues on histone tails and thereby facilitating chromatin condensation and transcriptional inhibition. Our studies indicate that Runx2 contains multiple autonomous repression domains that are sensitive to histone deacetylase inhibitors. Co-immunoprecipitation experiments revealed that HDAC3 interacts with an amino-terminal repression domain of Runx2. To determine the functional significance of the interaction, we tested the effects of HDAC3 on Runx2 transcriptional activity. Runx2 activates the bone-specific osteocalcin promoter by three to five-fold. HDAC3 did not effect the basal activity of the osteocalcin promoter but completely blocked Runx2-dependent activation of this promoter. Thus HDAC3 may interact with Runx2 to regulate osteoblast-specific gene expression.

M200

TWIST Stimulates Osteoblast Type I Procollagen Expression by a Transcriptional Mechanism. T. Yan*[1], D. Strong[2], T. Linkhart[2], S. Flanagan*[3], C. Glackin[3]. [1]Molecular Medicine, Beckman Research Institute City of Hope, Duarte, CA, USA, [2]Loma Linda University and VAMC, Loma Linda, CA, USA, [3]Beckman Research Institute City of Hope, Duarte, CA, USA.

TWIST is a basic helix-loop-helix (b-HLH) transcription factor that is important for cell type determination and differentiation. We have transfected human SaOS-2 osteoblasts with sense or antisense *TWIST* expression vectors to generate stable cell lines that have increased or decreased *TWIST* expression. *TWIST* sense cells (TS) express significantly higher *TWIST* levels and have lower ALP activity compared to parental SaOS-2 cells as evidenced by RT-*PCR*, Northern, and western analyses. *TWIST* antisense cells (TAS) have low *TWIST* and high ALP expression. TS cells have a spindle shaped morphology characteristic of osteoprogenitors, while parental and TAS cells exhibit a cuboidal morphology representing a more differentiated phenotype. To investigate whether other changes in gene expression characteristic of osteoblast differentiation also occurred, we examined mRNA levels of type I procollagen α 2 (ColIA2) in the cell lines. Both RT-*PCR* and northern analyses indicate that TS cells express significantly higher levels of ColIA2 when compared to parental or TAS cells. We hypothesized that the over-expression of *TWIST* may play a role in osteoblast differentiation by regulating the expression of ColIA2 and that the ColIA2 promoter may be a target of *TWIST*. To address this hypothesis, we have performed LM-PCR *in vivo* footprinting on the proximal human (h) ColIA2 promoter (-267 to +1). Automated LM-PCR *in vivo* footprinting is a powerful technique developed in our laboratory that characterizes changes in transcription factor binding to a promoter region in intact cells. Results demonstrate that an E-Box binding site on the ColIA2 promoter are protected in TS cells and not in parental and TAS cells *in vivo*. Transient cotransfection studies with a -276 to +45 hColIA2 pGL3 -luciferase reporter construct and a pcDNA3-Twist expression vector in ROS 17/2.8 cells showed, surprisingly, that *TWIST* over-expression dose dependently and significantly *trans*-activated the hColIA2 promoter (2 fold increase in luciferase activity compared to vector control ($P < 0.05$)). Site-directed mutagenesis of the "E-box' in the promoter sequence abolished *trans*-activation of the ColIA2 promoter by *TWIST*. In summary, these experiments suggest that *TWIST* increases collagen expression by a transcriptional mechanism through an E-box in the hColIA2 promoter. Results from this study provide strong evidence to support the hypothesis that hColIA2 is a target of *TWIST* and that *TWIST* may function to maintain an early osteoblast phenotype by up-regulating ColIA2 expression.

Enhanced *In Vitro* Mineralization of Primary Bone Marrow Stromal Cells Following Runx2/Cbfa1 Overexpression via Retroviral Gene Delivery. B. A. Byers*, A. J. Garcia. Woodruff School of Mechanical Engineering, Georgia Institute of Technology, Atlanta, GA, USA.

We previously demonstrated that forced expression of the osteoblast-specific transcription factor Runx2/Cbfa1 in the MC3T3-E1 osteoblast-like cell line enhanced osteoblastic phenotype expression and upregulated *in vitro* mineralization. In the current study, we investigated sustained Runx2 overexpression in primary bone marrow stromal cells using retroviral gene delivery, hypothesizing that the osteogenic cell population in bone marrow would be highly responsive to exogenous Runx2 expression. Primary bone marrow stromal cells harvested from femora of young adult rats were transduced with Runx2 or empty vector control retrovira and cultured in α-MEM supplemented with 10% FBS, 1% pen-strep, 3 mM β-glycerophosphate, 50 μg/ml ascorbic acid, and with or without 10 nM dexamethasone (dex). Gene expression, including Runx2, osteocalcin (OCN), bone sialoprotein (BSP), alkaline phosphatase (ALP), and osteopontin (OPN), was investigated by real-time RT-PCR, ALP activity was examined by a biochemical assay, and matrix mineralization was quantified by von Kossa staining. Results reported are from three separate donors with two replicates each (n=6). Quantitative PCR revealed significant upregulation in Runx2 (10-fold) and OCN (10-fold) expression in dex-treated, Runx2-infected cultures compared to dex-treated controls ($p<0.001$), while no differences were observed in BSP, ALP, or OPN expression. In the absence of dex, however, Runx2-expressing cultures demonstrated significantly higher transcript levels for all of these osteoblast-specific genes compared to no dex controls ($p<0.0001$). ALP activity was upregulated two-fold in Runx2-infected cultures compared to controls at 7 days ($p<0.005$). Most notably, Runx2-expressing stromal cultures demonstrated upregulated mineralized surface area in the presence or absence of dex at 7 (5-fold), 14 (2-fold), and 21 (1.5-fold) days compared to matched controls ($p<0.001$). FT-IR analysis revealed peaks characteristic of biological mineralization in both Runx2-infected and control cultures. These results demonstrate the *in vitro* response of primary bone marrow stromal cells to Runx2 overexpression and suggest that in the absence of other osteoinductive agents, such as dex, exogenous Runx2 expression upregulates multiple osteoblast-specific genes. Additionally, Runx2 overexpression significantly enhances the *in vitro* mineralized matrix production of primary bone marrow stromal cells. Primary stromal cells overexpressing Runx2 may offer a promising solution to address the clinical need for an osteogenic cell source to be used in the treatment of damaged or diseased bone.

Evidences for a Role of p38 MAP Kinase in Prostaglandin E1 Induced ALP Activity in Osteoblast-like Cells. A. Suzuki[1], J. Caverzasio[2], A. Kakita*[3], M. Kotake*[1], Y. Miura*[3], Y. Oiso*[3], M. Itoh*[1]. [1]Division of Endocrinology, Department of Internal Medicine, Fujita Health University, Aichi, Japan, [2]Division of Bone Diseases, Department of Internal Medicine, University Hospital of Geneva, Geneva, Switzerland, [3]1st Department of Internal Medicine, Nagoya University, Nagoya, Japan.

Prostaglandins are important regulators of bone formation and resorption. Among them, prostaglandin E1 (PGE1) has been reported to stimulate cellular cAMP and induce alkaline phosphatase (ALP) activity, a marker of osteoblastic cell differentiation. Recently, we have shown that p38 mitogen-activated protein (MAP) kinase mediates the stimulation of ALP activity induced by activation of a Gi protein-coupled receptor agonist in mouse osteoblast-like MC3T3-E1 cells. In the present study, we investigated whether p38 MAP kinase is involved in the regulation of ALP induced by PGE1 in MC3T3-E1 cells. PGE1 dose-dependently enhanced ALP activity in the concentration range of 1 nanoM to 1 microM with a maximal effect of 2.3 fold. SB203580 at 10 microM, a specific inhibitor of p38 MAP kinase, decreased the stimulation of ALP activity induced by PGE1 by more than 85%. Immunoprecipitation and Western blotting analysis indicated that PGE1 enhances p38 MAP kinase activity. This effect was mimicked by both Bt2cAMP, a permeable analogue of cAMP, and forskolin, which directly activates adenylate cyclase. H-89, a potent inhibitor of protein kinase A (PKA), significantly reduced the stimulation of p38 MAP kinase induced by PGE1. Taken together, the results of this study strongly suggest that the stimulation of ALP activity induced by PGE1 involves a PKA-dependent activation of p38 MAP kinase. In conclusion, the results of this study suggest the existence of a cAMP-PKA-dependent mechanism of p38 MAP kinase activation by PGE1 in osteoblast-like cells which mediates changes in ALP activity. This observation suggest a significant role of p38 MAP kinase in the regualtion of osteoblastic cell differentiation by calciotropic factors acting through cAMP second messenger signaling.

Cytokine Induced Upregulation of Bradykinin B1 and B2 Receptors in the Human Osteoblastic Cell Line MG-63. A. Bernhold Brechter*, I. Lundgren*, U. H. Lerner. Oral Cell Biology, Odontology, Umeå University, Umeå, Sweden.

The inflammatory mediator bradykinin (BK) has previously been shown to stimulate bone resorption in vitro and to synergistically potentiate the stimulatory effect of IL-1α/IL-1β on bone resorption and prostaglandin biosynthesis. In the present study the effects of a variety of kinins and kinin analogues, on unstimulated and cytokine stimulated prostaglandin biosynthesis, were studied in a human osteoblastic cell line, MG-63. In addition, the effects of different cytokines on BK B1 and B2 receptor expression were assessed using radioligand binding and semi-quantitative RT-PCR. Co-treatment of MG-63 cells with BK and IL-1α, IL-1β or TNFα resulted in synergistic stimulation of PGE_2 and PGI_2 formation. IL-1β induced PGE_2 formation was synergistically potentiated by several kinins and kinin analogues with affinity for BK B1 and B2 receptors. These interactions were specifically inhibited by B1 and B2 receptor antagonists. Pretreatment of MG-63 cells with IL-1β or TNFα resulted in a time- and concentration-dependent enhancement of both B1 and B2 receptor ligand binding. Pretreatment with the B2 receptor agonist BK caused a down-regulation of [^{3}H]-BK binding, whereas pretreatment with the B1 receptor agonist des-Arg^{10}-Lys-BK did not affect the binding of [^{3}H]-des-Arg^{10}-Lys-BK. In cells where B1 and B2 receptor binding sites had been upregulated by pretreatment with IL-1β for 24 hours, B2 receptor agonists caused a rapid burst of PGE_2 formation, whereas B1 receptor agonists caused a delayed PGE_2 response. Semi-quantitative RT-PCR showed that IL-1β and TNFα increased the mRNA expressions of both BK B1 and B2 receptor subtypes. In agreement with radioligand binding data BK decreased B2 receptor mRNA, whereas des-Arg^{10}-Lys-BK did not affect B1 receptor mRNA. The osteotropic cytokines IL-6, IL-11, IL-17, OSM, TGF-β and LIF did not potentiate B1 and B2 receptor induced PGE_2 formation, nor did these cytokines affect B1 and B2 receptor radioligand binding or the mRNA expression for the B1 and B2 receptors. These results show that IL-1 and TNFα synergistically potentiate BK B1 and B2 receptor mediated stimulation of prostaglandin biosynthesis, in MG-63 cells, and that cytokine induced upregulation of B1 and B2 receptor expression seems to contribute to this phenomenon. The mechanism by which B1 receptors activate prostaglandin formation seems to be different from that of B2 receptors as assessed by the large differences in the kinetics. The delayed stimulation of PGE_2 formation caused by B1 receptor ligands is not due to auto- or hetero-induction of B1 receptors.

M204

Inactivation of Menin Inhibits the Commitment of Multipotential Mesenchymal Stem Cell to Osteoblast Lineage. H. Sowa*[1], H. Kaji[1], T. Yamaguchi[1], L. Canaff*[2], G. N. Hendy[2], T. Sugimoto[1], K. Chihara*[1]. [1]Endocrinology and Metabolism, Kobe University Graduate School of Medicine, Kobe, Japan, [2]Department of Medicine, McGill University, Montreal, PQ, Canada.

Menin is the product of MEN1 gene responsible for multiple endocrine neoplasia type1. Although menin is ubiquitously expressed, its physiological roles are not known. We previously demonstrated that menin interacts with the transforming growth factor type β (TGF-β)-receptor-regulated Smad, Smad3 (PNAS 2001), and that Smad3 stimulates alkaline phosphatase (ALP) activity and mineralization in mouse osteoblastic MC3T3-E1 cells (MC) (JBMR, in press). Moreover, homozygous menin knockout mice exhibit cranial and facial hypoplasia, and bone mineral density is decreased in Smad3 knockout mice. We, therefore, investigated the role of menin in osteoblastic differentiation. Menin antisense oligonucleotides (AS) reduced the endogenous menin expression and TGF-β-induced transcriptional activity in mouse mesenchymal stem cell line, C3H10T1/2 cells (10T1/2) and osteoblastic MC. In 10T1/2, AS antagonized ALP activity and the expression of type I collagen, Runx2 and osteocalcin induced by bone morphogenic protein 2 (BMP-2). Control menin sense oligonucleotides did not affect the expression of these genes and AS did not affect retinoic acid-induced ALP activity. In contrast to the effect on osteoblastic markers, AS did not affect adipogenic markers (Oil Red stain and PPARγ) and chondrogenic markers (Alcian Blue stain and the type IX collagen) induced by BMP-2 in 10T1/2. In MC, AS did not affect BMP-2-stimulated ALP activity nor the expression of Runx2 and osteocalcin . Inactivation of menin in MC by stable expression of menin antisense cDNA increased ALP activity, mineralization, and the expression of type I collagen and osteocalcin. In 21-day cultures of MC and BMP-2-treated 10T1/2, endogenous menin expression increased up to day 14 and declined thereafter. In summary, the data indicate that menin inactivation specifically inhibits the commitment of pluripotent mesenchymal stem cells to osteoblast lineage. Menin seems to be important for both early differentiation of osteoblasts and inhibition of their later differentiation.

M205

Effects of Prostaglandin E_2 (PGE_2) and Selective Prostaglandin E Receptor (EP) Agonists on 3',5' Cyclic Adenosine Monophosphate (cAMP) Production in Osteoblastic Cells from Wild Type and EP2 or EP4 Knockout Mice. Y. Sakuma[1], C. C. Pilbeam[1], L. C. Pan[2], L. G. Raisz[1]. [1]Endocrinology, University of Connecticut Health Center, Farmington, CT, USA, [2]Groton Laboratories, Pfizer Global Research and Development, Groton, CT, USA.

PGE_2 can stimulate cAMP production and bone resorption through two prostaglandin E receptor pathways, EP2 and EP4. Selective agonists for these receptors have been developed, Ono-AE1-259 for EP2 (EP2A) and Ono-AE1-329 for EP4 (EP4A). We compared the effects of these agonists with PGE_2 on cAMP production in calvarial osteoblastic cell cultures from wild type mice and mice lacking either EP2 or EP4 receptors (EP2KO or EP4KO). We also examined down-regulation of cAMP responses in primary cultures of osteoblasts after pretreatment with PGE_2, EP2A or EP4A. Cells were cultured for 7 days and serum deprived for 24 hours. In some experiments cells were cultured during serum deprivation and treatment with NS-398 (0.1 μM), a selective inhibitor of inducible cyclooxygenase-2 (COX-2), to block the major source of endogenous prostaglandin production. cAMP was measured by immunoassay after 15 minutes of treatment in the presence of a phosphodiesterase inhibitor (IBMX). In the presence of NS-398, cAMP levels were significantly increased by all three agonists; the mean response to PGE_2, EP2A and EP4A in five experiments were 25-fold, 10-fold and 4-fold, respectively. In the absence of NS398, the cAMP increases were reduced to 19, 7 and 2-fold, respectively. The cAMP responses to PGE_2, EP2A and EP4A were dose-related from 0.01 to 10 μM. In EP4KO cells, the responses to PGE_2 and EP2A were not significantly reduced, but the response to EP4A was abrogated. In EP2KO cells, in the presence of NS-398, PGE_2 responses were reduced by 80% or greater, EP2A responses were abrogated and EP4A responses were still present. In the absence of NS398, EP2A still produced a small stimulation of cAMP in EP2KO cells. In primary osteoblastic cell cultures, pretreatment with PGE_2 or EP2A for 1 hour reduced the cAMP response to PGE_2 by about 50% while pretreatment for 24 hours reduced the response by 80% or greater. Pretreatment with EP4A for 1 hour had little effect, but after 24 hours the response to PGE_2 was reduced by about 50%. We conclude that the cAMP response to PGE_2 in cultured osteoblastic cells is mediated by both EP2 and EP4 receptors with the EP2 pathway predominant. The loss of response in cells lacking the cognate receptors confirms the specificity of EP2A and EP4A as selective agonists. Down-regulation of cAMP responses by pretreatment with PGE_2, EP2A or EP4A is proportional to their initial cAMP effect.

Prostaglandin E EP4 Receptor Agonist Induces the Bone Formation by an Alteration of the Osteoblast and Osteoclast Dynamic State. M. Tanaka*[1], N. Sahara*[2], T. Katayama*[1], K. Yamaguchi*[1], A. Hosoya*[2], N. Mishima*[2], S. Matsuura*[2], H. Ozawa[3]. [1]Fukui Institute for Safety Research, ONO Pharmaceutical Co.,Ltd., Fukui, Japan, [2]Oral Anatomy, Matsumoto Dental University, Nagano, Japan, [3]Dental Science Institute, Matsumoto Dental University, Nagano, Japan.

Recently it has been shown that an activation of EP4, one of prostaglandin E receptor subtype, induced the *de novo* bone formation. To investigate part of the elucidation of the mechanism of the bone formation by activation of EP4, an osmotic pump was implanted to the rats on the back subcutaneous and EP4 agonist (ONO-4819 CD) was administered to rats at dose of 100 ng/kg/min for up to 28 days. Morphology of femur was observed on Day 0, 1, 3, 5, 7, 14 and Day 28. In the ONO-4819 CD-treated rats, proliferation of the osteoclasts in the metaphysis was observed on Day 1. The number of osteoblasts showed an increase from on Day 3. In addition, the endosteal bone formation in the metaphysis and diaphysis was observed from on Day 5 and peaked on Day 28. Serum alkaline phosphatase activity showed a transient decrease on Day 1, and thereafter it showed the increase. The concentration of osteocalcin (Gla) showed an increase from on Day 1. On the other hand, the excretion volume of urinary deoxypyridinoline increased on Day 3, and it showed a transient decrease on Day 5. But it showed an increase from on Day 7. These results indicate that EP4 agonist-induced bone formation is related to an increase of the osteoclast in the early stage and a subsequent increase of the osteoblast. In addition, the adipocyte in the bone marrow was markedly reduced in the EP4 agonist-treated rats as compared with that of the control ones on Day 28.

Analysis of PDE4 Subtype Expression During BMP-2 and Dexamethasone Induced Osteoblastic Differentiation. A. Houghton, M. Jankowsky*, J. Wos*, S. Pikul*, M. W. Lundy. Discovery, Procter & Gamble Pharmaceuticals, Mason, OH, USA.

The cAMP specific PDE4 family is comprised of 4 separate gene products (A-D), which are characterized by their specificity for cAMP and sensitivity to inhibition by Rolipram. Recent literature reports have demonstrated that inhibitors of PDE4 are able to increase bone formation in vivo, however to date the relative expression of all four subtypes during human osteoblast differentiation has not been reported. We therefore analyzed the expression of these subtypes during both BMP-2 and dexamethasone induced osteoblastic differentiation using Taqman. RNA was obtained at various time points from human primary cultures of mesenchymal stem cells (MSCs) induced to undergo osteoblastic differentiation by treatment with either BMP-2 or dexamethasone. Of all the four subtypes PDE4D was the most highly expressed subtype during all stages of osteoblastic differentiation, with significant increases in expression apparent in BMP-2 and dexamethasone treated samples by 48 hours, rising to a maximum level of expression by 72 hours which was sustained until day 14. PDE4A was the second most abundant subtype in the MSC cells however no regulation of expression was observed by either BMP-2 or dexamethasone when compared to untreated controls. PDE4B was the third most abundant mRNA measured in these samples and was increased in the presence of BMP-2 by 72 hours, but no regulation of expression by dexamethasone was observed at any time point. PDE4C was the least abundant subtype expressed, with some small increases in expression noted in response to both agents. Tissue analyses using Taqman demonstrated that PDE4 subtype expression in MSCs was somewhat similar to that seen in brain, liver and heart tissue, however expression of all subtypes in MSCs was significantly less than seen in spleen, stomach, small intestine and lung. In order to determine whether the observed changes in subtype expression regulated MSC responses to PDE4 inhibitors, untreated MSCs and BMP-2 treated MSCs were used to measure the effects of PDE4 inhibitors on PGE_2 stimulated increases in intracellular cAMP. These experiments determined no differences in the potencies of PDE4 inhibitors when tested in untreated or BMP-2 treated MSCs. In conclusion these data demonstrate that PDE4D is the predominantly expressed subtype in human primary osteoblasts, with osteoblastic differentiation regulating the expression of all subtypes except PDE4A. This regulation of expression implies differential modulation of cAMP levels during differentiation and raises the possibility that specific intervention by agents selective for one or more of the PDE4 subtypes might be used to induce bone formation.

Mice Deficient in nNOS Have Increased Bone Mass; Possible Indications for a Central Mechanism of Regulation for Bone Turnover. R. J. van 't Hof*, K. J. Armour, S. Penman*, M. H. Helfrich, S. H. Ralston. Medicine & Therapeutics, University of Aberdeen, Aberdeen, United Kingdom.

Nitric Oxide (NO) is a highly reactive molecule synthesized by the nitric oxide synthases (NOS), that plays an important role in bone metabolism. Inducible NOS (iNOS) plays a role in inflammation mediated bone loss, whilst endothelial NOS (eNOS) is important in regulating osteoblast function and bone formation. The third NOS isoform, neuronal NOS (nNOS) is predominantly expressed in the brain and act as a neurotransmitter . The role of nNOS in bone metabolism has so far been little studied. In 2 studies, no nNOS immunoreactivity was observed in bone, while in another study only weak mRNA expression was detected in whole bone RNA extracts. In order to determine whether nNOS plays a role in bone metabolism, we studied bone density in the proximal tibiae of 10-week-old nNOS knockout (nNOS-KO) mice and wild type (nNOS-WT) littermates using a Stratec pQCT machine. Bone density of nNOS-KO mice was 8.4% ($p<0.01$) higher than that of nNOS-WT mice. The difference was particularly pronounced in the trabecular compartment, where bone density was 29% higher in nNOS-KO than in WT controls ($p<0.001$), with a smaller (3%) increase in the cortical bone density ($p=0.02$). In addition, we observed a 10% increase in cortical thickness in the nNOS-KO animals ($p<0.01$). The fact that nNOS influences bone density by such a large amount is quite surprising, as it is expressed at only very low levels by bone cells. This suggests that nNOS deficiency may affect bone metabolism indirectly by a central nervous system (CNS) based relay, as has been suggested for the effects of Leptin on bone metabolism. In summary, we have found that nNOS knockout mice have substantially higher bone density than wild type littermates. As virtually no nNOS is expressed in bone, it is possible that nNOS regulates bone mass by a CNS based mechanism.

Platelet-type 12-Lipoxygenase Expression and Activity in Adult Human Osteoblast-like Cells. M. Pacurari*[1], F. J. Secreto*[1], J. A. West*[1], A. Grover*[1], J. D. Blaha*[2], P. E. Keeting[1]. [1]Biology, West Virginia University, Morgantown, WV, USA, [2]Orthopedics, West Virginia University, Morgantown, WV, USA.

Arachidonic acid (AA) can be metabolized into a variety of hydroxyeicosatetraenoic fatty acids (HETEs) by the action of various lipoxygenases (LOX). The HETEs and the prostaglandins, collectively, comprise a group of bioactive lipids referred to as eicosanoids. At least 18 different LOX sequences have been published, and while the biological actions of many of the LOX products remain uncertain, links with apoptosis, angiogenesis, and mitogenesis have been established in various tissues. In the course of our investigations of arachidonic acid metabolism by adult human osteoblast-like (hOB) cells, we have radiolabeled the cell's glycerophospholipid pools by the addition of [14C]AA, leading to the production of radiolabeled eicosanoids. We have found an hOB cell radiolabeled product that co-migrates with authentic 12(S)-HETE in thin layer chromatographic analyses of extracted cell-conditioned media. The product appears to be formed constitutively, and the application of the osteotropic cytokines TGF-beta, TNF-alpha, or EGF to the cells for 24 hr were without apparent effect on its elaboration. The appearance of the 12-HETE could have been the consequence of cytochrome P450-related monooxygenase activity, or even the spontaneous oxidation of arachidonic acid rather than LOX-dependent generation. Accordingly, an analysis of hOB cell RNA preparations by classical RT-PCR methods was undertaken to determine if these cells expressed the gene encoding one of the 12-LOXs. A band was found in specimens in which intron-exon spanning primers to the human platelet-type 12-LOX were employed following 35 cycles of amplification, using a hybridization temperature of 56 C. Sequencing of the cloned RT-PCR product confirmed its identity as the human platelet-type 12-LOX. Related analyses using primers for the leukocyte-type 12-LOX gave negative results in hOB cell RNA preparations. The biological significance to hOB cells of a possibly constitutively produced 12-HETE remains undetermined.

M210

Zoledronate Is Anabolic for Human Osteoblast-Like Cells. B. Pan*[1], D. M. Findlay[2], L. B. To*[1], G. J. Atkins*[2], A. Evdokiou*[2], A. Labrinidis*[2], S. Bouralexis*[2], A. C. W. Zannettino*[3]. [1]Haematology, Institute of Medical and Veterinary Science, Adelaide, Australia, [2]Orthopaedic Surgery and Trauma, Univeristy of Adelaide, Adelaide, Australia, [3]Haematology, Institute of Medical and Veterinary Science, Adelaide, South Australia, Australia.

Bisphosphonates (BP) exhibit high affinity for the hydroxyapatite mineral in bone and are selectively taken up and adsorbed to mineral surfaces at sites of increased bone turnover. BPs are potent inhibitors of osteoclast (OC)-mediated bone resorption and are used extensively for the treatment of skeletal diseases. BPs inhibit bone resorption by acting directly on OC and indirectly *via* effects on osteoblasts (OB). The newer nitrogen-containing BPs inhibit the mevalonate pathway, with wide ranging cellular effects that include induction of apoptosis in osteoclasts and inhibition of osteoclast formation by osteoblasts. Zoledronate (ZOL), represents a new generation, nitrogen-containing BP and is the most potent inhibitor of bone resorption currently in use. We used an established model of OB-differentiation (Gronthos *et al*, JBMR,1999 14:47) to investigate the effect of ZOL on the molecular expression and and cellular phenotype of cultured human osteoblast-like cells. Human OB-like cells, derived from explants of posterior iliac crest and proximal femoral trabecular bone, were cultured in the presence of ZOL at concentrations ranging from 0.05 to 50μM. At concentrations up to 5 μM, ZOL was strongly cytostatic, blocking cell replication in S and G2/M phase. At higher concentrations, ZOL dose-dependently induced cell death in each of the human OB cultures tested. Using dual colour FACS and CFSE staining, it was shown that cells expressing high levels of the stromal stem cell marker, STRO-1, were more susceptible to ZOL-induced cytostasis and cell death, consistent with the greater proliferative potential of this population. Associated with this loss of STRO-1^+ cells was a concomitant increase in the proportion of cells, which exhibited a more differentiated phenotype. Molecular analysis revealed that the expression of the bone-associated matrix proteins bone sialoprotein and osteocalcin were significantly elevated in cultures treated with ZOL. Consistent with these observations, *in vitro* mineralisation studies showed that ZOL enhanced mineral formation in cultures from all donors, at concentrations in the range of 5-25 μM. Our studies therefore show that in addition to its effects on OC, ZOL also has direct effects on the proliferation and survival of OB-like cells *in vitro*. Our observations support the notion that ZOL is anabolic in bone by increasing the proportion of differentiated OB and enhancing the bone-forming activities of these cells.

A Method to Separate Human Umbilical Vein Endothelial Cells (HUVEC) from Human Bone Marrow Stromal Cells (HBMSC) After Co-culture: Analysis of HUVEC Effects on HBMSC Differentiation. B. Guillotin*[1], F. Villars*[2], S. Pallu*[2], R. Bareille*[2], V. Conrad*[2], J. Amedee[2], O. Chassande*[1]. [1]INSERM U 443, Bordeaux, France, [2]INSERM U443, Bordeaux, France.

Osteogenesis relies on a balanced activity between bone forming cells (osteoblasts) in one hand and bone resorbing cells (osteoclasts) on the other hand, and occurs in striking interaction with angiogenesis. Furthermore, bone formation, remodelling and repair are at least partly regulated not only by growth factors and cytokines that are contained in the mircroenvironment of bone but also by cell-to-cell communication. Thus, numerous studies show that gap junctions, especially composed of connexin43 in bone, participate to the regulation of bone biology. This is why we have been interested for few years in the role of endothelial cells and connexin43 on the differentiation of osteoprogenitor cells. Indeed, our studies on primary cultured cells have shown for the first time that endothelial cells could likely participate to osteogenesis through gap junctions formed of connexin43 between endothelial cells and osteoblasts. Our purpose is now to eventually identify one signaling pathway connexin43-dependent involved in our culture model, and more particularly the function of Cbfa1 in this pathway. To assess the specific effect of HUVEC on osteoblastic gene expression in co-culture, we separated HUVEC from HBMSC after 1, 3, 8 and 24 hours of co-culture with magnetic beads coupled to a CD31 antibody. CD31 is a membrane marker expressed by HUVEC but not by HBMSC. Highly efficient separation is shown by quantitative measure of phosphatase alkaline activity in beads fraction that contains enriched HUVEC population and supernatant fraction that contains enriched HBMSC population. Also, RT-PCR was performed using total RNA extracted from these fractions to study Cbfa1 expression. Our results show a strong amplification of Cbfa1 cDNA in supernatant fraction but a very weak amplification of Cbfa1 in beads fraction. Thus, our data indicate that HUVEC and HBMSC are well separated into two homogenous populations after passage on anti-CD31 coupled magnetic beads. This method will now allow us to answer the following questions. First, are the expression and activity of Cbfa1 regulated in HBMSC or HUVEC in co-culture? Second, are expression and activity of connexin43 regulated in HBMSC or HUVEC in co-culture? Finally, does a signalling link exist between the activation of both connexin43 and Cbfa1?

M212

Lack of Connexin43 (Cx43) Causes Global Osteoblast Dysfunction. F. Furlan, J. Screen, J. Stains, R. Civitelli. Bone and Mineral Diseases, Washington University, St Louis, MO, USA.

Osteoblasts are highly coupled by gap junctions formed primarily by connexin43 (Cx43). Interference with Cx43 expression or function disrupts transcriptional regulation of osteoblast genes, and deletion of the Cx43 gene in the mouse causes skeletal malformations, delayed mineralization, and osteoblast dysfunction. Here, we studied the mechanisms by which genetic deficiency of Cx43 alters osteoblast development using calvarial or bone marrow stromal cells isolated from newborn Cx43 null (Cx43-/-) or wild type (Cx43+/+) mice. In calvarial cultures, the number of mineralized nodules and total mineralized area were lower in Cx43-null osteoblast compared to wild-type cells during the first 3 weeks in mineralization medium (b-glycerophosphate and ascorbic acid). However, after 4 weeks in culture, Cx43-/- cells reached the same degree of mineralization as did Cx43+/+ cultures. Accordingly, alkaline phosphatase activity, which peaks at around day 7 in normal calvarial or bone marrow stromal cell cultures, increased significantly in mutant cells only after 3 weeks, a 2-week delay. Similarly, Cbfa1 and type I collagen mRNA abundance (assessed by real time RT-PCR) was consistently lower in Cx43-/- cells during the first 2 weeks of culture, reaching the levels present in Cx43+/+ cells only after 12-15 days. Furthermore, basal levels of RANK-L mRNA were 3-fold lower in Cx43-/- calvaria or bone marrow stromal cells relative to Cx43+/+ cells whereas OPG mRNA was slightly increased, reflecting a poor support of osteoclastogenesis by Cx43 deficient cells. The number of TRAP-positive multinucleated cells formed in co-cultures with Cx43-/- calvaria cells was 5-fold lower compared to those formed in co-cultures with Cx43+/+ calvaria cells. While cell proliferation rates were similar in osteoblastic cells derived from calvaria of Cx43-null and wild type mice, spontaneous and camphothecin-induced apoptosis rates - assessed by caspase 3 expression - were 5-fold and 3-fold higher, respectively, in mutant compared to wild-type osteoblasts. Therefore, lack of Cx43 leads to a delay in the development of a fully differentiated and functioning osteoblasts. The defect is global, affecting all osteoblast gene products, including those that produce bone matrix and those involved in support of osteoclastogenesis. In addition to regulating gene transcription, Cx43 gap junctional communication favors osteoblast differentiation by inhibiting programmed cell death.

Enhanced Marrow Adipogenesis and Bone Resorption in Estrogen-deprived Rats Treated with the PPARgamma Agonist BRL49653 (Rosiglitazone). M. Kneissel*, V. Sottile*, K. Seuwen*. Bone Metabolism Unit, Novartis Pharma AG, Basel, Switzerland.

Osteoporosis is characterised by loss of bone tissue and increased bone marrow fat content. Since osteoblasts and adipocytes originate from a common mesenchymal precursor cell, it has been proposed that osteoporosis might in part result from a switch of cell differentiation favouring adipogenesis. We tested this hypothesis by evaluating the effect of the thiazolidinedione BRL49653 (Rosiglitazone), a potent stimulator of adipogenesis acting through the nuclear hormone receptor PPARgamma, on bone tissue and marrow of intact and estrogen-deprived female rats. In a first step skeletally mature intact rats were treated for 8 weeks with 5, 10, or 20 mg/kg of BRL49653 or vehicle. Increased body weight and decreased plasma triglyceride levels confirmed the effectiveness of the treatment. No change in bone mass or fat marrow volume was observed as evaluated by DEXA, pQCT, and histomorphometry. However, the study of marrow cultures established at necropsy revealed a significantly higher responsiveness to adipogenic treatment of cultures established from the 10 mg/kg group compared to vehicle control. However, this adipogenic effect appeared disconnected from the osteogenic potential of these marrow cells, since mineral deposition under standard osteogenic stimulation remained evenly high. We then studied rats that had been estrogen-deprived by ovariectomy (OVX). Treatment with the 10 mg/kg dose for 12 weeks resulted in a significantly increased loss of tibial bone mass (+31% based on pQCT), compared to vehicle-treated OVX animals. Ex vivo DEXA measurements demonstrated that bone mass was also significantly reduced in the femur and lumbar spine of treated OVX animals compared to OVX controls. The tibiae were excised at necropsy and histomorphometry of the proximal metaphysis revealed that the fat marrow volume, which had increased 4.6-fold upon OVX compared to sham control, was increased more than 10-fold in the treatment group. Interestingly, osteoblast number was comparable in vehicle and BRL49653-treated OVX animals. Bone resorption parameters, however, were significantly increased in the treatment group (+27% osteoclast number, +30% eroded surface). Our data suggest that the thiazolidinedione BRL49653 did not lead to a measurable decrease in osteoblast number. However, it has the potential to induce marrow adipogenesis and to potentiate bone loss stimulated by estrogen deprivation. TZD-induced increase in sensitivity of marrow cells towards adipogenic signals has hence tangible consequences on the skeleton in a situation of imbalance, as created here by estrogen loss.

Strontium (Sr) Impairs the In Vitro Osteoblast (OB) Differentiation and Hydroxyapatite Formation. S. C. E. Verberckmoes*, M. E. De Broe, P. C. D'Haese*. Nephrology - Hypertension, University of Antwerp, Wilrijk, Belgium.

Recent data from epidemiological studies in dialysis patients together with experimental findings in a chronic renal failure (CRF) rat model established a dose-related multiphasic effect of strontium (Sr) on the bone formation process. To confirm these in vivo findings an in vitro set-up, consisting of mineralizing primary OB cultures derived from 20 day old fetal rat calvaria, was applied. Several Sr concentrations (0.5, 1.0, 2.0, 5.0, 10, 20 and 100 µg/ml) were added to the cultures. Alkaline phosphatase (AP) and calcium (Ca) incorporation, used as an index for mineralization, were determined at various time points in the culture medium. At the end of the experiment, the protein profile was assessed in the medium using 2D-PAGE and the nodule formation (mineralized + unmineralized area) was quantified by means of a digital imaging system. Hydroxyapatite (HA) crystal quality was evaluated using X-ray diffraction (XRD) analysis. A significantly reduced nodule formation in the presence of an intact mineralization was found for the 0.5 and 1 µg/ml doses indicating a defective OB differentiation. No differences were noted for the 2 and 5 µg/ml doses. For the 20 and 100 µg/ml Sr doses a reduced mineralization was noted in the presence of an intact nodule formation. At these concentrations XRD ana1ysis revealed a significant distortion of the crystal lattice. The AP activity fully reflected the multiphasic pattern of the nodule formation while the Ca incorporation correlated well with the multiphasic pattern of the mineralized segments of the formed nodules. No variations in cell proliferation were found, as the total DNA content did not differ between the various groups. Northern blot analysis revealed Sr to interfere with the OB at the level of the mRNA synthesis of various phenotypic parameters. Differential analysis of the 2D-PAGE profile of control cultures versus cultures treated with 1 µg/ml Sr indicated 70 spots out of 250 to be significantly up-regulated and 49 spots to be significantly down-regulated (intensity ratio 1.5; $p<0.05$). Using the proposed in vitro model we confirmed the multiphasic effect of Sr on the bone formation previously shown in a CRF rat model. The presented data allow us to suggest that at low concentrations Sr interferes with the bone formation at the level of the cell differentiation. At high Sr concentrations the disturbed mineralization in combination with an intact nodule formation suggests a physicochemical interaction of the element with the hydroxyapatite formation.

Comparison of Proliferation and Differentiation of Calvarial Osteoblast Culture Derived from Wild Type and Msx2-Deficient Mice. I. Marijanovic[1], M. S. Kronenberg[1], I. Erceg*[1], H. Chin*[1], I. Satokata*[2], R. Maxon*[3], R. Maas*[2], D. W. Rowe[1], A. C. Lichtler[1]. [1]Department of Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, USA, [3]Department of Biochemistry and Molecular Biology, U.S.C. School of Medicine and Norris Cancer Center, Los Angeles, CA, USA.

Msx2 is a homeodomain-containig protein that has been shown to be involved in regulation of skeletal development. Msx2 protein is expressed in many tissues during different stages of development. Strong expression of Msx2 is found in cells at the extreme ends of the osteogenic fronts of the calvarial sutures. Msx2 knockout mice have defects of skull ossification and persistent calvarial foramen. Our previous studies in cultured chick calvarial osteoblasts suggest that Msx2 inhibits differentiation and stimulates proliferation. To extend these studies into a mammalian system we investigated the proliferation and differentiation of calvarial osteoblast from Msx2 knockout mice. For experiments we used 5-8 days old wild type, heterozygous and knockout animals derived from heterozygous breedings. Cells from calvariae (no sutures) from the three groups were plated at the same density and observed for differences in proliferation and differentiation. Proliferation rate was assessed by counting cell number, BrdU and CalceinAM labeling. Cell number at day 6 in homozygous culture was 20% lower than in wild type. At day 6 wild type culture had 21.6% , heterozygous 20.9% and homozygous 16.8% BrdU labeled cells. CalceinAM marks all living cells so scanning the entire well for fluorescence is a visual way of presenting cell number. Wild type cultures showed higher intensity of fluorescence than homozygous cultures. Differentiation of cell cultures was assessed by several methods. Von Kossa staining showed increased mineralization at later time points (day 14 - day 21) in homozygous cultures. Hybridization of total cell RNA to collagen and osteocalcin probes showed increased collagen message in homozygous knockout cultures when compared to the wild type and heterozygous cultures. After infecting cells with Col2.3 GFP retrovirus, which is induced when osteoblasts differentiate, we observed that GFP comes on earlier in homozygous culture marking more developing nodules. Cultures from heterozygous mice had an intermediate phenotype but were not significantly different from wild type. Based on our experiments we suggest that calvarial osteoblasts derived from Msx2 knockout mice have a lower rate of proliferation and demonstrate increased osteoblastic differentiation compared to cells derived from wild type mice.

M216

Dlx3, 5 and 6 May Have Redundant Effects On Bone Development. I. Marijanovic[1], M. S. Kronenberg[1], I. Erceg*[1], M. L. Stover*[1], W. B. Upholt*[2], A. C. Lichtler[1]. [1]Department of Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Department of Biostructure and Function, University of Connecticut Health Center, Farmington, CT, USA.

Our previous studies have shown that retroviral overexpression of Dlx5 cDNA has a stimulating effect on chick calvarial osteoblast differentiation. Although Dlx5 knockout mice display significant defects in craniofacial skeletal development, the limbs and axial skeleton are relatively normal. This has led us to investigate the possibility that redundant function of other Dlx genes compensates for the lack of Dlx5. There are six Dlx genes (Dlx1, Dlx2, Dlx3, Dlx5, Dlx6 and Dlx7) and their expression is primarily found in regions undergoing differentiation where they function as homeodomain-mediated transcriptional activators. For our studies we have chosen Dlx6 and Dlx3. The Dlx5 and Dlx6 genes are localized in the same chromosomal locus and are regulated from the same intergenic region. It is reported that Dlx6 has the same expression pattern as Dlx5 but mRNA levels for Dlx6 are lower. Dlx3 is most similar to Dlx5 in terms of protein sequence. Its inactivation in mice resulted in placental failure and a human Dlx3 mutation is responsible for tricho-dento-osseus (TDO) syndrome which is characterized by abnormal hair, teeth and bone. We have detected endogenous Dlx3 mRNA in mouse calvarial osteoblasts and bone marrow stromal cell cultures, which suggests that Dlx3 may have a similar role in bone development as Dlx5. Dlx6 cDNA was amplified by RT-PCR from total RNA extracted from chicken long bone, cloned into an RCAS(A) avian retrovirus vector, and used to infect chick calvarial osteoblast cultures. The effect of Dlx6 overexpression was assessed by alkaline phosphatase and Von Kossa staining through time course of the culture. Von Kossa staining of Dlx6 overexpressing culture showed increased mineralization at a late time point compared to control. By Northern hybridization we showed that Dlx6 is overexpressed by the retrovirus and we observed an increase in mRNA levels of osteoblast differentiation markers such as collagen and osteocalcin compared with cultures infected with RCAS(A) alone. Dlx3 cDNA has also been cloned into an RCAS(A) retrovirus vector, and similar experiments will be performed. In conclusion our data show that Dlx3 is expressed in osteoblasts, and that Dlx6 has similar but less potent effects on osteoblast differentiation than has been previously shown for Dlx5.

Analyses of Osteoblasts Lacking the Vitamin D Receptor. K. Sooy, M. B. Demay. Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA.

Vitamin D is the major steroid hormone that plays a role in mineral ion homeostasis. Its molecular actions are thought to be mediated by the vitamin D receptor (VDR). The development of VDR knockout mice has demonstrated an important physiological role for the VDR. These mice exhibit a variety of defects, including rickets and osteomalacia, which are evident at day 35. These defects can be prevented by normalization of mineral ion homeostasis via dietary means. However, the role of the VDR in bone formation is not completely understood. In order to reconcile the in vivo versus in vitro effects of the VDR on osteoblast development, we isolated calvarial osteoblasts from 3 day old wild type and VDR knockout mice. Osteoblasts isolated from VDR knockout mice form more mineralized matrix as assessed by alizarin red staining than those from wild type mice, with cultures from knockout mice containing 161± 1.4 nodules per 50,000 cells plated versus 44.5 ± 6.4 nodules for wild type mice. This trend of increased alizarin red positive nodules in knockout cultures was observed at all time points from day 18 to day 35 post plating, indicating that the VDR and $1,25(OH)_2D_3$ may play an inhibitory role in osteoblast differentiation or mineralized matrix formation. Studies were also undertaken to examine the effects of ablation of the VDR on bone marrow stromal cells. Mice were weaned at day 18 and fed a diet high in calcium, phosphorus and lactose to eliminate any effects due to hyperparathyroidism or abnormal mineral ion homeostasis. Osteoprogenitor differentiation was evaluated by examining alkaline phosphatase activity and mineralization (von Kossa staining) of nodules. There was a reduction in the number of alkaline phosphatase positive nodules in the VDR knockout mice (22.3 ± 2.5 per 1.5 x 10^6 cells plated versus 31.9 ± 2.3 for the wild type mice). However, there were no differences observed in the mineralization of the nodules isolated from wild type and VDR knockout mice, with 45 ±5% of alkaline phosphatase positive wild type cells being von Kossa positive, while 41 ± 9% of knockout cells were double stained. Further studies will be required to evaluate whether VDR ablation similarly affects other markers of differentiation in the osteoblasts that give rise to intramembranous and endochondral bone.

Developmental Regulation of SOST Gene Expression in Osteogenetic Precursor Cells Derived from Fetal Mouse Cranial Tissues. Y. Ohyama*, Y. Maeda, A. Nifuji, M. Noda. Molecular Pharmacology, Medical Resarch Institute,Tokyo Medical & Dental University, Tokyo, Japan.

Bone morphogenetic proteins (BMP) play a pivotal role in growth and differentiation of skeletal cells. Several BMP inhibitors are expressed in skeletogenesis and are known to modulate intrinsic BMP signals. However, expression and regulation of these BMP inhibitors in osteogenic differentiation are not yet fully understood. To examine if BMP inhibitors function in embryonic osteogenesis, we investigated developmental regulation of BMP inhibitors' expression by using primary osteogenic cells derived from embryonic cranial tissues. We especially focused on SOST, a novel secreted protein, whose mutation causes sclerosteosis in human. At first, we characterized the embryonic osteogenic cells, which we obtained by sequential enzymatic digestion from 15.5dpc fetal mouse cranial tissue. We plated the cells at 10k/cm and added ascorbic acid (AA) and b-glycelophosphate (bGP) after reaching confluency (day 0) to induce differentiation into mature osteoblasts. We analyzed ALP enzymatic activity, osteocalcin (OC) mRNA expression and mineralized nodule formation. ALP level was very low on day 0, and peaked at day 7. We could not detected OC expression on day 0 by RT-PCR. OC expression was induced by the addition of AA and bGP and was increased at least up to day 14. Mineralized nodule formation appeared on day 14, suggesting that the immature cells differentiated into mature osteoblasts at this stage. Then, we examined if BMP inihibitors were expressed in these cell. At confluency, the cells express various BMP inihibitors such as chordin, tsg and gremlin. Expression of another BMP inhibitor, SOST, was observed at low level on day 0, and its level was increased in a time-dependent manner up to day 14 in parallel to OC expression, suggesting that SOST expression was enhanced as the ostogenesis proceeded. Finally, we examined the expression of SOST in fetal mouse embryos by in situ hybridization. In 14.5dpc embryos, SOST was expressed at high level in the central layer of cranial mesenchymal tissues. In summary, during embryonic osteogenesis, BMP inhibitors are expressed and SOST expression increased following osteogenic differentiation. Theses data suggest that embryonic bone formation requires proper levels of BMP activity.

M219

Direct Leptin Exposure and Mechano-stimulation of Human Osteoblastic Cells Promote Proliferation and Differentiation, While Inhibiting Apoptosis. J. O. Gordeladze[1], S. Reppe*[1], K. M. Gautvik[1], C. A. Drevon*[2], J. E. Reseland*[2]. [1]Institute of Medical Biochemistry, University of Oslo, Oslo, Norway, [2]Institute of Nutritional Research, University of Oslo, Oslo, Norway.

We have demonstrated the expression of leptin and its receptor in normal human osteoblasts (hOBs). Furthermore, we have shown that mechano-stimulation of hOBs enhance cell proliferation and de novo collagen synthesis. The present report demonstrates how hOBs and human stromal cells (hSCs) respond to leptin (100 ng/ml) exposure and to mechano-stimulation at 1200 µE. Leptin exposure and mechano-stimulation of hOBs stimulated proliferation, de novo collagen synthesis and mineralisation. Both treatments also enhanced expression of hOB specific differentiation markers (like Cbfa1, ALP and osteocalcin). Leptin also protected against retinoic acid-induced (100 nM) apoptosis, as estimated by DNA laddering patterns, bax-a and bcl-2 mRNA expression, as well as DNA-array analysis of death-associated proteins and transcriptional factors (Stratagene). Leptin facilitated transition of cultured osteoblasts into preosteocytes, as evidenced by a reduction in Cbfa1/CD44 mRNA expression ratio. Leptin also augmented the mRNA levels of both interleukin-6 (IL-6) and osteoprotegerin (OPG). Expression of leptin during hOB differentiation showed marked culture time and donor variation, however, leptin mRNA was markedly enhanced upon mechano-stimulation. Human SCs exhibited less susceptibility to leptin and mechano-stimulation, however, hSCs behaved more like hOBs upon priming with an osteoblast differentiating medium (containing calcitriol and cortisol). Thus, through several factors common to osteoblast and adipocyte differentiation (e.g. PPARg, C/EBPa, and SREBP) leptin may determine their entry into different functional stages, and holds the potential to sustain a certain number of optimally functioning osteoblasts in bone tissue.

M220

Mode of Administration of Human Parathyroid Hormone (hPTH) Determines its Opposing Effects on Osteoblast Growth and Function at the Cellular and Molecular Levels in MC3T3-E1 Osteoblast-like Cells. S. S. Lu[1], K. Yokoyama[2], R. Lindsay[3], A. Iida-Klein[4]. [1]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Regional Bone Center, Hellen Hayes Hospital, West Haverstraw, NY, USA, [3]Regionl Bone and Clinical Research Centers, Helen Hayes Hospital, Columbia University, West Haverstraw, NY, USA, [4]Regional Bone Center, Helen Haye Hospital, West Haverstraw, NY, USA.

Intermittent administration of PTH exerts a potent anabolic effect on bone in humans and animals in vivo, while hyperparathyroidism in patients or continuous administration of PTH to animals results in active bone resorption, decreased bone formation and reduced bone mass. However, the effects of PTH on osteoblasts in vitro are controversial. To determine whether the mode of exposure of cultured cells to PTH affects osteoblastic cell growth and function, we examined the effects of intermittent and continuous exposures of mouse osteoblast-like MC3T3-E1 cells to PTH on cell proliferation and mineralization, as assessed by 5-bromo-2'-deoxyuridine (BrdU) incorporation and Von Kossa staining in the presence of ascorbic acid and b-glycerophosphate (bGP), respectively. In addition, we also examined mRNA expression of PTH type I receptor (PTH1R), osteoprotegerin (OPG), receptor activator of Nk-B ligand (RANKL), type I procollagen (Col I), and alkaline phosphatase (ALP) by RT-PCR and northern analysis. MC3T3-E1 cells were cultured in a-MEM, and hPTH1-34 (0.1-100 nM) was added, either continuously or by cyclic exposure for 6hr of each 48 hr-cycle. After 2 cycles of treatment (96 hr), continuous PTH inhibited cell proliferation in a dose-dependent manner by 11% (NS), 17 % ($p<0.05$) and 21 % ($p<0.01$) at 0.1, 10 and100 nM, respectively, while intermittent PTH stimulated cell proliferation by 13 % ($p<0.05$) at 0.1 nM. After 6 cycles(288 hr), continuous PTH inhibited cell mineralization by 95 % at 10 n M, while intermittent PTH stimulated cell mineralization by 2-fold at 10 nM. Continuous PTH (10 nM) completely suppressed gene expression of PTH1R, Col I and ALP (all $p<0.01$) and inhibited OPG expression by 34 % ($p<0.05$), but stimulated RANKL gene expression by approximately 2-fold. Conversely, intermittent PTH (10 nM)significantly increased gene expression of PTH1R, OPG, Col I and ALP with decreased RANKL expression. Thus, intermittent PTH in mouse osteoblast-like cells exhibited positive effects on osteoblast proliferation and function, while continuous PTH inhibited on in vitro osteoblast proliferation and function in MC3T3-E1 cells. The present data may explain in part the in vivo actions of PTH; PTH is anabolic when administered intermittently, while PTH is catabolic when administered continuously.

M221

LIF Differentially Regulates the Fate Choice and Differentiation Program of Adipocyte and Osteoblast Progenitor Cells In Vitro. D. Falconi[1], D. Kipp[2], J. Bodnar*[1], J. E. Aubin[1]. [1]Department of Anatomy and Cell Biology, University of Toronto, Toronto, ON, Canada, [2]Department of Nutrition, University of North Carolina at Greensboro, Greensboro, NC, USA.

Osteoblasts and adipocytes derive from a common mesenchymal precursor and their differentiation is often reciprocally affected by particular treatments in vitro and in vivo. We wish to understand how leukemia inhibitory factor (LIF) inhibits osteoblast differentiation stage-specifically in the rat calvaria (RC) cell model. Amongst genes we identified by differential display were four genes involved in lipid metabolism (low-density lipoprotein receptor related protein, Lrp; hormone-sensitive lipase, Lipe; STAT6; and hyaluronan synthase 2, HAS2) that were up-regulated by LIF specifically during the osteoblast inhibition-sensitive period. We therefore asked whether LIF acts, at least in part, by redirecting the fate of osteoprogenitors toward an adipogenic program. RC cells were cultured under osteogenic conditions (50 µg/ml ascorbic acid and 10 mM β-glycerophosphate) and with or without the PPARγ agonist BRL49653 (10^{-6}M). Mature adipocyte (sudan IV-positive lipid-containing cells) foci were induced in RC cells treated with BRL49653 alone, a condition that had no effect on the number of mineralized bone colonies (von Kossa-positive bone nodules), suggesting that osteo- and adipoprogenitors are recruited independently by this treatment. As expected, LIF (5 ng/ml) decreased the number of bone nodules formed, in the presence or absence of BRL49653. However, while LIF alone did not induce adipocytes, combined LIF and BRL49653 increased the number of adipocyte foci but those developing in the presence of LIF stained only faintly with sudan IV, suggesting that they contain immature adipocytes. The total number of adipocyte foci formed was lower than the number of bone nodules in untreated cultures, again suggesting that the adipocyte foci are recruited from committed preadipocytes independently from committed osteoprogenitors. To address this in more detail, we collected and analyzed RNA from discrete developing osteoblast colonies in LIF-treated RC cultures. Strikingly, many LIF-treated osteoblast colonies expressed both osteoblast and adipocyte markers (i.e., alkaline phosphatase, bone sialoprotein, osteocalcin, PPARγ and aP2). We conclude that LIF diverts the fate of at least some osteoprogenitors towards an adipogenic program but alone is not sufficient to induce adipocyte maturation. In addition, LIF blocks the maturation of committed preadipocytes in vitro, an effect dominant over the effects of the PPARγ agonist BRL49653 and consistent with the pro-cachexic effect of the LIF/IL-6 family of cytokines in vivo.

M222

Phenotypic Analysis of Osteoprogenitor (CFU-O) Recruitment, Self-Renewal and Differentiation in Response to Hormone Supplementation. K. A. Purpura*[1], P. W. Zandstra*[1], J. E. Aubin[2]. [1]Institute of Biomaterials and Biomedical Eng., Chemical Eng. and Applied Chemistry, University of Toronto, Toronto, ON, Canada, [2]Department of Anatomy and Cell Biology, University of Toronto, Toronto, ON, Canada.

Depending on concentration and exposure time, hormones such as parathyroid hormone (PTH) and glucocorticoids (e.g., dexamethasone (dex)) either stimulate bone formation or induce bone loss. To develop a greater understanding of these processes, 21 d. fetal rat calvaria (RC) cells obtained by sequential enzymatic digestion were plated at varying densities and maintained in αMEM with 10% FBS, antibiotics, 50 m µg/ml ascorbic acid, 10 mM β-glycerophosphate, and either vehicle control (0.11% ethanol), 10-9M PTH (1-34), or 10-8M dex. Osteoprogenitor cell self-renewal, proliferation and differentiation were functionally and phenotypically examined using the bone nodule/colony (CFU-O) assay and fluorescence activated cell sorting (FACS) analysis of alkaline phosphatase (ALP) and parathyroid hormone/parathyroid hormone related protein receptor (PTH1R). Serial passaging of untreated or hormone-treated RC cells showed that dex-treated cultures exhibited enhanced proliferative capacity compared to vehicle- or PTH-treated cells. CFU-O were detectable for 6-9 subcultures in both vehicle and dex, but a 10-fold expansion in nodules was observed in dex-treated cells re-plated in vehicle and a 6-, 8- or 45-fold expansion was observed for vehicle-, PTH-, and dex-treated cells respectively, re-plated in dex. Similar population cell doubling times (32.1 +/- 0.5 h) amongst the treatment groups indicated that none of the treatments provided a growth advantage. However, the differences in nodule output suggest that the proliferative rates of CFU-O may be different; different fractions of CFU-O may be recruited by the treatments, or a shift between self-renewal and differentiation of CFU-O may occur. To address this further, RC cells were fractionated by cell sorting into ALP-/PTH1R-, ALP+/PTH1R-, ALP-/PTH1R+ and ALP+/PTH1R+ populations. The frequency of CFU-O formation was determined in the sorted fractions and compared to unsorted control cultures. Our results indicate a hierarchy in bone formation capacity such that ALP+/PTH1R+ > ALP+/PTH1R- > ALP-/PTH1R+/- populations. PTH blocked nodule formation reversibly and dex stimulated nodule formation in all fractions. These data suggest that the balance between recruitment, self-renewal capacity and differentiation of CFU-O in RC populations is markedly affected by PTH and dex treatments and that fractionation on the basis of ALP and PTH1R expression is a useful method for marked enrichment of CFU-O.

M223

Lipophilic Statins Increase RANKL and OPG mRNA Levels in Human Osteoblast Cells. G. G. Reinholz[1], M. M. Reinholz*[2], B. Getz*[3], P. C. Roche*[2], T. C. Spelsberg[3]. [1]Department of Orthopedics, Mayo Clinic and Foundation, Rochester, MN, USA, [2]Division of Experimental Pathology, Mayo Clinic and Foundation, Rochester, MN, USA, [3]Department of Biochemistry and Molecular Biology, Mayo Clinic and Foundation, Rochester, MN, USA.

Several reports have suggested that lipophilic statins may modulate bone metabolism and osteoblast cell differentiation. We recently observed that mevastatin decreases human fetal osteoblast (hFOB) cell proliferation and mineralization in culture. Here we examine the effects of statins on bone morphogenetic protein-2 (BMP-2), receptor activated nuclear factor-kB ligand (RANKL) and osteoprotegerin (OPG) mRNA levels in hFOB and MG-63 cells using quantitative real-time PCR. Treatment of hFOB and MG-63 cells with mevastatin or simvastatin, but not pravastatin, increased BMP-2, RANKL and OPG mRNA levels. However, the induction of RANKL mRNA levels was greater than the induction of OPG mRNA resulting in a decrease in the ratio of OPG/RANKL mRNA. The mevastatin-induced increase in BMP-2, RANKL and OPG mRNA was dose-dependent and reversible with mevalonate co-treatment. Interestingly, treatment of hFOB cells with a polyclonal antibody directed against BMP-2 decreased basal RANKL mRNA levels and reversed the mevastatin-induced increase in RANKL mRNA. These results suggest that statins can increase RANKL mRNA levels through BMP-2 induction in human osteoblast cells. In order to determine if the effects of mevastatin on hFOB cell proliferation and mineralization are a result of increased RANKL expression, we treated hFOB cells with mevastatin with or without a polyclonal antibody directed against RANKL (RANKL pAb). As observed previously, mevastatin treatment decreased both hFOB cell proliferation and mineralization. Interestingly, treatment of hFOB cells with RANKL pAb alone increased hFOB cell proliferation and decreased mineralization, suggesting that endogenous RANKL inhibits hFOB cell proliferation and induces differentiation. RANKL pAb also partially reversed the anti-proliferative effect of mevastatin on hFOB cells but further reduced hFOB cell mineralization. Therefore, while the observed mevastatin-induced decrease in hFOB cell proliferation may be in part due to increased RANKL expression, the mevastatin-induced decrease in hFOB cell mineralization appears to be due to other unknown mechanisms. Taken together, these results suggest that the observed effects of statins on the skeleton may involve modulation of RANKL and OPG expression via BMP-2 and support a role for RANKL in the differentiation of osteoblast cells.

M224

Comparison of Bone Induction by Bone Marrow Stem Cells and Subperiosteal Injection of a Cell Growth Factor. B. S. Strates[1], F. Cordoba*[2], M. E. Nimni*[3]. [1]Department of Orthopaedics and Rehabilitation, University of Florida, Gainesville, FL, USA, [2]Departments of Surgery and Biochemistry, University of Southern California, Los Angeles, CA, USA, [3]Departmens of Biochemistry and Surgery, University of Southern California, Los Angeles, CA, USA.

In two preliminary works, we have reported on: (a) endochondral ossification post-injection of a cell growth factor subperiosteally and (b) bone induction by bone marrow (BM) cells. The purpose of this study was to examine the effects on bone induction and ossification of adding hydroxyapatite (HA) to a BM cell culture as compared to the effects of rhTGFß1 + HA. Stromal-enriched BM cells, obtained from long bones post-sacrifice of young-adult lab animals, were seeded at 1 x 106 cells/ml in 10 ml DMEM and cultured as described (Cordoba F et al: Orthop Trans JBJS 17-3:644, 1993-4). Adherent cells with HA were collected and implanted i.m. in filter chambers (MILLIPORE®, 0.3 µm pore diameter) in allogeneic animals. rhTGFß1 (Genetics Institute, Cambridge, MA) + HA were injected subperiosteally with 2 ml buffered saline as described (Kilagbian V et al: Orthop Trans JBJS:16-2:392, 1992-3). The former implants were excised at intervals up to 4 weeks and periosteal implants up to 10 weeks. Bone alkaline phosphatase (bAP) in cultured BM cells and excised implants was determined periodically up to 21 days and all implants were examined radiographically and histologically. In summary, implants of BM cells + HA exhibited bone induction with fibroblast-, chondroblast- or osteoblast-like cells peripherally and a bone-like cell aggregation centrally. Conversely, implants of rhTGFß1 + HA formed mature bone tissue through endochondral ossification. These findings may provide useful clues on the mechanism of bone induction and the bone repair process.

Bone Marrow- Derived Adult Stem Cells: Gene Discovery, Skeletal Tissue Engineering and Stem Cells Plasticity. G. Pelled*, G. Turgeman*, Y. Zilberman, H. Aslan*, I. Bar*, Y. Gafni*, A. J. Domb*, Z. Gazit*, D. Gazit. Skeletal Biotech Lab, Hebrew University-Hadassah Medical Center, Jerusalem, Israel.

Bone marrow-derived stem cells (BMSCs) are multipotent cells that can replicate and differentiate into various lineages. We hypothesized that BMSCs could serve as a powerful tool in three major fields: 1) Novel gene discovery, 2) Skeletal gene therapy and tissue engineering and 3) stem cell plasticity. 1) Novel gene discovery: Adult Mesenchymal Stem Cells (AMSCs), isolated from murine bone marrow were treated in vitro with 17b Estradiol (E2). RNA samples were subjected to robotic high-throughput differential display polymerase chain reaction (RADE) and Gene Chip analysis. Bioinformatic analysis revealed that E2 up-regulated osteogenesis-related genes, and down-regulated adipogenesis-related genes. The novel ESTs are currently being utilized for the discovery of novel genes and their function. In addition, we are currently applying an advanced Gene Chip analysis on samples obtained from a unique in vivo system of engineered AMSCs. 2). Skeletal gene therapy and tissue engineering: We recently published that genetically engineered AMSCs, conditionally expressing rhBMP2, were utilized as a platform for skeletal gene therapy (Mol. Ther. 3:449-461. 2001, J. Gene Med. 3:240-251 2001). We have been able to imply engineered AMSCs for ex vivo skeletal tissue engineering. Based on a novel concept, a hybrid tissue was formed ex vivo, containing primitive capillary network and an osteogenic component originating from genetically engineered AMSCs. Two distinct polymeric scaffolds made of PLA filaments and Arabinogalactan- Chitosan micro-beads, were seeded with engineered AMSCs and endothelial cells, and cultured in a Synthecon rotary bioreactor. The engineered tissue demonstrated a hybrid structure in which osteogenic and angiogenic compartments are combined. Following the ex vivo dynamic culture, in vivo experiments are currently conducted in order to assess capillary and osteogenic tissue functionality. Our novel platform could lead to the ex vivo formation of vascularized matured bone tissue ready for implantation. 3) Stem cell plasticity: We have investigated whether the novel idea of stem cell plasticity could be relevant in skeletal biology. A primitive stem cell population from hematopoietic origin, known as Side Population (SP) cells, was isolated from bone marrow of transgenic mice expressing luciferase under human osteocalcin promoter. The osteogenic potential of these primitive stem cells, expressing luciferase, was shown in vivo. Our study indicates that SP cells can provide an unanticipated avenue for treating bone diseases.

Colony Forming Efficiency of Circulating Skeletal Stem Cells (CSSCs) and Colony Forming Units-Fibroblasts (CFU-Fs) During Fracture and Repair. A. I. Leet, J. S. Lee, N. Ziran*, S. Shi*, S. A. Kuznetsov*, P. G. Robey. Csdb/nidcr, NIH, Bethesda, MD, USA.

Repair of long bone fractures has been well characterized to occur through a process reminiscent of endochondral bone formation during development. However, cell dynamics during this process have not been well defined to date. In this study, we analyzed the colony forming efficiency (CFE) of circulating skeletal stem cells (CSSCs) and colony forming units-fibroblasts (CFU-Fs) at various intervals following fracture in order to determine a potential time frame in which introduction of factors known to enhance osteogenic differentiation of skeletal stem cells may be of clinical benefit. Our model used 3 point fixation to create a closed tibial fracture in adult guinea pigs. After fracture, the animals were splinted for 2 and 6 hrs, and 1, 3 and 6 weeks. At the various intervals, the animals were lethally sedated, arterial and venous blood was sampled by cannulation, and the fractured tibia and opposite tibia were harvested for either histology or determination of CFU-F in the marrow. Blood and bone marrow were plated at a concentration of 10 5 nucleated cells per 75 cm2 flask and were stained for CFE after 11 days. There was no statistically significant difference in CFE of either CSSCs or CFU-F between the time points for either the fractured or opposite-side tibiae, although there was a trend towards an increase in CSSCs in blood of fractured animals, and in CFU-F in marrow of the fractured tibia. The circulating skeletal cells yielded two populations of cells: polygonal and fibroblastic. Counts of both phenotypic cell types were also similar in fractured and unfractured animals, and at different time points following fracture. Our studies indicate that during fracture healing, there is not a significant expansion of either the CSSC or CFU-F populations as had been previously suggested based on histological localization of proliferating cells, and points to other cell types in the marrow and periosteum that contribute to the proliferative phase of fracture healing.

Identification of an Adult Stem Cell for the Osteoblast. E. Olmsted-Davis[1], F. H. Gannon*[2], K. J. A. Jackson*[3], H. D. Shine*[3], K. D. Hirschi*[3], M. K. Brenner*[3], M. A. Goodell*[3], A. R. Davis*[3]. [1]Pediatrics/CAGT, Baylor College of Medicine, Houston, TX, USA, [2]Orthopedic Pathology, Armed Forces Institute of Pathology, Washington, DC, USA, [3]Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, TX, USA.

The purpose of this study was to determine if primitive adult stem cells underlie the production of osteoblasts. Accordingly the "side population" (SP) cells of murine bone marrow were isolated from C57Bl/6-Rosa-Ly5.1 mice based upon their unique ability to efflux Hoechst 33342 dye and transplanted into lethally irradiated C57Bl/6-Ly5.2 mice. Four weeks after transplantation, the percentage engraftment in bone marrow was determined by use of the β-galactosidase marker in the SP cells. Engraftment was typically greater than 80%. Animals then either 1.) remained untreated 2.) were subjected to cranial injury or 3.) were induced to form heterotopic bone in muscle. Thereafter, the long bone of the untreated animals, the calvarium of the injured animals, and the heterotopic bone formed in the animals receiving transduced cells were analyzed for the presence of the β-galactosidase marker in the newly formed bone. In each case the marker was found in osteoblasts as defined by co-staining with the osteoblastic marker osteocalcin. These results indicate that osteoblasts arise from SP cells in each of the three model systems studied. During normal remodeling, osteoblasts in newly formed woven bone rather than osteocytes in lamellar bone were derived from SP cells. In the cranial injury model, osteoblasts derived from SP cells were found at the site of injury.

M228

Perivascular Niche of Postnatal Mesenchymal Stem Cells in Human Bone Marrow and Dental Pulp. S. Shi*[1], P. Bianco[2], P. Gehron Robey[1], S. Gronthos*[3]. [1]Craniofacial & Skeletal Diseases Branch, NIDCR, National Institutes of Health, Bethesda, MD, USA, [2]Dipartimento di Medicina Sperimentale e Pathologia, Universita' La Sapienza, Roma, Italy, [3]Division of Haematology, Institute of Medical and Veterinary Science, Adelaide, South Australia, Australia.

Stem cell populations have been identified in adult bone marrow and dental pulp that upon in vivo transplantation are capable of regenerating the bone and its stroma, and dentin-pulp-like structures, respectively. The maintenance and regulation of these normally quiescent cells is tightly controlled by the local micronenvironment, however, little is known about the anatomical niches that these cells occupy. In this study, we sought to identify these niches using STRO-1, which has previously been shown to recognize bone marrow stromal stem cells (BMSSCs) and dental pulp stem cells (DPSCs). By immunohistochemistry, STRO-1 was found to localize to stromal elements in marrow and to perivascular cells not only in dental pulp, but in other tissues as well. Based on this perivascular localization, freshly isolated STRO-1 positive BMSSCs and DPSCs were tested for expression of the smooth muscle antigens known to be expressed by pericytes (alpha-smooth muscle actin, MUC-18 (CD146) and pericyte-associated antigen, 3G5) by immunohistochemistry, FACS and/or immunomagnetic bead selection. Both BMSSCs and DPSCs expressed alpha-smooth muscle actin and MUC-18, while only DPSCs expressed 3G5. These results strongly suggest that these stem cells are, in fact, pericytes. The finding that BMSSCs and DPSCs share a common perivascular niche, regardless of their diverse ontogeny and developmental potentials, may have further implications in understanding the factors that regulate the formation of mineralized matrices and other associated connective tissues. Furthermore, the data implicates pericytes of other tissues as the source of stem cells that are induced to form mineralised tissue either by addition of exogenous factors or through disease processes.

Oxysterols Promote Osteoblastic and Inhibit Adipogenic Differentiation of Marrow Stromal Cells: Possible New Anabolic Molecules. F. Parhami[1], D. Shouhed*[1], Y. Tintut*[1], T. J. Hahn[2], L. L. Demer*[1]. [1]Medicine, UCLA, Los Angeles, CA, USA, [2]West L.A. VA Medical Center, Los Angeles, CA, USA.

Osteoporosis is still a major cause of morbidity and mortality and is mainly treated by agents that interfere with osteoclastic bone resorption. However, osteoporosis also involves decreased bone formation as a result of reduced osteoblastic cell number and bone forming activity. The mechanism(s) underlying these changes in cellular profile and function in osteoporosis is not clear. We recently reported that the cholesterol biosynthetic pathway of marrow stromal cells (MSC) is important in their osteoblastic differentiation, as demonstrated by the inhibitory effects of HMG-CoA reductase inhibitors, which could be reversed by mevalonate. In the present study we identify several oxysterols as possible products of the cholesterol biosynthetic pathway that are important in mediating osteoblastic differentiation of MSC. Oxysterols are formed by oxygenation of cholesterol in part through the actions of cytochrome P450 enzymes. M2-10B4 (M2) mouse marrow stromal cells undergo osteoblastic differentiation in an osteogenic medium containing fetal bovine serum, ascorbate and ß-glycerophosphate. Treatment of M2 cells with the oxysterols 22(R)-, 22(S)-, and 20(S)-hydroxycholesterols (1-10 μM) significantly enhanced alkaline phosphatase activity, an early marker of osteoblastic differentiation, as early as 2 days post-treatment, and with relative potencies: 20(S)>22(S)>22(R). This enhancement was between 2-10 fold and was persistent up to 12 days. After 10 days of treatment with the oxysterols, mineralization, a late marker of osteoblastic differentiation, was also enhanced 2-5 fold. In contrast, 7-ketocholesterol (1-10 μM) did not have these effects. Furthermore, two other products of the cholesterol biosynthetic pathway, farnesol and geranylgeraniol had no effect or an inhibitory effect, respectively, on markers of osteoblastic differentiation. Osteoporosis is also characterized by increased marrow adipocytes at the expense of osteoblastic cells, and marrow stromal cells undergo adipogenic differentiation in the presence of PPAR-gamma agonist troglitazone. Interestingly, the osteoinductive oxysterols also inhibited troglitazone-induced adipogenesis of M2 cells. Oxysterol-mediated stimulation of osteoblastic bone formation and inhibition of adipogenesis of progenitor cells are potential new strategies for prevention and treatment of osteoporosis.

Evidence for the Maturation-Dependent Expression of an Osteoclastogenic Phenotype in Human Osteoblasts. G. J. Atkins*[1], A. C. W. Zannettino*[2], P. N. Kostakis*[1], B. Pan*[2], A. Farrugia*[2], A. Evdokiou*[1], D. M. Findlay[1]. [1]Orthopaedic Surgery and Trauma, University of Adelaide, Adelaide, Australia, [2]Haematology, IMVS, Adelaide, Australia.

Normal human bone-derived cells (NHBC) are a mixed population of osteoblast (OB)-like cells, separable on the basis of their stage of osteogenic differentiation using the cell surface markers STRO-1 and alkaline phosphatase (AP) (Gronthos et al, J Bone Miner Res 14:47, 1999). We compared the cell surface expression of STRO-1 and AP with that of molecules central to osteoclast (OC) formation, namely RANKL and OPG, to examine the dual functionality of the human osteoblastic stromal cell. NHBC were sorted, using fluorescence activated cell sorting (FACS), into STRO-1bright and STRO-1dull populations. The expression of RANKL and OPG mRNA, as well as the cell surface RANKL expression, was examined in each population in response to 1,25(OH)2vitaminD3 (vitD3) and dexamethasone (DEX). STRO-1bright and STRO-1dull populations were both positive for RANKL mRNA and cell surface RANKL expression. While STRO-1 positivity did not correlate with the basal level of RANKL or OPG mRNA, vitD3 treatment of these populations resulted in an increase in the RANKL:OPG mRNA ratio to a greater extent in the STRO-1bright cells than the STRO-1dull cells. This suggests a greater sensitivity of immature OB to pro-osteoclastogenic factors. Furthermore, vitD3 treatment increased the percentage of immature (STRO-1+/AP-, STRO-1+/AP+) populations over a culture period of 6 days. DEX treatment alone had little effect on the expression of RANKL, downregulated OPG mRNA, and had a profound effect on the maturation of unfractionated NHBC, as indicated by an increase in the percentage of cells expressing AP. The RANKL:OPG mRNA ratio was associated negatively with an increase in the overall maturation of the NHBC cultures in response to DEX. To investigate the effect of hemopoietic cells on human osteoblasts, human PBMC were incubated in co-culture with NHBC. Using the fluorescent dye, CFSE, to label NHBC, we found that human PBMC promoted the proliferation and maintenance of an immature NHBC phenotype. In addition, coculture provoked a vigorous release of PGE2, synthesis of IL-6, and an increase in the RANKL:OPG mRNA ratio that was indomethacin-sensitive. Together, our findings are consistent with the hypothesis that immature OB are more responsive to pro-osteoclastic stimuli than mature OB, and that some of these signals derive from the hemopoietic element in bone. Our data suggest that the dual functionality of OB in supporting OC formation or forming bone is a function of the maturation state of the same lineage of cells.

M231

The Role Of Bone Marrow Adipocytes In BMP-2-Induced Bone Resorption And Formation. J. M. Owens, K. McDermott*, J. Li, J. Wozney, H. Seeherman. Musculoskeletal, Wyeth Research, Cambridge, MA, USA.

Recombinant human BMP-2(rhBMP-2) stimulates significant transient bone resorption, followed by dramatic bone formation in a non-human primate core defect model (Seeherman et al., ORS, 1998 and 2000). Histological analysis indicates rhBMP-2-induced bone resorption is associated with fatty marrow in this model. RhBMP-2-induced de-novo intraosseous bone formation is often initiated in narrow gaps between marrow adipocytes. Numerous spindle cell condensations with associated osteoid matrix production and mineralization are observed in these areas. These findings prompted an investigation to determine whether adipocytes play a role in the response to rhBMP-2. We treated the well-characterized 3T3-L1 mouse pre-adipocyte cell line with 10-8 M 1,25(OH)D3 and 10-6M prostaglandin E2 (PGE2) for 2 days, and observed upregulation of RANKL expression, the factor required for osteoclast differentiation. Addition of 100 ng/ml rhBMP-2 further increased expression of RANKL in these cells. We also examined if rhBMP-2 has similar effects on mature adipocytes. 3T3-L1 cells differentiated into mature adipocytes, under appropriate conditions. Maturation into adipocytes was confirmed by Oil Red O staining. These cells also expressed RANKL, upon stimulation with 1,25(OH)2D3 and PGE2, at levels comparable to those in pre-adipocytes. The addition of 100 ng/ml rhBMP-2 further upregulated expression of RANKL. These results indicate that rhBMP-2 can act on both pre- and mature-adipocytes to increase expression of RANKL which stimulates osteoclastogenesis. We also found that rhBMP-2 suppressed formation of mature adipocyte colonies as assessed by Oil Red O staining. This suggests that rhBMP-2 may block differentiation of adipocytes and/or promote their de-differentiation. Since adipocytes and osteoblasts are derived from common progenitor cells, 3T3-L1 cells were examined for expression of an osteoblastic marker, alkaline phosphatase (ALP). 3T3-L1 cells demonstrated minimal levels of ALP activity. Interestingly however, treatment of 3T3-L1 cells with 100 ng/ml rhBMP-2, in the presence of 1,25(OH)2 D3 and PGE2 for 7 days upregulated ALP activity by 5 fold over control levels. The physiological significance of this rhBMP-2-induced upregulation of ALP in adipocytes is unknown, but the data may imply that adipocytes are involved, either directly or indirectly, in the appearance of numerous osteoblastic cells in our non-human primate core defect model. These results provide further evidence that the in vivo induction of bone resorption and bone formation, stimulated by rhBMP-2, is a complex process that may involve interactions between multiple bone marrow cell types, including adipocytes.

M232

The Isoflavone Genistein Differentially Regulates Osteogenic- and Adipogenic Differentiation of Human Bone Marrow Stromal Cells. M. Heim*[1], O. Frank*[2], N. Sochocky*[1], A. Barbero*[2], G. Kampmann*[1], I. Martin*[2], P. Fuchs*[1], P. Weber[1], W. Hunziker[1], I. Bendik*[1]. [1]Human Nutrition and Health, Roche Vitamins Ltd., Basel, Switzerland, [2]Dept. of Surgery, Research Division, University of Basel, Basel, Switzerland.

There is evidence that dietary phytoestrogens like the isoflavone genistein (Gen) act similarly to17ß-estradiol (E2) by exerting some of their bone-sparing effects via osteoblasts. Currently, not much is known about the function of these estrogens during osteogenic/adipogenic commitment of mesenchymal precursor cells. Therefore, we investigated the transcriptional effects of Gen and E2 on several osteogenic and adipogenic marker genes at various stages of differentiation. Bone marrow samples from six healthy premenopausal donors were expanded with dexamethasone/bFGF. Subsequently, the bone marrow stromal cells (BMSC) were differentiated in osteogenic medium. For the transcriptional profiling the cells were stimulated with DMSO (vehicle), 10nM Gen, 1µM Gen and 10nM E2. Total RNA was harvested at days 3, 7, 11, 15 and 18 postconfluence and reverse transcribed to cDNA. The cDNA samples were tested in multiplex TaqMan real-time quantitative RT-PCR assays. We have previously shown that osteogenic commitment and maturation is associated with the transcriptional activation of BSP-2, osteopontin and BMP-2. These markers were not significantly changed after treatment with Gen or E2, nor were the mRNA levels of other osteoblast markers such as cbfa-1, osteonectin, osteocalcin or collagen type 1 changed. Only alkaline phosphatase mRNA was observed to increase at day 18 of osteogenic differentiation after estrogenic treatment. Interestingly, the expression of OPG and TGFbeta1, which regulates the coupling between osteoblasts and osteoclasts, was up-regulated by Gen and E2 starting from day 11. Furthermore, we showed during the differentiation timecourse that the early adipogenic transcription factors PPARgamma and C/EBPalpha were progressively down-regulated. This suppression was more prominent in the presence of Gen or E2. Using dexamethasone and insulin, BMSC were differentiated to adipocytes and mRNA levels of several adipocyte markers were determined at day 21. Gen and E2 had strong effects on late adipocyte expression markers, whereas the PPARgamma and C/EBPalpha were only mildly affected at this stage. Morphologically, the adipogenic cultures treated with the estrogenic compounds had lower numbers of adipocytes with smaller lipid droplets. Thus, our results give evidence that the soy isoflavone genistein like the natural hormone positively favours the BMSC commitment towards the osteogenic lineage.

Adipose Derived Adult Stem (ADAS) Cells Differentiate into Bone Synthesizing Osteoblasts In Vivo. K. C. Hicok[1], Y. Zhou*[2], Y. Pucilowska*[2], Y. Halvorsen*[1], L. F. Cooper[2], J. M. Gimble[1]. [1]Research, Artecel Sciences Inc, Durham, NC, USA, [2]Department of Prosthodontics, University of North Carolina, Chapel Hill, NC, USA.

