Mammary-specific Deletion of PTHrP Reduces Bone Turnover and Preserves Bone Mass During Lactation. J. VanHouten,*[1] P. Dann,*[1] A. Stewart,*[2] C. Watson,*[3] A. Karaplis,*[4] J. Wysolmerski.*[1] [1]Yale Medical School, New Haven, CT, USA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, [3]University of Cambridge, Cambridge, United Kingdom, [4]McGill University, Montreal, Canada.

Lactating mammals secrete large amounts of calcium into milk. Much of this calcium appears to come from the maternal skeleton, for lactation is associated with reversible increases in bone resorption and reductions in bone mass. Neither PTH nor 1,25 dihydroxyvitamin D are necessary or sufficient to account for the mobilization of calcium during lactation, and the regulation of calcium transfer from mother to milk remains poorly understood. The PTHrP gene is highly expressed in mammary epithelial cells (MEC) during lactation, and milk is the most abundant physiological source of PTHrP. It has been suggested that PTHrP might contribute to the regulation of bone turnover during lactation, but because mammary development fails in the absence of PTHrP, traditional PTHrP knockout mice have not addressed this question. In order to examine this issue, we utilized Cre-lox technology to delete the PTHrP gene in MEC, but only at the onset of lactation after development was complete. We created mice that were hemizygous for an ovine β-lactoglobulin (BLG) promoter-driven Cre transgene and that were compound heterozygotes at the PTHrP locus, with one allele containing a disrupted exon 4 and the other containing an exon 4 flanked by loxP sites. In these Cre-lox mice, upon induction of the BLG milk gene promoter during lactation, the one functioning PTHrP allele is removed by Cre-mediated recombination specifically in MEC. Littermate controls had identical PTHrP loci, but no BLG-Cre. Nearly all MEC of lactating Cre-lox, but not virgin Cre-lox or control mice, expressed Cre. PTHrP RNA was almost completely absent in mammary glands from lactating Cre-lox mice. Milk PTHrP was reduced by 75% in these mice, but significant amounts (4.7ng/ml) remained. Circulating levels of PTHrP were reduced, as was urinary cAMP excretion. In addition, compared to controls, lactating Cre-lox mice had lower rates of bone resorption as measured by histomorphometry and urinary excretion of type I collagen fragments, and higher bone mass. In summary, we have successfully deleted the PTHrP gene within the lactating mammary gland. This lowers PTHrP levels in milk and in the maternal circulation. It also lowers maternal bone resorption rates and preserves maternal bone mass. We conclude that MEC secrete PTHrP into both milk and the maternal circulation during lactation. This mammary-derived PTHrP increases bone resorption and leads to a decrease in bone mass, thus contributing to the efflux of calcium from the maternal skeleton during lactation.

Essential Role of HIF-1alpha in Growth Plate Development. E. Schipani,[1] H. E. Ryan,*[2] T. Kobayashi,[1] M. Knight,*[1] R. S. Johnson.*[2] [1]Endocrine Unit, MGH-Harvard Medical School, Boston, MA, USA, [2]Division of Biology, UCSD, San Diego, CA, USA.

The growth plate is an avascular tissue. However, no data are available that directly address the issue of the degree of oxygenation of the growth plate during embryogenesis, and the role of hypoxic response in that tissue.To ascertain the presence of hypoxia in mammalian fetal cartilage, we injected a marker for bio-reductive activity into pregnant female mice E15.5. This marker, the nitroimidazole EF5, allowed us to study distribution of the molecule in the fetal growth plate via a rhodamine-coupled anti-EF5 antibody .We found that the fetal growth plate is hypoxic in its interior but not at its periphery, indicating that there is a gradient of oxygenation evolved during the growth of this tissue.In vitro the transcripion factor HIF-1alpha is a major modulator of the trancriptional response to hypoxia, by regulating expression of genes involved in metabolic processes and angiogenesis.We thus postulated that HIF-1alpha could be critical for growth plate development. Mice nullizygous for HIF-1alpha die at approximately E9. Therefore, in order to determine the role of HIF-1alpha in chondrocyte activity and, in general, to investigate its role in survival of hypoxic cells in vivo, we conditionally inactivated HIF-1 alpha in growth plate chondrocytes. Newborn mutant mice lacking HIF-1 alpha in the growth plate were smaller than control littermates with characteristic shortening of the limbs and died within a few hours of birth. Their growth plates were misshapen and disorganized. In particular, the center of both the proliferative and the hypertrophic zones was either remarkably hypocellular or occupied by abnormal cellular elements with irregular nuclei.The presence of cells expressing typical chondrocyte markers such as collagen type II and/or collagen type X at the periphery of the mutant growth plate indicated that the lack of HIF-1alpha had not significantly altered the process of chondrocyte proliferation and differentiation per se. However, the absence of collagen type II mRNA expression and the presence of numerous TUNEL positive cells in the central core of the growth plate provided evidence that chondrocytes in the core of the mutant cartilaginous element underwent massive cell death and that, therefore, HIF-1alpha was required for survival of hypoxic chondrocytes. This severe and unique phenotype was associated with downregulation of mRNAs encoding both VEGF and enzymes of the glycolytic pathway.This is the first in vivo model that demonstrates the physiological role of HIF-1alpha in cellular adaptation to hypoxia during fetal development; as such, it points out the essential role micro-physiological response plays in mammalian ontogeny.

Heterozygous PPARγ-Deficient Mice Exhibit High Bone Mass with Increased Osteoblastic Differentiation from Bone Marrow Progenitors. T. Akune,[1] N. Kubota,*[2] Y. Harada,[3] Y. Azuma,[3] T. Kadowaki,*[2] K. Nakamura,[1] H. Kawaguchi.[1] [1]Orthopaedic Surgery, University of Tokyo, Tokyo, Japan, [2]Metabolism, University of Tokyo, Tokyo, Japan, [3]Teijin Co. Ltd., Tokyo, Japan.

Possible regulation of osteoblastic differentiation by peroxisome proliferator-activated receptor γ (PPARγ), a nuclear receptor that plays a pivotal role in adipocyte differentiation, has been reported in several mesenchymal cell cultures. To investigate the role of endogenous PPARγ in vivo, we created mice lacking the PPARγ gene by homologous recombination in mouse embryonic stem cells. Although homozygous PPARγ-deficient embryos died at 10-11 dpc due to placental dysfunction, heterozygous PPARγ-deficient (+/-) mice developed normally except for lower fat mass than wild-type (+/+) mice on a high-fat diet. However, bone densitometry and 3D-μCT analyses revealed significant increases of both trabecular and cortex bone volumes in +/- mice compared to +/+ littermates. Histomorphometric analysis at 8 weeks showed that bone volume (BV/TV) was 38% higher and parameters for osteoblast number (Ob.S/BS, OS/BS, & MS/BS) were 92-114% higher in +/- mice. On the other hand, bone formation parameters normalized to the number of osteoblasts (MAR & BFR/Ob.S) and bone resorption parameters (Oc.N/B.Pm & ES/BS) were slightly (5-12%) but not significantly higher in +/- mice. In bone marrow cell culture derived from +/- mice, osteoblastogenesis determined by ALP-positive CFU-F and Alizarin red / von Kossa-positive CFU-OB was markedly increased compared to that in +/+ marrow cell culture. Troglitazone, a ligand of PPARγ, notably stimulated adipogenesis (oil red O-positive CFU-AD) and inhibited osteoblastogenesis in +/+ marrow cell culture, while both effects were much milder in +/- marrow cell culture. +/- marrow cells showed lower PPARγ but higher Cbfa1 mRNA levels than +/+ marrow cells. Osteoblastic proliferation and matrix synthesis in the primary calvarial osteoblast culture did not differ between +/- and +/+ cultures. Osteoclastogenesis in the M-CSF-dependent bone marrow macrophage culture in the presence of soluble RANKL, osteoclastogenesis / resorbed pit formation in the co-culture of osteoblasts and marrow cells, and isolated osteoclast survival were not different between +/- and +/+ cultures. We conclude that deficiency of PPARγ in +/- mice increases bone mass by stimulating osteoblastogenesis from bone marrow progenitors without affecting mature osteoblasts or osteoclast-lineage cells. Because human aging is associated with a reciprocal increase in adipocytes and a decrease in osteoblasts in bone marrow, PPARγ may be clinically involved in the pathophysiology of bone loss with aging as a suppressor of osteoblastogenesis.

Dysfunctional Osteoblasts, Impaired Osteoblastogenesis, Reduced Bone Formation and Severe Osteoporosis in a Calcineurin Aα Null Mouse. Molecular Implications for Understanding Immunosuppressant Bone Loss. L. Sun,[1] O. A. Adebanjo,[1] X. H. Liu,*[1] B. S. Moonga,[1] A. Inzerillo,*[1] A. Koval,*[1] X. Y. Wu,*[1] X. B. Wu,*[1] P. J. R. Bevis,[1] H. C. Blair,[2] D. Conner,*[3] J. Seidman,*[3] B. R. Troen,[1] S. Epstein,[1] E. Abe,[1] M. Zaidi.[1] [1]The Mount Sinai Bone Program and Bronx VA GRECC, NY, USA, [2]University of Pittsburgh, PA, USA, [3]Harvard Medical School, MA, USA.

The widely used immunosuppresants, cyclosporine A (CsA) and tacrolimus (FK506) cause profound bone loss. Both compounds potently inhibit calcineurin A, a calmodulin-activated cellular phosphatase. We report here that: (a) calcineurin Aα null mice are severely osteoporotic with reduced bone formation; (b) calcineurin Aα directly stimulates bone formation; and (c) the genes for calcineurin A and its signaling molecules, NFAT1c and ryanodine receptors are co-regulated. Calcineurin Aα null mice exhibited runted long bones (~20%) and reductions in tibial metaphyseal diameter (~15%) and diaphyseal cortical thickness (~40%). Femoral bone mineral density was significantly decreased. Dual tetracycline labeling indicated a ~40% reduction in bone formation *in vivo* consistent with diminished osteoblast maturation (CFU-F formation) *in vitro.* Together, the findings provided compelling evidence for a role for calcineurin A in osteoblast formation and thus prompted further studies. We therefore cloned both calcineurin Aα and Aβ genes from a cDNA library. Immunostaining, confocal imaging, Western immunoblotting, RT-PCR and single cell *in situ* RT-PCR indicated that calcineurin Aα was localized to both osteoblasts and osteoclasts. We next synthesized and purified a TAT-calcineurin Aα fusion protein. Note that the fusion of any protein with TAT, a 12 amino acid long Arg-rich sequence, results in its receptor-less movement across cell membranes. Likewise, MC3T3.E1 osteoblastic cells were transduced with high, ~90%, efficiency with the TAT-calcineurin Aα. Noteworthy is that the transduced fusion protein dramatically enhanced osteoblastic maturation (alkaline phosphatase positivity). This, together with the bone formation defect seen in the calcinueirn Aα null mouse, suggested clearly that calcineurin Aα was directly anabolic to bone. Finally, we found that the calcineurin A signaling molecules, ryanodine receptor and NFAT1c, were co-regulated upon calcineurin Aα transfection of MC3T3.E1 cells as well as in the calcineurin Aα null mouse. Taken together, the evidence strongly favors a new role for the calcineurin pathway in osteoblastic bone formation. The inhibition of this pathway may underlie the low turnover osteoporosis seen with CsA and FK506.

Stimulated Osteoclastogenesis is Impaired in NF-κB Inducing Kinase Knockout Mice Despite an Intact NF-κB Signaling Pathway. D. V. Novack, L. Yin,* R. D. Schreiber,* F. P. Ross, S. L. Teitelbaum. Pathology, Washington University, St. Louis, MO, USA.

RANKL activates NF-κB in osteoclast precursors. Mice lacking RANKL, RANK, or both the p50 and p52 subunits of NF-κB fail to generate osteoclasts (OCs). NF-κB inducing kinase (NIK) is a non-receptor serine/threonine kinase thought to link a number of cell surface receptors with the NF-κB pathway. Given the central role of the RANKL/RANK/NF-κB pathway in osteoclastogenesis, we asked if NIK is essential for OC formation. Concentrations of RANKL as high as 10 fold the optimal dose for wild-type (WT) cells fail to induce OC differentiation of marrow macrophages derived from $NIK^{-/-}$ mice ($p<0.001$ compared to WT). Those $NIK^{-/-}$ OCs that do form do not spread normally nor resorb bone-like substrates. Because TNFα and TGFβ synergize with suboptimal doses of RANKL in normal cells, we asked if these cytokines would enhance osteoclastogenesis in NIK-deficient cultures. TNFα, and especially TGFβ, substantially rescues the capacity of $NIK^{-/-}$ macrophages to form functional OCs, but only when combined with doses of RANKL 5-10 times higher than those needed in WT cultures. OC number is completely normalized by the combination of TNFα and TGFβ in the presence of high dose RANKL. Having established that absence of NIK impairs osteoclastogenesis in vitro, we turned to the role of the kinase in vivo. OCs are present in normal numbers in the bones of unmanipulated, NIK-deficient mice, perhaps due to the presence of TNFα and/or TGFβ in vivo. However, these animals fail to respond to the potent osteoclastogenic agent parathyroid hormone (adminis-

tered over the calvarium every 6 hours for 3 days), with either stimulated osteoclastogenesis or enhanced resorption, as determined by calvarial OC number and porosity. Studies performed in other cell types, and involving other membrane receptors, have linked NIK with the NF-κB pathway at various levels. Absence of NIK, however, does not diminish NF-κB activation in OC precursors in response to RANKL. RANKL induces normal IκBα degradation in $NIK^{-/-}$ precursors, with subsequent nuclear translocation of NF-κB and up-regulation of the NF-κB responsive genes IκBα, ICAM, and TLR-2. Moreover, NIK has also been implicated as the molecule required for processing of p100 to p52, but we find normal p52 levels in RANKL-stimulated OC precursors. These events establish that, despite their inability to undergo osteoclastogenesis, $NIK^{-/-}$ macrophages show full activation of NF-κB by RANKL. Thus NIK, while not required for basal osteoclastogenesis, is essential for stimulated osteoclastogenesis and bone resorption, and has critical functions in OC recruitment beyond the activation of NF-κB.

Osteoclast Inhibitory Lectin – A Family of New Osteoclast Inhibitors. H. Zhou, V. Kartsogiannis, J. M. W. Quinn, J. Elliott,* C. Ly,* K. W. Ng, M. T. Gillespie. St. Vincent's Institute of Medical Research, Melbourne, Australia.

Osteoclast Inhibitory Lectin (OCIL) is a predicted type II membrane-bound molecule of 207aa containing a C-lectin domain in its extracellular domain. Recombinant protein to the extracellular domain of mOCIL inhibits osteoclast formation in murine osteoblast with spleen cell cocultures, murine spleen and adherent spleen cell cultures treated with RANKL and M-CSF, and in human monocyte cultures treated with M-CSF and RANKL. These results suggest that OCIL acts upon hemopoietic cells to inhibit osteoclast formation.We have identified two novel C-lectins that share substantial identity with murine OCIL. These new molecules have been designated OCILrp1 and OCILrp2. The novel OCIL-related proteins were identified by nucleic acid sequence analyses of RT-PCR products derived from RNA extracted from murine osteoblasts treated with IL-11 for 24 hr. Full length OCILrp1 and OCILrp2 were cloned and predicted to encode type II membrane-bound C-lectins of 218 and 217aa, respectively. The predicted intracellular domains of OCILrp1 and OCILrp2 shared 83% identity, but showed no identity with the intracellular domain of OCIL. The extracellular domains of OCILrp1 and OCILrp2 share 83% and 75% identity, respectively, with the extracellular domain of OCIL. The extracellular domains of OCILrp1 and OCILrp2 were expressed in E. coli, and each protein inhibited osteoclast formation in murine spleen cultures treated with M-CSF and RANKL with similar potencies to OCIL (IC50 0.2 ng/ml).Immunohistochemistry using antipeptide antibodies to the intracellular domain of OCILrp1/2 and to OCIL demonstrated that OCIL and OCILrp1/2 were concordantly expressed in osteoblasts, chondrocytes and in extraskeletal tissues. Further, their cellular distribution was identical to that of RANKL. Distinct genes encoded the three OCIL family members. OCIL and OCILrp1 genes were of 6 and 9kb, containing 5 and 6 exons, respectively, with 4 intron/exon boundaries conserved suggesting gene duplication. A TATA promoter controlled OCIL expression and a GC-rich promoter controlled OCILrp1. Consistent with these promoters, OCIL mRNA expression in primary murine osteoblasts was upregulated by calciotropic agents (PTH, 1,25(OH)2 vitamin D3 and IL-11), while OCILrp1 and OCILrp2 were constitutively expressed. Notably, osteoblast OCIL was upregulated by calciotropic agents that also upregulate RANKL; in contrast these factors typically down regulate OPG production by osteoblasts.The identification of three distinct genes and OCIL proteins implies redundancy for OCIL, and their concordant expression with that of RANKL suggests that the RANKL : OPG axis may be further influenced by OCIL family members.

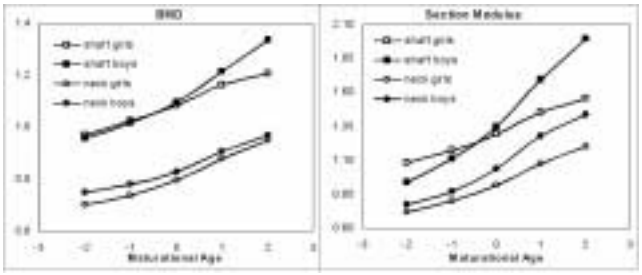
Gender Differences In Bone Geometry During The Adolescent Growth Spurt. D. A. Bailey,[1] T. J. Beck,[2] M. R. Forwood,[3] R. L. Mirwald,*[1] W. A. Wallace,*[1] R. A. Faulkner.*[1] [1]College of Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada, [2]Radiology, The Johns Hopkins University, Baltimore, MD, USA, [3]Anatomical Sciences, The University of Queensland, Brisbane, Australia.

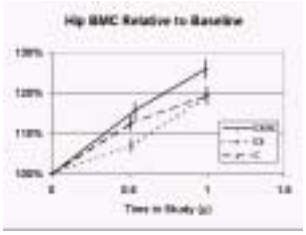
To investigate whether there are gender differences in the bone geometry of the proximal femur during the adolescent years we used an interactive computer program ?Hip Strength Analysis? developed by Beck and associates (Beck et al., Invest Radiol. 1990,25:6-18.) to derive femoral neck geometry parameters from DXA bone scans (Hologic 2000, array mode). We analyzed a longitudinal data-set collected on 70 boys and 68 girls over a seven year period. Distance and velocity curves for height were fitted for each child utilizing a cubic spline procedure and the age of peak height velocity (PHV) was determined. To control for maturational differences between children of the same chronological age and between boys and girls, section modulus (Z) an index of bending strength, cross sectional area of bone (CSA), sub-periosteal width (SPW), and BMD values at the neck and shaft of the proximal femur were determined for points on each individual?s curve at the age of PHV and one and two years on either side of peak. To control for size differences, height and weight were introduced as co-variates in the two-way analyses of variance looking at gender over time measured at the maturational age points (-2, -1, age of PHV, +1, +2). The following figure presents the results of the analyses on two variables, BMD and Z at neck and shaft regions:After the age of peak linear growth (PHV), independent of body size, there was a gender difference in BMD at the shaft but not at the neck. Section modulus at both sites indicated that male bones became significantly stronger after PHV. Underlying these maturational changes, male bones became wider (SPW) after PHV in both the neck and shaft and enclosed more material (CSA) at all maturational age points at both regions. These results call into question the emphasis on using BMD as a measure of skeletal integrity in growing children.



1008

Exercise without Sufficient Calcium Does Not Increase Rate of Bone Mass Accrual in Pubertal Females. J. M. Lappe, J. A. Stubby,* K. M. Davies, R. R. Recker. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

The link between optimal development of the skeleton in childhood and prevention of fractures late in life is widely acknowledged. Although it is recognized that exercise is necessary for optimal skeletal development, our understanding of the effects of exercise on bone strength of growing females is incomplete. Further, we do not know whether increased exercise enhances skeletal development in the absence of sufficient calcium. These questions are particularly salient in light of the current low levels of physical activity and calcium intake in American youth. The purpose of this study is to determine if weight-bearing exercise increases bone mass accrual in pubertal females and whether the combination of weight-bearing exercise and a high calcium diet has a greater effect than exercise alone. The convenience sample includes 101 healthy premenarchal females who were 9 to 10 years old and in Tanner Stage 1 upon entry into study. Participants were randomly assigned to 1 of 3 groups: 1. (EX) participate in a weight-bearing exercise program that meets 3 times/week and consume usual diets; 2. (EXHC) participate in the weight-bearing exercise program and consume at least 1500 mg/day of calcium from foods; or 3. (C) consume usual diet and maintain customary activity level. Bone mineral content (BMC) is measured with dual energy absorptiometry (DXA) at the hip, spine, radius and total body. Calcium intake is determined by 3-day diet diaries. This is an interim report made 1 yr. into a 3-yr study.There were no differences in anthropometric or bone mass values at baseline. Mean baseline hip bmc by group was: EX 15.6(3.4) g; EXHC 14.4(3.0) g; and C 15.2(3.3) g. Mean daily intake of calcium by group during the study was: EX-898 mg; EXHC-1644 mg; and C-847 mg. One way ANOVA indicated that after 1 year of treatment the EXHC group demonstrated a significantly greater rate of increase in hip BMC than both the EX and the C groups ($p<0.05$). (See figure). Rate of gain of BMC at the other sites did not differ between groups. We conclude that exercise-related increases in bone mass accrual in pubertal girls are dependent on sufficient calcium intake.



1009

The Effect of Dietary Sodium on Calcium Retention in Black and White Female Adolescents. K. Wigertz,[1] C. Palacios,[1] A. Kempa-Steczko,*[1] B. Martin,[1] G. McCabe,*[1] M. Peacock,[2] J. H. Pratt,*[2] C. M. Weaver.[1] [1]Purdue University, West Lafayette, IN, USA, [2]IU School of Medicine, Indianapolis, IN, USA.

Dietary sodium is believed to be a major determinant of calcium excretion in urine. A metabolic study was undertaken to test the hypothesis that high sodium intake may lead to decreased calcium retention in adolescent girls. A total of 36 girls (age 12 ± 1 years in blacks and 13 ± 1 years in whites) participated in two sessions of summer camp, simulating a free-living environment. Each session of the camp was three weeks long separated by a two-week wash-out period. The controlled diet consisted of 815 mg calcium and one of two levels of sodium (1.3 g and 4.0 g). The diet was also constant in magnesium, potassium, phosphorus, protein, fat, and fiber. The two levels of sodium were tested using a randomized crossover design. The study indicated that black girls had significantly ($P < 0.05$) higher calcium retention than white girls regardless of dietary sodium level. The daily urinary calcium output in white girls was significantly ($P < 0.05$) higher with the high sodium diet than with the low sodium diet. Black girls excreted significantly ($P < 0.01$) less calcium in the urine than white girls on the high sodium diet. This indicates a possible genetic predisposition to the effect of salt on the kidney in the white population. In summary, increased dietary sodium led to increased urinary calcium in the white adolescent girls only. No effect of salt intake on urinary calcium was seen in the blacks.

Table 1. Daily urinary and fecal calcium excretion, calcium retention, and apparent calcium absorption in black and white adolescent girls

	Race	Low Sodium diet	High sodium diet

Urinary calcium excretion (mg/day)	Blacks	44 ± 39	48 ± 36**
	Whites	62 ± 35a	101 ± 41 a**
Fecal calcium excretion (mg/day)	Blacks	292 ± 136*	325 ± 153
	Whites	480 ± 260*	508 ± 202
Calcium retention (mg/day)	Blacks	516 ± 158**	469 ± 182*
	Whites	265 ± 246**	213 ± 219*
Apparent calcium absorption (%)	Blacks	23 ± 13	20 ± 13
	Whites	12 ± 21	17 ± 20

Mean ± SD
[a] Group means were statistically significant at P < 0.05 between diets
* Group means were statistically significant at P < 0.05 between races
* * Group means were statistically significant at P < 0.01 between races

Underdiagnosis of Vertebral Fractures Is a Worldwide Problem: The IMPACT Study. P. D. Delmas,[1] N. Watts,[2] R. Eastell,[3] G. Von Ingersleben,*[4] L. van de Langerijt,*[5] D. L. Cahall.[6] [1]University Claude Bernard, Lyon, France, [2]Emory University, Atlanta, GA, USA, [3]University of Sheffield, Sheffield, United Kingdom, [4]Synarc, San Francisco, CA, USA, [5]Aventis Pharma, Hoevelaken, The Netherlands, [6]Aventis Pharma, Bridgewater, NJ, USA.

Two thirds of fragility vertebral fractures do not come to clinical attention. In addition, it has been reported in retrospective studies that vertebral fractures are underdiagnosed in radiology reports. We have looked at the accuracy of the radiology report of vertebral fractures in a large prospective trial, the IMPACT study. The primary aim of the study is to assess the impact of using bone turnover marker monitoring of risedronate treatment on patient compliance and persistence. Over 7166 women aged 65-80 yr were screened for osteoporosis by DXA in 172 centers in Europe, North and Latin America. 2386 women that had osteoporosis, i.e. a T score ≤ -2.5 at the spine and/or hip or a T score between -2.5 and -1 with a peripheral fragility fracture, and who were willing to be enrolled into the trial, had lateral radiographs of the thoracic and lumbar spine that were subsequently reviewed centrally by an expert radiologist and classified according to the semiquantitative method of Genant. The presence of a vertebral fracture was not a criteria for study entry. Out of 1860 evaluable radiographs analyzed centrally so far, 592 women (32%) had one or more vertebral fracture(s). In 252 of them the diagnosis of vertebral fracture was not made by the local radiologist, i.e. a false negative rate (FNR) of 43%. The underdiagnosis of vertebral fractures was highly prevalent worldwide, with a FNR of 57% in centers in North America, 35% in centers in Europe and 62% in Latin America. Conversely, 117 women without vertebral fractures according to the central reading were diagnosed locally as having vertebral fracture(s), leading to a false positive rate of 9.2% globally, 9.4% and 1% in North and Latin America respectively, and 10.2% in Europe. We conclude that vertebral fractures are markedly underdiagnosed in the radiology report, a pattern that probably contributes to the undertreatment of postmenopausal osteoporosis.

Disclosures: Aventis Pharma,3.

Long-Term Prediction of Incident Hip Fracture Risk in Older White Women. B. C. Taylor,*[1] P. J. Schreiner,[1] K. L. Stone,[2] S. R. Cummings,[2] M. C. Nevitt,[2] K. E. Ensrud.[3] [1]University of Minnesota, Minneapolis, MN, USA, [2]University of California, San Francisco, CA, USA, [3]VA Medical Center & University of Minnesota, Minneapolis, MN, USA.

Previous studies have shown bone mineral density (BMD), age and other factors to be strong predictors of incident hip fracture over relatively short follow-up periods. Using risk factor data from the Study of Osteoporotic Fractures (SOF), we examined the relationship of BMD and other factors to hip fracture risk during long-term follow-up.At the second SOF exam (1988-90), we measured total hip BMD by DXA in 8,070 women age 67 years and older. We then followed these women for an average of 8.5 (+/-2.4) years; during this time 444 incident hip fractures occurred. At the first and second exams, risk factors for fracture, including anthropometry, muscle strength, a variety of physical performance measures, self-reported personal and family fracture history, reproductive history, health status, personal habits, cognitive function, medication use, functional status and other measures were collected. Measurements from the first exam included parity, maternal history of hip fracture, height at age 25 and type 2 diabetes status; the remainder were from visit 2.Using Cox regression, best subset and stepwise techniques were used to identify independent risk factors. Variables that remained significantly related to hip fracture (p<0.05) in a multivariate model are shown in the table below with and without adjustment for total hip BMD.

Variable (unit change)	HR Without BMD (95% CI)	HR With BMD (95% CI)
Mom hip fracture after 50 (yes/no)	1.64 (1.24, 2.16)	1.51 (1.14, 2.00)
Age at viswit 2 (5 years)	1.54 (1.39, 1.71)	1.42 (1.28, 1.57)
Fractured any bone after age 50 (yes/no)	1.50 (1.23, 1.84)	1.27 (1.04, 1.56)
He8ght at age 25 (6cm)	1.18 (1.07, 1.31)	1.21 (1.10, 1.34)
Digit SWymbol Test (12 completed)	0.83 (0.74, 0.93)	0.84 (0.75, 0.94)
Walking speed (0.22 m/s)	0.77 (0.69, 0.86)	0.80 (0.71, 0.89)
Percent weight change 25 to visit 2 (20%)	0.75, (0.67, 0.84)	0.95 (0.84, 1.07)
Parity: 1-3 children vsw no children and 4 or more children vs no children	0.76 (0.60, 0.96) 0.49 (0.34, 0.69)	0.75 (0.59, 0.94) 0.48 (0.34, 0.69)
Total hip BMD (013g/cms2)		0.53 (0.47, 0.61)

Type 2 diabetes, current smoking and thyroid medication use were also significantly associated with increased rates of hip fracture. When total hip BMD was added to the multivariate model, all variables remained significant except for current smoking and percent weight change from age 25.We conclude that while BMD is strongly related to hip fracture risk in elderly white women, other risk factors are also independent predictors of long-term risk and may provide additional insight into prevention of fracture in high risk women

1012

Bone Mineral Density and Verbal Memory Impairment: The Third National Health and Nutrition Examination Survey (NHANES III). Y. Q. Zhang,[1] S. Seshadri,*[2] R. C. Ellison,*[3] T. Heeren,*[4] D. T. Felson.[3] [1]Arthritis Center, Boston University, Boston, MA, USA, [2]The Framingham Heart Study, Framingham, MA, USA, [3]Boston University School of Medicine, Boston, MA, USA, [4]Boston University School of Public Health, Boston, MA, USA.

While numerous studies have examined the relation of either a single measurement of endogenous estrogen levels or estrogen replacement therapy to the risk of poor cognitive function among women, the results have been inconclusive. No study has examined this relation in men. Bone mineral density (BMD) has been proposed as a marker of cumulative estrogen exposure, with several studies showing that high BMD is associated with an increased risk of some estrogen-related diseases, such as breast cancer. We studied the association between BMD and the prevalence of verbal memory impairment in both men and women. 2,115 men and 2,189 women in NHANES III (age 60-91 years) had BMD measurement and verbal memory assessment between 1988 and 1994. BMD was measured in five regions of the proximal femur with dual-energy x-ray absorptiometry. Verbal memory was assessed using the 3-delayed item recall and the 6-delayed story recall, with a combined score ranging from 0 to 9. The memory impairment was defined as a combined score < 4 (Pekins, et al, Am J Epidemiol 1999;150:37-44). Since sex, age and ethnicity are important determinants of memory and are strongly associated with BMD, we created age, sex, and ethnicity-specific quintiles of BMD. We used SUDDAN statistical software to incorporate sample weights and to account for the complex survey design in the variance estimates. 305 men and 231 women had verbal memory score less than 4. Prevalence decreased from 8.35% in the lowest quintile of femoral neck BMD to 5.74, 5.22, 5.00 and 3.38% among increasing quintiles of BMD in women, and 11.54, 7.27, 8.47, 6.29, and 5.89% among men, respectively. After adjusting for age, sex, ethnicity, education, income, smoking, alcohol consumption, history of stroke and hypertension, the prevalence ratios of verbal memory impairment for men and women combined from the lowest to the highest quintiles of BMD at femoral neck were 1.0, 0.64, 0.65, 0.55, and 0.44, respectively (p for trend < 0.001). A similar association was also found when BMD assessed at other proximal femoral sites were used. The relationship was consistent across almost all strata of other potential risk factors assessed above, and was robust when different cut-points, i.e., combined score < 3 or combined score < 5, were used to define the verbal memory impairment. The results from NHANES III showed that BMD in elderly men and women is strongly associated with performance on tests of verbal memory, suggesting that cumulative exposure to estrogen may play a role.

1013

C-Type Natriuretic Peptide (CNP) as Novel Positive Regulator of Endochondral Ossification - The Analysis of CNP Knock Out Mice. H. Chusho,* Y. Komatsu, N. Tamura,* Y. Ogawa,* A. Yasoda,* M. Suda,* T. Miyazawa,* M. Miura,* K. Tanaka, K. Nakao.* Medicine and Clinical Science, Kyoto University, Kyoto, Japan.

We have reported that the transgenic mice with elevated plasma level of B-type natriuretic peptide, and with targeted overexpression of C-type natriuretic peptide (CNP) in the growth plate both exhibit marked skeletal overgrowth accompanied by increased endochondral ossification. We also showed the *in vivo* CNPmRNA expression in the growth plate chondrocytes, suggesting that CNP can affect the endochondral ossification. However, the physiological role of CNP in the bone is undefined. To investigate the physiological significance of CNP *in vivo*, we generated mice with a disrupted CNP allele (*Nppc*$^{-/-}$ mice) by gene targeting in 129/Sv mice-derived embryonic stem cells. Neither *Nppc*mRNA, nor CNP protein was detected in the cerebellum or cartilage from *Nppc*$^{-/-}$ mice. In *Nppc*$^{-/-}$ mice, dwarfism with short tails and extremities became prominent as they grew. The naso-anal lengths of *Nppc*$^{-/-}$ mice were 60-70% of those of *Nppc*$^{+/+}$ mice at the age of 4-10 weeks. Soft x-ray analysis revealed that the longitudinal growth of vertebrae and tail and limb bones is affected in *Nppc*$^{-/-}$ mice. Histological analysis showed that *Nppc*$^{-/-}$ mice display striking narrowing of the growth plate of vertebrae and long bones at the age of 7 days. *In situ* hybridization analysis revealed no appreciable difference in the intensity of type II and type X collagen mRNA expression between genotypes. However the width of cell layers expressing Indian hedgehog was narrowed in *Nppc*$^{-/-}$ mice. The ratio of the height of the hypertrophic zone to that of the proliferative zone was decreased by 50% in *Nppc*$^{-/-}$ mice. There was a significant reduction of BrdUrd-labeled cells in *Nppc*$^{-/-}$ mice relative to *Nppc*$^{+/+}$ mice, demonstrating that CNP promotes chodrocyte proliferation *in vivo*. Expression of mRNA for the CNP receptor, GC-B was detected predominantly in the proliferative and prehypertrophic zone in both *Nppc*$^{-/-}$ and *Nppc*$^{+/+}$ mice. The organ culture study using the tibiae from 16.5-d fetus of *Nppc*$^{-/-}$ mice with 10^{-7} CNP achieved the 35%

increase of the total length, comparable to the result of *Nppc*$^{+/+}$ mice, suggesting that local application of CNP can rescue the skeletal defect in *Nppc*$^{-/-}$ mice. This study demonstrates that CNP is the novel endogenous positive regulator of endochondral ossification *in vivo.*

1014

C-type Natriuretic Peptide is Essential for Post-Natal Skeletal Growth. M. E. Steinhelper,*[1] L. M. Libby,*[2] A. D. Garcia,*[1] R. A. Rees,*[2] J. Rosser,*[3] B. Story,*[3] M. C. Naski,[4] L. F. Bonewald,[3] S. W. M. John.*[2] [1]Physiology, UTHSCSA, San Antonio, TX, USA, [2]HHMI, The Jackson Laboratory, Bar Harbor, ME, USA, [3]Medicine, UTHSCSA, San Antonio, TX, USA, [4]Pathology, UTHSCSA, San Antonio, TX, USA.

Extracellular signaling molecules that increase intracellular cGMP are likely to regulate postnatal skeletal development. The particulate or membrane guanylate cyclases include ligand-activated receptors for the natriuretic peptides (NPs). To investigate the potential role of the most evolutionarily conserved member of the NP gene family, C-type natriuretic peptide (CNP), we generated by homologous recombination mice with a deletion of Nppc exon 2 that encodes CNP. At birth, the expected Mendelian ratio was observed, and null mice had similar body mass (1.18 +/- 0.05) as compared with their wild-type (1.32 +/- 0.05) and heterozygous siblings (1.34 +/- 0.07). Alcian blue-alizarin red stained skeletons showed no obvious structural or developmental patterning defects in cartilage and skeleton during the embryonic period or at birth. Postnatal growth of heterozygotes was not different from wild-type controls, however, nulls showed markedly reduced postnatal growth. Appendicular bones of nulls showed significant 20-30% reductions in length at day 5, decreased longitudinal growth (30% reduction in crown-rump length), a characteristic "dome-shaped" cranium and shortened mandible which likely contributed to malocclusion, although tooth eruption appeared normal. Survival of the homozygous mice was significantly reduced (median survival of 21 days) as compared to their wild-type and heterozygous littermates (>150 days). Radiography showed a significant 37% reduction in femoral and tibial cortical thickness in the nulls on postnatal day 10. At 20 days, femoral cortical thickness was reduced significantly by 52%, as was tibial cortical thickness, 45%. These findings indicate reduced cortical bone growth during the postnatal period. Histomorphometric analysis showed a marked decrease in the width of the hypertrophic zone of growth plates at 10 and 20 days of age. New trabecular bone was severely reduced at the distal femoral and proximal tibial growth plates consistent with the reduction in hypertrophic chondrocytes. Similar changes were observed in vertebral growth plates. In conclusion, the present study demonstrates that CNP is essential for normal postnatal skeletal development in mice. Further studies will be necessary to determine the specific cellular targets of CNP action within the developing bone as well as at extraskeletal sites that contribute to the development of chondrodysplasia, dwarfism, and lethality in these mice.

Interleukin-4 Reversibly Inhibits Osteoclastogenesis via Inhibition of NF-κB and MAP Kinase Signaling. S. Wei, M. W. H. Wang, S. L. Teitelbaum, F. P. Ross. Pathology, Washington University, St. Louis, MO, USA.

Interleukin-4 (IL-4), a Th2 cytokine, inhibits osteoclastogenesis, in vitro and in vivo, and this study was designed to investigate the mechanism(s) mediating this event. We find that IL-4 inhibits formation of osteoclasts (OCs) when primary bone marrow macrophages (BMMs) are treated with M-CSF plus RANKL. The T cell-derived cytokine is effective only when added during the first two days of culture, suggesting it targets early OC precursors. Withdrawal of IL-4, up to five days after its addition to OC-generating cultures, restores OC differentiation, revealing that inhibition of OC formation is reversible. To define the molecular mechanism(s) by which IL-4 inhibits osteoclastogenesis, we examined RANKL-induced signaling pathways. Immunoblot analysis reveals that IL-4 does not alter levels of RANK, TRAF6 or IKKβ, all components of NFκB and/or MAP kinase activation. In contrast, pretreatment of BMMs with IL-4 decreases RANKL-induced IκBα phosphorylation, thus blocking degradation of this protein. As a consequence, IL-4 inhibits NFκB activation by 70%, as assessed by EMSA of nuclear extracts. Consistent with this finding, IL-4 down-regulates RANKL-induced expression of the NFκB-dependent genes IκBα, ICAM-1 and TLR-2. Turning to the MAP kinase pathway, pretreatment of BMMs with IL-4 inhibits RANKL-dependent activation of JNK, p38 and ERK signals. The abnormalities in NF-κB and MAP kinase activation, which mirror the effect of IL-4 on osteoclastogenesis, can be reversed by withdrawal of the cytokine for 24 hours. Consistent with these observations, and in contrast to previous reports, we find that the MEK inhibitors PD98059 and U0126 dose-dependently block both OC differentiation and BMM proliferation. Withdrawal of the MEK inhibitors partially rescue OC formation, demonstrating ERK activation is required for osteoclastogenesis. To further dissect the signaling pathway mediating the inhibitory effect of IL-4 on osteoclast formation, we used mice lacking either the transcription factor STAT6 or the phospholipid 5' phosphatase SHIP, both of which transduce signals from the IL-4 receptor. IL-4 fails to inhibit RANKL/M-CSF-induced osteoclastogenesis by BMMs derived from STAT6, but not SHIP, knockout mice, despite a ten fold increase in OC number in the latter. In keeping with this observation, the inhibitory effects of IL-4 on RANKL-induced NFκB and MAP kinase activation are STAT6-, but not SHIP-, dependent. We conclude that IL-4 reversibly arrests osteoclastogenesis in a STAT6-dependent manner by 1) preventing IκBα phosphorylation and thus NFκB activation, and 2) blockade of the JNK, p38 and ERK MAP kinase pathways.

1016

Stimulation of Bone Resorption and Repression of Bone Formation are Key Mechanisms by which Interleukin-7 Plays a Central Role in the Pathogenesis of Ovariectomy Induced Bone Loss. M. N. Weitzmann, C. Roggia, L. Weitzmann, R. Pacifici. Division of Bone & Mineral Diseases, Washington University & Barnes-Jewish Hospital, St. Louis, MO, USA.

Estrogen (E2) deficiency leads to bone loss as bone formation, although enhanced, is unable to keep pace with increased rates of bone resorption. The mechanism driving this uncoupling of bone formation from bone resorption remains poorly understood. The cytokine Interleukin-7 (IL-7) is a powerful inducer of osteoclast formation in vitro and bone resorption in vivo. The mechanism by which IL-7 induces bone resorption involves production of the key osteoclastogenic cytokine RANKL by T cells. We now show that ovariectomy (ovx) increases bone marrow IL-7 mRNA by 2 fold, as measured by semi-quantitative RT-PCR, resulting in a >30% increase in IL-7 protein levels in the bone marrow, as determined by a murine IL-7 ELISA. This data suggests that IL-7 may play an important role in the bone loss associated with E2 deficiency. In support of this notion, neutralization of IL-7 in vivo, by injection of anti-IL-7 antibody into mice, completely prevented ovx induced bone loss, as measured by pQCT and DEXA. IL-7 neutralization prevented bone loss by blunting bone resorption and enhancing bone formation. These data suggest that in vivo, IL-7 limits the ovx induced increase in bone formation thus preventing bone formation from reaching the magnitude necessary to compensate for enhanced bone resorption. We further characterized this novel inhibitory effect of IL-7 on bone formation in vitro and found that IL-7 completely suppressed the formation of new bone growth in neonatal calvarial organ cultures. In addition, IL-7 inhibited both osteocalcin mRNA, determined by semi-quantitative RT-PCR, in the osteoblastic cell line ROS 17/2.8, and alkaline phosphatase activity in purified calvarial osteoblasts in vitro, demonstrating that IL-7 is a powerful inhibitor of bone formation. Consistent with this data, IL-7 was found to inhibit promoter activity of the key osteoblast specific factor, CBFA-1 by 50%, when transiently transfected into ROS 17/2.8 cells. In addition IL-7 blocked by 50% the transactivation of a minimal osteocalcin promoter driven by CBFA-1 responsive elements. In conclusion, our data suggests that IL-7 disrupts bone homeostasis by upregulating osteoclastic bone resorption, while simultaneously limiting the magnitude of the compensatory rise in osteoblastic bone formation characteristic of E2 deficiency. The net effect of IL-7 action is thus the uncoupling of bone formation from bone resorption, leading to the reduced bone mass characteristic of postmenopausal osteoporosis.

Neuropeptide Y2 Receptor Has a Role in Bone Homeostasis Independent of Body Weight. P. A. Baldock,*[1] G. P. Thomas,*[1] A. Sainsbury,*[2] M. Couzens,*[3] R. F. Enriquez,*[1] H. Herzog,*[3] E. M. Gardiner.[1] [1]Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia, [2]Metabolism Program, Garvan Institute of Medical Research, Sydney, Australia, [3]Neurobiology Program, Garvan Institute of Medical Research, Sydney, Australia.

Absence of leptin signalling has been shown to increase bone mass in mice by a central regulatory mechanism, possibly through neuropeptide Y (NPY) signalling. Leptin-responsive neurons in the arcuate nucleus, a hypothalamic structure, co-express both the leptin and the neuropeptide Y2 receptors. The role of NPY in bone was therefore assessed in mutant mice lacking the Y2 receptor (Y2 KO), either as a germline null mutation or as a conditional knockout induced by bilateral injection of CRE recombinase-expressing adenovirus into the arcuate nucleus of adult mice carrying Lox P-modified Y2 receptor genes. Distal femurs of 4 month-old male Y2 KO and control mice were histomorphometrically assessed by light and UV microscopy.The germline Y2 KO animals had elevated trabecular bone volume (12.4% ± 1.7 vs 5.3% ± 0.2; P<0.05). This difference was associated with increased thickness of trabeculae (29.9μm ± 2.0 vs 18.9μm ± 0.7; P<0.005) and a non-significant increase in trabecular number (4.0/mm ± 0.3 vs 2.8/mm ± 0.002; P<0.06). These bone changes were similar to those described for the leptin knockout (ob/ob) mouse but occurred in the absence of obesity, as the germline Y2 KO mice tended to low body weight.To assess the central nature of this regulation, bones from arcuate-specific Y2 receptor knockouts were examined. Five weeks after injection of CRE-adenovirus, results were similar to the previous observations in germline Y2 KO mice, with greater trabecular bone volume (9.9% ± 1.0 vs 5.5% ± 0.1; P<0.01) and trabecular thickness (30.9μm ± 0.3 vs 19.6μm ± 0.3; P<0.0005) than in CRE-adenovirus injected wildtype controls. Bone formation in the arcuate-specific knockout mice was elevated due to an increase in mineral apposition rate (1.4μm/d ± 0.1 compared to controls, 0.96μm/d ± 0.03; P<0.02). Bone resorption was not altered in either germline or arcuate-specific Y2 knockout mice.NPY signalling through the Y2 receptor is therefore strongly implicated in the control of bone formation. The bone effect was independent of body weight, consistent with the previous report that the high bone mass phenotype in ob/ob mice preceded the onset of obesity. The results of the arcuate-specific knockout are consistent with a central action of NPY through the Y2 receptor that can indirectly modulate bone formation. The NPY pathway thus appears to mediate a central anabolic effect on bone.

Statins Stimulate Bone Formation by Enhancing eNOS Expression. I. R. Garrett, G. Gutierrez, D. Chen, A. Escobedo,* D. Horn,* J. Esparza,* G. R. Mundy. OsteoScreen, San Antonio, TX, USA.

Statins, drugs used to lower cholesterol, have recently been shown to enhance bone formation. The mechanism by which they elicit this effect is not clear. Statins reduce cholesterol production by inhibiting the rate-limiting enzyme in the mevalonate pathway, hepatic HMG-CoA reductase. Statins stimulate bone formation in murine neonatal calvaria and in vivo by increasing BMP2 protein, since noggin, the endogenous inhibitor of BMPs, blocks effects in vitro, and lovastatin (10mg/kg/day) was ineffective in stimulating bone formation in vivo in transgenic mice with truncated mutant unresponsive BMP receptors targeted to the osteoblast lineage. To determine the mechanism by which the statins increase BMP2 expression, we examined the effects of immediate downstream metabolites of the HMG-CoA reductase enzyme, mevalonate (100uM) and GGPP (10uM), and found they inhibited bone formation and BMP-2 transcription stimulated by the statins. Previous studies have indicated that statins mediate beneficial effects on ischemic stroke through enhanced expression of eNOS in endothelial cells and do so by effects on prenylated proteins such as Rho. We therefore examined a specific inhibitor of Rho, clostridium botulinium C3 transferase (50ug/ml), which stimulated bone formation in organ cultures, suggesting the involvement of Rho GTPase and subsequent prenylated proteins. We next examined the

effects of NOS inhibitors on statin-mediated bone formation. We found that a preferential inhibitor of eNOS (L-NAME - 2uM) inhibited bone formation by 86% in calvarial cultures treated with statins whereas a less potent inhibitor of eNOS (1400) did not. We further found statins increased NO production and enhanced the expression of eNOS mRNA and protein in osteoblastic 2T3 cells. To confirm the role of eNOS in mediating statin effects on bone, we examined calvarial cultures from eNOS -/- mice, which have recently been shown by others to have a bone phenotype characterized by decreased bone formation, and compared the effects of simvastatin to those in bone cultures from control eNOS+/+ mice. We found that calvaria from null mutant mice showed reduced bone formation responses. We conclude that statins mediate effects on bone formation by inhibition of the enzyme HMG-CoA reductase in osteoblasts. Inhibition of this pathway leads to a reduction in Rho prenylation, which enhances expression and activity of eNOS in osteoblasts. In turn, increased generation of NO from eNOS enhances BMP2 expression, which causes osteoblast differentiation and bone formation. These results suggest additional molecular targets for drug discovery for anabolic agents and the central role of eNOS in statin-stimulated bone formation.

Null Mutation in Collagenase-3 (Matrix Metalloproteinase[MMP]-13) Affects Maturation of Growth Plates. Y. Wang, M. H. Byrne,* M. Inada, M. U. Rahman,* S. M. Krane. Medicine, Massachusetts General Hospital, Boston, MA, USA.

Remodeling of the extracellular matrix (ECM) of cartilage and bone during embryonic development is an important event. To assess the role of collagenases in ECM resorption, we introduced, by homologous recombination in ES cells, a null mutation into the gene encoding MMP-13 and obtained germline transmission. The mutation results in splicing out Exon 5 (Exon 5 encodes the critical, catalytic, Zn-binding domain) which would lead to an inactive enzyme. Heterozygous MMP-13 -/+ mice were bred and viable MMP-13 -/-, -/+ and +/+ offspring were obtained. By in situ hybridization using a riboprobe specific for Exon 5, MMP-13 expression was observed in distal growth plate and primary centers of ossification in the MMP-13 -/+ and +/+ mouse embryos (E) 15.5 through early adulthood but not in the MMP-13 -/- mice; using ribroprobes for portions of MMP-13 mRNA other than for Exon-5, expression of MMP-13 was observed (although at a markedly decreased level) in the MMP-13 -/- mice as well, indicating reduced transcription or increased degradation of mRNA. Using riboprobes for MMP-8, -9 and -14, we observed increased skeletal expression in the MMP-13 -/- mice; e.g., a signal for MMP-8 was seen in MMP-13 -/- embryos at E 15.5 and 17.5 but not in +/+ embryos, but appeared at a detectable although lower level in newborn MMP-13 +/+ mice. Expression of MMP-14 was also increased in MMP-13 -/- vs. MMP-13 +/+ mice. The width of the total growth plate was increased by ~ 50% and the width of the hypertrophic zone by ~ 100% in MMP-13 -/- vs. +/+ E-15.5, 17.5 and newborn mice; this was associated with increased uptake of BrdU in the proliferating zone in the MMP-13 -/- mice. Increased width of the growth plate persisted through ~4-6 weeks of age. In newborn MMP-13 +/+ mice, there was staining with Mab 9A4 for the collagenase-cleavage epitope in type II collagen and with a polyclonal antibody to mouse MMP-13 in the septae of the distal growth plates; no staining with Mab 9A4 or MMP-13 antibody was seen in the MMP-13 -/- mice. That the increased width of the growth plates in the MMP-13 -/- mice was associated with decreased maturation is supported by ~ 8-9 % decrease in femoral length in 1 and 3 month-old MMP-13 -/- vs. +/+ mice. MMP-13 is normally expressed predominantly in the distal growth plates and centers of ossification in developing embryos. Thus, a targeted mutation in the MMP-13 gene, with decreased transcription and translation of a protein that is no longer a proteinase, results in increased width of the hypertrophic zone of growth plates and decreased maturation. MMP-13-mediated degradation of skeletal ECM must be important in normal endochondral ossification.

Induction of RANKL and MMPs in Bone with Metastasis of Breast Cancer. C. Miyaura, T. Ohshiba,* M. Inada, A. Ito.* Biochemistry, Tokyo University of Pharmacy and Life Science, Tokyo, Japan.

Bone metastasis of breast cancer induces severe osteolysis with increased bone resorption, and is one of the most serious problems in breast cancer patients. Osteoclast differentiation regulated by receptor activator of NF-kB ligand (RANKL) in osteoblasts and matrix degradation induced by matrix metalloproteinase (MMPs) are thought to be involved in the process of bone resorption, but the role of RANKL and MMPs in bone metastasis is not known. In this study, we investigated the expression of RANKL and MMPs in bone with metastasis. In vivo study, nude mice were injected with human breast cancer cells (MDA-MB-231), and metastases in the femur and tibia were identified by soft-X ray and morphological analysis. When the MDA tumor was close to the bone surface, severe osteolysis occurred with increased bone resorption. The number of TRAP-positive osteoclasts and resorption pits were markedly elevated, and the degradation of bone matrix markedly progressed. Expression of RANKL, MMP-13 (collagenase 3) and MT1-MMP mRNA was markedly elevated in tibia and femur with metastasis compared with control bone. In vitro, MDA cells were embedded in type-I collagen gel and cultured on calvaria collected from 5 days-old mice. Some MDA cells in the gel were in contact with the surface of the calvaria, and co-culture with MDA markedly induced calcium release from calvaria and osteoclast formation. Numerous osteoclasts were detected on the surface of calvaria attached to MDA-gel. After co-culture, MDA cells in collagen gel were removed from calvaria, and the expression of RANKL and MMPs in calvaria was examined. We detected the marked induction of RANKL, MMP-2, MMP-9 and MMP-13 in calvaria after co-culture with MDA. Adding OPG, a decoy receptor for RANK, and BB94, an inhibitor of MMPs, significantly suppressed bone resorption induced by co-culture with MDA. The separation of MDA-gel from calvaria showed decreased bone resorption in the co-cultures, suggesting that cell-to-cell and/or cell-to-matrix interaction is essential for cancer-induced resorption in bone. These results suggest that RANKL-induced osteoclast formation and MMP-dependent matrix degradation are associated with osteolysis due to bone metastasis.

Bone Sialoprotein Binds to and Modulates Pro-Matrix Metalloproteinase-2 Activity. N. S. Fedarko,*[1] A. Jain,*[1] A. Karadag,*[2] L. Fisher.[2] [1]Department of Medicine, Johns Hopkins University, Baltimore, MD, USA, [2]Craniofacial and Skeletal Diseases Branch, NIDCR, NIH, Bethesda, MD, USA.

Bone sialoprotein expression is induced in osteoblasts, osteoclasts and in many cancers. Also, BSP has been shown to be angiogenic in vivo. We have previously reported a mechanism for BSP-mediated protection of cells from humoral surveillance involving an initial binding of BSP to the vitronectin receptor (alphaVbeta3), subsequent binding of the complement-dampening protein Factor H, which then results in quenching of complement activity. BSP could also compete with pro-matrix metalloproteinase-2 (pro-MMP-2) that has been reported to be bound to the vitronectin receptor. If this were the case then BSP expression would not only confer enhanced survival via protection from complement surveillance, but also contribute to MMP release from the osteoblast, osteoclast or tumor cell surface into the extracellular environment. To test this possibility, normal and cancer cell lines were treated with recombinant BSP and the release of MMPs into the medium was followed as a function of time. Treatment of human marrow stromal fibroblasts with normal BSP caused a large increase in pro-MMP-2 in the medium in as little as 2 minutes. This suggests that the release is not a downstream event requiring synthesis and secretion, but rather a direct consequence of BSP binding. Addition of BSP in which the integrin-binding RGD was changed to the inactive KAE did not cause the release of the pro-MMP-2. KG1A cells (a CD4 positive human hemopoetic precursor cell line) express proMMP-2, but treatment with rBSP did not cause MMP-2 release. KG1a cells express alpha4beta1 and alpha5beta1 but not the alphaVbeta3 integrin so this is consistent with the BSP-mediated release of MMP-2 involving the alphaVbeta3 integrin. Kinetic studies using a fluorescein-labeled gelatin substrate and pure pro-MMP-2 revealed a BSP-dependent activation of gelatinase activity that could be blocked by the addition of 1,10 phenanthroline. The binding of BSP to pro-MMP-2 was characterized by titration studies utilizing the intrinsic tryptophan fluorescence of pro-MMP-2 and revealed 1:1 stoichiometry and a binding constant in the nM range. BSP did not bind to pro-MMP3 or pro-MMP-9. Our results indicate that BSP selectively interacts with pro-MMP-2 and modulates its activity. Thus, BSP expression may lead to local release and activation of pro-MMP-2 in both normal bone and in many tumors

Targeted Expression of Constitutively Active BMP Receptor 1A in Chondrocytes Causes Lethal Skeletal Dysplasia with Shortening of Growth Plate. T. Kobayashi,[1] A. P. McMahon,*[2] H. M. Kronenberg.[1] [1]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, [2]Department of Molecular and Cellular Biology, Harvard University, Cambridge, MA, USA.

Bone morphogenetic proteins (BMPs) play crucial roles in skeletal development. In addition to their roles in early limb bud outgrowth, several lines of evidence suggest that BMP signaling stimulates formation of the mesenchymal condensation as well as differentiation of mesenchymal cells into the chondrocytic lineage. However, little is known about BMP action on differentiated chondrocytes in vivo. Overexpression of a constitutively active mutant BMP receptor 1A (caBMPR1A) delayed hypertrophic differentiation in chick developing limbs after recombinant retroviral infection (Zou H et al, 1997 Genes Dev. (11) 2191). To extend these observations to the setting of mammalian development, we expressed caBMPR1A in mouse growth plate chondrocytes. Since initial experiments suggested that transgenic expression of this gene was lethal, a bigenic system was used to allow the reproducible generation of the transgenic mice. Gal4 transgenic mice express yeast Gal4, a transcription activator, under the control of the rat type II collagen promoter. UAS-caBMPR1A transgenic mice carry caBMPR1A cDNA downstream of UAS sequences (Gal4 binding sites), followed by a Wnt –1 minimal promoter. In the double transgenic mice, GAL4 transactivates UAS-caBMPR1 gene transcription exclusively in chondrocytes. Double trangenics die perinatally, showing skeletal abnormalities including short limbs and domed skulls. Histological examination at E 17.5 showed shortening of the growth plates, especially the columnar proliferating layer. After BrdU labeling, chondrocyte proliferation was unchanged, and a pulse-chase analysis revealed that hypertrophic cells were produced at a reduced rate in the mutant. At day E 12.5, mutant bones were already smaller than controls. In conclusion, missexpression of caBMPR1A in growth plate chondrocytes leads to short bones through reduction of the initial mass of the cartilage premordia and reduced rate of hypertrophic cells produced.

1023

Osteopontin-Deficiency Induces PTH-Activation of Cortical Bone Formation and Enhances PTH-Activation of Cancellous Bone Formation in Mice. K. Kitahara,*[1] M. Ishijima,[1] S. R. Rittling,[2] K. Tsuji,[1] H. Kurosawa,*[3] A. Nifuji,[1] D. T. Denhardt,*[2] M. Noda.[1] [1]Dept of Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Rutgers University, Piscataway, NJ, USA, [3]Juntendo University, Tokyo, Japan.

Treatment of osteoporosis patients, especially those who already have lost significant amount of bone, requires therapeutic measures to increase bone mass by enhancing formation of bone. Intermittent administration of parathyroid hormone (PTH) has been known to be one of the promising treatments for osteoporosis to enhance bone formation. Recent observations on the transgenic mice expressing constitutively active PTH/PTHrP receptor indicates that PTH signaling increases cancellous bones while it reduces cortical bones. However, the downstream events which are involved in the differential PTH activation of bone formation is still unclear. Osteopontin (OPN) is a non-collagenous bone matrix protein and cytokine, and PTH suppresses OPN gene expression via cyclic AMP and protein kinase A in vitro. We hypothesized that OPN could be one of the target molecules that may be involved in PTH actions to increase bone in vivo. Therefore, we examined the effect of PTH on the bone metabolism in OPN-deficient mice in comparison to its effect on bone in wild type mice. PTH treatment was conducted by injecting 80mg/kg PTH (1-34) subcuta-

neously, daily for 5 days a week for 4 weeks. In wild type mice, as reported previously, treatment with PTH for 4 weeks increased cancellous bone volume. In contrast, OPN-deficiency further enhanced the PTH-dependent increase in trabecular bone volume more than the increase observed by PTH treatment in wild type mice. PTH did not alter cortical bone volume, cortical bone thickness and bone marrow area in wild type mice. In sharp contrast to such inability of cortical bones to respond to PTH in wild type mice, OPN-deficient mice showed increase in cortical bone volume and cortical bone thickness, and decrease in bone marrow area in response to PTH treatment for 4 weeks. DEXA analyses indicated that the total BMD (bone mineral density) in the whole femur was not increased by the treatment with PTH in wild type. In the absence of OPN, however, BMD of the whole femur was increased significantly by PTH treatment. TRAP-positive multinucleated cell number per area but not per bone surface in the trabecular bone was increased by the treatment with PTH in osteopontin-deficient mice. Our data indicated that OPN -deficiency potentiated PTH activation of bone formation in the cortical bone. Therefore, the long-standing question about how cortical bone differs from cancellous bones with regard to their responses to PTH could be explained at least in part by the presence of OPN.

Long Bone Development in Transgenic Mice Overexpressing Human Osteoblast Stimulating Factor-1. G. Li,*[1] S. McQuaid,*[1] P. Masterson,*[1] M. Mushipe.*[2] [1]Department of Trauma and Orthopaedic Surgery, The Queen's University of Belfast, Belfast, United Kingdom, [2]Department of Mechanical Engineering, The Queen's University of Belfast, Belfast, United Kingdom.

Osteoblast stimulating factor-1 (osf-1), a heparin binding Lys-rich 18 Kda protein, was first identified as a neurogenic growth factor, and later found to have potent effects on regulation of osteoblast recruitment, proliferation and differentiation. Osf-1 is highly expressed in the mesenchymal tissues prior to bone formation, and overexpression of osf-1 results in an increase in total bone mass. The aim of this study is to elucidate the effects of osf-1 overexpression on long bone development in a transgenic mouse model.Trangenic mice expressing the human osf-1 gene under the control of the human osteoclacin promoter were made (Masuda, et al., Biochem Biophy Res Comm, 1997). Male osf-1 mice and the background BDF1mice were used and 4 mice from each group were killed at age of 1, 2, 4 and 6 months. Femora and tibiae were collected, digital radiographs were taken and images were analyzed using NIH software Scion Image. The length of the tibia and femur, diameters of both femoral and tibial metaphysis, diaphysis and cortical thickness were measured. The bone samples were also examined using peripheral quantitative computed tomography (XCT960). Total bone mineral density, trabecular and cortical density, trabecular percentages were recorded. Finally, the bone samples were subject to 3-point bending test, and the maximum load of failure was recorded. The osf-1 mice were found to have longer, thicker, denser and stronger femora in comparison with the BDF1 mice. The femora of the osf-1 mice have narrower bone marrow spaces, and the osf-1 overexpression appeared to enhance cortical bone maturation in femora resulting in a significant reduction of the femoral trabeculae percentages. However, in the tibiae, the observation was opposite to what was found in the femora. At 1, 2 and 4 months the tibiae of the osf-1 mice appeared to be longer but thinner, lighter and weaker than that of the BDF1 mice, and the bone marrow spaces were wider but all of the difference diminished at 6 months between the two groups. The development of the femora and tibiae in the osf-1 overexpression mice over the initial 6 months exhibited a transiently different pattern. The results suggest that the effects of osf-1 overexpression on long bones may be linked with other factors, such as abundance of bone precursor cells in surrounding tissues, sufficient blood supply and the mechanical environment. The current study highlights the important role of osf-1 in regulating long bone development and its possible interactions with other local factors.

Leptin Prevents Disuse-Induced Bone Loss in Tail-Suspended Female Rats. T. Thomas, R. De Vittoris,* V. N. David,* L. Vico, M. Lafage-Proust, C. Alexandre. LBBTO, INSERM E9901, St-Etienne, France.

Beside leptin effects on central nervous system in modulating bone metabolism, there is growing evidence that leptin also exerts direct and positive effects on bone cells. Thus, we tested the hypothesis that leptin could at least in part prevent trabecular bone loss and microarchitecture disruption induced by local disuse in the tail-suspended rat model as early as one week after suspension begins. The uncoupling pattern of bone remodeling in this specific model of bone loss is of great interest since it allows to separately studying the effects on either bone resorption or formation. Fifty female 12-week old Wistar rats (weight 250 ± 10 g) were randomly assigned to 1 of the following groups: tail-suspended rats treated with leptin (A) or vehicule (B), non-suspended rats treated with leptin (C) or vehicule (D), and baseline group (E). After one week of acclimatation, rats were tail-suspended and human recombinant leptin (0.35 mg/kg/d) was continuously administered using intraperitoneal Alzet osmotic pumps. Bone parameters were measured by double energy X-ray absorptiometry using PIXImus (Lunar Corp.). Animals were measured at baseline and day 7, and bone samples were collected for histomorphometry analysis after sacrifice at day 7. After 7 days of tail suspension, group B presented a decrease in bone mineral density (BMD) at the tibial proximal metaphysis, a trabecular bone site (0.162 ± 0.003 vs 0.173 ± 0.004; P<0.01), whereas no change was observed at the femoral diaphysis, a cortical bone site (0.195 ± 0.005 vs 0.190 ± 0.004; NS) as compared to baseline. Leptin treatment prevented disuse-induced BMD loss in the group A at the tibial metaphysis (0.181 ± 0.005 vs 0.179 ± 0.003; NS), and induced an increase in BMD at the femoral diaphysis (0.188 ± 0.003 vs 0.183 ± 0.003; P<0.05). Interestingly, leptin treatment significantly increased BMD in the non-suspended group C (0.182 ± 0.003 vs 0.178 ± 0.003 and 0.194 ± 0.003 vs 0.183 ± 0.002 at tibial metaphysis and femoral diaphysis bone sites, respectively; P<0.01) while no change was observed in the group D. These data suggest that peripheral administration of leptin could either prevent the increase in trabecular bone remodeling induced by immobilization and/or stimulate cortical bone modeling. In addition, leptin may have positive indirect effects by inhibiting the transitory and initial phase of stress previously described in these experimental conditions, as suggested by the prevention of weight loss observed at day 3 in group B (-5% as compared to baseline, P<0.05). Further histomorphometric studies are needed to clarify the putative dual leptin effects on bone depending on the route of administration, the stage of bone growth and the targeted bone tissues.

Transforming Growth Factor-ß Prevents and Reverses Bone Marrow Adipogenesis Induced by Skeletal Unloading in Rats. S. Ahdjoudj,*[1] F. Lasmoles,[1] X. Holy,*[2] E. Zérath,[2] P. J. Marie.[1] [1]Hopital Lariboisiere, INSERM U349, Paris Cedex 10, France, [2]IMASSA, Bretigny, France.

Skeletal unloading in rats induces osteopenia resulting from decreased osteoblastogenesis. We determined the effects of skeletal unloading on bone marow stromal cell differentiation into adipocytes and the responsiveness and mechanisms of action of transforming growth factor-ß2 (TGF-ß2) on adipogenesis. Skeletal unloading was induced by hindlimb suspension for 7 days in 4-weeks old rats. Suspended rats were treated continuously with rhTGF-ß2 (2 µg/kg bw /day, Novartis, Basel) by osmotic minipump, given either as a preventive treatment (0-7 days of suspension) or as a curative treatment (4-7 days of suspension). At 0, 4 and 7 days, long bones from suspended and control rats were processed for bone histomorphometry, and mRNA in metaphyseal bone and marrow stroma were prepared separately. Skeletal unloading for 4-7 days markedly decreased bone formation and bone volume in long bone metaphysis compared to control rats. This was associated with a marked reduction in mRNA levels for Cbfa1/Runx2, osteocalcin, type I collagen and TGF-ß signaling receptor II in metaphyseal osteoblasts, as shown by RT-PCR analysis. Conversely, unloading for 4-7 days induced a 10-fold increase in mRNA levels for PPARγ, a specific adipocyte transcription factor, in the marrow stroma. This was associated with a 5-fold increase in lipoprotein lipase (LPL) and aP2 mRNA levels, and a 2-3-fold increase in adipocyte number and volume in the marrow stroma at 7 days of unloading. Both preventive and curative treatments with TGF-ß2 corrected the abnormal expression of Cbfa1/Runx2, osteocalcin and type I collagen mRNAs, and normalized the reduced bone formation in unloaded metaphyseal bone. Furthermore, treatment of unloaded rats with TGF-ß2 decreased PPARγ and C/EBPα mRNA levels at 4 and 7 days, corrected aP2 and LPL overexpression and normalized adipocyte number and volume in the bone marrow stroma at 7 days. These results show that skeletal unloading in rats enhances adipocyte differentiation of marrow stromal cells concomitantly with reduction of osteoblastogenesis. Moreover, exogenous TGF-ß prevents and reverses the increased bone marrow adipogenesis by inhibiting adipocyte gene expression in marrow stromal cells, and concomitantly corrects the defective osteoblastogenesis by stimulating osteoblast marker genes in metaphyseal osteoblasts. We suggest that the reduced endogenous TGF-ß expression and signaling induced by unloading leads to promote adipocyte differentiation and to turn down the osteoblast differentiation program, which provides a mechanism for the altered osteoblastogenesis and adipogenesis induced by skeletal unloading.

1027

Defects in In Vitro Mineralization and Osteoclast-Spreading Are Associated with Resistance to Unloading-Induced Bone Loss in Osteopontin-Deficient Mice. M. Ishijima,[1] S. R. Rittling,[2] T. Yamashita,[1] K. Tsuji,[1] H. Kurosawa,*[3] A. Nifuji,[1] D. T. Denhardt,*[2] M. Noda.[1] [1]Dept of Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Rutgers University, Piscataway, NJ, USA, [3]Juntendo University, Tokyo, Japan.

We recently reported that the presence of osteopontin (OPN) was required for the effects of mechanical stress on bone as OPN-null (OPN-/-) mice showed neither enhancement of bone resorption nor suppression of bone formation when they were subjected to unloading by tail-suspension (J. Exp. Med. 2001. 193. 399-404). However, no further mechanisms underlying the phenomenon have been known. To obtain further insight into the role of OPN in mediating mechanical stress effect on bone, we examined the in vitro mineralization and osteoclast-like cell formation in bone marrow cells and the in vivo vascular systems in hindlimb bones of OPN-/- mice after tail-suspension. OPN-/- and wild type mice were subjected to tail-suspension for 2 weeks. After tail-suspension, bone marrow cells obtained from the femora were cultured in the presence of ascorbic acid and beta-glycerophosphate for mineralized nodule formation assay or for osteoclast-like cell formation assay in the presence of M-CSF and RANKL. We also counted the number of vessels in the secondary spongiosa in the tibiae. The numbers of mineralized nodules formed in cultures tended to be less in the marrow cells from tail-suspended mice compared to the cells from loaded mice in wild type. In OPN-/- mice, the numbers of mineralized nodules were less than those in wild type regardless of the tail-suspension or loading (about 70% reduction, p<0.05). The maximal diameters of the osteoclast-like cells developed in the marrow cells from tail-suspended mice were significantly greater (about 50%, p<0.05) than those from loaded mice in wild type. Spreading of these cells was significantly reduced in the bone marrow cells obtained from loaded OPN-deficient mice compared to loaded wild type mice (about 50% reduction, p<0.05). Unloading-induced enhancement of spreading of these cells was still observed compared to the cells from loaded OPN-/- mice (about 50% enhancement, p<0.05). The numbers of vessels within the secondary spongiosa in the tibiae were similar between loaded and suspended mice in both genotypes. These data revealed that the defects in in vitro mineralization by osteoblasts and in osteoclast spreading were associated with the resistance to unloading-induced bone loss in OPN-/- mice.

Modulating Osteotomy Gap Healing with Motion Exercise. K. M. O'Connor,[1] S. H. Park,*[2] M. C. Salud.*[1] [1]Biokinesiology and PT, University of Southern California, Los Angeles, CA, USA, [2]J. Vernon Luck Orthopaedic Research Center, Orthopaedic Hospital, Los Angeles, CA, USA.

The purpose of this pilot study was to ascertain whether the application of recoverable axial interfragmentary motion (RAIM) exercise would promote significant ingrowth of new bone into diaphyseal osteotomy gaps in the tibia of skeletally mature rabbits. Osteoto-

mies with 10 mm interfragmentary gaps were surgically created in the left tibia of 6 rabbits and stabilized with four-pin double-bar external fixators to heal for 6 weeks. Three rabbits received daily RAIM exercise beginning 4 days after surgery. RAIM exercise consisted of unlocking a telescoping mechanism in the fixator to permit 4 mm of axial sliding at the interfragmentary gap of the osteotomy (40% strain). Motion was generated as the investigator gently moved the hind limb through 20 passive range of motion cycles, each beginning at knee and ankle extension and moving into knee and ankle flexion. Control animals received exercise while the fixator remained locked. Axial excursion during the exercise sessions was monitored by a strain transducer attached to the fixator. Ingrowth of mineralized tissue into the osteotomy gap was quantified with peripheral quantitative computer tomography (pQCT). The gap region was divided into 5 cross-sectional slices of 2 mm thickness (voxel size: .2x.2x2 mm). The threshold was set at 200 mg/cm^3, which excluded fibrous tissues but included low density mineralized tissues. No areas within the gap region measured at or above 900 mg/cm^3 indicating the absence of cortical bone. Mean axial excursion during RAIM exercise declined from 3.76 mm at post-op day 4, to 3.05 mm at 3 weeks and 1.02 mm at 6 weeks ($p = 0.0001$). Axial excursion of the control group (noise level) remained constant at a mean of 0.14 mm throughout the healing period ($p = 0.66$). The space volume created by the 10 mm gap was 500 mm^3. The volume of mineralized tissue within the gap that was detected at a threshold of 200 was 87 mm^3 (17% filled) for the control group compared with 413 mm^3 (83% filled) for the RAIM group ($p = 0.002$). Mineral content within the gap was 33 mg and 196 mg for the control and RAIM groups respectively ($p = 0.004$). The volumetric density of the mineralized tissue that formed in the gap was higher in the RAIM group (471 mg/cm^3 vs. 385 mg/cm^3) but the associated p-value was marginal at 0.07. Mineral content in all specimens declined toward the center of the gap ($p = 0.025$) indicating that bone ingrowth occurred from both the proximal and distal cortical surfaces. These observations suggest that RAIM exercise, administered at an initial strain near 40%, is a potent stimulus for osteogenic ingrowth in diaphyseal osteotomies with gap size of approximately 1 cm.

Mechanical Strain Decreases the *in vivo* Expression of Estrogen Receptor-α in Osteocytes. P. J. Ehrlich,*[1] B. S. Noble,[2] H. L. Jessop,*[1] H. Y. Stevens,[3] J. R. Mosley,*[2] L. E. Lanyon.[1] [1]Royal Veterinary College, London, United Kingdom, [2]Univ. of Edinburgh, Edinburgh, United Kingdom, [3]Univ. of California, San Diego, CA, USA.

We have previously reported that estrogen and mechanical strain: 1) independently stimulate proliferative responses that can be blocked by estrogen receptor (ER) modulators[a], 2) stimulate ERK-mediated phosphorylation of ERα[b] and, 3) increase activity of estrogen response elements[c]. We hypothesize that ERα provides a common pathway through which both estrogen and strain regulate bone remodelling activity. If true, reduction in ERα number could explain bones' limited ability for adequate mechanically adaptive remodelling after menopause.As osteocytes are ideally located to respond to strain, we examined whether their *in vivo* strain environment influenced the expression of ERα. We examined the immunofluorescent labeling of rat cortical bone osteocytes in sections from normal neonatal and adult, male and female rat ulnae (n=3 of each gender and age), and adult male rat ulnae which, in addition to normal locomotor loading, had been axially loaded daily as previously described[d] for 10 minutes at 2 Hz to generate peak strains of either -3000 (n=3) or -4000 (n=5) microstrain. In normal neonatal and adult bones 14 +/- 1.3% (mean +/- SEM) of all osteocytes were positive for ERα with no influence of either gender or age. In loaded bones, there were significantly fewer osteocytes expressing ERα (7.5 +/- 0.9%) than in contralateral controls (14 +/-1.7%) ($p=0.01$, median diff=6.4, 95% confidence interval=2.6, 10.3). Within both loaded and control bones, the number of osteocytes labeled for ERα was inversely related to the peak strains engendered at that location (Fig). These data support the hypothesis that ERα is involved in bone cells' responses to strain, with high strains decreasing the number of osteocytes expressing ERα. Reductions in ERα accompanying the high strains assumed to occur in osteoporosis may compound the reduction of ERα expression associated with estrogen deficiency[e] thus further impairing the capacity for appropriate adaptive remodelling following the menopause. Mechanical Strain Rapidly Activates Osteoblastic Protein Kinase B (PKB): An Upstream Modulator of eNOS Activity. T. S. Grewal,*[1] R. J. Tolley,*[1] S. C. F. Rawlinson,*[2] L. E. Lanyon,[2] T. M. Skerry.[1] [1]Biology, University of York, York, United Kingdom, [2]Royal Veterinary College, London, United Kingdom.

Protein Kinase B (PKB/Akt) has been shown to mediate the activation of eNOS-dependent release of NO from endothelial cells in response to fluid flow. We therefore hypothesised that a similar mechanism may also be responsible for the obligatory NO release from osteoblasts in response to mechanical strain. The PKB intracellular signalling pathway is initiated by activation of phosphatidylinositol-3-kinase (PI-3-K). The resultant phosphorylation of PKB at Ser473 and Thr308 leads to its activation. The major downstream targets of activated PKB include eNOS, the pro-apoptotic proteins Bad/Bax, and the forkhead family of transcription factors. To investigated the role of PKB in osteoblasts, we subjected cells to mechanical strain *in vitro* using either a FX-3000 Flexercell or a four-point bending system. Cells (SaOS-2, TE-85 and calvarial-derived primary rat osteoblasts (ROBs)) were mechanically stimulated with cyclical strain (four-point bending: 1,100-3,800με; FX-3000: 4,500-7,000 με) of 1 Hz for 10 minutes and total protein extracted at various times post-stimulation. In the case of the primary ROBs, cells were either maintained in medium alone or supplemented with osteoinductive media to induce osteoblast differentiation for 7 days prior to mechanical stimulation. Protein lysates were analysed by immunoblotting using specific phospho-PKB (Ser473) antibody. Immunoblots were subsequently stripped and analysed with an antibody to PKBα to control for protein loading. In clonal cells (SaOS-2 and TE-85), a significant 2.5-fold increase in phosphorylation of PKB at Ser473 was evident within 2 minutes of the end of the straining regimen and peaked at 20-40 minutes. In all cases this response to strain was completely blocked by pre-treatment of cells for 30 minutes with specific PI-3-K inhibitors (wortmannin, 500 nM or LY294002, 10 μM) but unaffected by GF109203X (a PKC inhibitor). In primary ROBs, PKB phosphorylation was significantly increased (3-fold) in differentiated osteoblasts subjected to mechanical strain, but not undifferentiated ROBs subject to the same stimulation. These findings demonstrate that in osteoblasts, PKB is rapidly phosphorylated in response to physiological levels of mechanical strain. Additionally, differentiating primary osteoblasts show a much greater mechanical induction of PKB activity than less differentiated cells. These finding suggest 1) a mechanism for regulation of the eNOS activity known to be an obligate step in the adaptive mechanism, and 2) that even early commitment towards the osteoblastic lineage sensitises cells to the effects of strain.

Smoothened Is Required for Osteogenesis in Endochondral Bone Development. U. Chung,[1] F. Long,*[2] J. McMahon,*[2] A. McMahon,*[2] H. Kronenberg.[1] [1]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, [2]Harvard University, Cambridge, MA, USA.

It has been recently shown that Indian hedgehog (Ihh), synthesized by prehypertrophic and hypertrophic chondrocytes, is locally required for maturation of osteoblasts in the bone collar, the precursor of cortical bone. It is, however, not clear yet whether the same Ihh is required for osteoblast development in the primary spongiosa, the precursor of trabecular bone, as well. To address this question, chimeric mice containing wild-type cells and cells homozygous for a null-mutation in the *Smoothened* gene (which encodes a membrane bound protein mediating Hedgehog signaling) were generated by blastocyst injection. The mutant cells were marked with a β-galactosidase transgene engineered to be expressed ubiquitously, and their contribution to osteoblasts in the primary spongiosa was analyzed by standard histology and in situ hybridization. *Smo*-deficient cells can contribute to mesenchymal tissues such as the muscle, tendon and cartilage. However, even though mutnat cells contribute to the perichondrium, they fail to contribute to bone-forming osteoblasts, while wild-type cells become osteoblasts and form bone collar in the perichondrium adgacent to prehypertrophic and hypertrophic chondrocytes. This finding further supports the crucial role of Ihh in bone collar formation. Furthermore, *Smo*-deficient cells fail to contribute to osteoblastic cells in the primary spongiosa of the chimeric mice so far generated (n=4), even though the mutant cells can contribute to vascular endothelial cells, hematopoietic cells as well as osteoclasts. These data strongly suggest that the Hh signal is required for osteoblast development in the primary spongiosa as well. Ihh from prehypertrophic and hypertrophic chondrocytes is the likely source of this Hh signal. This Ihh provides a crucial signal necessary for osteogenesis in both the primary spongiosa and the bone collar. Ihh, which also regulates chondrogenesis, thereby links chondrogenesis and osteogenesis during endochondral bone development.

1032

Phosphatidylinositol 3 Kinase (PI 3-K) and Akt Serine Threonine Kinase Regulate BMP-2-Induced Osteoblast Differentiation and Smad-Dependent Transcription of BMP-2 Gene. N. Ghosh-Choudhury,*[1] S. L. Abboud,[2] G. Ghosh Choudhury.*[3] [1]Pathology, Univ. Tx. Hlth. Sc. Cntr., San Antonio, TX, USA, [2]UTHSCSA, San Antonio, USA, [3]GRECC, STVA Hospital, San Antonio, USA.

Interplay of different signal transduction pathways converge into the nucleus to induce transcription of specific genes necessary for lineage specific cellular differentiation. Bone morphogenetic protein-2 (BMP-2) stimulates osteoblast differentiation of progenitor cells. The precise mechanism by which different signaling pathways regulate BMP-2-induced osteogenesis has not been explored. We investigated the involvement of PI 3-K in BMP-2-induced osteoblast differentiation of 2T3 mouse mesenchymal precursor cells. BMP-2 stimulated PI 3-K activity in PI 3-K and anti-phosphotyrosine immunoprecipitates in a time-dependent manner, indicating BMP-2-induced association of PI 3-K with tyrosine phosphorylated proteins. Incubation of 2T3 cells with a pharmacologic inhibitor of this enzyme, Ly 294002 (Ly), prevented BMP-2-induced PI 3-K activity. Ly blocked BMP-2-induced mature bone nodule formation in 2T3 cells. Osteoblastic differentiation induced by BMP-2 precedes expression of specific marker protein, such as alkaline phosphatase. Ly as well as expression of dominant negative PI 3-K inhibited BMP-2-induced alkaline phosphatase expression, indicating that PI 3-K is necessary for expression of osteoblast-specific protein marker. One of the downstream target of PI 3-K is the serine threonine kinase Akt which regulates many biological activities of PI 3-K. BMP-2 stimulated Akt in a PI 3-K-dependent manner. Inhibition of Akt activity by expression of a dominant negative mutant abolished BMP-2-induced alkaline phosphatase expression. In contrast, a constitutively active mutant of Akt increased BMP-2-induced alkaline phosphatase. We previously demonstrated that BMP-2 stimulates BMP-2 mRNA expression during osteoblast differentiation. Expression of dominant negative PI 3-K inhibited BMP-2-induced BMP-2 gene transcription. In fact the transcriptional effect of BMP-2 is mediated by BMP

specific Smads. Expression of either Smad 1 or Smad 5 stimulated BMP-2 gene transcription independent of addition of the ligand. To investigate the cross talk between PI 3-K and Smad signaling, we used dominant negative PI 3-K in transcriptional assay. Dominant negative PI 3 kinase inhibited Smad 1 as well as Smad 5-dependent transcription of BMP-2 gene. Together these data provide the first evidence that activation of BMP receptor serine threonine kinase activates PI 3 kinase/Akt pathway and define a role for this signaling cascade for BMP-2-induced osteoblast differentiation and Smad-dependent gene transcription.

Regulation of Osteoblast Differentiation by Proteasome Control of Smad1. D. Chen,[1] M. Zhao,[1] M. Qiao,*[1] R. Garrett,[1] Z. Mi,*[1] C. Crews,*[2] G. Mundy.[1] [1]Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, [2]Molecular, Cellular and Developmental Biology, Yale University, New Haven, CT, USA.

Recently we have found that proteasome inhibitors (PIs) stimulate bone formation in vitro and in vivo. Since the effects of PIs mimic those of BMP-2 and proteasome inhibitor 1 (PS-1) enhanced BMP2-induced bone formation in vitro and in vivo, in the present studies, we examined the effects of PIs on Smad1, an essential molecule in the BMP signal pathway. We found that overexpression of Smad1 in C2C12 myoblast/osteoblast precursor cells induced osteoblast differentiation and enhanced BMP-2 responsiveness as assessed by increased alkaline phosphatase (ALP) activity and osteocalcin production. Smad1 degradation was induced by Smurf1, an ubiquitin E3 ligase, in a dose-dependent manner. In contrast, Smad2 degradation was not affected by Smurf1. When Smad1 was co-transfected with mutant Smurf1 (C710A) in C2C12 cells, the steady-state levels of Smad1 were not significantly changed. In the mutant Smurf1, the cysteine residue in the hect domain that is responsible to form a thiolester bond with ubiquitin was replaced by alanine. These results suggest that ubiquitin is required for Smad1 degradation. Overexpression of mutant Smurf1 acted in a dominant-negative fashion and increased ALP activity, osteocalcin production and BMP-2 responsiveness in C2C12 cells. Structurally unrelated PIs, MG-132 (2.5 μM), lactacystin (10 μM), epoxomicin (20 nM) and PS-1 (50 nM), completely prevented Smurf1-mediated Smad1 degradation. Addition of these PIs at same concentrations also enhanced endogenous Smad1 protein levels up to 6-fold in C2C12 cells. To determine which specific activity of the proteasome is responsible for Smad1 degradation, two different substrate specific PIs, Ac-hFLFL-epoxide (chymotryptic specific) and YU-102 (post-glutamyl peptide hydrolyzing specific) were utilized. Ac-hFLFL-epoxide significantly reversed Smurf1-mediated Smad1 degradation in a dose-dependent manner. In contrast, YU-102 had no significant effect on Smad1 degradation in C2C12 cells, suggesting that chymotryptic activity of the proteasome is responsible for Smad1 degradation. These results are consistent with the results that inhibition of chymotrypsin-like activity caused new bone formation in bone organ culture assay. Our findings indicate that PIs may enhance effects of BMP-2 by preventing Smad1 degradation and increasing intracellular steady-state levels of Smad1. The increase of Smad1 leads to enhancement of BMP-2 signaling and subsequent osteoblast differentiation and bone formation.

Identification of a Novel BMP-2 Induced Gene, which Dramatically Accelerates Osteoblast Differentiation. F. Gori, M. B. Demay. Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA.

Endochondral bone formation is a complex process controlled by a wide variety of factors including transforming growth factor (TGF)-βετα superfamily members and more specifically the bone morphogenetic proteins (BMPs). Using differential display (dd) PCR, we have isolated and cloned a novel gene, named BIG-3 (BMP-2 Induced Gene 3kb), that is induced as a murine prechondroblastic cell line, MLB13MYC clone 17, acquires osteoblastic features in response to BMP-2 treatment. The 3 kb mRNA encodes a 33 KDa protein belonging to the family of WD-40 repeat proteins, which have a wide variety of cellular functions including signal transduction, mRNA processing and gene regulation. Northern analyses using RNA isolated from MLB13MYC clone 17 cells revealed that BIG-3 was induced 3.5-fold after 24 h of BMP-2 treatment. BIG-3 mRNA was also expressed in conditionally immortalized murine bone marrow stromal cells, osteoblasts, osteocytes and growth plate chondrocytes as well as in primary calvarial osteoblasts. By Northern analyses BIG-3 mRNA expression was detected in mouse brain, heart, kidney, muscle, skin, spleen, thymus and testis. In addition, Western analyses using cell lysate from MLB13MYC clone 17 cells treated with BMP-2 (0-200 ng/ml), showed that BIG-3 protein was also induced after 24 h of treatment. To characterize the functional role of BIG-3 in osteoblast differentiation, MC3T3E1 cells were stably transfected with the full length coding region of BIG-3 (MC3T3E1-BIG3) cloned into an expression vector (pcDNA3.1) under a CMV promoter. Three pools of 10 clones for both MC3T3E1-BIG3 and cells transfected with the empty vector (MC3T3E1-EV) were initially characterized in these studies. Pooled clones transfected with BIG-3 expressed alkaline phosphatase activity earlier and, at 7 d achieved a peak level of activity 28-fold higher than MC3T3E1-EV cells. In addition, cAMP production in response to PTH was increased 10 and 14-fold at 7 d and 14 d, respectively in MC3T3E1-BIG3 cells, relative to MC3T3E1-EV cells. Overexpression of BIG-3 also accelerated formation of mineralized nodules (21 d) compared to MC3T3E1-EV cells (35 d) as assessed by Alizarin Red S and increased calcium accumulation in matrix by 12 and 44-fold at 21 d and 25 d, respectively, as assessed by methylthymol blue. In conclusion, we have identified a novel WD-40 protein induced in response to BMP-2 treatment, which dramatically accelerates the program of osteoblastic differentiation in stably transfected MC3T3E1 cells.

Δ2ΔFosB Expression Positively Regulates BMP Signalling Pathways in Osteoblast Cell Lines *In Vitro*. G. Sabatakos,[1] M. Kveiborg,[1] M. Wu,*[1] S. Roman-Roman,[2] W. C. H. Horne,[1] R. Baron.[1] [1]Yale School of Medicine, New Haven, CT, USA, [2]Aventis Pharma, Paris, France.

The AP-1 family of transcription factors consists of Fos- and Jun-related proteins that have been shown to be important regulators of bone cell differentiation both *in vivo* and *in vitro*. We have reported previously that overexpression of δFosB, which arises from alternative splicing of the *fosB* transcript, in transgenic mice leads to increased bone formation and progressive osteosclerosis. *Ex vivo* osteoblast cultures and *in vitro* overexpression studies have shown that δFosB isoforms stimulate osteoblast marker gene expression and bone formation in a cell-autonomous manner. The aim of the present study was to further elucidate the molecular mechanism by which δFosB isoforms regulate osteoblast differentiation and function *in vitro*. For this purpose we have generated stable transfectants of δFosB, as well as of mutants expressing only the full length δFosB or the N-terminally truncated δ2δFosB isoform in the bipotential cell lines C2C12 and ST2. Analysis of the effect of these mutants on osteoblast differentiation in response to BMP-2 demonstrated an increase in the expression of osteoblast markers of only in cells expressing the truncated δ2δFosB isoform. Moreover, studies on the downstream Smad signalling pathway demonstrated that the levels of BMP-2 as well as of its receptors (BMPR Ia and Ib) or their phosphorylation were not affected by δFosB isoforms. In contrast, the expression of the receptor activated Smads 1, 5 and 8 and of Smad4 were differentially regulated by δFosB isoforms. In particular the mRNA levels of Smad1 were increased only in cells expressing δ2δFosB and this increase correlated with earlier and higher translocation of phospho-Smad1 to the nucleus. This response was not due to new protein synthesis in response to BMP-2 but rather to a direct effect on Smad1 transcription. In addition the ability of δFosB isoforms to regulate inhibitors of Smad signalling such as Smad6 and Tob was studied. The levels of both Smad6 and Tob were dramatically down-regulated in response to BMP-2 in cells expressing the truncated δ2δFosB isoform, suggesting an additional role for δ2δFosB as a suppressor of inhibitors of Smad pathway. Since osteocalcin expression is regulated by BMP-2, we then analyzed the osteocalcin promoter. EMSA binding on specific AP-1 elements and transient transactivation studies revealed higher binding activity and transactivation potential only in cells expressing the δ2δFosB isoform. It is therefore concluded that the δ2δFosB truncated isoform of δFosB is a potent regulator of osteoblast differentiation *in vitro* which differentially regulates both activators and inhibitors of the BMP-2 signalling pathway.

COX-2 is Critical for Mesenchymal Cell Differentiation During Skeletal Repair. X. Zhang,* L. Xing, B. F. Boyce, J. E. Puzas, R. N. Rosier, E. M. Schwarz, R. J. O'Keefe. Center for Musculoskeletal Research, University of Rochester, Rochester, NY, USA.

NSAIDs are among the most commonly used drugs in our society. While agents specific for the inhibition of cyclooxygenase-2 (Cox-2) have recently been introduced and have an improved safety profile, it has become apparent that cyclooxygenase activity is important in skeletal reparative processes. However, the relative role of Cox-1 and Cox-2 isoforms, and the target cells and tissues involved in this process have not been clearly defined. In this study we used both in vivo and in vitro models in wild type and Cox-2 -/- mice to demonstrate that COX-2 plays a critical role in mesenchymal cell differentiation during skeletal reparative processes. Osteoblast and chondrocyte differentiation was examined in vitro in isolated bone marrow stromal cell cultures obtained from wild type and Cox-2 -/- mice. The expression of the bone cell and chondrocyte differentiation markers, osteocalcin and col X were much greater in cultures of wild type cells under both basal conditions and following BMP-2 induction. In vivo skeletal reparative responses were examined in wild type and Cox-2 -/- animals using 2 models. In the first model, closed intramedullary-pin-stabilized tibia fractures were created in 2-3 month old mice and fracture healing evaluated by radiographs and histomorphometry. At day 7, both wild type and Cox-2 -/- animals had abundant mesenchymal cell proliferation and little or no bone formation. However, while cartilage was forming in wild type animals, less cartilage was found in Cox-2 -/- animals. By 14 days, 70% of the callus in wild type animals was bone, compared to only 30% in Cox-2 -/- animals (n=3, $p<0.001$), while mesenchymal cells predominated in the Cox-2 -/- callus (60% in Cox-2 -/- and 13% in wild type; $p< 0.001$). By 21 days, cartilage was completely replaced by bone in wild type mice. In contrast, Cox-2 -/- mice now had significantly more cartilage, as well as three times more mesenchymal tissue at the fracture site (n=8, $p<0.001$). There was less bone, and less radiographic evidence of healing. Osteoclast numbers were also reduced by 57% (n=5, $p<0.001$), indicating a deficiency in osteoclastogenesis in COX-2 -/- mice. In another model, recombinant human fibroblast growth factor-1 (FGF-1) was injected subcutaneously (1ug/day x 3 days) onto the calvaria to examine growth factor induced intra-membranous bone formation. The Cox-2 -/- mice had 60% less (n=5, $p<0.0001$) new bone formation, as well as markedly reduced calvarial osteocalcin expression compared to wild type animals. Altogether, these studies provide direct evidence for a critical role of COX-2 in the differentiation of mesenchymal cells, with subsequent effects on bone formation and bone healing.

1037

Estrogen and Testosterone have Opposite Effects on Circulating OPG Levels Following Induction of Hypogonadism and Aromatase Inhibition in Normal Elderly Men: Potential Mechanism for Differential Effects of Estrogen Versus Testosterone on Bone Resorption. S. Khosla,[1] E. J. Atkinson,*[2] C. R. Dunstan,*[3] W. M. O'Fallon,*[2] B. L. Riggs.[1] [1]Endocrinology, Mayo Clinic, Rochester, MN, USA, [2]Biostatistics, Mayo Clinic, Rochester, MN, USA, [3]Amgen, Thousand Oaks, CA, USA.

Previously, we demonstrated that in normal elderly men, estrogen (E) was the dominant sex steroid regulating bone resorption (JCI 106:1553, 2000). Since both E and testosterone (T) directly inhibit osteoclastic activity and IL-6 production by osteoblastic lineage cells, it

is unclear why T is less potent than E in inhibiting bone resorption in vivo. Osteoprotegerin (OPG) is a soluble neutralizing receptor that binds to and inactivates RANK ligand (RANK-L), the final mediator of osteoclastogenesis. We have previously reported that E increases and T decreases OPG production by osteoblastic cells, but whether this occurs in humans in vivo is unclear. In the present study, we analyzed serum for OPG levels from our previous study in which 59 elderly men were made acutely hypogonadal using a GnRH agonist and were also placed on an aromatase inhibitor, letrozole, to block conversion of androgens to estrogens. Concomitant with the induction of hypogonadism, they were fully replaced for 3 weeks with T and E. Following baseline studies, they were then randomized to 4 groups and restudied 3 weeks later: Group A (-T, -E) had withdrawal of both the T and E patches; Group B (-T, +E) stopped the T patch; Group C (+T, -E) stopped the E patch; and Group D (+T, +E) continued both patches. The table below shows the baseline values and percent changes in serum OPG levels over the 3 week intervention period in the 4 groups (mean ± SEM).

Group	Baseline serum OPG, pg/ml	Serum OPG, % change from baseline	P-value
A (-T, -E)	115 ± 14	+10.0 ± 6.5	0.145
B (-T, +E)	104 ± 11	+18.6 ± 7.9	0.033
C (+T, -E)	115 ± 10	-10.0 ± 7.9	0.256
D (+T, +E)	97 ± 8	-3.2 ± 6.1	0.606

As evident, the group treated with E alone (group B) had a significant increase in serum OPG levels. By contrast, OPG decreased by an average of 6.4 ± 5.0% in the +T groups (C and D) whereas it increased by 14.5 ± 5.1% in the the -T groups (A and B), and using a 2-factor ANOVA model, there was a highly significant T effect (P = 0.006) on decreasing serum OPG levels. In this analysis, the T effect on decreasing OPG levels dominated, since the effect of E in the ANOVA model was not significant. Taken together, however, these data suggest that, in vivo, T decreases OPG levels, whereas E tends to have the opposite effect. These differential effects of E versus T on OPG production may, in part, explain why T has weaker effects than E on inhibiting bone resorption in vivo in humans

Vitamin D Dose Response Relationships. R. P. Heaney,[1] M. J. Barger-Lux,[1] K. M. Davies,[1] T. C. Chen,[2] M. F. Holick.[2] [1]Creighton University, Omaha, NE, USA, [2]Boston University, Boston, MA, USA.

Vitamin D inputs required to achieve or maintain any given serum 25(OH)D level are not known. Our objective was to establish the quantitative relationship between controlled steady state vitamin D input and resulting serum 25(OH)D concentration, and to estimate the proportion of the daily requirement during winter that is met by vitamin D reserves in body fat stores. We studied four groups of 16-18 men each, living at 41.5° N. latitude (age 38.7 ± 11.2), with habitual milk intakes of one serving per day or less. We gave oral doses of 0, 25, 125, and 250 µg vitamin D per day for 20 weeks across the winter months (when concurrent cutaneous production is close to zero at this latitude). We measured the time course of serum 25(OH)D concentration at intervals over the course of dosing. From a mean baseline value of 93.2 nmol/L, serum concentration of 25(OH)D fell on the zero dose, as is commonly observed. At the other doses, 25(OH)D rose to respective plateau values by 20 weeks, and the resulting equilibrium values were in direct proportion to dose (slope = 0.970 nmol/L for each 1 µg vitamin D input). The calculated oral vitamin D input required to sustain the autumn serum 25(OH)D level was 11.5 µg (460 IU)/d, while the total vitamin D input for a constant 25(OH)D level from all sources (supplement, food, fat stores) in these men, was ~96 µg (~3800 IU)/d. Since dietary intake was under 5 µg/d, by difference therefore, fat stores were providing ~80-84 µg vitamin D/d. These findings indicate that in healthy young adults probably better than 80% of their winter vitamin D utilization comes from cutaneous solar synthesis that had occurred during the preceding summer months. It follows that currently recommended vitamin D intakes are inadequate to maintain serum 25(OH)D concentration in the absence of substantial cutaneous production of vitamin D.

Homocysteine Serum Levels Predict the Risk of Osteoporotic Fractures in Postmenopausal Women. J. B. J. van Meurs,*[1] M. van der Klift,*[2] R. de Jonge,*[3] J. Lindemans,*[3] J. Witteman,*[2] A. Hofman,*[2] J. P. T. van Leeuwen,[1] A. G. Uitterlinden,[1] H. A. P. Pols.[1] [1]Internal Medicine, Erasmus University Rotterdam, Rotterdam, The Netherlands, [2]Epidemiology and Biostatistics, Erasmus University Rotterdam, Rotterdam, The Netherlands, [3]Clinical Chemistry, Academic Hospital Dijkzigt, Rotterdam, The Netherlands.

Very high levels of homocysteine (homocystinuria) are associated with a high prevalence of vascular disease, mental retardation and osteoporosis. Mild increases in serum homocysteine (Hcy) give rise to increased risk for artherosclerotic and thromboembolic disease. Homocysteine has also been suggested to interfere with the crosslinking of collagen type I, the major matrix component of bone.This raises the question whether mildly elevated Hcy levels increase the risk for osteoporosis. We therefore examined total serum homocysteine at baseline and determined its relationship to baseline bone mineral density (BMD) and risk of incident fractures. Hcy levels were determined in a population based sample of 429 women (aged 55-85 years), randomly drawn from a cohort of 4250 women participating in a large prospective follow-up study. BMD was measured at the lumbar spine and femoral neck by DEXA. Incident non-vertebral fractures were recorded over a mean follow-up period of 6 years. For 264 women lateral radiographs of the spine from the T4 to L5 were available and analyzed for the presence of vertebral fractures. We divided the women in three categories according to serum Hcy. Women in the highest tertile were 5 years older (p<0.001), had a higher body mass index (BMI) (p=0.03) and had lower mean dietary calcium intake (p=0.001). Mean femoral neck and lumbar spine BMD (crude or adjusted for age, BMI and dietary calcium intake) was not significantly different in the three groups. However, we observed an overrepresentation of fractures in women in the upper tertiles of the homocysteine level. Logistic regression showed that in comparison with the lowest tertile, women in the middle tertile had a 1.5 times increased risk (95% CI 0.6-4.0) for non-vertebral fractures and a 4 times increased risk for vertebral fractures (95%CI: 1.3-12.8). This increased to 2.7 (95%CI: 1.1-6.9) and 6.1 (95%CI: 1.9-19.5) in the highest tertile. These relative risks did not change essentially after adjustment for potential confounders like age, BMI, BMD, or dietary calcium intake. This study suggests that elevated serum homocysteine level is associated with increased risk for osteoporotic fractures in postmenopausal women. This risk is largely independent of differences in age or bone mineral density.

Bone Response to Estrogen Replacement in OVX Double Estrogen Receptor-(α and β) Knockout Mice. M. A. Gentile, H. Zhang,* S. Harada, G. A. Rodan, D. B. Kimmel. Bone Biology and Osteoporosis, Merck Research Laboratories, West Point, PA, USA.

α and β isoforms of the estrogen receptor (ER) are known, but their role in bone has not been fully established. The object here was to evaluate the skeletal effects of 17-β-estradiol (E2) in ovariectomized (OVX) double ER knockout ERα(-/-)β(-/-) (DRKO) mice obtained by F2 crosses of ERα(+/-)β(-/-) founders, derived from original ERα and ERβ null lines.DRKO and age-matched wild type (WT) mice were OVX or Sham-OVX at age 29 weeks. OVX groups were given 0, 0.04, or 0.2mg/kg 3X/wk E2 in sesame oil for eight weeks. Uterine weight (UWt, mg), femur length and distal 20% bone mineral density (DF-BMD, mg/cm2; pDXA, Norland) were measured after necropsy. The four groups within each genotype (all N=~11) were compared by Kruskal-Wallis ANOVA with Student Neuman-Keuls post-hoc test. All DRKO mice were compared to all WT mice for femur length (t-test of means).

Geno/Surg	E2	UWt	DF-BMD	F-Lgt
WT/Sham	0	143±50#	64±8#	16.2±0.3
WT/OVX	0	23±5	57±6	16.5±0.4
WT/OVX	0.04	127±29#	63±6#	16.1±0.3
WT/OVX	0.2	165±30#	67±9#	16.4±0.4
DRKO/Sham	0	47±25#*	64±7#	15.6±0.7
DRKO/OVX	0	18±7	57±5	16.1±0.4
DRKO/OVX	0.04	21±4	58±5	15.6±0.5
DRKO/OVX	0.2	63±38#	64±6#	15.8±0.4

Mean±SD; #diff from OVX/same genotype (P<.04) *Less than WT/Sham (P<.001)

KO/Sh mice had lower UWt and shorter femurs (P<.005), but similar DF-BMD, compared to WT. As expected, OVX reduced UWt in WT, but also in DRKO (P<.001) and lowered DF-BMD (P<.04) similarly in both genotypes. While 0.04mg/kg E2 protected against loss of UWt and DF-BMD in WT, 0.2mg/kg E2 was required in DRKO mice, that have high E2 levels prior to OVX. We conclude that: 1) OVX causes bone loss in DRKO; and 2) OVX-induced bone loss is prevented by high E2 (0.2mg/kg) in the absence of ERα and β. The higher E2 dose required in DRKO than WT suggests that E2 may act via conversion to testosterone or other non-ER mediated mechanism.

Gender-Independent Suppression of CFU-OB Replication by Either Estrogens or Non-Aromatizable Androgens in Bone Marrow Cultures from Males and Females. G. B. Di Gregorio, R. L. Jilka, S. Kousteni, S. C. Manolagas. Division of Endocrinology & Metabolism, Center for Osteoporosis and Metabolic Bone Diseases, and the Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Estrogens can restore bone mass in males with androgen deficiency, while non-aromatizable androgens can protect the female skeleton against the adverse effects of estrogen deficiency. However, the mechanisms of these phenomena are unknown. Based on evidence that a key mechanism of the anti-remodeling effects of estrogens in females may be the suppression of osteoblast progenitor (CFU-OB) replication, we examined whether androgens have similar effects to estrogens on replication of CFU-OB from females and whether estrogens have similar effects to androgens on the replication of CFU-OB from males. In these experiments CFU-OBs were identified in bone marrow cultures maintained for 25 days in the presence of ascorbate-2-phosphate, by their ability to form von Kossa stained colonies of mineralized matrix. CFU-OB replication was determined by measuring the difference in the number of colonies in these cultures, versus cultures from the same marrow maintained for 6 days in collagen gels, and then replated for an additional 25 days as above. The number of CFU-OB increased by 5-8 fold in cultures from adult female or male Swiss Webster mice maintained without sex steroids. However, in cultures maintained in the presence of either 17β-estradiol (E_2) or dihydrotestosterone (DHT), at doses ranging from 0.01 to 100 nM, CFU-OB replication was suppressed dose-dependently by E_2 or DHT irrespective of the sex of the bone marrow donor. In the case of either class of sex steroids the maximal inhibition of replication was 40-60%. Semi-quantitative RT-PCR analysis of ERα, ERβ and AR transcripts in 5-day cultures of bone marrow cells revealed similar levels for each one of the three receptors in cultures from females or males. These results suggest for the first time a mechanism by which the increased remodeling caused by estrogen deficiency can be reversed by androgens and vice versa. Moreover, in view of previous evidence that the suppressive effect of E_2 on CFU-OBs was abrogated in mice lacking ERα, our findings suggest that gender-independent suppression of remodeling by

either estrogens or non-aromatizable androgens results from sex steroid actions through their respective receptors. Whether suppression of remodeling alone can account for the anti-osteoporotic efficacy of androgens in females and estrogens in males, or additional gender-independent effects on the life span of osteoblasts and osteoclasts are involved will require future studies.

Tumor Necrosis Factor-a (TNF) Plays a Prominent Role in Protein Undernutrition-induced Bone Resorption. P. Ammann,[1] I. Garcia,[2] J. Bonjour,[1] R. Rizzoli.[1] [1]University Hospital, Div of Bone Diseases, Geneva, Switzerland, [2]Dpt of Pathology, Geneva, Switzerland.

Protein undernutrition is associated with an accelerated bone loss, resulting from an unbalance in bone turnover, with increased bone resorption and decreased bone formation. Whereas the latter could be ascribed to a marked decrease in serum IGF-I, the mechanisms underlying the increased bone resorption are still not understood. In analogy with sex hormone deficiency-induced bone loss, where TNF plays a crucial role, we investigated whether TNF would be involved in protein undernutrition-stimulated bone resorption, by evaluating the effects of isocaloric low (2.5%, LP) or normal (15%, NP) protein diets in 6-month old female transgenic mice expressing high levels of soluble TNF receptor-1 fusion protein, which blocks the actions of TNF (TNFtrans). Negative littermates (NegLit) were used as controls. We measured tibia areal BMD in vivo by DXA, and midshaft tibia bone strength after 16 weeks of isocaloric low or normal protein diets, together with serum IGF-I and osteocalcin. The BMD decrease (% of baseline) was significantly less pronounced in TNFtrans (-6.4±3.1*° vs +7.9±5.4, LP vs NP) than in NegLit (-19.6±2.6* vs +7.0±3.6 %) (*, p<0.05 vs NP;°, vs LP NegLit, by ANOVA, x±SEM). Bone strength was significantly decreased in NegLit (8.5±0.6* vs 11.2±0.8 N), but not in TNFtrans (9.2±1.1 vs 10.9±0.3, NS). Tibia midshaft diameter was similarly lowered in both NegLit (1.12±0.02* vs 1.25±0.01 mm) and TNFtrans (1.18±0.01* vs 1.25±0.02) mice fed the low protein diet. This suggests a reduced periostal apposition. Similar decrease in IGF-I (88±3* vs 161±7 in NP, and 93±4* vs 176±17), and in osteocalcin (80±9* vs 126±13, and 81±16* vs 152±13) occurred in NegLit and TNFtrans fed the isocaloric low protein diet. Thus, the increased bone loss and decreased bone strength induced by protein undernutrition were markedly attenuated by blocking TNF. In contrast TNF did not seem to be involved in the inhibition of bone formation. This is the first evidence of a causal relationship between a bone resorption stimulating cytokine and bone loss induced by protein undernutrition.

Pamidronate to Prevent Bone Loss in Men Receiving Gonadotropin-Releasing Hormone Agonist Therapy for Prostate Cancer. M. R. Smith,*[1] F. J. McGovern,*[1] A. L. Zietman,*[1] M. A. Fallon,*[1] D. L. Hayden,*[1] D. A. Schoenfeld,*[1] P. W. Kantoff,*[2] J. S. Finkelstein.[1] [1]Massachusetts General Hospital, Boston, MA, USA, [2]Dana Farber Cancer Institute, Boston, MA, USA.

Gonadotropin-releasing hormone agonist treatment decreases bone mineral density and increases the risk of osteoporotic fracture in men with prostate cancer. There have been no controlled studies for the prevention or treatment of osteoporosis associated with gonadotropin-releasing hormone agonist administration in men.In a 48 week open label study, we randomly assigned 47 men with locally advanced, node-positive, or recurrent prostate cancer to receive either leuprolide 3-month depot (22.5 milligrams intramuscularly every 12 weeks) alone or leuprolide 3-month depot and pamidronate (60 milligrams intravenously over 2 hours every 12 weeks). Men with bone metastases or secondary causes of osteoporosis were excluded. Bone mineral densities of the posterior-anterior lumbar spine, total hip, and total body were measured by dual energy x-ray absorptiometry. Trabecular bone mineral density of the lumbar spine was measured by quantitative computed tomography.Mean changes in bone mineral density at the posterior-anterior lumbar spine, trochanter, and total hip and trabecular bone mineral density of the lumbar spine differed significantly between the two groups (P<0.05 for each comparison). In men treated with leuprolide alone, mean (± SE) bone mineral density decreased by 3.3 ± 0.7 percent in the posterior-anterior lumbar spine, 2.1 ± 0.6 percent in the trochanter, and 1.8 ± 0.4 percent in the total hip (P= 0.001 for each comparison) and mean trabecular bone mineral density of the lumbar spine decreased by 8.5 ± 1.8 percent (P<0.001) over the 48 week study period. In contrast, mean bone mineral density did not change significantly at any skeletal site in the men treated with both leuprolide and pamidronate (P>0.05 for each comparison).Pamidronate prevents bone loss in the hip and lumbar spine of men receiving gonadotropin-releasing hormone agonist treatment for prostate cancer.

A Pilot Investigation Evaluating Progression of Coronary Artery Calcification in Patients Taking Alendronate for Osteoporosis. J. A. Hill,*[1] J. G. Goldin,*[1] H. Yoon,*[2] L. D. Greaser,*[1] D. Gjertson,*[3] A. M. Emerick,*[1] B. Hu,*[4] D. R. Aberle,*[1] J. S. Adams.[5] [1]Radiological Sciences, UCLA School of Medicine, Los Angeles, CA, USA, [2]Radiology, University of Utah School of Medicine, Salt Lake City, UT, USA, [3]Bioststatistics, UCLA School of Medicine, Los Angeles, CA, USA, [4]Pathology, UCLA/Cedars-Sinai Medical Center, Los Angeles, CA, USA, [5]Burns and Allen Research Institute, UCLA/Cedars-Sinai Medical Center, Los Angeles, CA, USA.

Subendocardial atherosclerotic plaque calcifies as it matures. Resorption of hydroxyapatite in plaque is controlled by macrophage-like 'foam' cells. In vitro 'foam' cells undergo apoptosis when exposed to physiological concentrations of aminobisphosphonates (Adams et al, unpublished). We hypothesized that bisphosphonate-induced apoptosis of plaque 'foam' cells would inhibit resorption of calcium from plaque, thereby increasing plaque mass. To evaluate this hypothesis in vivo we under took a prospective pilot study tracking coronary artery calcification (CAC) progression by elecron beam computed tomography (EBCT) and bone mineral density (BMD) by dual energy x-ray absorptiometry (DEXA) over a 5-year period in 59 patients taking alendronate 70 mg per week for treatment of osteoporosis. Rates of progression of in patients taking alendronate were compared to those from a larger, sex-matched "control" cohort (n=225) as well as to 59 CAC-score-age-, sex-, and cardiac risk factor-matched control subjects not taking alendronate. As anticipated, the alendronate-treated group experienced a significant increase in femoral neck and lumbar spine DEXA scores (paired t-test p<0.004 and p<0.001, respectively). There was significant progression of CAC scores in the alendronate-treated (p<0.05) and both control groups (p<0.02), most notably in those patients whose baseline CAC score was above 100. No statistical difference was detected in the absolute change or rate of change among the alendronate-treated and control cohorts. The results of this pilot suggest that there is no increase in the progression of CAC in patients treated with alendronate for osteoporosis; similar observations have recently been made in alendronate-treated, hypercholesterolemic pigs with baloon injury-induced arterial plaque formation (Hill et al, unpublished). We theorize that the discrepancy between our clinical findings and those in vitro with isolated 'foam' cells is failure of the bisphosphonate to penetrate the vascular endothelial barrier which separates circulating drug from the exposed hydroxyapatite matrix of plaque.

Novel, Non-steroidal Selective Androgen Receptor Modulators (SARMs) Increase Bone Mass and Reduce Androgenic Virilizing Effects in Adult Osteoporotic Rats. K. Furuya,* N. Yamamoto,* H. Nejishima,* K. Ichikawa,* S. Amano,* M. Tsunashima,* Y. Sumita,* K. Inoguchi,* M. Miyakawa,* T. Nakamura,* K. Hanada.* Drug Discovery Research Department, Kaken Pharmaceutical, Co., Ltd., Kyoto, Japan.

Cumulative evidences clearly indicate that androgens stimulate bone formation and increase bone mass in osteoporotic animal models and patients. However, androgen therapy has been hampered by its undesirable, dose-limiting side effects such as prostate stimulation and other virilizing effects. We have successfully generated a novel, non-steroidal small molecule library containing several hundreds of compounds that can bind androgen receptor (AR) as strongly as non-steroidal antiandrogens, casodex. To find out bone-selective AR agonists, these compounds were evaluated for tissue selectivity in comparison with testosterone propionate (TP) and DHT in orchiectomized (ORX) rats. The compounds were administrated subcutaneously (sc) or orally into ORX rats once daily for 4 weeks. Bone mineral density (BMD) of femurs was measured by dual energy X-ray absorptiometry (DEXA) and ventral prostates were weighed for representative index of virilizing effects. Among our non-steroidal library, Compound K1 and K2 (30mg/kg) dose-dependently increased in the BMD as markedly as TP and DHT, but did not elevate prostate weight over the normal at any doses tested. In contrast, TP and DHT showed 1.5-2 fold elevation in prostate weight as compared with the normal rats at efficacious dose of BMD increase in ORX rats (1~10mg/kg). To further analyze the virilizing effects, Compounds were given to the normal rats for 4 weeks and evaluated for prostate stimulation. The Compounds did not affect the prostate size, whereas the prostates of DHT-treated rats were about 1.5-fold larger than those of the normal. When the Compounds were administrated into ORX rats with TP, they competitively prevented prostate hypertrophy induced by TP and restored prostate to normal size. These data strongly suggested that our Compounds had the similar bone formation activity as natural androgen steroids, but the lessor virilizing effects than them. To confirm bone anabolic effects, the Compound K1 was given sc to ovariectomized (OVX) rat for 2 months and BMD of femurs was measured. The Compound significantly increased in BMD of femoral midshaft (cortical bones) as well as DHT and TP, whereas estrogen, anti-bone resorptive hormone, did not. Collectively, our novel Compounds were candidates of SARMs which had unique tissue selectivity with high potency for bone formation and lower impact upon prostate. The candidates are promising drugs for osteoporosis and androgen-deficient disease (androgen replacement therapy).

Osteoprotegerin (OPG) Prevents Bone Loss in a Rat Model of Glucocorticoid-Induced Osteopenia. S. Morony,[1] J. Lu,*[1] C. Capparelli,[1] C. R. Dunstan,[2] D. L. Lacey,[1] P. J. Kostenuik.[1] [1]Pharmacology/Pathology, Amgen, Inc., Thousand Oaks, CA, USA, [2]Development, Amgen, Inc., Thousand Oaks, CA, USA.

The prolonged use of glucocorticoids such as prednisolone (Pred) often results in osteoporosis by mechanisms which include osteoclast stimulation and osteoblast suppression. The osteoclast response to glucorticoid therapy may be mediated by increased osteoblast expression of OPGL/RANKL (a physiological activator of osteoclasts) and decreased expression of OPG (a physiological inhibitor of osteoclasts) (Hofbauer et al, Endocrinology 140: 4382, 1999). Recent reports indicate that antiresorptives suppress bone resorption and increase bone mass in the glucocorticoid-treated skeleton. We therefore tested the effects of recombinant OPG in male SD rats (8-10 weeks old, n=6-7/group) which were implanted SC with pellets containing placebo or Pred (1 or 2 mg/kg/day). Animals were treated (SC) for 45 days with vehicle (PBS) or recombinant OPG (1 mg/kg, 3X/week) starting immediately after pellet implantation. On days 0, 15, 30 and 45, BMD was measured by DEXA and blood was drawn for biochemical markers of bone turnover. Both doses of Pred caused significant decreases in BMD in the femur/tibia compared to placebo-challenged rats. The Pred-related decrease in BMD was not accompanied by a histological decrease in bone volume, suggesting that the bone formed during Pred therapy may be hypomineralized. OPG treatment prevented the Pred-induced decrease in BMD, and restored BMD to levels significantly greater than in normal untreated rats. Pred challenge was associated with a significant increase in osteoclast surfaces, and OPG treatment reduced osteoclast surfaces to levels lower than in normal untreated rats. OPG also caused significant reductions in serum TRAP (a marker of bone resorption) in both Pred- and placebo-challenged rats. These anti-osteoclast effects were associated with significant increases in bone volume. Osteoblast suppression may also have contributed to bone loss

in this model, as evidenced by a significant reduction in serum osteocalcin in Pred-challenged rats. OPG did not reverse the Pred-related decrease in osteocalcin. These data suggest that Pred-induced bone loss in rats is mediated by a combination of increased bone resorption and suppressed bone formation. OPG treatment reversed the Pred-related increases in bone resorption, and reduced osteoclast numbers to subphysiological levels. These effects translated into increased BMD and bone volume in the tibia/femur to levels greater than in untreated normal rats. Recombinant OPG therapy may therefore represent a novel therapeutic approach for glucocorticoid-induced bone loss.

Subcutaneous Administration of Insulin-Like Growth Factor (IGF)-II/ IGF Binding Protein-2 Complex Stimulates Bone Formation and Prevents Loss of Bone Mineral Density in a Rat Model of Disuse Osteoporosis . C. A. Conover,*[1] R. T. Turner,[1] E. W. Johnstone,*[1] F. J. Ballard,*[2] P. M. Doran,[1] S. Khosla.[1] [1]Mayo Clinic, Rochester, MN, USA, [2]GroPep, Adelaide, Australia.

We have previously reported that elevation in serum levels of IGFBP-2 and a precursor form of IGF-II is associated with marked increases in bone formation in patients with hepatitis C-associated osteoscelerosis (J Clin Invest 101:2165, 1998). Furthermore, in vitro studies indicated that IGF-II in complex with IGFBP-2 has high affinity for bone matrix and is able to stimulate osteoblast proliferation. The purpose of this study was to determine the ability of IGF-II/IGFBP-2 complex to stimulate bone formation in vivo. Osteopenia of the femur was induced by unilateral sciatic neurectomy in rats. At the time of surgery, 14-day mini-osmotic pumps containing vehicle (NaCl/1% BSA, n=6) or 2 µg IGF-II/100 g body weight/day + 9 µg IGFBP-2 (n=5) were implanted under the neck skin. Bone mineral density (BMD) measures were taken immediately before surgery and 14 days later using a PIXImus small animal densitometer. Fluorochromes were administered on day 8 and day 13 for bone histomorphometry. Results for the BMD (mean ± SE) are presented in the Table.

	R Femur (sciatic neurectomy)		**L Femur (control)**	
	Day 0	Day 14	Day 0	Day 14
Vehicle	0.217 ± 0.005	0.197 ± 0.007*	0.215 ± 0.003	0.216 ± 0.004
II/BP-2	0.214 ± 0.004	0.220 ± 0.003	0.214 ± 0.006	0.233 ± 0.003*

*P<0.05 vs Day 0

Neurectomy (R femur) resulted in a 10% decrease in BMD that was prevented by the IGF-II/BP-2 complex. Of note, even in the control (L femur), the IGF-II/BP-2 complex resulted in a significant (9%) increase in BMD. Our preliminary bone histomorphometric analyses indicate an increase in endocortical bone formation rates with IGF-II/IGFBP-2 treatment. These results demonstrate that short-term administration of IGF-II/IGFBP-2 complex can prevent loss of BMD associated with disuse oteoporosis and stimulate new bone formation in adult rats. Success in further preclinical trials may indicate a novel approach to stimulating new bone formation and to increasing bone mass in humans with osteoporosis

Novel Bone-Targeted Src Tyrosine Kinase Inhibitors Prevent Bone Loss and Stimulate Osteoblast Activity. B. Boyce,[1] L. Xing,*[1] S. Bain,*[2] V. Shen,*[2] C. Liu,*[2] H. Chen,*[2] Y. Wang,*[3] W. Shakespeare,*[3] C. Metcalf,*[3] R. Sundaramoorthi,*[3] T. Keenan,*[3] R. Bohacek,*[3] M. R. van Schravendijk,*[3] D. Dalgarno,[3] J. Iuliucci,[3] M. Weigele,*[3] T. Sawyer.[3] [1]Univ. Rochester Med Ctr, Rochester, NY, USA, [2]SkeleTech, Bothell, WA, USA, [3]ARIAD Pharmaceuticals, Cambridge, MA, USA.

Src is a non-receptor tyrosine kinase required for osteoclast (ocl) activation and bone resorption. Thus, it is a well-validated therapeutic target for prevention of postmenopausal and other forms of bone loss. To this end, we have used rational drug design to develop novel, potent (IC50s in nM range) non-peptide Src tyrosine kinase inhibitors (MW < 500) selective against several other protein kinases. We targeted them to bone by specific chemical moieties with high affinity for hydroxyapatite and tested their effects on bone resorption. Selected lead compounds (AP23286; AP23317; AP23381; AP23451): 1) dose-dependently inhibited ocl resorption *in vitro* (pit area and number reduced by 55-97% at 1 µM and by 98-100% at 10 mM) after pre-incubation on bone slices and 6d treatment, and without pre-incubation, at 10 µM (AP 23317 and AP 23381), effects comparable to alendronate at 1 and 10 mM; 2) prevented PTH-induced hypercalcemia (50-100% inhibition) and bone resorption (osteoclast number/mm calvarial bone surface (4.5+/-1.3 AP23381 + PTH vs 11.1+/-1.5 PTH alone; AP23451: 1.7+/-1.7 vs 14.4+/-3.3) when given twice daily s.c(10 mg/kg) to mice for 5d; 3) prevented Ovx-induced vertebral (DEXA: .063+/-.0001 vs .056+/-.002 g/cm^2) and femoral metaphyseal (pQCT: 571+/-8 vs 455+/-14 g/cm^3) bone loss, with associated decreased ocl activity (Oc.S/BS: 4+/-0.3 vs 17+/-1.5%) and increased vertebral breaking strength (12.9 +/- 1.3 vs. 6.5 +/- 0.9 N/mm^2) and elastic modulus (300 +/- 27 vs. 139 +/- 16 MPa) (AP 23317, 10mg/kg s.c. once daily for 35d). In addition to its required role in osteoclasts, Src also negatively regulates bone formation. In preliminary studies to examine this latter role for Src, 6d treatment of fetal rat calvarial cells with Src inhibitors increased alkaline phosphatase activity 2-fold. Furthermore, AP23317 given once daily to intact mice for 35d increased bone mass in vertebrae (DEXA: .066+/-.002 vs. .059+/-.002 g/cm^2) and in femoral metaphyses (pQCT: 639+/-9 vs 447+/-22 mg/cm^3; cancellous bone volume: 15.7+/-1.3% vs 7.8+/-1.0%). Our findings provide the first evidence that this specifically-designed class of bone-targeted Src tyrosine kinase inhibitors prevent bone loss and maintain bone strength by inhibiting osteoclastic resorption, and suggest that they also stimulate bone formation. Thus, they may have a dual action on bone, suggesting efficacy not only in the prevention of osteoporosis, but also in its treatment.

Activation of Unliganded AF2 Defective Vitamin D Receptor Mutant by Phosphorylation. F. Barletta,*[1] L. P. Freedman,[2] S. Christakos.[1] [1]Biochemistry and Molecular Biology, UMDNJ-New Jersey Medical School, Newark, NJ, USA, [2]Memorial Sloan-Kettering Cancer Center, New York, NY, USA.

The vitamin D receptor (VDR) normally acts in the presence of 1,25dihydroxyvitamin D_3 [1,25$(OH)_2D_3$] as a ligand inducible transcription factor by binding as a heterodimer with the retinoid X receptor to hormone response elements in target genes. The ligand dependent transcriptional activation function (AF2) is located in the ligand binding domain (LBD). The C terminal helix 12, the core AF2 domain, contains residues that function as an interaction surface for coactivators. In this study COS-7 cells were cotransfected with 500 ng wild type (WT) VDR or the AF2 defective mutant L417S (the leucine residue 417 at the C terminus of the predicted helix 12 in VDR was mutated to serine) and 3µg of a chloramphenicol acetyltransferase (CAT) reporter plasmid containing multiple copies of the rat 24(OH)ase vitamin D response element (VDRE) (-151/-137) or the mouse OPN VDRE (-757/-743). Cells transfected with WT VDR exhibited a 9.4±0.2 fold and a 5.6±0.9 fold induction in CAT activity respectively after treatment with 1,25$(OH)_2D_3$ (10^{-8}M for 24h). In cells transfected with L417S mutant VDR, vitamin D dependent transactivation was abolished. In contrast, in the presence of the phosphatase inhibitor okadaic acid (OA; 50nM, 24h), the AF2 defective mutant was able to activate the VDRE tk CAT constructs in a ligand independent manner (3 -4 fold induction compared to basal, $p < 0.05$). These results show that activation by phosphorylation can be independent of the conserved leucine in the AF2 domain. In addition, phosphorylation rescued the recruitment of DRIP205, a subunit of the DRIP coactivator complex, to the AF2 defective mutant. COS cells transfected with L417S mutant VDR were treated with vehicle, 1,25$(OH)_2D_3$ or OA (50 nM) for 24h. Nuclear extracts containing equal amounts of L417S mutant VDR were incubated with immobilized GST-DRIP205 and bound L417S was subsequently visualized by Western analysis. The defective receptor was unable to bind to DRIP205 in the presence or absence of 1,25$(OH)_2D_3$. However, treatment with OA was able to cause a ligand independent recruitment of DRIP205 to the AF2 defective VDR. Binding of L417S mutant VDR to DRIP205 was further increased in the presence of both OA and 1,25$(OH)_2D_3$. These findings suggest that phosphorylation results in a conformational change in the AF2 defective mutant that creates an active interaction surface with coactivators. These results demonstrate a novel mechanism by which an inactive VDR can be converted to an effective transcriptional activator.

Osteopenia in Male Androgen Receptor Deficient Mice. H. Kawano,[1] T. Sato,*[1] H. Kawaguchi,[2] S. Kato.[1] [1]Institute of Molecular and Cellular Biosciences, Univ. of Tokyo/ CREST, Tokyo, Japan, [2]Orthopaedic Surgery, Univ. of Tokyo, Tokyo, Japan.

Androgen is physiologically important for male skeletal formation and reproductive organs; however, its action on bone at molecular levels remains largely unknown, mainly due to the lack of androgen receptor-knock out (ARKO) mouse line. As ARKO males are expected to exert testicular feminization mutant (Tfm) abnormalities with infertility, it is impossible to generate ARKO mouse lines by either conventional KO methods or natural mutations. To avoid this problem, we applied a Cre/loxP system, and succeeded in generating an ARKO mouse line. We further performed in vivo and in vitro analyses of the bone of ARKO males. We first generated the floxed AR mice, in which the AR gene locus was flanked by loxP sites. The floxed mice were fertile and expressed AR protein normally. By mating them with CMV-Cre transgenic mice expressing Cre recombinase ubiquitously, the AR gene was disrupted during embryogenesis. ARKO males grew normally with typical features of Tfm abnormalities, and genital organs were atrophic with a marked decrease in the serum testosterone level. Bone densitometry and 3D-µCT analyses revealed significant decreases of both trabecular and cortex bone volumes in ARKO males compared to wild-type (WT) littermate males at 6-16 weeks of age. Histomorphometric analysis at 8 weeks showed that bone volume (BV/TV) was 29% lower. Parameters for both bone formation (Ob.S/BS, MAR) and resorption (Oc.N/B.Pm , ES/BS) were higher in ARKO males than WT littermates, and the increase in bone resorption (40-50%) exceeded that in formation (15-20%), indicating a state of high turnover osteopenia. To investigate the cellular mechanism of this osteopenia, we compared functions of bone cells derived from ARKO and WT males. Neither osteoclastogenesis in M-CSF-dependent bone marrow macrophage culture in the presence of soluble RANKL nor isolated osteoclast survival rate was different between ARKO and WT cultures, indicating that AR signaling in cells of osteoclastic lineage is not important. However, osteoclastogenesis and resorbed pit formation in the co-culture system of osteoblasts and marrow cells were up-regulated only when osteoblasts were derived from ARKO mice independently of the origin of marrow cells, and ARKO osteoblasts showed higher RANKL mRNA expression. These results demonstrate that AR deficiency in osteoblasts stimulates the supporting ability of osteoclastogenesis causing high turnover osteopenia. Since the serum estrogen levels were similar between ARKO and WT males, androgen signaling was shown to play a critical role in maintaining male bone turnover and preventing bone loss in an independent mechanism of estrogen signaling.

Osteoblast-Targeted Expression of Stretch Activated Cation Channels Enhances the Anabolic Effect of Mechanical Stimulation on Bone. N. L. Kizer,[1] U. Alvarez,*[2] J. L. Chaudhary,[1] K. Tustison,*[2] T. Clemens,[3] J. W. Pike,[3] K. Hruska.[1] [1]Internal Medicine/Renal, Washington University, Saint Louis, MO, USA, [2]Internal Medicine/Renal, Barnes-Jewish Hospital, Saint Louis, MO, USA, [3]Molecular/Cellular Physiology, University of Cincinnati, Cincinnati, OH, USA.

Osteoblasts respond to chronic mechanical stimulation by increasing matrix protein synthesis and increasing the activity of plasma membrane stretch-activated cation channels

(SA-cat). We hypothesize that SA-cat channels function as a mechanosensor mediating exercise-induced bone growth. To investigate the role of the SA-cat channel in vivo we have generated transgenic (SA-cat Tg) mice that over-express the channel in osteoblasts and osteocytes. Northern analyses demonstrated that osteoblasts from SA-cat Tg mice expressed nearly 5 fold more SA-cat mRNA. SA-cat Tg specific RT-PCR indicated that the additional channel transcripts were due to transgenic mRNA. SA-cat Tg +/- mice express age dependent increases in bone strength, toughness and flexibility. To test the hypothesis that expression of the transgene increases the sensitivity of bone to mechanical stimulation, we subjected the SA-cat Tg +/- and wild type mice to in vivo tibial flexing. The left tibia was flexed in the medial direction using four-point bending with a bending moment of 12 Nmm applied at 2 Hz for 36 repetitions. The animals were stimulated each day for two weeks. Visual inspection of the left (flexed) tibia indicated periosteal hypertrophy in many of the bones. Tibia from transgenic mice averaged 100% more hypertrophy than their wild type counterparts as measured by maximum thickness of the tibia in the area subjected to 4 point bending ($P<0.05$). Application of 4-point pressure without bending did not result in hypertrophy of the tibia. Analysis of flexed and non-flexed bones from wild type and transgenic mice using pQCT revealed an 8.3% reduction ($p < 0.01$) of cortical thickness in the transgenic mice while cortical area and density remained unchanged. The change in cortical geometry was further reflected by a 13.9% ($p < 0.05$) increase in cross-sectional moment of inertia and an increase of 8.7% ($p < 0.02$) in polar moment of inertia. Furthermore, calcein labeling indicated that bone turnover was accelerated in the transgenic mice. These data taken together with our previous findings, lead us to conclude that the SA-cat channel functions as a mechanosensor in vivo, participating in the regulation of bone mass and strength. Overexpression of SA-cat lowers the set point for mechanotransduction resulting in a fundamental alteration of cortical bone material and geometry leading to a more flexible and stronger bone that retains bone properties of much younger animals.

Mice with Null Mutation in Collagenase-3 (Matrix Metalloproteinase[MMP]-13) Exhibit Altered Bone Remodeling and Increased Bone Mass. M. Inada,[1] Y. Wang,[1] M. H. Byrne,*[1] C. Miyaura,[2] S. M. Krane.[1] [1]Medicine, Massachusetts General Hospital, Boston, MA, USA, [2]Biochemistry, Tokyo University of Pharmacy and Life Science, Tokyo, Japan.