The presence in bone marrow of multi-potential cells capable of osteoblastic differentiation is now well established. For reasons of accessibility and low abundance, these cells are also sought in other more "accessible" tissues. Adult subcutaneous fat tissue is an excellent and abundant source of multi-potent cells. In vitro, adipose-derived adult stem (ADAS) cells express bone marker proteins including alkaline phosphatase, type I collagen, osteopontin, and osteocalcin and produce a mineralized matrix as shown by alizarin red staining. In this study, ADAS cell ability to form bone in vivo was determined. ADAS cells isolated from liposuction waste of two different donors and a control osteoblastic cell line, hFOB 1.19, were expanded for 1 week in either DMEM: F12 plus 10% (v/v) FBS or in this media plus an osteoinductive cocktail (10 nM 1,25 dihydroxy-vitamin D_3, 10 nM dexamethasone and 50 µg/ml ascorbic acid). 3 x 10^6 cells were loaded onto either hydroxy-apaptite/ tricalcium phosphate (HA/TCP) cubes or the collagen/ HA/TCP composite matrix, Collagraft®, and were implanted subcutaneously into SCID mice. After 6 weeks, implants were removed, fixed, demineralized and sectioned for hematoxylin and eosin staining. Bone formation was observed in 75% of HA/TCP implants loaded with ADAS cells from both donors. Only 17 % of Collagraft implants were positive for the presence of bone matrix. While 50% of HA/TCP implants loaded with hFOB 1.19 cells formed bone, when Collagraft was loaded with hFOB 1.19 cells, intermatrix spaces displayed a high degree of adipose tissue formation. Immunostaining of serial sections for human nuclear antigen (HNA) demonstrated that cells embedded within and lining regions of bone were of human origin. Little or no bone formation was observed in the control HA/TCP or Collagraft matrices without cells. In summary, the data demonstrates the ability of ADAS cells to form bone matrix in vivo. Because of their abundance and accessibility, ADAS cells may provide an important and renewable source of osteoblasts for tissue engineering based therapeutics of bone injury and disease.

Tumor Necrosis Factor Signaling Effects Marrow Stromal Cell Recruitment Into the Osteogenic Lineage. G. L. Barnes, C. Edgar*, K. Hebert*, L. C. Gerstenfeld. Department of Orthopaedic Surgery, Boston University Medical Center, Boston, MA, USA.

Tumor Necrosis Factor alpha (TNFa) is one of the major pro-inflammatory cytokines and has been demonstrated to be an important mediator of bone healing. We have previously demonstrated that TNFa receptor deficient mice (p55-/- /p75-/-) exhibit delayed bone healing and that the delay in healing is primarily due to a defect in removal of the calcified cartilaginous callus. However, examination of these animals also demonstrated a marked absence of the typical intramembranous bone formation that normally occurs on the periosteal surface adjacent to the fracture site in response to the trauma of fracture. In order to independently examine the TNFa effect on direct bone formation, we utilized a bone marrow ablation model system in which repair occurs solely by intramebranous bone formation. TNF-a receptor deficient animals display delayed intramembranous healing in this bone marrow ablation model system. These data suggest that in the absence of TNFa signaling fewer osteogenic precursor cells are present or that these cells are deficient in their response to the inductive signlas directing the induction of osteogenic differentiation. To examine these deficiencies in the absence of TNFa signaling, we examined osteogenic differentiation in a Marrow Stromal Cell (MSC) culture system. Comparison of osteogenesis in MSC cultures from wild type and TNFa receptor null animals demonstrated 50-60% fewer mineralized nodules in the absence of TNFa signaling. This data supports the conclusion that in the absence of TNFa signaling there is a diminished recruitment of mesenchymal stem cells into the osteogenic lineage. In correspondence with the decreased number of osteogenic cells in the TNFa receptor deficient cultures, we observed a decrease in the expression of several osteoblast related matrix genes including osteopontin, bone sialoprotein and osteoclacin (OPN, BSP and OC, respectively). No expression of chondrogenic associated genes, including type II and X collagen, was observed suggesting chondrogenesis does not occur in these cultures. Comparison of the BMP profiles between wild type and TNFa defiecient cultures demonstrates several unique alterations in the BMP profiles of the marrow stromal cells in the absence of TNFa signals including decreased levels of BMPs 1, 2, 3 and 8A and increased expression of BMPs 3B and 5. Our data demonstrate that in the absence of an intact TNFa signaling system fewer mesenchymal stem cells are recruited into the osteogenic lineage and suggest that this decrease may be related to alterations in the expression of specific BMPs.

Characterization of Autologous Rabbit Bone Marrow Stromal Cells for Use in Bone Tissue Engineering. W. Huang, B. Carlsen, G. Rudkin*, M. Berry*, K. Ishida*, D. T. Yamaguchi, T. A. Miller*. VAGLAHS, Los Angeles, CA, USA.

In the search for a synthetic bone graft substitute (BGS) that will be useful in the repair of craniofacial defects, we have explored using autologous rabbit bone marrow stromal cells to establish three-dimensional (3-D) cell cultures on biocompatible scaffolds. Bone marrow was harvested from the iliac crest and nucleated adherent stromal cells were isolated. The isolation technique yielded 80% alkaline phosphatase positive colonies without rhBMP-2 treatment. Unlike human bone marrow stromal cells, rabbit cells showed cessation of growth after three passages in vitro. Osteogenesis, as indicated by alkaline phosphatase activity and mineralization, was significantly enhanced by rhBMP-2. Treatment with rhBMP-2 resulted in a sigmoidal dose response curve with optimal alkaline phosphatase activity at a dose of 50 ng/ml rhBMP-2. Time course studies with rhBMP-2 showed a detectable increase in alkaline phosphatase activity occurred at day 8, and the activity increased steadily through day 16. Mineralization studies, likewise, showed an increase in mineral deposition by von Kossa stain after rhBMP-2 treatment. Interestingly, mRNA level of osteopontin exhibited a significant decrease in first three days of rhBMP-2 treatment and remained low in a course of 2 weeks. Osteonectin, however, remained unchanged during rhBMP-2 treatment. TGF-beta1 exhibited an inhibitory effect on cell growth by cell count studies. Using autologous bone marrow stromal cells, we then established an in vitro 3-D cell culture system, in which cells were cultured within a poly(lactide-co-glycolide) based scaffold. The scaffold is porous, moldable, and absorbable at a rate similar to bone formation when implanted in vivo. Stromal cells were able to attach and proliferate on the surface area inside and outside of the scaffolds. Differentiation of marrow stromal cells was highly responsive to the BMP-2 treatment as indicated by the amount of collagen deposit detected by Masson's Trichrome stain. These cellular scaffolds will be tested in rabbits for their ability to heal a critical-sized cranial defect.

HGF and SCF Support Proliferation of Human Osteoclast Precursors *In Vitro*. H. C. Blair, R. Bu, J. I. Oakley*, S. E. Kalla*. Pathology and Physiology & Cell Biology, University of Pittsburgh, Pittsburgh, PA, USA.

CSF-1 and RANKL are sufficient for osteoclast differentiation. However, osteoclast numbers vary, so a mechanism to expand preosteoclasts must exist. HGF (met ligand) and SCF (kit ligand) stimulate pathways overlapping with CSF-1 and increase osteoclasts in marrow cultures. We hypothesized that HGF or SCF support osteoclast expansion. We compared effects of HGF, SCF, and CSF-1 on growth of preosteoclasts from human blood. Monocytes were recovered on ficoll and purified by CD14 selection (MACS, Miltenyi Biotec). These were plated in DMEM, IL-1β, and IL-6, 10 ng/ml each and serum. This was supplemented with HGF, SCF, or CSF-1, 10 ng/ml, for 10 days. In CSF-1, few cells were nonadherent by 2 d, and proliferation was insignificant. With HGF, ~50% of harvested cells were nonadherent and ~30% were nonadherent with SCF. In SCF or HGF, nonadherent cells grew colonies of 4-~64 cells. Expansion of nonadherent cells from d 2- 10 was ~10 fold in SCF (~5 to >20, n=10) and ~30 fold, in HGF (n=6), although CD14 cells were limited to ~5-6 cell division cycles under conditions tested. In either case, nonadherent cells replated in CSF-1 attached and expressed α-naphthyl acetate esterase. Flow cytometry indicated that the nonadherent cells expressed monocytic markers CD11, CD34, and CD64. Occasional cells with blastic phenotype were seen, <3%. IL-6-R increased nonadherent cells ~50% at 10 days with SCF. IL-3, IL-11, GM-CSF, and 1,25 dihydroxyvitamin D augmented osteoclast differentiation but did not affect colony growth. SCF effects were intermediate between HGF and CSF-1; after four weeks with SCF, ~50% of the cells attached and formed giant cells with weak osteoclast-like phenotype, but very low adherence (<3%) and maturation (TRAP, cathepsin K, or acid lakes) were seen in HGF. However, when nonadherent cells from HGF media were replated on bone in media with TNFα or RANKL and CSF-1, osteoclastic features developed. After 28 d, adherent cells expressed TRAP, with strong secretion onto bone, and produced pits on the dentine slices. To confirm the effect of HGF, nonadherent cells grown in basal medium with SCF were re-sorted using monocytic and size markers and re-plated in SCF or HGF. HGF induced the formation of colonies > 8 cells after culture in SCF, but SCF did not allow re-growth. Re-grown cells also developed osteoclast markers when HGF was removed and CSF-1 plus RANKL was added. These results indicate that HGF and SCF stimulate the proliferation of osteoclast precursors but are not sufficient for osteoclast maturation. HGF had a greater effect on cell number, and SCF weakly replaced CSF-1 in differentiation. These effects appeared to be independent of other factors that augment osteoclastic differentiation.

M237

Nitric Oxide Regulates Acid Secretion Bidirectionally in Human Osteoclasts. G. Hao*[1], Y. N. Li[1], S. E. Kalla*[1], J. I. Oakley*[1], M. Zaidi[2], H. C. Blair[1]. [1]Pathology and Physiology & Cell Biology, U Pittsburgh, Pittsburgh, PA, USA, [2]Medicine and Geriatrics, Mount Sinai School of Medicine, New York, NY, USA.

Nitric Oxide (NO) is an important bone signal, produced by stimulated osteoblasts or macrophage-family cells including osteoclasts. Most NO effects are mediated by the cGMP dependent protein kinase. However, variable and contradictory effects of NO on osteoclasts have been noted, some of which may be related to mixed cell populations. We investigated effects of NO on osteoclasts using CD14-selected circulating monocytes expanded in vitro using a cytokine cocktail, then replated with bone, CSF-1, and RANKL. These cells were devoid of mesenchymal or osteoblastic cells, and express cathepsin K and TRAP, and form acid lakes and pits on bone. These cells were exposed to (±)-S-nitroso-N-acetylpenacillamine (SNAP), an NO donor with a long half life, at concentrations from 3 to 100 μM for periods from zero to 24 hours, monitoring effects on osteoclastic acid secretion using Lysotracker red DND (Molecular Probes, Eugene, OR). Effects on G-kinase were evaluated by anti-kinase antibody binding visualized with Alexafluor 488, and osteoclastic attachment was studied using actin labeling with Alexafluor-568 phalloidin. Cell survival was examined by annexin V binding. We found that at 3 μM SNAP, acid lake intensity decreased within 10 min to near zero, while at concentrations 30-100 μM the effect abruptly switched to increase in acid secretion that lasted 30-60 min. Over longer times (60 min-24 h), at 3 μM, the cells retained other characteristics, but surprisingly, at 100 μM, SNAP, strong acid secretion faded and osteoclast attachment was lost as demonstrated by loss of actin rings and podocytes, which correlated with redistribution of cGMP-dependent kinase from cytoskeletal and cytoplasmic compartments to granular cytoplasmic and nuclear labeling, followed by changes consistent with apoptosis. Time courses showed that cells survived 24 hours in 0-10 μM SNAP, while apoptosis occurred in 30-100 μM SNAP. We conclude that the response of human osteoclasts to NO is distinctly variable, with inhibition of acid secretion at low concentrations, while at higher concentrations NO caused strong acid secretion, but prolonged NO exposure at high concentrations caused redistribution of actin and G-kinase including strong nuclear labeling, followed by cell death. Our findings show that, in cultures without mesenchymal cells, NO at low concentrations inhibits osteoclast acid secretion, possibly a mechanism for osteblastic regulation of osteoclasts by diffusion of NO. In constrast, high NO concentrations, which might result from autocrine NO, increase acid secretion but are proapoptotic if maintained.

Effects of Extremely Low Frequency Pulsed Electromagnetic Field on Osteoclast Formation and Activity. C. Shih[1], W. H. Chang*[2], P. Chu[3]. [1]Biology and Anatomy, National Defense Medical Center, Taipei, Taiwan Republic of China, [2]Biomedical engineering, Chung-Yuan University, Chung Li, Taiwan Republic of China, [3]Nephrology, Tri-Service General Hospital, Taipei, Taiwan Republic of China.

Treatment of osteoporosis has been focused on drug therapies, such as estrogen, calcitonin, bisphosphonates. Alternatives such as physical stimuli are applied to treat osteoporosis whereas cause no adverse effects to other tissues. Previous studies have demonstrated the efficacy of electromagnetic fields in treating and preventing ununion fractures, failed arthrodeses, disuse osteopenia, and osteoporosis. Although there are growing evidences showed that extremely low frequency pulsed electromagnetic fields (ELF-PEMF) could exert significant effects on bone, the effects and possible mechanism of ELF-PEMF on osteoclasts are still not well known. Thus, the purpose of this study was to investigate the effects of ELF-PEMF on osteoclast formation and activity and the underlying mechanism using mouse bone marrow culture system. Bone marrow cells($1x10^6$ cells/well) isolated from 8 week-old ICR male mouse tibiae and femurs were cultured in 10% a-MEM with Vitamin D_3 (10 nM) and prostaglandin E_2(1 000 nM). Multinucleated cells satisfied major criteria of osteoclast, such as TRAP activity, calcitonin receptor, cAMP production in response to salmon calcitonin and the ability to form resorption pit. Secretions of inter-leukin-1, tumor necrosis factor(TNF) were assayed using enzyme-linked immunosorbent assay. TRAP-positive osteoclast formation and activity were significantly enhanced($p<0.05$) in cultures exposed to 0.8 mv/cm electric field and significantly suppressed when exposed to 0.2 mv/cm. In addition, IL-1 and TNF secretion were significantly increased in 0.8 mv/cm and decreased in 0.2 mv/cm as compared to the controls. There was high correlation between osteoclast formation and amount of cytokine secretion. The results of this study demonstrate that ELF-PEMF could enhance and suppress osteoclast formation and activity depending on induced electric intensity. In addition, cytokine secretion may play an important role between osteoclast formation and PEMF exposure.

Truncation Mutants of RANKL Inhibit RANKL-induced Osteoclast Differentiation and Activation. M. H. Zheng*[1], J. W. Tan*[1], C. Wong*[1], J. Li*[2], J. Cornish*[2], J. Xu*[1]. [1]Dept of Surgery (Orthopaedics), University of Western Australia, Nedlands, Australia, [2]Dept of Medicine, University of Auckland, Auckland, New Zealand.

Receptor activator of NF-kB ligand (RANKL) is a key factor necessary for osteoclastogenesis and activation of osteoclasts. We hypothesis that residues or domains of RANKL affect the binding affinity to the decoy receptor OPG and the active receptor RANK; and as a consequence residues or domains of RANKL are involved in biological activity both *in vitro* and *in vivo*. To determine the active ligand domain of the C-terminal extracellular region, a series of overlapping regions of the TNF-like core region were cloned into the bacterial expression vectors pGEX. Soluble forms of recombinant rat RANKL (rRANKL) were affinity-purified and their biological activities were investigated using $RAW_{264.7}$ cell culture and isolated rat osteoclast culture. As expected, GST-rRANKL (aa160-318) containing the full TNF-like core region had the highest capability to induce the formation of osteoclast-like cells from $RAW_{264.7}$ cells whereas GST-rRANKL (aa239-318), (aa160-268), (aa160-291), (aa246-318) had a reduction of osteoclast inductivity. Interestingly, competition studies showed that GST-rRANKL (aa239-318), (aa160-268), (aa160-291), (aa246-318) inhibit RANKL (aa160-318) induced osteoclast formation in various degrees. Among of them RANKL mutant (aa246-318) was the most potent one. Furthermore, RANKL mutant (aa246-318) significantly blocks RANKL (aa160-318) induced osteoclastic bone resorption in isolated rat ostoelcast cultures. An in vitro protein-protein interaction has been carried out to examine the interaction of various RANKL mutants with RANK. Truncated GST-rRANKL (aa239-318), (aa160-268), (aa160-291), (aa246-318) showed efficient binding to Flag tagged RANK in a GST pull down assay. In order to examine the effect of RANKL mutants on activation of NF-kB, a stable Raw cell line expressed a reporter luciferase gene under the control of NF-kB binding site was established. Dose response and time course studies showed that there is a reduced effect on the activation of NF-kB and ERKs by the mutants. In short, these results suggest that truncated mutants of the TNF-like core domain of RANKL can be used to inhibit RANKL induced osteoclast differentiation and activation.

Bone Histomorphometric Analysis of PD-1 Deficient Mice - The Regulation of Tcell Activation and Bone Metabolism. K. Nagahama*[1], K. Aoki[2], K. Nonaka[2], K. Ohyama*[1], K. Ohya[2]. [1]Section of Maxillofacial Orthognathics, Graduate school, Tokyo Medical and Dental University, Tokyo, Japan, [2]Section of Pharmacology, Department of Hard tissue Engineering, Graduate school, Tokyo Medical and Dental University, Tokyo, Japan.

The involvement of lymphocytes in metabolic bone disease and/or local bone destruction has recently been focused. Amgen group showed the decreased bone volume and the increased number of osteoclasts in tibia and femur of the cytotoxic T lymphocyte-associated antigen 4 (CTLA-4/ CD152) deficient mice (Nature 402: 304-309, 2000). CTLA-4 is a negative regulator of T cell activation, and actually the defect of this molecule induces T cell activation. On the other hand, Programmed Death-1 (PD-1) molecule is structurally similar to CTLA-4 working as a negative regulator of T cell activation similarly. The inhibitory mechanism, however, have proved to be different from CTLA-4. We report here the

novel bone phenotype of PD-1 deficient mice, which is quite different from the report of CTLA-4 deficient mice. The trabecular bone mineral density (BMD) of tibia in the 6week-old male PD-1 deficient mice was measured under the anesthesia by pQCT. However, there was no difference between wild type and PD-1 deficient mice. Then we measured it again using the same animals after 6 weeks. Interestingly, the BMD of tibia was significantly increased in the 12 week-old PD-1 deficient mice, which is the opposite phenotype of CTLA-4 deficient mice (see Table 1). The histological and histomorphometric analysis confirmed this phenotype. The primary and the secondary spongiosa of tibia were increased and the long cartilage remnants in the primary spongiosa of tibia was also increased in PD-1 deficient mice relative to wild type mice. The osteoclast number in both cortical and the cancellous regions of tibia were not increased in PD-1 deficient mice, that is different from the report of CTLA-4 deficient mice. T cell activation is not continuously promoted in PD-1 deficient mice, that might be one reason why the different bone phenotype was appeared. Taken together, these results indicate that the structurally related molecules, although those are the same negative regulators of T cell activation, have a different influence on bone metabolism that might depend on the different mechanism regulating T cell activation.

Table 1. The BMD measured by pQCT was significantly increased in the PD-1 deficient mice.

Data were presented as mean ± SD.	Wild type (mg/cm3)	PD-1 KO (mg/cm3)	statistics (compared to wild type)
Cortical BMD of tibial midshaft	1051.6 ± 21.3	1117.3 ± 16.1	$p < 0.005$
Trabecular BMD of proximal tibia	230.8 ± 11.0	288.7 ± 24.8	$p < 0.005$
Total BMD of proximal tibia	329.9 ± 18.8	417.3 ± 47.1	$p < 0.01$

Divergent Effects of Interleukin (IL)-6 and IL-11 on Glucocorticoid Receptor Number in Human Osteoblast-Like Cells. A. Dovio*[1], M. L. Sartori*[1], B. Ceoloni*[1], L. Saba*[1], P. Prolo*[2], F. Chiappelli*[2], A. Angeli[1]. [1]Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy, [2]Laboratory of Oral and Molecular Immunology, UCLA School of Dentistry, Los Angeles, CA, USA.

Glucocorticoid (GC)-induced osteoporosis is admittedly the most frequent secondary osteoporosis. The pathogenesis still has many unresolved issues. While the effects of GC on cytokine production and action have been extensively studied, little is known on the effects of cytokines on GC action at the target level. Cytokines belonging to the interleukin (IL)-6 or gp130 cytokine family are known as pro-resorptive cytokines, in that they promote osteoclastogenesis. We have previously shown that IL-6 up-regulates GC receptor type II (GR) number, in both an autocrine and a paracrine way. Aim of the present investigation was to study the effects of another gp-130 osteotropic cytokine, IL-11, on GR in two widely used human osteoblast-like cell lines, Saos-2 and MG-63, which have remarkably different constitutive expression of these cytokines and GR as well (Table I). Cytokine secretion was assessed by ELISA; GR number and affinity were determined by radioligand binding assay and Scatchard analysis. When exposed to IL-11 (0.1-100 ng/ml), a significant dose-dependent decrease of GR was observed in MG-63 but not in Saos-2 cells. Incubation with anti-IL-11 monoclonal antibody significantly increased GR in both cell lines. Neither IL-11 addition, nor IL-11 deprivation modified GR affinity. Specific STAT-3 inhibition yielded data compatible with the view that Jak-STAT pathway is involved in the cytokine modulation of the GR. While exerting opposite effects on GR number, neither IL-6 nor IL-11 did significantly modify GC effects on osteoprotegerin (OPG) release, assessed by ELISA. In conclusion, IL-6 and IL-11 have divergent effects on GR in two well-characterized osteoblast-like cell lines. Our data are consistent with the concept of autocrine-paracrine modulatory loops of GC action in bone microenvironment involving pro- and anti-inflammatory cytokines. These loops may have clinical relevance for the dynamics of bone loss in patients given GC and conceivably having high concentrations of these cytokines in the bone microenvironment.

Table I. Functional phenotype of MG-63 and Saos-2 cells

	MG-63	**Saos-2**
IL-6 (pg/10^6 cells)	856 ± 130	4.6 ± 1.2
IL-11 (pg/10^6 cells)	15 ± 1.1	621 ± 40
OPG (pg/10^6 cells)	39273 ± 10912	857 ± 56
GR (binding sites/cell)	110380 ± 4499	31783 ± 1847

Data are expressed as mean ± SE.

Macrophage Colony-Stimulating Factor Suppresses Calcitriol-Induced but Augments Prostaglandin E_2-Induced Osteoclast Formation in Rat Bone Marrow Cell Culture. J. K. Yeh, D. I. Sima*, J. Evans*, J. F. Aloia. Medicine, Winthrop-University Hospital, Mineola, NY, USA.

Macrophage-Colony Stimulating Factor (M-CSF) is a critical early modulator of osteoclastogenesis with a primary action on early monocytic stem cells to induce osteoclast precursor formation. Calcitriol (1,25-D_3) and prostaglandin E_2 (PGE_2) are known to influence osteoclast formation indirectly through their effects on osteoblasts. Evidence indicates that 1,25-D_3 induces the expression of M-CSF which facilitates the formation of osteoclasts. The purpose of the present study is to investigate the effect of $1,25D_3$ at 10^{-8} M and/or PGE_2 at 10^{-7} M in the presence of M-CSF (10 ng/ml) on osteoclast formation in rat bone marrow cell culture. Our data shows that rat bone marrow cells cultured with basal medium (αMEM medium supplemented with 50ug/ml ascorbic acid, 10% fetal bovine serum, antibiotic/antimycotic) developed a few multinucleate osteoclast-like cells with Tartrate-Resistant-Acid Phosphatase (TRAP) positive staining on days 7 through 11 of culture. Treatment with $1,25D_3$ alone resulted in numerous TRAP-positive osteoclast formations. Interestingly, the combined treatment of $1,25D_3$ with M-CSF resulted in an 80±11% suppression of the osteoclast formation at all times as compared to the respective $1,25D_3$ alone group. Treatment with PGE_2 alone also resulted in numerous TRAP-positive osteoclast formations. However, a combined treatment of M-CSF and PGE_2 resulted in a 400±120% increase in the osteoclast formation at all times as compared to the respective PGE_2 alone group. The combined treatment of $1,25D_3$ and PGE_2 had a synergistic effect on osteoclast formation as compared to each treatment alone. Again, in the presence of M-CSF, the formation of osteoclasts was suppressed to less than 20% of the $1,25D_3$ + PGE_2 group. How M-CSF suppresses $1,25D_3$ induction, but augments PGE_2 induction on osteoclast formation is not known, however, the current study results suggest that $1,25D_3$ and PGE_2 induce osteoclastogenesis in rat bone marrow cultures through different mechanisms.

RANKL Regulates Fas Expression and Fas-mediated Apoptosis in Osteoclasts. x. wu[1], G. Pan*[1], M. McKenna[1], J. M. McDonald[2]. [1]Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, [2]University of Alabama at Birmingham, Veterans Administration Medical Center, Birmingham, AL, USA.

Apoptosis of osteoclasts, together with the osteoclast differentiation rate and osteoclast activity determine the rate of bone resorption. The Fas receptor mediates apoptosis in many cells, especially of the immune system. RANKL, which regulates osteoclastogenesis, is a potential cytokine linking the immune system to bone remodeling. Here we investigated the role of RANKL in regulating Fas expression and Fas-mediated apoptosis in osteoclasts. Mouse osteoclasts were generated by treating osteoclast precursors (bone marrow macrophages) isolated from C57bl/6 mice with soluble mouse RANKL and recombinant mouse M-CSF. Osteoclasts generated either from RAW 264.7 cells treated with RANKL or from human peripheral blood monocytes supplemented with human M-CSF and RANKL were also used. Fas expression was determined by flow cytometry, Western analysis and its peripheral location was detected by immunohistochemistry. By flow cytometry, only a small portion of stem cells (6%) isolated from bone marrow had Fas expressed on their surfaces. Fas expression was highly upregulated from 6% positive cells at day zero to 94% positive cells after 6 days of incubation with M-CSF. Most of the increase in Fas expression occurs between day 3 and day 6. Addition of RANKL decreased the peak fluorescence for Fas expression by two logs compared with M-CSF alone. Addition of RANKL decreased Fas expression at both day 3 and day 6. A similar but somewhat less pronounced observation was seen with the RAW cell line. Incubation of RAW cells with M-CSF alone increased Fas expressing cells from 7% at day 3 to 46% at day 6. Addition of RANKL decreased the peak fluorescence by 50%. Flow cytometry results with mouse osteoclasts were confirmed by Western blot. Fas activation induced apoptosis (51%) in osteoclasts generated in the presence of 50ng/ml RANKL; however, cells differentiated in the presence of a higher dose of RANKL (150ng/ml) were resistant to apoptosis induced by Fas antibody. These results demonstrate that in mouse osteoclasts, M-CSF increases Fas expression and RANKL decreases it. RANKL also decreases Fas-mediated apoptosis in osteoclasts by regulating Fas receptor expression. The distribution of RANKL in tissues and its regulation of Fas expression and Fas-mediated apoptosis imply that not only cells of stromal/osteoblast lineage but also of the immune system participate in regulating osteoclast number, therefore regulating the balance between bone resorption and bone formation.

SDF-1 Recruits Osteoclast (OC) Precursors via Inducing MMP 9: A Mechanism Independent from MMP-9 Induction During RANKL-mediated OC Differentiation. X. Yu, Y. Huang*, P. Collin-Osdoby, P. Osdoby. Department of Biology, Washington University, St. Louis, MO, USA.

The directional movement of pre-OC from the circulation into bone occurs via complex mechanisms involving cell surface, matrix, and chemoattractant signals that enable proteinase-dependent transmigration. Although MMP-9 is involved in such pre-OC movement, bone signals that attract pre-OC or regulate MMP-9 are poorly defined. Chemokines direct cell migration, activation, and invasion in normal and pathological states, and are elevated in osteopenic disorders such as periodontal disease, rheumatoid arthritis, or multiple myeloma. Thus, chemokines may aid in the recruitment or formation of OC. To examine this, we analyzed chemokine receptor expression and actions during OC development in murine RAW 264.7 cells (RAW) differentiated by RANKL to yield TRAP+ multinucleated bone-resorptive OC (RAW-OC). CXCR receptor mRNA expression analyzed by multi-probe RPA showed CXCR4 expression in both RAW and RAW-OC, with higher levels in RAW cells that declined as RAW-OC developed. Because SDF-1 is the sole ligand for CXCR4, the key homing signal for hematopoietic cells to the bone marrow, and an activator of MMPs in cell migration, we examined if SDF-1 regulated pre-OC recruitment or differentiation. SDF-1 stimulated pre-OC (RAW) chemotaxis, and increased RAW cell MMP-9 activity (by gelatin zymography) and MMP-9 mRNA levels (by RT-PCR). In comparison, RANKL did not cause RAW cell chemotaxis, although it increased RAW cell MMP-9 activity and mRNA levels. SDF-1 differed from RANKL in evoking a more modest and transient elevation in MMP-9 mRNA expression compared to RANKL. SDF-1 did not further raise high MMP-9 levels in RAW-OC. Consistent with their upregulation of MMP-9, both SDF-1 and RANKL stimulated RAW cell transmigration through collagen-coated transwell membranes via an MMP-dependent process blocked by the general MMP inhibitor GM6001. In contrast to RANKL-mediated RAW-OC formation, SDF-1 did not induce cathepsin K mRNA expression or promote TRAP+ multinucleated bone resorptive RAW-OC formation. Therefore, SDF-1 serves as an important recruitment signal for inducing the directional movement and targeting of pre-OC into and within the bone marrow via chemotactic and MMP-9 stimulated mechanisms. Recruited precursors subsequently decrease CXCR4 and increase MMP-9 in response to RANKL as they develop into bone-resorptive OC. Consequently, MMP-9 induced by SDF-1 or RANKL plays distinct roles in pre-OC and OC: an early SDF-1 regulated role in pre-OC homing and a later RANKL regulated role in bone resorption. Together, SDF-1 and RANKL work in concert to home and target pre-OCs to bone resorption sites for their development and function.

M245

Synergistic Effects of TNF-alpha and RANKL on Osteoclast Differentiation from Bone Marrow Cells of Type-II collagen Induced Arthritis Mice. Y. Azuma[1], E. Ochiai*[1], K. Kaji*[2], K. Kanazawa*[2], T. Kamimura*[1], J. Inoue*[3], A. Kudo[2]. [1]Pharmacological Research Department, Teijin Institute for Biomedical Research, Tokyo, Japan, [2]Depatment of Life Science, Tokyo Institute of Technology, Yokohama, Japan, [3]Facalty of Science and Technology, Keio University, Yokohama, Japan.

The severe local osteolysis in the joint of patients suffered from rheumatoid arthritis associates with up-regulation of osteoclastic bone resorption by the interaction of several inflammatory cytokines. Although TNF-alpha (TNF) synergistically stimulates RANKL-induced osteoclast differentiation from osteoclast progenitor cells, its pathological role has remained unclear. To elucidate the involvement of the TNF-synergy with RANKL in osteoclastogenesis of autoimmune arthritis, we examined the TNF and/or RNAKL-induced osteoclastogenesis by using bone marrow cells (BM-cells) and osteoclast progenitor cells (M-CSF dependent bone marrow macrophages; MDBM cells) from murine type-II collagen induced arthritis (CIA mice). DBA/1J mice were immunized with type II collagen in adjuvant, and the mice were observed for 9 weeks during which time arthritis was scored. Severe inflammation after 5-weeks and the bone destruction of the synovial joints after 7-weeks were observed, respectively. BM cells were obtained from long bone of CIA mice at 1,3,5,7,9 weeks after first immunization, and cultured in the presence of M-CSF. BM-cells were treated with various combinations of TNF and RANKL. The results demonstrated that co-treatment with TNF and RANKL synergistically stimulated the formation of TRAP-positive multinuclear cells (TRAP(+)-MNCs) from BM-cells of both CIA mice and intact mice at all time points. However, at 5, 7 and 9 weeks after immunization, TNF was 2 or 3 times more synergistic with RANKL in BM-cells derived from CIA mice than in that derived from intact mice, suggesting that the high-sensitive population toward the co-treatment with TNF and RANKL increased in the bone marrow cells of CIA mice. Tumor necrosis factor receptor-associated factor (TRAF) 6 is involved in the RANKL and/or TNF-induced osteoclast differentiation from osteoclast progenitor cells, we examined the expression of TRAF6 protein in the TNF-treated MDBM cells. In the process of TNF-induced osteoclastogenesis, the expression of TRAF6 protein increased, suggesting TRAF6 up-regulation by TNF associates with synergistic effects of TNF and RANKL. These results suggest that the up-regulation in the sensitivity toward the co-treatment with TNF and RANKL in the osteoclast progenitor cells involves the local osteolysis in the synovial joints of CIA mice.

M246

ECF-L Is a Critical Co-Factor For RANK Ligand-Induced Osteoclastogenesis. Y. Oba, S. J. Choi*, G. D. Roodman. Medicine, University of Pittsburgh, Pittsburgh, PA, USA.

We produced an osteoclast precursor cell line that formed large numbers of osteoclasts (OCL) and used a subtraction hybridization approach to identify genes upregulated in mature OCL compared to precursors. Using this approach, we recently identified eosinophil chemotactic factor-L (ECF-L) as a novel factor produced by OCL and OCL precursors that enhances OCL formation. Conditioned media from 293 cells transfected with the ECF-L cDNA or recombinant ECF-L significantly increased OCL formation in a dose-dependent manner in mouse and human bone marrow cultures in the presence of low concentrations of 1,25-$(OH)_2D_3$ (10^{-10}M) or RANK ligand (2.5 ng ml) (RANKL),but did not induce significant levels of OCL formation by itself. OCLs induced in mouse marrow cultures treated with ECF-L formed increased pit numbers and resorption area per dentin slice compared to mouse cultures treated with 1,25-$(OH)_2D_3$ alone. Time course studies demonstrated that ECF-L acted at the late stages of OCL formation. Transfection of OCL precursors with an antisense construct to ECF-L inhibited OCL formation in murine marrow cultures. To further examine the role of ECF-L in osteoclastogenesis, osteoprotegerin (OPG), RANK-Fc, or a neutralizing antibody to ECF-L were added to mouse and human bone marrow cultures treated with ECF-L in the presence of 10^{-10}M 1,25$(OH)_2D_3$ or RANKL (10 ng/ml). ECF-L-induced OCL formation was significantly inhibited by OPG and RANK-Fc. Importantly, a neutralizing antibody to ECF-L blocked RANKL (50 ng/ml) or 1,25-$(OH)_2D_3$ (10^{-9}M)-induced OCL formation in mouse bone marrow cultures. RT-PCR and Western blot analyses showed that ECF-L did not enhance RANKL or RANK expression in human or mouse bone marrow cultures. Furthermore, chemotactic assays demonstrated that ECF-L was chemotactic for OCL precursors (TRAP(+) mononuclear cells), and this effect was inhibited by the anti-ECF-L antibody. Taken together, these data suggest that ECF-L is a novel chemoattractant for OCL precursors and appears to be a critical co-factor for osteoclastogenesis induced by RANKL.

M247

The Macrophage Mannose Receptor Is Required for Osteoclastogenesis. S. Wei, S. L. Teitelbaum, F. P. Ross. Pathology, Washington University School of Medicine, St. Louis, MO, USA.

The mannose receptor (MR) is a glycoprotein, which binds to and internalizes high mannose-containing macromolecules. Since the MR is expressed on osteoclast precursors in the form of bone marrow macrophages (BMMs), we examined expression and function of this molecule during OC formation. Using RT-PCR analysis of c-fms positive BMMs treated with M-CSF and RANKL, we find MR levels increase gradually during differentiation, with both RANKL and M-CSF individually enhancing expression. Since MR preferentially recognizes α-linked oligo-mannose with branched rather than linear structures, we used the branched polysaccharide mannan to examine the role of MR in osteoclastogenesis. Mannan blocks OC formation dose-dependently only during the first two days of culture, an effect reversed by withdrawal of the sugar up to five days after initial addition. A second MR inhibitor, BSA with 22 moles of mannose per mole (man-BSA) exhibits the same dose-dependent inhibitory effect on OC formation as mannan. Treatment of BMMs with either mannan or man-BSA enhances cell number, indicating that neither molecule is toxic. Suggesting that inhibitor treatment results in blunting of MR function, BMM-mediated uptake of horseradish peroxidase, an MR ligand, is significantly decreased when the cells are pre-treated with glucosidase inhibitors castanospermine (CAST) or 1-deoxynojirimycin (DNJ). Consistent with this observation, we find that, like mannan and man-BSA, both CAST and DNJ inhibit OC formation dose-dependently. To examine the role of the MR in a more physiological setting we added man-BSA or CAST to a neonatal calvaria whole organ culture treated with RANKL and find that the inhibitors decrease cytokine-induced formation of tartrate-resistant acid phosphatase positive, multinucleated cells by 96% and 99 %, respectively. In addition, we find when OCs are generated on dentin in the presence of mannan, man-BSA, CAST or DNJ, pit area/cell and % resorbing area/field are decreased by about 90% and 85%, respectively, further proving that these agents functionally inhibit osteoclastogenesis. Consistent with the observation that MR is involved in cell-cell fusion in other cell types, mannan, man-BSA and both glucosidase inhibitors dose-dependently inhibit a second form of BMM fusion, interleukin (IL)-4 induced formation of foreign body giant cells (FBGCs). Furthermore, the presence of IL-4 in cultures of BMMs treated with M-CSF and RANKL results in formation of FBGCs and not OCs. In both settings IL-4 treated cell exhibit high MR levels. Thus the MR facilitates fusion of OC precursors during osteoclastogenesis.

M248

Toll-like Receptors Modulate Differentiation and Survival of Osteoclasts. M. Takami, N. Kim*, J. Rho*, Y. Choi*. Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA, USA.

Immune responses to microbial pathogens are often triggered because various microbial components induce the maturation and activation of immunoregulatory cells such as macrophages or dendritic cells by stimulating Toll-like receptors (TLRs). Since osteoclasts arise from the same precursors as macrophages, we tested whether TLRs play any roles during osteoclast differentiation. Osteoclast precursors prepared from mouse bone marrow cells with M-CSF differentiated into osteoclasts in the presence of TNF-related activation-induced cytokine (TRANCE) and M-CSF. Osteoclast precursors expressed all known murine TLRs (TLR1-TLR9) and had capacities of zymosan-particle incorporation by phagocytosis. However, after differentiating into mature osteoclasts, phagocytic capacities were lost. Peptidoglycan (PGN), double-strand RNA [poly(I:C) RNA], lipopolysaccaride (LPS), and CpG motif of unmethylated DNA (CpG DNA), those are the ligands for TLR2, 3, 4, and 9, respectively induced NF-kB activation and upregulated TNF-alpha mRNA

expression in osteoclast precursors. TLR stimulation of osteoclast precursors by these TLR ligands strongly inhibited their differentiation into multinucleated, mature osteoclasts. Rather, TLR stimulation maintained the phagocytic capacities of osteoclast precursors. Although the intracellular signaling pathways from IL-1 receptors are quite similar to that from TLRs, IL-1 alpha did not inhibit osteoclast differentiation, suggesting that signaling molecules unique to TLR stimulation pathway play roles in the inhibition of osteoclast differentiation. On the other hand, TLR 2 and 4 were prominently expressed in mature osteoclasts. When multinucleated osteoclasts were purified and cultured in the absence of any stimuli, all osteoclasts died within 12 h. However, PGN and LPS but not poly(I:C) RNA and CpG DNA supported the survival of purified osteoclasts. Taken together, these results suggest that TLR stimulation inhibits the differentiation into non-inflammatory mature osteoclasts and simultaneously supports the survival of mature osteoclasts during microbial infection. TLRs are thus likely to regulate the balance of immune responses and bone metabolism during acute attacks of vertebrae hosts by various microbes.

M249

Osteoclastogenesis: Multinucleation Is A True Differentiation Process That Imposes A Major Molecular Stress On Macrophages. J. Zhang[1], J. Li*[2], H. Sterling*[1], G. Peet*[2], R. Barton*[2], A. Vignery[1]. [1]Yale School of Medicine, New Haven, CT, USA, [2]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT, USA.

Multinucleated osteoclasts originate from the fusion of cells that belong to the mononuclear phagocyte lineage, and are characterized by a powerful ability to resorb bone. These cells play a central role in osteoporosis and cancer. Yet, despite their potency, their differentiation mechanism remains largely unknown. To study osteoclastogenesis, our laboratory has used primary macrophages isolated from rat lungs, as these cells spontaneously fuse when plated at high density and cultured in the presence of serum (see Int J Exp Pathol 81:291, 2000). This assay has allowed us to clone MFR, and identify its ligand CD47, along with CD44 as surface molecules highly, but transiently induced at the onset of multinucleation. The present study was designed to identify the genes expressed during macrophage multinucleation using oligonucleotide microarray analysis (Affymetrix). To this end, macrophages were either freshly isolated or cultured for 1 h, 24 h or 120 h so as to identify genes expressed in response tissue culture stress, cell-cell fusion, and multinucleation, respectively. Our data revealed limited arrays of genes that were induced in a regulated manner so as to construct the resorption machinery of these cells, yet maintain their intracellular ion homeostasis. Cytokines and chemokines known to activate osteoclast differentiation and activity, such as TNF-a along with growth factors and their receptors, and extracellular matrix proteins were highly and time-dependently up regulated, suggesting auto-regulatory mechanisms and / or control of the microenvironment. The most striking and shared feature was the magnitude with which specific transcripts were up regulated during multinucleation, revealing the role of transcription factors and signaling molecules, and suggesting a high level of stress imposed on the protein synthesis machinery. This was supported by the sequentially up-regulated expression of specific chaperone molecules. This analysis has revealed multinucleation of macrophages as a true and sophisticated differentiation process, and provided important and novel targets to control osteoclastogenesis and bone resorption.

M250

Regulation of OSCAR Gene Expression by the Microphthalmia Transcription Factor. N. Kim*, H. So*, M. Takami, J. Rho*, Y. Choi*. Pathology, University of Pennsylvania School of Medicine, Philadelphia, PA, USA.

Osteoclasts are multinucleated giant cells which resorb bone and differentiated from hematopoietic cells by contact with osteoblasts/stromal cells in response to several osteotropic factors. Two essential factors, M-CSF and the tumor necrosis factor (TNF) family member TRANCE, are well known for osteoclastogenesis. In addition, other factors produced by osteoblast/stromal cells can affect differentiation of osteoclasts. We have recently reported the identification of a novel member of the leukocyte receptor OSCAR (osteoclast-associated receptor) which has two immunogloblin (Ig)-like domains. It has also shown that OSCAR may be an important bone-specific regulator of osteoclast differentiation. We report here that human OSCAR is expressed specifically in osteoclast cells and involved in the differentiation of osteoclasts from PBMC. Five different transcript forms of human OSCAR gene have been identified. To examine the regulation of OSCAR gene, we have analyzed the promoter region of OSCAR. Three PU.1, one NF-kB, and two Mitf binding sites were founded in 1.7 Kb OSCAR promoter region by sequence analysis. Spleen-derived osteoclast cells from mi/mi mutant mice showed 3-fold reduction of OSCAR gene expression compared with osteoclasts derived from normal mice. To examine whether Mitf can directly regulate OSCAR expression, we used reporter assay using the transient transfections into 293T cells with a series of OSCAR promoter constructs. When 1.7 Kb OSCAR fragment was cotransfected with the different amount of wild type Mitf, the luciferase activity was increased in a dose dependent manner, but not by Mitf dominant negative type. The activity of 1.7 Kb OSCAR promoter-reporter gene was increased to 10-fold by wild type Mitf compared with control vector. This induction was totally abolished in mutant type of E-boxes of OSCAR promoter. These results implicate that the relationship between Mitf and OSCAR may be important for osteoclastogenesis. Thus the more studies of regulations between these osteoclast-specific genes may provide a tool for therapeutic approach to treat bone diseases.

M251

RANKL-Induced Osteoclast Formation Is Associated with Upregulation of Connexin 43 Gene Expression and Decreased by a Gap Junction Blocker,Carbenoxolone. M. Ransjö, A. Lie*. Oral Cell Biology, Umeå University, Umeå, Sweden.

Gap junctions are membrane-spanning channels that faciliate intercellular communication by allowing small signaling molecules, such as calcium ions, inositol phosphates and cyclic nucleotides, pass from cell to cell. Connexins (Cx) are the proteins that form gap junctions and more than a dozen different Cx have been identified. It has earlier been demonstrated that osteoblasts are highly coupled by gap junctions formed primarily by Cx43. It is well known that osteoblasts/stromal cells stimulate osteoclast differentiation and activation through cell-cell-contacts. Receptor activator of NF-kB ligand (RANKL) is expressed as a membrane-associated factor on osteoblasts/stromal cells in response to PTH and several other bone resorbing factors. We have recently demonstrated that PTH and forskolin increase Cx43 expression in mouse bone marrow cultures and furthermore, the stimulatory effect on osteoclast recruitment is inhibited by carbenoxolone, a gap junction blocker (paper submitted). In the present study, we wanted to investigate possible interactions between RANKL and gap junction communication on osteoclast recruitment. Mouse bone marrow cells were isolated from 6-9 weeks old CsA mice and cultured for 7-8 days with or without the addition of rmRANKL and in the absence or the presence of different concentrations of carbenoxolone. RANKL (100 ng/ml) significantly increased the number of TRAP-positive multinucleated cells formed in the marrow cultures. RT-PCR analysis demonstrated an upregulation of Cx43 mRNA levels in RANKL-stimulated cultures as compared to control cultures. The expression of mRNA was analysed by semiquantitative measurements performed in the midlinear range of PCR amplification and assessed as the ratio of the optical density of the band normalized to the band of corresponding GAPDH. The gap junction blocker carbenoxolone produced a dose-dependent (10-60 uM) inhibition of the number of TRAP-positive multinucleated cells formed in response to RANKL. These data suggests that gap junction communication may be involved in osteoclastogenesis mediated by RANKL.

Expression of the bHLH Transcription Factor Stra13 Is Up-regulated During Osteoclast Differentiation. B. L. Vincent*, L. Wunderlich*, M. J. Glimcher, K. P. McHugh. Orthopaedic Research, Children's Hospital and Harvard Medical School, Boston, MA, USA.

In the course of expression profiling osteoclasts and their precursors, we have identified Stra13 as a transcription factor that is specifically up-regulated during osteoclast differentiation. Stra13 was originally identified as an induced gene during retinoic acid-dependent neuronal differentiation of P19 embryonic carcinoma cells. Overexpression of Stra13 in P19ec cells leads to expression of neuronal genes and neuronal differentiation. Recently, Stra13 has been shown to mediate inhibition of adipogenesis by hypoxia, as well as to inhibit B lymphocyte activation. Stra13 belongs to the bHLH family of transcription factors and has been shown to function as a repressor of activated transcription in several cell types. Stra13 does not bind canonical bHLH DNA binding motifs, however specific DNA sequences are required for the transcriptional repressor activities of Stra13. We show here, by qualitative RT-PCR, that Stra13 expression is up-regulated during osteoclast differentiation of primary mouse bone marrow macrophages (BMMs), as well as by osteoclastogenic clones of RAW264.7 cells. To further quantify Stra13 expression during osteoclast differentiation, we performed quantitative RT-PCR on RNAs from a time course of BMMs grown with M-CSF, as compared with RNAs from osteoclastogenic cultures grown with M-CSF plus RANKL. After culture with RANKL for 5 days, TRAP, Cathepsin-K, and β_3 integrin are at their maximum expression levels as measured by quantitative RT-PCR. We find that during osteoclastic differentiation Stra13 expression increases while decreasing in cultures grown with M-CSF alone. At 5 days, Stra13 is also expressed at its highest expression level, with a difference in Ct values of 5.25 between osteoclasts and macrophage cultures. This difference in Ct values represents a change in initial PCR target abundance of >32 fold. To demonstrate that the change in message level is reflected by expression of the Stra13 protein, we performed Western blots on osteoclasts derived from BMMs grown with M-CSF plus RANKL, as compared to BMMs grown with M-CSF alone. We find that osteoclastic differentiation enhances Stra13 protein expression. Western blots of osteoclastogenic clones of RAW264.7 cells confirm that Stra13 protein is expressed in a time dependent manner through osteoclast differentiation. In conclusion, Stra13 expression is specifically induced during osteoclastic differentiation at both the RNA message and protein levels. Stra13 may therefore play an important role in osteoclastogenesis, potentially as a transcriptional repressor of macrophage genes.

M253

Microarray, Differential Display, and Northern Analysis of Mouse Bone Cell Gene Expression Early After Cd Gavage. M. H. Bhattacharyya, A. Regunathan*, D. Glesne*. Argonne National Laboratory, Argonne, IL, USA.

We developed an in vivo model for Cd-induced bone loss in which mice excrete bone mineral in feces starting 8 h after Cd gavage. Female mice of 3 strains [CF1; metallothionein-wildtype (MT+); MT1,2-deficient (MT-)] were placed on a low Ca diet for 2 weeks. Each mouse was gavaged with 200 µg Cd or vehicle only. Fecal Ca was monitored daily for 8 days, starting 3 days before Cd gavage, to document the bone response. For CF1 mice, bones were taken from 4 groups: +/- Cd, 2h after Cd; +/- Cd, 4h after Cd. MT+ and MT- strains had 2 groups each: +/-Cd, 4 h after Cd. PolyA RNA was isolated from marrow-free shafts of femura and tibiae, and RNA from each +/- Cd pair was submitted to Incyte Genomics for microarray analysis. To validate the microarray results, the same polyA RNA preparations were subjected to Northern analysis; probes were prepared from 18 clones of genes shown by microarray to be key to the bone response to Cd. Other RNA samples (4 h +/- Cd) were subjected to conventional DDRT-PCR. Fecal Ca results show that the 3 mouse strains differed in amount of bone Ca excreted after Cd (CF1 0.24+0.08 mg; MT+ 0.92+0.22 mg; MT- 1.7+0.4 mg). Differential display results show that 4 cloned bands had Cd down-regulation confirmed by Northern analysis; 2 of the 4 were mitochondrial. One other clone (12-5) displayed 98% identity to integrin linked kinase (Ilk) mRNA; the other was 74% identical to 2 mouse cDNAs of unknown function. Gene microarray results show that nearly all ~8500 arrayed mouse genes were unaffected by Cd. However, MT1 and MT2 had +Cd/-Cd expression ratios >1 in all four groups, while all ratios for MT3 were essentially '1', showing specificity. Both probes for MAPK 14 (p38 MAPK) had expression ratios >1, while no other MAPK responded to Cd. Other genes stimulated by Cd were: vacuolar proton pump ATPase and integrin alpha v (osteoclast genes), transferrin receptor (iron deficiency?), src-like adaptor protein, and two hypothetical proteins. Genes down-regulated by Cd included procollagen type IX and a gene of unknown function. Our validation by Northern analysis included genes expected by microarray results to increase, decrease, or show no change in response to Cd. Results clearly confirmed the above microarray results for all genes except two whose expression levels were too low to effectively quantitate changes by Northern analysis. Recent results in the literature demonstrate that p38 MAPK plays a central role in osteoclast differentiation (Matsumoto et al, JBC, 275:31155-61, 2000; Karsdal et al, JBC, 276:39350-8, 2001, Lee et al, Bone, 30:71-77, 2002). Our results support the hypothesis that Cd stimulates bone demineralization via a p38 MAPK pathway leading to increases in osteoclast-mediated bone resorption.

M254

Runx Factors are Expressed in the Osteoclast and Regulated During Osteoclast Differentiation. Z. Bar-Shavit[1], H. Drissi*[2], A. Javed[2], J. Ribadeneyra*[2], A. J. van Wijnen[2], J. L. Stein*[2], J. B. Lian[2], G. S. Stein[2]. [1]Hebrew University Faculty of Medicine, Jerusalem, Israel, [2]Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA.

Runx factors are obligatory for cellular differentiation. While Runx2 is essential for osteogenesis, Runx1 is required for hematopoiesis. Osteoclasts originate from the hematopoietic lineage. Furthermore, Runx2 increases osteoprotegerin (OPG), an inhibitor of osteoclast differentiation, suggesting that Runx factors may be involved in osteoclast activities. Given the overlap in expression between Runx1 and Runx2 in hematopoietic lineage cells, we addressed whether osteoclasts express Runx factors and if their expression is modulated during osteoclastogenesis. Osteoclast differentiation in vitro was studied using the macrophage like cell line RAW 264.7 (treated with RANKL) and bone marrow mononuclear cells from Balb/c mice (treated with RANKL and M-CSF). At selected times over a 7 day culture period, we examined Runx1 and Runx2 mRNA levels by RT-PCR, protein by in situ immunofluorescence, and DNA-binding activity by EMSA (competition studies and antibody supershift). At the single cell level, using specific antibodies, we observe Runx1 and Runx2 protein in both mononuclear precursors and multinucleated cells. Both Runx factors and the p50 subunit of the NF-κB transcription factor are organized in distinct nuclear domains in all osteoclast nuclei. BrUTP labeling and RNA polymerase II immunoreactivity established that all osteoclasts are transcriptionally active. Expression of Runx factors in mononuclear cells did not change throughout the culture period, while nuclei of osteoclasts exhibited fewer punctate foci by conventional and confocal fluorescence microscopy. TNFα treatment of the osteoclasts resulted in a marked reduction of Runx2 in nuclei. In contrast, transcription factor NF-κB was strikingly increased in osteoclast nuclei in response to TNFα . Expression of Runx proteins was also revealed by gel shift assays. These findings indicate that Runx proteins are present in nuclei of osteoclast lineage cells, form functional DNA binding complexes, and may contribute to the regulation of osteoclast differentiation and/or activity.

M255

The Effects of Pasteurella Multocida Toxin on Osteoclast Differentiation and Activity. D. Harmey[1], G. Stenbeck*[2], A. Lax*[3], A. E. Grigoriadis[1]. [1]Craniofacial Development, King's College London, London, United Kingdom, [2]Bone and Mineral Centre, UCL, London, United Kingdom, [3]Oral Microbiology, King's College London, London, United Kingdom.

Pasteurella multocida toxin (PMT) is a bacterially-produced toxin that causes the porcine bone resorbing disease, atrophic rhinitis. PMT is a potent mitogen and stimulates phospholipase C leading to activation of protein kinase C, and increases in inositol phosphates and intracellular calcium. PMT also induces actin rearrangements via the small GTPase Rho. The mechanisms by which PMT affects bone remodelling are unknown, although we have recently shown that PMT inhibits osteoblast differentiation and gene expression, in part, via a pathway involving Rho and Rho kinase. Here, we aim to determine the effects of PMT on osteoclast differentiation and activity. In co-cultures of primary mouse calvarial osteoblasts (MC) with bone marrow cells, PMT inhibited the number of TRAP-positive multinucleated cells in a dose-dependent manner, with a concomitant decrease in resorption. PMT also affected the morphology of the TRAP-positive mono- and multinucleated cells that formed, inducing a contracted cell morphology. 24h pre-treatment of either the osteoblasts or the haematopoietic cells with PMT prior to co-culture, caused a significant inhibition of TRAP-positive cell number and resorption, suggesting that PMT exerts its inhibitory effects via both populations. To determine the possible mechanism of inhibition, we performed RT-PCR analysis of RANKL and OPG expression. In MC cells PMT caused a decrease in RANKL expression with a concomitant increase in OPG levels. Moreover, addition of exogenous RANKL to PMT-treated cultures partially rescued the block in osteoclast differentiation, suggesting that the effects on osteoblast-mediated osteoclastogenesis are partially mediated by altered RANKL/OPG levels. PMT also dose-dependently inhibited osteoclast differentiation and resorption in stroma-free cultures containing RANKL and M-CSF, and also induced cell contraction. Pulse experiments showed that a 3d pulse at the start of the culture period was sufficient to significantly inhibit differentiation. However, in contrast to differentiation cultures, PMT treatment of mature primary osteoclasts did not significantly inhibit resorption. Surprisingly, preliminary results indicate that PMT disrupted actin ring formation without a parallel decrease in resorption. Taken together, these results demonstrate that PMT inhibits osteoclast differentiation via independent effects on stromal cells and haematopoietic precursors, and causes cytoskeletal changes in primary osteoclasts.

M256

Osteoclastic Differentiation in Primary Mouse Bone Marrow Cultures Is Affected by Addition of Cystatin C. M. Brage*[1], A. Grubb*[2], U. H. Lerner[3]. [1]Oral Cell Biology, Umeå University, Umeå, Sweden, [2]Dept Clinical Chemistry, University of Lund, Lund, Sweden, [3]Dept Oral Cell Biology, Umeå University, Umeå, Sweden.

Osteoclastic bone resorption is dependent on the activity of proteolytic enzymes, among which the cysteine protease chathepsin K has been shown to play a key role in bone matrix degradation. We have previously reported that cystatin C, an inhibitor of papain-like cysteine proteases, inhibits bone resorption in mouse calvariae primarily by inhibiting degradation of bone matrix proteines. This effect is also gained by using a peptide, Arg8-Leu9-Val 10-Gly 11 (RLVG), mimicking part of the cystatin C N-terminal end that binds to the active cleft of cysteine proteinases. We have also reported that not only the activity, but also the formation of osteoclasts is inhibited by addition of cystatin C and Arg8-Leu9-Val10-Gly11. Furthermore, PTH and D3 stimulated osteoclast formation is inhibited also by addition of leupeptin and E64. The present study aims to further elucidate the inhibitory effect of cystatin C on osteoclastic differentiation. In 9 days mouse bone marrow cultures stimulated by PTH and stained for TRAP, the increased number of multinucleated TRAP positive cells caused by PTH treatment was reduced to 40-60% by addition of cystatin C or OPG. The number of osteoclasts was reduced to 90-100% by addition of cystatin C and OPG in combination. The inhibitory effect of cystatin C was found to be exerted at day 4 of culturing. The mRNA expression of OPG was reduced by PTH after 9 days and this reduction was abolished by cystatin C. PTH also reduced the expression of c-fms after both 2 and 9 days and addition of cystatin C abolished PTH-induced down regulation of c-fms. The macrophage cell surface molecule F4/80 was highly expressed in untreated bone marrow cells. PTH treatment totally reduced F4/80 cell population. Addition of cystatin C, together with PTH, abolished this reduction and even increased the number of F4/80 cells. PTH + OPG treated cells were F4/80 negative, whereas PTH + OPG + cystatin C resulted in a great amount of F4/80 positive cells. These data together indicate that the effect of cystatin C on osteoclastogenesis may partly be explained by increased levels of OPG but that other mechanisms also contribute. The CD14 positive OC precursors might, while treated with cystatin C, persist as, and develop towards, macrophages at a specific differentiation stage at day 4 during PTH stimulation.

CamKII Regulates Osteoclastogenesis. L. Zhang*, J. M. McDonald. Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Previous work in our laboratory has demonstrated that calmodulin plays an important role in regulating the function of mature osteoclasts. In the present study, we explored the hypothesis that calmodulin is involved in osteoclastogenesis. Mice bone marrow monocytes were isolated and then cultured in the presence of RANKL and M-CSF. Calmodulin antagonists TFP (trifluoperazine), W7 and tamoxifen were added either on the first day or on the fourth day of culturing, then cells were fixed and cytochemically stained for TRAP activity on the fifth day of culturing. Meanwhile, cell lysates from parallel culture plates were obtained to measure TRAP activity in solution. All calmodulin antagonists dose-dependently inhibit osteoclast formation only when added on day 4 but not when added on day 1. IC50s for TFP, W7 and TMX are 3 µM, 5 µM and 1 µM respectively. Inhibition reached 60% for 3 µM TFP, 90% for 10 µM W7 and 80% for 3 µM TMX. These data suggests that calmodulin plays a role in the late stage of pre-osteoclast fusion, resulting in a dramatic reduction of osteoclast formation. To further identify downstream members of the calmodulin signaling pathway that regulate pre-osteoclast fusion, we have treated the cells with cyclosporin A, a specific inhibitor of the calmodulin dependent phosphatase, calcineurin, or KN93, a specific inhibitor for calmodulin kinase II (CamKII). KN93, but not cyclosporin A, inhibited osteoclast formation with an IC50 of ~1 µM (80% maximum inhibition obtained at 2 µM), indicating that CamKII but not calcineurin is involved in the formation of osteoclasts. Studies with a permeable caspase inhibitor, and TUNEL assays showed that apoptosis is not responsible for the action of TFP or KN93 on osteoclast formation. Preliminary electrophoretic mobility shift assays show that KN93 but not TFP blocks RANKL-stimulated NFκB activity. Taken together, our data indicate that CamKII mediates the preosteoclast fusion process, which is a key step in forming multinucleated mature osteoclasts.

M258

M-CSF: Its Role as an Osteoclast Differentiation Factor. R. Faccio[1], J. Chappel*[2], A. Zallone[3], F. P. Ross[2], S. L. Teitelbaum[2]. [1]Human Anatomy, University of Bari, Italy, and Pathology, Washington University, St. Louis, MO, USA, [2]Pathology, Washington University, St. Louis, MO, USA, [3]Human Anatomy, University of Bari, Bari, Italy.

ERK plays an important role in the proliferation of osteoclast (OC) precursors and survival of the mature cells. In this report we show that M-CSF induced ERK signaling, which activates RSK and upregulates c-fos, is also required for OC differentiation. These experiments took advantage of our observation that bone marrow macrophages (BMMs) derived from β_3 integrin knockout mice fail to differentiate into multinucleated OCs in the presence of a concentration (25 ng/ml) of M-CSF which promotes osteoclastogenesis in WT cells. In this study we show that the failure of M-CSF to induce osteoclastogenesis in β3-/- cells is correlated with attenuation of ERK phosphorylation, RSK activation and c-fos expression. Interestingly, high dose M-CSF (100 ng/ml) that rescues β3-/- OC formation, also nomalizes ERK and RSK activation and c-fos expression. Using the ERK inhibitor UO126 we find the ERK signal is required between day 2-3 of OC differentiation. Inhibition of ERK signaling within this time frame, reduces the number of TRAP positive cells by 50%. We next turned to the mechanisms of M-CSF activation of ERK in OC precursors. While M-CSF activates Ras/Raf1, such activation persists for only 15 min. On the other hand, Rap1 and B-Raf activation, which we demonstrate for the first time in OC precursors, mirrors the prolonged ERK phosphorylation, induced by M-CSF, being maintained for at least 2 hrs following cytokine exposure. In contrast to the profound effect of M-CSF on ERK activation, RANKL is a weak agonist. Since c-fos is activated by a prolonged ERK signalling and is required for osteoclastogenesis, we turned to its regulation by M-CSF or RANKL. We find that while M-CSF, alone, has little effect on c-fos expression by BMMs, the level of the proto-oncogene gradually increases during osteoclastogenesis. Interestingly, we find that pre-treatment with RANKL for minimal of 2 hours is indispensable to lead maximal c-fos expression in response to M-CSF alone. In fact RANKL itself is not sufficient to induce c-fos expression in BMMs or OCs. Thus, ERK induction during OC differentiation is principally a product of M-CSF signaling. On the other hand M-CSF maximal induction of c-fos, an event essential to the osteoclastogenic process, requires previous incubation with RANKL. Importantly, these data provide the first insights into the mechanism by which M-CSF promotes OC differentiation.

M259

Anti-SIRPα Inhibits Osteoclastogenesis in Human Osteoclast Progenitors. R. Faccio, F. P. Ross, M. Colonna*, S. L. Teitelbaum, D. V. Novack. Pathology, Washington University, St. Louis, MO, USA.

In the last few years, protocols to obtain human osteoclasts (hOC) from peripheral blood have been developed, but these require long and somewhat variable culture times to obtain mature cells. In this study we used hOC derived from primary human precursors (Cambrex product Poietics # 2T-110), which differentiate into mature bone-resorbing osteoclasts within seven days in the presence of M-CSF and RANKL, with addition of TGFβ during the last four days of the culture. As we have previously observed in OCs derived from other human and murine sources, mature hOCs derived from the Cambrex precursors are TRAP positive and express αvβ3 integrin in the podosome. When plated on dentin slices or an artificial mineral matrix, they show resorptive capabilities. We next examined the signaling capacity of the progenitor cells in response to RANKL stimulation. We found an increase in ERK and JNK phosphorylation, IκBα degradation and NF-κB DNA binding, with a similar timecourse to murine cells. Having established that these hOCs represent a robust model system, we examined the expression of several transmembrane receptors previously found on monocytes. The ILT (Ig-like transcript) family is characterized by 2 or 4 Ig-like extracellular domains. ILT's 2, 3, and 8 are members of a subset with cytoplasmic tails containing ITIMs (immunoreceptor tyrosine-based inhibitory motifs), and can inhibit cell activation via recruitment of phosphatases. ILT2 binds a subset of MHC class I molecules, while the substrates for ILT 3 and 8 are unknown. Signal-regulatory protein α (SIRPα) is a similar transmembrane protein with extracellular Ig-like domains, and a cytoplasmic ITIM. Antibodies to these proteins are available with human, but not murine, specificity. Immunofluorescent staining of hOCs was analyzed by confocal microscopy. ILT2 was expressed more highly on mononuclear cells than on mature hOCs, with a membrane staining pattern. ILT3 and SIRPα showed strong membrane staining in mature hOCs. ILT8 appeared to be intracellular, with a perinuclear distribution. We next attempted to determine whether these proteins modulate osteoclastogenesis by adding supernatants containing antibodies to these proteins, or an Ig control, to hOC cultures at days 0, 2, and 4. Compared to Ig control, only anti- SIRPα had any effect, blocking osteoclastogenesis almost completely. Anti- SIRPα treated cultures fixed and TRAP-stained at day 7 contained no spread multinucleated OCs, and only rare mononuclear TRAP positive cells (<2%). Previous reports have proposed a role for SIRPα as a fusion factor, but the effect of the blocking antibody suggests a more fundamental role at earlier stages of OC differentiation.

M260

RANKL Stimulates iNOS and NO Production in Developing Osteoclasts via NF-kB: An Autocrine Negative Feedback Mechanism to Regulate Osteoclastogenesis and Bone Resorption. H. Zheng, X. Yu, P. Collin-Osdoby, P. Osdoby. Department of Biology, Washington University, St. Louis, MO, USA.

RANKL is the key signal required for the full development, activation, and survival of resorptive osteoclasts (OC), via pathways involving NF-kB activation. Nitric oxide (NO) potently inhibits, while inhibitors of NO production stimulate, OC differentiation and bone resorption both in vivo and in vitro. During studies to examine RANKL-mediated OC formation (RAW-OC) from murine RAW 264.7 cell precursors, we discovered that NO levels (reflected in medium nitrite) became elevated. Thus, RANKL (35 ng/ml) elicited the in vitro development of multinucleated TRAP+ bone pit-resorptive RAW-OC that expressed mRNA for TRAP, MMP-9, cathepsin K, and calcitonin receptor. Concurrently, RANKL stimulated NO release and iNOS mRNA expression in RAW cells in a dose- and time-dependent manner, and these increases were sustained throughout the differentiation of RAW cells into RAW-OC. We therefore examined if autocrine NO production induced by RANKL in differentiating RAW cells had an inhibitory influence on OC formation or function. Aminoguanidine (AG) and L-NIL, selective inhibitors of iNOS-mediated NO release, each blocked RANKL-induced NO rises in the RAW cells and significantly enhanced the differentiation and fusion of RAW cells into TRAP+ multinucleated bone-resorptive RAW-OCs. Consistent with this, RANKL-mediated developmental increases in MMP-9, TRAP, cathepsin K and calcitonin receptor mRNA expression were further raised by L-NIL. Most importantly, bone pit resorption by RAW-OC was significantly potentiated if AG or L-NIL was present during their RANKL-mediated differentiation. Similar results were obtained with primary isolated murine bone marrow cells (MA). Thus, RANKL significantly increased iNOS mRNA expression and NO production throughout the differentiation of MA into TRAP+ multinucleated bone-resorptive OC, and L-NIL augmented bone pit resorption by OC during their RANKL-induced formation in vitro from MA. NF-kB activation was implicated in the signaling pathways by which RANKL both stimulated RAW-OC formation and induced iNOS mRNA and NO production because PDTC, a specific NF-kB inhibitor, blocked each of these RANKL-induced responses. Our results have therefore revealed that a novel mechanism through which NOS inhibitors promote OC differentiation and bone resorption involves their suppression of RANKL induced iNOS-derived NO. RANKL stimulated NF-kB dependent NO production therefore serves as an autocrine negative feedback regulatory signal to buffer osteoclastogenesis and bone resorption.

M261

Hyperlipidemia Enhances Osteoclastic Potential of Bone-Marrow Preosteoclasts. Y. Tintut*[1], B. Saedi*[1], T. Saini*[1], S. Arias-Magaloona*[1], F. Parhami[1], L. L. Demer*[2]. [1]Medicine, UCLA, Los Angeles, CA, USA, [2]Medicine & Physiology, UCLA, Los Angeles, CA, USA.

Emerging evidence suggests that lipid oxidation products, which are increased in tissues of hyperlipidemic subjects, play a role in both vascular calcification and osteoporosis. We previously found that lipid oxidation products have a paradoxical role in vascular and bone tissues: enhancing osteoblastic differentiation in vascular cells but inhibiting osteoblastic differentiation in bone marrow stromal cells as well as preosteoblasts in vitro. In addition, mice fed an atherogenic high fat diet have lower bone density than mice fed a normal chow diet. It is not known whether the decreased bone density was due to decreased osteoblastic function and/or increased osteoclastic function. We recently found that lipid oxidation products enhance osteoclastic potential of bone-marrow preosteoclasts in vitro. In this study, we determined whether hyperlipidemia enhances osteoclastic potential ex vivo. Osteoclastic function was determined in bone marrow preosteoclasts isolated from 1 year-old normolipemic (C57BL/6) and hyperlipidemic (low density lipoprotein receptor (LDLR) null) mice. The non-adherent bone marrow preosteoclasts were cultured in the presence of M-CSF (25 ng/ml) and RANKL (40 ng/ml), and TRAP and resorption assays were determined at 5 and 7 days, respectively. Results showed that LDLR null mice, which had higher triglyceride and total cholesterol levels, had a 3-fold increase in the number of TRAP positive cells and a 6-fold increase in the number of resorption pits compared to those of wild-type C57BL/6 mice. In additional experiments, preosteoclasts from bone marrow cells of LDLR null mice that were fed a high fat diet (which also causes aortic calcification) had increased numbers of TRAP positive cells and increased resorption pits compared with those of C57BL/6 mice. These results suggest that preosteoclasts from hyperlipidemic mice have higher osteoclastic potential than those of normolipemic mice supporting the hypothesis that hyperlipidemia may contribute to osteoporosis.

M262

TWEAK, a Novel TNF Homolog, Induces Osteoclast Differentiation of RAW264.7 Cells. T. C. Polek*, K. Ashikawa*, M. Talpaz*, B. G. Darnay, T. Spivak-Kroizman*. Bioimmunotherapy, U.T. M.D. Anderson Cancer Center, Houston, TX, USA.

TWEAK (TNF-like WEAK inducer of apoptosis) is a new member of the TNF family that has been shown to induce apoptosis in a limited number of cell lines and was implicated in angiogenesis. We describe herein a potential novel function for TWEAK as an osteoclastic factor. We demonstrate that a glutathione-S-transferase (GST)-fusion protein, GST-TWEAK, but not GST alone, induces the differentiation of RAW264.7 cells into large, multinuclear, TRAP positive osteoclasts within four days. RAW cells, a mouse monocyte/macrophage cell line, are often used as a model system to study osteoclastogenesis in response to receptor activator of NF-kB ligand (RANKL), a major osteoclastic factor. Like RANKL, TWEAK induces the differentiation of RAW cells into functional osteoclasts as determined by their ability to resorb an artificial bone matrix. TWEAK-induced differentiation and bone resorption activities are specific, since osteoprotegerin (OPG), a decoy receptor for RANKL, fails to block TWEAK action. Moreover, antagonistic anti-RANKL antibodies had no effect on TWEAK-induced osteoclast formation. TWEAK was less efficient than RANKL in inducing osteoclast differentiation of RAW cells, with its maximal activity reaching about 80% of RANKL activity. Interestingly, TWEAK and RANKL exhibited additive and not synergistic osteoclastic effects when used in combination, suggesting that they both utilize similar signaling pathways. RANKL-induced differentiation of RAW cells involves activation of the NF-kB, ERK1/2, and JNK signaling pathways. We demonstrate that like RANKL, TWEAK also activates these pathways in RAW cells. Using electromobility shift assays, we show that TWEAK induces the binding of the p50/p65 NF-kB heterodimer to DNA. NF-kB activation was accompanied by degradation of its inhibitor, I-kB. Furthermore, we show that TWEAK stimulates the phosphorylation of ERK1/2 and activates JNK in RAW cells. The ability of TWEAK to induce osteoclast differentiation of RAW cells may open new avenues for understanding processes controlling bone homeostasis and pathogenesis.

M263

Microphthalamia Transcription Factor Protein Expression Is Modulated by RANKL in Fusing Osteoclast Precursors. N. Dowland*, K. N. Weilbaecher. Internal Medicine, Washington University School of Medicine, St. Louis, MO, USA.

Microphthalmia transcription factor (Mitf) is a helix-loop-helix factor that plays a critical role in osteoclast(OC) development and fusion. Mitf mutant mice develop osteopetrosis secondary to non-functioning immature mononuclear tartrate resistant acid phosphatase (TRAP) positive osteoclasts. To characterize the regulation of Mitf expression in osteoclasts, we induced osteoclast differentiation using primary bone marrow macrophages stimulated with RANKL and M-CSF. On Day 0, osteoclast precursors are mononuclear and do not express TRAP. Mononuclear TRAP + precursors appear at day 1, by days 2 and 3 in culture the TRAP+ OC precursors begin to fuse and by day 4 large, spread, highly multinucleated osteoclasts develop. Using this primary cell system, we found that Mitf mRNA transcript levels are similar in macrophages and throughout all stages of osteoclast development; however Mitf protein levels were highest in fusing osteoclasts. We found that RANKL stimulation, which plays a critical role in osteoclast fusion, induced a rapid induction of Mitf protein in fusing osteoclasts (days 2 and 3) but not earlier at days 0 and 1. After RANKL stimulation of day 2 and 3 fusing osteoclasts, Mitf protein levels increased within 5 minutes and peak at 30 minutes. We have previously shown that Mitf is rapidly phosphorylated by ERK upon M-CSF stimulation of osteoclasts and that this ERK-mediated Mitf phosphorylation enhances osteoclast fusion. It has been also been shown that ERK mediated Mitf phosphorylation couples Mitf transactivation to proteasome-mediated degradation. Here we demonstrated that blockade of ERK activity by MEK inhibition did not prevent RANKL induction of Mitf levels. Thus, we find that RANKL induces a rapid increase in Mitf protein at a stage of osteoclast differentiation when mononuclear TRAP + osteoclast precursors are fusing. RANKL mediated induction of Mitf protein is not dependent on ERK mediated phosphorylation Mitf. We conclude that the stage specific induction of Mitf protein represents one mechanism by which RANKL could affect osteoclastogenesis.

Effect of PPAR-Agonist on Bone Metabolism. L. Thommesen*[1], B. Theimann*[2], U. Syversen*[3]. [1]Institute of Physiology and Bioengineering Techniques, Norwegian University of Science and Technology, Trondheim, Norway, [2]Faculty of Medicine, Norwegian University of Science and Technology, Trondheim, Norway, [3]Institute of Intraabdominal diseases, Norwegian University of Science and Technology, Trondheim, Norway.

PPARs are nuclear transcription factors controlling the expression of genes involved in lipid homeostasis. PPARs activate transcription in response to a variety of compounds, including fatty acids and hypolipidemic drugs (e.g. Wyeth 14643 and ciprofibrate). We have recently shown that the PPAR-alpha agonist Wyeth 14643 increases bone mineral density (BMD) in female rats. Furthermore, previous studies indicate that supplementation with gamma-linoleic acid and EPA that are natural ligands for PPARs, has a beneficial effect on BMD in elderly patients with osteoporosis. In order to examine if the in vivo effect of PPAR agonists was related to an interference with osteoclast differentiation, we incubated human peripheral blood mononuclear cells (PBMC) with Wyeth 14643, ciprofibrate, gamma-linoleic acid and EPA in addition to osteoclast differentiating factors, RANK-L, MCSF and dexametazone. We found that Wyeth 14643 and ciprofibrate at a concentration of 50 uM reduced osteoclast differentiation by 40 - 50% compared to control. Wyeth 14643 and ciprofibrate also inhibited proliferation of the preosteoclast cell line RAW 264.7 in a dose-dependent manner. A potential cytotoxic effect was measured with MTT-assay, revealing a 20% reduction with the highest concentration used. Generation of osteoclasts from PBMC was inhibited in a dose-dependent manner upon stimulation with gamma-linolenic acid, linoleic acid or EPA. A concentration of 50 uM resulted in 60 -70% reduction of osteoclasts. Gamma-linolenic acid and EPA also increased proliferation of the murine osteoblast cell line MC3T3-E1 in a dose-dependent manner. In conclusion, these studies indicate that Wyeth 14643- and fatty acid-induced increase of BMD may be caused by reduced osteoclastogenesis, mediated by apoptotic and /or anti-proliferative effects on osteoclasts and preosteoclasts.

Src Kinase Activity Is Involved in Osteoclastic Bone Resorption, but Not Their Survival. T. Miyazaki[1], A. Sanjay[1], L. Neff[1], S. Tanaka[2], W. C. Horne[1], R. Baron[1]. [1]Yale University, New Haven, CT, USA, [2]The University of Tokyo, Tokyo, Japan.

It has been reported that the kinase activity of Src is not important for osteoclastic bone resorption and that, in contrast, Akt activation mediated by c-Src kinase is important for osteoclast survival by RANKL. To further examine the role of Src kinase in these two regulatory events of osteoclast function, we constructed an adenovirus carrying kinase-dead Src (Src KD). Src KD was expressed in infected osteoclast-like cells (OCLs) in a dose-dependent manner. Src KD-OCLs do not display the typical rounded appearance of non-infected OCLs, and actin ring formation is disrupted in >90% of Src KD -OCLs. This morphology of Src KD-OCLs is similar to that of Src-/- OCLs. In addition, pit-forming activity was also severely inhibited in proportion to the expression level of Src KD protein. Since the autophosphorylation of Src promotes the adaptation of the fully open active conformation, the SrcKD might not be an effective adaptor, preventing us from concluding whether it is the open conformation or the kinase activity of Src that are required. To rule out this possibility, OCLs were co-infected with AxSrcKD and AxCskKD, which prevents the phosphorylation of the negative regulatory Y527 preventing the closed conformation of Src and promoting the availability of the SH2 and SH3 domains to bind other proteins. Phosphorylation of Tyr-527 in OCLs co-infected with SrcKD and CskKD was decreased to the level seen in the cells infected with CskKD only. The inhibitory effect of AxSrcKD on osteoclast function was not reversed by co-infection with AxCskKD, confirming that c-Src kinase activity, together with the adaptor function of Src, is indispensable for osteoclastic bone resorption., Next, we investigated the role of Src kinase activity in osteoclast survival. Recently, Akt activation mediated by c-Src kinase was reported to be important for RANKL-induced osteoclast survival. On the other hand, it has also been reported that it is the Ras/ERK signaling pathway that is responsible for osteoclast survival, since dominant negative Ras overexpression rapidly induced the apoptosis of OCLs, whereas ERK activation by constitutively active MEK1 (MEKCA) lengthened their survival. To examine the role of c-Src in regulating osteoclast survival, we co-infected OCLs with AxMEKCA and either AxSrcKD, AxCskWT, or AxCskKD. Neither SrcKD, CskWT, nor CskKD had any effect on the survival of OCLs infected with or without AxMEKCA. Interestingly, MEKCA overexpression led to prolonged survival of OCLs infected with AxSrcKD or AxCskWT. These results indicate that c-Src kinase activity is important for cytoskeletal organization and bone-resorbing activity of OCLs, but not for their survival.

The Effect of Gu-Sui-Bu (Drynaria fortunei) on Bone Cell Activity: A Preliminary Study. G. I. Anderson[1], J. Sun*[2], B. L. Theriault*[1]. [1]Surgery/Biomedical Engineering, Dalhousie University, Halifax, NS, Canada, [2]Orthopedics, University of Taipei, Taiwan, Taiwan Republic of China.

Gu-Sui-Bu (Drynaria fortunei), a traditional Chinese herbal remedy, has been widely used as a therapeutic agent for bone disorders. Given the recent popularity of natural products and their increasing use by the Western population, there is concern about the potential toxicity of these herbal medicines, as well as interest in their mechanism(s) of action. In this study, we investigated the biological effects of Gu-Sui-Bu using in vitro bone cell cultures, to investigate a potential mechanism of action. In vitro cell culture – Rabbit osteoclasts and osteoblasts were isolated and cultured with five different concentrations of Gu-Sui-Bu (0.001, 0.01, 0.1, 1, 10 mg/mL) extract. Tartrate-Resistant Acid Phosphatase (TRAP) positive cell counts, and quantitation of osteoclast resorption pits on bovine bone slices were performed. Alkaline Phosphatase (AP) positive cell counts and mineralized nodule formation were established in osteoblast cultures. Mouse osteoclasts were isolated from marrow of long bones and cultured in the same conditions, with determination of TRAP+ multinucleated osteoclast counts and resorption pit formation. Determination of cellular mediators – Osteoclast precursors were harvested from the marrow of mouse long bones and cultured with identical extract doses. Levels of PGE2, M-CSF, OPG and RANKL were evaluated on days 1, 4, 6 and 8 of culture using Enzyme-Linked Immunosorbent Assays (ELISAs). Rabbit and mouse osteoclasts showed an increase in number and size of resorption pits as well as formation of TRAP+ multinucleated osteoclasts over time when treated with the lowest dose of extract (0.001 mg/mL). Rabbit osteoblasts did not show any significant change in number of AP+ colonies or mineralized nodule formation at low doses but were inhibited by 0.1 mg/mL or higher. The highest dose (10mg/mL) inhibited proliferation of all cell types. At lower doses of extract (0.01 and 0.001mg/mL) cultures exhibited increases in RANKL during the culture period. However, OPG levels did not increase at these doses but did at doses >/= 0.1 mg/mL. The higher extract treatment (10mg/mL) produced a marked decrease in PGE2, RANKL and OPG levels, while M-CSF secretion increased. Lower doses of Gu-Sui-Bu have positive effects on osteoclast proliferation, survival and resorptive activity that are possibly mediated by stimulatory action via the RANKL/OPG pathway, and possibly through prostaglandin secretion, while higher doses are potentially detrimental to osteoclast survival. High doses are also effective inhibitors of AP+ cell and bone nodule formation.