We have previously described abnormal bone remodeling, including decreased bone-resorptive responses to parathyroid hormone (PTH) in mice with a targeted mutation in Col1a1 that encodes resistance to collagenase cleavage at the helical locus of type I collagen. MMP-13 can degrade collagen at neutral pH and is expressed in growth plates and bone during embryonic development and postnatally. To determine the specific role of MMP-13 in bone remodeling, we targeted a null mutation in the MMP-13 gene that results in splicing out Exon 5 which encodes the critical catalytic, Zn-binding domain leading to an inactive enzyme. Homozygous mutant mice (MMP-13 -/-) demonstrated increased width and delayed maturation of the growth plate, using histological analysis of tibias and femurs. In mice > 1 month of age there was an apparent increase in mass of metaphyseal bone. Furthermore, soft X-ray analysis of femurs from 1 and 3 month- old mice revealed a decrease in length, increase in width and increase in metaphyseal trabecular bone in MMP-13 -/- vs. MMP-13 +/+ mice. Changes in bone mineral density (BMD) of femurs were quantified using DEXA. In 1 month-old mice, mean distal BMD was 33.0 mg/cm2 ± 1.70 (SEM) in MMP-13 +/+ vs. 37.5 ± 0.72 in MMP-13 -/- ; in 3 month-old mice, distal BMD was 39.2 mg/cm2 ± 1.60 in MMP-13 +/+ vs. 48.2 ± 1.18 in MMP-13 -/-. Organ cultures of calvariae from newborn mice incubated for 4 days were used to assess bone resorption responses to PTH and interleukin-1a (IL-1a). In 3 separate experiments, the responses to PTH and IL-1a measured by changes in medium [Ca]were significantly suppressed ($p<0.01$) in MMP-13 -/- vs. MMP-13 +/+ mice. Western blot analysis showed a marked increase in medium MMP-13 protein induced by PTH or IL-1a in cultures of MMP-13 +/+ calvariae; in contrast, no detectable MMP-13 protein was induced by PTH or IL-1a in cultures of MMP-13 -/- calvariae. Nevertheless, expression of other MMPs (e.g. MMP-2 and -9), measured using casein and gelatin zymography, was induced by PTH or IL-1a in cultured calvariae from MMP-13 -/- as well as +/+ mice.In conclusion, disruption of the function of MMP-13 in mice results in abnormalities of bone remodeling with increases in metaphyseal BMD. Although MMP-13 is expressed predominantly in osteoblasts and related cells, osteoclastic bone resorption appears to be decreased in the MMP-13 -/- mice. Compensatory increases in other collagenolytic MMPs may partially ameliorate the effects of loss of function of MMP-13.

1053

RANK Ligand Stimulates Anabolic Bone Formation. J. Lam,[1] F. P. Ross,[1] S. L. Teitelbaum.[1] [1]Washington University School of Medicine, Saint Louis, MO, USA.

We have made the surprising observation that murine RANK ligand (RANKL), the key osteoclastogenic cytokine, when administered as an amino-terminal glutathione-S-transferase (GST) fusion protein, profoundly stimulates anabolic bone formation in vitro, ex vivo, and in vivo. Diurnal subcutaneous injection of GST-RANKL (158-316) (5 μg/kg to 4.5 mg/kg) for 7 days in mice results in a dose-dependent net increase in the number of activated osteoblasts in long bones, maximizing at 25-fold relative to control (624 ± 43 ob/mm^2 experimental vs. 28 ± 4 ob/mm^2 control, $p < 0.001$). In contrast, GST-RANKL fails to affect osteoclast number (45 ± 10 oc/mm^2 experimental vs. 39 ± 5 oc/mm^2 control). Systemic administration of GST-RANKL for 7 days induces as much as a 3-fold increase in cortical bone thickness, structural augmentation of the microarchitecture of the primary spongiosa, and a 10% increase ($p < 0.01$) in bone mineral density by DEXA. Dual fluorochrome labeling in animals receiving 1.5 mg/kg/day GST-RANKL for 7 days demonstrates a mineral apposition rate (MAR) of 3.59 ± 0.18 μm/day in the parietal bones of GST-RANKL-treated animals, compared with 0.18 ± 0.03 μm/day in the parietal bones of control animals, ($p < 0.001$). Marrow derived from mice administered 1.5 mg/kg/day GST-RANKL for 14 days exhibits a 100-fold increase in mineralizing bone nodules, when cultured under osteoblastogenic conditions ex vivo. Furthermore, administration of GST-RANKL for 12 hours, given on days 1 and 4 of ex vivo whole organ culture, induces a dose-dependent increase in the thickness of calvaria, maximizing at 2-fold (46.1 ± 3.97 μm experimental vs. 20.7 ± 1.5 μm control, $p < 0.001$). Consistent with the osteogenic properties of GST-RANKL, we find that its receptor RANK is expressed by primary mesenchymal osteoprogenitor cells, and that these cells respond to GST-RANKL with activation of the NFκB and MAPK pathways. Attesting to the function of RANKL-RANK signaling in osteoprogenitor cells, expression of the osteoblast transcription factor Cbfa1 is enhanced within 1 hour of in vivo treatment with GST-RANKL. Thus, a chimeric derivative of the pro-resorptive cytokine RANKL can induce bone formation by a mechanism involving RANK signaling in early osteoblast precursors to enhance Cbfa1 expression and induce commitment to the osteogenic phenotype. RANKL, or derivatives thereof, therefore presents itself as a potential anabolic agent for bone.

1054

Cells of the Osteoblastic Lineage from Transgenic Mice Over-Expressing Cbfa1 Induce Increased Bone Resorption in Vitro. V. Geoffroy,*[1] M. Kneissel,[2] B. Fournier,*[2] P. Matthias.*[1] [1]Friedrich Miescher-Institute, Basel, Switzerland, [2]Bone Pharma, Novartis, Basel, Switzerland.

The transcription factor Cbfa1 is required for bone formation. It acts as a differentiation factor during mesenchymal condensation and is also important for proper osteoblastic function, but its role in adult bone remodeling is not fully understood. To address this question we generated transgenic mice overexpressing Cbfa1 under the control of the rat collagen type I promoter. These mice present a severe osteopenic phenotype associated with high bone turn-over, cortical bone loss, and multiple fractures.To understand the origin of the increased bone resorption, we developed bone marrow stromal cell cultures and reciprocal co-culture of primary osteoblasts and spleen cells from wild type and transgenic mice followed by TRAP staining. The culture of bone marrow stromal cells under osteoclastogenic conditions showed that stromal cells of transgenic genotype induced an increased number of TRAP positive multinucleated cells compared to wild-type cells. To confirm these results we performed co-culture experiments from osteoblasts derived from calvaria and spleen cells. As expected primary osteoblasts derived from transgenic mice trigger the generation of more TRAP positive osteoclastic cells suggesting that primary osteoblasts as well as bone marrow stromal cells from transgenic mice have stronger osteoclastogenic properties compared to cells derived from wild-type animals. We then investigated the candidate genes that could trigger this increase of TRAP positive osteoclasts and analyzed the expression of bone markers in calvaria-derived cells and stromal cells isolated from wild type and transgenic animals. In these cells, we showed by semi-quantitative RT-PCR experiments, that the transgene was expressed in both cell populations and that the expression of RANK-ligand and collagenase 3, two factors involved in formation-resorption coupling, were markedly increased in transgenic cells. These results are consistent with an increase of these two factors measured in RNA prepared from long bone of transgenic animals. Our data rather suggest that the overexpression of Cbfa1 in cells of the osteoblastic lineage, including bone marrow stromal cells, have a positive effect on osteoclast differentiation and consequently on bone resorption. These findings also indicate that the increase of bone turn over observed in the mice overexpressing Cbfa1 under the control of the collagen type I promoter is partly due to the high expression level of RANK-ligand and collagenase 3 in bone marrow stromal cells.

Longitudinal Transmenopausal Changes in Three-Dimensional Trabecular Microarchitecture and Connectivity of Human Iliac Crest Bone Biopsies. Y. Jiang,[1] J. Zhao,[1] R. R. Recker,[2] M. W. Draper,[3] H. K. Genant.[1] [1]Osteoporosis and Arthritis Research Group, University of California, San Francisco, CA, USA, [2]Osteoporosis Research Center, Creighton University, Omaha, NE, USA, [3]Lilly Research Laboratories, Indianapolis, IN, USA.

This study was designed to capture true longitudinal transmenopausal changes in three-dimensional (3D) trabecular architecture, which may improve our ability to understand the pathophysiology of osteoporosis and other bone disorders, and to estimate bone biomechanical properties in terms of fracture resistance as the mechanical competence of trabecular bone is a function of its apparent density and 3D distribution. During aging and diseases such as osteoporosis, trabecular plates are perforated and connecting rods are dissolved, with a continuous shift from one structural type to the other. Such changes can not be evaluated by 2D histological sections. In histomorphometry, there is debate about whether trabecular thinning occurs, or rather trabecular disappearance occurs with aging and/or menopause based on 2D sections using the parallel plate model. We examined paired bone biopsies from the iliac crest, not a primary weight bearing anatomical site, from 20 Caucasian women. The first biopsy was from normal, premenopausal women, age 46.3 – 53.5 years (mean ± SD, 49.1 ± 2.7 years), and the second biopsy from the same group of women, but 12 months postmenopausal, occurring 2.3 – 8.4 years (5.0 ± 1.7 years) after the first biopsy. The specimens were scanned using a micro computed tomography scanner (μCT 20, Scanco) with isotropic resolution of 20 μm. 3D trabecular structural parameters were directly measured without stereological model assumption. Values of 0 and 3 for the structure model index represent an ideal plate structure and rod structure, respectively, while values ranging from 0 to 3 indicate a structure with both plates and rods of equal thickness, depending on the volume ratio of rods and plates. After menopause, there was a significant change in 3D trabecular bone volume fraction (-5.4%/yr), trabecular number (-1.2%/yr), trabecular thickness (-3.3%/yr), trabecular separation (+2.0%/yr), structure model index (+11.3%/yr), degree of anisotropy (-0.7%/yr), and connectivity density (-2.0%/yr). The percentage change over the mean 5-year period was greater in 3D trabecular thickness (-16.4%) than in trabecular number (-6.1%) and trabecular separation (+9.9%). Thus, there is a rapid deterioration of 3D trabecular structure and connectivity in the iliac crest in the initial postmenopausal year. Trabecular thinning does occur and trabeculae dramatically shift from a plate-like structural type to a rod-like pattern, and become more isotropic.

1056

A Novel Therapeutic Vaccine That Prevents Pathological Bone Destruction in Models of Osteoporosis and RA. T. Juji,[1] K. Aoki,[2] D. Horie,*[2] K. Ohya,[2] M. Herz,*[3] A. Gautam,*[3] S. Mouritsen,*[3] H. Oda,*[1] K. Nakamura,[1] S. Tanaka.[1] [1]Department of Orthopaedic Sugery, Faculty of Medicine, The University of Tokyo, Tokyo, Japan, [2]Section of Pharmacology, Department of Hard Tissue Engineering, Graduate school, Tokyo Medical and Dental University, Tokyo, Japan, [3]M & E Biotech A/S, Hørsholm, Denmark.

The receptor activator of NF-kappaB ligand (RANKL) is a novel member of tumor necrosis factor family cytokines, which is critically involved in osteoclast differentiation and activation, and therefore important for normal bone development. There is accumulating evidence that RANKL also plays important roles in the pathological bone destruction such as osteoporosis and rheumatoid arthritis. The natural inhibitor of RANKL, osteoprotegerin (OPG), has potent therapeutic effects on such conditions. However, repeated administration of OPG in larger dosescould potentially be immunogenic and may elicit antibody responses, limiting its long-term effectiveness. Here we describe a simple and effective method of active immunization against self RANKL as a possible treatment of bone diseases. RANKL protein vaccines were generated by inserting a promiscuous foreign T helper (Th) peptide into the RANKL cDNA. Immunization with these vaccines resulted in a rapid and sustainable polyclonal anti-RANKL antibodies in mice. No apparent macroscopic abnormality was observed in any organs of the immunizedanimals. To determine the therapeutic effects of theses vaccines, we utilized ovariectomy and arthritis models. Female BALB/c mice were immunized with either control antigen or the Th peptide-modified RANKL vaccine four times at two week intervals before subjecting them to ovariectomy. Mice immunized with RANKL vaccines were resistant to bone loss in response to ovariectomy. Importantly, both osteoclast numbers as well as bone resorption surface were significantlyreduced in RANKL vaccinated mice. We next examined the effect of the vaccine on SKG mice, a natural mutant of BALB/c background, that develops spontaneous rheumatoid arthritis-like inflammatory joint disorders and bone destruction. Immunization with RANKL vaccines almostcompletely prevented the bone destruction in these mice. Osteoclast numbers in various regions of bones were also dramatically reduced following this vaccination. These results demonstrate that a therapeutic vaccine approach targeting RANKL can be used to inhibitbone destruction in a variety of pathological bone loss conditions such as osteoporosis and rheumatoid arthritis.

1057

Targeted Deletion of the Histidine Decarboxylase Gene in Mice Increases Bone Formation and Protects Against Ovariectomy-Induced Bone Loss. C. Horvath,[1] A. Falus,*[2] E. Buzas,*[2] A. Mester,*[3] A. Nagy,*[4] L. Fitzpatrick,[5] J. Barsony.[6] [1]1st Dept Internal Medicine, Semmelweis University, Budapest, Hungary, [2]Dept Biology, Semmelweis University, Budapest, Hungary, [3]Dept Radiology, Semmelweis University, Budapest, Hungary, [4]Samuel Lunenfeld Institute, Mount Sinai Hospital, Toronto, Canada, [5]Dept Medicine, Mayo Clinic, Rochester, MN, USA, [6]LCBB, NIH/NIDDK, Bethesda, MD, USA.

Few studies have suggested a role for increased histamine production in osteoporosis and a bone-protective effect of antihistamines. To understand the role of histamine, we developed a knockout mouse model by targeted disruption of the histidine decarboxylase (HDC) gene, the only enzyme responsible for histamine production. Dramaticly decreased tissue histamine levels, decreased mast cell number and degranulation, impaired passive cutaneous anaphylaxis, decreased gastric acid secretion and nocturnal locomotor activity indicated the validity of the histamine deficient model (KO). The bone phenotype was investigated by measurements of bone mineral content by DEXA (BMC), computer tomography (CT), double calcein labeling, histomorphometric analysis, and laboratory parameters of calcium homeostasis. Groups of 5-7 wild-type (WT) and KO animals were also evaluated 45 and 90 days after sham-operation or ovariectomy. BMC was higher in KO than in WT animals and was also higher in KO after ovariectomy ($p<0.002$). Radiographs of femora showed increased cortical bone thickness in KO mice, as early as 45 days after ovariectomy. Quantitative CT also showed an increased cortical thickness in sham operated and ovariectomized KO mice compared to WT. Histology revealed a marked increase in cortical bone in the femoral diaphysis of KO mice by endochondral ossification, while the epiphysis was unchanged from the WT. Morphometric measurements showed increases in mineralizing surface ($p<0.004$) and in surface or volume-based parameters of bone formation rates ($p<0.006$; $p<0.007$). These differences were augmented after ovariectomy. Serum calcium, phosphorus, and 25-hydroxyvitamin D levels were the same in WT and KO animals and were within normal ranges. Serum alkaline phosphatase and 1,25-dihydroxyvitamin D levels were significantly elevated, and PTH levels were lower ($p<0.001$) in KO, consistent with increased bone formation. These results show that histamine deficiency causes an increase in cortical bone mass, bone formation rate, and reduces bone loss after ovariectomy. Our findings indicate that histamine negatively regulates bone formation and support the potential use of antihistamines for the treatment of postmenopausal osteoporosis.

Demonstration that FGF-23, a Factor Produced by Tumors Associated with Phosphate Wasting, Inhibits Phosphate Transport *In Vitro*. S. M. Jan de Beur,*[1] A. E. Bowe,*[2] J. Y. Cho,*[1] R. Finnegan,*[2] R. Kumar,[3] M. A. Levine,[1] S. C. Schiavi.*[2] [1]Medicine and Pediatrics, The Johns Hopkins University, Baltimore, MD, USA, [2]Genzyme, Framingham, MA, USA, [3]Medicine, Mayo Clinic, Rochester, MN, USA.

Oncogenic osteomalacia (OOM) is an acquired hypophosphatemic syndrome that resembles genetic forms of hypophosphatemic rickets but which is associated with primitive mesenchymal tumors. The clinical and biochemical similarity of the two disorders has led to the hypothesis that the secreted protein produced by mesenchymal tumors in OOM is also responsible for the phosphaturia present in patients with the inherited forms of hypophosphatemic rickets, Autosomal Dominant Hypophosphatemic Rickets (ADHR) and X-linked Hypophosphatemic Rickets (XLH). The recent identification of activating mutations of the FGF-23 gene in ADHR has led to speculation that this secreted protein might also play a role in XLH and OOM. Using serial analysis of gene expression (SAGE), we previously demonstrated that FGF-23 was over-expressed in hemangiopericytomas but not sarcomas removed from patients with OOM. Using RT-PCR to analyze total tumor RNA, we now show that FGF-23 is expressed in 7/7 OOM tumors and 0/7 control hemangiopericytomas. Sequence analysis of the FGF-23 cDNA from three OOM tumors did not reveal any mutations in the coding region. To test the ability of FGF-23 to inhibit sodium-dependent phosphate transport, we seeded opossum kidney cells (OK) into 24-well dishes at densities ranging from 2,500/well to 80,000/well. OK cell cultures were incubated for 3 hours with conditioned media from COS-7 cells that had been transfected with empty vector or recombinant vectors expressing V5-tagged wild type FGF-23, FGF-23 R179Q (ADHR mutation), or PTH(1-34). Compared to conditioned medium from COS-7 cells transfected with vector only, medium containing wild type or R179Q FGF-23 inhibited radiolabeled phosphate uptake by 34-78%, which was comparable to that observed with medium containing PTH(1-34). Inhibition of phosphate uptake was inversely proportional to the density of OK cells. The addition of 10 ug/ml heparin sulfate, which binds FGF, abolished the inhibition of phosphate transport. Because increasing pH inhibits phosphate transport by ubiquitous sodium-dependent phosphate transporters but not the proximal tubular type II sodium-dependent phosphate transporter (NaPi-II), we performed the radiolabelled phosphate uptake at pH 9.5. The FGF-23 mediated inhibition was maintained suggesting that FGF-23 inhibits NaPi-II. These findings indicate that FGF-23 can inhibit renal phosphate uptake, and supports a functional role of FGF-23 in acquired and inherited forms of renal phosphate wasting.

Transgenic Mice Expressing Fibroblast Growth Factor 23 (FGF23) Demonstrate Hypophosphatemia With Low Serum 1,25-dihydroxyvitamin D [1,25(OH)2D] and Rickets/Osteomalacia. T. Shimada,*[1] T. Yoneya,*[1] R. Hino,*[1] Y. Takeuchi,[2] S. Fukumoto,[3] T. Yamashita.[1] [1]Pharmaceutical Research Laboratories, KIRIN Brewery CO.,LTD., Takasaki, Japan, [2]Division of Endocrinology, Department of Medicine, University of Tokyo School of Medicine, Tokyo, Japan, [3]Department of Laboratory Medicine, University of Tokyo Branch Hospital, Tokyo, Japan.

We have recently cloned FGF23 as a causative factor of tumor-induced rickets/osteomalacia (TIO). Administration of recombinant human FGF23 reduced serum phosphate and 1,25(OH)2D in mice. Furthermore, nude mice implanted with CHO cells stably expressing human FGF23 showed bone abnormalities resembling rickets/osteomalacia (T. Shimada et al, PNAS in press). In the present study, biochemical and histological features of transgenic mice expressing human FGF23 were analyzed to clarify the developmental and biological effects of FGF23 and the mechanism of hypophosphatemia by FGF23. Human FGF23 cDNA driven by CAG promoter was injected into 233 fertilized eggs and they were impregnated into 9 BDF1 mice. Thirteen genetically positive mice were obtained in 61 born mice. Before weaning, 3 transgenic mice died from unknown reasons. At 8 weeks old, most transgenic mice demonstrated retarded growth with curving backbones (body weight 17.9+/-1.4 vs 24.4+/-1.2 g, $p<0.005$). Serum phosphate and 1,25(OH)2D levels of transgenic mice were significantly reduced compared to those of FGF23-negative littermates (phosphate 3.41+/-0.45 vs 7.49+/-0.26 mg/dL, $p<0.0001$, 1,25(OH)2D 29.8 vs 103.3 pg/mL). Immunohistochemistry for renal Npt2, which is believed to be a responsible transporter for physiological phosphate reabsorption, indicated that expression levels were decreased in transgenic mice. However, serum PTH levels of transgenic mice were not different from those of control mice. Histological analysis of sternum and femur showed marked increase of osteoid and widening of growth plate. Thus, overexpression of FGF23 during fetal life does not result in lethality. It is shown that FGF23 induces hypophosphatemia by reducing expression of Npt2 without changing PTH levels. In addition, it is confirmed that FGF23 induces pathophysiological changes similar to those of TIO. Therefore, FGF23 seems to play a key role in maintaining phosphate homeostasis in mammals.

Trabecular Bone from Two Strains of Mice is Differentially Mechanosensitive at the Tissue and Molecular Level. S. Judex,[1] M. Hadjiargyrou,[1] L. Donahue,[2] C. Rubin.[1] [1]Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA.

The identification of molecular mechanisms underlying mechanically stimulated bone formation and disuse related bone loss will be critical for the discovery of novel drug targets and effective physical interventions. Here, we subjected two distinct strains of mice to hindlimb suspension and extremely low level but high frequency mechanical stimulation (<10 microstrain) and cross-compared changes in trabecular bone formation rates (BFR) as well as altered transcription levels of two candidate genes. Female 16wk old Balb/cByJ and C57BL/6J mice were assigned to control, mechanically stimulated, and disuse groups (n=13 each). Mice in the mechanically stimulated group were placed on a vibrating plate (45 Hz, 0.25g) for 10 min/d. Disuse animals were subjected to tail suspension. Four animals per group were culled 4d into the protocol for determining gene expression levels (semi-quantitative RT-PCR) while the remaining animals were sacrificed after 21d for the assessment of bone formation rates (BFR). In Balb/c mice, hindlimb suspension caused a 52% decrease in trabecular BFR of the proximal tibia while low level mechanical stimulation increased BFR by 30%. In contrast, trabecular bone of C57BL/6 mice was unresponsive to both mechanical stimulation and disuse. After 4d of disuse, tibial type I collagen mRNA expression was significantly reduced by 35% in Balb/c mice but not in C57BL/6 mice. Inducible nitric oxide synthase (iNOS) transcription levels were significantly lower (25%) in mechanically stimulated mice of both strains than in controls. These data demonstrate that trabecular bone from Balb/c and C57BL/6 mice is differentially mechanosensi-

tive. While both the histomorphometric and molecular data are intriguing, together they reveal a great limitation when correlating gene expression levels with mechanically related bone formation without an appropriate negative control model. For example, iNOS was significantly down-regulated by mechanical vibration in both strains, yet only one mouse strain responded to the mechanical stimulus with new bone formation, suggesting a limited role of iNOS in mechanically mediated bone formation at the time point considered. This opportunity of eliminating candidate genes by cross-comparing a mechanically sensitive to a mechanically unresponsive (at the tissue level) strain will be particularly critical in future studies in which large numbers of candidate genes are considered (i.e., microarrays). Furthermore, the differential tissue level response can be exploited for searching for the genomic basis of bone's mechanosensitivity (e.g., quantitative trait loci).

Low Bone Mass, Low Body Weight and Abnormal Eye Vascularization in Mice Deficient in Lrp5, the Gene Mutated in Human Osteoporosis Pseudoglioma Syndrome (OPS). R. Levasseur,*[1] M. Kato,[2] M. S. Patel,[1] L. Chan,*[2] G. Karsenty.[1] [1]Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, [2]Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX, USA.

Bone formation by osteoblasts balanced by bone resorption by osteoclasts maintains normal bone mass. Little is known about extra to intracellular signal transduction pathway(s) favoring bone formation. Here we show that low density lipoprotein receptor-related protein-5 (Lrp5), a homolog of Drosophila Arrow and a putative Wnt coreceptor, regulates bone formation. Lrp5-deficient mice develop an osteoporosis resulting from decreased osteoblast proliferation and function. Skeletal preparation analyses and histomorphometric studies revealed that Lrp5-deficient mice have a delay of osteogenesis already at birth and a decrease in bone formation that worsen over time. In addition Lrp5-deficient mice have a persistence of embryonic vascularisation of the eye, a feature observed in osteoporosis-pseudoglioma patients (OPS). *LRP5* is the gene mutated in OPS patients. Statins completely correct the bone loss of mutant mice indicating that they could be used to treat human patients. Additionally, Lrp5-deficient mice are abnormally lean, confirming the existence of a coregulation of bone mass and body weight. We suggest that unidentified Wnt protein(s), acting postnatally, regulate(s) bone formation, body weight and eye vascularization.

X-linked Recessive Hypoparathyroidism Is Caused by a Molecular Deletional-insertion Involving Chromosomes Xq27 and 2p25. M. R. Bowl,[1] M. A. Nesbit,*[1] B. Harding,*[1] E. Levy,*[2] D. Schlessinger,*[3] M. P. Whyte,[4] R. V. Thakker.[1] [1]Nuffield Department of Clinical Medicine, Oxford University, Oxford, United Kingdom, [2]Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, [3]National Institutes of Health and Ageing, Baltimore, MD, USA, [4]Center for Metabolic Research, Shriners Hospitals for Children, St Louis, MO, USA.

X-linked recessive hypoparathyroidism (XLHPT), which is due to isolated congenital absence of the parathyroids, has been reported in two families from Missouri, USA, and mitochondrial DNA studies have established that these kindreds are related. Affected individuals, who are males, suffer from potentially lethal epilepsy due to hypocalcaemia during infancy, whilst the females are healthy and normocalcaemic. Genetic mapping studies have located XLHPT to chromosome Xq27 and defined a 1.5 million base pair (Mbp) region flanked centromerically by Factor IX and telomerically by DXS984. DNA sequence analysis of 4 candidate genes (proto-dbl, AS6, U7snRNA and SOX3) did not reveal abnormalities, and the occurrence of deletions of this entire critical region in some haemophilia B patients who do not have XLHPT, indicated that other mechanisms may cause XLHPT. We therefore embarked on characterising this region further, in 6 affected males, by combined analysis of single nucleotide polymorphisms (SNPs) and sequence tagged sites (STSs). This approach identified a centromeric recombinant that reduced the interval containing XLHPT to 1.3 Mbp, and revealed a telomeric molecular deletion of <30 Kbp. However, this deletion did not contain any genes, and further characterisation using DNA fibre-fluorescence in situ hybridisation (FISH) and pulsed field gel electrophoresis revealed that the abnormality also contained an insertion that was >75kb. Analysis of 48 members (6 affected males, 18 carrier females, and 24 unaffected members) established co-segregation of this deletional-insertion with XLHPT, with a peak LOD score >+5 at 0% recombination. The combined use of a flow-sorted X chromosome specific library generated from an affected male, a modified Vectorette PCR protocol, and DNA sequence analysis enabled the centromeric and telomeric breakpoints of this deletional-insertion to be characterised. The additional use of a mono-chromosomal somatic cell hybrid DNA panel, and FISH using metaphase spreads of chromosomes revealed that the insertion originates from chromosome 2p25. Thus, XLHPT is caused by a molecular deletional-insertion involving chromosomes Xq27 and 2p25. These results, which identify a novel genetic abnormality causing hypoparathyroidism, will help to advance our understanding of the molecular basis of parathyroid development.

A Large-Scale Whole-Genome Linkage Scan Identifies Several Genomic Regions with QTLs Underlying Bone Size Variation. H. Shen,*[1] F. H. Xu,*[1] H. T. Zhang,*[1] H. Y. Deng,*[2] T. Conway,[2] Q. H. Xia,*[1] J. Chen,*[1] Y. Z. Liu,*[1] Y. J. Liu,*[1] Q. Y. Huang,*[1] K. M. Davies,[1] R. R. Recker,[1] H. W. Deng.[1] [1]Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA, [2]Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Bone size is an important determinant of osteoporotic fractures. Using a whole-genome linkage scan, we have set out to identify genomic regions that may contain QTLs underlying variation in bone area (DXA). For a sample of pedigrees that includes 1,249 sib pairs, 1,098 grandparent-grandchildren pairs and 1,172 first cousin pairs, we performed a whole-genome scan using 400 microsatellite markers (with an average heterozygosity of ~0.75 and spaced ~10cM apart throughout the whole genome) from the ABI PRISMTM Linkage Mapping Set Version 2 (Applied Biosystems, Foster City, CA). For chromosomes 9-22 and chromosome X, the genotyping has been completed with a rate of missing and error data (determined by sample replication and pedigree consistency check) of ~0.3%. For chromosomes 1-8, the genotyping finished with one round of repeat experiments yielding a rate of ~3% for missing and error genotype data. Further rounds of repeat experiments are being performed to reduce the missing and error data rate from the current 3.0% to ~0.3% for chromosomes 1-8. Adjusting for age, sex, weight and other significant co-varieties, we conducted two- and multi-point linkage analyses to identify genomic regions that may contain QTLs underlying bone size variation. Several genomic regions were identified. For example, the genomic region near the marker D17S787 on chromosome 17 may contain a QTL for wrist (ultra distal) bone size variation (with a two-point analysis LOD score of 3.98 and a multi-point analysis LOD score of 3.00). The genomic region near the marker D11S4046 on chromosome 11 may contain a QTL for spine bone size variation (with two-point analysis LOD score of 2.78). The genomic region identified on chromosome 17 for wrist bone size seems to be consistent with that identified for the region identified for femur head width (Koller et al. 2000, JBMR 15 (supplement), 1094). Our results are compared with one earlier study and discussed.

The Naturally Occurring Autosomal Dominant Hypophosphatemic Rickets (ADHR) Mutations Stabilize Full-Length FGF-23. K. E. White,[1] G. Carn,*[1] B. Lorenz-Depiereux,*[2] T. Meitinger,*[2] T. M. Strom,*[2] M. J. Econs.[1] [1]Indiana University School of Medicine, Indianapolis, IN, USA, [2]Institut fuer Humangenetik, Neuherberg, Germany.

We identified the gene for the phosphate wasting disorder ADHR as FGF23, a secreted protein related to the fibroblast growth factors (FGFs). In previous studies, missense mutations R176Q, R179W, and R179Q were detected in FGF23 from ADHR kindreds, however the relationships between the mutations and the etiology of ADHR are unknown. The amino acid substitutions replace critical R residues within the possible FGF-23 subtilisin-like proprotein convertase (SPC) cleavage site 176RHTR179 (RXXR motif), therefore our goal was to determine if the mutations lead to FGF-23 protease resistance. The mutations were introduced separately into the human FGF-23 cDNA and were transiently transfected into HEK293 cells. Western blots of conditioned media using an antibody directed downstream of the SPC site revealed that native FGF-23 protein resolved as two species, a full-length 32 kD band and a 12 kD band. In contrast, the mutants appeared only as the intact, full-length 32 kD species. To test for the presence of an upstream cleavage fragment, an N-terminal FLAG-FGF-23 and FLAG-R176Q were transfected into HEK293 cells and the media analyzed with an anti-FLAG antibody. The native FLAG-FGF-23 was again detected as two species, the full-length 36 kD (32 kD plus the FLAG tag) protein and a pronounced 26 kD cleavage fragment. FLAG-R176Q resolved essentially as the full-length species, with only a faint band at 26 kD, indicating that the mutants are resistant to proteolysis. To determine the cellular localization of cleavage, native FGF-23 conditioned media was applied to HEK293 cells. There was no difference in the relative levels of the 32 and 12 kD bands after 24 h, supporting the idea that FGF-23 can be processed before or during secretion by HEK cells. FGF-23 and mutant conditioned media were also incubated with heparin sepharose to compare their relative heparin binding abilities. The full-length native and mutant proteins bound heparin equally, indicating that gross loss of FGF-23 integrity due to the mutations does not occur. In summary, we demonstrated that R176Q-, R179W-, and R179Q-FGF-23 could be produced by mammalian cells at levels similar to wild type FGF-23. These mutations, however, create analogs far less sensitive to proteases than native FGF-23. Thus, the naturally occurring ADHR missense mutations protect FGF-23 from proteolysis, thereby potentially elevating circulating concentrations of FGF-23 in ADHR patients, which leads to phosphate wasting.

Paget's Disease of Bone: Mapping of Two Loci at 5q35-tel and 5q31 and Genetic Heterogeneity. N. Laurin,*[1] J. P. Brown,[2] A. Lemainque,*[3] A. Duchesne,*[1] D. Huot,*[4] Y. Lacourcière,*[5] G. Drapeau,*[6] J. Verreault,*[7] V. Raymond,*[1] J. Morissette.*[1] [1]Centre de recherche en endocrinologie moléculaire et oncologique, CHUL Research Center, Ste-Foy, PQ, Canada, [2]Rheumatology - Immunology, CHUL Research Center, Ste-Foy, PQ, Canada, [3]Centre national de génotypage, (CNG), Evry, France, [4]Centre hospitalier de la région de l'Amiante, Thetford Mines, PQ, Canada, [5]CHUL Research Center, Ste-Foy, PQ, Canada, [6]Hôtel-Dieu d'Arthabaska, Victoriaville, PQ, Canada, [7]Centre universitaire de santé de l'Estrie, Sherbrooke, PQ, Canada.

Paget's disease of bone is characterized by focal increases of the bone remodeling process. It is the second most common metabolic bone disease after osteoporosis. Genetic factors play a major role in the aetiology of Paget's disease of bone and two loci have been mapped for the disorder: PDB1 at 6p and PDB2 at 18q21-q22. The gene(s) causing the typical form of the disorder still remain to be characterized. To decipher the molecular basis of Paget's disease of bone, we performed genetic linkage analysis in 24 large French-Canadian families (479 individuals) in which the disorder was segregating as an autosomal dominant trait. After excluding PDB2, a genome-wide scan with 379 microsatellite markers was performed on the three most informative family nuclei. Regions with LOD score values between 1.0 and 3.0 were assessed by higher-density mapping and haplotype analysis in the extended families. Genetic heterogeneity was investigated using the HOMOG program. We report strong evidence for linkage at chromosome 5q35-tel in eight of the kindreds. Significant evidence for heterogeneity was observed at D5S408 (c2=3.86; p<0.05). Under heterogeneity, the maximum LOD score value of 8.71 was obtained at D5S2073. The same characteristic haplotype was shown by all pagetic patients in these eight families, suggesting a founder effect. Recombination event in a key family confined the disease region to a 6 cM interval between D5S469 and the telomere. The 16 other fam-

ilies, with very low conditional probability of linkage at 5q35-tel, were further used to map a second locus at 5q31. Under heterogeneity, a maximum LOD score value of 3.70 was detected at D5S500 with q=0.00 (c2=10.13; p<0.0002). Key recombination events in the two families refined the 5q31 disease region to a 11.2 cM interval between D5S642 and D5S1972. Finally, two other kindred were excluded from both the 5q35-tel and 5q31 loci. These observations demonstrate the mapping of two novel loci for Paget's disease of bone and provide further evidence for the genetic heterogeneity of this disorder.

1066

Assessing the Genetic Determinants of Vertebral Trabecular Bone Density and Microarchitecture in Mice. M. L. Bouxsein,[1] R. Mueller,[2] T. Uchiyama,*[2] J. Mytar,*[3] C. H. Turner,[4] L. R. Donahue,[3] C. J. Rosen,[3] W. G. Beamer.[3] [1]Orthopedic Biomechanics, Beth Israel Deaconess Med Center, Boston, MA, USA, [2]Beth Israel Deaconess Med Center, Boston, MA, USA, [3]Jackson Laboratory, Bar Harbor, ME, USA, [4]Indiana University Medical School, Indianapolis, IN, USA.

Genetic factors have been shown to play an important role in the regulation of bone mineral density (BMD). Yet, in addition to BMD, other traits that affect bone strength, such as trabecular architecture, may be genetically regulated. To identify heritable determinants of vertebral trabecular architecture, we evaluated adult female mice from the F2 intercross of C57BL/6J (B6) and C3H/HeJ (C3H) progenitor strains. Micro-computed tomography (μCT, 17 μm resolution) was used to assess trabecular bone volume fraction (BV/TV), thickness (Tb.Th), separation (Tb.Sp), and number (Tb.N) in the 5th lumbar vertebral body of the progenitors (n = 8/strain) and B6C3H-F2 progeny (n=914). B6 mice had greater vertebral trabecular BV/TV (+114%), Tb.N (+68%), and lower Tb.Sp (-42%) compared to C3H (p<0.001 for all). F2 progeny were genotyped for all autosomes using PCR and regression analysis used to find quantitative trait loci (QTL) contributing to the vertebral trabecular bone traits. Whole genome scans revealed that 6 to 10 QTL's associated with each trait. LOD scores ranged from 3.2 to 14.4. QTL's on Chr 4 and 8 were common for all the vertebral trabecular traits. BV/TV, Tb.N, and Tb.Sp also shared common QTL's on Chr 1, 9, 12, and 13. For BV/TV, the LOD scores, variance explained in the F2 population by the major QTL's, and allele effects are shown in the Table. Note that C3H alleles, which have previously been associated with high cortical bone mass, had both positive (Chr 1, 4) and negative (Chr 6, 8, 9, 12, and 13) effects on trabecular BV/TV. Several of the QTL's identified here were previously identified as major regulators of vertebral BMD (Chr 1, 4, 6, 9, and 13). However, two of them (Chr 8 and 12) appear to be unique to vertebral trabecular architecture, and two (Chr 8 and 9) appear to influence vertebral architecture independently of femoral BMD. In summary, we identified several genetic determinants of vertebral trabecular bone density and architecture in mice, and showed that C3H alleles contribute both positively and negatively to trabecular bone density. LOD score,% variance, and allele effects (mean ± SD) for the major QTL's for BV/TV (%) .

	Chr 1	Chr 4	Chr 8	Chr 9	Chr 12
LOD	5.2	10.7	10	9.8	12.5
Variance (%)	3.5	5.5	4.5	6.3	6
B6/B6	21.0 ± 0.4	20.4 ± 0.4	23.7 ± 0.4	24.1 ± 0.5	24.6 ± 0.4
B6/C3H	22.2 ± 0.3[b]	22.5 ± 0.3[b]	22.4 ± 0.3 [b]	22.2 ± 0.4 [b]	22.2 ± 0.3 [b]
C3H/C3H	24.1 ± 0.4 [a, c]	24.8 ± 0.5 [a,c]	21.3 ± 0.4 [a,c]	20.3 ± 0.6 [a,c]	20.7 ± 0.4 [a,c]

a: C3H/C3H vs B6/B6; b: B6/C3H vs B6/B6; c: C3H/C3H vs B6/C3H (p<0.05)

Secreted Frizzled-related Protein (sFRP-1) Binds to RANKL to Inhibit Osteoclast Formation. K. D. Hausler,*[1] N. J. Horwood,[1] A. Uren,*[2] J. Ellis,*[2] C. Lengel,*[2] T. J. Martin,[1] J. S. Rubin,*[2] M. T. Gillespie.[1] [1]St. Vincent's Institute of Medical Research, Melbourne, Australia, [2]National Cancer Institute, NIH, Bethesda, MD, USA.

sFRP-1 is a secreted member of the Frizzled (Fz) family of proteins that binds to wnt proteins to modulate their activity. Wnt signaling is crucial in the processes of organogenesis and limb development, and the development of colorectal cancer.After isolating cDNA for sFRP-1 during mRNA analysis of osteoblastic stromal cells, we noted that sFRP-1 was differentially expressed in osteoblastic cell lines and was elevated in those capable of supporting osteoclast formation. Furthermore, in situ hybridization studies showed that sFRP-1 mRNA was expressed in osteoblasts and chondrocytes in murine bone. We therefore investigated the possibility that sFRP-1 might influence osteoclast formation.Neutralizing antibodies against sFRP-1 enhanced TRAP positive mononuclear and multinuclear osteoclast formation (3 and 2-fold, respectively) in cocultures of murine osteoblasts with spleen cells treated with PGE2 (10-7M) and 1,25 (OH)2 vitamin D3 (10-8M). This effect was more pronounced (10 and 7-fold) under conditions of submaximal osteoclast formation. Recombinant sFRP-1 was able to dose dependently inhibit osteoclast formation in either osteoblast / spleen cocultures, RANKL+M-CSF-treated splenic cultures or in RANKL-treated RAW264.7 cell cultures, indicating a direct action of sFRP-1 upon hematopoietic cells. Although RAW264.7 cells expressed sFRP-1, its production was lower than that of T cells and this, along with other data, suggests that sFRP-1 derived from T cells or tonically expressed by stromal osteoblasts exerts inhibitory control upon osteoclast formation. Consistent with the likely lack of a dynamic controlling function from the osteoblastic source is the fact that sFRP-1 mRNA expression was only marginally enhanced by dexamethasone or IL-11 (2-fold by 2 and 8hr, respectively), whilst many other osteotropic agents (eg., IL-1, IL-6, calcitrol, PTH) were without any effect.sFRP-1 is thought to act as a decoy receptor binding to wnts and thus regulating the interaction of wnts with their transmembrane Fz signaling receptors. However, another mechanism appears to account for the ability of sFRP-1 to inhibit osteoclast formation. Screening of a peptide phage display library revealed a sFRP-1 binding motif that corresponds to a sequence present in RANKL. Subsequent experiments demonstrated that recombinant RANKL bound specifically to sFRP-1 in an ELISA format. This finding raises the possibility that sFRP-1 limits osteoclast formation by binding directly to RANKL, and suggests that sFRP-1 may act as a decoy receptor mimicking OPG activity.

1068

Deletion of the Genes Encoding c-Cbl or Cbl-b Alter the Ability of Osteoclasts to Migrate During Development, Delaying Resorption and Ossification of Cartilage in Long Bones. R. Chiusaroli,[1] J. Juel,*[1] L. Neff,[1] A. Sanjay,[1] M. Naramura,[2] H. Gu,[2] W. C. Horne,[1] R. Baron.[1] [1]Yale University, New Haven, CT, USA, [2]NIH, Bethesda, MD, USA.

Osteoclast (OC) recruitment and migration through the perichondrium and the bone collar is required for the vascular invasion of the cartilaginous anlage and the formation of the primary and secondary centers of ossification. We have previously shown that c-Cbl lies downstream of the vitronectin receptor and forms a complex with c-Src and Pyk2 in a signalling pathway that regulates cell adhesion and motility. Furthermore, OCs that lack either c-Src or c-Cbl display decreased migration in vitro. Since migration is essential in order for OC precursors to reach the bone collar and for newly formed OCs to penetrate the hypertrophic cartilage during long bone development, we analyzed these events in c-Cbl and Cbl-b knockout mice to determine whether the decreased motility we observed in vitro translated into decreased cell migration in vivo. Analysis of metatarsals at E18 showed that the initiation of vascularization and replacement of cartilage by bone are delayed in c-Cbl -/- mice. This delay is apparently due to the decreased ability of osteoclasts to invade the hypertrophic cartilage through the bone collar. Metatarsals from c-Cbl +/- and c-Cbl -/- E18 mouse embryos were analyzed to determine the numbers of large TRAP+ cells localized both outside the bone collar and inside, in contact with and resorbing the hypertrophic cartilage. In c-Cbl +/- metatarsals, the numbers of TRAP+ cells/total area (mm^2) were 11.4 ± 0.7 and 22.4 ± 10.1 outside and inside the bone collar, respectively, whereas in c-Cbl -/- metatarsals the numbers of TRAP+ cells/total area were 24.5 ± 7.7 outside and only 6.2 ± 5.8 inside the bone collar (p<0.05 vs. c-Cbl +/- for both outer and inner TRAP+ cells). The total number of large TRAP+ cells was not changed (33.8 ± 10.5 vs. 30.7 ± 5.1, p = n.s.). Furthermore, at day P10 both c-Cbl -/- and Cbl-b -/- mice display a delay in the formation of the secondary center of ossification in the tibia proximal epiphysis, which is also dependent on osteoclast invasion of the mineralized cartilage. Detailed histomorphometric analysis of adult c-Cbl -/- mice failed to demonstrate any significant changes in bone volume or in bone resorption parameters, except that the hypertrophic zone of the growth plate was thicker in c-Cbl -/- 18 day old mice (119.8 ± 17.7 vs. 90.8 ± 14.8 μm, p<0.05), also suggesting a slowing down of osteoclast resorption of the calcified cartilage. Thus, the observed decrease in the in vitro motility of the c-Cbl-/- osteoclasts may result in a decreased ability of osteoclasts to invade and resorb the mineralized cartilage in the bone primordium and the growth plate.

***c-myc* Is Required for Osteoclastogenesis.** R. Battaglino,*[1] D. Kim,*[2] P. Stashenko.*[1] [1]Cytokine Biology, The Forsyth Institute, Boston, MA, USA, [2]Harvard School of Dental Medicine, Boston, MA, USA.

RANKL (receptor activator of NF-kB ligand), a TNFα-related cytokine, is essential for osteoclast formation. RANKL is secreted by osteoblasts in response to specific signals and binds to its receptor, RANK, expressed in osteoclast precursors. Even though the role of RANKL in osteoclastogenesis has been established, the activated downstream signaling pathways remain largely unknown. In order to identify genes that play a role in osteoclastogenesis we developed and characterized a model that reproduces *in vitro* the differentiation of multinucleated osteoclasts from mononucleated precursors. RAW 264.7 mouse monocytes were induced to differentiate into osteoclast-like cells (OCL), after culturing them for four days in medium supplemented with RANKL. Morphologically, OCL were TRAP positive multinucleated giant cells. Northern Blot analysis showed that OCL differentially expressed a number of markers for osteoclast differentiation, among them: *trap* , *gelatinase B* , *cathepsin K* , *atp6i* , the 116KDa subunit of an osteoclastic proton pump and the protooncogene *c-src*. OCL were also able to form resorption pits on sub-micron calcium phosphate films. Conversely, only undifferentiated RAW 264.7 cells expressed *CD-14* , a macrophage surface marker. Using gene arrays we found that the protooncogene *c-myc* was strongly up regulated in RANKL-induced OCL, but was absent in undifferentiated cells. Northern blot analysis showed *c-myc* mRNA expression as early as one hour after RANKL stimulation. *c-myc* expression declined after four days of stimulation. NF-kB activation, a step required for osteoclast differentiation, follows RANKL stimulation. TPCK, an inhibitor of RANKL-induced NF-kB activation, was able to block *c-myc* expression, suggesting that RANKL-induced *c-myc* upregulation required NF-kB activation. Expression of c-Myc partners, Max and Mad, was constant during OCL differentiation, suggesting that the c-Myc-Max-Mad system is primarily regulated at the level of c-myc transcription. The expression of *c-myc* in response to RANKL stimulation, suggested a role for *c-myc* in OCL formation. To test that hypothesis, we generated RAW 264.7 cell lines stably transfected with an expression vector carrying a dominant negative version of c-Myc. Our results showed that a cell line that expressed high levels of the dominant negative message was unable to fully differentiate into OCL upon RANKL stimulation. Furthermore, Northern Blot analysis revealed a delay and a significant reduction in the level of mRNA for TRAP and Cathepsin K. We conclude that RANKL-induced *c-myc* expression requires NF-kB activation and is required for osteoclastogenesis.

1070

Upregulation of α2β1 Integrin in β3 Null Type Glanzmann Thrombasthenia Enables Bone Resorption. M. A. Horton,[1] U. Seligsohn,*[2] H. M. Massey,*[3] A. M. Flanagan.[3] [1]Medicine, University College London, London, United Kingdom, [2]Chaim Sheba Medical Center, Tel-Hashomer, Israel, [3]Histopathology, University College London, London, United Kingdom.

A large body of evidence supports a central role for αvβ3 in the development, activation and function of osteoclasts (OCs); inhibition of αvβ3 results in reduced bone resorption in vitro and in various animal models of osteoporosis. The development of integrin antagonist drugs for bone disease has stressed the need to elucidate the impact of chronic inhibition/lack of αvβ3 integrin (vitronectin receptor) upon OC function. Most patients with Glanzmann Thrombasthenia (GT) of Iraqi-Jewish origin have complete absence of the integrin β3 chain due to an 11bp deletion in exon 12 of the β3 (CD61/GPIIIa) gene. This results in defective platelet function and a haemorrhagic diathesis, the clinical hallmark of GT, due to lack of the platelet fibrinogen receptor, αIIbβ3 integrin. We examined the impact of the absence of β3, and hence of αvβ3, in OCs generated by in vitro culture of peripheral blood monocytes (PBM) from patients with GT. These were cultured on bone slices in the presence of 30ng/ml RANKL and 25ng/ml M-CSF for up to 14d and examined by confocal microscopy for expression of OC integrins (αv, αvβ3, α2, β1) and macrophage proteins and other integrins (β5, α3, α5; CD11b, 14, 44, 68). Bone resorption was assessed by reflection and scanning electron (SEM) microscopy. 5 patients with β3 null GT were compared with 2 cases of αIIb deficient GT and 3 normal controls. Phenotypically and functionally normal OCs were generated from normal and αIIb deficient GT; both expressed similar levels of αvβ3. In contrast, OCs derived from β3 null GT PBMs failed to express αvβ3 (<1% control levels); the normally low level of αvβ5 in OCs was not increased; quantification of α2 and β1 levels showed significant 2.4 - 4.3-fold increases ($p<0.01$) in expression. β3 null osteoclasts resorbed less bone (44% and 59% decreases in pit number and depth, respectively, $p<0.001$). Examination of resorption lacunae by SEM showed shallower pits with less defined edges when compared with normal controls; the balance between removal of collagen and mineral, though, appeared grossly similar. The OC phenotype caused by the β3 null mutation in humans is thus similar to that of the β3 knockout mouse. We conclude that chronic deficiency of αvβ3 in human OCs is accompanied by a compensatory rise in α2β1 expression. This is sufficient to enable bone resorption to proceed, albeit to a sub-maximal extent, explaining why affected individuals do not present with osteopetrosis.

1071

Granzyme A Stimulates Osteoclast Formation by Inducing TNF-α Production. C. Menaa,[1] J. Lieberman,[2] S. M. Sprague.[3] [1]Evanston Hospital, Evanston, IL, USA, [2]Harvard Medical School, Boston, MA, USA, [3]Northwestern University Medical School, Evanston, IL, USA.

T cells play a major role in rheumatoid arthritis (RA) and postmenopausal osteoporosis (PO). T cell-secreted products have been shown to affect bone remodeling through their ability to regulate osteoclast (OC) activity. Granzyme A (GrA), a serine proteinase which induces apoptosis, is secreted from activated T cytotoxic and natural killer cells. Evidence suggesting that GrA plays a role in the development of RA includes the following: 1) GrA expression and concentration are elevated in serum and synovial fluid of patients with RA; 2) GrA can activate thrombin receptor, a pathway reported to regulate OC formation and/or activation; and 3) GrA induces matrix dissolution and inflammatory cytokine production (i.e. IL-6, TNF-α and IL-8). TNF-α and IL-6 are responsible, in part, for bone loss in PO and RA. The role of GrA in bone remodeling has not been elucidated. Therefore, the effect of GrA on OC formation was determined. Treatment of mouse bone marrow cells with recombinant GrA induced multinucleated cells which satisfied the major criteria of OC, including, TRAP activity, expression of β-integrin and calcitonin receptor, and the ability to form resorption pits on dentine slices. This effect was dose dependent (0.01 to 7 μg/ml) and independent of RANK/RANKL signaling pathway, as osteoprotegerin, at a dose sufficient to block the effect of 10 ng/ml of RANKL, was unable to abrogate OC formation. To determine whether this effect required accessory cells, highly purified OC precursors (CFU-GM or RAW 264.7) were incubated with GrA. GrA stimulated OC formation without osteoblast/stromal cells demonstrating a direct effect. The formation of OC appeared to be mediated by TNF-α, as the stimulatory effect of GrA on OC formation was inhibited by neutralizing antibody to TNF-α. Furthermore, GrA induced TNF-α expression by osteoclast precursors suggesting an autocrine/paracrine effect. To further examine the role of GrA activity, including whether the effect is thrombin receptor mediated, Raw cells were stimulated with human thrombin and with inactive GrA (mutation of the active site serine to alanine). Thrombin (10 U/ml) was unable to induce OC formation and the osteoclastogenesis effect of GrA was not related to the enzyme activity. In conclusion, these data demonstrate that GrA is a potent osteoclastogenesis factor. Its effect is not related to the enzyme activity, is RANK/RANKL independent and requires the induction of TNF-α production by osteoclast precursors, which induces these precursors to differentiate into mature osteoclasts via a paracrine/autocrine fashion. These data suggest that GrA plays a crucial role in the development of bone destruction in RA.

1072

The HIV Protease Inhibitor Ritonavir Inhibits Osteoclast Differentiation and Function, in Vitro and in Vivo, Via the NF-κB and AKT Pathways. M. W. H. Wang, R. Faccio,* S. L. Teitelbaum, F. P. Ross. Pathology, Washington University, St. Louis, MO, USA.

We find that HIV infected patients treated with protease inhibitors (PIs) have diminished bone mineral density t ($p=0.02$) and Z ($p=0.04$) scores relative to similarly-infected individuals not receiving these drugs. Because accelerated resorptive activity may contribute to systemic bone loss, we studied the effects of two commonly used PIs, Ritonavir and Indinavir, on osteoclast (OC) differentiation and function, in vitro and in vivo. We find that neither PI enhances OC number in cultures consisting of OC precursors, in the form of bone marrow macrophages, cultured with RANKL and M-CSF. Surprisingly, however, Ritonavir, but not Indinavir which blocks bone formation (this meeting), virtually eliminates osteoclastogenesis in these cultures. The 50% inhibitory dose of Ritonavir occurs at a pharmacologically relevant concentration of 10μg/mL. The effect of the drug is not due to toxicity, as its removal from culture completely normalizes osteoclast formation. To determine if Ritonavir impacts OC function, as well as differentiation, the drug was added to cultures of mature OCs maintained on dentin slices. In this circumstance, OC actin ring formation is disrupted and dentin resorption arrested, even though OC number is unchanged. Confirming that Ritonavir is bone sparing, the drug, systemically administered, completely blunts PTH-induced osteoclastogenesis in mice. We next asked if Ritonavir blunts signaling induced by the key osteoclastogenic cytokine RANKL, which stimulates the MAPK, NF-κB, and Akt pathways. Ritonavir has no effect on RANKL-induced activation of the p38, SAPK/JNK, or ERK1/2 components of the MAPK pathway. While serine phosphorylation of IκBα remains intact, the protein is not degraded in the presence of the drug, suggesting the inhibitory effect is at the level of a ubiquitin ligase or the proteosome. Consistent with a lack of cytoplasmic IκBα degradation in cells treated with Ritonavir, the drug decreases nuclear translocation of NFκB, as measured by EMSA. Ritonavir also suppresses the third osteoclastogenic signaling pathway, Akt activation, as measured by its phosphorylation at threonine 308, with a resultant failure to phosphorylate an Akt substrate, Forkhead. This event is RANKL specific, as Ritonavir does not block M-CSF induced Akt activation. Thus, Ritonavir arrests osteoclastogenesis by blocking RANKL induction of the NF-κB and Akt pathways. Because it is specifically bone sparing, Ritonavir presents itself as a promising choice to prevent PI-induced osteopenia in HIV infected patients.

1073

Relative Contributions of Bone Density, Bone Turnover and Clinical Risk Factors to Long-Term Fracture Prediction. L. J. Melton III,[1] C. S. Crowson,*[1] W. M. O'Fallon,*[1] M. K. O'Connor,*[2] B. L. Riggs.[3] [1]Health Sciences Research, Mayo Clinic, Rochester, MN, USA, [2]Radiology, Mayo Clinic, Rochester, MN, USA, [3]Endocrinology, Mayo Clinic, Rochester, MN, USA.

The long-term predictability of osteoporotic fractures using bone mineral density (BMD) remains controversial, as does the additional contribution from assessing bone turnover or clinical risk factors. Although theoretical analyses suggest that fracture predictability degrades rapidly with time, no population-based prospective data on hip or spine BMD extend beyond a decade. We assessed bone density at various sites (including proximal femur and lumbar spine) on an age-stratified sample of 304 Rochester, MN women in 1980. We also made baseline measurements with biochemical markers of bone turnover and assessed over 150 clinical variables exclusive of laboratory data. Multiple fractures per subject were accounted for using the Anderson-Gill model, an adaptation of the Cox proportional hazards model. The 225 women who were postmenopausal at baseline were followed subsequently for 2982 person-years (median, 16 years per subject; range 54 days to 19 years) during which time they experienced 289 new fractures; 56% involved the proximal femur, thoracic or lumbar vertebrae or distal forearm, and 80% resulted from only minimal to moderate trauma. Moderate trauma fractures in aggregate were best predicted by baseline femoral neck BMD (age-adjusted relative hazard [RH] per 1 SD decrease, 1.41; 95% CI, 1.17-1.69), while forearm fractures due to moderate trauma (n = 18) were best predicted by distal radius BMD, hip fractures (n = 27) and vertebral fractures (n = 95) by femoral neck BMD and other fractures (n = 92) by midradius BMD. Compared to the first decade of follow-up (RH, 1.29; 95% CI, 0.99-1.67), femoral neck BMD performed better in predicting overall fracture risk more than 10 years after baseline (RH, 1.58; 95% CI, 1.21-2.05). The biochemical markers available at the time (serum osteocalcin and alkaline phosphatase, urinary hydroxyproline) were not independently predictive of long-term fracture risk, but modern assays were not evaluated. Other than bone density, consistent risk factors for the different fractures were not identified but statistical power was limited. A weighted clinical risk factor score (median, 6; range, 0 to 38.5) predicted fractures in general (RH per unit increase, 1.02; 95% CI, 1.003-1.04) and vertebral fractures specifically in multivariate modeling. The clinical approach to fracture prevention requires knowledge of the patients at greatest risk, but identifying them many years in advance is a challenge. It is reassuring that femoral neck BMD can predict the overall risk of moderate trauma fractures even a decade later.

1074

Natural History of Kyphosis: A Prospective Study of Change in Thoracic Curvature in Men and Women in The Framingham Study. E. J. Samelson,[1] H. N. Rosen,[1] I. D. Iloputaife,*[1] M. T. Hannan,[1] D. T. Felson,[2] D. P. Kiel.[1] [1]Research & Training Inst, Hebrew Rehab Ctr, Boston, MA, USA, [2]Bos Univ Sch Med, Boston, MA, USA.

Kyphosis has been related to aging, vertebral fracture (VF), and height loss, as well as to adverse outcomes, including reduced lung and physical function, pain, and deformity. Little is known about natural history of kyphosis in women and men. The purpose of this study was to describe natural history of kyphosis in a population-based group of older women and men followed for 17 years.Thoracic spine x-rays, obtained in 1975 and repeated in 1992, were available for 275 cohort members of the Framingham Study (193 women, 82 men; mean baseline age, 63 years; range, 50-79). Thoracic vertebrae were classified as normal or fractured using a semiquantitative method. An adjustable triangle was used to measure kyphosis angle (KA) determined by lines drawn from the superior border of T4 and inferior border of T12. Change in kyphosis was calculated by subtracting baseline KA from follow-up KA, such that increase in KA corresponds to increase in kyphosis, and decrease in KA corresponds to decrease in kyphosis. Mean KA at baseline was 39.6º in women and 34.0º in men. Curvature increased an average of 10.9º in women and 6.7º in men. Improvement of >5º in KA occurred in a small number of women (2%) and men (6%). Baseline age did not influence change in KA. Mean change in KA was similar for women with incident VF (12.5º), prevalent VF (10.8º), and without VF (10.6º). Similarly, mean change in KA did not differ between men free of VF (5.6º) and with prevalent VF (7.8º), but KA change was twice as high in men with incident VF (12.0º) than without VF, although the difference did not reach significance ($p=.08$). About ½ the women and ¼ the

men, regardless of VF status, increased KA >10º. When women and men were combined, prevalent VF did not increase risk of increasing KA >20º (OR=1.7; 95% CI=0.6-5.2), although incident VF was associated with >20º increase in KA (OR=3.6; 95% CI=1.4-9.5). The combined influence of both prevalent and incident VF accounted for < 3% of the variance in KA change. Baseline KA did not affect KA change in women (trend, p=.97), but men with low baseline KA had greater increase in KA change (10º vs. 4º for lowest vs. highest quartile of baseline KA; trend, p=.009).This study provides a unique description of change in thoracic curvature for a population-based cohort of elderly women and men followed for nearly two decades. Results indicate increase of >10º in curvature occurs in ½ of older women and ¼ of older men whether or not they have prevalent or incident VF. Moreover, kyphosis is largely determined by factors other than VF. These findings need to be extended to determine clinical implications related to longitudinal change in kyphosis.

1075

Excess Bone Loss Attributable to Hip Fracture. J. Magaziner,[1] W. Hawkes,*[1] K. Stone,*[2] M. Hochberg,*[1] L. E. Wehren,[1] J. R. Hebel,*[1] L. Fredman,*[3] D. Orwig,*[1] S. I. Zimmerman.*[4] [1]University of Maryland Baltimore, Baltimore, MD, USA, [2]University of California, San Francisco, CA, USA, [3]Boston University, Boston, MA, USA, [4]University of North Carolina, Chapel Hill, NC, USA.

Although hip fracture is associated with substantial bone loss in the next year, most women who sustain hip fractures do not receive interventions to improve bone mineral density (BMD). The extent of bone loss that is attributable to the hip fracture itself, beyond losses due to normal aging in the frail elderly, is unknown. To evaluate this, 84 white female hip fracture patients participating in the Baltimore Hip Studies who had BMD measurements of the contralateral hip at time of fracture and 12 months later were matched with 168 control subjects from the Study of Osteoporotic Fractures (SOF). Matching factors included age and total hip BMD. Mean age of the combined sample was 79.0 years; mean BMD was 0.602 gm/cm2. Expected one-year bone loss at the total hip and femoral neck was estimated in the SOF subjects and compared to observed losses in the fracture subjects, controlling for baseline weight and smoking. BMD loss in SOF subjects was 0.6% at the total hip and 0.4% at the femoral neck. In contrast, the observed BMD loss in hip fracture subjects was 3.5% at the total hip and 4.7% at the femoral neck, with adjusted excess loss of 2.9% (95% CI 2.2%, 3.5%) at the total hip and 4.3% (95% CI 3.1%, 5.5%) at the femoral neck. BMD loss in the year after hip fracture was, therefore, 5.4 times the expected amount at the total hip and 12.5 times that expected at the femoral neck. Viewed another way, the 1-year impact of hip fracture on BMD is equivalent to aging 5.4 to 12.5 years. This finding may partially explain the high rate of subsequent hip fracture seen in those who have hip fractures and strongly suggests that interventions should be targeted to increasing BMD.

1076

Weight Loss in Elderly Women Increases the Risk of Hip Fracture Irrespective of Current Weight and Weight Loss Intention. K. E. Ensrud,[1] S. K. Ewing,*[2] K. L. Stone,[2] P. J. Bowman,*[1] T. M. Knudson,*[1] J. A. Cauley,[3] S. R. Cummings.[2] [1]VA Med Center & Univ of MN, Minneapolis, MN, USA, [2]Univ of CA, San Francisco, CA, USA, [3]Univ of Pittsburgh, Pittsburgh, PA, USA.

Weight loss is a strong risk factor for hip fracture (fx) in older women, but the effects of current weight and weight loss intention on this relationship are uncertain. To test the hypothesis that women with recent weight loss are at increased risk of hip fx irrespective of current weight or weight loss intention, we measured weight at baseline and 4th exams (average 5.7 years between exams) in a cohort of 6785 women age ≥65 years at baseline participating in the Study of Osteoporotic Fractures. During this time, 16% of participants gained ≥5% of their baseline weight (weight gain), 55% had <5% change from their baseline weight (stable weight), and 29% lost ≥5% of their baseline weight (weight loss). After an average of 5.6 years of 98% complete follow-up, 259 (4%) women suffered a first hip fx. Proportional hazards models were used to analyze the association between weight change and hip fx; all analyses were adjusted for age, health status, smoking status, medical conditions, prior fx, estrogen use, physical activity, falling, height, and hip BMD. Recent weight loss was a strong risk factor for hip fx. Among both heavier and thinner women, women with weight loss compared with women with stable weight had increased risks of subsequent hip fx (p>0.24 for interaction between weight loss and current weight). Similarly, weight loss increased the risk of hip fx irrespective of weight loss intention (p>0.93 for interaction). Among heavier women trying to lose weight, women with weight loss compared with those with stable weight had a 3-fold increased risk of hip fx (RH 3.17, 95% CI 1.39-7.20).

	Relative Hazards (RH) of Hip Fx (95% Cl)		
	Weight Loss	**Stable Weight**	**Weight Gain**
Overall Cohort	1.8 (1.4-2.4)	1.0 (Referent)	0.9 (0.6-1.5)
Current Weight 65+ kg*	2.6 (1.6-4.3)	1.0 (Referent)	0.6 (0.3-1.3
Current Weight <65 kg*	1.5 (1.1-2.2)	1.0 (Referent)	1.6 (0.9-2.8)
Trying to Lose Weight	2.1 (1.1-4.1)	1.0 (Referent)	0.6 (0.3-1.6)
Not Trying to Lose Weight	1.7 (1.3-2.4)	1.0 (Referent)	1.1 (0.7-2.0)

*Median weight=65 kg

Weight loss in later years is associated with increased hip fx risk irrespective of current weight or weight loss intention. We conclude that even voluntary weight loss in overweight women increases the risk of hip fracture.

1077

A Large Proportion of Fractures in Postmenopausal Women Occur with Baseline Bone Mineral Density T-score >-2.5. S. A. Wainwright,*[1] K. R. Phipps,[1] J. V. Stone,*[1] J. A. Cauley,[2] M. T. Vogt,[2] D. M. Black,[3] E. S. Orwoll.[1] [1]Oregon Health Sciences University, Portland, OR, USA, [2]University of Pittsburgh, Pittsburgh, PA, USA, [3]University of California at San Francisco, San Francisco, CA, USA.

While low bone mineral density (BMD) measurements are related to increased fracture risk, not all elderly women who fracture have low BMD. To determine the proportion of elderly women who fracture despite having baseline BMD measurements higher than generally considered to place these women at risk, we analyzed data from the Study of Osteoporotic Fractures (SOF). Measurements of hip and lumbar spine BMD were obtained using DXA. Incident non-traumatic hip and non-vertebral fractures occurred in 469 and 2055 subjects, respectively, during the 10 years after BMD measurement.
In the 5 years following baseline BMD measurement, the probability of incident hip fracture was 8.5% for those with total hip BMD (TBMD) T-score ≤-2.5 and 2.1% for those with T-score >-2.5. However, the majority of those with incident hip fracture (54%) or any incident non-vertebral fracture (74%) had baseline TBMD T-score >-2.5 (Table). Additionally, this phenomenon was noted even when a combination of BMD sites was assessed. Forty two percent of those with hip fracture and 53% of those with any non-vertebral fracture had both total hip and lumbar spine BMD T-scores >-2.5. Many fractures occurred at an even higher baseline BMD. Thirty two percent of those with hip fracture and 54% of those with any non-vertebral fracture had baseline TBMD T-score >-2.0. Results for those with hip and any non-vertebral fracture were similar if observation was continued for 10 years after DXA measurement.

Table: Proportion of Fractured Subjects With Baseline BMD T-score >-2.5

BMD Site	**Hip Fracture**	**Any Non-vertebral Fracture**
Total Hip	54%	74%
Lumbar Spine	54%	60%
Total Hip and Lumbar Spine	42%	53%

In summary, a large proportion of elderly women who suffer hip or any non-vertebral fracture have BMD measures higher than conventional osteoporosis diagnostic thresholds. As a result, a significant number of these fractures are not adequately predicted by BMD measures. New methods to identify women with higher BMD at risk for fracture are essential to direct effective preventive strategies

1078

Bone Loss Predicts Cognitive Decline in Older Women. L. L. Lui,[1] K. L. Stone,[1] J. A. Cauley,[2] T. A. Hillier,[3] K. Yaffe.*[1] [1]University of California, San Francisco, San Francisco, CA, USA, [2]University of Pittsburgh, Pittsburgh, PA, USA, [3]Kaiser Center for Health Research, Portland, OR, USA.

Previous studies have suggested that low bone mineral density (BMD) is associated with poor cognitive function and a greater risk of cognitive deterioration in elderly women and men. However, it is not known whether bone loss predicts subsequent cognitive decline independently of current bone mass. Prior studies have been limited by using a single BMD measurement or assessing bone loss and cognitive decline in the same period of time. No studies have examined whether rate of recent change in BMD is associated with subsequent cognitive decline among elderly women.We studied 4462 women age 70 and older (mean age = 75.8 years old), who were part of the Study of Osteoporotic Fractures (SOF). Total hip BMD was measured at 2 and 6 years after enrollment (mean follow-up 3.5 years) and we expressed rate of annualized % change in BMD in quartiles. We administered the modified Mini-Mental Status Exam (mMMSE) at 6 and 10 years after enrollment (mean follow-up 4.5 years). Cognitive decline was defined as a >= 3-point decline on repeat mMMSE score. Women with more rapid hip BMD loss were more likely to experience subsequent cognitive decline. Cognitive decline occurred in 12%, 14%, 16% and 20% of women in the lowest, second, third and highest hip BMD change quartiles, respectively (p for trend <0.001). The trend remained significant after adjustment for age, education, history of stroke, functional status, body mass index and smoking. Compared to women in the lowest quartile, those in the highest quartile of BMD change were almost 50% more likely to develop cognitive decline (table).

Annualized % change in hip BMD	**Adjusted OR (95% CI) for cognitive decline**
Lowest Quartile (mean increase 1.11%)	1.0 (reference)
2nd Quartile (mean decrease 0.04%)	1.20 (0.93 – 1.55)
3rd Quartile (mean decrease 0.78%)	1.36 (1.06 – 1.75)
Highest Quartile (mean decrease 2.12%)	1.46 (1.14 – 1.86)

This relationship was similar after further adjustment for estrogen use and final BMD (measured at the same visit as the initial cognitive score). Results remained the same if we substituted absolute change instead of % change in BMD.Women with more rapid hip bone loss were more likely to experience cognitive decline than those with less hip BMD loss or gain. This association was not explained by differences in functional status and comorbidities. Further investigation is needed to determine the underlying mechanisms that explain this relationship, and to determine whether therapies to retard bone loss may also prevent cognitive decline

1079

Familial Isolated Hyperparathyroidism: Clinical and Genetic Characteristics of Thirty-Six Kindreds. W. F. Simonds,[1] L. A. James-Newton,*[1] S. K. Agarwal,*[1] B. Yang,*[2] M. C. Skarulis,*[3] G. N. Hendy,[2] S. J. Marx.[1] [1]Metabolic Diseases Branch, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, USA, [2]Departments of Medicine, Physiology and Human Genetics, McGill University, Montreal, Canada, [3]Division of Intramural Research, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, USA.

The identification of the gene for multiple endocrine neoplasia type 1 (MEN1) has allowed genetic screening to define a population of patients with familial hyperparathyroidism due mainly to other etiologies. Thirty-six kindreds with apparent familial isolated hyperparathyroidism (FIH) were studied at the National Institutes of Health. Each index case and other relatives had detailed biochemical and bone imaging tests, as well as mutation testing of the MEN1 and calcium-sensing receptor (CaSR) genes. None had evidence of MEN1 by clinical, biochemical and mutational criteria. During this time approximately 100 kindreds with MEN1 were diagnosed, but none had FIH. Approximately 60 kindreds with familial hypocalciuric hypocalcemia (FHH) were diagnosed by biochemical criteria, and excluded. Unexpected mutations in the coding region of the CaSR gene, inactivation of which accounts for most cases of FHH, were found in the probands of five of the FIH kindreds included in our study. Based on the presence of parathyroid carcinoma, bilateral renal cysts and/or fibro-osseous jaw tumors, three other kindreds had the hyperparathyroidism-jaw tumor syndrome (HPT-JT). The remaining twenty-eight kindreds with FIH exhibited a spectrum of manifestations, some with associated non-parathyroid tumors. No kindred was large or distinctive enough to define a new clinical category. One kindred showed cosegregation of parathyroid tumors and breast cancer in three generations. Two kindreds each had renal angiomyolipomas or lipomas in association with FIH. In conclusion, most occurrences of FIH appear to result from mutation of unknown genes. Further study of such families may expand the range of phenotypes associated with HPT-JT, and help to identify other novel tumor suppressors or oncogenes.

Vitamin D Levels and Prevalence of Secondary Hyperparathyroidism in a Spanish Population-Based Sample Aged 54 to 89. C. Gómez-Alonso, M. Naves-Díaz,* J. L. Fernández-Martín,* J. B. Díaz-López,* M. T. Fernández-Coto,* J. B. Cannata. Servicio de Metabolismo Oseo y Mineral, Hospital Central de Asturias, Oviedo, Spain.

Vitamin D deficiency is common in elderly people and it may contribute to increase the prevalence of metabolic bone disorders. Serum 25-hydroxyvitamin D (25OHD) is a good indicator of the vitamin D status. However, due to several reasons there is no clear threshold to separate "normal" and "abnormal" values. It is accepted that levels of 25OHD <5 ng/ml leads to osteomalacia, <10 ng/ml leads to secondary hyperparathyroidism, and >18ng/ml could be considered "normal". The purpose of this study was to assess the vitamin D status and the prevalence of secondary hyperparathyroidism in a random sample of 312 people (159 women and 153 men, 68±9 years old; ranged 54 to 89) who participated in the European Vertebral Osteoporosis Study (EVOS) in who we performed a study including among others, BMD, 25OHD, calcitriol, iPTH, alkaline phosphatase. From this EVOS sample we included in this analysis only those people who never received any kind of treatment for osteoposis (n=268, 86% of the sample). There were no differences in age, sex or season of blood withdrawal between the 44 treated (any kind of therapy), and the 268 non-treated people. Nevertheless, serum 25OHD was higher in the treated people (24.5±11.7 vs 15.9±8.7 ng/ml, p<0.005).In the 268 people analysed in this abstract, serum 25OHD showed a significant seasonal relationship, observing lower values in winter (12.9±5.9 ng/ml) and spring (14.4±7.4 ng/ml) respect to summer (20.9±8.8 ng/ml) and autumn (18.7±7.8 ng/ml) without differences between sexes. We observed a weak relationship between age and serum 25OHD (r=-0.19, p<0.02) that disappeared when season was included in the analysis.Serum 25OHD showed a significant relationship with iPTH (r=-0.3, p<0.01) and calcitriol (r=0.3, p<0.01) and 25OHD was the strongest independent factor in the multivariate analysis. Serum 25OHD levels were "deficient" (<10 ng/ml) in 27% of people, "borderline" (10-18 ng/ml) in 40% and "normal" (>18 ng/ml) in 33% of people. The prevalence of secondary hyperparathyroidism (iPTH ≥65 pg/ml) according to 25OHD levels was 33% (<10ng/ml), 16% (10-18 ng/ml) and 12% (>18 ng/ml). There was no a single case of secondary hyperparathyroidism with 25OHD levels ≥40ng/ml.In conclusion, the 25OHD levels currently used in clinical practice to define "normal" or "abnormal" status needs to be reviewed and redifined in order to avoid a non negligible amount of secondary hyperparathyroidism likely due to "inadequately low" levels of 25OHD.

PTH(1-84) and N-truncated PTH Fragment in the Serum and Parathyroid Glands of Patients with Primary Hyperparathyroidism. A. Cohen,*[1] P. LoGerfo,*[1] P. Gao,[2] I. B. Brown,*[1] S. Trokan,*[1] T. Cantor,[2] J. P. Bilezikian,[1] S. J. Silverberg.[1] [1]College of Physicians & Surgeons, Columbia University, New York, NY, USA, [2]Scantibodies Lab Inc., Santee, CA, USA.

The new immunoradiometric assay (wPTH), using antigenic determinants at the extreme N-terminal end (1-4) of the PTH molecule, detects only whole PTH(1-84). This assay is more sensitive for the diagnosis of primary hyperparathyroidism (PHPT) than the "intact" PTH IRMA (iPTH), which measures PTH(1-84) as well as the large N-truncated PTH fragment (i.e. PTH[7-84]) which is present in serum from normal subjects, and in patients with renal failure. As this fragment does not have classic PTH-like activity, the ratio wPTH/iPTH provides an index of the percent of biologically active PTH. In this study, we report on the presence of whole PTH(1-84) and N-truncated PTH fragment in adenomatous parathyroid glands, and in the circulation of patients with PHPT. 21 consecutive patients undergoing surgery for PHPT (ages 43-89; 76% female) were enrolled, and levels of wPTH (nl: 7-36 pg/ml) and iPTH (nl: 10-65 pg/ml) were measured in serum and in the parathyroid gland. Pathology revealed adenomas in 18 patients and hyperplasia in 3 patients (latter excluded from analysis). Baseline serum calcium was 11.5 ± 0.1 mg/dl (nl: 8.7-10.8). In the parathyroid adenomas, iPTH was 1.8-fold higher than wPTH (697,090 ± 267,061 vs. 390,605 ± 116,385 pg/ml), although these values were highly correlated (R=+0.963, p <0.0001). In the serum, PTH levels were also higher (1.3-fold) by the iPTH assay (132 ± 14 pg/ml; wPTH: 96 ± 10 pg/ml; p<0.0001). Glandular PTH levels correlated with serum PTH in the wPTH (R=+0.578, p<0.05) but not the iPTH assay. Serum calcium levels correlated with glandular PTH in both assays (wPTH: R=+0.569, p<0.05; and iPTH: R=+0.544, p<0.05), but not with either PTH measurement in the serum. The mean percent of bioactive PTH(1-84) in the adenomas was 66 ± 3%, not different from bioactive hormone levels in the serum of these patients (73 ± 2%; paired T-test P=NS), and similar to previously reported amounts in normal serum (65%). While the serum of normal and uremic patients shows wide variability (20-90%) in percent of bioactive PTH(1-84), all patients with PHPT had >60% bioactive hormone. The data suggest that 1) the proportion of PTH(1-84) and N-truncated PTH fragment in the adenomatous gland is similar to the proportion found in the serum; 2) the peripheral metabolism of hormone and fragment, in the liver or kidney, does not alter the proportion of bioactive PTH in the circulation. Finally, this study provides the first evidence that both whole PTH(1-84) and large N-truncated PTH fragments are produced in the adenomatous glands of patients with PHPT.

Osteoprotegerin Inhibits Artery Calcification Induced by Warfarin and by Vitamin D. P. A. Price, J. R. Buckley,* H. H. June,* M. K. Williamson. Division of Biology, University of California, San Diego, La Jolla, CA, USA.

Previous studies have shown that doses of the amino bisphosphonates alendronate and ibandronate that inhibit bone resorption will potently inhibit the calcification of arteries induced by treatment with warfarin (Arterioscler. Thromb. Vasc. Biol.(2001) 21(5) in press). These observations support the hypothesis that artery calcification is linked to bone resorption. In the present investigations we have carried out an additional test of this hypothesis by determining whether the selective inhibition of bone resorption with osteoprotegerin will also inhibit artery calcification.

In the first test, artery calcification was induced by treating 22-day-old male rats with warfarin, a procedure that inhibits the γ-carboxylation of matrix Gla protein and thereby inactivates the calcification inhibitory activity of the protein and causes progressive calcification of the artery media. Compared with rats treated for 1 week with warfarin alone, rats treated with warfarin plus osteoprotegerin at a dose of 1 mg/kg/day had dramatically reduced Alizarin red staining for calcification in the aorta and in the carotid, hepatic, mesenteric, renal, and femoral arteries, and 90% lower levels of calcium and phosphate in the abdominal aorta (p< 0.001) and in tracheal ring cartilage (p< 0.01).

More rapid artery calcification was induced by treating 49-day-old male rats with high doses of vitamin D. Rats treated for 96h with vitamin D alone had widespread Alizarin red staining for calcification in the aorta and the femoral, mesenteric, hepatic, renal, and carotid arteries, while rats treated with vitamin D and osteoprotegerin had no evidence for Alizarin red staining for calcification in any of these arteries. Chemical analysis further showed that rats treated with vitamin D alone and examined at 96h had 6-fold higher levels of calcium and 20-fold higher levels of phosphate in their abdominal aorta than found in control rats (p< 0.001), while the levels of calcium and phosphate in the abdominal aorta of rats treated with vitamin D plus osteoprotegerin were at control values. The ability of osteoprotegerin to inhibit artery calcification in vitamin D-treated rats cannot be explained by an effect on serum calcium, since serum calcium values in rats treated with vitamin D alone (14.6 ± 0.5mg/dl) and with vitamin D plus osteoprotegerin (14.9 ± 0.8mg/dl) were the same.

We conclude that doses of osteoprotegerin that inhibit bone resorption are able to potently inhibit the calcification of arteries that is induced by warfarin-treatment and by vitamin D treatment. These results support the hypothesis that artery calcification is linked to bone resorption.

Paresis of a BMP4 Antagonist Response In Fibrodysplasia Ossificans Progressiva. J. Ahn,* L. Serrano de la Pena,* E. M. Shore, F. S. Kaplan. Orthopaedic Surgery (JA, LS, EMS, FSK), Genetics (EMS) and Medicine (FSK), University of Pennsylvania, Philadelphia, PA, USA.

Formation of the human skeleton requires inductive signals that are meticulously balanced with antagonist signals in a highly regulated negative feedback system. Patients with fibrodysplasia ossificans progressiva (FOP), a clinically catastrophic genetic disorder, form an ectopic skeletal system post-natally as muscle and deep connective tissues are replaced with heterotopic bone. Recombinant bone morphogenetic protein-4 (BMP4), a potent osteogenic morphogen, can induce endochondral osteogenesis at an ectopic site in a manner identical to that seen in FOP. Moreover, BMP4 mRNA and protein are uniquely overexpressed in lymphocytes and lesional cells from patients who have FOP. However, the BMP4 gene is not mutated in FOP, and the BMP4 locus has recently been excluded from linkage to the condition.The cellular effects of bone morphogenetic proteins (BMPs) are specified in part in a dose-dependent fashion by tightly-regulated morphogenetic gradients of BMPs and secreted antagonists such as noggin, chordin, and gremlin. Although the various BMP antagonists are unique proteins, they share the functional property of binding specifically to extracellular BMPs preventing them from interacting with their transmembrane receptors. Several recent studies have indicated that BMP4 upregulates expression of noggin and gremlin, thereby establishing an autoregulatory negative feedback loop.We hypothesized that a defect in the feedback pathway between BMP4 and one or more of its extracellular antagonists could plausibly contribute to elevated BMP4 activity in fibrodysplasia ossificans progressiva. Therefore, we investigated basal and BMP4-induced expression of noggin, chordin, and gremlin mRNA in control and FOP cell lines (LCLs).We found that cells from patients with FOP fail to upregulate the expression of noggin and gremlin in response to a BMP stimulus; control cells exhibit marked increases in noggin and gremlin mRNA expression (as measured by RT-PCR) whereas patient-derived cells

exhibit a dramatically attenuated response. Our data suggest that a loss of negative feedback due to an insufficient BMP antagonist response may account in part for increased BMP4 activity in FOP. Such a defect suggests the loss of a critical negative feedback mechanism by which cells normally regulate the magnitude and boundaries of ambient morphogenetic signals. These findings from a disabling human disease support the importance of a critical balance between an inductive morphogen and its secreted antagonists in the formation of an ectopic organ system and suggest the potential of BMP antagonist-based strategies in the therapy of FOP.

Platelet-Derived Growth Factor A Chain (PDGF-A) Antagonism with Triazolopyrimidine (Trapidil) Inhibits Marrow Fibrosis in a Rat Model for Osteitis Fibrosa Cystica. S. Lotinun, G. L. Evans,* M. Zhang,* R. T. Turner. Department of Orthopedics, Mayo Clinic, Rochester, MN, USA.

The skeletal disorder osteitis fibrosa cystica is associated with hyperparathyroidism. Similar disorders (e.g. renal osteodystrophy) are associated with chronic secondary hyperparathyroidism. The histological presentation of these diseases suggests that excess parathyroid hormone (PTH) results in local release of one or more growth factors by cells of the osteoblast lineage which in turn stimulate fibroblast over growth. The purpose of this study was to identify the putative causative factor. First, we established a rat model for osteitis fibrosa cystica. Adult rats were infused continuously for one week with human PTH (1-34) (40 mg/kg/d) delivered using sc implanted ALZET osmotic pumps. This treatment resulted in moderate hypercalcemia and bone histological changes similar to patients with primary hyperparathyroidism. The changes included increased bone formation, focal bone resorption and severe peritrabecular marrow fibrosis. Next, we compared gene expression between rats given continuous PTH and those given the hormone once daily sc. The latter treatment induces bone formation without detrimental side effects. Using a cDNA microarray having over 5000 genes, we found a set of genes differentially regulated by continuous PTH. One of these genes was PDGF-A, a known mitogenic and chemotactic factor for fibroblasts. Verification of the regulation of PDGF-A expression was accomplished using an RNase protection assay which showed that continuous PTH increased PDGF-A mRNA levels 3-fold ($p < 0.001$), whereas pulsatile PTH had no effect. Finally, we investigated the effect of trapidil on our rat model for osteitis fibrosa cystica. Four groups of animals were studied: (i) vehicle, (ii) trapidil, (iii) PTH pump, (iv) PTH pump and trapidil. Trapidil, itself did not have any effect on bone histomorphometry. The combination of PTH and trapidil showed a dramatic 74% ($p < 0.001$) reduction in marrow fibrosis compared to continuous PTH, whereas the stimulatory effects of PTH on bone formation were maintained. These results suggest that excess PDGF-A is responsible for PTH-induced marrow fibrosis and that drugs which target PDGF-A can reduce or prevent development of skeletal pathology occurring in hyperparathyroid patients.

Distinct and Overlapping Actions of PTH and PTHrP in Bone and Cartilage Development. D. Miao, B. He,* A. C. Karaplis, D. Goltzman. Dept. of Medicine, McGill University, Montreal, PQ, Canada.

To assess the role of PTH and PTHrP in bone and cartilage development we analyzed the skeletons of newborn mice homozygous for targeted ablation of the genes encoding PTH (PTH-/-), PTHrP (PTHrP-/-) or PTH and PTHrP (PTH-/-;PTHrP-/-) and compared these to each other and to wild type mice. Although PTH-/- mice are viable, PTH-/-;PTHrP-/- mice died at birth with skeletal malformations including short-limbed dwarfism, which were more severe than in PTHrP-/- animals. Analysis of the tibial growth plate revealed a marked decrease in the proliferation zone in both PTHrP-/- and PTH-/-;PTHrP-/- mice, which was not seen in PTH-/- animals. This was associated with diminished proliferating cell nuclear antigen positive chondrocytes and increased apoptosis in the PTHrP deficient animals. In contrast, the hypertrophic zone was increased in all three models but in the two PTHrP deficient animals it contained increased type X collagen, and was disorganized. Mineralization of the cartilage matrix, as assessed by van Kossa staining, was reduced in the two PTH-deficient mice but enhanced in PTHrP-/- animals. In long bone, cortical thickness was increased in all three models compared to wild type mice. In sharp contrast, trabecular bone volume was diminished in the PTH-/- mice and the PTH-/-;PTHrP-/- mice, but was slightly increased in the PTHrP-/- mice at birth. TRAP positive osteoclast number and size were reduced in all three models but osteoblast number was diminished in the two PTH deficient models and increased in the PTHrP-/- mice. Overall, the cartilage phenotype of the double "knockout" mice approximated more closely the PTHrP-/- mice, whereas the bone phenotype resembled more closely the PTH-/-animals. These results suggest that PTH and PTHrP have discrete and overlapping effects in skeletal development, which require coordinated action to achieve normal cartilage and bone growth. The unique effects of each molecule may reflect temporal or spatial differences in exposure of skeletal target cells to the two molecules or differences in molecular action of the two peptides despite their capacity to interact with a common receptor.

Mice Lacking Both PTH and PTHrP Have Novel Defects in Fetal Growth and Bone Mineralization. C. S. Kovacs,[1] L. L. Chafe,*[1] N. Fudge,*[1] N. R. Manley.*[2] [1]Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF, Canada, [2]Institute of Molecular Medicine and Genetics, Medical College of George, Augusta, GA, USA.

In fetal life, both PTH and PTHrP are present in the circulation, and both appear to contribute to the regulation of fetal calcium metabolism. We have previously shown that lack of PTH (in *Hoxa3* null mice) causes hypocalcemia and hyperphosphatemia, but no effect on placental calcium transfer. Lack of PTHrP (in *Pthrp* null mice) also causes hypocalcemia and hyperphosphatemia, and placental calcium transfer is reduced. In the current study, we have examined the relative contributions of PTH and PTHrP to fetal calcium and bone metabolism by creating double-knockouts for *Hoxa3* and *Pthrp*. Compared to wt siblings, single mutant *Hoxa3* null fetuses had a normal weight, crown-rump length and limb length; single mutant *Pthrp* null fetuses also had a normal weight and crown-rump length but displayed the previously described chondrodysplasia with shortened and misshaped limbs. Double-knockout fetuses were significantly smaller with lower body weight, crown-rump length and markedly foreshortened limbs. Whole mount skeleton preparations showed the double-knockout to have abnormal mineralization of costal cartilages, similar to the *Pthrp* null. In addition, growth plates of the double-knockout showed more severe shortening and disorganization as compared to the *Pthrp* null. Alizarin red and von Kossa studies demonstrated that the *Hoxa3* null and the double-knockout both had accreted less skeletal mineral, while the *Pthrp* null had normal skeletal mineral content. Wt fetuses had a blood calcium of 1.70 ± 0.04 mmol/l; single mutant *Pthrp* null fetuses had a modestly reduced blood calcium (equal to maternal) of 1.40 ± 0.03 mmol/l; single mutant *Hoxa3* null fetuses had a markedly reduced blood calcium (below maternal) of 1.20 ± 0.04 mmol/l; and double-mutant fetuses had the lowest blood calcium at 1.02 ± 0.02 mmol/l (ANOVA: $p<0.01$ among all 4 genotypes). Our results show that lack of both PTHrP and PTH resulted in more severely reduced blood calcium compared to the single mutants, as well as new defects in skeletal mineral accretion and overall fetal growth. These findings suggest: 1) that PTH may play a more dominant role than PTHrP in regulating the fetal blood calcium; 2) that the blood calcium level is an important determinant of skeletal mineral accretion independent of placental calcium transfer rate; and 3) that lack of both PTH and PTHrP (but not either alone) will cause fetal growth restriction.

1087

Altered Bone Mass and Microarchitecture in Beta-Arrestin2 KO Mice. S. L. Ferrari,[1] F. Lin,*[2] R. J. Lefkowitz,*[2] M. L. Bouxsein.[3] [1]Div. of Bone Diseases, University Hospital, Geneva, Switzerland, [2]Howard Hughes Medical Institute Laboratories, Duke University Medical Center, Durham, NC, USA, [3]Orthopedic Biomechanics Laboratory, Beth Israel Deaconess Medical Center, Boston, MA, USA.

Beta-arrestins are cytoplasmic molecules involved in intracellular trafficking and signaling of G protein-coupled receptors (GPCRs). Beta-arrestins are expressed in osteoblasts and we have previously shown that beta-arrestin2 (b-arr2) mediates endocytosis of agonists--parathyroid hormone (PTH)/PTH-related protein (PTHrP) receptor and regulates PTH-stimulated cAMP signaling. Mice null for b-arr2 develop normally and show no gross phenotypic abnormalities. However, due to the central role of PTHrP and PTH on bone development and remodeling, respectively, we hypothesized that bone mass and microarchitecture might be altered in these mice. Adult b-arr2 KO mice and their wild-type (wt) littermates were evaluated for whole body and femoral bone mineral density (BMD) by pDXA (PIXImus®). High resolution micro-computed tomography was used to evaluate trabecular and cortical bone mass and architecture at the proximal tibia and femoral midshaft, respectively.No differences in skeletal morphology were observed between six adult b-arr2 KO and wt mice on conventional radiographs. In contrast, compared to wt, b-arr2 KO mice had lower whole body and femoral BMD (-9%), trabecular number (TbN, -7%) and connectivity (-119%), increased trabecular separation (TbSp, +7%), and decreased cortical bone volume (BV, -13%) (all $p<0.05$ by nonparametric Mann-Whitney U-test). There also was a trend for lower trabecular bone volume fraction (BV/TV, -17%) and thickness (TbTh, -8%), as well as cortical thickness (Th, -6%) in b-arr2 KO mice. Body composition also markedly differed in b-arr2 KO and wt mice, as fat mass was 33% lower in the former ($p<0.05$). Since beta-arrestin1 (b-arr1) is also expressed in bone and could partly compensate for the loss of b-arr2 function, we further evaluated twelve mice generated by crossing b-arr2 KO with b-arr1 KO mice. Double homozygous b-arr1/b-arr2 KO mice were embryonnically lethal. However, in b-arr1 (+/-)/b-arr2 KO mice, BMD was decreased by up to 20%, TbTh by 17% (both $p<0.05$), and cortical BV and Th by up to 18% ($p=0.12$) compared to b-arr1(+/-)/b-arr2(+/-) mice.In summary, adult mice null for b-arr2 exhibit reduced BMD, cortical bone mass, and altered trabecular microarchitecture. These features appeared to be even more prominent with the additional loss of one b-arr1 allele. These in vivo findings confirm the important role of beta-arrestins in regulating GPCRs activity in bone and suggest that the skeletal phenotype observed in b-arr2 KO mice may result from a sustained activity of PTH.

1088

ADAMTS-1: A Cellular Disintegrin and Metalloprotease with Thrombospondin Motifs Is Essential for Normal Bone Growth and PTH Regulated Bone Metabolism. J. E. Onyia, Y. L. Ma, E. Galbreath,* Q. Zhang,* Q. Zeng, R. Cain,* J. Hoover,* R. R. Miles,* D. L. Halladay,* L. V. Hale,* R. F. Santerre, A. K. Harvey, S. Chandrasekhar, N. Fox,* D. D. Yang.* Lilly Research Labs, Eli Lilly and Company, Indianapolis, IN, USA.

Recently, we discovered ADAMTS-1 as potential PTH target gene in genomic analysis of bone response to PTH. ADAMTS-1, a new secreted member of the ADAM (A disintegrin and metalloprotease) gene family, is selectively up-regulated in rat and mouse bones by parathyroid hormone. In vivo, acute exposure to anabolic PTH results in a rapid and transient increase in ADAMTS-1 expression while catabolic continuous PTH infusion leads to a rapid and sustained induction of ADAMTS-1. To validate the function of ADAMTS-1 and understand the biology in an animal model, we generated ADAMTS-1 knockout mice by gene targeting. ADAMTS-1(-/-) mice are viable, but suffer from growth retardation, impaired female fertilization with delayed sexual development, and renal abnormalities that involve enlargement of renal calices and reduction of corticomedullary tissue. Dual energy X-ray (DEXA) analyses showed a significant reduction in whole body bone mineral content in ADAMTS-1(-/-) mice. Histomorphometric analyses of the proximal tibia of 6 month old mice showed decreases in trabecular bone volume (TBV), thickness (Tb.Th), and number (Tb.N) in ADAMTS-1(-/-) mice. No significant difference was observed in mineralizing surface (MS/BS), but there was an increase in matrix apposition rate (MAR) in ADAMTS-1(-/-) mice. Osteoclast number normalized to bone surfaces (N.OC/BS) or on trabecular area (N.OC/T.Ar) was significantly increased in ADAMTS-1(-/-) mice. Histomorphometric differences between mutant and wildtype mice were diminished in tibia from 9 month old female mice due to normal age related bone loss in wild type animals. Intermittent PTH challenge increased trabecular bone mass and markedly

upregulated serum osteocalcin (a marker of osteoblast differentiation) in mutant mice. Additionally, ADAMTS-1(-/-) mice were resistant to bone resorption induced by continuous PTH infusion. These data underscore an essential role for ADAMTS-1 in bone metabolism and are consistent with the hypothesis that ADAMTS-1 is a critical mediator of PTH actions in bone. We speculate that under normal physiological conditions ADAMTS-1 is an inhibitor of PTH-induced bone formation and is required for PTH-induced resorption.

1089

The Protooncogene c-*fos* Is Critical for Anabolic Effects of Parathyroid Hormone in Bone. B. Demiralp,*[1] H. Chen,[1] A. J. Koh,*[1] C. Chen,*[1] J. Dai,*[2] E. T. Keller,[2] L. K. McCauley.[1] [1]Perio/Prev/Geriatrics, Univ Michigan, Ann Arbor, MI, USA, [2]Unit for Lab Animal Medicine, Univ Michigan, Ann Arbor, MI, USA.

Parathyroid hormone (PTH) has both anabolic and catabolic actions in bone that are not well understood. AP-1 family members such as c-*fos* are critical transcriptional mediators, and are highly regulated by PTH. The purpose of this study was to examine the anabolic mechanisms of PTH, and specifically the role of *c-fos* during endochondral bone growth. Mice, c-*fos* (-/-), wildtype (+/+), and heterozygous (+/-) littermates, were genotyped by PCR. An anabolic regime of PTH (0.05 µg/g) was administered s.c. from postnatal d4-23, or a single PTH (20 µg) was administered. FAXITRON radiography, dual x-ray absorptiometry, histology, serum and bone ash biochemistry and whole organ gene expression by northern blot were performed. Effects of PTH *in vivo* were dramatically different in wild-type and heterozygous vs. c-*fos* deficient mice. The +/+ mice had increased bone mineral density (BMD), and bone mineral content (BMC) with daily PTH; whereas PTH caused a reduction in BMD and BMC in -/- mice ($p<0.05$). Daily PTH treatment also decreased the calcium/ash weight of -/- femurs but not +/+ or +/- ($p<0.01$). Serum calcium levels of +/+ mice were higher than -/- mice ($p<0.05$), and with anabolic PTH administration, calcium levels decreased in +/+ but increased in -/- mice. Histologically, PTH resulted in an increase in proliferating chondrocytes in +/+ mice, but a decrease in proliferating chondrocytes and an increase in hypertrophic chondrocytes in -/- mice. This resulted in an exacerbation of the already widened growth plate in -/- mice. Daily PTH also increased the thickness of calvaria in +/- mice but not -/- mice. The c-*fos* -/- mice had lower bone sialoprotein (BSP) and osteocalcin (OCN) ($p<0.05$) mRNA expression in calvaria than c-*fos* +/+ mice but there was no difference in PTH-1R mRNA expression in calvaria and kidneys of c-*fos* +/+ or -/- mice suggesting the PTH-1 receptor was not altered by the c-*fos* deficiency. Short term PTH administration (8h) resulted in an increase in BSP ($p<0.01$), a decrease in OCN ($p<0.01$), and no change in PTH-1R mRNA expression in calvaria of +/- and +/+ mice whereas there was no alteration in gene expression for BSP, OCN or PTH-1R in -/- mice. These studies suggest that c-*fos* is critical for gene expression of BSP and OCN in bone. *In vitro* studies with an inhibitor of c-*fos* and c-*jun* (U0126) and pre-osteoblastic cells similarly indicated that AP-1 signaling is required for basal OCN expression and for PTHrP downregulation of OCN. These data suggest that c-*fos* is critical for anabolic effects of PTH and that this role of c-*fos* may be associated with genes that regulate extracellular matrix mineralization.

1090

Direct Binding of the PTH/PTHrP Receptor (PTH1R) to the Na-H Exchange Regulatory Factor 2 (NHERF2) Selectively Transfers Signaling from Adenylate Cyclase to Phospholipase C Pathways. M. J. Mahon,*[1] M. Donowitz,*[2] G. V. Segre.[1] [1]Endocrine Unit, MGH, Harvard University, Boston, MA, USA, [2]Department of Gastroenterology, Johns Hopkins University, Baltimore, MD, USA.

The intracellular carboxyl-terminal "tail"(C-tail) of the PTH1R, when used as "bait" in the yeast two-hybrid system, binds to NHERF2 through an interaction with an atypical PDZ consensus motif (ETVM) and the more C-terminal of two PDZ domains in NHERF2. NHERFs are known to function as scaffolding proteins capable of binding several molecules. A GST-fusion protein containing the PTH1R C-tail strongly interacted with NHERF2 in overlay assays. In contrast, PTH1R C-tail containing a C-terminal 20 amino-acid truncation or single alanine point-mutations at M591 T589, or E588, located on the C-terminus disrupted binding to NHERF2. However, V590A replacement had no effect on this interaction, which is consistent with known properties of PDZ binding. Furthermore, the PTH1R C-tail exclusively interacted with NHERF2's C-terminal PDZ domain, not with the N-terminal PDZ domain. The specificity of these interactions was confirmed and extended in mammalian cells with full length wild-type (WT) and mutant PTH1Rs and NHERF2 by co-immunoprecipitation. WT PS 120 cells are fibroblasts devoid of Na-H Exchangers (including NHE3), NHERFs and PTH1Rs. Stable cells lines expressing NHE3 were first generated, and then modified to stably express either the WT PTH1R or PTH1R lacking a functional PDZ interaction motif (PTH1R-Cdelta20 and M591A), and in the absence or presence of NHERF2. Stable cells co-expressing the WT PTH1R and NHERF2 generated only 2-fold increases in cAMP when treated with 100 nM PTH (1-34). In contrast, cells co-expressing either PTH1R-Cdelta20 or M591A and NHERF2, or cells co-expressing WT PTH1R in the absence of NHERF2 displayed PTH-mediated increases in cAMP of 10-15 fold. Importantly, cell lines co-expressing WT PTH1R and NHERF2 preferentially signaled via the IP pathway, displaying a PTH-mediated increase of 25-30 fold. However, cell lines co-expressing PTH1R-Cdelta20 or M591A and NHERF2, or stables lines expressing WT PTH1R in the absence of NHERF2 displayed only a 2-4 fold increase in IPs in response to PTH (1-34). In summary, PTH1R's C-terminal recognition domain directly interacts with NHERF2 via its C-terminal PDZ domain. This interaction results in a NHERF2-dependent shift in PTH-mediated signaling from the adenylate cyclase pathway to the phospholipase C pathway. Thus, NHERF2 functions as "switch" to select the signaling pathway activated by the PTH1R. Studies are in progress to examine the physiological significance of this interaction in cells not over expressing these molecules.

Modulation of T Cell TNF Production via Antigen Presenting Cells: A Novel Immune Mechanism by which Estrogen Prevents Bone Loss. S. Cenci, C. Roggia, G. Toraldo, Y. Gao, M. N. Weitzmann, J. L. Kindle,* F. Starkey,* R. Pacifici. Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA.

T cells are essential players in the mechanism by which ovariectomy (ovx) induces bone loss, as demonstrated by the failure of ovx to induce bone loss in T cell deficient (nude) mice. Since ovx increases T cell TNF production in vitro, we investigated if ovx induces bone loss in vivo through upregulated T cell TNF production. Nude mice were reconstituted with T cells from wild-type (WT) or TNF deficient (-/-) donor mice and bone density measured by pQCT on excised tibiae. In nude mice reconstituted with T cells from WT mice, ovx caused a 25 % bone loss in 4 weeks. In contrast, ovx caused no bone loss in nude mice reconstituted with TNF -/- T cells. Thus, increased T cell TNF production is crucial for ovx induced bone loss in vivo. Ovx upregulated TNF production by increasing T cell activation, a phenomenon leading to an increased number of bone marrow TNF producing T cells. In vitro estrogen (E2) treatment did not repress T cell proliferation and TNF production, suggesting that E2 regulates T cells indirectly, either targeting accessory cells or T cell precursors, which become E2-insensitive when reach maturity. Injection of mature T cells from ovx mice into sham nude recipients caused a 2-week period of rapid bone loss, due to T cell TNF production. Between week 2 and 4 there was no additional bone loss due to T cell deactivation. Injection of sham T cells into ovx nude mice induced no bone loss in the first 2 weeks, T cell proliferation at 2 weeks, and rapid bone loss thereafter. Thus, endogenous E2 regulates mature T cells in vivo. Since antigen (Ag) presenting cells (APC) are central modulators of T cell activation, we investigated if APC mediate the effects of ovx in vivo. Thus, bone density was measured in ovx DO11.10 mice, a strain with impaired cross-talk between APC and T cells. DO11.10 mice were completely protected against ovx induced bone loss, a finding which establishes the central role of APC in ovx induced bone loss. Finally, we found that ovx increases APC activity by twofold, as assayed in vitro by measurement of proliferation of target T cells in presence of the whole unprocessed Ag. In contrast, no difference between sham and ovx APC activity was observed when the immunogenic fragments of the Ag were used, indicating that E2 deficiency increases Ag presentation by enhancing Ag processing. Together, the data demonstrate that ovx induced bone loss is a consequence of upregulated T cell TNF production resulting from increased APC activity. The observed link between the immunosuppressive and the bone-sparing effects of E2 provides a novel paradigm as it identifies immune cells as an essential target of E2 in bone.

1092

Rapid Activation of MAP Kinases by Estrogens or Androgens Leads to Potent Downstream Regulation of the Transcription of the Serum Response Element and AP-1: A Link Between Nongenotropic and Genotropic Functions of their Classical Receptors. S. Kousteni, L. Han, M. E. McIntire,* T. Bellido, R. L. Jilka, S. C. Manolagas. Division of Endocrinology & Metabolism, Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Estrogens or androgens activate the Src/Shc/ERK signaling pathway via an extranuclear function of the classical estrogen (ER) or androgen (AR) receptors. Based on this and evidence that ERK or JNK kinases activate Elk-1 or c-fos/c-jun, respectively, we investigated whether nongenotropic activation of MAP kinases by ER or AR leads to activation of these transcription factors. HeLa cells were transiently transfected with either ERα or AR, or a construct consisting of the ligand binding domain (E) of the ERα fused either to a membrane (E-Mem) or a nuclear localization (E-Nuc) sequence together with one of two reporter plasmids carrying promoters interacting with either Elk-1 or c-fos/c-jun. Binding of Elk-1 to the cis serum response element (SRE), or c-jun/c-fos to an AP-1 site in these constructs drives the expression of secreted human alkaline phosphatase (SEAP). 17β-estradiol (E_2) or dihydrotestosterone (DHT) at 10^{-8} M upregulated (~8-fold) the transcriptional activity of Elk-1. On the other hand, either steroid downregulated (~7-fold) the AP-1-dependent transcription from the AP-1-SEAP. These effects could be demonstrated in cells transfected with the wild type ERα, or with the AR, or with the E-Mem mutant; but, were completely eliminated in cells containing the E-Nuc. Moreover, these effects resulted from downstream activation of kinases, as co-transfection with dominant negative mutants for Src, Shc or ERK activation completely abrogated them. In agreement with the evidence that Elk-1 and c-fos/c-jun transcriptional regulation is a consequence of a nongenotropic kinase activation, an estren which has no transcriptional activity via the ER but is a potent inducer of ERK activation, also stimulated SRE-SEAP activity. On the other hand, a pyrazole with potent transcriptional activity, but no effects on ERK activation was unable to induce SRE-SEAP activity via either receptor. These results demonstrate that rapid signals originating from membrane-associated receptors influence transcription. Nonetheless, in contrast to the present evidence that rapid activation of MAP kinases by membrane-associated ERα suppresses AP-1 activity, E_2-activated ERα stimulates AP-1 activity directly. Therefore, the response of a target cell to sex steroids may be determined by the balance between membrane- and nucleus-associated receptor actions.

1093

Gender-Independent Induction of Murine Osteoclast Apoptosis In Vitro by Either Estrogens or Non-Aromatizable Androgens. J. R. Chen, S. Kousteni, T. Bellido, L. Han, G. B. Di Gregorio, R. L. Jilka, S. C. Manolagas. Division of Endocrinology & Metabolism, Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

In rodents and humans sex steroids influence the survival of osteoclasts and osteoblasts in opposite directions: they promote osteoclast, but prevent osteoblastic/osteocytic cell

apoptosis. The latter effect evidently results from a nongenotropic, sex-nonspecific action of the classical estrogen (ER) or androgen (AR) receptor and it can be transmitted by either the ER or the AR with similar efficiency irrespective of whether the ligand is an estrogen or an androgen. To determine the mechanism, and in particular the sex steroid- and gender-specificity of the pro-apoptotic effect of estrogens and androgens on osteoclasts we examined the effect of 17β-estradiol (E_2) or the non-aromatizable dihydrotestosterone (DHT) on the survival of osteoclasts derived from bone marrow cell cultures from 4-8 week old C57Bl/6 male or female mice. In one set of experiments non-adherent cells were harvested 2 days following the establishment of the culture and placed in medium containing 30 ng/ml M-CSF and soluble RANK ligand; in a second set both adherent and non adherent cells were cultured together in the presence of 10^{-8} M 1α,25-$(OH)_2D_3$. Cultures were grown until a maximum number of multinucleated osteoclasts were observed (7-8 days from female-derived cells and 5-8 days for male-derived cells) and were then treated with vehicle or 10^{-10} to 10^{-7} M E_2 or DHT alone or in the presence of equimolar concentrations of the estrogen receptor antagonist ICI 182,780 or the androgen receptor antagonist flutamide. 24 h later apoptosis was assessed both by direct visualization of apoptotic features in TRAP-positive cells and by measuring caspase 3 activity in cell lysates. Both E_2 or DHT stimulated osteoclast apoptosis in a dose-dependent manner, by as much as 3 -fold over vehicle, in either assay. E_2 or DHT were equally effective irrespective of whether the donor mouse was a male or a female, or whether stromal/osteoblastic support cells were present or absent from the cultures. More important and as shown before in the case of the anti-apoptotic effects of sex steroids on osteoblasts, the pro-apoptotic effect of E_2 was abrogated by ICI as well as flutamide and the effect of DHT by flutamide as well as ICI. These results strongly suggest that the opposite effects of sex steroids on osteoclast and osteoblast apoptosis are mediated via a similar mechanism of action and that in both cases are sex-nonspecific and gender-independent.

A Pure Anti-estrogen ICI 182780 Inhibits Osteosclerotic Bone Metastases in an Animal Model of Breast Cancer. B. Yi, P. J. Williams,* M. Niewolna,* T. Yoneda. Medicine/Endocrinology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

Breast cancer has a predilection for spreading to bone. Several clinical studies have reported that estrogen receptor (ER)-positive breast cancers more preferentially spread to bone than ER-negative breast cancer. Although ER-positive breast cancers respond well to anti-estrogen therapy, the effects of anti-estrogens on bone metastases have not been specifically explored to date. Here, we tested ICI 182780, a new compound with pure anti-estrogen activity, for its potential to suppress bone metastases caused by ER-positive breast cancer. To approach this, we established an animal model in which the ER-positive MCF-7 human breast cancer cells overexpressing the oncogene Neu (MCF-7/Neu) developed osteosclerotic bone metastases following left cardiac ventricle inoculation in female nude mice with no requirement for estrogen supplementation. The ICI 182780 was found to profoundly inhibit transcriptional activity of ER using an ERE-CAT reporter construct in MCF-7/Neu cells. Histomorphometric examination showed that ICI 182780 (5mg/mouse, sc, once a week) significantly decreased metastatic tumor burden in bone and tumor-induced osteosclerotic lesions compared with control mice. ICI 182780 given according to this protocol was shown to have little effects on bone in control non-tumor-bearing mice radiologically and histologically. Since it has been shown that MCF-7/Neu cells produce PDGFBB in culture and that PDGFBB plays a critical role in the development of osteosclerotic bone metastases in mice, the effects of ICI 182780 on PDGFBB production in MCF-7/Neu cells were next examined. We found that ICI 182780 dose-dependently decreased the production of PDGFBB. Furthermore, histological examination demonstrated that the conditioned media harvested from ICI 182780-treated MCF-7/Neu cells had reduced bone-forming activity as assessed in organ cultures of mouse neonatal calvariae. Finally, ICI 182780 inhibited anchorage-independent growth of MCF-7/Neu cells. In summary, our results suggest that a pure anti-estrogen ICI 182780 decreased osteosclerotic bone metastases caused by MCF-7/Neu human breast cancer with inhibition of cell growth and production of osteosclerotic PDGFBB through suppressing transcriptional activity of ER. The new anti-estrogen ICI 182780 may be an effective agent in endocrine therapy for bone metastases in ER-positive breast cancers.

The Role of Estrogen Receptor-beta (ER-b) in the Early Age-Related Bone Gain and Later Age-Related Bone Loss. H. Z. Ke, K. L. Chidsey-Frink, H. Qi, D. T. Crawford, H. A. Simmons, T. A. Brown, D. N. Petersen, M. R. Allen, J. D. McNeish, D. D. Thompson. Pfizer Global Research and Development, Groton Labs, Groton, CT, USA.

The mechanism of action of estrogens in skeletal tissue remains unclear. The purpose of our study was to understand the role of ER-b on cortical and cancellous bone during growth and the aging process by comparing the bone phenotype of 6- and 13-month-old female mice with or without ER-b. Groups of 11-14 wild-type controls (WT) and ER-b knockout female mice (BERKO) were necropsied at 6 and 13 months of age. At both ages, BERKO did not differ significantly from WT mice in uterine weight, indicating that ER-beta does not regulate the growth of uterine tissue. At 6 months of age, pQCT analysis of the distal femoral metaphysis (DFM) showed that BERKO mice had significantly higher total content (+24%), total bone area, cortical content (+19%), cortical area (+16%), and periosteal circumference (+7%) as compared with WT controls. Femoral length increased significantly by 5.5% in BERKO compared with WT. These results demonstrated that ER-b plays a role in periosteal bone formation, and longitudinal and radial bone growth during the growth period. There was no difference between BERKO and WT in trabecular density and marrow cavity area by pQCT, or trabecular bone volume (TBV), formation and resorption indices by histomorphometry of DFM at 6 months of age. In WT mice, TBV (-41%), trabecular density (-27%) and cortical thickness (-18%) decreased while marrow cavity area (+18%) and endocortical circumference (+19%) increased significantly at 13 months of age as compared with those at 6 months of age. These results indicate an age-related decrease in cancellous and endocortical bone in WT mice. These age-related changes did not occur in BERKO mice between 6 and 13 months of age. At 13 months of age, BERKO mice had significantly higher TBV (+157%), total content (+30%), total density (+24%), cortical content (+32%), cortical area (+36%), cortical thickness (+54%) and trabecular density (+48%) in DFM as compared with WT controls. Furthermore, BERKO mice had significantly lower osteoclast surface (-51%), osteoclast number (-50%) and bone turnover rate (-85%) in DFM compared with WT at 13 months of age. These results indicate that ER-b knockout protected against age-related bone loss in the cancellous and endocortical bone by decreased bone resorption and bone turnover in the aged female mice. These data demonstrate that estrogen receptor-beta plays an inhibitory role in periosteal bone formation, longitudinal and radial growth during the growth period, while it plays a role in stimulation of bone resorption, bone turnover and bone loss on cancellous and endocortical bone surfaces during the aging process.

Estrogen Receptor-β Is the Key Receptor Supporting Protection of Bone Mass by Estrogen. L. Cao, R. M. McKeon, R. Bu, H. C. Blair. Pathology and Cell Biology & Physiology, University of Pittsburgh, Pittsburgh, PA, USA.

How estrogens or estrogen-like molecules protect skeletal mass remains controversial. We studied the dependence of osteoblast function and osteoclast differentiation on estrogen receptors [ERs]-α and -β by modifying the human osteosarcoma cell line MG63 to make stable cell lines expressing only ERα, ERβ, or both receptors. Cells where ER-α or ER-β were not expressed at detectable levels by Western analysis were made using plasmids with neomycin resistance and strong viral promoters driving antisense ERs. We examined estrogen-dependent protein expression, and support of osteoclast differentiation from human monocytes, by these cells. ER-α negative cells supported reduced osteoclast formation in co-cultures with normal human monocytic precursors when 10 nM estradiol was added, but there was no detectable difference between osteoclasts produced by co-cultures of these cells and control cells. However, when ER-β was not expressed, estrogen (estradiol, 10 nM) no longer affected osteoclast differentiation measurably. Surprisingly, RANKL and CSF-1 expression, with or without estrogen, did not change significantly in ER-α or -β-negative cells, suggesting that accessory growth factors are important in estrogen effects. ERs also affect expression of several key proteins in osteoblastic differentiation and induction of bone turnover. These were studied by Western analysis or semi-quantitative PCR. No significant differences between cell types, with or without estrogen, were seen when analyzing osteoprotegerin or BMPs 2 and 4. Collagen and alkaline phosphatase responded significantly to estrogen in control cells and ERα negative cells, but not in ERβ negative cells. It has also been questioned whether estrogen affects osteoclast formation from the standpoint of the monocytic precursors. While we have not tested effects of estrogen on promonocyte proliferation, no effect of estrogen on osteoclastic differentiation was seen when differentiation of human monocytic precursors was supported with CSF-1 and RANKL (without osteoblasts). Monocytes were derived from peripheral blood by apheresis. This suggests that estrogen effects, reported using marrow-derived monocytic cells, may result from mixed cell populations or may reflect effects on earlier stages of monocyte growth and differentiation. We conclude that, in a human osteoblast-like osteosarcoma-derived cell line that retains key features of osteoblastic differentiation, the major estrogen response in bone synthesis and protection from bone degradation is dependent on ER-β, and that the major effects on osteoclastic differentiation are mediated by the osteoblast, not by ERs in pre-osteoclastic monocytic cells.

Conditional Mutagenesis of the IGF1 Receptor Gene in Osteoblasts Reduces Cancellous Bone Volume and Increases Turnover. M. Zhang,*[1] S. Xuan,*[2] M. L. Bouxsein,[3] D. von Stechow,*[3] M. Faugere,[4] H. Malluche,[4] G. Zhao,*[1] C. J. Rosen,[5] A. Efstratiadis,*[2] T. L. Clemens.[1] [1]Department of Medicine, University of Cincinnati, Cincinnati, OH, USA, [2]Department of Genetics and Development, Columbia University, New York, NY, USA, [3]Department of Orthopedics, Beth Israel Deaconess Medical Center, Boston, MA, USA, [4]Department of Medicine, University of Kentucky, Lexington, KY, USA, [5]Department of Medicine, St. Joseph's Hospital, Bangor, ME, USA.

Insulin like growth factor 1 (IGF1) exerts anabolic effects on bone and is thought to amplify other osteogenic signals. However, the cellular and molecular mechanisms that mediate the anabolic actions of IGF1 have been difficult to address experimentally primarily due to the complexity of the IGF system. To study the paracrine actions of IGF1 in skeletal tissue in a physiological context, we have used Cre-mediated recombination to disrupt selectively in mouse osteoblasts the gene encoding the type 1 IGF receptor (IGF1R). Mice expressing the site-specific recombinase gene (*cre*) under the control of the human osteocalcin (OC) promoter were crossed with Z/AP reporter mice which express β-galactosidase in the absence of Cre, but human placental alkaline phosphatase in its presence. Offspring from these matings demonstrated high levels (>90%) of recombination in bone osteoblasts and osteocytes. The OC-*cre* mice were then crossed with mice in which the 3rd exon of both *Igf1r* alleles was flanked by *loxP* sites ("floxed"; *Igf1r* $^{flox/flox}$). Progeny with an OC-*cre/Igf1r* $^{flox/+}$ genotype were then intercrossed. PCR analysis using DNA templates from tissues of OC-*cre/Igf1r* $^{flox/flox}$ offspring demonstrated that Cre-mediated recombination had occurred exclusively in bone. Six week old mice (*Igf1rδflox/δflox* in bones) were of normal size and weight. Micro CT analysis on femurs in groups of female mice (N=6) revealed a striking decrease in cancellous bone volume (78% of control), connectivity (53%), and trabecular number (86%), and an increase in spacing (119%). No significant changes were observed in cortical bone. The reduction in cancellous bone volume was confirmed by histomorphometric analysis. Surprisingly, however, the conditional *Igf1r* mutants had significantly greater osteoblast surface (146% of control), osteoid volume (170%), and increased osteoclast number (144%) and osteoclast erosion surface (185%). Thus, disruption of IGF1 signaling in mouse osteoblasts appears to cause a state of accelerated cancellous bone turnover possibly due to loss of inhibitory effects of IGF1 on bone resorption. These results establish a valuable model to investigate further the role of IGF1 signaling in bone development and turnover.

1098

Mice Lacking Insulin Receptor Substrate-2 Exhibit Osteopenia with Decreased Bone Formation and Increased Osteoblast-Mediated Osteoclastogenesis. T. Akune,[1] N. Ogata,[1] K. Hoshi,[1] N. Kubota,*[1] T. Kadowaki,*[1] H. Takagi,[2] Y. Azuma,[2] K. Nakamura,[1] H. Kawaguchi.[1] [1]Univ. of Tokyo, Tokyo, Japan, [2]Teijin Co. Ltd., Tokyo, Japan.

Insulin receptor substrates (IRS-1 and -2) are essential for intracellular signaling by IGF-I and insulin, anabolic regulators of bone metabolism. We previously reported that IRS-1 is important for maintaining bone turnover as a signaling molecule of IGF-I / insulin using IRS-1 deficient mice. We this time created mice lacking the IRS-2 gene (-/-) by homologous recombination in mouse embryonic stem cells, and investigated the role of IRS-2 in bone. Although -/- mice developed normally, significant decreases in both trabecular and cortex bone volumes were observed by bone densitometry and 3D-μCT analyses compared to wild-type (+/+) littermates at 4-16 weeks of age. Histomorphometric analysis at 8 weeks showed that bone resorption parameters (Oc.N/B.Pm & ES/BS) were approximately 40% increased in -/- mice compared to +/+ mice. Although osteoblast number was proportionally increased in -/- mice, bone formation parameters (MAR & BFR/BS) were 30-40% decreased. To investigate the cellular mechanism, we compared functions of primary calvarial osteoblasts (OBs), M-CSF-dependent bone marrow macrophages (BMMϕ), and osteoclasts isolated from co-culture of OBs and marrow cells (OCLs) derived from -/- and +/+ littermates. Although IRS-2 was expressed in all +/+ cells but none of the -/- cells, IRS-1 was expressed only in OBs and showed no compensatory increase in -/- OBs. Cultured -/- OBs showed similar proliferation ([^{3}H]-TdR) but markedly reduced differentiation and matrix synthesis as determined by ALP, Alizarin red, and von Kossa stainings, compared with +/+ OBs. IGF-I or insulin stimulated differentiation, matrix synthesis, and tyrosine phosphorylation of intracellular proteins in +/+ OBs, but not in -/- OBs. Neither osteoclastogenesis from soluble RANKL-stimulated BMMϕ nor OCL survival rate was different between -/- and +/+ cultures, indicating that IRS-2 signaling in cells of osteoclastic lineage is not important. Osteoclastogenesis and resorbed pit formation by $1,25(OH)_2D_3$, PGE_2 or IL-11 in co-culture of OBs and marrow cells were up-regulated only when OBs were derived from -/- mice independently of the origin of marrow cells, and -/- OBs showed greater induction of RANKL mRNA by these resorptive factors. It is concluded that IRS-2 deficiency causes osteopenia through impairment of bone formation and enhancement of osteoblast-mediated osteoclastogenesis. We propose that osteoblastic IRS-2 has anabolic actions on bone not only as a signaling molecule for IGF-I / insulin but also as an inhibitor of RANKL independently of IGF-I / insulin or IRS-1 signaling pathway.

1099

p57^{Kip2}, and p107 & p130, Regulate Chondrocyte Proliferation *in Vivo*, and May Be Targets of PTHrP Action. H. E. MacLean,[1] D. Cobrinik,*[2] P. Zhang,*[3] H. M. Kronenberg.[1] [1]Endocrine Unit, Mass. General Hospital & Harvard Medical School, Boston, MA, USA, [2]Medicine, Columbia University College of Physicians & Surgeons, New York, NY, USA, [3]Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX, USA.

Targeted ablation of the negative cell cycle regulators, p57^{Kip2}, and p107 and p130, have shown that they are required for normal chondrocyte function. We have examined the chondrocyte phenotype of p57 knockout mice, and of p107/p130 double knockout mice, and explored possible relationships between PTHrP signaling and expression of p57, p107 and p130. Absence of either p57, or both p107 and p130, causes similar abnormalities in chondrocytes. In both cases, knockout chondrocytes show increased cell density, with prolonged proliferation at E14.5, delayed appearance of hypertrophic chondrocytes, and delayed mineralization of bone collar. These data are consistent with the hypothesis that p57, p107 and p130 are required to coordinate the cessation of chondrocyte proliferation, and transition to differentiation. We have previously shown that PTHrP maintains chondrocytes in the proliferative pool, with absence of PTHrP causing accelerated transition of chondrocytes from proliferation to differentiation, and shortened zones of round proliferative and columnar chondrocytes. We have also shown that overexpression of a constitutively active PTH receptor in transgenic mice results in decreased p57 expression. Therefore, we studied PTHrP/p57 double knockout mice, and PTHrP/p107/p130 triple knockouts, to determine if absence of these cell cycle factors could compensate for loss of PTHrP. Absence of either p57, or p107 and p130, causes partial reversal of the accelerated chondrocyte differentiation that occurs in PTHrP null mice. In the tibia, ulna, vertebrae and ribs of PTHrP/p57 double knockouts, or PTHrP/p107/p130 triple knockouts, the region of chondrocyte proliferation is expanded compared to PTHrP null littermates. There is a concomitant reversal of the accelerated differentiation that occurs in the PTHrP knockouts. The onset and extent of expression of hypertrophic chondrocyte markers including collagen X, are relatively normal compared to the early, expanded expression seen in PTHrP knockouts. The ulna, vertebrae and ribs of double and triple knockouts also show partial restoration of the zones of round and columnar proliferating chondrocytes, that are reduced in the PTHrP null. These results indicate that loss of either p57, or p107 and p130, can partially compensate for the absence of PTHrP *in vivo*. This suggests a potential model in which PTHrP is upstream of p57, p107 and p130, with PTHrP acting in part through down-regulation of these negative cell cycle factors.

Targeted Disruption of the PTH Gene Leads to Abnormalities in Skeletal Development and Calcium Homeostasis. D. Miao,[1] B. He,*[1] B. Lanske,[2] D. Goltzman,[1] A. C. Karaplis.[1] [1]Dept. of Medicine, McGill University, Montreal, PQ, Canada, [2]Molecular Endocrinology, Max-Planck-Institut für Biochemie, Munich, Germany.

Parathyroid hormone (PTH) and parathyroid hormone-related peptide (PTHrP) bind to and activate the same PTH/PTHrP receptor. Targeted disruption of either the PTHrP gene or the PTH/PTHrP receptor gene leads to acceleration of differentiation of growth plate chondrocytes. To explore further the functional relationships of PTHrP, PTH, and the PTH/PTHrP receptor, we deleted the PTH gene using embryonic stem cell technology and investigated the consequences associated with PTH deficiency. Heterozygous mice were phenotypically normal. Crosses between these animals produced mice homozygous for the null PTH allele at the predicted Mendelian frequency. Although severe hypocalcemia and lethality were anticipated based on studies of Gcm2-null animals, over 95 percent of PTH-deficient mice were viable and had mild to moderate hypocalcemia and hyperphosphatemia associated with complete absence of circulating PTH, as determined by ELISA. Moreover, they developed normally and were fertile, although females had difficulty maintaining pregnancies and nursing their pups. Histological analysis of the parathyroids showed massive, diffuse enlargement of the glands consistent with their continuous stimulation by hypocalcemia. Since PTH has major effects on bone remodeling, we then analyzed the skeletons of PTH-negative animals at E18.5 and postnatally at 2, 4, 6 and 9 months of age. Cartilage development prenatally was characterized by a modest increase in the length of the growth plate compared to wild-type littermates, which was attributed primarily to an increase in the zone of hypertrophy. These changes, however, were not evident at any of the post partum periods examined and there were no other cartilage abnormalities. In mutant fetuses, trabecular bone volume was decreased whereas cortical thickness was increased. Postpartum, however, both trabecular and cortical bone consistently increased, and were associated with a low turnover state.These findings indicate that: first, in view of the normal viability of the mutant mice, the PTH gene is unlikely to encode the only thymus-derived calcium regulating factor; second, the effect of PTH on cartilage plate development prenatally is distinct from that of PTHrP and diminishes postpartum; and third, PTH exerts influences on bone remodeling which differ in the fetus and in growing animals. In the fetus, PTH appears to be necessary for promoting trabecular bone formation while limiting the development of cortical bone, whereas in the postpartum period it is required for establishing normal bone turnover and sustaining calcium homeostasis.

The Transcription Factor C/EBP beta Promotes the Differentiation of Pluripotent Mesenchymal Stem Cells toward Osteoblasts. K. Hata, F. Ikeda,* T. Hiraga, K. Yamashita,* T. Nokubi,* R. Nishimura, T. Yoneda. Biochemistry, Osaka University Graduate School of Dentistry, Osaka, Japan.

C/EBP beta (C/EBPb) is a transcription factor which plays a contributive role in controlling the differentiation of mesenchymal stem cells into adipocytes in cooperation with PPAR gamma and C/EBP delta. Accumulating evidence that the mesenchymal stem cells are pluripotent and capable to differentiate into osteoblasts as well as adipocytes raises the possibility that C/EBPb also plays a role in osteoblastic differentiation. We studied this yet-unexplored hypothesis using the C3H10T1/2 pluripotent mesenchymal stem cells which differentiate into osteoblasts and adipocytes in the presence of appropriate stimuli. Osteoblastic and adipocytic differentiation were assessed by determining alkaline phosphatase activity and oil-red O staining, respectively. Upon treatment with BMP2, C3H10T1/2 cells showed osteoblastic and adipocytic differentiation with up-regulated C/EBPb expression. Overexpression of C/EBPb using an adenovirus vector induced not only adipocytic but also osteoblastic differentiation in the absence of BMP2. Promotion of osteoblastic differentiation by C/EBPb was enhanced in the presence of BMP2 or by co-infection of Smad1 and Smad4, whereas Smad6 blocked it. Moreover, co-infection of Cbfa1 with C/EBPb enhanced the osteoblastic differentiation, while dominant-negative Cbfa1 blocked it, suggesting an interaction between C/EBPb and Cbfa1. Consistent with this notion, we found that there was a physical association between C/EBPb and Cbfa1 as determined by co-immunoprecipitation experiments and that C/EBPb together with Cbfa1 activated osteocalcin gene transcription using a luciferase reporter construct. To further define the role of C/EBPb in the osteoblastic differentiation, we next examined the effects of a naturally-occurring isoform of C/EBPb ,LIP, which inhibits intact C/EBPb in a dominant-negative fashion. Surprisingly, introduction of LIP in C3H10T1/2 cells promoted osteoblastic differentiation in the absence of BMP2 and this effect was enhanced in the presence of BMP2 or by Cbfa1 overexpression. LIP also formed a complex with Cbfa1. Of note, LIP inhibited adipocytic differentiation induced by BMP2 or overexpression of C/EBPb and C/EBPdelta. In conclusion, our results suggest that C/EBPb, which has been thought to be an adipogenesis-regulating transcription factor, also promotes osteoblastic differentiation of mesenchymal stem cells with or without collaboration with Smad and Cbfa1. The results also suggest that the isoform of C/EBPb, LIP, may play a key role in directing the differentiation of the mesenchymal stem cells toward osteoblasts and adipocytes.

Col1a1 Promoter-Targeted Expression of p20C/EBPbeta, a Truncated C/EBPbeta Isoform, Causes Osteopenia in Transgenic Mice. J. R. Harrison,*[1] P. L. Kelly,*[1] Y. Huang,*[2] D. J. Adams,*[3] M. Nahounou,*[3] G. Gronowicz,[3] S. H. Clark.*[4] [1]Department of Orthodontics, University of Connecticut Health Center, Farmington, CT, USA, [2]Department of Oral Diagnosis, University of Connecticut Health Center, Farmington, CT, USA, [3]Department of Orthopedics, University of Connecticut Health Center, Farmington, CT, USA, [4]Department of Genetics, University of Connecticut Health Center, Farmington, CT, USA.

Osteoblasts (OB) and adipocytes (AD) share a common progenitor in bone marrow, and C/EBP transcription factors are known to promote AD differentiation. We therefore hypothesized that overexpression of dominant negative p20C/EBPbeta in pluripotent progenitors might enhance OB differentiation by blocking adipogenesis. A construct was prepared in which the 3.6 kb Col1a1 promoter and first intron drive expression of FLAG-tagged p20C/EBPbeta. Previous studies have shown that pOBCol3.6 is expressed early in the OB lineage, prior to expression of differentiated OB markers. Four lines of pOBCol3.6-FLp20C/EBPbeta transgenic (TG) mice were established. Analysis of FLp20C/EBPbeta mRNA expression indicated that the transgene is targeted to bone, with low levels of expression in lung, skin and adipose tissue. Line 00-63 TG mice were obtained in Mendelian ratios, whereas survival was around 72% in lines 00-50-9 and 00-50-10, and 23% in line 00-65. TG mice from lines 00-50-10 and 00-65 were reduced in size compared to wild-type (WT) littermates, while lines 00-50-9 and 00-63 were of normal size. The abdominal fat pads in line 00-50-10 and 00-65 TG mice were noticeably reduced, indicating that adi-

pogenesis was inhibited. These lines also showed a dental phenotype manifested by malocclusion, overgrowth and breakage of incisors. Surprisingly, all four lines of TG mice showed evidence of osteopenia ranging from moderate to severe. By microCT, femoral trabecular bone volume (TBV) at 6 weeks of age was 19% in WT mice, compared to 10%, 5% and 1.5% in TG mice from lines 00-63, 00-50-10 and 00-65, respectively. TBV in line 00-50-9 TG mice was not different from WT at 6 weeks, but histomorphometry on 5 month-old TG mice revealed a significant decrease in trabecular bone area. No increase in osteoclast number per unit bone surface was observed in the lines examined (00-50-9 and 00-50-10), suggesting that osteopenia is not due to increased bone resorption. Moreover, long bones and calvariae of TG mice showed reduced OB marker mRNA levels, including COL1A1 and osteocalcin, consistent with an inhibition of bone formation in this model. These data suggest that C/EBP transcription factors, which are known regulators of AD differentiation, might also function as important determinants of OB differentiation and bone mass.

The Role of Infection in Gender Differences in Mortality after Hip Fracture. L. E. Wehren,[1] W. Hawkes,*[1] D. L. Orwig,*[1] J. R. Hebel,*[1] S. I. Zimmerman,*[2] J. Magaziner.[1] [1]University of Maryland Baltimore, Baltimore, MD, USA, [2]University of North Carolina, Chapel Hill, NC, USA.