Vav1 and Vav 3 Differentially Impact Osteoclast Formation and Function. R. Faccio[1], W. Swat*[2], M. W. H. Wang[2], A. Zallone[3], S. L. Teitelbaum[2], F. P. Ross[2]. [1]Human Anatomy, University of Bari, Italy, and Pathology, Washington University, St. Louis, MO, USA, [2]Pathology, Washington University, St. Louis, MO, USA, [3]Human Anatomy, University of Bari, Bari, Italy.

Osteoclasts (OCs) are motile cells, which must attach to bone and polarize before degrading the matrix. While many signals mediate cell migration, adhesion and polarization, one potential common pathway involves the small GTPase, RhoA, a regulator of cell motility, podosome formation and cytoskeletal re-organization. Activation of RhoA, in turn, is controlled by the Vav family of proteins. By histomorphometric analysis of long bones, Vav1-/- trabecular bone volume (BV/TV) is slightly increased about 38% ($p<.05$). In contrast Vav3-/- BV/TV is enhanced 270% ($p<.01$) and that of mice lacking both Vavs, 340% ($p<.01$). Moreover, radiographic analysis of tibia obtained from same age and sex matched mice confirms the increased trabecular bone of Vav3-/- and Vav1/Vav3 null animals. Despite data in Hela cells regarding the capacity of Vav3 to regulate cell division, M-CSF dependent proliferation of Vav1, Vav3 and Vav1/Vav3 null OC precursors, i.e. bone marrow macrophages (BMMs), is comparable to WT cells from 25ng/ml to 100ng/ml M-CSF. To test the hypothesis that OC formation and/or function are suppressed in mice lacking Vav1 and/or Vav3, we incubated BMMs with RANKL and M-CSF. While the rate of Vav1-/- osteoclastogenesis is delayed approximately 2 days, TRAP positive polykaryons appear by day 5 and function as normal OCs. In contrast, those OCs generated from Vav3 or Vav1/Vav3 null mice have a strikingly abnormal phenotype in that they are smaller, irregular and less spread. Confocal analysis of cells lacking Vav3 or both Vavs reveals dramatic changes in cytoskeletal organization, with failure to form regular actin rings at the cell periphery. Instead, actin is present in clusters of podosome-like structures widely distributed on the cell membrane. As a consequence of the aberrant cytoskeleton, OCs generated from Vav3 and Vav1/3 precursors fail to resorb mineralized matrix or generate pits on dentine slides. Importantly, retroviral transduction of Vav3 completely rescues the morphology and resorptive defect of both Vav3 and Vav1/Vav3 null OCs. Thus, Vav1 and Vav3 differentially impact the OC. Specifically, Vav 1 regulates the rate of OC differentiation and Vav3 the morphology and function of the cell.

Development of a Novel Osteoclast Culture System Using Mouse Mandibular Body. N. Suda, Y. Kitahara*, T. Kuroda*, K. Ohyama*. Maxillofacial Orthognathics, Tokyo Medical and Dental University, Tokyo, Japan.

Mouse bone marrow cell culture, and co-culture of hematopoietic and stromal cells are highly reproducible and widely-used systems to generate osteoclastic cells, in vitro. It is known that osteotropic hormones or growth factors are required for osteoclast formation in these culture systems. Previously, we have reported that high expression of RANKL in dental follicle cells as well as osteoblasts lining on the alveolar bone surface. In addition, we have shown that the organ culture system of mouse tooth germ with surrounding tissues (dental follicle and mandibular alveolar bone) can generate TRAP-positive multinucleated osteoclastic cells without the addition of serum or any additives to the culture. These results suggest that developing mouse tooth germ and its surrounding tissues create a local environment highly inductive for osteoclast formation. To verify this hypothesis and to develop a novel mouse osteoclast culture system not requiring any osteotropic hormones or growth factors, we isolated and cultured primary cells from mandibular bodies. Primary cells were isolated from 9-11 day old mouse mandibular bodies including tooth germs and their surrounding tissues, and cultured in 15% FBS-aMEM. TRAP-positive multinucleated osteoclastic cells started to appear eight days after inoculation and the number continued to increase until day 14 of the culture. This progressive increase in osteoclastic cells is indicative of de novo cell formation. Cathepsin K and calcitonin receptor were localized in these osteoclastic cells, and the pit formation were observed when cells were cultured on dentin slices. The number of osteoclastic cells were significantly suppressed by OPG treatment. When primary cells were isolated from mandibular bodies that were free from tooth germs or their surrounding tissues, TRAP-positive multinucleated osteoclastic cells were not seen in the culture. These results suggest that functional cultured osteoclasts are formed in this culture system via RANK-RANKL. It is shown that tooth gems and the surrounding tissues are essential for the appearance of osteoclast in this system, corroborating our hypothesis that these tissues are creating a local environment highly inductive for osteoclast formation.

Use of Peptide Phage Display to Identify Novel Stromal Cell Surface Molecules that Support Osteoclast Differentiation. P. He*[1], B. Wang*[2], E. M. Greenfield[1]. [1]Orthopaedics, Case Western Reserve University, Cleveland, OH, USA, [2]Medicine, Case Western Reserve University, Cleveland, OH, USA.

We previously identified three peptides from a phage display library that bind to ST2 cells cultured with 10 nM 1,25-D_3 but not to ST2 cells cultured without 1,25-D_3. Peptide #3 inhibits formation of multinucleated TRAP-positive osteoclasts induced by 1,25-D_3 in spleen cell / ST2 cell co-cultures. Maximal effects (~50% inhibition) are induced by 140 nM peptide #3. In contrast, peptides #1 and #2, as well as a scrambled form of peptide #3, have no detectable effect on osteoclast differentiation. We have now identified a fourth phage display peptide that also inhibits formation of multinucleated osteoclasts by ~50%. Peptide #4 is maximally effective at 14 pM, 10,000-fold lower than the maximally effective concentration of peptide #3. Both peptide #3 and #4 inhibit formation of multinucleated osteoclasts without affecting formation of osteoclast precursors (TRAP-positive mononuclear cells). Thus, the effects of peptides #3 and #4 are distinct from those of osteoprotegerin, which inhibits formation of both multinucleated osteoclasts and their mononuclear precusors. To identify extracellular matrix or cell surface molecules that bind to the peptides, we stably expressed Fc-fusion proteins encoding the peptides in HEK293 cells and purified them on Protein G-Sepharose. The Fc-fusion proteins were used to immunoprecipitate binding proteins from lysates of ST2 cells that had been surface biotinylated after culture for six days with or without 1,25-D_3. Western blots of the immunoprecipitated proteins showed that Fc fused to peptide #4 specifically binds to a biotinylated protein of approximately 230 kDa expressed by ST2 stromal cells cultured with 1,25-D_3. This protein is not bound to Fc alone and is not observed in samples from ST2 cells cultured without 1,25-D_3. The 230 kDa protein may be an importantant stromal cell surface molecule that regulates osteoclast differentiation.

Characterization of Commercially Available Cryopreserved Primary Human Osteoclast Precursors. D. E. Greenwalt*, E. Bruno*. R&d, Cambrex, Walkersville, MD, USA.

Use of high-throughput screening techniques in the discovery of new drugs for osteoporosis is limited by both the absence of appropriate assays and the availability of osteoclasts and their precursors in large numbers. We herein report the characterization of a commercially available preparation of cryopreserved primary human osteoclast precursors isolated, after limited expansion, from hematopoietic CD34-positive progenitors. When thawed, 1 million or more osteoclast precursors, with viability at > 90%, were routinely recovered/cryovial. Precursors were resuspended in cell culture medium with supplements and growth factors and immediately seeded in 96-well cell culture plates. In some cases, the precursors were cultured on dentine discs. After 5 to 10 days, the cells were either stained for tartrate-resistant acid phosphatase or analyzed for CD61 expression (plates) or stained with Toluidine Blue to quantify resorption pits (discs). No changes of culture medium were required. The presence of M-CSF and soluble RANK ligand were required for osteoclast differentiation. M-CSF and sRANKL optimal concentrations were determined to be 25 ng/ml for each factor. It was found that addition of TGF-beta 1 (1 ng/ml) at day 3 of culture enhanced cell differentiation. The optimal seeding density was found to be 10,000 cells/well, which, on day 7 of culture, produced as many as 500 multinucleated TRAP-positive cells/well. Differentiated cells contained from 2 to >10 nuclei/cell. Bone resorption increased dramatically from day 7 to day 10. Interferon gamma dramatically inhibited differentiation of the precursors. The number of osteoclasts obtained from precursors isolated from three different donors varied less than 20%. The availability of large numbers of osteoclast precursors is required for high-throughput screening efforts. For example, 1 million cells are required to seed a 96-well bone resorption plate for subsequent assay by a robotic image analysis system. The primary human osteoclast precursors are available in large numbers and offer convenience of a cryopreserved product. The relatively minor variation observed due to donor sources insures screen-to-screen consistency. In addition the biological relevance offered by use of human cells decreases the occurrence of false negatives that might otherwise occur as a result of species-specific receptor binding. The osteoclast precursors will be of use in both the characterization of lead compounds that target osteoporosis and in high-throughput screening efforts in drug discovery programs.

Application of Laser Capture Microdissection for the mRNA Analysis of Cultured Bone Marrow Cell. M. Nakamura, Q. Yang*, K. Takeda*, T. Hisamatsu*, Y. Nakamura*, I. Mori*, K. Kakudo*. Pathology, Wakayama Medical University, Wakayama, Japan.

Laser capture microdissection (LCM) is a new tool useful for recovering small amount of tissue samples and enables us to collect even individual cells from tissue sections. This method facilitates the separation of histologically different cells so that proteins, DNA, or RNA from these cells can be analyzed in isolation from the surrounding cells. Whether this method is applicable for culture cells is still unknown. The purpose of this study is to establish a method of dissecting single cultured bone marrow cell and test it captured cells are available for mRNA analysis. Bone marrow cells and spleen cells were obtained from 8 to 10 weeks-old male C57BL/6 mice. Both the cells were co-cultured on the LCM film (Leica Microsystems Co.) in α-MEM supplemented with 10% fetal calf serum and 10-8 M $1,25(OH)_2$ D for 6 to 8 days at 37 ºC. Cells were fixed on the film for 1 min by ethanol and stained for 3 min by filtrated hematoxylene followed by washing with sterilized water and air-dried for 10 min. 50-100 cells of osteocalsts or osteoblasts were captured from cultured cells using Application Solutions Laser Mycrodissection System (Leica Microsystems Co.). Total RNA was extracted from LCM captured cells using TRIzol LS Reagent. The SUPERSCRIPT TM One-Step RT-PCR with PLATINUM *Taq* (Invitrogen life technologies Co.) was used to synthesize cDNA and PCR. β-actin, calcitonin receptor, and receptor-activity-modifying-proteins (RAMP) primers were used for RT-PCR analysis. All PCR products were detected by above method. This approach will allow us to study single group cultured in various conditions.

Osteoclastic Potential of Human Cord Blood Mononuclear Cells and Derived CFU-GM: Effects of M-CSF, GM-CSF and IL-3. J. M. Hodge*[1], M. A. Kirkland*[2], C. J. Aitken*[1], D. E. Myers*[1], G. C. Nicholson*[1]. [1]Department of Clinical and Biomedical Sciences, The University of Melbourne, Geelong, Australia, [2]Douglas Hocking Research Institute, Barwon Health, Geelong, Australia.

Osteoclasts (OC) and dendritic cells differentiate from hematopoietic cells of the monocyte/macrophage lineage. However, how and when their precursor cells diverge from this lineage is unclear. To further investigate OC lineage commitment we performed progenitor assays of human umbilical cord blood mononuclear cells (CBMC) followed by *in vitro* studies of osteoclastogenesis. CBMC were cultured in semi-solid media containing GM-CSF, IL-3 and stem cell factor. Pooled colonies or individual colonies identified as CFU-GM or CFU-M were harvested following 14 days of culture and transferred into 96-well plates containing dentine slices in the presence of RANKL and human M-CSF for a further 6 days. The efficiency of OC formation, calculated by dividing the number of nuclei resulting within mature OC by the initial seeding density, was 20% for CBMC and increased to 37% when precursors were obtained from pooled colonies. OC formation from precursors derived from CFU-GM was further increased by 88% and resorption by 45% compared to pooled colonies. However, more committed cells derived from CFU-M were very poorly osteoclastogenic. Pre-treatment of pooled colonies with M-CSF for 7 or 14 days prior to RANKL exposure for 14 days decreased OC size by 41% and 52% and resorption by 26% and 51%, respectively. In contrast, pre-treatment with IL-3 (plus M-CSF) for 7 days reduced OC number by 96%, and in the case of GM-CSF (plus M-CSF) completely inhibited OC formation in favour of TRAP-negative cell clusters indicative of dendritic cell activation. These results demonstrate that (i) clonal expansion of CFU-GM progenitors from human CBMC markedly increases osteoclastogenic potential. More committed CFU-M-derived progenitors appear to have lost their capacity to form OC; (ii) exposure of pooled colonies to M-CSF prior to RANKL only moderately reduces osteoclastogenic potential; (iii) exposure of pooled colonies to GM-CSF or IL-3 prior to RANKL stimulus completely inhibits osteoclastogenesis, directing cells instead towards dendritic cell differentiation.

M273

Transforming Growth Factor-β Induced Osteoclasts Survive by Activating Divergent Survival Pathways. A. Gingery[1], G. A. Gorny*[2], M. J. Oursler[3]. [1]Biochemistry and Molecular Biology, University of Minnesota, Duluth, MN, USA, [2]Biology, University of Minnesota, Duluth, MN, USA, [3]Biology, Biochemistry and Molecular Biology, Medical Microbiology and Immunology, University of Minnesota, Duluth, MN, USA.

Transforming Growth Factor - β (TGF-β) is a multifunctional growth factor that can either stimulate apoptosis or promote survival, depending on the target cell. During elevated bone resorption, osteoclasts release active TGF-β from the bone matrix. TGF-β has been reported to induce osteoclast apoptosis, yet there is no evidence of increased osteoclast apoptosis when bone resorption is elevated. Since osteoclasts differentiate in the presence of TGF-β within the bone environment, we investigated how the presence of TGF-β during in vitro differentiation influences osteoclast apoptosis. Once mature, osteoclasts were either maintained or withdrawn from TGF-β treatment for up to 24 hours. We observed that osteoclasts maintained in TGF-β survived longer than withdrawn cells. For this reason we have explored the mechanism of this survival. The second messenger PI3K has been implicated in survival in a number of cell types. We therefore examined two PI3K inhibitors with differing inhibitory mechanisms, LY294002 and wortmannin, for impacts on osteoclast survival. Wortmannin, but not LY294002, inhibited TGF-β withdrawn osteoclast survival whereas both the PI3K inhibitors inhibited TGF-β maintained osteoclast survival. PI3K activates multiple survival signals, including AKT and Raf/MEK/ERK. We have examined these pathways. There was increased AKT phosphorylation in the TGF-β maintained but not in the withdrawn osteoclasts. Using an inhibitor to MEK1/2 (U0126) we found that survival decreased in both the TGF-β maintained and withdrawn osteoclasts when MEK was blocked. MEK1/2 and ERK1/2 were phosphorylated in TGF-β maintained and withdrawn osteoclasts, providing evidence of MEK and ERK activation in these cells. Raf inhibition with Geldanamycin resulted in decreased survival of TGF-β maintained osteoclasts while it had no impact on survival of TGF-β withdrawn osteoclasts. We conclude from these data that osteoclast that are differentiated in the presence of TGF-β and at maturity are either maintained or withdrawn from TGF-β have divergent survival pathways. In particular, TGF-β maintained osteoclasts appear to activate the survival pathways AKT and Raf/MEK/ERK. In contrast, TGF-β withdrawn osteoclast survival, although requiring PI3K and MEK, do not require Raf activation. The increased understanding of survival signals for osteoclasts should provide future benefit in terms of both understanding normal osteoclast activity and pathological conditions of excess bone loss.

M274

Roles of NO for TNF-α Stimulation of Osteoclast Survival. S. Lee*[1], Z. Lee[2], H. Kim[3]. [1]National Research Laboratory for Bone Metabolism, Chosun University, Gwangju, Republic of Korea, [2]NRL for Bone Metabolism, Microbiol.&Immunol., Dental School, Chosun University, Gwangju, Republic of Korea, [3]Research Center for Proteineous Materials, Microbiol.&Immunol., Dental School, Chosun University, Gwangju, Republic of Korea.

Tumor necrosis factor α (TNF-α) has been shown to potently stimulate the survival of osteoclasts. We have previously demonstrated that the phosphatidyl inositol 3 kinase (PI 3-kinase)/Akt and the extracellular signal-regulated kinase (ERK) signaling pathways function for the TNF-α-promoted survival of osteoclasts. In the present study we investigated what downstream targets of PI 3-kinase/Akt and ERK are involved in the survival mechanisms. Treatment of mature osteoclasts with TNF-α did not induce cIAP-1, cIAP-2, XIAP, $Bcl X_L$, genes known to be antiapoptotic. Neither a change in phosphorylated Bad nor tBid, reported to regulate apoptosis, was detected. However TNF-α stimulation was found to cause induction of iNOS gene expression in purified mature osteoclasts. Blocking the generation of NO with the NOS inhibitor L-NAME suppressed the TNF-α-induced survival of osteoclasts, whereas treatment with SNP, a NO donor, stimulated osteoclast survival. Our findings suggest that NO produced by iNOS plays an important role in osteoclast survival by TNF-α.

M275

Inhibition of Protein Prenylation by Risedronate Causes Activation of Rac and PAK. J. E. Dunford*, F. P. Coxon, M. J. Rogers. Medicine & Therapeutics, University of Aberdeen, Aberdeen, United Kingdom.

Nitrogen-containing bisphosphonates drugs (N-BPs), such as risedronate (RIS), act by inhibiting farnesyl diphosphate synthase in osteoclasts. This prevents the synthesis of isoprenoid lipids required for prenylation of small GTPases, such as the Rho family proteins (Rho, Rac and Cdc42). Prenylation is essential for the correct function of small GTPases since it enables their interaction with specific subcellular membranes, where they can be activated by exchange of GDP for GTP. We therefore sought to confirm that N-BPs affect the activity of Rho family GTPases in J774 macrophages. In these cells, like osteoclasts, RIS treatment causes apoptosis. The activity of Rho GTPases was measured using a pull-down assay utilising agarose beads conjugated to the GTPase-binding domain of an effector molecule (Rhotekin or p21 activated kinase/PAK) that specifically binds the active, GTP-bound form of Rho, Rac or Cdc42. Precipitated, GTP-bound Rho, Rac or Cdc42 was then quantitated by western blotting. Surprisingly, treatment of J774 cells for 20 hours with 100μ M RIS caused an increase in the amount of GTP-Rac but had no effect on the amount of GTP-Cdc42 or GTP-Rho. Inhibition of Rac geranylgeranylation by 10μM GGTI-298 also caused an increase in active, GTP-Rac, but 1mM clodronate (a bisphosphonate that does not inhibit protein prenylation) had no effect. We next examined whether the active, GTP-bound Rac in RIS-treated J774 cells was prenylated or unprenylated. Cells were metabolically labelled with [14C]mevalonate in the absence or presence of RIS. GTP-Rac was then precipitated from lysates of RIS-treated cells using PAK-agarose. When lysates from untreated cells were incubated with GTPγS to maximally activate small GTPases, the precipitated GTP-Rac was radiolabelled and hence in the prenylated form. However, precipitated GTP-Rac from RIS-treated cells was not radiolabelled and hence was in the unprenylated form. To determine whether the active, unprenylated Rac that accumulated in RIS-treated cells was capable of activating downstream pathways, the activity of the Rac effector PAK was analysed using a [32P]-kinase assay with PAK immunoprecipitated from cell lysates. Treatment for 20 hours with 100μM RIS or 10μM GGTI-298 caused an increase in the kinase activity of PAK. These studies demonstrate that, in J774 cells, inhibition of protein prenylation by RIS causes activation rather than inhibition of Rac. The unprenylated, activated form of Rac can stimulate downstream PAK activity. Since prolonged Rac activation can cause apoptosis in some cell types, RIS may cause J774 apoptosis as a result of inhibition of prenylation and hence activation of Rac.

Possible Involvement of Proapoptotic BH3-only Protein Bim in Osteoclast Apoptosis. T. Akiyama*[1], T. Inaba*[2], T. Okada*[3], P. Bouillet*[4], A. Strasser*[4], H. Oda*[1], K. Nakamura*[1], S. Tanaka*[1]. [1]Department of Orthopaedic Surgery, The University of Tokyo, Tokyo, Japan, [2]Department of Molecular Oncology, Hiroshima University, Hiroshima, Japan, [3]Departments of Molecular Biology, Jichi Medical School, Tochigi, Japan, [4]The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia.

The anti- and pro-apoptotic members of the Bcl-2 protein family play a central role in the signaling events leading to apoptosis in various types of cells. The BH3-only subfamily members are pro-apoptotic molecules, which trigger apoptosis via interaction with anti-apoptotic Bcl-2 members. A number of BH3-only proapototic molecules have been identified in mammals, including Blk, Bad, Bik, Hrk, Bid, Bim, Noxa, Puma, and Bmf, and it has been revealed that pathways to apoptosis induced by different damage signals involve distinct BH3-only proteins in their initiation. In an attempt to identify a key initiator of osteoclast apoptosis, we examined the expression of BH3-only proteins in osteoclasts. Osteoclast-like cells (OCLs) generated in co-cultures of mouse osteoblasts and bone marrow cells are subjected to rapid apoptosis in the absence of supporting cells or stimulatory cytokines. Interestingly, the apoptosis stimuli caused rapid increase in the protein level of Bim in the cells as determined by Western blotting, while the expression of other members did not show such dramatic changes. This increase appears to be due to the posttranscriptional regulation because Bim mRNA level did not change after the stimuli as determined by RNase protection assay and RT-PCR. Immunohistochemical analysis showed the time-dependent translocation of Bim to the mitochondrial membrane, which corresponded to the cytochrome *c* release to the cytosol. To further elucidate the role of Bim in osteoclast apoptosis, we utilized adenovirus vector expression system and Bim -/- mice. We constructed the adenovirus vector carrying Bim gene and successfully overexpressed Bim protein in OCLs. Adenovirus vector-induced overexpression of Bim induced rapid apoptosis in OCLs, which was inhibited by co-expression of anti-apoptotic Bcl-2 family protein, Bcl-xL. We finally compared the phenotypes of OCLs generated from Bim-deficient mouse bone marrow cells with those of wild type OCLs. OCLs differentiated from Bim -/- bone marrow cells showed remarkable resistance to the apoptosis stimuli, and about 100% cells survived after 48hrs of cytokine withdrawal compared to 0% survival in wild type OCLs. These results demonstrate that proapoptotic BH3-only protein Bim plays an essential role in osteoclast apoptosis

M277

Regulation of Osteoclast Survival by Nitric Oxide: Possible Involvement of NMDA-R. R. Mentaverri*, S. Kamel, M. Brazier. Laboratoire de Pharmacie Clinique, Amiens, France.

Nitric oxide (NO) has been shown to play a biphasic activity on osteoclast. At concentration greater than 10 μM, it was responsible for an inhibition of osteoclastic bone resorption while lower concentrations seem to be necessary to normal bone resorption. It is now clearly established that osteoclasts express inducible NO synthase (iNOS) which is upregulated by proinflamatory cytokines and produce large amount of NO. However, little is known about constitutive NOS isoenzymes which product small amounts of NO in osteoclast. In this work, using RT-PCR amplification, we demonstrate for the first time that mature osteoclasts prepared from 10-day-old rabbit express mRNA encoding for both endothelial and neuronal NOS suggesting that these two enzymes could be involved in production of low output of NO. In order to precise the possible involvement of constitutive NO in bone resorption process we assessed the effect of carboxy-PTIO, a NO scavenger, on osteoclast survival. Our results have shown that addition of carboxy-PTIO (10 - 100μM) induced osteoclast apoptosis in a dose dependent manner. After 18h of culture, the rate of apoptosis was three fold increased in osteoclasts treated with 100 μM of Carboxy-PTIO compared to untreated cells. The carboxy-PTIO-induced apoptosis was dependent of caspase 3 activity (measured with Ac-DEVD-AMC as substrate). These results suggest that basal concentration of NO is necessary to osteoclast survival. It has been recently demonstrated that osteoclasts express functional N-Methyl-D-Aspartate receptors (NMDA-R). In central nervous system, this receptor was involved in NO biosynthesis through a physical coupling with the calcium dependent neuronal NOS (nNOS). Therefore in this study, we tested the hypothesis that NMDA-R could be implicated in NO production in osteoclast. We first demonstrated that blockade of NMDA-R with MK-801 or DEP, two non-competitive specific NMDA-R channel blockers, leads to a rapid decrease in intracellular calcium concentration monitored by Ca2+-sensitive fluorescence dye (Fura2-AM). Concurrently, we observed a decrease in osteoclast survival in the same extent as those observed with carboxy-PTIO and that SNAP, a NO donor, was able to partially prevent the MK-801-induced osteoclast survival inhibition. Taken together, these results suggest strongly that in osteoclast, calcium entry throughout the NMDA-R channel could be involved in nNOS activation. In turn the NO production by this way may be important for the regulation of osteoclast survival.

RANK Signaling through Calcineurin and Protein Kinase C Accelerates NF-κB Activation in Osteoclasts. S. V. Komarova*, S. J. Dixon, S. M. Sims*. CIHR Group in Skeletal Development and Remodeling, The University of Western Ontario, London, ON, Canada.

The binding of RANK ligand to its receptor RANK stimulates bone resorption by increasing osteoclast formation and activity. RANK activates the transcription factor NF-κB resulting in translocation of NF-κB from the cytoplasm to the nuclei. We have previously shown that RANK ligand activates phospholipase C in rat osteoclasts, leading to transient elevation of cytosolic free calcium, which in turn accelerates nuclear translocation of NF-κB. The purpose of this study was to investigate the mechanism underlying the effect of cytosolic calcium on NF-κB activation. Osteoclasts were isolated from neonatal rat long bone and nuclear translocation of NF-κB was assessed using immunofluorescence. Soluble RANK ligand (100 ng/ml) induced transient translocation of NF-κB from the cytosol to the nuclei, with maximal translocation at 15-30 min and reversal within 60 min. We examined the role of two calcium-sensitive effectors known to contribute to activation of NF-κB in other systems -- the calcium-calmodulin-dependent phosphatase, calcineurin, and protein kinase C (PKC). The calcineurin inhibitors, cyclosporin A (CsA, 1 μM) or FK-506 (10 nM) applied 30 min before addition of RANK ligand, suppressed initial NF-κB translocation (7 min), with no significant effect at later times (15-30 min). This finding is consistent with transient activation of calcineurin secondary to RANK ligand-induced elevation of cytosolic calcium. The PKC inhibitor bisindolylmaleimide I (BI, 100 nM), but not the inactive control bisindolylmaleimide V (BV, 100 nM) applied 30 min before addition of RANK ligand suppressed NF-κB translocation at 7 and 15 min, with no significant effect at 30 min. This finding is consistent with a role for PKC, activated following stimulation of phospholipase C by RANK ligand. The effects of calcineurin inhibitors and BI were additive at 7 min, however calcineurin inhibitors had no additional effect at 15 min. Taken together, these data indicate that calcineurin and PKC are downstream effectors of RANK that accelerate activation of the key transcription factor NF-κB. The kinetics of NF-κB translocation may be critical for controlling the transcription of genes regulated by NF-κB in concert with other factors. Moreover, these heretofore unrecognized signaling events may help explain the complex effects of immunosuppressants such as cyclosporin A on osteoclastic resorption.

M279

P38 Mediates RANKL-Induced NF-kB Activation and Osteoclastogenesis. S. Abbas*, Y. Abu-Amer. Orthopaedics & Cell Biology and Physiology, Washington University School of Medicine, St. Louis, MO, USA.

Receptor activator of NF-kB ligand (RANKL) is essential for differentiation of marrow macrophages into bone resorbing osteoclasts. RANKL binds to the cell surface receptor RANK and triggers several down stream signal transduction pathways, most of which have been shown to be involved in the osteoclastogenic process. Two such pathways are NF-kB activation pathway and the p38 MAP kinase pathway. Activation of these factors can be blocked by specific inhibitors. In this regard, earlier studies from our group as well as others documented that blockade of either pathway attenuates osteoclast development. Thus, we asked if these two pathway intersect throughout the osteoclast differentiation process. In the current study we have utilized purified marrow macrophages. In the presence of soluble RANKL, these cells form giant multi-nucleated osteoclasts that express tartrate-resistant acid phosphatase and resorb bone. First we show that administration of dominant-negative (DN) IkB, which blocks NF-kB activation, and selective inhibitor of p38, namely SB203580, significantly block osteoclastogenesis. We next examined if DN-IkB affects P38 status. P38 kinase activity which was induced by RANKL, appeared unaffected by DN-IkB, so as protein levels of the kinase. In contrast, we find that SB203580 dose-dependently inhibits osteoclastogenesis, which coincides with diminished NF-kB activity. Specifically, SB203580 at 0.1 - 10 microM blocked over 75% of NF-kB-DNA binding activity (by EMSA), and virtually inhibited entire osteoclastogenesis. These effects were reversible upon SB203580 withdrawal from the media, thus excluding cytotoxicity. Using co-imunoprecipitation studies, no direct physical interactions were observed between p38 and NF-kB, suggesting other co-factor(s) may be mediating this event. Supershift analysis was then employed to determine which NF-kB subunits are affected by p38 inhibition. Our data indicate that at least p65 NF-kB subunit is inhibited in the presence of p38 kinase inhibitor. We conclude that p38 participates and may be required for RANKL-activation of NF-kB in marrow macrophages and differentiating osteoclasts. Thus, inhibitory strategies targeting p38 may impede NF-kB-fueled inflammatory osteolysis.

Mutation of the Src SH3 Binding Site on Cbl Reduces Src-Cbl Interaction, Cbl Phosphorylation and Bone Resorption in Osteoclasts. A. Sanjay, T. Miyazaki, W. C. Horne, R. Baron. Yale University, New Haven, CT, USA.

c-Cbl (Cbl) is a substrate of the non-receptor tyrosine kinase Src. Cbl is phosphorylated downstream of integrins in osteoclasts (OC) and like Src is involved in the regulation of OC motility. Cbl also negatively regulates Src kinase activity either by binding to the autophosphorylated tyrosine within the Src kinase domain or by ubiquitinating the activated Src kinase. We have found two distinct interactions between Src and Cbl, the first between the SH3 domain of Src and the proline-rich region (PR, aa 481-690) of Cbl and the second between the phosphorylated tyrosine 416 of Src and the phosphotyrosine binding domain (PTB) of Cbl. Mutation of the PTB domain did not prevent the interaction of Src and Cbl indicating that it is primarily due to the binding of the Src SH3 domain and the PR of Cbl. Using an in vitro peptide-binding assay we demonstrated that 540RDLPPPPPPPDRP binds to the Src SH3 domain. The binding of Src to a mutant c-Cbl protein in which these six prolines were replaced by alanines (Cbl6PA) was reduced in 293 VnR cells and in adenovirus-infected osteoclast like cells (OCLs). Cbl6PA phosphorylation was also reduced. Consistent with the role of Cbl as negative regulator of Src kinase, co-expression of Cbl and constitutively activated Src in 293 VnR cells led to a 80% decrease in Src kinase activity. This inhibition was partially prevented (55 %) by the co-transfection of Cbl 6PA indicating that the Src SH3/PR interaction is required for the inhibition of Src kinase activity. Interestingly, the pit forming activity of OCLs infected with Cbl 6PA was also significantly albeit moderately inhibited (25% decrease). This data supports our hypothesis that Cbl's interaction with Src, which is largely dependent on the SH3/PR binding and regulates the Src kinase activity and, thereby, bone resorbing activity. Thus, the interaction of Cbl with Src, which leads to phosphorylation of Cbl and the down regulation of Src kinase activity, is important for osteoclastic bone resorption.

M281

Inhibition of p38 MAPK Inhibits Bone Resorption Associated with Inflammation. G. Mbalaviele, A. L. Jones*, G. Anderson*, P. De Ciechi*, S. Settle*, J. Portanova*. Arthritis and Inflammation, Pharmacia Corporation, St. Louis, MO, USA.

MAPKs are proline-directed kinases, which include the insulin/mitogen-regulated extracellular signal-regulated kinase (ERK), the stress-activated protein kinases/c-Jun NH_2 terminal kinases (JNK) and the p38 kinases (p38). The ERK family is typically strongly stimulated by growth factors while the JNK/p38 pathways are activated by cellular stresses and inflammatory cytokines. Recent data indicate that TNF-α and IL-1β, potent activators of MAPKs are involved not only in inflammation, but also in bone resorption, in synergy with RANKL. These observations suggest that blockade of production and/or signaling of these cytokines is important to protect bone from destruction in inflammatory diseases such as rheumatoid arthritis. Thus, this study was designed to test this concept by using a novel selective p38 inhibitor, known to block inflammatory cytokine production. Human bone marrow $CD34^+$ hematopoietic stem cells and murine RAW 264.7 cells expressed p38α, but not p38β, p38δ and p38γ isoforms. Exposure of these cells to RANKL resulted in a rapid phosphorylation of p38, heat shock protein (HSP-27, downstream of p38), ERK, c-Jun (downstream of JNK) and IκB-α (NF-κB pathway). This inhibitor blocked 100% RANKL-induced HSP-27 phosphorylation, but not c-Jun and IκB-α phosphorylation in RAW 264.7 cells and $CD34^+$ cells. This inhibitor also decreased RANKL-induced DNA binding activity of transcription factor, myocyte-enhancing factor 2 (MEF2C, downstream of p38) as determined by electrophoretic mobility shift assay. To determine the role of p38 in bone resorption, human $CD34^+$ cells, murine bone marrow cells or RAW 264.7 cells were treated with p38 inhibitor (0-10 μM) and RANKL alone or in combination with TNF-α in the presence of M-CSF. RANKL and TNF-α-dependent osteoclast (Ocl) formation and activity were blocked in a dose-dependent manner up to 100% by the inhibitor. Finally, the role of p38 in bone resorption *in vivo* was tested in streptococcal cell wall-induced rat arthritis. In this model, p38 inhibitor prevented joint swelling (up to 80%), Ocl numbers and bone destruction assessed by radiography, micro-computed tomography and histomorphometry. While this inhibitor had no effect *in vivo* on OPG, MMP-3 mRNA expression, it did block ~ 95% RANKL, TRAP, MMP-9, -13, IL-6, and IL-1β mRNA , and DNA binding activity of MEF2C. In conclusion, these data demonstrate that p38 regulates the expression and signaling of osteoclastogenic factors, and selective inhibition of this pathway is sufficient to inhibit bone resorption associated with inflammation

Protein Kinase C Affects Activities of a Voltage-gated Proton Channel in Murine Osteoclasts. H. Mori*[1], H. Sakai[2], H. Morihata*[3], M. Kuno[1]. [1]Physiology, Osaka City University Graduate School of Medicine, Osaka, Japan, [2]Orthopedic Surgery, Osaka City University, Osaka, Japan, [3]Neurology, Osaka City University, Osaka, Japan.

Osteoclasts, bone resorbing multinucleated giant cells, were differentiated from mononuclear preosteoclasts originated from the monocyte-macrophage lineage of hematopoietic stem cells. Osteoclasts attach to bone surface, form bone resorption pit sealed at clear zone, and then secrete a great amount of proton (H^+) ions and proteolytic enzymes into the pit to absorb bone mineral and matrix. Although the H^+ secretion is mediated mainly by a vacuolar type H^+-ATPase, osteoclasts are equipped with various pH regulating mechanisms, such as, $Cl^-/HCO3^-$ exchangers, Na^+/H^+ exchangers and a voltage-gated H^+ channel. The voltage-gated H^+ channel is opened at the membrane potential positive to the reversal potential determined by the pH gradient through the membrane. As the H^+ channel can extrude massive H^+ ions rapidly, the channel activation may induce drastic changes in intracellular and extracellular pH environments of osteoclasts. In this study, we have examined effects of protein kinase C (PKC) on the H^+ channel activity, because PKC activity is reported to modulate osteoclast functions. The whole cell H^+ currents were recorded from murine osteoclasts generated in the presence of a soluble form of receptor activator of nuclear factor kappa B ligand (sRANKL). The H^+ current density varied greatly among cells: generally, the current density was much larger in osteoclasts with < 5 nuclei than those with ≥ 6 nuclei. When cells were pretreated with a strong activator for PKC, phorbol 12-myristate 13-acetate (PMA; 1 μg/ml) for 30 min - 2 hrs, the current density and the activation rate in cells with < 5 nuclei were almost same to those in non-treated cells. In cells with ≥ 6 nuclei, the current-density and the activation rate tended to be enhanced by PMA and decreased by a PKC inhibitor, staurosporin (10 nM), but the changes were not significant. To evaluate the amount and temporal pattern of the effects of PMA in individual cells, the H^+ current was recorded in the permealized patches, where the intracellular machinery required for activation of PKC was preserved. In cells with small current density in control, PMA increased the current density up to 500 - 600% and decreased the activation time constant to less than 30 - 40% within 10 - 20 min. In cells with the large H^+ current activity, the effects of PMA were only slight. These results suggest that PKC is an activator for the voltage-gated H^+ channel in osteoclasts, although its efficacy may alter among cells dependently on the activation status of the channel.

M283

The Role of Postural Sway in the Maintenance of Bone Mass. K. J. McLeod*[1], J. P. Ryaby[2], J. M. McCabe*[3]. [1]Department of Bioengineering, Binghamton University, Binghamton, NY, USA, [2]Exogen Products, Smith & Nephew, Inc., Somerset, NJ, USA, [3]McCabe Research Associates, White Plains, NY, USA.

Osteoporosis is a common occurrence in the aged, but a similar pattern of bone loss also develops during extended bed rest, cast immobilization, and exposure to microgravity. These observations, and the established role of fluid flow in mediating bone formation and resorption led us to hypothesize that postural sway activity (resulting in enhanced bone fluid flow and skeletal muscle pump activation) should be associated with greater bone mass in individuals of comparable age. To address this question, we measured postural sway, bone mineral density, and blood pressure response to orthostatic stress, in a relatively homogeneous group of 13 post-menopausal women (mean age 76 ± 5 years). Bone density was assessed by DEXA, with duplicate measurements. Response to orthostatic stress was assessed by blood pressure and heart rate changes following three minutes of quiet standing. Postural sway was measured by recording the angular acceleration of a balance platform on the axis of medial lateral sway of the subjects. Acceleration recordings were converted to the frequency domain by Fast Fourier analysis, then converted to displacements, which were plotted on a log-log scale as a function of frequency. Postural sway was defined as the peak sway at 1 Hz, as obtained by linear regression. Postural sway measurements were repeated five times for each subject over the five month study period. Postural sway was observed to be highly correlated to bone density in the femoral neck region (R^2=0.72; P=0.0005). While increasing age was found to be associated with decreased postural sway (R^2=0.49; p=0.01), indicating a prevalence to a more rigid stance with advancing age, stepwise linear regression showed that neither age, body mass, or other body size indices were significant predictors of bone density in this group of women. Blood pressure changes in response to orthostatic stress also demonstrated significant correlations to both postural sway (p=0.005) and bone mineral density (p=0.04). We interpret these findings as indicating that postural sway provides a dominant stimulus for the maintenance of bone mass through its influence on blood flow and interstitial fluid flow in the lower appendicular and axial skeleton. We suggest that therapies which assure both adequate filtration through maintenance of normal capillary pressure, and adequate blood and lymphatic return through skeletal muscle pumping, will provide the most successful approaches to the prevention and treatment of osteoporosis.

Modifiable Lifestyle Factors Associated with BMD in Adolescent Women. D. Scholes[1], A. Z. LaCroix[1], L. E. Ichikawa*[1], W. E. Barlow*[1], S. M. Ott[2]. [1]Center for Health Studies, Group Health Cooperative, Seattle, WA, USA, [2]Dept. of Medicine, University of Washington, Seattle, WA, USA.

Maximizing peak bone mass is essential for prevention of future morbidity from osteoporosis. Heritable factors predominate, but identification of modifiable risk factors offers opportunities for interventions aimed at improving bone health. We conducted a cross-sectional evaluation of lifestyle factors (6 dietary factors, physical activity, and current smoking) for their association with BMD in a population-based cohort of 174 adolescent women ages 14-18. Participants were enrollees of a Washington state HMO who were selected using the HMO's computerized databases. Data on risk factors were collected via exam and health and food frequency questionnaires. BMD was measured at the hip, spine and whole body using DEXA. After adjustment for the effects of age, height, weight, ethnicity, number of periods in the past year, and hormonal contraception, lifestyle factors most significantly and consistently associated with bone density at one or more anatomic sites were higher dietary intake of magnesium (positively associated) and consumption of caffeinated cola beverages (negatively associated). Current smoking and higher calcium and protein intake were also marginally significant in the expected directions (0.10≤adj. p≤0.13) for at least two anatomic sites. Factors examined but not significantly associated with bone density were weight-bearing physical activity, alcohol (drinks/mo., and g/day) and total caffeine (any, and mg/day) consumption.

Variable	Adjusted BMD (g/cm2)		
	Hip	Spine	Whole body
Magnesium (mg/d)	0.958	0.962	1.066
<180	0.952	0.976	1.072
180-<360	0.999	1.058	1.169
360+	adj. p=0.29	adj. p=0.04	adj.p=0.002
Cola drinks (drinks/day)	0.969	0.985	1.095
0-1	0.938	0.978	1.053
2+	adj. p=0.12	adj. p=0.72	adj. p=0.01

Consistent with other studies of this age group, two dietary factors-magnesium intake and cola drinking-were significantly associated with BMD and offer possible avenues for intervention. However, most of the lifestyle factors examined were not significantly associated with BMD in this cohort of healthy adolescent women. When compared to inherited and hormonal influences, these exposures may have relatively modest effects on bone density and peak bone mass attainment.

M285

Vitamin A Intake and Bone Mineral Density in Postmenopausal Women. P. B. Rapuri[1], J. C. Gallagher[1], V. Haynatzka*[2]. [1]Bone Metabolism Unit, Creighton University, Omaha, NE, USA, [2]Creighton University, Omaha, NE, USA.

The association between excess vitamin A intake and bone mineral density (BMD) is not clear. Some studies suggest that ingestion of excess vitamin A leads to accelerated bone loss and increase the risk of fracture while others found no association. In a population of 205 postmenoupausal women aged 55-72 years participating in a nutritional study, we examined at baseline the relationship between the total vitamin A intake (including both the dietary and supplemental vitamin A, expressed as retinol equivalents(RE)) and BMD at the spine, femoral neck, total body and mid-radius.Dietary vitamin A intake was assessed by 7-day food diary and information about the use of vitamin A supplements was also obtained from the subjects. The BMD at multiple skeletal sites were analyzed by quartiles of total vitamin A intake and also according to quartiles of dietary vitamin A intake after controlling for confounding factors (age, weight, smoking, alcohol intake, calcium and caffeine intake). There was no significant association between the BMD at all skeletal sites tested and vitamin A intake (both total and dietary).

Bone Mineral Density by Quartiles of Total Vitamin A Intake

quartiles (RE)/ variable	spine BMD	femoral neck BMD	trochanter BMD	total body BMD
1 (<6350)	1.10±0.14	0.88±0.10	0.76±0.10	0.92±0.12
2 (6350-10035)	1.06±0.16	0.84±0.09	0.73±0.09	0.87±0.09
3 (10035-13114)	1.13±0.19	0.87±0.11	0.76±0.11	0.92±0.12
4 (>13114)	1.07±0.15	0.89±0.10	0.75±0.10	0.90±0.10

High Prevalence of Vitamin D Deficiency and Hyperparathyroidism in Elderly Population from the City of São Paulo, Brazil. G. L. Saraiva*[1], M. S. Cendoroglo*[2], J. R. Ramos*[2], L. M. Quirino*[2], I. Kunii*[1], V. A. Lui*[1], V. C. Z. Borba*[1], J. G. Vieira*[1], M. Lazaretti-Castro[1]. [1]Endocrinology, Unifesp, São Paulo, Brazil, [2]Geriatric, Unifesp, São Paulo, Brazil.

Osteoporotic fractures, mainly at the hip are events of high morbi-mortality in elderly population. European and American studies show correlation between these fractures with vitamin D deficiency and secondary hyperparathyroidism. In Brazil, a sunny country, vitamin D deficiency was never thought to be a medical problem. Intending to check the real situation of calcium metabolism in our elderly population, this study is being made. We evaluated 352 patients, 172 (118 women and 54 men) living in geriatric hospitals for at least 6 months (group A) with a median age of 77 y.o. (60 and 100 y.o), and 180 patients (129 women and 51 men) who live in their own houses (group B) with median age of 79 y.o (61-93 y.o.). A third group (C) of young healthful volunteers (median 32 y.o.) were analyzed to compare biochemistry values. We excluded recent bedfast patients or those with renal or hepatic insufficiency. Fasting blood samples were collected and intact PTH (normal range (NR): 10-70 pg/mL), 25-hydroxivitamin D3 (25OHD) (NR: 16-74 ng/mL) and ionized calcium (Cai) (NR: 1.12-1.32 mM) were analyzed. All patients had a quantitative calcaneus ultrasound measurement (USQ- Sahara, Hologic). The statistics analysis were made using Mann Whitney test and Spearman correlation and if p<0,05 it was considered significant. The median values of 25OHD were different in groups A, B and C (10.5; 18.8; 35.6 ng/mL, respectively), the PTH were also different in three groups (95.0; 80.0 and 42.0 pg/mL; respectively) and the Cai also differ in the three groups (1.29; 1.25 e 1.20 mM, respectively). We find the presence of 19 cases (11%) in group A and 9 cases (5%) in group B of hypercalcemia in association with inadequate PTH levels. The PTH in group A> group B (p=0,02) > group C (p<0,0001). The 25OHD in group A< group B (p=0,04) < group C (p<0,0001) and in group A 54% and in group B 35.5% of the patients showed vitamin D values below normal range. Using the A plus B group, age and calcium have positive correlation (p=0.01), PTH and 25OHD show positive correlation (p=0.003) and 25OHD and BUA also show a positive correlation (p=0.05); when these parameters were checked in each group, no correlation was found. The BUA (broad ultrasound attenuation) were lower in group A when compared with group B (p<0,0001). This study shows a high prevalence of vitamin D deficiency and hyperparathyroidism in brazilian population and it were more intense in the institutionalized patients. The elderly population may have benefits with vitamin D treatment but caution is recommended because of high prevalence of hypercalcemia.

M287

Fruit and Vegetable Intake Is an Independent Predictor of Bone Mass in Early-Pubertal Children. F. A. Tylavsky[1], K. Holliday*[2], R. K. Danish[1], C. Womack[1], J. Norwood*[1], K. M. Ryder*[1], L. D. Carbone[1]. [1]University of Tennessee, Memphis, TN, USA, [2]University of Memphis, Memphis, TN, USA.

Adequate intake of fruits (F) and vegetables (V) is recommended for optimum growth and development in children. The objective of this study was to determine if the consumption of 3-5 servings of fruits and vegetables is beneficial to bone mass in children. 58 white females in Tanner stage II recorded dietary intake on 3 independent days. The number of servings of fruits and vegetables were recorded for each day, tallied and divided into 2 groups for analysis. 21 participants reported consuming < 3 servings of F & V a day (4.5 ± 0.3 (mean ± SD)) with 37 reporting ≥ 3 per day (11.5 ± 0.5). Bone area (BA), bone mineral content (BMC) and density (BMD) of the whole body (WB), and lumbar spine (LS) were assessed using a QDR 2000 (Hologic, Inc). 24-hour urine samples were analyzed for the excretion of calcium (Ca) and sodium (Na). There were no differences between the low and adequate groups with respect to age (10.3 ± 0.3 vs. 9.9 ± 0.2) or BMI (19.5 ± 0.7 vs. 18.8 ± 0.5). Bone area, BMC and BMD for the WB and LS, and Na and Ca excretion were compared between the consumption groups, adjusting for age and BMI. Means (SD) for the dependant variables are reported in table 1.

Table 1 Mean (SD)

F & V intake	WB Area	WB BMC	WB BMD	Urine Na	Urine Ca
(N)	cm2	g	g/cm2	mmol/liter	mmol/liter
Low (21)	1189 (32)	957(41)	0.799(0.012)	146 (11.9)	3.8 (0.4)
Adequate (37)	1322 (25)	1099(28)	0.828(0.008)	142 (9.0)	2.2 (0.3)
% Diff (Adeq. vs. Low)	11.2	14.8	3.6	-2.7	-42.1
P value	0.02	0.03	0.32	0.78	0.002

Those with adequate F & V intake also had higher Area (p=0.03), BMC (p=0.10), and BMD (0.49) for the LS. Nutrient analysis showed that those with low F & V intake had lower calcium, potassium, vitamin A, and vitamin C intake (p<0.01). There were no differences in kilocalories, protein, fat, carbohydrate, magnesium or vitamin D intake between the consumption groups. Multivariate analysis showed the relationships between F& V consumption and WB Area and BMC remained after adjusting for calcium, potassium, vitamin A and vitamin C intake. Our data suggests that adequate F & V intake is an independent predictor of bone size and BMC of the total body in early-pubertal children. The increased excretion of calcium in the urine by those with low F & V intake is consistent with the acid-ash hypothesis that the consumption of F & V intake produces an alkaline diet and conserves the loss of calcium.

M288

Dairy Products Effects on Body Fat and Bone Composition in Children. T. P. McNaught*, G. M. Chan. Pediatrics, University of Utah, Salt Lake City, UT, USA.

Dietary calcium (Ca) may play a beneficial role in controlling body fat. Calcitropic hormones in a low Ca state may stimulate fat cells. In children, a critical time of fat development is between 4 and 8 years. It is hypothesized that children with additional dietary Ca from products will have low body fat. To test this hypothesis, 50 healthy children with low Ca intakes (< 800 mg/day) aged 2.5-8.8 years with mean age of 6±2 years (± SD) were studies for 6 months. The children were randomly divided into a dairy (14 females, 11 males) or control (15 females, 10 males) group. The dairy group was supplemented to 1200 mg Ca or four servings of dairy foods daily. Weight, height, and 2 day dietary records were recorded at the start, 3, and 6 months. Bone mineral content (BMC) and body fat determinations by dual energy X-ray absorptiometry body scans were recorded at the start and 6 month. Weights and heights were similar between the dairy and control groups at start, 3, and 6 month visit. At the start, total body fat between the two groups was similar. By 6 months, the controls had gained more body fat, 9.1±3.8 to 10.6±4.7 kg (paired t, P<0.001), while the dairy group's body fat was similar during the study 9.3±4.4 to 9.6±4.3 kg (NS). Bone mineral mass was similar between the two groups during the study. Daily dietary intakes of total calories, total fats, saturated fats, sodium, and carbohydrates were similar between the two groups during the study. At the start, Ca, protein, and vitamin D were similar between the two groups. By 6 months, the dairy group had higher daily Ca intakes (1317±233 vs. 753±426 mg, P<0.001), protein (66±15 vs. 48±20 g, P<0.001), and vitamin D (7.6±2.5 vs. 2.0±1.5 mcg, P<0.0001). In conclusion, children supplemented with additional Ca from dairy product gain less body fat than controls.

M289

Environmental Risk Factors and Quantitative Ultrasound Parameters in French Canadian Menopausal Women. S. Dodin[1], C. Blanchet*[1], M. Dumont*[2], N. Laflamme*[3], F. Rousseau*[4]. [1]Centre Ménopause Québec, Québec, PQ, Canada, [2]Nuclear Medecine Department, HSFA, Québec, PQ, Canada, [3]Signalgène, Montréal, PQ, Canada, [4]Research Unit in Human and Molecular Genetics, Québec, PQ, Canada.

The purpose of the study was to evaluate the prevalence of environmental risk factors among 3466 healthy French Canadian menopausal women (age : 60.5 ± 8.0 years, weight : 66.0 ± 12.1 kg, height : 157.1 ± 6.0 cm and body mass index (BMI) : 26.3 ± 4.8). Bone parameters of the right calcaneus, such as broadband ultrason attenuation (BUA; mean : 109.8 ± 10.1), speed of sound (SOS; mean : 1539 ± 30.7), and stiffness index (SI; mean : 84.0 ± 13.8), were measured by a AchillesTM ultrasound bone densitometry (QUS). All women answered a detailed questionnaire and anthropometry measurements were recorded. In order to identify the risk factors associated with QUS parameters, we performed Pearson correlation. Age, BMI, current hormone replacement therapy (HRT) use, smoking habits and history of family fracture were positively associated with bone mass assessed by ultrasound parameters. Then, a multiple linear regression model was built with stepwise removal of non-significant independent variables. The independent predictors of stiffness were age, BMI, leisure physical activity, current HRT users, smoking habits, history of family fracture, dairy product intake, and wrist fracture. These variables accounted for 20% of the variance in the stiffness(r2 = 0.1996). Similar models were built with BUA and SOS as dependent variables. In conclusion, many environmental risk factors are associated with QUS parameters, and these associations remains significant after controlling for potential confounding factors.

Hypovitaminosis D in an Urban European Population. J. L. Sackrison*[1], J. J. Body[2], D. L. Ersfeld*[1], J. S. Fenske*[1], H. Cheblal*[2], C. M. Van Patten*[1], A. B. Miller*[1], M. Calleri*[3], G. D. MacFarlane[1]. [1]Research and Development, DiaSorin Inc, Stillwater, MN, USA, [2]Institut Jules Bordet, Brussels, Belgium, [3]DiaSorin s.r.l., Saluggia, Italy.

Serum 25 OH vitamin D (25 OH D) concentrations generally vary with latitude, season, and the composition of the populations studied. There is growing recognition that rather than seasonal specific decline in serum 25 OH D, a significant proportion of the population may exhibit asymtomatic subclinical vitamin D insufficiency. Vitamin D insufficiency has been described in populations at risk, such as nursing home residents and the homebound elderly. We assessed a population of normal, apparently healthy volunteers at a single European urban center for 25 OH vitamin D sufficiency. All samples were drawn in accordance to the Declaration of Helsinki. Serum 25 OH D concentrations were determined using an automated LIAISON® 25 OH Vitamin D assay (DiaSorin, Stillwater, MN). For the purposes of this study, vitamin D insufficiency was defined as a serum 25 OH D concentration of < 15 ng/ml. Of the total population (n = 126) 34% exhibited 25-OH D concentrations of < 15 ng/ml. The mean (±SD) serum 25 OH Vitamin D concentration among the total, sufficient, and insufficient populations was 19.4 ± 7.7, 23.6 ± 6.4, and 12.1 ± 2.3 ng/mL. Intact PTH, as assessed by the LIAISON® N-tact® PTH assay (DiaSorin, Stillwater, MN) showed no difference between the sufficient and insufficient populations (means = 34.4 pg/mL *vs.* 35.6 pg/mL respectively). From these data, we conclude that 25 OH D insufficiency is more common than previously thought, and is not restricted to high-risk groups such as the homebound elderly.

Risk Factors for Hip Fracture in Men. S. Muraki*[1], S. Yamamoto*[2]. [1]Orthopedics, Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan, [2]Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan.

Risk factors for hip fracture in elderly men with hip fracture were studied and compared with those found in elderly women with hip fracture. As subjects for this study, 1376 patients with hip fracture aged 65 years or older, who were admitted to Tokyo Metropolitan Geriatric Hospital from June in 1989 to May in 2001, were enrolled. At admission, risk factors for osteoporosis and accidental falls were examined. Risk factors for osteoporosis included diabetes mellitus (DM), chronic lung disease, chronic liver disease, chronic renal disease, a history of gastrectomy, a history of colonectomy, hyperthyroidism, rheumatoid arthritis, a history of uterectomy or ovarectomy before menopause (only female), a history of steroid administration, excessive smoking, and excessive alcohol intake. Risk factors for accidental falls included hemiplegia, Parkinson disease or syndrome, dementia, psychosis, and visual disorders. Among risk factors for osteoporosis, complication rates for excessive smoking, chronic lung disease, excessive alcohol intake and diabetes mellitus in elderly men with hip fracture was high, while, chronic lung disease and diabetes mellitus exhibited the same complication rates in elderly women. Among the aforementioned four factors, complication rates for all of them, except for diabetes mellitus, were significantly higher in elderly men with hip fracture than in elderly women with hip fracture. Among the risk factors for accidental falls, the complication rates for dementia, hemiplegia and visual disturbance was high in elderly men with hip fracture and the same in elderly women with hip fracture. Among the aforementioned three factors, the complication rate for hemiplegia was significantly higher in elderly men with hip fracture than in elderly women with hip fracture. The number of risk factors for osteoporosis in each patient was significantly larger in elderly men than in elderly women. Moreover the number of risk factors for hip fracture, which are risk factors for osteoporosis and risk factors for accidental falls, was significantly larger in elderly men with hip fracture than in elderly women with hip fracture. In elderly men with hip fracture, about 90% of all patients were complicated with more than one risk factor for hip fracture. Most risk factors could likely be prevented, however, systematic social efforts are required to do this, which is a problem to be solved.

M292

Use of Instant Vertebral Assessment in an Internal Medicine Practice. D. Greenblatt*[1], L. A. Jones*[2], K. E. Wilson[2]. [1]Internists of Fairfield, Fairfield, OH, USA, [2]Hologic, Inc., Bedford, MA, USA.

This study looked at the prevalence of vertebral fractures with respect to age and BMD status in patients referred for osteoporosis evaluation from within a multi-specialty internal medicine group. The patients had total AP spine, total hip, and femoral neck BMD measurements and an Instant Vertebral Assessment (IVA) exam. IVA is a low-dose, 10 s, single-energy, lateral X-ray exam of T4-L4. All measurements were performed using a Hologic Inc. QDR Delphi densitometer. The practice consisted of 4 internists, 2 rheumatologists, 2 pulmonologists and 2 nurse practioners, all of whom could refer patients for osteoporosis assessment. A number of the patients referred were undergoing care for chronic conditions, including those whose pathology or treatment are known to affect skeletal health. For this analysis, only female patients over the age of 50 years were considered. There were 172 patients (mean age 68.2 ± 9.8 years, maximum age 91). The subjects were classified by the lowest BMD T-score of the three measured sites and the WHO criteria. The IVA exams were read using the Genant's semi-quantitative method. The patients were also stratified into age decades.

Age	Total	# with fractures	% with fractures
50 - 59	42	2	5%
60 - 69	54	11	20%
70 - 79	54	24	44%
80 - 91	22	9	41%

The percentage of patients with fractures between ages 60-64 (5 of 22) was not statistically different from the number of fractures between the ages of 65-69 (6 of 32).

WHO	Mean age	Total	# with fractures	% with fractures
Normal	64.1	37	6	16%
Osteopenia	67.9	83	19	23%
Osteoporosis	71.4	52	21	40%

In this study population, the presence of Normal or Osteopenic BMD did not rule out the possibility of a prevalent vertebral fracture. 20% of the women in the age range of 60-69 and >40% of the women over the age of 70 had a prevalent vertebral fracture.

Disclosures: ***D. Greenblatt****, Hologic, Inc. 2.*

Prevalence and Severity of Vertebral Fractures Among Patients with Chronic Obstructive Pulmonary Disease (COPD) in Canada. N. Ferko*[1], A. Papaioannou[2], J. D. Adachi[2], G. Ioannidis[2], E. Jurrianans*[2], L. Probyn*[2], G. Cox*[2], W. Parkinson[3], G. Stephenson[4]. [1]Clinical Health Sciences, McMaster University, Hamilton, ON, Canada, [2]Dept. of Medicine, McMaster University, Hamilton, ON, Canada, [3]School, Rehabilitation Sciences, McMaster University, Hamilton, ON, Canada, [4]Procter & Gamble Pharmaceuticals Canada Inc., Toronto, ON, Canada.

The severity of vertebral fractures has been correlated with reduced quality of life and chronic pain. The purpose of this study is to determine 1) the prevalence of vertebral fractures among patients with COPD admitted to acute care settings compared to age-matched controls and 2) the extent to which COPD patients with vertebral fractures were discharged on osteoporosis therapy and 3) the severity of fractures experienced by those with COPD. The design is a case-controlled study of 149 COPD patients identified by ICD-9 codes and 145 sex-and age matched controls, 50 years of age and over who were randomly identified from admissions in 1999 to acute care hospitals in Hamilton, Ontario. Outcomes were established using a chart review to identify diagnosis, medication use, and chest radiograph interpretations. The sample included 154 women and 140 men with a mean age of 72.2 (SD 12.2) and 71.9 (SD 8.2), years respectively. 246 chest radiographs were available for radiology review. Two radiologists blinded to the diagnosis applied Genant's criteria yielding disease severity in three categories: grade 1 (mild), grade 2 (moderate) and grade 3 (severe) deformities. Radiology review of chest radiographs indicates the prevalence of any type of vertebral fracture to be 38/124 (30.6%) in the COPD patients and 30/122 (24.5%) in the control patients, p=0.2834. The prevalence of grade 1 fractures was found to be 43/122 (35.3%) in the COPD patients and 39/124 (31.5%) in the control patients, p>0.5. The prevalence of grade 2 fractures was found to be higher for COPD patients, 19/124 (15.3%) and 8/122 (6.5%) for control patients, p=0.003. Similarly, the prevalence of grade 3 fractures is higher in COPD patients being 24/124 (19.3%) than in control patients, 4/122 (3.3%), p=0.0001. Of all patients with vertebral fractures, 7/18 (38.8%) had a diagnosis of osteoporosis indicated in their medical records. This study demonstrates an increased severity of vertebral fractures in those with COPD. This high-risk group should be targeted for the prevention and treatment of osteoporosis related fractures.

M294

Different Risk Factors of Forearm Fractures and Hip Fractures in 113.000 Scandinavian Women. The Scandos Study. M. G. Stenstrom[1], J. Stakkestad*[2], A. Skaag*[3], E. Öijfjord*[2], O. Johnell[4], D. Mellstrom[5]. [1]Geriatric Medicine, Goteborg University, Goteborg, Sweden, [2]University of Bergen, Center of Osteoporosis, Bergen, Norway, [3]Universty of Bergen, Center of Osteoporosis, Bergen, Norway, [4]Dep of Orthopedic Surgery, Malmoe University, Malmoe, Sweden, [5]Dep of Geriatric Medicine, Goteborg University, Goteborg, Sweden.

Scandinavian women have the highest known risk for hipfracture and vertebral fracture. A former fracture is a major risk factor to experience a new fracture. The question is if risk factors are the same for fracture in forearm and hip? A postal enquiry about issues concerning osteoporosis was answered by 113.000 women (aged 50-80 years) in the western part of Norway and Sweden. Mean age was 63.6 years. The prevalence of forearm fractures was14.472 and 2.482 women had sustained a hip fracture. A multivariat model showed that increased age and body height were risk factors and late menopause and higher body weight were protective factors for both forearm and hip fractures. Cortisone treatment (OR 1.965) and smoking (OR 1.241) were signifikant risk factors only for hip fracture. Daily walking was a protective factor against hip fracture (OR 0.749) and a risk factor for forearm fracture (OR 1.131). Estrogen treatment was only protective against forearm fracture (OR 0.697). This study showes that there are different risk factors for hip fractures and forearm fractures. Daily walking was a risk factor for forearm fracture and protective against hip fracture. Smoking and cortisone treatment were risk factors for hipfracture exclusively.

M295

Fracture Risk and Low Bone Mass: The Relationship Holds for Women Aged 80+. E. S. Siris[1], S. K. Brenneman*[2], T. W. Weiss*[2], S. Barlas*[2], Y. Chen*[2], P. D. Miller[3], E. Barrett-Connor[4]. [1]Columbia University, New York, NY, USA, [2]Merck & Co., Inc., West Point, PA, USA, [3]Columbia University, Lakewood, CO, USA, [4]University of California, San Diego, CA, USA.

Current knowledge of the risk factors for fracture is based largely on cohorts of women aged 60-79. Few studies have enrolled enough women age 80+ to specifically evaluate the association of fracture risk with bone mineral density (BMD). NORA enrolled 200,160 postmenopausal women aged 50 years and older. Baseline BMD was measured at the heel, forearm, or finger. In the current analysis, we included 163,935 NORA subjects who completed a one-year follow-up survey containing questions regarding incident fractures (wrist/forearm, rib, spine, hip) since baseline. Of these, 8517 were aged 80+, representing the largest known osteoporosis study cohort of this age group. Women were categorized into 3 age groups: 50-64 (53%), 65-79 (41%) and 80+ (5%). The prevalence of low BMD (T-score ≤ -2.0) was 6 % in those aged 50-64, 22 % in the age 65-79 group, and 47 % among those aged 80+. 2439 (1.5%) osteoporosis-related fractures were reported. Using logistic regression, the constellation of risk factors (i.e., BMD, years since menopause, education, health status, fracture history, race/ethnicity, BMI, glucocorticoid use, estrogen use, smoking status, exercise, and alcohol use) was predictive of fracture risk across age groups. Adjusted for these risk factors, older age was associated with greater risk for fracture. The relationship between low bone mass and increased fracture risk was statistically significant and comparable for each age group. (Table).

	50 - 64	**65 - 79**	**80+**
N	86690	66289	8517
# Fractures (%)	904 (1.0)	1206 (1.8)	329 (3.7)
Risk per age category (reference 50 - 64 years)	1.00	1.04 (.9, 1.2)	1.56 (1.2, 2.1)
Risk per 1 SD decrease in T-score (95% CI)	1.4 (1.3, 1.5)	1.4 (1.3, 1.5)	1.3 (1.1, 1.5)
Risk per T-score category (reference category >-1.0)			
-2.0 to -1.0 (95% CI)	1.7 (1.5, 2.0)	1.5 (1.3, 1.8)	1.5 (1.0, 2.2)
<= -2.0 (95% CI)	2.5 (2.0, 3.1)	2.4 (2.1, 2.8)	2.2 (1.5, 3.2)

In a large cohort of postmenopausal women, the relationship between BMD and fracture risk persisted regardless of age group. In women age 80+, fracture risk continued to be significantly associated with low BMD, after adjusting for other risk factors. The strength of the association was comparable with those of their younger counterparts.

Hearing Acuity and the Risk of Incident Fracture in Older Women: The Study of Osteoporotic Fractures. E. L. Purchase-Helzner*[1], J. A. Cauley[1], E. Talbott*[1], S. Pratt*[2], J. Zmuda[1], M. Hochberg*[3], K. L. Stone*[4]. [1]University of Pittsburgh, Pittsburgh, PA, USA, [2]Universtiy of Pittsburgh, Pittsburgh, PA, USA, [3]University of Maryland, Baltimore, MD, USA, [4]University of California, San Francisco, CA, USA.

Hearing acuity may be related to bone health. Demineralization of the cochlear capsule and/or the internal auditory canal has been associated with hearing loss, and demineralization may be linked to osteoporosis. Hearing loss may also result in balance problems that may influence fracture risk by increasing the risk of falling. The purpose of this study was to test the hypothesis that hearing loss is related to decreased bone mineral density and increased risk of incident fracture in 6,718 older women (GE 65 years) from the Study of Osteoporotic Fractures. Hearing acuity at 25 and 40 decibels (dB) at 1000 and 2000 Hz was ascertained in both ears via screening audiometry. Women were classified as having normal hearing (passed screening at 25 and 40 dB); mild hearing loss (failed screening at 25dB only) or significant hearing loss (failed screening at both 25 and 40 dB), according to a modification of AAO guidelines. Classification was based on performance in the better ear. Incident non-spine fractures were ascertained every four months and confirmed by radiographic report. ANCOVA was used to assess the relationship between hearing loss and hip and calcaneal BMD, adjusting for age, BMI and estrogen use. Adjusted mean calcaneal BMD (g/cm^2) was 0.379 in the normal hearing group, 0.374 in the mild loss group, and 0.371 in the significant loss group (p=0.043). No significant difference in total hip BMD was seen across the hearing loss categories. Cox Proportional Hazards regression was used to evaluate the relationship between hearing loss and fracture risk over an average of 6.7 years, using women with normal hearing as the referent group (See Table 1). Based on age-adjusted models, women with mild or significant hearing impairment had no increase in all fracture risk, hip fracture risk and wrist fracture risk compared to women with normal hearing. In conclusion, preliminary results indicate only modest differences in BMD at the calcaneus across hearing loss categories, and results do not support the hypothesis that hearing impairment is a risk factor for fracture.

Table 1

Hearing Loss Category	Fracture Type	# women with Fracture	Hazard Ratio (95% CI)
Mild Loss (n=1764)	All non-spine, non-trauma	435	1.00 (0.89, 1.12)
	Hip	135	1.13 (0.91, 1.40)
	Wrist	87	0.96 (0.74, 1.24)
Significant Loss (n=937)	All non-spine, non-trauma	246	0.95 (0.92, 1.10)
	Hip	78	0.98 (0.75, 1.28)
	Wrist	48	0.94 (0.68, 1.31)

M297

Knowledge of Osteoporosis in a Fracture Population. R. K. Wilson*[1], V. Stas*[1], R. Ridout[1], N. Mahomed*[2], A. Gross*[3], A. M. Cheung[1]. [1]Department of Medicine, University Health Network & University of Toronto, Toronto, ON, Canada, [2]Department of Orthopaedics, University Health Network, Toronto, ON, Canada, [3]Department of Orthopaedics, Mount Sinai Hospital, Toronto, ON, Canada.

Osteoporosis places a substantial burden on patients, their social supports, and the health care system, and is an increasing public health concern as our population ages. It is known that patients with previous fragility fractures are at increased risk of future fractures. This study was designed to assess the knowledge of osteoporosis among fracture patients and to identify what social factors, health behaviours, and other characteristics determine this level of knowledge. Fracture patients aged 40 and over attending fracture clinics at two academic hospitals in Toronto were approached to fill out a questionnaire based on the "Facts on Osteoporosis Quiz" (FOOQ) [1], which has true/false/don't know questions on risk factors for osteoporosis as well as prevention and treatment. Our questionnaire included the FOOQ, which has a content validity of 0.92 and a reliability of 0.83, as well as a few additional questions. Of 259 eligible fracture patients, 204 (78.8%) agreed to participate. Respondents were predominantly (63.7%) female. Just over half (56.8%) of respondents were between 40 and 60 years of age, and most of them (84.8%) were Caucasian. The mean number of correct responses was 16.5 out of 30 (54.8%). There were no differences between the two hospitals with respect to level of knowledge or patient characteristics. We found that women had a higher level of knowledge than men (p<0.001) and that post-menopausal women taking estrogen therapy knew more than those who did not (p=0.030). Other characteristics associated with a greater number of correct responses were English as the first language (p=0.004), having a post-graduate education (p=0.004), taking calcium supplements (p=0.001), having had a BMD test previously (p<0.001), having osteoporosis (p=0.007), knowing someone with osteoporosis (p<0.001), and having received information about osteoporosis (p=0.001). The level of osteoporosis knowledge in the fracture population in our study seems inadequate, as the average score of 54.8% represents a fairly low level of knowledge. More needs to be done to educate fracture patients about osteoporosis risk factors, prevention and treatment. This study has also highlighted certain groups that should be targeted for osteoporosis educational initiatives, so as to appropriately reduce the risk of future fractures in this population.

Associations of Number and Type of Vertebral Deformities with Back Pain among Japanese Women. H. Kitahara[1], K. Aoyagi[2], P. D. Ross*[3]. [1]Nagasaki University, Dept of Surgery, Nagasaki, Japan, [2]Dept of Public Health, Nagasaki, Japan, [3]Merck & Co.,Inc, Rahway, NJ, USA.

Vertebral deformity is a classical hallmark of osteoporosis. Three types of vertebral deformity are often described: crush, wedge and endplate. However, there are few data concerning the descriptive epidemiology of the individual deformity types, and the relative clinical impact in Japanese women. We examined the associations of number and type of vertebral deformity with back pain among 584 Japanese women ages 40 to 89 years. Lateral spine radiographs were obtained and radiographic vertebral deformities were assessed by quantitative morphometry, defined as vertebral heights more than 3 SD below the normal mean. Vertebrae which met this criterion for the posterior height were classified as crush; among the remaining vertebrae, those that had an anterior height reduction were called wedge, and those that only had a central height reduction were called endplate. A self-administered questionnaire was used to survey participants about back pain in the previous one month. The overall prevalence of back pain was 30% and was relatively constant after age 50. Endplate (84 vertebrae) and wedge (82 vertebrae) were the most frequent types of deformity, and there were 50 vertebrae with crush deformity. The prevalence of deformity was highest in the T12-L4 region, with a smaller peak centered at T8. In an age-adjusted logistic regression model, the odds of back pain was 2.3 (95% CI: 1.2-4.4) times higher for women with a single wedge deformity, and 5.0 (95% CI: 1.7-14.1) times higher for women with 2 or more wedge deformities, compared to women with no wedge deformity. Both a single any deformity (odds ratio, OR: 2.6, 95% CI: 1.3-5.1) and 2 or more any deformities (OR: 2.4, 95% CI: 1.3-4.6) were associated with back pain, independent of age. Separate analyses of endplate and crush deformities yielded associations that were smaller in magnitude, and were not significant. Additional adjustment for body mass index and number of other painful joints did not alter these findings. These data suggest that vertebral wedge and endplate deformities are more common than crush deformity, and that wedge deformities may be more strongly associated than endplate or crush deformities with back pain in Japanese women.

M299

Hip, Wrist, and Lower Extremity Fractures Predict the Development of Future Hip Fractures. B. J. Edwards[1], A. Bunta*[2], L. Fitzpatrick[3], M. Bolander*[4], C. Simonelli[5]. [1]Medicine, Northwestern University, Chicago, IL, USA, [2]Orthopaedic Surgery, Northwestern University, Chicago, IL, USA, [3]Medicine, Mayo Clinic, Rochester, MN, USA, [4]Orthopaedic Surgery, Mayo Clinic, Rochester, MN, USA, [5]Medicine, Health East, Minneapolis, MN, USA.

The Fracture Intervention Work group was established in 2000, with the goal of developing and establishing clinical algorithms for the evaluation and treatment of osteoporosis-related hip fractures between. All subjects admitted with low trauma hip fractures between 1999-2001were assessed. High-speed trauma, known metastatic cancer or metabolic bone disease were excluded. Clinical data such as patient demographics, co-morbid medical conditions, prior fractures, location of prior fractures, prior diagnosis and treatment for osteoporosis were analyzed. Statistical analysis was performed with SPSS using t-test and chi square. A total of 638 patients were assessed Age: 80 ± 12 yrs. for females, and 73 ± 12 years for males (p=0.002). Predominant ethnic origin was white (> 90%) and a female : male ratio of 4:1. Female weight 61 ± 16 Kgs., and males 78 ± 18 Kgs. (p=0.001). 263 patients (41%) with current hip fractures had presented a prior minimal trauma fracture, in (7) 3% of cases these were multiple fractures. Prevalence of prior fractures was highest at Northwestern University with 62%, and comparable at Health East and Mayo Clinic at 40 and 41%. The sites of previous fracture included: hip (101) 38%, wrist (84) 32%, lower extremity : femur, tibia, fibula, ankle, foot (55) 21%, vertebral (27) 10% and pelvis fractures (9) 3%. Among the lower extremity fractures ankle fractures were the most common (29) 50%. Individuals were cognitively impaired in (10) 9% of the Northwestern cohort while this increased to 25% of the Health East and Mayo Clinic subjects. In a similar fashion nursing home residence was lowest at Northwestern (11%) while higher at Health East and Mayo Clinic. The presence of a prior minimal trauma fracture increased the likelihood of osteoporosis being diagnosed (p< 0.05) However, in spite of a diagnosis of osteoporosis, these individuals were no more likely to receive osteoporosis treatment than those without this diagnosis (<15%) Gait disorders were present in 61% and 55% of subjects at Northwestern University with or without prior fractures. (p= NS) Our results suggest that although prior fractures are common in patients who subsequently develop hip fractures, the presence of such does not increase the likelihood of being diagnosed or ttreated for osteoporosis.

Validity of Self-Report of Fractures among a Postmenopausal Multiethnic Cohort ---Results from the Women's Health Initiative. Z. Chen[1], C. Kooperberg*[2], M. B. Pettinger*[2], T. Bassford*[1], J. A. Cauley[3], A. Z. LaCroix[2], C. E. Lewis[4], S. Kipersztock*[5], M. C. Borne*[6], R. D. Jackson[7]. [1]University of Arizona, Tucson, AZ, USA, [2]Fred Hutchinson Cancer Research Center, Seattle, WA, USA, [3]University of Pittsburgh, Pittsburgh, PA, USA, [4]The Universityof Alabama at Birmingham, Birmingham, AL, USA, [5]University of Florida, Gainesville, FL, USA, [6]UCLA Medical Center, Los Angeles, CA, USA, [7]The Ohio State University Medical Center, Columbus, OH, USA.

The purpose of this study is to examine the validity, and factors associated with the accuracy, of self-reported fractures. This study was conducted in Women's Health Initiative (WHI) Clinical Trial (CT) and Observational Study (OS) cohorts. All women were postmenopausal at the time of enrollment; populations included American Indian, Asian/pacific islander, black, Hispanic, and non-Hispanic white. The average time of follow-up was 4.4 years. Self-reported hip fractures were adjudicated by reviewing medical records, while non-hip fractures were only confirmed for all participants in the CT and OS participants in the three WHI bone mineral density (BMD) centers. We included 160,703 women (67,838 were CT participants and 92,865 were OS participants) in the analyses for hip fracture. Non-hip fractures were studied among 74,989 women from the CT and the three BMD centers. Multiple fractures from a single event were not included in this report, and only the first self-reported fracture for each woman was counted here. Of the 623 self-reported hip fractures, 78.2% were confirmed by medical records, and 2.5% were adjudicated as other fractures. Among the non-hip fractures, the overall accuracy of self-report was high for arm fractures (83-86%) and lower leg fractures (77.8-83%). About half (52%) of self-reported spine fractures had a confirmed fracture at the exact or an adjacent skeletal site. Confirmation of reported tailbone fractures was low (46%). Results of the multivariate analysis indicated several factors were significantly related to the accuracy of self-report of fractures. Minorities, except Hispanic women, were more likely to over-report fractures than non-Hispanic whites. Large body mass index, history of osteoporosis, history of fracture, more than three falls in the last 12 months, high physical activity level, depression and living in the midwest or south region of the United States were associated with lower accuracy of self-reported fractures. In conclusion, results of our study suggest that some osteoporotic fractures (hip, lower arm) are reported with high accuracy whereas other types of fractures (spine, tailbone) have unacceptably low rates of confirmation. The validity of self-report of fractures may be affected by multiple factors.

M301

Maternal Hip Fracture and Current Smoking Are not Associated with Hip Fracture Risk in Elderly Women in the UK. S. K. Bal*[1], K. Kayan[1], A. Richards*[1], S. Vasireddy*[1], J. Cliffe*[1], A. Hinch*[1], C. McGurk*[1], T. Jalava*[2], M. Beneton*[1], J. A. Kanis[1], E. V. McCloskey*[1]. [1]University of Sheffield, Sheffield, United Kingdom, [2]Leiras Oy, Helsinki, Finland.

An assessment tool for fracture risk, developed from the SOF study, has been tested in an elderly French female population. In French women, fracture risk was underestimated compared to US women suggesting that some risk factors may not have the same relevance in different populations. For this reason, we studied the value of risk factors identified in the SOF study to women in the UK. We studied 4347 community dwelling women aged ≥ 75 years selected randomly from Sheffield and the surrounding area who were enrolled subsequently to a randomized placebo-controlled study of bisphosphonate treatment. At entry, each woman underwent a detailed assessment of their health including questions and measurements similar to that in the SOF tool for risk assessment (age, prior fracture, maternal history of hip fracture, low weight, current smoking, difficulty in sit-to-stand and DXA-measured total hip BMD). The gradients of risk for incident hip and all osteoporotic fractures were computed from univariate logistic regression analysis and all factors were entered to a multivariate forward conditional regression to determine their independent contribution, if any, to fracture risk. During a median follow-up of 4 years, one or more incident osteoporotic fractures occurred in 454 women (10.4%) including hip fractures in 131 women (3%). With regard to hip fracture risk, only 4 of the 7 assessments were significantly associated with increased risk of fracture in univariate models. Maternal history of hip fracture (OR and 95%CI, 1.2, 0.5-2.7), prior fracture after age 50 years (1.1, 0.7-1.5) and current smoking (0.8, 0.3-1.9) were not significant predictors of risk. In multivariate analyses, body weight (<57 Kg) was only significant in models that excluded total hip BMD T-score. For all osteoporotic fractures, maternal history and current smoking were again not significantly associated with fracture risk in univariate models (1.2, 0.7-1.9 and 0.7, 0.5-1.2 respectively). In multivariate models, age was not a significant independent contributor to fracture risk and, similar to the observation for hip fracture alone, weight was only a significant predictor in the model excluding hip BMD. We conclude that maternal history of hip fracture and current smoking are not significantly associated with the risk of osteoporotic fractures in elderly women in the UK. Caution is required in accepting the utility of risk factors derived from one region to another. There is a need therefore for international validation of putative risk factors before they can be applied globally.

Determinants of Bone Mass, Size, Architecture and Distribution in Middle Aged and Older Men. R. Daly[1], M. Brown*[1], S. Bass[1], C. Nowson*[1], E. Briganti*[2]. [1]School of Health Sciences, Deakin University, Melbourne, Australia, [2]Dept of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia.