At present, men sustain 25-30% of all hip fractures and are approximately twice as likely to die during the 1 to 2 years following hip fracture as women. In a cohort of 804 community-dwelling men and women in the Baltimore Hip Studies, this difference was not explained by differences in age, pre-fracture functional ability or comorbid illness, type of fracture or surgery, or postoperative complications. The objective of this report is to compare cause-specific mortality during the 2 years following hip fracture for men and women. Overall mortality was relatively greater for men than women when compared to age- and gender-specific mortality in the general, with the most marked difference seen during year 1. Among men, the largest increases in cause-specific mortality relative to the general population of males aged 65+ were seen in infections: pneumonia, influenza, and septicemia. To determine whether gender differences in cause-specific mortality exist, death certificates for women from this cohort who died within 2 years of hip fracture were reviewed and death rates compared to cause-specific rates for the general population of females aged 65+. As had been seen for men, rate ratios for women were highest for septicemia and pneumonia/influenza during year 1, with some decline in year 2. If deaths due to these infections are omitted, mortality for men and women after fracture is much more similar and excess mortality is limited to the first year after fracture. Deaths attributable to infection appear to explain the gender difference in mortality in these elderly patients. These results suggest that immune competence may be differentially compromised in men and women after fracture, and that increased surveillance for infection may be warranted for both genders. Rate ratios (95% CI) for death compared to general population aged 65+

		Year 1	Year 2
All cause	Men	5.19 (2.77, 9.74)	1.31 (0.69, 2.47)
	Women	3.24 (2.18, 4.82)	1.55 (1.01, 2.38)

Recombinant Human Parathyroid Hormone (1-34) Therapy Reduces the Incidence of Moderate/Severe Vertebral Fractures in Men with Low Bone Density. E. Orwoll,[1] W. H. Scheele,*[2] A. D. Clancy,*[2] S. Adami,*[3] U. Syversen,*[4] A. Diez-Perez,*[5] S. L. Myers,*[2] B. H. Mitlak.[2] [1]Oregon Health Sciences University, Portland, OR, USA, [2]Eli Lilly and Company, Indianapolis, IN, USA, [3]University of Verona, Valeggio sul Mincio (VR), Italy, [4]University Hospital, Trondheim, Norway, [5]Hospital del Mar, Barcelona, Spain.

Recombinant human parathyroid hormone (1-34) [rhPTH(1-34)], given once daily, increased vertebral bone mineral density (BMD) and reduced vertebral fractures by 65-69% in postmenopausal women with osteoporosis (19-month median PTH exposure). Osteoporosis is common in men but there have been few large trials of therapies to prevent fractures in men. Thus, we performed a randomized, double-blind, placebo-controlled clinical trial of the effects of rhPTH(1-34) on bone mineral density in 437 men (mean age 59 yr) with spine or hip BMD >2 SD below male young adult mean. Men were randomly assigned to receive either placebo (n=147), PTH 20µg/day (n=151) or PTH 40 µg/day (n=139) by once-daily subcutaneous injections. The median study drug exposure was 11 months. After stopping therapy, 81% (355) of the men volunteered for an 18-month observation study of subsequent effects on BMD (data not shown) and fractures. During treatment and observation periods, all subjects received daily calcium and vitamin D supplements. Other osteoporosis treatment use was reported by 22% (79/355) of the men (placebo, 29%; PTH20, 16%; PTH40 22%) during the observation period. Vertebral fracture incidence was assessed from lateral spinal radiographs using a semi-quantitative grading score in 269 men with radiographs at both the original study baseline and 18 months after discontinuation of rhPTH(1-34) (placebo, 101; PTH20, 87; PTH40, 81). At baseline, 41% of the men had ≥1 prevalent vertebral fractures. During the entire study period (median 30 months), 22 men had at least one new vertebral fracture [placebo =12 (12%) and combined PTH = 10 (6%)]. For the combined PTH treatment groups, the relative risk of new vertebral fractures was 0.50 (P=0.086; 95% CI, 0.23-1.12), comparable to that found in women during a similar observation period (RR=0.53; P<0.001; 95% CI, 0.42-0.68). There were fewer men with moderate or severe vertebral fractures in the PTH treatment groups than in placebo [placebo=7 (7%); combined PTH =2 (1%)]; relative risk 0.17 (P=0.029; 95% CI, 0.04-0.81). Therefore, rhPTH(1-34) treatment over 11 months significantly reduced the risk of moderate or severe vertebral fracture during a 30 month period including 18 months following discontinuation of parathyroid hormone treatment. rhPTH(1-34) is an effective therapy for osteoporosis in men.

1105

Incident Vertebral Fractures During an 18-Month Observation Period Following Discontinuation of LY333334 [Recombinant Human Parathyroid Hormone (1-34), rhPTH(1-34)] Use in Postmenopausal Women with Osteoporosis. R. Lindsay,[1] W. H. Scheele,*[2] A. D. Clancy,*[2] B. H. Mitlak.[2] [1]Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Eli Lilly and Company, Indianapolis, IN, USA.

In a controlled clinical trial, 20 (PTH20) or 40 (PTH40) µg of parathyroid hormone (1-34) [rhPTH(1-34)] was shown to significantly reduce vertebral fractures by 65-69% in 1637 postmenopausal women with osteoporosis (19-month median PTH exposure). Lumbar spine bone mineral density (BMD) increased from baseline by 1.1% in the placebo group, compared with significant increases of 9.7% and 13.7% with PTH use (P<0.001). Of the original study population, 77% (1262/1637) of the women volunteered for an 18-month observation study to determine the effects of discontinuation of PTH on vertebral bone density and fractures. At 6 months after discontinuation of therapy, 29% of the women reported use of other forms of osteoporosis therapy; by 18 months after discontinuation, 54% of the women (57%, 53%, 52% for placebo, PTH20, PTH40, respectively, P=0.35) reported use of other therapies. Use of other treatments was permitted based on the treating physician's judgment. The primary analysis for incident vertebral fractures was performed without adjusting for other prescriptions. Vertebral fracture incidence was assessed from lateral spinal radiographs using a semi-quantitative grading score (Genant et al. JBMR 1993) in 1043 women with radiographs from original study endpoint and 18-month observation period. During the treatment period (baseline to 21 months), participants had an absolute risk reduction for ≥1 incident vertebral fracture of 9% and 10% for PTH20 and PTH40, respectively, and after an additional 18 months of observation (baseline to 39 months), the absolute risk was 13% for each PTH group. For new moderate and severe fractures, the absolute risk reduction was 8% and 6% for PTH20 and PTH40, respectively, after the 21-month treatment period. For moderate or severe incident vertebral fractures during the 39-month period (21 months treatment plus 18 months observation), the absolute risk reduction was 11% for both PTH study groups. Therefore, there is evidence of durable effects of treatment of rhPTH(1-34) for vertebral fracture efficacy even after treatment is stopped.

The Calcimimetic AMG 073 Reduces Serum Calcium (Ca) in Patients with Primary Hyperparathyroidism (PHPT). M. Peacock,[1] D. M. Shoback,[2] W. E. Greth,[3] T. A. Binder,*[4] T. Graves,*[4] R. M. Brenner,*[4] S. A. Turner,*[4] R. Marcus.[5] [1]Indiana Univ Sch Med, Indianapolis, IN, USA, [2]SF Veterans Affairs Med Ctr, UCSF, San Francisco, CA, USA, [3]Clinical Research Ctr of Reading, LLP, Reading, PA, USA, [4]Amgen Inc., Thousand Oaks, CA, USA, [5]Veterans Affairs Med Ctr, Palo Alto, CA, USA.

Calcimimetics reduce PTH secretion, and subsequently serum Ca, by increasing the sensitivity of the parathyroid calcium-sensing receptor to extracellular Ca. In a prospective, double-blind, 24 week trial, 78 patients with PHPT and Ca levels > 10.3 mg/dL and ≤ 12.5 mg/dL were randomized to receive twice daily oral doses of 30 mg AMG 073 or placebo. Twenty-three percent of patients had recurrent PHPT after surgical parathyroidectomy. Patients were dose titrated to a maximum dose of 50 mg bid AMG 073/placebo to achieve a serum Ca within the normal range. They were then treated with a fixed dose for 12 weeks in a maintenance phase (MP). The effects of AMG 073 and placebo on predose serum Ca are shown (Figure 1). The normal range is shaded. In the AMG 073 group, 88% of patients ("responders") experienced a reduction in predose serum Ca of at least 0.5 mg/dL and a mean predose serum Ca over the MP of ≤ 10.3 mg/dL as compared with 5% of placebo-treated patients (Figure 2). Maximum reductions in mean PTH were observed 2 to 4 hours after AMG 073 dosing (approx. 50%). During the MP, there was a 7.6 (± 22.9)% reduction in mean (SD) PTH at 12 hours post-dose in the AMG 073 group as compared with an increase of 7.7 (± 26.6)% in the placebo group (p=0.009). No differences between the two groups were observed in the change from baseline in 24-hour urine calcium/creatinine ratio.In this 24-week study of patients with PHPT, AMG 073 was well-tolerated; adverse events were similar in the two treatment groups. In this study, AMG 073 effectively reduced serum Ca to the normal range with concurrent reductions in PTH in patients with PHPT.

Antifracture Efficacy of Risedronate: Prediction by Change in Bone Resorption Markers. R. Eastell,[1] I. Barton,[2] R. A. Hannon,[1] P. Garnero,[3] A. Chines,[2] S. Pack,[2] P. D. Delmas.[3] [1]Bone Metabolism Group, Division of Clinical Sciences (North), University of Sheffield, Sheffield, United Kingdom, [2]Procter and Gamble Pharmaceuticals, Cincinnati, OH, USA, [3]INSERM, Lyon, France.

The early decrease in vertebral fracture risk with antiresorptive therapy could be explained by the early decrease in bone resorption markers. We have tested this directly by measuring the bone resorption marker, N-telopeptide of type I collagen (NTX) in the VERT study. We studied 2442 women with at least one vertebral deformity (mean age, 69 years, SD 7) who were treated with calcium supplement (and vitamin D if required) and placebo or risedronate 5 mg/day for 3 years. Samples were collected at baseline, 3 and 6 months on a subset of 28% of the total. We measured NTX in second morning void urine samples using an automated immunoassay analyser (Ortho Clinical ECi, CV<4%) and expressed the result as a ratio to creatinine. Vertebral fracture was assessed by morphometric and semiquantitative approaches (with adjudication in discrepant cases)-the overall reduction over the 3 years was 43%. We examined the relationship between NTX/Cr and fracture risk using non-parametric (Classification and Regression Tree, CART) and parametric (logistic regression) analyses. The median NTX/Cr at baseline was 70 nmol BCE/mmol and the median decrease at 6 months with calcium and placebo was 22% and with calcium and risedronate 55%. A baseline NTX/Cr of more than 49 nmol BCE/mmol in the calcium and placebo group (or more than 64 in the calcium and risedronate group) predicted increased risk of fracture (CART analysis P<0.05). There was a significant association with decrease in NTX/Cr at 3 months in the calcium and risedronate group (logistic regression, P<0.05). This predicted that for a 30% reduction in NTX/Cr (placebo vs. risedronate difference) there would be a 17% decrease in vertebral fracture risk. Thus, 40% of the effect of risedronate on vertebral fracture risk could be explained by the change in NTX/Cr at 3 months (17%/43%=40%). The relationship between the change in NTX/Cr and fracture risk was best fit by a cubic logistic regression model, especially at the 6-month time point. There was little further improvement in fracture benefit below a decrease of 60% in NTX/Cr. Thus high bone resorption predictes increased vertebral fracture risk in the placebo group; decrease in bone resorption markers predict up to 40% of the effect of risedronate on vertebral fracture risk; there may be no further benefit in decreasing bone resorption to very low levels.

Fall Prevention by Vitamin D and Calcium Supplementation: A Randomized Controlled Trial. H. A. Bischoff,[1] H. B. Staehelin,*[2] W. Dick,*[3] R. Akos,*[3] R. Theiler,[4] M. Pfeiffer,[5] B. Begerow,[5] R. A. Lew,*[1] M. Conzelmann.*[6] [1]Rheumatology, Immunology and Allergy; the Robert B. Brigham Multipurpose Arthritis Center, Brigham and Women's Hospital, Boston, MA, USA, [2]Geriatrics, University Basel, Basel, Switzerland, [3]Orthopeadics, University Basel, Basel, Switzerland, [4]Rheumaltology, Kantonsspital Aarau, Aarau, Switzerland, [5]Institute for Clinical Osteology, Bad Pyrmont, Bad Pyrmont, Germany, [6]Geriatrics, Felix Platter Spital, Basel, Switzerland.

We prospectively studied the combined effect of vitamin D and calcium supplementation upon the risk of falling and muscle strength in the elderly. In a double-blind randomized controlled trial we studied 122 elderly women in long-stay geriatric health care institutions (mean age in years: 85.3; range: 63-99). Falls were recorded for a 6 week pretreatment and for a 12 week treatment period. Subjects received either 1200 mg calcium plus 800 IU cholecalciferol (Cal+D-group; n = 62) or 1200 mg calcium (Cal-group; n = 60) per day. Poisson-adjusted number of falls (having 0, 1, 2-5, 6-7, >7 falls) were compared between groups. Adjustments were performed for observation time during treatment, number of falls during the pretreatment period, number of fallers during the pretreatment period, age, body mass index, days in the institution before study entry, use of a walking aid, Folstein Mini Mental Status, Charlson Comorbidity Index, number of medications, baseline 25-hydroxyvitamin D, baseline 1,25-dihydroxyvitamin D and baseline musculoskeletal function, expressed as a summed score of knee flexor and extensor strength, grip strength and the timed up&go test. Before treatment, 22 falls occurred in the Cal+D-group and 20 in the Cal-group. After treatment, there were 25 falls in the Cal+D-group and 55 in the Cal-group. The Cal+D treatment accounted for a 49% reduction of falls (95% Confidence Interval [14%; 71%]; p < 0.01). Also, musculoskeletal function improved significantly in the Cal+D-group (p = .0094). Among subjects in the Cal+D-group, there were significant increases in median serum 25-hydroxyvitamin D (+ 71%) and 1,25-dihydroxyvitamin D (+ 8%), respectively significant decreases in serum iPTH (-29%), alkaline phosphatase (-7%), urinary dpd (- 30%) and urinary N-telopeptides (-26%). A single intervention with vitamin D plus calcium over a 3 month period reduced the risk of falling by 49%. This effect could be explained by an improvement in musculoskeletal function.

BMP-antagonist Sclerostin is Expressed in Mineralized Bone and Blocks BMP-induced Bone Formation In Vitro. R. L. van Bezooijen,[1] M. Karperien,[1] A. Visser,*[1] H. Hamersma,*[2] D. Winkler,*[3] T. Hayes,*[3] J. Skonier,*[3] K. Staehling-Hampton,*[3] J. A. Latham,[3] S. E. Papapoulos,[1] C. W. G. Lowik.[1] [1]Dept. of Endocrinology, Leiden Univ. Med. Center, Leiden, The Netherlands, [2]Florida Park, Roodepoort, South Africa, [3]Celltech, Bothell, WA, USA.

Sclerosteosis is a skeletal dysplasia characterized by progressive skeletal overgrowth. Bone formation is largely increased while resorption is not affected or slightly inhibited. Sclerosteosis results from loss of the SOST gene product sclerostin, a protein that shares similarity with cystine knot-containing factors belonging to the BMP-antagonist family. In the present study, we studied SOST expression in relation to bone formation and the effect of sclerostin on BMP-activity.Mouse bone marrow cells and osteoblastic KS483 cells were cultured under bone formation inducing conditions (ascorbic acid and beta-glycerophosphate). In these cultures, SOST mRNA expression was found after induction of osteocalcin mRNA expression and onset of mineralization, i.e. from day 14 and 17 onwards in KS483 and mouse bone marrow cultures, respectively. In human bone marrow cultures, which form a mineralized matrix without nodules in the presence of ascorbic acid, beta-glycerophosphate, and dexamethasone, SOST mRNA was at low levels and less clearly expressed, but tended to be higher after onset of mineralization. Stimulation with BMP-4 (50 ng/ml) or BMP-6 (100 ng/ml) induced SOST mRNA expression after 24 and 72 hours in undifferentiated human bone marrow cells.Alkaline phosphatase (ALP) activity induced by BMPs was blocked by recombinant sclerostin produced by SF-9 cells. Sclerostin blocked BMP-6 (100 ng/ml)-induced ALP activity dose-dependently with an IC50 of 100 ng/ml. Sclerostin, up to 5 µg/ml, decreased BMP-4 (50 ng/ml)-induced ALP activity by only 56%.Expression of SOST mRNA was further studied by in situ hybridization (ISH) in fetal and neonatal bones and by RT-PCR in adult bone. In 17.5-day-old mouse embryos, SOST expression was found in all mineralized bones of both intramembraneous and endochondral origin. The other tissue with significant SOST mRNA expression were arteries adjacent to the heart. In 5-day-old neonatal radii and ulnae, expression was again found within mineralized bone. Finally, SOST expression was found in RNA isolated from tibia of adult mice and a human femur head.In summary, in vitro and in vivo SOST mRNA expression data suggest that expression of sclerostin is restricted to embryonic and adult mineralized bone, possibly by mature osteoblasts and/or osteocytes. Blocking of BMP-induced ALP activity by sclerostin in osteoblastic KS483 cells suggests that increased bone formation in sclerosteosis is due to unopposed anabolic BMP activity.

JAB1 Promotes Smad4 Degradation through Proteasome-Ubiquitin Pathway. M. Wan, X. S. Cao,* Y. Wu,* S. Bai, L. Wu,* X. Shi, X. Cao.* Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Smad4 is the common mediator in the TGF-β, activin and BMP signaling pathways. Degradation of Smad proteins is an important means of regulating functional activity in the TGF-β superfamily. Smurfs have been shown to mediate the degradation of both regulatory Smads (R-Smads) and inhibitory Smads (I-Smads), but not common partner Smad4. The regulation of Smad4 protein steady-state level remains unknown. Here we report the mechanism of Smad4 degradation. JAB1 (a protein initially identified as a co-activator of c-Jun) directly interacts with Smad4 and induces its ubiquitination for degradation. To examine the mechanism of JAB-1 that opposes TGF-β activity, we tested potential interaction between JAB-1 and Smads in yeast two-hybrid assays. Results of β-gal activity indicated that JAB-1 interacts with Smad4, but neither Smad1 nor Smad3. We then examined the effects of the interaction on endogenous Smad4 steady-state level. HA-JAB1 expression plasmid was transfected in Mv1Lu cells treated with or without TGF-β. We found JAB1 dose-dependently down-regulates Smad4. Lactacystin and LLM, inhibitors of the 26S proteasome, were found to inhibit degradation of Smad4, indicating that Smad4 is targeted for degredation by JAB1 through the ubiquitin-proteasome pathway. Moreover, pulse-chase assay was also performed to detect the effect of JAB1 on Smad4 stability. JAB1 largely enhanced the protein degradation rate of newly synthesized proteins. Again lactacystin treatment of COS-1 cells transfected with JAB1 yielded a decrease in the rate of protein degradation of newly synthesized proteins in comparison with untreated cells. Proteins destined for degradation by the 26S proteasome are marked by covalent attachment of ubiquitin chains, which can be recognized by the 26S proteasome. Therefore, we examined whether JAB-1 induces ubquitination of Smad4. Conjugated ubiquitin of Smad4 is detected when cells are transfected with ubiquitin expression plasmid together with HA-JAB1, confirming that the degradation of Smad4 by JAB1 is through proteasome-ubiquitin pathway. Finally, we determined the functional relevance of JAB1-mediated Smad4 down-regulation by luciferase assay. As we expected, JAB1 dose-dependently inhibited TGF-β-induced gene transactivation in Mv1Lu cells. Our data suggest that JAB-1 antagonizes TGF-β function by inducing degradation of Smad4 through Proteasome-Ubiquitin Pathway. These findings suggest that JAB1 may play a critical role in regulating cell proliferation and cell differentiation in response to TGF-β and BMP through a distinct degradation pathway.

1111

Functional Analysis of GDF-6/BMP-13 During Skeletogenesis. L. W. Gamer,*[1] K. A. Cox,[1] G. Hattersley,[2] V. Rosen.[3] [1]Genetics Institute, Cambridge, MA, USA, [2]Millenium Pharmaceuticals, Cambridge, MA, USA, [3]Forsyth Institute, Boston, MA, USA.

Bone Morphogenetic Proteins (BMP) and Growth and Differentiation Factors (GDF) play important roles in formation of the embryonic skeleton. During limb development, Gdf-5 is expressed in the interzone of all joints while the highly related Gdf-6/Bmp-13 localizes only to the forming wrists and ankles. Gdf-5 has been shown to be essential for appendicular skeletal development, acting during the initial stages of chondrogenesis to promote cell adhesion and later during joint formation to control the growth of the epiphyseal cartilages. While mutations in the Gdf-5 gene in mice in humans have identified a direct role for Gdf-5 in skeletal patterning, the role of Gdf-6/Bmp-13 in the skeleton remains unclear. To understand the function of GDF-6/BMP-13 in the appendicular skeleton, we overexpressed the protein in chick limb by bead implantation. BMP-13 increased the size of the cartilage elements but did not cause the induction of ectopic of joint tissue. Mesenchymal cells around the BMP-13 bead appeared disorganized and immature and in situ hybridization studies revealed that BMP-13 caused a delay or disruption of chondro-

cyte maturation as measured by reduced levels of ihh and collagen type X. Unlike GDF-5, BMP-13 did not induce more cartilage by increasing cell number. Instead, BMP-13 treatment appeared to divert mesenchymal cells into the chondrocyte lineage, as we saw an inhibition of the muscle marker, MyoD in BMP-13 treated limb after 24 hrs. We next looked at the pathway of BMP-13 induced chondrogenesis by testing the effects of BMP-13 on MLB13MYC, a skeletal progenitor cell line. When MLB13MYC cells were treated with BMP-13 protein, they expressed cartilage markers collagen type II and aggrecan, but failed to express markers of more mature cells like ihh, PTH/PTHrP receptor, or collagen type X. Even at high doses and long culture periods, BMP-13 treatment did not result in a bone phenotype or the expression of joint markers such as chordin or Gdf-5. Our data indicate that BMP-13 induces more cartilage in the limb in two ways: early in limb formation it recruits stem cells into chondrocytes; and, later in limb development it delays chondrocyte maturation, resulting in radial thickening of the skeletal elements. In comparison, GDF-5 causes a similar enlargement of the skeletal elements through a different pathway, increasing proliferation and adhesiveness in the affected cartilage cells. Taken together, our data suggest that individual GDFs play multiple roles in the later stages of joint formation, functioning as secondary secreted signals from the interzone region that act on the adjacent cartilages to control their growth and differentiation.

An Osteoblast Phage Display Library Identifies TRIP to Have High Affinity for TRAP. J. E. Puzas, T. J. Sheu,* E. M. Schwarz, R. J. O'Keefe, R. N. Rosier. Orthopaedics, University of Rochester, Rochester, NY, USA.

In normal bone remodeling, bone resorption is coupled to bone formation at all sites in the adult skeleton. This coupling occurs in both a temporally and spatially coordinated fashion. In order to investigate the site specificity of this process, we have used a T7 phage-display library expressing proteins produced by osteoblasts to probe components of an osteoclast resorption surface. Our initial studies have documented that TRIP (TGF beta receptor interaction protein) has a very high affinity for the osteoclast lysosomal enzyme, TRAP (type V tartrate resistant acid phosphatase). The phage-display cDNA library utilizes T7 phage to express proteins from a cDNA osteoblast library. The phage are then used to detect specific protein-protein interactions with a biopanning technique. The target material is purified TRAP immobilized on plastic culture dishes. After 3 rounds of selection/amplification, individual clones are characterized by DNA sequencing. In order to test if TRAP could activate TGF beta signaling pathways we exposed osteoblasts to soluble TRAP and measured parameters of cell differentiation. We also transfected osteoblasts with a TGF beta reporter (P3TP-Lux) and a dominant negative type II TGF beta receptor construct to characterize the effect of TRAP on signaling. A mammalian two-hybrid system was used to verify the association between TRIP and TRAP. We sequenced the clones that demonstrated high affinity binding. The DNA sequence that demonstrated one of the highest affinities for TRAP was TRIP. TRIP is known to bind to the type II TGF beta receptor and modulate its activity. Our results show that both TGF beta and TRAP strongly stimulate alkaline phosphatase activity, osteoprotegerin expression and cbfa1 levels in osteoblasts. TRAP also strongly up regulates TGF beta reporter activity and this effect can be negated by the co-transfection of a dominant negative TGF beta type II receptor construct. Co-transfection of a gal-4 fusion protein containing TRIP with a VP16 fusion protein containing TRAP into MG-63 cells in a mammalian two-hybrid system demonstrated a positive protein/protein interaction between TRIP and TRAP. TRIP was selected from an osteoblast phage display library as having high affinity for TRAP (tartrate resistant acid phosphatase). This affinity was verified in a mammalian two hybrid system. Functionally, TRAP appears to activate the TGF beta signaling pathway and can mimic the effects of TGF beta on osteoblast differentiation. From these data we conclude that TRAP can have a growth factor-like effect in osteoblasts. Given its localization within resorption lacunae TRAP may act as a site-directing molecule for bone formation.

1113

c-fms and the αvβ3 Integrin Collaborate During Osteoclast Differentiation. R. Faccio,*[1] S. Takeshita,[1] D. V. Novack,[1] X. Feng,[1] A. Zallone,[2] F. P. Ross,[1] S. L. Teitelbaum.[1] [1]Pathology, Washington University, St. Louis, MO, USA, [2]Human Anatomy, University of Bari, Bari, Italy

While the αvβ3 integrin is important for osteoclast (OC) function we also find that the number of OCs generated, in vitro, from αvβ3-/- marrow macrophages is substantially diminished (10 fold, $p<0.001$). Thus, the αvβ3 integrin also modulates OC differentiation. Reflecting this differentiation arrest, RT-PCR demonstrates a decrease in calcitonin receptor (12 fold), TRAP (2 fold) and cathepsin K (3 fold) expression in αvβ3 deficient OCs precursors. Moreover, the mRNA level of microphthalmia, a transcription factor involved in formation of mature OCs, is also dampened in β3-/- cells (5 fold) after 3 days in culture. Interestingly, we find that, while high doses of RANKL have no effect, increasing the concentration of M-CSF from 10 ng/ml - to 100 ng/ml completely rescues the differentiation defect in β3-/- OC precursors, normalizing the number of TRAP positive cells, and restoring expression of the above OC markers. Thus, signals transduced by the M-CSF receptor, c-fms, and the αvβ3 integrin collaborate in osteoclast formation. To identify the residues within the β3 integrin responsible for its ability to compensate for c-fms, various β3 mutants were retrovirally transduced into the β3-/- OC precursors. While expression of wild type β3 integrin restores OC differentiation, deletion of the entire β3 integrin cytoplasmic tail abrogates this effect. Point mutational analysis demonstrates OC differentiation is mediated by S752 in the β3 cytoplasmic domain. We next turned to the component of c-fms critical for osteoclastogenesis in the absence of the β3 integrin. To this end, we retrovirally transduced OCs precursors with a chimeric receptor consisting of the external domain of the erythropoietin (Epo) receptor and the transmembrane and cytoplasmic domains of c-fms (EpoR/c-fms). Cells bearing this chimeric receptor differentiate into OCs in the presence of Epo and RANKL, without the necessity for M-CSF. In this circumstance, Epo activates c-fms mediated signals via the chimeric, but not endogenous, M-CSF receptor. We then mutated 6 tyrosines in the c-fms cytoplasmic tail of this chimeric receptor, a strategy known in other circumstances, to dampen M-CSF signaling. Only one EpoR/c-fms mutant, Y697F, differentially affects the osteoclastogenic capacity of β3+/+ and β3-/- cells. Specifically, while not impacting β3+/+ cells, this mutation diminishes the capacity of β3-/- macrophages to differentiate into OCs by 3 fold ($p<0.001$), even at high doses of Epo. Thus, c-fms, via Y697, and the β3 integrin, via S752, compensate for each other in the osteoclastogenic process.

The Crystal Structure of RANKL Reveals Determinants of Receptor-Ligand Specificity. J. Lam, C. A. Nelson,* F. P. Ross, S. L. Teitelbaum, D. H. Fremont.* Department of Pathology and Immunology, Washington University School of Medicine, Saint Louis, MO, USA.

To determine the precise structural elements of RANK ligand (RANKL) that mediate its osteoclastogenic properties, we have crystallized the ectodomain of murine RANKL and solved its structure. RANKL (158-316) crystallized by vapor diffusion as two forms: rhombohedral space group R3 with 7 molecules per asymmetric unit (ASU), arranged as 2 trimers with a seventh monomer situated on a 3-fold axis of rotational symmetry, creating an additional trimer; and orthorhombic space group $P2_12_12_1$ with 1 trimer per ASU. The structure of RANKL was solved by molecular replacement and refined to a resolution of 2.6 Å (crystallographic R factor 23.5% and R-free 28.0%). Each RANKL monomer comprises a β-sandwich conforming to a jellyroll topology, with 2 antiparallel β-pleated sheets formed by strands A, H, C, and F in one sheet, and strands B, G, D, and E in the other. The inner AHCF β-sheet forms the trimeric interface, while the BGDE β-sheet forms the outer surface. RANKL monomers self-associate tightly along a 3-fold axis of rotational symmetry to form a bell-shaped homotrimer, assembling such that one edge of the β-sandwich (strands E and F) in each monomer packs against the inner hydrophobic face of the AHCF β-sheet of the neighboring monomer. Importantly, within the TNF family, the RANKL structure displays unique conformations of the AA' (170-193), CD (224-233), DE (245-251), and EF (261-269) loops. These solvent-accessible surface loops and flanking regions of adjacent β-strands form unique structural patterns of electrostatic charge in two regions that may act as interfacial sites for the receptor RANK. To assess the biological relevance of this structural prediction, and to identify regions of RANKL that are necessary for biological activity, a structure-based mutagenesis was performed to delete a portion of the AA' loop (δ177-183), swap the AA' loop of RANKL with that of TNF (δLS), or induce a single amino acid substitution in the DE loop (I248D). The δ177-183 and δLS mutants demonstrate a 90-100% decrease in osteoclastogenic capacity relative to native RANKL, while the I248D mutant exhibits an 8-fold decrease in potency (100 ng/ml ED_{50} for I248D RANKL vs. 12 ng/ml ED_{50} for native RANKL). Furthermore, the morphology of osteoclasts generated with I248D RANKL does not recapitulate that of resorptive polykaryons generated with native RANKL. These observations confirm a critical role for the AA' and DE loops in conferring the osteoclastogenic capacity of RANKL. Such structural determinants of receptor-ligand specificity may be of relevance in the design of therapeutic compounds for osteopenic disorders.

1115

Integration of Age, Prevalent Fracture Status and DEXA Bone Density to Provide Precise 5 Year Risks of Fracture. R. L. Prince,[1] D. Doherty,*[1] S. S. Dhaliwal.*[2] [1]Dept. of Medicine, Univ. of Western Australia, Perth, Australia, [2]Dept. of Endocrinology and Diabetes, Sir Charles Gairdner Hospital, Perth, Australia.

Appropriate clinical care for osteoporosis is directed at management to prevent fractures occurring in the future. As with any disease the intervention must be appropriate to the risk. We have recently published precise 5-year risks of appendicular and axial fracture by age dichotomised by the presence or absence of previous fracture (Doherty et al Osteoporo. Int. 2001;12:16-23). We now include DEXA bone density measurement in the risk evaluation. Using data from Marshall et al (BMJ. 1996;312:1254-59) we have selected the total hip site as representative of the approach. At this site the change in risk per SD change in BMD is 2.6. We apportioned the population risk of fracture by bone density SD (Z score) taking into account the proportion of the population in each SD category. We then calculated the proportion of fracture patients in each Z score category. Finally we have illustrated the effects in a population of 75 to 79 year old women without prevalent spine fracture who have a 5-year risk of first clinical spine fracture of 3.3%.

SD group (Z score)	Relative risk of fracture (2.6/SD)	Proportion of total population	5 year Z score group risk (%) for a total population risk of 1%	5 year Z score group risk (%) for a total population risk of 3.3%
3.5 - 2.5	0.057	0.006	0.03	0.1
2.5 - 1.5	0.148	0.061	0.09	0.3
1.5 - 0.5	0.385	0.242	0.24	0.8
0.5 - -0.5	1.000	0.383	0.61	2.0
-0.5 - -1.5	2.600	0.242	1.59	5.3
-1.5 - -2.5	6.760	0.061	4.14	13.7
-2.5 - -3.5	17.576	0.006	10.77	35.5

Calculation of age specific fracture rates which include DEXA bone density Z scores and previous history of fracture provide a simple clinical tool to make treatment decisions in consultation with the patient. Large controlled trials have illustrated the treatment benefit of therapy in patients with a T score of –2.5 which corresponds to a Z score of –1 in 75 to 79 year old women. In these patients spine fracture rates are reduced by up to 50 % of baseline risk. Thus the absolute fracture risk reduction should be a saving of approximately 2.8 to 17.6 fractures per 100 women per 5 years depending on BMD category. Similar simple risk calculations can be made for other fracture sites at other ages. These calculations should aid clinical decision-making.

1116

Standardised Fracture Risk Criteria: Alternative to T-scores for Identifying Subjects at Risk. C. C. Glüer,[1] D. M. Reid,[2] R. Eastell,[3] D. Felsenberg,[4] C. Roux.[5] [1]University Hospital Kiel, Kiel, Germany, [2]University of Aberdeen, Aberdeen, United Kingdom, [3]University of Sheffield, Sheffield, United Kingdom, [4]Free University Berlin, Berlin, Germany, [5]René Descartes University, Paris, France.

Different diagnostic approaches identify different subjects as "osteoporotic" when using T-scores for diagnosis of osteoporosis. We developed standardised fracture risk criteria based on the probability of having a vertebral fracture as predicted by dual x-ray absorptiometry (DXA) or quantitative ultrasound (QUS). Probability of fracture *p(fx)* was modelled using age-adjusted logistic regression. We defined a standardised risk classification criterion p_{cc}, as the cut-off level of p(fx) at which the number of cases considered "at risk" ($p(fx)>p_{cc}$) approximates the true number of cases with prevalent deformities for the most predictive techniques. Using the same p_{cc} cut-off for all techniques we calculated sensitivity, specificity, and Kappa scores among techniques. To assess a technique's power for classification beyond age-related risk estimates, we derived a multiplicative model for the odds of having a fracture: ODDS (total) = ODDS (age) * ODDS (method). The equivalent Z-score derived from this model reflects the difference in BMD or QUS results (expressed in units of standard deviations of age-adjusted population variance) associated with a doubling of the risk of having a vertebral deformity. The model was tested using data from a population-based sample of 1236 women, (aged 55 to 80 years), 195 of whom had a prevalent vertebral fracture, who participated in the Osteoporosis & Ultrasound (OPUS) study. All subjects had DXA of the lumbar spine and the total hip and QUS of the heel on 4 devices (Lunar Achilles+, Osteometer DTU-one, Quidel/Metra QUS-2, and DMS UBIS 5000) and of the finger on one device (IGEA DBM Sonic BP). For a cut-off level of p_{cc} = 0.25, corresponding to a T=-2.5 at age 65 for BMDhiptot NHANES III data, the number of women classified as "at risk" of vertebral deformity was close to the true number with some techniques (Table). Applying our new technique resulted in Kappa scores ranging from 0.43 to 0.63 compared to 0.07 to 0.35 when using T-scores.

Technique	no."at risk"*	Sensitivity*	Specificity*	Equivalent Z-score
DXAspine	187	32%	88%	1.53
DXAhiptot	198	34%	87%	1.71
DXAhipneck	171	29%	89%	1.86
Achilles SOS	194	29%	87%	1.63
DTU-one SOS	187	28%	87%	1.88
UBIS 5000 SOS	185	29%	88%	1.83
QUS-2 BUA	167	28%	89%	2.12
DBM AD-SoS	165	22%	88%	2.92

*: "at risk" criterion: p(fx)>0.25 The new approach provides a coherent framework for fracture risk assessment across different techniques and reduces discrepancies in classification.

Disclosures: Igea,2; Quidel,2; Osteometer,2; DMS,2.

Distal and Mid-Shaft Tibia Bone Mass Assessment Using Peripheral Quantitative Computed Tomography (pQCT) in Healthy Children and Adolescents. L. J. Moyer-Mileur,* R. Roberts,* S. D. Ball.* Pediatrics, University of Utah, Salt Lake City, UT, USA.

This cross-sectional study used pQCT to evaluate the influences of age, gender, body size, and puberty on bone acquisition in healthy children and adolescents. The pQCT technique provides analyses of volumetric bone mineral density (vBMD, gm/cm^3) for total bone and bone compartments and bone strengthexpressed as polar strength strain index (PSSI, mm^2). Bone mass of the non-dominant tibia by pQCT (XCT 2000, Norland Medical Systems, Inc) was measured in 287 healthy Caucasian children and adolescents (166 girls; 121 boys; 4 to 19 y). Measurements were obtained at 4% and 66% from the distal end plate. The distal site (4%) assessed trabecular bone, and the mid-shaft site (66%) assessed total and cortical bone and muscle cross-sectional area (MCSA). Age, gender, weight, height, body mass index (kg/m2), and pubertal stage were recorded. Mean age, weight and height were 12.2 ± 4.2 y; 46.7 ± 21.7 kg, and 1.46 ± 0.2 m, respectively and pubertal stage distribution (Tanner 1-5) was 47%, 10%, 15%, 11%, and 17%, respectively. Age, gender, weight and height correlated with total, cortical, and trabecular bone mineral content (BMC, mg), bone area (BA, cm^2), vBMD, PSSI, and MCSA. Only cortical vBMD was influenced by puberty. Multiple regression found 69% of the variance in cortical vBMD explained by pubertal stage and age, 23.5% of the variance in trabecular vBMD explained by age and gender, and >75% of the variance in PSSI and MCSA explained by body weight ($p<0.001$). Boys had greater trabecular vBMD values than girls (317.9 vs 284.8 mg/cm^3; $p=0.001$) while total and cortical vBMD values were similar. Both genders had a 10% decrease in trabecular vBMD and 14% increase in total and cortical vBMD with age (Graph). We conclude that bone measurements by the pQCT technique provides information on bone acquisition, architecture, and strength that may prove useful in the assessment of normal bone growth and development as well as pediatric bone disease.

A Prospective Study of Dry Calcaneal Quantitative Ultrasound and Fracture Risk in Older Women: The Study of Osteoporotic Fracture. D. C. Bauer,[1] L. Palermo,[2] D. M. Black,[2] T. A. Hillier,[3] J. A. Cauley.[4] [1]Department of Medicine, UCSF, San Francisco, CA, USA, [2]Department of Epidemiology and Biostatistics, UCSF, San Francisco, CA, USA, [3]Kaiser Center for Health Research, Portland, OR, USA, [4]Department of Epidemiology, University of Pittsburgh, Pittsburgy, PA, USA.

Prospective studies have found that low calcaneal quantitative ultrasound (QUS) is associated with an increased risk of hip and non-spine fractures. Newer dry devices have not been evaluated prospectively. We studied the ability of a dry QUS device and BMD to predict fractures in older women as part of the Study of Osteoporotic Fractures (SOF).4,153 women (mean age 80.0 ± 4.6 yr.) were examined at four clinical centers. Duplicate calcaneal QUS measurements (Hologic Sahara) and femoral neck BMD (Hologic QDR 1000) were obtained. Calcaneal BMD (Dove Medical) was measured at 3 clinics. Subsequent hip and other non-spine fractures were documented by central review of x-rays or x-ray reports. The relationships between QUS, BMD, and fracture were examined with proportional hazard models adjusted for age and clinic; results are presented as relative risk (RR) with 95% confidence intervals (CI).Over a mean follow-up of 2.3 years, a total of 216 non-spine fractures were confirmed, including 41 wrist fractures and 39 hip fractures. Both low QUS and low BMD were associated with an increased risk of any non-spine fracture (Table), while only QUS was associated with wrist fracture risk, and only BMDfn was associated with hip fracture risk.In this study of very elderly women, calcaneal QUS measured with a dry device, and BMD measured at either the calcaneous or hip, were similarly associated with the short-term risk of any non-spine fracture. These preliminary findings suggest that dry QUS measurements do not predict hip fracture risk in this population, but these results need to be confirmed in other studies and with longer follow-up.

1119

Experimental Determination of Mechanical Failure Loads at the Femur, Spine and Radius, and their Correlation with DXA, QCT, pQCT, and Quantitative Ultrasound. F. Eckstein,[1] R. Mueller,[2] E. M. Lochmüller.*[3] [1]Musculoskeletal Research Group, Institute of Anatomy, München, Germany, [2]OBL, BIDMC and Harvard Medical School, Boston, MA, USA, [3]1. UFK, LMU, München, Germany.

The purpose of this study was to test the hypotheses that mechanical failure loads in elderly individuals display substantial heterogeneity among clinically relevant sites, that site-specific measurements permit to predict mechanical failure strength significantly better than non-site-specific analysis - even in situ with spatially variable soft tissue errors, and that ultrasound adds significant independent information to site-specific analysis. In 120 cadavers (age 80 ± 10.6 years, 78 female, 42 male), DXA measurements were obtained including intact soft tissues in the femur, lumbar spine, and distal radius. pQCT was performed at the distal radius and tibia, QCT at the lumbar spine, and quantitative ultrasound (QUS) at the calcaneus. The bones were then excised and mechanically tested to failure, using a material testing machine (Zwick 1445). The femora were tested in a side-impact configuration, two vertebrae (one thoracic, one lumbar) in axial compression (3-segment method), and the distal radius also in axial compression. The failure loads displayed only very moderate correlations among the femur, spine, and radius (r2 =30% to 37%). Site-specific in situ DXA predicted 53% (r2) of the variability in failure loads at the femur, 64% in the spine, and 71% in the distal radius. Spinal QCT (65%) and radial pQCT (69%) were equivalent to site-specific DXA, but pQCT at the distal tibia (16%) was significantly inferior ($p < 0.01$; Fischer z-transformation) to femoral DXA. Non-site-specific measurements displayed significantly ($p < 0.01$) lower correlations with failure loads at all sites. The correlation between QUS and failure load was 27% for the femur, 26% for the spine, and 35% for the radius. These coefficients were significantly ($p < 0.01$) lower than those for site-specific DXA, and they were either equivalent or inferior to non-site-specific DXA. In multiple regression models, QUS contributed significant information to site-specific data for failure loads of the distal radius, but not for the femur or spine. We conclude that loss of mechanical competence in osteoporosis is governed by strong regional variation and does not appear to represent a strictly systemic process. Site-specific measurements, therefore, predict mechanical strength significantly better that non-site specific measurements, despite spatially variable soft tissue errors. Quantitative ultrasound is able to add significant independent information to site-specific analysis in the radius, but not in the spine or femur.

1120

Vitamin D Status, Sex Hormone Binding Globulin, IGF-1 and Markers of Bone Turnover as Determinants of Bone Mass and Fractures in the Longitudinal Aging Study Amsterdam. P. T. A. Lips,[1] S. M. F. Pluijm,*[2] C. Popp-Snijders,[1] J. H. Smit.*[3] [1]Department of Endocrinology, Vrije Universiteit Medical Center, Amsterdam, The Netherlands, [2]EMGO-Institute, Amsterdam, The Netherlands, [3]Department of Sociology and Social Gerontology, Vrije Universiteit, Amsterdam, The Netherlands.

Endocrine diseases cause osteoporosis and fractures by increasing bone resorption and decreasing bone formation. The role of vitamin D status, parathyroid hormone (PTH), sex hormone binding globulin (SHBG), insulin-like growth factor 1 (IGF-1), and markers of bone turnover as determinants of bone mass and fractures was assessed in a cohort of 1350 community-dwelling women and men (≥ 65 years) from the Longitudinal Aging Study Amsterdam. Fasting blood and urine samples were obtained in 1995-96 and serum 25(OH)D, PTH, SHBG, IGF-1, osteocalcin and urinary deoxypyridinolin (DPD)/creatinine were measured by (radio)immunochemical methods. Broadband ultrasound attenuation (BUA) and velocity of sound (VOS) were measured in the heel using the CUBA Clinical instrument. Serum 25(OH)D was 53.2±24.1 nmol/l, serum PTH was 3.7±2.5 pmol/l, serum SHBG was 48.4±22.4 nmol/l, serum IGF-1 was 14±5 nmol/l, serum osteocalcin was 2.2±1.1 nmol/l and urine DPD/creat was 5.7±2.7 nmol/mmol. BUA of the heel was significantly predicted by serum 25(OH)D, IGF-1, SHBG, osteocalcin and urine DPD/creat ($P<0.001$). VOS through the heel was predicted by the same variables and serum PTH ($P<0.001$). Most associations remained significant after adjustment for age and sex. During 3 years of follow-up 88 subjects reported 108 fractures, i.e. 23 hip, 26 wrist and 59 other fractures. The following variables were associated with an increased fracture risk: serum 25(OH)D<30 nmol/l (vs >30 nmol/l) RR 1.65 (CI: 1.02-2.68); a high serum osteocalcin in men, RR 1.32 per SD increase (CI: 1.04-1.63); A high urinary DPD/creat, RR 1.30 per SD increase (CI:1.04-1.63). A high serum osteocalcin was protective, RR 0.78 per SD increase (CI: 0.62-0.98). In conclusion, the assessed biochemical variables are significant determinants of bone mass in elderly living in the community. A low serum 25(OH)D and high concentration of bone turnover parameters can predict fractures, whereas a high serum IGF-1 appears to be protective.

Genome Screen for Quantitative Trait Loci Contributing to Bone Mineral Density: Framingham Osteoporosis Study. D. Karasik,[1] R. H. Myers,*[2] M. T. Hannan,[1] D. R. Gagnon,*[3] L. A. Cupples,*[3] A. Herbert,*[2] D. P. Kiel.[1] [1]Hebrew Rehab Ctr for Aged & Harvard Med Sch, Boston, MA, USA, [2]Neurogenetics, BU Sch of Med, Boston, MA, USA, [3]Epidem/Biostat, BU Sch of Public Health, Boston, MA, USA.

To identify chromosomal regions that might be linked to normal bone mineral density (BMD), considered as a quantitative trait, we performed a genome-wide scan in a randomly ascertained set of 330 Caucasian families (1326 persons with BMD measures) from the population-based Framingham Osteoporosis Study. A set of 401 microsatellite markers (set 8A) spaced at a 10 cM average density throughout the genome were typed by the Mammalian Genotyping Service (Marshfield, WI). BMDs at lumbar spine, trochanter, femoral neck, and Ward's area, were adjusted for age, age2, body mass index, height, alcohol and caffeine consumption, calcium and vitamin D intake, smoking status, physical activity, and estrogen use in females, by each sex and generation, separately, and these adjusted measures were used for linkage analyses. A strong familial resemblance (heritability values between 0.526 and 0.633) was found for all sites. Two-point and multipoint quantitative linkage analyses were performed for each BMD site using the maximum likelihood variance components method as implemented in the computer package SOLAR. By two-point screening, loci of suggestive linkage were identified on chromosomes 6, 12, and 21. The maximum two-point LOD score was 2.41 for trochanter with D21S1446 (62 cM). Chromosome 6pter showed evidence of linkage with both femoral neck and lumbar spine BMDs, at D6S2427 (LOD score 2.20 and 1.88, respectively, 54 cM). Lumbar spine BMD was also linked to chromosome 12q23 with LOD score 2.08 (137 cM). Ward's area was weakly linked to D8S373 (LOD = 1.63, 164 cM).Multipoint linkage analysis revealed suggestive linkage of trochanteric BMD at a broad (~20 cM) interval on chromosome 21q, with the peak linkage located close to D21S1446 (LOD = 3.10). Another region of suggestive linkage was at chromosome 14q with lumbar spine BMD (LOD > 1.90, 50-52 cM). No significant multipoint linkage was shown for femoral neck BMD. For Ward's area, again low LOD was obtained at 8q24 in multipoint analysis (LOD = 1.76).Possible candidates in the chromosomal regions are bone morphogenetic protein 6 (BMP-6) at 6p24, osteoprotegerin at 8q24, and BMP-4 at 14q22. The region of large size on chromosome 21q (~20 cM) is suggestive of linkage but it is still premature to address candidate genes at the current time. To our knowledge, this is the largest genome screen to date for genes underlying normal variation in BMD in population sample and represents an important step toward identifying genes contributing to osteoporosis in the general population.

1122

A Large-Scale Whole-Genome Scan Suggests Several Genomic Regions Containing QTLs for BMD Variation. H. W. Deng,[1] F. H. Xu,*[1] H. Shen,*[2] H. T. Zhang,*[1] H. Y. Deng,*[2] T. Conway,[2] Q. Y. Huang,*[1] J. Chen,*[1] Q. H. Xia,*[1] Y. Z. Liu,*[1] Y. J. Liu,*[1] K. M. Davies,[2] R. R. Recker.[2] [1]Osteoporosis Research Center and Biomedical Sciences, Creighton University, Omaha, NE, USA, [2]Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Osteoporosis is an important health problem, particularly in the elderly women. Bone mineral density (BMD) is a major determinant of osteoporosis. We have set out to identify genomic regions that may contain QTLs underlying BMD variation using a whole-genome scan. For a sample of pedigrees that contains 1,249 sib pairs, 1,098 grandparent-grandchildren pairs and 1,172 first cousin pairs, we performed a whole-genome linkage scan using 400 microsatellite markers (with an average heterozygosity of ~0.75 and spaced ~10cM apart throughout the whole genome) from the ABI PRISMTM Linkage Mapping Set Version 2 (Applied Biosystems, Foster City, CA). Each pedigree was ascertained through a proband with BMD Z-scores < -1.28 or > 1.28 at the hip or spine, i.e., the proband belongs to the bottom or top 10% of the population BMD variation. For chromosomes 9-22 and chromosome X, the genotyping has been completed showing a rate of missing and error genotype data (determined by sample replication and pedigree consistency checks) of ~0.3%. For chromosomes 1-8, the genotyping has been finished with some repeat experiments to be done to reduce the missing and error data rate from the current ~3.0% to ~0.3%. Using the raw BMD values adjusted for age, sex, weight and other significant covarieties, we conducted two- and multi-point linkage analyses to identify genomic regions that may contain QTLs underlying BMD variation. Several genomic regions were identified. For example, the genomic region near the marker D3S1580 on chromosome 3 may contain a QTL for hip BMD variation (with two-point analysis LOD score of 2.14 and multi-point analysis LOD score of 1.99). The genomic region near the marker D12S1723 on chromosome 12 and marker D13S285 on chromosome 13 may contain QTLs for spine BMD variation (with two-point analysis LOD score of 2.17 and 1.77 and multi-point analysis LOD score of 2.96 and 2.38, respectively). The genomic regions identified will be subject to extension studies with more samples and denser markers for confirmation. Once confirmed, subsequent fine mapping studies will be pursued using methods we developed to pinpoint the QTLs to genomic regions smaller than 1cM for eventual identification of the major functional genes involved. The inconsistency of the genomic regions identified in this and earlier few reports was explored and explained, from statistical genetics point of view, in terms of sample size and statistical power in whole-genome linkage studies.

1123

A Quantitative Trait Locus on Chromosome 4p Influences Variation in Bone Mineral Density at the Wrist and Hip. B. D. Mitchell,*[1] C. M. Kammerer,[2] J. L. Schneider,*[2] S. A. Cole,*[2] J. E. Hixson,*[3] R. Perez,*[4] R. L. Bauer.[4] [1]Medicine, University of Maryland School of Medicine, Baltimore, MD, USA, [2]Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA, [3]University of Texas Health Science Center at Houston, Houston, TX, USA, [4]University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

The San Antonio Family Osteoporosis Study (SAFOS) was designed to identify the genetic determinants of bone mineral density in large Mexican American families. Between 1996 and 2000, a total of 898 individuals from 34 large families were recruited into the SAFOS. As part of this study, we conducted a genome-wide linkage analysis using 389 highly polymorphic microsatellite markers spaced approximately 9.9 cM apart to locate and identify quantitative trait loci (QTLs) that affect bone mineral density (BMD). These analyses are based on 657 subjects aged 20 years and over (399 women, 258 men) from the 23 largest families included in a genome scan. The mean age of study subjects was 42.7 yrs. We measured BMD using dual x-ray absorptiometry, at 11 skeletal sites: radius (3 sites), ulna (3 sites), femur (4 sites) and spine. Heritabilities of all traits ranged between 0.40±0.07 and 0.75±0.08. To locate quantitative trait loci (QTLs), we performed a multipoint genome scan using maximum-likelihood based, variance components linkage analysis methods. We obtained strong evidence that a QTL affects BMD of the radius midpoint and is located on chromosome 4p (multipoint lod= 4.05; empirically estimated p-value=0.00001). Peak evidence for linkage occurred at marker D4S2639 at position 40 cM from pter. Additionally, peak evidence for linkage to BMD at the hip (intertrochanter) was observed in this region (multipoint lod = 2.2). We found little evidence for QTLs affecting BMD at any site linked to chromosomes 1, 5, or 11, as has been reported in other studies. Interestingly, in men, but not women, there was moderate evidence for linkage (lod = 3.1, empirically estimated p-value=0.00008) to BMD at the hip (intertrochanter) to a region on chromosome 13 near marker D13S800, approximately 67 cM from pter, which has been linked to variation in forearm BMD in a previous study of Chinese families. We conclude that QTLs influencing variation in BMD may be located on chromosome 4p, and possibly on chromosome 13q.

Mapping of Quantitative Ultrasound of the Calcaneus to Chromosomes 1 and 5 by Genome-Wide Linkage Analysis. D. Karasik,[1] R. H. Myers,*[2] M. T. Hannan,[1] D. R. Gagnon,*[3] R. R. McLean,[1] L. A. Cupples,*[3] D. P. Kiel.[1] [1]Hebrew Rehab Center for Aged & Harvard Med Sch, Boston, MA, USA, [2]Neurogenetics Dept., BU Sch of Medicine, Boston, MA, USA, [3]Epidemiology/Biostat Dept, BU Sch of Public Health, Boston, MA, USA.

Quantitative ultrasound (QUS) may predict the risk of fracture independent of bone density. Evidence suggests that QUS phenotypes are largely determined by genetic factors, yet little is known of chromosomal localization of these gene(-s). The aim of this study was to identify, using quantitative trait linkage analysis, chromosomal regions that might contain genes influencing variation in calcaneal QUS in a set of families from the general population. To accomplish this aim, we conducted a genome-wide autosomal scan in 330 Caucasian families (1187 measured individuals) from the Framingham Osteoporosis Study, using a set of 401 Marshfield microsatellite markers with a 10 cM average density map. QUS measurements included broadband ultrasound attenuation (BUA), speed of sound (SOS), and quantitative ultrasound index (QUI). These phenotypes were regressed on age, age2, body mass index, height, alcohol and caffeine consumption, smoking status, physical activity, as well as estrogen use in females, by each sex and generation, separately. Standardized residuals were then used in the quantitative genetic analyses by the maximum likelihood variance components method (SOLAR package). Estimating familial resemblance of QUS phenotypes demonstrated a strong heritability ranging from 0.45 for SOS to 0.52 for BUA. By two-point genome screening, principal loci of possible linkage were identified on chromosomal regions 1p36.3 and 5p15.2. The maximum LOD score attained was 2.74 for BUA with D1S468 (4 cM) and 2.69 for SOS with D5S817 (23 cM). Both identified loci were phenotype-specific. QUI, a linear combination of the SOS and BUA, showed linkage with both markers: maxima were obtained for D1S468 (LOD = 2.1) and D5S817 (LOD = 2.2). Multipoint linkage analysis of BUA also revealed a peak linkage located close to D1S468 (LOD = 2.4). However, no indication of suggestive multipoint

linkage (LOD < 1.9 by Lander-Kruglyak criteria) was obtained with any chromosomal location for either SOS or QUI. The loci for QUS do not overlap with those seen in our genome scan for BMD in the same pedigrees. To our knowledge, this study is the only genome screen for QUS phenotypes in the general population, and our results suggest that there may be genetic determinants for QUS phenotypes separate from BMD. These results should encourage further investigations of the genetic source of QUS variability.

1125

Linkage Disequilibrium Mapping at Chromosome 1p36.2 for Bone Mineral Density. L. D. Spotila,[1] H. Rodriguez,*[2] M. Koch,*[2] S. Stoltzfus,*[2] W. Epley,*[2] H. S. Tenenhouse,[3] A. Tenenhouse.[4] [1]Bioscience and Biotechnology, Drexel University, Philadelphia, PA, USA, [2]Drexel University, Philadelphia, PA, USA, [3]McGill University, Montreal, PQ, Canada, [4]Montreal General Hospital, Montreal, PQ, Canada.

Two candidate genes located on chromosome 1p36.2 have been investigated for linkage and association to low bone density. Non-parametric linkage analysis has delimited a 30 cM interval defined by markers D1S468 (distal) and D1S507 (proximal) that is potentially linked to low bone density. The physical distance of this interval is 12 Mb. There are at least two genes with potential significance for bone function and metabolism located within 1 Mb of one another: TNFRSF1b (tumor necrosis factor receptor 2) and PLOD (lysyl hydroxylase). There is significant association of the polymorphism within the 3' untranslated region (UTR) of the TNFRSF1b gene to low bone density (Spotila et al., JBMR, 2000; Albagha et al., CTI, 2000). We have scanned the exons and flanking intronic regions of the genes TNFRSF1b and PLOD for single nucleotide polymorphisms (SNPs) in a population of 160 unrelated individuals selected for low bone density. In addition to known sequence variants in the 3' UTR and within intron 4 of TNFRSF1b, we have examined the frequency of a third variant within exon 6 (T677G) that alters a methionine codon to arginine (M196R). There were no additional sequence variants within TNFRSF1b that occurred with a frequency greater than 1% in the test population. The variant M196R however, is associated with low bone density of the spine ($p = 0.001$). This site is in significant linkage disequilibrium with the intron 4 microsatellite and the SNP at position 188 of the 3' UTR in the test population ($p<0.0001$ and $p = 0.001$, respectively). In contrast to TNFSF1b, the PLOD gene has 12 SNPs within the 19 coding exons and flanking intronic regions as well as a complex repeated sequence within intron 16. Of these variants, 3 are the most likely to be of functional significance: a G/A variant in exon 3 that coverts an alanine codon to threonine (A99T), a T/G SNP at position -17 from the 3' splice junction of intron 6, and a C/T SNP in exon 14 that alters an arginine codon (R512C). Genotypes at these three sites within the PLOD gene were not individually associated with bone density after correction for multiple testing. However there is significant linkage disequilibrium between the exon 3 and intron 6 SNP's although they are separated by 4.9 kb ($p<0.0001$).In summary, we have utilized linkage, association and linkage disequilibrium analysis to examine the potentially important contribution of chromosome 1p36.2 to variation in bone density. Additionally, that variation may reflect contribution from two individual genes.

1126

Major Genetic Influence on Femoral Stiffness and Strength Identified on Mouse Chromosome 4. C. H. Turner,[1] Q. Sun,*[1] M. L. Bouxsein,[2] C. J. Rosen,[3] L. R. Donahue,[3] K. L. Shultz,[3] W. G. Beamer.[3] [1]Orthopaedic Surgery, Indiana University, Indianapolis, IN, USA, [2]Beth Israel/Deaconess Medical Center, Boston, MA, USA, [3]The Jackson Laboratory, Bar Harbor, ME, USA.

The C3H/HeJ (C3H) inbred mouse strain has superior femoral bone biomechanical properties, compared to C57BL/6J (B6) mice. Genetic analyses of femoral biomechanical properties from 906 B6C3H-F2 adult female mice identified 11 quantitative trait loci (QTLs) linked to strength, stiffness or work to failure on chromosomes 1, 4, 6, 8, 10, 11, 12, 13, 14, 17 and 18. Of these, the QTL on Chr 4 had the strongest influence on femoral biomechanics. A congenic strain of mice was developed by transferring the Chr 4 QTL region from C3H onto the B6 background by 6 generations of selective backcrossing. The new congenic strain (denoted B6.C3H-4t) contains the C3H Chr 4 QTL on a 98% B6 background. Excised femora from this congenic strain of mice were analyzed biomechanically in 3-point bending to test the effect of the donated C3H QTL on bending force to fracture (F), stiffness (S) and work to failure (U) of the mid-diaphyseal region. The C3H alleles in the Chr 4 QTL significantly influenced the mechanical properties of the femoral midshaft, particularly stiffness (Table 1). Average biomechanical properties for the B6.C3H-4t congenic strain were compared to B6, C3H, and B6C3H-F1 hybrid mice (N=10-16). In Table 1, significant differences ($p<0.05$) from B6, C3H, and B6C3H-F1 are denoted "b", "c", and "f", respectively.Compared to B6 mice, C3H had 76% greater femoral strength (F), 35% greater stiffness (S), and 105% greater work to failure (U). The B6.C3H-4t congenic mice also had improved femoral biomechanical properties: F was greater than B6 by 21%, S by 35%, and U by 29%. Consequently, the Chr 4 QTL donated from C3H accounted for between 28% and 100% of the difference in biomechanical properties between B6 and C3H mice. The observation that femoral stiffness for B6C3H-F1 hybrid mice was equal to C3H suggests that there is a dominant influence of the C3H allele on femoral stiffness. Interestingly, this dominant effect appeared to be captured completely within the Chr 4 QTL. The Chr 4 QTL spans over 30 cM and contains hundreds of genes, so it is unclear at this point which gene is responsible for the effect on femoral stiffness and strength. Nevertheless, there is a strong genetic influence on femoral bone biomechanics within the defined QTL region on mouse Chr 4.

Telomerase Expression Extends Life Span and Prevents Senescence-Associated Impairment of Human Osteoblast Functions *in Vitro* and *in Vivo*. J. L. Simonsen,*[1] C. Rosada,*[1] J. Justesen,*[1] K. Stenderup,*[1] C. Bischoff,*[2] F. Dagnaes-Hansen,*[3] E. F. Eriksen,[1] S. I. S. Rattan,*[4] T. G. Jensen,*[2] M. Kassem.[1] [1]University Department of Endocrinology and Metabolism, University Hospital of Aarhus, Aarhus, Denmark, [2]Institute of Human Genetics, University of Aarhus, Aarhus, Denmark, [3]Department of Medical Microbiology and Immunology, University of Aarhus, Aarhus, Denmark, [4]Department of Molecular and Structural Biology, University of Aarhus, Aarhus, Denmark.

Cellular senescence of human osteoblasts is associated with limited proliferative potential, substantial alterations in gene expression, and impaired osteoblast functions. These changes are associated with telomere shortening suggesting that cellular senescence may be related to telomere effects. Thus, we studied the effects of maintaining telomere length on cellular characteristics of the human bone marrow stromal cells (hMSCs). hMSCs cultured from bone marrow aspirates, were stably transduced by a retroviral vector containing the catalytic subunit of the human telomerase gene (TERT) driven by a Moloney murine leukemia virus. Efficiency of transduction was close to 100%, as assessed by green fluorescence protein expression. The presence of an active telomerase enzyme in hMSC-TERT$^+$ cells was demonstrated by the telomerase repeat amplification protocol (TRAP) and mean telomere length, determined by terminal restriction fragment analysis, was maintained during continuous *in vitro* culture. The hMSC-TERT$^+$ cells exhibited extended life span *in vitro* and have, until now, undergone more than 130 population doublings (PDs) while control cells exhibited senescence-associated proliferation arrest at 25 PDs. Morphologically, the hMSC-TERT$^+$ cells are similar to early passage young cells and they do not stain for senescence-associated β-galactosidase. Analysis of gene expression of hMSC-TERT$^+$ cells demonstrates the maintenance of gene expression of osteoblastic markers such as Cbfa1, collagen type I, alkaline phosphatase, and osteocalcin during continuous subculturing. The hMSC-TERT$^+$ cells combined with a hydroxyapatite-tricalciumphosphate vehicle and implanted subcutaneously in immunodeficient mice, were able to form normal lamellar bone quantitatively similar to what was formed by young cells and there was no evidence for tumor formation. Furthermore, chromosome analysis using the comparative genomic hybridization technique showed minimal evidence of chromosomal abnormalities. Our findings demonstrate that maintenance of the telomere pathway can prevent senescence-associated impairment of osteoblast functions and provide important targets for pharmacological intervention to increase bone formation.

Cell-Autonomous and Endocrine Deficiencies Contribute to the Hypoplastic Skeletal Phenotype of Ku70 – Deficient Mice. D. M. Willis, A. Loewy,* J. Shao,* M. Bidder, D. M. Ornitz,* D. A. Towler. Washington University Medical Center, St. Louis, USA.

Basic fibroblast growth factor (FGF2) stimulates the proliferation and recruitment of undifferentiated calvarial osteoprogenitors to the mature osteoblast lineage, reflected in the upregulation of osteocalcin (OC) gene expression. Previously, we mapped a transcriptional response to fibroblast growth factor receptor activation to a GCAGTCA motif (OC FGF response element; OCFRE) at nucleotides -144 to -138 relative to the rat OC promoter transcription initiation site. We purified the OCFRE DNA binding activity (OCFREB) from MG63 osteosarcoma cells, and identified Ku70, Ku80, and a novel acetyltransferase as core constituents of the OCFRE DNA binding complex using techniques of reverse phase liquid chromatography-triple quadrupole mass spectrometry fingerprinting and sequencing. In phenotypically immature MC3T3E1 cells and primary murine calvarial osteoblasts, FGF2 regulates both the accumulation (increased) and serine phosphorylation (decreased) of Ku70, but does not regulate Ku80. To further define the role of Ku70 in skeletal physiology, we have initiated the characterization of mice homozygous for disruption of the Ku70 gene. Compared to Ku70 /+ littermates, Ku70 -/- mice are small, discernable ca. 7 days post partum and persistent throughout life in both genders. Tibiae and femurs from Ku70 -/- mice are more gracile than those of Ku70/+ littermates. Primary calvarial osteoblasts derived from E18.5 Ku -/- mice exhibit significant osteogenic deficiency in vitro. As compared to Ku70 +/+ mice, the formation of mineralized nodules by Ku70 -/- calvarial osteoblasts is decreased by 50% ($p = 0.07$), quantified by von Kossa staining and digital image analysis. Moreover, both mineralized nodule area ($p = 0.006$) and intensity ($p = 0.02$) are decreased by 80% in Ku70 -/- calvarial osteoblasts cultured under mineralizing conditions. Consistent with these in vitro observations, serum alkaline phosphatase levels -- a reflection of bone formation and osteoblast numbers -- are decreased in 1 month old Ku -/- mice, but to a greater extent in female mice (31%, $p = 0.01$) than in male mice (15%; $p = 0.06$). Notably, levels of serum IGF1 -- a major skeletal growth factor -- are also reduced by 30% in Ku -/- mice (269 +/- 104 ng/ml) compared to Ku +/+ mice (386 +/- 49 ng/ml; $p = 0.03$), consistent with smaller size and global deficiencies in growth. In toto, these data confirm the role of Ku70 in osteoblast gene expression, mineralization, and skeletogenesis. Deficiencies in both cell-autonomous control and endocrine regulation of bone growth and net osteoblast synthetic functions contribute to the hypoplastic skeletal phenotype of Ku70 -/- mice.

Secreted Frizzled-Related Protein (SFRP)-1: A Novel Regulator of Osteoblast and Osteocyte Apoptosis. P. V. N. Bodine,[1] R. A. Moran,*[1] H. E. Ponce-de-Leon,*[1] S. A. McLarney,*[1] J. Green,*[2] G. S. Stein,[2] J. B. Lian,[2] B. S. Komm.[1] [1]Women's Health Research Institute, Wyeth-Ayerst Research, Radnor, PA, USA, [2]Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA.

We have used differential display-polymerase chain reaction analysis to characterize osteogenic pathways in a collection of conditionally immortalized adult human osteoblast (HOB) cell lines. This collection contains representatives of 4 stages of differentiation: pre-osteoblasts (pre-OBs), mature osteoblasts (OBs), pre-osteocytes (pre-OCYs) and mature osteocytes (OCYs). These cell lines were treated for 24 hr with various osteogenic agents including prostaglandin E2 (PGE2) and transforming growth factor-beta1 (TGF-beta1). Eighty-two differentially expressed genes were identified from these experiments. Of these genes, only the secreted Wnt antagonist, SFRP-1, was regulated by numerous osteogenic agents and in multiple stages of differentiation. Basal SFRP-1 mRNA levels increased up to 24-fold during HOB differentiation from pre-OBs to pre-OCYs. Expres-

sion of SFRP-1 mRNA was increased up to 38-fold following PGE2 treatment of pre-OBs and OBs, but not after treatment of pre-OCYs. PGE2 treatment of primary rat and normal human OBs also increased SFRP-1 mRNA levels over 10-fold, supporting the developmental regulation of this gene. In contrast, SFRP-1 expression was down-regulated by as much as 80% following TGF-beta1 treatment of pre-OCYs. Additional growth factors, cytokines, and hormones also regulated SFRP-1 expression in osteoblasts. Message levels for this gene were increased up to 5-fold in various HOB cell lines after treatment with interleukin-1beta and retinoids, but were decreased by as much as 75% following treatment with bone morphogenetic protein-2, insulin-like growth factor-1, vitamin D3, dexamethasone and fetal bovine serum. Over-expression of SFRP-1 in HOB cells accelerated the rate of cell death 3-fold, and this was blocked by treatment with an SFRP-1 antibody. Consistent with this finding, treatment of pre-OBs and OBs with PGE2 increased apoptosis up to 3-fold, while treatment of pre-OCYs with TGF-beta1 decreased cell death by 50%. Finally, transfection of HOB cells with SFRP-1 suppressed Wnt signaling by as much as 70%. These results demonstrate for the first time that SFRP-1 is a key regulator of osteoblast and osteocyte survival, and that Wnt proteins are important modulators of bone forming cells.

Connexin43/Src Interaction and Src Activity Link Connexin43 Hemichannels with the ERK Pathway: Mechanism of Anti-Apoptosis by Bisphosphonates in Osteocytes. L. I. Plotkin,[1] J. Davis,*[1] R. Civitelli,[2] S. C. Manolagas,[1] T. Bellido.[1] [1]Endo/Metab. Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. of Arkansas for Medical Sciences, Little Rock, AR, USA, [2]Bone & Min. Diseases, Washington Univ. School of Medicine, St. Louis, MO, USA.

Preservation of the mechanosensory function of osteocytes by inhibiting their apoptosis might contribute to the anti-fracture efficacy of bisphosphonates (BPs). These agents prevent apoptosis of MLO-Y4 osteocytic cells by opening connexin43 (Cx43) hemichannels and subsequently activating the extracellular signal regulated kinases (ERKs). However, the mechanism by which Cx43 hemichannel opening leads to ERK activation is unknown. We report that embryonic fibroblasts and osteoblastic cells derived from Cx43 deficient mice or osteoblastic cell lines with very low levels of Cx43 were not protected from apoptosis by BPs. This effect was specific for Cx43, as transfection of Cx43 - but not Cxs 26, 31, 32, 37, 40, or 45 - into HeLa cells rendered them responsive to the anti-apoptotic effect of BPs. The cytoplasmic C-terminus is unique to each Cx, and Cx43 contains Src SH2 and SH3 binding sites in this region. Therefore, we examined whether opening of Cx43 hemichannels by BPs may activate ERKs and prevent apoptosis by activating Src. We found that a Cx43 mutant, which forms channels with normal permeability but lacks the C-terminus, did not confer BP-induced anti-apoptosis. On the other hand, co-expression of this mutant together with the C-terminus of Cx43, but not the C-terminus alone, did confer BP-induced anti-apoptosis. Hence, both the pore forming and the C-terminus regions of Cx43 are required for anti-apoptosis. BPs also prevented apoptosis in HeLa cells transfected with Cx43 and wild type Src, but not Src mutants lacking either the SH2 or SH3 domains or kinase activity. Consistent with this, anti-apoptosis and ERK activation by BPs in osteocytes were abolished by the inhibitor of Src kinases PP1 and were absent in embryonic fibroblasts derived from Src deficient mice. These results suggest strongly that cell communication with the extracellular space is not sufficient for anti-apoptosis by BPs and that interaction between Cx43 and Src and the resulting activation of Src are required. Lastly, we determined that ERK activation lies downstream of Cx43, by showing that a dominant negative MEK that prevents ERK activation abolished Cx43-mediated survival and a Cx43 mutant that cannot be phosphorylated by ERKs conferred anti-apoptosis as effectively as wild type Cx43. These findings reveal a novel and gap junction-independent function of Cx43 in the regulation of survival signaling pathways.

1131

ERKs as well as PI3K/Akt, but not p38, Mediate the Anti-apoptotic Effect of Sex Steroids in Osteoblasts and Osteocytes, in Part by Phosphorylating Bad. S. Kousteni, T. Bellido, L. Han, R. L. Jilka, S. C. Manolagas. Division of Endocrinology & Metabolism, Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

MAP or PI3 kinases transduce chemical and physical signals from the cell surface to the nucleus thereby controlling cell proliferation, differentiation and survival. A particular cellular fate may depend on the dynamic balance between different MAP kinases rather than on the activation of a particular family. ERKs, JNK and p38 MAPKs as well as PI3K can all be regulated by estrogen through a nongenotropic mechanism; and estrogens acting via a nongenotropic ERK-mediated mechanism protect osteoblasts and osteocytes from apoptosis via physical association of their receptor with kinases within pre-assembled scaffolds. Based on these lines of evidence, we have investigated whether other kinases besides ERKs play a role in mediating the anti-apoptotic effect of estrogens. The ability of 17β-estradiol (E_2) to prevent etoposide-induced apoptosis was assessed in calvaria-derived murine osteoblastic cells in the presence or absence of the specific inhibitor of PI3K, wortmannin, or the p38 inhibitor, SB203580. Wortmannin dose-dependently attenuated the anti-apoptotic effect of E_2 with maximal efficacy at a concentration of 30nM. On the other hand, SB203580 at concentrations as high as 30μM did not interfere with the anti-apoptotic effect of E_2. Activated ERKs and PI3K/Akt phosphorylate the pro-apoptotic protein Bad, a member of the Bcl-2 family of proteins that control release of caspase activating factors from the mitochondria. Bad phosphorylation prevents Bad from activating the death program, thereby rescuing cells from apoptotic stimuli. In support of the contention that the anti-apoptotic effects of estrogen are mediated by kinases which in turn phosphorylate Bad, we found that a dominant negative Bad lacking the ability to undergo phosphorylation at serines 112, 136 and 155 (because of substitution by alanine) abrogated the anti-apoptotic effect of estrogen in ERα-transiently transfected cells. These results suggest that activation of both the ERK and PI3K pathways by estrogens is indispensable for their anti-apoptotic effects; while the p38 cascade is not involved in these effects. Moreover, Bad phosphorylation by at least one of these pathways is required for the anti-apoptotic action of estrogens.

Osteoprotegerin (OPG) binds TNF Family Proteins Including TNFα and Protects Osteoblasts from TNFα-Induced Apoptosis: A Complementary Function in Addition to Effects of OPG on Osteoclast Differentiation via RANKL. R. Bu, R. M. McKeon, L. Cao, H. C. Blair. Pathol and Cell Biol & Physiol, U Pitt, Pittsburgh, PA, USA.

Bone turnover is balanced by osteoclast/ osteoblast activity via cytokine interactions that control differentiation and activity of both cell types. Degradation requires osteoclasts, but recent work points to involvement of osteoblast/ osteocyte apoptosis. Osteoclasts may promote apoptosis, in part, by TNF secretion. TNFα in particular promotes apoptosis in osteoblasts. The potential importance of osteoclast TNF secretion was confirmed by Western analysis of supernatants of human osteoclast cultures, which showed TNF α at concentrations exceeding 10 ng/ml. Osteoblastic cells have been noted to secrete both RANKL and OPG, a paradoxical situation, since RANKL is the key cytokine for terminal fusion and osteoclast differentiation, while OPG is the most efficient factor protecting bone from degradation, including RANKL binding that blocks the activation of RANK. Our studies confirmed that both RANKL and OPG are expressed by osteoblasts. However, interaction of monocyte precursors with RANKL-expressing cells mediated osteoclast differentiation on mineralized substrate efficiently despite significant OPG. In light of recent findings of an interaction of OPG with TRAIL (another TNF family protein), these results suggested that OPG also interacts with additional TNFs in bone. ELISAs with OPG as the target, or immunoprecipitation using TNFα, RANKL, or TRAIL as the targets, showed OPG binding to TNFα and RANKL at similar affinities, and weaker binding of OPG to TRAIL. RANKL competitively inhibited TNFα binding to OPG at ~equimolar concentrations, confirming these results and suggesting that binding of TNFα by OPG involves a common molecular site. However, whether this interaction is physiologically relevant was uncertain. We examined the affect of OPG on TNFα-induced osteoblast apoptosis, using annexin assays or TUNEL/cell survival to determine early and late apoptosis. TNFα at 3-10 ng/ml induced apoptosis in cultures of MG63 cells in 2-4 h, but this effect was dramatically diminished by OPG at 10-30 ng/ml. MG63 cells in contiguous clusters were affected, involving 20-50% of cells; ~2% background apoptosis of individual cells occurred with or without TNFα and was not affected by OPG. Our studies suggest that, in addition to effects on osteoclast differentiation, OPG protects osteoblasts from TNFα-induced apoptosis. These results reconcile the co-expression of OPG and RANKL, and indicate that OPG is of more general importance in balancing bone formation and catabolism than has been indicated by models focusing solely on its interaction with RANKL.

Incidence and Risk Factors for Second Hip Fracture. The Study of Osteoporotic Fractures. R. D. Chapurlat, D. C. Bauer, M. C. Nevitt, K. L. Stone, T. Blackwell, S. R. Cummings. Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA, USA.

Women with hip fracture have an increased risk of second hip fracture. But few of them currently receive adequate therapy, so that many remain at high risk of second hip fracture. The epidemiology of second hip fracture, however, is poorly understood as few studies, mostly retrospective, have addressed this issue.To determine the incidence and risk factors for second hip fracture, we conducted a prospective cohort study in postmenopausal women aged 65 years and older. Among 9,704 community-dwelling participants recruited at baseline, 632 women suffered a first hip fracture after enrollment. These 632 hip fracture cases were then followed for occurrence of a second hip fracture for an average of 3.7 years (0.1-12.7). Clinical risk factors and bone mineral density (BMD) were assessed at the baseline for the study. We estimated the incidence rate of second hip fractures among women who had a first incident hip fracture, and we used a stratified proportional hazards analysis with robust estimate of variance to identify independent risk factors of the second hip fracture.Fifty three second hip fractures occurred during an average 2.3 years following the first fracture. Women with first hip fracture had a 2.3% per year risk of second hip fracture. In multivariate analysis, women with a first hip fracture who walked for exercise at baseline were less likely to sustain a second hip fracture (RR=0.49 [0.27-0.90]), as were those who had normal depth perception (RR=0.51 [0.29-0.92]). Women who either did not gain or lost weight after age 25 had an increased risk of second incident hip fracture compared to the others (RR = 2.69 [1.56-4.62]). Risk of second hip fracture was also increased in those who had the lowest calcaneal BMD (RR=1.47 [1.11-1.96] per SD decrease in BMD). Current use of estrogen replacement therapy at baseline was protective (RR=0.49 [0.26-0.93]) up to 2 years of follow-up after baseline. Age was not a significant predictor of the risk of second hip fracture.In conclusion, women with a first hip fracture have a high risk of second hip fracture, especially if they are inactive, have impaired depth perception, have low BMD or if they have lost weight. These risk factors may be affected by simple interventions.

1134

Risk Factors for Falls in Older Women in Residential Care in Australia. L. Flicker,[1] K. Mead,*[2] C. Nowson,*[3] S. Scherer,*[4] M. Stein,*[2] J. Thomas,*[1] J. L. Hopper,*[5] J. D. Wark.[2] [1]Medicine, University of Western Australia, Perth, Australia, [2]Medicine, University of Melbourne, Melbourne, Australia, [3]Deakin University, Melbourne, Australia, [4]Royal Freemasons Homes of Victoria, Melbourne, Australia, [5]Public Health, University of Melbourne, Melbourne, Australia.

Approximately one third of all hip fractures occur in women in residential care, and most of these fractures are preceded by a fall. Residential care in Australia is divided into high and low levels based on disability. Common risk factors for falls and bone fragility in these women may produce a deleterious synergy, magnifying the risk for osteoporotic frac-

ture.This prospective study spanned three states of Australia and 2454 female high level and 1797 low level residents were approached. Informed consent was obtained from the facility, the subjects, and where appropriate, their caregivers, with 952 high level and 667 low level residents consenting to the study, yielding a response rate of 38%. Subjects had their age, weight, cognitive function (using the Abbreviated Mental Test Score (AMTS)), walking ability, psychotropic drug use and previous fractures recorded. Vitamin D nutrition was measured by serum 25-hydroxyvitamin D level (25D) using the Incstar assay (lower limit of reference range, 25nmol/l). Residential care supervisors recorded falls in monthly falls diaries for a mean period of 159 days and there was on average 1.5 falls per year, which occurred in 26% of the residents after a median period of 44 days.Mean age of residents was 83.7 years. Median vitamin D level were 34.6 nmol/l for the low level and 26.1 nmol/l for the high level residents with 22% and 45% having frank vitamin D deficiency respectively. Using a Cox proportional hazards multivariate model with time to fall as the outcome measure, the following variables were associated with falls, after excluding those individuals who were bedbound:

	Hazard Ratio	95% CI	p
Natural Log 25D	0.64	0.47-0.89	0.004
Natural Log Weight	0.42	0.21-0.83	0.013
Past Colles Fracture	2.43	1.43-4.16	0.001
Neuroleptic Use	1.95	1.37-2.76	< 0.001
Walking with a frame	1.43	1.04-2.00	0.030
Mild impairment AMTS	1.68	1.20-2.33	0.002
Severe impairment AMTS	1.52	1.04-2.22	0.029

Vitamin D level was independently and inversely associated with falls in women in residential care even allowing for fall risk factors and may interact with known deleterious effects on bone to produce a markedly increased risk of fracture.

1135

Risk Factors for Hip Fractures in Predominantly African-American Veteran Male Population. E. Barengolts,[1] D. Karanouh,[2] L. Kolodny,[3] S. Kukreja.[4] [1]University of Illinois and VA CHCS, Chicago, IL, USA, [2]University of Illionois, Chicago, IL, USA, [3]University of Illinois, Chicago, IL, USA, [4]VA CHCS, Chicago, IL, USA.

We performed a case-control study to determine potential risk factors for hip fractures in VA male patients. Charts of 218 patients admitted to VA Chicago Health Care System over 1988-2000 period for hip fractures and 218 race- and age-matched controls were reviewed. For this analysis we chose several risks prevalent in our population and known as predictors of hip fractures from previous studies. These included age, height, weight, body mass index (BMI), smoking, alcohol use; medical conditions: stroke, dementia, Parkinson's disease, and seizures; medications: hydrochlorthiazide (HCTZ), phenytoin, statins, and levothyroxine; and laboratory values reflecting nutritional status and disease burden: albumin, creatinine, blood urea nitrogen, cholesterol, and hemoglobin. Racial distribution reflected distribution in our VA population, 137 men were African-American (AAM, 63%) and 81 men were Caucasian (CM, 37%). For cases and controls mean values ± SD were similar for age (69.9 ± 11.2 vs 69.6 ± 10.5 years, due to matching). Body weight (68.8 ± 14.5 vs 82.3 ± 18.7 kg) and BMI (22.6 ± 4.7 vs 27.2 ± 6.1 kg/m2) were significantly lower in cases than in controls ($p < 0.01$ for both). In multivariate logistic regression analysis significant independent predictors of hip fracture were identified (Table). Higher BMI and albumin, and use of HCTZ and statins were protective (Table).

Risks	OR, Odds ratio	95% CI, confidence interval	P value
Alcohol	3.38	1.56-7.33	0.0008
Cigarette smoking	2.59	1.14-5.89	0.0321
Dementia	12.77	3.03-53.77	0.0005
Phenytoin	28.44	4.05-199.84	0.0008
HCTZ	0.34	0.12-0.98	0.0467
Statins	0.21	0.05-0.86	0.0295
BMI	0.89	0.83-0.97	0.0075
Albumin	0.41	0.21-0.82	0.0115

Comparison of CM and AAM groups showed some difference in hip fracture predictors. For CM significant independent predictors included alcohol: OR 7.3, CI 1.6-34.8, cigarette smoking: OR 5.8, CI 1.4-25.2, and dementia: OR 25.5, CI 3-218.7, while protective factors included higher albumin: OR 0.2, CI 0.04-0.8 and use of HCTZ: OR 0.1, CI 0.004-0.8. For AAM these predictors included alcohol: OR 3.4, CI 1.4-8.3, dementia: OR 14, CI 1.3-147, and phenytoin OR 24, CI 2.2-261, while protective factors were higher BMI: OR 0.84, CI 0.46-0.93, albumin: OR 0.26, CI 0.11-0.61, and use of statins: OR 0.6, CI 0.01-0.42. This is the first study of hip fracture risks in predominantly AAM population. It shows differences in risks and protective factors between CM and AAM. Further investigation is necessary to explain roles of various factors predicting risks and providing protection for hip fractures in diverse populations

Prevalent Vertebral Fractures in African-American Women. J. A. Cauley,[1] K. Stone,[2] S. Ewing,[2] M. C. Nevitt,[2] T. Hillier,[3] D. M. Black,[2] M. Vogt.*[1] [1]University of Pittsburgh, Pittsburgh, PA, USA, [2]University of California, San Francisco, CA, USA, [3]Kaiser Center for Health Research, Portland, OR, USA.

Vertebral fractures (VFx) are strong predictors of future fractures. Little is known about the prevalence and correlates of VFx among African American women. As part of the Study of Osteoporotic Fractures (SOF), we enrolled 662 African American (AA) women, age 61 to 94, into a longitudinal study of bone loss. Of these, lateral spine x-rays were available on 481 (73%) women. Prevalent VFx were ascertained by morphometry using identical methods as in our study of SOF women and defined as a vertebra race-specific height ratio >3 SD below the mean for normals. Total Hip BMD (DXA) and calcaneal ultrasound (Sahara) were measured. A total of 55 (11.4%) of AA women had a VFx. This compares to a VFx prevalence of 20% in white women in SOF ages 65-99. Among AA women, prevalent VFx increased with age: age <70 year, 3.6%; 70-74, 9.1%; 75-59, 11.6%; 80+, 20%. AA women with a VFx in comparison to AA women without a VFx, respectively, were older (77y vs. 75y, p=0.02); weighed less (70 kg vs. 76 kg, p=0.002), and reported higher caffeine intake (141 mg/d vs. 111 mg/d, p=0.11). There was no difference in physical activity, alcohol intake or cigarette smoking between the 2 groups. AA women with a VFx in comparison to AA women without a VFx, respectively, were more likely to report poor/fair health status (32% vs 24%, p=0.006), falling in the past 12 months (42% vs 27%, p=0.02), a fracture since age 50 (33% vs 21%, p=0.04) and performed more poorly on several performance measures of function (grip strength, 17 kg vs 20 kg p=0.0002). Total hip bone mineral density (BMD) was lower among women with a VFx compared to women without a VFx: 0.75 g/cm2 and 0.83 g/cm2 p=0.0001, respectively. A one standard deviation (SD) decrease in BMD or ultrasound parameter was associated with increased odds of having a VFx (table). Table: Age Adjusted Odds Ratio (OR)(95% Confidence Intervals) per one SD Decrease

Skeletal Parameter	OR	95%CI
Total Hip BMD	1.99	(1.4-2.8)
Broadband Ultrasound Attenuation	1.80	(1.1-3.0)
Speed of Sound	1.75	(1.1-2.9)

In conclusion, the prevalence of VF x in AA women is about 50% lower than white women. Correlates of VFx in AA women are similar to those observed for white women.

1137

Vertebral Deformities in Urban Chinese Men: The Beijing Osteoarthritis Study. M. Nevitt,[1] S. Bent,*[1] L. Lui,[1] Y. Zhang,[2] W. Yu,*[3] S. Cummings,[1] D. T. Felson,[2] L. Xu.*[3] [1]Univ. of California, San Francisco, San Francisco, CA, USA, [2]Boston University, Boston, MA, USA, [3]Peking Union Medical College Hospital, Beijing, China

The prevalence and correlates of vertebral deformity among men in mainland China have not been studied. Prior studies indicate similarities in the prevalence of vertebral deformity between Chinese and Caucasian women, and between Caucasian women and men. It is uncertain if prevalence rates are similar in Chinese men and women. We conducted a population-based study of older men living in Beijing to determine the prevalence of vertebral deformity and correlation with potential risk factors and outcomes of the disease. Beijing residents 60 years and older were recruited door-to-door in randomly selected neighborhoods. 588 men (82% of those contacted) completed an interview, a clinic exam, and lateral spine x-rays. Radiographic methods, assessment and definition of deformity, and risk factor and outcome measurements were identical to those used in our previous studies of older women in Beijing (Xu, et al. JBMR 2000;15: 2019)*. We defined a vertebral deformity as a reduction of > 3 SDs (severe deformity > 4SDs) from level-specific normal means of vertebral height ratios derived from the Beijing men. The prevalence of vertebral deformity in men increased with age and was nearly identical to the prevalence in women in Beijing, with an age standardized prevalence ratio for men vs. women = 1.0, 95% CI 0.8 to 1.2.

Prevalence of Vertebral Deformity in Beijing by Age and Gender

Age Group (n of men)	Men (95% CI)	Women* (95% CI)
60-69 (363)	9.9% (6.8, 13.0)	10.5% (4.6, 16.3)
70-79 (184)	16.3% (11.0, 21.6)	15.0% (8.0, 22.0)
80+ (41)	24.4% (11.2, 37.5)	31.2% (21.8, 40.6)

Verrtebral deformity in men was associated with low total hip BMD (age-adjusted OR per -1 SD: 1.8; 95% CI 1.4 to 2.4) and with values below the median for quadriceps strength (OR 2.2; 1.3, 3.8) and BMI (OR 1.7; 1.0, 2.8), but not with low spine BMD, smoking, alcohol use, or heavy manual labor. Deformity was associated with an increased time to complete five chair stands (P=0.01), and there was a non-significant association of severe deformity with back pain (1.7; 0.9, 3.3). Relationships were similar for severe deformity and after exclusion of possible nonosteoporotic deformities (12% of total).We conclude that the prevalence of vertebral deformity in older Beijing men is the same as in Beijing women, and similar to that reported in studies of Chinese men living in Hong Kong and Taiwan and Caucasian men in Europe. The association of deformity with low hip BMD suggests that osteoporosis is an important contributing factor. Vertebral deformity is common, associated with poorer physical function, and is likely to become an increasingly important health problem in China as the population ages

Disclosures: Eli Lilly and Company,2.

Carotid Atherosclerosis Is Associated with Increased Bone Mineral Density (BMD) in Mexican American Men, but Decreased BMD in Women. C. M. Kammerer,[1] D. L. Rainwater,*[1] J. L. Schneider,*[1] D. H. O'Leary,*[2] R. L. Bauer,[3] B. D. Mitchell,*[4] [1]Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA, [2]Tufts-New England Medical Center, Boston, MA, USA, [3]University of Texas Health Science Center, San Antonio, TX, USA, [4]Medicine, University of Maryland School of Medicine, Baltimore, MD, USA.

Several previous studies, the majority conducted in women, have reported an association between osteoporosis and/or bone mineral density (BMD) and markers of sub-clinical atherosclerosis. We investigated this relationship in men and women studied as part of the San Antonio Family Osteoporosis study, a population-based genetic epidemiology study of BMD and its correlates in large Mexican American families. We measured BMD using dual x-ray absorptiometry at 11 skeletal sites: radius (3 sites), ulna (3 sites), femur (4 sites) and spine. Sub-clinical atherosclerosis was assessed by ultrasound measurement of the intimal-medial thickness (IMT) of the far wall of the carotid artery and measurements were Z-transformed. Measurements of both BMD and IMT were available on 460 women and 290 men (average age 42.7 years) from 34 families. We used maximum likelihood methods, conditioned on the pedigree structure to account for familial relationships, to estimate correlations between BMD and IMT, while accounting for potential confounders, including age, body mass index, diabetes, physical activity, and, in women, menopause and breast feeding. Men and women were analyzed separately. In women > 40 years of age (n=246), IMT was negatively correlated with BMD at two ulna sites and the spine ($P < 0.05$ at each site), a finding that is consistent with other reports. In contrast, we observed positive relationships in men (n=344; both older and younger) between IMT and BMD in 5 of 10 arm and femur sites ($P < 0.05$ at each site). We further examined the relationship between BMD and low-density lipoprotein particle size (LDL size), a strong risk factor for coronary heart disease, and observed strong correlations between atherogenic small LDL size and high BMD ($p < 0.05$ in 9 of 11 sites), again supporting a link between atherosclerosis and high BMD in men. LDL size was not correlated with BMD in women. Thus, compared to women, the relationship between BMD and CHD risk factors in men is stronger, but in the opposite direction. These results imply that if common etiologic factors affect BMD and CHD, the effects are mediated differently in men and women.

Role of T Cells and T to B Signaling Through CD40 in the Pathogenesis of Estrogen Deficient Osteoporosis. K. Watanabe,[1] Y. Uchiyama,[2] A. Sugita,*[2] S. Takeda,*[2] A. Hishiya,*[1] K. Ikeda.[1] [1]Dept of Geriatric Res, Natl Inst for Longevity Sci, Obu, Japan, [2]Chugai Pharmaceutical, Gotemba, Japan

We have previously demonstrated that B220-positive cells, which are increased in bone marrow in estrogen deficiency, contribute to accelerated osteoclastic bone resorption by presenting RANKL on their cell surface (JBMR 2000) and differentiating into osteoclasts themselves (JBMR 2001). In order to clarify the role of T cells in the pathogenesis of osteoporosis, we studied bone metabolism in nude mice (defective in T cells), SCID mice (defective in both T and B cells) and Balb/c mice as their control. Following ovariectomy (OVX), the number of B cells in bone marrow increased substantially in Balb/c mice, whereas this increase was not seen in nude or SCID mice. Accordingly, both nude and SCID mice were resistant to bone loss following OVX, suggesting that T cells play a role in bone loss in estrogen deficiency presumably by signaling to B cells. Next, the involvement of CD40, a receptor molecule on B cells which is liganded by CD40L on T cells and important for the growth and activation of B cells, was therefore investigated by using stimulating as well as blocking antibody, and CD40 knockout mice. When anti-CD40 activating antibody was administered into intact mice, an increase in B cells in bone marrow was observed concomitantly with a decrease in BMD at L2-4 (with intact ovary). Unexpectedly, however, when OVX mice were treated with anti-CD40L antibody that inhibits the activation of CD40, bone loss was even more severe than in untreated OVX mice, raising the possibility that CD40 may act to protect against bone loss in estrogen deficiency. Interestingly, it was confirmed that bone loss after OVX was also exaggerated in CD40 knockout mice. The mechanism by which CD40 knockout mice are more sensitive to estrogen deficiency is being investigated by detailed histomorphometry. In conclusion, our results suggest that in addition to B cells, T cells in bone marrow regulate BMD, and that, in estrogen-replete animals, CD40 activation causes bone loss by increasing the number of B cells in bone marrow, while CD40 may protect bone loss in estrogen deficiency.

1140

Both Estradiol and Testosterone Play Fundamental Roles in the Maintenance of Normal Bone Turnover in Men. B. Z. Leder,*[1] D. A. Schoenfeld,*[2] K. LeBlanc,*[1] J. S. Finkelstein.[1] [1]Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA, [2]Dept. of Biostatistics, Massachusetts General Hospital, Boston, MA, USA.

Hypogonadism is an important cause of osteoporosis in men, but the mechanisms underlying hypogonadism-induced bone loss are incompletely understood. A fundamental unresolved question is whether androgens, estrogens, or both are involved in the physiological maintenance of normal bone turnover in men. To address this question, we randomized 55 men between the ages of 20 and 44 (mean +/- SE, 32 +/- 1) to receive one of three treatment regimens:

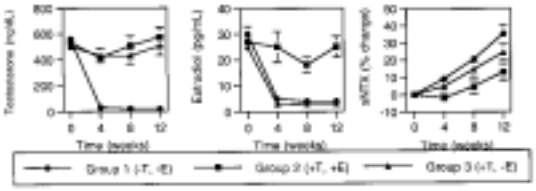
Group 1 (n=20): a GnRH analog (goserelin acetate 3.6 mg SC q 4 wks) alone for 12 weeks (to suppress endogenous gonadal steroids to pre-pubertal levels).

Group 2 (n=17): goserelin plus transdermal testosterone (Androderm 5 mg topically QD) (to normalize circulating testosterone (T) and estradiol (E) levels).

Group 3 (n=18): goserelin plus testosterone plus an aromatase inhibitor (anastrozole 1 mg po QD) (to induce selective E deficiency).

To assess the effects of these regimens on bone resorption, serum N-telopeptide (sNTX) levels were measured every 4 weeks for 12 weeks.

Baseline serum T and E levels and sNTX levels were similar in all groups. Over the 12-week treatment period, mean +/- SE sNTX increased by 35 +/- 5%, 13 +/- 5%, and 24 +/- 5% in the hypogonadal (Group 1), eugonadal (Group 2) and selectively estrogen deficient subjects (Group 3), respectively. Changes in T, and E, and sNTX are shown in the figure.



Between group differences were assessed by a random slopes models and the corresponding P values (1-sided) are shown in the table.

	T	E	sNTX
Group 1 vs. 2	<0.001	<0.001	<0.001
Group 1 vs. 3	<0.001	0.490	0.033
Group 2 vs. 3	0.364	<0.001	0.043

These data demonstrate that the selective E deficiency increases bone resorption in men. Bone resorption increases even further, however, in men with both T and E deficiency. Thus, these data strongly suggest that both estradiol and testosterone play fundamental and independent roles in the maintenance of normal bone turnover in men.

1141

Estrogen Withdrawal Augments PTH-Induced IL-6 and IL-6 Soluble Receptor Production by the Liver. U. S. Masiukiewicz,[1] M. Mitnick,[2] A. Grey,[2] L. Rios-Velez,[2] K. Augustyn,[2] K. Insogna.[2] [1]Endocrinology, Yale University, New Haven, CT, USA, [2]Yale University, New Haven, CT, USA.

Increased skeletal sensitivity to the resorbing actions of PTH may be one mechanism for estrogen-deficiency bone loss. Interleukin-6 (IL-6) and its soluble receptor (IL-6sR) appear to be key mediators of PTH-induced bone resorption in vivo. Continuous PTH administration increases circulating levels of IL-6 and IL-6sR, and these increases correlate with accelerated bone turnover in rodents, and in human. The magnitude of this increase is considerably augmented following estrogen withdrawal. The tissue source(s) of circulating IL-6 and IL-6sR, released in response to PTH are uncertain but it has recently been reported that PTH induces production of large amounts of immuno- and bioactive IL-6 and IL-6sR by the liver.The current study was designed to determine whether estrogen withdrawal affects PTH-induced hepatic IL-6 and IL-6sR production. Ex-vivo perfusion with 100 pM (1-84)hPTH for 130 minutes induced substantially greater release of IL-6 by livers isolated from ovx as compared to sham/ovx rats. In ovx animals IL-6 rose by 51.8 pg/ml (3.9Æ55.7) while it only increased by 26.1 pg/ml in the sham/ovx animals (3.9Æ30) ($p<0.001$, by 2-way ANOVA). PTH perfusion led to a more rapid increase in IL-6sR production by livers from ovx animals such that by 10 min the mean value in hepatic effluent was 65.3 pg/ml as compared to a value of 7.0 pg/ml in livers from vehicle-perfused ovx animals and 7.0 pg/ml in PTH-perfused livers from sham/ovx animals. Peak IL-6sR values were also highest in the PTH-perfused livers from ovx animals, 186.3 pg/ml vs 59.3 pg/ml and 141.6 pg/ml in vehicle-perfused ovx and PTH-perfused sham/ovx groups respectively ($p<0.001$ for effect of ovx and PTH by 2-way ANOVA). Since hepatocytes are the predominant cell type in the liver, the effect of estrogen withdrawal was investigated in these cells. Cultured primary hepatocytes isolated from ovx rats demonstrated a significantly greater release of IL-6 following PTH treatment than did cells isolated from sham/ovx animals, 3.8-fold vs. 1.7-fold ($p<0.001$).These data indicate that estrogen withdrawal sensitizes the liver to PTH and may account for the greater increase in circulating levels of IL-6 and its receptor seen following PTH exposure in the estrogen-deficient state. We conclude that increased skeletal sensitivity to PTH, associated with estrogen withdrawal, may be mediated, in part, by the liver.

1142

The Effect of Gonadectomy and Growth Hormone Deficiency on Periosteal and Endocortical Growth, Cortical Thickness, Ash Density and the Breaking Strength of the Femoral Midshaft in Male and Female Rats. B. T. Kim,*[1] L. Mosekilde,[2] X. Z. Zhang,*[1] L. Tornvig,*[2] J. S. Thomsen,*[2] E. Seeman.[1] [1]Department of Endocrinology, Austin & Repatriation Medical Centre, University of Melbourne, Melbourne, Australia, [2]Department of Cell Biology, Institute of Anatomy, University of Aarhus, Aarhus, Denmark.

To study the sexual dimorphism in the growth of the femoral midshaft and its regulation, the effects of gonadectomy (Gx) at 4 weeks of age were studied in 200 male and female growth hormone replete (GH+) and deficient (GH-) rats. During 8 months, periosteal expansion was ~5 times greater in males than females producing a wider bone; periosteal expansion accounted for 95% of the increase in cortical thickness placing bone further and further from its neutral axis. Medullary diameter changed little in males but contracted in females so that endocortical contraction accounted for 70% of the increase in cortical thickness in females and placed most of the bone nearer the neutral axis. Gx diminished some of these sexually dimorphic features; Gx GH+ males reduced periosteal expansion by ~50%, endocortical diameter was unaffected; the smaller bone had a thinner cortex and reduced strength relative to nonGx GH+ males. Gx GH+ females increased periosteal expansion and abolished endocortical contraction; cortical thickness was reduced but greater periosteal expansion maintained bone strength similar to nonGx GH+ females. GH-

had less deleterious effects in males than females; periosteal expansion was not abolished in males; endocortical diameter remained unchanged; the smaller bone had reduced cortical thickness and strength relative to GH+ males. In GH- females, periosteal expansion and medullary contraction were abolished; the smaller bone had reduced cortical thickness and strength relative to GH+ females. Bihormonal deficiency in Gx GH- males and females abolished periosteal expansion and increased endocortical contraction in both sexes. In summary, sexual dimorphism in the size, mass and strength of the femur is the result of greater periosteal expansion in males, and greater endocortical contraction in females. In males, GH and androgens independently promote periosteal expansion; abolition of growth occurs only when both regulators are absent (in Gx GH- males). Estrogen inhibits periosteal expansion and promotes GH dependent endocortical contraction; periosteal expansion in estrogen deficiency is also GH dependent. Sex hormone deficiency has a less severe effect in females than males because of the release from inhibition of periosteal expansion while GH deficiency has more deleterious effects in females than males because of the dual independent control of the periosteum in males.

1143

Tob-deficient Mice Exhibit Preservation of Bone Mass Even After Ovariectomy-Induced Bone Loss. M. Usui,[1] Y. Yoshida,*[2] K. Tsuji,[1] A. NIfuji,[1] T. Yamamoto,*[2] M. Noda.[1] [1]Dept of Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]University of Tokyo, Tokyo, Japan.

Tob(transducer of ErbB2) is a member of novel antiproliferative family consisting of Tob, Tob2, ANA/BTG3, BTG2/PC3/TIS21, and BTG1. Tob-deficient mice reveal high levels of bone mass in adult, due to increase in bone formation without major alteration in bone resorption. Further analyses revealed that Tob acts as an antagonist against BMP2-induced Smad signaling to activate transcription via association with Smads in vitro and that in vivo BMP function to enhance orthotopic bone formation is also enhanced by the absence of Tob (Yoshida Y. et al., Cell, 2000). Although Tob-deficiency revealed its phenotype in adult mice, the role of Tob in osteoporosis such as those after ovariectomy (OVX) – induced alteration in bone metabolism has not yet been understood. Thus, this paper examined the effect of Tob-deficiency on OVX-induced bone loss. Tob-deficient and wild-type female mice (9 weeks old) were ovariectomised (OVXed) and control mice were subjected to sham operation. OVX resulted in reduction in uterine weight by about 80% in both Tob-deficient and wild-type mice compared to sham operated mice. Quantification of the two-dimentional trabecular bone volume in the distal end of the femur was conducted by using automated image analyzer. Trabecular bone volume in the wild type mice was significantly reduced 4 weeks after OVX compared to that in the sham-operated wild-type mice (3% vs 8% respectively). In contrast, although bone volume in Tob-deficient mice was reduced after OVX (7%) compared to sham-operated Tob-deficient mice (12%), the fianal levels were still comparable to the sham-operated wild-type mice (7% vs 8%). We further examined bone mineral density (BMD) of the femur. The BMD of femur of wild-type mice after OVX was significantly less than that in sham-operated wild-type mice, and such reduction was also abserved after OVX in Tob-deficient mice. However, even after OVX, BMD levels in Tob-deficient bone were comparable to those in sham operated wild-type bones, and was higher than that in OVXed wild type bones (wild-type mice, OVX;48.5mg/cm2, Tob-deficient mice, OVX;50.8mg/cm2). Futhermore, cortical bone volume in OVXed wild-type mice was less than that of sham operated mice and that of OVXed tob-deficient mice, and no significant difference was observed between the cortical bone volume levels in sham-operated wild-type mice and OVXed Tob-deficient mice. These data indicate that Tob-deficiency preserves bone mass even after the bone loss due to OVX, suggesting that modulation of the Tob fnction could give a clue to develop novel therapeutic measures for the treatment of osteoporosis.

1144

Parallel Development of Vascular Calcification and Osteoporosis in Hyperlipidemic Mice: Evidence for the Role of Lipid Oxidation Products. F. Parhami,[1] A. D. Watson,*[1] A. Dominguez,*[1] W. G. Beamer,*[2] S. Hama,*[1] M. Navab,*[1] T. A. Drake,*[3] X. Wang,*[1] Y. Tintut,*[1] T. J. Hahn,*[4] L. L. Demer.*[1] [1]Medicine, UCLA, Los Angeles, CA, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA, [3]Pathology, UCLA, Los Angeles, CA, USA, [4]Medicine, West LA VA Medical Center, Los Angeles, CA, USA.

Vascular calcification and osteoporosis are debilitating diseases that have been linked with atherogenesis and hyperlipidemia in humans. Common mechanisms that could explain the parallel development of these diseases are not known. We have recently reported that atherogenic oxidized lipids induce osteoblastic differentiation and mineralization of calcifying vascular cells, whereas the same lipids inhibit those in osteoblastic cells. Therefore we hypothesized that formation and accumulation of atherogenic oxidized lipids in the artery wall and in bone may be common mediators that contribute to vascular calcification and osteoporosis, respectively. In this report we present evidence that diet-induced hyperlipidemia promotes both the development of vascular calcification and osteoporosis in low density lipoprotein receptor (LDLr) null mice. Eight 1-month old male LDLr null mice were placed on high fat or control diets for 11 and 22 weeks. Vascular calcification was assessed by histologic examination and quantitative area measurement. Bone mineral density (BMD) was determined in the femurs by quantitative CT scanning. Aortic calcification was induced in the animals on the high fat diet, occurred in close proximity to atherosclerotic lesions, and was greatly increased with time (mean calcified area vs. 309±550 vs. 9944±7630 mm2/section at 11 and 22 weeks, respectively). BMD was also reduced during the experiment, and at 22 weeks animals on the high fat diet had 8% lower BMD than those on the control diet (471±45 vs. 512±55 mg/mm3; $p<0.01$ by paired analysis). These changes in vascular calcification and BMD in the high fat fed mice were associated with increased circulating lipid hydroperoxides (LOOH) compared to animals on control diet (26.6 vs. 1.9 mg/mg protein). In a separate experiment we found that LOOH and cholesterol increased 2-3 fold in bone marrow from C57BL/6 mice fed an atherogenic high fat vs. control diet for 5 weeks. Furthermore, mass spectrometric analysis of fatty acids from those mice after 8 weeks of high fat diet showed accumulation of oxidized lipids similar to those previously identified in oxidized LDL and in atherosclerotic arteries. Altogether, these observations further support the hypothesis that lipid oxidation may be a common mechanism underlying atherosclerotic vascular calcification and age-related osteoporosis, as well as providing evidence for the accumulation of oxidized lipids in bone.

1145

Physical Activity and Bone Strength at the Proximal Femur during the Adolescent Growth Spurt. M. R. Forwood,[1] D. A. Bailey,[2] T. J. Beck,[3] R. L. Mirwald,*[2] W. A. Wallace,*[2] T. L. Oreskovic.*[3] [1]Anatomical Sciences, University of Queensland, Brisbane, Australia, [2]Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada, [3]Radiology, Johns Hopkins University, Baltimore, MD, USA.

To investigate the influence of physical activity on bone strength during the adolescent years we analyzed seven years of longitudinal data from 70 boys and 68 girls who were part of a longitudinal study monitoring bone mineral and bone geometry changes in healthy, growing children. Physical activity and dietary information along with anthropometric measurements were secured every six months and DXA bone scans of the total body, hip and lumbar spine were measured annually (Hologic QDR2000, array mode). Applying the Hip Strength Analysis software protocol developed by Beck and associates (Beck et al., Invest Radiol. 1990, 25:6-18) to our hip DXA scans allowed us to estimate important structural determinants of bone strength including the section modulus at the femoral neck. Distance and velocity curves for height were fitted for each child utilizing a cubic spline procedure and the age of peak height velocity (PHV) was determined. To control for maturational differences between children of the same chronological age, section modulus values were determined for points on each individual's curve at the age of PHV and one and two years on either side of peak. Subjects were categorized into activity groupings using all their physical activity assessments as measured by the (PAC-Q) physical activity inventory score. This was transformed into an age specific mean Z-score. On the basis of mean Z-score ranking, subjects were compared between the most and least active activity quartiles. There were no statistical differences between these activity groups in terms of attained height and weight at the age of PHV. Section modulus of the femoral neck for the active and inactive groups of boys and girls is shown in the figure below.Two way analyses of variance revealed significant ($p<.05$) activity and maturational age effects in both boys and girls. These results suggest that a modifiable lifestyle factor like physical activity may play an important role in the optimization of bone strength at the proximal femur during the adolescent years.

Bone Mineral Change in Prepubertal Asian and Caucasian Boys: Effects of Jumping Intervention, Body Mass, and Ethnicity. K. J. MacKelvie, H. A. McKay, M. A. Petit, K. M. Khan. Human Kinetics, University of British Columbia, Vancouver, BC, Canada.

Only one study has investigated the effects of an exercise intervention on bone mass in an independent group of prepubertal boys, and none have reported an ethnic-specific response. Therefore, we asked 2 questions: 1) Does a 7-month, school based load-bearing exercise program benefit bone mineral content (BMC, g) and areal density (aBMD, g/cm^2) in prepubertal boys and 2) Do Asian and Caucasian boys respond differently to this intervention? Boys from 14 elementary schools were randomized to control (Con) and intervention (Int) groups. Intervention boys participated in a 10 minute, circuit-training jumping intervention, 3 x/week. Primarily, we investigated outcomes in boys who were below the 75th percentile (40.6 kg) of the cohort mean for baseline body mass. There were 41 Asian (19 Con, 22 Int) and 50 Caucasian (25 Con, 25 Int) prepubertal (Tanner stage 1) boys. Age and weight did not differ between groups, and boys were 10.2 (0.6) yrs old and weighed 31.7 (4.1) kg, on average. We measured BMC and aBMD by DXA (Hologic QDR 4500) for the total body (TB), lumbar spine (LS), proximal femur (PF), femoral neck (FN) and trochanter (TR) at 0 and 7 months. Lean mass (g) and fat mass (g) were DXA-derived. Calcium intake and physical activity were assessed by questionnaire. Changes in height, weight, lean mass, fat mass, and average yearly calcium intakes and physical activity did not differ between Int/Con or ethnic groups (ANOVA). We used ANCOVA (with baseline weight, final Tanner stage, change in height, and physical activity as covariates) to analyze change in bone. Intervention boys gained significantly more TB BMC (9.6 vs. 7.7%, $P<0.01$, PF aBMD (3.2 vs. 1.8 %, $P<0.05$), and TR aBMD (3.4 vs. 1.4 %, $P<0.01$) compared with controls; change in LS BMC approached significance (10.0 vs. 8.2 %, $P=0.050$). Change in bone mineral did not differ between Asian and Caucasian boys. Secondarily, we investigated the bone mineral change in those prepubertal boys who were in the highest quartile for baseline body mass. Control (N=16, 10.5 (0.6) yr and 50.3 (8.8) kg) and intervention (N=14, 10.4 (0.7) yr and 47.8 (6.8) kg) boys did not differ in changes in height, weight, lean mass, fat mass, and average yearly calcium intakes and physical activity. Using a similar ANCOVA analysis as described above, 7-month change in bone mineral did not differ between control and intervention groups at any site. These data suggest that jumping exercise augments bone mineral accrual at several regions equally in prepu-

bertal Asian and Caucasian boys who are of average or low body mass. However, the intervention offered no bone mineral advantage to prepubertal boys who were in the highest quartile (>40.6 kg) for body mass.

1147

Bone Structural Adaptation to Exercise in Pre- and Early- Pubertal Girls: A Randomized Intervention Trial. M. A. Petit,[1] H. A. McKay,[1] K. J. MacKelvie,[1] A. Heinonen,[1] K. M. Khan,[1] T. J. Beck.[2] [1]Human Kinetics, University of British Columbia, Vancouver, BC, Canada, [2]Radiology, Johns Hopkins University, Baltimore, MD, USA.

Growing bone may conceivably respond to loading by altering its geometric properties independent of changes in bone mass. However, very little is known about changes in bone strength in response to load-bearing in pediatric groups. Therefore, we compared total bone cross-sectional area, subperiosteal and endosteal width and section modulus (bone structural variables) at the proximal femur at baseline and after 7 months of load bearing exercise in 174 pre- and early- pubertal girls. Girls rated as Tanner breast stage 1 at baseline were considered prepubertal (PRE; n = 43 intervention (I), n = 25 control (C)); while Tanner stage 2 and 3 girls were classified as early-pubertal (EARLY; n = 43 I, n = 63 C). Mean (SD) age was 10.0 (0.6) and 10.5 (0.6) for the PRE and EARLY groups, respectively. Schools randomized to intervention group participated in a 10-minute, 3x per week high impact, progressive circuit training program. Physical activity and calcium intake were assessed by questionnaire 3 times during the year. Control schools conducted regular elementary school PE. We used proximal femur DXA scans (Hologic QDR-4500) and Beck et al's. hip structural analysis (HSA) program to estimate cross-sectional geometry and BMD in narrow regions across the femoral neck (FN), intertrochanter (IT), and femoral shaft (FS). There were no significant differences between I and C groups for baseline height, weight, calcium intake or physical activity or for change over 7-months ($p > 0.05$). We used ANCOVA to examine group differences for change in bone structural variables adjusting for baseline weight, height change, Tanner breast stage, and physical activity. There were no significant group differences for change in adjusted bone structural variables at any site in the pre-pubertal girls. However, the more mature girls (EARLY) in the intervention group showed significantly greater gains in FN (+2.6%, p=0.03) and IT (+1.7%, p=0.02) BMD. Underlying these changes were increased bone cross-sectional area and reduced endosteal expansion in the intervention group. Changes in subperiosteal width did not differ at any site. Structural changes led to a greater increase in bone bending strength (section modulus) at the FN (+4.0%, p=0.04), but not the IT region. There were no differences at the primarily cortical femoral shaft. These data highlight the complexity of the bone adaptation to mechanical loading which varies depending on the bone site and region and the characteristics of the participants (pubertal stage).

1148

A Randomized, Placebo Controlled, Pilot Trial of Low Magnitude, High Frequency Loading Treatment of Low Bone Mineral Density in Children with Disabling Conditions. K. A. Ward,*[1] C. W. Alsop,*[1] S. Brown,*[2] J. Caulton,*[3] J. E. Adams,[1] Z. Mughal.*[4] [1]Clinical Radiology, Imaging Science and Biomedical Engineering, University of Manchester, Manchester, United Kingdom, [2]Smith and Nephew Group Research Centre, York, United Kingdom, [3]School of Physiotherapy, Central Manchester Healthcare Trust, Manchester, United Kingdom, [4]Pediatric Medicine, Saint Marys Hospital, Manchester, United Kingdom.

Children with certain disabling conditions, such as cerebral palsy, are prone to atraumatic fractures, which are associated with low bone mineral density. The aim of this randomized, double blind, placebo controlled, pilot trial (RCT) was to determine whether low magnitude, high frequency loading would lead to an increase in tibial and spinal volumetric trabecular bone mineral density (vTBMD, mg/ml) in children with disabling conditions.A heterogeneous group of 20 pre-or post pubertal disabled but ambulant children (14 males, 6 females; mean age 9.1 ± 4.3 years, range 4-19 years) took part in this RCT. They were randomized to standing on active (n = 10; 0.3G, 90Hz,) or placebo (n = 10) devices (Exogen Optimass Device, Smith & Nephew) for 10 minutes/day, 5 days/week for 6 months. This G-force results in approximately 5 microstrain in the tibia of a standing sheep (Dr C Rubin, Personal Communication). Quantitative computer tomography (Philips SR-400), in conjunction with a spiral 3-D software (QCT-Pro, Mindways Software Inc) was used to measure vTBMD of the proximal tibia and the lumbar spine (L2). Repeat analysis precision was 0.9% for proximal tibia and spine. Median duration of treatment received by subjects in the active and placebo groups was 35.5 days (range 15 - 117 days); median standing time 481 minutes (range 88 - 1206 minutes). Mean proximal tibial vTBMD showed a significant effect of treatment (p=0.0036) after adjusting for covariates of body weight, disability category, pubertal status, calcium intake, baseline vTBMD and number of days in the study. Mean change in proximal tibial vTBMD in children who stood on active plates was +11.6 mg/ml; and in those who stood on placebo plates it was - 6.7 mg/ml. The net increase in mean proximal tibial vTBMD was 18.2 mg/ml (95% CI: 7.3 to 29.1); in spinal vTBMD was 3.8 mg/ml, (95% CI: -6.4 to 13.9; p=0.43). Based on the results of this pilot RCT we conclude that low magnitude, high frequency loading treatment administered by the Exogen Optimass Device offers a non-invasive and non-pharmacological approach to improving trabecular bone mineral density in children with disabling conditions.*Exogen Optimass Devices used in this study were on loan from Smith & Nephew, Memphis, USA.*

Disclosures: Smith & Nephew Inc, Memphis, Tennessee, USA,2.

Bone Mineral Gain Following Calcium Supplementation in Teenage Girls is Reversed Two Years After Withdrawal of the Supplement. K. D. Ghatge,*[1] H. L. Lambert,*[2] M. E. Barker,*[1] R. Eastell.[2] [1]Centre for Human Nutrition, University of Sheffield, Sheffield, United Kingdom, [2]Bone Metabolism Group, University of Sheffield, Sheffield, United Kingdom.

Supplementation with milk or calcium during childhood and adolescence enhances bone mineral accrual. The extent to which this beneficial effect persists beyond the period of supplementation is less clear. The relative merits of milk and elemental calcium as a supplement are also not known. We conducted an 18-month randomised, controlled calcium supplementation trial in 86, 11-12 year-old girls, with follow-up 2 years after stopping the supplement. The supplement was 800mg/day calcium in the form of citrate malate (CCM). Subjects were randomised to a calcium or control group, stratified by baseline calcium intake and pubertal stage (Tanner breast stage). Calcium intake was assessed by weighed intake (7-days at 0 and 18 months, 4-days at 42 months). Total body bone mineral content (TBBMC) and bone mineral density (BMD) of the total body (TB), lumbar spine (LS) and total hip (TH) were measured by DXA at baseline, at the end of supplementation (18 months) and 2 years after stopping the supplement (42 months). The mean baseline calcium intake was 658mg/day. After 18 months this had increased to 972mg/day in the calcium group, with no change in the control group. At 42 months the mean calcium intake was 652mg/d, and with no differences between the groups.At the end of the supplementation period the calcium group had gained significantly more TBBMD than the control group ($P<0.05$, t-test). This effect was completely reversed 24 months after stopping the supplement (table 1). The results for TBBMC, LSBMD and THBMD showed a similar trend.

Table 1. Percent change in BMD: mean (SD)

	TBBMD		LSMBD		THBMD	
Group	**0-18 months**	**18-42 months**	**0-18 months**	**18-42 months**	**0-18 months**	**18-42 months**
Calcium	8.4 (3.1)	5.9 (3.2)	15.2 (4.8)	9.5 (7.0)	12.8 (5.6)	5.4 (5.5)
Control	6.8 (2.9)	7.9 (3.2)	13.2 (6.6)	13.7 (8.1)	11.9 (7.4)	7.5 (6.8)
t	2.21	-2.31	1.49	-2.33	0.53	-1.46
p	0.03	0.02	0.14	0.02	0.60	0.15

Two-tailed, unpaired t-test

The pattern of the effect of CCM suggests that the observed gain in BMD is likely due to suppression of bone remodelling, and a contraction of the remodelling space, which is reversed when the supplement is withdrawn. This pattern is not seen with milk[1], indicating that the mechanism for the effect of this supplement differs to that of elemental calcium. We plan to confirm the effect of the contribution of the remodelling space using longitudinal change in biochemical marker levels.[1]Cadogan J., Eastell R., Jones N. and Barker M.E. (1997) Milk intake and bone mineral acquisition in adolescent girls: randomised, controlled intervention trail. *British Medical Journal*, **315**, 1255-1260.

The Growing Skeleton: A Comparison of MRI, DXA, and Cross-Sectional Geometric Changes at the Proximal Femur Over 7-Months. H. A. McKay,[1] A. Heinonen,[1] M. A. Petit,[1] K. M. Khan,[1] K. Forkheim,*[2] B. Forster,*[2] [1]Human Kinetics, University of British Columbia, Vancouver, BC, Canada, [2]Radiology, University of British Columbia, Vancouver, BC, Canada

Bone may alter its geometric properties independent of changes in bone mass. Further, two-dimensional measurement modalities such as DXA are confounded by size increases during growth and do not allow us to study the structural basis of skeletal change. Therefore, we assessed 7-month changes in bone structural parameters at the femoral neck by magnetic resonance imaging (MRI) and with the Hip Structural Analysis program (HSA), and total bone area, bone mineral content and BMAD by dual energy X-ray absorptiometry (DXA) in 18 prepubertal girls. Total bone cross-sectional area was also calculated from high resolution T1-weighted MRI oblique axial images of the femoral neck. We used proximal femur DXA scans (Hologic QDR-4500) and Beck et al's HSA program to estimate bone cross-sectional area (CSA), subperiosteal bone width, and section modulus at the femoral neck. We used ANCOVA to examine group differences (controlling for age and change in lean body mass) to assess percent change (95% confidence intervals. We also determined short-term precision for MRI with repositioning on 10 adult subjects. Mean percent change (95% CIs) from baseline in TBA, adjusted for covariates was 8.5% (4.9 to 12.1%) as measured by MRI and 5.1% (0.8-9.5%) by DXA. A significant increase was also noted for BMC (9.6% (6.0-13.2%)) and cross-sectional geometry (subperiosteal width +2.4% (0.2-4.6%), cortical thickness +5.2% (1.9-8.6%), section modulus +11.3% (6.9-15.6%)) between trials. BMAD showed a non-significant change (2.1% (-0.9 to 5.0%)). Spearman rank order correlation was significant between absolute values for total bone area measured by MRI and total bone area by DXA ($r=0.45$, $p<0.10$), section modulus ($r = 0.40$, $p<0.10$), and subperiosteal width ($r=0.45$, $p<0.10$) by HSA. Precision (CV%) for total bone area, cortical and trabecular bone CSA by MRI were 1.5%, 6% and 1.8%, respectively. This is the first prospective study in a pediatric group to utilize MRI to assess change in bone parameters at the proximal femur in growing girls. Findings highlight the independent change in bone mass and size at the femoral neck by MRI with no concomitant change in bone mineral apparent density (by DXA). MRI is a reproduceable method to assess total bone and trabecular bone change at the proximal femur.

1151

Effect of Age, Size and Muscularity on Peripheral Quantitative Computed Tomography (pQCT) Measures in Children. B. Zemel,[1] M. C. Nelson,*[1] A. V. Owen,*[1] V. A. Stallings,[1] M. B. Leonard.[2] [1]Division of GI and Nutrition, The Children's Hospital of Philadelphia, Philadelphia, PA, USA, [2]Division of Nephrology, The Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Assessment of bone health in children is complicated by the effects of growth and changing body composition on bone dimensions. These influences are important in light of the altered growth and body composition that commonly occur in children with chronic diseases for whom bone health is a significant concern. Size-related effects in DXA bone density measurements are recognized, but are less well understood for pQCT. The goal of this preliminary study was to examine the effects of age, body size and muscularity on pQCT measures in healthy prepubertal children. Healthy children, ages 7.0 to 10.9 years were recruited. Exclusion criteria included obesity, chronic illnesses or medication use affecting growth, bone density or dietary intake. pQCT measurements of the left distal tibia were obtained using a Norland-Stratec XCT2000. At the 4% site, trabecular bone mineral content (BMC), area and density (BMD) was measured, as were cortical BMC, area, and BMD, and the polar moment of inertia (PMI) at the 20% site. Height and tibia length (TL) were assessed. Upper arm muscle area (UAMA) was derived from arm circumference and triceps skinfold measures. UAMA z-score was based on NCHS reference data. Grip strength was measured using a hand-held dynamometer. Data were analyzed in Stata 6.0 (College Station, TX) using t-tests and regression analysis. A dummy variable for pQCT analysis mode at the 4% site was included in regression models as appropriate. 51 children (30F) were evaluated. Age was significantly associated with most pQCT measures except for trabecular and cortical BMD, and TL was a better predictor than age (see Table). Gender differences were not evident. Grip strength and UAMA-Z were also significantly associated with BMC, area and PMI but not BMD. Regression models using TL and grip strength were significant, with R^2 = 80% for cortical BMC and 72% for PMI. TL and UAMA-Z were significant predictors of cortical area (R^2 = 60%). Table: Percent of variance explained (R^2) by age and size for pQCT measures

	4% distal Tibia*			20% distal Tibia			
	BMC	**Area**	**BMD**	**BMC**	**Area**	**BMD**	**Polar MI**
Age	0.51	0.56	ns	0.37	0.29	ns	0.34
TL	0.64	0.68	ns	0.69	0.57	0.10	0.69

Note: *adjusted for pQCT analysis mode at 4% site; $p<0.05$, ns = not significant Consistent with other reports, in prepubertal children, BMD is not associated with age. Size and muscularity are significant predictors of BMC, area and PMI (an indicator of bone strength). These findings underscore the importance of body size and composition in assessing bone health even within a narrow age range of prepubertal children

1152

The Use of Inhaled Corticosteroids Is Not Associated with an Increased Risk of Fracture in Children. T. P. van Staa,[1] C. Cooper,[2] H. G. M. Leufkens,*[3] N. Bishop.[4] [1]Procter & Gamble Pharmaceuticals, Staines, United Kingdom, [2]University of Southampton, Southampton, United Kingdom, [3]Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands Antilles, [4]Sheffield University, Sheffield, United Kingdom

Oral corticosteroids are known to increase the risk of fractures. It is unknown whether children using inhaled corticosteroids have an increased risk of fracture due to systemic absorption. We undertook a population-based nested case-control study using medical records of general practitioners in the UK (from the General Practice Research Database). Children aged 4 to 17 years taking inhaled corticosteroid were compared to children taking only noninhaled/nonsystemic corticosteroid prescriptions (topical, aural, ophthalmic, or nasal). Incidence rates of fracture during follow-up were estimated for each cohort. Each fracture case was then matched by age, sex, practice, and calendar time to one child without a fracture.It was found that the incidence of fracture for both the reference and inhaled corticosteroid cohorts rose before puberty, reached a peak around puberty, and fell thereafter. The risk of fractures for boys was generally higher than that for girls (rate of 2.1 fractures per 100 person-years in boys versus 1.3 in girls). There were 97 387 children taking inhaled corticosteroids, of whom 3754 suffered a fracture during treatment. With an average daily dose of 200 µg/day or less (standardized to beclomethasone dipropionate), the crude odds ratio for fracture relative to children taking only noninhaled/nonsystemic corticosteroids was 1.09 (95% CI 0.98-1.21), with 201 to 400 µg 1.05 (0.95-1.15) and over 400 µg 1.22 (1.06-1.41). The excess risk in the high daily dose group disappeared after adjustment for indicators of asthma severity (adjusted odds ratio of 1.02 [95% CI 0.87-1.20]). There were also higher risks of fracture in children with more previous cumulative exposure to inhaled corticosteroids, but this also disappeared after adjustment.Asthma itself, rather than the use of inhaled corticosteroids, is associated with an increased risk of fracture in childhood. The mechanism underlying this increase in risk remains to be determined.

1153

CIZ, a Transcription Factor Shuttling between Nuclei and Cell Adhesion Plaque, Enhances Cbfa1 (Runx 2) Gene Expression but Counteracts against BMP Signaling to Resume Osteopontin and to Suppress Collagen Gene Expression in Osteoblast Like Cells. Z. Shen,[1] K. Tsuji,[1] T. Nakamoto,[2] H. Hirai,[2] A. Nifuji,[1] M. Noda.[1] [1]Dept of Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]University of Tokyo, Tokyo, Japan.

CIZ (Cas interacting zinc finger protein) (NP/NMP4) is a nucleocytoplasmic shuttling protein, which binds to p130CAS at focal adhesion plaques and also binds to DNA to regulate expression of genes encoding MMPs and type-I collagen. Thus, CIZ could act as a novel type of transcription factor expressed in osteoblast. Although osteoblastic functions are regulated by matrix-signaling through their adhesion to the ECM proteins (out-side-in signaling) and the matrix formation and reorganization are tightly controlled by osteoblasts (in-side-out signaling) under the control of cytokine signals including BMP, the molecular mechanisms involved in this relationship between matrix-induced signals and gene regulation in osteoblasts are not well understood. Here, we examined cross talk between the actions of CIZ and BMP signaling in MC3T3E1 osteoblastic cells. CIZ was overexpressed stably in MC3T3E1 cells and clonal cell lines were established using geneticin selection. Overexpression of CIZ enhanced Cbfa1 (Runx 2) gene expression in the clonal cell lines. Promoter sequence analysis of Cbfa1 gene also identified CIZ-binding sites of G/CAAAAA. BMP treatment enhanced Cbfa1, alkaline phosphatase (ALP), and osteocalcin (OC) expression in control MC3T3E1 cell lines transfected with an empty vector. In contrast, CIZ overexpression suppressed the BMP-induced enhancement of Cbfa1, ALP, and OC gene expression. BMP2 treatment also enhanced type-I collagen mRNA expression over 7.8-fold in the control MC3T3E1 within 3-days and this enhancement was still observed at 7 and 14 days. In contrast, CIZ overexpression completely blocked the BMP2 effects on type-I collagen mRNA expression at all the time points. These data reveal the presence of CIZ inhibition of BMP signaling. Either CIZ overexpression or BMP2 treatment alone suppressed osteopontin (OPN) expression while the presence of both signaling systems cancelled out the suppressive effects of each other ending up with the recovery of basal level of OPN expression, indicating another line of the interference between the two signaling systems. Thus, our data indicate the dual role of CIZ, i.e activaion of Cbfa1 gene expression in the absence of BMP2 and inactivation of BMP signaling-induced events. As Cbfa1 and BMP signaling are required for osteoblastic differentiation and function, CIZ would act as a critical modulator to balance the two major signaling systems in osteoblasts under the control of matrix.

Runx2-C/EBP Molecular Interactions and Functional Synergism Support Maximal Expression of Osteocalcin in Osteoblasts. A. Javed,* S. E. Gutierrez,* D. K. Tennant,* M. van Rees,* M. Montecino,* A. J. van Wijnen, G. S. Stein, J. B. Lian, J. L. Stein.* Cell Biology, UMASS Medical School, Worcester, MA, USA.

CCAAT/enhancer binding proteins (C/EBP) members of the leucine zipper family of transcription factors are critical for normal cellular differentiation, although their functional role(s) in osteoblast development have not been determined. Here we show that C/EBP β and C/EBP δ mRNAs are expressed from growth to maturation stages with an increase (3-5 fold) at the onset of osteocalcin transcription. Peak expression of both mRNAs occurs during the mineralization stage. Furthermore, vitamin D_3, a physiologic regulator of osteoblastic gene expression, mediates 3-6 fold upregulation of C/EBP β and δ, suggesting that C/EBP(s) contribute to osteogenic differentiation. We characterized a C/EBP regulatory element in the proximal promoter of the rat osteocalcin gene. Mutational analyses and forced expression studies demonstrate that this element mediates a 4-8 fold transcriptional enhancement in both osseous and non-osseous cells. This enhancer activity is equivalent to that mediated by the Runx2 transcription factor. Functional studies show that C/EBP and the bone-related Runx2/Cbfa1 transcription factor interact synergistically to enhance OC transcription (35-40 fold). We established by point mutations that this synergism is mediated through the C/EBP responsive element in the OC promoter. Furthermore mutant Runx2 protein lacking the C/EBP interaction domain fails to exhibit synergism. Taken together, our findings indicate that C/EBP and Runx2, are both principal transactivator of the OC gene that directly interact and cooperate to regulate physiologic induction of the bone-tissue specific osteocalcin gene during osteoblast differentiation.

1155

FHL-2, A LIM Only Transcription Factor, Is a Binding Partner for IGF Binding Protein (BP)-5 in Normal Human Osteoblasts (OB). Y. Amaar, G. Thompson,* T. A. Linkhart, S. T. Chen,* D. J. Baylink, S. Mohan. MDC, Pettis VAMC, Loma Linda, CA, USA.