Osteoporosis represents a major public health problem in men. Many factors may contribute to an individual's risk of developing osteoporosis and subsequent fracture, but bone mass is a primary determinant. While bone mass is related to bone strength, bone size (cross-sectional area, CSA), architecture and the structural distribution of bone (cross-sectional moment of inertia, CSMI) also influence bone strength. However, little is known about the determinants of these parameters in older men, and it is uncertain whether risk factors for bone mass are the same as for CSA, architecture and CSMI. To investigate determinants of parameters related to bone strength in middle aged and older men (n=144) aged 49 to 87 years (mean ± SD, 61.8 ± 7.6 yrs), we measured femoral neck BMC, BMD, CSA and CSMI (DXA, hip strength analysis), as well as heel BUA. Explanatory variables included age; height, weight, fat mass and lean mass; exercise, smoking, and calcium, tea, coffee and alcohol intake; history of fracture after the age of 45 years, hypertension, diabetes, asthma and arthritis; use of antihypertensives, thiazide diuretics, diabetes and lipid lowering agents, antidepressants and corticosteroids; and family history of osteoporosis. BMD T-scores indicating osteopenia (-1.0 to -2.5 SD) and osteoporosis (below -2.5 SD) were found in 34.7% and 6.2% of the men, respectively. The initial regression model included explanatory variables with a P-value <0.20 on univariate analysis. The final model was determined by purposeful backward stepwise regression using the log likelihood ratio test, with a P-value <0.10 considered significant (Table). The total variance for FN bone traits explained by these models ranged from 17-34%.

Beta-coefficients	BMC g	BMD g/cm^2	CSA mm^2	CSMI mm^4	Heel BUA dB/MHz
Weight, per kg	+0.050	+0.005	+1.5	-	-
Height, per cm	-	-	+0.6	+183.4	-
Fat mass, per kg	-0.040	-0.004	-1.3	-	-
Lean mass, per kg	-	-	-	+276.2	-
Hypertension	-0.409	-0.061	-16.5	-	-
Fx history	-	-0.056	-	-	-
Use of antihypertensives	-	-	-	-	-5.89
Daily coffee intake, per cup	-	-	-	-	+1.58
Adjusted R^2	31.3%	16.7%	31.5%	34.3%	4.3%

In summary, hypertension, fat mass and weight were important determinants of bone mass and size, while history of fx was associated only with bone mass and height only with bone size. In contrast, only lean mass and height were associated with the structural distribution of bone. These results indicate that different parameters related to FN bone strength may be affected by different clinical risk factors. The role of hypertension as a determinant of bone strength parameters requires greater attention.

M303

Body Composition Correlates of Total Hip Bone Mineral Density in Afro-Caribbean Men: Tobago Bone Health Study. D. D. Hill*[1], J. A. Cauley[1], A. Patrick*[2], J. M. Zmuda[1], V. Wheeler*[2], C. H. Bunker*[1]. [1]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [2]Scarborough Regional Hospital, Scarborough, Trinidad and Tobago.

Body weight is a strong determinant of bone mineral density (BMD). Body weight consists of several components, including fat mass and lean mass. The relative contribution of lean mass and fat mass to BMD is uncertain, particularly among men and non-Caucasian populations. To test the hypothesis that lean mass and fat mass are independently correlated with BMD in men of African ancestry, we studied the relationship between body composition (lean mass and fat mass) and BMD in a cohort of 2,076 Afro-Caribbean men, aged 40 and over, who were enrolled in the Tobago Bone Health Study. Body composition and BMD were measured with a Hologic QDR 4500W densitometer. The mean age and height of men were 59.2 ± 11.2 years and 82.8 ± 14.6 kilograms, respectively. Both lean mass (r = 0.46) and fat mass (r = 0.26) were correlated with total hip BMD. In models considering lean mass or fat mass separately, both were independently related to hip total BMD. We then analyzed mean total hip BMD across quintiles of lean mass, fat mass, and lean mass + fat mass interaction, adjusting for age and height using ANCOVA. There was no association between fat mass and total hip BMD. Total hip BMD increased across increasing quintiles of lean mass (Table 1). Within each fat mass quintile, total hip BMD increased across quintiles of lean mass and was 14-22% higher in men with the greatest lean mass. Similar results were observed for femoral neck BMD and BMAD. In this population, lean mass was a significant independent contributor to total hip BMD. These results emphasize the relative importance of lean mass as a correlate of BMD in men of African ancestry.

Table 1. Adjusted Mean Total Hip BMD (g/cm^2) across Quintiles of Lean Mass and Fat Mass[a]

Lean Mass	Fat Mass				
	1	2	3	4	5
1	1.01	1.05	1.05	1.06	1.04
2	1.09	1.09	1.11	1.11	1.09
3	1.14	1.17	1.14	1.14	1.14
4	1.18	1.17	1.19	1.18	1.18
5	1.29	1.27	1.23	1.23	1.26

[a] Controlling for age and height;
p (lean mass) <0.0001
p (fat mass) = 0.95
p (lean mass x fat mass) = 0.15

M304

The Usefulness of an Osteoporosis Risk Profile for Men in Three Racial/ Ethnic Groups. D. L. Broussard*, J. H. Magnus. Tulane University Health Sciences Center, New Orleans, LA, USA.

Risk factor profiles for low bone mineral density (BMD) have been determined in White women and men to indicate when BMD measurement is needed. The purpose of this study was to determine if a risk factor profile for White men identifies low BMD in African-American (AA) and Mexican-American (MA) men. Only three risk factors were found to be consistent for White men in published population-based, longitudinal and cross-sectional studies; body mass index (BMI), cigarette smoking, and calcium intake. This profile was evaluated among 574 AA, 554 MA, and 1274 White men, between the ages of 50 and 79 years, who participated in the household interview and BMD measurement of the Third National Health and Nutrition Examination Survey (NHANES III). Osteoporosis T-scores were calculated for each race/ethnic group as ≥2.5SD below the young male adult (20-35 years) mean BMD for the total femur using NHANES III data. Osteopenia T-score was defined as between 1 and 2.5SD below the race/ethnic group-specific young male adult mean. Low BMD was defined as BMD below 1SD of the race/ethnic relevant young adult mean. The sensitivity, specificity, and positive and negative predictive values (PPV and NPV) of individuals with total femur osteoporosis based on T- scores were calculated. Based on the race specific T-scores, the overall prevalence of osteoporosis in this NHANES III population was 4.9%, 4.0%, and 3.8%, respectively, for AA, MA, and White men. The presence of two risk factors identified osteoporosis with a sensitivity and specificity of 61% and 78% in AA men, and 50% and 77% in MA men, respectively. The NPVs across all race/ethnic groups were approximately 97% and the PPVs ranged from 8-12%. Osteopenia was present in 35.9%, 31.1%, and 32.2% of AA, MA, and White men, respectively. Between 47% and 59% of men reporting two risk factors were classified with low BMD. In all race/ethnic groups, more subjects with low BMD reported two risk factors ($p<0.0001$). As expected, sensitivity and NPVs decreased while the PPV values increased when low BMD was assessed. Among AA men, the sensitivity and specificity for low BMD were 35% and 83%. Logistic regression analyses revealed statistically significant associations between the presence of two risk factors and osteoporosis, osteopenia, and low BMD in all race/ethnic groups. The age adjusted relative risks for low BMD given two risk factors were 2.6 (95% CI, 1.8-4.0) for AA men, 2.2 (95% CI, 1.5-3.3) for MA men and 1.9 (95% CI, 1.5-2.4) for White men in this population. These results suggest that AA, MA, and White men with any of the two risk factors studied are more likely to be osteoporotic or osteopenic. The usefulness of this as a screening tool in a clinical setting needs further investigation.

M305

The OST Risk Tool Is Valid in American Men. R. A. Adler, M. T. Tran*, V. I. Petkov*. Endocrinology, McGuire Veterans Affairs Medical Center, Richmond, VA, USA.

The simple-to-administer OST risk tool was first developed to identify Asian postmenopausal women at increased risk of osteoporosis. It has been validated in Caucasian women. The calculated risk index is based on self-reported age and weight: [(weight in kg - age) X 0.2, truncated to an integer]. Does the OST risk tool work in men? We used data from two prospective studies conducted among patients enrolled in Pulmonary and Rheumatology clinics at a single Veterans Affairs Medical Center. The studies evaluated the usefulness of screening methods to predict osteoporosis as defined by central DXA (Hologic 4500). Only those patients who did not have a previous DXA were eligible to participate. The OST- tool index was calculated, and ROC curves were constructed. Sensitivity and specificity were determined at different cut-offs of the risk index. One hundred and eighty men (132 white, 64 black, 4 other) filled out a questionnaire and within a month underwent central DXA (total hip, femoral neck, and lumbar spine). The mean (SD) age was 63.3 (13.1) years, and the mean weight was 91.1 (21.4) kg. The OST risk index ranged between - 5 and 25, (mean 5 ± 5). By DXA, 15.6% of the men had a T of ≤-2.5 and 33.9% had a T of ≤-2 at one of the measured sites. The OST-tool index yielded areas under the ROC curves of 0.837, 95% CI [0.749, 0.925] and 0.816, 95% CI [0.747, 0.885] for T≤-2.5 and T≤-2, respectively. As shown in the table, the OST-tool index was categorized as low risk ≥ 4, moderate risk from -1 to 3 and high-risk ≤ -2. Defining osteoporosis as a T-score of ≤-2.5, an OST cut-off of 3 provided sensitivity of 93%, specificity of 66%, positive predictive value of 33%, and negative predictive value of 98%. Similar results were obtained when white and black men were analyzed separately. In conclusion, we found the OST-tool to be valid in male veterans from 2 specialty clinics. We will extend the study to general practice clinics to determine if the results can be applied to other groups of American men. The simple OST-tool appears to be an excellent method to identify men at high and low risk for osteoporosis.

Prevalence of osteoporosis in veteran men by risk tool categories and central DXA T-score

OST Category	T-score ≤-2.5	T-score ≤-2.0
≥ 4 (Low Risk)	2.0% (2/102)	15.7% (16/102)
-1 to 3 (Moderate Risk)	26.9% (18/67)	52.2 (35/67)
≤ -2 (High Risk)	72.7% (8/11)	90.9% (10/11)

M306

Serum Leptin Concentrations and Bone Mass: Differential Association Among Obese and Non-Obese Men. M. Lee, J. M. Zmuda, S. Wisniewski*, S. Krishnaswami*, R. W. Evans*, J. A. Cauley. Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA.

Recent animal studies suggest that the adipocyte derived hormone, leptin, may be a potent and centrally acting inhibitor of bone formation. In clinical studies, however, leptin has been inconsistently related to bone mass. In the present study, we further evaluated the relationships among body composition, serum leptin levels, and bone mineral density (BMD) in a cohort of community-dwelling older men. Total fat and lean mass and hip BMD were measured with a Hologic QDR-2000 densitometer. Men with a history of osteoporosis and those taking glucocoticoids or medications known to alter sex steroid hormone metabolism were excluded from analyses. The final sample consisted of 297 men aged 58 - 91 yrs (Mean ± SD; 73 ± 7 yrs). In the total cohort, serum leptin levels were not significantly related to femoral neck BMD (r_s=0.03, p =0.64) after adjusting for age, height and body composition. To further evaluate the association between serum leptin levels and BMD, we stratified the sample into obese (BMI >30 kg/m^2; n=78) and non-obese (BMI <30 kg/m^2; n=219) men. As expected, obese men had markedly higher serum leptin levels than non-obese men (12.2 ±1.7 ng/ml *vs* 5.7 ± 1.6 ng/ml; P<0.01). In analyses adjusting for age, height and body composition, serum leptin levels were inversely correlated with femoral neck BMD among obese men (r_s= -0.26, $p<0.05$) but not among non-obese men (r_s= 0.05, p=0.44). Multiple regression analysis revealed that serum leptin levels explained 4.6% of the variation in femoral neck BMD among obese men. Similar results were observed for femoral neck bone mineral apparent density (BMAD). Our results suggest that serum leptin may be differentially associated with bone mass among obese and non-obese men.

M307

Bone Mineral Density (BMD) in HIV Patients on Stable First Line Treatment. S. Azriel*[1], M. Torralba*[2], G. Martínez*[1], E. Jódar*[1], R. Rubio*[2], F. Hawkins[1]. [1]Endocrinology Service, Hospital Universitario 12 de Octubre, Madrid, Spain, [2]HIV Unit, Hospital Universitario 12 de Octubre, Madrid, Spain.

Several studies have reported osteopenia and osteoporosis in HIV infected patients. Antiretroviral therapy and HIV infection itself may be involved as aetiological factors. Our goal was to describe osteoporosis/osteopenia prevalence in HIV patients who had been treated with the same antiretroviral drugs since they started therapy and to investigate the possible relationship between low bone mass and lipodystrophy syndrome. Observational cohort of 65 HIV patients who were treated with the same antiretroviral drugs at least 12 months. Severity of body changes was scored as: 0=no changes; 1= mild; 2= moderate and 3 =severe. Body changes were considered to be present if both physician and patient agree with lipodystrophy and at least score 2 was present in one of them. Dual X Ray Absorptiometry (DXA) of the lumbar spine and femoral neck was done. 67% of subjects were males. Median age of patients was 38 years (36-42 IQR). Weight was 68 kg (60-76 IQR) with BMI 23.7 Kg/m^2 (21,65-26,64 IQR), and waist 87,5 cm (81-93,75). Median CD4 cells/ml were 549 and 94% of the patients had VL < 500 copies/ml. The median-time of treatment was 41 months (26-53 IQR). 25% were treated with nuclease-reverse transcriptase inhibitor bitherapy (NRTI). 19% were treated with 2 NRTI plus non-nuclease-reverse transcriptase inhibitor (NNRTI) and 57% with NRTI plus PI (highly active antiretroviral therapy, HAART). Body shape abnormalities were detected in 45% patients (lipoatrophy: 38%, lipohypertrophy: 17% and mixed:11%). According to WHO definitions using T score, 62% of patients in the whole group had osteopenia and 11% were osteoporotic. Males were more severely affected: 71% had osteopenia and 14% osteoporosis. Premenopausic women presented osteopenia in 43% and osteoporosis in 5% of cases. There was no statistical association between lipodistrophy and osteopenia. However low bone mass was less frequently found in NRTI cohort (31,3%) than in HAART (62,2%) (p=0.033). There is a high prevalence of low bone mineral density as well as of body shape abnormalities in a cohort of HIV patients who never have switched treatment. Association between osteopenia and body shape abnormalities have not been found. Osteopenia is less prevalent in NRTI bitherapy regimens.

M308

Intra-uterine and Early Postnatal Growth Influence Proximal Femoral Geometry and Mechanical Strength in Late Adulthood. S. Lekamwasam*[1], M. K. Javaid*[2], E. M. Dennison*[2], H. E. Sydall*[2], N. Loveridge*[1], J. Reeve*[1], T. J. Beck*[3], C. Cooper[2]. [1]Medicine, Addenbrooke's Hospital, Cambridge, United Kingdom, [2]Medical Research Council Environmental Epidemiology Unit, Southampton, United Kingdom, [3]Radiology, Johns Hopkins University, Baltimore, MD, USA.

The proximal hip is the most important site of osteoporotic fracture in terms of morbidity, mortality and healthcare costs. Both femoral geometry and bone mass are independent predictors of hip strength and fracture. While growth in early life is known to influence adult bone mass, its effect on hip geometry is not known. We therefore investigated the relationship between intra-uterine and early postnatal growth and hip geometry/ strength in a sample of men and women, aged 60- 75 years, who have been characterised for both birthweight and weight at one as well as current anthropometry, diet and lifestyle factors. Hip geometry was derived from proximal femur images (Hologic QDR1000). The images were analysed using the Hip Strength Analysis software. Women had significantly ($p<0.001$) lower femoral width, cross-sectional moment of inertia (CSMI) at all sites and shorter femoral neck lengths than men. Despite these gender differences, there were significant ($p<0.002$) relationships between weight at age one year and measures of femoral width (intertrochanteric [IT] and femoral neck) as well as IT CSMI, among both men and women. Relationships with birhweight were less pronounced. There was no association between weight in infancy and femoral axis length. The relationships with measures of femoral width but not CSMI remained after adustuting for adult body weight and for lifestyle correlates of bone mass (smoking, alcohol consumption, dietary calcium intake and physical activity). These results support the hypothesis that different patterns of growth in utero and during the first year of life lead to persisting differences in proximal femoral geometry and mechanical strength thereby mediating the effects of early growth on risk of hip fracture.

Relationship between femoral geometry and birthweight and weight at one year

Birthweight	Birthweight		Weight at one year	
	Unadjsuted	Adjusted*	Unadjusted	Adjusted*
Men (n=178) Femoral neck length	-0.03 (0.67)	-0.06 (0.47)	0.12 (0.11)	0.08 (0.33)
IT width	0.22 (0.003)	0.18 (0.02)	0.37 (<0.001)	0.31 (<0.001)
IT CSMI	0.14 (0.06)	0.06 (0.41)	0.23 (0.002)	0.11 (0.15)
Women (n=155) Femoral neck length	0.05 (0.50)	0.03 (0.73)	0.08 (0.31)	0.04 (0.65)
IT width	0.19 (0.02)	0.11 (0.21)	0.40 (<0.001)	0.32 (<0.001)
IT CSMI	0.19 (0.02)	0.05 (0.54)	0.28 (<0.001)	0.14 (0.09)

Figures are correlation coefficients with p values.
*adjusted for adult weight and lifestyle factors.

Genetic and Hormonal Influences in Bone Mass of Postmenopausal Women. M. E. Muñoz-Torres[1], P. Mezquita-Raya*[1], F. Lopez-Rodriguez*[1], J. M. Quesada*[2], F. Luque-Recio*[2], G. Alonso*[1], J. D. Luna*[3], B. Torres*[1], F. Escobar-Jiménez*[1]. [1]Bone Metabolic Unit. Endocrinology Division, University Hospital San Cecilio, Granada, Spain, [2]Endocrinology Division, University Hospital Reina Sofía, Cordoba, Spain, [3]Biostatistics Department, School of Medicine, Granada, Spain.

Bone mass and its mineral content are under genetic and hormonal control. Genetic factors are now recognized to be one of the most important determinants of bone mineral density (BMD). Also, several studies have shown that bone mass is under diverse hormonal influences. However, the relationship between genetic and hormonal factors in postmenopausal bone mass is not well established. **AIMS:** to examine the association of the COLIA1, VDR and ER genotypes, IGF-I and 25OHD with bone mineral density in postmenopausal women.**SUBJECTS AND METHODS:** We determined anthropometric parameters, lifestyle factors, serum levels of IGF-I and 25OHD, the COLIA1 (MlsI), VDR (BsmI, FokI) and ER (Xba, Pvu) polymorphisms by PCR and BMD by dual X-ray absorptiometry in 141 ambulatory postmenopausal spanish women (61±7 yrs). **RESULTS:** there was a significant overrepresentation of the "s" allele in osteoporotic women ($p=0.009$). After controlling for all other variables, lumbar spine BMD was found to be significantly associated with 25OHD, IGF-I, COLIA1, body mass index (BMI) and years after menopause ($R2=0.347$; $p<0.001$). For femoral neck, significant independent predictors of BMD were 25OHD, IGF-I, COLIA1, body mass index (BMI) and years after menopause ($R2=0.4$; $p<0.001$). None of the remaining genotypes entered the multiple linear regression models.**CONCLUSION:** our study shows that COLIA1 polymorphism, 25OHD and IGF-I concentrations are associated with bone mineral density independently of anthropometric parameters and lifestyle factors.

M310

Bone Mineral Density in Young Adults with Cystic Fibrosis. O. Lamy*[1], I. Pache*[1], E. Udry*[2], P. Burckhardt[2], A. Sauty*[1]. [1]Internal Medicine, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland, [2]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.

Aims: To determine the bone mineral density (BMD) and its relation with body mass index (BMI), 25-OH-vitamin D (25-OH-D) level, calcium and vitamin D supplementation, and pulmonary function tests, in young adults with cystic fibrosis (CF). Methods: 25 adult patients with a stable disease or on a waiting list for lung transplantation. Results: The mean age at the first BMD was 26.4 + 5.8 years. 12 (48%) patients had osteoporosis on > 1 site, 8 (32%) had osteopenia on > 1 site and only 5 (20%) had a normal BMD. The site where we most frequently found a low BMD were the lumbar spine (90%) and the femoral neck (85%). Seven out of 8 patients waiting for lung transplantation had osteoporosis and one had osteopenia on three different sites. Calcemia, phosphatemia and alkaline phosphatase values were similar in all patients. 25-OH-D values were also similar with 79% of the patients having a level < 25mmol/l. Only 50% of the patients with low BMD received calcium and vitamin D supplementation before this evaluation. 25-OH-D values were not higher in patients under 800 UI oral vitamin D supplementation. None of the patients with normal BMD had been prescribed long term steroids. No difference in the frequency of steroids administration was found between the patients with osteoporosis compared with those with osteopenia. Patients with a low BMI had a significantly lower BMD ($p=0.04$). Low BMD was more prevalent in patients with low forced expiratory volume in 1 second (FEV1) and low forced vital capacity (FVC), $p<0.02$. We did not found any relationship between the presence or absence of colonisation with Pseudomonas aeruginosa and BMD. Conclusions: Low BMD is a frequent problem in young adults with CF and is more prevalent in patients with low FEV1 and FVC. The first bone evaluation occurred rather lately in the life of these patients and only half of them received a calcium and vitamin D supplementation before densitometry assessment. In order to prevent complications related to osteoporosis or graft-induced osteoporosis, such as vertebral fractures, more attention should be given to the bone status of these patients. Earlier bone evaluation would lead to a better prevention of osteoporosis.

M311

Pregnancy Associated Decrease of Skeletal Integrity Assessed by Phalangeal Ultrasonometry. P. Hadji[1], C. Wüster[2], L. Hellmeyer*[1], S. Schmidt*[1], V. Ziller*[1], K. Schulz*[1]. [1]Dept. of Obstetrics and Gynecology, Philipps-University of Marburg, Marburg, Germany, [2]Dept. of Endocrinology, University of Heidelberg, Heidelberg, Germany.

Due to the substantial transfer of calcium from mother to fetus during pregnancy, reproductive factors such as parity have been associated with osteoporotic fractures in later years. This study was aimed to elucidate skeletal integrity by phalangeal ultrasonometry during pregnancy. Quantitative ultrasonometry (QUS) of the phalanges (digits II to V) was performed by using the DBM Sonic 1200 (IGEA, Italy). The device measures the Amplitude dependent Speed of Sound (Ad-SoS), the graphic trace of the ultrasound wave which is highly correlated to bone structure and calculates the Ultrasound Bone Profile Index (UBPI). We performed a cross-sectional study including 128 pregnant women (mean ±SD age, 28.7 ± 5.9 years) in whom diseases and drug treatments known to affect bone metabolism had been excluded. The ultrasonometry variables Ad-SOS and the UBPI were assessed in accordance to the week and trimenon of pregnancy. The results showed a decrease of Ad-SOS and the UBPI during pregnancy, however the results did not reach statistical significance (fig. 1&2). The additional multiple linear regression analysis did not show any significant influence of pregnancy on QUS variables. There was no significant decrease of phalangeal ultrasonometry variables during prgnancy. Since QUS does not require exposure to radiation, is easily accessible, fast, portable and cheap, QUS seems to be especially useful for evaluation of skeletal integrity during pregnancy. Further longitudinal studies are need to improve our understanding of the mechanism of bone changes during pregnancy.

M312

The Influence of Age, Testosterone and Estrogen on Quantitative Ultrasonometry (QUS) of Bone in Healthy German Men. P. Hadji, U. Saeger*, K. D. Schulz*. Dept. of Obstetrics and Gynecology, Philipps-University of Marburg, Marburg, Germany.

The aim of this study was to evaluate the influence of age, testosterone and estrogen levels on quantitative ultrasonometry (QUS) of the os calcis in a large sample of healthy German men. 484 healthy men aged 20 to 80 years (mean age, 54.4 ± 15.4 years) not on medication known to effect bone metabolism were randomly recruited. Before entry to the study, all men had answered a detailed questionnaire on important risk factors. Speed of sound (SOS), broadband ultrasound attenuation (BUA) and stiffness index (SI) of the os calcis were measured using the Achilles ultrasonometer (GE/Lunar). Additionally, serum testosterone and estrogen levels were determined. BUA, SOS and SI decreased continuously from age 20. The total age-related decline was 17% for BUA, 2.4% for SOS and 17.4% for SI ($p<0.001$). This occurred over a 47-year period. The annual decrease derived from age regressions was -0.4% for BUA, -0.05% for SOS, and -0.39% for SI. There was a significant decrease of serum testosterone with age ($p<0.001$), while estrogen showed no such association. There was a significant correlation of testosterone to SOS and SI ($p<0.01$), but non of estrogens to QUS variables. This significant correlation diminished after performing a multiple linear regression analysis. Hereby only age remained as a significant predictor of QUS variables. Like in women, men show a significant age related decline of QUS variables. In contrast to women, the QUS variables decline continuously from the age of 20 years. There is no age-independent influence of testosterone or estrogens on QUS variables.

M313

Premenopausal Women with Type 1 Diabetes Have Poor Bone Quality Assessed by Quantitative Ultrasound (QUS). E. S. Strotmeyer, J. A. Cauley, J. S. Dorman*. Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA.

Little is known about bone quality in women with type 1 diabetes compared to women without diabetes before or after the menopausal transition. Bone quality was assessed in premenopausal women, with type 1 diabetes (n=60) and without diabetes (n=143) by heel QUS using broadband ultrasound attenuation (BUA) and the speed of sound (SOS) (Sahara System, Hologic Inc.). Type 1 diabetes registry cases and non-diabetic community controls were enrolled in the ProHealth Study to evaluate their menopausal transition. Mean diabetes duration for cases was 31 years and mean HbA1C was 8%. Hormone use (HRT, OC), smoking status, fracture history and menstrual data were collected by questionnaire. Mean age was lower in cases vs. controls (42±4 vs. 44±4 years; p<0.001). Cases were similar to controls in current smoking (26% vs. 20%; ns) and any current hormone use (14% vs. 18%; ns). Both cases and controls had 29 mean days between their last two menstrual cycles (ns). Weight (69±14 vs. 73±20 kg; p=0.16) was slightly lower and waist-hip ratio (WHR) (0.81±0.06 vs. 0.79±0.06; p=0.03) was higher for cases. Mean clinical Michigan Neuropathy Screening Instrument (MNSI) score was 1.8±1.4 for cases vs. 0.9±1.0 for controls (p<0.001). More cases reported fractures after age 20 years (30% vs. 18%; p<0.05). Cases had lower mean BUA (68±18 vs. 83±19 dB/MHz; p<0.001) and SOS (1555±34 vs. 1574±34 m/s; p<0.001), indicating a much poorer bone quality. Multiple linear regression analyses were performed with BUA (dependent variable) and variables described above. Type 1 diabetes was (p<0.001) negatively related to BUA (R^2=0.133; p<0.001). Using the same modeling for SOS, type 1 diabetes (p<0.01) and current smoking (p=0.01) were both negatively related to SOS (R^2=0.097; p<0.001). Considering only women with diabetes, and adding duration and HbA1C to the model, increased weight (p=0.002) and decreased cycle length (p=0.05) were related to lower SOS (R^2=0.135; p<0.01). In conclusion, type 1 diabetes was strongly associated with poorer bone quality in premenopausal women. Menstrual cycle length, possibly as a marker of perimenopause, and weight may affect poor bone quality for women with type 1 diabetes. Type 1 diabetic women may be at high risk of osteoporosis. Appropriate screening and preventive efforts may be warranted.

M314

Osteoporosis in Patients with Depression. J. Menczel[1], Y. Gelfin*[2], B. Shapira*[2]. [1]Institute of Osteoporosis, Herzog Hospital, Jerusalem, Israel, [2]Schonbaum Depression Department, Herzog Hospital, Jerusalem, Israel.

Osteoporosis and depressive disorders (MDD) are major health problems affecting a large proportion of the population. The prevalence of osteoporosis increases with age; MDD has a rate of incidence between 10 to 25% for women and 5-12% in men. Higher prevalence of osteoporosis in patients with depression has been reported, but not confirmed, by others. A greater incidence of falls and fracture of the neck of femur was observed in these patients. Twenty-five patients with major depression were examined and Bone Mineral Density (BMD) with a Lunar Prodigy Dual Photon Absorptiometer (Dexa) were performed. BMD of lumbar spines and both hips were measured. Hamilton, depressive scale ratings, were performed in all patients. The Hamilton score ranged between 13 and 31. Of the 25 patients with major depression, 12 had definite osteoporosis (48%), 14 of them were females and 11 males. The BMD of the neck of femur ranged from t = -1.6 to -4.3, and L2 - L4, from -0.6 to -3.8. Only patients who had a t lower than minus 2.5, either of the neck of femur or L2 - L4, were included. Seven were females and 5 were men. The ages of the 25 patients ranged between 42 to 84 years and 13 were under the age of 64. Osteopenia, defined as a BMD measurement with a t of one of the sites between -1 to -2.5, was found in 5 patients. All 5 patients were females and their ages ranged from 26 to 73 years. It can be deducted that 48% of the patients with major depression had a loss of bone mass greater than expected. Five who had a t lower than -2.5 were over 75 years. Each patient underwent an interview and risk factors for osteoporosis and fractures were recorded. Two of the patients with a low BMD had a body mass index (BMI) below 20, being underweight. Ten had a normal weight with a BMI between 20 to 25, 10 were overweight with a BMI between 25 to 30, and 2 of these were obese and osteopenic. High BMI has a protective influence against bone loss due to peripheral estrogen production by adipose tissue. We do not have a matched control group of the same age and sex, and the results were compared to published prevalence figures. A higher incidence of osteoporosis was found. Taking into consideration the higher prevalence of a low bone mass in patients with major depression disorders, and that they suffer from falls, preventive and therapeutic measures should be started to avoid fractures, especially of the neck of femur.

M315

Correlation of Height Loss with Fracture History and Bone Mineral Density (BMD). R. D. Pathak*, A. L. Burshell. Section on Endocrinology, Ochsner Clinic Foundation, New Orleans, LA, USA.

Multiple vertebral compression fractures markedly increase the risk of future fractures. We studied self reported, greater than or equal to 2 inches height loss and its association to BMD and self reported fractures. Data were analyzed from 2571 subjects who completed a BMD evaluation and clinical questionnaire at Ochsner Clinic Foundation from July 2001 to March 2002. Most patients were postmenopausal women with risk factors for osteoporosis, but a minority were premenopausal or men. Subjects completed 20 questions via computer or paper forms and underwent both hip and lumbar BMD performed on Hologic Delphi SN 70045 scanner. Subjects were divided into 4 groups on the basis of height loss, positive or negative (HL+), (HL-) and fracture history (Fx+), (Fx-) and femoral neck and total hip BMD were measured. HL+ was present in 11% of the subjects and BMD was lower in this group. Fx+ defined as any fractures were present in 39% of the subjects, 52% of HL+ and 37% of HL- subjects. The combination of HL+, Fx+ was associated with the lowest femoral neck and total hip BMD. HL+, Fx- group had a lower BMD than Fx+, HL-. Self reported history of 2 inches or greater height loss is associated with low hip BMD and together with fracture history may help identify very high risk patients for fractures.

BMD and Clinical Data

No of Subjects	149	135	857	1430
Height Loss	HL+	HL+	HL-	HL-
Prior Fracture(s)	Fx+	Fx-	Fx+	Fx-
Mean Femoral Neck BMD (gm/cm2)	0.624	0.681	0.705	0.741
Mean of Total Hip BMD (gm/cm2)	0.751	0.819	0.853	0.893
Weight (kg)	67.6	67.2	73.0	72.4

M316

Public Release of Data from the Study of Osteoporotic Fractures: Design of the Website. D. Kimmel*[1], S. Ewing*[1], K. Stone[1], C. Fox*[1], J. Cauley[2], K. Ensrud[3], M. Hochberg[4], T. Hillier[5], M. Nevitt[1], S. Cummings[1]. [1]The Study of Osteoporotic Fractures Research Group, Univ of California San Francisco, San Francisco, CA, USA, [2]Univ of Pittsburgh, Pittsburgh, PA, USA, [3]Univ of Minnesota, Minneapolis, MN, USA, [4]Univ of Maryland, Baltimore, MD, USA, [5]Kaiser Permanente Center for Health Research, Portland, OR, USA.

The multi-center Study of Osteoporotic Fractures (SOF) has 16 years of prospective data about osteoporosis that has served as the basis for many findings about osteoporosis and aging in women ≥ age 65. In addition to adjudication of fractures, SOF has tracked cases of incident breast cancer, stroke, and total and cause-specific mortality. The data include serial measures of bone mineral density, measurements of sex and calcitropic hormones, tests of strength and function, cognitive exams, use of medication, health habits and much more. We are introducing a public website and process for releasing SOF anonymized data to the broader research community. Through dynamic internet technology, the website provides interactive documentation on 6,000 variables collected over seven principal visits of this unique cohort of nearly 10,000 older women. Users can browse variables by category or perform variable searches, viewing search results in a convenient longitudinal format of variable availability across visits. Users may link to the study data collection forms, as well as view descriptive statistics (e.g., means or frequency distributions). We expect that investigators in many fields will use the website to formulate and submit analysis plans of the dataset. The website facilitates online submission of these plans as well as the means to search for and view previously submitted plans by other researchers. Over 170 publications, 40 of which by external researchers, have already been published using SOF data. We hope that the dataset will prove increasingly fruitful by providing online access to new investigators who may propose unique research topics to be studied in SOF. Furthermore, as the trend continues toward mandatory public release of data from NIH-funded studies, this website will serve as a template for future data releases from our other studies. We hope our web-based applications can serve as a model for others as they address this important need. We encourage investigators in osteoporosis to discuss the website and processes with us and make use of this valuable public resource.

M317

Osteoporosis Perceived Vulnerability, Worry and Stress in Healthy Women. I. Vered[1], P. Werner*[2], D. Olchovsky*[3]. [1]Endocrinology, Sackler School of Medicine, Tel Aviv University, Sheba Medical Center, Tel Hashomer, Israel, [2]Department of Gerontology, Faculty of Social Welfare & Health Studies, University of Haifa, Haifa, Israel, [3]Department of Medicine, Sackler School of Medicine, Tel Aviv University, Sheba Medical Center, Tel Hashomer, Israel.

The relationship between perceived vulnerability and worries about a specific disease and preventive behaviors has been established for several diseases such as breast cancer, prostate cancer and AIDS. However, little attention has been paid to these relationships regarding osteoporosis, and no studies have yet examined the correlates of these variables. The aim of the present study was to assess predictors of perceived vulnerability, worry and stress about developing osteoporosis in healthy women. Two-hundred and forty one women (mean age = 53.94; 71.4% Jewish and 28.6% Arab) were interviewed regarding their perceived likelihood to develop osteoporosis, their perceived concern about developing the disease, and their perceived stress should they develop the disease. Background variables (age, marital status, ethnic group, education, and income), health variables (being menopausal, taking hormone replacement therapy and having a first-degree relative suffering from osteoporosis), and cognitive variables (knowledge about osteoporosis and health locus of control, i.e., internal, powerful others and chance locus of control) were also assessed. Seventy percent of the women were menopausal, a fifth of them were taking HRT, and a fifth reported having a family member diagnosed as suffering from osteoporosis. The participants had a relatively low level of knowledge about osteoporosis, (mean score of 11 points in an osteoporosis quiz with a maximal score of 23). Higher scores were reported in the internal and powerful others' dimensions than in the chance dimension. The participants reported moderate levels of vulnerability and moderate to strong levels of concerns about developing osteoporosis. Results of path analyses indicated that having a family member suffering from osteoporosis, higher knowledge, lower internal beliefs, and higher powerful others locus of control, were associated with higher perceived vulnerability. Additionally, higher feelings of vulnerability were associated to greater worries, which were associated with greater stress. The results have implications for the construction of educational programs designed to acknowledge feelings of osteoporosis worries and stress.

M318

Evaluation of the Sensitivity and Specificity of Screening Tools for Referring Women for Bone Densitometry. S. K. Brenneman[1], A. Z. LaCroix*[2], D. S. M. Buist*[2], Y. Chen*[1], T. A. Abbott[1]. [1]Merck & Co., Inc., West Point, PA, USA, [2]Center for Health Studies, Group Health Cooperative of Puget Sound, Seattle, WA, USA.

Low bone mineral density (BMD) is a strong predictor for fracture related to osteoporosis. However, BMD testing of all postmenopausal women is not standard practice. This study examines the diagnostic properties of 2 screening tools for selecting women for BMD testing and subsequent intervention: Simple Calculated Osteoporosis Risk Estimation (SCORE: 6 weighted risk factors) and a Study of Osteoporotic Fracture (SOF)-based screening tool (SOF-based: prior fracture or ≥ 5 of 17 risk factors). Women aged 60+ without previous osteoporosis diagnosis were randomly selected from a managed care population and invited to receive a BMD test. 416 women participated in the study. Women were classified using 3 different intervention strategies: WHO diagnostic criteria (t-score <-2.5), NOF criteria (t-score < -2.0 or < -1.5 with ≥ NOF 1 risk factor), and the SOF-based criteria (prior fracture or age 60-64: t-score <-2.5 or age ≥ 65: z-score <-0.43 and ≥ 5 risk factors). The percentage of women identified for BMD testing were 82% by SCORE and 26% by the SOF-based tool. Sensitivity, specificity and area under the receiver operating characteristic (AUROC) curve are shown below.

	Sensitivity (95% CI)	Specificity (95% CI)	AUROC (SE)
NOF intervention guidelines: N=275 (66%)			
SCORE	89.8 (79.9, 99.6)	34.8 (23.7, 45.8)	.73 (.03)
SOF-based	30.2 (22.1, 38.9)	80.9 (72.9, 89.4)	.56 (.03)
WHO (t-score ≤ -2.5): N=126 (30%)			
SCORE	93.7 (88.3, 99.1)	23.8 (9.6, 38.0)	.73 (.03)
SOF - based	31.8 (26.6, 38.6)	75.9 (63.5, 88.6)	.54 (.03)
SOF-based intervention: N=115 (28%)			
SCORE	98.3 (92.7, 100.4)	24.3 (9.7, 38.8)	.68 (.03)
SOF - based	85.2 (77.8, 91.9)	96.0 (89.0, 102.6)	.90 (.03)

For NOF and WHO criteria, SCORE demonstrates better utility to discriminate high vs. low risk women for intervention compared to the SOF-based screening tool. In general, SCORE correctly identified more high-risk women for intervention, whereas the more restricted SOF-based screening tool correctly ruled out more low-risk women. The appropriate selection of a screening tool depends upon the objective for intervention and trade-off between not identifying women for BMD testing who are at high-risk and identifying more women who are at low-risk.

M319

Validation of a Patient Questionnaire, 'Osteoporosis and You,' Designed to Assess Osteoporosis-related Attitudes, Knowledge and Behavior. S. K. Brenneman[1], E. M. Blau*[2], Y. Chen*[1], T. A. Abbott[1]. [1]Merck & Co., Inc., West Point, PA, USA, [2]Kaiser Permanente, San Diego, CA, USA.

The questionnaire, "Osteoporosis and You", is a 20-item self-report questionnaire designed to assess the attitude, knowledge and behavior of women about osteoporosis. The items are grouped to form three sections hypothesized to assess different domains: Knowledge, Attitude/Actions related to Osteoporosis, and Health Behavior. This study examined the validity of the questionnaire in a patient population. 500 women over the age of 20 were recruited consecutively during January 2001 until there were 100 women in each age cohort (under 40, 40-49, 50-59, 60-69, and 70+). Validity was examined by item analysis, internal consistency, confirmatory factor analysis, and hypothesized relationships between responses and demographics. Of the 500 respondents, 76% were Caucasian, 9% Hispanic, 6.4% African-American and 5.4% Asian. The responses to the Knowledge items indicated overall awareness and knowledge of osteoporosis. Response distribution varied across age groups. The Action section showed a hierarchical pattern consistent with increasing level of intervention. Greater than 50% of respondents were concerned that she might get/have osteoporosis and only 6% were prescribed medication for osteoporosis. The item responses for the Behavior section were distributed across the scale. Good internal consistency was found (Cronbach's alpha = 0.75). Confirmatory factor analysis supported the division of the questionnaire into the 3 sections. Hypothesized relationships among responses and demographics were supported. Results show significant differences in Knowledge and Behavior by age group. Women < 50 years were less knowledgeable and demonstrated fewer behaviors than women 60+ years of age. There were also differences in Knowledge and Behavior related to the level of response to Action items. The results of this study support the use of the questionnaire to obtain information about current knowledge of women about osteoporosis, from which educational interventions could be customized. Confirmation of the findings in populations of different characteristics merits further investigation.

M320

Standardized Documentation of Osteoporosis Patients in Germany. K. Abendroth[1], M. A. Dambacher[2], A. Defer*[3], E. Bitzer*[4], B. Birkner*[5], K. Wawra*[6]. [1]Regional Experts Groups Osteoporosis (REKO), Jena, Germany, [2]Regional Experts Groups Osteoporosis (REKO), Konstanz, Germany, [3]Regional Experts Groups Osteoporosis (REKO), Dresden, Germany, [4]Institute for Social Medicine, Epidemiology and Health Systems Research (ISEG), Hannover, Germany, [5]Quality Management, Gastroenterology Practice, Munich, Germany, [6]Procter&Gamble Pharmaceuticals, Weiterstadt, Germany.

Osteoporosis is an under-diagnosed and under-treated disease in Germany. The handling of the disease by many different medical specialties complicates improvements in osteoporosis care. As one step for improvement, a standardized documentation of the diagnostic and therapeutic options in osteoporosis care was designed by the REKO (Regional Expert Groups Osteoporosis) in Germany. In a pilot phase the documentation with the standardized data set was tested for practicability and delivery of meaningful data in daily practice. Data from 2649 patients, with possible or known osteoporosis, were gathered by 78 office-based physicians throughout Germany. The data was then centrally analyzed. 86.8% of the patients were women, 13.2% men, mean age 63.9 years. Based on densitometry findings (WHO definition), 51.5% of the patients had osteoporosis, 29% had osteopenia, and 19.4% had normal bone density. For analysis, 95%-confidence intervals (CI) and effect-tests at the multiple 5%-level were used. Selected results of risk factors and clinical findings are shown in the table below. The use of the standardized documentation in daily practice delivers meaningful data. It is a practical tool for giving insights into the status of osteoporosis care in Germany.

	Osteoporosis	Osteopenia	Normal Bone Density	Effect-test
History: Fracture after age of 40	35.9% (CI:33.4-38.5)	24.1% (21.0-27.0)	18.7% (15.3-22.0)	p<0.05
Back pain	66.2% (63.2-69.2)	61.0% (57.6-64.5)	50.0% (45.7-54.3)	p<0.05
Estrogen exposition < 30y	24.5% (22.2-26.8)	19.9% (17.0-22.7)	21.0% (17.5-24.5)	n.s.
Clinical findings: Kyphosis	47.5% (44.8-50.1)	29.8% (26.6-33.0)	22.7% (19.1-26.3)	p<0.05
Localized back pain	66.2% (63.7-68.7)	61.5% (58.1-65.0)	51.3% (47.0-55.6)	p<0.05
Decrease in height (cm)	3.1cm (2.9-3.2)	1.8cm (1.6-2.0)	1.6cm (1.4-1.8)	p<0.05
Radiological findings: Vertebral fracture	29.5% (27.1-31.9)	17.0% (14.4-19.7)	11.1% (8.4-13.8)	p<0.05

Disclosures: ***K. Wawra****, Procter&Gamble Pharmaceuticals 3.*

What Occult Disorders Should Be Screened in a Patient with Osteoporosis. R. B. Wagman[1], S. R. Cummings[2], R. Marcus[1]. [1]Division of Endocrinology, Gerontology, and Metabolism, Stanford University Medical Center, Stanford, CA, USA, [2]Departments of Medicine and Epidemiology and Biostatistics, University of California, San Francisco, CA, USA.

While hyperthyroidism and hyperparathyroidism have demonstrated causality in the development of osteoporosis, systematic review has not been performed to describe other potential occult causes of skeletal fragility. We conducted a MEDLINE and PubMed search, reviewing all articles published in the English language since 1966 using the search terms Cushing's syndrome, hypercortisolism, diabetes mellitus, pernicious anemia/aenemia, vitamin B12 deficiency, celiac/coeliac disease, sprue, systemic mastocytosis, osteoporosis, and fracture. We collected data on the following: 1) number of patients enrolled, 2) use of a control group, 3) type of bone densitometry equipment, 4) anatomical site measured, and 5) change in bone mineral density (BMD). We found 85 studies, many of which demonstrated methodological problems. We found reasonable evidence for association between osteoporosis and Cushing's syndrome, diabetes mellitus Type 2, and mastocytosis. Patients with active Cushing's syndrome had an average 16-20% decrease bone density in the lumbar spine and 15-17% decrease in the femoral neck than controls. While patients with diabetes mellitus Type 2 demonstrated increased bone density than controls, concomitant increased fracture incidence was found in the hip, proximal humerus, and foot. In patients with mastocytosis, the prevalence of osteopenia by spine radiograph was 14-100% with a fracture prevalence of 36-100%. We found weaker associations between skeletal fragility and celiac disase and diabetes mellitus Type 1, and an indeterminate association with pernicious anemia. We conclude that it is worth screening a patient with low bone density or fragility fracture for Cushing's syndrome in the context of clinical and/or biochemical stigmata, as well as diabetes mellitus Type 2. Our review indicates inconsistent value of screening for celiac diase and insufficient data to recommend screening for pernicious anemia. The rarity of mastocytosis makes it difficult to recommend routine screening.

M322

Performance of a Simple Clinical Tool (FOSTA) for Identifying Japanese Women with Osteoporosis based upon Heel Bone Density. K. Aoyagi[1], P. D. Ross[2]. [1]Public Health, Nagasaki University, Nagasaki, Japan, [2]Merck & Co., Inc., Rahway, NJ, USA.

The Female Osteoporosis Self-assessment Tool for Asians (FOSTA) has been validated in numerous Asian and (with slight modification) Caucasian populations for classifying the risk of osteoporosis based on spine and femoral neck bone mineral density (BMD). However, central site (hip or spine) BMD measurements are not available in all communities. Heel BMD performs at least as well as central BMD measurements for predicting the risk of vertebral and nonvertebral fractures. We therefore evaluated the performance of the FOSTA tool among postmenopausal Japanese women in a population-based study (Mitsugi Bone and Joint Study (MBJS)) using peripheral (heel) BMD to define osteoporosis (T < -2.5). The subjects were 315 women aged 40 years and older (average age 64±8.1 years) with heel BMD measurements between 1994 and 1995. The index achieved 99% sensitivity and 30% specificity, which was similar to previous findings using femoral neck BMD in Japanese women. Using three previously-reported risk categories, 22% of all women were categorized as high risk (FOSTA -1). Physicians might be advised to consider treating women with osteoporosis. Almost all (86%) of the high risk patients had osteoporosis (heel BMD T-score < -2.5). Among women with low risk (18% of all women), only 2% had osteoporosis, and BMD measurements are probably not necessary. Approximately 40% of the moderate risk women had osteoporosis; BMD measurements are useful in this group to determine which individuals have osteoporosis, and which individuals do not. In summary, the FOSTA tool performed well for classifying the risk of osteoporosis based on heel BMD, as has been reported previously using femoral BMD. This free and simple tool could help clinicians actively assess osteoporosis and determine the need for BMD measurements to assess fracture risk and initiate appropriate intervention before fractures occur.

M323

Validation of a Simple Questionnaire of Risk Factors to Identify Postmenopausal Osteoporosis. M. Diaz-Curiel, M. Garcés*, A. Rapado. Internal Medicine, Fundación Jimenez Diaz, Madrid, Spain.

Bone densitometry is the best option to detect osteoporosis in postmenopausal women, although its use may be limited by the availability of equipment and cost. The aim of this study, which was completed at our Outpatient Clinic, was to validate a simple questionnaire of the risk factors for low bone mass and to assess the predictive character of osteoporosis of each factor. A cross-sectional population-based study was completed on 105 postmenopausal women, aged between 41 and 86. The questionnaire included details of the patient's height and weight, drug history, years of menopause, existence of early menopause, oophorectomy, fracture history - after the age of 50, or family history of osteoporosis, physical activity, symptoms of dementia, smoking or alcohol consumption, and low calcium intake. BMD of the lumbar spine and femoral neck were measured using dual-energy X-ray absorptiometry (DXA Hologic 4500), which classified the women as "normal' or "abnormal' (osteopenia and osteoporosis), based on the WHO criteria. Univariate analysis was used to exclude factors that did not show a relationship with BMD (p>0.3). Multivariate stepwise forward logistic regression analysis, using BMD values as the dependent variable, were performed to identify the remaining factors, these being the most predictive factors of low bone density at the lumbar spine, and at the femoral neck. Sensitivity, specificity and predictive values, by receiver operating curves (ROC) analysis, were also analysed. A simple scoring system was devised based on a regression model: more than ten years of menopause (5), prior fracture (4), osteoporosis family history (2), weight (<55kg:3; 55-60kg:2; >60:1) and age (70 or >70:3; 60-69:2; 50-59:1). The cut-off score, to discriminate between normal and osteopenic women, was 5: (Sensitivity 91.4%; specificity 42.9% at lumbar spine, and 87.9% and 41.9% respectively, at the femoral neck). The cut-off score, to discriminate between normal and osteoporotic women, was 8: Sensitivity 61.9%; specificity 85.7% at lumbar spine, and 65.1% and 76.2% respectively, again at the femoral neck. The use of a simple questionnaire, to score for risk factors of low bone mass, could be useful to facilitate the diagnosis of osteopenia or osteoporosis. However our questionnaire should be further validated on a larger sample of the postmenopausal population.

M324

Osteoporosis in COPD Patients. I. Holme*[1], L. Henriksen*[1], V. Petersen*[1], V. Backer*[1], P. Schwarz[2]. [1]Respiratory unit Department of Internal Medicine, Bispebjerg Hospital, University Hospital of Copenhagen, Copenhagen, Denmark, [2]Department of Endocrinology, Hvidovre Hospital, Copenhagen, Denmark.

Purpose: Evaluation of the incidence of osteoporosis in patients with COPD. Methods:Out-patients from the espiratory unit with COPD, FEV1 less than 1,3 L., and age between 50-70 years were included. All had a questionnaire concerning smoking habits, sun exposure and medication taken (steroids, calcium and Vitamin D). A blood sample were drawn for specific analysis and furthermore a spirometry (FEV1 and FVC), a 5 minutes exercise-test, X-ray of the thoratic-lumbal spine and a DXA-scan of the femur and lower back (L2-L4). Results: Of 181 invited patients, 71 patients were included of who 54 were females (93% post menopausal). All had symptoms of COPD and had a severe airflow limitation with a mean (sd) FEV1 0,9 (0,4) L, mean daily dietary intake of calcium was 500 mg of vitamin D 5 micrograms. We found 7 patients had secondary hyperparathyroidism. In 16 patients X-ray showed not previously known compression fracture, DXA-scan showed osteoporosis in 37 patients including the 16 with X-ray diagnosed osteoporosis. Furthermore 14 patients had osteopenia defined from DXA-scan. Conclusions: A high frequency (72 %) of unknown osteoporosis or osteopenia was found among COPD patients. The present study indicates that many patients receiving corticosteroid treatment need osteoporosis prophylaxis. Prospective studies of prophylactive treatment are though urgently needed, as the current population at risk for developing corticosteroid-induced fractures is of major economic interest, since 15 % of the adult population in Denmark suffer from COPD.

M325

Hip Geometry and Bone Mineral Density in Postmenopausal Women. R. A. Brownbill, C. Lindsey, J. Z. Ilich. School of Allied Health, University of Connecticut, Storrs, CT, USA.

Both femoral neck strength (FNS) and hip axis length (HAL) have been shown to influence hip fracture, although these relationships are not always clear due to different radiological tools used to calculate these values and different study conditions. Our objective was to obtain both FNS and HAL values from left and right femurs scanned by DXA and evaluate their relationship with femoral BMD. Participants were 136 Caucasian women, (age range 57.4-88.6 y), all healthy and not taking medications known to affect bone. The dual hip measurements were performed using DPX-MD bone densitometer (GE Medical Systems, LUNAR Corp. Madison, WI). HAL was determined automatically by software. FNS analysis uses femoral geometry to calculate stresses at the femoral neck for two loading conditions: Safety Factor Index (SF) indicates risk of fracture for forces generated during a one-legged stance, and Fall Index (FI) indicates risk of fracture for forces generated during a fall on the greater trochanter. As both these values get closer to "1", the risk of fracture increases. Multiple regression analyses with regions of hip as dependent variables and corrected for height, weight, and age were used to determine predictive ability of HAL, SF, and FI for respective BMD values. Results showed that longer HAL values of the left hip were negatively related to neck, trochanter, shaft and total hip BMD with R square (adjusted) ranging from 0.27 to 0.33 (p less than 0.05). HAL was not significantly associated with any of the right hip BMD regions. FI was significantly associated with all sites of the hip BMD with R squared (adjusted) ranging from 0.24 to 0.39 (p less than 0.05),while SF was associated with neck and wards BMC with R squared (adjusted) ranging from 0.35 to 0.49 (p less than 0.05). We conclude that having a longer HAL is associated with lower BMD, and higher FI values are associated with higher bone mass. It appears HAL, SF and FI all play a key role in estimating fracture risk and should be assessed along with BMD when using DXA.

Bone Changes in Ovariectomized (OVX) Rats Evaluated by DXA and Micro-CT. P. J. Masarachia, S. Adamski*, G. A. Rodan, D. B. Kimmel. Bone Biology and Osteoporosis, Merck Research Laboratories, West Point, PA, USA.

Micro-computed tomography (M-CT) may provide new information about bone changes in OVX rats. Six month old S-D rats were OVXd or Sham-OVXd. OVX rats were treated orally for 6wks with 0 or 0.6 mg/kg/d ethinyl estradiol (OVX+EE). At necropsy, right femora were fixed in 70% ethanol. Bone density was measured by dual energy x-ray absorptiometry (BMD-X, mg/cm^2) (DXA) in a uniform cylindrical volume (Table 1) containing cortical and cancellous bone. A 0.02mm resolution tomographic reconstruction of the distal 16mm of all femurs was obtained (EVS Corp; London, Ontario; CAN). The metaphyseal region of most marked cancellous bone loss was identified by qualitatively comparing OVX and Sham images. A uniform cylindrical volume (Table 1) containing only cancellous bone and representing that region was identified. M-CTBMD (mg/cc) and bone volume (M-CTBVTV, %) were computed. The three groups were compared (ANOVA with Fisher PLSD). Group coefficients of variation (CV) were computed. BMD-X was 20% lower in OVX than Sham; BMD-X of OVX+EE rats was 96% replete to Sham. M-CTBMD was 67% lower in OVX than Sham; M-CTBMD of OVX+EE rats was only 33% replete to Sham. M-CTBVTV and M-CTBMD data were similar. CV's were higher for M-CT endpoints than BMD-X (20-50% vs. 7-10%). In EE-treated OVX rats that show BMD equal to intact rats by DXA, M-CT discloses marked differences in bone mcroarchitecture. Though CVs of the M-CT endpoints are greater than BMD-X, the larger OVX-related difference seen by M-CT suggests that M-CT can increase power of OVX rat studies.

Iliac Three-Dimensional Trabecular Microarchitecture in Premenopausal Healthy Women and Postmenopausal Osteoporotic Women with and without Fracture. J. Zhao[1], Y. Jiang[1], R. R. Recker[2], M. W. Draper[3], H. K. Genant[1]. [1]Oarg, University of California, San Francisco, CA, USA, [2]Osteoporosis Research Center, Creighton University, Omaha, NE, USA, [3]Lilly Research Laboratories, Indianapolis, IN, USA.

Capturing true 3D trabecular microstructural information may help understand the pathophysiology of osteoporosis and estimate fracture risk as bone mechanical competence is a function of its density and 3D distribution. In histomorphometry based on 2D sections using the parallel plate model assumption, whether trabecular thinning or disappearance occurs with aging and/or menopause remains unresolved. We scanned bone biopsies from the iliac crest of healthy premenopausal women (Pre, n=20, age mean ± SEM, 49 ± 1 years), and osteoporotic postmenopausal women without fracture (Post, n=20, 56 ± 1 years) and with vertebral osteoporotic fracture (Post+Fx, n=20, 70 ± 2 years), using a Scanco micro CT with isotropic resolution of 17 $\propto m^3$. 3D trabecular microstructure was directly measured without stereological model assumptions. Among the 3 groups (Table), ANOVA showed significant differences in 3D trabecular bone volume fraction (BV/TV, %), trabecular number (Tb.N, 1/mm) and thickness (Tb.Th, ∝m) and separation (Tb.Sp, ∝m), structure model index (SMI, values 0 or 3 represent a perfect plate or rod structure, respectively), degree of anisotropy (DA), and connectivity density (CD, $1/mm^3$). Adjusted for age, most odds ratios (OR) discriminated fracture. The annual percentage change was greater from Pre to Post in Tb.Th (-3) and SMI (18) than from Post to Post+Fx (Tb.Th -0.1, SMI 1), and greater in CD from Post to Post+Fx (-5) than from Pre to Post (-3). Thus, dual phases were observed: deterioration of all 3D parameters in the initial years of osteoporotic postmenopausal women without fracture, and further deterioration of 3D connectivity in the later years with fracture. In the initial years, trabecular thinning does occur. Trabeculae dramatically shift from a plate-like structural type to a rod-like type, and become more isotropic. In the later years, the remaining trabeculae are more widely separated and less connected, and some mechanically significant trabeculae may undergo compensatory thickening and reinforcing, resulting in an increase in trabecular anisotropy. Changes in 3D trabecular microstructure play important roles in osteoporotic fracture.

	Pre	Post	Post+Fx	OR (95% CI)
BV/TV	22.2±1.7	16.3±1.3	9.1±1	3.9 (1.7-9.5)
Tb.N	1.61±0.03	1.46±0.04	1.12±0.06	1.5 (1.3-1.9)
Tb.Th	166±9	137±5	136±6	1.1 (0.2-5.5)
Tb.Sp	615±12	694±23	929±47	1.9 (1.3-4.6)
SMI	1.06±0.12	2.34±0.08	2.63±0.07	1.7 (1.1-3.2)
DA	1.41±0.03	1.32±0.03	1.48±0.03	2.4 (1.3-4.6)

The Effect of Ovariectomy on Bone Changes Differs between the Edentulous and the Dentate Mandible. E. S. Elsubeihi*. Faculty of Dentistry, University of Toronto, Toronto, ON, Canada.

Whether postmenopausal osteoporosis in humans is associated with decreased bone mass in either the dentate or the edentulous mandible or both is unclear at the present. We have shown previously that ovariectomy (OVX) in rats reduced bone mineral density (BMD) of the edentulous mandible but not of the dentate mandible. Whether OVX affects alveolar ridge resorption and/or cancellous bone volume of the edentulous mandible still needs to be resolved. To accomplish this, we first investigated the healing process of mandibular extraction sockets of molars and the incisor on one side of the mandible of adult female rats at 2, 4, 8, 12 and 16 weeks after extraction. After having established that complete healing of the extraction sockets occurred 4 months after extraction, we next ovariectomized animals 4 months after teeth extraction to investigate the effect of OVX on bone changes in the edentulous and dentate mandible at 6 weeks, 6- and 9-months after ovariectomy. Bone changes were assessed using BMD, backscattered electron microscopy and light and fluorescent microscopy. The results show that extraction of teeth resulted in a 16% reduction of the residual ridge 4 months after extraction. The decrease in residual ridge height of edentulous mandible of control animals reached to about 35% at 10 months after extraction. OVX did not increase residual ridge resorption. However, BMD and bone volume measurements showed that OVX resulted in significant bone loss in the edentulous but not in the dentate mandible. Static and dynamic parameters of bone formation and resorption indicated that there was a significant increase in mineralizing surfaces (2 fold P=0.039) as well as eroded (1.9 fold P=0.012) and osteoclast (2 fold, P=0.0073) surfaces and bone formation rate (2 fold, P=0.03) together with loss of cancellous bone volume (18%, P=0.006) in the edentulous mandible of OVX as compared to control animals at 6 months post-OVX. There were no significant differences between dentate mandibles of OVX and control animals. In summary, teeth extraction caused significant reduction in residual ridge height, and OVX did not affect the residual ridge height of the edentulous mandible. Furthermore, OVX caused a significant reduction in cancellous bone volume of the edentulous mandible but not of the dentate mandible. We also established that bone loss in the edentulous mandible of ovariectomized animals is the result of an increase in bone turnover, and that masticatory force controls the rate of bone turnover in the dentate mandible.

M329

Inverse Relationship between Osteoporosis and Spondylosis in Postmenopausal Women. N. Miyakoshi[1], E. Itoi*[2], H. Murai*[2], I. Wakabayashi*[2], H. Ito*[2], T. Minato*[2]. [1]Orthopedic Surgery, Akita University School of Medicine, Alita, Japan, [2]Orthopedic Surgery, Akita University School of Medicine, Akita, Japan.

The literature contains both studies that have demonstrated an inverse relationship between osteoporosis and spondylosis, as well as those in which insufficient support for such a relationship has been documented. However, in these previous studies, only limited-range grading systems (e.g., grades 1 to 4) were used to evaluate the severity of spondylosis. Therefore, the purpose of this study was to examine the possible inverse relationship between osteoporosis and spondylosis by evaluating the association between bone mineral density (BMD) and osteophyte formation or intervertebral disc narrowing using a semi-quantitative scoring system. A total of 104 postmenopausal women aged over 60 underwent BMD measurement of the lumbar (antero-posterior, lateral, and mid-lateral) and proximal femur (femoral neck, trochanter, and Ward's triangle) using dual-energy X-ray absorptiometry. Raw data representing semi-quantitative osteophyte score and disc score, as well as the number of vertebral fractures, was obtained using spinal X-ray. Correlation between each BMD and radiologic variable was then analyzed. Significant negative correlation was found between all BMD data and the number of vertebral fractures ($p<0.05$). Moderate and positive correlations were observed between osteophyte score and BMD data, as well as between disc score and BMD data ($p<0.05$). Based on the finding that in postmenopausal women, spondylotic changes exhibited positive correlation with not only lumbar BMD but also with remote site BMD, such as at the proximal femur, this study supports the view that osteoporosis has an inverse relationship with spondylosis.

M330

The Dynamic Mobility of Vertebral Compression Fractures. F. E. McKiernan[1], T. Faciszewski*[2]. [1]Center for Bone Diseases, Marshfield Clinic, Marshfield, WI, USA, [2]Department of Orthopedic Spine Surgery, Marshfield Clinic, Marshfield, WI, USA.

Vertebroplasty is a minimally invasive procedure that relieves vertebral compression fracture (VCF) pain but is not thought to restore lost vertebral height. We have observed that many VCFs are dynamically mobile and that significant height recovery and sagittal realignment can be achieved during vertebroplasty with careful patient positioning alone. Herein we report the frequency and magnitude of osteoporotic vertebral fracture mobility. This is a retrospective radiographic analysis of 41 consecutive patients with 65 VCF who underwent vertebroplasty. Preoperative standing and supine cross-table lateral radiographs were evaluated to assess dynamic vertebral fracture mobility. Postoperative standing lateral radiographs were evaluated to assess restoration of height and vertebral area and reduction of kyphotic angle. Restorations are reported as percent of original, pre-vertebroplasty fracture dimensions. Dynamic fracture mobility was demonstrated in 44% of patients and 35% of treated vertebrae. In mobile fractures, average posterior, middle and anterior vertebral height restorations were 15%, 93% and 106% respectively. Mean lateral vertebral area increased from 48% to 80% of normal and kyphotic angle decreased 40%. This radiographic series documents the surprising frequency and substantial mobility of many osteoporotic vertebral compression fractures. Dynamic VCF mobility must be considered when performing vertebroplasty and when reporting and interpreting the significance of vertebral height restoration. The definition and epidemiology of VCF, the pathophysiology of vertebral fracture healing and the distinction between Kummel's disease and severe, dynamically mobile VCFs need reconsideration in light of these observations.

M331

Methods for Enhancing Depth of Field and Information Content in Scanning Electron Microscopic Imaging of Porotic Bone. A. Boyde. Dept of Anatomy and Developmental Biology, University College London, London, United Kingdom.

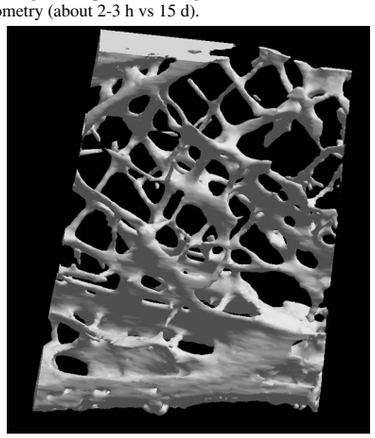
The scanning electron microscope (SEM) is an ideal tool box for imaging macerated trabecular bone specimens, which holds more methods than are generally employed in the bone research field, but there are problems with the instrument and the samples. Commonly, the secondary electron (SE) signal is used because it is strong and the collection efficiency great, so that an acceptable depth of field can be obtained by using a small beam defining aperture and a long working distance. However, the depth of field is limited, and this becomes more of a problem as trabecular bone becomes overtly porotic. Further, SE images give little clue as to bone composition and SE collection has little directionality, so they are poor at encoding surface slope. Further, it is difficult to prevent the untoward effects of electrostatic charging with dried samples (and 'wet' SEMs can give only a very small field of view at a very short working distance). Charging is greatly reduced if only fast backscattered electrons (BSE) are employed, and these have straight, line-of-sight paths to appropriate detectors. Here, a greater beam current is required for a reasonable signal level, implying the use of a larger beam defining aperture at a shorter working distance and a consequent reduction in the depth of field. The present work aims to exploit the directionality of BSE paths and detectors and to enhance the depth of field in the resultant image. Direction and slope of the surface generate false color when assigning each of three separate detectors as red, green or blue in a composite image. The detectors may be symmetric or asymmetric with respect to the normal electron beam path. Admixture of color enhances both information content and interest in morphologic SEM images, which, of course, exceed the resolution possibilities of any other current bone imaging technique which gives contextual cues. The problem of depth of field has been overcome by recording series of images taken at different mechanical focus distances of the sample, and using computer image processing to extract the best in-focus (high frequency) component at each XY patch in the Z stack. Inevitably, we are considering wide field images and therefore a

perspective projection. This is turn necessitates a correction of scale for each separate image plane because magnification also varies with distance in this projection. Finally, we have the first in-focus, 3D color images of stunning beauty and meaning, which illustrate key features of bone micro-anatomy and pathology.

M332

Histomorphometry and Micro-Computed Tomography on Human Bone Biopsies: Comparison Insight Measurements. D. Chappard, E. Legrand, M. Audran, M. F. Baslé*. LHEA-GEROM, Angers, France.

Osteoporosis due to a decrease in bone mass associated with a deterioration of the trabecular bone architecture. Bone histomorphometry is used to explore the various metabolic bone. The technique is done on then microscopical two dimensional (2D) and several methods have been proposed to extrapolate 2D measurements to the 3D dimension. X-ray micro-computed tomography (microCT) is a recently developed imaging tool to appreciate 3D architecture. Recently the use of 2D histomorphometric measurements have been shown to provide discordant results when compared with 3D values obtained directly. 96 human bone biopsies were removed from patients prententing metabolic bone diseases. Complete bone biopsies were examined with the SkyScan-1072 microCT. Bone volume (BV/TV), Tb.Th and Tb.Sp were measured on the 3D models reconstructed from X-ray scanned sections. Thichness were measured by a method based on the sphere algorithm. In addition, 6 scanned images (separated by 100 µm) were transferred to an image analyzer and bone volume (B.Ar/T.Ar-x) and trabecular characteristics were measured after thresholding of the images. Bone cores were embedded undecalcified; histological sections were prepared and measured by routine histomorphometric methods providing B.Ar/T.Ar-h and trabecular characteristics. Comparison between the differents methods were done by using regression analysis, Bland and Altman plots and Passing-Bablock plots. Correlations between BV/TV and B.Ar/T.Ar-h were highly significant (r=0.94) but the microCT overestimated bone volume by about 5-15%. Using the mineralized bone volume instead of total bone volume did not improved the results. Overestimation may be due to the less potent methods available in 3D to remove artefactual particles. Also the countours of the trabeculae are often more difficult to threshold on X-ray scans than on highly contrasted histologic sections. BV/TV and B.Ar/T.Ar-x were also highly correlated (r=0.96) and similar findings were obtained with B.Ar/T.Ar-h and B.Ar/T.Ar -x (r=0.96). Correlations between Tb.Th values obtained by 3D or 2D-x or 2D-h measurements were lover (r=0.70) and 3D analysis always overestimated thickness by about 50%. In clinical practice, microCT appears to be an interesting method providing reliable morphometric results in less time than conventional histomorphometry (about 2-3 h vs 15 d).



M333

Relationship between Dietary Intake and Bone Mineral Density in Postmenopausal Women: A 20-Year Study. N. M. DiMarco, S. L. Bonnick, A. J. Cox*, E. DeVries*. Institute for Women's Health, Texas Woman's University, Denton, TX, USA.

The relationship between dietary intake variables and bone mineral density (BMD) in postmenopausal women was examined to determine if dietary intake can predict BMD and if significant differences in dietary intakes and BMD over a 20-year period exist. Thirty postmenopausal women were selected from a population of 352 men and women who completed a 20-year study of phalangeal and radial bone density conducted between 1950 and 1981. The mean age at 20-year follow-up was 67 years (34 to 91). Thirteen had a natural menopause and 17 had a surgical menopause. Carbohydrate, protein, fat, calcium, vitamin D, phosphorus, and total kilocalorie intakes were determined using a 7- and 3-day dietary record and analyzed using Nutritionist V, version 5.0 software (N-Squared Computing, San Bruno, CA). Only documented dietary intakes were used with no inclusion of vitamin or dietary supplements. At both the initial and 20-year follow-up, a questionnaire was used to obtain demographics, medications, reproductive history, recreational habits, and fracture history. Descriptive statistics were performed on each variable. Pearson product moment correlation was used to determine if there was a significant relationship between dietary intake variables and BMD. Multiple regression analyses were used to determine which diet variables were significantly correlated with BMD values. Paired t-tests were used to detect differences between mean dietary intake variables, and mean BMD measures at the two time points. There was a significant correlation between protein intake at baseline and RG of the second metacarpal region (r=0.39;p=0.04). There was also a significant correlation between baseline fat intake and SPA (r=0.42;p=0.02). BMD results are shown in the table. There were no significant dietary predictors of BMD at baseline or 20-year follow-up. There were no significant differences between dietary intake variables at baseline or 20-year follow-up. There were significant differences between baseline and 20-year follow-up BMD measurements for RPD and RG.

BMD changes over 20 years

	Baseline	20-year Follow-up	p value
RPD 5-2, mm Al/mm bone	0.22 (0.004)	0.17 (0.004)	0.000
RG 2nd metacarpal, um	0.58 (0.017)	0.52 (0.016)	0.002
RG 3rd metacarpal, um	0.51 (0.015)	0.48 (0.015)	0.02
SPA, g/cm2	NA	0.40 (0.015)	

M334

The Relationship between Urinary Sodium Excretion and Bone Mineral Metabolism of Climacteric Women in Korea. K. W. Oh[1], E. S. Oh*[1], S. W. Kim*[1], D. C. Lee*[2], S. I. Roh*[3], S. H. Song*[3], M. I. Kang[4]. [1]Internal Medicine, Miz Medi Hospital, Seoul, Republic of Korea, [2]Family Medicine, Miz Medi Hospital, Seoul, Republic of Korea, [3]Obstetrics and Gynecology, Miz Medi Hospital, Seoul, Republic of Korea, [4]Internal Medicine, Catholic University of Korea, College of Medicine, Seoul, Republic of Korea.

High oral intake of sodium is known to increase urinary calcium excretion in experimental animals and humans, and there is well-documented correlation between urinary sodium and calcium excretion in 24-hour urine collections from normal subjects and postmenopausal women. To investigate relationship between urinary sodium excretion and bone mineral metabolism of climacteric women, we measured 24-hour urinary sodium, calcium, and creatinine level; serum osteocalcin level, serum alkaline phosphatase (ALP) level, serum follicular stimulating hormone (FSH) level; urine deoxypyridinoline (DPD) level; and bone mineral density (BMD) in 430 climacteric women in Korea (331 postmenopausal and 99 premenopausal women). The postmenopausal women had higher ($p <$ 0.05) value for mean urinary sodium to creatinine ratio of 0.225±0.078 mmol/mg vs. 0.209±0.061 mmol/mg and higher ($p < 0.001$) value for mean urinary calcium to creatinine ratio of 0.261±0.125 mg/mg vs. 0.209±0.081 mg/mg than the premenopausal women. Significant positive correlation was noted between urinary sodium to creatinine ratio and urinary calcium to creatinine ratio (r =0.426, $p < 0.001$). Negative correlation was found between urinary sodium to creatinine ratio and femur neck BMD (r = -0.099, $p < 0.05$). Although urinary sodium to creatinine ratio was not significantly correlated to serum FSH level (r = 0.066, p = 0.088), serum ALP level (r = 0.067, p = 0.083), urine DPD level (r = 0.077, p = 0.056), and lumbar bone mineral density (r = -0.067, p = 0.083), but there is a weak trend in it. There is not only an increase in urinary calcium excretion at postmenopausal women, but also an increase in the urinary sodium excretion. It seems that subjects with a high urinary sodium excretion show a higher urinary calcium excretion that may have some effect on bone mineral metabolism. However, further studies are required to establish whether urinary sodium excretion have a direct effect on bone mineral metabolism of climacteric women in Korea.

M335

First Morning Urine Measured With pH Paper Strips Reflects Acid Excretion. S. J. Whiting[1], J. Bell*[1], S. E. Brown[2]. [1]College of Pharmacy and Nutrition, University of Saskatchewan, Saskatoon, SK, Canada, [2]605 Franklin Park Drive, Osteoporosis Education Project, East Syracuse, NY, USA.

Net acid excretion (NAE) is implicated in bone loss, as increased calcium loss is seen with a high net acid excretion. Dietary protein is identified as a significant producer of acid whereas fruit and vegetable may counteract this effect through the production of metabolizable organic anions which buffer acid. Determination of NAE is important in recognizing the effect diet may have on bone. Most commonly, a 24-hour urine collection is obtained for measurement of NAE where NAE is measured as titratable acidity minus bicarbonate (TA-bicarb) plus ammonium (NH_4^+). However, this measurement can be inconvenient and pH measured on first morning urine with semi-quantitative paper strips may be a practical estimator of NAE. We recruited 23 (4M, 19F) healthy subjects age 20-50 y who recorded dietary intake for a day during which they collected urine from approximately 7 am to 11 pm in one container (“day”) and approximately 11 pm to 7 am (“overnight”,ON) in a separate container. The first morning void contained ON urine. Subjects also provided a two-hour fasting urine at 9 am. pH paper strips (colorpHast ®, EM-Reagents, range 4-7) were used to measure pH of the ON urine, as would be done in practice. A second set of strips (pH range 6.5-10) was used if initial pH read high. Although measurement with pH paper strips was not significantly correlated with 24-hr NAE, there was a significant correlation with 24-hour TA-bicarb (r= -0.466, p<0.025). Further, pH strip measures were significantly correlated with ON NAE (r= -0.710, p<0.005). We noted that ON NAE was correlated with total NAE (r=0.504, p<0.014). We conclude there is useful information is measuring first morning urine pH (which provides pH of urine formed overnight) to obtain an estimate of acid excretion. pH paper strips appear to be useful in the absence of longer (more invasive) urine collections.

M336

The Effect of Low-Fat Dietary Intervention on Bone Turnover. L. E. Ryan*, D. Zaqqa*, H. N. Nagaraja*, R. D. Jackson. The Ohio State University, Columbus, OH, USA.

Osteoporosis affects more than 25 million women and is a major cause of excess morbidity due to the functional impact of fractures on quality of life. In postmenopausal women, estrogen deficiency is an important factor contributing to the development of accelerated bone loss and risk of fracture. Recent epidemiologic data suggest that postmenopausal women with estradiol (E2) levels less than 5 pg/ml have lower bone mass and a higher fracture risk than women with higher E2 values. Studies have suggested that a low-fat diet can result in a decrease in E2 by an average of 17%. We hypothesized that low-fat dietary intervention in postmenopausal women might have an adverse effect on osteoporosis by increasing markers of bone turnover due to the effect of lowering E2 levels. Sixteen postmenopausal women without osteoporosis were recruited and completed a 9 mo low-fat dietary intervention study. Each woman served as her own control. After a 3 mo washout period, all participants began a dietary intervention which included reduction of fat intake to $\leq$ 20% of daily calories; dietary change was maintained for 6 mo. At baseline, after a 3 mo washout period, and after 3 and 6 mo on dietary intervention, serum E2, osteocalcin (OC), bone-specific alkaline phosphatase (BSAP), and N-telopeptide (NTx) levels were measured. All participants significantly decreased their daily fat intake from baseline (mean decrease of 56.36 %); 88% of the women reached the intervention goal. In response to the lowered fat intake, the E2 significantly decreased by 23% (p= 0.001) from baseline and was maintained. There were no significant changes in any of the bone turnover markers (OC, BSAP, or serum or urine N-Tx) between baseline and after 3 or 6 months on a low-fat diet. Subgroup analyses also failed to show any significant change in turnover markers in those participants who dropped their E2 levels below 5 pg/ml after dietary intervention. In conclusion, in our group of postmenopausal women, despite successful reduction in dietary fat intake with a corresponding significant reduction in E2, there was no change in bone turnover markers. These findings suggest that a diet low in fat will likely not adversely affect bone metabolism.

M337

Comparative Effects of Dietary Omnivore and Vegan Protein on Calcium Homeostasis. R. H. Raphael*[1], J. E. Kerstetter[1], C. M. Svastisalee*[1], K. O. O'Brien*[2], D. E. Wall*[3], M. M. Mitnick*[3], D. M. Caseria*[3], K. L. Insogna[3]. [1]School of Allied Health, University of Connecticut, Storrs, CT, USA, [2]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, USA, [3]School of Medicine, Yale University, New Haven, CT, USA.

In adults, a low-protein diet (from omnivorous sources) leads to hypocalcuria and secondary hyperparathyroidism (2^0 HPT). Using dual stable isotopic methods, it was reported that low-protein diets decrease intestinal Ca absorption, which in part, explains the 2^0 HPT. The impact of vegan proteins on Ca absorption and circulating levels of parathyroid hormone is unknown. The purpose of this study was to directly compare vegan sources of dietary protein (primarily soy) with omnivorous protein on Ca homeostasis. Sixteen healthy women (8 premenopausal and 8 postmenopausal) were studied. The protocol consisted of 2 weeks of a well-balanced diet containing moderate amounts of Ca, Na, and protein followed by 4 days of an experimental diet. Subjects randomly received all 4 experimental diets (high-protein vegan, low-protein vegan, high-protein omnivore, low-protein omnivore). The high-protein diet contained 2.1 g protein/kg and the low-protein diet contained 0.7 g protein/kg. In the low and high vegan diets, soy supplied 22$\pm$1 g and 89$\pm$3 g of the total daily protein, respectively. Experimental diets consisted of ordinary foods that were prepared in a metabolic kitchen and contained controlled amounts of Ca (800 mg), P (1100-1500 mg), Na (2400 mg), and energy (2200 kcal). Caffeinated beverages were limited to one a day and alcohol was not allowed. The isoflavone content of all diets was very low (<35 mg/d). Within 4 days of the low-protein omnivore diet, 2^0 HPT developed in all women as evidenced by a 2.6-fold rise in PTH, 1.3-fold rise in $1,25(OH)_2$ vitamin D, and a 1.2-fold rise in NcAMP in comparison to baseline (p<0.0001). At day 4 of the low-protein diet, serum PTH was higher during the vegan in comparison to omnivore diet (57$\pm$2 vs. 46$\pm$1 nleq/ml, p<0.00001), as was serum $1,25(OH)_2$ vitamin D (59$\pm$1 vs. 54$\pm$1 pg/ml, p<0.00001) and NcAMP (2.10$\pm$0.05 vs. 1.87$\pm$0.03, nmol/100 ml GF, p<0.0001). Hypercalciuria was greater during the high-protein omnivore diet compared to the high-protein vegan diet. These data clearly demonstrate that vegan proteins are changing Ca homeostasis differently than protein from omnivorous sources. Whether this difference is due to an effect on Ca absorption or bone turnover or a combination of effects is currently under investigation. The more pronounced 2^0 HPT and blunted calciuric response are consistent with, but do not prove, reduced Ca bioavailability from vegan protein sources.

M338

Factors Modifying the Degree of Secondary Hyperparathyroidism in Hypovitaminosis D. J. A. Pasco*[1], M. J. Henry*[1], M. A. Kotowicz[1], E. Seeman[2], G. C. Nicholson[1]. [1]Clinical and Biomedical Sciences, Barwon Health, The University of Melbourne, Geelong, Australia, [2]Medicine, The University of Melbourne, Heidelberg, Australia.

There is an inverse relationship between serum 25-hydroxyvitamin D (25OHD) and parathyroid hormone (natural log transformed, lnPTH). However, elevated PTH is not observed in all persons with low 25OHD. To characterise women with low vitamin D status for factors associated with PTH, fasting serum samples were analysed for 721 women (aged 20-92 yr) who were free from drugs and diseases known to influence calcium metabolism, recruited at random for the Geelong Osteoporosis Study. Serum 25OHD was measured by RIA (Incstar; precision 6% intra, 15% inter-assay), intact PTH by ICMA (Immulite; precision 5% intra, 5% inter-assay), and total calcium and phosphate by standard techniques. Dietary calcium intake was estimated using a food frequency questionnaire. We confirmed the inverse relationship between 25OHD and lnPTH in the entire group and identified 105 women (median age 64.1 yr, range 21-90) with low 25OHD (<38 nmol/L), for whom mean lnPTH (±SD) was 1.71 (±0.51). There was a logarithmic relationship between PTH and age, the largest single predictor identified, contributing 17.9% of the variance in PTH. Women with PTH levels above compared with below mean PTH for age had lower dietary calcium intakes (576±294 vs 697±451 mg/d, p=0.1), lower serum calcium (2.25±0.11 vs 2.29±0.1 mmol/L, p=0.04) and lower serum phosphate (1.01±0.14 vs 1.08±0.14 mmol/L, p=0.01) levels. Age-adjusted lnPTH was inversely related to dietary calcium intake (partial r^2=0.02; p=0.1) and serum calcium (partial r^2=0.04; p=0.03). A similar association was observed for serum phosphate (p<0.001), probably reflecting the phosphaturic effect of PTH at the kidney. These provisional data suggest that secondary hyperparathyroidism in the face of low vitamin D can be offset by calcium supplementation and so may reduce the increased cortical bone remodeling and bone loss accompanying secondary hyperparathyroidism associated with hypovitaminosis D.

M339

Effect of Atrophic Gastritis on Bone Mineral Density. C. B. Lee*[1], Y. C. Jeon*[2], I. K. Park*[3], Y. S. Park*[4], D. S. Kim*[5], W. H. Choi*[6], Y. H. Ahn*[4], T. W. Kim*[6]. [1]Internal Medicine, Hanyang University Hospital, Kuri, Republic of Korea, [2]Hanyang University Hospital, Kuri, Republic of Korea, [3]Clinical Pathology, Hanyang University Hospital, Kuri, Republic of Korea, [4]Hanyang University Hospital, Kuri, Republic of Korea, [5]Hanyang University Hospital, Seoul, Republic of Korea, [6]Hanyang University Hospital, Seoul, Republic of Korea.

Hydrochloric acid has been demonstrated to be important for the absorption of calcium in intestinal mucosa, and the bone loss is often seen in human after total gastrectomy. The observations that gastric acid secretion decreases with aging in Asian were in contrast to those from many Western countries. One of causative mechanisms of impairment of gastric acid secretion has been attributed to a higher prevalence of H pylori infection in Asian countries. And also it is well known that H pylori causes atrophic damage to secretory tissue of stomach mucosa. The aim of our study was to document the change of calcium and bone metabolism in the patients with decreased capacity of gastric acid secretion like chronic atrophic gastris. The study sample consisted of chronic atrophic gastritis group and control group. Chronic atrophic gastritis group was 20 post-menopausal females (age: 60.3 ±5.1 yr) who was confirmed by gastroscopic biopsy, demonstrating atrophic change of gastric mucosal secretory tissue. Control group had 21 healthy females (age: 58.7 ±6.5 yr) with normal gastroscopic biopy results. Serum levels of calcium, phosphorus, total alkaline phosphatase, intact PTH, and bone mineral density (Delphi, Hologic, USA) were monitored in all the patients in both group before medication. There were no significant differences of calcium (8.9 ±0.9 vs 8.8 ±1.4 mg/dL, p > 0.05), phosphorus (3.2 ±1.5 vs 3.5 ±0.9 mg/dL, p > 0.05), total alkaline phosphatase (72.5 ±24.5 vs 60.3 ±22.4 U/L, p > 0.05) and intact PTH (29.3 ±5.1 vs 27.2 ±3.8 pg/ml, p > 0.05) between chronic atrophic gastritis group and control group. Bone mineral density showed decreased average value in atrophic gastritis group comparing control group (0.78 ±0.27 vs 0.85 ±0.31 g/cm2, p = 0.09). H pylori micro-organism was detected in 10 cases in the atrophic gastritis group and 6 cases in control group. In conclusion, chronic atrophic gastritis which have lower capacity of gastric acid secretion may cause decrease of bone mineral density. And this mechanism may be one of the pathogenesis of senile osteoporosis.

Rate of Weight Loss Influences Calcium Absorption. S. A. Shapses[1], M. Cifuentes*[1], R. Sherrell*[2], C. Riedt*[1]. [1]Nutritional Sciences, Rutgers University, New Brunswick, NJ, USA, [2]Inst. Marine Coastal Sci., Rutgers University, New Brunswick, NJ, USA.

Weight loss (WL) is associated with reduced bone mass and an increased fracture risk, but mechanisms regulating calcium metabolism are not clear. In this study we assessed the effect of 6 weeks of WL at 2 levels of calcium intake (normal intake, NCa; and high intake, HCa) on true fractional calcium absorption (TFCA) and bone-regulating hormones in overweight (BMI of 28.4±1.8 kg/m2) postmenopausal women. Average WL was 0.5±0.3 kg/wk. Due to a wide range of loss (0.1-1.3 kg/wk), we divided the subjects into faster (>0.5kg/wk F-WL, n= 24) and slower (<0.5kg/wk, S-WL, n=18) WL groups. Total calcium intake was lower in the NCa intake (957±213 mg/d) compared to HCa (1794±206 mg/d) group and in the slower compared to faster WL group (p<0.05). Baseline TFCA for all women was 25±8%. The rate of WL affected TFCA differently in normal compared to high calcium subjects (interaction, p<0.05; Table). This interaction notwithstanding, a faster rate of WL decreased total calcium absorbed more than slower WL (p<0.05; Table). Multiple regression analysis showed that none of the measured variables explained the variance in TFCA in the HCa group. However, in the NCa group, the changes in parathyroid hormone (PTH) and 25-hydroxy-vitamin D together accounted for 42% of the variance in TFCA. It is suggested that 1 g/d calcium intake during WL does not meet calcium demands and the body compensates by activating the calcium-PTH axis to absorb more calcium. These results support and extend previous findings that supplemental calcium intake suppresses serum PTH levels during wt loss (1-2). In addition, these data suggest that a slower rate of moderate wt loss in overweight postmenopausal women may preserve calcium stores and bone mass. (1)Ricci et al. JBMR 1998 (2) Jensen et al. JBMR 2001. Supported by NIH AG12161.

% Change in Ca Intake & Absorption

	NCa S-WL	NCa F-WL	HCa S-WL	HCa F-WL
Ca Intake	30±51	-6±25	114±45	87±39
TFCA	-13±20	2±23	-12±16	-28±12
Ca absorbed	19±69	-5±34	85±37	37±40

Effect of Alendronate Withdrawal on Bone Mineral Density (BMD) in a Comunity Clinic. C. L. Smith. Department of Medicine, Division of Nephrology, Hennepin County Medical Center, Minneapolis, MN, USA.

Following withdrawal of estrogen or calcitonin there is a resurgence of bone loss from the skeleton. This may not be true of the bisphosphonates as one study has shown that BMD can remain stable for some time after discontinuation of alendronate (Am J Med 103:291 [97]). Another study, however, suggested that bone loss resumes after alendronate is withdrawn (J Clin Endoc & Metab 85:1492 [00]). Patients seen in the clinic are given the option of discontinuing alendronate when the BMD has stabilized (usually at three years). We reviewed the BMD data on eleven patients who had discontinued alendronate. There was one male and ten females with a mean age of 55±10 years (range 35-72 years) who had taken 20mg of alendronate per day for three years. BMD was measured using dual energy x-ray absorptiometry at the spine, femoral neck and the 33% and ultradistal sites of the radius. Measurements were obtained prior to alendronate and at yearly intervals for five years: three years on alendronate and two years off alendronate. Serum osteocalcin and urine deoxypyridinoline were obtained at years three through five. BMD data are expressed as the mean ± SEM of the percent change from baseline. There was no significance difference between year 1, 2 or 3 and year 4 or 5 at any site (Table). No significant changes in osteocalcin or deoxypyridinoline were present from year 3 to 5. BMD and bone cell markers remained stable in these patients for up to 2 years after withdrawal of alendronate.

Percent Change in BMD During Three Years of Alendronate Treatment and Two Years of Withdrawal

Time	Spine	Femoral Neck	33%	Ultradistal
1 year	6.2±1.5	1.5±1.3	0.06±0.03	2.0±1.3
2 year	8.1±2.1	1.8±3.6	0.06±0.54	1.7±1.4
3 year	10.0±1.7	1.6±2.5	0.28±0.73	2.8±1.5
4 year	9.2±1.5	3.5±3.0	0.1±0.94	4.4±3.0
5 year	8.8±1.9	5.1±3.2	-0.58±1.24	8.0±3.3

A Randomized Controlled Trial with ONO-5920 (Minodronate/YM529) in Japanese Patients with Postmenopausal Osteoporosis. H. Morii, Y. Nishizawa, Y. Taketani, T. Nakamura, A. Itabashi, H. Mizunuma, H. Hagino, M. Fukunaga, T. Miki, K. Yamazaki, T. Nakamura, T. Matsumoto, T. Minamide, T. Makita. ONO-5920 Phase II Osteoporosis Treatment Research Group, Osaka, Japan.

ONO-5920 is a recently developed bisphosphonate which has 200-fold effectiveness in increasing bone mineral density (BMD) and 10,000-fold activity in suppressing osteoclastic function in in vitro study compared with etidronate. Written informed consents were obtained from postmenopausal women with ages between 40 and 75 years who were diagnosed as having osteoporosis accoriding to Japanese criteria of diagnosis. Subjects were those who have fragility vertebral fracture with BMD of L2-4 less than 80 % of YAM (Young Adult Mean) or those with BMD of L2-4 less than 70 % of YAM and without vertebral fracture. They were classified into 4 groups to each of which 0.5, 1.0 and 1.5 mg of ONO-5920 or placebo was administered for 36 weeks at 24 facilities. To placebo group as well as other groups calcium lactate was prescibed at a daily dose of 0.8 g. Among 352 patients registered number of PPS (Per Protocol Set) was 323 and that of FAS (Full Analysis Set) was 345. Number of patients for safety analysis was 351. Primary endpoint was the percentage change of BMD. The percentage change of L2-4 BMD was 100.72 % in placebo group, 105.65 % in 0.5 mg, 106.42 % in 1.0 mg and 105.93 % in 1.5 mg group recpectively. Latter 3 groups showed significant increases compared with placebo group. There were significant decreases of urinary deoxypyridinoline/creatinine and NTX/creatinine at 4 weeks of treatment with 3 doses of ONO-5920 compared with the placebo group. There were significant decreases of serum bone specific alkaline phosphatase at 12 weeks of treatment with 3 doses. Incidence of adverse drug reactions (ADRs) was 13.2 %, 23.3 %, 22.9% and 27.3 % in placebo, 0.5 mg, 1.0 mg and1.5 mg group recpectively. Although the incidence of gastrointestinal ADRs was 0 %, 12.6 %, 6.3 % and 11.1 % in placebo, 0.5 mg, 1.0 mg and 1.5 mg group recpectively, serious adverse events have not been reported. In conclusion ONO-5920 is a new bisphosphonate which shows the efficacy and safety in patients with osteoporosis.

Alendronate Reverses Methotrexate Associated Osteopenia without Adverse Effect on Longitudinal Growth in Skeletally Immature Animal Model. J. A. Spadaro, T. A. Damron*, R. Chen*, D. A. Clemente*, J. Feak*, B. Margulies*, J. Horton*, I. Cherrick*. Upstate Medical University, Syracuse, NY, USA.

Bisphosphonates have yet to be rigorously evaluated to prevent chemotherapy induced osteopenia during childhood. The hypothesis was that in a growing animal model methotrexate (MTX) would decrease BMD and longitudinal growth while concurrent treatment with alendronate (ALD) would prevent this effect without further adverse effect on growth. Twenty-four 5 week old male Sprague-Dawley rats were divided into 4 groups. The ALD group received alendronate, 0.30 mg/kg SC once per week for 6 weeks. The CTL and MTX groups received IP injection of either vehicle or methotrexate 0.75 mg/kg/day, respectively, in a 2-cycles (5 d on/9 d off/5 d on). The MTX+ALD group had both regimens as above. After 6 weeks the bone density was studied by pQCT (vBMD) and DXA (aBMD). Hind limb bone lengths were measured and histological sections examined. The MTX group showed an 11% decrease in aBMD of the femur, a 3% decrease in whole body aBMD, and 3% shortening vs. controls (Table 1). ALD with MTX treatment resulted in a 19% greater femoral aBMD than CTL and 7.5% greater whole body aBMD. Cross sectional area in the MTX+ALD femurs was greater than CTL, especially distally near the more active growth plate. Femoral length remained less than CTL in the MTX+ALD animals. ALD and MTX+ALD groups were similar in all endpoints, suggesting that ALD overwhelmed the effect of MTX. Striking transverse hyperdense banding corresponding to the weekly ALD in both ALD and MTX+ALD groups was seen in radiographs and microscopically in growth areas of the skeleton. Femoral lengths for the ALD group were NS different from CTL. ALD administered in a pulsed dose fashion more than reverses the effects of MTX on aBMD in growing areas, but with little effect on the minor growth losses induced by MTX. ALD had no additional significant independent adverse effect on growth. Bisphosphonates such as ALD may be useful in prevention of treatment associated osteopenia in patients with pediatric malignancies.

Table 1: % Difference from Controls. ns = p>0.05

	MTX	MTX+ALD	ALD
aBMD whole body (DXA)	-2.8 %	+7.5 %	+7.3 %

The Effect of Three-years Treatment of Incadronate Disodium on Accumulation of Microdamage, Microarchitecture and Strength in Dog Vertebra. S. Komatsubara*[1], S. Mori[1], T. Mashiba*[1], M. Ito*[2], J. Kawanishi*[1], T. Akiyama*[1], K. Miyamoto*[1], Y. Cao*[1], H. Norimatsu[1]. [1]Department of Orthopaedic Surgery, Kagawa Medical University, Kagawa, Japan, [2]Department of Radiology, Nagasaki University, School of Medicine, Nagasaki, Japan.

This study aimed to investigate the effect of long-term suppression of bone resorption by bisphosphonate on microstructure, accumulation of microdamage and mechanical properties of trabecular bone. 29 beagles (15 males, 14 females), 1year old were divided into three groups. The control (CNT) was treated daily with vehicle, and the other two groups were treated with incadronate at a dose of 0.3 mg/kg/day (LOW) or 0.6 mg/kg/day (HIGH) orally for 3 years. After sacrifice, the second thoracic vertebra was scanned with micro-CT. The left side of second thoracic vertebra was stained with Villanueva bone stain for histomorphometry. The right side was stained en block with basic fuchsin for microdamage measurement. Fourth lumbar vertebra was mechanically tested in compression. Incadronate concentration in bone was measured in eleventh thoracic vertebra using high performance liquid chromatography (HPLC). Micro-CT analysis demonstrated the plate-like trabecular structure and increased concave surface of trabeculae in the thoracic vertebra of incadronate treated groups. Three years incadronate treatment significantly suppressed activation frequency by 56% in LOW and by 67% in HIGH without impairment of mineralization, and increased microdamage accumulation in both treated groups. Trabecular bone volume was significantly increased in both LOW (31%) and HIGH (31%), and vertebral strength was significantly increased in HIGH when compared with CNT. However, no significant differences were found among groups in any intrinsic material property. Regression analysis showed a significant linear relationship between suppressed bone remodeling and increased microdamage accumulation. Incadronate concentration in bone was dose dependent. There was significant linear relationship between increased incadronate concentration in bone and reduced Ac.f. Also significant linear association was found between increased incadronate concentration in thoracic vertebra and increased Cr.Dn and Cr.S.Dn. This study suggested that long-term suppression of bone remodeling increased microdamage accumulation, but this was not necessarily associated with vertebral fragility because of compensated increase of bone mass and improved microarchitecture.

One-year Alendroante Administration Is Effective to Prevent Bone Loss and Decline of Bone Strength in Severe Osteoporotic Patients -A pQCT Study. P. C. Or*[1], W. S. Chan*[2], L. Qin[2], M. A. Dambacher*[3], E. Lau[1], P. C. Leung*[1]. [1]The Jockey Club Osteoporosis Centre for Care and Control, The Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China, [2]Department of Orthopaedics and Traumatology, The Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China, [3]Universitätsklinik Balgrist, Zürich, Switzerland.

High risk patients with established osteoporosis should be treated for the prevention of further fractures. Antiresorptive drugs have been developed and shown to be effective treating Caucasians in western countries and we want to test the same drugs for Asians. In this study, we evaluated the treatment effects of Alendronate in 120 postmenopausal Chinese women aged between 55 to 83, with history of vertebral fracture. After randomization, patients received either oral administration of 10mg/day Alendroante or placebo for one year. Daily supplemental of 1200mg calcium was given to both groups. Baseline and follow-up multislice pQCT measurement (Densiscan 2000) was performed in the non-dominant distal radius. 42 patients in alendronate group and 43 patients in placebo group completed one-year follow-up. Results in table 1 showed that alendronate was effective to prevent both trabecular and cortical bone loss as compared with placebo. In addition, the alendronate might be effective to prevent bone resorption on the surface of shaft marrow cavity (positive changes in shaft cross-sectional area (CSA) in alendronate treated group as compared with placebo group). This might result in significant protective effects on the decline of bone shaft strength as shown in the non-invasive bone strength index (BSI) of distal radial cortical bone. Since osteoporosis is a systemic bone health problem and oral alendronate has systemic antiosteoporotic effects, the benefits of alendronate shown in distal radial shaft BSI might also positively influence the femoral neck, which could not be measured in the current study due to methodological limitations. Long-term follow-up is needed to reveal the benefits of alendronate treatment in reducing osteoporotic fractures in Chinese population.

Comparison of percentage changes in BMD, CSA, CSMI and BSI for different parts of distal radius

Measured Region in Distal Radius			Percentage Changes (%) (Mean ± SD)		p-value

Etidronate Retards Radiological Disease Progression And Prevents Axial And Appendicular Bone Loss in Rheumatoid Arthritis (RA) – A Randomaized Controlled Study. M. Ide[1], Y. Suzuki[2], G. Itoh*[1], R. Uehara[1], Y. Ohsone*[3], Y. Okano*[4], Y. Matsuoka*[3], M. Akizuki*[4], Y. Ichikawa*[5], S. Ozaki*[1]. [1]Rheumatology, St. Marianna Univ. School of Med., Kawasaki, Japan, [2]Rheumatology, Tokai Univ., Isehara, Japan, [3]Internal Medicine, Kawasaki Municipal Hosp., Kawasaki, Japan, [4]Internal Medicine, Yokohama Municipal Hosp., Yokohama, Japan, [5]Internal Medicine, St. Joseph Hosp., Yokosuka, Japan.

Etidronate, an analog of inorganic pyrophosphate, its main biologic effect is the inhibition of bone resorption by suppression of osteoclast function. Recently, favorable effects of etidronate was reported on bone loss in RA. On the other hand, it was suggested that osteoclast like cell derived from synovium of RA patient was participated with joint destruction in RA. We focus on whether etidronate influences progression of joint destruction and prevents bone loss in RA. **Methods.** Twenty eight women with active rheumatoid arthritis (defined by a level of serum CRP >1mg/dl, and/or an erythrocyte sedimentation rate >20 mm/h) enrolled for this study. The patients were randomly allocated into one of two treatment group; etidronate group (400mg/day, 14 days/3 months) or control group (calcium lactate 1g/day). We measured lumbar and radial bone mineral density (periarticular region and 33% distal shaft) by DXA at baseline and 1 year later. Furthermore, the radiological development of erosions and joint space narrowing on hands were scored using Sharp method modified by van der Heijde et al. at the same time as DXA. **Results.** 1) The parameters of RA activity, age, administration of DMARDs, and bone mineral density were similar in 2 groups at baseline. 2) The lumbar BMD at 1 year later was significantly lower than at baseline in control group (1.056 vs 1.013 g/cm^2, mean±SEM, p <0.05). On the other hand, the lumbar BMD in etidronate group at 1 year later was significantly higher than at baseline (1.023 vs 1.058, p <0.05). 3) The periarticular and 33% distal shaft BMD at 1 year later in control group were significantly lower than at baseline (0.337 vs 0.323, 0.596 vs 0.562, p <0.05), whereas the both BMD were maintained as well as at baseline in etidronate group (0.342 vs 0.343, 0.530 vs 0.529, NS). 4) Although the change of serum CRP in both groups was similar, the progression score in etidronate group was significantly smaller than in control group (2 vs 7, p <0.05). **Conclusion.**These results suggest that etidronate is not only prevents bone loss but retards progression of joint destruction in RA .

M347

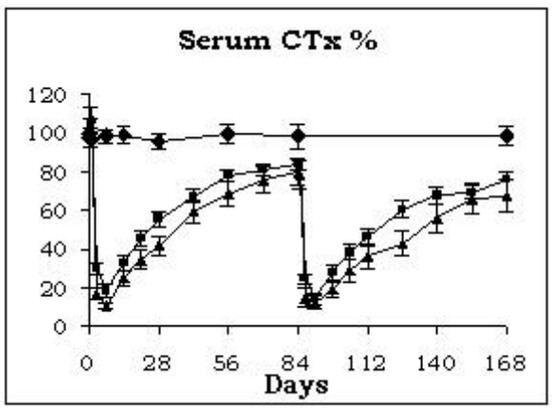
Three-Monthly 2mg Intravenous Ibandronate Injections Restore Bone Turnover to Premenopausal Levels. S. Adami[1], C. Christiansen*[2], A. Burdeska*[3], K. Coutant*[3], P. Mahoney*[3]. [1]University of Verona, Verona, Italy, [2]CCBR, Ballerup, Denmark, [3]F. Hoffmann-La Roche Ltd, Basel, Switzerland.

For some patients, oral bisphosphonates (BPs) have limitations that may reduce compliance. Intravenous (i.v.) administration avoids these problems, thereby potentially enhancing acceptability. Less frequent dosing may further improve compliance. A pivotal phase III fracture study of 3-monthly ibandronate (0.5mg and 1.0mg) i.v. injections showed suboptimal increases in BMD and suppression of bone turnover, such that the fracture reduction did not reach significance (Recker R, et al. Osteoporos Int 2000;11: abstract 565). Preliminary results from a trial examining the impact of increasing dose (Adami S, et al. IOF World Congress on Osteoporosis 2002; abstract O36) support the conclusion that insufficient dose was a key reason for this finding. This double-blind, parallel-group phase III study of 1mg versus 2mg ibandronate i.v. injection every 3 months as treatment of PMO enrolled 520 postmenopausal women (aged 55-75 years, at least 5 years since menopause onset) with established osteoporosis (mean BMD T-score at the lumbar spine <-2.5 SD). Patients were randomized to receive either 1mg (n=131) or 2mg (n=261) ibandronate or placebo (n=128), plus daily calcium (500mg) and vitamin D (400IU). The primary endpoint was the relative change in lumbar spine BMD. Secondary endpoints included change in the rate of bone turnover, as measured by assessing serum C-telopeptide (CTx) concentration, urinary CTx excretion (ratio of CTx/creatinine) and serum osteocalcin concentration at baseline, and every 3 months thereafter (before injection). Three-monthly 2mg i.v. ibandronate provided greater increases in lumbar spine BMD versus 1mg after 1 year (5% vs 3%, respectively; p<0.0001), with no increase in the placebo group. These BMD gains were associated with a significant reduction in markers of both bone resorption and bone formation after 12 months, relative to placebo. The effects on bone turnover were more pronounced in the 2mg versus 1mg ibandronate group: serum CTx levels, urinary CTx excretion and serum osteocalcin levels were reduced by 60.4% versus 44.1%, 60.9% versus 42.0% and 52.7% versus 47.9%, respectively, after 12 months. This study provides evidence that increasing the ibandronate dose to 2mg effectively reduces biochemical markers of bone turnover to premenopausal levels and provides more sustained suppression of bone turnover and significant increases in BMD that could translate into fracture benefit. This study also underscores the importance of examining bone marker patterns in conjunction with BMD increases.

M348

Dose Dependent Effects on Bone Resorption and Formation, on a Group and an Individual Level, of Intermittently Administered Intravenous Ibandronate. A. Moelgaard*[1], S. Christgau*[2], P. Qvist*[2], L. Wieczorek*[3], N. Hoyle*[3], C. Christiansen[1]. [1]Center for Clinical & Basic Research A/S, Ballerup, Denmark, [2]Nordic Bioscience A/S, Herlev, Denmark, [3]Hoffmann-La Roche Ltd., Basel, Switzerland.

To delineate in detail the dose-dependent effects of intermittent intravenous (iv.) ibandronate treatment on markers of bone turnover. The study included 73 healthy postmenopausal women with a spinal BMD between -5 and -1 T-score. Two groups received an intravenous injection every three months of either 1 mg or 2 mg ibandronate and one group served as control. Study duration was 168 days and treatment was administered on day 0 and day 84. Serum CTx and NMid were measured on samples drawn on 19 occasions. Three (3) days after drug administration s-CTx in the 1 mg and 2 mg groups had decreased by -70% and -83%. At day seven (7) nadir was reached with a decrease of -81% and -90%, respectively. Two weeks after drug administration s-CTx started to rise again in both the 1 mg and 2 mg groups reaching -16% and -20% at day 84 i.e. immediately before the second drug administration. The 1 mg and 2 mg curves were parallel, but the 2 mg curve was consistently and significantly (p<0.001) lower than the 1 mg curve. S-NMid had completely different dynamics with a steady decrease that reached a nadir of -35% after 5 months (140 days) of treatment. The 1 mg and 2 mg doses resulted in parallel curves. On group level, the suppression of bone resorption was greater or equal to the suppression of bone formation at all time points. On the individual level, however, the different dynamics of resorption and formation in response to the iv. ibandronate treatment resulted, in several time points where more individuals had higher resorption than formation, suggesting that bone loss resumed periodically. This tendency became worse with increasing treatment time.The data suggests that the reasons why a 3-year fracture study using 1 mg and 0.5 mg iv. ibandronate every 3 months yielded a sub-optimal effect on bone mineral density and failed to show a significant reduction in the incidence of vertebral fractures, can be found in both the timing of the drug administration and the dose. Furthermore, it demonstrates that the analysis of bone marker data on an individual level may be at least as important as the conventional evaluation on a group basis.



M349

The Efficacy of 12-month Oral Ibandronate Treatment in Postmenopausal Osteoporosis When Taken 30 min Versus 60 min Before Breakfast. L. B. Tankó*[1], M. R. McClung[2], R. C. Schimmer*[3], P. Mahoney*[4], C. Christiansen[1]. [1]CCBR A/S, Ballerup, Denmark, [2]FACE, Oregon Osteoporosis Center, Portland, OR, USA, [3]F.Hoffmann-La Roche Ltd, Basel, Switzerland, [4]Roche Products Ltd, Welwyn Garden City, United Kingdom.

The purpose of the study was to demonstrate comparable efficacy of oral ibandronate 2.5 mg daily to increase bone mineral density (BMD) and suppress bone turnover when the post-dose fasting period is reduced from 60 to 30 min. Forty-eight week, multi-center, open-label, randomized non-inferiority study. Subjects (n=184) were postmenopausal women 55-80 years old with lumbar spine BMD T-score ≤-2.5. All participants received a daily dose of 2.5 mg ibandronate supplemented with 500 mg calcium and 400 IU of vitamin D. Subjects were randomly assigned to take ibandronate exactly 30 or 60 min before breakfast. Time of drug intake with reference to breakfast was registered in diaries. Change in spine BMD (L1-L4) and proximal femur (trochanter, femoral neck, total hip) from baseline was measured by DEXA, whereas changes in markers of bone turnover (serum osteocalcin and urinary CTx excretion) were assessed by ELISA. Baseline efficacy parameters were similar between the intervention groups. Both groups adhered tightly to the dosing regimen, with a more narrow distribution in the 30-min fasting group. After 48 weeks of treatment, the increase in spine BMD from baseline was lower in the 30-min (3.1%) compared to the 60-min group (5%) to an extent that the pre-specified non-inferiority criteria were not met. Similar results were found at the trochanter, femoral neck and total hip, although the magnitude of the difference between the treatment groups at these sites was smaller than at the lumbar spine (Figure 1). Less suppression of the markers of bone turnover, assessed by the mean change from baseline of creatinine-corrected urinary CTx (-48.49% versus -61.75%) and serum osteocalcin concentration (-34.77% versus -43.78%) was observed in the 30-min compared to the 60-min group, respectively. Ibandronate was well-tolerated in both treatment groups. A reduction of the fasting interval following drug intake decreases the efficacy of treatment. Intermittent dosing regimens, currently under clinical testing, are expected to further improve the convenience and compliance of oral treatment with bisphosphonates.

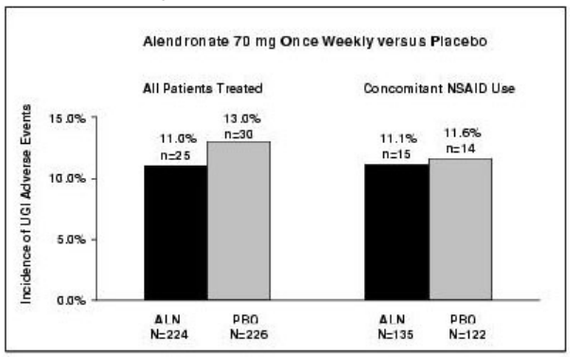
Upper GI Tolerability of Once-Weekly Alendronate 70 mg with Concomitant NSAID Use. A. E. de Papp, J. Palmisano*, G. P. Geba*. Clinical Development, Merck & Co., Inc., West Point, PA, USA.

Safety assessments of oral bisphosphonates have focused on upper gastrointestinal (GI) adverse events (AEs), because of the known potential for bisphosphonates to irritate the upper GI mucosa. Similarly, nonsteroidal anti-inflammatory drugs (NSAIDs) may induce gastric mucosal damage, and are frequently used by the same patient population that is prescribed bisphosphonates. In order to determine the rate of clinical adverse GI events with exposure to once-weekly alendronate 70 mg (ALN), and NSAIDs, we performed an analysis on a subgroup of 257 patients who received both medications concomitantly during a 12 week, randomized, placebo controlled osteoporosis trial. Survival analysis was performed using Kaplan Meier estimation, and significance was assessed using the log rank test. Logistic regression was used to assess the effect of treatment, NSAID exposure and interaction on the rate of upper GI AEs. 450 women and men with osteoporosis, from 48 US sites were randomized to treatment with once-weekly ALN, or placebo (PBO) in a 1:1 ratio. 60.2% (135/224) of ALN patients, and 53.9% (122/226) of PBO patients, reported concomitant use of NSAIDS or aspirin during the study. In the analysis of upper GI AEs of the "all patients treated" population, 25 ALN patients and 30 PBO patients reported one or more upper GI AEs, (11% and 13% respectively; p= NS). In the subgroup of patients taking NSAIDs concomitantly, 15 ALN patients, and 14 PBO patients reported upper GI AEs (11.1 % vs 11.6% respectively; p = NS). Logistic regression revealed no significant interaction between once-weekly ALN and concomitant NSAID use.



We conclude that once-weekly alendronate 70 mg was generally well tolerated, and when used concomitantly with NSAIDs, did not increase the rate of upper GI AEs relative to placebo over a 3 month study period.

Effect of Pamidronate and Alendronate on Bone Mineral Density in Osteoporotic Patients - A Control Matched Study. R. M. Noord*[1], R. Minkowitz*[2], P. Maid*[1], J. M. Lane[1]. [1]Hospital for Special Surgery, New York, NY, USA, [2]Weill Medical College of Cornell University, New York, NY, USA.

A substantial fraction of osteoporotic patients cannot be treated with alendronate due to treatment failure or gastrointestinal contraindication. Therefore, date are needed regarding the bone mineral density (BMD) increases achieved with alternative bisphosphonate regimens compared to those provided by alendronate. This study aims to investigate the efficacy of IV pamidronate, compared to alendronate, in increasing BMD in patients with low BMD. The experimental group consisted of 28 consecutive, pamidronate-treated (30mg IV q 3 months), osteoporotic (27) or severely osteopenic (1) patients from an office orthopaedic practice. Included were 2 males with a history of a fragility fracture, 11 females without fracture history and 15 females with a fracture history. Experimental patients were matched to a control patient treated with alendronate (10mg qd). Control patients were of similar sex, fracture history and bone mineral density before treatment. Dual-energy x-ray absorptiometry was used to measure patients' BMD both before and after treatment. Overall, 81% of patients treated with pamidronate experienced an increase in lumbar spine (LS) BMD, with a mean age of +2.40%/year. In comparison, 85% of patients treated with alendronate had an increase in LS BMD, with a mean change of +3.00%/year. In the femoral neck (FN), 60% of patients experienced improved BMD in the pamidronate group, with a mean change of +.22%/year, and 61% of patients in the alendronate group had an increase in FN BMD, with a mean change of +.12%/year. In females without fracture history, 64% of those treated with pamidronate increased LS BMD (mean change of +.95%/year), and 64% increased FN BMD (mean change of +.52%/year). In similar females treated with alendronate, 90% had a LS BMD increase (mean change of +3.30%/year), and 54% had an increase in FN BMD (mean change of +.72%/year). In females with a fracture history, 93% of those treated with pamidronate incresed LS BMD (mean change of +3.19%/year), and 66% increased FN BMD, with a mean change of +.68%/year. In the alendronate group, 80% of females with a fracture history had increased LS BMD (mean change of +2.64%/year), and 60% increased FN BMD (mean change of -.69%/year). In conclusion, data shows no statistical difference between the effects of pamidronate patient and alendronate matched patient on the overall study population's lumbar spine or femoral neck bone mineral densities.

Alendronate Reduces Risk of Vertebral Fracture in Women with BMD T-scores Above -2.5: Results from the Fracture Intervention Trial (FIT). D. Black[1], D. Thompson[2], S. Quandt[3], L. Palermo[1], K. Ensrud[4], O. Johnell[5]. [1]University of California, San Francisco, CA, USA, [2]Merck & Co., Inc., West Point, PA, USA, [3]Wake Forest University, Winstom-Salem, NC, USA, [4]University of Minnesota, Minneapolis, MN, USA, [5]Malmo General Hospital, Malmo, Sweden.

Alendronate has been shown to be effective in reducing risk of non-vertebral, hip and vertebral fractures among women with BMD T-scores below -2.5. However, several studies have suggested that bisphosphonates are less effective in reducing risk of non-vertebral and hip fractures among women with BMD above -2.5. The question of whether reductions in vertebral fractures depend on initial BMD has not been fully explored. We performed an analysis of data from FIT in order to examine whether reductions in vertebral fractures were larger in those with lower BMD. FIT was a randomized trial of 6459 women with femoral neck T-scores below -1.6 of whom 2027 had existing vertebral fractures. In this analysis, we combined data from women with and without existing vertebral fracture. Women were assigned to alendronate (5 mg for first two years, then 10 mg) or placebo and followed for an average of 3.8 years. We stratified the population according to initial femoral neck T-score into those with T-scores at or below -2.5 and those with T-scores above -2.5. We analyzed the effect of alendronate on incidence of morphometric and clinical vertebral fractures within those strata.

	FN BMD T≤-2.5 (n=2715)		FN BMD T>-2.5 (n=3741)	
Type of Fracture	N	RR (aln vs. pbo)	N	RR (aln vs. pbo)
Morph. Vertebral	214	0.50 (0.37, 0.67)	130	0.57 (0.39, 0.82)
Clinical Vertebral	78	0.62 (0.39, 0.98)	41	0.41 (0.21, 0.80)

We found no significant differences between the two groups in reductions of morphometric vertebral fractures or clinical vertebral fractures. We conclude that alendronate is effective in reducing the risk of both morphometric and clinical vertebral fracture in women with BMD T-scores above -2.5. There is no evidence that the effect of alendronate on vertebral fractures is different in those with lower BMD.

Upper GI Tolerability of Alendronate (FOSAMAX) 70 mg Once Weekly Is Similar to Placebo. J. Eisman[1], R. Rizzoli[2], K. A. Gaines*[3], N. Verbruggen*[3], M. E. Melton[3]. [1]St. Vincent's Hospital, Sydney, Australia, [2]University Hospital Geneva, Geneva, Switzerland, [3]Merck & Co., Inc., Whitehouse Station, NJ, USA.

Alendronate has established efficacy for treatment of osteoporosis whether given daily or in a more convenient once weekly regimen. To further investigate the tolerability of once weekly alendronate, this study examined the overall and upper gastrointestinal (GI) tolerability profiles of alendronate given in a 70-mg once weekly regimen as compared to placebo. In 19 countries representative of Europe, the Americas and Asia-Pacific, 449 men and women with osteoporosis were recruited for this study. Subjects were randomized to either alendronate 70 mg or placebo once weekly for 12 weeks and advised to take the tablets using standard morning dosing. The incidence of any adverse experience was evaluated. Upper GI adverse experience and discontinuation of therapy due to a drug-related upper GI adverse experience between groups were assessed using Kaplan-Meier estimation at week 12 for the time-to-first-event data. The change from baseline in urinary NTx/Cr was also assessed. The subjects were aged 64 +/- 9 years, 94% women, 66% Caucasian, 18% Asian and 12% Hispanic. Urinary NTx/Cr excretion decreased significantly in the group receiving alendronate (-43%) compared to placebo (+8%, P<0.001 alendronate vs. placebo). Overall safety and tolerability was similar between groups, with similar proportions of subjects reporting an adverse experience in each group (alendronate 40%, placebo 38%). A similar proportion of alendronate and placebo subjects reported an upper GI adverse experience (9.8% and 9.4%, respectively) and a similar proportion of subjects discontinued therapy due to a drug-related upper GI adverse experience (2.7% and 2.2%, respectively). Neither these proportions nor the time-to-first event differed significantly between the alendronate and placebo groups. Thus, similar to results from an earlier US study (Greenspan et al., JBMR 2001;17(Suppl 1):S405), alendronate 70 mg once weekly significantly decreased bone turnover and had an upper GI and overall tolerability profile indistinguishable from placebo.

Effect of Bisphosphonates in Osteoporosis Secondary to LHRH Analogs for Prostate Cancer. S. Yaturu[1], C. DePrisco[2], S. DjoDjo*[3]. [1]Endocrinology, Overton Brooks VAMC/LSUHSC, Shreveport, LA, USA, [2]Endocrinology, LSUHSC, Shreveport, LA, USA, [3]LSUHSC, Shreveport, LA, USA.

Prostate Carcinoma is the most common visceral malignancy in men. Treatment with Leutinizing Hormone Releasing Hormone (LHRH) analogs improves survival. Therapy with LHRH analogs decreases bone mineral density and increases the risk of osteoporotic fractures in men with prostate cancer. Several in vitro studies have shown the benefit of bisphosphonates in the prostate cancer cell lines. Our main goal is to compare the effect of alendronate on patients with osteoporosis secondary to prostate cancer on GnRH analogs compared to the age matched patients with osteoporosis in men. We compared the changes in the bone mineral densities of 12 patients with osteoporosis secondary to LHRH analogs in comparison to 27 patients without prostate cancer and have osteoporosis. The changes in the bone mineral density at lumbar spine and both hips were measured by dual energy x-ray absorptiometry in both groups over one year on bisphosphonates.The data is expressed as mean plus or minus standard error.

Mean Changes

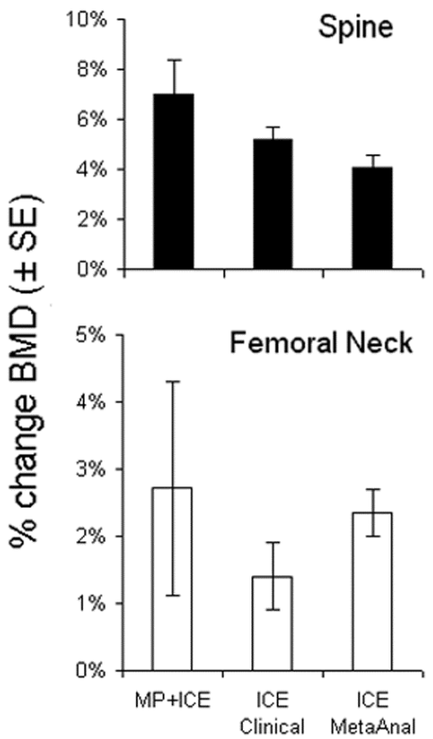
	Group1(n=12)	Group2(n=27)	*p*
Spine	-0.75±2.4	0.98±2.3	0.65
Right Hip	-5.06±1.74	-0.47±0.60	0.158
Left Hip	-3.77 ±1.7	0.05±0.44	0.007

Mean changes in bone mineral density differed significantly between the two groups (P<0.05) at the left hip but not at the lumbar spine and total hip. This data suggest that bisphosphonate therapy is beneficial at spine and effective for patients with prostate cancer.

M355

Medroxyprogesterone Augments Positive Bone Mineral Density Effects of Cyclic Etidronate in Menopausal Women. J. C. Prior, C. L. Hitchcock*. Endocrinology/Medicine, U of British Columbia, Vancouver, BC, Canada.

The purpose of this study is to determine whether co-therapy of medroxyprogesterone (MP) with intermittent cyclic etidronate (ICE) has a more positive effect on bone mineral density (BMD) change than ICE alone. Progesterone and progestins cause osteoblast-related bone formation *in vitro* (Tremollieres, 1992; Ishida, 1997). Premenopausal bone change is positively related to luteal lengths and progesterone levels (Prior, 1990; Sowers, 1998). A prospective cohort control study showed greater effects of MP with estrogen versus estrogen alone (Grey, 1996). Increased bone formation from PTH therapy reduces vertebral and non-vertebral fragility fracture rates (Neer 2001). **Design:** Retrospective clinical cohort study using randomly sampled charts of women with osteopaenia or osteoporosis from a single endocrinology practice. 263 charts were randomly selected and reviewed, of which 19 were eligible. These data were compared with published data, because insufficient numbers were available on ICE alone from this practice. **Inclusion criteria**: women past menopause, full dose therapy with MP (10mg/d) or oral micronized progesterone (OMP; 300mg/d) as well as ICE, BMD baseline data within 6 months of starting therapy and 1-4 y later. Diseases or steroid use were not exclusion criteria. **Cohort Characteristics:** These 19 menopausal women were 58.3 y (SD 5.6) at baseline, with BMI 23.5 (3.35). All were taking at least 500 mg supplemental calcium and 400 IU vitamin D/d. Baseline spine (LS) BMD was 0.786 (0.114) g/cm^2 and femoral neck (FN) 0.673 (0.126) g/cm^2. **Results:** LS BMD change on MP plus ICE was LS: 6.99% (SD 5.76, n=16) and FN 2.71% (SD 6.41, n=16) over 2.7 (95% CI: 2.3,3.1) y. A comparable clinical study of ICE alone over 2 y (Crilly, OI, 2000) showed BMD changes of LS: 5.20 (7.39)%; FN: 1.40 (7.50)%). MP plus ICE produced a 1.79% greater increment in LS (t_{224} = 12.95, P < 0.0001) and 1.31% greater gain in FN BMD (t_{253}=9.17, P <0.0001) than ICE alone. MP plus ICE BMD changes (7% spine and 2.7% FN) are also greater than from a meta-analysis of ICE clinical trials (4.1% and 2.4% respective increments over placebo)(Cranney, OI, 2001). **Conclusion:** These data suggest MP and OMP increase bone formation in menopausal women and, combined with anti-resorptive agents, may improve fracture prevention. Randomized, controlled trial data are needed.



M356

Ibandronate Decreases Femoral Head Flattening in a Piglet Model of Ischemic Necrosis of Femoral Head. H. K. W. Kim[1], D. Pringle*[1], D. Hunter*[1], W. Pritchard*[1], F. Bauss[2]. [1]Shriners Hospital for Children, Tampa, FL, USA, [2]Roche Diagnostics GmbH, Penzberg, Germany.

Ischemic necrosis of growing femoral head, as seen in children with Legg-Calve-Perthes disease, is associated with development of permanent deformity of femoral head and premature degenerative arthritis in adulthood. A piglet model of ischemic necrosis has been shown to reliably produce progressive flattening of the femoral head by 6 wks, and radiographic and histopathologic changes resembling Perthes disease. An imbalance of bone resorption and formation following revascularization has been identified as one of the mechanisms of femoral head deformity. We hypothesized that anti-resorptive agents, such as bisphosphonates, will minimize the deformity following ischemic necrosis by decreasing bone loss and allowing time for new bone formation. Purpose of the study was to determine the effects of ibandronate on femoral head deformity following ischemic necrosis in the piglet model. Ischemic necrosis was induced surgically in 12 male piglets by tightly placing a ligature around the femoral neck. The animals were assigned to one of 4 groups (3 animals per group): Grp 1: Ibandronate started 1 wk prior to ischemia (prophylactic grp), Grp 2: 1wk post-ischemia, Grp 3: 3wks post-ischemia, and Grp 4: saline only (control). Ibandronate was administered subcutaneously 3X per wk and total dose was 1.5 mg/kg. All animals were sacrificed at 6 wks following surgery. Histologic and radiographic assessments were performed. Radiographically, the infarcted heads from Grp 1 (prophylactic grp) animals had no flattening. Mild flattening with small areas of bone resorption was observed in the infarcted heads from Grp 2 animals. The infarcted heads from Grp 3 and 4 animals showed severe flattening and large areas of bone resorption. Histologically, all groups of animals showed revascularization of the infarcted marrow space of the femoral head. However, the presence of osteoclasts and bone resorption was most prominent in the infarcted heads from Group 3 and 4 animals, whereas, it was limited in the infarcted heads from Grp 1 and 2 animals. To our knowledge, this is the first study of the role of bisphosphonate in a large animal model of ischemic necrosis. The results suggest that it is feasible to minimize the femoral head deformity using an anti-resorptive agent, ibandronate, in the piglet model. However, early treatment (started 1 wk post-ischemia at least) is required to minimize the deformity in this model. We conclude that further studies are required to determine the optimal dose and treatment regimen of ibandronate to prevent femoral head deformity following ischemic necrosis.

M357

Loading Doses of Bisphosphonates: A New Concept to Enhance the Efficacy of Bisphosphonates on BMD, and to Expedite Fracture Reduction in Osteoporosis. S. J. Wimalawansa. Department of Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ, USA.

Efficacy of bisphosphonates in enhancing the bone mineral density (BMD) and decreasing the fracture rates is now well-established. However, the absorption of bisphosphonates is usually less than 1% of that of the orally administered dose (e.g., alendronate, risedronate, etidronate, tiludronate, etc.). Therefore, generally it may take several months or up to a year or more to get an adequate amount of a bisphophonate incorporated into bone, to be highly effective in the reduction of bone turnover and the reduce fracture incidence. This is also true for the standard doses of bisphosphonate administered intravenously (pamidronate, ibandronate and zolendronate). We hypothesized that if we could get adequate amount of the bisphosphonate into bone earlier in the course of a treatment, then one would expected to see a rapid response, and also enhance the beneficial effects on BMD and fracture reduction. We have been examining the effectiveness of loading doses of oral and intravenously administered bisphosphonates on BMD in comparison with the standard doses of the same agent. We have compared the effects of loading doses of alendronate, risedronate and pamidronate with their standard recommended doses for osteoporosis over a one-year period. Results demonstrated a significant increase of BMD in both oral and intravenously administered agents with in 3-6 months (with significant decrease of biomarkers within the first 4-8 weeks), in comparison with the 6-12 months for the standard therapy. If the fracture efficacy of an anti-resorptive drug is depends on the rapidity of the reduction of bone turnover and enhancement of the BMD, then this new approach of administration of bisphosphonates should significantly enhance the fracture reduction with bisphosphonate therapies. This novel approach with bisphosphonates (and some other osteoporosis therapies as well) should be particularly beneficial for the patients with high bone turnover, and also those who are with established osteoporosis.

M358

Improvement in Nutrition Reduces Bone Resorption in Elderly Women with Osteoporosis and Low Body Mass Index : A Randomised Controlled Trial. G. Hampson[1], F. C. Martin*[2], K. Moffat*[3], S. Vaja*[1], G. Blake*[4], I. Fogelman*[4]. [1]Chemical Pathology, St Thomas Hospital, London, United Kingdom, [2]Elderly Care Unit, St Thomas Hospital, London, United Kingdom, [3]Dietetics, St Thomas Hospital, London, United Kingdom, [4]Nuclear Medicine, Guy's Hospital, London, United Kingdom.

Malnutrition is a risk factor for osteoporosis and hip fractures. We investigated the effects of dietary advice and nutritional supplementation on bone metabolism in 71 women aged ≥70 years with a low BMI(kg/m^2) (mean [SD] 20.1 [1.9]) and osteoporosis at the hip. They were randomised to 2 groups; Group 1 (n=36) received 1 gram of calcium and 800 units of cholecalciferol only, Group 2 (n=35) also received dietary advice and nutritional supplements to increase their BMI by ≥$1kg/m^2$ over 12 months. Bone mineral density (BMD), body composition (DXA), calciotrophic hormones, biochemical markers of bone remodelling and dietary intakes were assessed. No significant difference was seen at baseline between the 2 groups. At the end of the intervention period, Group 2 increased their weight significantly (mean [SD] Group 2 : 2.42 [2.82] kg, Group 1: 0.15 [2.45] kg, $p < 0.01$). There was an increase in fat mass (Group 2 : 1894 [1754] g, Group 1: -266 [1865], $p < 0.0002$). Although there was a trend towards an increase in lean body mass (LBM) and body mineral content (BMC) in Group 2, this was less marked than the gain in fat mass (LBM Group 2: 478 [944] g, Group 1 : 241 [1063], BMC Group 2 : 28.9 [54.9] g, Group 1: 5.5 [70] g). No significant difference was seen in the one - year percentage change in BMD at the spine, femoral neck and total hip (%), although we observed a positive trend at the total hip in Group 2 (Total hip Group 2 : 1.33 [3.23], Group 1 : 0.27 [5.72]). A significant reduction in serum C-terminal telopeptides of Type 1 collagen (CTx) (pM), a marker of bone resorption was seen in Group 2 compared to Group 1 at 1, 3, 9 and 12 months (change from baseline :1 month Group 2 : -583 [721], Group 1 : -269 [387] p= 0.036, 3 month: -774 [878], -208 [824] p= 0.009, 6 month : -554 [1211], -184 [633] p= 0.12, 9 month: -526 [930], - 4.1 [705] p= 0.015, 12 month: -525.4 [1120], 174 [717.9] p= 0.005). We observed an increase in serum osteocalcin (ng/ml) in Group 2 at 6, 9, and 12 month (6 month Group 2 : 2.0 [2.7], Group 1 : -0.2 [2.3] p=0.024, 9 month: 2.2 [3.0], 0 [1.7] p=0.022, 12 month: 2.3 [3.0], -0.7 [2.9] p=0.011). There was no significant difference in serum PTH and 25 (OH) D_3 between the 2 groups. A higher proportion of subjects in Group 2 reported feeling better at the end of the study (Group 2 : 48%, Group 1 : 20% p=0.029). Dietary improvement in elderly underweight women is associated with a reduction in bone resorption with a 'net' positive effect on bone formation. This may have a favourable impact on fracture risk.

M359

Effects of Long-term L-Arginine Supplementation on Bone Metabolism. N. Kamps*[1], R. Gerzer*[1], E. Schoenau[2], M. Heer[1]. [1]DLR-Institute of Aerospace Medicine, Cologne, Germany, [2]University Children´s Hospital, Cologne, Germany.

In the present study we aimed at the effect of oral L-Arginine supplementation on bone metabolism in healthy postmenopausal women. As Nitric Oxide (NO), synthesised from the nonessential amino acid L-Arginine, is an important regulator of bone turnover in humans exerting an anabolic effect on bone cell activity, oral supplementation with L-Arginine might be highly potential to effect bone cell activity via NO synthesis from L-Arginine. Thirty healthy, postmenopausal women took part in the study. Fifteen (mean body weight (BW): 66.3 ± 10.5 kg; mean age: 54.5 ± 4.1 years) received a six months oral supplementation with 18 g L-Argininehydrochlorid. Another fifteen volunteers (mean body weight (BW): 64.2 ± 9.1 kg; mean age: 55.3 ± 4.4 years) received a placebo of 18 g Dextrose for six month. Physical activity was documented in an activity protocol. To calculate protein, fat and carbohydrate as well as calcium and L-Arginine intake a food frequency questionnaire (FFQ) was chosen. To eliminate side effects the volunteers were asked not to change their activity or eating behaviour during the six months of the study. For the analyses of IGF 1, bone formation markers PICP, bAP, osteocalcin, the bone resorption marker CTX, calcium and PTH blood was drawn at baseline and after 2, 4 and 6 months. 24 hour urinary excretion of nitrogen was analysed during two days of each study period at baseline and after two, four and six months. The volunteers did not change protein (mean intake 66,8 ± 7,4 g), fat (mean intake: 89.4 ± 13.2 g) and carbohydrate (mean intake: 213.7 ± 22.4 g) intake during the six months of intervention. Moreover calcium (mean intake: 1128.0 ± 143.9 mg) and L-Arginine (mean intake: 3.7 ± 0.43 g) intake remained constant. The volunteers physical activity was unchanged during the investigation. Nitrogen excretion, as an indicator for compliance, rose from 448.2 ± 30.92 µmol/min during baseline to 635.9 ± 24.1 µmol/min during treatment in the L-Arginine group. In contrast, nitrogen excretion remained constant in the placebo group (443.7 ± 36.6 during baseline 419.6 ± 25.7 µmol/min during placebo application). Contrary to our hypothesis our results showed neither a change in bone formation markers nor in bone resorption marker. PTH, IGF 1 and transformed calcium concentrations were unchanged as well. We conclude from these results that mere L-Arginine supplementation does not have an effect on overall bone cell activity.

M360

Bicarbonate in Mineral Water Inhibits Bone Resorption. P. M. Burckhardt[1], S. Waldvogel Abramowski*[1], J. M. Aeschlimann*[2], M. J. Arnaud*[3]. [1]Internal Medicine, University Hospital, Lausanne, Switzerland, [2]Nestle Research Center, Lausanne, Switzerland, [3]Nestle Water Institute, Vittel, France.

Not only nutritional Calcium, but also a nutritional alcaline load seems to lower bone resorption and urinary Calcium (Ca) excretion. Oral bicarbonate positivated Ca-balance in postmenopausal women (Sebastian et al NEJM 1994). Therefore, bicarbonate in mineral water could serve as a natural inhibitor of bone resorption. Three groups of 10 healthy young women (20-38 yrs) drank 1.5 L/day of one of 3 mineral waters during 4 weeks on a free diet aiming at 1g Ca, 6g NaCl, and 80 g proteins/day, which was evaluated 1 week before, and 1 week after the beginning of the study, by 24 hrs recall and food frequency questionnaire. Blood and urine (fasting and 24 hrs) were examined at time 0,1,2 and 4 weeks, for Ca, Na, K, C-telopeptides, alk.phosphatase (ALP), osteocalcine, pH, bicarbonate. For this presentation the results from weeks 1,2,4 are pooled. But they were analysed for variance by ANOVA. Nutritional intake was not different in the 3 groups. Ca intake was ±806 mg before and ±1040 mg after the first week of the test, and increased with the mineral water to ±1340 mg in A and C, to ±1850 mg in B. Blood Ca and bicarbonate, ALP and osteocalcine did not change. Urine pH (fasting and 24 hrs) increased slightly in A, and decreased in B and C (n.s.). 24 hour-urine Na/creatinine increased slightly with A; K/creatinine decreased slightly with C (both n.s.). 24 hour-urine Ca/creatinine increased by ±31% in B,as expected, and by ±24% in C, and remained unchanged in A. Fasting serum C-telopeptides decreased slightly in A and increased slightly in B and C (n.s.). Fasting urine C-telopeptides / creatinine decreased by ±25% in A, at week 4 by -41%, significantly different from B (ANOVA p<0.05), and remained unchanged in B and C. Increased intake of bicarbonate as mineral water lowers bone resorption independently of the concomitant intake of Calcium.

Table

Mineral Water.....: A:Quezac... B:Contrex.... C:San Pellegrino

Interaction of Nutritional Calcium and HRT in Prevention of Postmenopausal Bone Loss. J. Sirola*[1], H. Kröger[2], R. Honkanen[3], L. Sandini*[2], M. Tuppurainen[4], J. S. Jurvelin*[5], S. Saarikoski*[6]. [1]University of Kuopio, OSTPRE Study Group, Kuopio, Finland, [2]Dpt of Surgery, Kuopio University Hospital, Kuopio, Finland, [3]Research Institute of Public Health, University of Kuopio, Kuopio, Finland, [4]University of Kuopio, Clinical Research Center, Bone and Cartilage Research Unit, Kuopio, Finland, [5]Dpt of Clinical Physiology & Nuclear Medicine, Kuopio University Hospital, Kuopio, Finland, [6]Dpt of Obstetrics and Gynaecology, Kuopio University Hospital, Kuopio, Finland.

The aim of the study was to investigate the interactive effects between nutritional calcium intake and intermittent HRT on bone loss. The study population, 937 women who had undergone natural menopausal transition before or during the follow-up, was selected from a random sample (n=2025) of the OSTPRE-study cohort. Out of them, 545 women had never used HRT whereas 392 women reported use of intermittent HRT during the follow-up (mean 6 years). Women were divided into tertiles according to self reported dairy nutritional calcium intake (mg/day, mean of baseline and follow-up report): <648 (1st), 648-927 (2nd), >927 (3rd). BMD at lumbar spine (LS) and femoral neck (FN) was measured with DXA absorptiometry at baseline in 1989-91 and at five year follow-up in 1994-97. In analysis of variance there were no statistically significant differences in bone loss rate between calcium intake tertiles in HRT never users. In intermittent HRT users the bone loss was significantly lower in the third tertile than in the second (p<0.05) and first (p<0.001) tertile at FN in contrast to no differences at LS. In linear regression model high calcium intake significantly predicted lower FN bone loss (p<0.001) in intermittent HRT users in contrast to no effect in HRT never users. At LS the corresponding linear calcium effect was weak in HRT users and of borderline significancy (p=0.063). In addition, at FN the difference in bone loss rate between HRT users/non-users was found statistically significant (p<0.001) only among women in the third calcium intake tertile whereas at LS this difference was significant in all tertiles but was greater in second (p<0.01) and third (p<0.001) tertile than in the first one (p<0.05). Analysis of interaction between HRT use and calcium intake showed statistically significant effect on bone loss at FN only (p<0.003). Adjustment for baseline age, baseline weight, baseline BMD, duration of menopause, bone affecting diseases/medications and use of calcium supplements did not change any of these results. In conclusion, nutritional calcium intake seems to improve the bone protective effects of even intermittent HRT, more clearly at FN than LS, and low nutritional calcium intake seems to be a significant risk factor for no response to HRT.

M362

Dietary Potassium Conserves Calcium After Menopause. K. M. Davies[1], R. P. Heaney[2], K. A. Rafferty*[1]. [1]Osteoporosis Research Center, Creighton University, Omaha, NE, USA, [2]John A. Creighton University Professor, Creighton University, Omaha, NE, USA.

Data from 8-day inpatient balance studies of healthy white women (Omaha Nuns) in the age range from 50 to 70, median age 59, all at or after the year of menopause, were analyzed for the effect of diet potassium on urinary calcium excretion. 208 data sets from 122 women were treated as independent because multiple visits were 5 years apart. Characteristics are in the Table. Based on their excellent correlation (Regression: $y = 0.9192x$; $R^2 = 0.8255$), we used Urinary K as a surrogate for Dietary K. Diet Calcium (Diet Ca) was obtained by ash-weight analyis of the actual diet. Calcium Absorbed (Ca Absrb) was determined by a tracer method. In stepwise regression, Na fails to enter as a variable, probably because of its uniformly low level. Expressed in terms of standardized coefficients, Ca Absrb (0.533 ± 0.061 SE, P<0.0001) is offset by Urinary K (-0.163 ± 0.061 SE, P<0.01) in the ratio 3/10. Conclusion: Potassium offsets excretion of Absorbed Ca . Eating one medium baked potato or one large banana can conserve about 60 mg of Ca.

Component (mmol)	average	St. Dev.
Urinary K	60.01	13.89
Diet Ca	20.59	9.16
Ca Absrb	4.70	2.01
Urinary Ca	3.60	1.44
Urinary Na	97.93	29.53

M363

Dairy Calcium Intervention Prevents Total Hip and Spine Bone Loss in Young Oral Contraceptive Users. P. A. Legowski*[1], C. W. Gunther*[1], R. M. Lyle*[2], G. P. McCabe*[3], C. M. Weaver[1], D. Teegarden[1]. [1]Foods and Nutrition, Purdue University, West Lafayette, IN, USA, [2]Health and Kinesiology, Purdue University, West Lafayette, IN, USA, [3]Statistics, Purdue University, West Lafayette, IN, USA.

This study examined the % change in total hip bone mineral density (BMD) and spine BMD among oral contraceptive users (OCont: n=57) and non-users (non-OCont: n=76) who were participating in a one year dairy calcium intervention trial. Healthy women (20.2 yr, range: 18-30) with initial calcium intakes <800 mg/day were randomized into control (n=43), recommended calcium (RecCa, 1000 mg/day, n=43) or high calcium (HiCa, 1250 mg/day, n=47) intake groups, achieved by increased dairy product intake. Hip and spine BMD were measured at baseline and 12 months (Lunar DXA). Baseline calcium intake was similar between calcium intervention groups (mean of groups =702±274 mg/day) and between OCont groups. While calcium intake in the control group did not change, calcium intake increased to 1046±307 and 1191±361 mg/day, respectively, in RecCa and HiCa groups by 3 months and remained similar over the year. Hip and spine BMD were not different between groups at baseline. Calcium intervention group assignment significantly predicted % change hip BMD (p=0.03). However, the effect of calcium intervention group assignment on % change hip BMD was noted in OCont users only (p=0.02, Figure 1); not non-OCont users (p=0.64). One year % change spine BMD was predicted by a model which included age, baseline weight, OCont use and interaction of OCont use by calcium intervention group assignment (p=0.009). Similar to hip BMD, calcium intervention group assignment predicted % change spine BMD, when controlled for age and weight, in OCont users only (p=0.001, Figure 1); but not non-OCont users (p=0.17). Adjustment for energy intake and physical activity did not affect results. Dairy calcium supplementation at 1000 mg/day or greater, protected the hip and spine BMD from loss observed in young healthy women with low calcium intakes who were taking OCont.

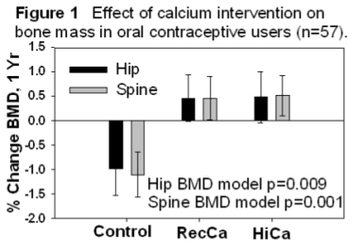

Figure 1 Effect of calcium intervention on bone mass in oral contraceptive users (n=57).

M364

Changes in Bone Turnover in Patients with Anorexia Nervosa during one Year of Dietary Treatment. C. Mika*[1], I. Grzella*[2], B. Herpertz-Dahlmann*[2], M. Heer*[1]. [1]DLR, Institute of Aerospace Medicine, Cologne, Germany, [2]Department of Child and Adolescent Psychiatry, Technical University, Aachen, Germany.

Anorexia nervosa (AN) is a common chronic eating disorder with an estimated prevalence of 0.5 to 1 % in female adolescents and young women. The restrictive eating pattern is associated with profound metabolic complications such as amenorrhea, growth hormone resistance, increased plasma cortisol, low production of insulin-like growth factor 1 (IGF1) and decreased leptin concentrations. One of the most important long-term somatic complications of AN is the decrease in bone mineral density, which often leads to spontaneous fractures. The aim of our study was to verify if dietary treatment including calcium intake of >2000 mg/d and 400 IU vitamin D/d in combination with an individually defined hypercaloric diet improves bone metabolism in patients with AN compared to a control group. We studied 19 female patients (age 14.13 ± 1.35 years; body weight 38.87 ± 5.04 kg; BMI 14.18 ± 1.38 kg/m2) with AN (ICD-10: F50.0, F 50.1) and a healthy control group (n=19, age 15.14 ± 2.25 years; body weight 56.28 ± 7.67 kg; BMI 20.80 ± 1.92 kg/m2) for 1 year. After a basal examination in the first week in hospital, 2000 mg calcium and 400 IU vitamin D were administered with the volunteers diet. Blood was drawn during BDC and at eight definite times (five times for the control group) in the following year for analyzing serum calcium, parathyroid hormone (PTH), bone formation (bone alkaline phosphatase (bAP) and C-terminal procollagen-I-propeptide (PICP)) and resorption markers (serum C-terminal telopeptide (CTX)),

leptin, IGF1, sexual hormones and cortisol. Comparing the two groups we found different baseline values for the bone formation marker PICP (p=0.0001), for BMI (p<0.0001), IGF1 (p<0.0001) and Leptin (p<0.0001), respectively. After 15 weeks of dietary treatment the patient group had still lower BMI values than the control group (p<0.0001). At that time we found an adjustment of the other parameters PICP, IGF1 and leptin for the two groups. At the end of the study levels of BMI (p<0.0001) and leptin (p<0.0001) were different between the two groups. There were no distinctions between anorexic patients and controls in bAP and CTX in the course of treatment. We summarized that for the patient group there were at least 15 weeks of high energy intake necessary in order to reach levels of bone formation of healthy adolescents. Bone resorption however remained unchanged. This underlies the importance of nutrition on bone turnover in anorectic patients.

M365

Vitamin K1 Supplementation Retards Bone Loss in Postmenopausal Women between 50 and 60 Years of Age. L. A. J. Braam*[1], M. H. J. Knapen*[1], P. Geusens[2], F. Brouns*[3], K. Hamulyak*[2], M. J. W. Gerichhausen*[4], C. Vermeer*[1]. [1]Biochemistry, Maastricht University, Maastricht, Netherlands, [2]Internal Medicine, Maastricht University, Maastricht, Netherlands, [3]Human Biology, Maastricht University, Maastricht, Netherlands, [4]Novartis Nutrition Research AG, Neuenegg, Switzerland.

The effect of vitamin K1 supplementation on bone mineral density (BMD) has never been studied, although many observational studies have shown an association between vitamin K-status and BMD. In a randomized placebo-controlled intervention study the potential synergistic effect of vitamin K1 and a mineral + vitamin D supplement was investigated on postmenopausal bone loss. 181 healthy postmenopausal women between 50 and 60 years old were recruited via newspaper advertisements and eventually 155 women completed the study. For three years they received daily either a placebo (n=60) or a supplement containing calcium, magnesium, zinc and vitamin D (MD-group, n=58), or the same supplement with additional vitamin K1 (MDK-group, n=63). The main outcome measure of this study was the change in BMD of the femoral neck and lumbar spine after three years, as measured by DEXA. The data were analysed according to intention-to-treat. The group receiving the supplement containing additional vitamin K1 showed reduced bone loss of the femoral neck. The differences in % BMD loss from baseline between the MDK-group and placebo [1.7%] (95% CI: 0.35 to 3.44) and between the MDK- and the MD-group [1.3%] (95% CI: 0.10 to 3.41) were statistically significant after three years (p<0.05) after adjustment for baseline BMD, age, BMI, and years since menopause. After three years, there was no significant difference in the % change from baseline in femoral neck BMD between the MD-group and placebo (mean difference: 0.4%, 95% CI: -1.51 to 1.79). Differences between the three groups with respect to change of BMD at the site of the lumber spine did not reach the level of statistical significance. In this study we have shown that a supplement containing minerals, vitamins D and K has a long-term beneficial effect on the prevention on bone loss in healthy postmenopausal women. Although the supplement used in this study did not result in a complete halt of bone loss, the rate of bone loss was substantially decreased. If this effect sustains during longer periods of intake, it may result in postponement of osteoporosis to later ages, and thus to a reduction of osteoporotic fractures.

M366

Soy Isoflavones May Enhance Bone Formation in an Aged Rat Model of Male Osteoporosis. M. P. Akhter[1], D. A. Khalil[2], E. A. Lucas*[2], D. S. Galloway*[3], L. J. Hammond*[2], B. J. Smith*[2], R. Recker[1], B. H. Arjmandi[2]. [1]Osteoporosis Research Center, Creighton University, Omaha, NE, USA, [2]Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, [3]Oklahoma Veterinary and Medical Teaching Hospital, Oklahoma State University, Stillwater, OK, USA.

Soy isoflavones have been reported to exert estrogen-like protective effects on the female skeleton. Since estrogen is also important in the maintenance of male bone health, we examined the effects of two doses of soy isoflavones (Iso) in the context of soy protein or casein on bone histomorphometry in aged orchidectomized rats. Thirteen-month old male F344 rats were either orchidectomized (ORX; 5 groups) or sham-operated (sham; 1 group). One ORX group served as control and was fed a casein-based diet whereas the remaining ORX groups received either a casein- or soy protein-based diet each with two levels of Iso (593 and 1186 mg/kg diet) for 180 d. Calcein was injected at 8 and at 1 day before necropsy and the proximal tibial metaphysis was assessed for bone histomorphometry. Treatment effects on trabecular separation (TbSP), trabecular numbers (TbN), bone volume as a percentage of tissue volume (BV/TV), mineralizing surface (MS/BS), and bone formation rate (BFR/BS) are presented below. Overall, results indicate that soy isoflavones irrespective of protein source exert beneficial effect on bone of male rats by preventing the orchidectomy-induced increase in TbSp and decrease in TbN and BV/TV without suppressing bone formation as evidenced by effects on MS/BS and BFR/BS.

	Protein Source	**Iso** (ppm)	**BV/TV** (%)	**TbSp** (µm)	**TbN** (mm^{-1})	**MS/BS** (%)	**BFR/BS** (mm^2/ mm/yr)
Sham	Casein	-	8.5±1.2	1504±480	0.94±0.13	10.3±3.0	0.03±0.01
ORX	Casein	-	3.5±1.2*	3110±480*	0.48±0.13*	19. 9±3.2*	0.06±0.01
ORX	Casein	593	5.9±1.2	1329±480†	0.84±0.13†	13.0±3.0	0.04±0.01
ORX	Casein	1186	6.0±1.2	1527±480†	0.75±0.13	20.7±3.2*	0.07±0.01*
ORX	Soy	593	5.8±1.2	1398±480†	0.83±0.13	16.7±3.2	0.05±0.01
ORX	Soy	1186	6.9±1.2	1426±480†	0.88±0.13†	16.1±3.0	0.05±0.01

Values are mean ± SE, n=7 for histomorphometric parameters, *ORX groups different from Sham controls (P<0.05); †ORX groups different from ORX controls (P<0.05).

M367

Calcium and Vitamin D in the Prevention of Hip and Other Fractures: An Update on the Women's Health Initiative CaD Trial. J. A. McGowan[1], R. D. Jackson[2], J. A. Cauley[3], A. Z. LaCroix[4]. [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, USA, [2]Ohio State University, Columbus, OH, USA, [3]University of Pittsburgh, Pittsburgh, PA, USA, [4]Fred Hutchinson Cancer Research, Seattle, WA, USA.

Several observational studies and randomized trials support a role for calcium and vitamin D in reducing bone loss and preventing fractures. The Calcium-Vitamin D (CaD) trial component of the WHI is a large, randomized controlled trial in a diverse population of healthy postmenopausal women designed to test the primary hypothesis that women who are randomized to receive calcium and vitamin D supplementation (500mg CaCO3 and 200 IU of Vitamin D, twice daily) will have a lower risk of hip fractures and secondarily, a lower risk of all fractures than women receiving the corresponding placebo. Over 36,000 postmenopausal women between the ages of 50 and 79 have been recruited at 40 clinical centers across the country and will be followed for about 7 years for ascertainment of hip and all fractures. Baseline measures include anthropometrics, lifestyle and nutritional habits, medical/medication status, fall history, personal and family fracture history, and bone density by Dual Energy X-Ray Absorptiometry (at 3 WHI clinics only). Analyses of the baseline characteristics by factors known to be associated with osteoporotic fracture indicate a relatively low risk population at the onset of the study. The mean age of the CaD trial cohort is 62.3 years with 37.5% aged 50-59, 45.2% aged 60-69, and 17.4% aged 70 and older. 17% are minorities, including 9% Black, 4% Hispanic, 2% Asian, 1% American Indian and 1% other/unspecified. There are few current smokers (7.7%) but 40 % smoked previously, and 72% use alcohol at least occasionally. The average calcium intake in the diet is 750 mg per day and 54% use some kind of calcium supplement. The majority of the trial cohort are overweight and the mean BMI is 29.1. A non-traumatic fracture has occurred in 12% of the subjects since age 55 but 40% have a parental history of fracture. The prevalence of osteoporosis based on the World Health Organization cut points was low: 4.5%, 2.7% and 0.35% of non-Hispanic white women, Hispanic, and black women respectively. However, as expected both osteoporosis and osteopenia were common in the women over seventy: 9.3% were osteoporotic and 56% were osteopenic. The WHI CaD Trial is the largest randomized clinical trial with the longest duration of exposure and follow-up (~7 years) focusing on the impact of calcium plus vitamin D supplementation on the incidence of hip and all fractures. All participants will complete intervention in March, 2005.

M368

Impact of an Educational Intervention for the Prevention and Treatment of Osteoporosis: A Health Plan's Perspective. P. Paccione*[1], R. Powell*[1], J. O'Neill*[1], T. W. Weiss*[2]. [1]HealthNow, Albany, NY, USA, [2]Merck & Co., Inc., West Point, NY, USA.

In the fall of 1999, Blue Shield of Northeastern New York initiated an ongoing health management program for their members who were found to be potentially at risk for osteoporosis and those already diagnosed with osteoporosis. The purpose of the program was to improve the diagnosis and management of members with osteoporosis. The program involved both interventions to members and their physicians. The member targeted intervention group was women aged 40+ years and men aged 65+ years. The physician targeted intervention group was the primary care physician and any physician who prescribed osteoporosis-related medications (including estrogens). Member interventions included NOF brochures with a cover letter encouraging them to schedule an appointment with their PCP to discuss getting a DEXA scan (a covered benefit), informal focus groups, the NOF newsletters, and 'Boning Up on Osteoporosis' booklet via free NOF membership. Members were also encouraged to visit a Rite Aid pharmacy for an Osteoporosis Education Day that included free heel US and pharmacist counseling. The physician interventions included practice guidelines along with NOF pocket guide, DEXA scan/QCT profile for targeted members, medication non-compliance profile, a CME credited seminar for PCPs, and BMD/medication reminder stickers. Within one year, these interventions demonstrated the ability to increase the percent of at-risk members screened, diagnosed, and compliant with osteoporosis medication (table). Conclusion: a health plan can implement a health management program to substantially improve the diagnosis and treatment compliance of its members with osteoporosis.

	Baseline (Jan-Dec '99)	Re-measurement (Jan- Dec '00)	% Change
DEXA scan/QCT usage*	51 per 1000	104 per 1000	104%
Osteoporosis Diagnosis*	47 per 1000	90 per 1000	92%
Medication Compliance**	45%	71%	58%

* Based on billing codes submitted

** Compliance was defined as filling prescriptions for osteoporosis medications at least 80% of the time

Disclosures: ***P. Paccione****, Merck & Co., Inc 2, 5.*

M369

Antiresorptive and Sex Steroid Therapies: Impact on Circulating Osteprotegerin. A. Rogers[1], P. M. Mah*[2], A. M. Braga de Castro Machado*[1], C. A. Pereda*[1], R. Eastell[1], A. Blumsohn[1]. [1]Bone Metabolism Group, University of Sheffield, Sheffield, United Kingdom, [2]Dept of Endocrinology, University of Sheffield, Sheffield, United Kingdom.

Osteoprotegerin (OPG) is a potent inhibitor of osteoclastogenesis and bone resorption *in vivo*. OPG production by osteoblasts *in vitro* is modulated by sex steroids, and by bisphosphonates. Assays for serum OPG are now available which may be useful for monitoring response to antiresorptive therapy. The aim of this study was to determine the effect of estrogen and bisphosphonate therapy on serum OPG in postmenopausal women and of testosterone therapy in men. We evaluated the change in bone turnover and serum OPG in response to: **1)** subcutaneous estradiol implant (25 mg implant replaced 6-monthly for two years) in postmenopausal women (n=10, ages 60 to 75 years). **2)** testosterone patch (6mg/day for 6 or 12 months) in men with hypogonadism (n=34, ages 40 to 77 years). **3)** alendronate (10mg/day for 6 months) in postmenopausal women with osteoporosis (n=15, ages 50 to 78 years). Serum OPG was determined using two assays, a commercial ELISA (Biomedica, Austria) and an in-house sandwich ELISA. Bone alkaline phosphatase (bone ALP), osteocalcin (OC) and urine N-telopeptides of type I collagen (UNTX) were measured using commercially available assays. Serum estradiol increased fourfold by the first month after implant and sixfold at 24 months (67± 3pmol/L at baseline to 422± 46 pmol/L at 24 months). Serum testosterone increased twofold over the course of treatment (8.2± 0.5 to 16.6± 2.1 nmol/L). There was a significant decrease in bone turnover in the estradiol and bisphosphonate treated models. However there were no significant changes in serum OPG using either OPG assay in any treatment model. (Table shows % change from baseline at the end of treatment ± SEM).

	UNTX	OC	Bone ALP	OPG
Estradiol	-47± 3**	-14± 4*	-12± 4*	-6± 4
Testosterone	-14± 5	-4± 3	-6± 3	+2± 3
Alendronate	-71± 5***	-34± 4***	-44± 5***	+1± 3

* P<0.05, ** P<0.01, *** P<0.001.

We conclude that circulating OPG is unlikely to be useful to monitor antiresorptive therapy in postmenopausal women and is also unresponsive to testosterone therapy in men. The tissue origin of serum OPG is uncertain, and measurements made in serum may be unlikely to reflect changes in OPG activity within the bone microenvironment.

M370

Prevention and Treatment of Osteoporosis by Postgraduate Resident Physicians. L. Graves[1], G. Smith*[2], B. P. Lukert[1]. [1]Internal Medicine, University of Kansas School of Medicine, Kansas City, KS, USA, [2]Internal Medicine, University of Missouri-Kansas City School of Medicine, Kansas City, MO, USA.

Previous survey studies of practicing physicians have revealed inadequate prevention, diagnosis and treatment of osteoporosis. The purpose of this study was to assess resident physicians in training for their level of understanding of osteoporosis, current practices in prevention and treatment, and their assessment of the curriculum in osteoporosis they received in medical school and residency. This survey canvassed post-graduate residents at two mid-western universities. Residents in the fields of internal medicine (IM), obstetrics and gynecology (Ob-Gyn), family medicine (FM) and orthopedics (OR) received a one page, two sided survey by mail, followed by one reminder phone call at 8-10 weeks. This survey took place between 1999-2000. Responses were received from 151 out of 404 residents surveyed (37%). 25-37% of IM, FM, and Ob-Gyn residents did not know their institution had the capability to perform bone densitometry (BMD). Less than 40% utilized BMD for diagnosing osteoporosis. Most residents estimated 10-30 outpatient encounters per week and estimated 40-60% being postmenopausal women, however, less than 50% reported ordering a bone density in the previous 3 months. The remaining residents reported ordering less than 5 BMD studies in the previous 3 months. In a series of case scenarios, hormone replacement therapy was selected most commonly for prevention and treatment of osteoporosis. In severe osteoporosis bisphosphonate therapy was chosen in less than 40% of responses. Calcitonin and raloxifene were chosen for prevention or treatment in less than 10% of responses. The majority of responders rated training in osteoporosis in medical school and residency as minimal. Greater than 60% of responders desired more training in indications, and interpretation of BMD and in the treatment of osteoporosis. Residents rated pharmaceutical programs and journals outside of their respective field as least important sources of information. Didactic conferences and journals within their specialty field were rated as important information sources. The majority of residents rated observation of faculty practice as the single most important information source. Current understanding and practice in prevention and treatment of osteoporosis is inadequate in this group of postgraduate residents. This important health problem should be adequately reflected in medical school and residency curriculum.

Disclosures: ***L. Graves****, Merck 2; Merck 8.*

Effect of Inliximab on Markers of Bone Metabolism in Patients with Rheumatoid Arthritis. M. Vis*[1], G. J. Wolbink*[2], R. M. van Soesbergen*[2], M. C. Lodder*[1], R. J. v.d. Stadt*[3], B. A. C. Dijkmans[1], W. F. Lems[1]. [1]Rheumatology, Vrije Universiteit medical center, Amsterdam, Netherlands, [2]Rheumatology, Slotervaart Hospital, Amsterdam, Netherlands, [3]Jan van Breemen institute, Amsterdam, Netherlands.

We studied the effect of infliximab (Remicade) on markers of bone metabolism in patients with rheumatoid arthritis (RA).All consecutive patients with active RA, who were treated with infliximab were included. Infliximab is a specific inhibitor of tumor necrosis factor (TNF), that significantly reduces disease activity in RA. Infliximab (3mg/kg) was administered intravenously at 0, 2 and 6 weeks. At all visits disease activity was measured by swollen-, tender joint counts, ESR and visual analogue scale for disease activity. From these 4 variables the disease activity score (DAS-28) was calculated. Blood samples were collected prior to each infusion and stored at -70°C. Serum markers of bone formation, (osteocalcin and aminoterminal propeptide of type I collagen (PINP)) and bone resorption (ß-isomerized c-terminal cross-linked telopeptide of type I collagen (ß-CTx) and crosslinked carboxyterminal telopetide of type I collagen (I-CTP)) were determined to evaluate bone metabolism. Bone markers at the 3 time points were compared by means of a paired t-test and by Wilcoxon signed rank test where appropriate. A total of 68 patients were enrolled. 79 % of the patients were female, mean (SD) age 55 years (13), median (range) disease duration of RA 10 years (0-59). At baseline all patients had active disease with a DAS-28 ≥ 3.2. Mean (SD) DAS-28 at baseline was 5.9 (1.4) and decreased significantly to 4.7 (1.4) after 2 weeks and to 4.1 (1.5) after 6 weeks. Both osteocalcin and PINP showed a significant increase when compared to baseline. Both markers of bone resorption seemed to decrease but only I-CTP was decreased significantly at 6 weeks when compared to baseline. (table)However in the subgroup of responders (DAS-28 decrease ≥ 1.2) both ß-CTx and I-CTP were significantly decreased after 6 weeks when compared to baseline. (p <0.05) The study suggests that infliximab has a favourable effect on bone metabolism, since in the early phase of treatment bone formation increases while bone resorption seems to decrease. Whether long-term treatment with infliximab has a positive effect on bone metabolism and subsequently on bone mineral density needs to be further investigated.

	T = 0 weeks	**T = 2 weeks**	**T = 6 weeks**

A Two-Year Randomized Controlled Trial of Hormone Replacement Therapy, Etidronate, Calcitonin, Vitamin D, or Vitamin K, in Women with Postmenopausal Osteoporosis. Y. Ishida, S. Kawai*. Department of Orthopaedic Surgery, Yamaguchi University School of Medicine, Yamaguchi, Japan.