BP-5 stimulates bone formation parameters and correlates with BMD, thus suggesting BP-5 is an important bone formation regulator. Recent studies using IGF-I knockout mice demonstrate that BP-5 itself is a growth factor with cellular effects not dependent on IGFs. Based on these findings and the findings that BP-5 contains nuclear localization sequence that mediates transport of BP-5 into the nucleus, we propose that BP-5 interacts with transcription factors to stimulate transcription of genes that lead to increased OB proliferation and/or differentiated functions. As a means of testing this hypothesis we undertook studies to identify proteins that bind to BP-5 using BP-5 as bait in the yeast two hybrid screen of U2 human osteosarcoma cDNA library. Five clones were identified that interacted strongly with the bait under high stringency conditions that corresponded to FHL2 gene (also known as SLIM-3), which contains four and a half LIM domains. One clone (1.4 kb) was full length encoding 297 amino acids while the other four were partial clones encoding the C-terminal region of FHL2. The smallest clone (0.8 kb) encoded LIM domains 3 and 4, thus suggesting that the C-terminal region of FHL2 containing the last two LIM domains is sufficient for FHL2 interaction with BP-5. In order to determine the specificity of FHL2 interaction with BP-5, we expressed FHL2 in E.coli and performed interaction studies between purified FHL2 and various IGFBPs *in vitro* using FHL2 antibody. We found that FHL2 interacted with BP-5 but not with BP-4 or BP-6. We next determined if FHL2 is expressed in normal human OBs and localized in the nucleus. Northern blot analysis showed that FHL2 is strongly expressed in normal human OBs derived from calvaria and rib besides U2 and SaOS-2 human osteosarcoma cells. Western immunoblot analysis using cytoplasmic and nuclear extracts revealed that the FHL2 protein is present in both of these extracts. Furthermore, nuclear localization of BP-5 in OBs was identified by immunofluorescence and by western immunoblot analysis using BP-5 specific antibodies, thus raising the possibility that the interaction between BP-5 and FHL2 could occur in the nucleus. Conclusions: 1) FHL2, a LIM only protein, has been identified as a binding partner for BP-5 in OBs. 2) Interaction between FHL2 and BP-5 is specific and involves C-terminal

region of FHL2. 3) Based on the findings that BP-5 stimulates bone formation and that LMP-1, another LIM-domain protein, is a positive regulator of bone formation, we predict FHL2 to be an important bone cell regulatory protein that functions to mediate the effects of BP-5 and other osteoregulatory agents in bone cells.

1156

Normalizing the Decreased Circulating Levels of Leptin in ΔFosB Transgenic Mice Fails to Rescue the Osteosclerotic Phenotype. M. Kveiborg, R. Chiusaroli, J. Juel,* G. Sabatakos, W. C. Horne, R. Baron. Yale University School of Medicine, New Haven, CT, USA.

Transgenic mice overexpressing δFosB isoforms exhibit an osteosclerotic phenotype (Sabatakos et al. Nature Med 6: 985-990, 2000). This effect was shown to be cell-autonomous, i.e. reproducible in vitro with osteoblasts isolated from transgenic animals or by transfecting δFosB isoforms in osteoblastic cell lines. We also observed that abdominal fat as well as numbers of marrow adipocytes were decreased in δFosB mice, as were serum leptin levels. Increased bone mass has been linked to deficient leptin and leptin receptor signaling in Ob/Ob and Db/Db mice (Ducy et al. Cell 100: 197-207, 2000), raising the possibility that, in addition to the direct effect of δFosB isoforms in cells of the osteoblast lineage, the reduction in leptin contributes to the increased bone mass. We therefore tested the hypothesis that, in addition to affecting directly osteoblastogenesis and bone formation, δFosB isoforms might increase bone mass indirectly via a decrease in leptin. For this purpose, we restored normal circulating levels of leptin in δFosB mice by infusing leptin via subcutaneous osmotic pumps for periods of 4 weeks. Infusion of 200 ng/hr restored circulating levels of leptin to the normal range in δFosB mice (saline: 0.94 ± 0.29 ng/ml vs leptin: 2.62 ± 0.70 ng/ml), but did not affect circulating leptin levels in control mice (saline: 2.00 ± 0.76 ng/ml vs leptin: 2.73 ± 0.76 ng/ml), due to decreased fat: Leptin infusion caused a significant decrease in abdominal fat in control mice (saline: 0.465 ± 0.040 g vs leptin: 0.256 ± 0.090 g), but did not further decrease fat weight in transgenic mice (saline: 0.117 ± 0.037 g vs 0.103 ± 0.053 g). Complete histomorphometric analysis demonstrated that trabecular bone volume was unchanged in the control mice (saline: 9.47 ± 1.29 BV/TV (%) vs leptin: 10.08 ± 3.70 BV/TV (%)) as well as in transgenic mice (saline: 28.60 ± 7.04 BV/TV (%) vs leptin: 22.70 ± 5.78 BV/TV (%)), independent of gender. Furthermore, bone formation parameters were unaffected by leptin treatment (MAR control mice, saline: 1.47 ± 0.55 μm/day vs leptin: 1.53 ± 0.46 μm/day; MAR δFosB mice, saline: 1.23 ± 0.22 μm/day vs leptin: 1.17 ± 0.27 μm/day) (BFR control mice, saline: 213.63 ± 99.06 $\mu m^3/\mu m^2$/year vs leptin: 195.60 ± 43.13 $\mu m^3/\mu m^2$/year; BFR δFosB mice, saline: 176.90 ± 89.90 $\mu m^3/\mu m^2$/year vs leptin: 170.10 ± 108.87 $\mu m^3/\mu m^2$/year). These results demonstrate that restoring circulating levels of leptin in δFosB transgenic mice failed to rescue the bone phenotype, further indicating that the marked increase in bone formation is autonomous to the osteoblast lineage.

AP-1/Interleukin (IL)-11 Signaling Cascades May be Involved in PTH-induced Bone Formation: ERK-dependent Induction of Delta-fosB and IL-11 by hPTH(1-34). S. Kido, D. Inoue, T. Matsumoto. First Department of Internal Medicine, University of Tokushima School of Medicine, Tokushima, Japan.

Intermittent PTH administration increases bone mass by stimulating bone formation in vivo. However, PTH-induced osteogenic signals remain to be determined. We have shown that delta-fosB, a fosB splicing variant, and IL-11, both of which have been shown to stimulate bone formation by in vivo over-expression in transgenic mice, are rapidly induced by mechanical stress both in vitro and in vivo osteoblasts. We have also demonstrated that IL-11 transcription is totally dependent on AP-1 and that impaired bone formation in the aged is associated with reduction in AP-1 activities and IL-11 expression in marrow stromal cells. These findings suggest that AP-1 and its target IL-11 may play universal roles in divergent osteogenic signaling pathways. We therefore tested a hypothesis that PTH induces bone formation via AP-1/IL-11 induction. Consistent with our hypothesis, we found that treatment of mouse primary osteoblasts (POB) with 100 ng/ml hPTH (1-34) induced delta-fosB mRNA expression in 30 min and IL-11 at 3 hrs. Intermittent PTH treatment (6 hrs/48 hrs x 3 cycles) of osteoblasts resulted in accumulation of Delta-FosB and Delta2-Delta-FosB, which is produced from the same delta-fosB mRNA by alternative ATG codon usage, in nuclear extracts. Furthermore, IL-11 neutralizing antibodies partially blocked PTH induction of ALP in POB. We also demonstrated that PTH activated ERK in POB and that PTH induction of delta-fosB/IL-11 was completely blocked by an ERK1/2 inhibitor U0126, but not by a p38 kinase inhibitor SB203580, indicating that PTH induction of delta-fosB is dependent on ERK. Interestingly, in vivo treatment of mice with PTH by peritoneal injection induced IL-11 mRNA expression in limb bones within several hours, and this induction was partially inhibited by pre-injection of dexamethasone (Dex). In vitro, pre-treatment of POB with 100 nM Dex completely blocked the PTH induction of IL-11, but not that of delta-fosB, consistent with the ligand-dependent inhibition of AP-1 activities by glucocorticoid receptors. IL-11 expression was also induced by a Ca-ionophore A23137 and DBcAMP, which was again completely inhibited by Dex. Taken together, these results suggest that the ERK/AP-1 (delta-fosB)/ IL-11 cascade participates in PTH-induced signaling pathways that leads to increased bone formation. Our findings also imply that suppression of IL-11 expression may contribute to the pathogenesis of glucocorticoid-induced osteoporosis. Thus, the AP-1/IL-11 cascade appears to be a critical component of various osteogenic signaling pathways under both physiological and pathological conditions.

Transcriptional Repression of Osteocalcin Gene Expression by Delta EF1. K. Sooy,* M. B. Demay. Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA.

The first intron of the rat osteocalcin gene contains a complex suppressor region from +106 to +142. Previous studies have identified unique silencer elements in this region that have a suppressive effect on rat osteocalcin-reporter fusion gene transcription. A search of the transcription factor database, "Transfac", using the sequence of the first intron of the rat osteocalcin gene, suggested several candidate transcription factors that may interact with the sequences in intron 1. The consensus sequence for one of these factors, delta EF1 (dEF1), showed extremely high homology with two pyrimidine rich repeats (CCTCCT). DNAse I protection analysis also demonstrated that these CCTCCT motifs were important contact sites for nuclear protein-DNA interactions. dEF1 was initially identified as a repressor of the chicken delta 1 crystallin gene enhancer. dEF1, a member of the zinc finger-homeodomain protein family and a vertebrate homolog of zfh-1 in Drosophila, is inversely expressed with type II collagen in chick limb bud mesenchymal cells and is able to repress Col2a1 promoter activity. Additionally, dEF1 knockout mice exhibit a severe skeletal phenotype, suggesting that dEF1 has a critical role in regulating skeletal gene expression. In order to further investigate a potential role of dEF1 in regulating osteocalcin gene expression, the sequence of intron 1 of the rat osteocalcin gene was placed upstream of the native promoter (-306 to +29) fused to a luciferase reporter gene, to determine whether overexpression of dEF1 is able to increase transcriptional repression by these sequences. Cotransfection of this fusion gene (wtOC-luc) with a dEF1 expression vector led to a 30% decrease in luciferase activity as compared to wtOC-luc cotransfected with empty vector. This repressive effect was not observed when the dEF1 vector was cotransfected with an osteocalcin luciferase fusion gene with mutations in both motifs (CCTCCT to atgCaT; mOC-luc), indicating that intact CCTCCT motifs are necessary for dEF1-mediated repression by these DNA sequences. In gel retardation assays, a wild type dEF1 consensus sequence was able to compete with the wild type osteocalcin oligonucleotide probe containing both CCTCCT motifs, for the generation of the DNA-protein complex. Mutations in the CCTCCT motif which abolished suppressor activity, also abolished competition for the DNA-protein complex, as did analogous mutations in the dEF1 consensus oligonucleotide. These data suggest that dEF1 interacts specifically with the CCTCCT motif and contributes to transcriptional repression of the rat osteocalcin gene in ROS 17/ 2.8 cells.

Localized Expression of Hypoxia Inducible Factor Family and Differential Expression of VEGF Splice Isoforms in Neovascularization and Bone Formation During Regenerating Bone and Bone Marrow After Drill-Hole Injury. S. Uchida,[1] H. Kudo,*[2] A. Sakai,[1] K. Narusawa,*[1] M. Tanaka,*[1] M. Watanuki,*[1] T. Nakamura.*[1] [1]Orthopedic Surgery, University of Occupational and Environmental Health, Kitakyushu, Japan, [2]Department of Anatomy, University of Occupational and Environmental Health, Kitakyushu, Japan.

The purpose of this study is to clarify the cellular events and the expression of Vascular Endothelial Growth Factor (VEGF) and Hypoxia Inducible Factor (HIF) on bone cells and vascular cells in the regenerating bone and bone marrow following drill-hole injury by RT-PCR, immunocytochemistry and in situ hybridization. Wistar rats aged 12-13 weeks were used in the present experiments. A hole of approximately 2.5 mm in diameter penetrating the bone marrow was drilled in the diaphysis of bilateral femur using a surgical drill. At days 1, 3, 5, 7, 11, 14, and 21 after surgery, the rats were sacrificed and bone wound regions were isolated and provided for the experiments Abundant ALP positive osteoprogenitor cells existed in the endosteum surrounding wound region at day 3. At the same period, growing capillaries invaded the wound region from the adjacent endosteum and bone marrow. Some ALP positive cells in the endosteum showed immunoreactivity for Flk-1 as a marker of angioblasts. At day 5, osteoblasts that had begun to express osteocalcin mRNA actively participated in bone formation. Between days 7 and 11, sinusoidal capillaries extended to interstices between trabecular bone networks of medullary callus. The expression of VEGF120 and VEGF165 mRNA were detected from day 3, and further VEGF189 mRNA began to exhibit from day 5. These expressions gradually declined after day 11. VEGF immunoreactivity and gene expression were strongly detected on angioblasts, osteoprogenitor cells and osteoblasts from days 3 and 7. Then the expression gradually declined thereafter. Immunoreactivity for Flk-1 was detected on vascular cells and immunoreactivity for Flt-1 was also detected on both bone cells and vascular cells between days 3 and 7. On the other hand, the gene expression of HIF-1 alpha was detected constitutively between day 1 and day 21 by RT-PCR. Immunoreactivity for HIF-1alpha and HIF-1beta was observed on vascular cells and growing capillaries from day 1 to day 7. However, these expressions were not detected on osteoprogenitor cells and osteoblasts. These findings suggest that alternative splicing of VEGF mRNA may play important role in the transformation of osteoprogenitor cells to osteoblast during bone formation, and HIF family may induce the expression of VEGF mRNA in neovascularization during regenerating bone and bone marrow following Drill-Hole injury.

1160

Expression of Serotonin Receptors in Bone. J. Klein-Nulend,[1] I. Westbroek,*[2] A. van der Plas,*[2] C. M. Semeins,*[1] E. H. Burger,[1] P. J. Nijweide.[2] [1]Oral Cell Biology, ACTA-Vrije Universiteit, Amsterdam, The Netherlands, [2]Molecular Cell Biology, Leiden University Medical Center, Leiden, The Netherlands.

The 5-hydroxytryptamine (5-HT) receptors 5-HT2A, 5-HT2B, and 5-HT2C belong to a subfamily of serotonin receptors. Their amino acid and mRNA sequences have been published for several species, including man. They have been described to act on nervous, muscle, and endothelial tissues. Here we report the presence of 5-HT2B receptors in chicken and mouse bone cells and on the possible functions of serotonin in bone. Using suppression subtractive hybridization we identified a large number of genes preferentially expressed in chicken osteocytes as compared to osteoblasts. One of the genes was the 5-HT2B receptor. RT-PCR and Northern blot analysis of chicken osteocytes, osteoblasts, and osteoblast precursor cells confirmed the preferential but not exclusive expression of 5-HT2B mRNA in osteocytes. To study the possible functions of serotonin in bone, we tested whether serotonin stimulated osteoblast precursor cell proliferation, as has been reported for vascular smooth muscle cell proliferation. We also examined whether serotonin modulated bone cell mechanosensitivity, which could offer a role for the relatively high 5-HT2B

receptor expression in osteocytes, the putative mechanosensory cells of bone. α-Methyl-5-HT, a 5-HT analogue which preferentially binds to 5-HT2 receptors, dose-dependently stimulated chicken osteoblast precursor cell proliferation. Similar effects were found with the 5-HT2B receptor-selective agonist BW723C86. An effective inhibitor of proliferation appeared to be SB215505, a 5-HT2B receptor-selective antagonist. However, ketanserin, a 5-HT2A receptor-selective antagonist, also inhibited cell proliferation to some extent. These pharmacological studies clearly indicate that the 5-HT2B receptor is involved in serotonin-regulated osteoblast precursor cell proliferation, but a possible role of 5-HT2A receptor is not excluded. mRNA expression of both 5-HT2A and 5-HT2B receptor variants was found in primary cultures of adult trabecular bone-derived mouse bone cells. These cells respond to pulsating fluid shear stress *in vitro* by rapid release of nitric oxide (NO) as we have reported earlier. Addition of α-methyl-5-HT to the flow medium reduced both basal and PFF-stimulated NO release by approximately 50%.These results suggest that serotonin has a functional role in bone metabolism by regulating bone precursor cell proliferation. The high expression of serotonin receptor in osteocytes, combined with the modulating effect of serotonin analogue on bone cell mechanosensitivity, suggest a role for serotonin in modulating bone adaptation to stress.

TRAF6 Expression Promoted by RANKL/RANK Signaling Plays an Important Role in Osteoclast Differentiation. Y. Kadono,* T. Akiyama,* A. Yamamoto, T. Ogata,* I. Nakamura, H. Oda, K. Nakamura, S. Tanaka. Department of Orthopaedic Surgery, The University of Tokyo, Tokyo, Japan.

Recent studies showed that RANKL (receptor activator of nuclear factor-kappa B ligand) and its receptor RANK play central roles in osteoclast development. Members of the family of TRAF (tumor necrosis factor receptor-associated factor) proteins are cytoplasmic adaptor proteins that have been shown to interact with the intracellular domains of cell surface receptors, and we and other groups demonstrated that TRAF6 is involved in RANKL/RANK signaling and plays an essential role in osteoclast differentiation. Although TRAF6 is also recruited to interleukin (IL)-1/IL-1 receptor signaling, RANKL cannot be substituted by IL-1 for osteoclast differentiation. When bone marrow cells cultured in the presence of macrophage colony-stimulating factor (M-BMMϕ) were stimulated with RANKL, the expression level of TRAF6, as detected by Western blotting, was elevated, while its expression did not change in response to IL-1 stimulation. To investigate the role of TRAF6 induction in osteoclast differentiation, we constructed a retrovirus vector carrying TRAF6 cDNA, and overexpressed TRAF6 in M-BMMϕ to the comparable level to that observed in RANKL-stimulated M-BMMf. Surprisingly, mere overexpression of TRAF6 in M-BMMϕ was sufficient to induce osteoclast-like multinucleated cell (OCL) formation. The OCLs formed in response to TRAF6 overexpression was positive for tartrate-resistant acid phosphatase activity, showed actin-ring, and expressed mRNA specific for osteoclasts such as MMP-9, cathepsin K and calcitonin receptors. When cultured on dentine slices, they formed resorption pits, satisfying major criteria of osteoclasts. Osteoprotegerin treatment did not suppress the OCL formation induced by TRAF6 overexpression, indicating that this OCL formation was not due to the intrinsic RANKL production by M-BMMϕ. In contrast, overexpression of either TRAF2 or TRAF5 did not induce OCL differentiation, nor did the overexpression of TRAF6 deleted either RING finger domain or TRAF-C domain. These results suggest that RANKL-induced TRAF6 upregulation is sufficient and essential for differentiation of osteoclasts. Further investigation is required to clarify the molecular mechanism of TRAF6-mediated osteoclast differentiation.

A TNF-α-Related Peptide Inhibits Bone Resorption in Vivo and Osteoclastogenesis in Vitro by Interfering with RANK/RANKL Interaction. K. Aoki,[1] Y. Suzuki,*[1] T. Shibata,*[1] R. Murali,*[2] W. C. Horne,[3] M. I. Greene,*[2] K. Ohya,[1] R. Baron.[3] [1]Tokyo Medical and Dental University, Tokyo, Japan, [2]University of Pennsylvania, Philadelphia, PA, USA, [3]Yale University, New Haven, CT, USA.

Therapeutic peptidomimetics that interfere with the TNF/TNF receptor(I) binding have been developed based on the crystal structures of TNF-α and the TNF-β/TNF receptor(I) complex (Nature Biotech. 15: 1266, 1997). The cyclized peptidomimetic WP9QY (YCWSQYLCY), which was designed to mimic the most critical TNF-α recognition site on the TNF receptor(I), efficiently antagonized the effects of TNF-α binding to the TNF receptor(I). We have previously reported that this peptide antagonist blocks vitamin D_3/PGE_2- and sRANKL-induced osteoclastogenesis in vitro (J. Bone Miner. Res. 14: S178, 1999). However, reports that TNF-α enhances RANKL-dependent OC formation raised the possibility that the effect of the peptide was due to an inhibitory effect on TNF-α/TNFR interactions and not to the inhibition of RANKL/RANK binding. We therefore examined the effect of WP9QY on sRANKL-induced osteoclast differentiation of bone marrow cells derived from wild type animals and TNF receptor (I)-deficient or TNF receptor (II)-deficient mice. In both cases, WP9QY inhibited osteoclastogenesis to the same extent in the KO cultures as in wild-type bone marrow, while a control peptide had no effect. These data further show that in this in vitro system the inhibitory effect of the peptide is due to the inhibition of RANKL/RANK interaction and not to an inhibition of TNF signaling. We further examined the effect of WP9QY on bone resorption in vivo. Male CD-1 mice (7 week-old) were fed with either a diet containing 0.5% Ca (normal Ca group) or a diet with 0.05% Ca (low Ca group) for 48 hours, a time sufficient to observe increases in bone resorption and bone loss. Half of the low Ca group received subcutaneous injections of WP9QY (9 or 24 mg/kg) every 3 hours. No apparent change of body weight was observed in the peptide-treated group. Trabecular bone density of tibial metaphyses, measured by pQCT, was significantly reduced from 190 mg/cm^3 in the normal Ca group to 156 mg/cm^3 in the untreated low Ca group. Most interestingly, WP9QY inhibited the trabecular bone loss in a significant and dose-dependent manner (-17.6% in untreated low Ca mice vs -1.1% and +9.3% with treatment). Histomorphometric analysis revealed that treatment with WP9QY, in addition to protecting bone volume, prevented both the increased osteoclast number and the increased osteoclast surface that were induced by the low Ca diet. These results indicate that the WP9QY peptide antagonizes osteoclastogenesis by blocking RANK/RANKL interaction, and is able to exert this effect in vivo as well as in vitro.

Inhibition of JNK1/c-Jun Signaling Pathway Decreases RANKL-induced Osteoclastogenesis. F. Ikeda,*[1] K. Hata,*[1] K. Yamashita,*[1] T. Watanabe,*[2] T. Kukita,[2] K. Yoshioka,*[3] R. Nishimura,[1] T. Yoneda.[1] [1]Dept Biochem, Osaka Univ Grad Sch Dent, Osaka, Japan, [2]Second Dept of Oral Anat, Kyushu Univ Grad Sch of Dent, Fukuoka, Japan, [3]Mol Pathol, Cancer Res Inst, Kanazawa Univ, Kanazawa, Japan

Recent studies suggest RANKL stimulates osteoclastogenesis through concomitant activation of the transcription factor NF-kB and a family member of MAP kinase JNK1. This notion is supported by the fact that mice deficient in NF-kB (p50/p52) show osteopetrosis due to impaired osteoclastogenesis. On the other hand, the role of JNK1 in osteoclastogenesis has not been established yet, since JNK1 knockout mice failed to show skeletal phenotype presumably due to compensation by other JNK family members and JNK1/JNK2 double knockout mice are embryonic lethal. Here, we studied the role of JNK1/c-Jun signaling pathway in osteoclastogenesis using the preosteoclastic cell line RAW-D that we recently cloned from the murine monocytic cell line RAW264. Osteoclastic differentiation was quantified by counting the number of tartrate-resistant acid phosphates-positive multinucleated cells (TRAP(+) MNC). Treatment with soluble RANKL (sRANKL) induced the differentiation of RAW-D cells into TRAP(+) MNC accompanied with an activation of JNK1, implying JNK1 in osteoclastic differentiation. To examine whether activation of JNK1 is critical to sRANKL-induced TRAP(+) MNC formation, we generated kinase-dead JNK1 (KD-JNK1) by introducing a point mutation in the ATP-binding 55 lysine. The KD-JNK1 showed no kinase activity and interfered with endogenous JNK1 activation in a dominant-negative manner. Expression of KD-JNK1 into RAW-D cells using an adenovirus vector markedly inhibited sRANKL-induced TRAP(+) MNC formation. In contrast, the dominant-negative or constitutively-active mutant of MKK3, which is a kinase specifically regulating another MAP kinase family member p38, had little effects on TRAP(+) MNC formation, suggesting a specific role of JNK1 for osteoclastic differentiation. Since JNK1 activates c-Jun and RAW-D cells expressing KD-JNK1 exhibited decreased TRAP(+)MNC formation and impaired c-Jun activation, we next examined the effects of c-Jun activation on TRAP(+) MNC formation. RAW-D cells were introduced with a dominant-negative c-Jun (DN-c-Jun) lacking the transactivation domain. We found these RAW-D cells showed a dramatic reduction in TRAP(+) MNC formation in response to sRANKL. In conclusion, our results suggest that activation of JNK1 and c-Jun by RANKL is critical to osteoclastogenesis and that identification of a target gene for JNK/c-Jun as well as NF-kB is important to further understand the molecular mechanism of osteoclastogenesis.

1164

Activation of c-Src, c-Cbl and RhoA, but not PYK2, in Osteoclasts, Requires the αvβ3 Integrin. R. Faccio,*[1] D. V. Novack,[1] X. Feng,[1] T. Kunicki,*[2] A. Zallone,[3] F. P. Ross,[1] S. L. Teitelbaum.[1] [1]Pathology, Washington University, St. Louis, MO, USA, [2]The Scripps Research Institute, La Jolla, San Diego, USA, [3]University of Bari, Bari, Italy

The FAK-like kinase, Pyk2, believed central to the mechanisms by which osteoclasts (OCs) resorb bone, is activated when OCs are plated on ligands recognized by the αvβ3 integrin. This observation has prompted the hypothesis that the defective bone resorptive capacity of αvβ3 deficient OCs reflects their failure to activate Pyk2. Surprisingly, we find that Pyk2 activation, as manifest by its phosphorylation, occurs equally in both β3-/- and β3 WT pre-osteoclasts plated on vitronectin for 30 and 60 min, but not in suspended cells. Thus, Pyk2 activation requires cell-matrix recognition, but does not depend upon αvβ3 occupancy. In contrast to tyrosine phosphorylation of Pyk2, activation of other components of the focal adhesion complex essential for bone resorption, namely c-src and c-cbl, is dependent on specific αvβ3 binding, as it does not occur in adherent β3-/- pre-OCs. In order to identify the structural components of the β3 subunit mediating these resorptive signals, we generated mutants known, in other systems, to affect integrin function and retrovirally expressed them in β3-/- OCs. Establishing the requirement for the β3 cytoplasmic domain, a construct consisting only of the extracellular and transmembrane domains (hβ3δc) does not rescue c-src and c-cbl activation. The point mutants S752P and Y747F/Y759F both impair platelet function but only S752P blocks adhesion-induced c-src and c-cbl activation, while Pyk2 phosphorylation remains intact. Consistent with this observation, hβ3δc and β3 S752 P, unlike WT and Y747F/Y759F β3, fail to mediate growth factor-induced (HGF or M-CSF) conformational change of αvβ3 from the basal to the activated state, as determined by the Ligand Induced Binding Site Ab, AP5. The functional consequences of the failure of αvβ3 activation, by β3 integrin mutation, include loss of growth factor induced adhesion and migration onto osteopontin in pre-OCs, and failure of αvβ3 integrin to localize to membrane ruffles in mature OCs. Reflecting these cytoskeletal inhibitory events, the same inactivating mutations specifically prevent HGF or M-CSF induced RhoA activation, assayed by affinity precipitation with the GTP-bound Rho and the Rho binding domain of Rhotekin coupled to GST. In conclusion, c-cbl , c-src, and RhoA, but not PYK-2, activation, in OCs, requires αvβ3 -transduced signals, including conformational change of the integrin, itself. These events are specifically mediated by β3 S752.

1165

Tyrosine 371 and the Phosphorylation of c-Cbl by c-Src are Required for the Ubiquitination of Both Proteins and for Src Kinase Down Regulation. A. Sanjay,[1] M. Yokouchi,*[1] T. Kondo,*[1] A. Bruzzaniti,[1] H. Zhang,*[1] W. C. Horne,[1] R. Baron.[2] [1]Yale University, New Haven, CT, USA, [2]Yale University, New Haven, USA.

Cbl is a Src substrate in osteoclasts that is required for in vitro bone resorption and for osteoclast motility. Cbl negatively regulates kinase activity of both receptor and non-recep-

tor tyrosine kinases either by binding to the regulatory tyrosine (as in the case of Src) via the PTB domain or by inducing their ubiquitination via a RING finger (RF)-dependent ubiquitin ligase activity. Ubiquitination of proteins involves sequential actions of the Ub–activating (E1), Ub-conjugating (E2) and Ub-protein ligase (E3) enzymes. E3 enzymes determine the specificity for the substrate and are ultimately responsible of the transfer of ubiquitin from E2 to the substrate. Using recombinant Cbl and Src proteins in an in vitro ubiquitination assay, we have shown that Cbl ubiquitinates both itself and Src. The process required the RF domain of Cbl as well as the kinase activity of Src. Recent crystal structure analysis of the Cbl PTB and RF domain bound to the E2 UbCH7 revealed that the linker region between the Cbl PTB and RF domains provides multiple sites of contact with both the PTB domain and UbCH7. We hypothesized that a mutation in the linker region of Cbl, (Y371F) that abolishes EGF receptor ubiquitination might disrupt the interaction between Cbl and UbCH7. As with EGF receptor, the Y371F mutation prevented the ubiquitination of both Src and Cbl. We next investigated whether the failure of Cbl Y371F to ubiquitinate is due to its inability to recruit UbCH7. Using the yeast two-hybrid assay we have previously shown that Cbl constitutively interacts with UbCH7 in a RF-dependent manner. In vitro binding assays using purified proteins show that in the absence of Src both Cbl and Cbl Y371F form stable complexes with UbCH7, indicating that the substitution at Y371 does not abrogate the ability of Cbl to recruit UbcH7 to the complex. Surprisingly, the presence of Src and ATP destabilizes Cbl-UbCH7 complex whereas addition of PP1 (2 uM) to the assay restores the binding of Cbl to UbCH7. Thus, these results demonstrate that the interaction of Src and Cbl, which occur after activation of the vitronectin receptor for instance, not only lead to the PTB-dependent inhibition of Src kinase activity but also to the ubiquitination of active Src and Cbl, probably leading to the degradation of the molecular complex. Given that Src and Cbl deletions result in reduced motility of osteoclasts, a process dependent on the rapid turnover of the podosomes, we propose that Cbl regulates cell adhesion not only by decreasing the Src kinase activity, but also by ensuring its ubiquitination and rapid degradation during the turnover of adhesion sites.

1166

The Protein-Tyrosine Phosphatase (PTP) Activity of PTP-oc Is Required for the Dephosphorylation of PY-527 and Activation of c-Src in Osteoclasts. K. H. W. Lau, S. M. Suhr, L. W. Wu,* D. J. Baylink. Pettis Mem. VAMC, Loma Linda, CA, USA.

We have cloned an osteoclastic PTP, termed PTP-oc, which is expressed predominantly in osteoclasts and precursors. Because the c-Src signaling pathway plays a pivotal role in osteoclastic resorption and the c-Src activity is regulated negatively by the protein-tyrosine phosphorylation (PY) of Y-527 of c-Src, this study tested the hypothesis that PTP-oc is a broad regulator of osteoclastic resorption (responsive to both resorption activators and inhibitors) and that its PTP activity is required for the dephosphorylation of PY-527 of c-Src in osteoclasts. Three sets of experiments were done to test this hypothesis. In the first set of experiments, we found that resorption activators [PTH, PGE2 and 1,25(OH)2D3 (1,25D)], which stimulated osteoclastic resorption (by 2-fold, P<0.001 for each), each increased PTP-oc expression (up to 75%, P<0.01 for each) and reduced (to as low as 20% of the vehicle control, P<0.01 for each) the PY level of c-Src in rabbit osteoclasts. Conversely, resorption inhibitors [calcitonin and alendondrate], which reduced osteoclastic resorption (by up to 50%, P<0.05), each decreased PTP-oc expression (by up to 20%, P<0.05) and increased (3- to 5-fold, P<0.01) the PY527 level of c-Src. That both resorption activators and inhibitors altered the PY-527 level of c-Src, apparently through changing PTP-oc expression suggests that PTP-oc is a broad regulator of osteoclastic resorption. We next tested if reduction in PTP-oc expression by PTP-oc antisense would increase the PY527 level of c-Src. We found that treatment with a PTP-oc antisense oligo reduced PTP-oc expression (by 70%, P<0.001) and increased PY527 level of c-Src (by 4-fold, P<0.001) without affecting the c-Src protein level in rabbit osteoclasts, suggesting that PTP-oc is a key regulator of c-Src in osteoclasts. To evaluate if the PTP activity of PTP-oc is required for c-Src activation, we tested if overexpression of the wild-type (wt) and dominant-negative (dn) PTP-oc in human U-937 cells would alter the PY527 level of c-Src. The dn PTP-oc overexpressing cells had only one-third of c-src protein as that in vector-transfected cells, but the PY-527 phosphorylated c-Src in these cells were 130% (P<0.05) of that in the control cells. In contrast, while the c-src protein in the wt PTP-oc overexpressing cells was similar to that in the control cells, the PY-527 level was only 24.5% (P<0.001) of that in control cells. Thus, the PTP activity of PTP-oc is clearly required for the dephosphorylation of PY-527 and the activation of c-Src in osteoclasts. In conclusion, we presented strong circumstantial evidence that PTP-oc is a broad regulator of the c-Src signaling pathway in osteoclasts.

Identification of Putative c-Fos Kinases in Osteoclast Progenitors. J. David, D. Mehic,* E. F. Wagner.* IMP, Research Institute for Molecular Pathology, VIENNA, Austria.

c-Fos knock-out mice develop osteopetrosis due to a block in osteoclast differentiation. Since Fos activity can be modulated by phosphorylation of a conserved motif located in the C-terminal domain (serine 362 and serine 374), the activation of putative Fos kinases in response to the osteoclastogenic signals M-CSF and RANKL was investigated in M-CSF-dependent bone marrow derived monocytes (MBMMs). The MAP kinases, ERK1/2, and the Phospho-inositol-3 kinase (PI-3 kinase) are strongly co-activated upon treatment of MBMMs with M-CSF alone, or with M-CSF and RANKL. Consequently, the MAP kinase activated protein, RSK2, a downstream target of ERK1/2 and PI-3-kinase, is activated. Both ERK1/2 and RSK2 have been put forward as putative c-Fos kinases in cultured fibroblasts. Using in-gel kinase assays, three M-CSF-inducible proteins of molecular weight of 90, 70 and 65 kDa which are able to phosphorylate a c-Fos peptide containing serine 362 were identified. The 90 kDa protein is not detected when serine 362 is mutated to alanine or after RSK2 immunodepletion confirming that RSK2 is, indeed, the main kinase phosphorylating c-Fos on serine 362. Using immunoprecipitation kinase assays, the 70 kDa protein was shown to be the P70S6 ribosomal kinase. We also demonstrate by immunodepletion that ERK1/2 is the main kinase specifically phosphorylating c-Fos on serine 374 in response to M-CSF.The M-CSF-dependent activation of ERK1/2 and RSK2 is blocked by pre-treatment of MBMMs with PD98059, a specific inhibitor of the MAP-kinase-kinase, MEK1. PD98059 does not affect c-fos induction by M-CSF at the mRNA level, but inhibits the induction of c-Fos protein. Thus, c-Fos phosphorylation by ERK1/2 and RSK2 might modulate post-transcriptionally the level of c-Fos induction by M-CSF. Functionally, PD98059 blocks the formation of osteoclasts generated either in co-culture of osteoclast bone marrow progenitors with supportive osteoblasts, or by direct treatment of hematopoietic osteoclast precursors with M-CSF and RANKL.These data provide the first evidence that c-Fos phosphorylation by ERK1/2 and its downstream kinase RSK2 may be a mechanism in which M-CSF regulates monocyte/osteoclast differentiation.

Dysfunctional Osteoclasts and Osteopetrosis in an ADP-Ribosyl Cyclase (CD38) Null Mouse. X. Y. Wu,*[1] O. A. Adebanjo,[1] B. S. Moonga,[1] A. Zhou,*[1] X. B. Wu,*[1] P. J. R. Bevis,[1] K. Jepsen,[2] M. Schaffler,[2] D. Kimmel,[3] A. Inzerillo,*[1] S. Epstein,[1] B. R. Troen,[1] E. Abe,[1] H. C. Blair,[4] M. Zaidi,[1] L. Sun.[1] [1]The Mount Sinai Bone Program and the Bronx VA GRECC, NY, USA, [2]Department of Orthopedics, Mount Sinai Medical Center, NY, USA, [3]Merck Research Laboratories, PA, USA, [4]University of Pittsburgh, PA, USA.

Previous physiological studies have predicted that the cyclic ADP-ribose (cADPr) generating enzyme, CD38, regulates osteoclastic bone resorption (J. Cell Biol. 142: 1349). Here we provide the first evidence for impaired osteoclastic bone resorption in the absence of CD38. CD38 null mice showed significant, ~15%, increases in bone mass and bone stiffness compared with wild type littermates. The most dramatic feature, however, was a >50% decrease in their resorptive areas (6.1% *versus* 13.9% in wild type controls). Equally impressive was a ~40% reduction in bone resorption by marrow-derived, CD38 null osteoclasts in the pit assay. This compelling evidence for a role of CD38 in bone resorption prompted us, next, to: (a) understand the structure-function relationship of the CD38 protein through deletion mutagenesis and (b) study gene regulation through promoter cloning and reporter-promoter assays. Deletion of 49 amino acids constituting the intracellular and transmembrane domains of CD38 expectedly prevented its plasma membrane localization. However, its ability to release Ca^{2+} from intracellular stores through cADPr remained intact. Attachment of a farnesylation or myristoylation signal to the N- or C-terminus respectively resulted in the membrane localization of CD38, *albeit* in an opposite topology. However, again its Ca^{2+} releasing activity remained conserved. Thus, contrary to previously held views, the membrane localization of CD38 was shown *not to be necessary* for its cADPr-generating and Ca^{2+} releasing function. We next cloned the 1.6 kb CD38 promoter from a rabbit genomic DNA library and established its transcriptional activity in a luciferase reporter assay. Truncation deletion of the promoter revealed a possible negative regulatory region (-1149 to -931 bp) that was rich in AP-1 sites likely responsive to NFκB, an osteoclast activator. Positive regulation was restored between -588 and -180 bp. The osteopetrotic phenotype of the CD38 null mouse together with the deletion mutagenesis and promoter analysis experiments strongly implicate CD38 as a critical regulator of osteoclastic bone resorption. By acting as a NAD^+ sensor/converter, CD38 likely couples cellular metabolism to Ca^{2+} signaling and bone resorption.

An Inverse Relationship between Prevalence of Osteoblast Apoptosis and Rate of Bone Formation with Intermittent, but not Sustained, Elevation of PTH in Mice. A. A. Ali, C. A. O'Brien, R. S. Weinstein, P. Roberson,* S. C. Manolagas, R. L. Jilka. Div. Endo/Metab, Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. of Arkansas for Med. Sci., Little Rock, AR, USA.

The ability of PTH to inhibit osteoblast apoptosis provides a potential explanation for its anabolic effect on the skeleton when given intermittently. To firm the relationship between suppression of osteoblast apoptosis and stimulation of bone formation, we conducted detailed dose-response and time kinetic studies. Swiss-Webster mice received daily s.c. injections of vehicle, or 3, 10, 30, 100 or 300 ng hPTH(1-34)/g body weight for 28 days. BMD was measured at the beginning and end of the experiment, and histomorphometric studies were performed on cancellous bone in the distal femur. We found that the minimal effective dose for both apoptosis suppression and the anabolic effect was 10 ng/g/d, and the maximal was 100 ng/g/d. More important, there was a significant inverse relationship between the prevalence of osteoblast apoptosis and osteoblast number (P<0.01), and bone formation rate (P<0.02). Kinetic studies showed that 100 ng hPTH(1-34)/g/d inhibited osteoblast apoptosis and stimulated bone formation as early as 7 days after initiation of treatment. We next examined whether similar relationships are seen when PTH is continuously elevated. Mice placed on a low Ca diet for 7 days exhibited a 3-fold increase in serum PTH as compared to mice on a normal diet. This sustained PTH elevation caused bone loss, with increased RANKL mRNA expression, osteoclast number and bone turnover; but serum Ca remained normal. However, unlike 7 days of intermittent PTH, sustained PTH elevation did not reduce the prevalence of osteoblast apoptosis or increase the number of osteoblasts. It is possible that the 3-fold elevation in PTH, though sufficient to stimulate the synthesis of RANKL, was insufficient to inhibit osteoblast apoptosis; but both are stimulated by cAMP, making this explanation unlikely. Studies presented elsewhere in this meeting show that addition of PTH to cultured osteoblastic cells induced transient cAMP-dependent survival signaling lasting ~ 12 hours, most likely due to desensitization of the PTH receptor. However, prolonged desensitization would not occur with intermittent PTH because the hormone is cleared rapidly from the circulation. We propose that the different effects of intermittent versus sustained PTH are due to differences in the frequency of the activation of anti-apoptotic signaling: repeated bursts in the former versus a single episode in the latter resulting in little, if any, effect on osteoblast life span.

1170

Influence of Intermittent PTH Treatment on Mineral Distribution in the Human Ilium: A Paired Biopsy Study Before and After Treatment. P. Roschger,*[1] B. M. Grabner,*[1] P. Messmer,*[1] D. W. Dempster,[2] F. Cosman,[2] J. Nieves,[2] R. Lindsay,[2] J. P. Bilezikian,[3] E. S. Kurland,[3] E. Shane,[3] P. Fratzl,*[4] K. Klaushofer.[1] [1]Ludwig Boltzmann Institute of Osteology & 4th Med. Dept., Hanusch Hospital & UKH Meidling, Vienna, Austria, [2]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, [3]College of Physicians and Surgeons, Columbia Univ., New York, NY, USA, [4]Erich Schmid Inst. of Mat. Sci., Austrian Acad. Sci. & Univ. of Leoben, Leoben, Austria.

Parathyroid hormone (PTH) plays an essential role in Ca homeostasis by promoting both bone resorption and formation. Intermittent administration of low dose PTH has been reported to increase bone density and to improve trabecular architecture and cortical width [1]. The aim of the present work was to study the influence of intermittent PTH on the bone mineralization density distribution (BMDD). Pairs of transiliac biopsies (7 men with osteoporosis, mean age = 49 and 6 estrogen-treated women with osteoporosis, mean age = 54) obtained before and after treatment (25 micrograms PTH(1-34)/d for 18 months (men) and 36 months (women) were studied by quantitative backscattered electron imaging (qBEI) [2]. Two parameters were obtained from the BMDD: CaMaxFreq (position of the peak = the typical Ca concentration) and FWHM (peak width of the distribution). qBEI revealed significant alterations in the BMDD due to PTH treatment (see Fig.). In cortical bone from the male patients, CaMaxFreq was slightly, but significantly reduced (-3.32%, p=0.02) and FWHM was increased (+18.80%) after treatment. Similarly, cancellous bone showed a tendency towards lower mineralization (CaMaxFreq -2.12%) and a significant increase in FWHM (+19.65%, p=0.02). In the PTH + estrogen-treated women CaMaxFreq was not altered, but FWHM increased for cortical (+18.14%, p=0.005) and trabecular bone (+21.59%). These data are highly consistent with the observation that intermittent PTH treatment stimulates bone turnover and new bone formation in cortical and cancellous bone. The significant broadening of the BMDD indicates a higher percentage of newly formed, but still not fully mineralized bone. Recent fracture studies indicate that, although not yet completely mineralized, this new bone contributes significantly to bone strength. PTH Treatment Directly Stimulates Bone Formation in Cancellous and Cortical Bone in Humans. D. W. Dempster,[1] H. Zhou,[1] F. Cosman,[1] J. Nieves,[1] J. D. Adachi,[2] L. J. Fraher,[3] P. H. Watson,[3] R. Lindsay,[1] A. B. Hodsman.[3] [1]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Dept. of Medicine, University of Western Ontario, London, ON, Canada, [3]Dept. of Medicine, St. Joseph's Health Ctr., London, ON, Canada.

The anabolic action of PTH is well established but the cellular mechanisms are poorly understood. Bone marker studies suggest that PTH initially stimulates bone formation without prior resorption. We tested this hypothesis by morphometric analysis of bone samples obtained after only 28 days of PTH treatment. Postmenopausal women (n=27) with severe osteoporosis (OP) were given hPTH (1-34)(50 mcg/d s.c) for 28 d. Tetracycline(tet)was given on days 12-14 and 26-28 and a biopsy was obtained on day 28. Results were compared with those from untreated, age-matched patients with severe OP. Pairs of adjacent sections were obtained. One was mounted unstained to reveal tet labels; the other was stained to reveal packets and cement lines. Forming packets were identified based on the presence of a double tet label. Three types of packets were observed on the cancellous (Cn) and endocortical (Ec) surfaces: 1. Packets with a scalloped reversal line indicating prior resorption (Remodeling-Based Formation, RBF). 2. Packets in which the reversal line was smooth indicating no prior resorption (Modeling-Based Formation, MBF) and packets with clearly visible arrest lines, indicating Resumption of Formation (RF).On the periosteal(Ps) surface, none of these types of packet could be reliably identified. In the PTH-treated patients, bone formation rate (BFR) was increased on Cn, Ec and Ps surfaces. On the Cn surface, biopsies from PTH-treated patients displayed packets with MBF and RF, both of which were completely absent in controls. On the Ec surface, PTH treatment increased the number of packets with RBF. This was found to be due an increase in the formation period in packets in which formation was underway at the start of PTH treatment.In conclusion, we have demonstrated that PTH treatment directly stimulates bone formation without prior resorption on Cn and En surfaces. We have also shown for the first time in humans that PTH stimulates bone formation on both the En and Ps surfaces of the cortex. This challenges the traditional view that PTH acts primarily on cancellous bone in humans and provides a further explanation for its potent anti-fracture efficacy.

A Randomized Controlled Clinical Trial to Compare the Efficacy of LY333334 [Recombinant Human Parathyroid Hormone (1-34)] and Alendronate Sodium in Postmenopausal Women with Osteoporosis. J. J. Body,[1] G. A. Gaich,[2] W. H. Scheele,*[2] P. D. Miller,[3] P. M. Kulkarni,*[2] A. B. Hodsman.[4] [1]Inst. J. Bordet, Univ. Libre de Bruxelles, Brussels, Belgium, [2]Eli Lilly and Company, Indianapolis, IN, USA, [3]Colorado Center for Bone Research, Lakewood, CO, USA, [4]St. Joseph's Health Care, London, ON, Canada.

Parathyroid hormone (PTH), given once daily, stimulates new bone formation and increases bone mass. A randomized, double-blind, placebo-controlled clinical trial was conducted to compare the effects of 40 µg of recombinant human parathyroid hormone (1-34) [rhPTH(1-34)] and 10 mg of alendronate sodium in postmenopausal women with osteoporosis (spine or hip T-score <-2.5). The women were randomized to either once-daily subcutaneous injection of rhPTH(1-34) plus placebo pill (PTH40, n=73) or alendronate plus placebo injection (ALN10, n=73). The median treatment period was 14 months. Treatment with rhPTH(1-34) increased bone mass significantly more than alendronate at the spine, proximal femur, and total body. At the lumbar spine, BMD increased significantly more in the PTH40 group than in the ALN10 group at 3 months and at every visit thereafter. There was no significant difference in BMD at the ultradistal radius but there was a significant decrease at the midshaft radius in the PTH40 group, compared with ALN10. Ten women (14%) in the ALN10 group sustained nonvertebral fractures compared with only 3 women (4%) in the PTH40 group (P=0.042). Back pain was reported significantly less frequently by women in the PTH40 group (6%) than in the ALN10 group (19%, P=0.012). Leg cramps were reported significantly more frequently by patients in the PTH40 group (8%) than in the ALN10 group (0%, P=0.012). There were no clinically significant increases in serum or urine calcium. Markers of bone remodeling were increased in the PTH40 group and decreased in the alendronate group. In summary, treatment with rhPTH(1-34) is well tolerated, stimulates new bone formation, increases bone remodeling, and produces larger and more rapid increases in BMD than alendronate, which reduces bone remodeling.

Skeletal site (% change from baseline to final visit)	PTH40 (mean ± SD)	ALN10 (mean ± SD)
Lumbar spine	12.2 ± 9.4*	5.6 ± 5.0
Total hip	4.0 ± 5.7*	2.5 ± 3.2
Femoral neck	4.8 ± 6.5*	1.7 ± 4.3
Ultradistal radius	0.2 ± 6.6	1.4 ± 5.1
Midshaft radius	-3.4 ± 3.8*	-0.2 ± 3.3
Total body BMC	3.5 ± 3.6*	1.9 ± 4.4

*P<0.05 PTH40 vs ALN10

Oral Calcitonin Inhibits Bone Resorption: A Pilot Dose-Finding Study. M. Cosma,*[1] T. Buclin,*[1] P. Burckhardt,[1] M. Azria,[2] M. Attinger,*[2] J. McLeod.[2] [1]Department of Medicine, University Hospital, Lausanne, Switzerland, [2]Novartis Pharma Inc., Basle, Switzerland.

An oral formulation of calcitonin was developed using a specific carrier. To investigate its pharmacokinetics and dose-effect relationships on bone resorption markers, 3 single oral doses of calcitonin (400 µg, 800 µg and 1200 µg), one oral placebo and one intravenous dose (10 µg = 50 IU) were administered to 8 healthy male adults (means ± SD: age = 26±6) in a randomised, cross-over, double-blind (except iv) 5-period study, under standardised diet.The calcitonin plasma concentrations reached a plateau during the iv infusion, followed by a rapid decay (half-life = 0.19±0.02 h). The oral doses were absorbed rapidly (Tmax for 400, 800 and 1200 µg: 0.38±0.13, 0.44±0.12 and 0.50±0.13 h, Cmax: 60±31, 93±66 and 370±350 pg/ml respectively). The absolute oral bioavailability was 0.54% for the 400 µg, 0.43% for the 800 µg and 1.53% for the 1200 µg dose (p=0.03, Friedman's test). All oral doses produced a marked drop (ca. 90%) in serum C-terminal telopeptide (CTX); ionized calcium concentrations decreased accordingly. Both variables displayed dose-related changes, with the effects of 1200 µg exceeding those of 10 µg iv. The CTX nadir increased from 2 h post-dose after 400 µg to 4 h after 1200 µg and 10 µg iv. The effects of 1200 µg lasted for ca. 12 h. Urinary CTX excretion changed similarly. Circadian fluctuations of CTX were observed after placebo. All calcitonin doses were well tolerated, with slight gastro-intestinal events usually associated with calcitonin treatment such as nausea and diarrhoea being observed mainly after the highest oral dose.In conclusion, various doses of a novel oral formulation of calcitonin displayed a significant absorption, with a dose ratio of approximately 100:1 compared to iv calcitonin. After 1200 µg, the inhibition of bone resorption markers appeared similar to the effect of 10 µg iv calcitonin. Thus, oral administration of calcitonin is feasible and could become a promising alternative for

the treatment of chronic conditions associated with bone loss.

Vitamin D Treatment Best for the Frailest to Prevent Hip Fractures?A Prospective Controlled Clinical Trial. O. Johnell,[1] M. Billsten,*[2] I. Sernbo,*[1] I. Rodine,*[2] E. Ornstein.*[2] [1]Department of Orthopaedics, Malmö University Hospital, Malmö, Sweden, [2]Department of Orthopaedics, Hässleholm-Kristianstad Hospital, Hässleholm, Sweden.

At present there are some studies with Vitamin D which show fracture reduction. The purpose of this study was to study the effect of Vitamin D on the frailestMethod. In a prospective controlled clinical trial, we investigated the effects of oral vitamin D supplements on hip fractures and other non-vertebral fractures. We included 2404 women 50 years of age and older (mean age 85.8±6.3) living in 174 nursing homes in the southern part of Sweden. The patients were followed for three years. One district was selected as treatment area and the surrounding districts as control areas.1594 women (men age 85.7 ±6.5) were assigned to receive 21000 IU vitamin-D3 once per month. The dose was distributed by a nurse as three drops of ergocalciferol (294000IU/ml) per month. In the control group we included 854 women (men age 85.9 ±5.9). The average daily dietary calcium intake was 650 mg. After 12 months 120 hip fractures had occurred with an odds ratio 0.66 (0.46-0.93) and after 36 months 220 with an odds ratio 0.85 (0.65-1.11) for the Vitamin D group, similar findings for other fracturesResults. Hip fracture: In a subgroup analysis we studied the effect of Vitamin D in those with at baseline a prevalent hip fracture N=383, after 12 months 42 had had a new hip fracture odds ration 0.28 (0.14-0.59). Interaction term P=0.0009. After 36 months 50 had had a new hip fracture odds ration 0.28 (0.14-0.59). Interaction term P=0.000. In those who had died during the 36 months follow-up N=1106 odds ratio for vitamin D treated group was 0.64 (0.43-0.96). Conclusion. The frailest women living in nursing homes have a greater chance to die without a hip fracture if they take three drops of Vitamin D per month.

1175

Impact of Adding Medroxyprogesterone Acetate (MPA) to Multiple Doses of Conjugated Equine Estrogens (CEE) on Bone Density in Postmenopausal Women. R. Lindsay,[1] J. C. Gallagher,[2] M. Kleerekoper,[3] J. H. Pickar.*[4] [1]Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Creighton University, Omaha, NE, USA, [3]Wayne State University, Detroit, MI, USA, [4]Wyeth-Ayerst Research, Philadelphia, PA, USA.

The impact of adding a progestin to currently prescribed and lower doses of estrogens on BMD in healthy postmenopausal women has not been thoroughly investigated. A 2-year substudy of 749 women enrolled in the double-blind, placebo-controlled, multicenter Women's Health, Osteoporosis, Progestin, Estrogen (Women's HOPE) study was conducted to evaluate the effects of commonly prescribed and lower doses of CEE, either alone or with one of two daily doses of MPA, on BMD. Postmenopausal women 40-65 years with normal BMD were randomized to receive CEE 0.625 mg/day, CEE 0.625/MPA 2.5 mg/day, CEE 0.45 mg/day, CEE 0.45/MPA 2.5 mg/day, CEE 0.45/MPA 1.5 mg/day, CEE 0.3 mg/day, CEE 0.3/MPA 1.5 mg/day, or placebo. All women also received calcium carbonate (600 mg elemental calcium daily). Women were between 1 and 4 years post menopause at enrollment.Lumbar spine (L2-L4), total hip, and total body BMD (Lunar DPX-L) were measured at baseline and every 6 months for 2 years. BMD scans were sent to a central site responsible for all analyses and quality control of BMD measurements. Data were evaluated in an intent-to-treat population with last observation carried forward. BMD changes from baseline were compared between groups using an analysis of covariance procedure with study site, years since menopause, and body weight at baseline included in the model. Statistical significance was set a priori at P<.05.By one year of treatment, all doses of CEE and CEE/MPA produced significant increases (P<.05) in BMD at all sites relative to placebo. Increases in BMD ranged from 1.1%-3.6% at the spine, 0.9%-2.8% at the hip, and 0.4%-1.1% for total body. A dose-response relationship was apparent for the spine, but not hip or total body. Placebo-treated patients lost 0.7%-2.6% of BMD at all sites over 2 years. The addition of MPA (2.5 mg/day) to CEE resulted in greater gains in spine BMD compared with CEE alone for the CEE 0.625 and CEE 0.45 groups. At 2 years, the increase in spine BMD was greater for the CEE 0.625/MPA 2.5 group (3.6%) compared with the CEE 0.625 group (2.4%, P<.05); for the 0.45/MPA 2.5 group, the increase in spine BMD (3.0%) was greater than that observed in the CEE 0.45 group (1.9%, P<.05). Although similar trends were apparent for the total hip and total body sites, statistical significance was not achieved.These data suggest that the addition of MPA may positively affect BMD in women administered CEE in the early postmenopausal years. Lower doses of CEE or CEE/MPA preserve BMD in healthy postmenopausal women.

Disclosures: Wyeth-Ayerst Research,5.

1176

Effect of Alendronate and Estrogen Replacement on Periosteal Bone Formation in Postmenopausal Women. R. Recker,[1] T. Coble,*[1] A. Burshell,*[2] A. Lombardi,*[3] G. Rodan,[3] D. Kimmel,[3] J. Yates.*[3] [1]Medicine, Creighton University, Omaha, USA, [2]Ochsner Clinic, Philadelphia, PA, USA, [3]Merck, Philadelphia, PA, USA.

Alendronate (ALN) and estrogen are antiresorptive agents used to prevent and treat postmenopausal osteoporosis. Both decrease bone resorption and formation at trabecular and endocortical surfaces. The purpose of this study was to evaluate the effect of ALN and estrogen on periosteal bone formation in women with postmenopausal osteoporosis. 98 postmenopausal women (age 67±3.5yrs) were treated for two years with: a)placebo (PBO), b) Premarin (0.625mg/d) (PREM), c) ALN 10mg once daily (ALN), or d) both (COMB). In vivo dual fluorochrome labeling was given to all. Transilial biopsy specimens were obtained, fixed in 70% ethanol, and processed undecalcified. All periosteal surface in two unstained 8µm sections separated by 250µm was studied for perimeter (P.Pm, mm), double label, single label, and mineral apposition rate (MAR, µm/d). Mineralizing surface (double plus half single label) (MSBS, %) was calculated. Groups were compared by Kruskal-Wallis ANOVA with Student Neuman-Keuls post-hoc test and two-factor (ALN or estrogen) ANOVA. Percentage of subjects with double label was lower in PREM and COMB than in ALN subjects. Similarly, MSBS was lower in both PREM and COMB than in ALN subjects. Mineral apposition rate was not affected significantly by either treatment. Two-factor ANOVA revealed a significant PREM reduction in periosteal formation (P<0.03) with no ALN effect.

Vbl	PBO (N=9)	PREM (N=30)	ALN (N=24)	COMB (N=35)
P.Pm	24±7	24±7	27±4	26±6
%	33	20*	62	17*
MSBS	1.1±2.7	0.5±1.3*	0.8±0.9	0.2±0.3*
MAR	0.83±0.08	0.72±0.46	0.71±0.45	0.55±0.20

Mean±SD; *less than ALN (P<.001); %= Percentage of subjects showing any double label

These data suggest that ALN permits continued periosteal apposition at a faster rate than does estrogen treatment, in agreement with observations in rats. This may play a role in the sustained rise in bone mineral density seen with up to seven years of ALN treatment

1177

Muscle Stem Cells Genetically Engineered With Osteogenic Factors Induce Bone Formation and Improve Bone Healing. H. Peng, V. Wright,* A. Usas, B. Gearhart, J. Cummins, J. Huard. Orthopaedic Surgery, University of Pittsburgh, Pittsburgh, PA, USA.

Muscle stem cells with osteogenic potential have been isolated from mice in our laboratory. These muscle stem cells can undergo osteogenic differentiation upon stimulation with recombinant human bone morphogenetic protein-2 (BMP-2). When transduced with adenoviral vector expressing BMP-2, muscle stem cells induced de novo bone formation in mice, both at the injection sites and in diffusion chambers implanted subcutaneously in SCID mice. These transduced muscle stem cells were shown to differentiate into osteoblasts and osteocytes. Transduced muscle stem cells expressing BMP-2 also induced orthotopic bone formation and completely healed calvarial defects created in SCID mice. However, it has been problematic to extend this study to normal animals, mainly because of the immune response triggered by viral proteins. This problem has been overcome by using retroviral vector, which does not express viral products. Muscle stem cells were transduced with retroviral vector CLBMP-2/4, which contained a BMP-2/4 hybrid construct and led to high-level human BMP-4 secretion from transduced cells. The efficiency of transduction was higher than 80%. The level of BMP-4 secretion was 250 to 612 ng/106 cells/24 hr. Most of the transduced muscle stem cells became osteogenic, as evidenced by alkaline phosphatase expression.To determine the in vivo bone induction ability of muscle stem cells transduced with retroviral vector expressing BMP-4, transduced cells were implanted together with collagen type I matrices into the muscle of normal mice. Chondrogenesis was found within the implanted matrices 1 week after implantation. Endochondral bone formation occurred within 2 weeks after implantation. Transduced muscle stem cells were also found within the osteoid, and they expressed osteocalcin, suggesting their differentiation into osteocytes. Interestingly, de novo bone formation occurred only within the collagen matrices, but not in the surrounding muscle or distant organs. In summary, this study demonstrates that muscle stem cells can be efficiently transduced by retroviral vector, are capable of osteogenic differentiation, and, more importantly, induce de novo site-directed bone formation in immune-competent animals.

Fracture Healing Impairment in Rats by an Angiogenesis Inhibitor Indicates a Requirement for Vasculature in Early Fracture Callus Development. M. R. Hausman,* M. B. Schaffler, R. J. Majeska. Leni and Peter W. May Department of Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA.

Angiogenesis inhibitory drugs have shown promise in treating cancer and other diseases; however, these agents may also impair normal physiological processes like fracture healing, which require new blood vessel formation. The purpose of this study was to test the effects of the angiogenesis inhibitor TNP-470 (provided by TAP Pharmaceutical Products, Lake Forest, IL) on fracture healing in an established rat model system. Closed, internally fixed femoral fractures were created in adult female Sprague-Dawley rats. Beginning one day after fracture, animals received alternate day subcutaneous injections containing

either vehicle or a dose of TNP-470 (30 mg/kg) known to block angiogenesis and tumorigenesis in vivo. Fracture healing was assessed morphologically by histology and radiography at 7, 14 and 21 days post-fracture, and functionally by biomechanical testing at 24 days post-fracture. In addition, RNA isolated from both treated and control fractures on day 3 was reverse-transcribed and hybridized to filters containing cDNA's coding for angiogenesis-related genes (Superarray Inc., Bethesda, MD). TNP-470 completely blocked fracture healing by all criteria examined. Treated animals failed to develop either a cartilaginous callus or subperiosteal woven bone, indicating suppression of both endochondral and intramembranous pathways of bone formation. In treated animals, a fibrous tissue at the fracture site resembled that seen clinically in atrophic nonunion fractures. Biomechanical testing showed that the treated animals recovered only 15% of the strength ($p<0.01$ vs control) and 7% of the stiffness ($p<0.001$ vs control) of intact bone, compared with 56% and 50% recovery, respectively, in non-treated bones. TNP-470 had no effect on the mechanical properties of intact bones. Of 19 genes whose expression was examined, 10 were up-regulated due to TNP-470 treatment, 5 were down-regulated and 4 (including GAPDH) remained largely unchanged. Genes up-regulated at Day 3 by TNP-470 treatment included VEGF, VEGF-B, VEGF-C and VEGF-D. Down-regulated genes included FGFs-1 and 2. These data support the concept that angiogenesis is essential for proper fracture healing, and further indicate that its importance in the earliest phases of the healing process. This demonstration is also of clinical interest since patients likely to receive antiangiogenic agents in cancer chemotherapy are also prone to undergo atraumatic fractures. Finally, the identification of early changes in gene expression may lead to a greater understanding of the mechanisms by which vasculature regulates fracture healing.

Insulin Receptor Substrate-1 (IRS-1) Is Essential for Bone Repair through Stimulation of Cell Proliferation at Its Early Stage. T. Shimoaka,[1] K. Hoshi,[1] T. Kadowaki,*[2] Y. Terauchi,*[2] K. Nakamura,[1] H. Kawaguchi.[1] [1]Orthopaedic Surgery, University of Tokyo, Tokyo, Japan, [2]Metabolic Diseases, University of Tokyo, Tokyo, Japan.

Insulin receptor substrate-1 (IRS-1) is an essential molecule for intracellular signaling by IGF-I and insulin both of which are potent anabolic regulators of bone and cartilage metabolism. We previously reported that IRS-1 is essential for maintaining bone turnover using IRS-1 deficient (-/-) mice. This study investigated the role of IRS-1 in bone repair by comparing the healing process of fracture created at the midshaft of the tibia and stabilized with an intramedullary nail between -/- and wild-type (+/+) mice at 8 weeks of age (n=15 each). This model was confirmed to show the fracture healing process with both endochondral and intramembranous ossification reproducibly in a definite temporal sequence in +/+ mice. Soft X-ray examination revealed that callus formation was detected at 1 week, and bony bridging at the fracture site appeared at 3 weeks after operation in all +/+ mice. After the callus size reached maximum around 4 weeks, it decreased due to bone remodeling throughout the observation period (up to 10 weeks). In contrast, fracture healing was extremely impaired in -/- mice: 13 out of 15 mice remained in a nonunion state even at 10 weeks, and 2 showed much weaker union with smaller callus than those of +/+ mice. Histologically, the retardation of the fracture healing was observed as early as 1 week after fracture in -/- mice. The number of both mesenchymal cells and chondrocytes associated with intramembranous and endochondral ossification, respectively, were markedly decreased, resulting in the reduced size of soft and hard callus. Few PCNA-positive cells were seen around the fracture site. In the small cartilageous tissue of -/- mice, type X collagen-positive hypertrophic chondrocytes were seen at 1 week, and some of them were TUNEL-positive, suggesting the acceleration of differentiation and apoptosis without sufficient proliferation of chondrocytes. Similar findings were observed in the growth plate of -/- mice: a smaller proliferative zone with decreased PCNA-positive cells and a wider hypertrophic zone with increased TUNEL-positive cells, as compared to that of +/+ mice. These results demonstrate that IRS-1 deficiency notably impairs the fracture healing ability by inhibiting the proliferation of mesenchymal cells and chondrocytes at the earlier stage. We propose that IRS-1 is essential for bone repair and can be clinically applied as a target molecule for bone regeneration such as fracture healing.

An Excessive Activation of Signal Transducer and Activator of Transcription 1 (Stat1) Accelerates Differentiation of Chondrocytes in FGFR3-Related Short-limb Dwarfisms. Y. Yamanaka,[1] H. Tanaka,[1] M. Koike,*[1] R. Nishimura,[2] Y. Seino.[1] [1]Pediatrics, Okayama University, Okayama, Japan, [2]Biochemistry, Osaka University Faculty of Dentistry, Osaka, Japan

Constitutively activated mutations in FGFR3 result in disturbing the growth of long bones in achondroplasia (ACH) and related disorders. We and others demonstrated that Stat1 is constitutively activated in chondrocytes of a severe type of ACH, thanatophoric dysplasia (TD), and implicated in inhibition of proliferation caused by this mutation in FGFR3. Little is, however, known about the role of Stat1 in differentiation of chondrocytes. Therefore, we investigated the functional role of Stat1 in FGFR3 signaling pathway by using chondrogenic cell lines, ATDC5 cells which were transfected the FGFR3 mutants, including G380R (ACH) and K650E (TD type II: TDII). The TDII receptor exhibited 61-fold greater phosphorylation of Stat1 than WT receptor, determined by immunoblot with anti-phospho-Stat1 antibody. In ACH cells, Stat1 was modestly phosphorylated. Immunoprecipitation assay and GST-Stat1 pull-down assay revealed that Stat1 bound FGFR3 (TDII). Preincubation with a synthetic phsphopeptide corresponding to codon 643-654 of FGFR3 including the major autophsphorylation site inhibited the binding GST-Stat1 fusion protein to FGFR3 (TDII). TDII cells exhibited 5-fold greater expression of type X collagen mRNA than WT cells, determined by real-time RT-PCR analysis. Importantly, introduction of dominant-negative (DN)-Stat1 into TDII cells suppressed type X collagen expression, while DN-Stat5a or DN-Stat5b had no effect (Figure). Consistently, constitutively active mutant of Stat1 increased 2.5-fold greater levels of type X collagen expression than an empty-vector. Furthermore, infection of an adenovirus vector carrying FGFR3 (ACH) in ATDC5 promoted alcian blue stain-positive cartilage formation whereas induction of DN-Stat1 inhibited cartilage formation in ACH cells.In conclusion, an excessive activation of Stat1 induced by the FGFR3 mutants accelerated differentiation of chondrocytes. Thus, our data suggest that Stat1 may account for the disturbance of endochondral bone formation in achondroplasia and its related disorders.

1181

Postpubertal Improvement in Bone of Knock-in Mouse Model (Brittle Mouse) for Osteogenesis Imperfecta Is Due to Fundamental Alterations in Bone Material Properties. K. M. Kozloff,*[1] E. P. Frankenburg,*[1] M. F. Spurchise,*[1] C. Berwitz,*[2] A. Forlino,*[2] J. C. Marini,[2] S. A. Goldstein.[1] [1]Orthopaedic Research Labs, U Michigan, Ann Arbor, MI, USA, [2]Sect on Connective Tissue Disorders, HDB, NICHD, Bethesda, MD, USA.

The Brittle mouse (Brtl) is a knock-in murine model for non-lethal osteogenesis imperfecta type IV. It carries a point mutation in one COL1A1 allele, resulting in a classic glycine substitution, G349C, in 50% of the alpha 1(I) collagen chains. Brtl reproduces the molecular, biochemical and skeletal features of type IV OI and provides a means to examine the natural history of the mechanical properties of OI bone, as well as to compare them to the well-known clinical finding of decreased fractures after puberty. We examined a total of 78 Brtl males and normal littermates (WT) at 1, 2, 6 and 12 months of age. Geometric properties of femoral mid-diaphyses were examined using micro CT. Biomechanical properties were tested by whole bone 4 point bending to failure; material properties of ultimate strength and elastic modulus were predicted using standard mechanics of materials equations. At 1 month, analogous to childhood in humans, Brtl bone shows a trend of reduced strength from 4-point bending compared to WT. At 2 months, comparable to pubertal age, Brtl bone is weaker in 4 point bending ($p<.05$) and shows a strong trend toward reduced stiffness compared to WT. This is likely explained by geometrical properties, as bending moment of inertia (MOI) was decreased ($p<.05$), while predicted ultimate strength and elastic modulus were comparable to WT. At 6 months, comparable to a mature young adult, Brtl bone achieves parity with WT in both strength and stiffness from 4 point bending. MOI is still reduced ($p<.05$), but Brtl predicted elastic modulus ($p<.05$) and ultimate strength are greater than WT at this age. This material property alteration may be explained by BMD measures. DEXA findings show that while Brtl femoral BMD is reduced at 1 and 2 months, by 6 months it equals WT. This matrix alteration may allow material properties to overcome geometric insufficiencies, leading to observed comparable stiffness and strength between Brtl and WT. At 1 year, Brtl bone is comparable to WT in stiffness and strength, and levels suggest a weakening vs. 6 months. Displacement ratios suggest that Brtl bone fails in a brittle fashion when compared to WT. These studies demonstrate that Brtl has a post-pubertal adaptation to increase bone structural integrity, as does the type IV OI patient, and that the mechanism is likely a fundamental alteration in bone material properties rather than mid-shaft geometry. Brtl is thus an excellent model to evaluate bone structure/function relationships and therapeutic interventions in OI.

1182

Measles Virus Preferentially Induces Vitamin D Receptor Gene Activation in Pagetic Osteoclast Precursors. N. Kurihara, S. V. Reddy, H. Maeda, G. D. Roodman. Medicine/Hematology, UTHSCSA/VAMC, San Antonio, TX, USA.

Osteoclasts (OCLs) cultured from marrow of patients with Paget's disease (PD) differ from normal OCLs. They contain paramyxovirus-like nuclear inclusions and are hypersensitive to 1,25-(OH)2D3. Normal OCL precursors transduced with the measles virus nucleocapsid gene (MVNP) form OCLs that are very similar to OCLs formed in PD. These cells are also hypersensitive to 1,25-(OH)2D3 and form OCLs at physiologic concentrations of 1,25-(OH)2D3 that are 1-2 logs less than required for normal OCL formation. To test the hypothesis that the increased sensitivity to 1,25-(OH)2D3 may result from induction of a coactivator of vitamin D receptor (VDR) by MV, GST-VDR binding studies were performed with cell lysates from bone marrow from PD patients and empty vector (EV)- or MVNP-transduced normal OCL precursors. A 100-kDa and 17-kDa peptide that bound VDR were detected in OCLs from PD patients, MVNP-transduced normal OCL precursors, but not EV-transduced normal OCL precursors. The 17-kDa protein was identified as TAFII-17/TAFII-20 by sequence analysis, a component of the TFIID transcription complex. TAFII-17 mRNA was highly expressed in MVNP-transduced normal OCL precursors and pagetic OCL precursors treated with 1,25-(OH)2D3 compared to controls. We then determined if MV preferentially activated VDR responsive genes. A luciferase reporter vector containing DR-3, the vitamin D response elements, or DR-5, the retinoic acid response elements, was transfected into NIH3T3 cells stably transduced with the MVNP gene (NIH3T3-MVNP), TAFII-17 gene (NIH3T3-TAFII-17) or empty vector (NIH3T3-EV) and then treated with 1,25-(OH)2D3 or retinoic acid. The MVNP-transduced cells and the TAFII-17 transduced cells were hypersensitive to 1,25-(OH)2D3 and showed increased reporter activity at 1,25-(OH)2D3 concentrations that were 1-2 logs less than required for the EV-transduced cells. In contrast, transduction of DR-5 into NIH3T3-MVNP, NIH3T3-TAFII-17 or EV cells demonstrated that although basal transcription was increased in these cells, the retinoic acid dose response curve of MVNP- and TAFII-17-transduced cells did not differ from that of EV-transduced cells. These data suggested that the enhanced response of NIH3T3-MVNP, NIH3T3-TAFII-17 cells to 1,25-(OH)2D3 is not simply due to a globally enhanced transcriptional response to steroid hormones, but rather to preferential transcription of VDR responsive genes. These data suggest that enhanced sensitivity of pagetic OCL precursors to 1,25-(OH)2D3 may be due to increased expression of a specific VDR coactivator or transcription of TAFII-17 by the MVNP gene and support a potential role for MV in the pathogenesis of PD.

Osteoclasts Stimulate Myeloma Cell Growth through Direct Cellular Interactions via Production of Osteopontin and Interleukin (IL)-6. M. Abe,[1] D. Inoue,[1] T. Hashimoto,*[1] S. Kido,[1] Y. Shibata,*[1] T. Oshima,*[1] S.

Ozaki,*[1] K. Hiura,[2] K. Moriyama,[2] T. Matsumoto.[1] [1]1st Dept. of Int. Med., University of Tokushima, Tokushima, Japan, [2]Orthodontics, University of Tokushima, Tokushima, Japan.

Multiple myeloma (MM) develops and expands in the bone marrow, causing bone destruction by inducing osteoclasts in their close vicinity. Therefore, interplays among the cellular components of the marrow microenvironment, i.e., osteoclasts, MM and stromal cells, appear to be critical to the development of myeloma bone lesions. We have found and reported that the CC chemokines macrophage inflammatory protein (MIP)-1alpha and beta play an important role in the pathogenesis of MM bone lesions. These chemokines are secreted by most MM cells, and induce MM cell adhesion to stromal cells via VCAM-1/VLA-4 interactions and stromal cell expression of RANKL, thereby enhancing osteoclast formation and function. Moreover, we demonstrated that thus induced osteoclasts (OCs) in turn supported MM cell growth and survival in a cell-cell contact dependent manner, suggesting formation of a vicious cycle. In the present study, we investigated the mechanism of MM growth enhancement by OCs. First we examined a role of IL-6, a major MM growth factor, and found that direct contact with MM cells induced production of IL-6 by OCs. However, the OC-mediated MM growth enhancement was only partially inhibited by an anti-IL-6 neutralizing antibody, suggesting a minor contribution of IL-6 at least under our experimental conditions. We then turned to osteopontin (OPN), a major extracellular matrix protein produced by OCs. We found that co-cultures with MM cells also increased OC production of OPN in a contact-dependent manner. Treatment with OPN resulted in significant enhancement of MM cell growth and/or survival in the presence of IL-6. Furthermore, MM cells strongly expressed an OPN receptor, CD44, which has been shown to be involved in survival signals in other hematopoietic cells. These results suggest that the osteoclast lineage cell also contributes to establishment of a microenvironment suitable for MM expansion at least partially through induction of OPN and IL-6 production by OCs. Consistent with critical roles of such cellular interplays, a bisphosphonate minodronate (YM529) almost completely suppressed the enhancement of MM cell growth by rabbit OCs on dentine slices at 0.1 to 1.0 microM, concentrations too low to induce apoptosis of MM cells. Taken together, these results suggest a role for the osteoclast lineage cells not only in bone destruction but also in MM cell growth and expansion, and provide a molecular basis of bisphosphonate therapy for MM.

Osteoprotegerin Gene Transfer into Muscle by Electroporation in Vivo as Efficient Gene Therapy for Osteolytic Bone Diseases. T. Michigami, M. Yamagata,* K. Ozono. Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, Japan.

The direct injection of plasmid DNA into muscle is a simple, inexpensive and safe technique for gene transfer in vivo. Although the application of this method has been limited by the relatively low expression of the transferred gene, it has recently been reported that in vivo electroporation markedly increases the efficiency. In the current study, we have investigated the effects of osteoprotegerin (OPG) gene transfer by direct injection of plasmid DNA into muscle followed by in vivo electroporation, using several kinds of animal models which manifest increased bone resorption. To obtain high levels of OPG expression, we utilized pCAGGS vector, which carries the CAG (cytomegalovirus immediate-early enhancer-chicken beta-actin hybrid) promoter. Plasmids were dissolved in saline, and injected into the muscles of hindlimbs of mice (50 microgram/leg) or rats (150 microgram/leg). For electroporation, stainless steel plate electrodes were utilized. The condition of electroporation was optimized by histochemical staining for beta-galactosidase activity in the muscle after transfer of pCAGGS-lacZ DNA with or without electroporation, and it has revealed the increase in the expression level of the gene by electric pulses of 50 V. Electrotransfer of pCAGGS-PTH[1-34] caused transient hypercalcemia, suggesting that muscles can function as a secretory organ when plasmid encoding secretory protein is transferred. Then, we have constructed pCAGGS-OPG-FLAG, which contains full-length rat OPG cDNA and FLAG-tag fused to the C-terminus of OPG cDNA in frame. In vitro osteoclastogenesis assay revealed that the product derived from pCAGGS-OPG-FLAG exhibited inhibitory activity against osteoclast formation. Then electro-transfer of pCAGGS-OPG-FLAG into muscles was performed in two kinds of rodent models of humoral hypercalcemia of malignancy. We found that serum Ca levels were restored in both models within a week after pCAGGS-OPG-FLAG gene transfer, but not when empty vector was transfected. Western blot analysis detected OPG-FLAG in the blood of the animals transferred pCAGGS-OPG-FLAG. Furthermore, OPG knockout mice undergone electro-transfer of pCAGGS-OPG-FLAG exhibited higher bone mineral density compared with the mice received pCAGGS empty vector, which was determined by DXA. Taken together, electrotransfer of OPG expression plasmid into skeletal muscles may provide an efficient nonviral gene thrapy for osteolytic bone diseases.

Alopecia in VDR Null Mice Is Secondary to a Keratinocyte Defect and Can Be Prevented by Targeting Expression of the Human VDR to Keratinocytes in Vivo. C. Chen, Y. Sakai, M. B. Demay. Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA.

Mice with targeted ablation of the Vitamin D receptor (VDR) develop alopecia regardless of mineral ion status. Previous studies in neonatal keratinocytes isolated from these mice failed to demonstrate a defect in keratinocyte proliferation or in acquisition of markers of keratinocyte differentiation. However, the VDR null mice do not respond to anagen induction, after hair morphogenesis is completed, demonstrating that the alopecia is secondary to a hair cycle defect. Normal hair cycling depends upon reciprocal interactions between the epidermal (keratinocyte) and mesodermal (dermal papilla) components of the hair follicle. To identify which of these cell populations was responsible for the defect in anagen initiation, hair reconsitution assays were performed in nude mice, using keratinocytes and activated dermal papilla cells isolated from neonatal mice. These studies demonstrated that morphogenesis was not affected by VDR status of either cell population. However, follicles reconstituted with VDR null keratinocytes did not respond to anagen initiation, regardless of the VDR status of the dermal papilla cells.Studies were, therefore, undertaken to examine whether expression of the VDR in the keratinocytes of the VDR null mice could prevent the development of alopecia in vivo. The human VDR was inserted into a cassette containing Keratin 14 upstream regulatory elements and the human growth hormone poly A region. Seven potential founders were mated with VDR null mice and offspring were characterized for expression of the transgene in skin, using rt-PCR with human VDR-specific primers. Further matings were performed in three transgenic lines, two with transgene expression and one without, to obtain transgene positive VDR null mice.VDR null mice from the control line, in which the transgene is not expressed, develop progressive hair loss and do not respond to anagen induction. In contrast, the VDR null mice who express the transgene do not develop alopecia and have hair regrowth in response to anagen induction.These studies demonstrate that the absence of the VDR in keratinocytes is responsible for the alopecia in the VDR null mice and that the defect can be prevented by targeting expression of the human VDR to the keratinocytes of the VDR null mice.

1186

Expression of Human Vitamin D Receptor in the Skin Prevents the Development of Alopecia in Vitamin D Receptor Null Mice and Promotes the Re-initiation of the Hair Cycle. J. Kong,*[1] X. J. Li,[2] D. Gavin,*[2] Y. Jiang,*[1] Y. C. Li.[1] [1]The University of Chicago, Chicago, IL, USA, [2]Genetics Institute, Andover, MA, USA.

In addition to impaired mineral ion homeostasis, alopecia is a predominant feature of vitamin D receptor (VDR) null mice and hereditary hypocalcemic vitamin D-resistant rickets patients. Recent studies have suggested that the alopecia is probably due to the failure of the initiation of the postnatal hair cycle. To directly determine the role of VDR in the regulation of hair growth, we used the human keratin 14 promoter to generate transgenic mice expressing human VDR (hVDR) in the skin as well as to generate VDR null mice that carry the hVDR transgene through breeding. Parallel studies were carried out in littermates of wildtype (WT), VDR null (KO), wildtype transgenic (TG) and VDR null mice expressing the hVDR in the skin (KO/hVDR) in two transgenic lines. The TG mice were grossly normal. The KO and KO/hVDR mice were growth-retarded, and developed hypocalcemia and secondary hyperparathyroidism after weaning. X-ray radiography and histological analyses of their skeleton revealed rickets and osteomalacia. However, in contrast to the KO mice, the KO/hVDR mice did not develop alopecia. The skin histological structure of the TG and KO/hVDR mice was indistinguishable from that of the WT mice. Immunohistochemical analyses revealed that hVDR was highly expressed in the basal layer of the epidermis and the outer root sheath of the hair follicle. In the first postnatal hair cycle, no major histological differences were seen in the skin of WT, KO, TG and KO/hVDR mice. When anagen was induced by depilation at 18 days after birth, the KO mice failed to initiate the hair cycle, whereas the KO/hVDR mice displayed the same pattern of anagen follicle initiation as the WT mice. Interestingly, the TG mice initiated the hair cycle one to two days earlier than the WT and KO/hVDR mice. These data demonstrate that the expression of VDR in the hair follicles prevents the development of alopecia in VDR null mice, and VDR plays a key role in the re-initiation of the hair cycle after birth.

A Novel Mechanism of Estrogen Receptor Regulation by Protein Turnover Mediated by Human *Seven in Absentia* (SIAH) Homologs. D. G. Monroe, S. A. Johnsen,* T. C. Spelsberg. Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA.

The actions of estrogen receptor (ER) isoforms, α and β, in osteoblasts (OBs) have important roles in the physiology and remodeling of the skeleton. Previous studies have indicated that the steady-state levels of ER-isoforms change throughout OB differentiation suggesting that the modulation of ER protein levels are important in the regulation of genes involved in OB function. Other studies have demonstrated that ERα is ubiquitinated and degraded by the proteasome-dependent pathway. Therefore, to understand the possible mechanisms involved in ER turnover during OB differentiation and OB function, we investigated the effects of overexpressing specific ubiquitin ligases on the function and steady-state levels of ERα and ERβ. SIAH-1 and -2 are the human homologs of the *Drosophila seven in absentia* ubiquitin ligase and are involved in proteasome-dependent degradation of specific proteins. Our data indicate that overexpression of SIAH-1 or -2 attenuates estrogen (E)-dependent transactivation of both ERα and ERβ by 50% on an ERE-reporter construct in transient transfection assays. Furthermore, western blot analysis demonstrates that SIAH-1 and -2 overexpression results in marked reduction of ERβ levels, whereas the reduction of ERα protein occurs only in the presence of SIAH-2. This suggests that SIAH-1 and SIAH-2 attenuate ERβ-dependent transactivation by directly degrading ERβ protein, whereas the turnover of ERα is dependent upon SIAH-2 and not by SIAH-1. These data also suggest that since SIAH-1 overexpression attenuates ERα transactivation but does not cause turnover of ERα protein, an alternate mechanism may be involved in which ERα recruits SIAH-1 to specifically degrade other components of the ERα transactivation machinery (e.g. steroid receptor coregulators or SRCs). This hypothesis is further strengthened by the observation that coimmunoprecipitation studies demonstrate a direct interaction of ERα with SIAH1. This represents a novel interaction with ER and a ubiquitin ligase. Collectively, these data are consistent with a model where SIAH-2 is the primary player in the attenuation of ERα and ERβ through receptor degradation, and that SIAH-1 may assist by degrading other components involved in the ER transcriptional machinery. Current studies testing the interaction of ERα with SIAH2, the interaction of ERβ with both SIAH homologs, and the effects of SIAH homologs on steady-state levels of the SRCs, are underway. In conclusion, these results demonstrate that SIAH-1 and -2 may be involved in the modulation of ER-dependent transcription in OBs through degradation of ERs by the ubiquitin-proteasome pathway.

Histone Deacetylase (HDAC) 2 Interacts With the Half Site of DR-3 Type Negative Vitamin D Response Element (nVDREm) in the Chromatin Immunoprecipitation Assay—The Link Between Chromatin

Hypoacetylation and Transcriptional Repression by Vitamin D. T. Okazaki,[1] E. Ogata,[2] T. Fujita.*[1] [1]Endocrine unit, Internal Medicine, University of Tokyo School of Medicine, Tokyo, Japan, [2]Cancer Institute Hospital, Tokyo, Japan.

We have previously shown that vitamin D alters VDR conformation by modulating its phosphorylation status through the action of DNA-dependent protein kinase. The “altered” VDR, in turn, exerts negative gene regulation through its monomeric interaction with nVDREm, the "half" site of DR-3. Further, our transfection assay suggested that negative gene regulation by the liganded monomeric VDR requires the recruitment of HDAC (histone deacetylase) 2, but not HDAC1.Here, we employed chromatin immunoprecipitation assay to directly examine the mechanism of selective recruitment of HDAC2 to the liganded VDR and nVDREm. COS7 cells were transfected with VDR-expressing plasmid along with nVDREm-reporter TK plasmid. Chromatin was immunoprecipitated from these cells treated with no or 10 nM of vitamin D for 40 hours. In this assay, HDAC1, HDAC2 and acetylated histone H3 were immunoprecipitated with the respective antibody, followed by analysis for the presence of the reporter DNA fragment by semi-quantitative PCR. As expected, vitamin D treatment decreased the degree of histone H3 acetylation, while it recruited HDAC2, but not HDAC1. These results imply that specific HDAC2 recruitment led to hypoacetylation of chromatin in the presence of vitamin D. Trichostatin A, an HDAC inhibitor, reversed acetylation status of histone H3 and blocked recruitment of HDAC2 in this assay, suggesting that the recruited HDAC2 possessed HDAC activity. On the other hand, when we used DR-3 positive VDRE-TK plasmid as a reporter, vitamin D treatment neither affected histone H3 nor recruited HDAC2, further supporting our hypothesis that there is selective interaction between nVDREm and HDAC2 in the negative gene regulation by vitamin D. We next performed gel shift assay by using nVDREm as a probe. In this assay, whole cell proteins from COS7 cells into which VDR-expression plasmid was introduced yielded several bands. One of them was block-shifted by anti-VDR antibody. The intensity of this band was augmented by vitamin D added in vitro. Of interest, anti-HDAC2 antibody also blocked the formation of this band only when the proteins were treated with vitamin D in vitro. In the absence of vitamin D, anti-HDAC2 antibody did not affect the formation of this band. Our results raise the possibility that not only unliganded but also liganded VDR utilize the activity of histone deacetylase, HDAC2, to exert negative gene regulation by vitamin D.

1189

The VDR Heterodimer Interacts with BAF60a, a Component of the Mammalian SWI/SNF Complex. N. Koszewski,[1] K. Henry,*[2] E. Lubert,*[2] D. Noonan.*[2] [1]Division of Nephrology, Bone & Mineral Metabolism, University of Kentucky, Lexington, KY, USA, [2]Department of Biochemistry, University of Kentucky, Lexington, KY, USA.

Previous studies have identified a direct repeat vitamin D response element (VDRE) from the avian PTH (aPTH) promoter that bound the VDR/RXRα heterodimer complex in vitro and conferred vitamin D-dependent repression of gene transcription. Based on these results, a modified yeast one-hybrid screen was used to isolate proteins capable of interacting with the heterodimer complex while driving expression from the negative VDRE. A commercial HeLa cell cDNA/Gal 4 activation domain (AD) hybrid library was screened for proteins capable of interacting with the full-length human heterodimer partners expressed in yeast. Positive clones were identified based on their ability to activate expression of a β-galactosidase reporter vector linked to the aPTH VDRE. Over 150,000 transformants were screened and, following secondary screening and analysis, a total of 10 independent colonies were isolated, plasmid DNA recovered and subjected to sequence analysis. Three of the ten isolates possessed an in-frame coding sequence for the identical full-length protein, while a fourth clone corresponded to an alternatively spliced isoform of the same protein. A database search matched these clones with the BAF60a (or SMARCD1) protein, a component of the mammalian SWI/SNF complex. Deletion studies in yeast were unable to localize a unique region of BAF60a responsible for interaction with the heterodimer complex as only the full-length protein would support β-galactosidase gene expression. GST pull-down analyses revealed that BAF60a failed to interact specifically with either recombinant VDR- or RXRα-containing extracts alone, but displayed strong interactions with the intact heterodimer complex. Transient transfection analysis in HeLa cells indicated that increased expression of BAF60a resulted in decreased transcriptional activity from a VDRE, but not from an estrogen responsive element. In summary, we have identified BAF60a as a factor that specifically interacts with the VDR heterodimer complex using a modified yeast one-hybrid selection strategy. This suggests that the VDR complex may also be a target for the mammalian SWI/SNF chromatin remodeling complex through its interaction with BAF60a.

1190

Inhibition of 1,25-Dihydroxyvitamin D3-dependent Transcription By Synthetic Peptide Antagonists That Target the Activation Domain of Retinoid X Receptor. P. Pathrose,*[1] C. Y. Chang,*[2] D. P. McDonnell,*[2] J. W. Pike.*[1] [1]Molecular and Cellular Physiology, University of Cincinnati, Cincinnati, OH, USA, [2]Pharmacology and Cancer Biology, Duke University, Durham, NC, USA.

The vitamin D receptor (VDR) is known to mediate the biological actions of 1,25-dihydroxyvitamin D3 (1,25(OH)2D3) through its actions on hormone-sensitive genes. Accordingly, the hormone-activated receptor binds to specific DNA sequences located within the promoter region of regulatable genes, recruits additional coregulatory molecules essential to the process, and initiates quantitative changes in gene output. The transcriptionally active form of VDR is believed to be a VDR/retinoid X receptor (RXR) heterodimer, which binds to vitamin D response elements (VDREs) in vitro with high affinity and selectivity. The absolute requirement for RXR in VDR-mediated transcription in mammalian cells has not been determined, however, due to the absence of a cellular model that is devoid of endogenous RXR expression. In order to determine the role of RXR in VDR action directly, we first identified a subset of novel peptide antagonists (LXXLL-motifs previously identified through phage display screening) that were selective in a hormone-dependent manner for the AF-2 region of either VDR or RXR using a mammalian COS 7 cell two-hybrid system. Peptides were introduced into cells and targeted to the nucleus through the use of an expression vector that encoded the specific peptide sequence fused to the C-terminus of the DNA binding domain of Gal4. LXXLL peptide sequences derived from the nuclear receptor (NR) boxes of both SRC-1 and GRIP interacted strongly with VDR as well as RXR. This screen revealed four categories of peptides: those that interacted with both VDR and RXR, those which were selective for either VDR or RXR and those which did not interact with either receptor. Antagonist peptides were then examined for their ability to block 1,25(OH)2D3-dependent transactivation of an osteocalcin promoter-luciferase reporter chimeric gene following transfection into osteoblastic MC-3T3-E1 cells. Peptides that interacted with both VDR and RXR, including those derived from the NR boxes of SRC-1 and GRIP blocked 1,25(OH)2D3-dependent transcription by up to 85% at the highest peptide concentrations examined. Interestingly, while several peptides that interacted selectively with RXR were inactive, two were as effective in blocking 1,25(OH)2D3 response as those that bound directly to VDR. These studies provide the first direct evidence that RXR participates in transcriptional regulation by 1,25(OH)2D3 in intact cells and may represent a novel approach for assessing the contribution of accessory proteins in nuclear receptor response.

Shuttling Vitamin D Receptors Transport the Hormone Into and Out of the Nucleus. J. Barsony, K. Prufer, C. Segovis.* LCBB, NIH/NIDDK, Bethesda, MD, USA.

Two alternative hypotheses have been put forth to explain the mechanism of steroid hormone uptake into the nucleus and release from the nucleus: one is based on free diffusion of the hormone, the other is based on carrier mediated import. We used advanced microscopy methods to investigate vitamin D receptor (VDR) shuttling and its possible role in transporting the hormone across the nuclear membrane. To detect the spatial and temporal relationship between calcitriol and VDR in living cells, we stably expressed green fluorescent protein chimera of the VDR (GFP-VDR) in rat osteosarcoma (ROS17/2.8) and porcine kidney (293) cells and developed biologically active red BODIPY labeled calcitriol (red calcitriol). Real-time multicolor confocal laser scanning microscopy allowed us to monitor the nuclear import of hormone and receptor simultaneously. These recordings revealed that calcitriol uptake into the cytoplasm is very rapid (half maximal at 5min). In contrast, hormone uptake into the nucleus was much slower (half maximal at 20min) and proceeded in parallel with GFP-VDR translocation into the nucleus. The intranuclear distribution patterns of VDR and red calcitriol were also similar. These results indicated a role for VDR translocation in nuclear hormone uptake. This was further investigated by mutational analysis. Mutations in the ligand-binding domain known to be important for hormone binding prevented red calcitriol accumulation in the nucleus. To evaluate the impact of receptor shuttling, we identified a region within the ligand-binding domain that confers nuclear import, and also used the import mutant that we generated earlier. GFP-VDR export from the nucleus was perturbed by a combination of point mutations or by leptomycin B treatment of the cells expressing the wild-type GFP-VDR (10nM for 2h). Preventing either nuclear import or export decreased nuclear hormone uptake by at least 70%. Final evidence for the VDR mediated calcitriol import and export came from a special type of fluorescence energy transfer experiment. This method visualized the interaction between VDR and red calcitriol by way of making the liganded receptors much brighter than the unliganded receptors in a small area of the nucleus or the cytoplasm upon the photobleaching of the red calcitriol. The movements of the liganded receptors from the cytoplasm into the nucleus and from the nucleus into the cytoplasm were then recorded. These experiments proved that the hormone is both imported and exported together with the receptor. Our studies gave new insights into the mechanisms of receptor subcellular trafficking and demonstrated that VDR shuttling controls the access of calcitriol to the nucleus.

Characterization of 5’-Flanking Region of Human RANK Ligand Gene. K. Kajimoto,* R. Kitazawa, S. Maeda,* S. Kitazawa. Division of Molecular Pathology, Kobe University Graduate School of Medicine, Kobe, Japan.

RANK ligand (RANKL), or osteoclast differentiation factor, has been identified as a prerequisite to osteoclastogenesis. Most of the bone resorptive factors, including 1α,25dihydroxyvitamin D_3 ($1,25(OH)_2$ D_3), are thought to modulate bone resorption by regulating RANKL expression on osteoblasts and stromal cells. To elucidate the mechanism regulating human RANKL gene expression, we first examined the effect of $1,25(OH)_2$ D_3 on the RANKL gene by a nuclear run-on analysis, and found that it accelerated the transcription rate of the RANKL gene in the SaOS2 cell line. We then focused on the promoter structure and cis-acting elements of the human RANKL gene that conducts $1,25(OH)_2$ D_3 signaling. From the human genomic library, we cloned a 12.5kb fragment containing the 5'-flanking region of the human RANKL gene and accessed its promoter activity by transient transfection assay. The basic promoter of human RANKL gene comprises inverted TATA- and CCAAT-boxes and putative RUNX2 binding sites. Three putative vitamin D responsive elements (VDRE) are located at -1585/-1571 (VDRE1), -1419/-1405 (VDRE2), and -1384/-1370 (VDRE3) from the transcription start site. Radio-labeled double stranded oligonucleotides corresponding to the three putative VDREs were generated, mixed with nuclear extract from $1,25(OH)_2$ D_3 -treated SaOS2 cells, and subjected to gel motility shift assay. Specific binding of the VDR and RXRα heterodimers to VDRE1 was observed as supershifted bands by anti-VDR and -RXRα antibodies. The presence of the functional VDRE was assessed by transient transfection studies. Promoter-luciferase constructs with (Luc-1787) and without (Luc-1041) VDRE1 were transfected into SaOS2 cells. The transfected cells were then treated with 10 nM $1,25(OH)_2$ D_3 for 6, 12, 24, and 48h prior to the luciferase assay. The treatment increased RANKL promoter activity to 160% in Luc-1784, which was almost nullified in Luc-1041. Introduction of mutation to the VDRE1 site of the Luc-1787 construct also nullified the inductive effect of $1,25(OH)_2$ D_3 on the RANKL promoter. These data indicate that the human RANKL gene promoter shares striking structural similarities with the mouse promoter, and that $1,25(OH)_2$ D_3 transactivates human RANKL gene through cis-acting VDRE located at -1585/-1571.

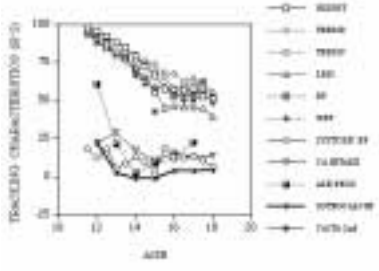
Low 25-Hydroxy-Vitamin D Concentrations Are Associated With Lower Cortical Bone Mass In 10-13 Year Old Girls (Calex-Study). C. Lamberg-Allardt,[1] H. Kröger,[2] A. Koistinen,[3] M. Kärkkäinen,*[4] A. Mahonen,[2] F. Tylavsky,[5] S. Cheng.[3] [1]Department of Applied Chemistry and Microbiology, University of Helsinki, Helsinki, Finland, [2]University of Kuopio, Kuopio, Finland, [3]University of Jyväskylä, Jyväskylä, Finland, [4]University of Helsinki, Helsinki, Finland, [5]University of Tennessee, Memphis, TN, USA.

The aim of this investigation was to study the association of serum25-OHD concentration with bone mass at different bone sites in growing girls. The subjects were 10-13 year-old girls (n=104)who presented with Tanner stage I- II and enrolled in an intervention study (CALEX). Serum(S) concentration of 25(OH)D and PTH was assessed with RIA (Diasorin) and IRMA(Nichols)respectively). Bone properties of the total body, hip, spine, radius and tibia were measured using DXA (Prodigy, Lunar) and pQCT (XCT 2000, Stratec). The mean concentration of 25-OHD was 36 nmol/l with a minimun of 19 nmol(l and maximum at 66 nmol/l(reference range 25-125 nmol/l).In a regression model we did not find any association between S-25-OHD and bone mineral content(BMC) or bone mineral density(BMD) at any site. However, when the subjects were divided into groups based on their serum 25-OHD concentration (25 nmol/l to be sufficient)we found lower cortical BMD measured with pQCT in the tibia (p=0.04) and radius(p=0.04) in those girls with S-25-OHD 25 nmol/l (n=82). When Tanner stage and age was introduced as covariates in the model the cortical bone density in the tibia was significantly lower (p=0.001) and tended to be so in the radius(p=0.07) in the group with S-25-OHD <25 nmol/l than in the group with values above this level. There was no difference in the trabecular BMD at any of these sites and at the total body, hip and spine measured with DXA. S-PTH was not associated with BMD.The results suggest that 20 % of the girls in this study may be compromising cortical bone mineralization due to marginal vitamin D status.

F004

Tracking Characteristics of Bone Mass, Body Composition, and Bone Biomarkers From Childhood to Young Adulthood. V. Matkovic,[1] N. E. Badenhop-Stevens,[1] J. D. Landoll,[1] S. L. Mobley,[1] E. J. Ha,[1] A. C. Clairmont,*[2] L. Nagode,*[2] J. L. Roehrig.*[1] [1]Bone and Mineral Metabolism Laboratory, OSU, Columbus, OH, USA, [2]OSU, Columbus, OH, USA.

We previously showed that peak bone mass is one of the main determinants of osteoporotic fracture in the population and that timing for peak bone mass occurs relatively early in life. Assuming minimal change in bone mass during skeletal maturity (age 18 to 50) it, therefore, seems plausible to consider the distribution of bone mass early in life as a good indicator of osteoporosis risk at the time of menopause, assuming that no intervention is applied to change its course. We, therefore followed a cohort (N=185) of healthy Caucasian females from age ~11 to ~18, or during the time period when more than 40% of total body bone mass is accumulated. Bone mass measurements of the total body (TBBMC & TBBMD) and of the distal forearm were measured annually for 7 years in addition to the radiogrammetry of the second metacarpal bone, basic anthropometry, dietary calcium, blood pressure, body composition, and bone biomarkers. Each set of measurements at subsequent time points was regressed on the baseline values and R^2 of each variable was plotted against age (Figure 1). The change in R^2 with time indicates a tracking characteristic of the variables from early puberty to late adolescence and young adulthood. R^2 for bone mass, stature, and body composition decreases with age and reaches a plateau by the age 15-16 with minimal change thereafter. TBBMD continues to decrease up to the age of 18 primarily due to the continuation of bone consolidation after bone modeling has been completed. The tracking characteristics of blood pressure, dietary calcium, and bone biomarkers remain to be significant after 7 years of follow-up, although at a much lower level. The above research data may have implications with regard to the primary prevention of osteoporosis, obesity, and hypertension in the population.



F005

Changes in Lumbar Spine Bone Mineral Density of Healthy Men and Women in the Third Decade of Life: A 10-year Longitudinal Study. R. K. Evans,* K. M. Sheehan,* B. C. Nindl,* C. J. Baker-Fulco,* R. P. Mello,* M. M. Murphy,* C. E. Wade,* C. R. Scoville.* Military Performance Division, USARIEM, Natick, MA, USA.

Maximizing peak bone mass during the growing years is advocated to prevent osteoporosis, yet there is no consensus on the age at which peak bone mass is reached. To effectively apply intervention strategies, a greater understanding of skeletal growth patterns is important. This longitudinal study followed healthy male (n = 48) and female (n = 59) West Point cadets from the age of 18 to 29 years to assess bone mineral changes in the lumbar spine. Dual-energy X-ray absorptiometry (LUNAR, Madison, WI) was used to assess lumbar spine (L2-4) bone mineral density (BMD), bone mineral content (BMC), and bone area biannually during college, and 6 years after graduation. Body mass and percent body fat assessed by skinfold (SF) were also examined. Time points used for analyses were: baseline (1989; age 18), senior year (1992-3, age 21), and 6 years following graduation (1999, age 29). A repeated-measures analysis of variance assessed time and gender effects. Our findings are presented in the following table.

	Men (n=48)			Women (n=59)		
Variable	**1989**	**1992-3**	**1999**	**1989**	**1992-3**	**1999**
BMD ($g \cdot cm^2$)	1.30 ± 0.14^a	1.36 ± 0.15^b	1.31 ± 0.15^a	1.26 ± 0.11^a	1.30 ± 0.12^b	1.31 ± 0.11^b
BMC (g)	63.1 ± 9.9^a	65.5 ± 10.5^b	63.9 ± 10.8^a	53.3 ± 7.0^a	54.6 ± 7.6^a	56.4 ± 7.5^b
Area (cm^2)	48.5 ± 4.8^{ab}	48.1 ± 4.7^a	48.9 ± 5.1^b	42.1 ± 3.3^a	42.0 ± 3.5^a	43.0 ± 3.7^b
Body mass (kg)	73.0 ± 8.5^a	78.0 ± 8.3^b	83.3 ± 13.9^c	60.8 ± 6.3^a	63.0 ± 6.0^a	66.3 ± 9.1^b
Body fat (%)	13.9 ± 3.7^a	15.4 ± 4.1^a	18.2 ± 5.9^b	26.1 ± 4.3^a	25.0 ± 3.9^a	26.3 ± 4.8^a
Suprailiac SF (mm)	12.3 ± 5.6^a	17.7 ± 7.9^b	20.5 ± 11.8^b	16.4 ± 6.3^a	14.7 ± 6.4^a	14.7 ± 7.7^a

Values are means ± SD. Same superscripted symbol across time points denotes lack of statistical significance (p>0.05). Female BMD increased (2.8 ± 4.5%) while at West Point, and was maintained at follow-up. Male BMD also increased while at West Point (4.7 ± 4.4%) but significantly decreased on follow-up (3.8 ± 5.1%). The increase in BMD in active men and women from the age of 18 to 21 suggests that bone mass continues to accumulate in the college-aged adult. Additionally, our sample exhibited a gender difference in skeletal growth patterns during the third decade of life. In the absence of any biological explanation for this gender difference, these findings should be interpreted cautiously. This apparent bone loss in the men could represent artifact produced by increases in male pattern intra-abdominal fat deposition. Men, but not women, accumulated significant body fat from age 21 to 29, although this was not correlated with BMD. Further studies are needed to determine the factors affecting bone mineral acquisition and loss in the young adult population.

F007

Late Normal Puberty in Men Is Associated With 1 SDS Lower Bone Mass in Spine and Hip at 21 Years of Age. A Longitudinal Study Among Young Healthy Men Between 16 and 21 Years of Age. M. G. Stenstrom,[1] E. Norjavaara,*[2] L. Hulten,*[3] L. Hallberg,[3] K. Albertsson-Wikland,*[4] D. Mellstrom.[1] [1]Geriatric Medicine, Goteborg University, Goteborg, Sweden, [2]Pediatric Medicine GP-GRC, Goteborg University, Goteborg, Sweden, [3]Clinical Nutrition, Goteborg University, Goteborg, Sweden, [4]Pediatric Medicine, Goteborg University, Goteborg, Sweden.

The effect of puberty and sex steroids on acquisition of bone mineral density is well known, but whether normal variations on the start of puberty influence the peak bone mass is not known. Both normal and decreased bone mineral densities have been reported for men with delayed puberty. The purpose of this study is to compare whether late onset of pubertal growth spurt influence the acquisition of bone mineral density. In the community of Göteborg, Sweden 250 teenagers of both sexes 16 years old were randomly selected and invited to participate in a longitudinal study with reapeated examination of bone mineral density, body composition and blood samples. 238 subjects initially responded (95%). The young men and women were examined at the age of 16, 17, 18, 19 and 21. All examinations and procedures were done at late afternoon in the same month every year. The young men were divided in quartiles regarding their height growth during five years (16-21). The quartile with the largest change in height growth was compared with the others, thus having less change in height. 54 young men were followed throughout the study. All of the subjects had started their puberty at age 16 indicated by serum testosterone, testicular volume and Tanner-score. At age 21 final height was reach for all subjects (change in height less than 1 cm). Mean growth in height among the quartile with the highest height velocity after the age of 16 was 10.8 cm versus 2.2 cm for the other quartiles. At the age of 21 the mean height were 181 cm versus 181.3 cm although a fully catch up in length the young men with late onset height growth were significantly slender, mean weight 68.0 kg versus 79.2 kg respectively. BMD, BMC and area were significantly lower at age 16 in men with late onset of the pubertal growth spurt. This differance in BMD and BMC persisted but there was no significant difference in area in spine and hip at age 21. Adjusted fore both weight and area bone mass was significantly lower at age 21 in men with late height growth. The difference in BMD in spine and hip at age 21 was >1 SDS below those men with earlier onset of pubertal growth spurt and also significantly lower than mean BMD (spine and hip) in young women at age 21. Late onset of puberty within the normal range for start of puberty is associated with 1 SDS lower bone mass in spine and hip at age 21.

Estrogen Inhibits Adipogenesis of Mesenchymal Progenitor Cells: Possible Mechanism of Action. Z. C. Dang,[1] R. L. van Bezooijen,[1] M. Karperien,[1] C. Oliveira,*[2] K. Willems van Dijk,*[2] S. Papapoulos,[1] C. Lowik.[1] [1]Endocrinology, Leiden University Medical Center, Leiden, The Netherlands, [2]Anthropogenetics, Leiden University Medical Center, Leiden, The Netherlands.

Osteoblasts and adipocytes arise from a common mesenchymal progenitor cell in bone marrow. Whether estrogen (E2) regulates the differentiation of progenitor cells into osteoblasts or adipocytes remains unknown. For this, we have used the mouse clonal cell line KS483 which differentiates into osteoblasts and adipocytes when cultured in charcoal-stripped FBS. E2 from 10-13 M to 10-6 M increased alkaline phosphate activity and nodule formation and stimulated mRNA expression of Cbfa1, PTH/PTHrP-receptor and osteocalcin. In contrast, E2 concurrently decreased adipocyte numbers and decreased mRNA expression of PPARg2, aP2 and lipoprotein lipase. The above E2 action was estrogen receptor (ER) mediated as shown by specific ER antagonists. Similar results were obtained in mouse bone marrow cell cultures, showing an ER-dependent reciprocal control of osteoblast and adipocyte differentiation by E2. Immunohistochemical staining showed the pres-

ence of ERa and ERb in osteoblasts and adipocytes. We identified a mouse splice variant ERb2 and found that E2 downregulated mRNA expression of ERb1 and ERb2. Transfection studies showed that ERb functioned as a transdominant inhibitor of ERa induced gene transcription in KS483 cells. The known adipogenic mixture of isobutylmethyl-xanthine, dexamethasone, and insulin (IDI) induced adipogenesis in KS483 cells and this induction was inhibited by E2. However, the PPARg agonist indomethacin induced adipogenesis more potently and this was only slightly inhibited by E2. Interestingly, overexpression of a constitutively active ERa by adenoviral mediated gene transfer completely blocked adipogenesis induced by indomethacin. These results suggested the existence of cross-talk between ERa and PPARg. PGC-1 is a common coactivator for PPARg and ERa. PGC-1 mRNA was abundantly expressed in KS483 cells and was upregulated by E2 and IDI during the first 11 days of culture and decreased afterwards. E2 activated an ERE-luc reporter construct. Cotransfection of ERa strongly enhanced ERE reporter activity. In contrast, cotransfection of PPARg2 into KS483 exposed to indomethacin inhibited E2 stimulated activition of an ERE-luc report construct. In conclusion, our results demonstrated that E2 stimulated osteogenesis and concurrently inhibited adipogenesis of mesenchymal progenitor cells in an ER-dependent way. This inhibition may occur at the transcriptional level by competition between PPARg and ERa for common coactivators like PGC-1.

F012

Noggin is a Negative Regulator of Bone Remodeling (Formation and Resorption) in Adult Mice: Evidence from Noggin Null Mice and Noggin Overexpressing Mice. X. B. Wu,*[1] L. Sun,[1] L. J. Brunet,*[2] R. M. Harland,*[2] E. Abe.[1] [1]The Mount Sinai Bone Program and the Bronx VA GRECC, New York, NY, USA, [2]Department of Biochemistry and Molecular Biology, University of California, Berkeley, CA, USA.

To date, studies on bone morphogenetic protein (BMP) and its inhibitor, noggin, have focused mainly on their role during skeletal development and fracture healing. Here we report potent inhibitory effects of noggin on the proliferation and differentiation of osteoblasts in *adult* bone. The expression of noggin was enhanced during osteoblast maturation, but with a different time course to BMP-2/4. Noggin expression was also detected in cells of the macrophage lineage, but not in mature osteoclasts. Furthermore, BMP-2/4 and not TGF-β enhanced noggin expression. Levels were also elevated by ~2-fold in bone tissues and bone marrow cell cultures from 20 month-old mice and senescence accelerated mice (SAM-P6) compared with 'young' controls, namely 4 month-old and SAM-R1 mice, respectively. This suggested that elevated noggin levels, by reducing BMP-induced osteoblast maturation, could potentially contribute to involutional osteopenia. We thus hypothesized that the balance between BMP and noggin production might in fact regulate bone remodeling. To investigate this, we developed several transgenic mouse lines that overexpressed noggin in mature osteoblasts under the control of the osteocalcin promoter. Noggin expression in bone tissue and calvarial cell cultures was 2 to 3-fold higher in transgenic mice compared with wild type littermates. However, up to 2 months, bone mineral density remained normal. We next deleted the noggin gene, but found that the homozygotes did not survive postnatally. They had no osteoblasts and in addition displayed abnormal joint formation, likely due to a cartilage abnormality. The regulation of noggin was then examined *in vivo* in heterozygotes by studying the expression of LacZ, a transgene that was incorporated at the site of gene deletion. Consistent with the *in vitro* data, LacZ expression was enhanced by BMP-2/4 in both osteoblasts and macrophage-like cells. Finally, and importantly, bone marrow cells isolated from the noggin heterozygotes showed a significant, ~30%, reduction in their ability to form alkaline phosphatase positive fibroblastoid colonies (or CFU-Fs) as well as TRAP-positive osteoclasts. Collectively, the data confirms a *hitherto* uncharacterized action of noggin (and BMP-2/4) on adult bone remodeling, notably on both formation and resorption. This is not only of physiological significance, but is also a prelude to future therapeutic intervention.

F014

The Type I BMP Receptors ALK3 & ALK6 Function Similarly in Controlling Osteoblast and Adipocyte Differentiation from Human Mesenchymal Stem Cells. J. G. Emery,[1] A. S. Mathur,*[1] D. J. Rieman,[1] M. T. Kaing,*[1] K. A. Geubtner,*[1] C. N. Bender,*[1] M. Gowen,[1] M. Lark,[1] L. J. Suva.[2] [1]Musculoskeletal Diseases, GlaxoSmithKline, King of Prussia, PA, USA, [2]Center for Orthopaedic Research, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Osteoblasts and adipocytes are derived from common mesenchymal precursor cells. Several lines of evidence suggest the existence of a reciprocal relationship between osteoblast and adipocyte differentiation. Bone morphogenetic proteins (BMPs) stimulate both osteoblast and adipocyte differentiation. In 2T3 murine calvarial cells, activation of the type IA BMP-receptor (ALK3) stimulates adipogenesis, whereas activation of the type IB BMP-receptor (ALK6) stimulates osteoblast differentiation (Chen et al., 1988, J. Cell Biol. 142:295). To investigate the role of BMP signaling during osteoblast and adipocyte differentiation in human cells, we established in vitro models of osteoblast and adipocyte differentiation from primary human mesenchymal stem cells (MSCs) and have examined the roles of BMPs, receptors, and Smads in these pathways. To determine if certain BMPs, receptors, or Smads are specific to a particular differentiation pathway, we examined the expression of each during osteoblast and adipocyte differentiation using real-time quantitative RT-PCR. BMP4 is the predominant BMP expressed in differentiating MSCs. ALK3, ALK6, and the type II BMP receptor are expressed in all conditions, although ALK6 levels are 10-fold lower than BMPR-II and ALK3. All Smads examined, including BMP pathway specific, common, and inhibitory Smads, were expressed in differentiating MSCs, although the level of expression was variable. For all genes examined, pathway-specific expression was not detected, suggesting that the balance between osteoblast and adipocyte differentiation is not determined merely by steady-state RNA levels of BMP signaling components. We next examined the roles of ALK3 and ALK6 in human MSC differentiation. Human MSCs were infected with recombinant adenovirus expressing dominant negative (DN) or constitutively active (CA) mutants of ALK3 or ALK6 and cultured under osteoblast or adipocyte differentiation conditions. DN mutants of either receptor inhibited BMP4-stimulated adipocyte or osteoblast differentiation, whereas CA mutants stimulated adipocyte or osteoblast differentiation in the absence of BMP4. However, in adipocyte medium, high concentrations of CA mutants caused the cells to elongate and inhibited adipogenesis. These data suggest that in contrast to their roles in murine cells, ALK3 and ALK6 are functionally redundant in controlling osteoblast and adipocyte differentiation from human MSCs.

HDAC-1 Mediates the Repressive Function of Smad6 in BMP Signaling. S. Bai, X. Cao. Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Smad proteins transduce BMP signaling from the cell membrane to the nucleus. Smad6 is one of the inhibitory Smads that preferably inhibits BMP signaling. Smad6 interacts with the activiated type I receptors and blocks the phosphorylation of the receptor regulated Smads. Smad6 was also identified as interacting with the phosphorylated Smad1, forming an inactive Smad1-Smad6 complex in the cytoplasm. Previously, we identified that Smad6 acts as a transcriptional co-repressor in BMP signaling through interacting with Hoxc-8. Here we report that Smad6 represses gene transcription by directly recruiting histone deacetylases (HDACs). HDACs are involved in chromatin modification and are recruited to specific gene promoters by transcriptional repressors or co-repressors that silence gene expression. Transfection studies demonstrated that the HDAC inhibitor, trichostatin A (TSA) partially blocks Smad6-mediated osteopontin promoter activity, indicating HDAC is involved. In immuno-precipitation assays, both Smad6 and Hoxc-8 were co-precipitated with HDAC-1. Furthermore, overexpression of HDAC-1 and Smad6 completely inhibited the BMP-induced osteopontin promoter activity. We also performed the HDAC activity assay with immunoprecipitated Smad6 protein complexes, in which 3H-labled acetylated histones were incubated with Smad6 complex. The result showed that the histones deacetylation rate with Smad6 complex is 25% comparing with the 1% in the control. In addition, we found that Smad6 MH1 domain directly binds to DNA, and the MH2 domain of Smad6 masks this binding activity, suggesting that Smad6 MH1 and MH2 domains associate reciprocally and inhibit each other's function. Interestingly, the interaction of Hoxc-8 with Smad6 induced Smad6 binding to DNA in gel-shift assay. Our data indicate that Smad6 and Hoxc-8 interact with HDAC-1, and recruit HDAC-1 to the osteopontin promoter, leading to inhibited BMP-induced transcriptional activity as the negative feedback loop in the BMP signaling pathway.

Volumetric Evaluation of Newly Formed Vessels in the Distracted Site of Callotasis in Rabbits Using Micro-CT Scan. K. Inui,[1] Y. Azuma,*[2] A. Matsumura,*[1] A. Shimazaki,*[1] Y. Yamano,*[1] T. Koike.[1] [1]Orthopaedic Surgery, Osaka City University Medical School, Osaka, Japan, [2]Pharmacological Research Department, Teijin Institute for Bio-Medical Research, Tokyo, Japan.

Ilizarov emphasized significance of the corticotomy on the surgical procedure in callotasis, so as to preserve blood supply of the distracted callus. However, the precise process how the vessels are forming within the distracted site during callotasis is not well understood. In this study we performed volumetric evaluation of newly-formed vessels in the distracted site during maturation period using micro-CT scan. Twelve male Japanese white rabbits were used in this study. Transversely osteotomised right tibia was fixed by a unilateral external fixator, followed by callotasis for 14 days after 7-days of waiting period at a rate of 1mm/day. On the next day of ceasing distraction (day 0), after 5 days (day 5), 7 (day 7) and 14 (day 14), 3 animals in each day group were sacrificed. After perfusion of heparinized physiological saline through their femoral artery, 15% of barium sulphate solution was perfused as contrast dye, sufficient to fill the femoral vein with dye. Axially scanning of the elongation site of callotasis was performed 10 mm in length, 50 mm in thickness. Only the images of vessels were obtained by subtracting the other images by setting the density threshold. Two hundred digitized images of each specimen were reconstructed in 3 dimensions. The volume of vessels were calculated from the boxels of these vascular images using the software, 3 dimensional evaluation software of bone structure (3D-TBSAS; Teijin, Tokyo, Japan). In the image on day 0, most of blood flow was supplied from circumferential periosteum and few vessels were observed inside of the new bone. On day 7, many capillary vessels were formed inside of the new bone, which were organized in axial direction on day 14. Volumes (V) and surface area (SA) of the vessels filled with contrast dye was shown in Table 1. The vascular volume of the distracted site was gradually increase until the end of this study, while peak value of the surface area was seen on day 7. The peak value of SA divided by V, representing the complexity of vessels, was seen on day 7. In summary, the newly formed vessels were seen circumferentially in the early stage of bone maturation period, subsequently the capillary-like structures connecting to the peripheral vessels grew inside of the neo-generated bone. Then, those vessels were organized in axial direction.

F024

Identification and Characterization of Cystatin 10, a Novel Chondrocyte-Specific Protein Inducing Endochondral Ossification. Y. Koshizuka,[1] S. Ikegawa,*[2] K. Hoshi,[1] T. Yamada,*[1] H. Kawano,[1] Y. Nakamura,*[1] K. Nakamura,[1] H. Kawaguchi.[1] [1]University of Tokyo, Tokyo, Japan, [2]Institute of Physical & Chemical Research, Tokyo, Japan.

We found that the systemic endochondral ossification of the *ttw* mouse, a model for ectopic ossification, was markedly enhanced by a high-phosphate diet. This study sought to identify genes involved in endochondral ossification *in vivo* by a differential display analysis of the auricular cartilage mRNA from *ttw* mice with high and low phosphate diets. Several genes including osteopontin that were up-regulated with a high-phosphate diet were identified. Among them, we isolated a novel gene whose mRNA expression was specific to cartilage in wild-type mice. The gene encodes a protein of 149 amino acids with a putative signal sequence at its N terminus showing 39% homology to cystatin C, a cysteine

protease inhibitor, and was named cystatin 10 (Cst10). In mouse chondroblastic ATDC5 cell cultures, Cst10 mRNA expression could not be detected without induction of differentiation by insulin; however, in the presence of insulin, it appeared at 3 days followed by the type X collagen expression, and the expression level was increased with differentiation thereafter. In mouse growth plates, Cst10 protein was localized at hypertrophic chondrocytes, but not at lower-differentiated chondrocytes as determined by immunohistochemistry. In COS7 cells transfected with Cst10 cDNA, Cst10 protein was shown to be co-localized with lysosome in the cytoplasm by the double staining of immunocytochemistry. To investigate the function of Cst10, the full-length Cst10 cDNA was stably transfected into ATDC5 cells, and several clones highly expressing Cst10 were selected by Western blot analysis. Although type II collagen expression and Alcian blue staining were similar between cultures of Cst10-expressing clones and control clones stably transfected with the vector alone, cell hypertrophy and type X collagen expression were observed earlier, and stainings of Alizarin red and von Kossa were markedly increased in cultures of Cst10-expressing clones. A flow cytometric analysis revealed an approximately 4-fold increase in the number of cells in the sub-G1 phase of the cell cycle in Cst10-expressing cultures compared with that in control cultures. These cells were frequently accompanied by fragmentation and condensation of nuclei, a loss of cell membrane phospholipid asymmetry, and significant activations of caspase 3, 8 and 9 (3-6 fold vs. control clones). These results demonstrate that a novel chondrocyte-specific protein Cst10 may play an important role in endochondral ossification as an inducer of later differentiation and apoptosis of chondrocytes.

Identification of Two Genes Involved in the Differentiation of Chondrocytes through Gene Trapping in Chondrogenic ATDC5 Cells. M. Watanabe,* M. Yamazaki,* T. Uchihashi,* T. Michigami, K. Ozono. Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, Japan.

The gene trapping method is a genome-wide approach applied to clarify the function of a gene based on the idea that the random insertion of the trap vector into a gene disturbs its function. To identify genes involved in the differentiation of chondrocytes, we used the method in ATDC5 cells, which can be induced to differentiate into mature chondrocytes in vitro. The trap vector pT1geo, which has neither its own promoter nor enhancer but has LacZ and neomycin-resistance (neo) genes driven by the promoter of the inserted gene, was introduced into ATDC5 cells by electroporation. The transfected cells were selected in the culture with G418. Approximately 1000 neomycin-resistant clones were obtained and then screened for the activity of b-galactosidase. Then, 15 trapped clones with high b-gal activity were studied in terms of the capability of chondrogenic differentiation. Under the culture condition allowing the ATDC5 cells to differentiate into chondrocytes, two of the trapped clones exhibited the impaired (clone A) and accelerated (clone B) differentiation into chondrocytes by alcian blue and alizarin red staining. The expression of genes characteristic to chondrocytes was examined by RT-PCR every week in clones A and B and ATDC5 cells cultured in differentiation-promotive media. The expression of collagen type II, X, XI, aggrecan, PTH/PTHrP receptor and ALP genes started late and early in clones A and B, respectively, compared with ATDC5 cells. The trapped genes were identified by 5'RACE. In clone A, the trapping vector was inserted in the intron 1 of the p85alpha subunit gene of the phosphatidylinositol 3-kinase (PI3K). As a result, the decreased level of full-length p85alpha and the fused protein of the N-terminal portion of p85alpha with LacZ and neo products were confirmed by western blot. The phosphorylation of Akt protein, one of the target proteins of PI3K, was reduced in clone A. The function of the gene trapped in clone B has not been reported so far. Interestingly, the alpha1 chain of the collagen type IX was not expressed in clone B. In conclusion, we obtained two clonal cells with altered capacity of chondrocytic differentiation by a gene-trap. One trapped clone showed the delay of chondrocytic differetiation associated with the reduced activity of PI3K. The other clone showed the accerelated chondrocytic differentiation, and helps us to identify the novel gene involved in the process.

F029

Abnormalities in Development of the Growth Plates of Thanatophoric Dysplasia Type II (TD II) Fetuses Result from Enhanced Vascular Invasion and Osteoclastic Activity. N. Amizuka,[1] M. Chen,*[2] T. Sasaki,[1] Y. Asawa,*[1] H. Ozawa,[1] J. E. Henderson.[3] [1]Oral Anatomy, Niigata University, Niigata, Japan, [2]Pathology, McGill University, Montreal, Canada, [3]Medicine, McGill University, Montreal, Canada.

Thanatophoric Dysplasia (TD) is the most common form of lethal osteochondrodysplasia. The molecular basis of TD Type II is a point mutation, which results in a K650E substitution in the second tyrosine kinase domain of the fibroblast growth factor receptor type 3 (FGFR3). The K650E substitution results in constitutive activation of the receptor, which has been shown to mediate an inhibitory influence on chondrocyte proliferation and differentiation in vivo and in vitro. In the present study we examined the cellular and molecular abnormalities of the growth plates of tibiae harvested from medically aborted TD type II fetuses of 18-20 weeks gestation. Irregular and aggressive invasion of connective tissue in the tibial epiphysis was marked by an increase in CD31-positive blood vessels, a lack of columnar organization of immature cells and a decrease in the zone of hypertrophic cells, which was also of uneven thickness. Intramembranous bone extended into the outer aspects of the hypertrophic zone and few bony trabeculae were observed in the medial aspect, adjacent to the region undergoing endochondral ossification. Vascular endothelial growth factor (VEGF) immunostaining was apparent mainly in the hypertrophic region of the epiphyseal cartilage while its cognate receptor Flk-1/KDR was localized primarily in the invading blood vessels, suggesting that the principal VEGF target cell in the growth plate is the vascular endothelial cell. Furthermore, cathepsin K-immmunopositive osteoclasts were abundantly present in the metaphyseal region of the TD type II-tibiae. To further explore the relationship between FGFR3 signaling and VEGF expression, CHO cells were transfected with cDNA encoding either wild-type FGFR3 or FGFR3 carrying the K650E mutation. VEGF expression, as assessed by RT-PCR, was upregulated in CHO cells expressing the mutant receptor compared with those expressing wild type FGFR3. In summary, these studies demonstrate that constitutive activation of FGFR3 in chondrocytes 1) stimulates VEGF expression and enhances vascular invasion in the growth plates of TD Type II fetal bones; 2) augments osteoclast formation in the region of newly formed trabecular bone. The defects in bone development associated with TD type II can therefore be attributed to aggressive vascular invasion of the epiphyseal growth cartilage as well as to a decrease in the proliferation of chondrogenic cells.

F031

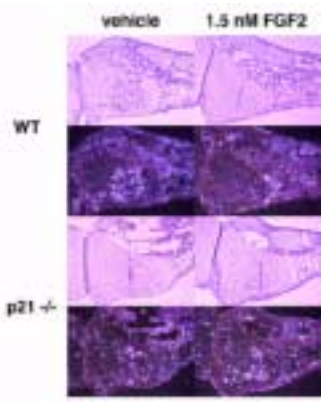
Targeted Overexpression of C-Type Natriuretic Peptide in the Growth Plate Rescued Dwarfism of the Transgenic Mice of Constitutive Active FGF Receptor 3. A. Yasoda,*[1] Y. Komatsu,[1] H. Chusho,*[1] T. Miyazawa,*[1] M. Miura,*[1] M. Suda,*[1] K. Tanaka,[1] Y. Ogawa,*[1] D. M. Ornitz,*[2] K. Nakao.*[1] [1]Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan, [2]Department of Molecular Biology and Pharmacology, Washington University School of Medicine, St. Louis, MO, USA.

The natriuretic peptide (NP) family consists of three ligands, atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP) and C-type natriuretic peptide (CNP). Although NPs were regarded as regulators of the body-fluid homeostasis, we have recently proposed that NPs, especially CNP is playing important roles in the regulation of the endochondral ossification. We have exhibited that CNP promotes the longitudinal growth of the growth plate cartilage in the organ culture experiments using fetal mouse tibiae. We have also reported the longitudinal overgrowth of the long bones and vertebrae observed in the transgenic mice that overexpress CNP specifically in the growth plate cartilage using the type II collagen promoter (CNP-Tg). In this study, we explore whether CNP acts on the skeletal defect and rescues the dwarfism observed in the transgenic mice of constitutive active FGF receptor 3 (FGFR3). FGFR3 has been identified as a critical regulator of the endochondral bone growth, as autosomal dominant mutations in FGFR3 cause the dwarfing chondrodysplasias in humans. A mouse model for human genetic disease, achondroplasia, has been generated by the targeted overexpression of the activated FGFR3 (containing the G380R mutation responsible for the human disease) in cartilage, using the type II collagen promoter (FGFR3-Tg). We mated FGFR3-Tg with CNP-Tg and analyzed the phenotypes of the F1 progeny. The naso-anal length of the resultant CNP-Tg/ FGFR3-Tg was 14% longer than FGFR3-Tg that were 19% shorter than their non-transgenic littermates. The soft X-ray analysis revealed that the growth retardation of the long bones and the vertebrae observed in FGFR3-Tg was partially recovered in CNP-Tg/ FGFR3-Tg. The shortening of the growth plate cartilage observed in the FGFR3-Tg by the histological analysis was also improved in the CNP-Tg/ FGFR3-Tg. These results suggest that CNP, at least one part, promotes the longitudinal growth of bones independently to the FGFR3 pathway of the regulation of the endochondral ossification, and that local application of CNP may be useful for the treatment of patients with achondroplasia.

F033

FGF Inhibits Chondrocytic Growth through Induction of p21 and Subsequent Inactivation of Cyclin E-Cdk2. T. Aikawa, G. V. Segre, K. Lee. Endocrine Unit, Massachusetts General Hospital/Harvard Medical School, Boston, MA, USA.

Fibroblast growth factor (FGF) and its receptor (FGFR) are thought to be negative regulators of chondrocytic growth, as exemplified by achondroplasia and related chondrodysplasias, which are caused by constitutively active mutations in FGFR3. To understand the growth-inhibitory mechanisms of FGF, we analyzed the effects of FGF2 on cell-cycle regulating molecules in chondrocytes. FGF2 dramatically inhibited proliferation of RCS (rat chondrosarcoma) cells, and arrested their cell cycle at the G1 phase. FGF2 increased p21 expression in RCS cells, which assembled with the cyclin E-cdk2 complexes, although the expression of neither cyclin E nor cdk2 increased. In addition, the kinase activity of immunoprecipitated cyclin E or cdk2, assessed with retinoblastoma protein (pRb) as substrate, was dramatically reduced by FGF-2. Moreover, FGF2 shifted pRb to its underphosphorylated, active form in RCS cells. FGF2 not only induced p21 protein expression in proliferating chondrocytes in mouse fetal limbs cultured in vitro, but also decreased their proliferation as assessed by the expression of histone H4 mRNA, a marker for cells in S phase (Fig.). Furthermore, inhibitory effects of FGF2 on chondrocytic proliferation were partially reduced in p21-null limbs, compared to those in WT limbs in vitro (Fig.). Taken together, FGF's growth inhibitory effects of chondrocytes appear to be mediated at least partially through p21-induction, and the subsequent inactivation of cyclin E-cdk2 and activation of pRb.



F035

FGF Signaling through FGFR1 or FGFR2 Is a Negative Regulator of Chondrocytic Growth in Fetal Growth Plate. T. Aikawa,[1] T. Koike,[1] G. V. Segre,[1] J. Colvin,*[2] D. Ornitz,*[2] K. Lee.[1] [1]Endocrine Unit, Massachusetts General Hospital/Harvard Medical School, Boston, MA, USA, [2]Department of Molecular Biology and Pharmacology, Washington University Medical School, St. Louis, MO, USA.

Fibroblast growth factor receptor 3 (FGFR3) has been thought to be a negative regulator of endochondral bone development. Mutations that render FGFR3 constitutively active cause achondroplasia and related dwarfisms in both humans and mice, and inactivation of FGFR3 results in skeletal overgrowth in mice. In contrast, constitutively active mutations in FGFR1 and FGFR2 are known to cause craniosynostosis syndromes in humans. However, although both FGFR1 and FGFR2 have been shown to be widely expressed in developing endochondral bones, their roles in regulating chondrocytic development are yet to be clarified. To test the hypothesis whether FGFR3 is the only FGFR that negatively regulates endochondral bone development, we first examined the expression of transcripts for FGFR1 and FGFR2, and then compared the effects of FGF2 on growth-plate chondrocytes in limbs isolated from FGFR3 (-/-) and Wild-type (WT) mouse fetuses. Transcripts for both FGFR1 and FGR2 were expressed in an indistinguishable manner in the growth plate of WT and FGFR3 (-/-) fetuses. When ED 16.5 fetal limbs isolated from WT mice were treated with 24 nM FGF2 for 2 days, both differentiation and proliferation of chondrocytes were completely suppressed, as evidenced by the disappearance of transcripts for Type X collagen and H4-histone, a marker for cells in S-phase, from the growth plate. In contrast, two-day FGF2 treatment only partially inhibited the expression of these two marker mRNAs in fetal limbs isolated from FGFR3 (-/-) mice; although, FGF2 completely suppressed their expression by 4 days (Fig.). These results demonstrate that not only FGFR3 but also FGFR1 and/or FGFR2 negatively regulates chondrocytic development in developing endochondral bones.

Tissue-specific Knockout of Smoothened Reveals a Critical Role for Hedgehog Signaling in Chondrocyte Proliferation. F. Long,* X. Zhang,* A. P. McMahon.* Harvard University, Cambridge, MA, USA.

Indian hedgehog (Ihh), one of the three mammalian Hedgehog proteins, plays an essential role in endochondral bone development by regulating chondrocyte proliferation, differentiation and osteoblast differentiation. Smoothened (Smo) is a transmembrane protein that transduces Hedgehog signals. In order to investigate further the regulatory functions of Indian Hedgehog (Ihh) during endochondral bone formation, we have used the CRE-LoxP approach to remove Smo activity in chondrocytes. These animals develop shorter long bone when compared to wild-type littermates. In contrast to Ihh-/- mice, chondrocyte differentiation appears to be relatively normal, and osteoblast differentiation does occur. However, like Ihh-/- mice, proliferation of chondrocytes is markedly reduced: Brdu analyses at E14.5 show that proliferation is about 50% of that of the wild type. This result suggests that Ihh directly regulates chondrocyte proliferation. By expressing either Ihh or a constitutively active Smo allele (Smo*) specifically in the cartilage using the bigenic UAS-Gal4 system, we demonstrate that proliferation of chondrocytes is significantly increased. Thus, activation of the Ihh signaling pathway is sufficient to promote chondrocyte proliferation. Taken together, the present study establishes Ihh as a key mitogen in the endochondral skeleton.