Although a number of medications are now available for the treatment of osteoporosis, there are few comparative treatment studies. This study was conducted to assess the effectiveness of various pharmacologic therapies on bone mineral density (BMD), biochemical bone markers and new fracture incidence in postmenopausal women and to identify predictors of changes in BMD after 2 years of treatment. Three hundred thirty-seven postmenopausal women, aged 45 to 75 years, attending metabolic bone disease outpatient clinics with established osteoporosis were randomly allocated into one of six treatment groups: control (no treatment); hormone replacement therapy (HRT); etidronate; calcitonin (CT); vitamin D3; and vitamin K2. BMD of distal 1/3 radius was measured every 3 months by dual energy X-ray absorptiometry, along with biochemical markers of bone turnover [serum bone specific alkaline phosphatase (BAP), serum osteocalcin (OC), urinary N-telopeptide of type I collagen (NTx) and urinary deoxypyridinoline (D-pyr)]. The occurrence of new vertebral fractures were determined by radiographs taken every 3 months. Over 2 years, the new vertebral fracture incidence in HRT, etidronate, CT, vitamin D3 and vitamin K2 groups was reduced by 70%, 47%, 62%, 34% and 35% relative to control, respectively. The control group showed a significant decrease in BMD from baseline after 2 years of treatment (-3.3%, p<0.001) while the HRT group showed a significant increase (+2.2%, p<0.001). Other treatments, etidronate, CT, vitamin D3 and vitamin K2 produced -1.4%, +1.9%, -3.6% and -1.9% changes in BMD from baseline, respectively. Logistic regression analysis revealed that changes in BMD at 3 months predicted changes in BMD after 2 years of treatment (odds ratio, 2.4; p=0.01). The associations between biochemical markers and BMD were too weak to allow for a valid individual estimation of future BMD changes based on the changes in biochemical markers. In contrast, the biochemical markers (NTx and D-pyr) were shown as valid tools for monitoring and prediction of treatment effect of antiresorptive medications (HRT, CT and etidronate). As a whole, groups of patients who gained more BMD experienced greater fracture protection, although the relationship was not clear on the individual level. In conclusion, antiresorptive medications (HRT, CT and etidronate) reduce bone turnover, increase BMD and produce a significant reduction in the incidence of vertebral fractures in postmenopausal osteoporosis, in which HRT is most potent. The data suggest that vitamin D3 and vitamin K2 can reduce the fracture incidence without significant rise of BMD.

M373

Characteristics of Non-responders to 5-years of Hormone Replacement Therapy. The Danish Osteoporosis Prevention Study (DOPS). L. Rejnmark[1], P. Vestergaard[1], C. L. Tofteng*[2], N. Kolthoff*[3], L. S. Stilgren[4], K. Brixen[4], L. Mosekilde[1]. [1]Dept. of Endocrinology and Metabolism, Aarhus Amtssygehus, Aarhus, Denmark, [2]The Osteoporosis Research Centre, Hvidovre Hospital, Hvidovre, Denmark, [3]Dept. of Clinical Physiology and Nuclear Medicine, Hilleroed Hospital, Hilleroed, Denmark, [4]Dept. of Endocrinology, Odense University Hospital, Odense, Denmark.

A nested case control study was performed to characterize perimenopausal women not responding to hormone replacement therapy (HRT) with an increase in bone mineral density (BMD). In the Danish Osteoporosis Prevention Study (DOPS), 2016 women three months to two years after menopause were allocated to a HRT- (n=723) or to a control-group (n=1293). After 5-years, 543 women had been treated continuously with HRT. Among these, paired DEXA-scans had been performed at baseline and after five years in 466 women receiving HRT. We defined densitometric non-responders as women on HRT, who had a decrease in BMD over 5-years similar to or grater than the mean bone loss in the control group. Baseline characteristics were used as exposures. In the control group, femoral-neck and lumbar spine BMD decreased by 6.3±0.2% (mean±SD) and 6.4±0.2%, respectively. In the HRT group, 10.7% and 6.0% were classified as non-responders according to their changes in femoral-neck and lumbar spine BMD, respectively. 2.6% were classified as non-responders at both measurement sites. Baseline measures of body weight, age, BMD, daily calcium- and vitamin D intake, smoking status, and biochemistry (urinary hydroxyproline, bone-specific alkaline phosphatase, 25-hydroxyvitamin D) did not differ between responders and non-responders to HRT at the femoral-neck, lumbar spine, or at both sites. Thus, only a small proportion of perimenopausal women who begin HRT do not benefit from the treatment as assessed by DEXA. However, non-responders are difficult (impossible?) to identify at the time of initiation of treatment.

M374

Osteoporosis Fracture Tracking Study: Medical Care Is Often Delayed for Patients of Orthopaedic Surgeons. J. G. Skedros. Utah Bone and Joint Center; Dept of Orthop Surg, U of UT, Salt Lake City, UT, USA.

Patients with osteoporotic fractures typically do not receive subsequent medical treatment for osteoporosis. We hypothesized that even if patients with osteoporotic fractures were specifically referred to their primary care providers (PCPs), the majority would not be treated within 84 days (12 weeks) of fracture. We evaluated the effectiveness of 14 surgeons in facilitating a timely PCP visit for their patients. Participating orthopaedic surgeons received remuneration for each patient completing the study. Patients who qualified were >50 years old, had an apparent osteoporotic (low-energy) fracture, and had no prior treatment for osteoporosis. Two letters requesting a PCP appointment were sent: the first letter within 10 days of fracture, and the second letter 3-10 weeks after fracture. Patients were also: 1) informed that they may have osteoporosis and may be at risk for subsequent fracture, and 2) instructed to make a PCP appointment for possible further work-up and treatment. Results showed that of 55 patients (48 females, 7 males: avg. age 70.8, range 51-90), 23 (42%) were not seen by a PCP within 84 days. 32 (58%) patients saw a PCP within 84 days, but osteoporosis was not addressed in 4 patients (avg. days to PCP, 38: range 7-71days). Of patients seen within 84 days, pharmacologic treatment (e.g., estrogen, bisphosphonate, etc.) was started in 19 (59 %), but typically not within 37 days of fracture. Of the 14 participating orthopaedic surgeons, five were non-compliant and six were inconsistent in their participation, forgetting to send the letters and to inform their patients to make a PCP appointment. These results indicate that standing discharge hospital orders (for medications, PCP follow up, bone density scanning, etc.) may be more effective in achieving timely medical treatment for patients with osteoporotic fractures.

Subsidizing Medications Does Not Ensure the Use of Potent Osteoporosis Drugs Following Low-Impact Fractures. Y. Liel*[1], H. Castel*[2], D. Y. Bonneh*[3]. [1]Endocrinology, Soroka Medical Center, Beer Sheva, Israel, [2]Medicine, Soroka Medical Center, Beer Sheva, Israel, [3]Southern District, Clalit Health Services, Beer Sheva, Israel.

Recently, potent anti-resorptive drugs (a bisphosphonate, and a SERM) were introduced into the National Health Basket in Israel for treatment of all osteoporotic women and for men with glucocorticoid-related osteoporosis. We carried out the present study to evaluate the effect of subsidizing osteoporosis drugs on the use of osteoporosis drugs in patients following low-impact fractures. Hospital charts of women and men age 50 and older with new fractures due to low or moderate impact treated in the emergency room (mostly peripheral bone fractures), orthopedic surgery and rehabilitation departments (mostly proximal-hip fractures), were reviewed. Notation of osteoporosis as contributing cause for the fracture, and treatment recommendations were abstracted from the records. In addition, we took advantage of the centralized pharmacy database of the largest health maintenance organization (HMO) in the area to follow dispensation of osteoporosis drugs in the community following fracture incidents. The cumulative data from the period of January and February of 2000 and 2001 ("post-basket") was compared with the cumulative data from January and February of 1998 and 1999 ("pre-basket"). Our results revealed a significant, approximately 2-fold increase in the baseline rate of dispensation of osteoporosis drugs between the pre- and post-basket periods. The rate of patients treated after a fracture incident also increased significantly 1.6 fold in the post-basket period. However, even in the post-basket period two-thirds of the patients remained untreated following a fracture incident and most of those treated received only calcium and vitamin D. Only about 15% received any of the potent osteoporosis drugs. Men were considerably less likely to be treated than women. In a univariate analysis, younger age, female gender, being treated in the emergency room, incident of fracture in the post-basket period and being treated for osteoporosis before the fracture incident, were significantly correlated with treatment following the fracture. In a multivariate model, age lost its effect and treatment before the fracture incident emerged as the far most influential variable. Subsidizing has a significant positive effect on osteoporosis drugs utilization. However, other factors are important. There is an ongoing need to increase awareness and encourage the use of potent pharmacological means for primary and secondary prevention of osteoporotic fractures.

Phytoestrogen-Rich Herbal Formula For Prevention Of OVX Induced Bone Loss In Rats. L. Qin*[1], G. Zhang*[2], W. Y. Hung*[3], M. A. Dambacher[4], P. C. Leung*[5]. [1]Orthopaedics & Traumatology, Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China, [2]Suguang Hospital, Shanghai University of Chinese Medicine, Shanghai, China, [3]Dept. of Orthopaedics and Traumatology, The Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China, [4]University Clinic of Balgrist, Zurich, Switzerland, [5]Institute of Chinese Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China.

The purpose of this animal experimental study was to investigate a phytoestrogen-rich herbal formula (genistein and daidzein at 250mAU) and calcium supplementation for prevention of OVX induced bone loss. In this study, tis phytoestrogen-rich herbal formula Xianlingubao (XLGB) with Epimedium Leptorhizum as the main component was developed and studied in 45 eleven-months old female Wistar rats, that were randomly grouped according to their body weight. These included one sham-operated (Sham) and four OVX subgroups, i.e. OVX along, OVX with XLGB, OVX with calcium, and OVX with HLGB and calcium (Table 1). Daily oral administration of XLGB (250 mg/kg) and/or element calcium (25 mg/kg) started immediately after OVX for 12 weeks before scarifying the animals. Left femur was prepared for BMD measurements at both proximal femur and femoral diaphysis using DXA. (XR36) for data comparison. BMD measurement results showed that osteoporosis was established in trabecular bone rich proximal femur but not in cortical bone dominant disphysis in the OVX rats as compared with Sham group. XLGB, calcium, and XLGB with calcium intervention all showed preventive effects against OVX induced bone loss in proximal femur. The mean BMD of proximal femur in OVX rats treated with both XLGB and calcium administration was higher than that of treated with XLGB along or with calcium along, however, without statistical significance (Table 1: *: $p<0.05$; **: $p<0.01$, as compared with OVX group). In conclusion, the phytoestrogen rich herbal formula HLGB was effective for prevention of OVX induced bone loss in the high turnover trabecular bone rich proximal femur. The additional calcium supplementation did not reveal additive effects in prevention of bone loss or in increase of BMD.

Table 1: Phytoestrogen-rich herbal formula and/or dietary calcium in prevention of OVX induced bone

Groups (n=9, each)	BMD measured by DXA (mg/cm2)	
	Proximal femur	Femoral diaphysis
Sham	191±10**	179±6
OVX	166±7	177±6
OVX+XLGB	184±11**	177±8

PremPro vs. FemHRT in Cynomolgus Monkeys. C. J. Lees. Pathology, Wake Forest University School of Medicine, Winston-Salen, NC, USA.

Women use FemHRT® (ethinyl estradiol and norethindrone) and PremPro® (conjugated equine estrogens and medroxyprogesterone) for the prevention of postmenopausal osteoporosis. The effects of these two treatment modalities on bone were examined in ovariectomized cynomolgus monkeys (*Macaca fasicularis*). Sixty female cynomolgus monkeys were imported from Indonesia, ovariectomized and randomized into 3 groups: 1) placebo (OVX), 2) FemHRT® (human equivalent of 1 mg norethindrone and 5 micrograms ethinyl estradiol) and 3) PremPro® (human equivalent of 2.5 mg medroxyprogesterone and 0.625 mg conjugated equine estrogens). Treatment lasted 1 year. Serum alkaline phosphatase (ALP) levels and fibular bone mineral density and cortical thickness (determined by pQCT) were measured at 12 months. Both PremPro® and FemHRT® groups had significantly lower ALP levels compared to OVX (OVX - 181 ± 9, FemHRT® - 117 ± 9, PremPro® - 97 ± 10, $p < 0.0001$). PremPro® treated monkeys had greater fibular cortical density (CRTDEN 1080 ± 12) and cortical thickness (CRTTHKC 1.54 ± 0.03) compared to OVX CRTDEN 1029 ± 12 ($p < 0.02$) and OVX CRTTHKC 1.44 ± 0.02 ($p < 0.02$). FemHRT® treated animals did not differ from either OVX or PremPro® treated animals in CRTDEN (1060 ± 12) or CRTTHKC (1.49 ± 0.02). PremPro® had a positive effect on bone mass in monkeys. Although, FemHRT® treatment suppressed ALP levels, FemHRT® did not induce significant changes in bone mass.

Effect of Time on Estrogen (E) Therapy and of E Therapy Begun at Menopause Vs. Delayed Onset of E Therapy on the Prevalence of Low Bone Mineral Density (BMD). G. Ding*, J. Javier*, D. J. Baylink, K. Jolley*, C. Libanati. J.L. Pettis VAMC, Loma Linda, CA, USA.

We report on the prevalence of low BMD at the spine & hip in a population of 355 postmenopausal females (F) (mean age= 67.9 ± 5.7 y/o, range 60-80) currently receiving HRT. To determine if the effect of HRT was similar in younger & older F, we divided the group into those F younger than 71 years (groups A and B, n=242), and those older than 70 years (groups C and D, n=113). Additionally, to examine the effect of onset time of HRT in relation to menopause, younger and older groups were evaluated based on continuous HRT use since menopause (groups A and C,) vs. delayed HRT use (groups B and D, HRT started >5 years post menopause).

Table 1: BMD and T-Scores at the spine, femoral neck (FN) & total hip (T Hip) for each group (G).

			BMD (in mg/cm2)			Mean T-Score		
G	**n**	**Age**	**Spine**	**FN**	**T Hip**	**Spine**	**FN**	**T Hip**
A	160	64.2±3.2	1016	743	891	1.02±0.2	-0.96±1	-0.43±1
B	82	65.2±3.1	896*	666*	820*	-1.4±1.4*	-1.65±0.8*	-1.0±0.9*
C	61	74.8±2.6	1005	719	879	-0.38±1.6	-1.4±2	-0.8±2.3
D	52	75.1±2.8	921*	646*	775* †	-1.19±0.2*	-1.65±1.3*	-1.4±1* †

* = p<0.001 compared to continuous users, † = p<0.05 compared to younger group.

Table 2: Percent prevalence of normal (N) & low BMD [osteopenia (P) & OP] at each skeletal site.

	Spine %			Femoral Neck %			Total Hip %		
Group	**N**	**P**	**OP**	**N**	**P**	**OP**	**N**	**P**	**OP**
A	69	26	5	47	48	5	69	29	2
B	37*	40*	23*	17*	62*	21*	52*	46*	2
C	62	28	10	34	56	10	65	33	2
D	42*	37*	21*	23*	54	23*	33*	61*	6*

* = p<0.001 compared to age matched group receiving continuous estrogen replacement.

In summary: a) younger & older postmenopausal F receiving HRT had similar BMD suggesting that age dependent bone loss is effectively attenuated by E and, b) continuous HRT since menopause (versus delayed onset) conferred maximum benefit against low BMD at all skeletal sites. Only 10% of F older than 70 who had received continuous HRT since menopause had OP. In conclusion: E therapy is effective in preventing bone loss up to 80 yrs of age but it must be continuous.

M379

Prevention of Ovariectomy-Induced Changes in the Sprague-Dawley Rat by the Selective Estrogen Receptor Modulator HMR 3339. S. Y. Smith[1], J. Jolette*[1], A. M. Leyshon*[1], C. H. Turner[2], M. Gaillard-Kelly[3], J. M. Vidal*[3], R. Baron[4]. [1]CTBR, Montreal, PQ, Canada, [2]Indiana University, Indianapolis, IN, USA, [3]Aventis Pharma, Romainville, France, [4]Proskelia, Romainville, France.

The purpose of this study was to determine the effects of 12 months of treatment with HMR 3339 on bone mass, strength and architecture in the ovariectomized (OVX) Sprague-Dawley rat. Twenty, 6-month old virgin females were randomly assigned to each of five groups: Sham Control, OVX Control, 3 OVX groups treated with HMR 3339 at 0.01, 0.1 or 0.5 mg/kg/day. Vehicle or test article was given daily by oral gavage. Blood and urine were evaluated for markers of bone turnover (osteocalcin (OC), free deoxypyridinoline, (DPD)). BMD by DXA was determined *in vivo* for the lumbar spine, femur and whole body. Histomorphometry was done for 10 animals per group at the tibia and lumbar vertebra (L3). Biomechanical strength testing was performed for the femur in 3-point bending, femoral neck shear and lumbar vertebra (L4) in compression for 10 animals per group. HMR 3339 dose-dependently prevented the OVX-induced rise in OC and DPD and decreases in BMD. BMD at the lumbar spine and femur was essentially maintained at pre-OVX levels at the mid and high doses with a partial preservation at the low dose. HMR 3339 preserved cancellous bone architecture (BV/TV) at the proximal tibia and L3 for the mid and high doses with a partial effect at the low dose. Reduction of bone turnover as measured by mineralized surface accounted for the preservation of bone architecture at these sites. HMR 3339 dose-dependently prevented the OVX induced expansion of the medullary area and total tissue area in the tibial diaphysis by decreasing bone turnover as measured by the labeled surface on the periosteal and endocortical envelopes. Peak load for all HMR 3339-treated groups was slightly greater than, or similar to Sham controls for the femur 3-point bending test and for the mid and high dose groups for L4 in compression. For treated groups, peak load was not significantly different from Sham controls at the femoral neck. In conclusion, treatment of aged OVX Sprague-Dawley rats with the SERM HMR 3339 at 0.01, 0.1 or 0.5 mg/kg/day for 12 months resulted in a treatment-related preservation of bone mass, strength and architecture at clinically relevant axial and appendicular skeletal sites.

M380

Equivalence of the Skeletal, but not the Reproductive, Actions of Estrogens and Androgens in Female and Male Mice. S. Kousteni, J. R. Chen, L. Han, A. M. Vertino, A. A. Ali, T. Bellido, R. S. Weinstein, C. A. O'Brien, R. L. Jilka, S. C. Manolagas. Division of Endocrinology and Metabolism, Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, U/sity of Arkansas for Medical Sciences, Little Rock, AR, USA.

In contrast to reproductive tissues, the sex specificity of the skeletal effects of estrogens and androgens is seemingly relaxed. To document this phenomenon and elucidate its cellular basis in an amenable experimental model, mature Swiss Webster mice (8 month old), n=8-10 per group, were sham-operated or gonadectomized (GNDX). The GNDX animals were then left untreated or were treated with slow release pellets containing 17β-estradiol (E_2) or dihydrotestosterone (DHT), at doses corresponding to physiologic replacement, as determined by restoration of uterine weight in the females and seminal vesicle weight in the males, respectively. Six weeks later, we determined BMD in live animals, osteoblastogenesis and osteoclastogenesis in ex vivo bone marrow cultures, osteoblast apoptosis in histologic sections of the vertebrae, serum osteocalcin, and wet uterine or seminal vesicle weight. Ovariectomy (OVX) or orchidectomy (ORX) caused upregulation of osteoclastogenesis, osteoblastogenesis and osteoblast apoptosis as well as the loss of BMD. All these changes were effectively prevented by either E_2 or DHT replacement, irrespective of the sex of the mouse. Further, E_2 or DHT prevented the increase of serum osteocalcin in females. DHT prevented the ORX-induced increase in serum osteocalcin, but E_2 was ineffective in this respect. In contrast to the equivalence of the skeletal actions of E_2 and DHT, E_2 administration to ORX males failed to restore seminal vesicle weight; however, DHT administration to OVX females did restore wet uterine weight, probably because of the 300-fold higher dose of DHT as compared to E_2; a uterotrophic effect of high DHT doses has been demonstrated previously by others in the rat. These findings establish that unlike their actions in reproductive tissues, skeletal actions of estrogens and androgens in adult female and male mice are equivalent and result from the same cellular changes. As shown elsewhere in this meeting, such equivalence results, at least in part, from interchangeable ligand/receptor interactions in bone cells from either sex. Elucidation of the differences in the sex specificity of the actions of sex steroids in non-reproductive tissues, like bone, versus reproductive ones, suggest novel means of preserving the beneficial effects of sex steroids on non-reproductive tissues during post-reproductive life, while minimizing or eliminating effects that are no longer needed (and are often harmful) on reproductive tissues.

M381

Effect of Menatetrenone Administration on Bone Mineral Density during Gn-RH Agonist Treatment for Endometriosis. K. Aisaka[1], S. Obata*[1], M. Kaibara*[2], H. Mori*[2]. [1]Obstetrics & Gynecology, Hamada Hospital, Tokyo, Japan, [2]Obstetrics & Gynecology, Teikyo University, Tokyo, Japan.

Objective: Gn-RH agonist therapy is widely used for treatment of endometriosis. However, it is well known that there are some side effects due to too much suppress of plasma estrogen levels. To prevent these problems, so-called the add back therapy using estrogen progestogen (EP) preparations is attempted and many reports show that the add back therapy is useful for prevention hypo-estrogenic symptoms. It is reported that estrogen suppresses osteolysis, while menatetrenone (vitamin K2) promotes osteogenesis. Present study was performed to elucidate whether menatetrenone administration with add back therapy could prevent bone loss more effectively during Gn-RH agonist treatment. Subjects and Methods: Twenty-six patients of endometriosis who were undertaken Gn-RH agonist treatment (Luprorelin, 1.88mg/month) were subjected. They were divided into two groups; add back therapy with EP preparations (Sophia-A, mestranol 0.05mg + norethisterone 1mg/day) only, 14 cases, group A, and EP add back with menatetrenone (Gra-K, 45mg/day), 12 cases, group B. Then, bone mineral density (BMD) of the lumber spine was examined before and 6, 12 months after the treatment. The biomarkers of the bone metabolism (urinary deoxy-pyridinoline (d-Pyr) and plasma intact osteocalcin (OC) levels) were also measured in the same time to evaluate the effects of these medications. The same examinations were also done in 6 cases of endometriosis who did not take the add back therapy during Gn-RH agonist treatment for the control (group C, treated for 6 months only). Results: There was a significant increase in BMD values of the group A and B during the treatment compared to those in the group C (A: 0.93+/-0.35, B: 7.34+/-1.26, C: -3.77+/-0.72 % increase from basal value, p<0.01). Urinary d-Pyr levels in the group C tended to increase during Gn-RH agonist treatment (before: 4.2+/-1.9, 6 months after: 5.5+/-2.7m mol/mol.cre), however, there were no changes in the group A and B. Plasma OC levels increased significantly in the group B (8.8+/-2.8) and C (8.2+/-2.5) compared those in the group A (7.3+/-2.4ng/dl, p<0.02). Conclusion: From these results, it was concluded that there was a beneficial effect for the BMD values during Gn-RH agonist treatment by the combination add back method of menatetrenone and EP preparations. And it was suggested that menatetrenone increased the BMD values through its osteogenic mechanism.

M382

The Decrease in Bone Mineral Mass and in Bone Strength induced by Ovariectomy in Adult Rats is corrected by the New Selective Estrogen Receptor Modulator HMR 3339. P. Ammann[1], F. Brunner[2], M. Gaillard*[2], J. M. Meyer*[3], R. Rizzoli[1]. [1]Department of Internal Medicin, Division of Bone Diseases, Geneva-14, Switzerland, [2]Aventis, Romainville, France, [3]Scholl of Dentistry, Geneva-14, Switzerland.

The selective estrogen receptor modulator (SERM) raloxifene (RAL) has been shown to prevent vertebral fracture. However, there is a need for SERMs with optimal profile, which could restore mechanical competence and reduce the risk of fractures at multiple sites. We investigated the effects of a new steroidal SERM, HMR 3339, on bone mineral density (BMD; mg/cm2) and bone strength (U St; N) at the level of the proximal tibia (PT), lumbar spine (LS) and femur in ovariectomized (OVX) osteoporotic rats, and compared these effects to those of RAL. Eight weeks after OVX, 8-month old rats were allocated to 5 groups (n=8) and given orally HMR at 0.03/0.1/0.3, or RAL at 3.0 mg/kg BW x day or the vehicle for 16 weeks. Changes from baseline are expressed as means±SEM; * indicates p<0.05 vs OVX and º vs baseline by ANOVA.

	PT BMD	PT U St	LS BMD	LS U St

OVX	1.3±1.3	134.7±12.0	-6.8±2.3	162.3±14.1
OVX HMR 0.03	3.0±1.2	194.7±17.4º*	1.0±1.7*	214.8±13.6º*
OVXHMR 0.1	6.8±1.7*	211.9±14.0º*	3.9±2.1*	221.5±14.7º*
OVXHMR 0.3	3.5±1.3*	189.5±11.5º*	4.7±1.4*	221.1±12.3º*
OVX RAL 3.0	4.0±0.6*	178.2±9.4º*	1.7±2.6*	195.4±13.9

In OVX rats, HMR increased BMD and ultimate strength at the level of lumbar spine and proximal tibia. Similar results were obtained at the level of the midshaft tibia and of femoral neck. Serum IGF-I measured at the end of the study was 495±31, 556±26, 672±21*, 732±31*, 765±54* and 610±41 in SHAM, OVX, HMR 0.03/0.1/0.3 and RAL. HMR increased IGF-I plasma levels above those of OVX, an effect not observed with RAL. This might account for the differences in response to HMR and RAL. In conclusion, HMR 3339 increased not only bone mineral mass, but also restored bone mechanical strength at multiple sites in aged osteoporotic rats, acting in a curative way.

M383

The New Selective Estrogen Receptor Modulator HMR 3339 Prevents Ovariectomy-Induced Bone Loss and Alteration of Bone Strength in Adult Rats. P. Ammann[1], S. Bourrin*[1], F. Brunner[2], M. Gaillard*[2], J. M. Meyer*[3], R. Rizzoli[1]. [1]Department of Internal Medicin, Division of Bone Diseases, Geneva-14, Switzerland, [2]Aventis, Romainville, France, [3]School of Dentistry, Genenva-14, Switzerland.

Prevention of bone loss after menopause with estrogen replacement therapy is not accepted by all women due to the fear of cancer. Thus, there is a need for alternative therapy like selective estrogen receptor modulators (SERMs) which could prevent bone loss and decrease bone fragility, while preventing breast cancer and lacking side effects on genital tract. We investigated the effects of a new steroidal SERM, HMR 3339, on bone mineral density (BMD; mg/cm2) and bone strength (US; N) as evaluated at the level of the tibia, and spine in ovariectomized (OVX) rats and compared its effects to those of raloxifen (RAL). Bone histomorphometry was investigated at the level of the proximal tibia. At the end of the study serum IGF-I was measured. Immediately after OVX, 6-month old rats were given orally HMR at 0.03/0.1/0.3, or RAL at 3.0 mg/kg BW x day for 16 weeks. The SHAM and OVX controls received the vehicle. Values are means±SEM and were all obtained at the level of the proximal tibia ;* indicates p<0.05 vs OVX and º vs RAL by ANOVA.

	BMD	US	BV/TV	Tb.N
SHAM	319.6±3.0	179.39±19.7	17.2±2.5	4.45±0.45
OVX	293.2±2.6	146.6±9.2	5.6±1.1	1.58±0.26
OVX HMR 0.03	312.1±3.3*	175.7±10.2	14.0±1.8*	3.56±0.33*
OVXHMR 0.1	315.6±1.9*	199.1±14.9*º	15.3±1.3*	3.91±0.26*
OVXHMR 0.3	322.9±3.7*	181.1±10.7*	16.0±2.3*	3.97±0.44*
OVX RAL 3.0	312.1±3.3*	161.7±4.25	13.2±0.8*	3.57±0.18*

Serum IGF-I measured at study completion was 506±24, 691±35, 694±35*, 778±38*, 725±37*º and 688±34 in SHAM, OVX, HMR 0.03/0.1/0.3 and RAL. Uterus weight was 462±23*, 93±16, 140±15, 115±14, 142±20 and 119±23 mg, respectively in the same groups. HMR prevents the decrease of BMD and maintains ultimate strength. Similar results were obtained at the level of the midshaft tibia, spine and femoral neck. Decrease of trabecular bone volume (BV/TV, %) and of trabeculae number (Tb.n, 1/mm) was also prevented. Combining all parameters, the optimal effect was obtained at a dose of 0.1mg/kg. HMR increased IGF-I plasma levels above those of OVX, an effect not observed with RAL. Uterus weight were not different from OVX control in HMR treated rats. In conclusion, HMR 3339 prevents OVX-induced bone loss and alteration of mechanical properties at multiple sites without significant increment of uterus weight in aged rats.

M384

Estrogen in the Establishment of Peak Bone Mass. J. E. Mulder[1], C. A. Sklar*[2], A. Klibanski[3], J. P. Bilezikian[1]. [1]Columbia University, New York, NY, USA, [2]Memorial Sloan-Kettering Cancer Center, New York, NY, USA, [3]Massachusetts General Hospital, Boston, MA, USA.

Advances in combination chemotherapy, radiation therapy, surgery, and bone marrow transplantation have resulted in markedly improved survival rates for many patients with cancer. These advancements in therapy, however, have led to new problems, namely, long-term consequences of effective treatments. Not infrequently, for example, men and women treated for cancer suffer the premature loss of gonadal function. Premature ovarian failure (POF) places women at great risk for bone loss and osteoporosis. The issues raised in this study, however, differ from usual considerations of age-related menopausal ovarian failure and the accelerated bone loss that ensues. This more typical clinical event follows well after the establishment of peak bone mass. The young women to be investigated in this study have become estrogen deficient before achieving peak bone mass. We will determine the importance of estrogen in achieving optimal peak bone mass in this setting. Other potential contributing factors, such as androgen deficiency, growth hormone deficiency, chemotherapeutic agents, nutritional, and other metabolic parameters will be evaluated. 26 female survivors of childhood cancer with POF and 10 female cancer survivors (age- and weight-matched) with normal ovarian function will be recruited from 2 centers. The main goals of the study are to characterize the skeletal profile of these young women, and then to determine the dosage of estrogen required to establish peak bone mass optimally in the subset of women with POF. The young women must be between 16-25 years of age. After the initial characterization, the young women with POF will be randomized to one of two treatment groups and followed for 2 years. Regimen I consists of "standard" replacement with estradiol 0.5 mg daily, plus micronized progesterone (MP) 200mg daily for 14 days. Regimen II (higher dose) consists of estradiol 2.0 mg daily, plus MP 200 mg daily for 14 days. Primary outcomes include individual percent change in BMD at the lumbar spine and hip by DXA. Other endpoint measurements include changes in BMD at peripheral sites (1/3 radial, phalangeal sites, as measured by peripheral DXA, and calcaneal site as measured by ultrasound) and changes in markers of bone remodeling. As of April 1st, 297 potential subjects have been identified from searching 2 different databases. It is expected that enrollment will proceed, and we will reach our recruitment goals over the next year.

M385

Evidence That Estrogen Receptor AF-1 Activity Prevents Bone Loss: Results From Selective Estrogen Receptor Modulator (SERM) Therapy In OVX Mice. D. von Stechow[1], N. Quibria*[2], S. Fish*[2], J. M. Alexander[2]. [1]Orthopedic Biomechanics Laboratory, BIDMC/Harvard Medical School, Boston, MA, USA, [2]Bone and Mineral Metabolism Unit, BIDMC/Harvard Medical School, Boston, MA, USA.

The aim of this *in vivo* mouse study was to compare estrogen (E2) replacement therapy with the effects of two SERMs, tamoxifen (Tam) and ICI 178,180, on bone in an ovariectomized (OVX) mouse model of osteoporosis. Previous *in vitro* data have determined that tamoxifen acts as a partial E2 antagonist by selectively inhibiting the AF-2 ligand binding domain of ER, while ICI is a pure anti-estrogen that inhibits both the AF-1 amino-terminal activation function and AF-2 domains of the ER. In this study, three-month-old Swiss-Webster mice underwent 5 weeks of treatment with either E2, Tam, or ICI (500 mcg weekly, *sc* injection) or vehicle. Animals were sacrificed after five weeks (Sham and OVX-vehicle controls, along with 3 treated groups). Femoral bones were analyzed by micro-computed tomography. Morphometric indices, such as bone volume density (%BV/TV), trabecular number (Tb.N), and trabecular thickness (Tb.Th) were quantitatively assessed at the distal metaphysis. In addition, marrow volume (%MV/TV) and cortical thickness (Ct.Th) were measured at the femoral diaphysis using direct 3D morphometry. OVX vehicle-treated control mice showed an 83% loss of metaphyseal trabecular bone compared to sham animals. This loss was associated with marked decreases in Tb.N and Tb.Th. E2-treated mice exhibited a significant increase in trabecular %BV/TV over vehicle-treated mice, largely through increased Tb.Th. While Tam treatment was protective for bone loss, ICI treatment had no protective effect, with ICI-treated mice showing bone loss comparable to OVX-vehicle treated mice. At the diaphysis, %MV/TV decreased significantly after E2 and Tam treatment, indicating cortical endosteal bone formation in both groups. E2 treatment caused a 13.5% increase in Ct.Th, but there were no significant differences observed in Ct.Th in Tam-treated versus Sham operated mice. ICI-treated mice were not significantly different from OXV-vehicle mice in any of the parameters measured in this study. We conclude that E2 treatment resulted in significant bone formation, while Tam, similar to its effect in other E2-sensitive tissues, has partial estrogenic activity in bone and is protective against OVX-induced bone loss. Conversely, ICI, a pure anti-estrogen, does not prevent OVX-induced bone loss. Therefore, our findings in OVX mice suggest that the protective effect of E2 and Tam in bone is mediated in part via the AF-1 domain of the estrogen receptor.

Influence of BMI on Changes in Bone Density After Treatment With Multiple Doses of Conjugated Equine Estrogens (CEE) and Medroxyprogesterone Acetate (MPA) in Early Postmenopausal Women. R. Lindsay[1], J. Gallagher[2], M. Kleerekoper[3], R. Northington*[4], K. Qi*[4], J. H. Pickar*[5]. [1]Internal Medicine, Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Bone Metabolism Unit, Creighton University School of Medicine, Omaha, NE, USA, [3]Division of Endocrinology, Wayne State University School of Medicine, Detroit, MI, USA, [4]Clinical Biostatistics, Wyeth Research, Philadelphia, PA, USA, [5]Clinical Research and Development, Wyeth Research, Philadelphia, PA, USA.

Body mass index (BMI) is an important determinant of bone mineral density (BMD). Whether BMI influences the BMD response to hormone replacement therapy (HRT) has not been well studied. The Women's Health, Osteoporosis, Progestin, Estrogen (Women's HOPE) study included a 2-year substudy of 749 women to evaluate the effects of different doses of CEE, either alone or with one of two doses of MPA, on BMD. Postmenopausal women 40-65 years were randomized to receive a daily dose of CEE 0.625 mg, CEE 0.625/MPA 2.5 mg, CEE 0.45 mg, CEE 0.45/MPA 2.5 mg, CEE 0.45/MPA 1.5 mg, CEE 0.3 mg, CEE 0.3/MPA 1.5 mg, or placebo. All women also received calcium carbonate (600 mg elemental calcium daily). At enrollment, women were between 1 and 4 years post menopause and were within 20% of normal body weight range. Lumbar spine (L2-L4) and total hip BMD and total body bone mineral content (BMC) were measured using a Lunar DPX-L. Correlation analyses between BMI and BMD or BMC changes from baseline at 1 year and 2 years were performed for all treatment groups. Statistical significance was set *a priori* at $P<.05$. Increases in BMD ranged from 1.7%-3.9% at the spine and 2.0%-3.1% at the hip, and total body BMC increased from 0.6%-2.3% at 2 years of active treatment; all doses of CEE and CEE/MPA produced significant increases ($P<.05$) in BMD and BMC relative to placebo. Placebo-treated patients lost 2.7 ± 3.3% (mean ± SE) of spine BMD and 0.9 ± 3.4% of hip BMD over 2 years; the loss of total body BMC averaged 2.8 ± 2.8%. Mean BMI (24.4 kg/m^2) was similar among groups and individual values ranged from 16.9-31.7 kg/m^2. Pearson correlation coefficients (r) for the relation between BMI and the percent change from baseline in BMD or BMC for all groups ranged from -0.24 to 0.19; no correlations were significant at year 1 or 2. These data indicate that BMI does not influence the beneficial effect of CEE, alone or combined with MPA, on BMD or BMC in early postmenopausal women who are within 20% of normal body weight range.

Estrogen Replacement Therapy and Tibial Bone Structure and Physical Performance in Postmenopausal Women. A. O. Heinonen*[1], H. Sievänen*[1], K. Uusi-Rasi*[2], I. Vuori[1]. [1]UKK Institute for Health Promotion Research, Tampere, Finland, [2]Johns Hopkins Outpatient Center, Baltimore, MD, USA.

Osteoporotic fractures are a common and increasing public health problem. Hormone replacement therapy (HRT) is one of the commonly recommended means for preventing osteoporosis and related fractures due to its ability to increase bone mineral density (BMD). However, BMD is only one factor affecting bone fragility. Also bone size, shape and architecture play a role. It has also been suggested that HRT may have anabolic effects and it might have a role in improving muscle strength or balance. The purpose of this cross-sectional study was to focus on factors associated with bone structure of lower limbs, and physical performance after menopause. Eighty non-smoking, healthy postmenopausal women participated in the study. They were classified into two groups by their use of hormone replacement therapy (HRT), either to the current users [n=43, age: 62 (SD 1) yrs, height: 161.0 (4.8) cm, weight: 68.2 (11.0) kg] or never or discontinued users [n=37, 62 (1) yrs, height: 161.3 (5.4) cm, weight: 73.9 ± 14.9 kg]. The tibial shaft and distal tibia were scanned with pQCT (Norland /Stratec XCT3000; Norland/Stratec, Pforzheim, Germany). For the shaft region, cortical density (CoD, g/cm^3), cortical area (CoA, mm^2) and section modulus (BSI, mm^3) were determined. For the distal part, the evaluated variables were ratio of cortical to total area (CoA/ToA), trabecular density (TrD, g/mm^3) and BSI. Isometric and dynamic muscle strength of the leg extensors, dynamic and static balance, and cardiorespiratory capacity (VO_2max) were measured. Between-group differences were evaluated with analysis of covariance body weight as a coavariate. Unadjusted values for all bone variables were slightly higher in the HRT-users compared to non-users, with the exception of TrD with no difference. After controlling for body weight, the mean differences (95% confidence interval) remained significant for CoD of the tibial shaft and BSI of the distal tibia only, the mean between group differences being 1.5% (95% CI 0.4 to 2.5%) and 23.0% (7.1 to 41.3%), respectively. No differences existed between two study groups for lower limb isometric or dynamic power, cardiorespiratory capacity or balance. These results suggest that HRT results in apparently stronger bone structure in tibia but its role in improving physical performance is not evident.

M388

Simvastatin Given Twice Daily Increases Cortical Bone Formation and Strength in OVX Rats. H. Oxlund[1], T. T. Andreassen[2]. [1]Department of Connective Tissue Biology, Institute of Anatomy, Aarhus, Denmark, [2]Department of Connective Tissue Biology, Institute of anatomy, Aarhus, Denmark.

Some of the statins possess bone anabolic properties. Statin increased expression of the BMP-2 gene in osteoblasts resulting in increased cancellous bone volume and a minor decrease in osteoclast number of 3-month-old rats (Mundy et al, Science 286, 1946-1949, 1999). Simvastatin increased the vertebral cancellous bone mass and compressive strength of one-year-old female rats (Oxlund et al., Calcif Tissue Int 69:299-304, 2001). In the present study the effects of statin on tibia cortical bone of OVX (ovariectomized) rats were studied. Sixty Wistar female rats, 4 months old, were allocated to 4 groups: 1. Baseline control, 2. Sham + placebo group, 3. OVX + placebo, 4. OVX + simvastatin. Simvastatin MSD (20 mg/kg) or placebo were given twice daily at 9 a.m. and at 3 p.m. by a gastric tube for 3 months. The rats were injected with tetracycline i.p. at day 11 and calcein i.p. at day 4 before sacrifice of the 7 months old rats. The mechanical properties of the tibia diaphysis were studied by a 3-point-bending test. The breaking strength of the OVX + statin group (111.2 +/- 2.1 newton, mean +/- SEM) was increased ($2p<0.02$) compared with the OVX group (102.4 +/- 2.8 newton), and increased ($2p<0.001$) compared with the sham + placebo group (97.5 +/- 2.2 newton). Cross-sections were cut and mineral apposition rates (MAR) at the different aspects and in different regions of the tibia were calculated from the fluorescent labels. In the upper part of the tibia diaphysis for example, the endosteal MAR of the OVX + statin group (1.7 +/- 0.1 micrometer/day) was increased ($2p<0.001$) compared with the OVX group (1.0 +/- 0.1 micrometer/day), and increased ($2p<0.0001$) compared with the sham + placebo group (0.4 +/- 0.1 micrometer/day). In conclusion, simvastatin given perorally twice daily increased the bending strength of the tibia diaphysis of OVX rats. The mineral apposition rates were increased in OVX rats given simvastatin. The new cortical bone exhibited a normal lamellar structure. Simvastatin increases bone formation, but seems to respect the regional pattern of bone resorption, formation and drift.

M389

Effects of Oral DHEA on Bone Density in Young Women with Anorexia Nervosa. C. M. Gordon[1], E. Grace*[1], S. J. Emans*[1], H. Feldman*[1], E. Goodman*[2], K. Becker*[1], C. J. Rosen[3], C. M. Gundberg[4], M. S. LeBoff[5]. [1]Children's Hospital, Boston, MA, USA, [2]Children's Hospital, Cincinnati, OH, USA, [3]St. Joseph Hospital, Bangor, ME, USA, [4]Yale-New Haven Hospital, New Haven, CT, USA, [5]Brigham & Women's Hospital, Boston, MA, USA.

Young women with anorexia nervosa (AN) have subnormal levels of dehydroepiandrosterone (DHEA) and estrogen that may be mechanistically linked to the bone loss commonly seen in this disease. The purpose of this study was to compare the effects of a 1-year course of oral DHEA treatment vs. conventional hormonal replacement therapy (HRT) in young women with AN. Sixty-one young women were randomly assigned to receive DHEA (50 mg/d) or HRT (20 mcg ethinyl estradiol/0.1 mg levonorgestrel). Anthropometric, nutrition and exercise data were acquired every 3 months, and bone mineral density (BMD) and body composition were measured by dual energy x-ray absorptiometry (DXA) every 6 months over 1 year. Serum samples were obtained for hormones, proresorptive cytokines, and bone formation markers, and urine for bone resorption markers at each visit. Total hip BMD increased significantly and similarly (+1.7%) in both groups. In those receiving DHEA, hip BMD increases were positively correlated with increases in IGF-I ($r=0.44$, $P=0.030$) and the bone formation marker, BSAP. There was no significant change in lumbar BMD in either treatment group. Both bone formation markers, BSAP and osteocalcin, increased transiently at 6-9 months in those patients receiving DHEA compared to the HRT group ($p<0.05$). Both DHEA and HRT significantly reduced levels of the bone resorption markers, NTx. There was a positive correlation between changes in IGF-I and changes in weight, percentage body fat and estradiol for both groups. In addition, patients receiving DHEA exhibited significantly lower scores ($p<0.05$) on 3 psychological instruments (Eating Attitudes Test, Anorexia Nervosa Subtest and Spielberger Anxiety Inventory), reflecting clinical improvement. Both DHEA and HRT resulted in significant increases in hip BMD. Maintenance of spinal BMD was seen, but there was no significant increase over 1 year. DHEA appeared to have anabolic effects, evidenced by the positive correlation between increases in hip DXA measurements and IGF-I, and the significant increase in bone formation markers seen in those subjects receiving DHEA. In both groups, IGF-I appeared to be nutritionally dependent, correlating with weight and percentage body fat. Both therapies significantly decreased bone resorption. As has been reported in the elderly, DHEA resulted in improvements in specific psychological parameters in these young women.

M390

Amylin(1-8) and a Stable Analog Are Anabolic after Local but not Systemic Administration in Rodents. J. A. Gasser, M. Heidl*, T. Buhl*, T. Petcher*, R. Beerli*. Arthritis & Bone Metabolism, Novartis Pharma AG, Basel, Switzerland.

Work in rodents indicates that amylin(1-8) may be anabolic for bone after local and systemic administration. We investigated the anabolic properties of amylin(1-8) and a stable octapeptide analog on the mineral apposition rate (MAR) after their direct administration to the calvaria surface in mice. In addition, eight-month old estrogen replete and ovarietcomized rats were treated daily s.c. for 4 weeks with 0.5 or 5mg/kg of the analog to investigate its bone anabolic and/or antiresorptive effects after systemic administration. Cancellous and cortical bone parameters were measured non-invasively by pQCT in the proximal tibia metaphysis at baseline, 2 and 4 weeks after the start of treatment. In mice treated for 5 consecutive days with local injections of 1, 10 or 100nM amylin(1-8), MAR increased significantly in a concentration dependent manner. The stable analog was more potent than the natural fragment and was therefore chosen for daily injections over 4 weeks at 0.5 or 5mg/kg to estrogen-replete and OVX rats. PTH(1-34) injected s.c. at 5µg/kg served as a positive control. In estrogen replete animals, PTH(1-34) increased total- and cancellous bone mineral density (10.3 and 11.6%, both $p<0.01$) and cortical thickness (40.8%, $p<0.01$). In contrast, no effect on any parameter was seen in rats treated with 0.5 or 5mg/kg of the amylin analog (all parameters NS vs sham-op). OVX-rats showed significant cancellous bone loss (17.0%, $p<0.01$) and cortical thinning (19.8%, $p<0.01$). PTH was fully protective on all parameters and increased cortical thickness by 5% (NS). The amylin analog reduced cancellous bone loss to 13.9% (NS vs OVX) and 11.8% ($p<0.05$ vs OVX) but did not show any significant protective effect on cortical thinning at 0.5mg/kg (22.9%, NS vs OVX) or 5mg/kg (18.1%, NS vs OVX). Our data suggests that the N-terminal amylin fragment or the stabilised octapeptide analogue is anabolic when administered directly to the bone surface in mice and rats. However, no anabolic effect was observed in rats after 'systemic' s.c. administration to estrogen replete animals and only mild but significant protective effects were seen in the OVX-prevention study. All effects of amylin or the analog were less pronounced compared to the anabolic agent PTH(1-34). The reasons for the discrepancy between the result of local and systemic administration of the amylin analogue is not known at this point.

M391

Agonist of the VEGF Receptor R1/flk-1/KDR Prevents Unloading-Induced Trabecular Bone Loss in the Rat by Increasing Osteoblastic Activity. M. H. Lafage-Proust[1], O. Barou*[1], V. David*[1], T. Thomas[1], P. Ruegsegger*[2], J. Plouët*[3], C. Alexandre[1], L. Vico[1]. [1]EM-INSERM 9901, St-Etienne, France, [2]ETH, Zurich, Switzerland, [3]GDR CNRS 1927, Toulouse, France.

There is growing evidence that a functional relationship links bone remodeling to angiogenesis. Hence, we postulated that unloading-induced bone loss is, at least in part, related to bone vascularisation alterations. Using the tail-suspended rat model, we first showed a concurrent decrease in both capillary number and bone formation rate (BFR) in tibia metaphysis after 7 days of unloading preceding bone loss. Moreover, we observed an early dramatic decrease in mRNA expression of the potent angiogenic factor VEGF in the bone marrow, metaphysis and periosteum of the unloaded tibia. Conversely, none of these changes occurred in normally loaded humeri. We next tested the effects of anti-idiotypic anti-VEGF receptor Kdr antibodies (KdrAb) administration in this model. KdrAb dimerises the receptor and mimics the VEGF pro-angiogenic effects,(Ortega et al, Am J Pathol. 1997,151:1215-24). 300g Wistar male rats were divided in 4 groups of 7 animals: tail-suspended rats (Susp) treated with intra-peritoneal KdrAb (5µg/kg bw) or vehicle (V), on days 0, 4, 7 and 11 ; non-suspended rats (Ctr) similarly treated with KdrAb or V. Trabecular bone volume (BV/TV, %), trabecular linear attenuation coefficient (LAC) (correlate of bone mineral density) and cortical area (mm^2) were assessed longitudinally (at days 0, 7 and 14) with micro-computerized tomodensitometry (VivaScan) on femur metaphysis. After sacrifice, at day 14, osteoclastic (OcS/BS) and osteoblastic activities (mineral apposition rate, MAR and mineralising surfaces, MS/BS) were measured with quantitative bone histomorphometry on tibia metaphysis secondary spongiosa. Results are given as mean ± SD.

Results

	Ctr V	Ctr KdrAb	Susp V	Susp KdrAb
BV/TV, %	9.5±1.8	10.4±1.9	5.6±2.2 a	7.5±3.2
LAC	0.745±0.021	0.760±0.032	0.653±0.054 a	0.700±0.071
Cortical Area	5.93±0.09	5.81±0.09	5.1±0.16 a	5.23±0.17 a
OcS/BS,%	15.7±2.5	14.4±3.6	14.9±3.3	14.4±2.9
MAR, µm/d	2.60±0.12	2.61±0.17	2.15±0.12 b	2.63±0.12
MB/BS, %	18.4±1.8	20.1± 5.9	11.7±1.3 b	13.5±3.3 b

Significant difference: a vs baseline (repeated measures ANOVA), b vs Ctr-V (Mann-Whitney).The unloading-induced decrease in growth plate and primary spongiosa width was not prevented by KdrAb treatment. Thus, KdrAb prevented unloaded-induced trabecular bone loss through an increase in osteoblastic activity. Whether KdrAb effects on bone were mediated through endothelial cells, direct osteoblastic stimulation or both remains to be elucidated.

M392

A Non-Prostanoid EP4 Receptor Selective Prostaglandin E2 (PGE2) Agonist Stimulates Bone Formation and Restores Bone Mass and Strength in Ovariectomized Rats. H. Z. Ke, D. T. Crawford*, H. QI, M. Li, V. M. Paralkar, T. A. Owen, L. C. Pan, T. A. Brown, K. O. Cameron*, B. A. Lefker*, P. DaSilva-Jardine*, B. Lu*, W. A. Grasser, H. A. Simmons, L. J. Yu*, D. O. Scott*, D. D. Thompson. Pfizer Global Research and Development, Groton, CT, USA.

PGE2 stimulates bone formation, increases bone mass and strength. However, the mechanism of PGE2's bone anabolic effects is not known. PGE2 binds to all four receptor subtypes, EP1-EP4. We hypothesized that the EP4 receptor plays an important role in the bone anabolism of PGE2. CP-A is a newly identified EP4 receptor selective agonist. CP-A binds selectively to the EP4 receptor with an IC50 of 54 nM, while it did not bind to EP1, EP2, EP3 and other prostanoid receptors including DP, FP, IP, and TP. CP-A stimulates the EP4 receptor to initiate signaling by the cAMP pathway with an EC50 value of 32.5 nM. CP-A increases osteogenesis in vitro as demonstrated by a dose-dependent increase in mineralized nodule formation in rat bone marrow cell cultures with an EC50 of 1 micromolar. The maximum effect of CP-A in this assay is equivalent to those of PGE2. Daily subcutaneous injection of CP-A at 3, 10, or 30 mg/kg was given for 4 weeks to 5.5-month-old rats that had been ovariectomized (OVX) for 5 weeks prior to the beginning of treatment. PQCT analysis of the distal femoral metaphysis (DFM) showed that CP-A dose-dependently increased total content (up to +16%), total density (up to +24%), cortical content, cortical thickness, and cortical area in OVX rats as compared with OVX controls. Proximal tibial metaphyseal (PTM) cancellous bone histomorphometric analysis showed that CP-A significantly and dose-dependently increased trabecular bone volume (up to +97%), thickness, number, mineralizing surface, mineral apposition rate, and bone formation rate in OVX rats. All bone mass and structural parameters in DFM and PTM in OVX rats treated with CP-A at 30 mg/kg did not differ from sham controls, indicating the complete restoration of bone mass in the OVX rats. Further, the indentation test of DFM and the compression test of the 5th lumbar vertebral body showed that CP-A dose-dependently restored ultimate strength back to level of sham controls in vertebral body and above the level of sham controls in DFM in the OVX rats. In summary, we report for the first time that a non-prostanoid EP4 receptor selective agonist increases osteogenesis in vitro and completely restores bone mass and strength to the levels equal to or greater than sham controls in the established osteopenic, OVX rat model by stimulating bone formation. Thus, EP4 receptor agonists may provide therapeutic potentials for prevention and treatment of skeletal disorders including osteoporosis and it related fractures.

Novel, Non-steroidal Selective Androgen Receptor Modulators (SARMs) Have Bone Anabolic Activity in Adult Osteoporotic Rats. K. Hanada*, K. Furuya*, N. Yamamoto*, H. Nejishima*, K. Ichikawa*, S. Amano*, Y. Sumita*, N. Oguro*, M. Miyakawa*, T. Nakamura*. Drug Discovery Research Department, Kaken Pharmaceutical, Co.,Ltd.,, Kyoto, Japan.

We successfully generated novel, non-steroidal small compounds as selective androgen receptor modulators (SARMs), which showed strong androgen receptor (AR) binding affinity and bone-selective agonistic activity. The Compounds showed AR-selective binding and therefore did not cross-reaction to AR-related nuclear receptors, progesterone and glucocorticoid receptors. When the Compounds were administrated into orchiectomized (ORX) rats, bone mineral density (BMD) of femoral diaphysis (cortical bones) assessed by dual energy X-ray absorptiometry (DEXA) was dose-dependently increased as same potency as androgen steroids, testosterone propionate (TP) and dihydrotestosterone (DHT). In contrast, their virilizing effects manifested by weight of ventral prostates were reduced in comparison with TP and DHT. These results strongly suggested that the Compounds were SARM candidates, which had unique tissue selectivity with high potency for bone formation and lower impact upon prostate. Current studies were undertaken to confirm the direct bone anabolic activities of the Compounds in osteoporotic animal models. Firstly, to exclude the possibility that the Compounds stimulate bone formation indirectly by enhancement of muscle strength, ORX rats were further subjected to sciatic neurectomy (NX). After 4-week s.c. injection with 30mg/kg of Compound N1, one of our lead compounds, BMD of immobilized tibia was significantly increased as compared with that of vehicle-treated NX+ORX rats, irrespective of severe muscle atrophy of hind limb. These data suggest that the Compound has direct bone anabolic activity. Moreover, Compound N1 did not elevate prostate weight above the normal level, confirming the diminished virilizing activity of it. We next investigated bone formation activity of the Compound N1 in ovariectomized (OVX) rats. The Compound N1 (10 and 30mg/kg) was given sc to OVX rat for 2 months and BMD of femurs was measured. The Compound significantly increased BMD of femoral diaphysis as well as DHT and TP, whereas estrogen, anti-bone resorptive hormone, did not. Combined administration of the Compound N1 and estrogen further increased BMD of femoral diaphysis as compared with single administration of the Compound. In addition, the Compound N1 significantly enhanced mechanical strength of cortical bones of femurs in 3-point bending experiments. Collectively, these results indicated that the Compounds had high potency of bone anabolic activity distinct from anti-resorptive agents. Bone histomorphometric analyses are now in progress.

M394

Effect of Nandrolone Decanoate on Bone Mineral Density and Vertebral Fracture in Osteoporotic Elderly Women: A Double-Blind, Randomized, Clinical Trial. A. Frisoli*[1], M. Pinheiro*[2], W. Braga*[2], V. Szejnfeld[2]. [1]Rheumatology and Geriatric Division, Universidade Federal de Sao Paulo, Sao Paulo, Brazil, [2]Rheumatology, Universidade Federal de Sao Paulo, Sao Paulo, Brazil.

A double blind, randomized, clinical trial was performed, for two years, to evaluate the effect of nandrolone decanoate(ND) on bone mineral density(BMD) of lumbar spine, femoral neck, trochanter, lean body mass and vertebral fracture rate. Sixty-five osteoporotic women aged 70 years old or more were divided in two groups: one, with 32 patients who took injections of 50mg nandrolone decanoate every 3 weeks, plus 500mg calcium tablets daily. The second group with 33 patients who took injections of placebo every 3 weeks, plus 500mg calcium tablets daily. Significant positive changes from baseline in BMD at the lumbar spine (3,4±6,0 e 3,7%±7,4; p<0,05) and femoral neck (4,1%± 7,3 e 4,7%±8,0; p<0,05) were observed in the first and second year in the nandrolone decanoate group. BMD of trochanter showed significant positive changes from the base line only in the first year (4,8%±9,3 e 3,1%±10,2; p>0,05). Otherwise, there was no significant difference between BMD of the lumbar spine of two groups. A significant statistical difference in the trochanter BMD of ND group and placebo group was observed between the first (p=0,003) and second year (p=0,02). Also for femoral neck BMD a difference between the two groups over the two years was observed (p=0,01). Lean body mass of ND group showed considerable increase from baseline, not only in first (6,2% ±5,8; p<0,00004), but also in the second year (11,9%±29,2; p<0,0001). New vertebral fractures were significantly lower in the ND group (21%; p<0,05), than in placebo group (43%). We conclude that treatment with nandrolone decanoate does increase the bone mineral density of proximal femur and lean body mass, and reduce the vertebral fracture of elderly women.

Discovery of CP-533536: an EP2 Receptor Selective Prostaglandin E2 (PGE2) Agonist That Induces Local Bone Formation. B. A. Lefker*, K. O. Cameron*, D. T. Crawford*, P. Dasilva-Jardine*, S. L. Deninno*, H. Gao*, W. A. Grasser, D. R. Healy*, N. C. Elliott*, H. Z. Ke, M. Li, B. Lu*, T. A. Owen, V. M. Paralkar, H. Qi, D. D. Thompson, C. M. Tjoa*, A. S. Wright*, L. J. Yu*, M. P. Zawistoski*, R. L. Rosati*, C. F. Ebbinghaus*. Cardiovascular and Metabolic Diseases, Pfizer Global Research and Development, Groton, CT, USA.

PGE2 stimulates bone formation in humans and animals when dosed systemically or locally. Of the four PGE2 receptor subtypes (EP1-EP4), EP2 and EP4 have been envisaged as the two receptors most likely to be responsible for PGE2's actions on bone. As part of a drug discovery program to identify agents that would induce local bone, we sought a non-prostanoid, subtype selective PGE2 agonist. We initiated our search by screening known PGE2 analogs most likely to be selective for EP2 and/or EP4. An in house compound, CMP-1, was identified as a mixed EP2/EP4 agonist (rEP2=27 nM, rEP4=219 nM) with good selectivity vs. other prostanoid receptors. CMP-1 was locally injected into the bone marrow of the proximal tibial metaphysis of 6-week-old male rats. A single 3 mg/kg injection was given on day 1, and the rats were necropsied on day 7. The injected tibia was analyzed using peripheral quantitative computerized tomography (PQCT), bone histomorphometry, and biomechanical testing. CMP-1 dose-dependently increased new bone formation in the injected site of the marrow cavity. Having confirmed that a mixed EP2/EP4 selective agonist was active in vivo in this model, we sought subtype selective agonists. CMP-2, reported previously, was characterized in our labs as a weak but selective EP2 agonist. The benzylic alcohol derivative, CMP-3, had similar potency and selectivity. In the local injection model, CMP-3 increased local bone formation to a similar extent as observed with the EP2/EP4 agonist, CMP-1. A range of aliphatic bottom chains, acid linkers, and alkyl and aryl sulfonamides were explored. This chemistry optimization led to the identification of a more potent and highly selective agonist, CP-533536 (50 nM IC50 for rEP2, 0.31 nM EC50 for rEP2, > 3200 nM IC50 for rEP4). Upon local injection, CP-533536 dose-dependently increased new bone formation in the injected site of the marrow cavity. At a dose of 3 mg/kg, CP-533536 increased total bone content by 54% and total mineral density by 28%. In summary, we have identified potent, EP2 selective agonists which produce significant new bone after a single local injection into the marrow cavity of young male rats. These agents have potential clinical utility as local bone healing agents.

Effect of Simvastatin on Bone Turnover and Bone Density in Postmenopausal Hypercholesterolemic women: A 1-year longitudinal Study. A. Montagnani*, S. Gonnelli, C. Cepollaro*, S. Mondillo*, S. Pacini*, C. Caffarelli*, M. S. Campagna*, M. B. Franci*, B. Lucani*, C. Gennari. Institute of Internal Medicine, University of Siena, Siena, Italy.

Experimental evidence has shown that the statins increase bone formation and some observational studies have reported a lower risk of osteoporotic fracture in hypercholesterolemic patients treated with statins. However longitudinal studies on the effects of statins on bone turnover and on bone mass are lacking. The aim of the present study was to evaluate BMD and bone turnover changes in hypercholesterolemic women after one-year treatment with simvastatin. From a large number of patients who attended the outpatient clinics of the Institute of Internal Medicine at University of Siena for atherosclerotic risk evaluation, 30 consecutive postmenopausal hypercholesterolemic women (61.2±4.8 years) were selected and treated for 12 months with simvastatin 40 mg/day. Thirty normocholesterolemic age-matched postmenopausal women provided control data. We made sure (by a validated questionnaire given a 6-month intervals) that dietary calcium intake was stable and of at least 1200 mg/day during the study period. In all subjects, at baseline and at 3-month intervals, serum lipids, calcium, phosphate, total and bone alkaline phosphatase (TALP and BALP) and carboxy-erminal fragment of type I collagen (CTx) were measured in a fasting blood sample. At baseline and after 6 and 12 months bone mineral density was measured at lumbar spine (BMD-LS) and at femur (BMD-F) by DXA (Hologic QDR 4500). In simvastatin treated-group TALP and BALP significantly (P<0.05) increased by 9% and 16% and by 3.7% and 9.3%, respectively at the sixth and the twelfth month. Instead, serum CTx showed a weak increase over study period without reaching the statistical significance. In treated women BMD-LS and BMD-F increased by 1.1% and by 0.4% at month 6 and by 2.8% and by 1.1% at month 12. In controls BMD-LS and BMD-F at the end of the study period decreased by 1.1% and 1.2%, respectively. At month 12 the difference between controls and simvastatin-treated patients was significant (p<0.05) for both BMD-LS and BMD-F. In conclusion our results, although obtained from a small sample of subjects, suggest that in postmenopausal hypercholesterolemic women, 1-year treatment with simvastatin 40 mg daily is able to moderately stimulate bone formation and to induce an effect on BMD, which is significant in comparison with the control group.

M397

Discovery of Highly Selective EP4 Receptor Prostaglandin E2 (PGE2) Agonists Which Stimulate New Bone Formation and Restore Bone Mass in Ovariectomized Rats. K. O. Cameron*, B. A. Lefker*, D. T. Crawford*, P. DaSilvaJardine*, S. L. DeNinno*, W. A. Grasser, H. Z. Ke, B. Lu*, T. A. Owen, V. M. Paralkar, H. Qi, D. O. Scott*, D. D. Thompson, C. M. Tjoa*, M. P. Zawistoski*. Cardiovascular and Metabolic Diseases, Pfizer Global Research and Development, Groton, CT, USA.

PGE2 stimulates bone formation and increases bone mass and strength in pre-clinical animal models of bone loss. Of the four PGE2 receptor subtypes (EP1-EP4), EP2 and EP4 have been delineated as the two receptors responsible for PGE2's anabolic actions on bone. We sought to identify EP-4 selective agonists that would promote bone formation with minimal side effects. Our initial screens identified, CP-1, a mixed EP2/EP4 agonist (rEP2 IC50=27 nM, rEP4 IC50=219 nM) with good selectivity vs. other prostanoid receptors. When dosed subcutaneously at 10 mg/kg in an ovariectomized (OVX) rat model, CP-1 produced significant increases in trabecular bone density (+30%) as compared with vehicle-treated OVX controls when measured by peripheral quantitative computerized tomography (PQCT). Having confirmed that bone anabolic effects were achievable with a mixed EP2/EP4 selective agonist, we sought specific EP-4 subtype selective agonists to test whether systemic bone anabolism could be achieved with an EP4 selective agonist. High throughput screening led to the identification of CP-A, an EP4 selective agonist with reasonable potency (rEP2 IC50 = >3200 nM, rEP4 IC50 = 54 nM, EC50 for rEP4 cAMP production = 32.5 nM). Chemical optimization of CP-A led to the identification of a more potent EP4 agonist, CP-B(rEP2 IC50 = >3200 nM, rEP4 IC50=21 nM, EC50 for rEP4 cAMP production =13.2 nM). Administration (subcutaneously at 1, 3, 10, and 30 mg/kg) of CP-B in an osteopenic rat model (5 weeks post-OVX) showed dose dependent increases in total bone content (up to 32.5%), total density (up to 23.7%), cortical content (up to 57.7%), cortical thickness (up to 124%), and cortical area (up to 67%) as compared with vehicle treated OVX controls as measured by pQCT. In summary, we have identified potent, EP4 selective agonists which produce significant new bone in an osteopenic rat model. These agents have potential clinical utility for the treatment of skeletal disorders such as osteoporosis.

Evidence of Altered Bone Homeostasis in Patients after Gastric Bypass Surgery. A. M. Novy*[1], H. J. Sugerman*[2], R. W. Downs[1], E. J. DeMaria*[2], J. M. Kellum*[2], L. G. Wolfe*[2], D. M. Biskobing[1]. [1]Medicine, Virginia Commonwealth University, Richmond, VA, USA, [2]Surgery, Virginia Commonwealth University, Richmond, VA, USA.

Surgery for obesity has become accepted therapy since it results in long-term weight loss in the majority of patients. In the past, jejunoileal bypass was known to be associated with fat soluble vitamin deficiencies such as vitamin D which may lead to osteomalacia. Current surgeries have been developed to produce less malabsorption in hopes of avoiding nutritional deficits. However, little data has been published on long-term effects on calcium homeostasis and bone status of these patients. Over the last 20 years, more than 2100 patients have undergone proximal gastric bypass surgery (PGBP) at the Medical College of Virginia. We reviewed the patient database for evidence of bone disease occurring at post-operative years one and five. 198 patients (182 women and 16 men) had laboratory follow-up at year one and year five. Overall, the frequency of hypocalcemia rose from 11% of patients at year one, to 23% at year five, (p=0.0039). In women, the frequency of hypocalcemia rose from 10% at year one to 20 % at year five, and corrected serum calcium levels decreased from 9.39 mg/dl +/-0.03 at year one to 9.18 mg/dl +/-0.03 at year five, (nl 8.9-10.5mg/dl, p<0.0001). In men, the frequency of hypocalcemia rose from 12.5% at year one to 62.5% at year five, (p<0.0005), and corrected serum calcium levels decreased from 9.46+/- 0.23 mg/dl at year one, to 9.02+/- 0.39 mg/dl at year five, (nl 9.2-10.7mg/dl, p<0.0001). The frequency of hypophosphatemia was 1.3% at one year and 3.8% at 5 years, (p=0.0170). The average serum phosphorus decreased from 3.87 +/- 0.05 mg/dl at year one to 3.57 +/-0.05 mg/dl at year five, (nl 2.5-4.6 mg/dl, p<0.0001). Alkaline phosphatase was elevated in 12% at year one and elevated in 20% at year five, (p =9.460E-08). The average serum alkaline phosphatase rose from 88.27 +/- 2.42 mg/dl at year one to 96.77 +/- 3.25 mg/dl at year five, (nl <115,p<0.0001). The average serum magnesium decreased slightly but was not clinically significant. These results show that hypocalcemia becomes more prevalent over time in patients after GBP surgery. Neither 25-OH vitamin D nor PTH are

routinely measured in GBP patients and were therefore not available. However, the decrease in calcium in conjunction with phosphorus suggests a nutritional deficiency of either calcium or vitamin D, or both. Over many years, this may result in deleterious effects on bone which could increase fracture risk. Further investigations of calcium metabolism in patients after PGBP surgery will be necessary to further characterize effects on bone to establish appropriate guidelines for follow up, treatment and prevention.

M399

Gastric Bypass Surgery for Morbid Obesity Leads to Increased Bone Turnover. P. S. Coates[1], R. Satyawadi*[2], M. H. Fernstrom*[1], P. R. Schauer*[1], S. L. Greenspan[1]. [1]University of Pittsburgh Medical Center, Pittsburgh, PA, USA, [2]Mercy Hospital, Pittsburgh, PA, USA.

Obesity is a growing problem worldwide associated with increased morbidity and mortality. Roux-en-Y gastric bypass achieves long-term weight loss of 60-70% excess body weight, and many morbidly obese patients are opting for this procedure. Very little is known about the effects of this surgery and subsequent weight loss on calcium metabolism and the skeleton. To examine these effects, we compared patients who underwent prior gastric bypass surgery with morbidly obese patients before the procedure. Age, gender and menopausal status were similar between the two groups. The postoperative patients had lower weight and BMI. Calcium and vitamin D intake was significantly higher in the postoperative group, reflecting prescription of supplements. However, 24-hour urinary calcium was not increased in these patients, suggesting that calcium absorption may be impaired after gastric bypass. Although vitamin D levels were higher in the postoperative patients, levels remained low normal and PTH levels remained high in this group, suggesting continuing vitamin D insufficiency. Markers of bone turnover were significantly increased in the postoperative patients. Radius BMD and heel ultrasound BUA did not differ between the pre-and post-operative patients. These results suggest that obese patients are at risk of reduced calcium absorption and increased bone loss after gastric bypass surgery. Longitudinal studies are needed to further characterize the effects of this procedure on the skeleton.

Intravenously Pamidronate in Bone Lesions of Gaucher`s Disease. Z. Man*, N. Chamoles*, A. Copquin*, J. Roel*, J. Falcon*. Centro TIEMPO, Universidad Favaloro, Buenos Aires, Argentina.

The pure bone form of Gaucher´s Disease is not so frequent and its processing is not clear. A man of 44 years old, that 10 years ago was diagnosed with idiopathic osteoporosis, after a fracture of right femoral neck caused by a minimum trauma, received processing with oral pamidronate (APD) (300 mg/d) and later, oral alendronate 10 mg, during this years, with few changes in the BMD. Two years ago, he presented aseptic necrosis in left femoral neck and a few months later a crisis of severe bone pain with the finding by MNR of a litic injury in distal left femur. He was treated with 90 mg of APD (IV infusion of 250 cc of dextrose 5% in two hours) and very high doses of morphine. A biopsy revealed Gaucher´s Disease. The existence of this pathology was certified itself with the seric determination of kitotriosidase 70.0 mU/ml (n v 0,05 to 1) and the reduction of the beta glucosidase in sanguineous leukocytes. The genotype was N37OS/N370S that corresponds to a heterozigote for the mutant gene with low enzymatic level, being the only member of his family who suffers this disease. The only affection of Gaucher´s Disease in this patient, were bone lesions. Then, he received processing with alglucerase (CEREDASE - Genzyme) (extracted enzyme of human placenta) during six months and afterwards, and still in treatment, with imiglucerase (CEREZYME- Genzyme) (recombinant enzyme) every 15 days (60 U/kg = 500 U). By digestive intolerance to oral alendronate, it was decided to administer 60 mg APD IV in quarterly form. At the end of the first year of treatment, the BMD increased (3% in spine and 5% in hip), being one of the most important results the fact that he didn`t display again a new crisis of bone pain. **Conclusion:** We considered that 60 mg APD IV every 3 months constitutes a valid alternative in Gaucher`s Disease with bone commitment and digestive intolerance to other bisphosphonates.

M401

Effects of Bacteroides forsythus on MG-63 Cell Cultures In Vitro. P. M. Loomer, R. Smith*, C. Hoover*. Stomatology, University of California, San Francisco, San Francisco, CA, USA.

Specific oral microorganisms have been implicated in the etiology and pathogenesis of periodontal diseases. Bacteroides forsythus, an oral bacterium, is considered to a putative periodontal pathogen largely based on data showing its presence in elevated proportions at diseased sites. However, the specific effects of its metabolic products on cells of the periodontium, including osteoblasts, are less known. Therefore, this study was undertaken to evaluate the effects of extracts of B. forsythus on osteogenesis in vitro. Cultures of B. forsythus were grown under anaerobic conditions and sonicate extracts were prepared after 7 days. Sonicate concentrations of 0, 0.01, 0.1, 1, 10, 100 ug/ml tissue culture media were subsequently added to confluent cultures of MG-63 cells, a human osteosarcoma cell line. The effects of bacterial extracts on parameters of osteogenesis were evaluated at days 2, 4, 6 and 14 by measuring alkaline phosphatase (AP) activity and mineral production (inorganic phosphate and calcium.) The results showed the extracts stimulated bone formation at concentrations of 10 and 100 ug/ml. AP activity increased 15-fold in 2-day cultures ($p<0.001$), 6-fold in 4-day cultures ($p<0.001$) and 2.7-fold in 14 day cultures ($p<0.001$), in comparison to controls. Comparable results were found for mineral content. Extracts from Porphyromonas gingivalis, another putative periodontal pathogen, showed similar increases in osteogenic activity of MG-63 cells. While previous studies have shown that extracts of these microorganisms inhibit bone formation in other in vitro culture systems, these results show they may also play a role in stimulating bone formation. This suggests that these bacteria exhibit both inhibitory and stimulatory effects on bone formation and thus may play a role in bone remodeling in periodontal diseases.

Effect of Growth Hormone (GH) on Cortical Bone Remodelling in Adult GH-deficiency - A 12 Month Double-blind Placebo Controlled Study. K. E. Koroma*[1], E. M. Hauge[2], H. Brockstedt*[3], J. S. Christiansen*[4], T. B. Hansen*[1], F. Melsen*[2], C. Hagen*[1], K. Brixen[1]. [1]Dept. of Endocrinology, Odense University Hospital, Odense, Denmark, [2]Dept. of Pathology, Aarhus University Hospital, Aarhus, Denmark, [3]Dept. of Endocrinology, Aarhus University Hospital, Aarhus, Denmark, [4]Dept. of Pathology, Rikshospitalet, Oslo, Norway.

Fracture incidence is increased and bone mineral density (BMD) reduced in patients with adult-onset GH-deficiency (GHD). Short-term GH-treatment decreases whereas long-term treatment increases BMD. It has been suggested that this initial decrease in BMD is explained by an increase in the remodelling space.(1)In this study we examined the changes in cortical bone remodelling. Twenty-nine patients with adult-onset GHD, aged 21-61 (mean 45.5)years (19 men and 10 women) were randomized to treatment with GH (Norditropin, Novo-Nordic, Denmark)2.0IU/m2/day or placebo. None of the patients had previous acromegaly. Substitution with other hormones than GH were continued unchanged throughout the study. GHD was defined as a maximal GH-peak of < 10 mg/l during insulin-tolerancetest (blood glucose < 2.0 mmol/l). Bone biopsies were obtained from the iliac crest before and after 12 months of treatment. Twenty-four paired biopsies were available for determination of cortical porosity (Ct.po),absolute cortical width (A.Ct.Wi), quiscent(QSi), formative (FSi),and eroded (ESi) cortical osteons, core width (C.Wi), fractional cortical width (F.Ct.Wi)and osteoid width (O.Wi). Moreover osteonal diameter (On.Dm), wall width (W.Wi), Haversian canal width (H.Ca.Dm) in quiscent (q) and formative (f) osteons, respectiveley, were measured as previously described (2). Results are shown intable 1. QSi decreased ($p=0.04$) and FSi tended to increase ($p=0.07$).1)Brixen, K et. al. J. Bone Miner. Res. 2000;15:293-300 2)Brockstedt H et. al.:Bone 1996;18:67-72

Mesenchymal Stem Cell Therapy for Osteoarthritis. F. Barry*[1], M. Murphy*[1], K. Kavalkovich*[1], R. Young*[1], B. Koller*[2], A. Laib*[2], R. Kapadia[2], R. A. Dodds*[1]. [1]Osiris Therapeutics, Baltimore, MD, USA, [2]Scanco Medical AG, Bassersdorf, Switzerland.

Meniscal injury significantly increases the risk of developing osteoarthritis (OA), a joint disease involving articular cartilage degeneration, and thickening of the subchondral and trabeculae bone. Mesenchymal stem cells (MSCs) differentiate to tissues such as bone, cartilage and tendon. In this study the ability of allogeneic MSCs to impact meniscal regeneration and influence OA progression in a goat model was studied. Bone marrow-derived MSCs were injected into the joint as a suspension in hyaluronan (HA). The MSCs were retrovirally transduced to express green fluorescent protein (GFP). 20 goats, unrelated to the donors, were randomized into 4 groups (n=5/group) and total unilateral medial meniscectomy was performed. After 1 or 6 weeks the operated joint was treated by injection of 1 x 10^7 MSCs in 5 ml of HA (4 mg/ml) or HA alone. Two weeks post-surgery, the goats were exercised daily until sacrifice (12 weeks). Knee joints were macroscopically and histologically assessed for meniscal regeneration and cartilage degradation. 3D microCT analysis determined changes to subchondral and trabecular bone structure in the central medial condyle. Parameters quantified were: subchondral bone thickness (Sb.Th), BV/TV, Tb.N, Tb.Th, Tb.Sp and ConnDens. Results were analyzed by ANOVA and ANCOVA (including contralateral femurs). Gross evaluation demonstrated regenerated neomeniscal tissue associated with the medial compartment in MSC treated animals. In goats injected with cells 1 week post-surgery the amount of neomeniscal tissue was significantly larger compared to knees treated with HA alone. Neomeniscal tissue sections demonstrated a dense, cellular matrix containing GFP positive cells (peripheral) positive for type I and II collagen and proteoglycan. Analysis of the cartilage on the medial femoral condyle and tibial plateau determined less degradation in cell-treated joints. Menisectomy caused thickening of the subchondral and trabecular bone in the medial femoral condyle. For the ANCOVA, the covariate was significant for Sb.Th ($p<0.002$), ConnDens ($p=0.013$), Tb.N ($p<0.005$) and Tb.Sp ($p<0.003$). The effect of MSC treatment compared to treatment with HA alone approached statistical significance for Tb.N ($p=0.066$) and Tb.Sp ($p=0.07$ ANOVA); there was no significant effect on Sb.Th. Tb.N was lower and Tb.Sp was higher in MSC-treated animals. The effect of time of administration was not significant for any parameter. Injection of allogeneic MSCs into OA joints resulted in regeneration of meniscus with concomitant chondro- and osteoprotective effects. This data suggests the therapeutic benefit of injected MSCs in the OA joint.

The Kidney and the Calcium Endocrine System of One-year-old Dahl Salt-sensitive and Salt-resistant Male Rats. S. B. Arnaud[1], S. Cephas*[2], A. De Paoli*[3], P. Sayavongsa*[2], S. Locklear*[1], M. Thierry-Palmer[2]. [1]Life Sciences Division, NASA Ames Research Center, Moffett Field, CA, USA, [2]Dept of Biochemistry, Morehouse School of Medicine, Atlanta, GA, USA, [3]Pathology, IDEXX Veterinary Services, Sacramento, CA, USA.

Dahl salt-sensitive (S) rats become hypertensive with age when fed standard rat chow (J Lab Clin Med 98:599, 1981; Biol Trace Element Res. 31:199, 1991). To determine the effect of age on the kidney and the calcium endocrine system we maintained Dahl S and salt-resistant (R) rats on standard diets (1% salt) for 12 months in vivarium cages. We then divided S and R rats into low (0.3%) and high (2%) salt diet groups and transferred them to metabolic cages for periodic urine collections 3 weeks before euthanasia. Renal histopathology, urine volume, calcium, sodium, protein, and creatinine clearance were compared in S and R rats. Plasma parathyroid hormone (PTH) concentration was assayed by ELISA, 25-hydroxyvitamin D (25-D) and 24,25-dihydroxyvitamin D (24,25-D) concentrations by protein binding assay, and 1,25-dihydroxyvitamin D (1,25-D) concentration by receptor binding assay. Renal changes in 11 S rats were characteristic of moderate to severe nephrosclerosis associated with hypertension; 14 R rats showed minimal changes consistent with the nephropathy of aging. Differences in dietary salt groups were confined to urinary sodium and 1,25-D; both higher in the high than low salt groups. Estimates of renal function revealed mean (±SD) urine volumes, calcium, and protein to be higher and creatinine clearances lower (108±41 vs. 152±33 ml/min/1/73m^2, $p<0.01$) in S compared with R rats. Salt sensitivity significantly affected total plasma calcium (2.22±0.13 vs. 2.35±0.03 nmol/L, $p=0.002$), 25-hydroxyvitamin D (6±3 vs. 27±10 nmol/L $p<0.001$), 24,25-dihydroxyvitamin D (1.4±0.7 vs. 19±15 nmol/L, $p=0.002$), and parathyroid hormone (316±94 vs 109±41 pg/mL, $p<0.001$). The modest decrease in plasma calcium, three-fold increase in PTH, low 25-D and 24,25-D but normal 1,25-D, are the principle differences in the calcium endocrine systems of aged S and R male rats. In spite of long term normal salt diets, S rats develop moderate to severe nephrosclerosis and impaired renal function with age. This is associated with changes in the calcium endocrine system of S rats that are characteristic of nutritional vitamin D deficiency. The metabolic processes that lead to apparent vitamin D deficiency remain to be elucidated.

Beneficial Impact of Calcium Supplementation on Gestational and Lactational Bone Loss: A Case Study. K. Kent[1], B. Wipfler*[2], R. Marcus[2]. [1]Musculoskeletal Research Laboratory, Stanford University and VA Medical Center Palo Alto, Menlo Park, CA, USA, [2]Stanford University, Stanford, CA, USA.

We report here the experience of a 35 year old, highly physically active, Caucasian densitometry technician with documented bone loss from spine, hip and whole body (DXA, Hologic 1000W) during each of 2 prior episodes of pregnancy and lactation. When a 3rd pregnancy was diagnosed, she increased dietary calcium to 800-1100mg/d and instituted calcium supplementation, 1500 mg/d as carbonate (ViactivTM). When this pregnancy was determined to be twins, her physician insisted she terminate all recreational exercise and also restricted her to bed rest for the last 9 weeks of gestation. BMD was measured 10d post-delivery of healthy full-term girls and again after 11 months of breast-feeding. BMD losses during the two earlier, non-supplemented, pregnancies were 10.4 and 6.8% (spine), 10% (hip), and 3.3 and 1.9% (Whole Body). Given twin pregnancy and profoundly decreased activity, even greater loss was predicted for the 3rd pregnancy. Contrary to expectation, gains in BMD of 4.1, 2.7, 4.9, and 1.5% (spine, total hip, femoral neck, Whole Body) were observed. Body weight and composition did not differ from values after the second pregnancy. After 11 months of lactation, despite continued calcium supplementation and restoration of exercise, BMD decreased by 11.6, 3.4, 5.7, and 3.6%, giving net losses of 8, 0.8, 1.1, and 2.2%. These did not differ from those of her earlier single infant delivery and lactation periods. These findings suggest that increased calcium supplementation effectively maintains BMD during pregnancy despite extraordinary fetal demands and reduced physical activity. In addition, supplemental calcium appears to have partially mitigated the increased bone loss expected from nursing two infants.

M406

Myostatin Gene Polymorphisms and Age-related Sarcopenia in the Italian Population. L. Masi[1], A. Gozzini*[1], A. M. Corsi*[2], A. Tanini[1], A. Falchetti*[1], M. L. Brandi[1], L. Ferrucci*[2]. [1]Department of Internal Medicine, University of Florence, Florence, Italy, [2]Department of Geriatric, I. N. R. C. A., Florence, Italy.

It has been hypothesized that the genetic variation of myostatin, a TGF-beta superfamily member, plays an important role in age-associated sarcopenia. Variants of the human myostatin gene have been originally reported in literature (Ferrell RE et al. Genomics 1999). Two polymorphisms of the encoding region, specifically an A to G change at codon 55 in the exon 1 (A55T) and an exon 2 (K153R), have been described. In particular, the K153R polymorphism was reported to be overrepresented in persons who did not show substantial increments in muscle mass after strength training. These findings were confirmed by Seibert MJ et al (J Am Geriatr Soc 2001), who found that older African-American women with an 153R allele tended to have low muscle strength. Using data from the InCHIANTI project, a large population-based epidemiological study of the causes and course of mobility/disability in older persons, we tested the hypothesis that myostatin polymorphisms may account for part of the variability in muscle mass and strength that is often found in older persons. From the original cohort, we selected a random sample of 450 subjects (mean age: 69.5+15.2 years, range: 22-96 years, 189 men and 261 women) and searched for myostatin gene polymorphisms. The A to G missense substitution at residue 55 in the exon 1 (A55T) was analyzed by PCR amplification followed by AluI enzymatic digestion and A to G substitution in exon 2 was studied by PCR amplification followed by direct sequencing in 120 DNA samples. Of the 450 DNA samples only two individuals showed an A55T polymorphism. Among the 120 DNA samples, analyzed for K153R variant, 6 K153R heterozygous, 1 R153R and 113 K153K homozygous individuals have been found. The presence of a 153R allele was associated with lower muscle strength (153R+: 18.8+2.2 Kg; 153R: 26.5+ 1.0 Kg; P=0.05). Our preliminary findings confirm those reported by Seibert et al. and suggest that the K153R genotype may be associated with accelerated sarcopenia. We are currently characterizing the entire InCHIANTI population for the K153R polymorphism.

M407

Association of Oral Exostosis with Higher Bone Mineral Density of Elderly Women. T. Yoda*[1], M. Yamaguchi*[1], H. Amano[2], H. Orimo[3], T. Hosoi[4]. [1]Department of Dentistry and Oral Surgery, Tokyo Metropolitan Geriatric Medical Center, Tokyo, Japan, [2]Department of Pharmacology, School of Dentistry Showa University, Tokyo, Japan, [3]Tokyo Metropolitan Geriatric Medical Center, Tokyo, Japan, [4]Endocrinolgy Section, Tokyo Metropolitan Geriatric Medical Center, Tokyo, Japan.

Osteoporosis is a systemic pathological condition, in which bone formation is overcome by bone resorption. On the other hand, oral exostosis, also prevalent in the elderly, is a disease of unknown origin and may be caused by an interplay of genetic and environmental factors. Then we hypothesized that the patients with oral exostosis may have higher bone mineral density (BMD) compared to those without exostosis. We recruited randomly the patients who visited the dental and oral surgery department of Tokyo Metropolitan Geriatric Medical Center (average age 77.5 years). We examined exostosis by a digital examination and measured the extent of elevation from the bone surface using study models. BMD of lumbar spine, femoral neck, and radius was measured by dual-energy X-ray absorptiometry (DXA, DPX-L IQ, Lunar Co.). Z score was used to analyze the data of BMD, which is a deviation from the weight-adjusted average BMD of each age. We compared the BMD in z scores between the subjects with palatal or mandibular exostosis and those without exostosis. As a result, the female subjects with palatal exostosis (n=9) had higher BMD than those without (n=24) at femoral neck (0.671+0.53 vs. 0.129+0.78, $p=0.03$) but not at lumbar spine and radius. The female subjects with mandibular exostosis (n=4) had higher lumbar spine and femoral neck BMD than those without (n=24) (1.225+ 1.15 vs.-0.529+1.01, $p=0.02$, 1.000+0.73 vs. 0.122+0.66, $p= 0.03$, respectively). On the other hand, no association was found between the presence of oral exostosis and radius BMD. There was not any association between oral exostosis and BMD measurements in male patients. Our results suggest that common mechanisms may increase the BMD of the elderly and cause oral exostosis. The effects of exostosis on BMD were restricted to the so-called loading bones, spine and femur. We speculate that the pathophysiology of oral exostosis may reflect the higher sensitivity to the mechanical stress resulting in excessive bone formation. Elucidation of the molecular mechanisms in oral exostosis would provide us a novel way for the prevention and treatment of osteoporosis.

M408

Circulating Levels of Fetal Fibronectin Correlate with the Decrease in Markers of Bone Formation in Non-Alcoholic Liver Disease. I. A. Nakchbandi, P. Feick*, A. Geursen*, M. V. Singer*. Medicine II, University of Heidelberg at Mannheim, Mannheim, Germany.

Hepatic osteodystrophy contributes significantly to the decrease in the quality of life of those affected. Previous research has established that hepatic osteodystrophy results mainly from decreased bone formation. The production of the cellular isoforms of fibronectin is markedly elevated in hepatocytes and stellate hepatic cells treated with toxins. It is known that the interaction between osteoblasts and matrix fibronectin is required for osteoblast differentiation, and that inhibitors of this interaction such as fragments encompassing the RGD sequence result in decreased osteoblast differentiation. We therefore hypothesized that an increase in cellular fibronectin (with defining domains close to the RGD sequence) in patients with autoimmune liver disease will inhibit the interaction between osteoblasts and matrix fibronectin and result in decreased osteoblast differentiation. We examined cellular fibronectin and osteocalcin in the blood of 20 patients with autoimmune liver disease without bilirubin elevation or vitamin D deficiency and compared them with 20 age-, sex-, BMI-, and menopausal age-matched controls. We found a statistically significant negative correlation between fetal fibronectin (by ELISA) and osteocalcin in the whole group as well as in the patients (all subjects: r= - 0.382, p<0.05; patients: r= - 0.488, p<0.05). We further found that circulating fetal fibronectin was elevated in patients as compared to controls albeit not statistically significantly so. (Results are expressed as Mean±SEM, patients: 4.0±0.56 ug/ml, controls: 3.0±0.22 ug/ml, p=0.14). Based on these data, we propose that the increase in fetal fibronectin production and release in the circulation directly contributes to the decrease in bone formation seen in autoimmune liver disease.

Biochemical, Densitometric and Histomorphometric Changes in an Experimental Model of Uremic Bone Disease: Possible Beneficial Effect of Bisphosphonates. S. N. Zeni[1], A. Tomat*[1], A. Gamba*[2], P. Mandalunis*[3], M. C. De Grandi*[1], J. Somoza*[1], S. Friedman*[2]. [1]Sección Osteopatías Médicas, Hospital de Clínicas, Buenos Aires, Argentina, [2]Cátedra de Bioquímica General y Bucal, Facultad de Odontología, Buenos Aires, Argentina, [3]Cátedra de Histología. Facultad de Odontología., Universidad de Buenos Aires, Buenos Aires, Argentina.

Rats with reduced renal mass are used as a model to assess pathophysiological aspects of bone metabolism in chronic renal failure. Bisphosphonates (BPs) are potent antiresorptive agents used successfully in several bone diseases associated with high bone resorption. The present experimental study was undertaken to determine changes in bone makers, bone mineral density (BMD) and histomorphometric parameters in rats with moderately impaired renal function. The effect of olpadronate (OPD) was also evaluated. Sixteen male Wistar rats, aged approximately 100 day old were 2/3 nephrectomized and divided into two groups. After 1 week (To), one group received placebo (Nx) (n=8) and the other, 16 ug OPD/100 g rat (Nx+ODP) (n=8), both, intraperitoneally once weekly for 4 weeks (Tf). A group of aged-matched SHAM rats (n=8) served as control (C). At To and Tf, BMD (Lunar DPX), blood and 24hs-urine samples were assayed. The tibia was evaluated histomorphometrically at Tf. At the end of the experimental time: serum calcium and phosphorus were significantly higher in the Nx group than in Nx+OPD and C rats; Deoxypyridinoline/Creatinine ratio (X±DS) was similar in Nx and C groups (1692±141 vs. 1661±318 nM/mM) but Nx+ODP rats attained the significantly lowest value (542±99nM/mM, p<0.0005). OPD treatment prevented the 21% decrease in tibia BMD observed in Nx rats. During the study, tibial BMD increased 8% in C group (CV=4%) compared to a 6% increase in Nx+OPD group (ns). Histomorphometrical studies showed the highest trabecular bone volume in Nx+OPD treated group. TRAP positive cell number was significantly higher in Nx compared to Nx+OPD rats (p<0.05). Conclusions: Although further consideration is necessary, bisphosphonates like ODP, may provide an attractive tool to manage high bone turnover associated to renal disease.

M410

Bone Mineral Density After Renal Transplantation: Implications For Prophylaxis. E. A. O'Shaughnessy*, D. C. Dahl*, B. L. Kasiske*, C. L. Smith. Division of Nephrology, Hennepin County Medical Center, Minneapolis, MN, USA.

Most studies showing a loss of bone density after renal transplantation have given mean values for the population. Since some have advocated giving all patients prophylactic bispohosphonates to prevent bone loss, we decided to examine individual logitudinal data to understand better the significance of universal prophylactic treatment. We examined data from 18 patients (12 men and 6 women) who received BMD studies as part of the transplant protocol. The protocol called for patients to receive a BMD within one month of transplant and again at 6 months. From April, 2000 through April, 2001 23 out of 96 patients fulfilled this protocol. Five female patients were on estrogen at the time of transplant and were excluded leaving 18 patients. All but one had been on dialysis (average 28 months) and none had had a prior transplant. The BMD at the lumbar spine (LS) and proximal femur (trochanter and femoral neck) were measured with DEXA. Osteopenia (OPe) and osteoporosis (OPo) were defined by the WHO criteria. Reproducibility in our lab is such that a 3% change at the LS and 6% at the femur are significant. At the lumbar spine baseline values showed 11 patients to be normal, 5 with OPe, and 2 with OPo. At 6 months, 9 patients (50%) had lost >3% of bone density. Five of these patients were within the normal range at baseline and remained in this category. One patient declined from OPe to OPo. Three patients increased their bone density and 6 remained stable. At the trochanter 5 patients were normal, 10 OPe, and 3 OPo. At 6 months 3 lost >6%, 1 gained and 14 remained stable. One patient changed from OPe to OPo. At the femoral neck 5 patients were normal, 13 had OPe and 0 had OPo. At 6 months 5 patients lost >6% with only one patient changing to OPo. Thirteeen patients had stable BMD. There were two fractures in this group of 18 patients and both of these could be identified as being at increased risk with the baseline study. The majority of renal transplant patients are not OPo at 6 months. An individualized approach based on baseline and followup BMD studies may be preferable to routine prophylaxis.

M411

Increased In Vitro Stimulation of Osteoblastic Cells in Non-Azotemic Nephrotic Syndrome (NS). M. Freundlich*[1], E. Alonzo*[2], E. Bellorin-Font*[2], J. R. Weisinger*[2]. [1]Department of Pediatrics, University of Miami, Miami, FL, USA, [2]Division of Nephrology, Hospital Universitario de Caracas, Caracas, Venezuela.

Diminished bone mass and altered bone histology have been reported in patients with NS even when GFR is normal. However, the osteomalacia and hyperparathyroidism noted by some investigators in adults and by us in children seldom correlate with the prevailing serum concentrations of PTH and vitamin D metabolites. Since other circulating factors affecting bone remodeling may be present in these patients, we cultured a normal human osteoblast (OB) cell line (NHost) in the presence of sera (N=27) obtained from 15 children, age 9.2±5.4 yr., with NS [urinary protein/creatinine (up/c) 4.2 ± 8.5 mg/mg, normal < 0.2] and normal GFR (127±27 ml/min/1.73 m2), and 4 normal controls. OB were incubated for 24 or 48 hours in the presence of increasing concentrations of sera (0,10 and 20%). Alkaline phosphatase (ALP) activity was determined in cell lyzates using nitrophenylphosphate as the substrate. Results are expressed as units of enzymatic activity per L per mg protein. ALP activity obtained from OB cultures in the presence of NS sera was increased when compared to OB incubated with normal control sera (11,826±13,889 vs 218±132, and 12,011±14,475 vs 764±865, for incubations with 10% and 20% serum, respectively). In 6 NS patients studied prospectively during both relapse and remission, ALP activity in remission declined by 33 ± 48% from relapse values. Furthermore, there was a significant correlation between up/c and ALP activity (r= 0.5, p<0.05) throughout both clinical stages. Treatment with corticosteroids did not affect significantly ALP activity (9,098±11,655 vs 7,085±9,94, before and during corticosteroid treatment, respectively). Neither serum bone-specific alkaline phosphatase nor osteocalcin concentrations correlated to ALP activity. Slot-blot of cell lyzates demonstrated increased RANK-L expression during relapse of the NS with decreased expression during the remission period. In summary, serum from NS patients increased human OB activity in vitro which correlates with the degree of proteinuria. These observations suggest that OB activation may play a role, independent of corticosteroids, in the pathogenesis of the bone alterations observed in patients with NS and normal GFR.

M412

Spectrum of Renal Bone Disease and Diagnostic Value of Biochemical Markers in ESRF. A. R. J. Bervoets*[1], G. Spasovski*[2], G. J. S. Behets*[1], M. E. De Broe[1], P. C. D'Haese*[1]. [1]Nephrology-Hypertension, University of Antwerp, Antwerp, Belgium, [2]Nephrology, University of Skopje, Skopje, The former Yugoslav Republic of Macedonia.

We assessed the spectrum of renal bone disease and the diagnostic value of various biochemical markers in an unselected population of 84 Macedonian patients with end-stage renal failure (ESRF) from one geographical region just before entering a dialysis programme. None of the patients took vitamin D whilst the only phosphate binder used in this population was calcium carbonate (70%). In all patients we performed a bone biopsy for histological and histodynamic examination. Bone histology was correlated with several biochemical serum markers of bone turnover. Aluminum (Al) and strontium (Sr) levels in serum and bone were not elevated. 38 % of the patients still had normal bone histology, 23 % had adynamic bone disease (ABD), 18 % manifested a mixed lesion, 12 % showed osteomalacia (OM) and only 9 % presented with hyperparathyroidism (HPTH). Patients in the group of OM tended to be older, whilst patient characteristics associated with ABD were male gender, later referral and diabetes. There was no difference in underlying renal diagnosis. Routine blood analysis and serum creatinine did not differ between groups. Significant (p<0.005) differences between groups were noted for some biochemical markers of bone turnover: intact parathyroid hormone (iPTH), total and bone alkaline phosphatase (TAP and BAP) and osteocalcin (OC). We could not find a difference for (deoxy)pyridinolines. For the diagnosis of ABD versus all other groups of ROD, OC had the best diagnostic performance showing a sensitivity of 83 % and a specificity of 68 % at a cut off value of 41.0 ng/l. By combining both these parameters the specificity could be increased up to 89 %. ABD and normal bone taken as one group versus all other types of ROD could best be detected by BAP and TAP, showing sensitivities of 72 and 88 % and specificities of 76 and 60 % at a cut off value of 25 U/l and 84 U/l respectively. As a conclusion, data of the present study show 62 % of the ESRF patients to have an abnormal bone histology before entering a dialysis programme. In the absence of Al or Sr overload the relatively high prevalence of OM is rather surprising. Although bone biopsy remains the golden standard for diagnosis of bone disease, OC, TAP and BAP can contribute to the non-invasive diagnosis of ABD/normal bone versus the other types of renal osteodystrophy.

M413

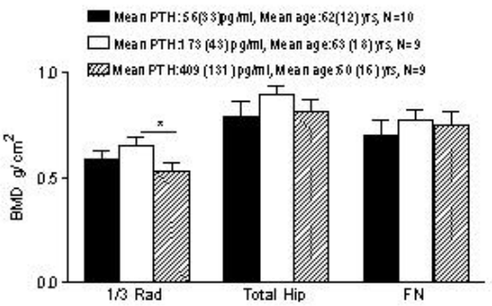
Development of Lumbar Bone Mineral Density in the Late Course Following Kidney Transplantation. V. M. Brandenburg*[1], W. J. Fassbender[2], M. Ketteler*[1], J. Floege*[1], T. H. Ittel*[1]. [1]Dept. of Nephrology, University Hospital Aachen, Aachen, Germany, [2]Medical Dept. I, Endocrinology, University Clinic Frankfurt, Frankfurt am Main, Germany.

Rapid bone loss is a frequent finding early after kidney transplantation. Only limited data are available on the bone mineral density (BMD) in long-term kidney transplant recipients. In 26 unselected kidney transplant recipients (13 men, 13 women; mean age 45.3+/-12.3 years) serum biochemical markers of bone metabolism and the BMD at the lumbar vertebrae L2-L4 were prospectively evaluated in three serial examinations (E1, E2, E3; method: dual-energy X-ray absorptiometry). Examinations were performed at 47+/-2 months (E1), 59+/-2 months (E2) and 71+/-2 months (E3) after renal transplantation. All patients received standard dual or triple immunosuppression including prednisolone (median daily dosage 7.5 mg). Over the study period the mean lumbar BMD was significantly lower ($p<0.05$) than in sex-matched young controls: T-score was -1.43+/-1.49 (E1), -1.39+/-1.40 (E2) and -1.44+/-1.30 (E3). The BMD did not change significantly from E1 to E3 (delta BMD-0.5+/-5.9%). No significant gender-related differences in BMD or delta BMD were seen. Multiple regression analysis did not show significant correlations between delta BMD and biochemical parameters or prednisolone dosage. No new lumbar vertebral fracture occurred. The mean intact parathyroid hormone (iPTH) was 110.1+/-97.5 (E1), 121.0+/-102.7 (E2) and 134.5+/-128.6 ng/l (E3). Serum creatinine (CREA) was measured as 127+/-40, 127+/-42 and 128+/-62 µmol/l. 10 patients (38.5%) showed an increase of BMD from E1 to E3 (+5.7+/-3.2%), 15 patients (57.7%) showed a decrease of -4.7+/-3.2% ($p<0.0001$). Both groups were different in T-scores at E1 (-2.29+/-1 vs. -0.88+/-1.5); iPTH, CREA, vitamin D levels or prednisolone dosage were not significantly different. Lumbar BMD is reduced in long-term kidney transplant recipients. However, during our 24 months observation period, overall lumbar BMD remained stable.

M414

Predictors of Bone Mineral Density in Patients on Hemodialysis. G. El-Hajj Fuleihan[1], D. Zayour*[1], M. Daouk*[2], W. Medawar*[2], M. Salamoun*[2]. [1]Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon, [2]American University of Beirut Medical Center, Beirut, Lebanon.

Renal osteodystrophy is a universal complication of uremia, and renal failure patients are at risk for low bone mineral density (BMD) and fractures. Parathyroid hormone (PTH) plays a pivotal role in the pathophysiology of uremic bone disease. Histomorphometric studies suggest that the maintenance of PTH levels between two -four times the upper limit of normal is associated with the least prevalence of two common forms of osteodystrophy: osteitis fibrosa cystica, and adynamic bone disease. The purpose of this study was to investigate whether the above recommendation for PTH levels in dialysis patients corresponds to a more optimal BMD, with a special emphasis on diabetic versus non-diabetic subjects. Twenty-eight patients with chronic renal failure on hemodialysis had serial measurement of PTH levels, and BMD at the lumbar spine, hip and forearm. They were divided into three groups based on a mean PTH level over two years: <120 pg/ml, 120-250 pg/ml, >250 pg/ml. A substantial proportion of patients on dialysis had osteoporosis.



Predictors of BMD were gender, duration on hemodialysis, diabetes, and PTH levels less than 120 pg/ml (12.7 pmol/L) or greater than 250 pg/ml (26.5 pmol/L). Our study therefore supports the histomorphometry-based studies suggesting that the maintenance of intact PTH levels two-four times the upper limit of normal is associated with better skeletal health in uremic patients on hemodialysis.

M415

Effects Of Sevelamer on Bone Histology in Comparison with Lanthanum Carbonate in a Chronic Renal Failure Rat Model. G. J. S. Behets*, M. Gritters*, G. Dams*, M. E. De Broe, P. C. D'Haese*. Dept. of Nephrology - Hypertension, University of Antwerp, Wilrijk, Belgium.

Both lanthanum carbonate and sevelamer (Renagel ®) have recently been proposed as new phosphate binding agents. Previous studies have shown that high La2(CO3)3 doses (1000 and 2000 mg/kg/day) may lead to a mineralisation defect in CRF rats (5/6 nephrectomy), which was suggested to be due to the induction of a phosphate depletion, in combination with a disturbed vitamin D metabolism. In the present study, the effects of La2(CO3)3 on bone are compared with those of sevelamer. Sevelamer is a non metal-containing polymeric compound, which is virtually not gastro-intestinally absorbed and thus does not accumulate in bone. Twenty-one male Wistar rats underwent a 5/6 nephrectomy and were treated with sevelamer (500 or 1000 mg/kg/day), La2(CO3)3 (1000 mg/kg/day) or vehicle only by oral gavage during 12 weeks. At sacrifice, bone histology showed the development of an impaired mineralisation in 1 of 5 (20%) of the La2(CO3)3 treated animals, and in 4 of 7 (57%) of the animals treated with sevelamer at 1000 mg/kg/day. Vehicle and sevelamer at 500 mg/kg/day did not induce any mineralisation defect. During the 12-week loading period, a clear decrease in phosphaturia was noted in all treatment groups. Animals receiving La2(CO3)3 showed a statistically decreased phosphaturia already after 2 weeks of treatment. Sevelamer showed decreased phosphaturia after resp. 4 and 6 weeks of treatment with 1000 and 500 mg/kg/day. The hypophosphaturia was observed in the absence of any hypophosphatemia. Interestingly, 1,25-(OH)2 vit D was dose-dependently reduced in the sevelamer treated animals, whilst this was not the case for the La2(CO3)3 treated group. In conclusion, these results confirm our hypothesis that the previously observed mineralisation defect after treatment with La2(CO3)3 and in the present study with sevelamer is secondary to a phosphate depletion resulting from the pharmacological actions of the phosphate binding agents, rather than being due to a direct toxic effect of these substances on bone. Further investigations on the effects of sevelamer on vitamin D and bone metabolism are needed. Furthermore, these results demonstrate that in this animal model, phosphate depletion can occur despite normal serum phosphorus levels.

M416

Importance of the Bone in Severe Absorptive Hypercalciuria. H. J. Heller, J. E. Zerwekh, C. Y. C. Pak. Center for Mineral Metabolism and Clinical Research, UT Southwestern, Dallas, TX, USA.

Absorptive hypercalciuria (AH), a stone-forming condition in which calcium is excessively absorbed from the intestine, is paradoxically associated with low bone mass. We hypothesized that in patients with severe AH, bone formation is impaired and the relative excess bone resorption contributes to hypercalciuria. Each subject without other causes of bone loss underwent bone biopsy after tetracycline labeling. They were placed on a stone-prevention diet for 3 weeks followed by baseline inpatient evaluation on a constant metabolic diet. On the same diet, provocative tests were used to probe the relative contribution of intestinal calcium absorption (sodium cellulose phosphate 5 g with meals X 3 days; S) and bone resorption (alendronate 10 mg/d X 2 weeks; A) to urinary calcium. Age ranged from 40 to 53. Bone volume and connectivity were markedly decreased and out of proportion to the osteopenia demonstrated by bone mineral densitometry. Relative to the controls, we found impaired bone formation in AH patients. Bone resorption was also lower than controls but to a lesser degree. There was no evidence of osteomalacia in AH patients. The mean decrement in urinary Ca was greater after S (-128 mg/d) than after A (-6 mg/d). However, fasting urinary Ca fell with both agents- S (-63%), A (-38%). PTH rose more with A (+58%) than with S (+12%). Intestinal calcium absorption and 1,25-(OH)2 D tended to increase with A, and bone resorption markers decreased. Thus, although 24-h urine Ca did not change with A, it appears that the greater quantity of absorbed calcium replaced some of the calcium derived from the bone. We conclude that severe AH is associated with low bone formation and that treatment with A, by reducing fasting renal calcium while increasing intestinal calcium absorption, may improve calcium balance in the short term.\

Elevated 14-3-3 Protein in Proliferating Cells of Uremic Rat Parathyroid Glands. C. S. Ritter*, S. Pande*, I. Krits*, Z. Huang*, E. Slatopolsky, A. J. Brown. Renal Division, Washington University School of Medicine, St. Louis, MO, USA.

Secondary hyperparathyroidism (2^{o}HPT) associated with chronic renal failure is characterized by hypersecretion of parathyroid hormone (PTH) and parathyroid (PT) cell hyperplasia. Control of hyperphosphatemia, the primary pathogenic factor for 2^{o}HPT, can both prevent and arrest development of the condition, but the precise cellular and molecular mechanisms of this regulation remain unclear. The 14-3-3 proteins are a family of isoforms that, through interactions with other proteins, modulate a number of cellular processes including regulation of the cell cycle and stimulation of calcium-dependent exocytosis. The involvement of 14-3-3 in these cellular functions in the PT gland is unknown. We investigated the expression of 14-3-3 in normal and hyperplastic rat PT tissue. PCR analysis of parathyroid tissue from normal rats revealed the presence of the beta, gamma, epsilon, zeta, theta and eta 14-3-3 isoforms. Gene array analysis (Clontech rat Atlas array) revealed increased 14-3-3 zeta in uremic rats fed a high phosphate diet (which promotes 2^{o}HPT) versus uremic rats fed a low phosphate diet (which prevents 2^{o}HPT). Immunohistochemical analysis using a pan-14-3-3 antibody showed that elevated levels of 14-3-3 were consistently found in the PT glands from uremic rats fed a high phosphate diet compared to normals. In addition, the 14-3-3 staining pattern in the hyperplastic PT glands was heterogeneous. Further analysis revealed that the areas of increased 14-3-3 immunostaining were associated with areas of PT cell hyperplasia (as detected by PCNA immunostaining). In conclusion, 14-3-3 gene and protein expressions were upregulated in hyperplastic parathyroid tissue in uremic rats, and up-regulation of the protein was associated with areas of cell proliferation. The exact role of 14-3-3 and control of cell proliferation, and possibly PTH hypersecretion, is currently being investigated.

M418

Hormonal Replacement Therapy in Chronic Renal Failure and Ovariectomy: Histomorphometric Study. A. Rodríguez-Rodríguez*, M. Naves*, M. Serrano*, A. González-Carcedo*, C. Díaz-Corte*, J. L. Fernández-Martín*, J. B. Cannata. Servicio de Metabolismo Óseo y Mineral, Hospital Central de Asturias, Oviedo, Spain.

The main goal of the renal osteodystrophy treatment is to control the secondary hyperparathyroidism, avoiding the induction of low-bone turnover. There are few studies focussed on the treatment of estrogens and calcitriol in postmenopausal women with chronic renal failure (CRF). The aim of this study was to compare the histomorphometric changes produced by the hormonal replacement therapy in rats with both CRF and ovariectomy. Six-month old female Sprague-Dawley rats were studied (n=31). All rats were ovariectomized and nephrectomized (7/8). One week after surgery, the rats were divided in 4 experimental groups: placebo, 17-β-estradiol at 45 mg/kg/day (E-45), calcitriol (CT) at 10 ng/Kg/day, and CT+E-45. A group of animals without any manipulation was used as control group. The rats were sacrificed after 8 weeks of treatment. All the treatment groups recovered the trabecular bone volume (BV/TV), 29.2±6.8 % vs to 15.4±5.5 % observed in the placebo group. The value of this histomorphometric parameter was in the range of the results observed in the control group. As table shows, treatment with E-45 alone, with CT alone, or with both E-45 and CT combined, decreased the osteoid surface (OS/BS). In addition, the E-45 group decreased both osteoclast surface (Oc.S/BS) and eroded surface (ES/BS). The antiresorptive effect of estrogens decreased with the addition of calcitriol. Despite dynamic studies with tetracyclines were not included in the study, the results from CT+E-45 group demonstrated the combined therapy achieved the highest bone-forming rate, similar to the control group (data not showed). They showed the highest level of osteoblasts surface (Ob.S/BS), a normal resorption rate (Oc.S/BS and ES/BS) and the lowest osteoid surface (OS/BS).

Treatment Groups	OS/BS (%)	Oc.S/BS (%)	ES/BS (%)	Ob.S/BS (%)
Placebo (n=7)	33.3 ± 7.6	18.9 ± 6.8	12,8 ± 3,1	27.6 ± 7.2
E_2-45 (n=5)	**6.7 ± 2.1[a]**	**11.4 ± 4.2[cd]**	**10,1 ± 3,3[d]**	28.0 ± 14.3
CT (n=7)	**3.8 ± 0.5[a]**	20.2 ± 4.9	13,4 ± 3,4	23.3 ± 3.0
CT+E_2-45 (n=7)	**3.3 ± 1.3[ab]**	20.0 ± 4.2	16,6 ± 2,8	**35.0 ± 9.4[c]**

[a,b,c,d] *p<0.05* with respect to placebo, E-45, CT and CT+E-45 respectively.

The histomorphometric study shows that the combination of CT+E-45 was the most effective therapy in rats with CRF and ovariectomy. The relationship between forming and resorbing parameters (some data not shown) were more equilibrated in this group of treatment. The addition of CT to E-45 seems to increase bone resorption, but at the same time it may increase bone formation enhancing osteoblast activity and mineralization.

M419

Acidosis-Induced Alteration in Bone Bicarbonate and Phosphate. D. A. Bushinsky[1], S. B. Smith*[1], J. M. Chabala*[2], K. L. Gavrilov*[2], R. Levi-Setti*[2]. [1]University of Rochester School of Medicine, Rochester, NY, USA, [2]Fermi Institute, University of Chicago, Chicago, IL, USA.

During an acute fall in systemic pH, clinically termed metabolic acidosis, there is an influx of hydrogen ions into the mineral phase of bone, which buffers the decrement in pH. We have previously shown that when bone is cultured in medium modeling metabolic acidosis, there is an influx of hydrogen ions coupled to a reduction of bone bicarbonate and phosphate. These ionic fluxes would be expected to result in buffering the excess protons and increasing the pH toward normal. We hypothesize that the surface of bone would respond to the increased concentration of hydrogen ions in a different manner than the interior of bone. In the current study we utilized a high resolution scanning ion microprobe with secondary ion mass spectroscopy to localize the changes in bone bicarbonate and phosphate and determine their relative contribution to the buffering of hydrogen ions during acute metabolic acidosis. Neonatal mouse calvariae were incubated in control medium (pH ~ 7.44, [HCO3-] ~ 27 mM) or in medium acidified by a reduction in bicarbonate concentration (pH ~ 7.14, [HCO3-] ~ 13). Compared to control, after a 3 hr incubation in acidic medium there is a 5 fold decrease in surface bicarbonate with respect to C2 (carbon-carbon bond) and a 3 fold decrease in surface bicarbonate with respect to CN (carbon-nitrogen bond) with no change in cross-sectional bicarbonate. Compared to control, after a 3 hr incubation in acidic medium there is a 10 fold decrease in cross-sectional phosphate with respect to C2 and a 10 fold decrease in cross-sectional phosphate with respect to CN with no change in surface phosphate. On the bone surface there is a 4 fold depletion of bicarbonate in relation to phosphate and in cross-section a 7 fold depletion of phosphate in relation to bicarbonate. Thus acute hydrogen ion buffering by bone involves preferential dissolution of surface bicarbonate and of cross-sectional phosphate.

CLX-0921, A Novel Thiazolidinedione Prevents Loss Of Cancellous Bone In Adjuvant Induced Arthritis (AIA) Rats. N. Lane[1], W. Yao[1], A. Burghardt*[1], S. Majumdar*[1], A. Sen*[2], C. Gross[2]. [1]Departments of Medicine and Radiology, University of California at San Francisco, San Francisco, CA, USA, [2]Calyx Therapeutics, Hayward, CA, USA.

Inflammatory arthritis results in significant peri-articular bone loss due to activation of cytokines that increase osteoclast activity. Thiazolidinediones (TZD) are insulin senstitizing agents that may inhibit TNFa production, an important factor leading to bone loss in the inflammatory arthritis. The purpose of this investigation was to determine if the CLX-0921, a TZD, and Etanercept (p55 TNF soluble receptor) would prevent bone loss in AIA rats. Arthritis was induced in male Lewis rats (Harlan, weight 150 g) by immunizing them with Freund's Complete Adjuvant containing Mycobacterium Butyricum (500ug) at the base of the tail. When the arthritic symptoms began to appear (by day 13), the animals were randomized to one of the four groups and treated from day 13-24: Group I: Sham + Vehicle (20% PEG-400 in water, p.o.), Group II: AIA + Vehicle, Group III: AIA + CLX-0921 (50 mg/kg, p.o.), Group IV: AIA + Etanercept (1.67 mg/kg, i.p.). Four joints per animal were individually scored from 0 (normal) to 4 (marked arthritis with swelling, erythemia, nodules, deformation, rigidity) by an observer blinded to the treatment groups. On day 24, AIA rats were sacrificed and the right femur + tibias harvested and the cancellous bone volume and microstructure of the proximal tibiae were accessed by MicroCT (mCT-20, Scanco Medical, Bassersdorf, Switzerland). Results: Body weights decreased 4.6% in the vehicle treated group and increased 2-4% in the CLX-0921 and Etanercept groups. Mean arthritic paw score (range 0-16) from day 13 to day 24 in the vehicle group was 1.9±0.5 to 5.9±4.2, in the CLX-0921 was 1.8±1.2 to 2.7±2.9 (p<0.02 from vehicle day 24) and in the Etanercept was 1.5±0.5 to 2.0±3.5 (p<0.01 from vehicle day 24). Cancellous bone mass and architecture changes were shown in the table. In summary, significant cancellous bone loss and microarchitecture changes occurred in AIA rats. However, in this AIA model, nearly 50% less cancellous bone was lost in animals treated with either CLX-0921 or p55 TNF soluble receptor; Etanercept. Therefore, CLX-0921 may be effective in reducing bone loss in inflammatory arthritis.

Bone Mineral Density (BMD) and Bone Biochemical Markers (BBM) in Lupus (*L*) and Control (*C*) Women (*W*) Stratified by Menopause Status. A. Bongu[1], C. Langman[2], S. Manzi*[3], S. Spies*[1], R. Ramsey-Goldman[1]. [1]Northwestern University, Chicago, IL, USA, [2]Childrens' Memorial Hospital, Chicago, IL, USA, [3]University of Pittsburgh, Pittsburgh, PA, USA.

Over the past 2 decades improved survival of *LW* lead researchers to focus on minimizing morbidity associated with disease and its treatment. Of the various complications facing *LW*, osteoporosis remains a problem. The goal of this study was to determine if BMD correlated with BBM in *LW* & *CW* matched by age +/- 4 yrs, race, and menopause status. In this cross-sectional study, data collected included: a lifestyle questionnaire and medication survey, BMD of the hip, spine, and distal forearm, urine for N-telopeptide (NTx), and blood for osteocalcin (OC), bone alkaline phosphatase (BAP). The mean age of *LW* & *CW* was 44.1yrs and 43.9 yrs respectively; the mean disease duration for *LW* was 9.7 yrs. 65 pairs were studied, of which 28 were post menopausal (PM) with a mean age of menopause in *LW* & *CW*, 41.6yrs and 44.3yrs respectively. When stratified by menopause status: BMD was lower in menstruating (M) *LW* vs. *CW* at the hip (0.913 vs. 0.940 gm/m^2) and spine (1.015 vs. 1.046 gm/m^2), and in PM *LW* vs. *CW* the BMD was lower at the spine (0.939 vs. 0.975 gm/m^2) and wrist (0.639 vs. 0.673 gm/m^2).

Median BBM in LW and CW Stratified by Menopause Status

BBM	MLW	MCW	PMLW	PMCW
NTX nM/mM	33.0	30.5	29.0	38.0
BAP U/L	13.4	13.8	17.7	19.7
OC ng/ml	7.0	6.6	6.3	7.4

There were no significant differences in median BBM between *LW* & *CW* stratified by menopause status. In PM *LW*: higher NTx correlated with lower BMD at the hip (r= -0.540, p= 0.003) and spine (r= -0.395, p= 0.038), higher BAP correlated with lower BMD at the hip (r= -0.424, p= 0.025), and wrist (r= -0.436, p= 0.029), and higher OC correlated with lower BMD at the hip (r= -0.545, p=0.003), spine (r= -0.381, p= 0.045), and wrist (r= -0.450, p= 0.024). In PM *CW*, higher NTx (r= -0.534, p= 0.005), BAP (r= -0.584, p= 0.002), and OC (r= -0.503, p= 0.009) correlated with lower BMD at one site, the wrist. In M *LW*, higher NTx correlated with lower BMD at the spine (r= -0.347, p= 0.035), and wrist (r= -0.396, p= 0.020), and higher OC correlated with lower BMD at the hip (r= -0.343, p= 0.038). Whereas, in M *CW*, only higher BAP correlated with lower BMD at the spine (r= -0.404, p= 0.012). In conclusion, there may be higher bone turnover in M & PM *LW* vs. *CW*. Thus, BBM may have a potential role in identifying *LW* at risk for low BMD and a high bone turnover state. Future studies include longitudinal follow up of subjects' to assess baseline BBM and BMD to predict subsequent BMD.

M422

The Relationship Between Osteoprotegerin (OPG) and Receptor Activator of NF-kB and Bone Mineral Density (BMD) in Lupus (L) and Control (C) Women (W). A. Bongu, S. Cole*, R. Pope*, E. Shamiyeh*, S. Spies*, R. Ramsey-Goldman. Northwestern University, Chicago, IL, USA.

In an inflammatory illness such as SLE, the balance between bone formation and bone resorption may be altered. However, the mechanisms driving the effect of the inflammatory process on bone metabolism is not clearly understood. Multiple hormones and cytokines regulate skeletal health; the final two effectors in osteoclast regulation are OPG and receptor activator of NF-κB or RANK ligand (RANK-L). The goal of this study was to determine if BMD correlated with OPG and RANK-L in LW & CW. In this cross-sectional study, all study subjects completed a lifestyle questionnaire and a medication survey; BMD was measured at the hip, spine, and distal forearm; and serum measured for OPG and RANK-L using Elisa kits from BioNet, Inc. Each Elisa sample was run in duplicate. The standard error of the mean was 2.6 for OPG and 0.81 for RANK-L. There were 146 LW and CW in which 55 LW and 45 CW women were postmenopausal (PM). The mean age of LW and CW was 41.4yrs and 41.8yrs respectively; with mean disease duration of 8.2yrs. The mean age of menopause in LW was 40.9 yrs vs. 44.0yrs in CW.

Mean BMD in LW and CW Stratified by Menopause Status

BMD Site g/m^2	M LW	M CW	PM LW	PM CW
Hip	0.911	0.953	0.872	0.882
Spine	0.999	1.051	0.953	1.006
Distal Forearm	0.687	0.695	0.649	0.679

BMD was lower at all sites in LW vs. CW regardless of menopause status but only differed significantly at the spine (p= 0.02) in menstruating (M) LW vs. CW and at the wrist (p= 0.04) in PM LW vs. CW.

Median OPG and RANK-L Levels Stratified by Menopause Status

Menopause Status	LW	CW
M OPG pg/ml	74.4	75.5
PM OPG pg/ml	93.4	78.9
M RANK-L pg/ml	6.1	4.0
PM RANK-L pg/ml	4.6	2.5

LW compared to CW had higher levels of OPG and RANK-L regardless of menopause status. OPG was significantly higher in PM LW vs. CW (P= 0.03). In M LW, higher RANK-L correlated with lower BMD at the wrist (r= -0.262, p= 0.02). Higher OPG correlated with higher BMD at the wrist in PM CW (r= 0.348, p= 0.02). In conclusion, M LW have lower BMD at the spine and PM LW have lower BMD at the wrist when compared to CW. Higher RANK-L was associated with lower BMD at wrist in M LW suggesting increased bone resorption. In contrast,higher OPG was associated with higher BMD at the wrist of PM CW, suggesting a protective effect on bone. LW are at an increased risk for osteopenia, identifying those who may benefit from prevention strategies.

M423

Fall Risk and Bone Density in Older Women with Rheumatoid Arthritis. S. Patel[1], D. Johnson*[1], H. Kaz Kaz*[1], U. Chinappen*[2], K. Tweed*[1]. [1]Department of Rheumatology, St Helier Hospital, Surrey, United Kingdom, [2]Department of Rheumatology, St George's Hospital, London, United Kingdom.

Previous studies suggest that the risk of hip fracture is doubled in patients with rheumatoid arthritis (RA). This is in part due to patients with RA having lower bone density at the hip compared to aged matched non-RA controls. However the risk of hip fracture occurring in an individual is determined by both hip bone density and the risk of falling. Although studies have been carried out of hip bone density in RA patients there are no studies of fall risk. The risk of falls may be higher in patients with RA because of lower limb joint disease, muscle weakness due to disuse and steroids. Visual acuity may also be affected in steroid treated patients due to cataract formation. The aim of this study was to determine whether fall risk was increased in women with RA and to determine high risk sub groups at risk of hip fracture. We performed a case control study examining fall risk and bone density in older women (aged > 65 yrs) with rheumatoid arthritis. The cases were recruited from a single centre treating patients with rheumatoid arthritis. The controls were women without rheumatoid arthritis or steroid use referred by their primary care physicians for bone densitometry. We recruited 99 RA patients and 198 controls matched for age to within 2 years. Cases and controls provided a history and underwent tests of falls risk previously shown to predict hip fracture. These were measurement of binocular corrected visual acuity (VA), tandem gait (EPIDOS grading) and ability to do 5 standups from a chair without arm use. Bone density was measured at the lumbar spine and femoral neck by DXA. Mean age of the patients and controls was 74 yrs (range 65 to 87). Ability to perform tandem gait normally was 39% in the controls versus only 18 % in the RA patients ($p < 0.05$), inability to perform standups was 10 % in the controls versus 32 % in the RA patients ($p < 0.05$). However VA was similar in the two groups. RA patients with poor functional status and high tender joint counts were more likely to have impairment of tandem gait and inability to perform standups. The prevalence of FN osteoporosis was 24 %, FN osteoporosis and abnormal tandem gait was 13 %, FN osteoporosis and inability to do standups 16 %, FN osteoporosis and VA < 0.5 was 7 %. These data suggest that fall risk is increased in women with RA, and is a major contributor to the increased risk of hip fracture associated with RA. Management of osteoporosis in patients with RA should include assessment of fall risk as well as drug treatment for osteoporosis.

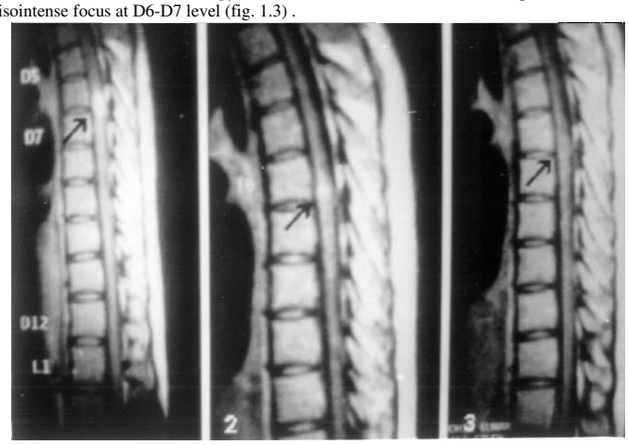
Intramedullary Spinal Tuberculoma - A Case Report. M. Garg*, S. Singh*. Orthopaedics, B.P.Koirala Institute Of Health Sciences, Dharan, Nepal.

Intramedullary tuberculoma is a rare form of central nervous system tuberculosis. A case report of intramedullary spinal tuberculoma detected on magnetic resonance imaging (MRI) is presented. Excellent results were obtained on medical therapy aloneconfirmed by MRI normalization. **Introduction :** Intramedullary spinal tuberculoma is an extremely rare disease entity. Early detection might help in reducing the morbidity associated with this benign and curable lesion. We present a case a intramedullary spinal tuberculoma detected on MRI and treated by antitubercular chemotherapy alone. **Case report :** A 18-year-old girl with no family history of tuberculosis presented with bilateral lower extremity weakness and numbness and bladder incontinence for the past two months. Neurologic examination revealed paraparesis (grade 3) with hyperactive deep tendon reflexes, positive Babinski sign and no clonus. There was sensory deficit to pin prick and light touch below D8 level with loss of superficial lower abdominal reflexes. Laboratory investigations revealed elevated ESR. X-rays of the chest, dorsal and dorso lumbar spine were normal. MRI of the dorsal spine revealed a ring enhancing intramedullary mass at D6 - D7 level with focal cord enlargement and oedema(fig.1.1) .A cerebrospinal fluid (CSF) analysis showed an elevated protein level of 100mg/dl glucose level of 40 mg/dl. Red blood cell count of $8/mm^3$ and white blood cell count of $18/mm^3$ (15 % polymorphs, 85% monocytes). CSF acid - fast bacillistains were positive and cultures grew M. tuberculosis. The lesion was diagnosed as an intramedullary tuberculoma. The patient was started on antitubercular chemotherapy with isoniazid, rifampicin, ethambutol and pyrazinamide. At three months follow-up, the neurologic improvement was satisfactory. The ATT (Isoniazid and rifampicin) was continued for another 15 months. At five months follow-up, patient showed significant neurologic improvement. Repeat MRI of the dorsal spine showed significant reduction in the size of the lesion with modular enhancement and minimal focal cord enlargement (fig. 1.2) . There was complete neurologic recovery after fourteen months of antitubercular therapy and MRI revealed small nonenhancing intramedullary isointense focus at D6-D7 level (fig. 1.3) .



M425

Acceleration of Autoimmune Arthritis in MRL/*lpr* Mice Transferred with RANKL-stimulated Dendritic Cells. T. Izawa*[1], K. Moriyama[1], Y. Hayashi*[2]. [1]Department of Orthodontics, School of Dentistry, University of Tokushima, Tokushima, Japan, [2]Department of Pathology, School of Dentistry, University of Tokushima, Tokushima, Japan.

Receptor activator of NF-kB ligand (RANKL) is a regulator of the immune system and of bone development. In vitro, RANKL promotes the survival of mature dendritic cells (DCs), and induces the production of proinflammatory cytokines, such as IL-1 and IL-6, and cytokines that stimulate and induce differentiation of T cells. The aim of this study was to analyze the effect of transfer of DCs stimulated with RANKL on the development of autoimmune arthropathy in MRL/*lpr* mice, and to evaluate the possible relationship between RANKL-mediated osteoclastogenesis. (Methods) Freshly isolated bone marrow cells were stimulated with IL-4 and GM-CSF for seven days and induced differentiation into DC (BMDC) by further stimulation of RANKL and type II collagen (CII) for three days. BMDC ($1x10^6$) activated with RANKL were subcutaneously injected into inguinal region. The mice were sacrificed after eight weeks and were histopathologically examined. We further analyzed various factors including surface markers on T cells, proliferation assay, anti-CII antibody, rheumatoid factors (RF), cytokine production, and osteoclast activation. (Results and Discussion) Acceleration of autoimmne arthritis accompanied by bone destruction of knee was observed in DC-transferred mice compared with age-matched controls. We detected an significant increase in T cells bearing memory type and DCs expressing MHC class II ($I\text{-}A^k$). In addition, an increased osteoclast formation, and the bone resorption pits cultured from bone marrow cells were observed in DC-transferred mice, suggesting that RANKL induce osteoclast formation by direct activation of osteoclast progenitors. These results indicate that RANKL pathway play a crucial role on acceleration of autoimmune arthropathy for promoting DCs and activation of osteoclastogenesis in a murine model for RA.

Uni-Axial Cyclic Stretch Induces Core Binding Factor Alpha 1 (Cbfa1) in Spinal Ligament Cells Derived from Patients with Ossification of the Posterior Longitudinal Ligament. K. Iwasaki*[1], K. Furukawa*[2], M. Tanno*[1], T. Kusumi*[3], K. Ueyama*[4], S. Harata*[5], S. Motomura*[2], S. Toh*[1]. [1]Orthopaedic Surgery, Hirosaki University School of Medicine, Hirosaki, Japan, [2]Pharmacology, Hirosaki University School of Medicine, Hirosaki, Japan, [3]Second Department of Pathology, Hirosaki University School of Medicine, Hirosaki, Japan, [4]Orthopaedic Surgery, Hirosaki Memorial Hospital, Hirosaki, Japan, [5]Orthopaedic Surgery, Aomori Prefectural Central Hospital, Aomori, Japan.

Ossification of the posterior longitudinal ligament of the spine (OPLL) is characterized by ectopic bone formation in the spinal ligaments. In some cases ossification enlarges in the spinal canal and compresses the spinal cord resulting in serious neurological damage. Mechanical stress, which acts on the posterior ligaments, is thought to be an important factor in the progression of OPLL. To elucidate this mechanism, we investigated the effects of in vitro cyclic stretch (120% peak to peak, at 1 Hz) on cultured spinal ligament cells derived from OPLL (OPLL cells) and non-OPLL (non-OPLL cells) patients. The mRNA expressions of type I collagen, alkaline phosphatase (ALP) and core binding factor alpha 1 (Cbfa1), an osteoblast- specific transcription factor, were increased by cyclic stretch in OPLL cells, whereas no change was observed in non-OPLL cells. The effects of cyclic stretch on the spinal ligament tissues derived from OPLL and non-OPLL patients were also analyzed by immunohistochemistry using an antibody against Cbfa1. The expression of Cbfa1 was increased by cyclic stretch at both the center and the enthesis of the spinal ligament tissues of OPLL patients, whereas no change was observed in tissues of non-OPLL patients. These results suggest that the mechanical stress which acts on the spinal ligaments or spinal ligament cells plays an important role in the progression of OPLL through an increase in Cbfa1 expression.

M427

Association of Analgesic Effects of the Bisphosphonate Zoledronic Acid with Its Anti-Osteoclast and Anti-Inflammatory Action. M. Nagae*, T. Hiraga, K. Iwata*, T. Yoneda. Dept Biochemistry and Oral Physiology, Osaka Univ Grad Sch Dent, Osaka, Japan.

Bone pain is one of the major causes of increased morbidity in patients with bone disorders including osteoporosis and skeletal metastasis. Although the mechanism of bone pain is totally unknown, large bodies of clinical studies have reported that bisphosphonates (BPs), which are potent and specific inhibitors of osteoclasts, have significant analgesic effects on bone pain. Moreover, it has been recently reported that osteoprotegerin, which is another specific inhibitor of osteoclasts, suppresses tumor-induced bone pain. These results raise the possibility that BP decreases bone pain by its anti-osteoclast action. To test this notion, we established an animal model in which a subcutaneous injection of complete Freund's adjuvant (CFA) into the hind paw of ddY mice induced inflammatory hyperalgesia with increased osteoclastic bone resorption in underlying bone. One day after the CFA injection, mice received either a bolus intravenous or intrathecal injection of or an orthotopic subcutaneous administration of the BP zoledronic acid (ZOL) (2.5, 25, 250, 2,500μg/kg). The analgesic effects of ZOL were evaluated by measuring paw withdrawal latency in response to thermal stimuli using the electronic clock circuit and a microcomputer. The intravenous and subcutaneous injection of ZOL significantly reduced the CFA-induced hyperalgesia in a dose-dependent manner, whereas the intrathecal administration of ZOL showed no effects, suggesting that the effects of ZOL are peripheral rather than central. No effects of ZOL were observed in the untreated right hind paws in the same animals. Histological examination revealed that ZOL inhibited CFA-induced bone resorption with reduced TRAP-positive osteoclasts and increased apoptotic osteoclasts. We next conducted the hind paw withdrawal experiments in c-src-deficient mice which had osteoclast dysfunction. We found that the CFA-induced hyperalgesia was significantly impaired in conjunction with reduced bone resorption in these c-src-deficient mice compared with wild-type mice. Since the CFA-induced hyperalgesia is primarily caused by local inflammatory reactions, we next examined whether ZOL exhibited anti-inflammatory effects. We found that a bolus intravenous injection of ZOL significantly suppressed CFA-enhanced vascular permeability determined by Evans Blue dye extravasation test to a similar extent with indomethacin. In summary, our data show that ZOL suppresses CFA-induced hyperalgesia, bone resorption and local inflammatory reactions. These results suggest that analgesic effects of ZOL on bone pain are associated with its anti-osteoclastic and anti- inflammatory actions.

Risedronate Conserves Periarticular Bone and Ligament Mechanical Properties in Early Osteoarthritis. M. R. Doschak*, G. R. Wohl*, D. A. Hanley, R. C. Bray*, R. F. Zernicke. McCaig Centre for Joint Injury and Arthritis Research, University of Calgary, Calgary, AB, Canada.

Periarticular loss of bone mineral density (BMD) early after anterior cruciate ligament (ACL) rupture in the knee has been well documented. The influence of periarticular BMD loss on joint function and osteoarthritic progression, however, has yet to be determined. The purpose of this study was to assess in an osteoarthritis (OA) model whether antiresorptive therapy altered periarticular bone and collateral ligament biomechanics and OA progression. We surgically transected the ACL in two groups of 15 rabbits. The first group was dosed (0.01 mg/kg s.c.) daily with Risedronate, a commercially available bisphosphonate (BP) for 6 wk. The second group was untreated for 6 wk and served as age-matched ACL-transected (ACLX) controls. A third group of 10 age-matched, normal (unoperated) controls was also evaluated. We measured distal femoral BMD (Dual Energy X-ray Absorptiometry: DEXA), medial collateral ligament (MCL) laxity, and bone mechanical function (bone cores mechanically tested in compression) 6 wk after ACLX. We also examined (micro computed tomography) bone mineral changes at the distal femoral insertion of the MCL. These measures were compared to cartilage/joint gross morphology and histology for evidence of early OA. The University of Calgary Animal Care Committee approved all procedures. BMD by DEXA in 6 wk ACLX animals was 18% less than normal controls ($p<0.01$). BP dosing conserved BMD; Risedronate-treated rabbits had distal femoral BMD only 5% less than normal controls. When the same bone cores were compressed to failure, both ACLX and BP-dosed animals were significantly weaker than normal controls ($p<0.05$). Blocking bone resorption with BP did not reduce capsular thickening or inflammatory angiogenesis, which were elevated in both untreated and BP-treated ACLX joints compared with normal controls ($p<0.05$). However, MCL-complex laxity was significantly less in BP-dosed animals (1.2 times that of normal controls) compared to untreated ACLX animals (1.7 times that of normal controls; $p<0.05$). Early loss of periarticular bone mineral after ACLX included significant loss at the MCL insertion ($p<0.02$). The loss of MCL insertional bone was less with BP dosing and was similar to normal control animals. Thus, compared to the untreated ACLX condition, administering BP immediately after ACL damage conserved periarticular bone and collateral ligament-bone properties in an early OA model.

Bone Mineral Density in Rheumatoid Arthritis: Disease Related Variables Associated with Low Bone Mineral Density. M. C. Lodder*[1], Z. de Jong*[2], P. J. Kostense*[3], E. T. H. Molenaar*[1], K. Staal*[4], A. E. Voskuijl*[1], J. M. W. Hazes*[5], B. A. C. Dijkmans*[1], W. F. Lems[1]. [1]Rheumatology, VU University Medical Center, Amsterdam, Netherlands, [2]Rheumatology, LUMC, Leiden, Netherlands, [3]Clinical Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, Netherlands, [4]Endocrinology, VU University Medical Center, Amsterdam, Netherlands, [5]Rheumatology, University Hospital, Rotterdam, Netherlands.

To examine the frequency of osteoporosis and variables associated with bone mineral density (BMD) in patients with rheumatoid arthritis (RA). 373 patients participating in 2 research projects were investigated. The first project was the RAPIT trial, a study after the effect of frequent weight-bearing exercise versus usual care. The second project concerned a cohort of patients in clinical remission. Demographic and clinical data were collected and bone mineral density (BMD) was measured by means of dual X-ray absorptiometry (DEXA). Associations between demographic and clinical measures on the one hand and BMD on the other were investigated in single and multiple regression analyses. The mean age (standard deviation (SD)) of the patients was 54 (12) years. 77% were female of whom 73% were premenopausal. The median (range) disease duration was 7 (1-50) years, 66% was rheumatoid factor positive. 83% never used corticosteroids. The median Larsen score of hands and feet, reflecting radiographic joint damage, was 27 (0-155). The mean BMD at the spine (L1-4) was 0.99 (0.16) g/cm2, at the femoral neck the BMD was 0.78 (0.13) g/cm2. 7 % of the patients had osteoporosis of the hip and 13 % osteoporosis of the spine (T score $\leq$ -2.5 SD). High age, female sex, and low BMI are related to low BMD at the hip and spine. Participation in the RAPIT trial and a high Larsen score were significantly associated with low BMD at the hip. Data on BMD in patients with RA are presented, demonstrating an association between radiological RA damage and low BMD at the hip.

M430

Amino-terminal and Mid-molecule PTHrP Peptides Stimulate Lung Phosphatidylcholine after Silica Injury. R. H. Hastings[1], R. A. Quintana*[1], R. Sandoval*[1], Y. Rascon*[1], D. W. Burton[2], L. J. Deftos[2]. [1]Anesthesiology, VA San Diego, San Diego, CA, USA, [2]Endocrinology, VA San Diego, San Diego, CA, USA.

PTHrP 1-34 stimulates synthesis and secretion of phosphatidylcholine, the major lipid in pulmonary surfactant, by cultured alveolar type II epithelial cells. This study investigated whether PTHrP regulates lung phosphatidylcholine levels in silicosis, an injury state marked by profound alveolar phospholipidosis. Silica lung injury was produced by intratracheal instillation of 10 mg Min-U-Sil silica in PBS per rat with or without 15 μg PTHrP peptide (1-34, 38-64, 67-86 or 107-138). Animals also received daily subcutaneous injections of 5 μg of the same peptide. Bronchoalveolar lavage liquid (BAL) phospholipids were extracted after four days and measured by phosphorus assay or TLC. Studies were approved by the IACUC. Type II cell proliferation was assessed by proliferating cell nuclear antigen (PCNA) immunostaining and type II cell numbers were evaluated after alkaline phosphatase or surfactant apoprotein C staining. In additional rats, lung PTHrP expression was assessed by immunostaining at 7, 14 and 28 days after silica. Primary cultures of rat type II cells were assayed for the effects of PTHrP peptides and neutralizing PTHrP antibodies on incorporation of tritiated choline into phosphatidylcholine. cAMP levels with and without PTHrP treatment were assayed by ELISA and inositol phosphate production was measured by incorporation of tritiated myo-inositol. The PTHrP 1-34 and PTHrP 67-86 treatment groups demonstrated a two-fold increase in BAL phosphatidylcholine compared to no treatment in silica-injured rat lung ($P < 0.05$). Other peptides had no effect. PCNA immunoreactivity and numbers of alkaline phosphatase positive cells did not increase after PTHrP 1-34 or 67-86 treatments. In cultured type II cells, PTHrP 67-86 caused a dose dependent increase in phosphatidylcholine synthesis, while PTHrP antibodies caused a significant 50% decrease in phospholipid production. PTHrP 1-34 and PTHrP 67-86 significantly stimulated cAMP and inositol phosphate levels by about 50%. PTHrP 67-86 immunoreactivity fell in silica injured lungs seven days after injury, but rebounded and surpassed baseline levels at 14 and 28 days, coinciding with the period of maximum alveolar phospholipidosis. Thus, increased PTHrP levels at 14-28 days may contribute to the phospholipid accumulation with silica injury. These data indicate that exogenous and endogenous PTHrP 1-34 and 67-86 stimulate phosphatidylcholine production and that PTHrP 67-86 may act through an as yet unrecognized G-protein coupled receptor in alveolar type II cells.

M431

Inhibition of Metastasis in Melanoma Following Targeted Disruption of the PTHrP Gene: Enhanced Visualization of the Invasion Process with Green Fluorescent Protein. D. C. Huang, R. Kremer. Medicine, Royal Victoria Hospital, Mcgill University, Montreal, PQ, Canada.

Tumoral production of parathyroid hormone-related peptide (PTHrP) is frequently elevated in advanced metastatic cancer associated with hypercalcemia. However, there is yet no direct evidence of PTHrP role in tumor invasion and metastasis. In this study we used a highly metastatic cancer cell line, the human amelanotic melanoma cell line A375, which expresses high levels of PTHrP (Abdaimi *et al.*, *Am J Physiol Cell Physiol* 279: C1230-C1238, 2000) and metastasizes to liver, lung, lymph nodes and bone. In order to evaluate the role if any of PTHrP in invasion and metastasis we inactivated both alleles of the PTHrP gene by targeted disruption and compared the metastatic potential of the knockout (KO A375) cell line to its parent cell line transfected with the vector alone (WT A375). To precisely determine the time course and the extent of the metastatic process, green fluorescent protein (GFP) transduced KO A375 and WT A375 cells were implanted into the left ventricle of nude mice. Mice were sacrificed at timed intervals and disseminated tumor cells expressing GFP were visualized by fluorescence microscopy. Survival and tumor progression was determined by histology and high sensitivity X-ray analysis of bone osteolytic lesions. Metastasis was visualized on a single cell basis by GFP expression and the kinetic of tumor cell dissemination demonstrated that trafficking of tumor cells via blood and lymph vessels was substantially reduced in animals injected with KO A375 cells. Furthermore the total number of metastasis and the % of animals with metastasis in each organ analyzed was drastically reduced in nude mice receiving KO A375 as compared to WT A375 cells (lung 4/14 vs 12/14, $p<0.01$; liver 5/14 vs 10/14, $p<0.01$; lymph node 3/14 vs 10/14, $p<0.05$ and bone 4/14 vs 9/14, $p<0.05$). Kaplan-Meier analysis revealed a highly significant survival benefit in nude mice injected with KO A375 cells as compared to WT A375 cells. Overall, our study provides the first direct evidence that PTHrP plays a major role in tumor invasion and metastasis and suggests that agents aimed at suppressing PTHrP may be beneficial in advanced metastatic cancer.

M432

Stability of Parathyroid Hormone-Related Protein mRNA Isoforms and its Regulation by TGF-beta. R. S. Sellers*[1], A. I. Luchin*[1], H. Iguchi*[2], T. J. Rosol[1]. [1]Veterinary Biosciences, The Ohio State University, Columbus, OH, USA, [2]National Kyushu Cancer Center, Fukuoka, Japan.

Humoral hypercalcemia of malignancy (HHM) is one of the most frequently occurring paraneoplastic syndromes and results in muscle weakness, cardiac arrhythmias, bone loss, and life-threatening renal failure. Parathyroid hormone-related protein (PTHrP) is the primary mediator of HHM. Alternative splicing at the 3'-end of PTHrP mRNA results in three different mRNA isoforms that encode three different peptides. These isoforms share the majority of the coding region, but differ in the 3'-end of the coding region and have completely different 3'-untranslated regions (UTRs). The 1-139 and 1-141 isoforms are relatively unstable, with half-lives ranging from 90 to 120 min and 45 to 90 min, respectively. The 1-173 isoform is much more stable with a half-life of 4 hr or more. It was previously reported that PTHrP mRNA is stabilized by TGF-beta, which may be an important determinant for the ability of cancer to induce hypercalcemia. The effect of TGF-beta on the stability of separate PTHrP mRNA isoforms has not been well studied. We utilized an in vitro mRNA stability assay containing cell extracts and radiolabeled PTHrP mRNAs to show that the half-life of the 1-141 isoform was increased 2-3-fold by TGF-beta- from 45 to 90 min in a canine oral squamous carcinoma cell line (SCC2/88) and from 90 min to 4.5 hr in a human lung squamous carcinoma cell line (HARA). TGF-beta, however, had no detectable effect on the stability of the 1-139 and 1-173 isoforms of PTHrP mRNA. The differences can most likely be attributed to different regulatory elements present in the 3'-UTRs of PTHrP mRNA. We also attempted to address the mechanism of stabilization of 1-141 isoform by TGF-beta. We previously reported the binding of the three unknown proteins, p27, p31 and p33 to the coding region of PTHrP mRNA in the canine SCC2/88 cell line. This binding was significantly reduced by TGF-beta (Sellers et al., Molecular and Cellular Endocrinology, 2002). We observed binding of the proteins to PTHrP mRNA with similar mobility in human HARA and HeLa cells lines. In addition, we observed binding of the three proteins (35-25 kDa) in S35-labeled cytoplasmic extracts from HARA cells. In conclusion, we demonstrated the selective regulation of stability of different isoforms of PTHrP mRNA by TGF-beta. This is most likely to be due to a different regulatory elements present in the 3'UTRs of PTHrP mRNA. We also identified three proteins that are possibly involved in the regulation of the stability of the PTHrP 1-141 isoform by TGF-beta.

Parathyroid Hormone-related Protein (PTHrP) Regulatory Interactions with Cytokines and Chemokine Receptor Expression in Pancreatic Cancer Cell Lines. M. Bouvet[1], R. Nassirpour*[1], O. A. Ahmadpour*[2], D. W. Burton[2], L. J. Deftos[2]. [1]Surgery, University of California and Department of Veterans Affairs, San Diego, CA, USA, [2]Medicine, University of California and Department of Veterans Affairs, San Diego, CA, USA.

PTHrP regulates the function and growth of many normal and malignant tissues, notably breast and prostate cancer. These growth-regulating effects are mediated by cytokines. For example, IL-6 (Interleukin-6) and IL-8 regulate cancer growth by angiogenic activity and growth-promoting effects. We have demonstrated regulatory interactions of PTHrP and cytokine expression in growth regulation of prostate cancer and pancreatic cancer. Recently, chemokine receptors, especially CCR-7, have been implicated in breast cancer metastasis, a PTHrP dependent process. Therefore, we sought to investigate the functional relationship of PTHrP, cytokines and chemokines in pancreatic cancer. Eight human pancreatic cancer cell lines demonstrated constitutive expression of PTHrP and IL-8, and 4 of the lines also showed expression of IL-6. We investigated the effect of PTHrP 1-34, PTHrP 67-86, PTHrP 107-138, PTHrP 140-173, and PTHrP140-173 scrambled (negative control) synthetic peptides on the production of IL-6 and IL-8 by pancreatic carcinoma cells and correlated PTHrP expression with chemokine receptor levels. The pancreatic cell lines were treated with each of these different PTHrP peptides at 1, 10, and 100 nM concentrations. After 48 hours of incubation, the media were collected and immunoassayed for IL-8 and IL-6. PTHrP 1-34 significantly stimulated IL-8 secretion in BxPC-3 pancreatic cell line in a dose-dependent manner. However, PTHrP140-173 inhibited the secretion of IL-8 in BxPC-3. In 50% of the pancreatic cell lines that secrete IL-6, PTHrP140-173 had inhibitory effects and in 75% of the cells, PTHrP1-34 stimulated IL-6 secretion. PTHrP 67-86 and 107-138 exhibited mostly inhibitory effects on IL-6 and IL-8 secretion. Differential expression of the chemokine receptors in pancreatic cancer cells was noted by RT-PCR. For example, MIA PaCa-2, a high expressing PTHrP cell line, also highly expressed the chemokine receptor CCR-7. In contrast, PANC 28, a low PTHrP expressor, had a lower relative expression of CCR-7 than MIA PaCa-2. These results establish a regulatory pathway among PTHrP, cytokine expression, and chemokine receptor activity in pancreatic cancer. These pathways serve to extend the growth regulatory effects of PTHrP from prostate and breast cancer to tumors of the pancreas. Further characterization of these molecular interactions can help to elucidate the regulatory pathways that PTHrP utilizes in mediating cell growth.

M434

Parathyroid Hormone Related Protein (PTHrP) Production in the Lamprey Geotria Australis: Developmental and Evolutionary Perspectives. M. K. Trivett*[1], I. C. Potter*[2], G. Power*[2], D. L. Macmillan*[3], T. J. Martin[1], J. A. Danks[1]. [1]St Vincent's Institute of Medical Research, Fitzroy, Australia, [2]School of Biological and Environmental Sciences, Murdoch University, Murdoch, Australia, [3]Department of Zoology, University of Melbourne, Parkville, Australia.

Parathyroid hormone-related protein (PTHrP) is a mediator of humoral hypercalcemia of malignancy in humans. It has been previously demonstrated in the tissues and circulation of both bony and cartilaginous fish. The origins of these jawed vertebrates, lies somewhere among the extinct jawless fish. The lampreys and hagfish, collectively called cyclostomes, are the only representatives of this group that survive today. This study examined the distribution of PTHrP antigen and mRNA in jawless fish. The animals used were the Southern Hemisphere lamprey, Geotria australis. This species which undergoes a radical metamorphosis to produce a juvenile adult that migrates downstream to the sea. The adult ultimately re-enters the rivers and migrates back upstream to spawning areas The tissue distribution of PTHrP was examined in larval lampreys, downstream migrants and upstream migrants. The different developmental stages were examined for the presence of PTHrP, by immunohistochemistry using antisera to human PTHrP (1-14). Positive and negative controls were included in each assay and all samples were assayed in duplicate. Sites of PTHrP mRNA production were demonstrated by in situ hybridization with a digoxigenin labeled riboprobe to Exon VI of the human PTHrP gene. A panel of positive and negative controls were included in every experiment. The results revealed widespread distribution of the PTHrP antigen and its mRNA in sites similar to those described in mammalian and avian species. In addition, novel sites of localization were demonstrated, such as in the gill and notochord. Some differences in PTHrP localization were noted between animals in different stages of the lamprey life cycle, indicating that the distribution of parathyroid hormone-related protein, and possibly its roles, change with the stage of development in this species. The widespread distribution of PTHrP in Geotria australis implies that parathyroid hormone-related protein may have diverse physiological roles in this animal. The presence of PTHrP in the lamprey, a representative of the oldest group of vertebrates, suggests that parathyroid hormone-related protein is of ancient origin.

M435

PTHrP Regulates Expression of DNA Repair Genes and Modulates Apoptotic Response. N. Ilievska*, R. J. Thomas*, T. J. Martin, M. T. Gillespie. St. Vincent's Institute of Medical Research, Melbourne, Australia.

Parathyroid hormone-related protein (PTHrP) is widely expressed in breast tumors and its production promotes osteolysis in bone. In addition, PTHrP affects cellular functions including differentiation, proliferation and apoptosis. To determine the potential roles of PTHrP within breast cancer cells, we have examined the effect of overexpressing PTHrP in the MDA-MB-231 and MCF7 cell lines. The growth rate, cell cycle parameters apoptosis rate and changes in gene expression were assessed in the PTHrP overproducing cells with respect to the parental cells. PTHrP overproduction had no demonstrable effect on cellular proliferation or cell cycle profiles. However, an enhancement of UV-induced apoptosis was noted in cells overexpressing PTHrP; this contrasts to previous reports that establish PTHrP to diminish apoptosis. To determine which genes altered their expression in response to PTHrP, we used differential display of mRNA comparing the mRNA fingerprints of overexpressing cells relative to the parental. Several candidate PTHrP-regulated genes were identified then subsequently confirmed by Northern analysis or RT-PCR. PTHrP was found to regulate genes involved with DNA repair (XPG, BRCA1, BRCA2 and Rad51), cell cycle (p21 and p53), and apoptosis-related genes such as Bcl-2: each is a UV-induced gene. PTHrP peptides (107-111 or 107-139 at 100 nM) encompassing osteostatin (TRSAW: 107-111) upregulated the expression of mRNA levels for these genes within 4 to 24 hrs in MCF-7 or MCF-10A cells, and changes were also noted in protein levels. A mutant form of osteostatin (PRSAW) or PTHrP peptides 1-34, 1-108, 106-139 or 122-139 did not effect mRNA or protein levels for these target genes. To determine the signal transduction pathway(s) involved in osteostatin-induced regulation of DNA repair genes, MCF-10A cells were treated with the NFkB inhibitor (N-acetyl-L-cystine), PKA inhibitor (H89) or PKC inhibitor (chelerythrine chloride) with and without TRSAW (100nM). Of these three inhibitors, only H89 was able to block the effects of TRSAW on DNA repair or cell

cycle genes. In contrast, N-acetyl-L-cystine blocked osteostatin induction of Bcl-2 implicating NFkB signaling for this action. Finally, since PTHrP and these DNA repair genes may attain nuclear / nucleolar localisation, the subcellular distribution of PTHrP and BRCA1 were analysed by green fluorescent protein constructs or by immunohistochemistry using confocal studies which identified that PTHrP and BRCA1 colocalised within the nucleolus. These studies indicate a potential role for PTHrP in DNA repair.

M436

Role of Cell Cycle Factors in Regulating Chondrocyte Proliferation, and Mediating PTHrP Action, *In Vivo*. H. E. MacLean, C. J. Paller*, H. M. Kronenberg. Endocrine Unit, Massachusetts General Hospital/Harvard Medical School, Boston, MA, USA.

We are investigating the role of positive and negative cell cycle factors in regulating chondrocyte proliferation and mediating PTHrP action during embryonic mouse development. We have previously shown that *in vivo*, absence of the cyclin dependent kinase (cdk) inhibitor (CKI) p57, or the Rb-related pocket proteins p107 and p130, causes increased chondrocyte proliferation and delayed differentiation; and loss of p57, or p107 and p130, also normalizes the PTHrP-null chondrocyte phenotype in the ulna, ribs, sternum and vertebrae. We have performed Western analysis on crude protein lysates from limbs of E18.5 wild-type and p57-null embryos, and observe increased levels of the hyper-phosphorylated form of p130 in the p57-null samples, consistent with loss of p57 causing increased cdk activity. This finding is currently being confirmed by using collagen-II-GFP expressing mice to isolate pure chondrocyte populations. We have examined the role of other cell cycle regulators during embryonic chondrocyte development, using *in situ* hybridization and immunohistochemistry. p21 and p27 mRNA and protein are expressed at very low levels in hypertrophic chondrocytes, and levels are unchanged in p57-null and PTHrP-null embryos. At E15.5 – E18.5, p21-null long bones are phenotypically normal, and p21/p57 double knockouts are indistinguishable from p57 single knockouts, suggesting p21 plays little role in regulating chondrocyte cell cycle exit during development. Cyclin D1 mRNA and protein are virtually undetectable in chondrocytes pre-natally, whereas cyclin D2 and D3 proteins are expressed widely in both proliferative and hypertrophic chondrocytes. Cyclin A protein is expressed in only a sub-set of chondrocytes in the proliferative zone. There is an increased percentage of cyclin A-positive chondrocytes in both p57 knockout and p107/p130 double knockout embryos, consistent with the elevated proliferation observed in these bones. There was no detectable difference in the levels of cyclin A, D1, D2 or D3 protein in PTHrP-null long bones compared to wild-type, suggesting little regulation of these factors by PTHrP *in vivo* during embryonic development. We examined the bone morphology and chondrocyte proliferation *in vivo* from cyclin D1-null embryos at E18.5. At this developmental stage, bones are morphologically normal, and chondrocyte proliferation rate is normal, indicating that in late embryonic stages, absence of cyclin D1 has no effect on chondrocyte function. We are currently investigating the potential redundancy of D-type cyclins in chondrocyte development.

M437

Altered Set-Point for Calcium-Stimulated Calcitonin Release in Calcium Sensing Receptor Gene-Ablated Mice. N. J. Fudge*, L. L. Chafe*, C. S. Kovacs. Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF, Canada.

The calcium sensing receptor (CaR) regulates serum calcium by suppressing parathyroid hormone; it also regulates renal tubular calcium excretion. Inactivating mutations of CaR raise serum calcium and reduce urine calcium excretion. Apart from parathyroids and kidney tubules, thyroid C-cells (which make calcitonin) also express CaR. Consequently, CaR might regulate calcitonin synthesis and secretion by C-cells. Since calcium stimulates release of calcitonin, the higher blood calcium caused by inactivation of CaR should increase serum calcitonin, unless CaR mutations alter the responsiveness of calcitonin to calcium. To demonstrate regulatory effects of CaR on calcitonin physiologically, we studied calcitonin responsiveness to calcium challenge in CaR ablated mice. In this model, heterozygous (het) mice have hypercalcemia and hypocalciuria, and live normal life spans. Homozygous (null) mice have severe hypercalcemia and die within three weeks of birth. Since fetal and neonatal mice were too small for the proposed studies, the comparisons were made between wild-type (wt) and het adults. 20 wt and 20 het mice, all first degree relatives, were studied. Ionized calcium was measured. Each mouse then received 500 µmol/kg injection of elemental calcium or an equal volume (500 µl) of normal saline. After 10 minutes, ionized calcium and serum calcitonin were measured. In wt, ionized calcium was 1.28 ± 0.02 mmol/l and rose to 1.34 ± 0.02 mmol/l after calcium ($p<0.02$). In het, ionized calcium was 1.45 ± 0.02 mmol/l and rose to 1.52 ± 0.02 mmol/l after calcium ($p<0.02$). In wt and het, ionized calcium was unchanged by saline. In wt, calcitonin was 13.3 pg/ml and rose to 41.2 ± 17.8 following calcium ($p<0.008$). In het, calcitonin was 11.2 pg/ml and rose to 60.0 ± 17.8 pg/ml following calcium ($p<0.003$). The peak responses of wt and het were not significantly different. Wt and het mice had the same calcitonin level at baseline, and similar peak calcitonin responses, despite a significantly higher blood calcium in het vs wt both before and after calcium injection. Calcitonin levels of het were consistently lower than predicted by their higher ionized calcium. Moreover, wt mice achieved a calcitonin level of 41.2 pg/ml at an ionized calcium level of 1.34 mmol/l, significantly higher ($p<0.002$) than the calcitonin level (11.2 pg/ml) of het mice at a higher baseline ionized calcium of 1.45 mmol/l. These results indicate that the sensitivity for calcitonin release in response to calcium is shifted to the right in het mice, resulting in lower calcitonin concentrations than expected. This confirms that the CaR is a physiological regulator of calcitonin.

Two Novel Mutations in the Calcium-Sensing Receptor Gene in Familial Hypocalciuric Hypercalcemia and Neonatal Severe Hyperparathyroidism. L. D'Souza-Li[1], M. B. D. Silva*[2], M. T. Grande*[2], D. Carvalho*[2], G. Guerra*[3]. [1]Center for Investigation in Pediatrics, State University of Campinas, Campinas, Brazil, [2]Boldrini Children´s Hematological Investigation Center, Campinas, Brazil, [3]Department of Pediatrics, State University of Campinas, Campinas, Brazil.

Neonatal severe hyperparathyroidism (NSHPT) is a rare disorder. In many cases, homozygous inactivating mutations of the calcium-sensing receptor (CASR) gene have been identified. Most heterozygous are clinically asymptomatic but manifest as familial hypocalciuric hypercalcemia (FHH). We report a 10-year old girl who presented with progressive growth of a mass in left maxilla. During the neonatal period, the child's hypotonia, failure to thrive and poor feeding were attributed to congenital toxoplasmosis. The child evolved with bone deformities, rachitic changes, mental retardation, intestinal obstipation and malnourishment. Physical evaluation revealed a wheelchair bound child with 11 kg, with a mass on the left maxilla and on the right knee. In the course of investigation, the biochemical profile showed serum Ca^{++} 18.3 mg/dl, ionized Ca^{++} 2.79 mmol/L, renal calcium clearance 0.0004, Phosphorus 2.04 mg/dl, Mg^{++} 3.37 mg/dl, serum alkaline phosphatase 2,268 IU/L and PTH 671 pg/ml. Several calcifications in pancreatic region and multiple osteolytic lesions on the metaphysis and the diaphysis of left tibia, right femur, left humerus were seen on radiographic images. The cranial CT showed multiple intracranial calcifications and an expansive mass eroding the left maxilla measuring 6.5 x 5.5 x 6.1 cm and invading the nasal and oral cavity, the maxillary sinus, ethmoid bone and the left orbital plate. Biopsy of the tumor was compatible with brown tumor. There is no consanguinity in the family. Serum Ca^{++} is normal in the mother (9.4 mg/dl) and above the higher limit in the father (10,7 mg/dl) with calcium clearance < 0.01. Sequencing of the CASR gene revealed a novel heterozygous point mutation c.1913.G>T [R638L] and also a silent mutation c.2244.C>G in the DNA from the proband and the mother. These mutations were not present in the DNA sample from the father. Due to the severe clinical manifestation in the child, she is probably a compound heterozygous and we are currently searching for another mutation in the father's and in the proband´s DNA samples. This is the first family with mutations in the CASR gene described in Brazil. Common associated factors contributed to the delay in the diagnosis and the irreparable damage to the patient.

M439

Severe Hypercalcemia in a 9-year-old Brazilian Girl Due to a Novel Inactivating Mutation (L13P) of the Calcium Sensing Receptor. K. Miyashiro*[1], T. D. Manna*[2], H. M. Filho*[2], H. Kuperman*[2], D. Damiani*[2], O. M. Hauache[1]. [1]Laboratório de Endocrinologia Molecular, Escola Paulista de Medicina - UNIFESP, São Paulo, Brazil, [2]Unidade de Endocrinologia Pediátrica, Instituto da Crianca - FMUSP, São paulo, Brazil.