F038

POEM: A Novel Pre-osteoblastic Ligand Molecule for α8β1 Integrin. N. Morimura,*[1] Y. Tezuka,*[1] N. Watanabe,*[1] M. Yasuda,*[1] S. Miyatani,*[2] N. Hozumi,*[1] K. Tezuka.[1] [1]Research Institute for Biological Sciences, Science University of Tokyo, Noda, Japan, [2]The Institute of Physical and Chemical Research, Wako, Japan

We have cloned a novel adhesion molecule from the mouse osteoblastic MC3T3-E1 cell line, by RT-PCR using a set of degenerate primers carrying EGF-repeat consensus sequences. This gene encoded a putative protein with 5 EGF-like repeats, an RGD cell binding motif, and a MAM domain. We named this novel protein POEM (**p**re-**o**steoblast **E**GF-repeat protein with **M**AM domain). POEM mRNA was expressed preferably at the pre-osteoblastic stage of MC3T3-E1 cells. By *in situ* hybridization using E16.5 day mouse embryo, strong expression of POEM mRNA was observed in the renal tubules of developing kidney, parathyroid and thyroid glands, developing bone, tooth germ, and midbrain. When expressed in COS-7 cells, POEM accumulated in dot like structures over the plasma membrane. More interestingly, in MC3T3-E1 cells, POEM was accumulated in intercellular space, suggesting that this molecule plays a role in the cell-cell interaction. Recombinant MBP-POEMc protein (MBP fused with POEM's RGD motif and MAM domain) was shown to promote adhesion, spreading, and survival of MC3T3-E1 cells. By mutating the RGD sequence to RGE, the spreading and survival activities were significantly decreased. The tissue distribution and RGD-based cell adhesion activity of POEM led us to hypothesize that POEM may be a target for α8β1 integrin. Therefor, we conducted the cell-binding assay using KA8 cells, a K562 leukemia clone stably expressing α8 integrin (kindly provided by L. F. Reichardt, University of California, San Francisco). KA8 cells bound and spread on MBP-POEMc. On the other hand, parental K562 cells, which express only α5β1 integrin, bound to fibronectin but not to POEM. Thus, POEM is a novel and preferable ligand for α8β1 integrin and may be involved in morphogenesis of kidney, bone, endocrine organs, and nerve systems.

F040

A Novel Mechanism for the Regulation of Osteoblast Differentiation: Transcription of Periostin, a Member of the Fasciclin I Family, Is Regulated by the bHLH Transcription Factor, Twist . A. Oshima,*[1] C. A. Glackin,*[2] S. D. Flanagan,*[2] G. Lowe,*[2] A. Kudo.[1] [1]Tokyo Institute of Technology, Yokohama, Japan, [2]Beckman Research Institute of the City of Hope, Duarte, CA, USA.

Periostin is a secreted protein that is highly expressed early in osteoblastic cells. It has a similar structure to proteins of the fasciclin I family. It is known that periostin supports cell adhesion and spreading in vitro. It is preferentially expressed in periosteum and periodontal ligament. Twist, a basic helix loop helix (bHLH) transcription factor is important for cell type determination and differentiation and has been shown to play an important regulatory role in osteogenesis. In order to examine the target genes that are regulated by Twist during osteogenesis, microarray analysis was performed. Results from microarray and northern analyses reveal that overexpressing Twist up-regulates periostin. Although the mechanisms of periostin transcription are poorly understood, these findings suggest that periostin expression may be regulated by Twist. Here we investigated the 5' flanking region of the periostin gene and the effects of Twist on periostin transcription. To characterize the mechanisms regulating expression of the periostin transcript, primer extension was carried out to identify the transcription start site. DNA sequence analysis of 3kb of the mouse periostin 5' flanking region revealed the presence of two Twist box sequences at -443 to -458 and at -2655 to -2670 respectively. Gel shift and super-shift experiments were performed using oligos, spanning the two Twist box sequences and a Twist polyclonal antibody using MC3T3-E1 nuclear extracts. Results confirmed that both Twist box sites were detected by gel shift and supershifts on the periostin promoter using a Twist antibody. In vivo footprinting experiments were then performed on the mouse periostin promoter surrounding the two twist box sequences. Both undifferentiated and differentiated MC3T3-E1 cells were used to identify the two twist box sites and additional cis-acting binding elements. In vivo footprinting results indicate that the twist box sequences and several additional binding sites are differentially protected in undifferentiated versus differentiated MC3T3-E1 cells. These data suggest that Twist remains bound to the periostin 5' flanking region in undifferentiated osteoblasts, consistent with the up-regulation of periostin expression by Twist as observed in the microarray data. To determine whether Twist actually regulates periostin expression, deletion analyses of the periostin 5' flanking region and overexpression of Twist in MC3T3-E1 cells are now in progress.

F042

Transcriptional Profiling of the Early Phases of Bone Regeneration via cDNA Library Construction and Custom Microarrays. F. Lombardo,*[1] D. White,*[2] A. Dhundale,*[1] C. T. Rubin,*[1] M. Hadjiargyrou.[1] [1]Biomedical Engineering, SUNY, Stony Brook, NY, USA, [2]Millennium Pharmaceuticals, Cambridge, MA, USA.

Bone regeneration occurs as an elaborate series of events that requires temporal and spatial orchestration of numerous cell types and expression of hundreds to thousands of genes. The healing of a fractured bone is, in essence, a recapitulation of embryonic bone development that proceeds through similar processes such as chondrogenesis, ossification and remodeling. In order to be able to influence these biological events and thus the overall bone regeneration process, a more comprehensive molecular understanding is essential. In an effort to identify gene expression patterns that occur during bone regeneration, a cDNA library was constructed. This library consisted of transcriptionally induced genes (pooled from RNA isolated from post fracture (PF) 3, 5, 7 and 10 day callus) that were subtracted following hybridization with RNA derived from intact bone. Following amplification, subtractive hybridization and cloning, 4,183 cDNA clones were identified as up-regulated genes and further characterized. Of these, 3,799 (91%) were successfully sequenced. These genes included 301 (8%) and 60 (1.6%) that showed homology to mitochondrial and ribosomal genes, respectively. In addition, 2,002 (52.7%) had homology to other known genes and represented multiple functional gene families. Further, more than one third of these clones had no functional information in the literature or public databases. Of these, 1,317 (34.7%) showed homology to expressed sequenced tags (EST's) and 119 (3%) were completely novel. To obtain a more comprehensive understanding of temporal gene expression and significance of the genes in the healing process, custom microarrays were constructed that contained all 4,183 clones. PF day 3, 5, 7, 10, 14 and 21 callus RNA samples were used to probe these microarrays and confirm that greater than 80% of cDNAs are up-regulated greater than two fold, on at least one of the PF days, in comparison with intact bone. We are currently investigating the differential expression of these genes as a function of time (i.e. progression of the healing callus), and performing cluster analysis to potentially assign function to the thousands of EST's, novel sequences and known genes that have not as yet been described as involved in the bone regeneration process. Taken together, these data provide a "window" into the molecular events responsible for the early phases of bone regeneration and suggest that many of the genes involved remain uncharacterized. Further experiments utilizing these custom cDNA microarrays should shed more light on the molecular complexity of wound repair.

F046

Development of a Connexin43 (Cx43) Conditional Gene Deletion in Mice. C. H. M. Castro,[1] S. S. Sheikh,*[1] F. Lecanda,[2] R. Civitelli.[1] [1]Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA, [2]School of Medicine, University of Navarra, Navarra, Spain

Osteoblasts are highly coupled by gap junctions formed primarily by Cx43. We have shown that either dominant-negative (Cx45 overexpression) or recessive (Cx43 ablation)

inhibition of Cx43 expression or function significantly alters the development of an osteoblast phenotype. Targeted null mutation of Cx43 in mice leads to developmental defects of the skeleton and cardiovascular malformations incompatible with adult life. To overcome the perinatal lethality of the Cx43 null mutation, and determine its physiologic role for bone mass achievement and maintenance in adult animals, we developed an in vivo model of conditional Cx43 deletion in osteoblasts, using the Cre/loxP method. A mutated Cx43 allele (Cx43 flox) was generated, in which the coding region was flanked by two loxP sites and a reporter Lac-Z cassette inserted between the 3' loxP site and the 3'UTR. These mice were mated with mice expressing bone specific Cre recombinase driven by the OG2 osteocalcin promoter to generate OG2-Cre;Cx 43 flox/ + and OG2-Cre;Cx 43 flox/ flox mice. Cre-mediated recombination removes Cx43 coding region, leaving Lac-Z under the control of the native Cx43 promoter ("knock-in"). These mice were then interbred with Cx43 null heterozygous mice (Cx 43 +/-) to generate a strain in which one Cx 43 allele is null in all cells and the other deleted only in osteoblasts (OG2-Cre;Cx 43 flox/ -). Genotyping was performed by PCR and deletion of the Cx43 flox allele confirmed by X-Gal staining of tail bone sections 8-10 days after birth. Whole body bone mineral density (BMD) was measured by DEXA (precision error= 1.34% CV). All genotype groups were obtained with the expected Mendelian frequency and were viable. At one month of age, BMD was lower in the OG2-Cre;Cx 43 flox/ - (46.8±3.4mg/cm2) than in most other groups (49.1±4.1mg/cm2 for Cx 43 flox/ flox, 48.9±3.4mg/cm2 for OG2-Cre;Cx 43 flox/ flox , 49.2±0.6mg/cm2 for OG2-Cre;Cx 43 flox/ + and 47±3.5mg/cm2 for OG2-Cre;Cx 43 +/+), but the difference was not statistically significant. Cx 43 flox/flox mice appeared to be smaller with a higher percentage of body fat compared to the other groups, probably reflecting a strain background effect. Since the OG2 gene promoter is expressed only at around birth, these results reflect only one month of Cx43 deficiency in differentiated osteoblasts. This Cx43 conditional deletion model will be useful to study the consequences of Cx43 deficiency in skeletal maturation and response to anabolic agents.

F049

Osteoblasts Define the Maintenance of Hematopoiesis and Progenitor Lineage Commitment in the Bone Marrow. D. Visnjic,*[1] Z. Kalajzic,*[2] V. Katavic,*[3] J. Lorenzo,[3] D. W. Rowe,[2] L. H. Aguila.*[4] [1]Department of Physiology, Zagreb University School of Medicine, Zagreb, Croatia, [2]Department of Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, [3]Department of Medicine, University of Connecticut Health Center, Farmington, CT, USA, [4]Department of Immunology, University of Connecticut Health Center, Farmington, CT, USA.

We have generated a transgenic mouse model expressing a modified herpes virus thymidine kinase (TK) gene under the control of collagen 2.3 promoter. This construct, Col2.3DTK, permits the expression of TK almost exclusively during early osteoblast lineage development. Upon treatment with Gancyclovir (Gcv), these animals are depleted of osteoblasts and present a drastic bone loss. This phenomenon is concurrent with a loss in bone marrow cellularity. Analysis of hematopoietic components during the early phase of treatment evidenced a loss of B cell, erythroid and osteoclast progenitors. However, cells expressing very early hematopoietic markers, similar to hematopoietic stem cells (HSCs), are still present. Interestingly, these bone marrow progenitors can progress normally towards differentiation in vitro.Active extramedular hematopoiesis is also observed, with a dramatic increase in cells with HSC phenotype in liver and spleen. The kinetics of osteoblast disappearance, loss of medullar hematopoiesis and appearance of progenitors and active hematopoiesis in periphery is concerted. Extramedular hematopoiesis seems to be sufficient to maintain the homeostatic hematological values in periphery. When the Gcv treatment was stopped, the osteoblast lineage is recovered and an exacerbated generation of bone and areas of active hematopoiesis are observed in the bone marrow. Gradually the extramedular hematopoiesis decrease to normal levels. This model provides, the first direct indication on the role of osteoblasts during the hematopoietic process, providing an exceptional tool to study interactions between bone remodeling mechanisms and hematopoiesis.

F051

The Osteonectin-null Mutation Compromises Osteoblast Formation and Maturation. A. M. Delany, E. Canalis. Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

Osteonectin or SPARC plays a critical role in the maintenance of skeletal integrity. It is necessary for normal bone remodeling and maintenance of bone mass, as osteonectin-null mice develop a low turnover osteopenia that becomes more severe as the animals age. The osteopenia is correlated with a progressive decrease in osteoblast surface and bone formation rate, however the molecular mechanisms involved are not known. To understand how osteonectin supports the osteoblast life-style, we studied primary cultures of osteoblasts and bone marrow stromal cells from control and osteonectin-null mice. In addition, we analyzed immortalized cell lines created by transduction of control and osteonectin-null osteoblasts and bone marrow stromal cells with retrovirus expressing the human papilloma virus E6 and E7 genes. We found that bone marrow stromal cells from osteonectin-null mice contained 15 to 20% fewer fibroblast-colony forming units than those from control mice, although differences in cell proliferation were minimal. DNA laddering assays in primary stromal cell cultures suggest that cells from osteonectin-null mice had increased apoptosis compared to cells from control mice. Osteonectin-null cultures contained fewer mineralized nodules, and PTH stimulation of these stromal cells resulted in decreased accumulation of cAMP compared with controls. Analysis of the stromal cell lines from control and osteonectin-null mice confirmed that mineralized nodule formation was decreased in the absence of osteonectin. Decreased mineralized nodule formation was also observed in cultures of primary osteoblasts from osteonectin-null mice. Compared to controls, these cultures had decreased levels of osteocalcin and alkaline phosphatase transcripts, but type I collagen mRNA was unchanged. Analysis of the osteoblast cell lines confirmed these findings. The ability of the cell lines to differentiate and form mineralized nodules, and the profile of osteocalcin, alkaline phosphatase and collagen mRNAs mimicked that of the primary cultures. In addition, the osteonectin-null osteoblast cell line had decreased accumulation of cAMP in response to PTH stimulation. Osteonectin is thought to modulate the response of cells to certain growth factors and cytokines. However, preliminary data suggest that the osteonectin-null osteoblast cell line is not differentially sensitive to the skeletal cytokines PDGF BB, TGF ß or IGF I. In conclusion, our data indicate that the absence of osteonectin causes multiple defects in osteoblast and stromal cell behavior, resulting in decreased formation of fully functional osteoblasts.

F053

Deletion of the Fibronectin Gene Causes a Dramatic Delay in Incorporation of LTBP1 into the Extracellular Matrix: Rescue With Exogenous Fibronectin. S. L. Dallas,[1] L. F. Bonewald,[2] D. Pesciotta Peters,*[3] C. Barley,*[1] J. L. Rosser,*[2] D. F. Mosher,*[3] C. M. Kielty.*[1] [1]Biochemistry, University of Manchester, Manchester, United Kingdom, [2]Medicine, University of Texas Health Science Center, San Antonio, TX, USA, [3]Medicine, University of Wisconsin, Madison, WI, USA.

Latent transforming growth factor beta binding proteins (LTBPs) are members of the fibrillin superfamily of extracellular matrix (ECM) proteins that bind transforming growth factor betas (TGFβs) and influence their availability. Mutations and deletions in members of this superfamily are associated with Marfan syndrome and related disorders, which often show skeletal abnormalities. LTBP1 regulates TGFβ activity in bone at multiple levels, including its secretion, extracellular matrix storage and its release during osteoclastic resorption. Given these critical functions, an understanding of the structural arrangement of LTBPs in bone ECM and the molecular mechanisms by which they regulate TGFβ availability is of major importance. The goal of these studies was to examine the molecular mechanisms for LTBP1 assembly into bone ECM, identify interacting proteins and determine the domains responsible for these interactions. Double-labeled immunofluorescence studies using primary cultures of fetal rat calvarial cells (FRC) and MG63 osteosarcoma cells showed that LTBP1 was initially deposited into the ECM in association with fibronectin but that by two weeks of culture, a large proportion of the LTBP1 was localized in fibrillin-1-positive microfibrils that lacked fibronectin. Fibrillin-1 was not required for the association of LTBP1 with fibronectin, since overexpression of LTBP1 in UMR-106 osteosarcoma cells, which lack endogenous fibrillin-1, still resulted in the association of LTBP1 with fibronectin. Disruption of fibronectin assembly using either a 70KDa N-terminal fibronectin peptide, or by using cells from fibronectin null mouse embryos, resulted in a dramatic delay in LTBP1 incorporation into the ECM, which was partially recovered with extended culture times (10-14 days). The delay in LTBP1 incorporation in fibronectin-null cells could be rescued by addition of exogenous fibronectin. Transient transfection experiments in 2T3 osteoblast-like cells using LTBP1 deletion constructs indicated that the 60KDa amino-terminus of LTBP1 was sufficient for incorporation into the ECM in association with fibronectin. These studies suggest that fibronectin is important in the initial assembly of LTBP1 into bone ECM. Therefore, in addition to its roles as an ECM protein and in regulation of cell differentiation and apoptosis, fibronectin may regulate TGFβ bioavailability via its interaction with LTBPs.

Acetylcholinesterase: A Secreted Bone Matrix Protein Regulated by Osteogenic Stimuli and Mechanical Loading. C. A. Inkson, T. S. Grewal,* A. C. Brabbs,* T. M. Skerry, P. G. Genever. Biology, University of York, York, United Kingdom.

Acetylcholinesterase (AChE) is best known for its role in cholinergic signaling, however a growing body of evidence indicates that AChE has multiple biological functions with roles in cell adhesion and stress response. Previously we have shown that osteoblasts express and secrete AChE and that AChE is present in osteoid seams and cement lines, implicating AChE in cell-matrix interactions in bone. We therefore investigated the regulatory pathways that control AChE expression during osteogenesis in vitro and in vivo, and its functional role in bone. Using a specific colorimetric assay, we demonstrated that AChE secretion increased significantly during differentiation of primary rat osteoblasts in vitro. Monensin and brefeldin A, blockers of golgi-ER export, inhibited AChE secretion and intracellular AChE co-localised with golgi-specific ceramide dyes, supporting a golgi-ER mediated secretion pathway for AChE in osteoblasts. Western blot analysis of whole cell lysates from primary rat osteoblasts and MG63 cells revealed that TGF-β1 (0.5-2ng/ml) and bFGF (0.5-5ng/ml) markedly increased AChE expression. Furthermore, TGF-β1 induced expression of an additional 55kDa AChE isoform, which was absent in untreated controls. In adhesion assays we demonstrated that specific AChE inhibitors, diisopropyl fluorophosphate and BW284C51 (10^{-7}M–10^{-4}M) and antisense oligonucleotides targeted to AChE, significantly and dose-dependently inhibited attachment of osteoblastic cells ($P<0.001$), compared to appropriate controls. Antisense inhibition of osteoblast adhesion was rescued by plating the cells on exogenous AChE substrates, but not by the addition of soluble AChE to the culture medium. To determine the effects of mechanical loading on AChE expression, TE85 osteoblast-like cells were grown on type I collagen-coated plates and subjected to cyclical strains of 4500με using a FX-3000 Flexercell device (10 min, 1Hz) and cell lysates collected at different time points up to 48h after loading. Using western blot analysis, we demonstrated that AChE expression increased markedly 4 hours after loading which was maintained for 48 hours compared to non-loaded controls. Following in vivo loading, immunolocalisation of AChE on sections of ulnae subjected to mechanical strain of ~4000με (3.3 min, 2Hz) on 5 consecutive days revealed a clear increase in expression of AChE on bone forming surfaces in regions of alkaline phosphatase positivity, which were absent in contralateral control ulnae. These findings indicate that AChE acts as a secreted bone matrix protein and may be instrumental in guiding remodeling events by regulating osteoblast adhesive interactions.

Increased Osteoblastogenesis in Thrombospondin-2-null Mice Protects Against Ovariectomy-induced Bone Loss. K. D. Hankenson,[1] P. Bornstein,*[1] S. Apone,[2] G. B. Stroup,[3] I. E. James,[3] S. M. Blake,[3] X. Liang,[3] M. W. Lark.[3] [1]University of Washington, Seattle, WA, USA, [2]Ostex Intl., Seattle, WA, USA, [3]GlaxoSmithKline Inc., King of Prussia, PA, USA.

Thrombospondin-2 (TSP2) is a 450 kDa ECM protein produced by osteoblast-lineage cells. Mice deficient in TSP2 (TSP2-null) form excess endosteal bone and have an increase in marrow stromal cell (MSC) number. In culture, TSP2-null MSC show an increased proliferation rate, but a delay in osteogenesis. Since cells of the osteoblast lineage, including MSC, are responsible for regulating osteoclasts and TSP2-null MSC are functionally different than WT, we postulated that TSP2-null mice could have an alteration in osteoclast development or function. Geometry of mid-diaphyseal femurs, harvested 5 weeks post-ovariectomy (OVX), was analyzed by pQCT. As previously reported, TSP2-null sham mice had a significantly greater cortical area (10%) relative to WT sham. When ovariectomized, WT mice showed a significant loss of bone relative to sham (14% increase in marrow area), but surprisingly, OVX did not alter TSP2-null bone geometry. To examine whether a decrease in osteoclastic activity was responsible for this observation, a bone-specific, cross-linked NH_2-telopeptide of type I collagen (NTx) that is released during bone resorption was evaluated by ELISA in serum collected 5 weeks post-OVX. Sham-operated WT and TSP2-null mice had equivalent levels of NTx, verifying that the TRAP+ multinucleated cells (MNCs) observed in TSP2-null bone were functional. With OVX there was an increase in both TSP2-null and WT NTx; however, TSP2-null mice had 50% less NTx released into serum than WT mice. This indicates that either there is a reduction in OCL function in TSP2-null mice or that OCL numbers are decreased relative to WT. The number of OCL in OVX mice is currently being determined by histomorphometry; however, we have found that an equal number of OCL develop in culture from TSP2-null and WT marrow-derived mononuclear cells. Although these results provide a partial explanation for the maintenance of bone geometry observed in TSP2-null OVX mice, enhanced endosteal bone formation may also compensate for the resorption that does occur. Evidence for an increase in bone formation in TSP2-null OVX mice is provided by a 3-fold increase in TSP2-null MSC number relative to MSC in WT OVX mice. Numerous studies have shown that the number of MSC is positively correlated with endosteal bone formation. Bone formation is also being evaluated by histomorphometry in sham and OVX samples. In summary, although sham-operated TSP2-null mice have fully functional OCL in vivo, we find that the osteoclastic response to OVX is decreased in TSP2-null mice relative to WT. This effect could be due to an increase in a soluble mediator, such as osteoprotegerin, which is produced by the increased number of MSC, which are also observed. To our knowledge, this is the first study to suggest that an overabundance of osteoblast progenitors is associated with decreased osteoclast formation and/or function.

F059

Matrix Protein Regulation of Collagenase-3 and Osteocalcin Gene Expression in Differentiating Osteoblastic Cells. R. C. D'Alonzo,*[1] N. C. Partridge,[1] A. Kowalski,*[2] D. T. Denhardt.[2] [1]Department of Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA, [2]Department of Cell Biology and Neuroscience, Rutgers University, Piscataway, NJ, USA.

Previously, we demonstrated that expression of collagenase-3 in primary rat osteoblasts is limited to post-proliferative stages of cell differentiation and reaches maximum levels during the mineralization stage. Here we show that clonal osteoblastic MC3T3-E1 cells follow a similar pattern and produce detectable levels of collagenase-3 mRNA one week after reaching confluence and dramatically increase mRNA after two weeks. This increase in collagenase-3 expression is dependent upon the presence of ascorbic acid and is inhibited in the presence of the collagen synthesis inhibitor, 3,4 dehydroproline (DHP). Transient transfection studies using the 148 base pairs upstream of the collagenase-3 promoter show that collagenase-3 promoter activity also increases during differentiation and requires the presence of ascorbic acid. Additionally, this stimulation is reduced by mutation of either the activator protein-1 binding site (*AP-1*) or the runt domain binding site (*RD*). The presence of DHP or the absence of ascorbic acid in the media of differentiating MC3T3-E1 cells also inhibits the expression of osteocalcin, as has been shown in other studies. Additionally, in the absence of β-glycerophosphate supplementation, osteocalcin expression increases, osteopontin expression decreases, and collagenase-3 expression is relatively unchanged. This led us to suspect that osteopontin may negatively regulate osteocalcin expression. In the presence of an RGD mimetic compound, which blocks the binding of the αv integrin subunit to osteopontin and other substrates, osteocalcin mRNA expression increases dose dependently. No significant change in collagenase-3 expression was noted. Based on these results, we conclude that collagenase-3 expression, like osteocalcin expression, increases during MC3T3-E1 cell differentiation and requires collagen synthesis. Further, both the *AP-1* and *RD* sites are required for full activation of the collagenase-3 promoter during cell differentiation. Finally, we observed that an increase in osteocalcin, but not collagenase-3, expression is correlated with a reduction of osteopontin expression and with the blockage of an osteopontin binding integrin. This finding suggests that osteopontin acts as a brake on osteocalcin expression during osteoblastic cell differentiation.

Human Myeloma Cells Upregulate RANKL and Downregulate OPG in Bone Environment: Evidence of OPG/RANKL Imbalance in Multiple Myeloma Patients. N. Giuliani,[1] R. Bataille,*[2] C. Mancini,*[3] M. Lazzaretti,*[3] S. Barille.*[2] [1]Chair of Haematology, Department of Internal Medicine, University, Parma, Italy, [2]INSERM U463, Nantes, France, [3]Pathology, University, Parma, Italy.

Multiple myeloma (MM) is a plasma cells malignancy characterized by the high capacity to induce bone destruction. The tight relationship between myeloma cells and bone environment is critical in the pathogenesis of bone lesions, even if the biological mechanisms are poorly understood. In murine system it was recently hypothesized a possible involvement of OPG and its ligand RANKL in MM-induced osteolysis. The aims of our study were to investigate whether human myeloma cells could directly produced RANKL or affect the physiological OPG/RANKL balance in the bone environment and to characterize this system in MM patients. First, we found that neither human myeloma cells lines (XG-6, XG-1, MDN, U266, RPMI, OPM-2, LP-1, and JJN-3), nor fresh myeloma cells isolated from 26 patients with MM did directly express RANKL and rarely produce a low amount of OPG. In a coculture system we demonstrated that XG-6 and XG-1 upregulate RANKL and downregulate OPG production in primary human bone marrow pre-osteoblast or stromal cells (BMSC) at both mRNA and protein levels. This effect was dependent on the cell-to-cell contact and partially blunted by anti VLA-4 mAb. On the contrary, an anti TNF mAb, or IL-1 mAb or IL-6 mAb have no effect. Human CD 34+ derived osteoclastogenesis was stimulated by XG-6 only in the presence of BMSC and reduced by rhOPG. With a semiquantitative RT-PCR, we have also observed that BMSC isolated by MM patients overexpressed RANKL mRNA in comparison to normal subjects. In addition, using an immunohistochemical staining, performed on bone marrow tissue sections, we confirmed that RANKL is not expressed by myeloma cells being detectable on stromal cells and that OPG is detected on osteoblastic and osteoclastic cells but not on plasmacells. A reduction of OPG expression in trabecular osteoblasts with an increase of RANKL positive stromal cells was observed in MM patients with bone lesions in comparison to patients without osteolysis or to control subjects. (OPG+ cell% ± SE: 3.2±0.7 vs. 6,5±1.6 and 6.7±1.2 respectively, $p < 0.05$; RANKL+/mm2 ± SE: 2.1 ± 0.03 vs. 0.91±0.08 and 0.93±0.18 respectively, $p<0.05$). In line with these observations, OPG serum levels were reduced in MM patients compare to normal subjects (mean±SD: 26.6±4.8 vs. 18.5±6.0 ng/ml;$p=0.009$). Our results clearly indicate that human myeloma cells donot produced RANKL but are able to induce an imbalance in OPG/RANKL ratio in the bone environment in favour to RANKL supporting the hypothesis that this system could be involved in the pathogenesis of MM-induced bone disease.

The Bisphosphonate Zoledronic Acid Inhibits Metastases to Bone and Liver with Suppression of Osteopontin Production in Mouse Mammary Tumor. H. Nobuyuki, T. Hiraga, P. J. Williams,* M. Niewolna,* N. Shimizu, G. R. Mundy, T. Yoneda. Div Endocrinol, Univ TX Hlth Sci Ctr, San Antonio, TX, USA.

Bisphosphonates (BPs) are effective therapeutic agents for bone metastases. Accumulating evidence indicates that BPs inhibit bone metastases through inhibition of osteoclastic bone resorption. On the other hand, recent in vitro studies have shown that BPs reduce cell-to-matrix attachment, inhibit growth and increase apoptosis in a variety of tumor cells. Moreover, the BP clodronate has been shown to suppress visceral metastases and prolong survival in breast cancer patients. These results suggest that BPs have direct actions on tumor behavior. Here, we examined the effects of the BP zoledronic acid (ZOL) on the behavior of breast cancer using the 4T1 mouse mammary tumor cells that spread to bone, lung, liver following orthotopic inoculation in the mammary fat pad in female Balb/c mice. These cells were stably transfected with firefly luciferase for quantitative measurement of tumor burden. Administration of ZOL (0.5 or 5ug/mouse, iv, once every 4 days) was started 7 days after 4T1 cell inoculation when tumor formation became visible and continued until mice were sacrificed at day 28. Radiologic and histomorphometric examination revealed that ZOL reduced metastatic tumor burden in bone with impaired osteoclastic bone resorption in a dose-dependent manner. Surprisingly, metastatic tumor burden in liver as determined by luciferase activity was also significantly decreased in ZOL-treated mice. Lung metastases were also marginally reduced. Since osteopontin (OPN) has been implicated in breast cancer metastasis and our study showed 4T1 cells produced large amounts of OPN, we hypothesized that ZOL suppressed metastases through affecting OPN production. In support of this notion, we found that ZOL inhibited OPN production by western analysis and transcription of the OPN gene using a luciferase reporter construct. Of note, ZOL inhibited the anchorage-independent growth of 4T1 cells in colony formation assay in soft agar. Collectively, these results suggest OPN contributes to 4T1 cell growth. Consistent with this notion, a neutralizing monoclonal antibody to OPN also inhibited the anchorage-independent growth of 4T1 cells and tumor formation in the orthotopic site. In conclusion, these results suggest that ZOL inhibits the growth of 4T1 breast cancer through inhibition of OPN production, thereby suppressing its metastases and that ZOL has direct anti-proliferation effects on 4T1 breast cancer cells. Our results also suggest that OPN is an autocrine growth-stimulating factor and may be a molecular target of ZOL actions in some breast tumors.

Myeloma Bone Disease and Tumor Burden Reversed by Neutralizing Antibodies to Macrophage Inflammatory Protein (MIP)-1α/CCL3 In Vivo. B. O. Oyajobi, P. J. Williams,* B. Story,* G. R. Mundy. Medicine/Endocrinology, UTHSCSA, San Antonio, TX, USA.

Multiple myeloma (MM) is commonly associated with severe bone destruction due to increased osteoclast (OC) activity induced by as yet unidentified factor(s) secreted by the tumor cells. MM cells produce MIP-1α, a CC chemokine whose levels are reportedly elevated in marrow plasma of MM patients compared with other lymphoid malignancies and normal controls. We recently showed that MIP-1α increases OC formation and bone resorption in vivo when expressed adjacent to bone surfaces, consistent with the notion that it plays an important role in the pathogenesis of osteolysis in MM. We therefore hypothesized that neutralizing MIP-1α bioactivity in vivo should limit development and/or progression of osteolytic lesions in a model of human MM. To test this, we used the murine myeloma (5TGM1) cell line which secretes MIP-1α constitutively. Following intravenous injection into syngeneic C57BL/KaLwRij or *bg-nu-xid* mice, 5TGM1 cells home to the bone marrow and spleen and expansion within these sites results in radiographically-detectable osteolytic lesions, greatly elevated titers of the monoclonal IgG2bκ (a marker of tumor load) in serum and splenomegaly. Here, we report that systemic administration of an antibody to MIP-1α was efficacious in ameliorating disease progression in this model.

Mice inoculated with 5TGM1 cells were randomized into groups and treated with a monoclonal rat anti-mouse MIP-1α antibody (R & D Systems) or an isotype rat monoclonal IgG2a (100µg i.p. twice weekly for 4 weeks). A third tumor-bearing group received PBS using the same dosing schedule. Treatment with anti-MIP-1α antibody resulted in a significant reduction in serum IgG2bκ titer in 7 out of 10 tumor-bearing mice (5.45 ± 1.56 mg/ml), below the median for the isotype IgG- and PBS-treated controls pooled (9.26 mg/ml; n=9). Serum paraprotein levels also directly correlated with splenic wet weights (r= 0.83). The mean surface areas of the lytic lesions visible on radiographs, assessed by blinded image analysis, were significantly reduced in mice that received the anti-MIP-1α antibody compared to control IgG- and PBS-treated mice (0.019 vs 0.031 mm^2). Histomorphometric analyses of bones revealed that blockade of MIP-1α function resulted not only in a diminution in tumor volume, but also a reduction in the number and intensity of staining of $TRAP^+$ OC. Together, these data strongly implicate MIP-1α in the pathogenesis of MM-induced bone destruction and possibly myeloma itself. Furthermore, our results suggest that small molecule antagonists of MIP-1α receptors (CCR-1 & CCR-5), which are now available, hold promise as beneficial adjuncts to current standard therapeutic approaches in MM.

F066

Effects of Tumor Secretion of Recombinant Osteoprotegerin (Opg) on Osteolytic Metastases. T. Oba, X. Sun, B. Grubbs,* Y. Cui,* R. Kakonen,* T. A. Guise, J. M. Chirgwin. Medicine, U TX Hlth Sci Ctr, San Antonio, TX, USA.

Osteoprotegerin inhibits bone resorption by binding to and neutralizing RANK ligand, the central physiological stimulator of osteoclast formation and activity. However, it can also protect tumor cells from apoptosis. Thus, the actions of Opg on osteolytic bone metastases may not be beneficial. We expressed osteoprotegerin in the MDA-MB-231 human breast cancer line, which causes osteolytic metastases, and the cells were tested in an animal model.Mouse Opg coding sequence was cloned, from RNA isolated from the ST2 cell line stimulated with 5ng/ml TGFbeta1, by RT-PCR into the expression vector pcDNA3neo. Conditioned medium from transfected cells inhibited osteoclast-like multinucleated cell formation in bone marrow cultures, confirming that the cDNA encoded functional Opg. Mouse Opg-Fc fusion protein and a polyclonal antibody against Opg were used to establish an ELISA for mouse Opg. Clones of MDA-MB-231 cells were selected for resistance to G418 and tested for continuing expression of Opg protein for at least 30 days in the absence of antibiotic selection. Three stable clones were chosen for testing in vivo. These produced 24, 60, and 150ng Opg/ml/105 cells/48hr. An empty vector clone (EV) produced no detectable Opg. All cell lines had the same growth rates. They were inoculated into female nude mice (10/group) via the left cardiac ventricle. Progress of osteolytic metastases was followed by x-ray. At 3 weeks the number of osteolytic lesions was less [number=4.2±1.3 vs. 12.0±2.2] in the three Opg-secreting groups pooled compared to control cells [$p<0.01$]. Area per lesion was not significantly different. Animals were sacrificed when paraplegic or cachectic. Tumor cells in bone continued to express Opg by immunohistochemistry. The two groups of animals with tumors producing moderate amounts of Opg showed delayed time to sacrifice, compared to the EV control [$p<0.05$]. However, the high Opg clone conferred no survival advantage. Tumor cells from this clone showed a 5-fold decrease in number of apoptotic nuclei in bone, relative to the other 3 groups [$p<0.001$ vs. EV].The results suggest that modestly increasing the local concentration of wild-type Opg can slow the progression of osteolytic lesions and provide a survival advantage in an animal model of bone metastasis. However, high concentrations of Opg may increase tumor growth by blocking apoptosis. Thus, reagents designed specifically to inhibit RANK ligand but not to affect apoptosis may be more effective against osteolytic metastases than osteoprotegerin.

F068

Synergistic Suppression of Metastatic Phenotype in Vitro and Metastasis in Vivo by a Bisphosphonate Plus a Farnesyl Transferase Inhibitor. V. Andela,*[1] E. Schwarz,*[2] R. O'Keefe,*[2] J. Rosenblatt,*[2] E. Puzas,[2] R. Rosier.[2] [1]Orthopaedics Research, Univ. of Rochester, Rochester, NY, USA, [2]University of Rochester, Rochester, NY, USA.

Bisphosphonates used in the management of metastatic bone disease have direct anti-tumor properties in addition to preventing osteoclast assisted bone metastasis. Aminobisphosphonates inhibit the mevalonate synthesis pathway, thus the generation of isoprenoid groups, that are enzymatically transferred (by farnesyl or geranyl geranyl transferases) unto such proteins as those of the Ras superfamily, (Ras, Rho, and Rac). Because isoprenoid generation and transfer represent two distinct targets, this study tested the hypothesis that synergistic inhibition of prenylation would result from combining an aminobiphosphonate and a farnesyl transferase inhibitor. Given the extensive implication of Ras proteins in malignancy, and the critical role of Rac and Rho in cytoskeletal architecture and function, it was hypothesized that this regimen would effectively inhibit tumor invasion and metastasis. Methods: Using a murine lung alveolar carcinoma cell line (Line 1), we characterized the sensitivity of the cells to 48 hr exposures of Alendronate and/or an FTI (R115777) in culture. Invasion assays and fluorescent imaging were used to analyze the cellular effects of these agents on basement membrane invasion and cytoskeletal architecture. In addition, Ras, Rho and Rac subcellular compartmentalization, downstream signaling events and MMP 9 secretion were analyzed. Finally the effects of the drug regimen was assessed in vivo using a murine pulmonary metastasis model.Results: Alendronate and FTI both had minimal inhibitory effects on tumor cell invasion, but the combination was synergistic. Western blot analysis of subcellular fractions showed decreased membrane association of Ras and increased membrane association of Rac and Rho, as well as suppression of downstream signaling events (phosphorylation of Erk1 Erk2, and p38). Fluorescent imaging showed a disruption of lamellopodia and membrane ruffles, and demonstrated an organellar distribution of Rho and Rac. As would be expected of the cytoskeletal compromise, MMP 9 secretion and activity was decreased. In vivo, Alendronate minimally suppressed metastasis, while FTI significantly inhibited metastasis and the combination was additive.Conclusion: Aminobisphosphonates and FTIs synergistically inhibit the prenylation and function of proteins involved in tumor cell invasiveness and metastasis thus FTIs could potentiate the antitumor activity of aminobiphosphonates, notably in soft tissue where aminobiphosphonates do not achieve high concentrations.

F070

Examination of Effects of Zoledronic Acid on Prostate Cancer. E. Corey, J. E. Quinn,* L. G. Brown,* M. P. M. Roudier, C. Higano,* R. L. Vessella.* Urology, University of Washington, Seattle, WA, USA.

Zoledronic acid is a third-generation bisphosphonate, which is a very potent inhibitor of bone lysis. Interest has recently arisen in potential direct anti-tumor effects of this compound, and in whether its use would be of benefit to prostate cancer (CaP) patients with bone metastasis. We have recently shown that zoledronic acid affects proliferation and apoptosis of prostate cancer cells, but only at concentrations higher than the peak plasma levels that can be achieved in patients. Here we report observations of the effects of zoledronic acid used in combination with Taxol on tumor cell proliferation and invasiveness *in vitro*. A combination of 10 mM zoledronic acid and 10 nM Taxol was more effective in decreasing proliferation of CaP cells than either of these compounds alone. Moreover, concentrations of zoledronic acid (0.1 µM and 1 µM) that did not affect CaP cell proliferation had significant effects on invasiveness. We also examined the effects of zoledronic acid on prostate cancer cells in subcutaneous (SC) tumors, as well as in an "osseous CaP" model. We detected no significant decrease in volume of subcutaneous PC-3, LNCaP, and LuCaP 23.1 tumors treated with zoledronic acid (5 µg per injection twice a week). The absence of observable effects on SC tumors may well be due to poor bioavailability of zoledronic acid, in part because the compound rapidly accumulates in bone. In contrast to the results with SC tumors, when we used an osseous CaP model consisting of direct injection of CaP cells into tibiae to evaluate the effects of zoledronic acid on CaP bone metastasis, we detected significant differences in bone density in zoledronic acid-treated animals bearing PC-3 tumors in tibiae. Bone histomorphometric analysis confirmed the differences in bone area between untreated and treated animals. LuCaP 23.1 in the osseous CaP model exhibited significant decreases in serum levels of PSA in animals injected with zoledronic acid either simultaneously with tumor cells or after the bone tumors were established (PSA of 5-10 ng/mL). Bone histomorphometric analysis is underway. In conclusion, we have shown that zoledronic acid has significant anti-tumor effects on CaP cells *in vitro* and *in vivo*.

F072

PTHrP Expression Promotes Prostate Cancer Metastases In Vivo. D. W. Burton,[1] P. Jiang,[2] M. Xu,[2] C. M. Lu,*[1] R. M. Hoffman,[2] L. J. Deftos.[1] [1]UC San Diego and Veterans Affairs Medical Center, San Diego, CA, USA, [2]Anticancer, Inc., San Diego, CA, USA.

Parathyroid hormone-related protein (PTHrP) is commonly expressed in prostate cancer. As in other cancers, this oncoprotein has been demonstrated to regulate the growth of prostate cancer cells in vitro. In order to study the effect of PTHrP on tumor pathogenesis, growth, and progression in vivo, we developed a mouse orthotopic prostate cancer model. We initially studied the DU 145 cell line, which was derived from a human prostate carcinoma brain metastasis. This line has a low constitutive PTHrP expression and does not grow well in mouse tumor models. We studied four types of DU 145 cells that were genetically-engineered to constitutively express green fluorescent protein (GFP): 1. Wild type cells, 2. PTHrP1-173 transformed cells, 3. PTHrP1-87 transformed cells and 4. Vector (pCi-neo) transformed cells. The stably transduced cells were injected subcutaneously into immunocomprised mice to form solid tumors, and 1-mm3 pieces of the tumor were then surgically transplanted into the prostate bed of SCID mice. The mice were evaluated by GFP imaging, x-ray, autopsy, and PTHrP studies on sera and tumors. The PTHrP expressing prostate cancer cells demonstrated significant tumor growth and metastases, while no subcutaneous tumor growth was observed in the wild-type and vector transformed groups. At 9 weeks after implantation, primary and metastatic tumor burden were determined and serum PTHrP was measured for each mouse. GFP visualization and radiographic analysis revealed the sites of metastases. The PTHrP transformed groups demonstrated bone and visceral metastases, and no metastases were observed in the two control groups. In the PTHrP-expressing cancers, serum PTHrP levels correlated with tumor volume (r = 0.99). PTHrP levels were not detectable in control mice with no tumor. Primary tumor specimens were analyzed by immunohistology, immunoassay, and westerns and demonstrated robust PTHrP expression. Our results demonstrate that PTHrP expression by prostate cancer cells promotes the development of skeletal as well as non-skeletal metastases by the malignancy and that PTHrP expression in prostate cancer cells was required for the development of skeletal metastases. PTHrP secreted into the blood of tumor-bearing animals served as a tumor biomarker by correlating with the primary prostate tumor volume and the degree of metastastic burden. Further studies can help to define the role of PTHrP in the pathobiology of prostate cancer. These animal models can generate clinical hypotheses designed to elucidate the role of PTHrP in human prostate cancer pathogenesis and to identify specific PTHrP species as diagnostic and therapeutic targets for this malignancy.

F076

Prediction of Fracture Risk in Postmenopausal Caucasian Women With Peripheral Bone Desitometry: Evidence From National Osteoporosis Risk Assessment (NORA). P. Miller,[1] E. Siris,[2] T. Abbott,[3] L. Wehren,[3] Y. Chen,[4] K. Faulkner,[5] E. Barrett-Connor,[6] M. Berger,[3] A. Santora,[3] L. Sherwood.[3] [1]Colorado Center for Bone Research, Lakewood, CO, USA, [2]Columbia Presbyterian Medical Center, New York, NY, USA, [3]Merck & Co., Inc., West Point, NY, USA, [4]Merck & Co., Inc, West Point, NY, USA, [5]GE Medical Systems/Lunar, Madison, WI, USA, [6]University of California, San Diego, CA, USA.

Low bone mineral density (BMD) is a risk factor for fracture. Several new peripheral technologies have been introduced. At present, there are few prospective data supporting these newer technologies. Using data from the National Osteoporosis Risk Assessment

(NORA), we evaluated the association between BMD measurements at peripheral sites using some of the newer technologies and subsequent fracture risk. Each participant had BMD measured at one peripheral site: heel SXA (Osteoanalyzer, Dover), forearm (pDEXA, Norland), finger (AccuDEXA, Schick), or heel ultrasound (US)(Sahara, Hologic). Women were divided into groups based on T-score: t>-1.0; -1.0>t>-2.5, and t<-2.5. Fractures occurring in the subsequent year were identified by self-report. This analysis is limited to 148,649 Caucasian women who had valid baseline BMD data and responded to the follow-up survey. A total of 2259 osteoporosis-related fractures (hip, rib, forearm/ wrist, and spine combined) were reported. Risk ratios for fractures according to site of BMD measurement are shown.

	Heel (SXA)	Forearm	Finger	Heel (US)
# women	79,200	51,949	10,837	7,563
#(%) osteo fractures	1224 (1.6)	781 (1.5)	133 (1.2)	121 (161)
% -1.0> T-score >-2.5	43.6	34.8	27.8	33.4
risk ratio*	1.77	1.86	1.75	2.15
95% CI	1.60-1.96	1.65-2.10	1.34-2.29	1.66-2.76
% T-score < -2.5	4.1	9.4	12.0	2.9
Risk ratio*	3.06	3.02	2.41	5.78
95% CI	2.59-3.63	2.60-3.52	1.77-3.28	3.73-8.96

Risk ratio compared to T-score > -1.0 using proportional hazard model adjusting for age and prior fracture. We conclude that low BMD identified at a peripheral site is a good predictor of fracture risk within one year of the measurement

F078

A Model for Clinical Assessment of Pediatric Bone Mineral Status: Total Body Bone Mineral (TBBM) Adjusted for Total Body Bone Area (TBBA), Body Size, Sex, Black vs. non-Black Ethnicity, Tanner Stage (TS), and Age. M. Horlick,*[1] J. C. Thornton,*[2] R. N. Pierson,*[2] L. S. Levine,*[1] J. Wang.*[2] [1]Pediatrics, Columbia University, New York, NY, USA, [2]Body Composition Unit, St. Luke's - Roosevelt Hospital Center, New York, NY, USA.

Areal bone mineral density (g / cm^2) by dual energy x-ray absorptiometry (DXA) compared to reference standards has established clinical correlates in adults, but the most valid approach for clinical assessment of bone mineral status in children and adolescents is unclear. Our purpose was to develop a predictive model for pediatric bone mineral by DXA that included known relevant variables. Healthy Asian, black, Hispanic, and white subjects from metropolitan New York [n=1125 (535 girls, 590 boys); mean age 12 ± 3.5 years (range 5 – 19)] had measurement of height (cm), weight (kg), TBBM (g) and TBBA (cm^2) by DXA (Lunar DPX), and pubertal status by the criteria of Tanner. TBBM was analyzed as the dependent variable, with TBBA, height, weight, sex, race, age (years), and TS as independent variables. TBBM was transformed to TBBM ^{½} for analysis. The model explained 98% of the variability of TBBM in this population. TBBM ^{½} was related to TBBA, weight, and height (all p<0.001), with the same coefficients for these variables for all subjects. There were main effects of black vs. non-black ethnicity (p<0.001), sex (p<0.001), age (p<0.001), and TS (p=0.03) on TBBM ^{½}. There were also two-way interactions of sex with age and TS with age and sex respectively (p<0.001 – 0.048), and a three-way interaction of TS with sex and age (p<0.001). Prediction Equations for TBBM ^{½}

	TS 1 - 4	TS 5
Girls: non-black	16.77 + 0.34 age + q*	19.39 + 0.19 age + q*
Girls: black	17.39 + 0.34 age + q*	20.01 + 0.19 age + q*
Boys: non-black	18.27 + 0.19 age + q*	14.42 + 0.47 age + q*
Boys: black	18.89 + 0.19 age + q*	15.04 + 0.47 age + q*

*(*q* = 0.018 TBBA + 0.033 weight – 0.071 height)

These equations allow assessment of individual TBBM in relation to peers. The effect of ethnicity is independent of all other variables. When age and TS are included as predictors, the influence of TBBA, weight, and height is uniform across sex and ethnicity. The results imply that TS 5 subjects continue to gain TBBM, with a greater effect of a given age in males than females. Hispanic (largely Dominican) and Asian (Chinese and Korean) subjects in this study did not differ in bone mineral from whites, but this may not be applicable to all Hispanic or Asian groups. These equations are specific for Lunar densitometers, but the principle is applicable to all manufacturers. We suggest that TBBM by DXA adjusted for these variables is more valid than areal bone mineral density for evaluation of bone mineral status in children and adolescents.

F080

Total Hip or Femoral Neck? Differences in WHO Classification in Postmenopausal Women. Influence of Body Weight. J. L. Mansur. Centro de Endoc y Osteop. La Plata, La Plata, Argentina.

Hologic and the last versions of Lunar equipments (IQ,Prodigy) measure the bone mineral density (BMD) of "Total Hip". This region includes femoral neck, trochanter and shaft (or intertrochanter). The ICSBM recommends to use standardized BMD of total hip (TH) instead of femoral neck (FN), since TH correlates with hip fracture in a similar way as FN, but with better precision (as the area of TH is bigger). Actually half of the abstracts presented (ASBMR 2000) are based in TH and the other half in FN, and NOF recommendations use the word "hip" or "proximal femur". Objective: To study characteristics of TH and to know if the WHO suggested classification differs if we choose TH or FN. Patients and methods: 200 postmenopausal women without HRT or treatment were measured with Lunar DPX (software IQ). CV:TH=0.9 %, FN=1.5 % . Results: TH is the addition of 3 regions that measure areas of different sizes: 1) Shaft: 14.37 cm(SD:1.0)=44.6 %; 2) Troch: 12.98 cm(SD: 2.2)=40.3 %; 3) FN: 4.83 cm(SD: 0.4)=15.0 %; (In Hologic systems the size of shaft is bigger and troch is smaller) Total hip: 32.19 cm(SD: 2.7)=100 %. Ward area is included in FN and Troch. We find that 83 % of the patients were in the same category (WHO classification), discordance: 17 %. BMD was lower in FN in 12.5 % and in TH in 4.5 % of the patients. Correlation R of TH: vs FN: 0.93; vs Troc: 0.95; vs Shaft: 0.98; vs Ward: 0.90. The difference in T-Score between FN and TH is 0.21 (-1.03 in FN and -0.82 in TH) and it depends on body weight. Dividing the total of patients in two groups, the difference is 0.14 in thinner group and 0.29 in heavier group. Dividing them in 3 groups, it is 0.06 in the women with less than 60 Kg, 0.20 in the group 60-80 Kg, and 0.40 in women with more than 80 Kg (more body weight = more differences are between FN and TH BMD). Weight and BMD of all regions are correlated (p<0.05): R= Ward: 0.38, FN: 0.40, Shaft: 0.43, TH: 0.48, Troc: 0.58. The R between weight and Troc BMD changes with age: 60 y: 0.70 , > 69 y: 0.77, and also vs TH BMD: < 61 years(y): 0.44, > 60 y: 0.65 , > 69 y: 0.69 Discussion: It is amazing that people use nearly as synonymous the regions FN and TH (or as NOF recommendations "hip" or "femur proximal") when there are regions with a different proportion of trabecular and cortical bone. As when we study a patient the objective is to know the risk of fracture, we propose to observe the T-Score of both regions and to inform the worst. Since 12.5% are in a better category if we use total hip, we suggest not to use this region as a routine. The discordance is bigger in heavier patients, that has a BMD better in Total Hip. The BMD of trochanter correlates with weight and produces this result, and in older women the correlation is higher.

F082

Digital X-Ray Radiogrammetry Predicts Hip Fracture in Elderly Women. R. U. Ashford,[1] A. Dey,*[1] K. Kayan,*[1] H. Delaney,*[1] D. Stabel Nissen,*[2] D. Arnbjerg,*[2] L. Reaney,*[1] C. McGurk,*[1] E. McCloskey.[1] [1]WHO Collaborating Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom, [2]Pronosco, Vedbaek, Denmark.

We have undertaken a comparative study of Digital X-ray Radiogrammetry (DXR) and DXA measurements to predict incident hip fractures in elderly community-dwelling women in the UK.A case-control analysis was performed within a randomized, double-blind prospective study of hip fracture prevention. The analysis remains blinded to treatment. Cases comprised 44 women aged 75 years or older who sustained an incident hip fracture during a median follow-up of 15 months. 173 women were randomly selected as controls from those who did not suffer a hip fracture. At baseline, DXA measurements of BMD were undertaken at the total non-dominant hip (Hologic QDR4500) and the distal and ultra-distal non-dominant forearm (DTX200, Osteometer, Denmark). Hand radiographs were analysed using the Pronosco X-posure SystemTM to derive DXR-BMD and DXR-MCI (metacarpal cortical index).At baseline, the cases were significantly older and thinner than the non-fracture controls. In addition, the cases had significantly lower forearm BMD (0.29 ± 0.07 vs. 0.36 ± 0.07, p<0.001), total hip BMD (0.64 ± 0.14 vs. 0.78 ± 0.13, p<0.001), DXR BMD (0.44 ± 0.05 vs. 0.41 ± 0.05, p<0.001) and DXR-MCI (0.29 ± 0.05 vs. 0.33 ± 0.05, p<0.001) than controls. All skeletal assessments showed significant gradients of risk (expressed as the odds-ratio per 1SD decrease in measurement) for incident hip fractures (Table). The odds-ratios remained significant after adjusting for age and weight in a forward conditional logistic model. The incidences of fracture in those subjects with DXR BMD and DXR-MCI in the lowest quartile of measurements were 49% and 46% respectively, compared to 12% and 9% in the highest quartiles. For total hip BMD, the incidence in the lowest and highest quartiles were 58% and 5% respectively.

	OR (95%CI)	OR (95%CI) adjusted
Total Hip BMD	3.13 (2.04-4.81)	2.99 (1.95-4.59)
DXR-BMD	1.91 (1.31-2.77)	1.76 (1.21-2.56)
DXR-MCI	2.19 (1.47-3.27)	2.02 (1.34-3.05)
Forearm BMC	2.61 (1.69-4.02)	2.50 (1.60-3.89)
Forearm BMD	2.89 (1.87-4.46)	2.76 (1.78-4.28)

We conclude that hip BMD is the most predictive skeletal assessment for future hip fracture. Measurements of DXR-BMD are also significantly predictive and may have advantages of wider applicability and relatively lower cost. Further analyses are required to compare the clinical utility of techniques with differing costs, sensitivities and specificities

Disclosures: Pronosco,2.

Ten Year Probabilities of Osteoporotic Fractures According to BMD and Diagnostic Thresholds. **J**. A. Kanis,[1] O. Johnell,[2] A. Oden,*[3] A. K. Oglesby,*[4] C. E. DeLaet,*[5] B. Jonsson.*[6] [1]WHO Collaborating Centre for Metabolic Bone Disease, University of Sheffield, Sheffield, United Kingdom, [2]Department of Orthopaedics, Malmo General Hospital, Malmo, Sweden, [3]Consulting Statistician, Gothenberg, Sweden, [4]Global Economic Affairs, Eli Lilly & Company, Indianapolis, IN, USA, [5]Institute for Medical Technology Assessment, Rotterdam, The Netherlands, [6]Centre for Health Economics, Stockholm School of Economics, Stockholm, Sweden.

The objectives of the present study were to estimate ten year probabilities of osteoporotic fracture in men and women according to age and bone mineral density (BMD) at the femoral neck. Probabilities were computed from the hazard of a first hip, distal forearm, proximal humerus and symptomatic vertebral fracture from patient records in Malmo, Sweden and future mortality hazard for each year of age for Sweden using Poisson models.

Fracture probability was computed using the Swedish population and cut-off values for T-scores based on the NHANES III female population. We assumed that the risk of fracture increased with decreasing BMD as assessed by meta-analysis in independent studies. The ten year probability of any fracture was determined from the proportion of individuals fracture free from the age of 45 years. With the exception of forearm fractures in men, 10 year probabilities increased with age and T-score. In the case of hip and spine fractures fracture probabilities for any age and BMD were similar between men and women. Ten year probabilities for hip fracture assessed by BMD at the hip are shown in the Table.

	T-score (men)			T-score (women)		
Age (Years)	**0**	**-1**	**-2**	**0**	**-1**	**-2**
50	0.2	0.6	1.9	0.2	0.4	1.1
60	0.3	0.8	2.2	0.4	1.0	2.7
70	0.6	1.8	4.8	0.7	1.9	5.3
80	1.1	2.9	7.7	0.8	2.4	6.8

The effect of age on risk independently of BMD suggests that intervention thresholds should not be at a fixed T-score but vary according to absolute probabilities. Intervention thresholds based on hip BMD T-scores are similar between sexes.

Females with Hip Fracture Have Smaller Femora. R. B. Mazess,[1] C. Mautalen.[2] [1]Department of Medical Physics, University of Wisconsin, Madison, WI, USA, [2]Centro de Osteopatias Medicas, Buenos Aires, Argentina.

It has been demonstrated for over a decade that patients with osteoporotic fracture have about 15% (1 SD) lower bone mineral density (BMD in g/cm^2) than age-matched controls at the fracture sites. While fracture patients also are lighter in weight (about 5 kg) than their peers, this accounts for only a few percent of the BMD deficit. Recently studies have shown that patients with spine and/or femur fractures also have smaller bones at these fracture sites. We examined the femur scans by DEXA (Lunar DPX) in 59 females with recent hip fracture (average age 72 years) to ascertain the influence of bone size. These results were compared to controls age 70 to 79 years (n=374). RESULTS: The fracture patients showed about 15% lower BMD than controls. For the femur neck and total femur, the relative deficit in BMC was only slightly greater than that for BMD, but at the trochanter site there was a pronounced BMC deficit (30%) compared to controls. This deficit was obscured using BMD because the bone area was much smaller (15%) in fracture patients. CONCLUSION: The smaller bone size of patients with hip fracture can obscure a larger BMC deficit when clinicians depend on BMD. This is particularly true for the trochanter site. Small size of the trochanter, which is the point of impact on falling, may predispose to fracture. This also suggests that the association of increased hip axis length (i.e., larger trochanter size) with fracture risk may be an epiphenomenon rather than a reflection of inherent bone strength.

The Influence of Bone Density Testing and Fractures on Prescriptions of Bone-sparing Medications in Elderly Women in Ontario, Canada: A Population-based Study. S. B. Jaglal,[1] L. Jaakkimainen,*[2] W. McIsaac,*[2] G. Hawker,[2] S. Cadarette,[2] K. Wu.*[3] [1]Rehabilitation Science, University of Toronto, Toronto, ON, Canada, [2]University of Toronto, Toronto, Canada, [3]Institute for Clinical Evaluative Sciences, Toronto, Canada.

The objective of this population-based cohort study was to determine the influence of bone mineral density (BMD) testing and fracture on prescriptions of bone-sparing medications in women 65 years and older in Ontario, Canada. Several studies have reported that having a BMD test influences a woman's decision to begin hormone replacement therapy. Previous studies were not population-based and reported on only one bone sparing medication, estrogen. Rates and types of prescriptions as well as discontinuation rates after the first prescription whether or not a woman had a BMD test in the past year were compared. Whether or not the patient suffered a hip or wrist fracture prior to their prescription of a bone sparing medication was also compared. BMD and non-BMD cohorts and their drug exposure were created by record linkage of the physician claims, drug benefit and hospital discharge abstract databases. In 1996, 23,119 women > 65 years had an incident BMD test (BMD cohort) and 759,361 women did not (non-BMD cohort). Women who had a BMD test were 6 times more likely to fill a prescription for a bone sparing medication (40.5% BMD vs. 6.8% non-BMD). Of those who filled a prescription, women with a BMD were more likely to fill a prescription for a bisphosphonate (58.5%) versus estrogen (29.5%) than were the non-BMD cohort (43.5% bisphosphonate vs. 48.5% estrogen). There was a strong relationship between age and type of bone-sparing drug prescribed. Only 46.7% of women in the 65 to 69 year old age range who had a BMD test were prescribed only a bisphosphonate compared to 86.6% of those over age 85 and older. Similarly for women who did not have a BMD test, the proportion being prescribed a bisphosphonate increased with age from 27.0% to 76.3%. Among women with a BMD test, more than half who were prescribed fluoride (64.0%), salmon calcitonin (62.5%) or an estrogen patch (53.3%) discontinued use after the first prescription compared to 20.2% for a bisphosphonate and 27.7% for oral estrogen. In the subgroup of women who did not have a BMD test (n=51,343) but had a new prescription for a bone-sparing medication only 2,273 (4.4%) had had a previous hip or wrist fracture in the year prior. These data suggest that BMD testing positively influences the decision to initiate drug treatment in older women but not hip or wrist fracture.

F089

Screening Paradox in Osteoporosis. M. van der Klift,*[1] E. Seeman,[2] C. E. D. de Laet,*[1] A. Hofman,*[3] H. A. P. Pols.[4] [1]Institute for Medical Technology Assessment, Erasmus Medical Center Rotterdam, Rotterdam, The Netherlands, [2]Austin and Repatriation Med Centre, University of Melbourne, Melbourne, Australia, [3]Department of Epidemiology and Biostatistics, Erasmus Medical Center Rotterdam, Rotterdam, The Netherlands, [4]Department of Internal Medicine, Erasmus Medical Center Rotterdam, Rotterdam, The Netherlands.

Currently, in fracture prevention only subjects at high risk are identified and treated (the high-risk, case finding approach). The alternative approach for prevention is the population approach, in which the entire population at risk is regarded.The WHO diagnostic criterion of a T-score < -2.5 is often used as a threshold for treatment. To investigate the effectiveness of this high risk versus the population-based approach for fracture prevention, we used the data from the Rotterdam Study. We modelled the effect of a 0.5 and 1.0 SD increase of BMD on fracture incidence. At baseline, bone mineral density was measured at the femoral neck by DEXA (Lunar DPX-L). T-scores were calculated based on reference data of the Dutch population. During an average follow-up of 5.3 years 337 non-vertebral fractures were reported, while during a mean follow-up of 6.3 years 164 subjects suffered at least one incident vertebral fracture (assessed using the McCloskey/Kanis method). Results: see Table.

	Only treat if T-score < -2.5	**Treat all**
N (% of total population)	550 (9.5%)	5794 (100%)
Non-vertebral fractures (% of total)	83 (22.0%)	337 (100%)
Nr of fractures prevented by intervention		
+ 0.5 SD	20 (5.4%)	100 (26.6%)
+ 1.0 SD	25 (6.6%)	169 (44.7%)

These analyses were repeated for subgroups of fractures. For wrist and vertebral fractures, results were in a similar direction. When we analysed hip fractures alone, we found that when we increased the T-score of BMD in the high risk group with 1.0 SD, we would prevent 29 fractures (24.4 % of all hip fractures), whereas if we would increase the BMD with 0.5 SD in the whole population we would prevent 54 fractures (42.9 %).The results of this study clearly indicate that when only a high risk subgroup is treated, only a small reduction of the total burden of fractures within the population will be obtained.

F092

Digital Topological Analysis of in Vivo MR Microimages of Trabecular Bone Reveals Structural Implications of Osteoporosis. F. W. Wehrli,[1] B. R. Gomberg,*[2] P. K. Saha,*[1] H. Song,*[1] S. N. Hwang,*[1] P. J. Snyder.*[3] [1]Radiology, University of Pennsylvania, Philadelphia, PA, USA, [2]Bioengineering, University of Pennsylvania, Philadelphia, PA, USA, [3]Medicine, University of Pennsylvania, Philadelphia, PA, USA.

Osteoporosis is a disease characterized by bone volume loss and architectural deterioration. The majority of work aimed at evaluating the structural implications of the disease has been performed on the basis of stereologic analysis of histomorphometric sections. Only recently noninvasive imaging methods have emerged that provide sufficient resolution to resolve individual trabeculae. Here we apply digital topological analysis (DTA), a technique recently developed in the authors' laboratory, to magnetic resonance (MR) microimages of the radius obtained at 137x137x350µm3 voxel size in a cohort of 79 women of widely varying bone mineral density and vertebral deformity status. DTA allows unambiguous determination of the three-dimensional topology of each voxel in a trabecular bone network. The analysis involves generation of a bone volume fraction map, which is subjected to subvoxel processing to alleviate partial volume blurring, followed by thresholding and skeletonization. The skeletonized images contain only surfaces, profiles, curves and their mutual junctions as the remnants of trabecular plates and rods. DTA parameters were compared with integral bone mineral density in the lumbar spine and femur as well as MR derived bone volume fraction. Vertebral deformities were determined

on the basis of sagittal MR images of the spine with a semiautomatic method and the number of deformities counted. DTA strucural indices were found to be by far the strongest discriminators of subjects with vertebral deformities from those without deformities. Subjects with deformities (N=29) had lower topological surface density ($p<0.0005$) and surface-to-curve ratio (SCR, a measure of the ratio of plate-like to rod-like trabeculae; $p<0.0005$) than those without. Profile interior density,a measure of intact trabecular rods, was also lower in the deformity group ($p<0.0001$). SCR was found to span a range one order of magnitude larger than bone volume fraction, thus greatly amplifying the effect of osteoporotic bone loss. The data in this work provide the first in vivo evidence of the structural implications inherent in postmenopausal osteoporosis accompanying bone loss, i.e. the conversion of trabecular plates to rods and disruption of rods due to repeated osteoclastic resorption.

F095

The Effect of Age on Serum Levels of Osteoprotegerin. S. Kudlacek,*[1] B. Schneider,*[2] P. Pietschmann,[3] W. Woloszczuk,[4] R. Willvonseder.*[5] [1]Medical Department, Barmherzige Brüder, Vienna, Austria, [2]Department of Statistical Medicine, University, Vienna, Austria, [3]Department of Pathophysiology, University, Vienna, Austria, [4]LBI of Experimental Endocrinology, University, Vienna, Austria, [5]Medical Department, Barmherzige Brüder & LBI of Aging Research, Vienna, Austria.

The purpose of the present study was to determine normative serum values of osteoprotegerin (OPG), playing an important role in the negative regultion of osteoclastic bone resorption.Regulation of the balance of osteoblastic and osteoclastic activity is critical for the understanding of normal and pathologic bone cell biology. The recent discovery of osteoprotegerin, a soluble member of the TNF receptor superfamily has provided new insights into the regulation of osteoclastogenesis. We therefore studied serum OPG levels in a large group of healthy Austrian females (n=630) and males (n=394). Participants were selected by chance from a population based register and contacted by a standard written invitation. A questionnaire was used to evaluate predefined exclusion criteria. OPG was detected by a sandwich enzyme immunoassay using a mouse monoclonal antibody and a rabbit polyclonal antibody for detection, and recombinant human OPG as standard material. (Biomedica, Vienna, Austria). The assay detects both monomer and dimeric forms of OPG, including OPG bound to its ligand. All samples were measured in duplicate and averaged, results differing of more than 20% were reassayed. In the whole group of subjects we found a significant increase of serum OPG levels with age. Stepwise regression analysis revealed that gender and age independently influenced OPG levels. Serum OPG levels were higher in females than in males (63,8±45 pg/ml vs. 41,7±30 pg/ml, $p<0.0001$).Our results give evidence of an increase of serum OPG levels with age, moreover OPG was negatively correlated with serum PTH levels ($r = -0.14$, $p<0.001$). We could not find an association of OPG levels with lumbar spine and femoral neck bone mineral density.

F098

The Type I Collagen Fragments ICTP and CTX Reveal Distinct Enzymatic Pathways of Bone Collagen Degradation. M. A. Karsdal,[1] P. Garnero,[2] M. Ferreras,*[1] J. Risteli,[3] P. Qvist,[4] N. Foged,*[1] J. M. Delaissé.[1] [1]OSTEOPRO A/S, Herlev, Denmark, [2]INSERM Research Unit 403 and Synarc, Lyon, France, [3]University of Oulu, Oulu, Finland, [4]Osteometer Biotech, Herlev, Denmark.

Bone resorption generates collagen fragments such as ICTP and CTX, that can be quantified in serum and/or urine by using specific immunoassays. Their concentrations correlate with the levels of bone resorption, but the relative abundance of ICTP and CTX varies according to the type of bone pathology, suggesting that these two fragments are generated through distinct collagenolytic pathways. In this study, we analysed systematically the release of ICTP and CTX from bone collagen by the proteinases believed to participate in the solubilization of bone matrix. First, we incubated collagen isolated from human cortical bone with cathepsin K, MMP-9, MMP-13, MMP-14, or MMP-2, all of which show high collagenolytic activity and are synthesized by osteoclasts or are closely related to resorbing osteoclasts. All incubations were performed for the same time and at the same concentration of active enzyme as determined by active site titration. We found that ICTP was efficiently released by MMP-2 and MMP-13, and to a lesser extent by MMP-14. In contrast, ICTP was not detected upon incubations of collagen with MMP-9 or cathepsin K alone, although large amounts of ICTP were generated after successive incubations with cathepsin K and MMP-9, respectively. CTX was efficiently released by cathepsin K, and to a small extent by MMPs, but the release of CTX was increased 2-fold when incubating cathepsin K-generated fragments with MMP-9. Second, we cultured mouse tibiae and calvariae with PTH to induce resorption, and tested the effect of inhibitors of MMPs or cathepsin K on the release of ICTP, CTX, and Ca in their culture media. In accordance with our test tube assays the release of ICTP was completely prevented by MMP inhibitors, but rather increased in the presence of cathepsin K inhibitor. The latter supports the view that MMPs compensate for lack of cathepsin K in pycnodysostosis and cathespin K knockouts. The release of CTX was partially inhibited when either cathepsin K or MMPs were inactivated, and completely inhibited when both were inactivated. The release of Ca was diminished in the presence of either type of proteinase inhibitors, thus confirming published data. In conclusion, we have shown both in test tubes and in native bone, that ICTP and CTX are generated by different collagenolytic pathways. These findings explain why these two markers may discriminate between different bone pathologies, and strengthen the view that specific antagonists of collagenolysis could be used selectively against given bone diseases.

F101

Comparison of Three Bone Ultrasounds for Determining Hip Fracture Odds-Ratios - Results of the Semof Study. M. Krieg, J. Cornuz,* P. Burckhardt and the Semof Study Group. Internal Medicine, University Hospital, Lausanne, Switzerland.

Background : Bone ultrasound (QUS) is known to discriminate subjects who suffered of fractures and subjects with no fracture history. QUS is predictive of fractures. The Swiss Evaluation of the Methods of Measurement of Osteoporotic Fracture Risk (SEMOF) study is a prospective multicenter study which compares 3 QUS devices for the assessment of hip fracture risk in a population-based sample of elderly Swiss women. The aim of this cross-sectional analysis was to compare the 3 QUS for determining hip fracture odds ratios (OR).Method : Among the 7702 women aged ±75.3 yrs (70 - 87) assessed during the inclusion phase of the SEMOF study. The history of previous hip fractures was obtained with a specific mailed questionnaire. 3696 had no fracture whereas 93 reported a low trauma hip fracture after 50 yrs. All the participants were measured with the 3 QUS: Achilles+ [Stiffness index (SI)], Sahara [Quantitative ultrasound index (QUI)], and DBM sonic 1200 [Amplitude-dependent speed of sound (ADSOS)]. New parameters, such as Speed of sound (SOS), time frame (TF), ultrasound bone profile index (UBPI) were calculated from the DBM data.Results : Mean QUS value (± SD) were adjusted for age and BMI, and ORs were calculated for 1 SD decrease, with 95% CI (***$p<0.001$, **$p<0.01$, *$p<0.05$ compared to non fractured group).Discussion : All the ultrasound parameters could discriminate elderly women with hip fracture from women with no fracture history. In this population of elderly women, discrimination was significantly higher with measurements on the heel than on the phalanges. This could be due to the high prevalence of osteoarthritis of the hands at this age, which could influence the results.

F103

Association of Quantitative Ultrasound Parameters and Bone Density with Osteoporotic Vertebral Deformities in a Population Based Sample: The OPUS Study. C. C. Glüer,[1] R. Eastell,[2] D. M. Reid,[3] F. Alenfeld,[4] S. Kolta,[5] R. Barkmann,[1] J. Clowes,[2] A. Stewart,[3] C. Roux,[5] D. Felsenberg.[4] [1]University Hospital Kiel, Kiel, Germany, [2]University of Sheffield, Sheffield, United Kingdom, [3]University of Aberdeen, Aberdeen, United Kingdom, [4]Free University Berlin, Berlin, Germany, [5]René Descartes University, Paris, France.

It is unclear whether the many different methods for measuring quantitative ultrasound (QUS) of bone have similar associations with osteoporotic fractures. To evaluate this in a systematic approach, we initiated the Osteoporosis & Ultrasound (OPUS) study. In 5 European cities we recruited a population-based sample of 2206 women (ages 55 to 80 years). Spinal radiographs were examined for vertebral deformity at a single centre (using a combined morphometric and visual approach). All subjects had dual-x-ray absorptiometry (DXA) of the lumbar spine and the total hip and QUS of the heel on 4 devices (Lunar Achilles+, Osteometer DTU-one, Quidel/Metra QUS-2, and DMS UBIS 5000) and of the finger on one device (IGEA DBM Sonic BP). We examined the association of these measurements with vertebral deformity by calculating standardised odds ratios (sOR, per one SD decrease of population variance), OR adjusted for age, and compared devices by calculating the area under the receiver operating characteristic (ROC) curve. This last analysis was performed in the 1236 women who had a complete set of measurements. We identified vertebral deformities in 362 women (16.4%).

Variable	n (for OR)	SOR	Age-adj. sOR	Area ROC (n=1236)
DXA spine BMD	2189	1.7	1.6 (1.4-1.8)	0.683
DXA hip BMD	2206	1.9	1.7 (1.5-1.9)	0.680
Achilles BUA	1788	1.6	1.4 (1.3-1.7)	0.660
DTU-one BUA	2170	1.5	1.3 (1.2-1.5)	0.660
UBIS 5000 BUA	2024	1.6	1.4 (1.3-1.6)	0.658
QUS-2 BUA	1477	1.7	1.5 (1.3-1.8)	0.664
Achilles SOS	1788	1.8	1.5 (1.3-1.8)	0.680
DTU-one SOS	2170	1.6	1.4 (1.2-1.6)	0.673
UBIS 5000 SOS	2024	1.7	1.5 (1.3-1.7)	0.673
DBM BP AD-SoS	2144	1.4	1.2 (1.1-1.4)	0.658
DBM BP UBPI	2132	1.5	1.3 (1.1-1.5)	0.658

The SOS measurements of the heel had ROC areas similar to DXA measurements, and larger than BUA of the heel using the same device ($p<0.05$); finger measurements had significantly lower ROC areas compared to DXA. Conclusion: SOS of the calcaneus demonstrated a discriminatory power comparable to DXA. Small but significant differences in performance were observed, but all QUS variables showed significant associations with deformities.

Genetic Dissection of Breaking Strength. R. F. Klein,[1] M. Shea,[2] M. Serang,*[2] R. J. Turner,*[1] J. K. Belknap,*[1] E. S. Orwoll.[1] [1]Bone and Mineral Unit, Oregon Health Sciences University, Portland, OR, USA, [2]Department of Orthopaedics, Oregon Health Sciences University, Portland, OR, USA.

An osteoporotic fracture represents a structural failure of bone whereby the forces applied to the bone exceed its load-bearing capacity. Quantitative trait loci (QTLs) have been identified that strongly influence bone mineral density (BMD) and femoral size in mice. However, additional properties (e.g., spatial distribution, micro-architecture, collagen content and fiber orientation, etc.) also influence the mechanical behavior of bone. We hypothesized that some of the genes regulating other important aspects of skeletal

integrity would be distinct from those that determine BMD. Using 16-week-old male mice from a panel of 18 BXD recombinant inbred (RI) strains, derived from a cross between C57BL/6 and DBA/2 progenitors, we measured mid-diaphyseal femoral cross-sectional moment of inertia (MOI) and failure load (FL) in 3-point bending and calculated Young's modulus (a measure of the intrinsic stiffness of the femoral bone tissue). The distribution of values among the strains for each of these biomechanical measures clearly indicated the presence of strong genetic influences, with an estimated heritability of 76%, 53% and 28% for femoral MOI, FL and modulus, respectively. Failure load, a summary measure of the ability of the femoral shaft to resist fracture, was strongly related to femoral MOI (r=0.62; p<5x10-20), but there was no correlation between FL and modulus (r=0.06; p=0.44). However, there was a strong inverse relationship between modulus and MOI (r=-0.36; p<2x10-6). Using a p <= 0.01 (two-tailed, single test) alpha level of significance, QTL analysis of the BXD RI strain series provisionally identified 7 chromosomal sites linked to MOI, 8 sites linked to FL and 9 sites linked to modulus. Only one provisional QTL (located on distal chromosome 4) was associated with all three phenotypes, and in each pair-wise comparison two additional distinct loci were shared: MOI and FL (chr 11 & 12); FL and modulus (distal chr 1 & 13); MOI and modulus (proximal chr 1 & 9). Two FL QTLs (chr 5 & 8) were not detected in analyses of either MOI or modulus, suggesting the presence of genetic influences on FL that were independent of these two major indices of femoral geometric and material properties. These results provide evidence of strong genetic contributions to the major determinants of bone strength in this mouse model. The finding of unique FL-related QTLs in addition to distinct QTLs for bone geometry (MOI) and intrinsic material properties (modulus) that appear to independently influence FL suggests the presence of a network of genes that are essential to skeletal integrity.

Differential Gene Expression Between a Congenic Strain That Contains a Quantitative Trait Loci (QTL) of High Bone Density from CAST/EiJ and Its Wild Type Strain C57BL/6J. W. Gu,[1] X. Li,[1] K. H. W. Lau,[1] B. Edderkaoui,[1] L. R. Donahue,*[1] C. J. Rosen,*[2] W. G. Beamer,[3] K. L. Shultz,*[3] A. K. Srivastava,[1] S. Mohan,[1] D. J. Baylink.[1] [1]MDC, Pettis VAMC, Loma Linda, CA, USA, [2]St. Joseph's Hospital, Bethesda, ME, USA, [3]The Jackson Lab, Bar Harbor, ME, USA.

Peak bone density is an important determining factor of future osteoporosis risk. We previously identified a QTL that contributes significantly to high bone density (30% of the variation of bone density) on mouse chromosome 1 from a cross between C57BL/6J (B6) and CAST/EiJ (CAST) mouse strains. We then generated a congenic strain, B6.CAST-1, in which this QTL region was transferred from CAST to the B6 background. Prior to this study, we constructed a BAC contig for the QTL region. In this study, cDNA microarray analysis was conducted by Incyte Genomic Systems on 8,734 gene accessions using mRNA from mouse femurs (free of marrow) of both the congenic and B6 strains to test two hypotheses: 1) microarray analysis will identify candidate genes for bone density; and 2) by comparing the gene expression profile outside of the QTL region between B6 and the congenic mice, we can better characterize the molecular phenotypic mechanisms that contribute to the high bone density QTL. Although the 8,734 gene accessions on microarray chips were derived from non-bone tissues, we found that approximately 60% of them were expressed in the femur of B6 mice. Comparison of expression levels of genes between B6 and the congenic mice (ANOVA) indicated that the gene expression of the two mouse strains had a similar pattern (P=0.468). Regarding hypothesis 1, out of a total of 19 known genes and 85 ESTs showing at least a 2-fold (significant) difference between these two strains, we found only one gene and two ESTs (i.e., candidate genes) that are known to be present in the QTL region. Regarding hypothesis 2, by comparing the gene expression profile outside of the QTL region, we found that expression levels of genes related to bone formation were lower in congenic than in B6 mice: Osteoblast specific factor 2 (OSF2) and procollagen, type I, alpha 1, were expressed between 2-3 times lower in congenics than in B6 at 6 and 14 weeks of age. Consistent with these microarray data, the serum alkaline phosphatase activity in the congenic was only 73% of that of B6 mice (P<0.01). Additionally, expression levels ofa potential osteoclast inhibitor (an EST sequence similar to SUR8) were significantly greater in the congenic than in the B6 mice. In conclusion, microarray analysis is useful for: 1) the identification of candidate genes of bone density; and 2) the characterization of molecular mechanisms of the QTL locus that regulate bone density.

F112

Testing In Vivo Effects of a Genetic Determinant of IGF-I Expression on Bone Phenotypes In a New Congenic Mouse. C. Ackert,[1] L. Donahue,*[1] C. H. Turner,[2] R. T. Turner,*[3] M. B. Bouxsein,[4] R. Muller,*[4] W. G. Beamer,*[1] K. L. Schultz,*[1] C. J. Rosen.[5] [1]The Jackson Laboratory, Bar Harbor, ME, USA, [2]Indiana University, Indianopolis, IN, USA, [3]Mayo Clinic, Rochester, MN, USA, [4]Beth Israel Deaconess Medical Center, Boston, MA, USA, [5]St. Joseph Hospital, Bangor, ME, USA.

IGF-I is an important growth factor for the skeleton. However its regulation is complex and, for the most part, heritable. We previously demonstrated that changes in both serum and skeletal IGF-I are related to strain specific differences in mouse BMD. We also identified several quantitative trait loci (QTLs) for serum IGF-I in F2 mice derived from progenitor crosses between C3H (high density high IGF-I) and B6 (low density, low IGF-I) strains. The most powerful QTL (LOD~ 9.0) accounts for >6% of the variance in serum IGF-I (*Igfls1*) and is located on the distal third of Chromosome 6. Paradoxically, IGF-I levels are lower in F_2 mice with C3 alleles in the Chr6 QTL. To test the size effect for *IgflsI* on both serum IGF-I and skeletal morphology, we initially generated a congenic mouse (B6C3H-6 c3/c3) by placing the Chr 6 QTL from C3H on a B6 background over 6 generations(N6F2). These mice are > 98% B6 in respect to their background genome, but maintain C3H alleles from *Igfls1*. We have now completed congenic construction (N10F2) for both males and females of this strain. IGF-I and skeletal phenotypes in N6 and N10F2 congenics were compared with age and gender matched B6. Serum IGF-I levels in male (M) and female (F) N6 and N10F2 congenics at 6 and 8 weeks of age were reduced by ~25%(p<0.01) compared to progenitors. There was a 40 % reduction in secreted IGF-I in conditioned media (CM) of calvarial osteoblasts (OB)from N6F2 congenics vs B6. F but not M congenics showed reduced vertebral and femoral BMD by pQCT compared to B6 (p<0.05). Congenics also had lower trabecular BMD when measured by uCT (vertebrae) and histomorphometry (proximal tibia) (p<0.01). Medial lateral dimensions of the femur were reduced in N6F2 B6C3H-6 c3/c3 compared to B6 (p<0.001).Femoral strength and cross-sectional moment of inertia were also significantly reduced in the congenics(p<0.01)compared to B6. In sum, we identified and tested, in vivo, a major genetic regulatory determinant for serum IGF-I. This factor has a profound effect on several skeletal phenotypes, which may be gender specific. We conclude that the congenic on Chr 6 will be a useful model for defining the regulation of serum and skeletal IGF-I, as well as testing the effects of genetic determinants on parameters such as BMD, skeletal morphology and strength.

F114

Genetic Relationships Among Bone Phenotypes Regulated by Sets of Quantitative Trait Loci (QTL) in B6C3F2 Mice. W. G. Beamer,[1] S. Sen,*[1] G. A. Churchill,*[1] C. J. Rosen,[1] L. R. Donahue,*[1] K. L. Shultz,[1] J. O. Mytar,*[1] C. H. Turner,[2] R. Muller,*[3] T. Uchiyama,*[3] M. L. Bouxsein.[3] [1]The Jackson Laboratory, Bar Harbor, ME, USA, [2]Indiana University, Indianapolis, IN, USA, [3]Beth Israel Medical Center, Boston, MA, USA.

It is axiomatic that skeletal properties of mineral density, size, shape, architecture, and bone quality are functions of both heritable and environmental determinants, however the complexity of the genetic regulation is just beginning to be elucidated. To gain insights about skeletal genetic regulation, we have analyzed data gathered on 36 physical, structural and functional phenotypes from femora and lumbar vertebrae of 4 month old adult B6C3F2 intercross progeny of C57BL/6J (B6) and C3H/HeJ (C3H) progenitor strain mice. Phenotypes were measured by pQCT, MicroCT 20, PIXImus, materials testing machines, and digital caliper instruments. The genome wide scans were based on genotyping of DNA obtained from ~1000 females for 107 markers across all 19 autosomes at average genetic distance of 14-15 centiMorgans. QTLs were identified by regressions analyses of phenotype on genotype using computer programs MapManagerQT (K Manly) and Pseudogene (G Churchill). Chromosomal markers with LOD scores greater than 2.8 (multiple test correction by permutation tests) were considered as suggestive, while LODs of 4.3 or better were considered as significant linkage with a phenotype. We found that every bone phenotype evaluated has complex genetic regulation dependent upon 2 to 9 QTLs, with LOD scores of 3.0 to 20.5. The phenotypic variance accounted for by individual QTLs ranged from 1 to 9%. Assessment of QTL x QTL interactions has been markedly variable, depending on phenotype being evaluated. As would be expected, some of the femoral and vertebral phenotypes revealed both shared and unique QTLs. Within the set of QTLs for each phenotype, the net phenotypic difference between the progenitor strains is the consequence of QTLs with major and minor effects. We also found that for each bone site and phenotype, either progenitor strain could contribute a QTL with alleles that increased the phenotype evaluated in the F2 progeny. The effects of the progenitor alleles for a given QTL on each phenotype proved to be either dominant-recessive or additive in action. Congenic strains developed from backcrossing C3H chromosome segments onto the B6 background has shown that QTL effects on strength, structure, or density are detectable. These data demonstrate that the complex genetic regulation of bone can be decomposed into basic, assessable elements that will be amenable to future molecular medicine diagnostic and therapeutic actions.

Linkage of Albers-Schönberg Disease (Autosomal Dominant Osteopetrosis Type II) to Chromosome 16p13.3. O. D. Bénichou,*[1] E. Cleiren,*[2] J. Gram,[3] J. Bollerslev,[4] M. de Vernejoul,[1] W. Van Hul.[2] [1]INSERM U 349, Hôpital Lariboisière, Paris, France, [2]Medical Genetics, University of Antwerp, Antwerp, Belgium, [3]Medicine, Ribe County Hospital, Esjberg, Denmark, [4]Endocrinology, Rikshospitalet, Oslo, Norway.

The osteopetroses are a heterogeneous group of conditions characterized by an increased bone density due to impaired bone resorption. Besides the at least two autosomal recessive types, two autosomal dominant forms of osteopetrosis are described, differentiated by clinical and radiological signs. Autosomal dominant osteopetrosis type II (ADOII), also known as Albers-Schönberg disease, is characterized by sclerosis, predominantly involving spine (vertebral endplate thickening, « Rugger Jersey spine »), pelvis (« bone within bone » sign), and the skull base. An increased fracture rate can be observed in these patients. By linkage analysis, the presence of a gene causing ADOII was previously suggested for chromosome 1p21. However, analysis of extra ADOII families indicated genetic heterogeneity within ADOII, with the chromosome 1p21 locus only being a minor locus.We now performed a genome linkage scan in an extended French ADOII-family allowing us to localize an ADOII gene in the chromosomal region 16p13.3. Analysis of microsatellite markers in five extra ADO II families could not exclude this chromosomal region in any of these. A maximum LOD score of +12.70 was generated with marker D16S3027 at a recombination fraction of 0. Based on the key recombinants in the families, a candidate region of 8.4 cM could be delineated flanked by markers D16S521 on distal and D16S423 on proximal side. Surprisingly, one of the families analysed is the Danish family previously suggested to be linked to chromosome 1p21. This family can clearly not be excluded from the chromosome 16p13.3 region and generates a maximum LOD score of +4.21 (at q = 0) with marker D16S3027. Since at present no other ADOII family has been proven to be linked to chromosome 1p21, the most likely localization of the disease causing gene in this family is definitely on chromosome 16p13.3 reopening the possibility that ADOII is genetically homogeneous caused by one gene on chromosome 16p13.3.

F119

Identification of Gene Loci Regulating Bone Size and Strength in Mice. J. E. Wergedal,[1] C. Ackert,*[2] M. H. C. Sheng,[1] W. G. Beamer,[2] D. J. Baylink.[1] [1]Musculoskeletal Disease Center, JL Pettis VA Medical Center, Loma Linda, CA, USA, [2]The Jackson Lab, Bar Harbor, ME, USA.

Bone structural properties are a very important determinant of bone strength. To determine if the genes regulating bone size could be determined by genetic studies in mice, we surveyed outer dimensions of the femur in 29 inbred mouse strains by peripheral quantitative computed tomography (pQCT) analysis. Significant variations between strains were found in all femur parameters. These data provided evidence that bone size is a heritable trait in inbred strains of mice (broad-sense heritability, 94%) and that mice are a suitable model for identifying the genes regulating bone size. There were strong correlation's (0.7 to 0.9) between parameters and body weight consistent with the hypothesis that genes regulating body size play an important role in determining bone dimensions. However, correction of midshaft size for body size by dividing by femur length did not remove all of the variation. Therefore some genes regulate bone size independent of overall body size or femur length. To investigate genes regulating bone size, we selected two inbred strains of mice (NZB/B1nJ and RF/J) that differ in femur midshaft size but not femur length. Total midshaft area was 40±2% higher in RF/J than NZB/B1nJ mice. Femur breaking strength was 85% higher in RF/J mice than in NZB/B1nJ mice. To identify genes responsible for regulating bone size, genetic analyses have been conducted in a cohort of F2 mice derived from intercross matings of (NZB/B1nJ x RF/J)F1. Femurs were isolated from 366 10-week-old females. Bone size data were obtained by pQCT and genotype data were obtained by polymerase chain reaction assays for polymorphic markers carried in genomic DNA of each mouse. Genome wide scans for co-segregation of genetic marker data with high or low bone size revealed loci on four different chromosomes. Loci on chromosome 7 and 11 achieved highly significant (LOD score of 7.5 and 8 respectively) linkage with bone size. Secondary loci were found on chromosome 12 and 15. Two strong QTL's were also identified for body weight (Chr 10, LOD 4.6: Chr12, LOD 8.0) These QTL's were different from the bone size QTL's. Femurs are currently being assessed for breaking strength to determine if strength loci overlap with size loci. Candidate genes include PTH and calcitonin on chromosome 7 and growth hormone on chromosome 11. In summary: 1) inbred mice show large variations in bone size independent of body size, 2) genetic analysis has identified four QTL's for bone size.

F122

Partitioning the Genetic Regulation of Bone Mineral Density: Loci Independent of Growth Hormone and IGF-I Regulation. L. R. Donahue,[1] W. G. Beamer,[1] M. L. Bouxsein,[2] R. Muller,[2] C. H. Turner,[3] K. L. Shultz,*[1] C. J. Rosen.*[1] [1]The Jackson Laboratory, Bar Harbor, ME, USA, [2]Beth Israel Medical Center, Boston, MA, USA, [3]Indiana University, Indianapolis, IN, USA.

We have demonstrated that areal BMD (DEXA, PIXImus, GE Lunar) is a polygenic trait and have discovered 4 loci (QTLs on Chrs 1, 4, 14, 18) for vertebral BMD utilizing F2s from C57BL/6J (B6), X C3H/HeJ (C3H) cross. To determine if these BMD QTLs were also QTLs for insulin-like growth factor-I (IGF-I), a growth factor for bone known to differ between B6 and C3H, we did an analysis for IGF-I in these F2s. The 4 IGF-I QTLs (Chrs 6,10,11, 15) identified were different from the BMD QTLs. To decompose the interaction between BMD and IGF-I, we made a model utilizing a spontaneous mutation in the mouse known as *little*. In C57BL/6J-*lit/lit* mice, GH is not detectable in circulation, IGF-I is fixed at low levels, and BMD, skeletal size, and body mass are reduced. We developed a new congenic strain by transferring the *little* mutation from the low BMD B6 to the high BMD C3H background. The new C3.B6-*lit/lit* mice have the same small body and skeletal size, but higher whole body areal BMD than the original B6-*lit/lit* mice. Size and whole body BMD in *lit/lit* strains at 4 months:

Strain	Sex	Body Wt (g)	Femur Lgth (mm)	BMD (g/cm^2)
B6/lit/lit	Male	15.0±1.0	12.0±0.1	.031±.001*
C3.B6-*lit/lit*	Male	16.5±1.2	12.4±0.1	.034±.001
B6-*lit/lit*	Female	13.0±0.6	12.0±0.1	.029±.001*
C3.B6-*lit/lit*	Female	12.0±0.4	12.3±0.1	.035±.001

(n=6-7); *p<.02; comparison between strains within sex

We have developed a model that can be used to locate BMD genes that are independent of GH/IGF-I and size effects. We have preliminary whole body areal BMD data from 457 adult F2 mice using a cross between B6-*lit/lit* and C3.B6-*lit/lit*, where all mice are homozygous *little* and segregating genes from the two background strains. We find a Gausian distribution of BMD values ranging from .027 to .040, indicating that the regulation of BMD in this population is polygenic and that it will be possible to find loci for BMD that are GH/IGF-I independent. By comparing the loci found in this homozygous *little* cross with the loci found in the B6C3F2 cross with normal GH/IGF-I values, we will be able to partition the BMD phenotype into GH/IGF-I dependent and independent loci.

F125

Osteoclast Formation in Transgenic Mice Overexpressing Fibroblast Growth Factor-2. T. Sobue,[1] X. Zhang,[1] L. G. Raisz,[1] J. D. Coffin,*[2] M. M. Hurley.[1] [1]Endocrinology, University of Connecticut Health Center, Farmington, CT, USA, [2]Pharmaceutical Science, University of Montana, Missoula, MT, USA.

Basic fibroblast growth factor (FGF-2) is an important regulator of bone formation and resorption as well as a potent mitogen for osteoblasts and stromal cells. We previously reported that overexpression of FGF-2 in transgenic (TgFGF2) mice caused premature and enhanced apoptosis in chondrocytes. In other studies, we showed that FGF-2 also stimulated osteoclast formation. In the present study, we investigated whether overexpression of FGF-2 would enhance osteoclast (OCL) formation as measured by the formation of multinucleated tartrate resistant acid phosphatase positive cells in response to 1,25(OH)2D3, PTH and PGE2 in bone marrow cultures using 6-8 week old non transgenic (NTg) and TgFGF2 litter mates. Few OCL formed in vehicle treated bone marrow cultures from NTg and TgFGF2 mice. Treatment with 1,25(OH)2D3, PTH or PGE2 stimulated OCL formation in both NTg and TgFGF2 bone marrow cultures but there were significantly fewer OCL formed in response to these agents in bone marrow cultures from TgFGF2 mice. In contrast, treatment with exogenous FGF-2 (0.01-10 nM) caused a significantly greater increase in OCL formation in bone marrow cultures from TgFGF2 mice than NTg mice. Differences were not due to the number of OCL precursors since similar numbers of OCL formed in bone marrow cultures from NTg mice and TgFGF2 mice treated with RANKL (10 ng/ml). Earlier reports indicated that FGF receptor-1 (FGFR1) is important in FGF-2 induced OCL formation. We therefore compared the expression of FGFR1, as well as RANKL and M-CSF, mRNAs in bone marrow stromal cell cultures from both genotypes. Northern blot analysis revealed that basal expression of FGFR1 was decreased by 60 % in TgFGF2 mice relative to NTg mice. Twenty four h of treatment with exogenous FGF-2 increased FGFR1 mRNA expression 280% in TgFGF2 bone marrow stromal cells but only 66% in NTg stromal cells. Basal expression of RANKL, M-CSF and OPG mRNA were similar in bone marrow stromal cell cultures from both genotypes. However, FGF-2 (10 nM) caused a greater increase in mRNAs for RANKL (386% vs 111%) and M-CSF (182% vs 114%) in bone marrow stromal cell cultures from TgFGF2 mice compared to NTg mice. We conclude that overexpression of FGF-2 enhances osteoclast formation in response to exogenous FGF-2 but not to other stimulators of resorption. We speculate that endogenous overexpression of FGF-2 may enhance OCL formation by increasing the sensitivity to exogenous FGF-2 including its ability to increase FGFR1.

F128

In Vivo Administration of Interleukin-1 Enhances Osteoblast Proliferation and Differentiation in Ex-Vivo Bone Marrow Cultures From Fgf-2 Null Mice but not Osteoclast Formation in Calvariae of Fgf2 Null Mice. T. Sobue,[1] X. Zhang,[1] J. D. Coffin,*[2] M. M. Hurley.[1] [1]University of Connecticut Health Center, Farmington, CT, USA, [2]University of Montana, Missoula, MT, USA.

The cytokines Interleukin-1 (IL-1) and fibroblast growth factor (FGF-2) are potent stimulators of bone resorption and formation. We reported that IL-1 increased Fgf2 mRNA and protein expression in normal human osteoblastic cells as well as osteoblasts from patients with osteoarthritis. To assess the physiological relevance of IL-1 regulation of FGF-2, we examined the effect of 3 days of injection of vehicle or IL-1 (2.5 µg) over the calvariae of wild type (Fgf2+/+), heterozygote (Fgf2+/-) and mice with disruption of the Fgf2 gene (Fgf2-/-). Mice were sacrificed one day after the last injection and histomorphometric analysis of calvariae was performed including tartrate resistant acid phosphatase (TRAP) staining for multinucleated osteoclasts (OCLs). IL-1 significantly increased osteoclast surface/bone area (3850 vs 1469 µm/µm^2, p<0.05) and osteoclast number (79 vs 37/ mm^2 bone area, p<0.05) in Fgf2+/+ mice relative to vehicle treated calvariae. The response was similar in heterozygotes. In contrast, there were no differences in osteoclast surface/ bone area (1637 vs 1433 µm/µm^2) or osteoclast number (36 vs 49/ mm^2 bone area) between IL-1 and vehicle in Fgf2-/- mice. In these experiments, long bones were flushed to measure bone formation ex vivo in marrow stromal cell cultures from vehicle and IL-1 treated Fgf2+/+, Fgf2+/- and Fgf2-/- mice. Cells were plated at 3x10^6 cells/well and cultured in differentiation media for 7, 14 and 21 days. Alkaline phosphatase positive (AP) colonies were 60% decreased in cultures from Fgf2-/- mice relative to Fgf2+/+ or Fgf2+/- mice. AP colony number was increased in IL-1 treated marrow cultures from all 3 genotypes at 7, 14 and 21 days. However, the absolute number of AP colonies were lower in cultures from Fgf2-/- mice. At 21 days, there was a greater increase in mineralization as determined by von-Kossa and Alizarin-red staining in bone marrow cultures from IL-1 treated mice from all 3 genotypes relative to vehicle treated mice. On Northern analysis, type1 collagen (COL1A1) and osteocalcin (OC) mRNA levels were reduced in vehicle treated cultures from Fgf2+/- and Fgf2-/- mice. However, IL-1 increased COL1A1 and OC mRNAs in all genotypes. We conclude that endogenous FGF-2 is important in IL-1 induced bone resorption in vivo. However, despite low basal levels in cultures from animals with no FGF-2 expression, IL-1 can increase colony formation and differentiation in vitro. We speculate that the different interactions between IL-1 and FGF-2 may be important in pathologic responses in bone.

F131

Molecular Cloning and Characterization of FGFR2 in Osteoblast-like Cells Derived from an Apert Syndrome Patient. Y. Tanimoto,*[1] M. Yokozeki,*[1] K. Matsumoto,[2] H. Nakanishi,*[2] K. Hiura,[1] K. Moriyama.[1] [1]Department of Orthodontics, School of Dentistry, University of Tokushima, Tokushima, Japan, [2]Section of Plastic and Reconstructive Surgery, University Hospital, University of Tokushima, Tokushima, Japan.

Apert syndrome characterized by craniosynostosis, hypertelorism, ocular proptosis and syndactyly is pathogenically associated with point mutations of fibroblast growth factor receptor (FGFR) 2 (S252W, P253R). We previously reported the high expression of osteoblastic marker genes and the acceleration of in vitro mineralization of osteoblast-like cells derived from two independent Apert syndrome patients (S252W). Between two major isoforms of FGFR2, FGFR2-IIIb and FGFR2-IIIc, that are created by alternative splicing in the third Ig-like domain (IgIII), FGFR2-IIIc is exclusively expressed and play critical roles in differentiation and function of mesenchymal cells. Therefore, in order to verify FGFR2 isoforms expressed in osteoblast-like cells derived from Apert syndrome patient (ApOB), RT-PCR was performed under appropriate informed consent by using a pair of the specific primers including the start and stop codons. It is proved from sequencing results that two clones isolated from ApOB were a complete form of FGFR2-IIIc gene with S252W mutation, and that fourteen clones were a variant of FGFR2-IIIc gene without mutation which lacked exon 3 encoding the first Ig-like domain (FGFR2-IIIcDIgI). Nine clones isolated

from osteoblast-like cells of a non-syndromic polydactyly patient (HOB) were all identified as FGFR2-IIIcDIgI without mutation. These clones contained the sequences relevant to the signal peptide, the acidic box, the second and the third Ig-like domains, the transmembrane domain, and the complete carboxyl termini. FGFR2-IIIcDIgI was expressed in ApOB and HOB in a predominant manner as compared with FGFR2-IIIc. Furthermore, FGFR2-IIIcDIgI was ubiquitously expressed in human heart, brain, placenta, lung, liver, skeletal muscle, kidney, and pancreas tissues, whereas FGFR2-IIIc expression was restricted in human liver, skeletal muscle and pancreas tissues. These results suggest FGFR2-IIIcDIgI may be the most commonly expressed variant in human osteoblasts, and may be implicated in the osteoblastic phenotype of ApOB and HOB.

Ovariectomy Induces Bone Loss by Increasing the Number of TNF Producing T cells. Y. Gao,[1] C. Roggia,[2] S. Cenci,[1] G. Toraldo,[3] M. N. Weitzmann,[1] J. Kindle,[1] R. Pacifici.[2] [1]Washington University School of Medicine, Saint Louis, MO, USA, [2]Washington University School of medicine, Saint Louis, MO, USA, [3]Washington university School of medicine, Saint Louis, MO, USA, [2]Washington University School of medicine, Saint louis, MO, USA.

It is now recognized that one of the mechanisms by which ovariectomy (OVX) induces bone loss is by increased TNF production by bone marrow T cells, but the mechanism of this phenomenon is unknown. In the present study, we utilized freshly isolated bone marrow from OVX and estrogen replete mice to investigate how estrogen regulates T cell TNF production in vivo using immunohistochemistry, flow cytometry and microarray (gene chip) analysis. Immunohistochemistry and quantitative flow cytometry analysis showed that average number of T cells (CD90 or CD3 positive cells) was 5 fold higher in OVX than in estrogen replete mice. OVX also caused a 2.5 fold increase in the total number of bone marrow cells, then the number of T cells, expressed as a percentage of total bone marrow cells, was 2 fold higher in OVX than in estrogen replete mice. Further studies revealed that OVX increased T cell numbers by stimulating T cell proliferation by 3 fold, as measured by thymidine incorporation. Double staining studies revealed that OVX increased by 2 fold the number of CD3+/TNF+ and CD90+/TNF+ cells (expressed as a percentage of total bone marrow cells), thus confirming that OVX increases the number of TNF producing T cells in bone marrow. However, the percentage of TNF producing T cells, expressed as a percentage of total T cells, was unchanged. Furthermore, the amount of TNF protein produced by individual T cells from OVX mice was identical to that produced by individual T cells from estrogen replete mice, thus demonstrating that estrogen does not upregulate TNF production per cell. Identical results were found in spleen cells, thus establishing that the regulatory effects of estrogen on cells are not confined to the bone marrow. Microarray (Affymetrix) analysis revealed equal TNF mRNA level in T cells from OVX and estrogen replete mice, a finding which confirms that estrogen does not directly regulate TNF gene expression in T cells. Together, the data demonstrate that OVX increases TNF levels in the bone marrow by increasing the number of TNF producing T cells by a mechanism involving enhanced T cell proliferation. Regulation of TNF production via modulation of the number of TNF producing cells, without changes in TNF production per cell, is a novel regulatory mechanism that contributes to explain the bone loss associated with estrogen deficiency.

Over-Expression of the Cell-Surface Isoform of Colony Stimulating Factor-1 in Osteoblasts Causes Increased Osteoclastogenesis and Bone Loss. G. Yao, J. Wu,* B. Sun, M. Mitnick, K. Insogna. Yale University, New Haven, CT, USA.

Alternative splicing of the CSF-1 gene gives rise to two protein products, soluble (sCSF-1) and cell-surface or membrane bound (mCSF-1) isoforms. Both isoforms are expressed by osteoblasts and osteotropic hormones regulate the expression of both. While sCSF-1 has been shown to stimulate osteoclastogenesis in vitro and in vivo, little data are available on the bioactivity of mCSF-1 in vitro and there are no in vivo data. To help clarify the role of mCSF-1 in bone, a transgenic mouse was developed in which targeted overexpression of human mCSF-1 in osteoblasts was achieved under the control of the 2.4 kb rat alpha I collagen promoter. A tissue survey by Northern analysis demonstrated overexpression of mCSF-1 in bone with no expression in lung, heart, skin, spleen, liver and kidney. Cultured calvarial osteoblasts from transgenic but not wild-type mice produced human CSF-1. Human mCSF-1 was also detected in purified calvarial osteoblast membranes from transgenic mice but not wild-type mice. Bone density determined by pQCT in 33 femurs from transgenic mice was compared to findings in 33 femurs from wild-type animals. Overall bone density was reduced by 8% in the transgenic mice as compared to wild type animals. When analyzed by sex, females were found to have 3-fold greater bone loss than males (-12% vs. -4%, $p < 0.05$). Histomorphometric analysis indicated the numbers of osteoclasts in bone (NOc/BPm, NOc/TAR, OcS/BS) was significantly increased in transgenic mice (1.8-2.0 fold, $p < 0.01$ for each) compared to wild-type animals. Osteoblast number and bone formation rate were no different in the two groups of animals. These data indicate that over-expression of mCSF-1 in osteoblasts increases bone resorption and are consistent with the hypothesis that this isoform plays a role in physiologic and perhaps pathologic states bone remodeling. Further, the female skeleton appears to be more sensitive to over-expression of mCSF-1. Since mCSF-1 has been reported to be selectively upregulated following estrogen withdrawal, this isoform may be a potential target for drug discovery.

F137

Toll-like Receptor 4 (TLR4) Is Essential for LPS-induced, mPGES-mediated PGE Production by Osteoblasts and Inflammatory Bone Loss. C. Miyaura, T. Ohshiba,* C. Matsumoto,* S. Harada,* A. Ito.* Biochemistry, Tokyo University of Pharmacy and Life Science, Tokyo, Japan.

Toll-like receptors (TLR) are a family of mammalian proteins homologous to Drosophila Toll, and play important roles in the host defense against pathogens. Recently, TLR2 and TLR4 have been shown to be involved in LPS signaling. Bacterial infection causes bone resorption in inflammatory bone disorders including periodontitis, but the role of TLR signaling in bone metabolism is not known. PGE is a typical mediator for inflammation, but the relationship between PGE and TLR-signaling is not known. In this study, we investigated which TLR mediate LPS action in inflammatory bone loss and in PGE production by osteoblasts in vitro and in vivo. LPS induced osteoclast formation in co-cultures of bone marrow cells and osteoblasts collected from C3H/HeN (control) mice. In this culture, PGE2 production was markedly elevated by LPS, and indomethasin completely suppressed osteoclast formation, which suggests that LPS induces osteoclast formation mediated by PGE2. When cells were collected from C3H/HeJ mice that contain a nonfunctional mutation in the TLR4 gene, neither osteoclast formation nor PGE2 production were observed in the co-cultures. Osteoblasts expressed both TLR2 and TLR4 mRNAs in northern blot, and the level of TLR4 mRNA was higher than that of TLR2. LPS markedly induced the expression of COX-2 and membrane PGE synthase (mPGES) mRNAs, and PGE2 production by osteoblasts collected from C3H/HeN mice, but not from C3H/HeJ mice. In vivo, mice were injected with LPS, and we measured the level of PGE2 in bone marrow fluid and femoral bone mineral density (BMD). In C3H/HeN mice, the level of PGE2 in bone marrow fluid was markedly elevated, and BMD was reduced by LPS administration due to the loss of cancellous bone by increased osteoclastic bone resorption. In contrast, LPS induced no PGE2 production and impaired bone loss in C3H/HeJ mice with the mutated TLR4 gene. Thus, LPS acts on osteoblasts to induce COX-2- and mPGES-mediated PGE synthesis via TLR4, and the TLR4-mediated osteoclast formation may contribute to the pathogenesis of bone disorders associated with inflammation.

F140

IL-10 GeneTherapy Inhibits Inflammatory Bone Resorption. E. E. Carmody,* J. E. Puzas, R. N. Rosier, R. J. O'Keefe, E. M. Schwarz. Center for Musculoskeletal Research, University of Rochester, Rochester, NY, USA.

Osteolysis frequently occurs following total joint arthroplasty and results in failure in up to 20% of prostheses. Osteolysis is associated with the generation of microscopic debris particles, leading to localized inflammation and osteoclast activation. This study investigates the ability of adenoviral vIL-10 gene therapy to block these events both in vitro and in vivo. Fibroblasts infected with adenoviruses expressing either vIL-10 or LacZ were cultured on transwell membranes and added to ANA-1 macrophage cultures stimulated with titanium particles. In the presence of LacZ infected fibroblasts, titanium stimulated macrophages exhibited a marked increase in TNFa (6.5-fold), IL-6 (13-fold), and IL-1 (5-fold) secretion. Co-culture with vIL-10 infected fibroblasts supressed cytokine secretion to basal levels, while addition of an IL-10 neutralizing antibody completely blocked this effect. Partial inhibition of cytokine secretion ocurred when vIL-10 infected fibroblasts were added after 12 or 24 hours, demonstrating the ability of vIL-10 to inhibit an established inflammatory response to particles. Osteoclastogenesis was assessed in murine splenocyte cultures treated with RANKL and mCSF in the presence of fibroblast co-cultures. A 10-fold decrease in the number of TRAP+, multinucleated cells was observed in cultures containing Ad-vIL-10 infected fibroblasts. Addition of an IL-10 neutralizing antibody to these cultures resulted in complete recovery in osteoclastogenesis to levels observed in cultures containing Ad-LacZ infected fibroblasts (900 TRAP+ cells/well). These findings indicate that viral IL-10 directly inhibits the ability of osteoclast precursors to undergo differentiation in response to mCSF/RANKL. The effect of viral IL-10 on osteoclastogenesis and bone resorption in vivo was examined using a well established mouse calvaria model of particle induced osteolysis that measures osteoclasts and bone resorption. In control animals, titanium implantation resulted in a 66% increase in osteoclasts ($p<0.05$) and a 55% increase in sagittal suture area ($p<0.05$). The increase over control levels was completely blocked in mice receiving IP injection of Ad-vIL-10, all of whom had measurable serum vIL-10 levels for the duration of the experiment. These findings demonstrate that vIL-10 inhibits both cytokine secretion and osteoclastogenesis in vitro, the two critical events involved in inflammatory bone resorption. Consistent with these findings, Ad-vIL-10 gene therapy completely inhibited particle induced bone resorption in vivo, defining IL-10 as a potential therapeutic candidate for the treatment of this disease.

F142

Suppression of IGF Signaling Propagation and NF-kB Activation Reduces Bone Metastases in Breast Cancer. T. Hiraga,[1] A. Myoui,[2] P. J. Williams,*[3] G. R. Mundy,[3] T. Yoneda.[3] [1]Dept. Biochemistry, Osaka Univ., Osaka, Japan, [2]Dept. Orthopedics, Osaka Univ., Osaka, Japan, [3]Div. Endocrinology, Univ. TX. Hlth. Sci. Ctr., San Antonio, TX, USA.

Bone abundantly stores growth factors including IGFs and TGF-beta (TGFb). Previous data have demonstrated the blockage of TGFb signaling activation in breast cancer cells inhibits bone metastases, suggesting that the bone-derived TGFb modulates behavior of metastatic breast cancer cells in bone. On the other hand, the effects of the bone-derived IGFs, which are more abundant than TGFb, on bone metastasis in breast cancer still remains unclear. To study this, the MDA-MB-231 human breast cancer cells (MDA-231 cells) were stably transfected with a dominant-negative IGF type-I receptors (MDA-231/IGFIR-486STOP) and examined for the capacity to develop bone metastases following heart inoculation in female nude mice. MDA-231/IGFIR-486STOP exhibited impaired propagation of IGF signaling pathways including IGFIR, IRS-1, PI-3 kinase and AKT/PKB in response to IGF-1. Radiographic and histomorphometric examination showed bone metastases were markedly reduced in MDA-231/IGFIR-486STOP compared with empty vector-transfected MDA-231 cells (MDA-231/EV). In vitro growth and tumorige-

nicity in orthotopic site were not different between MDA-231/IGFIR-486STOP and MDA-231/EV. Since AKT/PKB has been shown to activate the transcription factor NF-kB and NF-kB has been implicated in the malignant behavior of breast cancer, the status of NF-kB activation was next examined in MDA-231 cells overexpressing wild-type IGFIR (MDA-231/IGFIR). We found IGF signaling pathways and NF-kB activation was up-regulated in these cells. Moreover, MDA-231/IGFIR showed increased bone metastases. To further study the role of NF-kB in bone metastasis, MDA-231 cells were stably transfected with a N-terminus-truncated dominant-negative IkB-alpha (MDA-231/IkB-alphaDN) and examined for the capacity to develop bone metastases. As expected, MDA-231/IkB-alphaDN exhibited decreased bone metastases. In addition, consistent with the notion that NF-kB is anti-apoptotic, apoptosis in MDA-231/IkB-alphaDN in bone metastases was significantly increased. There was no change in the production of PTH-rP, a cytokine which plays a central role in bone metastasis, in MDA-231/IkB-alphaDN compared with MDA-231/EV. In conclusion, our results suggest that bone-derived IGFs reduce apoptosis in breast cancer cells through activation of IGF signaling pathways, AKT/PKB and NF-kB, thereby stimulating bone metastases. The results also suggest that IGF signaling molecules and NF-kB are potential targets in design of pharmacological interventions for bone metastasis in breast cancer.

F144

Insulin-like Growth Factor Binding Protein (IGFBP)-5 Overexpression Decreases Bone Formation in vivo. R. D. Devlin,[1] Z. Du,[1] V. Jorgetti,[2] E. Canalis.[1] [1]Saint Francis Hospital and Medical Center, Hartford, CT, USA, [2]Universidade de Sao Paulo, Sao Paulo, Brazil.

IGFBP-5 is unique among the six IGFBPs synthesized by skeletal cells. IGFBP-5 has been considered to be anabolic, since it enhances bone cell growth in vitro and biochemical markers of osteoblastic function in vivo. However, the true role of IGFBP-5 in bone formation and bone resorption in vivo is not known. To determine in a definitive manner the function of IGFBP-5 in bone, we created transgenic mouse lines overexpressing IGFBP-5 under the control of the osteocalcin promoter so that IGFBP-5 would be expressed in the bone microenvironment. A transgenic line carrying approximately 8 copies of the transgene was analyzed at 4, 8, 12 and 26 weeks of age using contact X-ray radiography, total bone mineral density (BMD) using a GE/Lunar Piximus densitometer, and static and dynamic bone histomorphometry. Transgenic mice were compared to age-matched control wild type mice. At 4 weeks of age, transgenic IGFBP-5 mice had a BMD that was 12% lower than age-matched controls, although X-ray analysis did not reveal the presence of severe osteopenia or fractures. Histomorphometric analysis revealed a 30% reduction in trabecular bone volume in the femurs of IGFBP-5 transgenic when compared to wild type mice. This decrease was due to a marked reduction in trabecular thickness. Although the number of osteoblasts in IGFBP-5 transgenic mice was normal, bone formation rate was 30% lower than in wild type mice, as determined by double calcein labeling, indicating impaired osteoblastic function. Osteoclast number and bone resorption were not altered in transgenic IGFBP-5 mice. To confirm skeletal overexpression of IGFBP-5 and to characterize changes in gene expression associated with this condition, Northern blot analysis was performed on RNA extracted from calvariae and femurs of 4-week-old transgenic and control mice. IGFBP-5 mRNA levels were 30 fold higher in transgenic than in control mice, confirming overexpression of IGFBP-5 in bone. Alkaline phosphatase mRNA levels in IGFBP-5 transgenic mice were decreased by over 50%, confirming impaired osteoblastic function. To further investigate this role of IGFBP-5, stromal cells from 7-week-old IGFBP-5 transgenic and control mice were cultured. Stromal cell cultures from transgenic mice displayed reduced differentiated function, confirming the in vivo observation. In conclusion, in contrast to prior knowledge, IGFBP-5 in excess inhibits the function of the osteoblast in vivo and in vitro. These inhibitory effects are opposite to those observed in transgenic mice overexpressing IGF I, suggesting that IGFBP-5 decreases bone formation by binding IGFs in the bone microenvironment.

F147

Human *Seven in Absentia* Homologues Regulate TGFβ Inducible Early Gene (TIEG) Stability and Function Through the Ubiquitin-Proteasome Pathway. S. A. Johnsen,* M. Subramaniam, R. Janknecht,* T. C. Spelsberg. Biochemistry & Molecular Biology, Mayo Clinic & Foundation, Rochester, MN, USA.

Transforming growth factor β (TGFb) is an important pleiotropic growth factor for skeletal development and osteoblast (OB) differentiation. The TGFβ inducible early gene (TIEG) was identified in our laboratory as an early downstream component of TGFβ signaling in osteoblasts. We have previously demonstrated that overexpression of TIEG mimics TGFβ action by increasing markers of OB differentiation in MG-63 osteosarcoma cells. More recently we have shown that TIEG functions to enhance TGFβ action by repressing the promoter of the TGFβ/Smad signaling inhibitor Smad7. In order to further understand the regulation of TIEG protein we utilized the yeast two-hybrid system and identified SIAH 1 and 2 as TIEG interacting proteins. Interestingly, *seven in absentia*, the *Drosophila* homologue of SIAH 1 and 2, acts downstream of the receptor tyrosine kinase, *Sevenless*, and serves to relieve repression of specific developmental genes involved in photoreceptor differentiation by targeting a transcriptional repressor for degradation by the ubiquitin-proteasome pathway. In an analogous manner, we show that co-expression of SIAH 1 or 2 with TIEG in mouse OB (MC3T3-E1) cells results in degradation of TIEG through the ubiquitin-proteasome pathway. Using western blot and immunofluorescence localization, we provide evidence that degradation of TIEG by the SIAH proteins requires nuclear localization and the amino terminal region of TIEG which interacts with SIAH1/2. The functional significance of the SIAH-mediated degradation of TIEG was demonstrated by the co-expression of SIAH1/2 along with TIEG completely reversing the repression of Smad7 promoter activity that is induced by overexpression of TIEG alone. These findings suggest a novel mechanism whereby the effects of TGFβ on OB differentiation may be regulated by proteasomal degradation of the downstream transcriptional repressor TIEG. In this manner, turnover of downstream effectors such as TIEG could serve to limit the duration and/or magnitude of TGFβ responses.

F149

TGFb Stimulates Osteoclast Resorption and Bone Formation Through Different Cells in the Osteoblast Lineage. Z. Mi,*[1] B. Oyajobi,[1] E. Filvaroff,*[2] S. Harris,[1] G. Mundy,[1] D. Chen.[1] [1]Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, [2]Endocrinology, Genentech, San Francisco, CA, USA.

Transforming growth factor b (TGFb) has complex effects on bone resorption. From in vitro studies, these effects appear to be mediated by cells in the osteoblast lineage. To determine the cell target for effects of TGFb on osteoclasts in vivo, we examined its effects in transgenic (tg) mice which overexpress a truncated dominant-negative type II TGFb receptor under the control of the osteocalcin promoter, which is expressed late in the osteoblast lineage. In these tg mice, osteoclast numbers were decreased significantly [103 ± 24 OC/mm in wild-type (wt) and 67 ± 14 OC/mm in tg]. Bone mineral densities were increased compared with the wt littermates (0.061 ± 0.003 mg/cm2 in wt and 0.071 ± 0.003 mg/cm2 in tg). Subcutaneous injection of TGFb (125 ug/kg/day, x5d) over the calvariae of one month old tg mice and wt littermates induced new bone formation, although less new bone was formed in the tg mice compared with their wt littermates (new bone width: 0.37 ± 0.05 mm in wt and 0.26 ± 0.04 mm in tg+/-). The formation of the bone marrow cavity in calvarial bones was enhanced by TGFb in wt mice but not in tg mice. These results suggest that osteoclast formation was inhibited in the tg mice and the target cells for effects of TGFb on bone formation are osteoblasts at an early differentiation stage that are not expressing osteocalcin. To further determine the role of osteoblasts in TGFb-induced osteoclast formation, we isolated osteoblasts from the calvariae of wt and tg mice and co-cultured these cells with spleen cells from wt mice in the presence of 10 nM 1,25-dihydroxy vitamin D3. We found that the osteoblasts isolated from tg mice but not from wt mice failed to support osteoclast formation even in the presence of 1,25-dihydroxy vitamin D3 (65 ± 15 MNCs/well in wt, 10 ± 5 MNCs/well in tg). To determine the downstream genes affected by the impairment of TGFb signaling, we examined mRNA expression of RANK ligand and OPG in osteoblasts from these mice using RT-PCR. Although RANK ligand was expressed at similar levels in both wt and tg mice, OPG expression in osteoblasts was significantly increased in the tg mice compared with their wt littermates. These findings demonstrate that TGFb stimulates osteocalcin-expressing (late stage) osteoblasts to activate osteoclast formation, but induces bone formation through non-osteocalcin-expressing osteoblasts earlier in the osteoblast lineage. It also demonstrates that TGFb is a critical mediator of osteoblast-mediated osteoclastic bone resorption in the basal state, since mice with unresponsive osteoblasts formed less normal osteoclasts or marrow cavities.

F151

α-Melanocyte Stimulating Hormone (α-MSH) - A Novel Factor Affecting Bone Turnover. J. Cornish,*[1] K. E. Callon,[1] K. G. Mountjoy,*[2] C. Lin,*[1] U. Bava,*[1] J. Lin,*[1] I. R. Reid.[1] [1]Department of Medicine, University of Auckland, Auckland, New Zealand, [2]Department of Paediatrics, University of Auckland, Auckland, New Zealand.

Recent evidence suggests that various neuropeptides that influence energy expenditure and body weight, in particular fat mass, also regulate bone mass. Fat mass is one of the principal determinants of bone density but the mechanism underlying this relationship remains controversial. The importance of central melanocortin pathways has been highlighted recently in genetic studies in obese humans and mice. Disruption of either the pro-opiomelanocortin (POMC) gene or the melanocortin-4 receptor (MC4-R) in mice and humans, as well as over-expression of agouti protein, which antagonises MC4-R, all result in obesity. MC4-R deficient human subjects have a marked increase in bone mineral density. The endogenous ligand most probably involved in the control of body weight is α-MSH which binds with high affinity to MC4-R. In addition, the peripheral administration of an α-MSH agonist to POMC knockout mice led to a substantial weight loss in the mutant animals as compared to the wild-type litter mates. Thus, there are data to suggest that peripheral actions of melanocortins, along with central pathways of action, are involved in controlling weight. Melanocortins circulate in the periphery and the receptors are found in peripheral tissues. Whether they act directly on bone is unknown but we have recently isolated MC4-R in primary rat osteoblasts and in the UMR106 osteoblast cell line, so this is a possibility. In the current study, we have investigated the effects of α-MSH on bone cells in vitro and in vivo.In primary cultures of fetal rat osteoblasts, α-MSH dose-dependently stimulated proliferation from nanomolar concentrations and greater. Similarly, α-MSH ($>10^{-10}$M) increased proliferation of cultures of canine chrondrocytes. In mouse bone marrow cultures, α-MSH ($>10^{-9}$M) stimulated osteoclastogenesis, but it had no effect on bone resorption in 2 assays using mature osteoclasts. Systemic administration of α-MSH to male adult mice (20 injections of 4.5 μg/day over 4 weeks) decreased the trabecular bone volume in the proximal tibiae (from 19.5 ± 1.8% to 15.2 ± 1.4%, p=0.03) and reduced trabecular number (p=0.001).It is concluded that there are direct effects of α-MSH on bone that tend to increase bone turnover, and that when α-MSH is administered systemically this leads to decreased bone volume. These results could explain the higher bone density measurements seen in subjects affected by mutations of the MC4-R gene. This data also suggests that α-MSH may have central and peripheral actions in regulating fat mass and bone density.

Mechanical Strain Increases Nitric Oxide Production in Murine Stromal Cell Culture. X. Fan, T. C. Murphy,* L. Zhu,* M. S. Nanes, W. R. Taylor,* J. Rubin. Department of Medicine, Emory University Medical School/VAMC, Atlanta, GA, USA.

Mechanical loading is an important regulator of skeletal mass and architecture. We have reported previously that mechanical strain decreased 1,25D stimulated osteoclast recruitment, and that this effect was due to down-regulation of receptor activator of NF-kappa B ligand (RANKL) expression. However, the mechanisms by which these adaptive responses are initiated and subsequently coordinated are unclear. Many reports have shown that nitric

oxide (NO) has a role in bone remodeling and that mechanically induced bone formation may require NO production. We have recently shown that NO inhibits RANKL expression. This suggested that the mechanism whereby mechanical strain decreases RANKL expression might involve NO. To investigate this hypothesis, primary bone marrow stromal cells from C57BL/6 mouse tibia and femurs were cultured on collagen-coated 6-well Bioflex plates. On day 6, media were replaced with phenol-red free α-MEM containing 2% FBS and strained at 1.8%, 10 cpm using Bioflex loading station for specified periods. NO was measured in the culture medium using 2,3-Diaminonaphthalene (DAN) to assess nitrite. NO production was significantly increased two-fold after 24 hours of strain application (nitrite in control was 32.8 ± 9 μM). There were no changes in NO production in cells strained ≤ 8 hrs compared to the control group. N_{ω}-nitro-$_L$-arginine methyl ester (L-NAME) at 500 μM, a nitric oxide synthase (NOS) inhibitor, blocked the strain induction of NO. The time required for strain to increase NO levels suggested that NOS protein level rather than activity might be mechanically regulated. Western blots showed that NOS type III (eNOS) expression increased at least three-fold in stromal cells after 24 hrs strain. The mechanical induction of eNOS protein was reflected in a similar increase in eNOS mRNA as assessed by RT-PCR. Our results suggest that increases in NO production by mechanical strain arise through stimulation of eNOS synthesis. These findings raise the interesting possibility that mechanical strain inhibits bone resorption through increasing NO production with a subsequent regulation of RANKL expression.

F156

Integrins and Src kinases Clustered in Caveolae Are Essential Components of the Signalsome that Mediates Mechanically Induced ERK Activation in Osteocytes. I. Mathov, J. Davis,* L. I. Plotkin, S. C. Manolagas, T. Bellido. Endo/Metab. Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. of Arkansas for Medical Sciences, Little Rock, AR, USA.

Osteocytes are key components of the sensory apparatus by which bone responds to mechanical stimuli. Similar to systemic factors, mechanical stimulation prevents osteocyte apoptosis and activates the extracellular signal regulated kinases (ERKs). ERK activation by mechanical signals involves the actin and tubulin cytoskeletons, and integrins connect the extracellular matrix with cytoskeletal and catalytic proteins. Therefore, we examined whether integrins take part in ERK activation induced by mechanical stimulation. MLO-Y4 osteocytic cells were plated on flexible-bottom wells coated with different substrates and subjected to biaxial stretching using a BioFlex Loading Station. Cells plated on collagen-I responded to stretching by a 2-3 fold increase in ERK phosphorylation, whereas stretching did not induce ERK activation in cells plated on the non-integrin-dependent substrate poly-L-Lys at any time or strain tested. On the other hand, ERK activation in response to serum or EGF was similar in cells plated on either substrate, indicating that integrins are specifically required for mechanically induced ERK activation. We next examined the effect of engagement of particular integrins using activating anti-integrin antibodies. Whereas stretching had no effect in cells plated on non-immune IgG or anti-β2 antibody, it did induce ERK activation in cells plated on anti-β1, or anti-α5, or anti-α2 antibodies. Moreover, stretching-induced ERK activation in cells plated on anti-β1 antibody in combination with either anti-α5 or anti-α2 antibodies was greater than in cells plated on each antibody separately. These results are consistent with the expression of integrin β1 in osteocytes in vivo and suggest that α2β1 (which binds collagen-I) and α5β1 (which binds fibronectin) are involved in osteocyte response to mechanical stimuli. Integrin β1 and signaling molecules that participate in the ERK pathway, such as Src, cluster in caveolae - plasma membrane domains rich in cholesterol and the protein caveolin; and caveolin may facilitate integrin clustering. Consistent with this, cyclodextrin - an agent that disrupts caveolae by sequestering cholesterol - or the specific inhibitor of Src kinases PP1, abolished stretching-induced ERK phosphorylation. These findings suggest that integrins clustered in caveolae transduce mechanical signals into ERK activation by activating Src kinases in osteocytic cells.

F157

Fluid Shear Stress Inhibits TNF-α-Induced Apoptosis in MC3T3-E1 Osteoblasts. F. M. Pavalko,[1] P. J. Gallagher,*[2] R. L. Gerard,*[2] S. M. Ponik,*[2] Y. Jin,*[2] S. M. Norvell.*[2] [1]Cellular and Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Indiana University School of Medicine, Indianapolis, IN, USA.

Mechanical loading of bone plays an important role in bone remodeling. Osteoblasts and osteocytes respond to the load-generated flow of interstitial fluid through the spaces inside bone by altering their biochemical and anabolic activities, however the mechanisms of this response are poorly understood. Increased growth and survival of osteoblasts subjected to fluid flow-induced shear stress may promote bone formation. A large proportion of bone-forming osteoblasts normally undergo programmed cell death (apoptosis) and we hypothesize that the absence of loading may further promote this process. We investigated the cellular mechanisms of load-induced bone remodeling by treating MC3T3-E1 osteoblasts with 1-50 ng/ml TNF-α in the presence of 10 μM cyclohexamide (CHX) for up to 4 hours to induce apoptosis and studied the effects of steady fluid shear stress on cell survival using a parallel plate flow chamber. We found that TNF-α/CHX treatment of cells in static culture conditions caused membrane blebbing characteristic of apoptosis and induced a dose dependent activation of caspases resulting in degradation of poly-(ADP ribose)-polymerase (PARP), the cell-cell adhesion molecule N-cadherin, and the cytoskeletal linker/signaling protein, β-catenin. In cells treated with 5 or 10 ng/ml TNF-α/CHX and subjected to fluid shear stress (12 dynes/cm^2), membrane blebbing was reduced and cleavage of PARP, N-cadherin and β-catenin were significantly inhibited compared to cells treated with TNF-α/CHX and maintained in static culture. Fluid shear stress also induces release of prostaglandin E2 (PGE_2) from MC3T3-E1 cells and causes upregulation of cyclooxygenase-2 (COX-2). Furthermore, in many cell types, inhibition of COX-2 blocks shear-induced PGE_2 release and promotes apoptosis suggesting that PGE_2 and COX-2 may contribute to shear-induced osteoblast survival. To test this hypothesis, MC3T3-E1 osteoblasts maintained in static culture were treated with 5 ng/ml TNF-α/CHX in the presence or absence of 10 μM PGE_2. Just as fluid shear stress inhibited apoptosis, the addition of PGE_2 to the cells in static culture inhibited TNF-α/CHX-induced membrane blebbing and cleavage of PARP, N-cadherin and β-catenin. These results suggest that fluid shear stress may enhance bone formation by inhibiting apoptosis and promote the survival of osteoblasts through a mechanism involving PGE_2 autocrine/paracrine signaling.

Activation of a Ca/ERK/Delta-fosB(AP-1) Cascade by Mechanical Stress in Osteoblasts, Leading to Up-regulation of an Osteogenic Cytokine, Interleukin (IL)-11. S. Kido, D. Inoue, E. Tohjima, S. Kato,* T. Matsumoto. First Department of Internal Medicine, University of Tokushima School of Medicine, Tokushima, Japan.

Mechanical stress to bone plays a critical role in maintaining bone mass and strength. Unloading such as immobilization and space flight results in rapid bone loss mainly due to impaired bone formation. However, the molecular mechanism of mechanical stress-induced bone formation remains to be fully elucidated. We have shown that delta-fosB, a fosB splicing variant which is known to stimulate bone formation in vivo, is rapidly induced by reloading in tail-suspended mouse bone as well as by fluid shear stress (FSS) in primary osteoblast (POB) cultures. As a candidate for AP-1 targets induced by mechanical stress, we identified an anti-adipogenic cytokine, IL-11, which has been shown to prevent aging-related bone loss by stimulating bone formation in transgenic mice. We have also reported that IL-11 transcription is totally dependent on AP-1 and that impaired bone formation in the aged is associated with reduction in activities of AP-1, particularly Jun D, and IL-11 expression in marrow stromal cells. In order to further delineate the mechanical stress-induced signaling pathways, we investigated the mechanism of AP-1/IL-11 induction by FSS in POB. The results indicated that induction of delta-fosB and IL-11 was completely blocked by gadolinium, an intracellular Ca chelator BAPTA, or an ERK1/2 inhibitor U0126, but not by a L-type Ca-channel blocker nifedipine, or a p38 kinase inhibitor SB203580. Conversely, a Ca ionophore A23187 activated ERK1/2 within 15 min and induced delta-fosB/IL-11 expression. We also demonstrated that intermittent FSS reduced stromal cell differentiation into adipocytes induced by troglitazone or indomethacine to less than 50%, consistent with the biological effects of IL-11. Surprisingly, FSS also induced Smad1 phosphorylation within 15 min in POB in an ERK-independent manner. Co-immunoprecipitation experiments revealed induction of a complex of endogenous Delta-FosB and Jun D by 3 hour FSS in POB, and association of over-expressed Delta-FosB/Jun D and Flag-Smad1 in Cos-7 cells. Moreover, EMSA using the IL-11 AP-1 site as a probe showed the presence of over-expressed Flag-Smad in the AP-1 complex only when delta-fosB was over-expressed. These results suggest a critical role of a Ca/ERK/AP-1/IL-11 cascade in mechanical stress-induced bone formation, and further imply participation of Smad in this signaling pathway. We propose that the mechanical stress-induced delta-FosB/Jun D complex may recruit and utilize Smad as a co-factor to efficiently induce IL-11 transcription, thereby stimulating bone formation.

F161

Fluid Flow Shear Strain Activates Multiple Pathways on Human Osteoblast Proliferation and Competing Pathways on Human Osteoblast Differentiation. S. Kapur,* D. J. Baylink, K. H. W. Lau. J. L. Pettis Memorial VAMC, Loma Linda, CA, USA.

Mechanical strain stimulates osteoblast proliferation and differentiation through multiple signaling pathways. This study sought to assess the role of several pathways in the fluid shear flow-induced proliferation and differentiation of human bone cells. In this regard, we confirmed that a 30-min fluid flow strain produced by the Cytodyne Flow Chamber at 20 dyne/cm^2 increased the proliferation ([^{3}H]thymidine incorporation) (2.3-fold, $P<0.01$) and alkaline phosphatase (ALP) activity (an index of differentiation) (1.6-fold, $P<0.05$) in human osteoblasts. This fluid flow also increased tyrosine phosphorylation of ERK1 and ERK2 (by 3-fold each, $P<0.001$) and expression of integrin b1 (by 1.5-fold, $P<0.001$). We then evaluated if specific inhibitor of the Gi pathway (PTX), the MAPK pathway (PD 98059), the NOS pathway (L-NAME), and the PGE_2 pathway (indomethacin) would inhibit the flow-induced proliferation and differentiation of normal human bone cells. The MAPK pathway inhibitor, PD98059, completely blocked the fluid flow-induced increases in ERK phosphorylation, [^{3}H]thymidine incorporation, and ALP activity ($P<0.001$ for each). Similarly, L-NAME and indomethacin each blocked ($P<0.001$) the fluid flow-induced increases in ERK phosphorylation, [^{3}H]thymidine incorporation and ALP activity, confirming that the MAPK, NOS, and PGE_2 pathways are essential for the flow-induced bone cell proliferation and differentiation. However, none of these three inhibitors had no effect on integrin β1 expression, suggesting that the integrin b1 expression is not essential for bone cell proliferation and differentiation. While PTX completely blocked the flow-induced increase in integrin β1 expression, this inhibitor had no effect on the flow-induced increase in the phosphorylation levels of ERK or in [^{3}H]thymidine incorporation. More intriguingly, PTX not only did not inhibit but also significantly enhanced ($P<0.05$, ANOVA) the stimulatory effect of fluid flow on ALP activity in human bone cells, suggesting that the PTX-sensitive G protein pathway may have an inhibitory role in osteoblast differentiation. In summary, we show that fluid flow shear strain activates multiple signaling pathways to stimulate human bone cell proliferation and that one of these signaling pathways (e.g., the PTX-sensitive G protein pathway) has completing effects with an unknown pathway on human bone cell differentiation.

F163

IGF-1 and Mechanical Loading Synergistically Enhance Bone Formation. T. S. Gross,*[1] T. L. Clemens,[2] S. Srinivasan.[1] [1]Orthopaedics and Sports Medicine, University of Washington, Seattle, USA, [2]Medicine, University of Cincinnati, Cincinnati, OH, USA.

IGF-1 and mechanical loading are both potential anabolic stimulants of bone formation. We hypothesized that low levels of either stimulus alone would not be sufficient to induce bone formation, but if the two stimuli were coupled bone formation would be synergisti-

cally induced. To examine this hypothesis, we used a recently developed non-invasive device to load the right tibia of transgenic mice selectively over-expressing IGF-1 in osteoblasts (18 wk of age). The wild type (FVB/N background, n=3) and over-expressing mice (n=3) underwent a brief 5 d low magnitude loading protocol (100 cycles per day, 1 Hz sawtooth waveform, 650 με peak strain). The mice freely ambulated within their cages during non-loading periods. Following the 5 d of external loading, the mice were allowed an additional 3 wk of free cage ambulation to facilitate consolidation of osteoblastic activation. Calcein (10 mg/kg, IP) was injected 1 d prior to the protocol and 1 d prior to sacrifice. Single labeled surface, double labeled surface, and interlabel widths were assessed to determine bone formation rate (surface referent) on the endocortical and periosteal surfaces. Wild type and IGF-1 over-expressing mice both demonstrated negligible periosteal bone formation at the mid-diaphysis of the contralateral tibia (0 and 0.0061 ± 0.0061 $\mu m^3/\mu m^2$/d, respectively). Low magnitude loading (inducing strains equivalent to walking) of the wild type mice did not induce periosteal bone formation. In contrast, the IGF-1 over-expressing mice demonstrated a sustained adaptive response to the same low magnitude loading, with periosteal bone formation rate elevated 5-fold versus contralateral bones (.032 ± .024 $\mu m^3/\mu m^2$/d). In this study, neither low magnitude mechanical loading or IGF-1 over-expression alone was sufficient to induce more than negligible bone formation. However, when the same two stimuli were combined, sustained bone formation was induced. One advantage of our approach over one in which locomotion is superimposed upon systemically administered factors (e.g., PTH) is that the synergism we sought to observe was confined to the tissue under examination and was not confounded by systemic influences. Our data highlight the potential for physiologic magnitude loading to diminish the dosage of drugs required to induce bone formation, which should lead to enhanced efficacy and reduced side effects.

F165

Longitudinal Survey of Trabecular Bone Architecture Deterioration in the Hindlimb Unloaded Female Rat Model Using 3D Micro-Computed Tomography. V. N. David,[*1] R. De Vittoris,[*1] A. Laib,[*2] B. Koller,[*2] S. Haemmerle,[*2] M. Lafage-Proust,[1] C. Alexandre,[1] P. Ruegsegger,[3] L. Vico.[1] [1]LBBTO, INSERM E9901, Saint-Etienne, France, [2]Scanco Medical, Bassersdorf, Switzerland, [3]IBT, Zurich, Switzerland.

Bone mass and microarchitecture are the main determinants of bone strength. Three-dimensional micro-computed tomography (3DμCT) has the potential to examine, in vivo, bones of small laboratory animals with high resolution in a non-invasive way. In this work, the proximal part of the tibiae of hindlimb unloaded (HU) and control (CTR) female rats (12 week-old, 250 ± 10g body weight) were measured with 3DμCT, and the secondary spongiosa of the scanned region was evaluated using direct evaluation techniques that do not require model assumptions. Kinetics of trabecular bone alterations and linear x-ray attenuation coefficient (likened to apparent bone mineral density) was analyzed at three time points during a 14-day tail suspension period.

PERIOD	BV/TV (%)	LIN ATT	TB.N (/mm)	Connectivity Density (/mm^3)
HU baseline	26.7 ± 6.3	1.011 ± 0.061	4.46 ± 0.40	45.4 ± 10.8
HU 1-wk	24.8 ± 7.3 *	0.989 ± 0.079 *	4.20 ± 0.60 *	38.9 ± 14.5 *
HU 2-wk	23.7 ± 7.6**	0.977 ± 0.081 *	4.17 ± 0.58 *	34.5 ± 12.1 **
CTR baseline	26.7 ± 8.8	1.005 ± 0.089	4.40 ± 0.66	44.8 ± 15.5
CTR 1-wk	28.2 ± 10.9	1.019 ± 0.103	4.50 ± 0.67	46.7 ± 14.1
CTR 2-wk	29.0 ± 10.1	1.028 ± 0.096	4.54 ± 0.67	48.7 ± 15.8

$p<0.05$ * vs HU baseline, ** vs HU 1-wk. N=10 per group

In HU animals, "individual" bone loss assessed either by BV/TV or LIN ATT (Linear Attenuation) was significant after a 1-wk period and plateaued at 2 weeks. It was associated to fewer trabeculae that were less connected while the trabecular thickness was not altered. When we compared HU and CTR rats, "group" bone loss was significant only after the second week of suspension. Furthermore, the trabecular structure type in HU rats became more rod-like (assessed by structure model index) and anisotropic than in CTR rats. We concluded that in vivo 3DμCT is a powerful tool allowing longitudinal survey. We showed that longitudinal comparisons have more discriminant power than transversal ones when the groups still greatly overlap.

F167

Pre-osteoblast Proliferation Following in vivo Mechanical Loading. S. J. Tanner,[1] J. A. Yee,[1] D. M. Cullen.[2] [1]Biomedical Sciences, Creighton University, Omaha, NE, USA, [2]Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

The appearance of osteoblasts following a brief bout of mechanical loading has been documented, but the proliferation of osteoblast precursors in the cellular periosteum has not yet been investigated. In this study, a single bending load (36 cycles, 2Hz, 2000 μstrain) was applied to the right tibia of adult female rats (351±20g) and the time course of periosteal pre-osteoblast (pOB) proliferation was examined. A single injection of bromodeoxyuridine (40mg/kg) was administered 1 hour prior to collection times at 12, 24, 30, 36, 42, 48, 60, and 72h post-load. Endpoints included surface type (osteoblast, flat cell, or unmeasurable), and pOB labeling index (LI, labeled/total *100). A cell was counted as a pOB if it: 1) resided within the cellular periosteal layer; 2) was not directly upon the bone surface; and 3) had a single round, ovoid, or elongated ovoid nucleus. Differences were tested by ANOVA and are reported as means (SD), $P<0.05$.

Endpoint	Leg	12h	24h	30h	36h	42h	48h	60h	72h
pOB LI (%)	nL	0.40 (0.90)	0.00 (0.00)	3.98 (5.59)	0.00 (0.00)	0.00 (0.00)	2.67 (3.62)	0.00 (0.00)	5.56 (12.4)
	L	6.75 (10.6)	4.79 (5.07)	6.07 (6.34)	17[abc] (8.18)	13.8[a] (5.38)	13.7 (7.36)	15.3[ac] (8.3)	14.2 (5.45)
Ob.S (%)	nL	7.41 (7.29)	4.93 (7.33)	4.22 (5.23)	2.93 (4.37)	3.03 (1.54)	4.26 (3.67)	7.94 (14.6)	3.45 (4.84)
	L	7.87 (6.64)	25.2 (16.4)	6.22 (4.93)	33[ab] (24.5)	32[ab] (25.6)	35[ab] (20.9)	34[ab] (13.6)	43[ab] (15.1)

[a]Loaded different from nonloaded leg; different from loaded leg at [b]12 and 30h, [c]24h

From 36-72h post-load, pOB LI and osteoblast surface in loaded legs were greater than in nonloaded legs, and also greater than in 12-30h loaded legs. Nonloaded legs did not differ with time or loading. The concurrent increases in Ob.S and pOB LI indicate that the early response to loading may be the conversion of non-proliferative surface cells into osteoblasts. Furthermore, these results show that a single mechanical load is sufficient to stimulate DNA synthesis (cell proliferation) among the pOB population within 36h post-load and maintain this response through 72h.

F169

Response of Growing Bones to a Jumping Protocol of Reduced Repetitions: A Randomized Controlled Trial. R. K. Fuchs,* D. P. Williams,* C. M. Snow. Exercise and Sport Science, Oregon State University, Corvallis, OR, USA.

We have previously reported significant (3 to 5%) gains in spine and hip bone mass in pre-pubescent children who performed 300 jump repetitions/week at a magnitude of 8 body weights at the ground. Our aim in this investigation was to examine the bone response at the hip and spine when jump repetitions are reduced by one half to 150 jump repetitions/week at the same load magnitude of 8 body weights at the ground. Ninety pre-pubescent children between the ages of 5 and 9 years were randomized into a jumping (n=23 boys, n=22 girls) or control group (n=24 boys, n=21 girls). The exercise intervention was incorporated into the curriculum during the school day, two times per week for 7-months. The jumping group performed 75, two footed jumps off 61cm boxes each session, while the control group performed non-impact stretching exercises during the same time period. Bone mineral content (BMC; g), bone area (BA; cm2) and bone mineral density (BMD; g/cm2) of the left proximal femoral neck and lumbar spine (L1-4) were assessed by DXA (Hologic QDR/4500-A). In addition, anthropometric characteristics (height, weight and body fat), Tanner staging, physical activity and dietary calcium intake were assessed. At baseline there were no differences between groups for height, weight, body fat, physical activity and bone variables. After 7-months, jumpers and controls had similar increases in height, weight and body fat. Both groups had similar intakes of calcium at baseline and 7-months (mean intake = 1,200 mg). Using repeated measures ANCOVA (dependent variable: absolute changes in bone; covariates: initial age and bone values and changes in height and weight) for bone mineral content, the primary outcome variable, jumpers and controls had similar increases at the femoral neck (jumpers: 0.157 ± 0.016 g vs. controls: 0.154 ± 0.016 g) and lumbar spine (jumpers: 1.43 ± 0.15 g vs controls: 1.68 ± 0.15 g). In repeated measures ANCOVA of secondary outcomes (BMD and BA), jumpers and controls had similar increases in BMD of the femoral neck (jumpers: 0.023 ± 0.004 g/cm2 vs. controls: 0.019 ± 0.004 g/cm2) and lumbar spine (jumpers: 0.016 ± 0.003 g/cm2 vs. controls: 0.012 ± 0.003 g/cm2), and similar increases in BA of the femoral neck (jumpers: 0.116 ± 0.020 cm2 vs. controls: 0.152 ± 0.020 cm2) and lumbar spine (jumpers: 1.52 ± 0.15 cm2 vs. controls: 2.16 ± 0.15 cm2). In conclusion, a jumping protocol previously shown to increase bone mass had no effect when repetitions were reduced by one half. This is the first report to examine the effect of varying jump repetitions while holding magnitude constant in the growing skeleton. The apparent synergy between load magnitude and repetitions warrants further investigation.

F172

Protein Kinase A-Dependent Phosphorylation and Inactivation of the Pro-apoptotic Protein Bad Mediates the Anti-Apoptotic Effect of PTH on Osteoblastic Cells. T. Bellido, L. I. Plotkin, J. Davis,* S. C. Manolagas, R. L. Jilka. Div. Endo/Metab, Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. of Arkansas for Med. Sci., Little Rock, AR, USA.

Inhibition of osteoblast apoptosis may account for the anabolic effect of intermittent PTH administration on the skeleton. Based on evidence that the anti-apoptotic effect of PTH is mediated by cAMP, and the role of intracellular kinase cascades in the regulation of cell survival, we carried out studies to elucidate the cAMP-regulated pathways and target proteins involved in apoptosis suppression. PTH (50 nM) prevented apoptosis of osteoblastic OB-6 cells induced by 6 hour treatment with 50 μM etoposide, as assessed by nuclear fragmentation, trypan blue uptake and caspase-3 activity. Sphingosine-1-phosphate, the product of sphingosine kinase, did not inhibit apoptosis, eliminating a role for this cAMP-activated kinase. Inhibition of extracellular signal regulated kinases (ERKs) with PD98059, or transfection with a dominant negative ERK kinase, also failed to block the anti-apoptotic effect of PTH; thus, ERKs are not involved either. However, the protein kinase A (PKA) inhibitors RpcAMP and H89 did prevent suppression of apoptosis by PTH, indicating a requirement for this cAMP-activated kinase. The pro-apoptotic protein Bad is a likely substrate of survival kinases because when phosphorylated at Ser136 and Ser155, it is inactivated, thus resulting in cell survival even in the face of a pro-apoptotic stimulus. Western blotting revealed that PTH induced a 3 to 5-fold increase in phospho-Ser155-Bad within 30-60 minutes, followed by a slow decline to basal levels at 6 hours. RpcAMP and H89 blocked PTH-stimulated phospho-Ser155-Bad production, confirming the role of PKA in this process. Bad phosphorylation was evidently essential for anti-apoptosis, as PTH did not promote survival in cells expressing a Bad mutant that cannot be phosphorylated at S155 or S136 (because of substitution by Ala). Moreover, apoptosis suppression was not sustained after phospho-Ser155-Bad had declined to basal levels. We conclude that cAMP-dependent PKA-mediated Bad phosphorylation is responsible, at least in part, for the anti-apoptotic effect of PTH, and thereby the stimulatory effect of intermittent PTH administration on bone formation. The transient nature of Bad phospho-

rylation may explain the need to give repeated injections of PTH to obtain an anabolic effect. It may also explain the failure (reported elsewhere at this meeting) of sustained PTH elevation to suppress osteoblast apoptosis in vivo, as only one transient episode of apoptosis suppression can be induced in this condition.

F175

Osteoblast Differentiation by BMP-2 Is Mediated by Down-Regulation of Cyclin-Dependent Kinase 6 (CDK6). T. Ogasawara, M. Katagiri, T. Miura,* T. Susami,* T. Takato,* K. Nakamura, H. Okayama,* H. Kawaguchi. Graduate School of Medicine, University of Tokyo, Tokyo, Japan.

Cell cycle control proteins such as cyclins, cyclin-dependent kinases (CDKs) and CDK inhibitors (CKIs) are known to regulate not only proliferation but also differentiation of cells, and cell cycle arrest at the G1 phase is a prerequisite for cell differentiation. To elucidate the possible regulatory mechanism of osteoblast differentiation by cell cycle control proteins, this study investigated the involvement of these proteins in the action of bone morphogenetic protein-2 (BMP-2), a potent inducer of osteoblast differentiation, on mouse osteoblastic MC3T3-E1 cells. Initially, we analyzed the expression of cell cycle control proteins that are known to affect the G1 phase: cyclin D1, D2, D3, E, CDK2, 4, 6, and CKIs (p15, p16, p18, p19, p21 & p27). Western blot analysis revealed that only the CDK6 level was markedly decreased by BMP-2 (300 ng/ml) at 24 h of culture and thereafter, while those of other proteins were not affected by BMP-2 throughout the culture period (up to 55 h). This effect of BMP-2 was not due to the stimulation of CDK6 protein degradation but to the inhibition of its expression because MG132, a potent proteasome inhibitor, did not change the effect. This inhibition, however, was not seen in MC3T3-E1 cells transfected with an inhibitory Smad, Smad6, using an adenovirus vector, indicating that this effect is mediated by the Smad signaling. We further established stable clones of MC3T3-E1 cells transfected with CDK6 cDNA, and selected several clones with high expression and low expression on Western blotting. Flow cytometric analysis showed that BMP-2 increased the number of cells in the G0/G1 phase of the cell cycle in cultures of low expressing clones, but not in those of high expressing clones. BMP-2 stimulated alkaline phosphatase activity and osteocalcin mRNA level in low expressing clones, whereas these effects were markedly reduced in high expressing clones. Since there was no significant difference in the doubling time of cells between low and high expressing clones, the inhibitory effect of CDK6 on osteoblast differentiation was shown to be independent of its effect on osteoblast proliferation. These results demonstrate that CDK6 is a critical mediator of the BMP-2 effect on osteoblast differentiation as a downstream effector of Smad signaling. Because we also found that fibroblast growth factor-2, a potent inhibitor of osteoblast differentiation, up-regulated the CDK6 protein level in this culture system, it is postulated that CDK6 is a key molecule determining the differentiation rate in osteoblasts.

The Orphan Receptor, Estrogen Related Receptor ERRα, Is Regulated by Estrogens in Bone and Is Involved in Not Only Osteoblast But Also Adipocyte Development. E. Bonnelye,[1] V. Kung,*[1] A. Samuels,*[2] J. H. Tobias,[2] J. E. Aubin.[1] [1]Department of Anatomy and Cell Biology, University of Toronto, Toronto, ON, Canada, [2]Rheumatology Unit, Division of Medicine, University of Bristol, Bristol, United Kingdom.

The orphan estrogen receptor related receptor, ERRα, is expressed by osteoblastic cells during development and modulation of its levels by over- and underexpression strategies alters osteoblast differentiation and bone formation in the 21 d. fetal rat calvaria (RC) cell model in vitro. ERRα is also expressed in adult osteocytes in calvariae and long bones, suggesting a function for ERRα in adult bone and diseases of bone, such as osteoporosis where bone loss is accelerated by a decrease in secretion of estrogens in post-menopausal women. We have therefore investigated the effects of estrogen (E2) on ERRα both in vitro and in vivo. Chronic treatment of 21 d. fetal rat calvaria (RC) cells by estrogen (E2) upregulates ERRα mRNA expression at early times in culture (day 6), suggesting a link between ERRα and E2 during osteoprogenitor proliferation. To determine whether E2 may elicit similar regulatory activity in vivo, we analysed ERRα expression levels in samples of mRNA extracted from femurs, from which bone marrow had been flushed, of mice treated with 17b-estradiol at doses known to elicit a large anabolic effect on endosteal bone. A marked stimulatory effect of E2 on ERRα expression levels was evident at day 1, 2 and 4 post-E2 treatment. Four weeks after ovariectomy (OVX) of rats, we found that ERRα remained highly expressed in osteocytes in the secondary ossification zone and cortical bone and osteoblasts associated with trabecular bone. The fact that ERRα is highly expressed in the osteoblastic cells present in the high turnover bone of the OVX rat model may indicate that ERRα expression is essential for osteoblast function in osteoporosis as in normal turnover. Given these observations, we next blocked ERRα in differentiating RC cell cultures using phosphorothioate-modified antisense oligonucleotides; sense oligonucleotides were used as control. As we observed previously, antisense but not sense oligonucleotides completely inhibited bone nodule formation. Interestingly, we observed a concomitant increase in adipocyte colony formation as well as an increase in PPARγ, CEBPα and PLA_2 mRNA expression levels. These results suggest that ERRα is important not only in osteoblast, but also in adipocyte development, suggesting that it may play a role in balancing stromal cell fate choices in the normal or OVX situation. They also suggest that agonists and antagonists of ERRα may be useful as therapeutic agents in a wide variety of bone metabolic and other diseases affecting bone.

F190

Translational Regulation Is a Control Point in RUNX2 (Cbfa1) Gene Expression. S. Sivasubramaniam,* Y. Li,* M. S. Katz, N. Elango.* Univ Texas Hlth Sci Center and GRECC, VAMC, San Antonio, TX, USA.

RUNX2/Cbfa1, a transcription factor implicated in the regulation of osteoblast differentiation and osteoblast specific gene expression, is expressed as two isoforms. The two isoforms, type-l and type-ll, are encoded by two different mRNAs with distinct 5'untranslated regions (type-1 5'UTR: 1015 nucleotides and type-ll: 210 nucleotides). In addition, type-l mRNA differs from type-ll mRNA by having 15 nucleotides encoding the amino terminal 5 amino acids MRIPV in place of 57 nucleotides encoding the amino terminal 19 amino acids MASNSLFSAVTPCQQSFFW of type-ll; the remaining 508 amino acids of the two isoforms are identical. Undifferentiated osteoblast precursor cells (MC3T3-E1 and ST2 cells) express RUNX2 mRNAs but not the osteoblast markers bone sialoprotein and osteocalcin, indicating that the expression of RUNX2 mRNAs is not sufficient for osteoblast differentiation. In this study we investigated expression of the RUNX2 gene at mRNA and protein levels in osteoblastic and non-osteoblastic cells, to determine whether translational regulation is a control point in RUNX2 gene expression. Total RNA from osteoblastic cells (fetal rat calvarial cells [FRC]; ROS 17/2.8, UMR-106, SaOS-2 and U2OS cells), osteoblast precursors (MC3T3-E1 and ST2 cells), and non-osteoblastic fibroblasts (COS-7, C3H10T1/2 and NIH3T3 cells) was subjected to Northern analysis using cDNAs of the 5' UTRs of type-l and type-ll mRNAs as probes. Northern blots demonstrated the presence of type-l mRNA in all cell types tested, and type-ll mRNA in osteoblasts and osteoblast precursors; type-ll mRNA was demonstrable in non-osteoblastic fibroblasts by RT-PCR analysis. Immunoblot analysis was performed using type-l specific antiserum raised against the synthetic peptide MRIPV, and type-ll specific antiserum generated against the synthetic peptide MASNSLFSAVTPCQQSFFW. Immunoblots revealed expression of both type-l and type-ll proteins in cells with the mature osteoblast phenotype (FRC; ROS 17/2.8, SaOS-2 and U2OS cells) but only type-l protein in immature osteoblastic cells (UMR-106); neither protein was detected in osteoblast precursors and non-osteoblastic fibroblasts. These results suggest that type-l protein is expressed earlier than type-ll protein in cells differentiating along the osteoblast lineage. Accordingly, type-l and type-ll proteins may respectively control the expression of early and late markers of osteoblast differentiation. In conclusion, the demonstration of RUNX2 mRNAs in differentiated and undifferentiated cells, but type-l and type-ll proteins only in differentiated osteoblasts, implicates control of RUNX2 expression at the translational level.

F192

Factors Possessing Histone Acetyltransferase and Deacetylase Activity Interact With Runx2 (Cbfa1) and Modify Its Transcriptional Activity. J. J. Westendorf,[1] X. Li,*[1] B. Lutterbach.*[2] [1]Orthopaedic Surgery and Cancer Center, University of Minnesota, Minneapolis, MN, USA, [2]Vanderbilt University, Nashville, TN, USA.

Runx2 (Cbfa1) is a transcription factor required for osteoblast differentiation and chondrocyte hypertrophy. Like other Runt-domain proteins, Runx2 is an activator and repressor of transcription. Multiple repression and transactivation domains have been previously identified in Runx2. Thus far, no chromatin-altering enzymatic activities have been directly linked to Runx2, therefore, the molecular mechanisms by which Runx2 regulates tissue-specific gene transcription are not clear. Associations between other lineage-required transcription factors and counteracting proteins possessing either acetyltransferase or deacetylase activity are crucial for tissue-specific gene expression and cell differentiation. Thus, histone acetyltransferase (HAT) activity is associated with relaxed chromatin structure and enhanced gene transcription, while histone deacetylase (HDAC) activity is linked to condensed chromatin and transcriptional repression. The purpose of this study was to determine if proteins possessing HAT or HDAC activity interact with Runx2 and modify its activity. In activation studies, we have found that the HATs, p300 and CBP, but not P/CAF, cooperate with Runx2 to synergistically activate the osteocalcin promoter. In repression studies, we found that Runx2 represses the p21(CIP1/WAF1) promoter in a manner that is partially dependent on the carboxy-terminus of Runx2. This repression is sensitive to the HDAC inhibitor, trichostatin A. In co-immunoprecipitation-immunoblotting experiments, the penultimate carboxy-terminal repression domain of Runx2 interacted with HDAC-6. To begin to understand how Runx2-interacting co-activators and co-repressors affect Runx2 activity during osteoblast differentiation, we examined the expression of several co-factors in differentiating MC-3T3-E1 cells. Interestingly, p300 and HDAC6 are differentially expressed during osteoblast differentiation. p300 is expressed at high levels during the first twelve days of differentiation, but at markedly lower levels during days 14-28. In contrast, HDAC6 is transiently expressed during early stages of differentiation (days 2-14) but at steady levels thereafter. We conclude that interactions between Runx2 and cofactors possessing either HAT or HDAC activity are crucial for regulating Runx2 target gene expression. Moreover, differential expression of the co-factors may be one level of regulation affecting Runx2 activity during osteoblast differentiation.

F194

The Osteoblast Differentiation Factor RUNX2/Cbfa1 Is Suppressed by Tumor Necrosis Factor-alpha. L. C. Gilbert,*[1] X. He,*[1] J. Rubin,[1] H. Drissi,*[2] A. J. van Wijnen,[2] J. B. Lian,[2] G. S. Stein,[2] M. S. Nanes.[1] [1]Division of Endocrinology and Metabolism, Department of Medicine, Emory University and VAMC, Atlanta, GA, USA, [2]Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA.

The transcription factor RUNX2 (Cbfa1/AML3/Pebp2alphaA) is critical for determination of osteoblastic lineage during bone formation. We investigated the effect of the inflammatory cytokine tumor necrosis factor alpha (TNF) on the regulation of RUNX2 expression since TNF is an important contributor to bone pathology after menopause and RUNX2 levels in bone diminish with age. TNF inhibits the differentiation of fetal calvaria pre-osteoblasts and of the clonal preosteoblast cell line MC3T3-E1 (Gilbert et al Endo-

crinol 141:3956, 2000). TNF treatment of fetal calvaria cells on culture day 7 (just prior to expected nodule formation) or MC3T3-E1 cells on day 2 (pre-differentiation) caused a dose-dependent suppression of RUNX2 steady-state mRNA as measured by RT-PCR using primers flanking the conserved RUNT homology domain. The IC50 for TNF inhibition was 0.6 ng/ml. The effect of TNF was also studied using RUNX2 isoform-specific primers. TNF suppressed expression of the type 1 isoform mRNA 95% (p56/MRIPV) while inhibiting expression of the type 2 isoform mRNA 50% (p57/MANSN). RUNX2 nuclear content was evaluated by EMSA using a rat osteocalcin promoter 32P-RUNX2 binding sequence as probe and by western analysis. Antibody-specific supershift confirmed RUNX2 identity in the EMSA. TNF reduced nuclear RUNX2 binding to the probe by >90%. Western analysis showed that TNF decreased nuclear RUNX2 protein by >90%. Inhibition of new protein synthesis with cycloheximide failed to prevent TNF inhibition of RUNX2 mRNA. The half-life of RUNX2 mRNA is 2.3 HR as measured using actinomycin D, a value not significantly changed by TNF treatment. The effect of TNF on RUNX2 gene transcription was evaluated using a 0.6 kB RUNX2 promoter-luciferase reporter in transient transfected MC3T3-E1 cells. TNF caused a dose-dependent inhibition of RUNX2 promoter transcription to 50% of control values, similar to the inhibition of mRNA. Deletion analysis of the RUNX2 promoter suggested localization of a TNF inhibitory region downstream of -108; however, further localization was obscured by loss of basal promoter activity with progressive deletion. Our results suggest that TNF regulates RUNX2 expression at the transcriptional level but may have additional post-transcriptional inhibitory effects on RUNX2 nuclear content. Suppression of RUNX2 by TNF may decrease osteoblast differentiation and inhibit bone formation in TNF excess states.

F196

CNBP Enhances Bone Formation by Promoting Osteoblast Cell Proliferation and Inhibiting Osteocalcin Expression. K. Shimizu,* W. Chen,* Y. Liang,* R. Isoda,* W. Deng,* Y. Li. Department of Cytokine Biology, Forsyth Institute, Boston, MA, USA.

There is clear clinical evidence that genetic modulated osteoporosis results from functional defects of the osteoblast. However, the genes underlying these genetic syndromes of osteoporosis remain largely unknown. The purpose of this study was to characterize osteoblast transcription factors that regulate bone formation. Subtractive-differential screening was used to clone the transcription factors selectively expressed in osteoblasts. We identified Cellular Nucleic Acid Binding Protein (CNBP) that is predominately expressed in mature osteoblasts. We confirmed that CNBP exhibits similar up-regulated expression as osteocalcin during osteoblast differentiation by Northern Blot and In Situ Hybridization. To study in vivo function of CNBP in bone formation, we generated a mutant mouse strain with null mutation of CNBP. Homozygous mutants died in the prenatal period, while about 40% heterozygous survive to develop postnatal abnormalities associated with altered bone formation and severe osteoporosis. Northern blot showed that expression of CNBP was largely reduced in the heterozygous when compared with that in wild type mice. Forced expression of CNBP in osteoblastic cells resulted in the cells grew significantly more rapidly. The number of cells was about 2.5 fold when compared with that in the control group. Cotranfection study demonstrated that osteocalcin promoter activity was reduced to 20% of that of the control group without CNBP expression. Previous study in other Laboratory indicated that osteocalcin is an inhibitor of bone formation. Our results suggested that CNBP is a key regulator of bone formation. CNBP enhances bone formation by promoting osteoblast cell proliferation and inhibiting osteocalcin expression. Mutation of CNBP may be responsible for one of syndromes of osteoporosis.

F198

The Yes-Associated Protein (YAP) Is A Suppressor of Runx2/Cbfa1 Dependent Activation of the Bone Specific Osteocalcin Gene. S. K. Zaidi,[1] A. J. Sullivan,*[1] Y. Ito,*[2] A. J. van Wijnen,[1] J. L. Stein,[1] G. S. Stein,[1] J. B. Lian.[1] [1]Cell Biology, UMass Medical School, Worcester, MA, USA, [2]Viral Oncology, Kyoto, Japan.

The Yes-associated protein (YAP) transduces signals from receptor tyrosine kinases to the nucleus and interacts with members of the Runx family of transcription factors. This interaction is mediated through the WW domain of YAP and the highly conserved PY motif (PPPY) of Runx proteins. Runx2, which is essential for bone development, is a strong activator of the bone-specific osteocalcin promoter. Here we addressed the functional role of YAP in Runx2 mediated regulation of osteocalcin. In transient transfection assays, YAP had no effect on the basal osteocalcin promoter activity. However, when YAP was co-expressed with Runx2, a dose-dependent repression of osteocalcin was observed. When expression constructs encoding differently tagged Runx2 and YAP proteins were co-transfected, a strong interaction of YAP with Runx2 was observed by co-immunoprecipitation and immunofluorescence microscopy. This interaction was abolished when the PY motif of Runx2 was mutated (Runx2 Y433A). Functional analysis of Runx2 Y433A mutant showed 3-4 fold higher activation of osteocalcin promoter activity compared to the wild type Runx2, suggesting that the Y433A mutation relieves the suppression contributed by the endogenous YAP. To confirm these findings, we co-expressed wild type Runx2 with a dominant negative inhibitor of YAP function (YAP 1-301) and observed a similar activation of the osteocalcin promoter as that of the Runx2 Y433A mutant protein with the wild type YAP. Thus, interfering with function of the endogenous YAP inhibits YAP mediated suppression of the osteocalcin promoter. Taken together, these findings demonstrate that YAP is a potent suppressor of Runx2 dependent activation of the bone specific osteocalcin gene and suggest that YAP may contribute to physiological regulation of osteocalcin expression osteoblast differentiation.

F200

Developmental Utilization of Distinct Promoters Regulating the Type I and Type II Isoforms of the Bone Runx2/Cbfa1 Transcription Factor. H. Drissi, A. Javed, E. Balint, C. Banerjee,* F. Adamidou,* A. J. Van Wijnen, J. L. Stein,* G. S. Stein, J. B. Lian. Cell Biology, Umass Med School, Worcester, MA, USA.

The importance of the Runx2/Cbfa1 transcription factor during osteoblast differentiation and skeletal development has been demonstrated both in vitro and in vivo. Runx2/Cbfa1 encodes two major N-terminal isoforms (type I/MRIPV and type II/MASNS) which originate from two distinct promoters and are functionally equivalent in the activation and repression of bone-specific genes. The promoter dependent mechanisms by which the levels of these isoforms are regulated in vivo remain to be established. In this study, we examined developmental expression of the type I and type II isoforms in mouse embryos, mesenchymal cells and osteoblasts. Northern blot analysis shows expression of at least four Runx2 splice variants during osteoblast differentiation of mouse osteoblastic MC3T3-E1 cells and rat primary osteoblasts (ROB). RT-PCR using primers specific for mRNA encoding the type I and the type II mRNA of Runx2 shows that both transcripts are expressed in ROB cells at the late proliferation stage. The type I mRNA is constitutively expressed during osteoblast differentiation, whereas the type II mRNA is up-regulated along with osteocalcin transcripts during matrix maturation and mineralization stages. Expression of each isoform in specific mouse tissues was examined. While type II mRNA is restricted to bone, the type I isoform is present at high levels in several soft tissues, suggesting that this isoform is ubiquitously expressed. During mouse embryogenesis Runx2 type I mRNA is detected as early as 9.5 dpc, prior to appearance of the type II isoform, which is significantly expressed at 11.5 dpc in early mesenchymal condensations. Thus, there is differential induction of the two Runx2 promoters. The type I mRNA remains constitutively expressed throughout development until birth. In contrast the type II transcript is up-regulated between 12.5 and 14.5 dpc during cartilage formation and then down regulated between 15.5 dpc and birth, suggesting in vivo responsiveness of the Runx2 upstream promoter driving expression of the type II isoform to osteogenic signals. The regulation of these two isoforms in mesenchymal cell lines was assessed upon treatment with the osteogenic factor BMP2. Our findings indicate that BMP2 specifically up-regulates type II transcript levels in preosteoblastic and prechondrocytic clonal cell lines whereas the type I isoform is not regulated. Therefore our results provide insight into the developmental induction and tissue specific utilization of the two promoters regulating Runx2 activity during osteogenesis.

F202

Identification of Novel Protein/DNA Interactions within the Proximal Promoter of the Bone-Related Transcription Factor Runx2/Cbfa1. H. Drissi, A. Pouliot,* J. L. Stein,* J. B. Lian, G. S. Stein, A. J. Van Wijnen. Cell Biology, Umass Med School, Worcester, MA, USA.

Runx2/Cbfa1, which belongs to the runt homology family of transcription factors, is essential during bone development and regulates osteoblast differentiation through control of osteoblast phenotypic genes. Defining the regulatory mechanisms that govern expression of Runx2 transcripts is necessary to understand the precise role of this transcription factor in modulating the events that control skeletal development. We have previously reported cloning and characterization of the bone related Runx2 promoter from both rat and mouse. Deletion analysis showed that the proximal segment of the rat promoter contains several activating domains between nt -288 and nt -92 which are flanked upstream by a purine rich region and downstream by a negative Vitamin D responsive element. We systematically examined transcription factor binding within this region using a series of overlapping oligonucleotides for gel shift assays. We found two novel protein/DNA interaction sites within the very proximal promoter that are mediated by sequence specific factors based on cross-competition experiments and point mutations. Gel shift immunoassays show that the first complex recognizes a non-canonical Runx2 site, whereas the other factor binds to a palindromic sequence. Site directed mutagenesis of the novel Runx2 motif reduces promoter activity (2 fold), suggesting that this site mediates enhancement of Runx2 promoter activity. However, point mutation of the palindromic motif induced a 2 to 3 fold activation of the Runx2 promoter indicating that the wild type sequence mediates strong repression. The Runx2 site and the palindromic element function in the context of other protein/DNA interactions within the initial 300 base pairs of the Runx2 promoter, which are currently under investigation. These studies, together with our previous findings of auto-suppression of the Runx2 promoter and negative regulation by the steroid hormone 1-25 (OH)2 Vitamin D3, suggest considerable complexity in the Runx2 promoter to accommodate physiological control of Runx2 gene expression.

F204

The Human Protein A Kinase Adaptor Protein 2 Is a TNFalpha Regulated Gene in Human Osteoblasts and Localizes to the Actin Cytoskeleton. N. Schuetze,[1] S. Reichel,*[2] U. Barthelmes,*[2] N. Ruecker,*[2] J. Pfeufer,*[3] A. Lechner,*[2] F. Jakob.*[2] [1]Labor fuer Molekulare Experimentelle Orthopaedie, Orthopaedische Universitaetsklinik, Wuerzburg, Germany, [2]Medizinische Poliklinik, Wuerzburg, Germany, [3]Orthopaedische Universitaetsklinik, Wuerzburg, Germany.

Protein kinase A adaptor proteins (AKAP´s) associate with discrete cellular structures such as the centrosome as well as other organelles and are able to bind to the regulatory subunits of type II of protein kinase A (PKA). Thereby, a specific localization of the PKA holoenzyme is achieved. Applying differential display PCR to immortalized human osteoblasts we identified the novel human protein kinase adaptor protein 2 (AKAP-2) as an early regulated gene. No RNA or protein data except for a partial sequence are available in the literature to date for AKAP-2.The 7.5 kbp cDNA sequence was obtained by sequencing the ddPCR product, IMAGE clones, cDNA array-filter derived clones and gene specific RT-PCR products. RNA levels were measured by Northern hybridization. Intracellular localization was determined by transient transfection of an AKAP-2-GFP fusion protein

and control immunohistochemistry analyses were performed with organelle-specific antibodies.The AKAP-2 mRNA was found to be transiently regulated by TNFalpha 5-fold with a maximum after 5 hours of treatment (3.5 ng/ml). Actinomycin D as well as cycloheximide cotreatments indicate a transcriptional mechanism of regulation. Further, phorbol ester (TPA) also markedly enhanced AKAP-2 mRNA levels via a transcriptional regulation. The AKAP-2 sequence obtained from human osteoblasts differs from the existing database entry by additional 2.5 kbp at the 3´-end. An AKAP-2-GFP fusion protein localized to an unpaired structure within the cytoplasm. The protein contains three regions of coiled coil structures often observed for centrosomal proteins. Control immunohistochemistry analyses with a centrosomal specific antiserum applied to AKAP-2-GFP transfected osteoblasts indicated no colocalization of AKAP-2 to the centrosome. However, cytochalasin D cotreatments showed an association of AKAP-2 with the actin cytoskeleton. Since expression of AKAP´s is the prerequisite for subcellular distribution of PKA enzyme activity and subsequently numerous signal transductions events occur in osteoblasts, these findings suggest an important link between bone relevant growth factor function and intracellular PKA-dependent signaling pathways in human osteoblasts.

F206

The Ontogeny of Phex Protein in the Developing Mouse Skeleton and Studies on the Subcellular Distribution of Phex Protein in Osteoblasts. D. L. Thompson,*[1] Y. Sabbagh,*[2] H. S. Tenenhouse,[2] P. C. Roche,*[1] M. K. Drezner,[3] J. L. Salisbury,*[1] J. P. Grande,*[1] E. M. Poeschla,*[1] R. Kumar.[1] [1]Mayo Clinic/Foundation, Rochester, MN, USA, [2]McGill University, Montreal, PQ, Canada, [3]University of Wisconsin, Madison, Madison, WI, USA.

PHEX, a phosphate regulating gene with homologies to endopeptidases on the X chromosome, is mutated in X-linked hypophosphatemia in humans and mice (*Hyp).* Although recent observations indicate that Phex protein is expressed primarily in bone and may play an important role in osteoblast function and bone mineralization, the expression patterns of the Phex protein in the developing skeleton and the subcellular localization of the protein in osteoblasts remain unknown. We examined the ontogeny of the Phex protein in the developing mouse embryo and its subcellular localization in mouse osteoblast cultures using a specific antibody to the protein. Immunohistochemical staining of mouse embryos revealed expression of Phex in osteogenic precursors in developing vertebral bodies and developing long bones on day 16 p.c. and thereafter. Calvaria from day 18 p.c. mice showed Phex epitopes in osteoblasts. No Phex immunoreactivity was detected in lung, heart, hepatocytes, kidney, intestine, skeletal muscle, or white adipose tissue of mouse embryos. Interestingly, embryonic mouse brown adipose tissue showed moderate amounts of Phex immunostaining. In post-natal mice, Phex expression was observed in osteoblasts and osteocytes. Moderate expression of Phex was seen in odontoblasts and slight immunoreactivity was observed in ameloblasts. In permeabilized osteoblast cultures derived from normal and *Hyp* mice, confocal microscopy revealed the presence of immunoreactive Phex protein in the Golgi apparatus and endoplasmic reticulum in normal osteoblasts but not in *Hyp* osteoblasts. However, following transduction of *Hyp* osteoblasts with a human Phex viral expression vector, Phex protein was detected in the same subcellular compartments as normal osteoblasts. Our data indicate that Phex protein is expressed in normal osteoblasts and osteocytes during the embryonic and post-natal periods and that Phex may be a unique marker for cells of the osteoblast/osteocyte lineage.

F210

Lovastatin Stimulates, Rather than Inhibits, Proteasome Activity in vitro and in Osteoblasts. E. J. B. Murray,* S. S. Murray. GRECC/Medicine, VAGLAHS/UCLA, Sepulveda, CA, USA.

Others have hypothesized that 3-hydroxy-3-methylglutaryl coenzyme A (HMG Co-A) reductase inhibitors ("statins") are anabolic with respect to bone through a mechanism involving inhibition of the chymotryptic activity of the proteasome. This hypothesis was based on structural similarities between some statins and some proteasome inhibitors. The aim of these studies was to determine the direct effects of lovastatin on proteasome activities in vitro and in MC3T3-E1 osteoblastic cells. The chymotryptic activity of the purified rabbit 20S proteasome was tested after preincubation with 0.0 to 5.0 uM lovastatin. The chymotryptic, tryptic, and peptidylglutamyl-peptide bond hydrolase (PGPH)-like activities of the proteasome were assayed in MC3T3-E1 osteoblastic cells after 4 hours to 4 days of treatment with lovastatin. Total protein and DNA were also measured in these cells in order to assess the possible anabolic effects of lovastatin on osteoblastic cells in culture. Lovastatin increased chymotryptic activity up to 20 fold in vitro in a dose dependent manner. Lovastatin increased DNA and protein content to a very modest degree in low density, but not high density, MC3T3-E1 cells. Lovastatin increased chymotryptic activity in low density cells. In high density cells, lovastatin increased chymotryptic and tryptic activities, but had no effect on PGPH-like activity. We conclude that lovastatin stimulates, rather than inhibits, proteasome activities in vitro and in cultured osteoblastic cells. Our studies do not support the hypothesis that lovastatin has an anabolic effect on bone that is mediated through an inhibition of the proteasome. Our results also suggest that other cell types in bone, such as osteoclasts, rather than osteoblasts, may be affected by lovastatin. Our conclusions are consistent with previous findings that indicate that proteasome activity is necessary for proliferation of osteoblastic cells.

F212

Wnt1, 2 and 3a Induce Osteoblast Commitment of Mesenchymal Pluripotent Cells C3H10T1/2 by a Beta-catenin Pathaway Dependent Signaling. G. Rawadi ,*[1] T. Garcia,[1] S. Spinella-Jaegle,*[1] S. Gallea,*[1] C. Faucheu,*[1] S. Kawai,*[1] R. Baron,[1] S. Roman-Roman.[1] [1]Aventis Pharma, Romainville, France.

Mammalian Wnt genes encode secreted glycoproteins that participate in normal embryonic development, tissue differentiation and cell proliferation. Several members of the Wnt family have been implicated in regulating chondrocyte differentiation and very recently Wnt3a has been shown to inhibit adipogenesis. Frizzled (Fz) genes encode seven membrane spanning proteins which act as receptors for Wnts. Data obtained by genome-wide expression analysis show the expression of Wnt and Fz genes in mouse calvaria and human trabecular osteoblasts. The involvement of Wnt signaling in osteoblast differentiation has not been so far addressed. We have investigated the effect of Wnt1, 2, 3a, 4 and 5a overexpression in the pluripotent mesenchymal cell line C3H10T1/2. Wnt1, 2, and 3a induced alkaline phosphatase (ALP) activity in this cell line whereas Wnt4 and 5a did not exhibit the same activity. In addition, Wnt 1, 2, and 3a synergized with BMP-2 to induce ALP activity in C3H10T1/2 cells. Molecular events leading to this synergy seems independent of Smad transcriptional activity. While Wnt1 and 3a signaling relays on beta-catenin, Wnt4 and 5a act independently of beta-catenin pathway. We have therefore examined the effect of beta-catenin in C3H10T1/2 cells. Interestingly, overexpression of a beta-catenin stable mutant mimicked the effect of Wnt1, 2, and 3a, strongly suggesting that these Wnt proteins induce ALP via beta-catenin signaling. Expression profiling of C3H10T1/2 cells treated with BMP-2 showed an increase in secreted related-frizzled protein 2 (SRFP-2) mRNA. SFRP proteins are known to act as a Wnt antagonist. Interestingly, overexpression of SRFP-2 significantly inhibited Wnt3a-induced ALP activity. On the contrary no inhibitory effect could be observed when cells were co-transfected with SRFP-2 and Wnt1 or 2. Altogether, our data suggest that Wnt/beta-catenin signaling play a role in osteoblast differentiation. The analysis of the activity displayed by different members of Wnt, Fz and SRFP families on osteoblast precursors and mature osteoblasts and the comprehension of the cellular events responsible for the activity described herein could help to define new approaches for treat osteopenia disorders.

F214

PGE2 Stimulates Bone Formation via EP4 Subtype of Prostaglandin E Receptor. K. Yoshida,*[1] T. Kobayashi,*[1] T. Tsuboyama,*[2] M. Matsushita,*[2] T. Nakamura,[2] S. Narumiya.*[1] [1]Department of Pharmacology, Kyoto University Faculty of Medicine, Kyoto, Japan, [2]Department of Orthopaedic Surgery, Kyoto University Faculty of Medicine, Kyoto, Japan.

Prostaglandins are proposed as important local factors that regulate both bone formation and bone resorption. Little has been known about their receptor mechanism in bone, though a receptor subtype EP4 was recently suggested to be the main factor in PGE2-induced osteoblast differentiation in vitro. In addition, PGE2 is known to induce a significant bone-forming effect when administered systemically or locally.To understand which of the four subtypes of PGE receptors (EP1-EP4) is involved in this process, we used mice deficient in each subtype of PGE receptors as well as subtype-specific agonists and antagonists. These compounds were examined by measuring the volume of newly formed callus after local infusion in vivo, and quantificaton of mineralized nodules in primary cultures of bone marrow cells in vitro.Each compound was infused locally into femoral periosteal tissue in the leg of mice with an implanted osmotic pump for 6 weeks, and the bone formation was investigated roentogenographically and histologically. PGE2 and a selective EP4 agonist caused a massive new bone formation on the cortices of femora in a dose-dependent manner, while agonists for other EP subtypes and two selective EP1 antagonists had little effect on bone. Infused PGE2 in mice lacking EP4 showed no bone-forming effect.On the other hand, each compound was added into primary bone marrow cell cultures from mouse femora. At the end of the 3-week culture period, the cells were stained by von Kossa method and the area of mineralized nodules was measured using an image analysis system. In these cultures, PGE2 and a selective EP4 agonist caused mineralized nodule formation in a concentration-dependent manner, while agonists for other EP subtypes and two selective EP1 antagonists had little effect. Bone marrow cells from EP4-deficient mice showed no increase in the area of mineralized nodules with PGE2 at all.In this study, we show that PGE2 and selective EP4 agonist stimulated new bone formation when administered in vivo, and induced mineralized nodule formation when added into the primary cultures in vitro. Consistent with these findings, PGE2 had neither osteogenic effect to EP4-deficient mice in vivo nor in vitro. These results suggest that the anabolic effect of PGE2 on bone formation is mediated via EP4 in vivo and in vitro.Recently, EP4 was also reported to be the main receptor in PGE2-induced osteoclast formation. The molecular cascade subsequent to the activation of EP4 in osteoblastic cells determining the two actions of PGE2 should be investigated in future studies.

F216

Loss of Pi Handling via Pit1, the Type III NaPi Cotransporter, Interferes with the Proliferation-Osteogenic Differentiation-Mineralization Sequence in Fetal Rat Calvaria Cell Populations. Y. Yoshiko,[1] K. Oizumi,[1] N. Maeda,*[2] J. E. Aubin.[1] [1]Anatomy and Cell Biology, University of Toronto, Toronto, ON, Canada, [2]Oral Anatomy, Hiroshima University, Hiroshima, Japan.

The ability of osteogenic cells to transport inorganic phosphate (Pi) appears to be an essential requirement for the onset of mineralization. Pi handling by osteogenic cells is thought to proceed via sodium-dependent phosphate (NaPi) cotransporters different from the kidney transporters. Recently, expression of type III NaPi cotransporters/retroviral receptor genes was determined in osteogenic cell lines and hypertrophic chondrocytes in vivo, but their functional roles have not yet been elucidated. We now report the molecular identity of NaPi cotransporters and their functional activities during the proliferation-osteogenic differentiation-mineralization sequence in fetal rat calvaria (RC) cell cultures. By RT-PCR of both RC cell populations and discrete single cell-derived RC osteogenic colonies, the type III (Pit1 and Pit2) and type Ib NaPi cotransporters were identified, but not the type Ia, type IIa and type IIb. Pit1 mRNA appears to be expressed at much higher level than Pit2 mRNA and the type Ib mRNA level is very low in RC cells. Unexpectedly, although NaPi uptake increased during the development sequence in RC cultures, Pit1 and Pit2 mRNA levels decreased. To investigate the possible involvement of Pi handling by osteogenic cells, the effects of phosphonoformic acid (PFA), an inhibitor of NaPi cotransport, were determined. Treatment of either monolyer or nodule-forming cells with PFA inhibited NaPi uptake. PFA treatment at different development time-windows, i.e., during proliferation, differentiation/nodule formation, or nodule maturation/mineralization stages,

caused distinct inhibitory effects on nodule formation and mineralization as well as osteoblast marker mRNA expression. An acute treatment for only 12-48 h before culture termination completely inhibited mineralization concomitant with a slight decrease in osteocalcin mRNA levels. Analysis of the early molecular consequences of PFA treatment also suggested that stanniocalcin 1, a newly identified calcium/phosphate regulator, rapidly increased. Treatment of cultures with antisense oligonucleotides to Pit1 mimicked PFA treatment. Taken together, these observations suggest that Pi handling via Pit1 activity in osteogenic cells plays a pivotal role not only in matrix mineralization but also in osteoblast development.

F219

FGD1, an Osteoblast Specific Cdc42GEF, Directly Interacts with mAbp1 and Cortactin, Actin-binding Src Kinase Targets. P. Hou,*[1] A. B. Vojtek,*[2] J. L. Gorski.*[1] [1]Pediatrics and Human Genetics, The University of Michigan Medical School, Ann Arbor, MI, USA, [2]Biological Chemistry, The University of Michigan Medical School, Ann Arbor, MI, USA.

Mutations in FGD1 result in faciogenital dysplasia, an inherited disease of skeletal formation. Consistent with its role in skeletal formation, FGD1 has a restricted pattern of expression that is limited to regions of incipient and active ossification including osteoblasts and osteosarcoma cell lines. FGD1 encodes a guanine nucleotide exchange factor (GEF) that specifically activates the p21 GTPase, Cdc42. By activating Cdc42, FGD1 stimulates actin cytoskeletal reorganization and filopodia formation. The FGD1 protein is composed of (in order) a proline-rich N-terminal region, a GEF domain, a pleckstrin homology (PH) domain, a FYVE domain, and a second PH domain (PH2) that are involved in signaling and subcellular localization; however, mechanisms by which FGD1 participates in osteoblast signaling remain unclear.Here we report the use of yeast two-hybrid analysis with an osteoblast derived cDNA library to identify two FGD1-interacting proteins, actin-binding protein 1 (mAbp1) and cortactin. Cortactin and mAbp1 are both Src kinase targets and contain similar functional domains including (in order) N-terminal actin-binding domains, a-helical regions, phosphorylation-targeted serine-/threonine-rich domains, and C-terminal Src homology 3 (SH3) domains. In yeast, FGD1 interacts with mAbp1 and cortactin SH3 domains via its N-terminal proline-rich region; studies show that the FGD1 SH3-binding domain (PQVPPKP) is responsible for the interactions. Far western blot analysis using purified FGD1 peptides show that FGD1 directly binds to purified mAbp1 and cortactin SH3 domains; in contrast, mutant FGD1 peptide fails to interact with these SH3 domains. Used to perform co-immunoprecipitation studies, cells overexpressing FGD1/mAbp1 or FGD1/cortactin show that FGD1 interacts with both mAbp1 and cortactin in vivo. These data indicate that FGD1 binds to mAbp1 and cortactin both in vitro and in vivo. Moreover, mAbp1 and cortactin colocalize with FGD1 to the subcortical actin cytoskeleton. This data indicates that the osteoblast specific Cdc42GEF FGD1 directly interacts with mAbp1 and cortactin. Accumulated data strongly suggest that FGD1 signaling plays an important role in osteoblast signaling and actin cytoskeletal reorganization.

F223

The Effect of IGF-I to Promote the Production of Osteoblast Progenitors Is Estrogen Dependent. Y. Kasukawa, L. Stabnov, N. Miyakoshi, D. J. Baylink, S. Mohan. Musculoskeletal Disease Center, JL Pettis VAMC, Loma Linda, CA, USA.

The pathogenesis of senile osteoporosis involves increased bone resorption that is not compensated by a corresponding increase in bone formation (BF). The age-related impairment in BF may be caused by a deficiency in the number of osteoblast progenitor cells (colony forming unit osteoblast, CFU-OB), which has been shown to decline with age. Based on the findings that the IGF-I level in both serum and bone decline with age and that IGF-I is an important regulator of BF, we proposed the hypothesis that a deficiency in the production and/or actions of IGF-I could contribute to the decline in the number of CFU-OBs and consequently impaired BF in old age. As a means of testing this hypothesis, we first tested if the number of CFU-OBs is decreased in the bone marrow cells (BMC) of growth hormone (GH) deficient lit/lit mice. We found that the number of CFU-OBs was decreased by 20% (361±50 vs 451±56 CFU-OB/106 BMC, P<0.01, n=7-9) in GH-deficient mice compared to age-matched control mice. Consistent with this data, we found that in vitro treatment of BMC derived from 8-week-old C3H mice with 30 ng/ml IGF-I for 10 days increased the number of CFU-OBs by 44% compared to vehicle-treated control cultures (P<0.01). We next evaluated if IGF-I treatment increases the number of CFU-OBs in vivo. Because recent findings demonstrate that estrogen activates the IGF-I signaling pathway by upregulating the expression of IGF-I downstream signaling molecules, we tested IGF-I effects on CFU-OBs in ovariectomized (OVX) and sham-operated C57BL mice at 12 months of age. Four weeks after surgery, IGF-I (2 ug/g body wt) or vehicle was administered twice on day 1, and 5 days later BMC were removed from femur and cultured for 10 days for CFU-OB assay (n=14-16 per group). IGF-I administration increased the number of CFU-OBs by 56% (P<0.001) and 28% (P<0.05), respectively, in sham and OVX mice compared to vehicle-treated control group. IGF-I treatment increased the total colony number by 28% (P<0.05) in the sham but not in the OVX mice (8%, P=0.44). As previously shown, OVX increased CFU-OBs and bone turnover markers significantly compared to sham mice. Serum IGF-I level was similar in OVX mice compared to sham mice, a finding which is different from that of rats in which OVX increases the serum IGF-I level. Conclusions: 1) The number of CFU-OBs was decreased in mice lacking GH. 2) IGF-I treatment increased the number of CFU-OBs both in vitro and in vivo. 3) IGF-I response on CFU-OBs was impaired in OVX mice compared to sham mice. 4) During estrogen deficiency, a decrease in the production and/or action of IGF-I could decrease the number of CFU-OBs and contribute to the age-related impairment in BF.

F225

Stromal Cells from Human Subcutaneous Adipose Tissue Support Hematopoiesis. J. M. Gimble,*[1] H. A. Leddy,*[2] S. Potiny,*[2] D. M. Franklin,*[3] K. Hicok,*[4] A. L. Kloster,*[4] R. W. Storms.[2] [1]Tissue Engineering, Artecel Sciences, Inc., Durham, NC, USA, [2]Duke University Medical Center, Durham, NC, USA, [3]Zen-Bio, Inc., Research Triangle Park, NC, USA, [4]Artecel Sciences, Inc., Durham, USA.

It is well established that bone marrow stromal cells capable of supporting hematopoiesis can also undergo adipocyte differentiation. The current study evaluated the converse hypothesis; can stromal cells derived from human subcutaneous adipose tissue support hematopoiesis? Flow cytometry revealed that adipose-derived stromal cells expressed cell surface proteins associated with hematopoietic support, including CD9, CD10, CD13, hyaluronate receptor (CD44), VLA4 (CD29/CD49d), endoglin (CD105) and ALCAM (CD166). In response to inducing agents, the adipose stromal cells expressed the following cytokines based on PCR and ELISA assays: M-CSF, GM-CSF, Flt 3 ligand, Kit ligand, LIF, TNFa, IL-6, IL-7, IL-8 and IL-11. To assess the stromal cells capacity to support hematopoiesis, human umbilical cord blood CD34+ cells were co-cultured with adipose stromal cells in vitro. The stromal cells promoted the growth of CD13+,CD14+ and/or CD15+ myeloid cells; myeloid colony forming units were present at a frequency of 40 per 100 CD34+ cells after 3 weeks and 82 per 1000 CD34+ cells after 6 weeks. After 12 days in co-culture, the total hematopoietic cell number increased by 5.1 ± 3.2-fold; 57.6% ± 9.7% of these cells were CD34+, reflecting a 2.7 ± 1.3-fold expansion. Over a 3 week period, the number of CD34+ cells in the co-cultures expanded by approximately 7-fold. In both the absence and presence of exogenous supplemental cytokines (KL, Flt3 L, IL-2, IL-7 and IL15), the adipose-derived stroma promoted the development of lymphoid lineage cells (CD7+, CD10+) within a 12 day period; the presence of lymphoid cells was maintained for up to 6 weeks in the co-culture conditions. This novel work shows that adipose tissue provides an alternative to bone marrow as a source of stromal cells for the ex vivo expansion of hematopoietic progenitors from umbilical cord blood or other sources. Since adipose tissue is accessible, abundant and replenishable, it has significant potential for tissue engineering applications in the clinical arena.

Regulation of Cathepsin K Promoter Activity. M. Gyda,* B. R. Troen. Mount Sinai School of Medicine, Bronx VAMC, Bronx, NY, USA.

Osteoporotic fractures lead to significant morbidity and mortality in the elderly. An essential component of bone resorption is the synthesis and secretion of cathepsin K (CTSK), a cysteine proteinase, by osteoclasts. In order to characterize the molecular mechanisms of bone resorption, we are studying the regulation of cathepsin K gene expression. We have isolated and cloned the rat cathepsin K gene and characterized its structure using a combination of sequencing and PCR. It has 8 exons and 7 introns, and exons 2 through 7 are the same size as in the mouse CTSK gene. The transcribed portion of the gene is 92% similar to the mouse gene, and the first, second and third introns of both rat and mouse genes display 73 to 82% similarity. There are no classical TATA or CAAT boxes in the 5' flanking region of the rat cathepsin K gene. The rat cathepsin K gene contains canonical binding sites in both the promoter and the first intron for nuclear factors that play critical roles in osteoclast development and activation; these include AP-1, PU.1, micropthalmia (Mitf), and interferon-γ (IFN-γ) activated (GAS) motifs. To investigate transcriptional regulation of the CTSK gene, we have transiently transfected RAW 264.7 cells with CTSK promoter-firefly luciferase reporter gene (CTSK-Luc) plasmids and normalized activity with a co-transfected renilla luciferase control vector. Cells transfected with rKLPE1 (containing 1628 bp of the promoter region of the cathepsin K gene) exhibit 50 fold greater activity than cells transfected with the promoterless vector (GL3B). Cells transfected with the rKSPE1 vector containing only 74 bp of the 5' flanking region of the gene exhibit no more luciferase activity than those transfected with GL3B. Nested deletion mutation analysis reveals a reproducible pattern of marked enhancement and reduction in CTSK-luciferase activity based upon the length of the promoter in the plasmid. IFN-γ treatment (25 ng/ml) of the cells transfected with rKLPE1 suppresses luciferase activity by 75%. In order to study the role of members of the ETS nuclear transcription factor family in regulating CTSK gene expression, we co-transfected SV40-PU.1 and SV40-ETS2 expression vectors with CTSK-Luc plasmids and observed increases in promoter activity of 2.5 to 5-fold. Therefore, IFN-γ inhibits transcription, whereas PU.1 and ETS2 stimulate transcription of the CTSK gene. Additional transfection and gel mobility shift analyses will allow us to identify critical motifs in the promoter that regulate CTSK gene expression in response to IFN-γ, PU.1, and ETS2, to characterize nuclear binding factors that mediate the responses to IFN-γ, and to further elucidate the molecular basis of osteoporosis.

Dynamin Plays a Role in Osteoclast Motility and its Interaction with Cbl is Differentially Modulated by the Expression of Src or Pyk2. A. Bruzzaniti,*[1] A. Sanjay,[1] L. Neff,[1] C. Bardelay,*[2] E. Antoine,*[2] K. Lee,*[1] P. DeCamilli,[1] R. Baron.[1] [1]Yale University School of Medicine, New Haven, CT, USA, [2]Aventis Pharma, Paris, France.

Osteoclast motility requires attachment to integrins, recruitment of signaling proteins and subsequent cystoskeletal reorganization resulting in the formation of podosomes. Following engagement of the vitronectin receptor (VnR), Cbl, Src and Pyk2 interact to form a trimolecular signaling complex which plays a role in osteoclast attachment and motility. The absence of this signaling complex most likely contributes to the osteopetrotic phenotype observed in Src-/- mice (Sanjay et al., JCB, 152:181-195, 2001). Since podosome formation requires rapid actin turnover, we examined whether dynamin, a large GTPase involvement in endocytosis and remodeling of the cell membrane, interacts with Cbl and other signaling molecules downstream of integrins and if so, whether it plays a role in osteoclast motility. Previously, we demonstrated that dynamin II co-localized with podosomes in osteoclasts and in v-Src transformed cells, and that mutation within the GTPase domain of dynamin abolished podosome formation (Ochoa et al., JCB, 150:377-389, 2000). In the current study, we used co-immunoprecipitation followed by Western blot analyses to demonstrate that Cbl constitutively interacts with endogenous dynamin in osteoclast-like cells. Cbl and dynamin were also co-immunoprecipitated when overexpressed in HEK-293 cells stably expressing the VnR (293-VnR). Formation of the Cbl-

dynamin complex was adhesion-independent, but was differentially modulated by the expression of Src or Pyk2. Interestingly, over-expression of c-Src had a dominant-negative effect on Cbl-dynamin association, while inhibition of c-Src kinase activity with PP1, increased their association. Unlike c-Src, over-expression of Pyk2 enhanced Cbl-dynamin complex formation, perhaps by sequestering c-Src to the cell membrane. We next examined the effect of cytokine-induced phosphorylation on Cbl-dynamin association. EGF treatment decreased Cbl-dynamin complex formation in 293-VnR cells, and disrupted podosome and actin ring formation in osteoclasts. Finally, cyclosporin A and cypermethrin, specific inhibitors of the Ca-dependent phosphatase calcineurin, prevented the dephosphorylation of dynamin, and also disrupted podosome formation and decreased osteoclast motility. Overall, these studies suggest that dynamin II plays a role in osteoclast attachment and motility, possibly by interacting with Cbl and thereby affecting the formation of the Src/Cbl/Pyk2 trimolecular complex.

F236

Interleukin-7 Is a Direct Inhibitor of Osteoclastogenesis. S. Lee, J. Kalinowski,* S. Jastrzebski,* V. Katavic,* L. Puddington,* J. A. Lorenzo. University of Connecticut Health Center, Farmington, CT, USA.

Some cells expressing B220, a B lymphocyte antigen, can differentiate *in vitro* into osteoclast-like cells (OCL). Interleukin-7 (IL-7) is a major regulator of B-lymphopoiesis that is produced in bone marrow stromal cells. Previous studies found that systemic IL-7 administration enhanced osteoclastogenesis *in vivo* and interleukin-7 receptor deficient mice had increased trabecular bone mass. We examined the direct effects of IL-7 on osteoclastogenesis in bone marrow cultures. We also examined *in vitro* OCL formation in cells from IL-7 deficient mice and their bone mass *in vivo*. OCL were measured as TRAP(+) multinucleated cells. Bone mass in the humerus was measured by μ computerized tomography (SCANCO μCT-20).IL-7 inhibited OCL formation in M-CSF and RANKL (both at 30 ng/ml)-stimulated bone marrow cultures. Significant inhibitory effects were seen at 1 (57%) and 10 ng/ml (86%). IL-7 (10 ng/ml) treatment for the first 4 days of a 6-day culture was as effective as treatment for the entire period (77% inhibition). IL-7 also inhibited ($p<0.05$) OCL formation in bone marrow cultures that were treated with vitamin D_3 (10^{-8}M) (60%) or PTH (100 ng/ml) (54%). We found no significant effect of IL-7 treatment on the expression of RANKL or OPG mRNA as measured by RT-PCR in bone marrow cultures (treated with or without vitamin D_3, PTH or RANKL). IL-7 (10 ng/ml) increased the number of $B220^+$ cells (from 47% to 85%) in bone marrow cultures by flow cytometry.Bone marrow cells from IL-7 -/- mice showed a significant ($p<0.05$) increase in TRAP(+) OCL numbers in cultures that were stimulated with vitamin D_3 (136±13.3%) or PTH (196±18.8%) compared to cells from IL-7+/-. In addition, the number of granulocyte-macrophage colony-forming units (CFU-GM) in bone marrow of IL-7 -/- mice was 3 fold greater than in +/- controls. $B220^+$ bone marrow cells from IL-7 -/- mice demonstrated a 9 fold increase in TRAP (+) OCL numbers compared to cells from IL-7 +/- ($p<0.05$). IL-7 -/- animals also showed a 37% reduction in trabecular bone volume (BV/TV) and a 66% increase in trabecular separation (Tb.Sp) compared to IL-7 +/- animals ($p<0.05$).These results demonstrate a direct inhibitory effect of IL-7 on OCL formation *in vitro*. We also found that bone marrow cell cultures from IL-7 KO mice have a markedly increased capacity to form osteoclasts in unfractionated and $B220^+$ cell cultures. Furthermore, IL-7 -/- animals had significant trabecular bone loss suggestive of increased osteoclast activity. These findings are in contrast to previous reports that examined *in vivo* IL-7 administration or IL-7 receptor deficient mice. We conclude that in the present mouse models IL-7 is a direct inhibitor of osteoclastogenesis, which affects bone turnover *in vivo*.

F238

RANKL or TNF-alpha-Induced Osteoclastogenesis Requires TRAF5. K. Kanazawa,*[1] Y. Azuma,*[2] H. Nakano,*[3] A. Kudo.*[1] [1]Tokyo Institute of Technology, Yokohama, Japan, [2]Teijin Institute for Biomedical Research, Teijin Limited, Tokyo, Japan, [3]Department of Immunology Juntendo University School of Medicine, Tokyo, Japan.

TRAF families are intracellular adapter proteins that are involved in signal transduction pathways initiated by cell surface receptors, mainly TNF receptor family. TRAF2,-5,-6 activate NF-kB and JNK that are essential for osteoclast differentiation. We investigated TRAF5 function by using TRAF5 deficient mice in-vitro and in-vivo. Osteoclast progenitors were obtained by culturing bone marrow cells in the presence of M-CSF. To examine the ability of osteoclast differentiation, TRAF5+/+ and -/- osteoclast progenitors were differentiated into TRAP positive multinucleated cells (MNCs) by treating with sRANKL (50ng/mL) or TNF-alpha (50ng/mL) in the presence of M-CSF. The number of TRAP(+)MNCs from TRAF5-/- compared to TRAF5+/+ was 75% with RANKL, or 50% with TNF-alpha. Resorption pits on the osteologics were detected in mature osteoclasts differentiated from TRAF5-/- osteoclast progenitors. As in-vivo system, we employed hypercalcemia model mice by the continuous injection of PTH, and serum Ca concentration was measured. Although the peak of the Ca concentration was observed at the third day after injection in TRAF5+/+ mice, however, it was detected at the fifth day in -/- mice, demonstrating the delay of osteoclast differentiation in -/- mice. Because the delay of osteoclast differentiation was thought as the functional disorder of stromal cells, we examined calvarial cells that expressed TRAF5. In the presence of VtD3, osteoclast progenitors were co-cultured with calvarial cells from TRAF5+/+ or -/-. Because the number of TRAP(+)MNCs from TRAF5-/- was similar to that from TRAF5+/+, we conclude that TRAF5-/- stromal cells didn't influence the defect of osteoclast differentiation. After stimulation with RANKL or TNF-alpha, NF-kB and JNK were activated in osteoclast progenitors from TRAF5-/- as well as +/+, suggesting the unknown signal pathways in osteoclast differentiation. The decline of osteoclast differentiation in TRAF5-/- in vitro reflects the delay of osteoclast differentiation in vivo. We speculate that in -/- mice, unknown signal pathways via TRAF5 are disrupted. Here, we have provided the first evidence demonstrating TRAF5 function in osteoclast differentiation.

Regulation of Mouse Osteoprotegerin Gene Expression by 1,25 Dihydroxyvitamin D_3. T. Kondo,* R. Kitazawa, S. Maeda,* S. Kitazawa. Division of Molecular Pathology, Kobe University Graduate School of Medicine, Kobe, Japan.

Vitamin D_3 ($1,25(OH)_2D_3$) promotes osteoclastogenesis by upregulating the expression of receptor activator of NF-κB ligand (RANKL) gene and by downregulating that of osteoprotegerin (OPG) gene. To investigate the mechanism of the latter process, we analysed the effect of $1,25(OH)_2D_3$ on cis-acting elements of the mouse OPG gene and on the posttranscriptional modification process. The 5'-flanking region of the mouse OPG gene was cloned, and a series of deletion constructs ligated with a pGL3-Basic vector plasmid (Luc -116, Luc -697, Luc -1125, Luc -1487) were transfected into ROS17/2.8 and ST2 cells and subjected to luciferase assay. Transfected cells were treated with $1,25(OH)_2D_3$ (10nM) for 12h to assess its effect on the promoter activity. A DNA construct containing 116bp upstream of the transcription start site demonstrated basic promoter activity. Vitamin D_3 reduced the promoter activity of Luc -697, Luc -1125, and Luc -1487 to 70%. Electrophoretic gel motility shift assay (EMSA) was then carried out to determine the protein-DNA binding on the putative AP-1 binding site (-293/-287, TGACTGA). The nuclear extract from ROS17/2.8 cells was subjected to the binding reaction with ^{32}P-labeled oligonucleotide spanning the putative AP-1 binding site, and antibodies against c-Jun, Jun-D, Jun-B, c-Fos, Fos-B, Fra-1, and Fra-2 were used for the supershift reaction. EMSA showed specific binding to the putative AP-1 site and the supershift with an anti c-Jun antibody; the mutation of the putative AP-1 site (TGACTGA to CTCCCTC) nullified the protein-DNA binding. A construct containing the mutated AP-1 binding site (Luc -1487m) showed reduced promoter activity. Moreover, the Luc -1487m construct was resistant to $1,25(OH)_2D_3$-driven suppression. Since the OPG promoter has no consensus negative VDREs, the negative effect of $1,25(OH)_2D_3$ on promoter activity may be mediated by an indirect mechanism, probably through the AP-1 binding site (-293/-287). To assess the effect of $1,25(OH)_2D_3$ on OPG mRNA stability, ST2 cells were treated with $1,25(OH)_2D_3$ (10nM) in the presence of actinomycin D (10nM) and subjected to Northern blotting. OPG mRNA decreased significantly in $1,25(OH)_2D_3$-treated ST2 cells, suggesting that $1,25(OH)_2D_3$ shortens the halflife of OPG mRNA. It is therefore speculated that $1,25(OH)_2D_3$ negatively regulates the OPG gene by accelerating degradation of OPG mRNA as a main pathway and, additionally, by suppressing the OPG promoter activity through the AP-1 site.

F241

Importance of IL-1 and TNF-a in Physiological Bone Remodeling. H. Yasuda,[1] Y. Lee,*[1] S. Nakae,*[1] R. Horai,*[1] K. Sekikawa,*[2] M. Asano,*[3] Y. Iwakura.*[1] [1]Institute of Medical Science, University of Tokyo, Tokyo, Japan, [2]Department of Immunology, National Institute of Animal Health, Tsukuba, Japan, [3]Institute of Experimental Animals School of Medicine, Kanazawa University, Kanazawa, Japan.

Inflammatory cytokines such as IL-1 and TNF-a play a major role in bone resorption in pathological conditions (e.g. Rheumatoid arthritis and Periodontal diseases). However, the roles of these cytokines in bone remodeling in physiological conditions are unknown. Previous studies demonstrated that no obvious abnormality in bone in IL-1 receptor type I (IL-1R1) KO mice and TNF-a receptor type I (TNFR1) KO mice whose genetic background were C57BL/6 x 129/SV. In the present study we addressed the role of IL-1 and TNF-a in physiological bone remodeling using IL-1a,b double KO mice, TNF-a KO mice, and IL-1a,b, TNF-a triple KO mice, all of which were backcrossed to BALB/cA strain mice for 8 generations. Measurement of Bone Mineral Density (BMD) of femur with dual energy X-ray absorptiometry revealed significant increases in 8-week old mice with each genotype; IL-1a,b KO, 12.1%; TNF-a KO, 9.9%; IL-1a,b, TNF-a KO, 24.8% relative to wild type. Radiographs showed massive increase in bone density especially in the epiphysis and metaphysis of femur of these KO mice. Histological analysis also showed that marked increase of bone volume in trabecular bone of these KO mice. The thickness of cortical bone also was increased in these KO mice. The morphology of the growth plate and the columnar organization of chondrocytes were normal, but cartilaginous remnants were markedly observed in the cortical bone of these KO mice, which suggests a decrease in osteoclastic activity in resorption of bone and cartridge. Preliminary results of in vitro culture showed that osteoclast differentiation and/or activation is partially impaired in bone marrow of these KO mice. Taken together these results indicate that IL-1 and TNF-a have an important role in physiological bone remodeling and their effects are synergistic.

F244

A Peptide Antagonist Mimicking the 3rd TNF-like Cysteine-Rich Domain of Mouse OPG Inhibits RANKL/M-CSF Induced Osteoclastogenesis. S. Li,*[1] E. Lee,*[1] Y. Jin,*[1] R. Namgung,[2] S. Lim.[1] [1]Internal Medicine, Medical School of Yonsei University, Seoul, Republic of Korea, [2]Department of Pediatrics, Medical School of Yonsei University, Seoul, Republic of Korea.

OPG, as a decoy receptor, is well known to inhibit osteoclastogenesis by preventing RANKL from binding to RANK. To study which region of OPG is important for its biological activity and to develop the therapeutic peptidomimetics, we deleted the extracellular domains of OPG and synthesized oligopeptides according to the sequence of the 3rd TNF-like cysteine-rich domain of mouse OPG. Several deleted forms of mouse OPG DNAs, encoding 401(OPG1)-, 194(OPG2)-, 123(OPG3)-, 110(OPG4)-, 73(OPG5)-, and 78(OPG6)-amino acid residues, were constructed by using PCR method. They were then subcloned into pMT/V5-His, an inducible expression vector for insect cell (S2 cell). After stable transfection to the S2 cell with the constructed DNAs, we obtained several S2 cell lines stably over-expressing different OPGs in the secreted forms, followed by identification with western blotting analysis. Osteoclasts were successfully induced from mouse bone marrow cells with 3~5 days treatment of M-CSF and RANKL, and were identified using TRAP assay and acid phosphatase assay. The CuSO4-induced media obtained from each cell lines were applied to the bone marrow cells together with M-CSF and RANKL at

the beginning of culture. Compared to the positive control that were treated only by M-CSF and RANKL, the OPG1 and OPG2 showed strong inhibitory effect on the osteoclast formation and the acid phosphatase activity after 3~5 days co-treatment. However, the induced media containing OPG3, OPG4, OPG5 and OPG6, respectively, failed to show any inhibitory activity in the TRAP assay and the acid phosphatase assay. In addition, three oligopeptides, which were designed according to the sequence of the 3rd TNF-like cysteine-rich domain of mouse OPG, were also tested to study if short oligopeptide could produce a similar inhibitory action as the fragmented OPGs. Interestingly, two of three oligopeptides showed the significantly inhibitory effect on osteoclastogenesis only at high concentration (10-4M). These results suggest that not only the domain 3 and 4, but also domain 1 and 2 do be necessary for full biological activity of OPG, and the short oligopeptide being capable of interfering RANK ligand and RANK interaction, thereby decreasing the osteoclastogenic potential of this cytokine, could be developed.

F246

Estrogen Regulates the Production of VEGF for Osteoclast Formation and Activity in Osteopetrotic *op/op* Mice Lacking Functional M-CSF. I. Kodama,[1] S. Niida,[2] M. Sanada,[1] Y. Yoshiko,[2] M. Tsuda,[1] N. Maeda,[2] K. Ohama.[1] [1]Obstetrics and Gynecology, Faculty of Medicine, Hiroshima University, Hiroshima, Japan, [2]Anatomy, Faculty of Dentistry, Hiroshima University, Hiroshima, Japan.

Purpose: It is recognized that the estrogen deficiency increases the macrophage colony- stimulating factor (M-CSF) production in stromal cells to support osteoclastic bone resorption. We recently demonstrated that angiogenetic cytokine, vascular endothelial growth factor (VEGF), could substitute for M-CSF in the osteoclast recruitment in the osteopetrotic *op/op* mice lacking functional M-CSF. Furthermore, we found that estrogen deficiency induced by ovariectomy (OVX) up-regulated osteoclastic bone resorption in these mice. We therefore assessed the effects of VEGF on the bone loss induced by estrogen deficiency in these mice. **Design and methods:** *Op/op* mice 8 weeks of age were bilateral OVX or sham-operated. Mice were sacrificed at 8, 10, and 12 weeks of age and femurs were removed for preparations. Some OVX mice were treated with the three consecutive injections of 120 micro liters per body of VEGF neutralizing antibody at 12 hours intervals starting from 36 hours before sacrificing at 4 weeks after OVX. VEGFR-1/Fc chimeric protein (600 micrograms / kg per day) setting in the implanting Alzet 1002 osmotic pumps or the implanting slow release subcutaneous pellets of 17beta-estradiol were administrated in a dorsal subcutaneous pocket of the mice at the time of OVX. These mice were sacrificed at 2 weeks after surgery. Changes of serum levels of VEGF were measured by enzyme linked immunosorbent assay (ELISA). Changes of messenger RNA (mRNA) levels of VEGF, VEGF receptor-1/Flt-1, and osteoclast differentiation factor (ODF/TRANCE/RANKL) in bone tissue were measured by RT-PCR. **Results:** Trabecular bone volume of femur decreased significantly in OVX-*op/op* mice. The number of TRAP-positive osteoclasts increased significantly in OVX mice. Osteoclasts induced by OVX predominantly expressed Flt-1. But we could not detect Flk-1/KDR in these osteoclasts. Osteoblasts in OVX mice expressed VEGF stronger than osteoblasts in Sham-operated mice. Increase of TRAP-positive cell number was inhibited by not only 17beta-estradiol treatment but also VEGF antagonistic treatment. Serum levels of VEGF demonstrated higher in OVX mice than Sham-operated mice. VEGF mRNA, Flt-1 mRNA, and ODF mRNA levels in bone tissue, demonstrated higher in OVX mice than Sham-operated mice. **Conclusions:** The production of VEGF stimulated by estrogen deficiency resulted in increase of the osteoclastic bone resorption in M-CSF deficient *op/op* mice. Furthermore, our results demonstrated that VEGF signal was predominantly mediated through Flt-1.

F248

The Novel Molecule on Mouse Stromal Cells, OCRA, Regulates Osteoclastogenesis. S. Arai,*[1] N. Amizuka,[2] Y. Azuma,[3] A. Kudo.[4] [1]Tokyo Institute of Tecnology, Kanagawa, Japan, [2]Niigata University, Niigata, Japan, [3]Teijin institute for Biomedical Research, Tokyo, Japan, [4]Tokyo Institute of Technology, Kanagawa, Japan.

Osteoclastogenesis is regulated by RANKL expressed on stromal cells. We have observed that RANKL expressed on the mouse pre-B cell lines stimulated none or less osteoclastogenesis, suggesting that RANKL alone on the cells hardly regulates osteoclastogenesis, and osteoclastogenesis requires another molecule or system on stromal cells for effective activation. Here, we tried to isolate new surface molecules on stromal cells by establishing monoclonal antibodies. The mouse stromal cell line, TSB13, which can support osteoclastogenesis, was immunized into a rat, and a monoclonal antibody, A15-1, was chosen. A15-1 bound to the surface antigen of TSB13, termed OCRA (osteoclastogenesis related antigen). A15-1 was positive for mesenchymal cell lines, but negative for hematopoietic cell lines analyzed by flow cytometry. The expression level of OCRA was slightly induced by the treatment of VtD3. Immunoprecipitation revealed that OCRA is 55 kDa. When A15-1 was incubated in the co-culture of osteoclast progenitors and TSB13 in the presence of VtD3, the osteoclast cell number was decreased in the antibody dose-dependent manner although no significant changes were observed in the RANKL-induced osteoclastogenesis in the same antibody conditions. The result showed that A15-1 inhibited only stromal dependent osteoclastogenesis. Using other osteotropic factors, PTH and IL-1β, the inhibition of A15-1 for osteoclastogenesis was also observed. Next, we examined the stage of A15-1 inhibition in the osteoclast differentiation system in various time courses, indicating that the initial 2 days treatment of A15-1 was good enough for inhibition, therefore A15-1 inhibits the early stage of osteoclast differentiation. The inhibitory effect of A15-1 was tested in the primary stromal cells derived from bone marrow. Bone marrow cells cultured in the presence of VtD3 were treated with A15-1, resulting that A15-1 inhibited osteoclastogenesis dose-dependently. The result showed that A15-1 acts on bone marrow stromal cells, which have the supportive activity for osteoclastogenesis. In in-vivo, mice for PTH-induced hypercalcemia were treated with A15-1. The enhanced number of osteoclasts was significantly decreased in the treatment of A15-1, and A15-1 restored the severe level of the osteoclast related parameters, ES/BS and N.Oc/B.Pm to the normal, although osteoblast related parameters were not significantly altered. This study revealed that A15-1 antigen, OCRA, regulates osteoclastogenesis on stromal cells.

F250

Ovariectomy-Induced Increases in Osteoclastogenesis in Mice Are IL-1 R1 Dependent and Mediated by B220$^+$ Bone Marrow Cells. V. Katavic,* S. K. Lee, H. L. Aguila,* L. Puddington,* J. A. Lorenzo. University of Connecticut Health Center, Farmington, CT, USA.

Ovariectomy (OVX) increases the number of osteoclast (OCL) and lymphocyte precursor cells in the bone marrow of mice. As a result, OCL formation increases and bone loss occurs. We suspect that osteoclasts and B-lymphocytes share a common progenitor within the bone marrow. This OCL progenitor appears to have a B220$^+$/RANK$^-$ phenotype. We previously showed that the number of OCL formed in B220$^+$ cell cultures from OVX mice is 2-fold greater than from sham operated (SHAM) mice. We also showed that type I interleukin-1 receptor (IL-1 R1) deficient (KO) mice do not lose bone mass after ovariectomy. In this study, we examined differences in OCL formation in bone marrow cell cultures from SHAM and OVX wild type (WT) and KO mice, 3 weeks after surgery. OCL formation was stimulated by treatment with M-CSF and RANKL (30 ng/mL for each, $1x10^5$ cells/well of a 96 well plate for 6 days). OCL were identified as TRAP$^+$ multinucleated cells. These cells expressed abundant calcitonin receptors and resorbed bone.The total number of bone marrow cells increased with OVX by 51.9±3.8% in WT ($p<.001$) and 22.8±2.6% in KO mice ($p<.001$). The percentage of B220$^+$ bone marrow cells increased 1.9-fold in WT mice (SHAM=24.7±2.0%, OVX=47.1±0.8%, $p<.001$), and 1.6-fold in KO mice (SHAM=25.3±1.9%, OVX=41.2±3.1%, $p<.001$). There were no differences between WT and KO mice in the ability of OVX to increase the number of pro-B or pre-B-lymphocytes (HSA^{low} or HSA^{high} respectively, both B220$^+$/IgM$^-$) or the percentage of cells expressing c-Fms (the M-CSF receptor) in bone marrow. Unfractionated bone marrow cultures from WT OVX mice showed a 1.8-fold increase in OCL formation compared to SHAM ($p<.05$). However, in cultures from KO mice, there was no change in OCL formation with OVX. Using FACS, we separated bone marrow cells into B220$^+$ (purity≥98.5%) and B220$^-$ populations (purity≥99.8%). In both WT and KO B220$^-$ cell cultures OCL formation was not affected by OVX. In B220$^+$ WT cells OVX increased the number of OCL by 2-fold ($p<.05$). In contrast, in B220$^+$ KO cells there was no effect of OVX on OCL formation.These results demonstrate that OVX increases the number of B-lymphocyte precursors in both WT and KO mice. However, OVX increases OCL formation in cultures of whole bone marrow and B220$^+$ cells only from WT and not KO mice, suggesting that OVX-induced increases in OCL formation are dependent on the presence of IL-1 R1. We conclude that the ability of estrogen withdrawal to increase osteoclastogenesis in bone marrow cells is mediated by changes in the B220$^+$ bone marrow population through an IL-1 R1 dependent pathway.

Phagocytosis Determines Lineage Destiny of Macrophage-Osteoclast Precursors Incubated in TNF-α/RANKL Through Smad7 Induction and Suppression of TGF-β Signaling. K. Fuller, K. E. Bayley,* T. J. Chambers. Cellular Pathology, St George's Hospital Medical School, London, United Kingdom.

It has recently been found that TNF-α, like RANKL, can induce osteoclast formation in vitro from cells of the mononuclear phagocyte system. This is unexpected, since TNF-α is considered crucial to macrophage activation in host defense, yet osteoclasts are not seen in inflammatory tissue. Presumably, there are additional factors in vivo that determine the lineage response of macrophage-osteoclast precursors to TNF-α. It has been suggested that osteoclast-induction by TNF-α in vitro is due to 'priming' by RANKL in stromal cell-contaminated cultures, but we could find no evidence for this. One of the characteristics of all inflammatory tissues is that they contain endocytogenic material. We therefore tested the response of osteoclast-macrophage precursors to TNF-α in the presence vs the absence of phagocytic targets. We found that formation of tartrate-resistant acid phosphatase positive multinuclear cells (TRAP cells) was strongly suppressed in cultures to which latex particles, glutaraldehyde-fixed red cells, or necrotic thymocytes were added. Inhibition was observed even when TGF-β was added to cultures, or when precursors were incubated on bone slices, conditions which otherwise strongly enhance osteoclast-induction. Importantly, incubation of precursors with powdered bone also strongly suppressed TRAP cell formation, suggesting that it is the act of phagocytosis, rather than the nature of the material ingested, that determines lineage. Induction of TRAP cells and bone resorption by RANKL was similarly inhibited by phagocytosis. The inhibition of TRAP cell formation was not attributable to an autocrine effect of release into the supernatant of osteoclast-inhibitory material by phagocytosing cells, or to changes in TRAF6 expression. It is known that TGF-β is essential for osteoclast formation. We therefore tested the effect of phagocytosis on components of the TGF-β signaling pathway. Phagocytosis increased levels of protein expression of the antismad Smad7, and suppression of TGF-β signaling, induced by overexpression of Smad7, suppressed TRAP cell formation. This may account for absence of osteoclasts in sites of inflammation. It also raises the possibility that RANKL might have actions on macrophages other than osteoclast-induction.

F254

The p38 Specific Inhibitor SB203580 Blocks Osteoclast Formation in RAW 264.7 Cells Through Down Regulation of cFos mRNA Expression and Reduced AP-1 Binding. S. Srivastava, N. K. Shevde, A. C. Bendixen, K. M. Dienger,* J. W. Pike. Molecular and Cellular Physiology, University of Cincinnati, Cincinnati, OH, USA.

RANKL and its receptor RANK are critical regulators of osteoclast (OC) formation. It is now well documented that RANKL signaling engages TRAF6 which in turn activates downstream MAPKs, NF-kB and the PI3 pathways that lead to activation of the transcription factors complex AP-1 (Fos and Jun) and NF-kB. We and others have previously shown that RANKL treatment simultaneously stimulates JNK and p38 pathways and that the p38 specific inhibitor SB203580 blocks osteoclast formation in a dose-dependent manner in both RAW264.7 cells and bone marrow monocytes. The exact molecular mechanism through which SB203580 blocks osteoclast formation is not known, however. To explore

this inhibitory effect, we transfected RAW264.7 cells with luciferase reporter genes under the control of either AP-1 or NF-kB transcription factors and then treated the cells with RANKL in the absence or presence of SB203580. AP-1 dependent luciferase activity was strongly induced by RANKL; inclusion of SB203580 (5uM), however, suppressed this luciferase activation. These results suggest that the p38 kinase might regulate either directly or indirectly the activity of either c-Jun or c-Fos. To further investigate whether decreased transcription activity was due to decreased DNA binding, we conducted EMSA using both AP-1 and NF-kB consensus DNA binding sequence as probes. Our results clearly demonstrate that SB203580 pretreatment suppressed AP-1 DNA binding in a dose-dependent manner while it had no effect on NF-kB DNA binding. SB203580 pretreatment had no effect on JNK1 activity and did not suppress the expression of c-Jun protein. We therefore hypothesized that SB203580 pretreatment might affect the expression of c-Fos. To determine whether the expression of c-Fos mRNA was altered by SB203580, we treated RAW264.7 cells with RANKL in absence or presence of SB203580 (5uM) for 3 hours, extracted total RNA using the Trizol reagent, prepared cDNA, and then subjected the samples to semi-quantitative cycle-dependent RT-PCR using primers to b-actin and c-Fos as well as NF-kB dependent IL-6 and AP-1 dependent TNF-a. SB203580 treatment significantly suppressed the expression of both c-Fos and TNF-a, but had no effect on the expression of mRNA for IL-6 . We conclude that activation of p38 by RANKL is essential for osteoclast formation in RAW264.7 cells and that at least one target of p38 action is c-Fos.

F256

TNF-alpfa and RANKL Synergistically Stimulate Murine Osteoclast Differentiation from TRAF6-deficient Osteoclast Progenitor Cells. Y. Azuma,[1] K. Kaji,*[2] A. Naito,*[3] T. Kamimura,*[1] J. Inoue,*[4] A. Kudo.[2] [1]Department of Pharmacology, Teijin Institute for Biomedical Research, Tokyo, Japan, [2]Department of Life Science, Tokyo Institute of Technology, Yokohama, Japan, [3]Department of Oncology, Institute of Medical Science, Tokyo, Japan, [4]Faculty of Science and Technology, Keio University, Yokohama, Japan.

Although tumor necrosis factor receptor-associated factor(TRAF)6 is required in RANK-RANKL signaling for osteoclastogenesis, it has been remained unclear whether TRAF6 is crucial in tumor necrosis factor-alpha(TNF)-induced osteoclastogenesis. We examined TRAF6 function in the TNF-induced osteoclastogenesis by using osteoclast progenitor cells (MDS-/- cells) from TRAF6-deficient mice. The results demonstrated that TNF did not effectively induce osteoclast differentiation from MDS-/- cells. These results demonstrated that TRAF6 is essentially involved in the TNF receptor(TNFR) signaling in osteoclast differentiation. However, a few mature multinucleated osteoclasts were left in TNF-treated MDS-/- cells and they have been resorption activity, suggesting that the some other signaling mechanism besides the TRAF6 pathway. In order to reveal how TRAF6 is involved in the TNF-induced osteoclast differentiation from osteoclast progenitor cells, we examined the expression of TRAF6 protein in the TNF-treated osteoclast progenitor cells. In the process of TNF-induced osteoclastogenesis, the expression of TRAF6 protein increased. TNF synergistically stimulated RANKL-induced osteoclast differentiation from osteoclast progenito cells, suggesting the relationship between TRAF6 up-regulation by TNF-treatment and RANK-RANKL signaling. To demonstrate that the role of TRAF6 in the synergy between TNF and RANKL, MDS-/- cells were treated with various combinations of TNF and RANKL. Surprigingly, co-treatment with TNF and RANKL rescued the failure of RANKL-induced osteoclast differntiation from MDS-/- cells. These results suggest that TNF and RANKL synergistic induction of osteoclastogenesis involves the cross-talk between TNF-TNFR and RANK-RANKL signaling pathways besides the TRAF6.

F258

Multiple RANKL-Induced Programs of Gene Expression are Suppressed by Estrogen During Osteoclast Differentiation. N. K. Shevde,[1] A. C. Bendixen,[1] D. E. Murphy,*[1] R. Sladek,*[2] T. J. Hudson,*[2] J. W. Pike.[1] [1]Molecular and Cellular Physiology, University of Cincinnati, Cincinnati, OH, USA, [2]Human Genome Center, McGill University, Montreal, Quebec, Canada.

Steroid deficiency leads to a substantial increase in bone turnover and a critical imbalance between bone formation and resorption. This imbalance results in a progressive loss of trabecular bone mass, due in part to an increase in osteoclast formation from monocytic precursors in bone marrow. We have used bone marrow monocytes and RAW264.7 cells as models of osteoclast (OC) differentiation to examine the ability of estrogens (E) to negatively regulate this process. Accordingly, we have found that E suppresses OC formation, largely through a downregulation of JNK1 activity and suppression of both c-Jun activation and expression. To examine E's actions more globally, we contrasted RNA expression profiles from RAW264.7 cells that had been treated with RANKL for periods up to 120 hr in the absence or presence of E using DNA microarrays. All changes in gene expression were confirmed using Realtime PCR analysis. RANKL induced rapid (1 to 4 hr) changes in the expression of members of several classes of genes including immediate early gene transcription factors such as c-Fos, c-Jun, JunB, EGR1 and 2 and others. In addition, RANKL prompted a massive induction of proinflammatory cytokine genes such as IL-1a, IL-1b, TNFa, and to a lesser extent IL-6, as well as numerous other cytokines, chemokines and inflammatory factors. These responses returned to baseline within 12 hr of RANKL treatment. While multinucleated OC were not detectable until 48 hours post RANKL treatment, transcripts for TRAP, MMP-9, cathepsin K, carbonic anhydrase II and others inherent to the osteoclast phenotype emerged beginning at 24 hr and accumulated significantly over the next 3 days. Transcripts responsible for the macrophage phenotype were simultaneously extinguished. The addition of E and RANKL together at 0 hr exerted a profound suppressive effect on RANKL- induced gene expression. Accordingly, numerous immediate early genes were strongly (50%) suppressed. E also suppressed transcripts for the proinflammatory cytokines, including those for IL-1a, IL-1b, IL-6 and TNF. E exerted numerous additional effects, acting to suppress the expression of transcription factors that may play a role in OC formation as well as the induction of genes representative of the OC phenotype. These and other observations suggest that E may play a dominant and pervasive role in regulating multiple facets of OC differentiation in RAW264.7 cells. Current studies are focused upon the mechanism through which small numbers of E receptors can mediate such profound effects on the formation of OCs in vitro.

Use of Phage Display to Identify Peptides that Inhibit Osteoclast Differentiation. P. He,*[1] N. Islam,*[1] B. Wang,*[2] E. M. Greenfield.[1] [1]Orthopaedics, Case Western Reserve University, Cleveland, OH, USA, [2]Medicine, Case Western Reserve University, Cleveland, OH, USA.

Stromal cells regulate differentiation and activity of osteoclasts through interactions that require direct cell-cell contact. Osteoprotegerin blocks these interactions by binding to RANKL expressed on the stromal cell plasma membrane. We employed peptide phage display to identify novel molecules that inhibit interactions between stromal cells and osteoclast precursors. For this purpose, a mixture of two peptide libraries ($X_2CX_{14}CX_2$ and X_2CX_{18}) was initially screened by four rounds of positive/negative selection. Positive selection depended on binding to stromal cells that had been cultured with 10 nM 1,25-dihydroxyvitamin D_3 (1,25-D_3) for six days, while negative selection depended on the absence of binding to cells cultured without 1,25-D_3. ST2 stromal cells were used for the first and third rounds of selection and MC3T3-G2/PA6 stromal cells were used for the second and fourth rounds. Thirty phage clones were isolated and DNA encoding the inserted peptides was sequenced. Three families of peptides were identified, none of which exhibit significant homology with known proteins or genes. This result is not surprising since peptide phage display often selects for "mimotopes" that mimic the three dimensional structure of endogenous proteins rather than their linear amino acid sequence. The ability of the isolated phage clones to bind to ST2 cells was measured. All 30 clones exhibited high affinity binding to ST2 cells that had been cultured with 10 nM 1,25-$D_3$for six days. In contrast, little or no binding was found using ST2 cells cultured without 1,25-D_3. Peptides corresponding to the consensus sequences of the phage families were synthesized. The effect of the peptides on osteoclast differentiation induced by 1,25-D_3 was assessed in co-cultures of murine spleen cells and ST2 cells. Peptide #3 inhibited osteoclast differentiation in a dose-dependent manner. Maximal effects were induced by 140 nM peptide #3, which inhibited formation of TRAP+ multinucleated cells by 81±4.5% (p=0.0001). Half-maximal inhibition was induced by 1.4 nM peptide #3 (p=0.005). In contrast, 140 nM of peptide #1, peptide #2, or a scrambled form of peptide #3 had little or no effect on osteoclast differentiation. Despite potently inhibiting formation of TRAP+ multinucleated cells, peptide #3 had little or no effect on formation of TRAP+ mononucleated cells. Thus, peptide #3 blocks a relatively late step in osteoclast differentiation through a mechanism of action that is distinct from that of osteoprotegerin, which blocks formation of both TRAP+ multi- and mono-nucleated cells. Peptide #3 should be a useful starting point for a peptidomimetic drug discovery program aimed at blocking osteoclast differentiation.

F262

Melatonin Increases Bone Mass by Suppressing Bone Resorption Through Down-Regulation of the RANKL-Mediated Osteoclastogenesis in Mice. K. H. W. Lau,[1] H. Koyama,*[1] O. Nakade,[2] Y. Takada,*[2] T. Kaku.[2] [1]Pettis Mem VAMC, Loma Linda, CA, USA, [2]Health Sciences University of Hokkaido, Hokkaido, Japan.

We and others recently reported that melatonin stimulates osteoblast activity in vitro. In this study, we sought to test if daily melatonin administration in mice would increase bone mass in vivo. Four groups of 4-week-old male ddy mice (n = 6 per group) received daily injections of solvent, 1, 5, or 50 mg/kg/day melatonin, respectively, for 4 weeks. The melatonin treatment significantly increased BMD (by DEXA) (by 36%, P<0.005), TV (by 49%, P<0.01), and Tb.Th (by 19%, P<0.05) in the tibia, supporting the premise that melatonin increases bone mass in mice. There was no significant increase in any of the test bone formation parameters (BFR/BS, MAR, OV/TV, OS/BS, Ob.S/BS) between melatonin- and vehicle-treated mice. In contrast, the bone resorption parameters were markedly reduced in a dose-dependent manner in melatonin-treated mice compared to vehicle-treated mice [i.e., Oc.S/BS (by 74%, P<0.05) and N.Oc/BS (by 76%, P<0.005)], indicating that melatonin increases bone mass through a suppression of bone resorption rather than a stimulation of bone formation. Further assessment of the effects of melatonin on bone resorption revealed that melatonin (up to 500 μM) caused a significant (P<0.001) dose-dependent inhibition of bone resorption activity (assayed with the pit formation assay) of osteoclasts in vitro, but only in the presence of osteoblasts. Melatonin had no effect on the bone resorption activity of isolated rabbit osteoclasts, suggesting that melatonin inhibits osteoclastic resorption through osteoblasts. Two osteoblastic proteins (RANKL and OPG) are potent regulators of bone resorption, in that RANKL increases and OPG inhibits osteoclastogenesis. Thus, we tested if melantonin treatment would affect the production of RANKL and/or OPG in the mouse MC-3T3-E1 osteoblastic cells. Melatonin (from 1 to 500 μM) significantly (P<0.001 for each) increased, in a dose-dependent manner, both the mRNA (up to 2-fold) and protein (up to 4-fold) levels of OPG. Conversely, melatonin at the same doses markedly (P<0.001) reduced the mRNA level of RANKL (to <20% of that of the vehicle-treated control). Thus, these findings support our contention that melatonin may inhibit osteoclastic resorption through an increased OPG expression as well as a decreased RANKL expression in osteoblasts. In conclusion, we have demonstrated for the first time that melatonin inhibits bone resorption through downregulation of the RANKL-mediated osteoclastogenesis, which subsequently leads to an increase in bone mass.

F266

A Signaling Complex Containing TAK1, TAB2, and TRAF6 Is Recruited to RANK in Response to the Ligand Stimulation. N. Sakurai,[1] J. Mizukami,*[1] N. Sato,*[1] M. Tsuda,*[1] H. Sakurai,*[1] G. Takaesu,*[2] J. Ninomiya-Tsuji,*[2] K. Matsumoto,*[2] H. Akatsuka.*[1] [1]Discovery Research Laboratory, Tanabe Seiyaku Co., Ltd., Osaka, Japan, [2]Dept. of Molecular Biology, Nagoya University, Nagoya, Japan.

Receptor activator of NF-κB(RANK) and its ligand, RANKL, are key molecules for differentiation and activation of osteoclasts. Recent studies have demonstrated that TNF

receptor-associated factor 6 (TRAF6) is a pivotal component of RANK signaling pathway. Previously, we showed that dominant negative forms of TGF-β activated kinase 1 (TAK1) and TAK1 binding protein 2 (TAB2), components in the TRAF6-mediated IL-1 signaling, suppressed NF-κB activation induced by overexpression of full-length RANK in HEK293T cells. However, the intracellular behavior of these proteins in the RANKL-induced signaling pathway under physiological conditions has been poorly characterized. Here, we investigate the mechanism of endogenous signal transduction induced by RANKL.To investigate the ligand-stimulated RANK signaling, we generated a clonal cell line of HEK293, 293RANK, stably expressing full-length RANK. Activations of NF-κB, JNK, and p38MAPK that are activated by RANKL in osteoclasts were induced in response to RANKL in 293RANK cells. Therefore, the 293RANK cells are useful for studying endogenous signaling events initiated by RANKL. RANKL induced the activation of endogenous TAK1 in 293RANK cells, with maximal activation at 2-5 min after stimulation. TAK1 activation was followed by activations of IKK and JNK that are situated downstream of TAK1 in IL-1 signaling. Furthermore, RANKL stimulation induced an interaction of TAK1 with TRAF6 at the comparable time of the TAK1 activation and then TAK1 was rapidly released from TRAF6. In IL-1 signaling pathway, TRAF6 and TAK1 are known to associate via TAB2. To examine the complex formation of these signaling components with RANK, immunoprecipitation experiments were performed. In the RANKL-treated 293RANK cells, RANK was coimmunoprecipitated as well as TRAF6 with anti-TAB2 antibody, indicating that associations of TAB2 with RANK and with TRAF6 also depend on the ligand stimulation. Surprisingly, the immunopricipitates of the RANKL-treated extracts with anti-TAK1 antibody also contained both RANK and TRAF6, suggesting direct and transient association of TAK1-TAB2-TRAF6 to RANK.These results suggest that the formation of a complex containing RANK, TRAF6, TAB2, and TAK1 is involved in the RANK signaling pathway and may regulate development and function of osteoclasts.

Identification of the Src SH3 Binding Site Within the Proline-Rich Region of Cbl. A. Sanjay, T. Miyazaki,* W. C. Horne, R. Baron. Yale University, New Haven, CT, USA.

Cbl is a substrate of the non-receptor tyrosine kinase Src which is phosphorylated downstream of integrins in osteoclasts and, like Src, is involved in the regulation of osteoclast motility. We and others have found two distinct interactions between Src and Cbl, the first between the SH3 domain of Src and the proline rich region (PR) of Cbl (residues 481-690) and the second between the phosphorylated Y416 of Src and the phosphotyrosine binding domain (PTB) of Cbl. The latter interaction both inhibited Src kinase activity and reduced cell adhesion of vitronectin receptor-expressing 293 cells to vitronectin. Mutation in the PTB domain of Cbl, however, did not prevent the Src-Cbl interaction, indicating that the primary interaction is between the Src SH3 and Cbl PR regions. Here, we have identified the specific sequence within the Cbl PR domain that associates with the Src SH3 domain.Analysis of the PR sequence revealed that two sites, RDLPPPPPPDR (Cbl540) and RPIPKVPV (Cbl592), matched the consensus sequence RxxPxxP for binding to the SH3 domain of Src. To determine which of these regions interact with Src, we performed a competitive binding assay, incubating 293 VnR cell lysates which contain endogenous Cbl with GST-conjugated SrcSH2, SrcSH3 and Src SH3SH2 domains in the absence or presence of either a positive control peptide (RALPPLPRA), Cbl540 or Cbl592. Western blot analysis revealed that Cbl bound to both GST-SrcSH3 and GST-SrcSH3SH2, but not to GST or GST-SrcSH2. Peptide Cbl540 prevented endogenous Cbl binding to both GST-SrcSH3 and GST-SrcSH3SH2, whereas peptide Cbl592 failed to compete with Cbl even at high concentrations, indicating that it is Cbl540 that contains the primary Src-binding motif within the PR region of Cbl. Theoretically, Cbl 540 might bind the SH3 domain in either the N-to-C (RDLPPPP) or the C-to-N (PPPPDR) direction. To determine in which orientation the SH3 domain binds to Cbl PR, we replaced prolines with alanines [RDLAPPA (Cbl540F) and APAPDR (Cbl540R)] and used the mutated peptides in the assay. Peptide Cbl540F had no effect whereas Cbl540R completely abolished the binding of Cbl to the SH3 domain of Src, indicating that it is the reverse orientation of the peptide Cbl540 which binds to Src. Expression of these mutated proteins either in the 293-VnR cells or in osteoclasts will help elucidate whether initial docking of Src at the Cbl PR region is required for the subsequent down regulation of Src kinase activity by Cbl, and/or for the Cbl-mediated ubiquitination of Src events that participate in the regulation of osteoclast adhesion and migration.

F270

PYK2 Autophosphorylation Site Y402, but Not Kinase Activity, Is Necessary for Adhesion-induced Phosphorylation of Yyrosines in PYK2 C-terminal Domain and Osteoclast Spreading. P. T. Lakkakorpi,*[1] A. J. Bett,*[2] L. Lipfert,*[3] G. A. Rodan,[3] L. T. Duong.[3] [1]Anatomy, Inst. of Biomed., Univ. of Turku, Turku, Finland, [2]Virus and Cell Biol., Merck Res. Labs., West Point, PA, USA, [3]Bone Biol. & Osteoporosis, Merck Res. Labs., West Point, PA, USA.

Ligand engagement of alpha v beta 3 integrins in osteoclasts induces PYK2 tyrosine phosphorylation, activation of its tyrosine kinase, its association with c-Src, and cytoskeletal reorganisation. PYK2 localises to podosomes, and in bone resorbing osteoclasts, to the sealing zone. Using adenovirus expressing PYK2 antisense we have recently shown that PYK2 is necessary for osteoclastic bone resorption. To further study the function of PYK2 in osteoclasts we examined the effects of overexpressing (using adenovirus) a PYK2 kinase-dead (K457A) mutant and an autophosphorylation site (Y402F) mutant on adhesion-mediated signalling, cell spreading and migration. Infection of co-cultures for 3-days, resulted in 3-4 fold higher expression, in purified pre-fusion osteoclasts (pOCs) or osteoclast-like cells, of exogenous wild type PYK2(wt) or its mutants, relative to endogenous PYK2. In adhered kinase-dead PYK2(K457A) cells, tyrosines Y402, Y579/Y580 and Y881 were phosphorylated to the same extent as PYK2(wt), whereas phosphorylation of these tyrosines was severely reduced in PYK2(Y402F) cells. Similarly, expression of kinase-dead PYK2(K457A) did not reduce pOC spreading, while expression of PYK2(Y402F) abolished cell spreading on vitronectin. Co-immunoprecipitation experiments showed that PYK2(wt) and (K457A) associate with c-Src, whereas PYK2(Y402F) does not. On the other hand, neither PYK2(wt) nor its mutants inhibited pOC chemotactic migration towards M-CSF. These observations are in agreement with previous findings, showing that diminished cell spreading and migration in Src-/- pOCs, was fully occurring with M-CSF. Interestingly, both PYK2 mutants localised to podosomes in osteoclasts seeded on glass, suggesting that podosomal targeting is independent of the ability to recruit c-Src. Taken together, PYK2 phosphorylation at Y402, but not its kinase activity, appears to be important for its adhesion-induced association with c-Src, which in turn phosphorylates additional tyrosines in the C-terminal domain of PYK2. This leads to further recruitment of downstream signalling molecules, important for the cytoskeletal reorganisation of osteoclasts. Furthermore, phosphorylation of kinase-dead PYK2(K457A) at Y402 suggests that a separate kinase can activate PYK2, which thus functions as an adaptor, associates with c-Src and allows normal osteoclast spreading.

Disclosures: Merck & Co., Inc..

F274

Body Composition Contributes to Higher Bone Mass in Older Diabetic White & Black Women, but Not Men. **E**. Strotmeyer,[1] J. Cauley,[1] A. Schwartz,[2] M. Nevitt,[2] H. Resnick,*[2] J. Zmuda,[1] D. Bauer,[2] A. Newman.*[1] [1]University of Pittsburgh, Pittsburgh, PA, USA, [2]University of California, San Francisco, CA, USA.

Older white women with type 2 diabetes have higher bone mineral density (BMD) but little information exists for men and older black adults. Higher BMD in type 2 diabetics may be due in part to greater obesity compared to non-diabetics. The purpose of the study was to determine if higher BMD in diabetics is accounted for by measures of body composition and fasting insulin. The Health, Aging, and Body Composition Study, which included white and black, physically able, men and women age 70-79 years, collected data on total fat, lean mass, and visceral fat from DXA and CT scans. BMD was measured by DXA (QDR 4500A, Hologic Inc, Bedford, MA). Those reporting diabetes, on diabetes medications, or with fasting glucose of $\geq$126 mg/dl were considered diabetic. Exclusion criteria were oral steroid use (n=69), diabetes diagnosis at age <20 years (n=5), or missing diabetes status (n=22). Of the remaining 2979 participants, 19% had diabetes at the Year 1 visit. Men were 57% of the diabetic and 47% of the non-diabetic group ($p<0.001$). Whites were 43% of the diabetic and 62% of the non-diabetic group ($p<0.001$). For both groups, mean age was 74$\pm$3 years. Mean fasting insulin (12$\pm$16 vs. 8$\pm$5 IU/ml; $p<0.001$), visceral fat (169$\pm$74 vs. 137$\pm$64 cm^2; $p<0.001$), total fat (26.0$\pm$9.1 vs. 23.8$\pm$8.6 kg; $p<0.001$), and bone-free lean mass (54.0$\pm$10.3 vs. 48.9$\pm$10.5 kg; $p<0.001$) were significantly higher in diabetics compared to non-diabetics. Higher hip BMD was found for diabetics vs. non-diabetics (0.96$\pm$0.17 vs. 0.73$\pm$0.14 g/cm^2, $p<0.001$). Multiple linear regression was performed to determine if diabetes was related to differences in BMD, independent of body composition measures, adjusting for age, race, and gender. Visceral fat ($p=0.25$) with adjustment for total fat, did not explain differences in hip BMD and diabetes remained a significant predictor of BMD ($p<0.001$). Total fat ($p<0.001$) and lean mass ($p<0.001$) were significantly related to BMD, with diabetes also remaining a significant predictor of hip BMD ($p<0.001$). Furthermore, diabetes remained an independent predictor of hip BMD ($p<0.001$) adjusting for all body composition measures and fasting insulin. The effect of diabetes was similar for whole body and femoral neck BMD. However, while diabetes was a significant and independent predictor of hip BMD in both white and black men after adjusting for all body composition measures, it was not among white or black women. In conclusion, diabetes is associated with higher BMD in men and women, both black and white. Body composition measures did not account for higher BMD in this diabetic population as a whole but may play a larger role in women than men.

F281

Dietary Contributions to Serum 25(OH) Vitamin D Levels [25(OH) D] Differ in Black and White Adults in the United States: Results from NHANES III. Y. K. Park,* C. N. Barton,* M. S. Calvo. Center for Food Safety and Applied Nutrition, Food and Drug Administration, Washington, DC, USA.

The relative importance of diet and sunlight to serum 25(OH) D levels varies with season, latitude, age and race. Our goal is to evaluate the contributions of vitamin D intake to serum 25(OH) D concentrations for data that reflect varied conditions of exposure to sunlight due to the variability in season or latitude when blood samples were taken. We explored the relationship between vitamin D intake and 25(OH) D levels in adult (> 20 y) Non-Hispanic White (n=5822) and Black (n=3617) men and women who participated in NHANES III (1988-94). Vitamin D intake, both 24 hr and usual, were estimated from food only and from food plus supplements. We used simple regression analysis to examine the relationship by age (<50, >50y), gender and race. For all four methods of estimating vitamin D intake, the intake showed a consistent significant association with 25(OH) D level in all age/gender groups of both races. For all age and gender groups, Black men and women had lower mean 25(OH) D levels and lower mean dietary intakes and reported a lower use of dietary supplements than Whites. Milk and ready-to-eat cereals are major sources of dietary vitamin D by fortification in the United States. Consumption of both of these foods was much lower in Blacks than in Whites. Despite their lower vitamin D intakes, the association between dietary intake and serum 25(OH) D was stronger for Blacks than for Whites. In addition, the ratio of vitamin D intake to serum 25(OH) D level was consistently higher in Blacks compared to Whites. This suggests that Blacks may need more dietary vitamin D than Whites to maintain comparable serum levels. Our findings in adults suggest that dietary contributions to 25(OH) D levels appear to be more critical in Blacks than in Whites and emphasize the need to improve vitamin D intakes of the Black population in the United States.

F283

Nulliparity and Fracture Risk in Older Women: The Study of Osteoporotic Fractures. T. A. Hillier,[1] J. Rizzo,*[1] K. L. Pedula,*[1] K. L. Stone,[2] J. A. Cauley,[3] D. C. Bauer,[2] S. R. Cummings.[2] [1]Kaiser Center for Health Research, Portland, OR, USA, [2]UCSF, San Francisco, CA, USA, [3]U of Pittsburgh, Pittsburgh, PA, USA.

Nulliparity is an established risk factor for breast cancer, but prior studies are conflicting on the relationship of nulliparity with bone mineral density (BMD) and risk of subsequent fractures. It is also unknown if parity may have a greater effect on weight-bearing skeletal sites. During the baseline examination, we assessed self-reported parity, number of live births, and other fracture risk factors in 9,699 postmenopausal women aged 65 years and older. Incident hip and wrist fractures were subsequently ascertained by contact of participants every 4 months after baseline, and verified by physician review of medical records, over an average follow-up of 9.8 years. Incident vertebral fractures were determined by morphometric criteria on serial thoracic and lumbar radiographs (mean follow-up=3.7 years). We used proportional hazards models to assess the independent contribution of nulliparity on hip and wrist fractures and multiple logistic regression for vertebral fractures. Nulliparous women had a greater risk of hip and vertebral, but not wrist fractures (Fx) on univariate analysis (see Table). This relationship remained significant on multivariate analysis for hip fracture. Among parous women, each additional birth resulted in a 14% risk reduction in hip fracture (HR=0.86, p=.007). Nulliparity was not associated with decreased BMD at the hip, spine, or, radius.

Parity		**Hip Fx**	**Vertebral Fx**	**Wrist Fx**
	n	***n(%)***	***n(%)***	***n(%)***
Parous	7864	435(5.5)	291(4.9)	520(6.6)
Nulliparous	1835	166(9.1)	98(7.3)	114(6.2)
Unadjusted risk+		1.72(1.43,2.05)	1.52(1.19,1.92)	0.96(0.78,1.18)
Adjusted risk+*		1.47(1.18,1.84)	1.30(0.99,1.73)	0.85(0.68,1.08)

+Risk is reported as hazard ratios for hip and wrist fractures and odds ratios for spine fractures, with 95% confidence intervals

*Adjusted for age, weight, BMD, family history of osteoporosis, age at menarche, years of menstruation, postmenopausal oral estrogen use, postmenopausal daily calcium intake (dietary+supplement), milk intake age 12-50, and physical activity at age 30

Nulliparous women were more likely to experience postmenopausal hip fractures independent of BMD. Additionally, among parous women, there was a strong relationship with each additional birth in reducing the risk of future postmenopausal hip fractures. More research is needed to elucidate possible mechanisms for this relationship such as altered hip geometry associated with pregnancy. Nulliparous women may also represent a unique risk group to target postmenopausal prevention strategies given their increased risk of breast cancer and potentially osteoporotic fractures

F285

BMD Independent Risk Factors for Hip Fractures in Elderly Women in England. K. Kayan,*[1] R. U. Ashford,[1] A. Dey,*[1] B. Kohler,*[1] J. Cliffe,*[1] A. Hinch,*[1] A. Ball,*[1] M. Marples,*[1] T. Jalava,*[2] J. A. Kanis,[1] E. V. McCloskey.[1] [1]WHO Collaborating Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom, [2]Leiras Oy, Helsinki, Finland.

In a prospective study of women aged at least 75 years, we examined BMD independent risk factors for hip fractures.4347 women were enrolled to a placebo-controlled study of the effect of clodronate(BONEFOS)on hip fracture risk. At entry, in addition to hip BMD, all women underwent assessments including quality of life (Euroqol), disability (OPCS disability survey), cardiovascular health, postural stability and muscle strength. Smoking and family fracture history aren't included in this analysis. All incident reported fragility fractures were verified from hospital and/or GP records.During a median follow-up period of 3.1 years, 91 (2.1%) women sustained a low energy hip fracture. In univariate analysis, an increased risk of hip fracture was noted in women with mobility problems (59.3%, OR 1.97; 95% CI 1.23-3.16), problems with usual daily activities (40.2%, OR 1.64; 95% CI 1.08-2.48), walking difficulty (67.8%, OR 1.95; 1.19-3.18), less than 2 child births (3.7%, OR 1.70; CI 1.12-2.57), self-reported prior hip (2.2%, OR 2.69; 1.07-6.79), prior vertebral fracture (1.1%, OR 3.15; 0.96-10.34), increased body sway (OR per 1SD increase in path length standing with eyes open on a firm surface, OR 1.27; 95% CI 1.03-1.55) and a decrease in quadriceps strength in right side dominant women (OR per 1SD decrease in the maximum or average right quadriceps strength, OR 1.32; 1.06-1.64) After adjustment for age, weight and total hip BMD, an increased risk of hip fracture was observed in women with a history of amenorrhoea (2.7%, OR 3.29; 1.45-7.48), those with self-care problems (14.4%, OR 1.91; 1.17-3.11), women who did not do any exercise at the time of assessment (35.0 %, OR 1.74; 1.12-2.73), hospital admission in the preceding year (17.5%, OR 1.64; 1.02-2.64), hospital outpatient /A&E clinic visit in the 3 months prior to study entry (28.9 %, OR 1.60; 1.03-2.48 and 4.7%, OR 2.02, 1.59-2.56 respectively) or aggressive behaviour (0.3%, OR 8.83;1.87-41.64). Difficulty in rising from a chair showed a borderline significant association with the risk of hip fracture (31.8%, OR 1.55; 0.98-2.43).Finally, in a forward conditional multivariate logistic model including hip BMD and all of the significant factors from the adjusted analysis, an increased risk of hip fracture continued to be significantly and independently associated with increasing age, prior amenorrhoea, no current exercise, prior hospital admission and aggressive behaviour.We conclude that relatively simple BMD-independent assessments can predict future risk of hip fractures in elderly women.

International Variations in Hip Fracture Probabilities: Implications for Risk Assessment. A. Oden,*[1] J. A. Kanis,[2] O. Johnell,[3] C. E. DeLaet,*[4] B. Jonsson,*[5] A. K. Oglesby.*[6] [1]Consulting statistician, Gothenberg, Sweden, [2]WHO Collaborating Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom, [3]Department of Orthopaedics, Malmo General Hospital, Malmo, Sweden, [4]Institute for Medical Technology Assessment, Rotterdam, The Netherlands, [5]Centre for Health Economics, Stockholm School of Economics, Stockholm, Sweden, [6]Global Economic Affairs, Eli Lilly & Company, Indianapolis, IN, USA.

It is recommended that intervention thresholds in the future should be based on absolute risk, but there is a large variation in hip fracture incidence in different regions of the world. The aim of this study was to examine heterogeneity of hip fracture probability in different regions from recent estimates of hip fracture incidence and mortality. Ten year probabilities of hip fracture were computed in men and women at 10 year intervals from the age of 50 years, and lifetime risks at the age of 50 years from the hazard functions of hip fracture and death. Lifetime risk at the age of 50 years varied from 1% in women from Turkey to 28.5% in women from Sweden. High lifetime risks in women were associated with high lifetime risks in men (r=0.83). There were also significant correlations of 10 year risk at any age between men and women. Ten year probability was standardised to that of men and women from Sweden (set at 1.0). There was a 13-fold range in 10 year probability from 1.07 in Norway to 0.08 in Chile and Korea. Countries were categorised by 10 year probabilities comprising very high risk (Norway, Sweden, Iceland and Denmark), high risk (Singapore, China (Taiwan), USA, Switzerland, Canada, Australia, Germany, Netherlands and the UK), medium risk (Greece, Kuwait, Argentina, Spain, Hungary, Portugal, Japan, China (Hong Kong) and France), and low risk (Venezuela, China, Turkey, Korea and Chile). The categorisation of hip fracture probabilities can be used to adjust intervention thresholds that are based on age, sex and relative risk from a reference population such as Sweden.

Osteocytic Expression of eNOS in the Femoral Neck Cortex: A Possible Role in Bone Fragility. N. Loveridge,[1] S. Fletcher,*[2] M. Parker,*[3] N. Rushton,*[1] V. Das-Gupta,*[2] J. Power,*[1] A. Caballero Alías,[1] J. Reeve,[1] A. Pitsillides.*[2] [1]University of Cambridge, Cambridge, United Kingdom, [2]Royal Veterinary College, London, United Kingdom, [3]Peterborough District Hospital, Peterborough, United Kingdom.

Intracapsular hip fracture is linked to increased porosity of the anterior and inferior femoral neck cortices with little change elsewhere. We showed previously that this results from the merging of haversian canals, through excessive resorption within spatially clustered remodelling osteons. As the inferior cortex is heavily loaded in compression during (normal) gait we have examined the possibility that hip fracture is associated with relative disuse or a defect in components of the adaptive response to load. Nitric oxide (NO) inhibits bone resorption and stimulates bone formation and its release from bone cells is increased by both mechanical strain and estrogen.Endothelial nitric oxide synthase (eNOS) is the principal isoform present in bone cells, particularly osteocytes. We have used immunocytochemistry to determine the location and density of osteocytes expressing eNOS (eNOS+ve) in cortical BMUs in sections from the femoral neck of 7 cases (female, 70-96y) and 7 controls (female, 68-96y). Their number and location in the superior and inferior regions was measured by image analysis. Osteocytes generally, were identified with propidium iodide (PI+ve). The median, and minimum distances of eNOS+ve and PI+ve osteocytes from the nearest canal surface was calculated for individual BMUs and averaged for both regions of each biopsy.The median distance of eNOS+ve osteocytes to the canal surface was higher than that for PI+ve osteocytes (eNOS: 66.6±2.0µm; PI: 54.7±1.2µm, $p<0.001$); this was independent of region and biopsy type. Also, the nearest eNOS+ve osteocyte was 57% further away from the canal surface than the nearest PI+ve osteocyte ($p<0.001$); this was more marked in cases than controls (+12.0±2.2µm, vs +17.5±2.9µm $p<0.001$) but independent of region. In controls, the density of eNOS+ve osteocytes was 93% higher in the inferior region ($p=0.001$). Cases differed substantially from controls with a 53% lower density of eNOS+ve osteocytes inferiorly ($p<0.001$), but not superiorly.In conclusion eNOS+ve osteocytes are peripherally located in cortical BMUs. They are more numerous in a region subjected to habitual compressive load. In cases of hip fracture, their density in that region, but not that loaded in tension, is substantially reduced. As NO inhibits osteoclast activity, eNOS+ve osteocytes may act as sentinels to confine resorption within cortical BMUs. eNOS+ve osteocytes may be key regulators of bone conservation and the regulation of eNOS expression requires further investigation.

F291

Repeat Hip Fractures in a Population-based Sample of Medicare Recipients in the US: Rates, Timing and Gender Differences. H. A. Bischoff,[1] D. H. Solomon,[2] B. Dawson-Hughes,[3] P. S. Wang,*[2] J. Avorn.*[2] [1]Div. of Rheumatology, Immunology and Allergy; the Robert B. Brigham Multipurpose Arthritis Center, Brigham and Women's Hospital, Boston, MA, USA, [2]Div. of Pharmacoepidemiology, Brigham and Women's Hospital, Boston, MA, USA, [3]Jean Meyer US Department of Agriculture; Human Nutrition Research Center on Aging, Tufts University, Boston, MA, USA.

To investigate rates, timing and gender differences of repeat hip fractures in subjects 65 years or older. All patients 65 years or older enrolled in Medicaid or Medicare and the Pharmacy Assistance for the Aged and Disabled program who underwent surgical repair of a hip fracture in 1994 in one large US State were part of the study cohort. Subjects with a high- or multi-trauma hip fracture or a hip fracture within 3 years prior to the index date were excluded. Over a 3 year follow-up period rates of repeat hip fractures and the time to

repeat hip fractures were assessed. Adjustments were performed for clinical characteristics (Charlson Comorbidity Index, number of prescribed drugs over 180 days prior to the index hip fracture) and age. Rates were compared between women and men. 1222 eligible patients underwent surgical repair of a hip fracture in 1994. 1014 women and 208 men. Mean age of women was 82.8 ± 7.4 and for men 80.0 ± 7.4. 10.3 % of these subjects (n = 126) suffered a repeat hip fractures within 3 years from their index hip fracture. Men had a significantly higher rate of repeat hip fractures (14.4%) compared to women (9.5%,chi-square p = .032). This difference remained significant after adjustment. Mean time to repeat hip fracture was 243.0 ± 240.0 days and did not differ by gender. Eighteen percent of repeat hip fractures occurred within 1 month, 51% within 6 months and 75% within 12 months of the index hip fracture. These data suggest that over a 3-year follow-up period repeat hip fractures occur at a rate of 10.3%. Rates are slightly higher in men than women. The majority of repeat hip fractures occur within one year following the index fracture.

F293

Incident Vertebral Fractures and Mortality in Older Women: A Prospective Study. D. M. Kado,[1] T. Duong,[2] K. L. Stone,[3] K. E. Ensrud,[4] M. C. Nevitt,[2] M. C. Hochberg,[5] G. A. Greendale,[1] S. R. Cummings.[3] [1]Medicine, University of California, Los Angeles, Los Angeles, CA, USA, [2]Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, USA, [3]Medicine, University of California, San Francisco, San Francisco, CA, USA, [4]Medicine, VA Medical Center, Minneapolis, MN, USA, [5]Medicine, University of Maryland, Baltimore, MD, USA.

Older persons with prevalent vertebral fractures have an increased risk of mortality. To test whether incident vertebral fractures are also associated with mortality, we prospectively followed 7,238 white women age 65 or older in the Study of Osteoporotic Fractures. Incident vertebral fractures were assessed by morphometry of paired lateral spine x-rays taken an average of 3.7 years apart. 389 (5.4%) women were identified as having a new vertebral fracture (≥ 20% and ≥ 4 mm decrease in at least one vertebral height dimension). During an average of 11.6 years additional follow-up, 1,617 (22%) died. Relative hazards were adjusted for age and 12 other predictors of mortality. Women with at least one new fracture had an age-adjusted 31% increased risk of mortality (R.H.= 1.3; 95% C.I.: 1.1-1.6; p = 0.003). After adjustment for age and baseline prevalent vertebral fracture, women had a 22% increased risk of mortality (R.H. = 1.2; 95% C.I.: 1.0 -1.5; p = 0.035). However, adjustment for age, weight change, and an inability to rise from a chair accounted for most of the association (R.H.= 1.1; 95% C.I.: 0.94-1.4; p = 0.20). Among women without a baseline prevalent fracture, those who had suffered 2 or more incident fractures were at the greatest age-adjusted risk of subsequent mortality (R.H.= 2.0; 95% C.I.: 1.2-3.3), but this, too, was accounted for by adjustment for other predictors of mortality (R.H.= 1.2; 95% C.I.: 0.88-1.7). We conclude that older women with incident vertebral fractures have an increased risk of subsequent mortality that is explained to a large degree by weight loss and physical frailty.

F295

Osteoporosis Diagnosis and Management Following Hip Fracture. J. N. Black,*[1] S. L. Follin,Pharm D,,*[1] M. T. McDermott,MD,.[1] [1]University of Colorado Health Sciences Center, Denver, CO, USA.

To evaluate the management of osteoporosis in patients with hip fractures, we reviewed the inpatient charts of 120 patients who were admitted to our teaching hospital for a diagnosis of hip fracture from 1993-1998. The median age of the patients was 72 years; 62% were female. Potential risk factors included tobacco use (43%), hypertension (43%), alcohol use (38%), diabetes mellitus (26%), and alcoholism (11%). A fall from the standing position preceded the fracture in 97% of the patients (3% couldn't recall). Numerous patients reported a history of previous fragility fractures (hip fracture, 18%; vertebral fracture, 4%; wrist fracture, 6%). The diagnosis of osteoporosis was noted in the chart in 14% of the patients during their hospitalization or in the discharge summary. Bone densitometry testing was performed in 3% of patients, chest x-rays were done in 68%, and lateral spine x-rays were done in 9%. Osteoporosis related blood and urine testing (serum PTH or vitamin D metabolites; urine calcium or bone resorption markers), was performed in < 2% of patients. Medications for the treatment of osteoporosis could be documented in only a small minority of patients at discharge (calcium, 10%; multivitamins, 10%; vitamin D, 3%; estrogen, 8%; alendronate, 2%; calcitonin, 1%). We then reviewed the outpatient records for the 95 patients who had follow-up visits (median, 2 visits) by physicians in our system in the year following their hip fracture. During this time, the diagnosis of osteoporosis was recorded in the charts of 24% of the patients. Bone densitometry testing was performed in 6% of the patients. Osteoporosis related blood and urine testing was performed in < 4% of patients. Documented treatment for osteoporosis was uncommon (calcium, 16%; multivitamins, 8%; vitamin D, 4%; estrogen, 9%; alendronate, 5%; calcitonin, 4%). Fall prevention education was recorded for only 3% of patients. New falls were reported in 13% of the patients (mean, 1.4 falls). New fractures occurred in 11 patients (21%) of the group (hip, 6%; vertebral, 2%; other sites, 5%). Of those patients who had new fractures, 5 (45%) were taking estrogens and none were on a bisphosphonate. Conclusion: In patients with hip fractures, osteoporosis is commonly not diagnosed or treated appropriately.

Disclosures: Merck,8; Procter and Gamble,8.

Circulating Levels of Osteoprotegerin Are Inversely Related to Biochemical Markers of Bone Turnover Measured in Serum in a Population Based Cohort of Postmenopausal Women. A. Rogers, G. Saleh,* R. A. Hannon, D. Greenfield,* R. Eastell. Bone Metabolism Group, Division of Clinical Sciences (North), University of Sheffield, Sheffield, United Kingdom.