Familial hypocalciuric hypercalcemia (FHH) and neonatal severe hyperparathyroidism (NSHPT) are consequent to inactivating mutations of the calcium sensing receptor (CaR) gene. FHH is usually associated with heterozygous inactivating mutations of the CaR gene, whereas NSHPT is usually due to homozygous inactivation of the CaR gene. FHH is generally asymptomatic and is characterized by mild to moderate hypercalcemia, relative hypocalciuria and normal intact PTH. In this study, we report a novel mutation (L13P) in the exon 2 of the CaR gene, identified in a Brazilian patient. The proband was a 9-year-old girl born to consanguineous parents who came to our attention complaining of severe headaches and vomits that started 6 months ago. Laboratorial evaluation revealed hypercalcemia [total calcium:14.1 mg/dL (reference values: 8.2-10.2 mg/dL); ionized calcium: 2.1mmol/L (reference values:1.12-1.32 mmol/L], hypophosphatemia [P: 2.1 mg/dL (reference values: 2.6-6.0 mg/dL)], intact PTH levels varied between 50-110 pg/mL (reference values: 11-62 pg/mL) and relative hypocalciuria (calcium to creatinine clearance ratio = 0.0042). Total parathyroidectomy was performed and revealed parathyroid hyperplasia. Direct sequencing of the CaR gene from this patient showed a novel homozygous mutation (L13P) in exon 2. In this context, nucleotide sequence analysis identified a T → C point mutation at nucleotide 38, resulting in the conversion of CTC (leucine) to CCC (proline) at codon 13 of the CaR gene. This mutation was confirmed by restriction endonuclease analysis using the enzyme *Ban* I. The T → C transition creates a *Ban* I restriction enzyme site (G↓GCACC) so that in the mutant sequence, the digestion results in 2 products of 189 and 61 base pairs (bp). The proband´s parents, who had mild asymptomatic hypercalcemia, showed the same mutation in the heterozygous form. The mutation described in this study is the inactivating missense mutation which is present at the most N-terminal end among the known CaR missense mutations. This study reinforces the fact that patients with homozygous inactivation of the CaR gene may present with severe hypercalcemia in different phases of life.

NF-kappaB Mediates Transcriptional Up-regulation of the Human Calcium-Sensing Receptor Gene by Interleukin-1beta and Tumor Necrosis Factor-alpha. L. Canaff, G. N. Hendy. Medicine, McGill University, Montreal, PQ, Canada.

The calcium-sensing receptor (CASR), expressed in parathyroid gland and kidney tubule, is essential for maintenance of calcium homeostasis. Transcription of the human CASR gene is driven by two promoters (P1 and P2) yielding transcripts having alternative 5' untranslated regions, but encoding the same receptor protein. We have characterized functional vitamin D responsive elements in both promoters (Endocrine Society Meeting, 2002), but other cis-acting elements remain to be identified. Hypocalcemia is common in critically ill patients although the underlying causes are not known. Circulating pro-inflammatory cytokines are increased in such patients, interleukin-1β (IL-1β) increases CASR mRNA levels in cultured bovine parathyroid fragments, and following burn injury in sheep the expression of the parathyroid gland CASR is increased. This would reduce the set-point for PTH suppression by extracellular calcium likely leading to the observed hypocalcemia and hypoparathyroidism. We have investigated whether pro-inflammatory cytokines, via NF-κB activation, upregulate transcription of the CASR gene thereby providing a mechanism for the above observations. Human CASR promoter/luciferase reporter gene constructs were transfected into human proximal tubule kidney (HKC) cells. IL-1β or tumor necrosis factor-α (TNF-α) (5 ng/ml) stimulated transcriptional activity of both P1 and P2 promoters 2-fold over basal. Several potential NF-κB responsive elements are in the human CASR gene promoters. One is in promoter P1, one in exon 1A, one in promoter P2, and one in exon 2. Cotransfection of CASR promoter/luciferase gene constructs with exogenous NF-κB proteins into HKC cells led to increased transcriptional activity with p65 only and the p50/p65 combination but not with p50 only. This is fully consistent with the p65/p65 homodimer and p50/p65 heterodimer being transcriptionally active whereas p50/p50 homodimers are not. Co-transfection with inhibitor I-κB abrogated the responsiveness of the CASR gene promoters to cytokines and exogenous NF-κB proteins. In electrophoretic mobility shift assay with in vitro transcribed/translated p50 and p65, complexes comprising p65/p65 homodimers and to a lesser extent p50/p65 heterodimers, formed on three of the putative NF-κB elements in the following order of intensity, exon 1A>P2>exon2. In conclusion, NF-κB elements in the CASR gene promoters mediate transcriptional up-regulation to pro-inflammatory cytokines. This is likely to contribute, in part, to the hypocalcemia in critically ill patients.

CASRdb, Calcium Sensing Receptor Locus-Specific Database for Mutations Causing Familial (Benign) Hypocalciuric Hypercalcemia, Neonatal Severe Hyperparathyroidism and Autosomal Dominant Hypocalcemia. S. Pidasheva*[1], L. D'Souza-Li*[1], D. E. C. Cole*[2], G. N. Hendy[1]. [1]McGill University, Montreal, PQ, Canada, [2]University of Toronto, Toronto, ON, Canada.

Familial hypocalciuric hypercalcemia (FHH) is caused by heterozygous loss-of-function mutations in CASR, in which the lifelong hypercalcemia is generally asymptomatic. Affected individuals from some FHH kindreds may experience pancreatitis, gallstones or chondrocalcinosis. Homozygous loss-of-function CASR mutations manifest as neonatal severe hyperparathyroidism (NSHPT), a rare disorder characterized by extreme hypercalcemia and the bony changes of hyperparathyroidism which occur in infancy. Activating mutations in the CASR gene have been identified in several families previously diagnosed with autosomal dominant hypocalcemia (ADH), autosomal dominant hypoparathyroidism, or hypocalcemic hypercalcemia. ADH affected individuals may have mild hypocalcemia, and relatively few symptoms. Seizures can occur, especially in younger patients, and these often happen during febrile episodes due to intercurrent infection. Parathesias, tetany and laryngospasm - other symptoms of hypocalcemia - are uncommon. The human CASR gene was cloned in 1993 and so far 80 naturally occurring mutations in it have been published. To have a better understanding of the mutations causing defects in the CASR gene and to define specific regions relevant for ligand receptor interaction and other receptor functions, the data on mutations was collected and the information was centralized in the CASRdb (http://data.mch.mcgill.ca/casrdb). It is easily and quickly accessible by search engine in several Internet servers for search and retrieval of specific information. The information can be searched by mutation, genotype/phenotype, clinical data, *in vitro* analyses and authors of published mutations. CASRdb is regularly updated for new mutations and it also provides a mutation submission form to insure up to date information. The home page of this database provides links to different web pages, which are relevant to the CASR, as well as disease clinical pages, sequence of the CASR gene exons, and position of mutations in the CASR. The CASRdb will help to better understand and analyze the mutations, and aid in structure-function analyses.

Functional Characterization of a Novel CaR Missense Mutation in an Italian Kindred with Familial Hypocalciuric Hypercalcemia. F. Cetani[1], E. Pardi*[1], S. Borsari*[1], E. Morabito*[1], G. Dipollina*[2], A. Pinchera*[1], C. Marcocci[1]. [1]Dipartimento di Endocrinologia & Metabolismo, Università di Pisa, Pisa, Italy, [2]Dipartimento di Endocrinologia e Metabolismo, Università di Pisa, Pisa, Italy.

We describe two unrelated Italian kindreds with familial hypocalciuric hypercalcemia (FHH), an autosomal dominant disease mostly caused by heterozygous inactivating mutations of the Ca^{2+} receptor (CaR). In the proband of family A direct sequencing of the entire coding region of the CaR revealed a novel heterozygous Y218C missense mutation in exon 4. The same mutation was identified in the affected, but not in the unaffected family members, and in any of the 50 unrelated Italian controls. Transient expression of the Y218C CaR in COS-7 cells revealed a blunted Ca^{2+}-evoked accumulation of inositol triphoshates, indicating that the Y218C is a loss-of-function mutation. Cotransfection experiments showed that the mutant receptor had no impact on the function of the wild type receptor, suggesting that a reduced expression of the normal CaR, rather than a dominant negative effect, account for the functional impairment. In the proband of Family B an already described heterozygous P55L missense mutation in exon 2 of the CaR gene was found. The same mutation was identified in the affected family members. In conclusion, we described the two FHH kindreds with loss-of- function mutations of the CaR gene and identified a novel heterozygous mutation (Y218C) characterized by a blunted response to Ca^{2+} stimulation compared to the WT receptor and no interference with the function of the WT CaR.

L-Amino Acids promote Ca2+-sensing Receptor Activity and Inhibit PTH Secretion from Human Parathyroid Cells. A. D. Conigrave*[1], L. Delbridge*[2], E. M. Brown[3], S. J. Quinn*[3]. [1]School of Molecular and Microbial Biosciences, University of Sydney, Sydney, Australia, [2]Department of Surgery, Royal North Shore Hospital, St Leonards, NSW, Australia, [3]Endocrine-Hypertension Division, Brigham and Womens Hospital, Boston, MA, USA.

We previously demonstrated that L-amino acids are allosteric activators of the human calcium-sensing receptor (CaR) stably expressed in HEK-293 cells (1,2). These data led to the prediction that aromatic and aliphatic, but not branch chain or basic L-amino acids, would activate parathyroid CaRs and acutely suppress PTH secretion. In the current study, CaR activation was assessed in collagenase-dispersed normal and adenomatous human parathyroid cells. CaR-induced intracellular Ca2+ mobilization was assessed in fura-2 loaded cells exposed to the CaR agonists Ca2+ and spermine in the presence or absence of L- or D-amino acids. PTH secretion was determined from separate parathyroid cell incubations (37 °C, 30 min) and, after storage of samples at –80 °C, intact PTH was measured using an autoanalyser. We confirmed that the aromatic amino acids L-Phe, L-Trp and the aliphatic amino acid L-Ala (0.3 – 10 mM), but not L-Leu, L-Ile or L-Arg stereoselectively activated parathyroid CaRs in the presence, but not the absence, of submaximal concentrations of the CaR agonists Ca2+ or spermine. Furthermore, active amino acids left-shifted the concentration-dependence curves for both Ca2+ and spermine. Similar behavior was observed in normal and adenomatous cells, however, the responses exhibited greater sensitivity in normal parathyroid cells. In addition, L-Phe stereoselectively inhibited intact PTH secretion from normal and adenomatous cells in acute 30 min incubations at 37 °C. This effect exhibited a leftward shift in the extracellular Ca2+ concentration dependence at lower amino acid concentrations (<= 3 mM) and a suppression of baseline PTH secretion at higher amino acid concentrations (10 mM). Acute activation of parathyroid CaRs by aromatic and aliphatic L-amino acids may contribute to the phenomena of high protein diet induced hypercalciuria (3) and/or low protein diet induced secondary hyperparathyroidism (4,5) in humans.

Calcium-Sensing Receptor Stimulates PTHrP Secretion by PKC Dependent p38 Pathway. J. Tfelt-Hansen*, R. J. MacLeod*, N. Chattopadhyay*, E. M. Brown. Endocrine-Hypertesion Division and Membrane Biology Program, Brigham and Women's Hospital, Boston, MA, USA.

PTHrP is the main mediator of Humoral Hypercalcemia of Malignancy (HHM).The xenotransplantable rat leydig cell cancer, H-500, is a well established model for HHM. Previously, we showed that activating the calcium-sensing receptor (CaR) increases PTHrP secretion from these cells. We show CaR activation upregulates PTHrP transcripts assessed by Northern analysis, because elevated extracellular calcium (Ca2+o) (8.0 mM) upregulated PTHrP mRNAs within 6 h. In order to understand the signaling mechanisms underlying the CaR-mediated increase in PTHrP secretion, we studied the involvement of various MAP kinase (MAPK) pathways by using specific pharmacological inhibitors. We found that a pan-PKC inhibitor, GF109203X (1 uM), inhibited PTHrP secretion in response to high Ca2+o (8 mM) by 30% of the control value while having no effect on basal (Ca2+o = 0.5 mM) PTHrP secretion. A similar pattern of inhibition was observed using the p38 MAPK inhibitor, SB-203580 (10 uM). Both PKC and p38 MAPK inhibitors together had no additive effect on the inhibition of PTHrP secretion in response to high Ca2+o, suggesting PKC-dependent activation of p38 MAPK by the CaR. In this study SB203580 and GF109203X inhibited high Ca2+o-stimulated PTHrP secretion by 67% of control, but had no effect on basal PTHrP secretion. Furthermore, we observed 77% and 63% attenuation of PTHrP secretion in response to 8 mM Ca2+o by the MEK inhibitor PD098059 (10 uM) and the JNK inhibitor, SP-625 (20 uM), respectively. However, basal PTHrP secretion was inhibited 49% and 61%, respectively, by these two inhibitors. Therefore, our data show that although PKC-dependent activation of p38 MAPK is the major mediator of CaR-stimulated PTHrP secretion, involvement of ERK1/2 and JNK pathways can not be overruled. Given the availability of the p38 MAPK inhibitor for in vivo use, these results may impact the therapeutic strategies available for treatment of HHM.

M445

$1,25(OH)_2D_3$ Regulates PKC via Two PLA_2-dependent Pathways: Lysophospholipid and PLC-beta v. Arachidonic Acid and PGE_2. V. L. Sylvia, Z. Schwartz, D. Shaked*, R. R. Hardin*, D. D. Dean, B. D. Boyan. Orthopaedics, The University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Phospholipid metabolism is critical to the regulation of protein kinase C (PKC) and PKC-dependent chondrocyte differentiation by $1\alpha,25\text{-}(OH)_2D_3$ (1,25). 1,25 causes rapid changes in arachidonic acid (AA) turnover and metabolism, as well as production of inositol 1,4,5-trisphosphate (IP3) and diacylglycerol (DAG) in chondrocytes from the prehypertrophic and upper hypertrophic zones of the costochondral cartilage growth plate. This implicates phospholipase A_2 (PLA_2) and phospholipase C (PLC) in the mechanism of PKC activation. Here, we examined if PLC-dependent PKC is regulated via PLA_2 in costochondral chondrocytes and determined which isoform of PLC is involved. 1,25 (10^{-10}-10^{-8}M) stimulated PLC and PKC activity in a dose-dependent manner. Increases were observed within 0.5 min and peak activity was at 9 min. $1\beta,25(OH)_2D_3$, $24R,25(OH)_2D_3$ and $24S,25(OH)_2D_3$ had no effect on either enzyme, demonstrating the specificity of the response. Activation of PLA_2 by mastoparan increased both PLC and PKC and inhibition of PLA_2 by quinacrine blocked the effect of 1,25 on both enzymes. However, AA and its metabolite PGE_2 only affected PKC. Moreover, PGE_2 (EP) receptor agonists only affected PKC. This suggests that lysophospholipid may mediate the PLA_2-dependent effect on PLC. To test this, cells were treated with lysophosphatidylcholine (LPC) and lysophosphatidylethanolamine (LPE), both of which activated PLC and augmented the effects of 1,25. The effects of PLA_2 stimulation on PLC and PKC, and of AA and PGE_2 on PKC were mediated by Gq protein. GDPβS blocked basal and 1,25-stimulated PLC and PKC, whereas the Gi inhibitor pertussis toxin did not. RT-PCR showed that the cells express PLC-β1a, PLC-β1b, PLC-β3 and PLC-γ1 isoforms. Antibodies to PLC-β1 and PLC-β3 blocked the stimulatory effect of 1,25 on PLC activity whereas antibodies to PLC-δ and PLC-γ had no effect. These results indicate that 1,25 regulates costochondral chondrocytes via two parallel membrane-mediated pathways. One pathway is through PLA_2-dependent production of lysophospholipid, activation of PLC, and DAG-dependent activation of PKC. The other is via PLA_2-dependent production of AA and PGE_2, which then activate PKC.

M446

Comparative Effects of Repletion with Calcium or Calcitriol in Chronically Hypocalcemic Vitamin D Depleted Rats on Bone Formation and Resorption Parameters. N. Dion, C. Deschênes*, G. Mailhot*, M. Gascon-Barré, L. G. Ste-Marie. Hôpital Saint-Luc, CHUM Research Centre, Montréal, PQ, Canada.

Adequate dietary intake of vitamin D (D) and calcium (Ca) are essential to ensure normal bone formation, mineralization and growth. To study the role of Ca and calcitriol (CT) in bone metabolism, non-rachitic rats with severe hypocalcemia secondary to D and Ca depletions (Ca-D-) were subjected to repletion protocols containing either a high dietary Ca content (Ca+) for 14 d or physiological i.p. concentrations of calcitriol (CT+) for 7 d or 14 d. Ca-D- rats matched for age and weight were also studied. Normocalcemic rats paired for weight served as controls (C). Histomorphometric measurements were performed on trabecular bone at the secondary spongiosa of proximal tibiae. Structural parameters (BV/TV, Tb.Th, Tb.Sp, Tb.N) were found to be similar in all groups. Ca-D- rats showed hyperosteoidosis (OV/BV $p<0.05$; OS/BS $p<0.01$; O.Th $p<0.001$) when compared to C. Although no tetracycline labeling (TL) was observed in the metaphysis, a few were seen in the epiphysis suggesting that some mineralization occurred in this group. Repletion with CT+ induced at 7d and 14d a significant normalization of static bone formation parameters to a level similar to that of C. The presence of linear TL confirmed ongoing mineralization but, at a slower rate than C as indicated by the absence of double TL. Moreover, in CT+14d rats, there was a significant reduction of the bone resorption parameter, ES/BS, compared to Ca-D- and C ($p<0.05$ and $p<0.001$, respectively). In addition, CT+14d showed a significant reduction of osteoclast number (N.Oc/B.Pm)compared to C. These changes in bone resorption parameters were dependent on time exposure as CT+7d rats were not significantly different from Ca-D- and C groups. In contrast, Ca+ rats tended to have lower static bone formation parameters than Ca-D- although they were found to be higher than in CT+ and C groups. Absence of well defined TL confirmed a severe mineralization defect despite the normalization of serum Ca and secondary hyperparathyroidism. Significant widening of the growth plate in Ca+ rats ($p<0.001$ compared to all groups) was mainly due to higher hypertrophic chondrocytes with intense alkaline phosphatase activity. The data indicate that chronic Ca and D depletions in the rat induces hyperosteoidosis with some impairment of bone mineralization. Calcitriol repletion alone induces normalization of bone formation and mineralization allowing bone recovery after Ca and D depletion diet. Despite normalization of serum Ca and reduction of trabecular osteoidosis, Ca+ repletion induces hypophosphatemia leading to the development of rickets and severe impairment of bone mineralization.

M447

NfκB Suppression of VDR Transactivation Is not due to Competition for p160 Nuclear Proteins. X. Lu*[1], H. W. Sepp*[1], X. He*[1], P. Farmer[2], J. Rubin[1], M. S. Nanes[1]. [1]Division of Endocrinology, Department of Medicine, Emory University and VAMC, Atlanta, GA, USA, [2]Department of Pathology, Emory University, Atlanta, GA, USA.

Vitamin D-stimulated gene transcription requires binding of a liganded VDR to DNA and assembly of a protein complex that modifies histone and activates RNA Polymerase II. The modification of histone may occur by acetylation (HA) or de-acetylation (HDAC). Multiple nuclear proteins participate in transcriptional activation, including the p160 co-activators CBP/p300 and also SRC-1, which contain intrinsic HA activity. We have previously shown that vitamin D-stimulated transcription is suppressed by the inflammatory cytokine TNF-α and that the suppression of VDR activity is due to activation of the transcription factor NfκB. Furthermore, NfκB suppression of VDR can be localized to the p65 subunit of NfκB. To determine if NfκB-p65 suppressed VDR transactivation by stimulating a histone de-acetylase (HDAC), ROS 17/2.8 cells were transiently transfected with a VDRE-luciferase reporter and treated with 1,25(OH)2D3 (vitD) in the presence or absence of the HDAC inhibitors trichostatin A (TCA) or sodium butyrate (NaBut). Forced expression of p65 inhibited vitD-stimulated transcription >90%, as expected. Treatment with either TCA or NaBut alone increased vitD-stimulated transcription but failed to prevent the p65 inhibition. These results showed that p65 did not suppress VDR function by activation of a HDAC and suggested that p65 may compete for HA or other accessory proteins. To determine if p65 competed with the VDR or RXR for binding to CBP or SRC-1, GST-VDR or GST-RXR fusion proteins were used in pull-down assay with in vitro translated 35S-CBP or 35S-SRC-1. 35S-CBP failed to bind VDR or RXR with or without their cognate ligands (vitD or 9-cisRA). VitD stimulated binding of the VDR to SRC-1 and this interaction was enhanced by addition of RXR. However, the addition of in vitro translated p65 failed to block VDR (or RXR) interaction with SRC-1. Additionally, in vitD-treated ROS 17/2.8 cells, p65 inhibition of the VDRE-luciferase reporter activity was not reversed by forced expression of CBP or SRC-1. These results suggest that NfκB suppression of VDR function is not due to competition for the p160 coactivators. NfκB may act on other accessory proteins, pre-initiation factors, or RNA Polymerase itself to inhibit vitamin D action.

M448

Regulation of CaT1 and ECaC1 mRNA Levels by Calcitriol in the Duodenum and Kidney of Mice. Y. Song*, J. C. Fleet. Interdepartmental Program in Nutrition, Purdue University, West Lafayette, IN, USA.

The calcium channels ECaC1 and ECaC2 (i.e. CaT1) have been proposed to play a role in calcium (Ca) transport in duodenum and kidney but their regulation has not been systematically studied in whole animals. Here we examined the regulation of CaT1 and ECaC1 mRNA levels by diet and calcitriol injection in mice. Calbindin D_{9k} (CaBP9k) mRNA was examined for comparison. Animals were raised on chow diet until 90 days of age. In study I, mice were fed a normal Ca (0.5% Ca, AIN76A base), high Ca (2% Ca), or low Ca diet (0.02% Ca) for 7 days. At day 97, duodenal scraping and kidney were harvested for mRNA analysis, and duodenal Ca absorption was measured by in *situ* ligated loops (2 mM Ca, 10 min incubation). Plasma calcitriol levels were decreased 83% on the high Ca diet, and increased 81% on the low Ca diet; duodenal Ca absorption was strongly correlated with plasma calcitriol levels (r^2=0.8). Duodenal CaBP9k, CaT1 and ECaC1 mRNA levels were reflective of changes in serum calcitriol and correlated with Ca absorption. Duodenal CaBP9k, CaT1 and ECaC1 mRNA were significantly decreased by 56%, 87% and 66% on the high Ca diet, and increased 120%, 100% and 160% on the low Ca diet, respectively. Renal CaBP9k mRNA was decreased by 53% on the high Ca diet and increased 50% on the low Ca diet while renal CaT1 and ECaC1 mRNA were not affected by diet. In study II, mice were given a 0.8% strontium diet for 7 days (to reduce serum calcitriol), injected with calcitriol (200 ng/100g body weight, s.c.), and tissues were harvested at 0, 1, 3, 6, and 16 hours after injection. The pattern of regulation was different among the genes in duodenum and kidney suggesting distinct regulatory mechanisms. Duodenal CaT1 and ECaC1 mRNA accumulation was rapid (peak induction of 12X and 11X at 3 h, respectively) and suggests transcriptional regulation. CaBP9k mRNA was gradually increased along the time course in duodenum (6X at 16 h) and kidney (3X at 16 h). Renal CaT1 and ECaC1 mRNA peaked at 6 hours (2X) and maintained this level to 16 h. This suggests that the renal CaT1 and ECaC1 as well as duodenal and renal CaBP9k mRNA levels may be regulated post-transcriptionally (e.g. by mRNA stabilization). In conclusion, our data show that CaT1 and ECaC1 mRNA levels are strongly regulated by calcitriol in vivo but that the mechanism of regulation is different in duodenum and kidney.

M449

Down-Regulation of the Gene for the cAMP-Dependent Protein Kinase Inhibitor: Requirement for the VDR and Analysis of the Promoter Region. B. Holmquist, R. Zielinski*, H. Shah*, H. L. Henry. Biochemistry, University of California, Riverside, CA, USA.

The seco-steroid hormone 1α,25-dihydroxyvitamin D_3 (1α,25$(OH)_2D_3$) is the major biologically active metabolite of vitamin D. The primary mechanism by which 1α,25$(OH)_2D_3$ generates biological responses is alteration of the expression of target genes through binding of the ligand-activated vitamin D receptor (VDR). These changes can be regulated both tissue-specifically and developmentally. Ligand activated VDR has been shown to increase gene transcription through binding as a heterodimer with the 9-cis retinoic acid receptor (RXR) to a vitamin D response element (VDRE) in the promoter region of 1α,25$(OH)_2D_3$ targeted genes. We have studied the tissue-specific regulation by 1α,25$(OH)_2D_3$ of the endogenous inhibitor of cyclic AMP-dependent protein kinase (PKI) in chick kidney. Treatment with 1α,25$(OH)_2D_3$ decreases PKI activity in primary cultures of chick kidney cells and also decreases steady state levels of chick kidney PKI mRNA both in vivo and in cell culture. In the present studies, we show by quantitative competitive RT-PCR that in the mouse, in which three separately encoded forms of PKI, designated α, β, and γ, have been identified, it is PKIα that is down-regulated by 1α,25$(OH)_2D_3$ in the kidney. Furthermore, down-regulation of PKIα does not occur in mice genetically homozygous for the absence of the VDR, providing confirmation that this is a VDR-mediated process. To further study the molecular mechanism of transcriptional repression of the PKIα gene, the chick genomic clone was obtained through library screening with the PKI cDNA. A putative negative VDRE (nVDRE) was found in the PKI promoter sequence within 50 bp of the TATA box along with an unusually large (363nt) 5'-untranslated region. We have established a functional assay for 1α,25$(OH)_2D_3$ –mediated down-regulation of this promoter region using various constructs of the PKI promoter linked to the secreted alkaline phosphatase (SEAP) reporter. Plasmid constructs were transiently transfected into primary cultures of chicken kidney cells and exposed to either 1α,25$(OH)_2D_3$ or vehicle. Using this assay we have found that the 5'-untranslated region is essential for reporter gene expression. Down-regulation of reporter expression by 1α,25$(OH)_2D_3$, which is consistently to approximately 50% of control levels, requires the 105bp immediately upstream of the transcription start site. Further analysis will focus on the relative contributions of sequence and position of this nVDRE to effective down-regulation of PKIα.

M450

1,25(OH)2-vitamin D3 Activates Muscle Cell PLC gamma through the Tyrosine Kinase c-Src and PI3-quinase. C. Buitrago*[1], V. Gonzalez Pardo*[1], A. Russo de Boland*[2]. [1]Dept. Biologia, Bioquimica & Farmacia, Universidad Nacional del Sur, Bahia Blanca, Argentina, [2]Biologia, Bioquimica & Farmacia, Universidad Nacional del Sur, Bahia Blanca, Argentina.

We have previously demonstrated that the steroid hormone 1α,25(OH)2-vitamin D3 [1α,25(OH)2D3] stimulates the production of inositol trisphosphate (IP3), the breackdown product of PIP2 by phospholipase C (PI-PLC), and activates the cytosolic tyrosine kinase c-Src in skeletal muscle cells. In the present study we examined whether 1α,25(OH)2D3 induces the phosphorylation and membrane translocation of PLCgamma and the mechanism involved in this isozyme activation. We found that the steroid hormone triggers a significant phosphorylation on tyrosine residues of PLC gamma and induces a rapid increase in membrane-associated PLC gamma immunoreactivity with a time course that correlates with that of phosphorylation in muscle cells. Genistein, a tyrosine kinase inhibitor, blocked the phosphorylation of PLCgamma. Inhibition of 1α,25(OH)2D3 -induced c-Src activity by its specific inhibitor PP1 or muscle cell transfection with an antisense oligodeoxynucleotide directed against c-Src mRNA, prevented hormone stimulation of PLCgamma tyrosine phosphorylation. The isozyme phosphorylation is also blocked by both wortmannin and LY294002, two structurally different inhibitors of phosphatidyl inositol 3-kinase (PI3K), the enzyme that produces PIP3 known to activate PLCgamma isozymes specifically by interacting with their SH2 and PH domains. The hormone also increases the physical association of c-Src and PI3K with PLCgamma and induces a c-Src-dependent tyrosine phosphorylation of the p85 regulatory subunit of PI3K. The time course of hormone-dependent PLCgamma phosphorylation closely correlates to the time course of its redistribution to the membrane, suggesting that phosphorylation and redistribution to the membrane of PLCgamma are two interdependent events. 1α,25(OH)2D3-induced membrane translocation of PLCgamma was prevented to a great extent by c-Src and PI3K inhibitors, PP1 and LY294002. Taken together, the present data indicates that the cytosolic tyrosine kinase c-Src and PI3-kinase play indispensable roles in 1α,25(OH)2D3 signal transduction cascades leading to PLCgamma activation.

Daily Skin Dose of Vitamin D_3 in Healthy Men with Intensive Summer Sun Exposure. M. J. Barger-Lux[1], R. P. Heaney[1], T. C. Chen[2], M. F. Holick[2]. [1]Creighton University, Omaha, NE, USA, [2]Boston University, Boston, MA, USA.

We report here the results of work to determine daily input of vitamin D_3 among outdoor workers with intensive summer sun exposure. Subjects were 30 healthy men who had just completed a summer of extended outdoor activity (e.g., landscaping, construction work, farming, or recreation). We estimated duration and extent of sun exposure as total daytime hours outdoors and body surface area exposed by usual outdoor attire, and measured serum 25(OH)D twice, to mark the end of summer sun exposure (Aug. 3 to Sept. 2) and the end of winter sun deprivation (Feb. 1 to Mar. 20). Between-visit intervals for the 26 subjects who completed both visits ranged from 158 to 227 days. Median seasonal difference in 25(OH)D was 48.6 nmol/L. In earlier work carried out during winter, we examined the dose-response relationship between oral vitamin D_3 and serum 25(OH)D in healthy men. For every μg of vitamin D_3 given daily, serum 25(OH)D settled at an equilibrium level that was higher by about 0.70 nmol/L. We used this relationship to estimate the daily skin dose of vitamin D_3 among the subjects of the present study. The median effect of summer sun exposure among our subjects was equivalent to an oral dose of 69.5 μg/d (2780 IU/d) of vitamin D_3. Over the winter, the median daily rate of decrease in 25(OH)D was 0.2758 nmol/L, and 25(OH)D of more than half of the subjects fell below 80 nmol/L. In general terms, a level of at least 80 nmol/L at the end of winter could be expected if serum 25(OH)D was at least 128 nmol/L in late summer. However only 12 of 26 (46%) of our subjects achieved late summer levels this high. If duration and extent of an individual's summer sun exposure are known, our data could be used to predict summer 25(OH)D increment. For example, a typical gardening hobbyist might accrue roughly 112 hours of summer sun exposure (i.e., 7 hr/wk for 16 wks) while exposing about 41% of body surface area (e.g., attired in a short-sleeved shirt, shorts, and a hat). These conditions predict a summer 25(OH)D increment of only about 6 nmol/L. This estimate is probably low, since cholecalciferol synthesis is greater in pale skin than in tanned. Nevertheless, casual sun exposure at mid latitudes is not sufficient to ensure optimal 25(OH)D levels year round.

Dahl Salt-sensitive Rats Excrete 25-Hydroxyvitamin D into Urine. M. Thierry-Palmer[1], A. Doherty*[1], M. A. Bayorh*[2], K. Griffin*[1]. [1]Biochemistry, Morehouse School of Medicine, Atlanta, GA, USA, [2]Pharmacology, Morehouse School of Medicne, Atlanta, GA, USA.

Plasma 25-hydroxyvitamin D concentration of Dahl salt-sensitive rats (S) is markedly decreased in response to high salt intake (J. Steroid Biochem. Molec. Biol. 66: 255-61, 1998). Exogenous 25-hydroxycholecalciferol, administered by osmotic pumps, did not increase plasma 25-hydroxyvitamin D concentration, suggesting a higher rate of metabolism and/or clearance of 25-hydroxyvitamin D when S rats are fed a high salt diet (J. Steroid Biochem. Molec. Biol. 67: 193-9, 1998). We have conducted studies to determine whether excretion into urine is a mechanism for the decrease in plasma 25-hydroxyvitamin D concentration of S rats during high salt intake. Dahl S and salt-resistant (R) female rats (120-130 g) were fed low (0.3%) or high salt (8%) diets for two weeks. Urine was collected at baseline and weekly. 25-Hydroxyvitamin D, purified from three ml of urine by HPLC, was determined by protein binding assay. 25-Hydroxyvitamin D binding activity in urine was determined by binding to tritiated 25-hydroxycholecalciferol (10,000 dpm) in the presence and absence of 200-fold unlabeled 25-hydroxycholecalciferol. Female S rats excreted 11 ± 3 ng 25-hydroxyvitamin D /24 hr into urine at week 2 of low salt intake, whereas excretion by female R rats was non-detectable. Female S rats excreted 104 ± 16 ng 25-hydroxyvitamin D/24 hr at week 2 of high salt intake. This level was five times that of female R rats at week 2 of high salt intake (20 ± 6 ng/24 hr) and nine times that of S rats at week 2 of low salt intake. The calculated 25-hydroxyvitamin D binding activity in the 24 hr urine of female S rats was 79 ± 11 pmol/hr at week 2 of high salt intake, two times that in the urine of S rats at week 2 of low salt intake (33 ± 10 pmol/hr) and greater than 35 times that in the urine of female R rats at week 2 of low (1.5 ± 1.4 pmol/hr) or high salt intake (2.1 ± 1.5 pmol/hr). We conclude that S rats excrete 25-hydroxyvitamin D and 25-hydroxyvitamin D binding activity into urine during low salt intake, and that this excretion is markedly increased during high salt intake. It has not yet been determined whether altered cubilin/megalin delivery of vitamin D binding protein/25-hydroxyvitamin D to the kidney of S rats explains the loss of 25-hydroxyvitamin D and 25-hydroxyvitamin D binding activity into urine during low salt intake.

1,25-Dihydroxyvitamin D_3 Modulates Voltage Sensitive Calcium Channel Expression and Function in Murine Osteoblastic Cells. J. J. Bergh*, E. Puente*, M. C. Farach-Carson. Department of Biological Sciences, University of Delaware, Newark, DE, USA.

The balance of osteoblast/osteoclast activity maintains bone density. Osteoclastogenesis is regulated by signals generated by osteoblastic cells responding to environmental cues. As serum Ca^{2+} levels decrease, an elevation in 1,25-dihydroxyvitamin D_3 (1,25$(OH)_2D_3$) production occurs. 1,25$(OH)_2D_3$ triggers secretion of receptor activator of NF kappa B ligand (sRANKL). sRANKL stimulates osteoclast maturation, leading to bone resorption and liberation of stored Ca^{2+}. The mechanism by which the osteoblastic response to 1,25$(OH)_2D_3$ stimulates sRANKL production and secretion remains unknown. We previously have shown that, within millisecs of exposure to 1,25$(OH)_2D_3$, an increase in Ca^{2+} influx across the osteoblast plasma membrane occurs via activation of L-type voltage-sensitive calcium channels (VSCCs). This elevation in intracellular Ca^{2+} initiates downstream signaling cascades, including secretion of various proteins, a process known as excitation-secretion coupling. Longer exposure to 1,25$(OH)_2D_3$ leads to changes in gene expression, including decreasing expression of the dihydropyridine (DHP)-sensitive α_1 subunit of the L-type VSCC ($Ca_V1.2$), previously shown to modulate plasma membrane permeability to Ca^{2+} in the proliferating osteoblast. Functional data show, however, that the DHP-sensitive current is replaced in the 1,25$(OH)_2D_3$-treated osteoblast with a novel Ca^{2+} current that is not sensitive to DHP. To identify the source of this current, we used real-time RT-PCR, confocal microscopy, and $^{45}Ca^{2+}$ flux assays to measure the changes in expression and activity of the α_1 subunit of different families of VSCCs. We find that as $Ca_V1.2$ expression decreases, there is a concomitant increase in the expression and activity of the T-type channel $Ca_V3.2$. We conclude that Ca^{2+} permeability of the osteoblast treated with 1,25$(OH)_2D_3$ is maintained through the up-regulation of $Ca_V3.2$, a process that we believe necessary to maintain a secretory state. We are currently examining how changes in the VSCC expression affect sRANKL secretion along with that of its regulatory partner, osteoprotegerin (OPG). (Supported by DE12641, to MCF-C).

The Effect of Differentiation on Nuclear Vitamin D Receptor (VDR) Function in Human Intestinal Cells. A. Klopot*[1], K. Hance*[1], L. Wang*[1], J. Barsony[2], J. C. Fleet[1]. [1]Foods and Nutrition, Purdue University, West Lafayette, IN, USA, [2]National Institutes of Health, Bethesda, MD, USA.

$1,25(OH)_2$ vitamin D_3 (calcitriol) regulates intestinal calcium absorption through VDR-mediated gene expression. We examined the effect of enterocyte differentiation on calcitriol-mediated transcriptional (25-hydroxyvitamin D-24-hydroxylase (CYP24) mRNA levels) and post-transcriptional actions (calbindin D9k (CaBP9k) mRNA levels) in proliferating (2d cultures), post-proliferative (8d) and differentiated (15d) Caco-2 cells. The induction of CYP24 mRNA by calcitriol (8h, 10 nM) was 15X higher in 8d cultures and 25X higher in 15d cells compared to 2d cells. In contrast, calcitriol (48h, 100 nM) increased CaBP9k mRNA levels by 2-fold at all stages of culture while CaBP9k mRNA levels increased 300X from 2 to 15d. These findings suggest that enterocyte proliferation is associated with blunted calcitriol-mediated transcription. VDR protein levels increase 2X between 2 and 15d cells and do not fully explain our observations. Using confocal microscopy, we examined whether cell stage influenced calcitriol-induced nuclear translocation of VDR in the BBe clone of Caco-2 using cells transiently transfected with a GFP-VDR expression vector. In 2d and 15d cultures, GFP-VDR distribution was 60% nuclear:40% cytoplasmic and evenly distributed from the basolateral to the apical membrane. Fluorescence recovery after photobleaching (FRAP, 8 mm2, 100% power, 10 sec) was used to assess GFP-VDR redistribution kinetics in response to 100 nM calcitriol. In both 2d and 15d cells, calcitriol induced a rapid translocation of GFP-VDR to the nucleus (2-fold above control at 2.5 min) that was complete within 15 minutes. This suggests that the resistance to calcitriol in proliferating cells is not due to a defect in nuclear translocation. DNA microarray analysis of BBe cell differentiation reveals that steroid receptor coactivator-1e mRNA levels increase 75% from 2d to 8d and 300% from 2d to 15d in culture. Future studies will be required to determine whether reduced coactivator levels or impaired VDR-protein or VDR-DNA interactions lead to lower vitamin D-mediated gene transactivation in proliferating Caco-2 cells.

1,25-dihydroxyvitamin D Downregulates Cell Membrane and Nuclear Growth Promoting Signals by the Epidermal Growth Factor Receptor. J. Cordero*[1], M. Cozzolino*[1], Y. Lu*[1], E. Sltopolsky[1], M. Vidal*[1], P. Stahl*[2], A. Barbieri*[2], A. S. Dusso[1]. [1]Renal Division, Washington University, St. Louis, MO, USA, [2]Cell Biology and Physiology, Washington University, St. Louis, MO, USA.

The severity of parathyroid (PT) hyperplasia in renal failure correlates with PT expression of transforming growth factor-α (TGF-α), a ligand for the epidermal growth factor receptor (EGFR). Since 1,25-dihydroxyvitaminD$_3$ [$1,25(OH)_2D_3$], the hormonal form of vitamin D, effectively suppresses PT growth, this study examined $1,25(OH)_2D_3$ regulation of TGFα/EGFR growth signals. Due to the lack of a PT cell line, we used human epidermoid A431 cells, which mimic hypeplastic PT cells in overexpressing TGF-α and EGFR. $1,25(OH)_2D_3$ inhibited autocrine and EGF-induced A431 cell proliferation. In the absence of exogenous ligand, $1,25(OH)_2D_3$ changed cellular EGFR localization from the plasma membrane to early endocytic compartments, leading to a reduction in ^{125}I-EGF-specific binding to cell surface EGFR. Consequently, $1,25(OH)_2D_3$ inhibited EGF-dependent activation by tyrosine-phosphorylation of EGFR and the downstream MAPK, ERK1/2. The cytosolic TGF-α/EGFR co-localization in $1,25(OH)_2D_3$-treated cells suggests that the sterol also impairs EGFR activation by the endogenous ligand. This is further supported by a marked reduction in phosphorylated ERK1/2 in the nucleus, an index of autocrine TGFα/EGFR signaling. However, not only is $1,25(OH)_2D_3$ inhibition of autocrine A431 growth more potent than that of saturating concentrations of a TGF-α neutralizing antibody, but simultaneous treatment with $1,25(OH)_2D_3$ and anti-TGF-α exerts additive inhibition of A431 growth. In fact, $1,25(OH)_2D_3$ also impairs nuclear translocation of activated EGFR and its binding to AT-rich DNA sequences, known to mediate EGFR-transactivation of cyclin D1. These results demonstrate that $1,25(OH)_2D_3$, alters EGFR trafficking, reducing its levels at the plasma membrane and in the nucleus, thus shutting down autocrine proliferation signals and impairing further EGFR activation by exogenous ligand.

Vitamin D Stimulates the Expression of Interleukin-1 Receptor Antagonist in Mouse Keratinocytes. J. Kong*, Y. Li. Medicine, University of Chicago, Chicago, IL, USA.

Interleukin-1 (IL-1) is a key mediator in inflammatory reactions. Keratinocytes are the largest source of pro-IL-1, and excessive production of IL-1 by keratinocytes has been implicated in psoriasis and other inflammatory and hyperproliferative skin diseases. One important cytokine that modulates the biologic effect of IL-1 is IL-1 receptor antagonist (IL-1Ra), which specifically binds to both type I and II IL-1 receptors to antagonize IL-1 signaling. Therefore, IL-1Ra regulates the activity of both IL-1a and IL-1b. Two isoforms of IL-1Ra resulted from alternative splicing of two distinctive first exons have been identified, and keratinocytes mainly express the intracellular isoform (icIL-1Ra). It is known that 1,25-dihydroxyvitamin D3 [1,25(OH)2D3] has immunosuppressive activity, and has been used to effectively treat psoriasis; therefore, we investigated the effect of vitamin D on icIL-1Ra expression in primary keratinocytes derived from 3-day old mice. Northern blot analyses showed that treatment of keratinocytes with 1,25(OH)2D3 stimulates icIL-1Ra mRNA expression in a dose- and time-dependent manner. The maximal stimulation (3 to 5-fold) was seen after 24-hour treatment with 10-8 M of 1,25(OH)2D3. Similar induction was also detected at the icIL-1Ra protein level. The increase of icIL-1Ra mRNA expression was abolished by cycloheximide, suggesting that new protein synthesis is required for icIL-1Ra stimulation. Moreover, 1,25(OH)2D3 had no effect on icIL-1Ra expression in VDR(-/-) keratinocytes derived from VDR null mice, but the stimulation was restored in keratinocytes derived from VDR(-/-) mice that specifically express human VDR in the skin, indicating that VDR is required to mediate the effect of 1,25(OH)2D3 on icIL-1Ra expression. When keratinocytes were transfected with a reporter plasmid containing 4.5 kb 5'-flanking sequence of human icIL-1Ra gene, the promoter activity was increased 3-fold by 1,25(OH)2D3 treatment. Thus it is concluded that 1,25(OH)2D3 increases icIL-1Ra gene transcription. These results suggest that vitamin D can suppress IL-1 activity and cutaneous inflammatory reactions through stimulation of IL-1Ra expression in keratinocytes.

Vitamin D-Induced Artery Calcification and Calciphylaxis Are both Inhibited in the Same Rat by Doses of Ibandronate that Inhibit Bone Resorption. P. A. Price, N. Omid*, T. Nguyen*, M. K. Williamson. Division of Biology, University of California, San Diego, La Jolla, CA, USA.

The present experiments were carried out to test the hypothesis that all ectopic calcifications induced by treatment with toxic doses of vitamin D are linked to bone resorption. In previous studies we showed that lethal doses of vitamin D cause extensive calcification of arteries, lungs, kidneys, and cartilage, and that doses of the amino bisphosphonate ibandronate that inhibit bone resorption completely inhibit each of these soft tissue calcifications and prevent death (ATVB (2001)21:817-824). In the present experiments we have examined the effect of ibandronate on an entirely different type of ectopic calcification, the calciphylaxis induced by administration of a challenger to rats previously treated with sublethal doses of vitamin D. The present studies show that ibandronate doses that inhibit bone resorption completely prevent artery calcification as well as, in the same rat, the Alizarin red-staining for calcification at sites of calciphylactic challenge by either subcutaneous injection of 300μg $FeCl_3$ or intrascapular epilation. Chemical analysis further showed that the level of calcium was increased by 40-fold at the $FeCl_3$-induced calciphylaxis site and by 100-fold at the skin epilation-induced calciphylaxis site, and that concurrent treatment with ibandronate reduced calcium to control levels at both sites. Since vitamin D treatment dramatically increased levels of bone resorption, and concurrent treatment with ibandronate normalized resorption, these results support the hypothesis that all soft tissue calcifications in the vitamin D treated rat may be linked to bone resorption. This hypothesis is also supported by the present observation that the effect of vitamin D dose on bone resorption activity, artery calcification, and caliphylaxis in the same animal are essentially identical. The underlying biochemical mechanism responsible for the linkage between bone resorption and ectopic calcifications is presently unknown. Since serum calcium levels in animals treated with vitamin D plus ibandronate are not significantly different from the elevated levels seen in animals treated with vitamin D alone, the ectopic calcifications induced by vitamin D-treatment cannot be caused by hypercalcemia per se. It is possible, however, that all vitamin D-induced ectopic calcifications are caused by the recently described fetuin mineral complex, a complex that is generated at sites of enhanced bone resorption and is found in blood (JBC (2002)277:3926).

Calbindin D28K Interacts with RanBPM and Undergoes a Large Ca2+-Induced Change Between Two Ordered Conformations. R. A. Venters*[1], L. M. Benson*[2], W. Lutz*[3], T. A. Craig*[3], K. H. Paul*[4], J. Bagu*[4], R. Thompson*[4], S. Naylor*[5], J. Cavanaugh*[4], R. Kumar[3]. [1]Duke University Medical Center, Durham, NC, USA, [2]MN, USA, [3]Mayo Clinic, Rochester, MN, USA, [4]North Carolina State University, Raleigh, NC, USA, [5]Beyond Genomics, Waltham, MA, USA.

Calbindin D_{28K} is a vitamin D-dependent EF-hand calcium-binding protein found in the central and peripheral nervous system, kidney, and intestine. There is a paucity of information concerning the mechanism of action calbindin D_{28K} and the effect of calcium on calbindin D_{28K} structure. Using yeast two-hybrid screening studies we show that calbindin D_{28K} interacts with Ran-binding protein M (RanBPM). Saccharomyces cerevisiae, AH109 cells, were co-transformed with pACT brain-derived cDNA library and the pGBKT7 vector expressing rat brain calbindin D_{28K} as a fusion protein with the Gal4 DNA binding domain. Yeast transformants expressing interactive proteins were selected by nutrient auxotrophy and galactosidase activity. This interaction between calbindin D_{28K} and RanBPM was verified by co-immunoprecipation experiments. We used NMR and electrospray ionization mass spectrometry (ESI-MS) to investigate calcium-induced conformational changes of calbindin D_{28K}, and we show that apo-calbindin D_{28K} has an ordered tertiary structure that transforms into a disordered intermediate as levels of Ca^{2+} increase. This disordered intermediate transitions into a different ordered tertiary structure upon a further increase in Ca^{2+} concentrations. This form of the protein continues to load calcium and persists until fully loaded. Our studies, therefore, identify two ordered calbindin D_{28K} conformations existing under differing calcium concentration levels partitioned by a state of conformational exchange. Our results suggest that calbindin D_{28K} has characteristics of both a calcium-sensor and buffer. We thus show conclusively that calbindin D_{28K} not only binds calcium as a buffer but also acts as a sensor to bind other intra-cellular proteins and we identify RanBPM as an important target.

M459

Antagonism of the RAR Signaling Pathway Induces Osteoblast Differentiation and Bone Formation. A. V. Sampaio*[1], R. A. S. Chandraratna*[2], T. M. Underhill[3]. [1]Physiology, University of Western Ontario, London, ON, Canada, [2]Retinoids Research Group, Allergan Inc., Irvine, CA, USA, [3]Faculty of Medicine and Dentistry, University of Western Ontario, London, ON, Canada.

The vitamin A metabolite retinoic acid has been shown to have various effects on the development and remodeling of bone. Retinoic acid functions through activation of the retinoic acid receptor (RAR), a member of the nuclear hormone receptor superfamily of transcription factors. The purpose of this study was to delineate the role of retinoid signaling in osteoblast differentiation and matrix synthesis. Combinations of molecular and pharmacological approaches were used to manipulate the retinoid signaling in either MC3T3-E1 (immortalized murine osteogenic cell line), primary cultures derived from 1 day-old rat calvaria, and *in vivo* studies. The consequences on the osteoblast phenotype were assessed using reporter gene analysis, histological analyses, proliferation and cell death assays, real-time PCR, northern blotting analysis, and bone mineral density (BMD) quantification by dual x-ray absorptiometry (DEXA) scans of bones. Pre-treatment of osteoblast cultures with 10nM $1,25(OH)_2$ vitamin-D_3 followed by treatment with 1000nM all-*trans* retinoic acid stimulated apoptosis to a greater extent than either ligand alone as measured by TUNEL assay and propidium iodide staining. Thus, it appears that $1,25(OH)_2$ vitamin-D_3 enhances retinoic acid-mediated cell death. Moreover, this synergistic effect also extended to bone nodule formation, as nodules were completely absent in cultures co-treated with retinoic acid and $1,25(OH)_2$ vitamin-D_3. Interestingly, the addition of an RARα-selective antagonist (AGN194301) or expression of a dominant-negative version of RARα ameliorated the effects of $1,25(OH)_2$ vitamin-D_3 on cell death and bone nodule formation and mineralization. Treatment with AGN194301 alone was found to cause precocious expression of osteocalcin and alkaline phosphatase activity and at low concentration (10 nM) induced a ~3-fold increase in matrix mineralization. Treatment of ovariectomized mice with AGN194301 for 4 weeks increased bone mineral density by ~15%. Further, antagonism of the retinoid-signaling pathway increased Cbfa1 activity. Together, these findings reveal novel and unexpected roles for $1,25(OH)_2$ vitamin-D_3 and retinoic acid in regulating the osteoblast phenotype–inhibition of osteogenesis by $1,25(OH)_2$ vitamin-D_3 involves stimulation of apoptosis through an RAR-dependent pathway, and abrogation of retinoid signaling is required for expression of the osteoblast phenotype.

M460

Retinoids Induce Envelope-specific Changes in Adult Endochondral Bone Resulting in Cortical Bone Destruction and Suppressed Cancellous Bone Turnover. M. Kneissel*[1], M. Susa[1], A. Boyde[2]. [1]Bone Metabolism Unit, Novartis Pharma AG, Basel, Switzerland, [2]Anatomy, University College, London, United Kingdom.

Retinoids play important and complex roles in the shaping of endochondral bone by mediating perichondrial invasion of the cartilage rudiment, promoting osteogenic differentiation, cartilage maturation and mineralization (1). Furthermore retinoid action can influence endochondral bone beyond development. We aimed to contribute to the understanding of this action by short-term application of the retinoid Ro 13-6298 to young and aged adult rats and determining its bone-envelope specific effects. Ro 13-6298 (30 microg /day sc. for 4 days) induced bone loss in the hind limbs of 12- and 56-week-old Wistar rats as detected by DEXA, plasma TRAP and calcium levels. This loss could be blocked by a bisphosphonate but not by estradiol. In vivo pQCT measurements demonstrated that bone mass decline was due to rapid subperiosteal bone loss in both age groups, reducing cortical bone mineral content, whilst cancellous bone mineral density was preserved and bone length unaffected over this short experimental period. Histomorphometric evaluation revealed that this cortical bone destruction was due to increased subperiosteal osteoclastic resorption (+73%). Conversely, bone resorption was suppressed (by 60%) in the entire cancellous bone compartment. The latter observation is in line with our in vitro finding that the retinoid suppressed osteoclastogenesis (dose-dependently: 1, 10, 100 nM, up to 50%) and pit formation (area, up to 90%) when added to osteoclast cultures stemming from the bone marrow of 21-week-old C57Bl/6J mice. Bone forming surfaces were significantly decreased at the subperiosteal cortex and in the secondary spongiosa, while the primary spongiosa was unaffected. Furthermore, quantitative back-scattered electron imaging revealed that the short-term retinoid treatment was sufficient to accelerate significantly cartilage mineralization (+17%). Thus retinoids have a complex impact on endochondral bone beyond embryonic stages. It has previously been shown that retinoids increase bone resorption and decrease bone formation in vivo in a generalised manner, but published in vitro results are multifaceted and conflicting. Our data suggest that in vivo effects also vary greatly between different bone envelopes and are partially opposing. The finding that the retinoid triggers principally subperiosteal cortical bone destruction in adult endochondral bone is interesting in the context of the finding that high intake of vitamin A, as retinol, is associated with an increased risk of hip fracture (2).

Phosphorylation of the Human Retinoid X Receptor α Inhibits the Signal Transduction Mediated by its Heterodimeric Partners. M. Macoritto*, R. Kremer. Medicine, Mcgill University, Montreal, PQ, Canada.

Via its heterodimeric association with numerous members of the nuclear receptor superfamily, the retinoid X receptor α (RXRα) defines itself as a necessary factor in a variety of signaling pathways. The RXRα affects the DNA binding and transcriptional activity of the vitamin D receptor (VDR), the thyroid receptor (TR), the peroxisome proliferator-activated receptor (PPAR) and the retinoic acid receptor (RAR). In *ras* transformed keratinocytes, the serine 260 of RXRα is phosphorylated by the *ras-raf*-map kinase cascade, resulting in the inhibition of signaling through VDR-RXR heterodimers. (Solomon, C., White, J. H., and Kremer, R. K. (1999) J. Clin. Inv. **103**, 1729-1735) The purpose of the present study is to determine whether the phosphorylation of serine260 of RXRα in *ras* transformed keratinocytes (HPK1A*ras*) inhibits signaling through PPAR-RXR, TR-RXR and RAR-RXR heterodimers as well as RXR homodimers. To determine whether the RXR heterodimers were able to recognize and bind DNA response elements, electrophoretic mobility shift assays were performed using nuclear extracts from the keratinocytes. TR-RXR, PPAR-RXR, RAR-RXR heterodimers and RXR-RXR homodimers were able to bind labeled oligos containing their cognate DNA response elements. To define the effects of the phosphorylation on transcriptional activity, reporter constructs bearing the cognate response elements for the receptors were transiently transfected into the HPK1A*ras* keratinocytes as well as the control immortalized keratinocytes (HPK1A). Treatment of the cells with increasing amounts of the receptors' respective ligand revealed that the phosphorylation of the RXRα resulted in an inhibition of the transcriptional activities of these receptors. Addition of a map kinase inhibitor, PD98059, reversed this transcriptional inhibition. Simultaneous transfection of a non-phosphorylatable mutant RXRαser260ala also reversed the inhibition. The ability of all trans retinoic acid (ATRA), a ligand of the RAR, to inhibit the growth of keratinocytes was significantly reduced in the HPK1A*ras* cells as compared to the control cell line HPK1A, but was restored with the addition of PD98059. HPK1A*ras* cells showed complete resistance to ATRA at 10^{-7}M, but pretreatment with PD98059 resulted in significant growth inhibition at 10^{-9}M. With the RXR synthetic ligand LG1069, HPK1A*ras* cell growth was significantly inhibited at 10^{-7}M, but pretreatment with PD98059 resulted in significant inhibition at 10^{-10}M. These results indicate that the *ras-raf*-MAPK cascade phosphorylation of RXRα impairs signaling through all its partners and suggests an important role in tumor biology.

WG1

Relationship Between Disease Specific Symptoms and Indices of Disease in Patients with Primary Hyperparathyroidism (PHPT): A Pilot Study in a Referral Center. I. Paek[1], L.Boboc[2], D. S. Rao[2], [1]Brown University School of Medicine, Providence, RI, USA, [2]Henry Ford Hospital, Detroit, MI, USA.

Patients with PHPT have symptoms that are specific (i.e., traditionally attributed to hypercalcemia) and those that appear to be non-specific (i.e., those not traditionally attributed to hypercalcemia). The latter symptoms are often used to recommend surgery in the absence of specific symptoms. Accordingly, we conducted a pilot study to ascertain the relationship between symptoms and indices of the disease (serum Ca and PTH). We hypothesized that polydipsia, polyuria, nausea, vomiting, dry mouth, and metallic taste (specific symptoms) would be related to serum Ca levels since they occur in all varieties of hypercalcemia and respond to treatment with some consistency. In contrast, fatigue, muscle weakness, headache, irritability, depression, lack of concentration, and memory problems (non-specific symptoms) would be related to serum PTH levels. 142 consecutive patients with PHPT completed a questionnaire consisting of the 14 questions. Physician input was sought when in doubt since a categorical answer was required. The relationship between the prevalence of various symptoms and disease indices was determined based on serum Ca and PTH levels, the two most important determinants of disease severity. We arbitrarily divided the patients with serum Ca < or > 11 mg/dl and serum PTH < or > 100 pg/ml. The latter was chosen based on our previous work with mild asymptomatic PHPT. For the entire study group the mean (SD) of Ca was 10.8 (0.6) mg/dl and PTH was 123 (68) pg/ml. Results (%) are shown in the Table.

Variable	Ca <11 mg/dl	>11 mg/dl	PTH <100 pg/ml	>100 pg/ml
Specific Symptoms (?Ca Related)				
Polydipsia	24	44	34	37
Polyuria	45	55	50	50
Nausea	12	17	16	11
Vomiting	3	8	16	11
Dry Mouth	39	49	45	50
Mettalic Taste	13	9	12	10
Constipation	35	37	35	36
Non-Specific Symptoms (?PTH Related)				
Fatigue	56	71	60	64
Muscle Weakness	33	38	37	33
Headache	26	29	26	31
Irritability	20	32	24	28
Depression	34	39	32	40
Lack of Concentration	30	35	34	30
Memory Problems	42	43	46	38

There appeared to be a trend for the specific symptoms related more to serum Ca than to PTH levels. However, with the exception of fatigue no consistent trend was seen in non-specific symptoms and PTH or Ca levels. This may partly relate to the fact that Ca and PTH levels are significantly correlated. Further studies are needed to confirm our preliminary results.

WG2

Hepatitis C Associated Osteosclerosis. S. Ortolani, R. Cherubini*, P.J. Meunier, E. Galbiati, S. Saraifoger*, M.L. Bianchi, Istituto Auxologico Italiano IRCCS, Milan, Italy and Hôpital E. Herriot, Lyon, France.

A new syndrome of acquired generalized osteosclerosis associated with hepatitis C virus infection (HCAO) has been firstly described in 1992 and ten cases have been reported since then. We present radiological, densitometric, histomorphometric and biochemical features of a new case of HCAO, with 1 year follow-up without treatment. A 65-yr-old women with hepatitis C virus infection from blood transfusion more than ten years earlier was referred in January 2001 for increasing pain of thighs, legs and upper arms, requiring high doses of analgesic and significantly reducing her walking ability. Radiographs showed diffuse osteosclerosis, with marked cortical and trabecular thickening involving all the skeleton, except the cranium. Bone morphology and structure was otherwise normal. Total body scan demonstrated diffusely increased radionuclide uptake. Consistent with bone scan, serum alkaline phosphatase, serum osteocalcin and urinary NTx were markedly increased, respectively 12, 4 and 20 times the upper normal limit. Intact PTH was moderately elevated, with serum calcium, 25-hydroxy-vitamin D and 1,25-dihydroxy-vitamin D within the normal range. BMD was measured at multiple skeletal sites by DXA (Hologic QDR 2000) resulting well above the expected values not only for the same age and sex, but also when compared to young normals, as indicated by T- and Z-scores, that were respectively +5.0 and +6.8 for lumbar spine, +5.3 and +6.7 for total hip, +1.7 and +3.3 for whole body. Moreover, whole body bone densitometry showed elevated values for all the skeletal sub-regions, except the head. Iliac crest bone histomorphometry demonstrated high remodeling osteosclerosis, lamellar bone texture and normal haematopoietic cells. Cancellous bone volume was 73% (normal 15.3±4.6%), eroded surfaces were 15.0% (3.6±1.1%), osteoid volume and osteoid surfaces were respectively 13% (1.6±0.7%) and 67% (8.6±3.9%), but osteoid thickness index was normal at 19.4 (18.5±2.5). Mineralization rate was slightly increased: 0.88 µm/day (0.72±0.12). One year later BMD was reassessed and showed marked increases at all skeletal sites: lumbar spine +10.5%, total hip +12.3% and total body +16.3%. This is the first case of HCAO reported from Europe and confirms the major landmarks described in the very few previous cases. Noteworthy, as in some of the other cases, cranium appears not to be much affected by this bone disorder, suggesting that the unknown pathogenetic mechanism should incorporate some interaction with mechanical stimuli, as cranium is the less weight-bearing bone of the skeleton. The good lamellar bone quality and the impressive increases in bone density observed in our case during the one year follow-up confirm that, although speculative, elucidation and control of the pathogenetic mechanism could result in effective treatment of osteoporosis.

WG3

Osteoporosis in patients with Turner's Syndrome - Presentation of two cases. S. Levy, G. Edelson, William Beaumont Hospital, Royal Oak, MI, USA.

The etiology and presentation of bone loss in women with Turner's Syndrome is still not fully understood. Also it is not clear to what extent does the estrogen deficiency contribute to the bone loss. Here we present two women who developed significant osteopenia. One was and one was not on estrogen replacement prior to the development of bone loss. Case1. S.E. is a 55 year old Caucasian with a past medical history significant for Hashimoto's thyroiditis and the diagnosis of Turner's Syndrome at the age of twenty. The patient was treated with hormone replacement therapy since the time of diagnosis. Currently is on Estradiol 0.1 mg/day (Vivelle patch) and Synthroid 0.075mg/day. The patient consumed 1000mg of calcium per day and was active physically (4 miles/day walking.) No bone loss risk factors identified. Patient had never been pregnant. At 55 years of age the patient presented with a complaint of height loss which was not quantitated. DEXA revealed L1 T score (Ts) -1.8, L2 -1.2 and Femoral Neck (FN) -1.3. Two years later, the patient had a repeat DEXA scan with a L1 Ts -2.6, L2 -1.2, FN -1.3. The patient was started of Fosamax 70mg/week and a year later her DEXA scan values were L1 Ts -1.5, L2 -1.1 and FN -0.8. Case2. M.H. is a 71 year old caucasian women who was found to have severe osteopenia. DEXA test L1-L3 Ts -1.64, FN -1.86. Because of short stature, wide carrying angle of the upper extremities and 0-1 fingerbreadth distance between rib cage and pelvic brim bilaterally, the patient karyotype was done and was found to be XO confirming Turner's Syndrome. The patient did not have known bone loss risk factors, and her estimated calcium consumption was 800 mg /day. The patient was never on estrogen replacement therapy and was never pregnant. The patient was started on Fosamax treatment. Repeat DEXA is still pending. These 2 cases support the notion that Turner's Syndrome associated osteopenia can not be solely attributed to estrogen deficiency. Though both patients are currently treated with Fosmax the efficacy of this treatment on the osteopenia seen in Turner's Syndrome is not clear.

WG4

Dysregulated Expression of BMP5 in a Patient with Deformed Helices, Axial Skeletal Defects, and Heterotopic Ossification: A Clue from the Short-Ear Mouse. G.J.Feldman[1], R.Patel[1], P.C.Billings[1], D.M.Kingsley[2], E.M.Shore[1], F.S.Kaplan[1], [1]Department of Orthopaedic Surgery, University of Pennsylvania, Philadelphia, PA, USA, [2]Department of Developmental Biology, Howard Hughes Medical Institute and Stanford University School of Medicine, Stanford, CA, USA.

Bone morphogenetic proteins (BMPs) play critical roles in embryonic patterning and skeletal formation and in adult skeletal repair and maintenance. The biological importance of the BMPs is highlighted by the fact that these genes have been conserved over a wide variety of species from worms to humans. Mutations in the protein coding region and in the downstream regulatory elements of the BMP5 gene cause a complex syndrome characterized by short ears and a broad range of axial skeletal malformations in the mouse (Kingsley et al Cell 71:399-410,1992). We examined a child, reminiscent of the short ear mouse, who has abnormally small external ears and multiple malformations of the axial skeleton as well as progressive heterotopic bone formation in the back and neck. We hypothesize that she has a mutation either in the BMP5 gene or in another gene that regulates BMP5 expression. We have examined the DNA sequence of the BMP5 gene in this patient and 800 bp of the 5'flanking sequence but identified no mutations. The possibility of mutations in regulatory regions further upstream or downstream of the examined region is currently being investigated. The mRNA expression of BMP2, BMP4 and BMP5 was examined by RT-PCR using a lymphoblastoid cell line established from the patient. We detected elevated levels of BMP5 and BMP4, but not BMP2 mRNA in this patient's cells relative to the levels detected in 14 unaffected individuals. To determine if this elevated BMP5 mRNA leads to increased production of secreted BMP5 protein, we performed immunoblot analysis using medium conditioned by the patient's cell line and an antibody against BMP5. BMP5 protein was detected in the patient's sample but was absent in 4 unaffected controls. Our data suggest that dysregulated expression of the BMP5 gene may be associated with an array of axial skeletal abnormalities in this patient.

WG5

Prevalence of Low Bone Mass (LBM) in Adult Celiac Disease (ACD): A Pilot Study in an Urban ACD Support Group Population. M.J. Scheafer[1], L. Teasdale[2], E.R. Phillips[2], D. S. Rao[2], [1]University of North Dakota School of Medicine, Grand Forks, ND, USA, [2]Henry Ford Hospital, Detroit, MI, USA.

Malabsorption of calcium and vitamin D is common in ACD and results in significant morbidity in patients with ACD. However, the prevalence of low bone mass, a known risk factor for fractures, is unknown. The recognition of ACD as a cause of osteoporosis in the US appears to be far from satisfactory. We have presented our experience on metabolic bone disease in patients with ACD, but the study involved only patients referred for evaluation based on symptoms, abnormal laboratory tests or low bone mineral density (BMD). To the best of our knowledge no systematic study of BMD in ACD has been reported from the US. Accordingly, we ascertained the status of bones in a group of individuals with established ACD. Study subjects were recruited during at a monthly meeting of the ACD support group in an urban community. All participants had an established diagnosis of ACD either by serologic tests and/or intestinal biopsy, and were following a gluten free diet for at least one year. BMD was measured by broadband ultrasound attenuation using Sahara bone densitometer (Hologic Inc). T-scores were calculated from the manufacturer's database. Low bone mass was defined as T-score <1.5 SD, although exact cut off criteria for low bone mass by ultrasound technique is yet to be defined. All subjects completed a questionnaire that included relevant information such as height, weight, menopausal status, hormone replacement therapy (HRT), smoking and fractures. Results (mean ± SD or %) are shown in the Table.

Variable	Total Group	Pre Menopausal	Post Menopausal	
			On-HRT	No-HRT
Number	59	11	24	24
Age (y)	58 ± 13	40 ± 7	60 ± 9	56 ± 16
BMI (kg/m^2)	24.4 ± 4.4	24.1 ± 5.2	23.5 ± 2.5	24.3 ± 5.0
BMD (g/Cm^2)	0.54 ± 0.14	0.63 ± 0.14	0.54 ± 0.13	0.53 ± 0.16
T-Score (SD)	-0.40 ± 1.22	0.43 ± 1.30	-0.38 ± 1.14	-0.44 ± 1.42
<-1.0 (%)	25	9	29	29
H/O Fx (%)	29	18	38	25
Calcium (%)	68	45	92	54
Vit.D (%)	36	27	29	46

Despite knowledge about ACD and adherence to a gluten free diet, the prevalence of low bone mass is high among individuals with ACD. As expected, there was an age-related decline in BMD. The proportion of individuals with a history of fracture was also high and the proportion taking supplemental calcium and vitamin D was disappointingly low. Conclusions: Prevalence of low bone mass and history of fractures is high among apparently "well informed" patients with ACD. Further studies are needed to establish the scope of the problem and to explore the impact of ACD on BMD and fracture.

WG6

Severe Osteoporosis and Persistent Bone Loss Leading to Late Diagnosis of Celiac Disease. M.L. Bianchi, M.T. Bardella*, E. Galbiati*, S. Saraifoger*, R. Cherubini*, S. Ortolani. Bone Metabolic Unit, Istituto Auxologico Italiano IRCCS and Gastroenterology Department, Università di Milano; Milano, Italy.

Two women of 62 and 64 years with severe osteoporosis, multiple fractures and persistent bone loss notwithstanding therapy were separately referred to our Bone Metabolic Unit. Both were caucasian, of normal weight, in menopause (at 52 and 53 yrs), with normal dietary calcium intake (1.2 and 1 g/day), doing regular physical activity, and with no other disease except osteoporosis. *Case 1 (62 yrs):* first fracture (D10) at 58 yrs; after fracture, spine BMD was measured (T-score -3.2) and alendronate (10 mg/day) was started; at 60 yrs, second fracture (L1); BMD decreasing (-2.3% yearly); alendronate was continued and a calcium supplement was added (500 mg/day); we first saw her at 62 yrs, one year after a third fracture (D11). *Case 2 (64 yrs):* first fracture (left foot) at 56 yrs (while on HRT); after a second fracture (left wrist) at 59 yrs, alendronate (10 mg/day) was started; third fracture (right wrist) at 61 yrs; BMD T-score -4.1 at spine, -4 at hip. At 64 yrs, after she broke her right humerus, with a BMD still decreasing (-2.5% yearly), she was sent to our attention. At admission, case 1: severe back pain and kyphosis; case 2: pain and functional impairment of right arm. No other signs/symptoms. Bone metabolism parameters (s = serum; u = urinary):

	sCa (mg/dl)	*sAP (U/l)*	*sPTH (pg/ml)*	*s25-OHD (ng/ml)*	*uNTx (nMBE/mMCr*
normal range	(8.1-10.4)	(50-300)	(13-54)	(9-47)	(29-58)
case 1	8.6	312	81	8	178
case 2	8.7	287	75	12	99

Case 1 had a slight increase in GOT (51 U/l) and GPT (58 U/l). Case 2 had moderate anemia (red-cell count 3.670.000/mm^3; Hb 11 g/dl; serum iron 32 mcg/dl). BMD: case 1, T-score -4.1 at spine and -3.9 at hip; case 2, T-score -4.5 at spine and -4.2 at hip. The persistent decrease in bone mass and the presence (case 1) of transaminase increase (not related to previous hepatitis) or (case 2) of hypochromic anemia, induced us to test the serological markers of celiac disease. In both cases, anti-endomysium antibodies were positive. Upper gastrointestinal tract endoscopy confirmed the diagnosis. A gluten free diet was started. Alendronate was maintained and calcifediol was added (35 - 50 mcg/day). In 4 months, a normalization of AP, PTH, NTx and an increase in calcium and 25-OH D were observed in both cases. After 2 years or more, BMD was persistently increasing: case 1: + 6.7% at spine and +5.6% at hip yearly; case 2: + 6% at spine and +5% at hip yearly. The patients did not have new fractures and pain was significantly decreased. In conclusion, even in the absence of specific intestinal signs and in advanced age, the progressive worsening of osteoporosis (bone loss plus fractures) notwithstanding therapy requires a thorough evaluation of the possible causes of secondary osteoporosis, among them celiac disease. In such cases, a gluten free diet and an over-correction of hypovitaminosis D can radically change the bone response.

WG7

Association Between Height, Weight, Body Mass Index and Discordant Regional Bone Mineral Density. R.L. Munasinghe, V. Botea, G.W.Edelson. Department of Medicine, Sinai-Grace Hospital, Wayne State University, Detroit, MI, USA.

Patients with osteoporosis have a body mass index (BMI) that is significantly lower than patients with normal bone mineral density (BMD). This study was conducted to study the associations between age, height, weight and body mass index in patients with discordant regional BMD. For the purpose of this study, discordant regional BMD was defined as having a BMD result that is in the osteoporotic range at one site while being normal at the other sites. Data from 7,095 qualifying bone densitometry scans from a suburban Detroit osteoporosis testing center were analyzed. A patient was classified as having generalized osteoporosis if the t score was less than –2.5 at the lumbar spine, femoral neck and distal radius and normal if the t score was greater than –1 at the same three sites. Patients were determined to have discordant lower BMD when the t score was less than –2.5 at one site while the t score was greater than –1 at the same three sites. Patients were determined to have discordant low BMD when the t score was less than –2.5 at one site while the t score was greater than –1 at the same three sites. Patients with generalized osteoporosis were older (mean age 72 vs. 54, *P*<.001), shorter (height 153 vs. 161 cm, *P*<.001) and had lower BMI (23.7 vs. 28.6 Kg/m2, *P*<.001) compared to patients with normal BMD. The distal radius was the site where discordant osteoporosis was most prevalent (64 patients, 0.9%). Patients with isolated low distal radius BMD were similar in age (mean age 70.5 vs. 72.2 years, *P*=NS), but were taller (height 158 vs. 153 cm, *P*<.001)and had BMI values that were significantly higher (BMI 28.9 vs. 23.7 Kg/m2, *P*<.001) than patients with generalized osteoporosis. Patients with discordant BMD at the distal radius have anthropometric characteristics that are significantly different from patients with generalized osteoporosis. These differences may represent differences in the etiology of osteoporosis and differential effects on cortical versus trabecular bone.

WG8

Association Between Age, Height, Weight and Bone Mass Index with Discordant Changes in Bone Mineral Density Detected on Sequential Bone Densitometry Scans. R. Munasinghe, V. Botea, G. Edelson. Department of Medicine, Sinai-Grace Hospital, Wayne State University, Detroit, MI, USA.

Osteoporosis is a systemic disease with age related concordant decline in bone mineral density at most major skeletal sites. Low body weight is another important risk factor for osteoporosis. In some patients detrimental change in BMD is discordant and limited to one skeletal site. This study was done to compare the anthropometric characteristics of patients with concordant and discordant changes in BMD on sequential bone densitometry scans. Data from 1180 patients with sequential bone densitometry scans were analyzed to evaluate changes in BMD at the lumbar spine, femoral neck and distal radius. Two methods were used to identify discordant and concordant change in BMD. In the first, changes in BMD were compared relative to the median rate of change for the entire cohort. In the second method absolute gain or loss of BMD from the first to the second scan were used. A patient was determined to be concordant for detrimental change in BMD when changes in BMD were detrimental at all three sites and discordant for a particular skeletal site when the detrimental change was limited to that site. The mean age, height, weight and body mass index (BMI) of these groups were compared. Discordant detrimental change in BMD was most prevalent at the distal radius independent of the method used to determine detrimental change in BMD. When defined using changes relative to the group median, patients with discordant detrimental change in BMD at the radius were significantly older (mean age 63.3 vs. 61.2, P<.05), shorter (mean height 157 vs. 159 cm, P<.01) and heavier (mean weight 65.1 vs. 63.5 Kg, P<.05, BMI 26.2 vs. 25.0 Kg/m2, P<.001) than patients with concordant detrimental change in BMD. The results were similar when the absolute changes in BMD were used to define discordancy. The differences in anthropometric characteristics between patients with concordant and discordant changes in BMD may represent differential effects on bone related to the etiology or treatment of osteoporosis, weight bearing and mechanical loading properties, or due to differential effects of these factors on cortical and trabecular bone.

WG9

Hypocalcemia in a Male with Polyglandular Failure in Association with an Antibody to the Calcium Sensing Receptor. M.S. LeBoff[1], O. Kifor[2], E. M. Brown[1]. [1]Skeletal Health and Osteoporosis, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA, [2]Endocrine Hypertension Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA.

Autoimmune-mediated hypoparathyroidism is a feature of polyglandular failure type I in children but not polyglandular failure type II. We describe a male who presented with hypocalcemia in the presence of adrenal crisis. PM is a 25 yo male admitted with 6 months of progressive fatigue, weight loss, vomiting, and salt craving, and hyperpigmentation over 2 years. The patient was hypotensive on admission with a Na 124 mmol/L, K 5.9 mmol/L, calcium 8.0 mg/dl, albumin of 4.4 mg/dl, and ionized calcium of 1.10 mmol/L (1.13-1.32). Past medical history revealed hypothyroidism for which he was treated with synthroid 100 mcg/d. Family history was positive for celiac disease (cousin). Laboratory evaluation revealed a PTH of 20 pg/ml and 25-hydroxyvitamin D level of 18.5 ng/ml. ACTH stimulation resulted in cortisol levels of a 0.2 and .5 mcg/dl at 0 and 60 minutes, respectively. The patient was treated with stress-dose hydrocortisone and fluid resuscitation. TPO antibody was 120 (0-20 IU) and an antiendomysial antibody was negative. In vitro studies to assess the presence and functional activity of antibodies to the calcium sensing receptor (CaR) showed:

- Positive Western blots of bovine parathyroid gland extracts.
- Positive ELISA against a peptide within the CaR's amino-terminal region.
- Stimulation of inositol phosphate generation compared to control serum in HEK cells transfected with the calcium sensing receptor.
- Inhibition of PTH release from dispersed human parathyroid cells compared with control serum.

In summary, this is an unusual case of a male with hypocalcemia, autoimmune-mediated hypothyroidism, presenting with adrenal crisis, a setting in which the calcium is expected to be elevated. Detailed analysis of his serum showed a normal 25-hydroxyvitamin D and PTH = 20 ng/ml in the presence of low calcium levels. In vitro studies revealed a functional antibody to the calcium sensing receptor that activates inositol phosphate generation and inhibits PTH release in association with hypocalcemia. These data indicate that hypocalcemia and antibodies to the CaR may represent a new feature of polyglandular failure Type II.

PEDIATRIC BONE AND MINERAL WORKING GROUP

WG10

I-cell Disease Presenting as Severe Neonatal Hyperparathyroidism. S. Unger[1], D.E.C Cole[1,2]. [1]Division of Clinical and Metabolic Genetics, Hospital for Sick Children, Toronto, Canada, [2]Departments of Pathobiology and Medicine, University of Toronto, Toronto, Canada.

I-cell disease (mucolipidosis II) is an autosomal recessive disorder of enzyme targeting that presents between 6 and 12 months of age with a clinical phenotype resembling Hurler syndrome and a radiographic phenotype of dysostosis multiplex. When I-cell disease is so severe as to be detected in the newborn period, its radiographic changes have been previously described as similar to hyperparathyroidism or rickets. The biological basis of these radiographic findings has not been explored and few biochemical measurements have been recorded. We describe a newborn with radiographic features of severe hyperparathyroidism including osteopenia, bent long bones due to in utero fracturing, metaphyseal fraying and expansion, and sub-periosteal cloaking. The first PTH measurement on day 12 of life was 876 ng/L (normal:10-65 ng/L) and PTH peaked at 1176 ng/L with subsequent resolution to normal by one month of age (39 ng/L). The alkaline phosphatase level followed a similar but delayed course: in the immediate newborn period it was dramatically increased and reached a peak value of 2883 U/L (normal: 185-555 U/L) at one month of age. However, the calcium level remained normal throughout (2.32mmol/L on day 4), while the phosphate was low (1.12 mmol/L) and 1,25(OH)2 D was normal (100 pmol/L -- reference range, 40-140 pmol/L). At 3 months of age, markedly elevated lysosomal enzymes in plasma established I-cell disease as the primary diagnosis. With normalization of PTH, the osteopenia, metaphyseal cupping and periosteal cloaking resolved and the typical changes of dysostosis multiplex became more obvious. We speculate that severe I-cell disease can be accompanied by hyperparathyroid bone disease early in life. The mechanism of the prenatal stimulation of the parathyroid glands and its spontaneous resolution remain unknown. However, one possible explanation would be that the enzyme targeting defect underlying I-cell disease resulted also in an uncoupling between the calcium sensing receptor (CASR) and PTH, but the maintenance of normocalcemia in spite of highly elevated PTH is unexplained.

WG11

Osteoporosis in Mucopolysaccharidosis type II (Hunter's syndrome) D. Rigante[1], G. Segni[1], R. Ricci, A. Di Stasio[1], P. Caradonna[2]. [1]Department of Pediatrics, Universita Cattoilca Sacro Curoe, Rome, Italy, [2]Department of Internal Medicine, Università Cattolica Sacro Cuore, Rome, Italy.

Mucopolysaccharidosis (MPS) type II or Hunter's syndrome is an X-linked recessive lysosomal storage disorder due to iduronate sulphatase deficiency displaying a wide spectrum of clinical severity. Skeletal involvement is constant in MPS type II: osteoporosis is a substantial cause of morbidity because of fracture risk. We have submitted two patients with MPS II to dual energy X-ray absorptiometry (DEXA, Hologic QDR 2000) in order to assess bone mineral density (BMD) and determine its relationship with disease severity. The features of our two patients and the results of our investigation, expressed in Z-scores calculated on the basis of the respective ages of normal males, are shown in the following table.

	Age	Bone storage	Onset	BMI	Deambulation	Puberty	Epilepsy	L-BMD	Z-score	F-BMD	Z-score
1	22 ys	present	3.5 ys	15.3	absent	absent	present	0.401	-6.49	0.281	-6.29
2	21 ys	present	5 ys	17.0	absent	present	absent	0.454	-4.73	0.638	-4.34

Patients with MPS type II may present restricted growth, mental/physical disability and a wide spectrum of functional bone impairment due to bone storage of undegraded mucopolysaccharides, inadequate body weight, malabsorption of calcium, decreased serum 25-hydroxyvitamin D, absent physical exercise and sex hormone deficiency. Lumbar and femoral neck BMDs were found to be very severely reduced in the two patients, with differences attributable to hypogonadal state and use of antiepileptic drugs altering vitamin D metabolism. Bone integrity needs to be overlooked in order to ameliorate the quality of life of these patients: dietary supplements (calcium, vitamin D) can slow the process of skeletal demineralization and physiotherapy can contribute to the construction of bone substance and pain alleviation. We conclude that DEXA determinations have a great utility for screening patients with disorders electively involving the skeleton at risk for osteoporosis.