Osteoprotegerin (OPG) is recently identified cytokine, which has been shown to be an important inhibitor of osteoclast differentiation and activation in rodent models. The aim of this study was to investigate the relationship between biochemical markers of bone turnover and bone density and circulating OPG in a population based cohort of postmenopausal women.Subjects were 180 women ages 50 to 85 years (mean 63 years). Markers of bone formation (bone alkaline phosphatase (Bone ALP), immuno-reactive bone alkaline phosphatase (IBone ALP), type I procollagen carboxy terminal peptide (PICP), osteocalcin (OC)) and bone resorption (immuno-reactive free deoxypyridinoline, pyridinoline, cross-linked N-telopeptides of type I collagen and serum cross-linked C-telopeptides of type I collagen (SCTX)) were measured by standard methods. Serum concentrations of OPG were determined by ELISA (Immundiagnostik, Germany), a sandwich assay designed to detect monomeric, dimeric and ligand bound forms of human OPG. Bone mineral density at total body (TBBMD), total hip (THBMD), femoral neck (FNBMD) and lumbar spine (LSBMD) was measured by DXA (Lunar DPX). The relationship between biochemical markers of bone turnover (after log transformation) and bone density and serum OPG was determined by Pearson's product moment correlation. Multiple regression analysis was used to determine possible confounders and results were adjusted for age (biochemical markers) and age and body mass index (bone density).We saw significant inverse relationships between OPG and serum bone turnover markers before and after adjustment for age. (Table)

Variable	r	p	r (adjusted)	p
Bone ALP	-0.22	0.003	-0.20	0.006
IBone ALP	-0.20	0.01	-0.19	0.02
PICP	-0.23	0.002	-0.21	0.006
OC	-0.16	0.04	-0.15	0.05
SCTX	-0.18	0.05	-0.17	0.05

There was a significant positive relationship between OPG and bone density at TBBMD, THBMD and FNBMD (r values from 0.17 to 0.2, p<0.05) which was lost after adjustment for age and body mass index. We saw no relationships between OPG and urine bone turnover markers.We conclude that circulating levels of OPG may reflect OPG activity in bone and that higher levels of OPG lead to lower rates of bone turnover and higher bone density in these postmenopausal women. We have previously reported high levels of variability in urine markers of bone resorption and we suggest that this could account for the absence of an association between these markers and circulating OPG

F305

Higher BMDs in NSAID Users Compared to Non-users: The Framingham Study. M. T. Hannan,*[1] K. Broe,*[2] S. Ferrari,[3] D. R. Gagnon,*[4] L. A. Cupples,*[4] D. P. Kiel.[1] [1]Hebrew Rehab Center & Harvard Medical Sch, Boston, MA, USA, [2]Hebrew Rehab Center, Boston, MA, USA, [3]BI Hospital, Boston, MA, USA, [4]BU Sch Public Health, Boston, MA, USA.

Non-steroidal anti-inflammatory drugs (NSAID) may have direct and indirect effects on bone metabolism inhibiting bone loss and preserving BMD; thus, we investigated the relation between NSAID and bone density (BMD) in the Framingham Offspring cohort. BMD was measured in g/cm^2 at femoral neck, Ward's area, trochanter and lumbar spine in 1996-00 using a Lunar DPX-L densitometer. NSAID use (current, former, never) including regular aspirin use was determined by physician query, while osteoarthritis (OA) was based on physician exam. Including aspirin as an NSAID was done to take into account possible confounding by indication for other NSAID use. We conducted sex-specific linear regression models to examine the relation between each BMD site and NSAID use first adjusting for age and weight and then further adjusting for height, OA and in women, current estrogen use and menopausal status.In the 2,903 Offspring (1276 M, 1627 F) with BMD data, 38% currently used NSAIDs (564 M, 531F). The mean age was 59 (sd 9.6, range: 29-86 years). After adjusting for age, current NSAID users had significantly higher BMDs (range 2-4%) at all sites compared to non-users(all 0.0001 < p < 0.05) for both men and women. Adding weight to the model attenuated this effect at all sites for women, but men continued to have higher BMDs in NSAID users at all bone sites. Adjustment for other covariates, including OA, did not change these results for men: NSAID users had 2-3% higher BMDs than nonusers (0.005 < p <0.06). For women, there were no differences in BMDs between current NSAID users compared to never users (all p<0.63). The mean BMD for former NSAID users was not statistically significantly different from either group for any analysis.In sum, these findings indicate the NSAID use is associated with higher BMDs for men but not women in the Framingham Offspring Study. For middle-aged women, the effect of NSAIDs upon BMD is attenuated by other major risk factors with an effect on bone, notably weight, menopause and estrogen use. These findings extend work with similar results from other cohort studies. Randomized studies are needed to test the hypothesis that NSAIDs favorably influence BMD as observational studies may still be affected by biases for which study design or analysis has not completely accounted.

F307

Association Between Lipid Profile and Bone Mass in Healthy Men. V. Braga, D. Gatti, M. Rossini,* S. Adami. Rheumatology Unit, Valeggio S/M, Italy.

It has been suggested that the cholesterol-lowering drug statins increase bone formation. In three case-control studies an association between statin use and lower risk of osteoporotic fractures was found. However, the results of other studies did not support this early finding and in the first and only prospective study so far published no evidence of an effect of statins on fracture risk was found. This might raise the suspicion that some positive results were driven by biases in the study population. From the data-set of an ongoing longitudinal study on the incidence of osteoporosis among healthy male subjects aged 40 to 70 years of our Health District (n. 427, mean age 57,61) we evaluated the relationship between lipid profile and bone mineral density (BMD) [QDR 4500, Hologic, USA] at the spine, femoral neck and total hip. The individuals with conditions or on treatment with drugs known to interfere with bone metabolism and those on statins or other lipid lowering

agents were excluded. The subjects were divided in three groups according to tertiles for values of LDL cholesterol, HDL cholesterol and LDL/HDL ratio respectively. The subjects with the most favorable lipid profile had consistently the lowest bone mass values expressed in terms of Z-score (Table: mean±SD BMD Z-scores; *p<0.05; †p<0.01 most versus less favorable lipid profile; °p>0.05 less versus mid favorable lipid profile).

Lipid profile subgroups	Lumbar spine BMD	Femoral neck BMD	Total hip BMD
LDL cholesterol (≤2.80 mmol/L)	-0.91 ± 1.46	-0.11 ± 1.37	-0.24 ± 1.01
LDL cholesterol (2.90-3.66 mmol/L)	-0.23 ± 1.91†	0.24 ± 1.26*	0.07 ± 1.13*
LDL cholesterol (3.67-5.62 mmol/L)	-0.35 ± 2.06†	0.18 ± 1.21*	0.06 ± 1.02†
HDL cholesterol (≤1.21 mmol/L)	-0.17 ± 2.12	0.28 ± 1.40	0.12 ± 1.07
HDL cholesterol (1.22-1.44 mmol/L)	-0.71 ± 1.84*	0.12 ± 1.28	-0.03 ± 1.08
HDL cholesterol (1.45-2.51 mmol/L)	-0.70 ± 1.49*	-0.09 ± 1.18†	-0.21 ± 1.02†
LDL/HDL (≤2.07)	-0.75 ± 1.50	-0.06 ± 1.31	-0.19 ± 1.05
LDL/HDL (2.08-2.86)	-0.59 ± 1.64°	0.03 ± 1.21°	-0.06 ± 1.10°
LDL/HDL (2.87-5.28)	-0.14 ± 2.32†	0.31 ± 1.32†	0.13 ± 1.05†

Body weight, BMI, age, smoking habit, dietary calcium intake were not different in the three groups of subjects and the level of significance in bone mass did not change after "adjusting" for all these variables. These results indicate that the lower incidence of osteoporotic fracture among statin users might be explained more by their prevailing higher bone mass rather than by a pharmacological effect of statins on bone metabolism.

F309

Serum Osteoprotegerin (OPG) Levels in Humans. N. A. Sarikaya,*[1] S. W. Martin,[1] D. Chen,*[1] H. Gunn,*[1] M. Arrighi,[2] D. Holloway,*[3] P. Bekker,[3] A. Nakanishi,*[4] C. Dunstan.[5] [1]Pharmacokinetics and Drug Metabolism, Amgen Inc., Thousand Oaks, CA, USA, [2]Health Economics and Epidemiology, Amgen Inc., Thousand Oaks, CA, USA, [3]Clinical Research, Amgen Inc., Thousand Oaks, CA, USA, [4]Biostatistics, Amgen Inc., Thousand Oaks, CA, USA, [5]Development, Amgen Inc., Thousand Oaks, CA, USA.

The objective of this study was to determine human serum OPG levels, and determine the relationship of OPG with age, gender, pre/post menopause, and bone mineral density.We collected serum samples from 311 normal volunteers in a single center, cross-sectional study. The subjects were women (n=154) and men (n=157), ranging in age from 20 to 80 years. Sera were assayed for OPG with two different sandwich ELISA formats. The first format included OPG ligand (OPGL) capture and HRP conjugated mouse anti-human OPG monoclonal antibody for detection (OPGL-Ab). The second format included mouse anti-human OPG monoclonal antibody for OPG capture and HRP conjugated rabbit anti-human OPG polyclonal antibody for detection (Ab-Ab). The assay range and quantification limit were 38.992 – 2495.5 pg/mL and 49.910 pg/mL, respectively, for OPGL-Ab format. For the Ab-Ab format, assay range and quantification limit were 19.496 – 2495.5 pg/mL and 30.380 pg/mL, respectively. Values of 19.496 and 38.992 pg/mL were imputed for the Ab-Ab and OPGL-Ab assays, respectively, for samples that were below quantification limit.Mean serum OPG levels were determined as 40.914 ± 17.2 pg/mL for Ab-Ab assay and 54.462 ± 20.5 pg/mL for OPGL-Ab assay. Although the percentage of samples below quantification limit is different, the two assay formats are highly correlated (Spearman rank, *P*<.0001). In both assay formats, mean serum OPG levels in females were greater than males (*t*-test, *P*<.001). Comparison of pre/post menopausal women, men -50 years showed that mean OPG levels were higher in post-menopausal women and men>50, with both assay formats. One-way ANOVA and categorical analyses showed statistically significant differences among the four groups (*P*<.001). In men, age and OPG levels are positively correlated in both assay formats. In women, correlation between age and OPG levels was observed with both assay formats. With Ab-Ab assay format, a weak association was observed between OPG levels and bone mineral density of spine, total body, and hip. Linear regression analysis of age, as a function of assay, gender, and bone mineral density, showed positive correlation with serum OPG levels.We conclude that the two assay formats provided different serum OPG levels yet with similar relationships with age, gender, and bone mineral density status. Serum OPG levels positively correlate with age, and women have higher serum OPG levels than men.

F311

Calcaneus Microarchitectural Assessment by Magnetic Resonance Imaging in Male Osteoporosis. B. Cortet,[1] N. Boutry,*[2] P. Dubois,*[2] A. Cotten,*[2] X. Marchandise.*[2] [1]Rheumatology, University-Hospital of Lille, Lille, France, [2]University-Hospital of Lille, Lille, France.

The present study aimed to characterize bone structure assessed by magnetic resonance imaging (MRI, Vision®, Siemens; Erlangen, Germany) at the calcaneus in male subjects suffering from osteoporosis. Fifty subjects were assessed (26 with osteoporosis and 24 control subjects matched for age). Osteoporosis was defined according to the World Health Organization classification (T-score < -2.5) either at the lumbar spine or hip. Seventeen subjects (65%) had a past history of low energy fracture mainly represented by vertebral fractures (11/26, 42%). A three-dimensional gradient-echo sequence was used with a slice thickness of 700 microns and in plane resolution of 172x172 microns. Ten consecutive median sagittal slices were selected for each subject and the mean of the results was taken into account. Bone structure analysis was performed using structural (binary and skeletonized images) and fractal analyses. Bone densitometry by DXA at the calcaneus was also performed. Bone mineral density (BMD) was decreased in osteoporotic patients compared with controls both at the lumbar spine and hip (p<0.01) but also calcaneus (p<0.05). Also thirteen microarchitectural features among 22 measured were significantly different between the 2 groups (p<0.05). The odds ratios for fracture per one control group standard deviation alteration after adjustment for body mass index and BMD at the calcaneus were significant for the following features (p<0.05): apparent BV/TV, 3.1 (1.5-6.5); marrow space star volume, 2.1 (1.2-4.0); apparent trabecular spacing, 1.7 (1.1-2.9); trabecular bone pattern factor, 2.4 (1.2-4.7); total skeleton length (trabecular network), 2.1 (1.1-3.9); interconnectivity index, 2.6 (1.3-5.3); node count, 3.0 (1.4-6.4); terminus count, 2.1 (1.0-4.1); node-to-node strut count, 3.7 (1.5-9.3); terminus-to-terminus strut count, 1.8 (1.2-2.8); node-to-node strut length, 2.7 (1.2-5.9); node-to-terminus strut length, 3.0 (1.4-6.7) and fractal dimension, 2.2 (1.0-4.9). Few and weak correlations (r<0.5) were found between BMD at the calcaneus measured with DXA and features obtained from MRI suggesting that these 2 methods give different informations about bone status.In conclusion male osteoporosis is a disease characterized by decreased bone mass but also microarchitectural deteriorations of bone tissue which are partly independent of BMD.

F313

Potassium Citrate Prevents Increased Urine Calcium Excretion and Bone Resorption Induced by a High Sodium Chloride Diet. D. E. Sellmeyer,*[1] M. Schloetter,*[2] A. Sebastian.*[2] [1]Medicine/Endocrine, University of California, San Francisco, San Francisco, CA, USA, [2]General Clinical Research Center, University of California, San Francisco, San Francisco, CA, USA.

The amount of sodium chloride in the diet of industrialized nations far exceeds physiological requirements. The impact of abundant dietary salt on skeletal health has yet to be established, but is potentially detrimental through increased urinary calcium losses. We examined the effect of increased dietary sodium chloride on urine calcium excretion and bone turnover in postmenopausal women and, further, whether oral potassium citrate attenuated the effects of increased dietary salt. Women were excluded if they were less than 2 years past menopause, on medications known to affect bone metabolism, had evidence of metabolic bone disease, renal insufficiency or medical conditions potentially worsened by increased dietary sodium or potassium. Study subjects (n=63) were placed on a low salt (87 meq/d sodium) diet for three weeks then randomized to a high salt (225 meq/d sodium) diet + potassium citrate (90 meq/d) or a high salt (225 meq/d sodium) diet + placebo. Fifty-two women (83%) completed the study. The primary reason for withdrawl was nausea from the salt supplements. The table below shows the mean ± SD for urine calcium, N-telopeptide (NTX), and serum osteocalcin measured at the end of the low salt and high salt periods.

	Low salt	High salt + Intervention	p-value vs Low salt
Intervention=Placebo			
Urine calcium (mg/d)	200 ± 14	242 ± 16	0.002
Urine NTX (nBCE/mmol Cr)	38.7 ± 4.2	45.1 ± 3.8	0.001
Osteocalcin (ng/ml)	11.2 ± 0.6	10.6 ± 0.6	0.01
Intervention=Potassium citrate			
Urine calcium (mg/d)	200 ± 14	192 ± 19	0.5
Urine NTX (nBCE/mmol Cr)	41.3 ± 3.6	43.3 ± 3.7	0.3
Osteocalcin (ng/ml)	10.9 ± 0.7	10.7 ± 0.6	0.3

The changes in urine calcium and NTX between the low and high salt periods were also significant between the placebo and potassium citrate groups (p=0.008 and 0.05 respectively, unpaired t-test). There were no significant differences in PTH or cyclic AMP between the low and high salt diets or between the potassium citrate and placebo groups. Increased dietary salt enhanced urinary calcium excretion and bone resorption without changes in PTH. The addition of oral potassium citrate to a high salt diet prevented the increased calcium losses and bone resorption caused by a high dietary salt intake. Diets containing generous amounts of sodium, typical of industrialized nations, may be detrimental to bone health. Reducing sodium chloride intake and increasing intake of dietary sources of alkaline potassium salts may be beneficial for postmenopausal women at risk for osteoporosis.

F322

Continuous Oral Glucocorticoid Therapy Is Associated with an Increased Rate of Hip Bone Loss in Older Women: The Study of Osteoporotic Fractures. M. C. Hochberg,[1] J. K. Tracy,*[1] M. Vogt,[2] K. Stone,[3] K. Ensrud.[4] [1]University of Maryland School of Medicine, Baltimore, MD, USA, [2]University of Pittsburgh School of Medicine, Pittsburgh, PA, USA, [3]University of California, San Francisco, CA, USA, [4]University of Minnesota School of Medicine, Minneapolis, MN, USA.

Oral glucocorticoid therapy is the most common cause of secondary osteoporosis and is associated with an increased risk of fracture. Data from short-term placebo-controlled clinical trials have documented bone loss in patients receiving oral glucocorticoids; however, no data are published on rates of bone loss in community-dwelling individuals treated with chronic oral glucocorticoid therapy. Longitudinal dual energy xray absorptiometry scans obtained a mean of 3.5 years apart on a Hologic QDR 1000 (Waltham MA) were analyzed from a total of 4,258 elderly white women (mean [SD] age 77.1 [5.1] years) participants in the Study of Osteoporotic Fractures who had complete data on use of glucocorticoids at Visits 1, 2 and 4. Rates of change in total hip and femoral neck bone mineral density (BMD), adjusted for age, weight, physical activity, smoking and self-reported health status at Visit 4, and weight change between Visit 2 and Visit 4, were compared among classes of oral glucocorticoid users: continuous users at all three visits (N=125), former users [use at either Visit 1 or 2 but no use at Visit 4] (N=202), and never users (N=3931). All groups lost BMD at both the total hip and femoral neck. The adjusted rate of bone loss among current

oral glucocorticoid users was significantly higher than in both the former users and the never users at both sites (see Table) (*P <.01 for all prespecified pair-wise comparisons). The differences in the adjusted rate of bone loss between former users and never users did not reach statistical significance at either site.

Adjusted Rate of Bone Loss (mean [SE]) by Class of Glucocorticoid Usage

	Continuous Users	Former Users	Never Users
Total Hip, mg/cm2/yr	8.77 (1)*	2.88 (1)	3.92 (0.2)
Total Hip, %/yr	1.30 (0.13)*	0.42 (0.10)	0.55 (0.02)
Femoral Neck, mg/cm2/yr	5.52 (1)*	1.63 (1)	2.57 (0.2)
Femoral Neck, %/yr	0.89 (0.17)*	0.25 (0.13)	0.39 (0.03)

These data demonstrate that elderly women taking chronic oral glucocorticoid therapy lose bone at a greater rate than those not on such therapy. Based on these and other data, we suggest that elderly women taking chronic oral glucocorticoid therapy should receive treatment to prevent bone loss as well as to reduce the increased risk of fractures.

F327

Ovariectomy Fails to Induce Further Bone Loss in Mice Transgenic for Granulocyte Colony-Stimulating Factor. T. Oda,[*1] T. Wada,[1] Y. Kokai,[*1] H. Kuwabara,[*1] N. Sawada,[*1] S. Ishii.[*1 1]Sapporo Medical University, Sapporo, Japan.

Both mice transgenic for granulocyte colony-stimulating factor (G-CSF) (G-Tg mice) and ovarietomized mice exhibit severe osteopenia with increased bone resorption and up-regulated hemopoiesis. To elucidate the relation between abnormal hemopoiesis and bone loss, we performed an ovariectomy (OVX) on G-Tg mice. The G-Tg mice were established using the human G-CSF gene under an SRα promoter. An OVX or sham operation was performed on 12-week-old G-Tg mice or littermates (LMs). Uterine weight, bone mineral density (BMD) of the tibia (by the Dual-energy X-ray Absorptiometry method) and urinary deoxypyridinoline (Dpyr) concentration were measured 8 weeks after the operation. The number of colony-forming units of granulocytes/macrophages (CFU-GMs) and B220-positive cells in the bone marrow were counted 3 weeks after the operation. The OVX did not significantly change the BMD or urinary Dpyr content in G-Tg mice, though a more than 70% decrease in uterine weight was observed irrespective of G-CSF transgene expression. The OVX up-regulated the number of CFU-GMs two-fold in the bone marrow of LMs, which was associated with a 3.6 fold increase in B220-positive cells. The OVX did not alter the number of either CFU-GMs or B220-positive cells in the marrow of G-Tg mice. Taken together, G-Tg mice appeared to be resistant to further bone mass loss via acute estrogen deficiency. This may reflect that the up-regulation of hemopoiesis by G-CSF changed the responsiveness of bone mass to estrogen regulation, suggesting a strong link between bone phenotype and hemopoiesis. There was an increase in CFU-GMs in the bone marrow in ovariectomized mice. No such increase occurred in the G-Tg mice, partly because of the enhancement of CFU-GMs. The changes in number of CFU-GMs in these animal models may be central to bone reduction as an up-regulation of the osteoclast pool in the marrow. Furthermore, progenitors of osteoclasts, including hemopoietic stem cells, may play a role in bone phenotypes, such as osteoporosis. An approach to counteract the G-CSF pathway may prove effective in suppressing osteoporosis, since the OVX did not induce bone loss or bone resorption in G-Tg mice.

Mice	Uterine Weight[a]	BMD[b]	Dpyr content[c]	CFU-GMs[d]	B220s[e]
LM sham	104.3±13.1	471±51	7.84±1.46	1170±120	0.9±0.2
LM OVX	17.6±5.6*	277±49*	12.29±4.77***	2420±210*	3.6±1.1*
G-Tg sham	86.4±4.6	240±42	12.92±3.33	2270±160	0.2±0.1
G-TG OVX	23.1±6.3**	222±46	13.81±3.88	2120±180	0.2±0.1

Expression of Interleukin-6 (IL-6) and IL-6 Receptor mRNA in Human Bone Samples from Pre- and Postmenopausal Women. T. Seck,[1] I. Diel,[*2] H. Bismar,[*3] R. Ziegler,[3] J. Pfeilschifter.[4] [1]Orthopedics, Yale University, School of Medicine, New Haven, CT, USA, [2]Gynaecology, University of Heidelberg, Heidelberg, Germany, [3]Internal Medicine, University of Heidelberg, Heidelberg, Germany, [4]Internal Medicine, University of Bochum, Bochum, Germany.

Interleukin-6 (IL-6) has been attributed with induction of osteoclastogenic-precursor cell proliferation and maturation. Estrogens suppress IL-6 production in stromal/osteoblastic cells in vitro. Conversely, estrogen withdrawal is associated with increased IL-6 production. IL-6 is therefore thought to be an important mediator of the increased bone resorption following menopause. However, evidence supporting a rise in the expression of IL-6 or the IL-6 receptor in human bone tissue with menopause is still lacking. To address this question we established a 5'-nuclease-assay to quantitate the expression of human IL-6 and the gp80 subunit of the IL-6 receptor in human bone samples. The number of mRNA copies was normalized to the number of copies of beta actin mRNA. Osteocalcin expression served as an independent control. The study population consisted of 169 women (mean age: 52.4 + 11.6 years) who underwent surgery for early breast cancer. Serum IL-6 was measured by ELISA, serum crosslaps as a marker of bone resorption were measured by ECLIA, serum osteocalcin was measured by chemoluminescence assays.RNA expression of osteocalcin in bone tissue from early postmenopausal women was higher compared with premenopausal women. Local osteocalcin expression was positively associated with circulating osteocalcin (r=0.24, P=0.05) and crosslaps (0.30, P=0.005) concentrations. Postmenopausal women also had higher circulating IL-6 levels, compared with premenopausal women, but circulating IL-6 levels were not associated with IL-6 expression in bone samples. There was no significant difference in the expression of either IL-6 or gp80 in postmenopausal women compared to bone samples from premenopausal women. In conclusion, in contrast to the higher expression of osteocalcin in bone samples of postmenopausal women, we did not observe a local increase in IL-6 or IL-6 receptor expression in human bone tissue with menopause. We can not exclude a small increase below the detection limit of our assay, however our data support the hypothesis, that the involvement of IL-6 in postmenopausal bone loss , could be better reflected by circulating IL-6 levels than by IL-6 production in bone.

F334

Attenuation of Post-Ovariectomy Bone Loss in Cathepsin K Null Mice. M. A. Gentile,[1] P. Saftig,[*2] G. A. Rodan,[1] D. B. Kimmel.[1 1]Bone Biology and Osteoporosis, Merck Research Laboratories, West Point, PA, USA, [2]Universitat Gottingen, Gottingen, Germany.

Cathepsin-K (CatK) is a collagen-degrading lysosomal cysteine protease important in osteoclastic bone resorption. CatK null (CatK KO) mice are osteopetrotic and model human pycnodysostosis, caused by mutations in the CatK gene. The purpose of this study was to examine the extent of bone loss caused by ovariectomy (OVX) in CatK KO mice. CatK KO mice were generated by targeted disruption of exon-7 via neo cassette insertion in L129SVJ embryonic stem (ES) cells. Two age groups (23 and 30 weeks; N=20 each) of wild type (WT) and CatK KO mice were OVXd or Sham-OVX. 8 weeks later bone mineral density (mg/cm2) was measured ex vivo by pDXA (Norland) in L3-L6 vertebrae (LV-BMD), proximal 25% (PF-BMD) and distal 25% (DF-BMD) of femora. Results were analyzed by Kruskal-Wallis ANOVA with Student Neuman-Keuls post-hoc analysis. Femur length (F-Lgt, mm) was measured.

Geno/Surg	Age (wks)	DF-BMD	LV-BMD	PF-BMD	F-Lgt
WT/Sham	23	64±4#	57±5#	64±3#	16.5±0.3
WT/OVX	23	54±6	47±4	59±3	17.1±0.6
CatKKO/Sham	23	72±14	62±8	65±8	15.8±0.6
CatKKO/OVX	23	71±8	63±5	66±4	16.1±0.5
WT/Sham	30	66±8#	64±7#	68±6#	16.9±0.3
WT/OVX	30	59±3	55±5	64±3	17.0±0.2
CatKKO/Sham	30	84±7#	68±5	72±5	15.7±0.3#
CatKKO/OVX	30	76±10	66±7	72±7	16.4±0.4

Mean±SD; #different from OVX/same genotype (P<.04)

At all sites CatK KO/Sh mice had higher BMD than WT/Sh (P<.001). CatK KO mice had shorter femurs than WT mice (P<.005). In WT mice, OVX induced significant bone loss at all sites at both ages. In CatK KO mice, OVX caused bone loss only in the distal femur of 30 week old mice; no other bone loss was seen. These data confirm that lack of cathepsin K increases BMD and indicate that OVX-induced bone loss is markedly attenuated in the absence of cathepsin K. These data make cathepsin K inhibition an attractive target for suppression of estrogen-deficiency bone loss in humans

F338

LHRH Analog Therapy Causes Early Bone Loss in Men Receiving Treatment for Prostate Cancer, P. Taxel,[1] P. C. Albertsen,[*2] R. Dowsett,[*3] P. M. Fall,[4] M. Trahiotis,[*4] J. Zimmerman,[*4] L. G. Raisz.[1 1]Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]Surgery, University of Connecticut Health Center, Farmington, CT, USA, [3]Radiation Oncology, University of Connecticut Health Center, Farmington, CT, USA, [4]General Clinical Research Center, University of Connecticut Health Center, Farmington, CT, USA.

Prostate Carcinoma (Ca) is the most commonly diagnosed Ca in U.S. men, and the second leading cause of Ca death. Recently, more men are receiving hormonal suppression with Luteinizing Hormone Releasing Hormone (LHRH) analogs for locally advanced disease. Some studies have shown that this therapy can lead to bone loss. As hip fractures are a major cause of morbidity and mortality in older men, the potential for compounding this problem with LHRH analogs is the rationale for this study. Bone mineral density (BMD) was measured by dual energy x-ray absorptiometry (DXA) at the lumbar spine (LS), femoral neck (FN), total hip (TH) and total body (TB) at baseline, prior to or within the first month of LHRH analog injection and every 6 months thereafter. Markers of bone resorption, including urinary cross-linked N and C-telopeptides of type 1 collagen (NTX and CTX), and markers of bone formation, including bone specific alkaline phosphatase (BSAP) and osteocalcin (OC) were measured at baseline and every 6 months. Data on 13 men, mean age 68 years (range 56-75), without bony metastases, who received 6 months of neoadjuvant therapy with LHRH analogs for prostate Ca are reported. At baseline, the mean (± standard deviation) BMD of the LS was 1.26 ± .17 gm/cm^2; FN .91 ± .19 gm/cm^2; TH 1.00 ± .13 gm/cm^2 and TB 1.21 ± .08 gm/cm^2. After 6 months of treatment, all 13 men lost more than 1.1% of BMD at at least one site. At the LS, 7 of 13 men lost up to 4.9% (mean loss 3%); at the FN, 6 of 13 men lost between 1 and 4.5% (mean loss 3%); at the TH 8 of 13 men lost between 1 and 6.7% (mean loss 3%). Moreover, men with the lowest baseline hip BMD showed the greatest % bone loss at this site. At 6 months there was a significant increase in NTX and CTX of 63 and 139% (p= .003 and .013), respectively. Nine of 13 men had repeat BMD measurements at 1 year. None regained BMD to pretreatment val-

ues despite discontinuation of LHRH analog therapy. Of these men, only 5 had testosterone levels that were restored to normal. NTX and CTX declined by 21 and 34%, respectively, from 6 to 12 months. We conclude that men treated with LHRH analogs are at risk for bone loss in the first 6 months of treatment, and may not regain bone mass within 6 months of discontinuation of this medication. This loss is associated with an increase in markers of bone resorption. We suggest that preventive measures to slow bone loss are indicated in men receiving LHRH analog therapy.

F340

Trabecular Bone Microarchitecture Is Related to Clinical Risk Factors in Osteoporosis in Men. É. R. Legrand, D. Chappard, M. Basle, M. Audran. CHU, Angers, Angers, France.

We have shown that trabecular bone connectivity is a major and independant determinant of vertebral fracture in men with mild osteoporosis (1) . To examine the relationships between risk factors for osteoporosis and trabecular bone microarchitecture (evaluated on transiliac bone biopsy) we included 152 men with low BMD (lumbar T-score < -2.5) in a prospective study. The risk factors were checked: age, BMI (80 gr/day), use of corticosteroids (> 10 mg of prednisone for at least 1 year), hypogonadism, chronic disease associated with bone loss. The histomorphometric analysis was done on a Leica quantimet image processor and the followings measures were performed : trabecular bone volume (BV/TV), trabecular thickness (Tb Th) and number (Tb N), Interconnectivity Index (ICI), Star Volume of the bone marrow, Characterization of the trabecular network (node and free-end count).table;The first results are in the TableI: the 36 men with at least 3 clinical risk factors had a marked disorganisation of the trabecular network with an increase in ICI, star volume and free-end and a decrease in trabecualr number and node. Furthermore, to evaluate the role of the different risk factors, logistic regression analysis was performed. Age, alcohol abuse and steroid were not associated with disorganisation of the bone microarchitecture. In contrast, smoking (OR 2.4, $p < 0.05$), low BMI (OR 1.6, $p< 0.05$), hypogonadism (OR 11.9 $p < 0.05$) and chronic disease (OR 1.4 $p < 0.05$) were significantly associated with a low trabecular bone connectivity. These results strongly suggest that, in men with low BMD, higher the number of clinical risk factors, lower the connectivity of the trabecular network and probably higher the fracture' risk.(1) E Legrand et al. Trabecular bone microarchitecture, bone mineral density and vertebral fractures in male osteoporosis. JBMR 2000; 15: 13-19. Table I Comparison of bone parameters in men with no clinical risk factors (RF), 1 or 2 RF or at least 3 RF for osteoporosis.*$p < 0.05$, ** $p <0.01$ versus men with 0 to 2 risk factors

F344

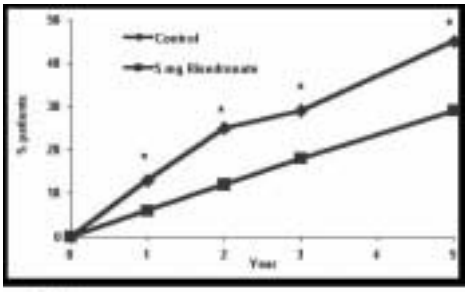
Smoking and Intestinal Calcium Absorption: Relationships with Vitamin D Metabolites in Postmenopausal Women. A. G. Need,*[1] A. Kemp,*[2] M. Horowitz,*[2] H. A. Morris.*[1] [1]Clinical Biochemistry, Institute of Med and Vet Science, Adelaide, Australia, [2]Department of Medicine, Royal Adelaide Hospital, Adelaide, Australia.

Smoking has been associated with poor intestinal calcium absorption, low bone density and fractures in postmenopausal women, but there are conflicting reports on how it affects the vitamin D endocrine system.In a group of 405 postmenopausal women attending our osteoporosis clinics we took a fracture history and measured intestinal calcium absorption efficiency (with 45Ca using a 20 mg calcium carrier and a single blood sample taken one hour after the dose), serum vitamin D metabolites (25 hydroxyvitamin D by competitive protein binding and calcitriol by HPLC and radioimmunoassay) and parathyroid hormone (PTH)(by immunoradiometric assay). We compared mean values in the 74 smokers and the 331 non-smokers and examined the relationships between the variables in each group. Vertebral fractures were more common in smokers than non-smokers (1.5(2.5SD) vs 0.7(1.4);P=0.013) as were peripheral fractures (1.2(1.8) vs 0.6(1.0);P=0.016). The hourly fractional rate of calcium absorption was less in smokers than non-smokers (0.56(0.29SD) vs 0.68(0.27) fx/h;P=0.001) as were serum calcitriol (95(32) vs 122(37) pmol/L;P<0.001) and PTH (3.8(1.6) vs 4.9(2.6) pmol/L;P<0.001). Serum 25 hydroxyvitamin D was similar in each group (60(25)nmol/L in the smokers vs 62(26) in the non-smokers;P=0.57). In the smokers, calcium absorption was 0.23+0.0034 x serum calcitriol fx/h (R=0.38;P=0.001) and in the non-smokers it was 0.42+0.0021 x serum calcitriol fx/h (R=0.28;P<0.001). There was no difference in this relationship between smokers and non-smokers. In the smokers serum calcitriol, in turn, was significantly related to serum PTH (P=0.001) and 25 hydroxyvitamin D (P=0.027). Hence the poor calcium absorption in the smokers was due to suppression of the PTH-calcitriol axis.We conclude that calcium absorption is decreased in smokers due to suppression of the PTH-calcitriol endocrine axis. This may aggravate their postmenopausal bone loss and also limit the effectiveness of calcium supplements.

F347

Sustained Fracture Risk Reduction Over 5 Years With Risedronate Therapy. N. B. Watts,[1] J. Brown,[2] D. Hosking,[3] S. Adami,[4] H. Mulder,*[5] J. Y. Reginster,[6] C. Kasibhatla,*[7] A. Chines.[7] [1]Emory University, Atlanta, GA, USA, [2]Le Centre Hospitalier Universitaire de Quebec, Quebec, Canada, [3]Nottingham City Hospital, Nottingham, United Kingdom, [4]Clinicizzato di Valeggio, Valeggio, Italy, [5]Research Center Good Clinical Practice, Rotterdam, The Netherlands, [6]University of Liege, Liege, Belgium, [7]Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Clinical extension trials involving bisphosphonates are usually open-labeled continuation of three year double blind studies. In the first placebo-controlled extension studies of a bisphosphonate, safety and efficacy of long term risedronate use were evaluated over 5 years by extending two large 3 year fracture efficacy studies (VERT-MN and VERT-NA) for two years. In VERT-MN, a total of 265 patients (placebo=130 and risedronate 5 mg=135) continued their originally assigned treatment in years 4 and 5. Overall, there was a statistically significant 49% vertebral fracture risk reduction. Non-vertebral fracture risk reduction with risedronate over this period was 37% (p=0.022). Adverse events including upper GI were comparable between the two groups. In VERT-NA, in the extension period (placebo=42, risedronate=44), BMD either was maintained or continued to increase. On biopsy, normal lamellar bone was observed after 5 years of risedronate treatment without any pathological findings. Bone turnover was reduced by 50%. In conclusion, risedronate treatment over 5 years provides sustained efficacy and safety as evidenced by histology showing no pathological abnormalities. Risedronate was well tolerated over the treatment period.



F349

Risedronate (Ris) Preserves Bone Architecture in Osteoporotic Postmenopausal Women as Measured by 3-D Micro-Computed Tomography: Effects of Bone Turnover. B. Borah,*[1] T. E. Dufresne,*[1] P. A. Chmielewski,*[1] M. C. Prenger,*[1] E. F. Eriksen.[2] [1]Procter & Gamble Pharmaceuticals, Mason, OH, USA, [2]Aarhus Artssygehus, Aarhus, Denmark.

It is well recognized that a combination of low bone mass and the deterioration of trabecular architecture underlies osteoporotic fractures. We present data that indicate for the first time that RIS preserves trabecular architecture in osteoporotic women. We investigated the effects of RIS on trabecular architecture in the iliac crest biopsies using 3-D micro-computed tomography (mCT) in a cohort of 38 postmenopausal osteoporotic women treated with 5 mg RIS (n = 21) or placebo (n =17) for 3 years. Each patient had a biopsy taken at baseline and at 3 yrs. Bone turnover parameters were collected using conventional histological techniques (Eriksen et. al., JBMR 14(suppl. 1):S404, 1999). The biopsies were then imaged using a Scanco Medical mCT scanner at 30 micron isotropic voxel resolution. The analysts were blinded to treatment assignment during image acquisition and architectural analysis. One-way ANOVA was performed to examine architectural changes from baseline and across treatment groups. When analyzing the entire dataset, no significant differences in trabecular architecture were observed between the placebo and RIS groups. However, we found a significant negative correlation ($p = 0.01$) between pairwise change in bone volume (BV/TV) and baseline Mineralizing Surface/Bone Surface (MS/BS) in the placebo group. In the RIS group, no such correlation existed ($p = 0.79$). This provided evidence that higher turnover induces bone loss leading to a higher risk of architectural degradation in osteoporotic patients. With this rationale, we performed subgroup analysis of patients who had baseline biopsies with MS/BS in the upper 50% of the entire cohort (range of 6.4% - 19.4%). In this subgroup, several architectural parameters differed in the placebo group relative to the RIS group, including a significant decrease of BV/TV ($p = 0.016$), a significant decrease of Trabecular Thickness ($p = 0.024$), a significant shift toward more rod-like structure (shown by an increase in Structural Measure Index ($p = 0.014$) and Bone Surface/Bone Volume ($p= 0.008$)), and a marginally significant increase in Marrow Star Volume ($p = 0.086$). In the RIS group, the bone volume and the architectural parameters did not alter significantly from baseline. However, the average gray level in the mCT images, which is proportional to bone density, showed marginal increase ($p = 0.061$), indicating a shift toward increased mineralization with RIS. In conclusion, these data indicate that among women with higher bone turnover, RIS preserves trabecular bone architecture.

F351

The Effect of 5-Year Risedronate Therapy on Bone Histology and Histomorphometry. E. F. Eriksen,[1] F. Melson,[1] E. Sod,[2] A. Chines,[2] L. Law.*[2] [1]Aarhus Artssygehus, Aarhus, Denmark, [2]Procter & Gamble Pharmaceuticals, Mason, OH, USA.

A recent 3-year double blind, placebo-controlled study demonstrated that 5 mg Risedronate (Ris) significantly decreased the incidence of vertebral and nonvertebral fractures in women with postmenopausal osteoporosis (JAMA 1999; 282:1344). All patients were supplemented with calcium (1000mg/d) and Vit D supplementation was provided for those with low levels. This study was extended to 5 years for a subset of women who had bone biopsies at baseline. There were 42 placebo women (mean 69.2 {S.D. 9.2} y, femoral neck T-score -2.3) and 44 Ris women (mean age 69.3 {S.D. 8.0} y, femoral neck T-score-2.8) in the extension. We now present biopsy data from 21 placebo and 27 risedronate patients who where evaluable for histomorphometric and/or histological analyses at baseline and 5 years. The table shows changes in selected parameters in patients with paired biopsies (baseline and post-treatment). For Ris patients, histology showed normal lamellar bone without pathological findings such as marrow fibrosis, osteomalacia, or woven bone. Bone mineralization was normal as assessed by Osteoid Thickness, Mineral Apposition Rate and Mineralization Lag Time. Bone turnover decreased in both treatment arms, but the change was statistically significant in the Ris arm only. Bone formation at the BMU level (wall thickness) was normal and did not change over time. Double tetracycline labels were present in all biopsy specimens indicating continuous bone turnover. Although cortical thickness decreased in both groups, the decrease was about 3-fold greater in the placebo group indicating that risedronate reduces cortical bone loss. These results are in general similar to those reported after 3 years of risedronate treatment (JBMR 1999;14: S404) and

show no further reduction in bone turnover.

	Placebo		Risedronate 5 mg	
	Baseline	**5 years**	**Baseline**	**5 years**
Osteoid Thickness (mm)	8.6	10	8.9	9.4
Mineralization lab time (days)	28	27	19	31
Mineral apposition rate (mm/d)	0.55	0.6	0.533	0.6
Mineralizing Surface (%)	6.8	4	6.3	1.2*
Activation Frequency (1/yr)	0.44	0.2	0.42	0.09*
Trabecular bone volume (%)	19	19	17	15
Wall Thickness (mm)	39	42	41.5	43
Cortical Thickness (mm)	1321	915*	1017	885*

In conclusion, these unique data from paired biopsy samples show normal bone formation and moderate and sustained decrease in bone turnover without negative effects on bone mineralization or structure after 5 years of risedronate treatment. These data demonstrate the long-term bone safety of risedronate.

F353

Zoledronic Acid, at a Total Annual Dose of 4 mg, Increases Bone Density at All Sites and Stably Reduces Bone Turnover for One Year when Administered as a Single or a 3-Monthly Intravenous Injection in Postmenopausal Osteoporosis. J. P. Brown,[1] P. Burckhardt,[2] I. R. Reid,[3] Z. D. Horowitz,[4] P. C. Richardson,[4] U. Trechsel.[5] [1]Centre de recherche du CHUL, Université Laval, Québec, Canada, [2]CHUV, Lausanne, Switzerland, [3]University of Auckland, Auckland, New Zealand, [4]Novartis, East Hanover, NJ, USA, [5]Novartis, Basel, Switzerland.

For the Zoledronic Acid Study GroupOral bisphosphonates have become an important therapeutic option for the treatment of postmenopausal osteoporosis but have limitations in terms of low bioavailablility and dosing instructions. Although intravenous (IV) use every 3 months has been studied, the use of very infrequent infusions has not been previously explored. In this study we explore whether the use of zoledronic acid allows very infrequent administration and results in a sustained suppression of bone turnover, whilst avoiding the limitations of regular oral dosing. In this 1-yr RCT, 351 postmenopausal women (age 45 to 80 yrs) with lumbar spine T-score < -2 (mean -2.9) and no prevalent vertebral fracture, zoledronic acid was given as an IV injection over 5 min. in doses of 0.25mg, 0.5mg and 1mg at 3 month (m) intervals. The total annual dose of 4mg was also given as a single 4 mg dose, or two 6-monthly doses of 2mg. All women received a calcium supplement (1g/d). BMD of the spine (LS), femoral neck (FN), total body (TB) and distal radius (DR) were measured by DXA. All BMD values were converted to a Hologic base. BMD results (ITT analysis) at 12 m are shown in the table below as mean % changes (± SEM) from baseline.

	Placebo	**4x0.25mg**	**4x0.5mg**	**4x1mg0**	**2x2mg**	**1x4mg**
LS	+0.4 (0.4)	+5.8* (0.4)	+5.6* (0.5)	+4.8* (0.4)	+4.9* (0.5)	+5.0* (0.5)
FN	-0.5 (0.4)	+2.7* (0.5)	+2.7* (0.3)	+2.5* (0.4)	+3* (0.4)	+2.6* (0.3)
TB	+0.6 (0.7)	+1.7§ (0.6)	+1.5 (0.6)	+1.4¥ (0.3)	+1.4¥ (0.4)	+1.7§ (0.3)
DR	-0.8 (0.4)	+0.1 (0.6)	+0.6¥ (0.4)	+0.7§ (0.4)	+0.5‡ (0.5)	+0.3‡ (0.4)

* p<0.001, § p<0.01, ¥ p<0.05, ‡ p=0.05 compared to placebo. Resorption markers dropped to a nadir at 1 m (median falls of 65-83% for serum CTX and 50-69% for urinary NTX). Suppression was maintained at 12 m in all groups and was significantly different from placebo (p<0.001). BSAP and osteocalcin showed similar responses with a nadir at 3 m and stable suppression until 12 m for all doses (p<0.001). Myalgia, pyrexia and transient bone pain occurred more commonly in the zoledronic acid groups. We conclude that zoledronic acid given at intervals of up to 1 year between injections significantly increases BMD at all sites and stably reduces bone turnover, and therefore should be considered for evaluation in the treatment of postmenopausal osteoporosis.

F355

Evidence for Mechanism-Based Irritant Effects of Nitrogen-Bisphosphonates on Soft Tissues. J. E. Fisher, G. A. Rodan, A. A. Reszka. Bone Biology and Osteoporosis Research, Merck Research Laboratories, West Point, PA, USA.

Nitrogen-bisphosphonates (N-BPs) act directly on the osteoclast by inhibiting the cholesterol pathway enzyme, farnesyl diphosphate (FPP) synthase. Though bisphosphonates have the potential to irritate the esophagus and skin, the mechanism for these effects has not been elucidated. Recently, in vitro mechanism-based N-BP suppression of cell growth has been demonstrated in keratinocytes, and has been associated with suppression of cdk phosphorylation of the growth-regulatory protein, retinoblastoma (Reszka et al. 2001. Mol. Pharmacol., 59:193-202). In the studies described here, we examine two new models of local irritation. In vitro, Ch1.Es esophageal fibroblasts were used to model esophageal tissues. Twenty four hour treatment with the N-BPs alendronate (ALN) or risedronate (RIS), at 300 micromolar, a concentration that might be present in the esophagus after reflux, induced apoptosis. This effect was associated with caspase cleavage of the pro-apoptotic kinase Mst1 and activation of p38alpha- and Jnk kinases. A loss of Erk1 and Erk2 kinase activities was also observed. Consistent with mechanism-based action, all N-BP-induced apoptotic and growth effects were mimicked by a selective inhibitor of protein geranylgeranylation, and completely blocked by co-incubation with the mevalonate pathway metabolite, geranylgeraniol. Modification of culture conditions or pharmacological intervention by inhibiting squalene synthase, an enzyme immediately downstream of FPP synthase, augmented intracellular levels of both FPP and geranylgeranyl diphosphate (GGPP), and increased the expression of HMG-CoA reductase. These changes completely blocked apoptosis induced by the N-BPs. In vivo we examined localized skin irritation produced, in growing male Sprague Dawley rats, by subcutaneous bolus injections of ALN or RIS. N-BPs were administered at 0.5 mg/kg on each of five consecutive days. Approximately twenty four hours after the last dose, animals were euthanized and skin from injection sites was dissected out, fixed in 10% neutral-buffered formalin and measured. N-BP treatments caused significant (volumetric) skin thickening characterized by disruption of cell-cell contacts and cellular infiltration into the stratum basale. Co-administration of an inhibitor of squalene synthase, to potentiate intracellular accumulation of FPP and GGPP, significantly suppressed skin thickening induced by ALN (46%, p<0.01) or RIS (45%, p<0.02). Taken together, these data suggest that local irritation produced by N-BPs, in esophagus or skin, occurs through suppression of FPP synthase, and provide in vivo evidence for this mechanism-based action.

Alendronate in the Treatment of Bone Loss after Spinal Cord Injury (SCI): Preliminary Data of a 2-Years Randomised Controlled Trial in 60 Paraplegic Men. M. Luethi,[1] Y. Zehnder,*[2] D. Michel,*[2] H. Knecht,*[2] R. Perrelet,*[1] M. Kraenzlin,*[3] G. A. Zaech,*[2] K. Lippuner.[1] [1]Osteoporosis Unit, University Hospital, Berne, Switzerland, [2]Swiss Paraplegic Center, Nottwil, Switzerland, [3]Endocrine Unit, University Hospital, Basle, Switzerland.

Bone loss appears early after SCI and leads to a high incidence of long bone fractures in paraplegics. To date, only few prospective studies evaluating therapeutic modalities for prevention or treatment of disuse osteoporosis have been published. Alendronate is effective in preventing and treating postmenopausal and male osteoporosis as well as glucocorticoid-induced osteoporosis. To investigate if alendronate is also effective in the management of disuse osteoporosis we performed the following trial.Sixty paraplegic men with posttraumatic SCI (Frankel A or B) were randomly allocated to one of the following treatment groups: alendronate, 10mg/d p.o. plus calcium, 500mg/d (ALN+Ca), or calcium 500mg/d alone (Ca). Subjects were stratified according to time since SCI. Bone mineral density (BMD) was measured at lumbar spine (LS), proximal femur (HIP), tibial diaphysis (T-DIA) and distal tibial epiphysis (T-EPI) at baseline and then every 6 months using dual energy X-ray absorptiometry (Hologic QDR 4500A). Today 51 paraplegics (26 ALN+Ca, 25 Ca) have completed their 18 months visit. Baseline characteristics (mean±SEM) are given in the table:

	ALN+Ca	**Ca**	**P (unpaired t-test)**
Age (years)	**38.4±1.5**	**37.6±2.1**	**0.8**
BMI (kg/m2)	23.7±0.6	22.5±0.5	0.1
Time since SCI (years)	10.6±1.4	9.5±1.5	0.6
BMD LS (g/cm2)	1.145±0.0393	1.119±0.031	0.6
BMD HIP (g/cm2)	0.717±0.0334	0.676±0032	0.4
BMD T-DIA (g/cm2)	1.163±0.041	1.163±0.035	1.0
BMD T-EPI (g/cm2)	0.464±0.035	0.449±0.029	0.8

BMD of LS increased in both groups over the 18 months, however with a significantly larger increase in the ALN+Ca (5.2±0.7%; mean±SEM) compared with the Ca group (2.0±0.8%; p<0.01, 2-way ANOVA). At HIP, BMD significantly decreased in Ca (-3.6±1.8%) whereas it remained stable in ALN+Ca (0.7±0.9%; p<0.05 between groups). Similarly, at T-EPI, BMD in Ca significantly decreased over time (-8.3±2.6%) but remained stable in ALN+Ca (-1.3±2.0%; p<0.05 between groups). The respective changes for T-DIA were: -3.0±0.9% in Ca (p<0.001 vs. baseline) versus –0.7±0.9% in ALN+Ca (p=n.s. vs. baseline).We conclude from these data that alendronate in combination with calcium is effective in preventing bone loss at distal limbs in paraplegic men, whereas calcium alone is not

F358

Efficacy of Risedronate in Decreasing the Incidence of Femoral Neck and Intertrochanteric Fractures in Older Women with Osteoporosis. R. Eastell,[1] M. R. McClung,[2] J. Y. Reginster,[3] W. G. Bensen,*[4] E. Seeman,[5] G. Cline,*[6] L. Law,*[6] A. Chines.[6] [1]University of Sheffield, Sheffield, United Kingdom, [2]Oregon Osteoporosis Center, Portland, OR, USA, [3]University of Liege, Liege, Belgium, [4]McMaster University, Hamilton, Canada, [5]University of Melbourne, Melbourne, Australia, [6]Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Epidemiological studies suggest a difference in pathophysiology between femoral neck (FN) and intertrochanteric (IT) fractures. Above age 80, there is a much stronger relationship between low BMD and the risk of IT than FN fractures (Vega et. al., OI 1:81, 1991). The relative risk (RR) for 1 SD decrease in femoral neck BMD for IT fractures is independent of age (RR=2.5) while the RR for FN fracture decreases significantly from 3.3 (CI: 2.3-4.8) for women between 65-79 years to 1.3 (CI:0.6-2.8) for women over 80 years (Nevitt et. al., OI 4:325, 1994). This suggests that nonskeletal factors such as falls contribute proportionately more to FN fractures in older patients. The effect of antiresorptive treatment on these two types of fractures is mostly unknown.

In a 3-year study of 9331 patients, risedronate decreased the risk of all hip fractures in women with osteoporosis by 40-60% (McClung et al, NEJM 344:333, 2001). We examined the effect of risedronate on the incidence of the two most commonly observed types of hip fractures from the above study. Results from this analysis are presented in the table below.

	Women 70-79 yr of Age with Osteoporosis				Women ≥ 80 yr of Age with ≥ 1 Clinical Risk Factors for Hip Fracture			
(# Subjects)	Control (1821)	Ris (3624)	RR	p-value	Control (1313)	Ris (2573)	RR	p-value
IT Fractures	14 (1.0)	15 (.5)	0.54	0.089	22 (2.2)	26 (1.4)	0.60	0.071
FN Fractures	28 (1.9)	34 (1.2)	0.61	0.048	25 (2.7)	53 (2.7)	1.1	0.772

RR=Relative risk; data are number of fractures (%)- incidence based on Kaplan-Meier estimates

For women who are 80 years of age or older and have at least one clinical risk factor for hip fracture, there is a trend towards reduction of risk for IT fractures while FN fractures are unaffected. For women who are 70-79 years of age with confirmed low femoral neck BMD, both IT and FN fractures show a trend toward risk reduction with FN achieving statistical significance.

In conclusion, the beneficial effect of risedronate on IT and FN fractures among women with confirmed osteoporosis and on IT fractures in older women (with at least 1 clinical risk factor for hip fractures), a fracture type closely associated with low bone mass, supports the idea that these fractures could have different pathophysiology as they appear to respond differently to bisphosphonate therapy.

F363

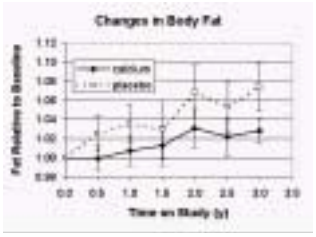
The Post-PTH Experience in Men with Idiopathic Osteoporosis: Bisphosphonates vs. Non-pharmacologic Therapy. E. S. Kurland,[1] S. L. Heller,[1] F. Cosman,[2] B. Diamond,[1] R. Lindsay,[2] J. P. Bilezikian.[1] [1]College of P&S, Columbia University, New York, NY, USA, [2]Helen Hayes Hospital, West Haverstraw, NY, USA.

We have previously reported that parathyroid hormone (PTH 1-34) has shown promise as an effective anabolic agent for the treatment of idiopathic osteoporosis (IO) in men. Important questions remain, however, about the preferred clinical strategy for managing patients beyond a 12-18 month course of PTH exposure. Are anti-resorptive agents useful or necessary after completing PTH therapy? Alternatively, might the cessation of PTH alone result in further gains in bone density, as has been observed after parathyroidectomy in patients with primary hyperparathyroidism? We followed 22 men with IO (mean age 50 +/- 1.9) who had been treated with PTH (1-34) for a mean duration of 23 +/- 7 months. 14/22 men (64%) began a bisphosphonate (BisP) immediately upon completing PTH, while 8/22 men (36%) took no medication. All patients continued to take 1200 mg of calcium and 400 units of vitamin D daily. During 2 years of follow-up, bone densitometry of the lumbar spine (LS), hip and forearm was performed at 6 month intervals with results for LS as follows: During the initial 6 months post-PTH the men on BisP had a mean further increase in LS bone density of 3.0 +/- 2.0% while the men on no additional treatment increased by 0.1 +/- 0.1%. One year post-PTH, men on BisP had no further increase (+0.2 +/- 0.1%) while the men on no treatment had declined minimally (-0.2 +/- 0.1%) (p =NS). The incremental gain in LS density in men on BisP was greatest in the initial 6 months of treatment and plateaued by 1 year. Six men (43%) who took PTH for a mean of 28 +/- 2 months had an increase in LS of 3.0 +/- 1.0% while 8 (57%) men who took PTH for a mean of 16 +/- 2 months experienced an increase of 7 +/- 2%. Six of the 8 men (75%) who initially chose no treatment began BisP within 1 year of discontinuing PTH. Mean change in LS density was -0.1 +/- 0.1% for this group at 6 months, in contrast to the 3.0 +/- 2.0% increase observed in men who started BisP immediately. Two men opted to take no additional treatment. Both experienced declines in LS bone density of 6.0% and 5.0% respectively, from maximal values achieved. We conclude that not only is there an additional gain in LS bone density that can be achieved when BisP immediately follows PTH therapy, but in the absence of such treatment, much of the bone mass accrued during PTH therapy is eventually lost. BisP appears to be most effective when administered sequentially after PTH treatment, with no further gains noted when BisP treatment is delayed. These data suggest that sequential administration of BisP should be an important component of any treatment strategy utilizing PTH as a therapy for IO in men.

F370

Calcium Supplementation May Attenuate Accumulation of Fat in Young Women. M. J. Barger-Lux,[1] K. M. Davies,[1] R. P. Heaney,[2] B. K. Chin,*[1] K. Rafferty.*[1] [1]Osteoporosis Research Center, Creighton University, Omaha, NE, USA, [2]University Professor, Creighton University, Omaha, NE, USA.

In earlier work, we found an inverse relationship between dietary calcium-to-protein ratio and fat mass in baseline data from several studies of female subjects. Here we report longitudinal data on body fat in young women who completed a 3-year, double-blind placebo-controlled trial of Ca supplementation (1500 mg/d) that included DXA scanning at 6-month intervals. For each subject, we expressed each DXA-generated value for total-body fat mass as a fraction of her baseline value. We generated dietary Ca:protein ratios (mg:g) from analyses of 7-day food diaries that the subjects kept prior to entry and at mid-study. For the present analysis, we included all subjects (n=52) with a full 36 months' of DXA data on fat mass. At entry, these subjects were aged 23.6 ± 2.8 years. They had BMIs of 22.3 ± 2.8 kg/m2, daily Ca intakes 591 ± 169 mg, and dietary Ca:protein ratios of 10.0 ± 2.0 mg:g. The figure shows timecourse of changes in total-body fat for the Ca and placebo groups (data as mean ± SEM). The curve of the placebo group is consistently above that of the Ca-supplemented group. The aggregate slopes were 2.2 %/yr for the placebo group and 1.1 %/yr for the Ca group; the slope of the Ca group falls below the 95% CI of the placebo group. We conclude that the benefits of Ca supplementation in young women may include attenuation of gain in total-body fat mass.



F374

Effects of Two Years of Exercise and Hormone Replacement Therapy on Bone Mineral Density in Postmenopausal Women. S. B. Going,[1] T. G. Lohman,[2] E. C. Cussler,*[2] R. M. Blew,*[2] L. B. Houtkooper,*[2] L. M. Metcalfe,*[2] H. G. Flint-Wagner,*[2] V. Stanford.*[2] [1]Physiology, University of Arizona, Tucson, AZ, USA, [2]University of Arizona, Tucson, AZ, USA.

Combination therapies are receiving increasing attention in the search for effective regimens to counter bone loss. The Bone, Estrogen and Strength Training (BEST) Study was designed to test the effects of exercise with and without hormone replacement therapy (HRT) on bone mineral density (BMD). Early postmenopausal women (age, 55.8 ± 4.8y) who used HRT (1 - 4 years; n = 108) or who did not use HRT (NHRT, ≥ 1 year, n = 105) were randomized to 24 months of exercise (EX) or no exercise (NEX). BMD and soft tissue composition was measured twice (averaged for analyses) at baseline, 12 months and 24 months by dual energy x-ray absorptiometry. All subjects received 800 mg/day calcium supplements. Exercise (3 days per week) entailed supervised high load, low rep weight lifting (70-80% 1 RM, 2 sets of 6-8 reps, 8 exercises), moderate impact aerobic weight-bearing (25 min), and steps/stair climbing with weighted vests. Baseline height (163.1 ± 6.4 cm), weight (67.1 ± 10.9 kg), percent fat (38.1 ± 6.5%) and BMD's at femur neck (FN, 0.87 ± 0.12 g/cm2), trochanter (FT, 0.74 ± 0.11 g/cm2), and lumbar spine (LS, 1.12 ± 0.15 g/cm2) were similar (p>0.05) among groups. BMD changes were examined using multiple regression to test contrasts of EX versus NEX within HRT and NHRT groups across sites. BMD adjusted for baseline BMD and years past menopause increased in women who exercised or used HRT by 1.0 - 1.5% and decreased in women who did not EX and did not use HRT. Trochanteric BMD was significantly (p<.05) increased at two years. Women who exercised and used HRT gained BMD (+1.24%) compared to women who used HRT and did not exercise (-1.70%) and controls (-1.6%), who lost BMD. We conclude the combination of exercise and HRT counters trochanteric bone loss in postmenopausal women. Supported by: NIH AR39559 and Mission Pharmacal

Are Placebo Controlled Trials Ethical for Women With Osteoporosis? S. R. Cummings,[1] K. Modelska,*[2] M. C. Nevitt,[3] D. M. Black.[4] [1]Medicine, University of California, San Francisco, CA, USA, [2]UCSF Coordinating Center, San Francisco, USA, [3]Epidemiology and Biostatistics, University of California, San Francisco, USA, [4]University of California, San Francisco, USA.

Several treatments reduce fracture risk in women with osteoporosis and guidelines recommend these treatments for women with osteoporosis. Is it still 'ethical' to enroll women with osteoporosis in placebo-controlled trials? We addressed this question by reviewing principles of Western medical ethics and systematically reviewing data about how much benefit a woman with osteoporosis may forfeit if she were assigned to placebo. The principle of beneficence requires an acceptable balance of benefits and risks; the principle of individual autonomy indicates that the individual woman has the right to balance the benefits and risks and decide whether to participate. Although hip or spine fracture have been associated with increased mortality rates in epidemiologic studies, a systematic review of randomized trials indicates that these treatments have not reduced mortality. Data from the Fracture Intervention Trial show that, on average, women with osteoporosis assigned to placebo (plus calcium & vitamin D) had 2.6 to 3.2 more days of fracture-related disability and 1.1 more days of bedrest due to back pain per year than those assigned to alendronate (P<.01). Women with a vertebral fracture within 2 years had a 4.8-fold higher risk of a subsequent vertebral fracture (16.3 % / yr) than did others (3.4% / yr) (P<.01).We conclude that among women with osteoporosis, the risk of mortality and morbidity from assignment to placebo is not sufficient to override an individual woman's right to make an informed decision to participate in a placebo-controlled trial. Women with recent vertebral fractures should be strongly advised to start approved treatment and not enroll in a placebo-controlled trial.

F382

Treatment of Osteoporosis Following a Hip Fracture: Sending Results of Bone Densitometry to Primary Care Physicians Does Not Increase Use of Pharmacologic Therapy. D. L. Orwig,*[1] L. Wehren,[1] J. YuYahiro,*[2] M. Hochberg,*[1] J. Magaziner.[1] [1]University of Maryland Baltimore, Baltimore, MD, USA, [2]Union Memorial Hospital, Baltimore, MD, USA.

Approximately 350,000 hip fractures occur annually in the United States. Hip fracture is associated with substantial excess morbidity and mortality, and people who have fractured are at increased risk of subsequent fractures. Almost all elders who sustain a hip fracture have low bone mineral density (BMD) at the time of the fracture and continue to lose up to 6% BMD in the femoral neck during the first year after the fracture. Although several pharmacologic agents are approved for the treatment of osteoporosis that have demonstrated anti-fracture efficacy, post-fracture management rarely includes bone-strengthening medication. This analysis examined the change over time in use of bone-strengthening

medications in patients who sustained a hip facture. Outcomes of hip fracture have been observed in more than 2000 participants in the Baltimore Hip Studies (BHS). Among a cohort of 205 women enrolled in the BHS,1992-95 (mean age of 81; mean baseline total hip BMD=0.588 gm/cm2), over 87% had osteoporosis as defined by the World Health Organization (femoral neck T score < -2.5) and met the National Osteoporosis Foundation (NOF) treatment guidelines. Among these women, fewer than 10% were taking bone-active medications at the time of fracture (5% estrogen; 5% etidronate), and only 10% received any bone-active medication within the year after fracture. In addition, only 15% were taking calcium while 75% were vitamin D deficient, as defined by low serum levels of 25 (OH) vitamin D. In a current BHS cohort (enrollment began in 1998), results of the baseline BMD measurement and a copy of the NOF's treatment guidelines are sent to participants and their primary care physician (PCP). Participants are strongly encouraged to discuss treatment options with their doctor. While 50% of women were taking calcium and/or vitamin D at the time of the fracture, only 13% received bone-active medication during the year following their fracture. These results suggest that providing BMD results with guidelines to PCPs does not increase the use of bone-strengthening medications in women who have a hip fracture. This work has demonstrated a need to examine the management and treatment of osteoporosis among this at-risk population in order to identify additional communication and intervention strategies to promote treatment.

F384

Dose-related Increases in Bone Mineral Density Due to Norethindrone Acetate in Postmenopausal Women Treated with Ethinyl Estradiol. J. C. Gallagher,[1] M. Greenwald,[2] R. Wasnich,[3] J. Symons.[4] [1]Bone Metabolism Section, Creighton University Medical Center, Omaha, NE, USA, [2]Osteoporosis Medical Center, Rancho Mirage, CA, USA, [3]Hawaii Osteoporosis Center, Honolulu, HI, USA, [4]Pfizer Global Research and Development, Ann Arbor, MI, USA.

Traditionally, the only benefit of the progestin component of hormone replacement therapy was thought to be prevention of endometrial carcinoma in women with intact uteri. However, recent evidence indicates that progestins can positively affect bone mineral density (BMD). This study was undertaken to examine the potential additive effect of norethindrone acetate (NA), when given in combination with ethinyl estradiol (EE), on BMD in postmenopausal women.This was a one-year, double-blind, placebo-controlled, parallel group, multicenter study. Female subjects with intact uteri who had undergone either spontaneous or surgical menopause within five years of the study start were eligible for enrollment. 945 subjects were randomized to one of eight treatment groups (NA in mg; EE in mcg): placebo; 0/5 NA/EE; 0.25/5 NA/EE; 1/5 NA/EE; 0/10 NA/EE; 0.5/10 NA/EE; 1/10 NA/EE; and an open-label arm of 0.625 mg conjugated equine estrogen/2.5 mg medroxyprogesterone acetate. All subjects received a supplement of 1000 mg of calcium carbonate daily. Dual-energy x-ray absorptiometry (DEXA) was used to determine BMD at four skeletal sites: femoral neck, total femur, lumbar spine (L1-L4), and total body. A central laboratory provided analysis of all DEXA scans and quality assurance of BMD data. Only data from the double-blind treatment groups are reported.At month 12, both doses of unopposed EE and all combination NA/EE doses demonstrated a mean increase in BMD at all skeletal sites. The difference was statistically significant compared with placebo at the lumbar spine, total femur, and total body. For both the 5- and 10-mcg doses of EE, there was a linear dose-response trend, with increasing NA dose resulting in a greater percent change in BMD from baseline. The largest increases in BMD were obtained in combination with 1 mg NA; a significant difference (P = 0.008) between the 0.5/10 and 1/10 dose groups was obtained at the lumbar spine.The effect of EE on BMD is dose-related and is potentiated with the addition of 1 mg NA. At all skeletal sites assessed, the combination of EE with 1 mg NA resulted in a greater percent change in BMD than unopposed EE. This confirms an independent effect of NA on bone metabolism.

Effect of Discontinuation of Estrogen, Calcitriol, and the Combination of Estrogen and Calcitriol on Bone Mineral Density and Bone markers. J. C. Gallagher,*[1] P. B. Rapuri,[1] G. Haynatzki,[2] J. R. Detter.*[1] [1]Bone Metabolism unit, Creighton University, Omaha, NE, USA, [2]Medicine, Creighton University, Omaha, NE, USA.

489 elderly women were randomized to ERT(hysterectomized) or HRT (CEE.625 mg +MPA2.5mg daily), calcitriol (0.25 mcg. b.i.d.), HRT+calcitriol, or placebo in a double blind, randomized osteoporosis prevention study. At the end of 3 years, treatment was discontinued and 358 subjects were followed for 2 more years. There were annual measurements of bone mineral density (BMD- DEXA), serum PTH, serum osteocalcin and urine crosslinks for 5 years. Calcium absorption (Ca45) and serum 25OHD were measured at baseline, 3 and 5 years. Statistical analysis was done by repeated measures and intention to treat (ITT). Spine BMD increased significantly on HRT and HRT + calcitriol (p<0.001), and calcitriol (p<0.01) compared to placebo. Femoral neck BMD increased significantly on HRT and HRT + calcitriol(p<. 001),but not on calcitriol compared to placebo. After discontinuation of treatment, there was more rapid bone loss in the two groups treated with HRT compared to the calcitriol and placebo groups, however, BMD remained above baseline (table).Most of the loss occurred in the first year after discontinuation. Calcium absorption which had increased in both calcitriol groups (p<.001)returned to baseline. Serum PTH, which decreased in both calcitriol groups(p<. 05), returned to baseline. Serum osteocalcin and urine crosslinks, which had decreased in both estrogen groups, returned to baseline. In conclusion, after discontinuing therapy, there was an increase in bone resorption and a decrease in BMD in all treatment groups. The loss in BMD was greatest in the groups receiving HRT and occurred more rapidly in the first year.Thus,prevention of osteoporosis needs to be long term.

BMD	Time (months)	HRT/ERT	Calcitriol	HRT/ERGT + Calcitriol	Placebo
Spine	36	4.5**	1.8*	5.1**	-0.7
Spine	60	2.3	1.2	1.8	-0.5
Femoral neck	36	3.0**	0.0	3.7**	-0.4

Effects of Raloxifene 60 mg/day on Risk of New Vertebral Fractures in Postmenopausal Women are Independent of Baseline Femoral Neck BMD. O. Johnell,[1] W. Wu,*[2] I. Pavo,*[3] J. L. Stock,[2] S. Sarkar,*[2] M. Wong,[2] K. D. Harper.[2] [1]Dept. of Orthopedics, Universitetssjukhuset MAS, Malmo, Sweden, [2]Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN, USA, [3]Lilly Area Medical Center, Eli Lilly and Company, Vienna, Austria.

The aim of this study is to assess the efficacy of raloxifene 60 mg/day (RLX) at 3 years on the risk of new vertebral fractures (VF) in postmenopausal women at different baseline BMD values and in women with osteopenia defined by no prevalent VF and baseline BMD T-score >-2.5. The MORE (Multiple Outcomes of Raloxifene Evaluation) trial randomized ≤ 80 years old, mean age 66.5 years) to placebo (PL, N=2576) or RLX (N=2557) [JAMA 282(1999): 637]. VF were identified in adjudicated radiographs taken at baseline and 3 years. Clinical VF were defined as new VF associated with signs or symptoms suggestive of VF reported at any post-baseline visit, and confirmed with radiographs. Femoral neck (FN) BMD T-scores were defined according to NHANES criteria. RLX had similar fracture efficacy irrespective of baseline femoral neck BMD (interaction term p=0.452). At 3 years, the relative risk (RR) of new VF in women without prevalent VF was 0.45 (95% CI 0.29, 0.71) in the RLX group compared to placebo. In the 1032 women without prevalent VF who had a baseline FN T-score >-2.5, 25 (4.8%) in the placebo group and 7 (1.4%) in the RLX group had new VF at 3 years [RR 0.29 (95% CI 0.09, 0.61)]. The numbers of women needed to be treated to prevent 1 new VF were 42 for women without prevalent VF and 29 for women without prevalent VF who had a baseline FN T-score >-2.5. The RR of new clinical VF was 0.13 (95% CI 0, 0.43) for the RLX group compared to placebo. In the women without prevalent VF and with both FN and lumbar spine T-scores >-2.5, only 7 (2.6%) in the placebo group and 4 (1.5%) in the RLX group experienced new VF, while 3 (1.0%) in the placebo group and none in the RLX group had new clinical VF. These reductions were not significant due to the small numbers of women in this subgroup. In conclusion, raloxifene 60 mg/day decreases the risk of at least 1 new VF at 3 years independently of baseline femoral neck BMD, and also in women with osteopenia defined by no prevalent VF with a baseline femoral neck BMD T-score of >-2.5.

Bone Density in Long-Term DMPA Users: A Double-Blind Randomised Controlled Trial of Estrogen Replacement Therapy. T. Cundy, R. Ames,* J. Clearwater,* A. Horne,* G. Gamble,* H. Roberts,* I. R. Reid. Division of Medicine, University of Auckland, Auckland, New Zealand.

A reduction in bone mineral density (BMD), particularly in the axial skeleton, is recognised to occur with long-term use of the injectable contraceptive depot medroxyprogesterone acetate (DMPA). The relative estrogen deficiency induced by DMPA is believed to be the likely mechanism underlying bone loss, but there are no data to prove this. We recruited 41 women who were long term DMPA users and had a lumbar spine BMD below the mean for age, and randomised them to receive either conjugated equine estrogens 0.625mg (CE, n=21) or matching placebo (PL, n= 20), once daily by mouth, for two years. All subjects continued their regular 12 weekly DMPA injections throughout the study. Areal BMD was measured 6 monthly at the lumbar spine, the femoral neck and total body sites (Lunar DPX). The primary outcome measure was the change in lumbar spine BMD. At randomisation the two groups were well matched in mean (SD) age (CE 37(7), PL 39(8) years), body mass index (CE 24.6 (5.0), PL 23.7 (3.1) kg/m^2), lumbar spine BMD (CE 1.068(0.087), PL 1.105 (0.069) g/cm^2), median (range) duration of DMPA use (CE 11 (2-22), PL 14 (2-26) years), and theproportion that were smokers (CE 38%, PL 25%). Twelve subjects dropped out of the study before completion(6 from the CE group and 5 from the PL group), mainly for social reasons. Adverse events were no more common in the CE group than the PL group, in particular the numbers reporting moderate or severe breast tenderness (4 CE vs 3 PL) and vaginal bleeding (3 CE vs 2 PL) were similar. Over the two year period lumbar spine BMD was unchanged in women taking CE (mean change +0.9%, 95% CI -0.6 to +2.4), but declined significantly in women taking PL (mean change -3.1%, 95% CI -4.7 to -1.5), p<0.001 for between group difference. Changes in the same direction, but of smaller magnitude, were seen in femoral neck BMD (p=0.037) and total body BMD (p=0.027). Adhesion to the medication was only fair. Of the 15 subjects allocated to CE who completed the study, the mean change in lumbar spine BMD was +2.3%, in the third with the best compliance, compared to +0.9% in the third with moderate compliance and -0.5 % for the third with the poorest compliance. This study confirms that induction of estrogen deficiency is the likely cause of DMPA-associated bone loss. Whilst oral estrogen replacement for women who wish to continue DMPA contraception can arrest bone loss, this may not be the best route of administration, given the relatively poor compliance.

F393

Brief Therapy with Recombinant Human Parathyroid Hormone (1-34) Increases Lumbar Spine Bone Mineral Density in Men with Idiopathic or Hypogonadal Osteopenia. E. Orwoll,[1] W. H. Scheele,*[2] S. Paul,*[2] S.

Adami,*[3] U. Syversen,*[4] A. Diez-Perez,*[5] G. A. Gaich.[2] [1]Oregon Health Sciences University, Portland, OR, USA, [2]Eli Lilly and Company, Indianapolis, IN, USA, [3]University of Verona, Valeggio sul Mincio (VR), Italy, [4]University Hospital, Trondheim, Norway, [5]Hospital del Mar, Barcelona, Spain.

Osteoporosis in men is common but there have been few large trials of potential therapies. Parathyroid hormone, given once daily, stimulates new bone formation and increases bone mass in patients with low bone mass. A randomized, double-blind, placebo-controlled clinical trial was conducted to assess the effects of recombinant human parathyroid hormone [rhPTH(1-34)] on bone mineral density (BMD) in 437 men with spine or hip BMD >2 SD below male young adult mean. The average age was 59 years; 59% had prevalent nonvertebral fractures and 49% had low testosterone (T) levels. No other causes of low BMD were present. Men were randomly assigned to receive either placebo (n=147), PTH 20 µg/day (n=151) or PTH 40 µg/day (n=139) by subcutaneous injections. The median study drug exposure was 11 months. All volunteers were provided with daily calcium (1000 mg) and vitamin D (400-1000 IU). BMD was measured by DXA at the lumbar spine, proximal femur, and total body. The treatment, rhPTH(1-34), increased BMD at the lumbar spine at months 3, 6, 12, and at the proximal femur and total body at month 12. At endpoint, BMD had declined in 57 (40%) men in the placebo group. In the PTH20 and PTH40 groups, 10 (7%) and 8 (6%) of the men did not increase lumbar BMD. More men in the PTH20 (55%) and the PTH40 groups (71%) had spine BMD increases ≥5% at endpoint, compared to the placebo group (10%) (P<0.001). rhPTH(1-34) increased BMD similarly in men with normal and low T levels. The proportion of responders in those with normal T levels was 68%, 91%, 94%, and 52%, 96%, 94% in those with low T levels for the placebo, PTH20, and PTH40 groups, respectively. In summary, therapy with rhPTH(1-34) rapidly and substantially increased BMD in men with osteoporosis, regardless of gonadal status.

Skeletal site (% change from baseline)	Placebo mean ± SD (n)	PTH20 mean ± SD (n)	PTH40 mean ± SD (n)	PTH20 or PTH40 vs Placebo
Lumbar spine BMD	0.5±3.9 (143)	5.9±4.5 (141)	9.0±6.5 (129)	P<0.001
Femoral neck BMD	0.3±4.1 (137)	1.5±4.0 (135)	2.9±6.3 (125)	P=0.029 (PTH20) P<0.001 (PTH40)
Total body BMC	-0.5±2.8 (87)	0.6±3.7 (84)	0.9 ± 3.7 (83)	P=0.021 (PTH20) P=0.005 (PTH40)

Twice-Weekly Injection of a Sustained-Duration PTH Construct Increases Cortical and Trabecular Bone Density in Adult Mice. P. J. Kostenuik,[1] S. Morony,[1] K. S. Warmington,*[1] M. V. Porkess,*[1] Z. Geng,[1] T. Boone,*[2] J. Delaney,*[2] D. L. Lacey.[1] [1]Pharmacology/Pathology, Amgen, Inc., Thousand Oaks, CA, USA, [2]Process Science, Amgen, Inc., Thousand Oaks, CA, USA.

PTH increases bone mass when injected daily (SC) but not when infused continuously. We hypothesized that SC delivery of a sustained-duration PTH construct might also be anabolic without the inconvenience of daily injections. We produced a sustained-duration PTH construct (SD-PTH) which has a significantly longer serum half-life in rats compared to PTH-(1-34). Male BDF1 mice (19 weeks old) were injected SC with daily PTH-(1-34) (80 ug/kg) or with twice-weekly SD-PTH (15, 50 or 150 nmol/kg), for 3 weeks (total weekly dose of PTH-(1-34) = 150 nmol/kg; SD-PTH = 30, 100 and 300 nmol/kg). PTH-(1-34) caused significant increases in total and trabecular BMD in the tibia (by pQCT), but not cortical BMD. SD-PTH caused significant and dose-dependent increases in total, trabecular, and cortical BMD in the tibia. The gains in BMD with SD-PTH were significantly greater than those obtained with daily PTH-(1-34). PTH-(1-34) increased trabecular bone volume (BV%TV) in the tibia by a non-significant 74%. SD-PTH caused dose-dependent increases in BV%TV which were significantly greater than those obtained with daily PTH-(1-34). At the highest dose, SD-PTH caused a 290% increase in BV%TV compared to vehicle. PTH-(1-34) caused a significant increase in osteoclast number and a non-significant increase in osteoblast number. SD-PTH caused significantly greater increases in both osteoblast and osteoclast numbers compared to vehicle or daily PTH-(1-34). Daily PTH-(1-34) had no significant effect on serum calcium, alkaline phosphatase (an osteoblast marker), or TRAP (an osteoclast marker). SD-PTH caused significant and dose-dependent increases in each of these parameters. The antiresorptive agent OPG blocked the hypercalcemic response of mice to SD-PTH, indicating that hypercalcemia was largely mediated by osteoclasts. The apparently greater efficacy and potency of SD-PTH compared to PTH-(1-34) could not be explained by increased bioactivity, as SD-PTH was 10-fold less potent than PTH-(1-34) in cAMP assays with murine osteoblasts. In summary, we have demonstrated potent bone anabolic activity for a sustained-duration PTH construct. Twice-weekly administration of SD-PTH caused greater increases in BMD and BV%TV compared to daily PTH-(1-34), suggesting that anabolic activity can be obtained with a sustained-duration PTH construct without the need for daily injections.

F400

Prevention of Early Postmenopausal Bone Loss by Strontium Ranelate: A Randomised, Two-Year, Double-Blind, Placebo-Controlled Trial. J. L. Reginster,*[1] R. Deroisy,*[1] Y. Tsouderos,[2] I. Jupsin,*[1] C. Roux.[3] [1]Bone and Cartilage Metabolism Unit, University of Liège, Liège, Belgium, [2]Institut de Recherches Internationales Servier, Courbevoie, France, [3]Rhumatology, Hôpital Cochin, Paris, France.

Postmenopausal bone loss remains a major public health problem because two-thirds of women do not want to receive, or cannot be treated with, hormone replacement therapy. Strontium ranelate is a novel agent that increases bone formation and appears to uncouple the processes of bone formation and resorption. One hundred and sixty healthy, early postmenopausal women were randomised to receive placebo or strontium ranelate (PROTOS®)125 mg/day, 500 mg/day or 1 g/day for 2 years (40 participants per group). All participants received a calcium supplement of 500 mg daily. The primary efficacy parameter was annual increase in lumbar bone mineral density (BMD), measured using dual-energy X-ray absorptiometry. Secondary efficacy parameters included biochemical markers of bone turnover. At month 24, only strontium ranelate 1 g/day demonstrated a significantly greater increase in adjusted lumbar BMD than placebo (p<0.05). The annual increase was 0.7%, compared with -0.5% with placebo, with an overall beneficial effect after 2 years of about 2.4% in the strontium ranelate 1 g/day group compared with the placebo group. There were no other significant between-group differences in adjusted lumbar BMD. During treatment with strontium ranelate 1 g/day, a trend toward increased levels of bone formation markers was observed, with no effect on markers of bone resorption. Strontium ranelate displayed a tolerability profile similar to that of placebo. The minimum dose at which strontium ranelate is effective in preventing bone loss in early postmenopausal women is 1 g/day. This dose produced significantly greater increases in BMD than placebo, and changes in bone turnover markers were consistent with the exertion of an uncoupling effect on bone turnover. Further studies are now required to assess the efficacy of strontium ranelate in patients with established osteoporosis.

F404

Growth Hormone Increases Bone Mineral Content in Postmenopausal Osteoporosis. K. L. L. Landin--Wilhelmsen, A. Nilsson. Endocrine Division, Dept. of Medicine, Göteborg, Sweden.

Growth hormone (GH) is an important regulator of bone. The aim was to study the effect of GH in osteoporotic, postmenopausal women. Eighty women, 50-70 years, ≥ 5 years after the menopause and ongoing estrogen therapy since ≥ 9 months were randomized to GH (Genotropin®), 1.0 U or 2.5 U/day vs similar amounts of placebo, subcutaneously, double-blind during 18 months. The placebo group then stopped the injections, but both GH groups continued another 18 months, in total 3 years with GH. Calcium 750 mg/day and vitamin D 400 U/day were given to all. Both the placebo group and the 2 GH groups are now followed-up until 4 years, i.e. one year after the GH treatment was terminated, but with continued estrogen and calcium/vitamin D supplementation. The 5-year follow-up will be completed in June 2001. Insulin-like growth factor-1 (IGF-1) and lean body mass increased dose dependently in both GH groups at 3 years (p<0.001) and decreased to pre-treatment levels at 4 years. Lumbar, femoral and areal bone mineral density and bone mineral content (BMC) increased 1-8% in all women, but no differences between the groups were seen after 3 years. Lumbar spine BMC increased 14% on 2.5 U GH and was higher than placebo (p=0.0006) at 4 years. Femur neck BMC increased 13% on 2.5 U GH and was higher than on 1.0 U GH (p=0.01). Total body BMC was higher on 2.5 U GH than on 1.0 U GH (p=0.05) and placebo (p=0.01), respectively. Bone formation in the tetracycline labelled iliac crest bone biopsy increased in the 1.0 U GH group at 3 years, but no differences were seen between the 3 groups. Body weight, height, quality of life, vertebral height on X-ray, handgrip strength and bone markers were unaltered after 3 years. One radius fracture occurred in the 1.0 U GH group. Compliance was good according to the IGF-1 levels, which were blind for the investigator during the double-blind phase. None of the 80 women dropped out. Side effects were rare. In conclusion, BMC increased up to 14% by treatment with 2.5 U GH/day during 3 years and further differentiated from the group treated with 1.0 U GH/day and the placebo group, respectively, at 4-years follow-up, in postmenopausal osteoporosis. There seems to be a delayed, extended and dose dependent effect of GH treatment on bone.

F414

Dermal Application of Lovastatin for 5 days Stimulates Bone Formation in Ovariectomized Rats by 160%. G. Gutierrez,[1] I. R. Garrett,[1] G. Rossini,*[1] A. Escobedo,*[1] D. Horn,*[1] M. Qiao,*[1] J. Esparza,*[1] D. Lalka,*[2] G. R. Mundy.[1] [1]OsteoScreen Inc., San Antonio, TX, USA, [2]West Virginia University, School of Pharmacy, Morgantown, WV, USA.

In recent years, it has been determined that statins, drugs which lower cholesterol by inhibiting HMG-CoA reductase, are also bone anabolic agents, causing substantial increases in bone formation in vitro and in vivo in rodents. Their effects in vitro on bone and when applied locally in vivo are more impressive than when they are administered systemically by oral gavage. Since statins are subject to first-pass metabolism by cytochrome P450 enzymes in the liver, we reasoned that dermal application may produce more sustained blood levels in the peripheral tissues such as bone, and cause more substantial effects on bone than those resulting from oral administration. We determined therefore if topical application of lovastatin to the skin of ovariectomized rats would lead to more sustained circulating blood statin concentrations and increases in bone formation rates. We used this model since it can produce alterations in the cancellous network similar to those seen in the human skeleton during aging and menopause. We measured statins in plasma by HMG-CoA reductase activity. We found that blood statin concentrations following a single dermal dose were higher and maintained longer than following an equivalent oral dose, indicating a greater AUC after dermal application. Rats were ovariectomized and treatment with oral or topical lovastatin was started the day following surgery. In the group treated orally, lovastatin was given daily by gavage for 35 days. In the group treated dermally, the statin was applied topically (upper back after shaving) for 5 days only. Bones were analyzed after 5 weeks for both groups. Sham controls were included in both experiments. Topical lovastatin (1 mg/kg/day) caused 57% increase in trabecular bone after only 5 days of treatment. There was >150% increase in bone formation rate, which persisted for 3 weeks without further treatment in the group treated topically. Oral lovastatin caused lesser but detectable increases in bone formation rates at a)10 times the dose, b)after more prolonged (35 days) treatment. When Lovastatin was given orally only for 5 days, there was no effect. These results suggest that topical application of lovastatin produces greater anabolic effects on bone than oral administration and that alternative modes of administration of the statins, such as topical application through a skin patch, improves biodistribution to bone. They also show that both in vitro and in vivo, intermittent statin treatment is more effective than continuous treatment.

Disclosures: OsteoScreen, Inc.,1,3.

The PPAR-alpha Agonist Wyeth 14643 Increases Bone Mineral Density in Female Rats. U. Syversen,*[1] I. Bakke,*[1] K. W. Slørdal,*[2] H. L. Waldum.*[1] [1]Department of Intra-abdominal Diseases, Norwegian University of Science and Technology, Faculty of Medicine, Trondheim, Norway, [2]Department of Physiology and Bioengineering Techniques, Norwegian University of Science and Technology, Trondheim, Norway.

Peroxisome proliferator-activated receptors (PPARs) are members of the steroid nuclear superfamily of receptors that have been shown to modulate the expression of genes involved in lipid metabolism and fat storage. Recently, the presence of PPARs has also been demonstrated in bone cells and a role in bone metabolism has been postulated.In the present study we have examined the effect of the PPAR alpha agonists Wyeth 14643 and ciprofibrate on bone mineral density (BMD) in female rats. Thirty female Fischer rats were divided into 3 groups and were given methocel (control group), Wyeth 14643 (50 mg/kg body weight) and ciprofibrate (50 mg/kg body weight) for 2 months. BMD in femur and total body in intact animals was measured using a Hologic QDR 4500A. Body weight was registered throughout the study. Blood samples were drawn for measurement of gastrin.There was no difference in body weight between control rats and Wyeth 14643-treated rats, while the body weight was significantly reduced in ciprofibrate treated rats. Serum gastrin levels were significantly increased after 2 months in rats receiving ciprofibrate (x3.3) and Wyeth 14643 (x2), compared to controls. There was a significant increase in total body BMD (0.154 ± 0.007 g/cm^2) in Wyeth 14643 treated rats compared to control rats (0.146 ± 0.004 g/cm^2), $p < 0.05$, while in rats receiving ciprofibrate, total body BMD (0.144 ± 0.004 g/cm^2) was significantly lower than in Wyeth 14643 treated rats. Femur BMD tended to be higher in Wyeth 14643 treated rats (0.263 ± 0.011 g/cm^2) than in control rats (0.251 ± 0.007 g/cm^2), and was significantly higher than in ciprofibrate treated rats (0.225 ± 0.014 g/cm^2), $p < 0.001$.In conclusion, treatment with the PPAR-alpha agonist Wyeth 14643 significantly increased BMD in female rats, while treatment with ciprofibrate resulted in a significantly decrease in BMD.

A Therapeutic RANKL Vaccine Induces Neutralizing Anti-RANKL Antibodies and Prevents Bone Loss in Ovariectomized Mice. M. Hertz,*[1] T. Juji,*[2] S. Tanaka,*[2] S. Mouritsen.*[1] [1]M&E Biotech A/S, Horsholm, Denmark, [2]Department of Orthopaedic Surgery, University of Tokyo, Tokyo, Japan.

Receptor activator of NF-kB ligand (RANKL) and the soluble decoy receptor osteoprotegerin (OPG) are the critical regulators of osteoclast activity. Overexpression of RANKL has been shown to be involved in the pathogenesis of resorptive bone diseases, such as osteoporosis. A therapeutic RANKL vaccine was developed by modifying the soluble TNF-like domain of murine RANKL (amino acids 158-316) to incorporate a promiscuous T helper (Th) epitope. The modified RANKL vaccine was well tolerated and able to bypass immunological tolerance and induce antibodies neutralizing native murine RANKL. Lymphoid organogenesis, lymphocyte development and activation were normal in RANKL-vaccinated mice in contrast to RANKL-deficient mice. Antiserum from vaccinated mice inhibited osteoclastogenesis in vitro. More importantly, the RANKL vaccine protected mice from ovariectomy-induced bone loss. Osteoclast numbers as well as bone resorptive surfaces were significantly reduced in RANKL vaccinated mice. Thus, vaccination against RANKL represents a novel approach for the treatment of osteoporosis, rheumatoid arthritis and other diseases associated with increased osteoclast activity and bone loss.

Novel Src Tyrosine Kinase Inhibitors Prevent Ovariectomy-Induced Bone Loss in a Swiss-Webster Mouse Model of Post-menopausal Osteoporosis. D. VonStechow,[1] J. M. Alexander,[1] S. Fish,*[1] M. Chorev,[1] R. Mueller,[1] M. Rosenblatt,[1] J. Illiucci,[2] Y. Wang,*[2] C. Metcalf,*[2] T. Keenan,*[2] R. Sundaramoorthi,*[2] W. Shakespeare,*[2] M. R. van Schravendijk,*[2] D. Dalgarno,[2] T. Sawyer.[2] [1]BIDMC/Harvard Medical School, Boston, MA, USA, [2]ARIAD Pharmaceuticals, Inc, Cambridge, MA, USA.

In this investigation, several novel Src tyrosine kinase inhibitors were evaluated in vivo to determine their ability to prevent ovariectomy-induced (OVX) bone loss in Swiss-Webster female mice. Three novel compounds (AP23236, AP23286, and AP23310) were assessed (10 and 25 mg/kg sc BID) and alendronate (0.1 and 1 mg/kg sc BID) was used as a positive control in 12-week old OVX Swiss-Webster mice following 4 weeks of treatment initiated immediately after OVX. The endpoints of this study included: 1) physiologic markers demonstrating estrogen-deficiency in this in vivo model system, and 2) bone mineral content and structure determinations by mCT evaluation of mouse femurs. MicroCT demonstrated a greater than 65% loss of metaphyseal trabecular bone volume (Tb BV/TV) in control vehicle-treated animals 4 weeks post-OVX, a value consistent with earlier findings in the Swiss-Webster mouse strain. This loss was associated with marked decreases in trabecular number and connectivity. Alendronate administration completely preserved Tb BV/TV during the 4-week study. AP23236 and AP23286 prevented OVX-induced trabecular bone loss (98% and 85% preservation of trabecular bone volume compared to OVX vehicle-treated control mice). Conversely, AP23310 (a less potent Src tyrosine kinase inhibitor) did not prevent OVX-induced trabecular bone loss (Tb BV/TV values between 19-41% of controls). These data demonstrate that Src tyrosine kinase inhibitors prevent OVX-induced bone loss in a mouse model of post-menopausal osteoporosis.

Short-Term Calcitriol Administration Improves Calcium Homeostasis in Adults with Cystic Fibrosis. S. A. Brown,*[1] D. A. Ontjes,[1] R. M. Aris,*[1] G. E. Lester,[2] R. K. Lark,*[1] M. B. Hensler,*[1] A. D. Blackwood,*[1] M. J. Caminiti.*[1] [1]Depts. of Endocrinology and Pulmonology, University of North Carolina, Chapel Hill, NC, USA, [2]National Institutes of Health, Bethesda, MD, USA.

Decreased bone mineral density (BMD) is a well-defined health risk for individuals with Cystic Fibrosis (CF). Among the many factors that contribute to low BMD, we have focused on the altered calcium homeostasis in individuals with CF. Patients with CF tend to have lower 25 hydroxyvitamin D (25(OH)D) levels and increased parathyroid hormone (PTH) values compared to controls suggesting that inadequate vitamin D due to malabsorption contributes to secondary hyperparathyroidism. We conducted a short-term pilot study to measure the effects of calcitriol (0.5mcg po bid for 14 days) on markers of calcium balance including fractional absorption (FA) of ^{45}Ca, urinary calcium:creatinine ratios, PTH, ionized calcium, 25(OH)D, 1,25 dihydroxyvitamin D ($1,25(OH)_2$ D) and urinary N-telopeptide (NTx) levels. Ten adults with CF (18-40 years old) and 10 healthy controls matched for age, sex and body mass index were studied at baseline and 2 weeks after taking calcitriol. At both visits, variables were measured before and after a high calcium meal containing ^{45}Ca for determination of FA. Calcitriol administration resulted in a significant increase in the FA of ^{45}Ca in both groups ($p<0.01$), although the FA in CF subjects remained below controls both before and after calcitriol. In both groups, the usual suppression of PTH levels in response to a high calcium meal was enhanced after treatment with calcitriol (p=0.003 CF, p=0.04 controls). Both groups also had increases in urinary calcium:creatinine ratios. Fasting urinary NTx levels, a marker for bone resorption, fell by 34% in CF subjects in response to calcitriol (96.0 ± 16.0 vs. 63.9 ± 12.7 SE BCE/mmol Cr, p=0.01) while controls had no significant change. Controls had an increase in $1,25(OH)_2$ D levels (29.1 ± 1.8 vs. 37.8 ± 4.0 pg/ml, p=0.02) following calcitriol; however, there was no statistically significant change in $1,25(OH)_2$ D levels in the CF group (25.9 ± 2.4 vs. 29.4 ± 3.0 pg/ml, p=0.19). There were no significant changes in either group in baseline ionized calcium or 25(OH)D levels. Calcitriol administration in this short-term pilot study appears to improve calcium homeostasis in adults with CF by improving fractional absorption of ^{45}Ca and lowering PTH levels while suppressing bone resorption as reflected by urinary NTx measurements. These data suggest that oral calcitriol may be an effective means of improving BMD. The impact of such treatment on bone accrual is being studied in a 2 year trial in children and young adults with CF.

F436

Oral and IV Bisphosphonate are Efficacious in Children with Osteogenesis Imperfecta. L. A. DiMeglio,[1] L. Ford,*[2] G. Liu,*[2] C. McClintock,*[2] M. Peacock.[2] [1]Pediatric Endocrinology, Indiana University, Indianapolis, IN, USA, [2]Medicine, Indiana University, Indianapolis, IN, USA.

Bone mineral density (BMD) and fracture rates in children with osteogenesis imperfecta (OI) improve with intravenous (IV) bisphosphonates. The efficacy of oral bisphosphonates has not been established. We have instituted an open-label, prospective, randomized clinical trial of oral compared to IV bisphosphonate in children with OI. Children are stratified into groups according to bone age, pubertal stage, and type of OI. They then are randomized to receive either IV pamidronate, 3 mg/kg over 3 days every 4 months or oral alendronate 1 mg/kg, from a minimum of 10 mg to a maximum of 40 mg daily. The primary efficacy outcome is BMD in g/cm2 and in SD units, measured at 4-month intervals. Secondary outcomes include: biomarkers of bone turnover, os calcis ultrasound characteristics, fracture incidence, calcium biochemistry, anthropometric measures, effect on dental anomalies, audiologic evaluations, assessment of quality of life, pain measures, and evaluations of gross motor function.Characteristics of eight randomized children (5 oral/3 IV) and two other children who were assigned to IV treatment due to chronic abdominal pain are presented below. In each group, 3 patients have type III/IV OI, while 2 have type I. The response in BMD in both groups is comparable and beyond what would be expected with normal growth. All children have experienced an increase in BMD on therapy.

	Oral (n=5)	**IV (n=5)**
Average age (range)	6.83 yr (3.8-9.5)	9.47 yr (3.4-13.6)
Ave Rx Time (range)	1.07 yr (0.38-1.40)	0.71 yr (.32-1.36)
Annualized % change L2-L4 BMD (range)	30.8% (7%-54%)	51.2% (31%-90%)**
Absolute change L2-L4 Z-score	=+1.0 SD	+0.3 SD**
Annualized % change Total Body BMD (range)	8.6% (2%-20%)	3.6% (1%-13%)
Absolute change Total Body Z-score	+0.4 SD	+0.4 SD

**n=4

Also, all have a concomitant decrease in bone resorption, measured by urine NTX/Cr ratios, which declined on average approximately 50% from baseline. There was no correlation between change in speed of sound by ultrasound at the os calcis and change in total body BMD (n = 7, r = -0.5, p= 0.5) or L2-L4 BMD (n = 7, r = -0.3, p = 0.5). Radiographs of patients on IV bisphosphonate demonstrated multiple, discrete dense bands under growth plates corresponding to treatment courses, whereas those of children on oral bisphosphonate demonstrated a uniform subepiphyseal band corresponding to the length of therapy. Other than fevers following the initial dose of IV bisphosphonate, no adverse effects of therapy have been noted. These data suggest that both oral and IV bisphosphonate therapy are safe and effective for children with OI.

F438

Camurati-Engelmann Disease: New Mutations in the Latency-Associated Peptide of the Transforming Growth Factor β-1 Gene. S. R. Mumm,[1] S. Obrecht,*[1] M. N. Podgornik,*[2] M. P. Whyte.[2] [1]Division of Bone and Mineral Diseases, Washington University School of Medicine and Barnes-Jewish Hospital Research Institute, St. Louis, MO, USA, [2]Center for Metabolic Bone Disease and Molecular Research, Shriners Hospitals for Children, St. Louis, MO, USA.

Camurati-Engelmann Disease (CED), also called progressive diaphyseal dysplasia, is an autosomal dominant disorder characterized by painful spreading hyperostosis of the diaphyses of major long bones beginning in childhood. Mutations in the latency-associated peptide (LAP)/transforming growth factor β-1 (TGFβ-1) gene have been implicated as the cause of CED in reports of several Japanese and European patients. The LAP and TGFβ-1 are co-expressed from the same gene as a single peptide, which is subsequently cleaved into separate LAP and TGFβ-1 proteins. A dimerized LAP remains noncovalently bound to a dimerized secreted TGFβ-1, presumably keeping the latter inactive. We have sequenced the coding region of the LAP/TGFβ-1 gene in 8 unrelated CED patients (3 sporadic, 5 familial), identifying mutations in all but one sporadic case diagnosed elsewhere. In 4 of these probands, previously reported mutations were documented in exon 1 (9 bp insertion causing a 3 Leu insertion in a poly-Leu region) and in exon 4 (Arg218His, Arg218Cys). In the remaining 3 cases, new mutations were identified. The novel mutations included a dinucleotide change in exon 4 (Cys223Ser) at a critical residue involved in disulfide bonding and tertiary structure of the LAP; a previously reported single nucleotide mutation results in the same amino acid change (Cys223Ser). The second was a C to T transition in exon 2 (C463T) causing an arginine to cysteine change (Arg156Cys); one may speculate that this newly created Cys residue could also interfere with disulfide bonding and tertiary structure. The two new mutations were not detected in 168 LAP/TGFβ-1 alleles from unaffected individuals, demonstrating the changes are mutations and not polymorphisms. Hence, all 7 of the mutations identified to date causing CED are located in the LAP; none are found within TGFβ-1. This finding suggests the underlying defect in CED is control, at the protein level, of an intact TGFβ-1.

F440

Lifelong Hypopituitarism and Growth Hormone Deficiency Decreases Bone Size but not Volumetric Density yet Increases Prevalence of Fractures. R. Bouillon,[1] K. Koledova,*[2] O. Bezlepkina,*[3] E. Chernikhova,*[4] E. Nagajeva,*[3] A. Bakulin,*[4] J. Nijs,*[5] V. Peterkova,*[3] I. Dedov,*[3] O. Oganov,*[4] A. Attanasio.*[6] [1]Endocrinology, Catholic University of Leuven, Leuven, Belgium, [2]Eli Lilly, Moscow, Russian Federation, [3]Endocrinological Research Center, Moscow, Russian Federation, [4]Space Phisiology Department, Moscow, Russian Federation, [5]Universitary Hospital, Leuven, Belgium, [6]Eli Lilly, Torino, Italy.

Growth hormone (GH) has major effects on bone modelling. Accordingly, lifelong growth hormone deficiency (GHD) will affect bone development and is therefore a good model to study the relationship between BMC, BMD and fracture risk. We studied 66 adults, all with idiopathic hypopituitarism of childhood onset: 18 isolated GHD and 48 GHD with multiple pituitary hormone deficiencies, MPHD. Replacement therapy with missing hormones had not been continuous in all subjects and hGH treatment had (virtually) never been given. As control group Hologic DEXA measurements obtained in more than 700 normal Russians (age 10-92) were used.Patients with isolated GHD (age 24 ± 10 years, height SDS -3.73 ± 1.5) had BMC values for lumbar spine, femoral neck or total body regions which were 54, 71 and 59% of that of age and sex matched controls (all p <. 001). Patients with GHD and MPHD had either open growth plates (GP) (n=28, age 25 ± 8 years; height SDS -4.00 ± 1.4) or closed growth plates (n=20;age 55 ± 12 years; height SDS-5.05 ± 1.4) and similarly decreased BMC at all sites (between 42 and 69 of expected values). The decrease in BMC in all regions was substantially greater in all subgroups than expected from their height differences (being 84, 83, 80% of matched Russian controls).The areal BMD Z-score for all DEXA measurements varied between -2 Z (isolated GHD) and -3 Z (MPHD + open GP) and -1.8 Z (MPHD + closed GP). The calculated volumetric bone density (BMAD) of adult patients with isolated GHD or MPHD + closed GP (Z-score of about +0.3) was however perfectly normal and only slightly decreased (-0.8 Z) in MPHD + open GP.The non-traumatic fracture prevalence was 7% (isolated GHD), 41% (MPHD open GP) and 75% (MPHD and closed GP), which is significantly increased when compared to Russian as well as Caucasian control populations.In conclusion: isolated as well as MPHD GHD of childhood onset very substantially affect adult height and BMC if poorly treated. While areal BMD is frankly decreased, volumetric bone density is unaffected. The recorded fracture incidence is, however, markedly increased indicating that bone size and shape rather than volumetric density determines bone strength.

F442

Blocking Macrophage Inflammatory Protein-1-Alpha in Myeloma Cells Decreases Bone Destruction and Tumor Burden by Decreasing Their Homing Capacity and Growth In Vivo. S. J. Choi, Y. Oba, J. L. Anderson,* G. D. Roodman. Medicine/Hematology, UTHSCSA/VAMC, San Antonio, TX, USA.

We reported that macrophage inflammatory protein-1-alpha (MIP-1-alpha) may be responsible for the bone destruction in multiple myeloma (MM). When the human MM-derived ARH-77 cell line was stably transfected with an antisense construct to MIP-1-alpha (AS-ARH) or an empty vector (EV-ARH) and transplanted into SCID mice, the levels of human IgG that indicate tumor burden in these mice were dramatically decreased in AS-ARH mice compared to EV-ARH mice (0.1-10 ug/ml vs. 80-120 ug/ml). AS-ARH mice lived longer than EV-ARH mice, and had no radiologically identifiable lytic lesions. In contrast, EV-ARH mice had extensive bone disease. Histomorphometric analysis demonstrated that the number of osteoclasts per mm2 bone area and per mm bone surface for AS-ARH mice was significantly less than EV-ARH mice (248 +/- 27.6 vs. 416 +/- 43.1; $p < 0.01$ and 4.4 +/- 0.8 vs. 7.2 +/- 0.8; $p < 0.05$). The percent tumor per total bone area was also significantly decreased in AS-ARH mice compared to EV-ARH mice. To determine if the decreased tumor burden and bone destruction in AS-ARH mice was due to decreased homing, engraftment or survival of the AS-ARH cells, mice were sacrificed at 3-day intervals after transplantation and mRNA expression levels of human specific GAPDH (hsGAPDH) were measured. hsGAPDH levels in AS-ARH mice were decreased by day 3 compared to EV-ARH mice, but were detectable, and decreased further by days 9 and 15. Since MIP-1-alpha enhances expression of adhesion molecules on cells, we then assessed if the decreased homing and survival of AS-ARH cells in AS-ARH mice may result from decreased adherence to marrow stromal cells. Adherence of AS-ARH cells to ST2 stromal cells was significantly decreased compared to EV-ARH cells. The adherence of myeloma cells to stromal cells is in part mediated by alpha4beta1 integrin expressed on myeloma cells. Interestingly, mRNA expression levels of human alpha4 integrin were similar in AS-ARH and EV-ARH cells, regardless of treatment with an anti-MIP-1-alpha neutralizing antibody or rhMIP-1-alpha. In contrast, mRNA expression levels of human beta1 integrin were upregulated by rhMIP-1-alpha in AS-ARH cells and downregulated by an anti-MIP-1-alpha neutralizing antibody in EV-ARH cells. Thus, blocking MIP-1-alpha activity has profound effects on MM cell growth, homing and bone destruction in this in vivo model of MM. These data suggest that the antagonists that block MIP-1-alpha activity in vivo may be useful agents for treatment of MM patients to decrease both their tumor burden and bone destruction.

F444

RANK (Receptor Activator of NF-KB) and RANK Ligand Expression in Multiple Myeloma. S. Roux,[1] V. Meignin,*[2] J. Quillard,*[3] A. Guiochon-Mantel,*[4] E. Milgrom,*[4] X. Mariette.*[1] [1]Rheumatology and Inserm U135, Bicêtre Hospital, Le Kremlin Bicêtre, France, [2]Pathology, Saint-Louis Hospital, Paris, France, [3]Pathology, Bicêtre Hospital, Le Kremlin Bicêtre, France, [4]Inserm U135, Bicêtre Hospital, Le Kremlin Bicêtre, France.

Recent discovery of new members of the TNF receptor-ligand family have pointed out the crucial role of RANKL and its receptor RANK in the osteoclast differentiation and activation. We wondered wether an increased expression of RANKL and RANK may be involved in the excessive bone resorption observed in myeloma. Our objective was to evaluate RANK and RANKL expression in human multiple myeloma by immunohistochemistry performed on bone marrow biopsies. To standardize the immunostaining we used Cos7 cells transiently transfected with a vector expressing human RANK or RANKL cDNA. Bone marrow biopsies (BM) were obtained at diagnosis in 15 patients with myeloma and 5 with monoclonal gammopathy of undetermined significance (MGUS), in addition to 10 normal BM. Plasma cells were not labeled with anti- RANKL nor anti-RANK antibodies in any biopsy specimens. In all biopsies, RANKL was expressed in endosteal bone surface, around vessels and predominantly in cells characterized by cytoplasmic expansions. These latter cells did not express CD45, a marker of the hematopoietic lineage, and were vimentine positive, corresponding therefore to bone marrow stromal cells. We found a greater expression of RANKL in myeloma specimens compared to MGUS and normal BM. In 5 myeloma specimens, characterized by a major plasma cell infiltration, the staining with anti-RANKL antibody was more pronounced in tumoral rather than non tumoral areas, leading sometimes to a reticular staining. With the anti-RANK antibody, a strong staining was observed as expected close to bone in osteoclasts. In addition, small mononuclear cells in the bone microenvironment were positive. These cells did not express CD3 nor CD20 antigens, were distributed in clusters, and had the typical morphologic aspect of erythroblast cells. There was no difference in the pattern of RANK expression in myeloma, MGUS and normal BM. In conclusion, we showed that malignant plasma cells did not express RANKL nor RANK. RANKL was expressed in dendritic stromal cells, with a greater intensity in myeloma specimens. These results suggest that RANKL may be overexpressed by bone marrow stromal cells in myeloma and therefore may participate to the high rate of bone resorption. Conversely, we did not find any changes of RANK expression in this disease.

F446

Shouldn't Ischemic Necrosis of Femoral Head Be Called Ischemic Necrosis and Apoptosis of Femoral Head? H. K. W. Kim,* D. J. Popp,* D. D. Hunter.* Shriner's Hospital for Children, Tampa, FL, USA.

Ischemic necrosis of the femoral head is one of the most serious complications that can arise following an injury or treatment of the pediatric hip. Although the hallmark of ischemic necrosis is cell death that occurs in the marrow and the trabecular bone of the femoral head, the mechanism of cell death following ischemic injury has not been investigated. It is assumed that cells in the femoral head die by necrosis. The purpose of this investigation was to determine whether apoptosis is one of the mechanisms of cell death that occurs in the femoral head following the induction of ischemic necrosis. Fourteen male piglets were used. A suture ligature was placed tightly around the right femoral neck to disrupt the blood supply to the femoral head. The animals were sacrificed 2, 6, 7, 10, 14, 21, and 28 days after disrupting the blood supply to the femoral head. Femoral heads were removed and divided into two halves. One half was fixed, decalcificed, embedded, and sectioned for TUNEL and caspase-3 immunostaining. The other half was used to isolate genomic DNA from the femoral head bone. To assay for the presence of nucleosomal ladders generated during apoptosis, the Ligation Mediated-PCR (LM-PCR) ladder assay kit was used. Since LM-PCR produces semiquantitative results, the femoral head samples were first subjected to 15 to 25 cycles of LM-PCR to determine which number of PCR cycles would be optimal for analysis.The operated femoral head samples clearly contained more nucleosomal ladders than the non-operated femoral head samples and the difference was most evident at 19 cycles. When all the DNA samples were analyzed after performing 19 cycles of LM-PCR, a dominant presence of nucleosomal ladders in the operated femoral head samples were clearly evident in the piglets sacrificed 6, 7, 10 and 14 days following the induction of ischemic injury. In contrast, the non-operated femoral head samples either failed to amplify nucleosomal ladders at all or they were significantly underrepresented as compared to the operated samples. The results of the femoral head samples from 2, 21, and

28 days were very different. The DNA samples failed to amplify nucleosomal ladders in both the operated and the non-operated femoral head samples. Increased TUNEL and caspase-3 staining were observed in the sections from the operated side compared to non-operated side. In conclusion, our results clearly demonstrate that cell necrosis is not the sole mechanism of cell death following ischemic necrosis of the femoral head. Both apoptosis and necrosis are involved. Our results open up the possibility of therapeutically modulating the apoptotic process to improve the clinical outcome following ischemic necrosis of femoral head.

F447

Novel Mutations in the Vitamin D 1α-hydroxylase Gene in Patients with 1α-hydroxylase Deficiency Confer Partial Enzymatic Activity in vitro. X. Wang, M. Y. H. Zhang,* W. L. Miller,* A. A. Portale. Pediatrics, University of California, San Francisco, San Francisco, CA, USA.

The rate-limiting, hormonally regulated step in the biological activation of vitamin D is its 1α-hydroxylation to 1,25(OH)$_2$D in the kidney, catalyzed by the mitochondrial P450 enzyme, P450c1α. We previously cloned human P450c1α (Mol Endocrinol 11:1961, 1997) and identified 14 different mutations, including 7 mis-sense, in 19 patients with 1α-hydroxylase deficiency (Am J Hum Genet 63:1694,1998), also known as vitamin D-dependent rickets type 1. None of the mis-sense mutations encoded a protein with significant enzyme activity in vitro. Affected patients show phenotypic variation, although the molecular basis is unknown. We analyzed 6 additional patients with clinical and radiographic features of rickets; in 4 patients the laboratory abnormalities were typical of 1α-hydroxylase deficiency, but in 2 they were unusually mild (mild hypocalcemia, normal serum 1,25(OH)$_2$D). Direct sequencing revealed that all patients had P450c1α mutations on both alleles. Five new and 2 known mutations were identified. The new mutations included a 5bp deletion with 6bp novel insertion causing a frameshift in exon 2, and a G to A change at +1 of intron 2 which prevented proper splicing; both led to premature stop codons. The 3 new mis-sense mutations identified were tested by expressing the mutant cDNA in mouse Leydig MA-10 cells. Enzyme activity of mutants R389G, L343F and E189G was 0%, 2.5% and 36%, respectively, compared to that of the wild-type control. The L343F and E189G mutations that confer partial enzyme activity in vitro, were found in the 2 patients with mild laboratory abnormalities, thus suggesting that such mutations contribute to the phenotypic variation observed in affected patients.

F449

Characterization of PHEX Catalytic Activity, Regulation and Role in Bone Matrix Mineralization and Phosphate Homeostasis. G. Boileau,[1] I. Lemire,*[2] N. Zhao,*[2] H. S. Tenenhouse,[3] L. DesGroseillers,*[1] P. Crine.*[2] [1]Biochemistry, University of Montreal, Montreal, PQ, Canada, [2]BioMep Inc., Montreal, PQ, Canada, [3]Pediatrics and Human Genetics, McGill University-Montreal Children's Hospital Research Institute, Montreal, PQ, Canada.

Mutations in the PHEX gene (Phosphate-regulating gene with homologies to Endopeptidases on the X chromosome) are responsible for X-linked hypophosphatemia and studies in the Hyp mouse model of the human disease implicate the gene product in the regulation of renal phosphate (Pi) reabsorption and bone mineralization. Although the mechanism for PHEX action is unknown, structural homologies with members of the M13 family of endopeptidases suggest a function for PHEX protein in the activation or degradation of peptide factors involved in the control of renal Pi transport and bone matrix mineralization. To understand the function of PHEX, we used site-directed mutagenesis of the transmembrane domain to generate a recombinant secreted and soluble form of human PHEX (secPHEX) by transfection of mammalian cells. We showed that purified secPHEX has peptidase activity by incubating the enzyme with several peptide substrates, including a variety of bone-related peptides, and analyzing the digest by HPLC. We found that PTHrP107-139 is a substrate for secPHEX. Mass spectrometry of the digestion products revealed that the enzyme cleaves at three positions within the peptide, all located at the amino terminus of aspartate residues. Furthermore, we showed that osteocalcin inorganic pyrophosphate and Pi, all of which are abundant in bone, are inhibitors of secPHEX activity. Inhibition of secPHEX activity by osteocalcin was abolished in the presence of mM Ca2+ with an IC50 of 2.5 nM. Moreover, the use of recombinant osteocalcin produced in E. coli showed that gamma-carboxylation of specific glutamate residues are important for osteocalcin inhibitory activity. The physiological role of PHEX was studied by daily intravenous injections to Hyp mice over a period of 4 days. Injection in Hyp animals resulted in further lowering of serum phosphate and decrease in alkaline phosphatase activity. We suggest that PHEX is involved in the control of the mineralization process and that its activity may be controlled in vivo by pyrophosphate/Pi and Ca2+.Ca 2+ regulation requires the participation of osteocalcin.

ADHR-Associated FGF 23 Mutation Interferes With Protein Processing and PHEX Cleavage. R. B. Finnegan,*[1] A. E. Bowe,*[1] R. Kumar,[2] S. M. Jan de Beur,[3] S. C. Schiavi.*[1] [1]Applied Genomics, Genzyme, Framingham, MA, USA, [2]Nephrology, Mayo Clinic, Rochester, MN, USA, [3]Endocrinology, The Johns Hopkins University School of Medicine, Baltimore, MD, USA.

Experimental and clinical data derived from three distinct diseases, oncogenic osteomalacia (OOM), X-linked hypophosphatemia (XLH), and autosomal dominant hypophosphatemic rickets (ADHR), provide evidence for the existence of a novel hormone termed "phosphatonin" that regulates phosphate homeostasis through a parathyroid hormone-independent mechanism. XLH results from mutation in a membrane bound endopeptidase, PHEX, whereas ADHR is associated with activating mutations of the FGF 23 gene that encodes a novel member of the fibroblast growth factor family. Recent data suggest that tumors from OOM patients synthesize significant levels of FGF 23, providing evidence that over-expression of FGF 23 may be involved in the pathogenesis of OOM. To evaluate a possible relationship between FGF 23 and PHEX, we tested the hypothesis that FGF 23 is a PHEX substrate. Accordingly, wild type FGF23 and an ADHR mutant form, FGF 23, R179Q, were cloned into a mammalian expression vectors containing a carboxy-terminal V5 epitope tag. Two V5-immunoreactive bands of approximately 35- and 15-kDa were detected in medium collected from COS cells expressing wild-type FGF 23 whereas only a 35-kDa immunoreactive band was detected in medium collected from COS cells expressing FGF23 (R179Q). These results are consistent with differential processing of the wild-type and mutant forms of FGF 23. The R179Q mutation occurs within a consensus furin site, but we were unable to demonstrate cleavage of FGF23 by purified furin. To test whether FGF23 is a phex substrate, PHEX, wild-type FGF 23, FGF 23 (R179Q) and several additional genes previously found to be over-expressed in OOM tumors were independently expressed in an in vitro rabbit reticulocyte lysate system. In vitro synthesized proteins were incubated with PHEX containing- or control lysates and the relative amounts of V5 tagged proteins were monitored by immunoblot analysis blot using anti-V5 antibody. After incubation with PHEX, there was a significant reduction in the wild type FGF 23 signal, but no change in signal of the other potential PHEX substrates, including mutant FGF 23. These results suggest that FGF 23 is a PHEX substrate and that the ADHR R176Q mutation reduces susceptibility of FGF 23 to PHEX proteolysis.

F451

Frizzled Related Protein 4 Expression Is Elevated in Tumors Associated With Oncogenic Osteomalacia and Inhibits Phosphate Transport in Vitro. J. Vassiliadis,*[1] S. M. Jan de Beur,[2] A. E. Bowe,*[1] R. B. Finnegan,*[1] M. A. Levine,[3] R. Kumar,[4] S. C. Schiavi.*[1] [1]Applied Genomics, Genzyme, Framingham, MA, USA, [2]Endocrinology, The Johns Hopkins University School of Medicine, Baltimore, MD, USA, [3]Pediatric Endocrinology, The Johns Hopkins University School of Medicine, Baltimore, MD, USA, [4]Nephrology, Mayo Clinic, Rochester, MN, USA.

Oncogenic osteomalacia (OOM) is a paraneoplastic syndrome characterized by hypophosphatemia, reduced renal tubular phosphate reabsorption, low to normal calcitriol concentrations, normal calcium, normal parathyroid hormone levels and defects in bone mineralization. Several lines of evidence suggest that oncogenic osteomalacia is due to secretion by the tumor(s) of one or more factor(s) termed phosphatonin that inhibit phosphate re-absorption and the formation of calcitriol. Using Serial Analysis of Gene Expression (SAGE), we previously identified 16 genes from OOM tumors that are consistently induced or over-expressed compared to profiles from histologically matched tumors from patients that do not have OOM. To determine whether any of these genes encoded a protein that inhibited phosphate transport, consistently over-expressed genes were isolated and transiently expressed in COS cells. Conditioned medium from cells transfected with secreted Frizzled Related Protein 4 (FRP-4) inhibited uptake of radiolabeled phosphate by opossum kidney (OK) cells and human osteoblast-like SaOS cells by approximately 30 to 80%. The addition of 10 ng/ml sodium heparin had no effect on phosphate uptake. Partially purified carboxy-terminal histidine tagged FRP-4 also inhibited phosphate uptake in OK cells. To assess whether FRP-4 protein possesses additional characteristics of phosphatonin, we evaluated it as a substrate for the endopeptidase, PHEX. Defective PHEX is responsible for X-linked hypophosphatemic rickets, an inherited form of renal phosphate wasting. V5-his-tagged FRP-4 was expressed in an in vitro transcription/translation system in the presence or absence of PHEX and assessed by immunoblot with an anti-V5 antibody. The signal intensity of immunoreactive FRP-4 was reduced when co-expressed with PHEX. By contrast, PHEX treatment of several additional candidate genes had no effect on the integrity of these proteins, suggesting that the apparent degradation of FRP-4 by PHEX is specific. Taken together these results suggest that FRP-4 over-expression contributes to the pathogenesis of OOM and may be important in phosphate homeostasis.

F452

Internalization Pathway of Renal Phosphate Transporter Mediated Chloride Channel. M. Iida,* K. Morita,* H. Yamamoto, Y. Taketani, E. Takeda. Clinical Nutrition, University of Tokushima School of Medicine, Tokushima, Japan.

Physiological/pathophysiological alterations in proximal tubular phosphate (Pi) reabsorption are associated with an altered brush-border membrane (BBM) expression of type IIa Na+/Pi co-transporter molecules (NPT2). We have studied that inhibition of proximal tubular Pi reabsorption by Parathyroid hormone (PTH) or calcitonin (CT) is achieved by an internalization of NPT2 from the BBM. In addition, our previous studies indicated that both PTH and CT induced NPT2 internalization through either protein kinase A and C. Although protein kinases are activated upon the binding of PTH or CT to its receptor, the target for activated kinases relevant for the internalization of NPT2 has not yet been identified. Recently, several investigators have identified chloride channel (ClC-5) activated by PTH in the proximal tubule. In addition, loss of function mutation of ClC-5 affected the internalization of the apical transporter NPT2. Therefore, in the present study we investigated the role of ClC-5 in the NPT2 endocytotic pathway. When PTH or CT was injected into TPTX rats, both hormones increased ClC-5 mRNA levels and decreased the amount of NPT2 protein. In the proximal tubule, ClC-5 protein is located in early endosomes co-localizing with rab5. Therefore, we next analyzed interaction of NPT2 protein with rab5. Rat renal BBM extracts were immunoprecipitated with NPT2 antibody and then immunoblotted with rab5 antibody. We found that NPT2 interacts with rab5 response to PTH or CT. In addition, mammalian two-hybrid experiments showed that the C-terminus 73 amino acid residues of NPT2 are necessary for the interaction with rab5. Our results suggest that both PTH and CT regulate ClC-5 expression for the efficient acidification of endosome vesicles for the degradation of NPT2 and that rab5 represent early endosomes is essential for the interaction of NPT2.

F456

Paget's Disease of Bone: Linkage to a Novel Region on Human Chromosome 18q23. D. Good,*[1] F. Busfield,*[1] B. Fletcher,*[1] D. Duffy,*[2] J. Kesting,*[1] J. Shaw.*[1] [1]Dept of Diabetes and Endocrinology, Princess Alexandra Hospital, Brisbane, QLD, Australia, [2]Queensland Institute of Medical Research, Brisbane, QLD, Australia.

Paget's disease of bone (PDB) is a common metabolic bone disorder characterised by localised areas of increased osteoclast activity and abnormal bone remodelling. Bone pain, deformity, pathological fracture, and an increased incidence of osteosarcoma are associated with PDB. A significant genetic component contributes to the etiology of the disease. Previous studies have demonstrated linkage between PDB and the HLA region on chromosome 6q21.3 (PDB1), and with chromosome 18q21.2-21.3 (PDB2) in some pedigrees. Mutations in TNFRSF11A on 18q21.2-21.3 have been identified segregating in two PDB pedigrees but evidence of genetic heterogeneity exists with other pedigrees showing negative linkage to PDB1 and PDB2 and absence of mutations in TNFRSF11A. We have ascertained a large multigenerational pedigree in which multiple family members are affected by PDB. The disease is inherited as an autosomal dominant trait in the pedigree with high penetrance by the sixth decade. Linkage analysis has excluded the PDB1 and PDB2 regions in this family, whilst sequencing has excluded mutations in TNFRSF11A. We proceeded to a genome-wide microsatellite scan, with 61 individuals typed for 474 markers in a 10cM scan. Initial linkage analysis of the data by FASTLINK v4.1 indicated evidence suggestive for linkage to chromosome 7p and chromosome 18q. Fine mapping, followed by further two point linkage analysis was performed in regions of interest on chromosomes 7p and 18q, including 88 subjects of whom 30 were affected. Peak LOD scores obtained were LOD = +2.75 at D7S507 and LOD +1.76 at D18S70. Multipoint analysis of markers flanking D7S507 did not support linkage to this region of chromosome 7 and haplotype analysis provided further evidence excluding linkage to this region. Haplotype analysis of markers flanking the region of interest on chromosome 18 showed a consistent haplotype associated with PDB in a large subfamily within the pedigree. This subfamily consists of 40 genotyped subjects of whom 13 are affected. The age at diagnosis is significantly lower in this sub-family than in the rest of the pedigree (51.2 + 8.5 vs 64.2 + 9.7 years, p=0.0012). Multipoint linkage analysis of this subfamily gave a peak LOD score of 3.23 at marker D18S1390 (theta = 0). This marker is located approximately 20 Mb telomeric of TNFRSF11A (draft genome browser v4, UCSC). Our data suggest that this locus on chromosome 18 contains a gene important in the development of Paget's disease of bone in our family, and we are continuing with fine mapping, haplotype analysis and candidate gene sequencing in this region.

F458

Expansile Skeletal Hyperphosphatasia is Caused by a 15-Base Pair Tandem Duplication in *TNFRSF11A* Encoding RANK and is Allelic to Familial Expansile Osteolysis. M. P. Whyte,[1] A. E. Hughes.[2] [1]Center for Metabolic Bone Disease and Molecular Research, Shriners Hospitals for Children, St. Louis, MO, USA, [2]Department of Medical Genetics, The Queen's University of Belfast, Belfast, United Kingdom.

Expansile skeletal hyperphosphatasia (ESH) is a familial metabolic bone disease characterized in 2000 in a mother and daughter featuring early-onset deafness, premature loss of teeth, progressive hyperostotic widening of long bones causing painful phalanges in the hands, accelerated bone remodeling, and episodic hypercalcemia likely inherited as a highly penetrant, autosomal dominant trait (JBMR 15: 2330-2344, 2000). Absence of large osteolytic lesions with cortical thinning in major long bones and the episodic hypercalcemia indicated that ESH is not a variant of *familial expansile osteolysis* (FEO). FEO is a rare autosomal dominant skeletal disorder characterized by early-onset hearing loss due to degeneration of middle ear ossicles, destruction of teeth, and painful focal bony expansion with cortical thinning from osteolytic lesions within major long bones. The histopathologic findings of the active osteolysis in FEO resemble the changes of *Paget disease of bone*. Here, we investigated the molecular basis of ESH after three families with FEO were reported to have an identical 18-base pair tandem duplication (84dup18) in the signal peptide sequence of the TNFRSF11A gene that encodes receptor activator of nuclear factor-κB (RANK) (Nat Genet 24: 45-48, 2000). We find that ESH is caused by a remarkably similar 15-base pair tandem duplication (84dup15) in *TNFRSF11A.* Sequencing of *TNFRSF11A* in both affected members of the ESH family revealed heterozygosity for this insertion mutation within exon 1. Cloning confirmed the presence of 84dup15. The in-frame insertion is predicted to elongate the signal peptide of RANK by five non-polar amino acids (LLCAL). This duplication overlaps with the reported duplications of six amino acids found in three FEO families and of nine amino acids found in a single family with PDB. The mutation was not identified in DNA from 70 patients with sporadic PDB or a similar number of controls. Hence, ESH and FEO are allelic diseases and ESH, like FEO, probably reflects increased activity in the skeleton of the RANK target, nuclear factor-κB (NF-κB).

F464

A Double Blind Randomized Placebo Controlled Trial of Alendronate in Primary Hyperparathyroidism. A. A. Khan,*[1] J. P. Bilezikian,[2] A. W. C. Kung,*[3] M. M. Ahmed,*[1] S. J. Dubois,*[1] A. Y. Y. Ho,*[3] Z. Motagally,*[1] M. Rubin,*[2] S. J. Silverberg,[2] T. I. M. Standish,*[1] Z. A. Syed.*[1] [1]McMaster University, Hamilton, ON, Canada, [2]Columbia University College of Physicians & Surgeons, New York, NY, USA, [3]The University of Hong Kong, Hong Kong, China.

This study was conducted to determine if alendronate maintains or improves bone mineral density in patients with primary hyperparathyroidism (PHPT). A randomized double blind controlled trial of placebo versus alendronate (10 mg daily) was conducted. Patients with PHPT were eligible if they did not meet surgical guidelines. Patients were randomized to placebo or active treatment arms and stratified for gender. Patients were assessed at baseline, 3, 6, 9 and 12 months. The primary outcome index, bone mineral density (BMD) in the lumbar spine (LS), femoral neck, total hip and distal one-third radius, was measured at baseline, 6 and 12 months with DEXA. Secondary indices of bone metabolism (calcium, phosphate, PTH (IRMA), bone spec. alk phos. urinary calcium, urineNTX, BHCG) were obtained at each visit. The data are provided for 34 patients who have completed 12 months of the protocol. A total of 44 patients are currently involved in the study. Two-tailed independent t-tests were conducted to compare treatment vs. control group 12 month minus baseline mean differences for the following: total hip, lumbar spine, and distal 1/3 radius BMDs; total calcium, ionized calcium, and phosphorus levels. The mean treatment group lumbar spine BMD increased by 5.3 % (0.03 grams/cm2, 95% CI: 3.6,7.0) from baseline, and total hip increased by 3.7 % (0.02 grams/cm2, 95% CI: 2.0,5.4). Radial BMD showed no statistically significant change (-0.002 grams/cm2, 95% CI: -2.2,0.8) . The mean control group BMD showed no statistically significant change at LS, total hip or radial sites.Change of +0.5 % (0.01 grams/cm2, 95% CI: -1.2,2.1) at lumbar spine, -1 % (-0.004 grams/cm2, 95% CI: -2.6,1.2) at total hip, and -1 % (-0.008 grams/cm2, 95% CI: -2.6,0.4) at distal radius.Mean differences were significantly greater for the treatment group BMD lumbar spine (t = 3.5, P=0.01) and BMD total hip (t = 3.37, P<0.01) when compared with the control group. BMD distal radius mean differences were not significant (t = 0.59, P=0.56) nor were total calcium (t = 0.07, P = 0.95), ionized calcium (t = 0.42, P = 0.67), or phosphorus levels (t = -1.97, P = 0.06). This is the first randomized placebo-controlled trial evaluating the effect of Alendronate on BMD in men and women with PHPT. Alendronate is effective in this population in significantly increasing BMD at the lumbar spine and total hip after only 12 months of therapy.

Somatic Mutation of Mitochondrial DNA in Parathyroid Adenomas. T. Tokura, A. Arnold. Center for Molecular Medicine, University of Connecticut School of Medicine, Farmington, CT, USA.

Much remains to be learned about the molecular pathogenesis of nonfamilial parathyroid adenomas, in addition to the already established roles of the cyclin D1/PRAD1 oncogene and the MEN1 tumor suppressor gene. The mitochondrial genome is an attractive target for mutations that could drive tumorigenesis, especially in a low-replication tissue like the parathyroid, because mitochondrial DNA replicates frequently and independently of the nuclear genome, and also has heightened potential to accumulate damage throughout life due to locally generated mutagenic reactive oxygen species. Furthermore, homoplasmic and clonal mutations of the mitochondrial genome have recently been reported in several human tumors and cell lines. Therefore, we rigorously sought possible acquired mitochondrial DNA mutations by amplifying and completely sequencing the entire 16.6 kb mitochondrial genome of each of ten sporadic parathyroid adenomas plus corresponding normal peripheral blood leukocyte control DNA from the same patients. Resulting sequences were analyzed and compared with the standard Anderson public mitochondrial DNA sequence and with the online Mitomap database of previously published mitochondrial DNA mutations and polymorphisms. A total of 128 homoplasmic sequence variants were detected in the parathyroid adenomas, most of which were previously reported or new polymorphisms found simultaneously in non-tumor control DNA, as predicted from the high level of variability in mitochondrial DNA in human populations. Notably, 8 tumor-specific homoplasmic mutations, 6 being novel, were identified in mitochondrial DNA from three parathyroid adenomas (30%). One mutation altered a noncoding transcriptional binding site, while the other 7 mutations were clustered within the coding regions for subunits ofthe NADH dehydrogenase complex, supporting their functional significance. Five of the 8 mutations were base transitions consistent with damage by reactive oxygen species, and most mutations affected residues that are highly conserved across multiple species. One mutation was a frameshift predicted to prematurely truncate one of the NADH dehydrogenase subunits, again suggesting its functional relevance. Two somatic mutations were silent, had been previously described as constitutional polymorphisms, and were more likely to have arisen through a random drift to homoplasmy. In summary, we detected clonal homoplasmic mutations of mitochondrial DNA in 30% of parathyroid adenomas. Several features of the mutations, including their nonrandom clustering, suggest they may confer a selective advantage and may contribute to the development of parathyroid adenomas.

Turnover and Rescue of Mutant PHEX Proteins Sequestered in the Endoplasmic Reticulum. Y. Sabbagh,*[1] G. Boileau,*[2] L. DesGroseillers,*[2] H. S. Tenenhouse.[3] [1]Biology, McGill University, Montreal, PQ, Canada, [2]Biochemistry, Université de Montréal, Montreal, PQ, Canada, [3]Biology, Pediatrics and Human Genetics, McGill University, Montreal, PQ, Canada.

Mutations in the *PHEX* gene are responsible for X-linked hypophosphatemia (XLH), the most prevalent form of inherited rickets in humans. The *PHEX* gene, which is predominantly expressed in bone and teeth, encodes a protein with high homology to the M13 family of zinc metallopeptidases. Of the 141 *PHEX* mutations that have been identified in XLH patients (http://data.mch.mcgill.ca/phexdb), missense mutations account for 24%. We undertook to examine the effects of three missense mutations, C85R, G579R, and S711R, on synthesis, glycosylation and cellular trafficking of the recombinant proteins. The mutant PHEX cDNAs were generated by PCR mutagenesis and expressed in HEK(293) cells. In contrast to wild-type (WT) PHEX protein, the three mutant proteins were sensitive to endoglycosidase digestion with endoH, indicating that they are not terminally glycosylated. Immunofluorescence of nonpermeabilized and permeabilized cells expressing WT and mutant PHEX proteins demonstrated that the WT protein is localized to the plasma membrane whereas all three mutant proteins are sequestered in the endoplasmic reticulum (ER). Co-immunoprecipitation studies showed that the ER sequestered mutant proteins interact with calnexin whereas only the core glycosylated form of the WT protein is associated with the molecular chaperone. Pulse-chase studies, conducted by labeling transfected cells with ^{35}S-met followed by a cold chase, demonstrated that all three mutant proteins are degraded in the ER, with half-lives of ~95 min for the C85R and G579R mutant proteins and ~55 min for the S711R mutant. Maturation of WT PHEX pro-

tein to a fully glycosylated species was evident after a 60 min chase. To determine whether the mutant PHEX proteins could be rescued from the ER to the plasma membrane, transfected cells were grown either in the presence of the chemical chaperone glycerol or at 26^{o}C. Only the S711R mutant protein achieved partial endo H resistance and cell surface expression in cells grown at the lower temperature. Our study represents the first characterization of WT and mutant PHEX protein expression, glycosylation and cellular targeting and provides a mechanism for loss of PHEX function in XLH patients expressing the C85R, G579R, and S711R mutations.

High 1,25-(OH)2D Levels in Patients with Active Crohn's Disease are Caused by Local Overexpression of 1-alpha Hydroxylase in Macrophages. V. Kantorovich,[1] E. Vasiliauskas,*[1] U. Gruntmanis,*[1] K. Papadakis,*[1] D. Zehnder,[2] M. Abreu,*[1] S. R. Targan,*[1] M. Hewison,[2] J. S. Adams.[1] [1]Burns and Allen Research Institute, UCLA/Cedars-Sinai Medical Center, Los Angeles, CA, USA, [2]Medical Sciences, University of Birmingham, Birmingham, United Kingdom.

Patients with Crohn's disease (CD) have a high incidence of low bone mass for age. We have previously shown that a significant proportion of patients with active CD has increased levels of 1,25-dihydroxyvitamin D (1,25-D; Kantorovich et al. J Bone Miner Res. 2000;15:S498). Here we expand our initial observations to 98 adult patients with active CD. 48% (n=47) of patients with active CD possessed elevated levels of serum 1,25-D (mean [±SE] 76.5±3.8), while in another 30% (n=29) of patients 1,25-D levels resided inappropriately in the upper third of the normal range (51.2±0.8). When compared to the group of CD patients with normal 1,25-D levels (n=22), CD patients with increased 1,25-D had significantly lower age- and sex-adjusted bone density at the lumbar spine (p=0.03) and hip (p=0.02), despite similar CD treatment protocols. Among CD patients 1,25-D levels correlated with the disease activity (Harvey-Bradshaw score, p=0.02). The mean Ca/Creat excretion ratio in CD patients was significantly elevated (p<0.02) compared to an age-matched normal control population without CD (n=59). We theorized that the increased circulating levels of 1,25-D resulted from extrarenal overproduction of the hormone by macrophages in the submucosa of CD-involved gut. Preliminary results indicate that primary cultures of affected gut inflammatory cells convert [3H]25-OHD3 to [3H]1,25-(OH)2D3 with a specific activity 11-fold greater than that of 1,25-(OH)2D3-producing HD-11 monocyte/macrophage cells. In addition, we compared 25-OHD-1alpha-hydroxylase immunostaining in the gut of normal subjects and patients with CD. Compared to normal, colon from patients with quiescent CD exhibited moderate staining of submucosal macrophages while colon from patients with active CD displayed intense staining of macrophages with 1-hydroxylase greatest in giant cells found in the center of submucosal granulomas. Based on these in vivo and in vitro studies, we conclude that: 1] active CD is associated with overexpression of 1 alpha-hydroxylase in intestinal macrophages and 2] increased local production of 1,25-D can "spill" over into the systemic circulation resulting in relative hypercalciuria and accelerated bone loss.

F476

Osteoprotegerin (OPG) and RANKL Expression in Tissues Near Bone in Diseases of Pathological Bone Loss: A Comparison of Rheumatoid Arthritis, Prosthetic Joint Failure and Periodontal Disease. T. N. Crotti,[1] M. D. Smith,*[2] H. Weedon,*[2] M. Capone,*[1] C. Holding,*[1] D. M. Findlay,[3] D. R. Haynes.*[1] [1]Pathology, University of Adelaide, Adelaide, Australia, [2]Rheumatology, Repatriation General Hospital, Adelaide, Australia, [3]Orthopaedics and Trauma, University of Adelaide, Adelaide, Australia.

Osteoprotegerin (OPG) inhibits bone resorption by blocking RANKL, the key regulator of osteoclast differentiation. There is increasing evidence that the relative levels of OPG and RANKL are important in determining osteolysis in disease. The aim of this study was to compare the expression of OPG and RANKL in tissues surrounding bone erosion from patients with rheumatoid arthritis, prosthetic joint loosening and periodontal disease and determine the cell lineage expressing the mediators in these tissues. We also compared patients with active and inactive RA.Immunohistologic analysis of frozen tissue sections was performed using monoclonal antibodies to detect OPG and RANKL expression. Synovial tissue samples were obtained from 30 patients with rheumatoid arthritis. 21 of these patients were classified as having active synovitis. Tissue from 10 patients undergoing revision and 6 patients with periodontal disease was also assessed. Control groups consisted of synovial tissue samples taken from patients with spondyloarthropathy (12), osteoarthritis (10) and normal individuals (14). Dual immunohistochemical evaluation was performed with lineage specific antibodies (macrophages [CD68], fibroblasts [CD55], lymphocytes [CD45Ro] and endothelial cells [Factor 8]) and RANKL or OPG, using commercial antibodies, to determine the cell lineage associated with the proteins. Sections were evaluated by computer-assisted image analysis and semi-quantitative analysis.RANKL was strongly expressed in tissues from the rheumatoid, prosthetic joint failure and periodontal disease patients. RANKL was associated with lymphoid aggregates in periodontal and rheumatoid tissues but appeared to be associated with macrophage and fibroblastic cells in peri-prosthetic tissue. Two different patterns of OPG expression were seen, one exclusively by endothelial cells in all tissues and one predominantly by macrophages in the synovial lining cells of the rheumatoid tissues. OPG was remarkably absent in tissues from patients with active rheumatoid arthritis.The findings support the contention that RANKL and OPG regulate bone lysis in these pathologies. In particular, the deficiency in OPG expression in the inflamed synovium of active RA patients may indicate that OPG expression regulates the joint destruction seen in this pathology.

F482

Analysis of Gene Expression by DNA Microarray Reveals Novel Clues to the Mechanism of the Catabolic and Anabolic Actions of PTH in Bone. J. E. Onyia,[1] L. Gelbert,*[1] M. Zhang,[2] K. Bemis,*[1] A. Maran,[2] X. Lin,*[1] S. Chandrasekhar,[1] C. Frolik,[1] M. Sato,[1] H. Bryant,[1] R. T. Turner.[2] [1]Eli Lilly & Company, Indianapolis, IN, USA, [2]Mayo Clinic, Rochester, MN, USA.

Parathyroid hormone (PTH) has complex effects on bone depending on the mode of administration. PTH given intermittently increases bone mass by stimulating osteoblast differentiation to increase bone formation, while continuously infused PTH decreases bone mass by stimulating a net increase in bone resorption. The molecular events that mediate these markedly different biological responses in bone are unknown. The present investigation was designed to delineate the genes and pathways that are regulated by intermittent and continuous PTH using DNA microarrays. rhPTH (1-34) was administered intermittently (once daily sc injection (8ug/100 g)) or continuously (sc infusion of 4 ug/100 g by osmotic mini pump) to 6 month-old female rats for 1 week to stimulate bone formation and resorption, respectively. Total RNA, isolated from femoral metaphyseal bone, was labeled by in vitro transcription and hybridized to an Affymetrix microarray containing 8500 rat genes. Gene expression analysis (P<0.05) demonstrated that 316 genes (3.6%) were regulated by intermittent PTH. In contrast, 917 genes (10.4%), a 3-fold greater number of genes, were regulated with continuous PTH. Of these regulated genes, 158 were unique to intermittent and 759 were unique to continuous PTH, while the remaining 158 genes were common to both treatments. The regulated genes included 55-60% known genes and 35-40% ESTs. Classification of the genes into pathways and functional hierarchy identified similarities and novel potential differences in pathways affected by the specific PTH treatment. Continuous PTH affected 3-4 fold more pathways and functional platforms than intermittent PTH. The pathway most represented in genes unique to continuous PTH was "protein cleavage and degradation" and included components of the ubiquitin-proteosome degradation complex, metalloproteases and their inhibitors, serine, threonine, aspartic, cysteine, and amino proteases. Based on functional classification, genes unique to continuous PTH encoded many 7 transmembrane/G protein-coupled receptors, and integral membrane proteins. Genes common to both intermittent and continuous PTH include many integral membrane proteins and extracellular matrix proteins. These results demonstrate that the bone anabolic and catabolic effects of PTH regulate both common and unique subsets of genes and pathways. We speculate that the common subset of genes leads to the similarities in the pathways while the unique subsets of genes account for the differences in the anabolic and catabolic effects of PTH.

The High Bone Mass Phenotype of Gcm2-Deficient Mice Is Caused by Hypocalcemia Not by PTH Deregulation. M. Priemel,[1] T. Günther,[2] J. M. Rueger,[1] G. Karsenty,[2] M. Amling.[1] [1]Trauma Surgery, Hamburg University, Hamburg, Germany, [2]Department of Human and Molecular Genetics, Baylor College, Houston, TX, USA.

Glial cells missing2 (Gcm2) is a cell specific transcriptional factor required for parathyroid gland development in mouse and humans. Gcm2-deficient mice lack parathyroid glands, exhibit a biologic hypoparathyroidism, but have a normal PTH serum concentration and a normal lifespan due to an auxiliary thymic source of parathyroid hormone (PTH). As a result of their chronic biologic hypoparathyroidism the Gcm2-deficient mice develop a low turnover high bone mass phenotype, that worsens over time. Here we compared the efficiency of 1,25-dihydroxyvitamin D3 (1,25-(OH)2 D3) and PTH to rescue this phenotype. Long term treatment with 1,25-(OH)2D3 normalizes serum calcium concentration and reduces serum PTH levels significantly. After 1,25-(OH)2D3 treatment urinary crosslink excretion was significantly decreased indicating that 1,25-(OH)2D3 significantly reduced osteoclast activity in Gcm2-deficient mice and histomorphometry confirmed that osteoclast number was also decreased. Thus, 1,25-(OH)2D3 treatment of Gcm2-deficient mice leads to an amplification of their low turnover state. In contrast, treatment with PTH lead to an increase in urinary crosslink excretion to normal levels, indicating an activation of osteoclast activity, and histomorphometric analysis of static and dynamic parameters confirmed that total bone turnover was activated. Regardless of the differences in mechanism of action between the two hormones, treatment with 1,25-(OH)2D3 or infusion of PTH resulted in a normal skeleton as assessed by histological and biomechanical analysis. Thus, normalization of calcium ion homeostasis overcomes the effects of hypoparathyroidism on bone mass irrespective of the mean used to control serum calcium concentration. Our results indicate that low serum calcium concentration alone causes the high bone mass phenotype of the Gcm2-deficient mice.

Roles of PTH/PTHrP Receptor Generated-Signals in RANKL-Induced Osteoclastogenesis. H. Kondo, J. Guo, U. Chung, H. M. Kronenberg, F. R. Bringhurst. Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Parathyroid hormone (PTH) is a major regulator of osteoclast formation and activation. In several systems, PTH-dependent osteoclastogenesis is accompanied by reciprocal up- and down-regulation of receptor activator of NFkB ligand (RANKL) and osteoprotegerin (OPG), respectively. The roles of specific downstream signals generated by the activated PTH/PTHrP receptor (PTH1R) - i.e., cAMP/PKA and PLC/PKC- in controlling osteoclastogenesis remain uncertain. To address this, we studied PTH regulation of RANKL, OPG, and M-CSF mRNA expression in, and support of osteoclast formation by, an established conditionally transformed clonal murine marrow stromal cell line (MS1). In the presence of dexamethasone, MS1 cells supported osteoclast (TRAP(+)MNC) formation from spleen-cell progenitors in response to PTH(1-34) or 1,25$(OH)_2D_3$. PTH-dependent cAMP generation in MS1 cells was approximately 1-, 10-, 80-, and 70-fold controls when assessed at 1, 3, 7 and 10 days, respectively, following transfer to nontransforming culture conditions. By Northern blot analysis, RANKL mRNA expression was stimulated (whereas OPG mRNA was suppressed) by 7 days of continuous hPTH(1-34) or by 6-24

hours of pulse treatment on day 7. PKA stimulators (8Br-cAMP or forskolin) exerted similar reciprocal up- and down- regulation of RANKL and OPG expression. These effects of PTH were blocked by the PKA inhibitor Rp-CAMPS but not by the PKC inhibitor GF109203X. [G^{1},R^{19}]hPTH(1-28), a PKA-selective PTH analog, exerted effects similar to PTH(1-34) on RANKL and OPG mRNAs and on TRAP(+)MNC formation, with a lowered potency predicted by cAMP responses measured in MS1 cells. Like PTH, forskolin and 8Br-cAMP induced TRAP(+)MNC formation in spleen-cell/MS1 co-cultures, whereas the direct PKC stimulator PMA did not induce MS1-cell RANKL mRNA, up-regulated OPG mRNA and antagonized osteoclast formation induced by 8Br-cAMP. Neither PTH(5-34) nor PTH(7-34) regulated MS1-cell RANKL or OPG expression. These results in spleen-cell/MS1 co-cultures were confirmed using primary bone marrow cell cultures. Finally, we generated PLC-defective PTH1R knock-in mice expressing only a mutant PTH1R(DSEL), that cannot activate PLC but normally stimulates adenylate cyclase. In bone marrow cultured from homozygous DSEL mice, hPTH(1-34) induced more TRAP(+)MNCs than in marrow cultured from normal littermates. Moreover, the tibial marrow space was enlarged in 8-week old DSEL mutant mice. These results strongly suggest that (a) cAMP/PKA signaling via the PTH1R controls RANKL-induced osteoclastogenesis and (b) PLC/PKC signaling may negatively regulate PTH/PKA-dependent osteoclastogenesis.

F490

Phospholipase C Signaling via the PTH/PTHrP Receptor Is Required for Normal Hypertrophic Differentiation During Endochondral Bone Formation. J. Guo, U. Chung, F. R. Bringhurst, H. M. Kronenberg. Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Mice lacking the PTH/PTHrP receptor (PTH1R) show accelerated chondrocyte differentiation, whereas constitutive activation of this receptor delays chondrocyte differentiation. To determine if phospholipase C (PLC) signaling via the PTH1R regulates chondrocyte differentiation, we created mice expressing a mutant form (DSEL) of the PTH1R that activates adenylyl cyclase but not PLC. Mice expressing only DSEL PTH1R show both delayed chondrocyte differentiation and an accumulation of columnar proliferating chondrocytes in the endochondral growth plate. Two hours after administration of BrdU in vivo at E16.5 or E18.5, the labeling index of cells in the proliferating chondrocyte layer of DSEL mutant embryos was increased by more than 50%, vs. wild type littermates. To assess the rate of cellular transition from the proliferating to the hypertrophic stage, we measured the delayed appearance of previously-labeled cells in the zone of (nonproliferative) hypertrophic chondrocytes. When BrdU labeling was analyzed 24-48 hours after in vivo BrdU administration to E16.5 or E18.5d animals, the labeling index in the mutant hypertrophic zone was decreased by approximately 40% (vs. wild type). Collectively, these observations indicate that PTH1R PLC/PKC signaling slows proliferation and hastens progression toward hypertrophic differentiation in proliferating columnar chondrocytes. Defects in both processes could contribute to the expansion of the proliferating columnar cell layer observed in DSEL mutant mice.To more directly examine the role of the PTH1R PLC/PKC pathway in chondrocyte proliferation and differentiation, we performed organ culture of intact metatarsal and tibia rudiments from E15.5 embryos. In 3-day cultures, 100 nM PTH(1-34) dramatically slowed chondrocyte hypertrophy in both mutant and wild type metatarsals, as shown by decreased or absent expression of collagen X, osteopontin and alkaline phosphatase mRNAs. PTH also increased proliferation comparably in explants of both genotypes, as shown by BrdU labeling in vitro. Treatment with active phorbol ester greatly enhanced generation of cells expressing collagen X mRNA. These results indicate that PLC/PKC activation via PTH1Rs is important for the normal rate of transition from a proliferative to a post-proliferative, more terminally differentiated phenotype in growth plate chondrocytes. Further, these PTH1R-inducd PLC/PKC actions are opposite to those of PTH1R-dependent PKA activation, the loss of which dominates the endochondral phenotype of PTH1R-null animals.

F492

Parathyroid Hormone Receptor Recycling: Regulation by Specific Structural Features of the Receptor. S. Chauvin,*[1] J. Vilardaga,*[2] M. Bencsik,*[1] T. Bambino,*[1] R. A. Nissenson.[1] [1]Endocrine Unit, VAMC, San Francisco, CA, USA, [2]Pharmacology and Toxicology, Wuerzburg, Germany.

Agonist binding to the parathyroid hormone receptor (PTHR) results in signaling that is terminated by desensitization and internalization of the receptor. Internalization of the receptor is thought to result either in routing of the receptor to lysosomes for degradation or resensitization and recycling of the receptor back to the plasma membrane. The present study was designed to investigate the role of specific structural features of the PTHR on receptor recycling. Confocal microscopy of recombinant PTHRs in HEK293 cells revealed that the wt PTHR was rapidly internalized into endocytic vesicles following treatment with PTH (t1/2= 3-5 minutes). Following removal of PTH, receptors recycled back to the plasma membrane with much slower kinetics (t1/2= 2-4 hours). Truncation of all but 16 amino acids of the cytoplasmic tail of the receptor resulted in a slowing of the rate of PTHR endocytosis, and resulted in marked impairment of receptor recycling. Analysis of a series of truncation mutants demonstrated that the region of the cytoplasmic tail required for efficient receptor recycling differs from that previously shown to be important for receptor endocytosis, with the recycling domain localized more distally in the cytoplasmic tail. For some G protein-coupled receptors, phosphorylation is required for efficient receptor recycling. However, a mutated PTHR lacking all of the sites of PTH-stimulated phosphorylation was recycled with kinetics similar to that of the wt PTHR. Activation of the PTHR induced rapid translocation of ß-arrestin2-GFP to the plasma membrane. After longer treatment with PTH (up to 1 hour), the PTHR and ß-arrestin2-GFP co-localized in endocytic vesicles. After removal of PTH, the PTHR recycled whereas arrestin became cytoplasmic. Biochemical studies demonstrated that the PTHR became dephosphorylated during the recycling process, with kinetics similar to those observed for receptor recycling to the plasma membrane. These studies indicate that: 1) withdrawal of PTH results in slow recycling of the PTHR to the plasma membrane; 2) determinants of efficient PTHR recycling are present in the cytoplasmic tail, and are distinct from the known endocytic motif; 3) neither phosphorylation nor persistent arrestin binding is required for PTHR recycling. In addition, the results suggest that dephosphorylation of the PTHR during recycling may facilitate functional resensitization of the receptor.

F494

Deletion of DNA Binding Domain of the Vitamin D Receptor Abrogates Genomic and Nongenomic Functions of Vitamin D, and Induces an Atypical Chronic Myeloid Leukemia-Like Disease in Aged Mice. R. G. Erben,[1] D. W. Soegiarto,*[2] K. Weber,*[1] U. Zeitz,*[1] M. Lieberherr,[3] R. Gniadecki,*[4] G. Möller,*[5] L. Quintanilla-Martinez,*[6] J. Adamski,*[5] R. Balling.*[2] [1]Institute of Animal Physiology, University of Munich, Munich, Germany, [2]Institute of Mammalian Genetics, GSF National Research Center for Environment and Health, Neuherberg, Germany, [3]INRA, Jouy-en-Josas, France, [4]Department of Dermatology, Bispebjerg Hospital, Copenhagen, Denmark, [5]Institute of Experimental Genetics, GSF National Research Center for Environment and Health, Neuherberg, Germany, [6]Institute of Pathology, GSF National Research Center for Environment and Health, Neuherberg, Germany.

The vitamin D hormone 1,25-dihydroxyvitamin D3 [1,25(OH)2D3], the biologically active form of vitamin D, is not only essential for mineral metabolism but may have important functions beyond calcium homeostasis. Using gene targeting, we sought to generate vitamin D receptor (VDR) null mutant mice carrying the reporter gene lacZ driven by the endogenous VDR promoter. Here we show that our gene-targeted mutant mice express a VDR with an intact hormone binding domain but lacking the first zinc finger necessary for DNA binding. Homozygous mice are a phenocopy of mice totally lacking the VDR protein, and showed growth retardation, rickets, secondary hyperparathyroidism, and alopecia. Responses to vitamin D metabolites in skin, bone, intestine, parathyroid glands, and kidney were absent in homozygous mice, indicating that the mutant receptor is non-functioning and that vitamin D signaling pathways other than that mediated through the classical nuclear receptor are of minor physiological importance. Furthermore, rapid, nongenomic responses to 1,25(OH)2D3 in osteoblasts were abrogated in homozygous mice, identifying the nuclear VDR as the receptor mediating nongenomic actions of 1,25(OH)2D3. Beyond the age of 6 months, homozygous mutant mice showed an age-dependent increase in the incidence of an atypical chronic myeloid leukemia-like disease characterized by splenomegaly, granulocytosis, thrombocytosis, and myelodysplasia with displacement of erythropoiesis in bone marrow. These findings uncover that the VDR is crucial for the long-term control of myeloid cell proliferation and differentiation in vivo. Thus, 1,25(OH)2D3 may be an important inhibitory factor in the onset and progression of myeloproliferative and myelodysplastic diseases.

F496

Molecular Analysis of Helix-1 and Helix-3 in the Human Vitamin D Receptor Reveals Functional Subdomains Mediating Hormone Binding, Protein Stabilization, Heterodimerization and Interaction with Coactivators. P. W. Jurutka, T. L. Lamb,* C. E. Dominguez,* G. K. Whitfield, J. C. Hsieh, P. D. Thompson, M. A. Galligan,* C. A. Haussler,* M. R. Haussler. Department of Biochemistry & Molecular Biophysics, College of Medicine, University of Arizona, Tucson, AZ, USA.

The biologic effects of 1,25-dihydroxyvitamin D_3 ($1,25(OH)_2D_3$) are mediated by the nuclear vitamin D receptor (VDR) which acts as a ligand-dependent transcription factor. The published crystal structure of the human (h)VDR ligand binding domain (LBD) (Rochel, et al., Mol Cell 5:173, 2000) reveals the positioning of helix-1 (H1) along one axis of the LBD with several charged amino acids exposed to solvent. In contrast, helix-3 (H3) in hVDR lies on the opposite side of the LBD and is slightly recessed within the ligand pocket in close proximity to helix-12/AF-2 (H12). Using the crystal structure as a guide, several H1 and H3 residues were selected for alteration via site-directed mutagenesis. The mutant VDRs were evaluated for transcriptional potency in transfected COS-7 and osteoblast-like ROS 2/3 cells, utilizing reporter constructs containing either the natural rat osteocalcin promoter or a synthetic vitamin D responsive element. H3 hVDR mutants (D232K, S235K, I238D, and I242D) all displayed significantly reduced transcriptional activity similar to that observed previously with hVDR H12 mutants. Because H12 and H3 form a molecular cleft for interaction with p160 coactivators in nuclear receptors, loss of activity in the hVDR H3 mutants likely results from impaired association of VDR with these coactivator proteins. Most mutations in H1 elicited more modest, yet significant attenuations in transcriptional activation. Specifically, δ123-130 and δ131-141 hVDR were reduced by 80% and 95% in transactivation, respectively, while E126K, E127K/Q128L, D137R and H139A displayed a 30-50% decrease in activity. Further analysis of mutants containing E126K or D137R alterations revealed an impaired ability to heterodimerize with RXR. In contrast, the E127K/Q128L mutant was rapidly degraded in COS-7 cells. We postulate that these latter two residues, which are required for corepressor interactions in other nuclear receptors, are essential for corepressor-mediated receptor stabilization of unliganded hVDR. Finally, H139A displayed a $1,25(OH)_2D_3$ dose-dependent rescue of the mutant phenotype, implicating H139, whose side-chain penetrates the LBD cavity, as pivotal in $1,25(OH)_2D_3$ binding/retention. Thus, distinct helical domains located on opposite faces of the hVDR LBD perform functionally discrete roles, which involve both hormone binding and interaction of VDR with accessory proteins that contribute to receptor activity.

F497

A Novel Mechanism of the Vitamin D Dependent Transcriptional Repression Through the Human 25-Hydroxyvitamin D3 1a-Hydroxylase nVDRE. A. Murayama, M. Kim,* K. Unno, K. Takeyama,* S. Kato. The Institute of Molecular and Cellular Biosciences, The University of Tokyo/ CREST, Tokyo, Japan.

25-Hydroxyvitamin D3 1a-hydroxylase (1a-hydroxylase) in kidney primarily hydroxylates 25(OH)D3 into 1a,25(OH)2D3, one of hormonal forms of vitamin D. Thus, it hence acts as a key enzyme in vitamin D biosynthesis. We have demonstrated that the negative regulation of renal 1a-hydroxylase by 1a,25(OH)2D3 and the positive regulations by PTH and calcitonin occur at transcriptional levels in intact animals and cultured cells. Subsequently, we identified a region responsible for negative regulation by 1a,25(OH)2D3 (1a-nVDRE) in the human 1a-hydroxylase 5'-flanking region. This ligand-dependent repression in transcription requires VDR/RXR. However, VDR/RXR heterodimer exhibits no direct DNA binding to 1a-nVDRE. In last ASBMR annual meeting, we reported identification of a transcriptional factor(VDIR), which binds directly to the 1a-nVDRE. The present study aimes to clarify the relationship between VDIR and VDR for the transcriptional repression by 1a,25(OH)2D3. In the absense of 1a,25(OH)2D3, VDIR activated transcription to 1a-nVDRE. The transactivation function of VDIR was further enhanced by PKA, which mimicked PTH action. In the presense of PKA, VDIR recruited a co-activator, p300/ CBP. On the contrary, in the presense of 1a,25(OH)2D3, VDR/RXR heterodimer exhibited a 'protein-protein' interaction with VDIR, and recruited co-repressors, HDAC2/Sin3A to repress the transcriptional activity. These results suggested that VDIR may be a key molecule related for both positive and negative regulations of 1a-hydroxylase gene expression. Moreover, this mechanism of the vitamin D-dependent transcriptional repression for 1a-hydroxylase may be different from the known repression mechanisms for PTH or PTHrP by 1a,25(OH)2D3.

F499

The Vitamin D Receptor Is not Required for the Rapid Activation of PKC and Rise in Intracellular Calcium Induced by 1,25-Dihydroxyvitamin D3 in Mouse Osteoblasts. R. Wali,*[1] J. Kong,*[1] M. B. Demay,[2] T. A. Brasitus,*[1] M. Bissonnette,*[1] Y. C. Li.[1] [1]The University of Chicago, Chicago, IL, USA, [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA.

The rapid non-genomic actions of 1,25-dihydroxyvitamin D_3 [$1,25(OH)_2D_3$] have been well described. The role of the nuclear vitamin D receptor (VDR) in these effects is, however, unknown. We have previously shown that $1,25(OH)_2D_3$ rapidly stimulates polyphosphoinositide hydrolysis, raises the concentration of intracellular Ca^{2+} ($[Ca^{2+}]_i$) and activates protein kinase C (PKC) in rat colonic epithelial cells. To directly determine the role of the VDR in the rapid activation of PKC and the increase in $[Ca^{2+}]_i$ induced by this secosteroid, we studied these responses in primary osteoblasts isolated from VDR null (-/-) and VDR wildtype (+/+) mice. The osteoblast cultures were established from calvaria of 3 day-old mice and cells were then treated with $1,25(OH)_2D_3$ or vehicle (ethanol). After plating on coverslips, cells were loaded with Fura-2 AM for 30 min and then treated with $1,25(OH)_2D_3$ or ethanol. The $[Ca]_i^{2+}$ was calculated from the ratio of the measured fluorescence intensity at 340 and 380 nm. The PKC kinase activity was determined by measuring the phosphorylation of a PKC substrate peptide in the presence of [g^{32}P] ATP. Within 1-3 min of $1,25(OH)_2D_3$ (100 nM) treatment, $[Ca]_i^{2+}$ was increased from 61±25 nM to 119±45 nM in VDR (+/+) cells, and from 49±15 nM to 102±41 nM in VDR (-/-) cells. By 5 min, $1,25(OH)_2D_3$ (100 nM) caused a 2.6- and 2.4-fold increase in PKC enzyme activity in VDR (+/+) and VDR (-/-) osteoblasts, respectively. Gö-6976, an inhibitor of Ca^{2+}-dependent PKC isoforms, significantly reduced PKC enzyme activity in both cell types. By quantitative Western blotting, $1,25(OH)_2D_3$ treatment was found to cause translocations of similar magnitude for PKC-α and -δ, but not PKC-ζ, from the cytosol to the membrane in both VDR (+/+) and VDR (-/-) cells. These experiments demonstrate conclusively in mouse osteoblasts that the $1,25(OH)_2D_3$-induced rapid increase in PKC activity and the rise in intracellular calcium are neither mediated by, nor dependent upon, a functional nuclear VDR.

F501

Estrogen Exerts Both Estrogen Receptor α/β Dependent and Independent Effects. M. K. Lindberg,*[1] N. Andersson,*[1] M. Erlandsson,*[2] S. H. Windahl,*[3] G. Andersson,[3] D. B. Lubahn,*[4] H. Carlsten,*[2] J. Å. Gustafsson,*[5] C. Ohlsson.[1] [1]Dept. of Internal Medicine/Endocrinology, Sahlgrenska University Hospital, Gothenburg, Sweden, [2]Dept. of Internal Medicine/Rheumatology, Sahlgrenska University Hospital, Gothenburg, Sweden, [3]Dept. of Biosciences, Karolinska Institute, NOVUM, Huddinge, Sweden, [4]Dept. of Biochemistry and Child Health, University of Missouri-Columbia, Columbia, MO, USA, [5]Dept. of Medical Nutrition, Karolinska Institute, NOVUM, Huddinge, Sweden.

Estrogen exerts a variety of important physiological effects, which have been suggested to be mediated via the two known estrogen receptors (ERs), ERα and ERβ. Three months old ovariectomized (ovx) mice, lacking either ERα (ERKO), ERβ (BERKO) or both receptors (DERKO), were given estrogen subcutaneously (2.3 mg/mouse/day for three weeks) and the effects on different estrogen responsive parameters, including skeletal effects, were studied. The amount of trabecular bone, as measured by peripheral Quantitative Computerized Tomography (pQCT) at the distal femur metaphysis, was increased in WT (204% over control) and BERKO (168% over control) while no effect was seen in ERKO and DERKO mice, demonstrating that the effect on trabecular bone was ERα-mediated. Similar results were seen using histomorphometry. Furthermore, some other well known effects of estrogen, including thymic involution, fat reduction and increased uterine weight, were also found to be ERα-mediated. Interestingly, estrogen increased the cortical bone parameters (cortical BMC, cortical area and cortical thickness in the diaphysis of femur) in all genotypes. This effect on cortical bone is the first in vivo demonstration of an ERα/β independent effect. One may speculate that estrogen exert its effect on cortical bone via an unknown ER (ERγ) or via the androgen receptor. In conclusion, the effects of estrogen on trabecular bone in ovx mice are mediated via ERα, while the effects on cortical bone are ERα/β independent.

F503

The Trabecular BMD Is Preserved both by an Activation of Estrogen Receptor α and by an Activation of the Androgen Receptor in Male Mice. S. E. Movérare,*[1] M. K. Lindberg,*[1] S. Skrtic,*[1] J. Å. Gustafsson,*[2] C. Ohlsson.[1] [1]Dept. of Internal Medicine/Endocrinology, Sahlgrenska University Hospital, Gothenburg, Sweden, [2]Dept. of Medicial Nuitrition, Karolinska Institute, NOVUM, Huddinge, Sweden.

Androgens may regulate the male skeleton either directly via a stimulation of the androgen receptor (AR) or indirectly via aromatisation of androgens into estrogens and, thereafter, via stimulation of estrogen receptors (ERs). There are two known estrogen receptors, ERα and ERβ. The first aim was to investigate the effect of orchidectomy (orx) in mice lacking one or both of the two estrogen receptors. The second aim was to study the effect of estrogen treatment in these orx mice. Seven months old male mice, lacking ERα (ERKO), ERβ (BERKO) or both receptors (DERKO), where orchidectomized and treated for three weeks with 0.7mg/mouse/day of 17β-estradiol or vehicle. Before orx, the length of femur and serum IGF-1 levels were decreased in ERKO and DERKO but not in BERKO mice. Estrogen treatment of orx mice did not affect the length of femur or serum IGF-1 levels in any genotype. Before orx the trabecular BMD of tibia, measured using peripheral quantitative computerized tomography (pQCT) technique, did not differ between WT, ERKO, BERKO and DERKO mice, demonstrating that neither ERα nor ERβ are required for the maintenance of a normal trabecular BMD in male mice with intact testis. Following orx, there was a similar decrease in trabecular BMD, resulting in equal levels of trabecular BMD in all groups. This reduction was completely reversed after estrogen treatment in WT and BERKO mice, while no effect was found in ERKO and DERKO mice. Thus, our results demonstrate that the trabecular BMD is preserved by an activation of ERα but not ERβ. Furthermore, our data indicate that activation of the AR also results in a preserved trabecular BMD in male mice.

Osteoclast Activity in Human Osteoclasts Is Decreased by Estradiol and Raloxifene in Vitro. D. Saintier,* M. Burde,* M. C. de Vernejoul, M. E. Cohen Solal. INSERM U349, Paris, France.

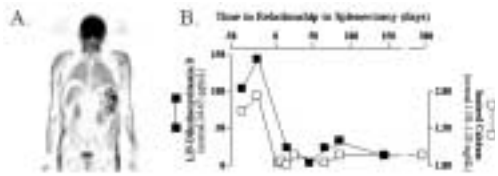
Estrogen defiency is responsible for bone loss in postmenopausal women. The increased bone resorption observed may be reversed by hormone replacement therapy as Estrogen and Raloxifene. The mechanisms of action of both steroids and the target genes regulated by estradiol have been studied in mice both in vivo and in vitro. However, data are rare for humans and might be different from the results obtained in rodents. We therefore studied the effect of estradiol and Raloxifene on bone resorption using a human osteoclast differentiation model in vitro. Peripheral blood mononuclear cells (PBMC) were obtained from healthy volunteers. Adherent PBMC were cultured in phenol red-free medium and 10% FCS and in the presence of RANK-L (30 ng/ml) and MCS-F (25 ng/ml). Cells were treated with vehicule (Controls C), 10^{-8}M estradiol (E2) or 10^{-8}M Raloxifene (Rlx) for 18 days. Cultures were performed in duplicate to evaluate the number of TRAP+ and vitronectine receptors+ multinucleated cells and onto dentine bone slices for pit formation. The pit area was significantly decreased in E2-treated cultures (2.4±1.4%) and in Rlx-treated cultures (1.88±1.1%) compared to controls (4.9±2.1%), (all $p<0.05$). However, there were no statistical difference in the number of TRAP+ multinucleated cells treated with E2 (41.2±20.1/mm^2) and Rlx (46.6±16.4) compared to controls (59.3±21.7). At the end of the culture, we observed no expression of estrogen receptors β, whereas estrogen receptors α was expressed in all cultures without any effect of E2 or Rlx. Expression of cathepsine K, TNF-α, c-jun, c-fos and β3 integrin were studied using nested RT-PCR. Cathepsin K expression was not regulated by E2 or Rlx (125±26% and 117.5±37% of controls), as well as TNF-α RNA expression. At day 18, the expression of c-jun mRNA was decreased to 42±15 % and 43±17 % by E2 and Rlx respectively compared to controls ($p<0.05$), in contrast to c-fos expression which remained unchanged (101±24 % and 76±15 % of controls respectively). We observed also that estradiol and Raloxifene decreased the mRNA expression of β3 integrin (60±17 % and 41±24% of controls, $p<0.05$) in parallel with vitronectine receptors + cell number which was decreased in E2 and Rlx-treated cells (38.7±12.2 and 37.9±8.9 /mm^2) compared to controls (47.8±15.4 /mm^2). In conclusion, we found that estradiol and Raloxifene are both effective to directly decrease in vitro bone resorption by human osteoclasts. Both steroids might act more on osteoclast activity than on osteoclast differentiation through β3 integrin, and involve mainly estrogen receptor-α in this human model.

F509

Vitamin D-Mediated Hypercalcemia in Lymphoma: Evidence for Hormone Production by Tumor-Adjacent Macrophages. V. Kantorovich,[1] H. R. Liker,*[2] A. J. Van Herle,*[2] P. Cohan,*[2] D. Zehnder,[3] M. Hewison,[3] J. S. Adams.[1] [1]Burns and Allen Research Institute, UCLA/Cedars-Sinai Medical Center, Los Angeles, CA, USA, [2]UCLA/Center for the Health Sciences, Los Angeles, CA, USA, [3]Medical Sciences, University of Birmingham, Birmingham, United Kingdom.

Hypercalcemia frequently complicates the course of lymphoma. While the most common cause of this phenomenon appears to be PTHrP secretion by the tumor, overproduction of 1,25-dihydroxyvitamin D (1,25(OH)2D) is also frequently observed (Seymour et al. Blood. 1993;82:1383-94). The cellular source of 1,25(OH)2D hormone was assumed to be lymphoma cell itself. Here we provide in vivo and in vitro evidence that lymphoma-adjacent macrophages are the source of the vitamin D hormone. A 75-year old male was diagnosed with symptomatic hypercalcemia resistant to bisphosphonate and mithramycin therapy. Extensive workup showed a high serum concentration of 1,25(OH)2D with a sup-

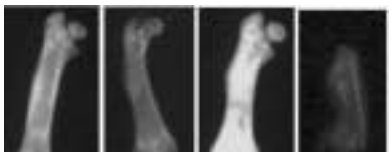
pressed serum PTH level (iPTH <2.0 pg/mL; normal 10-65) and normal PTHrP level (0.2 pmol/L; normal 0-1.3). Whole body computed tomography (CT) and positron emission tomography (PET) revealed evidence of tumor localized to only spleen (panel A, Figure 1). Hypercalcemia was cured with splenectomy and removal of a B-cell lymphoma (panel B, Figure 1). Splenic samples were subjected to immunostaining with antiserum raised against human renal 25-OHD 1alpha-hydroxylase (1-OHase). Lymphoma cells as well as the uninvolved spleen did not stain for the 1-OHase. However, a well-defined sub-population of CD68-positive macrophages bordering the normal spleen-lymphoma interface showed strong expression of 1-OHase. The fact that splenectomy was curative indicated that the spleen harbored cells responsible for either synthesis of 1,25(OH)2D, induction of synthesis, or both. The prominent staining of CD68-positive macrophages bordering stain-negative lymphoma cells, suggested that splenic lymphoma cells produced a locally-active soluble substance which promoted expression of a 1-OHase gene in adjacent macrophages. While the identity of the locally-active paracrine stimulator of the macrophage 1-OHase remains unknown in lymphoma and other granuloma-forming disease, preliminary evidence (Hewison et al., unpublished) suggests that signaling through the toll-like receptor-coupled NFkappaB pathway is a key regulator of enzyme expression.



F510

Vitamin D is a Negative Regulator of the Excessive Bone Formation. H. Tanaka,[1] K. Kinuta,[1] N. Inoue,*[1] M. Shinohara,*[1] S. Kato,[2] Y. Seino.[1] [1]Department of Pediatrics, Okayama University, Okayama, Japan, [2]Tokyo University, Tokyo, Japan.

Vitamin D is an important hormone in bone metabolism, but there is little evidence that vitamin D directly participates in this process. Vitamin D receptor (VDR) null mice have provided new insights in vitamin D metabolism and its role in vivo. However, like other nuclear receptor gene knockout, calcium supplementation experiments aimed at establishing physiological direct functions of VDR in many organs including bone have been inconclusive owing to essential roles of mineral in biological function. Although calcium supplementation showed apparent cure of rickets, we could not exclude the compensatory mechanisms such as hyperparathyroidism in this process. To evaluate the direct function of vitamin D in bone, we analyzed ectopically transplanted VDRKO bone in wild mice. As expected, wild bone in VDRKO showed marked bone resorption because of hyperparathyroidism and high $1,25(OH)_2D$. However, the VDRKO bone in wild mouse (KOW) showed dramatic increase in bone density compared with wild bone in wild mouse (WW). Bone volume was 0.175 mm^3 in KOW and 0.105 mm^3 in WW at 4 weeks after transplantation. Similarly, bone thickness of calvaria was 180 microm, which was 2.7 fold compared to WW. To exclude the possible contamination of the host cells, we next transplanted calvariae wrapped with membrane filter. Even in the absence of the wild type host cells, KO calvarie showed increased bone thickness. To explore the mechanism, we next examined mRNA expression of the genes, which may play key roles in bone metabolism, by quantitative RT-PCR in the transplanted bone. The results demonstrated increased expression of Cbfa1, BMP4 and OPG in KO bone. From these results, we conclude that vitamin D may play an important role in normal bone by protecting it from excessive bone formation through suppressing the expression of Cbfa1, BMP4 and OPG.



F512

Active Vitamin D Inhibits Osteoclastogenesis by Interfering With AP-1/ NF-κB Activity in Osteoclast Precursors. H. Takasu,[1] S. Takeda,*[1] A. Sugita,*[1] T. Kake,*[1] N. Kubota,*[1] E. Ogata,[2] K. Ikeda,[3] Y. Uchiyama.*[1] [1]Fuji Gotemba Res. Lab., Chugai Pharmaceutical Co., Ltd., Shizuoka, Japan, [2]Cancer Inst. Hosp., Japanese Foundation for Cancer Res., Tokyo, Japan, [3]Dept. of Geriatric Res., Natl. Inst. for Longevity Sci., Aichi, Japan.

We have demonstrated that active vitamin D inhibits bone resorption *in vivo* in estrogen deficient rodent models of high turnover osteoporosis (*JBMR 2000*). This contradicts the prevailing notion that $1,25D_3$ induces RANKL in bone marrow stromal cells, thereby promoting differentiation and activation of osteoclasts *in vitro*. In order to solve this discrepancy and to clarify the mechanism by which active vitamin D inhibits osteoclastic bone resorption, we examined the effects of $1,25D_3$ on osteoclastogenesis induced by M-CSF and RANKL in murine marrow cultures. Bone marrow cells from 6-8-week-old male *ddy* mice were cultured with M-CSF for 3 days, and adherent cells consisted mainly of bone marrow macrophage (BMM) were further cultured with M-CSF and sRANKL for additional 3-5 days. The number of TRAP-positive multinucleated cells (more than 3 nuclei) was counted. Addition of $1,25D_3$ inhibited the formation of osteoclasts dose-dependently, with IC50 being 10^{-8}M and 10^{-7}M $1,25D_3$ inhibiting by 70-80%. The expression of VDR in BMM was confirmed, and $1,25D_3$ had no inhibitory effect in bone marrow cells from VDR knockout mice, pointing to a VDR-mediated process. Addition of $1,25D_3$ during the first 3 days had no effect, while its co-presence with sRANKL during the latter half period fully inhibited osteoclastogenesis, and treatment with $1,25D_3$ did not affect RANK level in BMM, suggesting that $1,25D_3$ acts downstream of RANK activation by RANKL. Phosphorylation of IκB at Ser 32 after treatment with sRANKL was not inhibited by $1,25D_3$. A novel vitamin D analog, DD-281, that we have identified on the basis of its greater ability to inhibit AP-1/NF-κB-mediated transcription (25-30x of $1,25D_3$) and weaker activity to induce VDRE-dependent transcription (1/10 of $1,25D_3$) inhibited osteoclast formation 10x more potently than $1,25D_3$ (IC50 being 10^{-9}M), raising the possibility that active vitamin D inhibits osteoclastogenesis by interfering with AP-1/NF-κB function in osteoclast precursors through binding to VDR. In conclusion, we think that the major *in vivo* pharmacological action of active vitamin D is not to induce RANKL ("soil") in marrow stromal cells but to inhibit osteoclastic bone resorption by acting on osteoclast precursors ("seeds") and interfering with RANK signaling, and that the latter action provides an attractive target for developing new VDR-based drugs for osteoporosis.

F513

The Anabolic Effect of Vitamin D Binding Protein-Macrophage Activating Factor (DBP-MAF) and a Novel Small Peptide on Bone. G. B. Schneider,[1] K. J. Grecco,*[1] F. F. Safadi,[2] S. N. Popoff.[2] [1]Division of Basic Medical Sciences, Northeastern Ohio Universities College of Medicine, Rootstown, OH, USA, [2]Department of Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA, USA.

Vitamin D binding protein-macrophage activating factor (DBP-MAF) has previously been shown to stimulate bone resorption and correct the skeletal defects associated with osteopetrosis in two non-allelic mutations in rats. This same protein and a small fragment of the protein have now been shown to demonstrate an anabolic effect on the skeleton of both newborn and young adult, intact rats. The novel peptide fragment was synthetically produced based on the human amino acid sequence at the site of glycosylation in the third domain of the native protein (DBP). The peptide tested is 14 amino acids in length and demonstrates no homologies other than to that region of DBP. Newborn rats were injected i.p. with saline, peptide (0.4 ng/g body wt.) or DBP-MAF (2 ng/g body wt.) every other day from birth to 14 days of age. On day 16 the rats were euthanized and the long bones collected for bone densitometry by pQCT. Serum was collected for evaluation of osteocalcin levels as an indication of bone formation and urine was analyzed for deoxypyridinoline (Dpd) as a measure of bone resorption. After two weeks of treatment with either the whole protein (DBP-MAF) or the small peptide, bone density was significantly increased in the treated animals compared to the saline controls. Serum osteocalcin levels were significantly enhanced and Dpd levels in the urine were significantly decreased in the protein and peptide treated animals. Young adult female rats were given s.c. injections of saline or peptide (0.4 ng/g body wt. or 5 ng/g body wt.) every other day for two weeks; two days after the final injections, the rats were euthanized and the femurs and tibias collected for bone densitometry. Both doses of the peptide resulted in significant increases in bone density as determined by pQCT. Young adult rats were injected locally with a single dose of the peptide (1 μg) or saline into the marrow cavity of the distal femur. One week after the single injection, the bones were collected for radiographic and histological evaluation. The saline controls showed no evidence of bone formation, whereas the peptide treated animals demonstrated bone development at the injection site. These data suggest that DBP-MAF and the synthetic peptide represent therapeutic opportunities for the treatment of a number of bone diseases and skeletal disorders. Systemic administration could be used to treat osteoporosis and a number of other osteopenias and local administration could be effective in fractures, bony defect repairs, spinal surgery and joint replacement.

F515

$1,25(OH)_2D_3$ Synergizes with the PPARγ-Selective Ligand, BRL-49653, to Increase Adipogenesis in Rat Calvaria Cell Cultures. K. Oizumi, Y. Yoshiko, J. E. Aubin. Anatomy and Cell Biology, University of Toronto, Toronto, ON, Canada.

To investigate the effect of $1,25(OH)_2D_3$ on the conversion of osteoprogenitor cells into adipocytes, rat calvaria (RC) cells were treated with $1,25(OH)_2D_3$ and/or BRL-49653, a potent PPARγ-selective ligand. The expression of PPARs and C/EBPs, which are two transcription factor families that regulate adipocyte differentiation, was also assessed. As reported previously, $1,25(OH)_2D_3$ induced adipocyte colonies and adipocyte marker expression, while completely inhibiting bone nodule formation and the expression of most osteoblast markers in RC cultures; an exception was that $1,25(OH)_2D_3$ increased OPN expression at early culture stages. Although the inverse relationship between osteoblast and adipocyte marker expression and osteoblast and adipocyte colony formation suggested the conversion of osteoprogenitor cells into adipocytes, the number of adipocyte colonies in $1,25(OH)_2D_3$-treated dishes was much less than the number of bone colonies/nodules in vehicle-treated dishes. This apparent discrepancy in fate redirection of osteoprogenitors to adipocytes was altered when RC cells were subjected to combined treatment with $1,25(OH)_2D_3$ and BRL-49653, which induced a large number of mature adipocyte colonies, suggesting that $1,25(OH)_2D_3$ has dual roles: inducing adipocyte maturation in some preadipocytes and inducing osteoprogenitor cells to select an adipocyte fate that is then completed in response to the PPARg selective ligand. Although both $1,25(OH)_2D_3$ and BRL-49653 increased PPARγ and C/EBPα expression, BRL-49653 had no effect on osteoblast differentiation. However, our data support the hypothesis that the inhibitory effect of $1,25(OH)_2D_3$ on osteoblast differentiation is based on its induction of C/EBPδ, which is induced eaerlier than PPARγ during initiation of adipogenesis. The present study suggests that committed osteoprogenitor cells in RC cell cultures are redirected in fate choice by $1,25(OH)_2D_3$ but undergo marked conversion into mature adipocytes only after combination treatment with $1,25(OH)_2D_3$ and the PPAR γ selective ligand.

Phosphorylation of the Human Vitamin D Receptor by Protein Kinase A Downregulates $1,25(OH)_2D_3$-dependent Transactivation by Reducing Retinoid X Receptor β Heterodimerization. J. C. Hsieh, H. T. L. Dang,* M.

A. Galligan,* G. K. Whitfield, P. W. Jurutka, P. D. Thompson, C. A. Haussler,* M. R. Haussler. Biochemistry & Molecular Biophysics, College of Medicine, University of Arizona, Tucson, AZ, USA.

Phosphorylation of the human vitamin D receptor (hVDR) includes protein kinase C (PKC) action at serine-51 and casein kinase-II (CK-II) phosphorylation of serine-208, posttranslational modifications that attenuate and potentiate receptor activity, respectively. Preliminary work from our laboratory suggested that protein kinase A (PKA) can also phosphorylate hVDR between amino acids 133 and 201. To elucidate the exact PKA phosphorylation site(s) of hVDR, a series of C-terminally truncated mutants (δ134, δ180, δ190 and δ202) were expressed in transfected COS-7 cells, immunoprecipitated with VDR antibody, and incubated with PKA and [^{32}P]ATP, in vitro. Visualization of these reactions by SDS-PAGE indicated that the major PKA phosphorylation site of hVDR is localized between residues 180-190, a region that contains a cluster of four consecutive serines, ^{182}Ser-Ser-Ser-Ser^{185}, and a single serine at position 187. These serines were individually mutated to alanine using δ190 hVDR, the native receptor, and S51A/S208A (to eliminate PKC and CK-II sites) as templates, and the resulting mutant hVDRs were tested for their ability to serve as PKA substrates, in vitro. The results showed that the S182A mutant hVDR was least able to serve as a PKA substrate. Furthermore, when intact transfected COS-7 cells were treated with [^{32}P]orthophosphate, the S182A mutant displayed the largest reduction in phosphorylation compared to the other alanine-substituted hVDRs. We therefore conclude that serine-182 is a primary PKA phosphorylation site in hVDR, both in vitro and in vivo. As a test of the functional consequence of this phosphorylation event, an aspartate-substituted mutant (S182D) was created to mimic the negative charge of a phosphorylated serine. Utilizing the mammalian two-hybrid assay, it was observed that, while the S182A mutant could associate normally with the retinoid X receptor-β (RXRβ) dimeric partner, S182D was significantly impaired in this interaction. Also, in cotransfection assays with a 1,25(OH)$_2$D$_3$-responsive reporter gene, S182A hVDR exhibited normal transactivation, but the S182D mutant possessed only 50% of wild-type hVDR activity. Taken together, these observations strongly suggest not only that serine-182 can be a target of PKA phosphorylation in hVDR, but that this postranslational event may significantly inhibit hVDR dimerization with RXRβ, thereby attenuating the ability of hVDR to mediate 1,25(OH)$_2$D$_3$-dependent transactivation of target genes.

F519

The Amino Bisphosphonate Ibandronate Prevents Vitamin D Toxicity and Potently Inhibits Vitamin D-Induced Calcification of Arteries, Lungs, and Kidneys. P. A. Price, J. R. Buckley,* M. K. Williamson. Division of Biology, University of California, San Diego, La Jolla, CA, USA.

The present experiments were carried out to determine whether doses of the amino bisphosphonate ibandronate that inhibit bone resorption will inhibit soft tissue calcification and death in rats treated with a toxic dose of vitamin D. These studies were prompted by the recent discovery that ibandronate doses that inhibit bone resorption will potently inhibit artery calcification induced by treatment with the vitamin K antagonist warfarin (Arterioscler. Thromb. Vasc. Biol.(2001) 21(5) in press).

All 16 rats treated with a toxic dose of vitamin D (0.5 million IU vitamin D$_3$/kg at t=0, 1, and 2 days) died by day 6 following the first vitamin D injection (median survival 4.5 days), while the 12 rats treated with vitamin D plus ibandronate (0.25mg/kg/day) were alive and in good health at day 10. Rats treated with the toxic dose of vitamin D alone and examined at day 4 had extensive Alizarin red staining for calcification in the aorta; the carotid, hepatic, mesenteric, renal, and femoral arteries; kidneys; and lungs, while rats treated with vitamin D plus ibandronate showed no evidence of Alizarin red staining for calcification in any of these tissues. Chemical analysis further showed that rats treated with vitamin D alone and examined at day four had 5- to 20-fold higher levels of calcium and phosphate in their abdominal aorta, lungs, and kidneys than was found in control rats ($p < 0.001$), while the levels of calcium and phosphate in tissues from rats treated with vitamin D plus ibandronate were at control values. Serum calcium levels were the same in rats treated with vitamin D alone (13.5 ± 0.9 mg/dl) and in rats treated with vitamin D plus ibandronate (14.0 ± 0.6 mg/dl), which shows that ibandronate does not prevent soft tissue calcification by simply lowering serum calcium levels.

To our knowledge, ibandronate is the first drug that has been shown to prevent soft tissue calcification and death in an animal that has received a toxic dose of vitamin D. The fact that an ibandronate dose that inhibits bone resorption is able to prevent soft tissue calcification induced by toxic doses of vitamin D further supports the hypothesis that soft tissue calcification is linked to bone resorption. The mechanism responsible for this putative linkage remains to be determined.

F520

Identification of a 25-hydroxyvitamin D-1alpha-hydroxylase Splice Variant in Skin, Prostate, and Colon. J. N. Flanagan,*[1] V. Tanpricha,*[1] T. Chen,[1] J. Reichrath,*[2] M. F. Holick.[1] [1]Physiology and Endocrinology, Boston University School of Medicine, Boston, MA, USA, [2]Dermatology, University of Saarland, Homberg, Germany.

The renal 25-hydroxyvitamin D-1α-hydroxylase (1α-OHase), a mitochondrial cytochrome P450, is responsible for producing serum 1α,25(OH)$_2$D$_3$. It has been established that other tissues including skin, prostate, and colon have the ability to convert 25(OH)D$_3$ to 1α,25(OH)$_2$D$_3$ and express the 1α-OHase. The presence of 1α-OHase in non-renal tissues may play an autocrine/paracrine role for locally modulating cell proliferation and differentiation. Since the cloning of the 1a-OHase, its expression has been detected in many other non-renal tissues and when compared to the renal 1α-OHase, the cDNAs sequences were established to be 100% identical. A 1a-OHase specific polyclonal antibody was made and used to characterize the tissue distribution of the enzyme. Western blot analysis of whole cell extracts from skin, kidney, prostate, and colon with 1α-OHase specific antibody revealed the predicted 1α-OHase protein product of 56 kDa in kidney, prostate, and colon but not in skin.However, a larger protein product of 59 kDa was observed in skin, prostate, and colon but not in kidney. A side-by-side comparison of whole kidney extract with whole skin extract demonstrated a size discrepancy of 3 kDa. Thus, no 56 kDa protein product was observed in the skin and there was no 59 kDa protein product observed in the kidney. In order to investigate the possibility of splice variants of the 1a-OHase, we designed sequence specific primers to the 1α-OHase expanding the 8 known introns. Using RT-PCR for the 1α-OHase in skin and kidney, we detected an insertion between exons 2 and 3 in skin but not in kidney. By sequence analysis it was determined that the skin variation contained the 3'-region of intron 2 using an alternative 5'splice signal -AG- in intron 2. This variant was not observed in kidney. This is the first report of an alternative mRNA splice variant and protein product for the 1α-OHase gene in skin, prostate, and colon. The tissue specific alternative spliced variant of 1α-OHase that contains intron 2 may represent a possible regulatory domain that could explain why the renal 1a-OHase is tightly regulated by parathyroid hormone and phosphate whereas the extra-renal 1a-OHase is not. It is also interesting that prostate and contained both splice variants whereas the skin and kidney contained one. The endogenous expression of 1α-OHase gene variants and differential tissue expression of these variants opens up a new paradigm in the understanding of the role of 25-hydroxyvitamin D$_3$ 1α-hydroxylase gene in the regulation of vitamin D physiology.

F522

Renal Cell-Specific Regulation of Type IIa Sodium-Dependent Phosphate Cotransporter Gene Expression by 1,25-Dihydroxyvitamin D3. H. Yamamoto,[1] K. Kobayashi,[1] Y. Tani,[1] Y. Taketani,[1] K. Morita,[1] H. Arai,[1] K. Miyamoto,[1] S. Kato,[2] J. W. Pike,[3] E. Takeda.[1] [1]Clinical Nutrition, School of Medicine, University of Tokushima, Tokushima, Japan, [2]Institute of Molecular and Cellular Biosciences, University of Tokyo, Tokyo, Japan, [3]Molecular and Cellular Physiology, University of Cincinnati, Cincinnati, OH, USA.

Physiological and pathophysiological alterations in renal Pi reabsorption are related to the altered brush-border membrane expression of the type IIa Na+-dependent phosphate (NaPi) cotransporter. We have shown that the expression of this cotransporter is restricted to renal proximal tubular cells which produce the active vitamin D metabolite 1,25-dihydroxyvitamin D3 (1,25(OH)2D3) and is regulated by 1,25(OH)2D3. The mechanisms through which NaPi cotransporter expression is regulated in renal proximal tubular cells remains unclear, however. To gain a better understanding of the mechanism through which 1,25(OH)2D3 regulates NaPi transporter gene expression, we have characterized the promoter region of the mouse NaPi cotransporter gene with regard to transactivation by the vitamin D receptor (VDR). We first cloned the NaPi-7 gene and isolated the 5' end of the gene containing the promoter. We next examined the activity of this promoter in both renal and nonrenal cell types including porcine LLC-PK1, murine MCT and opposum OK kidney cells as well as COS-7 cells, and contrasted its activity with that of promoters for human osteocalcin and rat 24-hydroxylase (24-OHase) genes. In each case, expression vectors for both VDR and retinoid X receptor were cotransfected together with the promoters to assess basal and 1,25(OH)2D3 response. Basal activity was evident for all of the promoters tested in all the cell types. Interestingly, while 1,25(OH)2D3 was capable of stimulating both the osteocalcin and 24-OHase promoters in all cell types, NaPi-7 promoter activity was enhanced by 1,25(OH)2D3 only in OK cells. A similar cell-selective activation by 1,25(OH)2D3 was also observed with the human NaPi cotransporter (NaPi-3) gene promoter. We next carried out a deletion analysis to define the sequence of the NaPi-7 promoter necessary for vitamin D response. Our results identified a novel region within the 5' end of the gene that acts not as an enhancer element, but rather dictates synthesis of a new transcript containing a novel exon (exon1a). Importantly, northern blot analysis showed that the expression of this exon1a was decreased in VDRKO mice. These findings suggest that an important cell-specific regulatory factor may play an essential role in the regulation of NaPi gene expression by 1,25(OH)2D3 and that this regulation involves a new NaPi-7 promoter.

F524

Histone Acetylation In Vivo at the Osteocalcin Locus is Functionally Coupled to Chromatin Remodeling and Vitamin D Dependent, Bone Tissue-Specific Gene Activation. J. Shen,*[1] J. B. Lian,[1] M. Montecino,*[2] G. S. Stein,[1] J. L. Stein,*[1] A. J. van Wijnen.[1] [1]Cell Biology, UMass Medical School, Worcester, MA, USA, [2]Biologia Molecular, Universidad de Concepcion, Concepcion, Chile.

The accessibility of regulatory elements in chromatin represents a principal rate limiting parameter in gene transcription, and is modulated by enzymatic transcriptional co-factors that alter the topology of chromatin or covalently modify histones (e.g., by acetylation or phosphorylation). The bone-specific activation and 1,25-dihydroxyvitamin D3 (VD3) enhancement of osteocalcin (OC) gene transcription are both functionally linked to modifications in nucleosomal organization. The initiation of tissue-specific basal transcription is accompanied by the induction of two DNase I hypersensitive sites, and this chromatin remodeling event requires binding of the key osteogenic factor RUNX2/CBFA1 to the OC promoter. Here, we define in vivo requirements for bone tissue-specific gene expression that have not been previously identified for Vitamin D responsive or osteoblast related genes. We analyzed the acetylation status of histones H3 and H4 when the gene is active (in osteoblastic ROS17/2.8 cells) or inactive (in fibroblastic ROS24/1 cells) using chromatin-immunoprecipitation (ChIP) assays with antibodies detecting acetylated histone H3 or H4. DNA fragments co-precipitating with the acetylated histones were purified and used in PCR reactions with several sets of gene-specific primers spanning the OC locus. The DNA products were resolved by gel electrophoresis and quantitated by digital imaging. We find that acetylated histone H3 and H4 proteins are associated with nucleosomes in the promoter of the OC gene only when it is transcriptionally active, and the acetylation status is relatively uniform across the OC locus under basal conditions. Acetylation of H4 and H3 at the OC gene is selectively increased following Vitamin D3 enhancement of OC transcription, and the most prominent changes occur in the region between the VD3 enhancer and basal promoter. Thus, acetylation of histones H3 and H4 in specific regions of the OC promoter appears to be functionally linked to the tissue-specific transcriptional activation and Vitamin D enhancement of OC gene expression, as well as chromatin remodeling at the OC locus. These findings provide important mechanistic insights into bone-specific gene activation within a native genomic context in response to developmental regulatory cues and steroid hormones.

F527

Targeted Ablation of the 25-Hydroxyvitamin D 1a-Hydroxylase Enzyme: Evidence for Skeletal, Reproductive and Immune Dysfunction. D. K. Panda,[1] D. Miao,[1] M. L. Tremblay,*[2] J. Sirois,*[2] G. N. Hendy,[1] D. Goltzman.[1] [1]Dept. of Medicine, McGill University, Montreal, PQ, Canada, [2]Dept. of Biochemistry, McGill University, Montreal, PQ, Canada.

The active form of vitamin D, 1α,25-dihydroxyvitamin D [1α,25$(OH)_2$D], is synthesized from its precursor 25 hydroxyvitamin D [25(OH)D] via the catalytic action of the 25(OH)D-1α-hydroxylase [1α(OH)ase] enzyme. Many roles in cell growth and differentiation have been attributed to 1,25$(OH)_2$D, including a central role in calcium homeostasis and skeletal metabolism. To investigate the in vivo functions of 1,25$(OH)_2$D and the molecular basis of its actions we developed a mouse model deficient in 1α(OH)ase by targeted ablation of the hormone-binding and heme-binding domains of the1α(OH)ase gene. After weaning, mice developed hypocalcemia, secondary hyperparathyroidism, retarded growth and skeletal abnormalities characteristic of rickets. These abnormalities are similar to those described in humans with the genetic disorder vitamin D dependent ricket type1 (VDDR-1). Altered non-collagenous matrix protein expression and reduced numbers of osteoclasts were also observed in bone. Female mutant mice were infertile and exhibited uterine hypoplasia and absent corpora lutea. Furthermore histologically enlarged lymph nodes in the vicinity of the thyroid gland and reduction in CD4- and CD8- positive peripheral T lymphocytes were observed. Alopecia, reported in vitamin D receptor (VDR)-deficient mice and in humans with VDDR-11, was not seen. The findings establish a critical role for the 1α(OH)ase enzyme in mineral and skeletal homeostasis as well as in female reproduction and also point to an important role in regulating immune function.

SA001

Calcium and Zinc Absorption from Lactose-Containing and Lactose-Free Whey-Based Infant Formulas. S. A. Abrams, I. J. Griffin,* D. C. Powledge,* P. Davila.* Pediatrics, Baylor College of Medicine, Houston, TX, USA.

Although calcium absorption is enhanced by lactose, the quantitative significance of this effect in infant formulas is uncertain as is the possibility of an effect of lactose on zinc absorption. We assessed the absorption of calcium and zinc using a multi-tracer, stable isotope technique in full-term infants fed ad libitum two partially hydrolyzed whey protein-based formulas. The formulas used either 1) lactose or 2) lactose-free (glucose polymers) carbohydrate sources. Calcium content of both formulas was 64 mg/100 kcal. Infants were studied in a blinded cross-over fashion after two weeks adaptation to each formula. Infants were randomized as to which formula was studied first. Isotope absorption studies were done using a 4-tracer method in which 70Zn and 44Ca were provided orally and 67Zn and 46Ca were given intravenously. Subsequently a 24-hour urine was collected to assess calcium absorption and a spot urine obtained at 48-72 hours post-dosing to assess zinc absorption. Eighteen infants completed the calcium absorption study. Data for zinc absorption was available for 14 or these 18. Mean age (78 d), weight (6.3 kg), length (60 cm), and formula intake (1100 ml/d) were similar at each study.

Group	Calcium intake (mg/d)	Percent absorption	Total calcium absorption (mg/d)
Lactose-containing	471 ± 97	66.5 ± 11.9	314 ± 82
Lactose-Free	465 ± 84	56.2 ± 15.3	259 ± 79
P-value of difference (paired t-test)	> 0.5	.002	.006

Zinc intake (5.5 ± 1.1 mg/d)), fractional zinc absorption (32 ± 11%) and total zinc absorption (1.8 ± 0.6 mg/d) were very similar between the two formulas. These data indicate that lactose enhances calcium, but not zinc absorption, from a partially hydrolyzed whey protein-based formula. Fractional calcium absorption from the lactose-containing milk was similar to that reported for human milk. Net calcium absorption from both exceeded that expected from human milk based on the higher calcium intake levels in the formula relative to human milk. We conclude that lactose-free formulas provide adequate absorption of calcium and zinc, but that to obtain levels of absolute calcium absorption comparable to lactose containing formulas, slightly higher concentrations of calcium would be required. This study was funded in part by Nestle, USA.

Correlates of Forearm Bone Mineral Density in Young Norwegian Women. The Nord-Trøndelag Health Survey. G. A. Hawker,[1] S. Forsmo,*[2] S. M. Cadarette,[1] B. Schei,*[2] S. B. Jaglal,[1] A. Langhammer,*[3] L. Forsén.*[4] [1]University of Toronto, Toronto, Canada, [2]Norwegian University of Science and Technology, Trondheim, Norway, [3]Hunt Research Centre, Norwegian University of Science and Technology, Verdal, Norway, [4]National Institute of Public Health, Oslo, Norway

Peripheral bone densitometry is gaining utility as a less expensive and portable alternative to axial assessments. The main objective of the study was to identify factors associated with forearm bone mineral density (BMD) in young adult women. Population-based data derived from standardized questionnaires among healthy women aged 19-35 years living in Nord-Trøndelag, Norway (N=963) were used. Participants with a history of fracture in the forearm tested, pregnant at the time of the examination, or missing weight data were excluded. Single x-ray absorptiometry was performed at the ultradistal and distal forearm. Multiple linear and logistic regression were used to assess factors associated with BMD (g/cm2), and low BMD (lowest quintile) at the ultradistal and distal sites separately. The mean age and weight of the cohort was 29.7 years (SD=4.7) and 68.6 kg (SD=12.5) respectively. The majority had post-secondary education (54%) and drank milk (91%). The mean BMD values were 0.386 (SD=0.048) and 0.478 (SD=0.042) for the ultradistal and distal sites respectively. In both linear and logistic models, none of vitamin D intake, physical activity, smoking, alcohol consumption, amenorrhea, oral contraceptive use, number of pregnancies, history of breast-feeding or family history of osteoporosis were found to significantly impact BMD. Consistent with prior studies, age and weight were positively associated with BMD at both forearm sites, while increasing age at menarche and lower daily milk consumption were associated with lower BMD levels. Body weight was the most important factor associated with forearm BMD, accounting for at least half of the explained BMD variation in regression models. Given that the forearm is not a weight-bearing site, body weight may be acting as a surrogate for other factors, such as endogenous estrogen exposure. Controlling for age and weight, women who did not drink milk daily were 2 times more likely to have low forearm BMD. This association was strongest at the ultradistal site (odds ratio=2.3; 95% CI=1.6-3.9). Results from this study are consistent with previous reports evaluating peak BMD at the hip and spine, and support the growing body of literature suggesting a benefit of milk consumption on peak BMD.

Bone Markers and Bone Mass in Healthy Pubertal Boys and Girls. S. C. C. van Coeverden,*[1] C. J. Netelenbos,[2] C. M. Ridder, de,[1] J. C. Roos,*[3] C. Popp-Snijders,*[4] H. A. Delemarre-van de Waal.*[1] [1]Pediatrics, VU University Medical Centre, Amsterdam, The Netherlands, [2]Internal Medicine, VU University Medical Centre, Amsterdam, The Netherlands, [3]Nuclear Medicine, VU University Medical Centre, Amsterdam, The Netherlands, [4]Clinical Chemistry, VU University Medical Centre, Amsterdam, The Netherlands

The aim of this study was to evaluate associations between the markers of bone formation and bone resorption, the sex steroids and growth factors with bone mineral content (BMC) and bone mineral density (BMD) during puberty in healthy boys and girls. In 155 boys and 151 girls we assessed height, weight, and pubertal stages according to Tanner. BMC and BMD were measured of the lumbar spine, femoral neck and trochanter and the total body using dual energy X-ray absorptiometry. All measurements were repeated after one year. At the first visit fasting blood samples and first-void urine samples were obtained to measure markers of bone formation and bone resorption, estradiol, testosterone, IGF-1, and IGF-BP3. BMC and BMD increased throughout puberty in both sexes. Bone turnover markers significantly increased until maximum values were reached at stage G4 in boys and stage B3 in girls with a significant decline thereafter in girls. Height velocity (HV) had a similar changing pattern. Sex steroids and IGF-1 increased and reached adult values at pubertal stage 4. The correlations between bone markers and BMC were highly significant in boys, while correlations between bone markers and the increase in BMC over one year were significant in both sexes, as was observed for the correlations with HV. Sex steroids and IGF-1 correlated positively with the bone markers in pubertal stages 2+3, but were not significant in pubertal stages 4+5 in boys and girls. Our data suggest that bone markers are good predictors of bone mass in boys and of bone mass increase in both sexes. In early puberty, sex steroids stimulate the pubertal growth spurt which gives rise to an increase in height and to an increase in bone turnover and bone mineral. In late puberty, high levels of estradiol inhibit growth, which leads to a decline in bone turnover. Bone mass still increases under the influence of sex steroids and IGF-1. The data in our study confirm previous reports that markers of bone turnover relate positively to height velocity.

The Influence of Serum Leptin Concentrations on Bone Mass Assessed by Quantitative Ultrasonometry (QUS) in Pre- and Postmenopausal Women. P. Hadji,[1] K. Bock,*[1] M. Gottschalk,*[1] M. Kalder,*[1] G. Emons,*[2] K. D. Schulz.*[1] [1]University of Marburg, Marburg, Germany, [2]University of Göttingen, Göttingen, Germany

This study was aimed to investigate the influence of serum leptin concentration on bone mass assessed by QUS in a large sample of healthy pre- and postmenopausal women. 555 pre- and postmenopausal (n=262 and n=293) women not on estrogens (mean age, 49.5 ± 17.2 years) were recruited at the University of Marburg on the occasion of a routine gynecological visit. Before entry to the study, all women had answered a detailed questionnaire on important risk factors. Speed of sound (SOS), broadband ultrasound attenuation (BUA) and stiffness index (SI) were measured using the Achilles ultrasonometer (GE/Lunar). We systematically investigated the specific influence of age, menopause and BMI on Leptin and QUS variables by allocating women into the following groups: (a) premenopausal women BMI< 25 kg/m² (N=177), (b) premenopausal women BMI>25 kg/m² (N=83), (c) postmenopausal women BMI< 25 kg/m² (N=124) and (d) postmenopausal women BMI> 25 kg/m² (N=168). Additionally we evaluated the influence of serum leptin, age and BMI on QUS variables by performing a multiple linear regression analyses. In the initial analyses premenopausal women showed a significantly lower mean age, weight, BMI, follicle stimulating hormone (FSH) and serum leptin concentration (P<0.001), a higher mean height, serum estradiol and QUS variables compared to postmenopausal women. Irrespective of the menopausal status, women with a BMI>25 kg/m² had significantly higher leptin concentration compared to women with a BMI<25 kg/m² (P<0.001). Only BMI but not Leptin was related to higher QUS variables, whereas increasing age was associated with decreased QUS variables.The multiple linear regression analyses confirmed that only age and BMI but not Leptin, were the only statistically significant independent predictor for QUS variables. Serum leptin concentration is significantly higher in pre- and postmenopausal obese women, compared with normal weight controls. Bone mass assessed by QUS is influenced by age and BMI but not by serum leptin concentration.

SA009

Changes in Bone Structure and Mass with Aging in the Male Mouse. B. Halloran,[1] V. Ferguson,[2] S. Simske,[2] A. Burghardt,*[3] L. Venton,*[4] L. Rudner,*[4] S. Majumdar.[3] [1]Departments of Medicine and Physiology, University of California, Division of Endocrinology, Veterans Affairs Medical Center, San Francisco, CA, USA, [2]Bioserve Space Technologies, University of Colorado, Boulder, CO, USA, [3]Department of Radiology, University of California, San Francisco, CA, USA, [4]Division of Endocrinology, Veterans Affairs Medical Center, San Francisco, CA, USA.

To determine whether the mouse is a suitable model to study age-related bone loss in humans, we examined the changes in bone structure and mass that occur during the normal aging process in the male C57B6 mouse. MicroCT was used to assess the structural and physical properties of the proximal tibia and tibial diaphysis in mice aged 1.5,3,6,12,18 and 24 months. Bone mass reached a peak at 12 months and declined thereafter. Cancellous bone volume declined continuously from a plateau at 6 m of 0.15% to 0.06% at 24 m. Trabecular number decreased and spacing increased beginning at 1.5 m of age. Trabecular thickness increased to 12 m and remained constant thereafter. Connectivity density fell dramatically between 1.5 and 12 m and then remained constant to 24 m. Using beam attenuation as a means of measuring bone density, trabecular mineral density (g hydroxyapatite/ mm3) reached a peak at 12 m and remained constant to 24 m. Cross-sectional area of the tibial diaphysis continued to increase to 18 m. Cortical thickness reached a peak at 6 m and declined continuously to 24 m. Cortical mineral density reached a peak at 3 m and remained constant to 24 m. We conclude that in the male mouse bone mass diminishes with normal aging. Cancellous bone restructures with age resulting in a decrease in total bone volume and a decrease in anisotropy (increased trabecular order). Cortical thickness diminishes but density remains intact. The changes observed in bone in the aging mouse are similar to those observed in human age-related bone loss. These findings support the use of the aging male mouse as an animal model to study age-related bone loss in humans.

Age-associated Changes in Bone Ultrasonometry of the Os Calcis. Expanded Data in Healthy German Women. P. Hadji, M. Meyer-Wittkopf,* M. Gottschalk,* M. Kalder,* K. D. Schulz.* University of Marburg, Marburg, Germany

This study updates age changes for quantitativeultrasonometry (QUS) of the os calcis in a large sample of healthy German women almost four times larger than our preliminary study published earlier. Speed of sound (SOS), broadband ultrasound attenuation (BUA) and stiffness index (SI) of the os calcis were measured in 5148 women (mean age 55.2 ± 10.6 years) using the Achilles ultrasonometer (GE/Lunar). Before entry to the study, all women had answered a detailed questionnaire on important risk factors. The short-term precision in 31 adults was 0.2% for SOS, 1.2% for BUA, and 1.3% for SI. There was an overall decline of 16% for BUA, 4% for SOS and 32% for SI between late adolescence and old age. In premenopausal women, BUA decreased only slightly (-2%), while postmenopausal women showed a significantly increased decline (-12%). In contrast, SOS continuously decreased from the age of 15; there was a decline of 2% from adolescence to the menopause. The SI of premenopausal women decreased only by 9%, but the postmenopausal decline of almost 21% was significantly greater. In accordance to our previous report, the age regression for SI in the larger sample differed from the earlier sample, indicating an increased bone loss with aging after the menopause. The SI values in premenopausal German women were comparable to those for British and American women age 20-50 years. After age 50, the SI of German women was significantly 3-7% higher (Fig.1) in comparison to the British and American reference population.

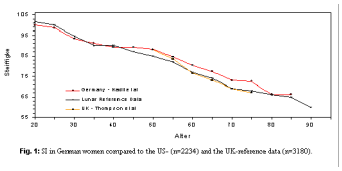

Fig. 1: SI in German women compared to the US- (n=2234) and the UK-reference data (n=3180).

Retinoic Acid Stimulates Transcription of the Type X Collagen Gene Through the BMP Signaling Pathway. School of Dental Medicine, University of Pennsylvania, Philadelphia, PA, USA.

Vitamin A plays an essential role in endochondral bone formation, acting at least in part by accelerating chondrocyte maturation and hypertrophy. However, the mechanisms by which RA induces expression of the type X collagen gene, the only known gene expressed exclusively in hypertrophic chondrocytes, are at present unknown. Thus we recently initiated experiments to determine whether RA activates type X collagen gene expression at the level of transcription, using a luciferase reporter plasmid driven by various fragments of the type X collagen promoter (Volk et al., J. Bone Min. Res. 13, 1521-1529, 1998). These constructs were transfected into prehypertrophic chondrocytes from embryonic chick sternum, which respond relatively rapidly to physiological concentrations of RA by increased expression of the endogenous type X collagen gene. The 640-bp proximal promoter displayed very low basal activity that was not stimulated by RA. Addition of an upstream 600 bp fragment (nucleotides -2648 to -2008) resulted in significant stimulation by RA, indicating that RA acts at the transcriptional level to stimulate type X collagen production. It is important to note that this same promoter construct is stimulated by bone morphogenetic proteins (BMPs) and by co-transfected Smads (Leboy et al., J. Bone Joint Surg., in press, 2001), suggesting a common pathway for RA and BMP stimulation. We have used 5' end deletion mutagenesis as an initial step toward identification of the sequences required for stimulation by RA and BMPs. We found that a 130-bp region of the type X collagen gene promoter (nucleotides -2648 to -2518) is essential for stimulation by RA and also appears to be important for stimulation by BMPs. This region does not contain recognizable binding sites for retinoic acid receptors (RARs), ligand-activated transcription factors that mediate RA signaling, but contains potential binding sites for Smads, the transcription factors that mediate BMP signaling; we have used electrophoretic mobility shift assays to demonstrate Smad binding to some of these sites. These results suggested that the action of RA on this promoter may be indirect, perhaps through activation of the BMP signaling pathway. We confirmed this suggestion by demonstrating that retrovirus-mediated expression of a dominant-negative BMP receptor IB prevented the increase in type X collagen promoter activity normally induced by RA. These studies provide the first mechanistic insights into the activation of type X collagen gene expression by retinoids.

Interaction Between Systemic Bisphosphonate Therapy and Bone Formation Induced by Local Delivery of rhBMP-2 in Non-Human Primates. M. L. Bouxsein, C. Blake,* C. Luppen,* J. A. Cooper,* J. M. Wozney, H. J. Seeherman. Genetics Institute, Andover, MA, USA.

Recombinant human bone morphogenetic protein-2 (rhBMP-2) is a potent differentiation factor for bone and cartilage precursor cells, and has been shown to induce bone formation in a variety of animal models. We previously reported that, in sheep and non-human primate models, intraosseous placement of rhBMP-2 (soak-loaded on an absorbable collagen sponge (ACS)) led to transient bone resorption followed by new bone formation [Seeherman et al, Trans ORS 1998, 2000]. The goal of this study was to determine whether systemic bisphosphonate therapy would inhibit the transient bone resorption induced by rhBMP-2 and still permit new bone formation. Bilateral core defects (3.5 mm diameter) were surgically created in the distal femurs of 13 adult male cynomolgus monkeys. In each monkey, one defect was treated with an rhBMP-2/ACS implant (360 µg rhBMP-2), and the contralateral defect received a buffer/ACS implant. Monkeys received monthly injections of either bisphosphonate (Ibandronate, 0.3 mg/ml, 0.15 mg/kg, n=8) or saline (VEH, n=5) starting 4 weeks prior to the surgery and continuing throughout the study. Thus, four treatments were evaluated: rhBMP-2/ACS + bisphosphonate (BP), buffer/ACS + BP, rhBMP-2/ ACS + VEH, and buffer/ACS + VEH. In vivo pQCT scans were acquired prior to surgery, immediately post-op, and 2, 4, 8, and 16 wks after surgery to monitor bone resorption and formation by assessing the size and density of the core defect region. At 2 wks, resorption was evident in the rhBMP-2/VEH group, as the area of the defect was approximately twice the size of the defect immediately after surgery. In addition, the defect area was 70% greater in the rhBMP-2/VEH group than in the other groups ($p<0.05$), which were not different from each other. Between 4 and 8 weeks after surgery, bone density in the core defect began to increase. After 16 weeks, the density in the core defect was highest in the rhBMP-2/BP and rhBMP-2/VEH groups (439 ± 137 and 332 ± 27 mg/cm^3, respectively), equaling or exceeding the baseline bone density in all cases, providing evidence of new bone formation and mineralization. In comparison, the density of the defect in the buffer/ BP and buffer/VEH groups was 203 ± 77 and 248 ± 94 mg/cm^3, respectively. In conclusion, these data confirm that delivery of rhBMP-2/ACS in an intraosseous environment induces transient bone resorption followed by bone formation. Systemic bisphosphonate therapy inhibits the bone resorption induced by rhBMP-2, but does not interfere with the subsequent new bone formation and mineralization.

Stimulation of Bone Formation by Rho-Associated Kinase Inhibitor. K. Itoh,[1] K. Yoshioka,*[1] T. Nakase,[2] H. Yoshikawa.[2] [1]Biology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan, [2]Orthopedic Surgery, Osaka University Medical School, Suita, Japan.

Bone morphogenetic protein (BMP), a potent inducer of bone formation in vivo, promotes differentiation of mesenchymal cells into osteoblasts. This process is regulated by several signal transduction pathways. The small GTPase Rho and Rho-associated protein kinase (p160ROCK) signal participates in a variety of biological functions including vascular contraction, tumor cell invasion, cellular differentiation and penile erection. However, its involvement in osteoblastic differentiation by BMP remains unknown. Continuous delivery of a specific ROCK inhibitor (Y-27632) using osmotic pumps markedly enhanced

ectopic bone formation induced by recombinant human BMP-2 (rhBMP-2) impregnated into an atelocollagen carrier in mice without affecting systemic bone metabolism. Treatment with Y-27632 also enhanced the osteoblastic differentiation of cultured murine neonatal calvarial, and undifferentiated mesenchymal 10T1/2, MC3T3-E1 and ST2 cells with and without rhBMP-2. These effects were associated with an increase in the gene expression of BMP-4. Transfection of ST2 cells with cDNA encoding a dominant negative mutant of ROCK promoted osteoblastic differentiation with increased expression of the BMP-4 gene. Conversely, the expression of a dominant active mutant of ROCK attenuated osteoblastic differentiation and the ROCK inhibitor reversed this phenotype. These results indicate that ROCK plays a negative role in osteogenesis, and a ROCK inhibitor in combination with the local delivery of rhBMP/collagen composite may be clinically applicable for stimulating bone formation.

SA018

Depot Medroxyprogesterone Acetate Contraception and Bone Mineral Density in Adolescent Women

D. Scholes,[1] A. LaCroix,[1] L. Ichikawa,*[1] W. Barlow,*[1] S. Ott.[2] [1]Center for Health Studies, Group Health Cooperative, Seattle, WA, USA, [2]Dept. of Medicine, University of Washington, Seattle, WA, USA.

Use of depot medroxyprogesterone acetate injectable contraception (DMPA) is associated with decreased bone mineral density (BMD), but bone effects in adolescents have received little study. We conducted a cross-sectional evaluation of the effects of DMPA use on BMD in a recently-recruited cohort of 174 adolescents ages 14-18 years. Participants are enrollees of a Washington state HMO who were selected via computerized databases if they had received DMPA (n=81) or were of similar age (comparison group, n=93). BMD was measured using DEXA at the total hip, P-A spine, and whole body. Data on DMPA and on other factors related to BMD acquisition and retention were collected via questionnaire and exam. Overall, 30% of the cohort is $\leq$ 16 years of age, 30% is non-white. Compared to non-users, DMPA users are significantly more likely to be of African-American ethnicity, to smoke, to have been previously pregnant, and to have lower calcium intake. Unadjusted mean BMD values for DMPA users, although lower at all anatomic sites, did not differ significantly from non-users (mean hip BMD=0.940 g/cm^2 vs. 0.970 g/cm^2, for DMPA users and non-users, respectively (p=0.10); and mean spine BMD=0.970 g/cm^2 vs. 0.992 g/cm^2 (p=0.20)). However, BMD declined with increasing DMPA exposure, with a significant trend at the spine:

		Total hip BMD (g/cm^2)	Spine BMD (g/cm^2)
# DMPA injections	**N**	**Mean**	**Mean**
0	93	0.970	0.992
1	24	0.950	0.994
2-3	26	0.943	0.972
4-7	17	0.927	0.960
8+	14	0.930	0.935
p-value for trend		0.08	0.05

These data suggest that, in this group of young women who have yet to attain peak bone mass, adverse effects on bone may accumulate with increasing duration of DMPA use.

RNA Retrieved from Frozen and Archival Osteoarthritic Tissue Utilizing Laser Capture Microdissection. T. Scharschmidt,*[1] R. Jacquet,*[1] J. Hillyer,*[1] S. Weiner,*[2] P. Flanagan,*[2] W. J. Landis.[1] [1]Biochemistry and Molecular Pathology, Northeastern Ohio Universities College of Medicine, Rootstown, OH, USA, [2]Orthopedic Surgery, Summa Health System, Akron, OH, USA.

This laboratory has initiated skeletal tissue studies utilizing novel laser capture microdissection (LCM) to isolate ("capture") single cells directly from sample sections. Coupled with RT-PCR, the approach permits correlation of molecular data with developmental, temporal and spatial features of a specimen. LCM has been applied to frozen, but not paraffinized archival, skeletal tissue. This investigation demonstrates that LCM can be used to retrieve RNA from paraffinized osteoarthritic (OA) human cartilage. OA tissue was obtained from femoral condyles following surgery of elderly patients. Samples were divided with one segment stored in RNAlater (Ambion, Austin, TX) at -20^{o}C and the remainder fixed in 10% neutral-buffered formalin and processed into paraffin within 4 hrs of surgery. The frozen specimens served as controls for comparing gene expression with that derived from paraffinized material that models archival tissue. Frozen samples were mounted with OTC in a cryostat and sectioned 5 µm thick on glass slides. Slides were fixed in 70% ethanol, stained with eosin, and dehydrated through alcohols. Paraffin-embedded specimens were likewise sectioned on slides, dipped in xylene to deparaffinize them, and stained with eosin. Sections were air dried and observed in a Pixcell LCM system (Arcturus Engineering, Mountain View, CA). Capture of 50-1000 chondrocytes was made with an infrared laser of 15 µm diameter, 70 mW power, and 2.5 ms pulse width. RNA from frozen sections was extracted from cells by microisolation (Stratagene, La Jolla, CA) and from paraffinized sections by a paraffin block RNA isolation kit (Ambion). RNA was DNAse-treated and reverse-transcribed. cDNA was amplified by PCR using AmpliTaq ® DNA polymerase (PE Applied Biosystems, Foster City, CA). Negative controls omitted reverse transcriptase. Ethidium bromide gel analysis revealed 18S rRNA from cells isolated by LCM from both frozen and paraffinized OA tissue. rRNA from frozen and paraffin-embedded specimens was detected from ~300 and ~1000 chondrocytes, respectively. Thus, RNA may be retrieved from cells isolated by LCM from both frozen and paraffin-embedded material. Paraffin processing requires greater cell numbers for measurable RNA compared to frozen samples. However, the fact that RNA can be obtained from paraffinized specimens is significant and shows unequivocally that molecular analysis of archival tissue is possible and can be uniquely correlated with temporal and spatial data from the same material.

SA021

Use of a Hip Structural Analysis Program to Estimate Bone Strength in Children Following Burns. G. L. Klein,[1] T. J. Beck,[2] E. G. Briscoe,*[3] J. I. Rosenblatt,*[4] D. N. Herndon.*[5] [1]Pediatrics, University of Texas Medical Branch & Shriners Burns Hospital, Galveston, TX, USA, [2]Radiology, The Johns Hopkins Medical Institutions, Baltimore, MD, USA, [3]Radiology, University of Texas Medical Branch, Galveston, TX, USA, [4]Biostatistics, University of Texas Medical Branch & Shriners Burns Hospital, Galveston, TX, USA, [5]Surgery, University of Texas Medical Branch & Shriners Burns Hospital, Galveston, TX, USA.

Burn injury results in loss of bone mineral content(BMC) and bone mineral density(BMD) over the first 6 mo post-burn, with low bone mineral accretion thereafter. Although annual extrapolated fracture rate is increased post-burn (J Pediatr 1995; 126:252), bone strength has not been assessed. We used the Hip Structural Analysis Program of Beck et al (J Bone Miner Res 2000; 15: 2297), using dual energy x-ray absorptiometric(DEXA) methods to determine sectional modulus(SeM) of the femoral neck(N) and shaft(S) in relation to subperiosteal width(W), cross-sectional area(CSA) and BMD. SeM is an index of bone bending strength; W is one of the dimensions measured in bone area; CSA, the amount of bone in the cross-section, correlates with BMC.Hip DEXA was performed in 21 children, 6-17 yr old, at 6 wk and 6 mo post-burn(range 5-80% body surface area).11 of 14(79%) had a fall in SeM at N regardless of burn size while at S SeM fell in burns >40% but not smaller(p=0.022, Fisher's exact test).CSA fell in 11/14(79%) at N and 9/14(64%) at S. There was a compensatory rise in W in10/14(71%) at N and in 11/14(79%) at S. Changes in SeM from 6 wk to 6 mo were highly correlated with changes in CSA in N and S, r2= 78%. Changes in BMD only accounted for 16% of changes in SeM at either N or S, possibly due to the compensatory increase in W. These data suggest that there is a decline in bone bending strength at the hip at 6 mo post-burn, consistent with the progressive loss of BMC recently reported in burn patients(Hart et al Ann Surg 2001;233: in press).

Osteopontin: Defining the Role of Phosphate Groups in Hydroxyapatite Inhibition. K. A. Robertson,*[1] H. A. Goldberg,*[1] T. M. Underhill,*[1] M. D. Grynpas,*[2] G. K. Hunter.*[1] [1]School of Dentistry, University of Western Ontario, London, ON, Canada, [2]Mount Sinai Hospital, Toronto, ON, Canada

The objective this study is to define which phosphorylated residues are important for the crystal inhibiting activity of osteopontin (OPN). OPN is a phosphorylated glycoprotein that is found in high levels in bone and at sites of ectopic calcification. Previous studies in our lab (Hunter *et al.* Biochem. J. 317, 59; 1996) and in others (Jono *et al.* J. Biol. Chem. 275, 20197; 2000) have demonstrated that OPN is a potent inhibitor of hydroxyapatite (HA) formation, and that phosphorylation of the protein is required for this activity. Native OPN was purified as previously described (Goldberg & Sodek, J. Tissue Culture Methods, 16, 211; 1994). Wild-type OPN was expressed in and purified from *E. coli* using the pET system (Novagen). Wild-type and mutant rat OPN were expressed and purified from rat osteosarcoma (ROS) 17/2.8 cells using mammalian expression vector pcDNA3 (Invitrogen). Mutagenesis of rat OPN cDNA was performed in a pGEM-cloning vector (Invitrogen) using the QuikChange 1-day site-directed mutagenesis kit (Stratagene). A constant composition autotitration assay was developed to test OPN inhibiting activity on *de novo* HA crystal formation. Under the conditions of the constant composition assay, HA formation commenced at approximately 10 minutes and was linear thereafter. Addition of native OPN caused a dose dependent increase in nucleation lag time. From plots of 1/lag time vs. log [OPN], it was calculated that lag time became infinite at approximately 6 ug/ml OPN. Prokaryotic recombinant OPN (non-phosphorylated) had no inhibitory effect on nucleation lag time of HA even at concentrations as high as 10 µg/ml. A mammalian OPN expression system has also been developed in our lab. Four sets of mutant constructs were created at identified sites of serine phosphorylation in rat OPN cDNA (Neame & Butler, Connective Tissue Research, 35, 145; 1996). Serine residues were converted to either alanine or glutamic acid to create two N-terminal mutants (10/11; 46/47) and two C-terminal mutants (250; 257; 262; deletion 295-298). These mutants have been expressed for functional analysis. The findings from this study show that phosphorylation of specific serine residues is required for the HA-inhibitory activity of OPN.

SA023

Function of Osteopontin Deduced from Laser Capture Microdissection and RT-PCR. W. J. Landis, R. Jacquet,* J. Hillyer,* J. Zhang.* Biochemistry and Molecular Pathology, Northeastern Ohio Universities College of Medicine, Rootstown, OH, USA.

Osteopontin (OPN), a phosphorylated glycoprotein, appears to play an important role in extracellular matrix development and ultimate mineralization of certain vertebrate connective tissues such as bone and cartilage. With respect to mineral formation, the precise action of OPN is not entirely clear with current evidence supporting alternative possibilites that the protein may be facilitative or inhibitory to mineral deposition. To gain insight into OPN function, normal growth plate cartilage from 1-11 day-old post-natal mice has been studied here by novel laser capture microdissection (LCM) and RT-PCR to measure OPN gene expression by chondrocytes of known age and specific location in this tissue. LCM identifies individual cells within a tissue section and uniquely isolates ("captures") them for a variety of molecular analyses. In this work, mouse tibiae were dissected and stored in RNAlater (Ambion, Austin, TX) at -20^{o}C. They were then mounted with OTC in a cryostat and 5 µm thick sections of the epiphyseal growth plates were obtained on glass slides, fixed in 70% ethanol, stained with eosin, dehydrated through alcohols, and air dried. Sections were examined in a Pixcell LCM system (Arcturus Engineering, Mountain View, CA) where ~200-1200 cells were captured using an infrared laser of 15 µm diameter, 70 mW power, and 2.5 ms pulse width. RNA was extracted from cells by microisolation (Stratagene, La Jolla, CA), DNAse-treated, and reverse transcribed. cDNA was amplified by PCR with AmpliTaq ® DNA polymerase (PE Applied Biosystems, Foster City, CA). Ethidium bromide gels revealed OPN mRNA from groups of chondrocytes isolated from whole cartilage and resting, proliferating, and hypertrophic zones of the mouse growth plates. Brain cells captured by LCM from the same mouse sections were positive controls and negative controls omitted reverse transcriptase. 18S rRNA was used to standardize expressed message from captured cells. RT-PCR of laser-captured whole cartilage showed a progressive qualitative loss of OPN mRNA as animal age increased. Youngest mice expressed equivalent OPN mRNA over all laser-microdissected cartilage zones. OPN expression in 7-11 day-old mice was greatest in resting and lowest in hypertrophic cartilage. Corresponding histology revealed mineral over only hypertrophic cartilage regions of tibiae beginning with 7 day-old mice. OPN expression correlated with mineral appearance in the tissue suggests that OPN functions to inhibit growth plate mineralization and its loss with increasing tissue maturation would be permissive to mineral onset and development.

Effect of Charged Groups (Carboxymethyl) or Alkaline Phosphatase on the Calcification of Poly (2-Hydroxyethyl) Methacrylate. R. Filmon,* F. Grizon,* M.F. Basle,* D. Chappard. LHEA, Fac Medicine, Angers, France

Poly(2-hydroxyethyl) methacrylate (pHEMA) has been extensively used as a biomaterial with potentially wide applications. The polymer possess numerous properties: it is highly biocompatible and allows the immobilization of cells or bioactives molecules (e.g., enzymes). When obtained by bulked-polymerization in water-free conditions, pHEMA has an hardness comparable to bone. We have found that immobilization of alkaline phosphatase (AlkP) in the pHEMA can initiate mineralization inside and outside the polymer in a manner that mimics the calcification process of cartilage and woven bone. Because numerous proteins known to initiate bone mineralization possess numerous -COOH species, we have modified the neutral electric surface of pHEMA by carboxy-methylation to study the effect of the negatively charged groups on the calcification process in an in vitro assay. pHEMA was prepared by redox polymerisation with benzoyl peroxide and N-N dimethyl paratoluidine. Calibrated pellets of pHEMA were obtained with a great regularity. Carboxymethylation of the pellets was done by reacting with 1M bromoacetic acid in 2M NaOH solution overnight at room temperature under gentle agitation. Pellets of pHEMA, pHEMA-AlkP and carboxymethylated polymer (pHEMA-CM) were incubated during 5, 10 and 15 days in two types of body fluid. A normal concentration of ions (1X) and a 1.5X concentration were used. Pellets were treated in HCl to completely dissolve the hydroxylapatite crystals and Ca and P were dosed. Carboxymethylation significantly increased the amount of deposited Ca by 1.8 folds in the 1X fluid and 15.8 folds in the 1.5X fluid. Presence of AlkP increased considerably the amount of deposited Ca: 25.9 folds in 1X and 23.3 in 1.5X. ROS 17/2.8 osteoblast-like cells were seeded on the three materials and examined by confocal microscopy after staining with Alexa Fluor 488 phalloidin. Cells grown on pHEMA alone appeared round while cells grown on the crystals deposited on the pHEMA-CM or pHEMA-AlkP were flattened. The presence of AlkP favours the mineralisation process more than the existence of surface negative groups on the polymer. Cells preferentially adhere to the polymer when hydroxylapatite crystals have developed.

High Concentrations of Urea Alters the Normal Patterns of Chondrogenesis of Limb Mesenchyme In Vitro. C. V. Andrade,*[1] M. A. Mello,[1] M. E. L. Duarte.[2] [1]Universidade Federal Fluminense, Rio de Janeiro, Brazil, [2]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Growth retardation secondary to chronic renal failure has a complex and multifactorial pathogenesis. Basically the extent of growth is determined by endochondral bone formation. Thus, the investigation of diminished linear growth in children with renal failure must include the epiphyseal growth plate. The present study was undertaken to test the possibility that in high concentrations, urea influences the proliferation and maturation of chondrocytes and therefore the determination of bone growth rates. We have used the embryonic limb mesenchyme micromass culture system to investigate the influence of high concentrations of urea on chondrocyte proliferation and maturation *in vitro*. The cells were cultured in DMEM/F12 medium containing 10% FCS and 20-200mg/dl of urea. At regular time points cultures were harvested for posterior analysis. The proliferative potential of the cells were assessed by proliferating cell nuclear antigen (PCNA) immunostaining and by [^{3}H] thymidine uptake. The maturation process was investigated by cell diameter and ECM amount measured microscopically, and by alkaline phosphatase activity. Programmed cell death was determined by terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL). In cultures treated with 200mg/dl of urea, PCNA immunoreactivity was detected only in a smalll number of cells and became negative with time in culture. [^{3}H] thymidine uptake was significantly lower ($p<0.01$) in all time points as well as alkaline phosphatase activity. In high concentrations of urea (≥100mg/dl) the cells were smaller ($p<0.001$) and synthetized a lesser amount ($p<0.01$) of extracelullar matrix. Apoptosis was detected as early as day 7 in a high percentage of the cells. Data from the present study have suggested that urea induces a concentration-dependent reduction of cell number accompanied by decreased ECM synthesis. The decrease in cell number results from inhibition of cell proliferation and from increased cell death by apoptosis.

Evidence for the Sequential Cleavage of Aggrecan in IL-1 Stimulated Bovine Articular Cartilage. S. M. Blake,[1] S. M. Hwang,*[2] B. Swift,*[2] A. M. Badger,*[2] T. Newman-Tarr,*[2] B. Bradley,*[2] I. E. James,[2] M. Gowen,[2] S. Kumar,[2] M. W. Lark.[2] [1]Muscoloskeltal Diseases, GSK Pharmaceuticals, King of Prussia, PA, USA, [2]GSK, King of Prussia, USA.

The ability of the large proteoglycan aggrecan to swell and hydrate the collagen fibrils in articular cartilage is central to its function of conferring (or imparting) compressibility and resilience to this tissue. Loss of aggrecan can therefore lead to cartilage degradation and, eventually, loss of joint function as exemplified pathologically by osteoarthritis. Two aggrecanase (1 and 2) enzymes, have recently been cloned. These enzymes are members of the A Disintegrin And Metalloprotease with ThromboSpondin motifs (ADAMTS) family of enzymes and are now referred to as ADAMTS-4 and -5. At least five specific sites, one within the interglobular domain (IGD) and four within the chondroitin sulphate (CS) rich domain of purified bovine aggrecan have been shown to be cleaved by recombinant ADAMTS4. It is still unclear if either ADAMTS 4 or 5, have the ability to generate these fragments in intact native cartilage. In the present study we have used a model system of interleukin-1 (IL-1) mediated matrix degradation of bovine articular cartilage (BAC) to further define the process of aggrecanase mediated aggrecanolysis. Anti-sera generated against two of the proposed CS rich domain cleavage sites as well as the sites within the IGD were used to follow the generation of these neoepitopes remaining within or released from the native articular cartilage by immunocytochemical, Western blot and histochemical techniques. Sections from BAC stimulated with IL-1 for 7 days resulted in an increased staining for the CS rich domain and IGD cleavage sites within the cartilage matrix compared to the unstimulated controls. Serial sections stained with safranin O to detect glycosaminoglycan (GAG) revealed that in the matrix in which GAG content remained high, only CS rich domain cleavage neoepitopes were detectable. Areas of matrix devoid of GAG were strongly immunopositive for the IGD neoepitope. Extending the period of IL-1 stimulation to 18 days resulted in loss of the neoepitopes for the CS rich domain cleavage sites. The intensity of staining for the IGD domain neoepitope was also diminished. Taken together these results suggest that IL-1 induced aggrecanolysis in cartilage occurs sequentially, originating in the CS rich domain of aggrecan prior to cleavage in the IGD domain.

Characterization of Cartilage Sub-types in the Rabbit. J. E. Dennis,[1] A. Naumann,*[2] A. Awadallah,*[3] A. I. Caplan.*[3] [1]Department of Biology, Case Western Reserve University, Cleveland, OH, USA, [2]Department of Otorhinolaryngology, Head and Neck Surgery, Ludwig-Maximilians-University, Munich, Germany, [3]Department of Biology, Case Western Reserve University, Cleveland, OH, USA.

The purpose of this study is to characterize the elastic, hyaline, and fibrous sub-types of cartilage from rabbit by immunochemical localization of extracellular matrix components, biomechanical testing, and glycosaminoglycan (GAG) content. Native cartilage was obtained from several 4-month-old male White New Zealand rabbits. Hyaline (nasal septum, articular), elastic (auricle, epiglottis), and fibrocartilage (meniscus) were removed and either fixed in 10% neutral buffered formalin for immunochemistry or placed in 0.1 M sodium chloride plus protease inhibitors for mechanical testing. For immunohistochemical staining, sections were incubated in 1 mg/ml pronase in PBS and immunostained with antibodies to collagen types I, II, V, VI, X, and elastin. Total GAG content was assayed by colorimetric intensity of saffranin-o, as previously described (1). The intrinsic material properties (aggregate modulus, Poisson's ratio, and permeability) of the different cartilage subtypes were derived from an indentation assay (2)Immunohistochemical staining revealed distinctive patterns of staining for each of the cartilage sub-types. Table I summarizes the intensity of staining within three sub-zones of the matrix: the matrix proper, the pericellular region, and the cellular region. GAG content assays showed that articular and nasal cartilage contain nearly 4 times the amount of GAGs than auricle and epiglottis; meniscus was intermediate in GAG content. The biomechanical testing showed significant differences in material stiffness (aggregate modulus) between cartilage sub-types, with auricle and nose cartilage having similarly high stiffness followed by articular, epiglottis and meniscus. These studies document that distinctive subtypes of cartilage can be identified by immunohistochemistry, and provides a basis for asking whether transplanted chondrocytes change their matrix and mechanical properties to match the transplant environment or retain the properties of the tissue of origin. A Metabolite of Estrogen, 2-Methoxyestradiol, Suppresses Proliferation and Induces Apoptosis in Rat Growth Plate. J. D. Sibonga, U. Sommer,* R. T. Turner. Orthopedic Research, Mayo Clinic, Rochester, MN, USA.

2-Methoxyestradiol ($2ME_2$), a metabolite of 17ß-estradiol, antagonizes both angiogenesis and induces apoptosis in some tumor cell lines. Suppressive effects on bone longitudinal growth have been previously reported in young rats. We examined the cellular response of growth plate chondrocytes to $2ME_2$ in ovariectomized rats. In a 21-day dose response study (0, 4, 20 and 75 mg/kg), $2ME_2$ was administered orally to recently ovariectomized rats at 10 weeks of age. Five untreated control rats and 5 rats each from higher-dosed $2ME_2$-treated groups (20 and 75 mg/kg/d) were pulsed-labeled with tritiated thymidine 2 hrs before sacrifice. Chondrocyte proliferation was evaluated with radioautography. Apoptosis-induced DNA fragmentation was detected by TUNEL assay. Longitudinal growth rates were determined with fluorochrome labeling. $2ME_2$ reduced the height of the growth plate ($p<0.05$). $2ME_2$ suppressed bone elongation ($p<0.05$), decreased the number of proliferating chondrocytes labeled with tritiated thymidine ($p<0.05$), and increased the percentage of hypertrophic chondrocytes that were apoptotic ($p<0.05$). An additional 2 x 2 experiment with weanling rats treated for one week with ± $2ME_2$ (4 mg/kg/d) or ± ICI 182,780 (1.5 mg/kg) indicated that ICI 182,780 had effects consistent with estrogen antagonism but did not influence the skeletal response to $2ME_2$. Furthermore, the one-week treatment with $2ME_2$ had no effect on the size of hypertrophic chondrocytes in weanling rats suggesting that $2ME_2$ does not influence the production of cartilage matrix. We conclude that $2ME_2$ 1) reduces the number of growth plate chondrocytes by suppressing proliferation and accelerating apoptosis, 2) has no impact on the matrix production by hypertrophic chondrocytes and 3) induces these actions through a non-estrogen receptor pathway.

Identification and Tissue-Specific Expression of Connective Tissue Genes that are Upregulated in Postnatal Chondroinduced Human Dermal Fibroblasts. K. E. Yates,[1] J. Glowacki.[2] [1]Skeletal Biology Research Center, Massachusetts General Hospital, Charlestown, MA, USA, [2]Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA.

Demineralized bone powder (DBP) induces postnatal endochondral bone formation in vivo and is now widely used for skeletal repair and reconstruction. We developed a novel chondroinduction system [Exp Cell Res 227:89, 1996] in which normal human dermal fibroblasts (hDFs) develop a chondrocyte phenotype (collagen type II, aggrecan) after 7 days in culture with DBP [Mat Sci Eng C6:199, 1998]. We used representational difference analysis, a PCR-based method of subtractive hybridization, to identify genes whose expression was altered by cellular interaction with DBP on day 3. Several functional families of genes (extracellular and cytoskeletal elements, protein synthesis/trafficking) were Upregulated early in chondroinduction [Exp Cell Res 265:203, 2001].In this study, we identified additional upregulated genes and surveyed their expression in adult tissues. Differentially expressed cDNAs were used to design and validate PCR primers. We prepared total RNA from human skin, articular chondrocytes isolated from osteoarthritic cartilage, cancellous bone, and bone marrow low-density mononuclear cells. RNA was treated with DNAse I and used in random hexamer-primed cDNA synthesis reactions for RT-PCR. Among the genes that were Upregulated in chondroinduced hDFs were several connective tissue genes that encode collagens (COL11A1, COL3A1, COL6A3), collagen receptors (α-11 integrin, β-1 integrin), and post-translational enzymes (lysyl hydroxylase 2, lysyl oxidase, lysyl oxidase-like protein 2). All of those genes were expressed in articular chondrocytes. In contrast, only a subset was expressed in skin (Table). Thus, several connective tissue genes identified as Upregulated in chondroinduced hDFs were expressed in cartilage but not in skin.

Gene	Skin	Chrondrocytes	Bone	Marrow
α-11 integrin	-	+	-	+
COL11A1	-	+	+	-
Lysyl hydroxlyase 2	-	+	+	+
Lysl oxidase	+	+	+	+
Lysyl oxidase-like protein 2	+	+	+	+
COL3A1	+	+	+	-
COL6A3	+	+	+	+
β-1 integrin	+	+	+	+

These data indicate that specific gene shifts in functional families occurred prior to full expression of cartilage-specific matrix genes and synthesis of extracellular matrix. Taken together, specific changes in architectural, matrix and functional genes characterize early events in chondroinduction. These changes may create an environment supportive of postnatal chondrogenesis. Such signals may be necessary because normal postnatal tissues lack the regulatory signals found in programmed milieux of embryonic tissues.

Expression and Regulation of Proline-rich Transcript of the Brain (prtb) in Osteoblasts. D. W. Sommerfeldt,[1] J. Zhi,*[2] C. T. Rubin,[3] M. Hadjiargyrou.[3] [1]Department of Trauma and Reconstructive Surgery, Hamburg University Hospital, Hamburg, Germany, [2]Center for Biotechnology, State University of New York at Stony Brook, Stony Brook, NY, USA, [3]Department of Biomedical Engineering, State University of New York at Stony Brook, Stony Brook, NY, USA.

To characterize the temporal expression of genes that play a functional role during the process of osteoblast adhesion we used differential display (DD-PCR) on mRNA from attached vs. suspended osteoblasts. A 200-bp fragment showing upregulation after 30 min and 60 min adhesion, was sequenced and showed 97% homology to prtb, a transcript previously only known to be expressed in mouse brain. Northern analysis confirmed a two-fold increase in prtb message during adhesion to tissue culture polystyrene, both in the presence and absence of surface-adsorbed serum proteins. Serum stimulation alone was also able to induce prtb expression, although to a lesser extent (1.5-fold), in cells in forced suspension (see figure below). In a tissue blot experiment strong expression in brain and

bone of adult rats could be detected. Furthermore, prtb expression analysis during osteoblast differentiation revealed high transcription levels independent of proliferation (day 0-7), matrix maturation (day 7-14), and mineralization (day 14-31). Time course analysis of prtb expression during adhesion of sensitized osteoblasts to serum-protein coated surfaces showed detectable mRNA at 5 min post plating and a peak at 10 min. Comparison with the two known serum-inducible immediate early genes c-fos and c-jun showed similar kinetics, with c-jun expression peaking at 15 min and c-fos expression at 20 min.Taken together, these data lead to the hypothesis of prtb functioning as an immediate early, serum-responsive and adhesion-inducible gene and are consistent with a possible involvement in processes such as cell cycle control, proliferation and adhesion.

The Human Extracellular Matrix Signal Molecule hCYR61 Expression is Associated with Conditions of Enhanced Bone Formation and with the Proliferative State of Osteoblasts. N. Schuetze,*[1] J. A. Hoyland,*[2] H. Siggelkow,[3] J. Pfeufer,*[4] C. Hendrich,*[4] J. Eulert,*[4] F. Jakob.*[5] [1]Labor fuer Molekulare Experimentelle Orthopaedie, Orthopaedische Universitaetsklinik, Wuerzburg, Germany, [2]Musculoskeletal Research Group, School of Medicine, Manchester, United Kingdom, [3]Schwerpunkt Endokrinologie, Universitaetsklinik Goettingen, Goettingen, Germany, [4]Orthopaedische Universitaetsklinik, Wuerzburg, Germany, [5]Medizinische Poliklinik, Wuerzburg, Germany

The human cystein-rich protein 61 (hCYR61, CCN1) belongs to a gene family (CCN family) whith plays a role in growth and differentiation, migration, adhesion, wound healing and angiogenesis. Previously, we showed that hCYR61 in human osteoblasts is regulated by 1,25(OH)2-vitamin D3 and growth factors at the mRNA and the protein level. The protein functions as an extracellular signaling molecule. This study was aimed to analyze the hCYR61 expression in human bone samples and in corresponding in vitro systems. Using a 1.5 kB cRNA probe to hCYR61 in in situ hybridization normal bone did not show expression of hCYR61 mRNA. In contrast human bone samples from fracture callus displayed expression of hCYR61 in osteoblasts and mesenchymal cells at sites of new bone formation. Applying immunohistochemistry with a polyclonal anti mouse CYR61 antiserum which crossreacts with the human protein, normal bone and cartilage samples did not show detectable hCYR61 protein. Again samples from fracture callus displayed highly positive staining at chondrocytes, mesenchymal cells and osteoblasts. In addition samples from heterotopic ossifications revealed positive staining on surfaces of mineralized structures. Samples from a human growth plate from a digitus of a 2 year old child indicated high hCYR61 expression in hypertrophic chondrocytes as was controlled by collagen X staining. Using hFOB-cells and primary osteoblasts of different maturation stages a high expression of the hCYR61 protein in proliferating cells was observed whereas differentiated cells revealed much lower signal intensity. In contrast, human chondrocyte cell lines T/AC62, T/C-28a and C-28/I2 displayed a high expression at the mRNA and protein level.hCYR61 expression was observed in situations of enhanced bone turnover/bone formation. Particularly, the expression of hCYR61 in fracture callus points towards a role during fracture repair. hCYR61 could be involved in endochondral ossification as is suggested by the expression at the human growth plate. The expression of hCYR61 in the proliferating stage of osteoblasts could indicate a role in amplifying precursors for bone formation. Thus hCYR61 in human bone combines angiogenic as well as osteogenic activities.

In Situ Analysis of Aggrecanase 1 and 2 Expression in Adult Human Normal and Osteoarthritic Articular Cartilage. J. R. Connor,[1] S. Blake,[2] S. M. Hwang,*[2] M. Gowen,[2] M. W. Lark,[2] S. Kumar.[2] [1]Musculoskeletal Diseases, GlaxoSmithKline, King of Prussia, USA, [2]GlaxoSmithKline, King of Prussia, USA.

The degradation and loss of the proteoglycan, aggrecan, one of the hallmarks of osteoarthritis (OA), results in cartilage degeneration and loss of joint function. The evidence for aggrecanase activity in human cartilage has been demonstrated with the detection of metabolic fragments of aggrecan (1). Recently, two members of the ADAMTS (a disintegrin and metalloproteinase with thrombospondin motif) protein family,ADAMTS4(aggrecanase 1) and ADAMTS5 (aggrecanase 2) were cloned and characterized (2,3). This study examined the in situ expression patterns of aggrecanase 1 and 2 mRNA and protein in adult human normal and OA articular cartilage. For in situ hybridization, cryostat sections of normal or OA cartilage were hybridized with 35S-labelled riboprobes to aggrecanase 1 and 2. For immunohistochemical studies, floating sections of cartilage were stained using antibodies generated against peptides derived from the catalytic domains of aggrecanase 1 and 2. By in situ hybridization analysis, aggrecanase 1 mRNA expression was variable between patient samples with similar stages of OA. Additionally, the level of expression varied between the superficial, mid- and deep zone chondrocytes. Aggrecanase 2 mRNA expression could be detected at high levels in some normal and OA cartilage samples. However, some samples which were positive for the expression of aggrecanase 1 had low levels of aggrecanase 2 mRNA expression. Similarly, by immunohistochemistry, aggrecanase 1 protein was detected at high levels in some samples of OA cartilage, while others expressed low levels of the protein. Additionally, the pattern of expression between the superficial, mid- and deep zones varied between samples. Aggrecanase 2 was detected in some OA cartilage, but was lower in most samples when compared to aggrecanase 1. In summary, aggrecanase 1 and 2 mRNA and protein could be detected in adult human normal and OA articular cartilage. Overall, the expression was highly variable between patient samples of cartilage with similar stages of OA. This apparent lack of coordinated aggrecanase expression has been suggested by previous studies (1). An increased understanding of the regulation and control of aggrecanase expression will provide valuable insights for the development of inhibitors of cartilage degradation in OA.Refs 1)Lark MW et al (1997) J Clin Invest 100, 93-106; 2) Tortorella MD et al (1999) Science 284, 1664-1666; 3) Abbaszade I et al (1999) J Biol Chem 274, 23443-23450.

Heparanase mRNA Expression during Fracture Repair. M. Saijo,*[1] R. Kitzazawa,[1] M. Nakajima,*[2] S. Maeda,*[1] S. Kitazawa.[1] [1]Division of Molecular Pathology, Kobe University Graduate School of Medicine, Kobe, Japan, [2]Novartis Pharma K.K., Research, Tsukuba, Japan

During fracture repair, cartilaginous callus is generated first and then gradually replaced by bony callus. Since angiogenesis is requisite to the recruitment of osteoclasts for the destruction of cartilage, vascular endothelial growth factor (VEGF) is thought to play a role in endochondral ossification. VEGF isoforms ($VEGF_{165}$, $VEGF_{189}$) bind heparan sulfate proteoglycans (HSPG) of the extracellular matrix and are stored in the cartilage and bone matrices. Heparanase is an endoglucuronidase which degrades heparan sulfate and HSPG, and releases heparin-binding growth factors including VEGF. We investigated the mechanism of VEGF recruitment at the boundary of the cartilaginous and bony callus of the fractured bone. After closed fractures were made on the proximal tibia of 12 week-old BALB/c mice, the bones were excised on days 3, 5, 7, 10, 14, 21 and tissue sections were prepared. Blood vessels were assessed by CD34 immunohistochemistry. The localization of VEGF and HSPG was assessed by immunohistochemistry and that of heparanase mRNA by *in situ* hybridization (ISH). The cDNA of mouse heparanase was amplified by RT-PCR, and the digoxigenin-labeled single stranded antisense DNA probe was prepared by unidirectional PCR. Osteoblastic cells of newly formed bone were detected by ISH for osteonectin. Osteoclasts were assessed by TRAP staining. At the initial stage (day 3; hematoma/ inflammatory phase), no signal for heparanase was detected. On day 5 when mesenchymal cells differentiated into chondrocytes and small vessels were formed, a few mature osteoclasts and TRAP-positive precursors expressed heparanase mRNA. On days 7-10 at the endochondral ossification site, VEGF and HSPG were colocalized in hypertrophic chondrocytes. Numerous osteoclasts, resorbing cartilaginous tissue, strongly expressed heparanase mRNA, which was followed by capillary vessel formation and woven bone with osteonectin-positive osteoblasts. On days 14-21 in the woven bone tissue, osteoblasts positive for VEGF and osteoclasts expressing heparanase were observed. These data suggest that VEGF, produced by chondrocytes and stored in HSPG, was released by heparanase from osteoclasts to promote blood vessel formation. Thus osteoclasts may contribute to the promotion of local angiogenesis as well as to the destruction of callus. Mesenchymal cells and osteoclasts, therefore, jointly contribute to local angiogenesis in endochondral ossification during fracture healing.

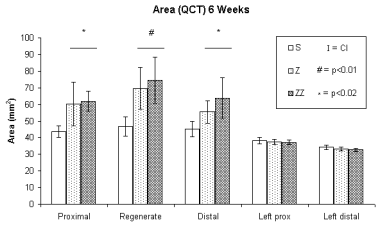
Zoledronic Acid Enhances Bone Formation and Mineralization in Distraction Osteogenesis in Immature Rabbits. D. G. Little,*[1] P. R. Williams,*[1] N. C. Smith,*[1] E. J. Smith,[1] J. Briody,*[2] C. T. Cowell,[3] L. E. Bilston.*[4] [1]Orthopaedic Research Unit, Children's Hospital at Westmead, Sydney, Australia, [2]Nuclear Medicine, Children's Hospital at Westmead, Sydney, Australia, [3]Endocrinology, Children's Hospital at Westmead, Sydney, Australia, [4]Mechanical Engineering, University of Sydney, Sydney, Australia

Poor bone formation and stress shielding remain problematic in distraction osteogenesis. We hypothesized that zoledronic acid would address both issues. 42 male 8-week-old NZW rabbits underwent right tibial osteotomy. 14 animals received saline (S), 14 zoledronic acid 0.1mg/kg at surgery (Z), and 14 zoledronic acid 0.1 mg/kg at surgery and two weeks post-op (ZZ). We distracted 10 mm over 2 weeks, followed by 4 weeks consolidation. 30 rabbits had DXA at 2, 4 and 6 weeks for BMC and BMD in 10 mm regions in

regenerate bone and also in the proximal and distal segments. Two equivalent segments were examined in the left (non-operated) leg. QCT was performed at 6 weeks for vBMD and cross sectional area. 4-point bend testing of all tibiae was performed in a standard manner. 12 rabbits underwent histologic analysis at 6 weeks.Bone mineral accretion in the distraction gap of the operated (right) tibia was significantly higher in both Z and ZZ versus S groups between 2 and 4 weeks, and was better maintained at 6 weeks (P<0.01 ANOVA). Stress shielding osteopenia seen in surrounding bone segments in S was abolished in Z/ZZ tibia, with significant increases in BMD and BMC (P<0.01 ANOVA). Cross sectional area increased 49% at 6 weeks in the regenerate in Z, and 59% in ZZ (Fig. 1). We also noted increased cross sectional area in surrounding segments. Z tibiae were 29% stronger in 4-point bending, while ZZ were 89% stronger than S (P<0.01 ANOVA). There was little detectable effect on the non-operated tibiae. Lamellar bone and TRAP positive osteoclasts were present in the regenerate bone at 6 weeks, consistent with active remodelling, despite zoledronic acid administration.



Zoledronic acid administration significantly increased bone area and matrix mineralization in this distraction osteogenesis model. The increases in bone area and retention of mineral despite stress shielding translated into a significant, dose-dependent increase in strength. Further research into the role of zoledronic acid as an adjunctive therapeutic agent in orthopaedic surgery is indicated

The Role of Angiogenesis in the Soft Callus of Long Bone Fracture. J. L. Ford,* D. E. Robinson,* B. E. Scammell. Orthopaedic and Accident Surgery, Nottingham University, Nottingham, United Kingdom

This study was conducted to examine angiogenesis within the cartilage of the soft callus in long bone fractures and to investigate its role in the bone remodelling process.A standardised tibial osteotomy was performed on New Zealand white rabbits, sacrificed at week 1,2,3 and 6 post-osteotomy. Tissue was processed and immunohistochemical techniques were employed to localise vessels using an endothelial cell marker. Basic fibroblastic growth factor (bFGF) was localised as it is known to induce angiogeneisis and initiate proteolysis. Urokinase plasminogen activator (uPA) was immunolocalised to investigate its possible action in the degradation of the cartilage matrix and osteonectin was identified to examine its potential role in the bone remodelling process. A blind arbitrary scoring system was employed to compare the degree of immunoreactivity in different locations within the tissue and at different time points post-osteotomy. Fracture tissue was stained with Sirius red and Alcian blue to examine the bone and cartilage matrix respectively. Electron microscopy was carried out to examine the matrix surrounding the soft callus in more detail.Results revealed that blood vessels formed around and within the soft callus tissue by week 1 post-osteotomy and that vascularisation increased in these areas during the weeks that followed. Osteonectin, bFGF and uPA was localised within the haematoma during the first week and within blood vessels in the following weeks. From week 2 post-osteotomy, uPA was detected in the cartilage of the soft callus and bFGF exhibited a pericellular distribution around the chondrocytes of the soft callus. Histology and TEM revealed that collagen I fibres of the bone matrix formed amongst the chondrocytes at the edge of the soft callus and in areas where cartilage tissue was adjacent to infiltrating vessels. The results indicate that blood vessels newly form in the soft callus as a result of injury and that angiogenesis plays a crucial role in the removal of the cartilage matrix and the formation of new bone in this area. The observed presence of bFGF and uPA in vessels strongly suggests that they are involved in the initiation of angiogenesis and proteolytic activity within the soft callus. Following angiogenesis, bone-producing cells appeared to initiate the production of bone matrix at the edge of the soft callus, infiltrating the cartilage tissue, thus eventually replacing the soft callus with bone matrix. The results presented indicate that angiogenesis within the soft callus is a physiological response to fracture and is likely to play a vital role in the healing process of long bone fractures.

Observation on Interstitial Fluid Flow in the Lacunar-Canalicular Network. S. Qiu, S. Palnitkar,* D. Rao. Bone and Mineral, Henry Ford Hospital, Detroit, MI, USA.

Bone fluid flow plays a fundamental role in the maintenance of osteocyte viability and the regulation of bone modeling and remodeling. To date, there is little empirical data for evaluating the characteristics of bone fluid flow due to lack of appropriate model. In this study, we developed a new methodology to assess interstitial fluid flow in the lacunar-canalicular spaces. Two fluorescent tracers, Evens blue (red) and isothiocyanate (FITC)-dextran (blue), were perfused intravenously in 12 rats and the tibial diaphyses were examined using confocal microscopy. Three different methods (3, 3 and 6 rats in each group) were used to determine the characteristics of fluid flow in the lacunar-canalicular network.1) FITC-dextran was perfused 1 hour before sacrifice and then the bone section was placed in basic fuchsin (red) for 24 hours, which was able to stain the entire lacunar-canalicular network. The lacunae stained with basic fuchsin were all overlapped by those labeled with FITC-dextran. 2) Both tracers were perfused simultaneously 1 hour before sacrifice. The lacunae with different tracers were completely overlapped, but the intensity of their fluorescence was not uniform in the entire lacunar-canalicular network.3) Two tracers were perfused at different times with one hour interval. The rats were sacrificed 1 minute after second perfusion. The rate of fluid flow was calculated by the percentage of overlapped lacunae labeled with different tracers. In this model, the tracer perfused 1 min before sacrifice occupied about 60% of the total lacunae labeled by the first perfusion. Compared with the periosteal side, the majority of lacunae containing second perfused tracer were located in the endosteal side (Fig).The results suggest: 1) one hour is long enough for tracers to penetrate into the entire lacunar-canalicular network, which can be used as control; 2) osteocytes can receive new fluid supply within 2 minutes and 3) the pattern of fluorescent intensities suggests that the interstitial fluid in the lacunar-canalicular network is provided by intermittent bulk volume infusion rather than continues diffusion

Reciprocal Interaction Between Human Endothelial Cells and Human Bone Marrow Stromal Cells Seems to be Mediated by the Production of Nitric Oxide. B. Guillotin, F. Villars, R. Bareille, L. Bordenave, J. Amedee. U443-INSERM Université Victor Segalen Bordeaux 2, Bordeaux, France

Recent studies revealed that vascular endothelial cells may be pivotal members of complex interactive communication network in bone with the others cell types. Our previous data demonstrated that Human Umbilical Vein Endothelial Cells (HUVEC) and Human Bone marrow Stromal cells (HBMSC) are coupled and that connexin43 may be involved in this heterotypic interaction between these two cell types. This coupling between HUVEC and HBMSC seems to be responsible of the increase of the osteoblastic phenotype (alkaline phosphatase activity, type I collagen synthesis) observed in HBMSC co-cultured with HUVEC. The aim of our study is to explore the signal transduction pathways involved in this cellular interaction. HBMSC were cultured alone in IMDM+10% FCS or with direct contact with HUVEC for 6 days in presence or not with inhibitors of NO synthase (NOS) (5-20µM aminoethylsothiouronium-bromide AET), guanylate cyclase (10µM NS 2028) or Phospholipase C (20µM U73122). These selected concentrations were choosen for their absence of cytotoxicity for HUVEC and HBMSC measured by MTT assays. Cell differentiation was evaluated by the measurement of alkaline phosphatase activity. Using RT-PCR analysis we have investigated the presence of isoforms of NOS (eNOS or iNOS) in both cell types. Among the different targets (phospholipase C, GMPcyclase, NO synthase) reached in our experiments, NO production in these cocultures could play a fonction in the enhancement of the osteoblastic phenotype of HBMSC observed only in direct contact with HUVEC. AET treatment of the coculture at 5,10 or 20µM for 6 days totaly abolished the increase of alkaline phosphatase activity observed in coculture with HUVEC, while the same treatment of HBMSC cultured alone did not modify the enzymatic activity. In conclusion, HUVEC could be considered as a NO donors such as sodium nitroprusside (SNP) tested in our coculture at 100 µM. The next step of our work will consist to establish the relation between the function of connexin43 in this coupling and the production of NO able to travel rapidly between cells through the membrane including perhaps gap jonctions. Others biological mediators involved in this transduction pathways do not be excluded from these investigations.

Isolation and Characterization of Preosteoblastic Cells from Human Long Bone Marrow. L. X. Bi, D. Yngve,* W. L. Buford,* E. Mainous.* The University of Texas Medical Branch, Galveston, TX, USA.

Long bone marrow contains stromal mesenchymal cells that are capable of differentiating into osteoblast cells. Our previous study demonstrated that bone marrow stromal cells comprise several physiologic populations which present a continuum of growth, osteogenic activity. To investigate the osteoblast precursor cells, we have isolated preosteoblasts (marrow sac cells) from the out surface of bone marrow of femoral bone and examined expression of bone morphogenetic protein-2 (BMP-2) and osteocalcin immunocytochemically, and alkaline phosphatase (ALP) histochemically. The human preosteoblast cells were cultured in a-minimum essential medium (a-MEM) and mineralizing medium (a-MEM, Dexamethasone (10^{-8}M), beta-glycerol phosphate (10mM) and ascorbic acid (50ug/ml)) containing 10% FBS for 7 days. Examinations for ALP and BMP-2 (anti-rhBMP-2 monoclonal antibody) and osteocalcin (monoclonal anti-osteocalcin antibody) were performed using commercial kit (Sigma Chemical Co., St. Luis, MO and VECTEASTAIN *Elite* ABC kit Vector Laboratories, Inc. Burlingame, CA). In control medium, the BMP-2 and osteocalcin were detectable in osteoblast precursor cells. The cells were moderately stained for ALP. In mineralizing medium, the expression of ALP was enhanced. The intensity of immunostaining for BMP-2 was significantly increased, for osteocalcin was unchanged, compared to that in a-MEM medium. Taken together, the results indicated that the preosteoblast cells could respond to mineralizing substances to differentiate into osteoblasts by increasing expression of some osteoblastic markers. In conclusion, we have established a new method for isolating and characterizing osteoblast precursor cells which reside proximate to endosteal osteoblasts from long bone marrow. These cells can be induced to differ-

entiate into cells exhibiting the osteoblast phenotype. They could be considered to be an osteogenitor pool from which replacement osteoblasts are normally recruited in vivo. This method provides a new tool to study the regulation of normal bone formation and bone diseases (osteoporosis , osteopenia etc.).

Selective Induction of Opn Expression in Osteoblasts Is Mediated by Different Integrin Ligands. R. S. Carvalho,*[1] P. J. Kostenuik,*[2] A. Bumann,*[3] E. Salih,*[4] L. C. Gerstenfeld.[5] [1]Orthopedic Surgery, Boston University, Boston, MA, USA, [2]Amgen, Thousand Oaks, CA, USA, [3]University of Southern California, Los Angeles, CA, USA, [4]Children's Hospital, Boston, MA, USA, [5]Boston University, Boston, MA, USA.

Bone remodeling is partly regulated by the mechanical environment of skeletal cells. However, some forms of signals derived from mechanical stimulation are only perceived by cells after adhesion has taken place. Therefore, signal transduction and gene expression events activated by the latter maybe similar, if not identical, to those induced by integrin-mediated cell adhesion. Recent studies have shown that osteopontin (OPN) mediates osteoblastic and osteoclastic interaction with the mineralized matrix. Thus, OPN is both associated with remodeling and formation. These studies examined whether osteoblasts discriminate cellular interactions with ECM ligands to mediate opn mRNA expression. Embryonic chicken calvaria osteoblasts were plated using identical cell numbers in plates coated with fibronectin (FN) (1mg/ml), collagen type I (ColI)(1mg/ml), denatured collagen type I (gelatin-G)(1mg/ml), osteopontin (OPN)(1mg/ml), vitronectin (VN)(1mg/ml), laminin (LN)(1mg/ml) or poly-L-lysine (pLp). Subsequently, a determination of the intracellular second signaling systems (protein kinases A and C) that are responsible for mediating the opn gene expression to cellular adhesion were determined. Finally, we evaluated the intracellular distribution of focal adhesion kinase (FAK), p-tyrosine (PT) and vinculin (VN) on surfaces coated with FN or pLp. Results indicated that FN generated the strongest induction of opn expression followed by Col1 and LN. While G was weakly inducing, neither OPN, pLp or VN was capable of inducing opn mRNA expression, suggesting that the latter molecules did not facilitate specific cell adhesion. Induction of PKA and PKC occurred concomitantly only in osteoblasts from FN-coated dishes, while the other ligands promoted PKA solely. Thus, specific effects on kinase activities appear to be dependent on the selective ligand interactions, which are distinct from that of cell adhesion alone. Similarly, osteoblast adhesion did not appear to alter the general intracellular localization of FAC or VN. By contrast, a strong induction was noted for PT with generalized changes of its distribution throughout the cells after adhesion was promoted with a specific integrin binding ligand. Taken together with the opn-mediated gene expression results, these data suggest that induction of intracellular second signal kinase activity are related to the specific nature of the ligand's interactions with the receptor and less with the process of cellular-mediated adhesion alone.

Increased IGF Binding Protein-5 (IGFBP-5) in Extracts of Cancellous Bone Matrix in End-Stage Osteoarthritis. C. A. Sharp,[1] S. J. Brown,*[1] P. Magnusson,[2] M. W. J. Davie,[1] S. Mohan.[2] [1]Charles Salt Centre, RJ&AH Orthopaedic Hospital, Oswestry, United Kingdom, [2]Jerry L Pettis VA Medical Center, Loma Linda, CA, USA.

End-stage osteoarthritis (OA) in the femoral head (FH) is associated with increased matrix turnover and architectural changes to cancellous bone. Of the molecular signals contributing to skeletal changes in OA, we considered IGFs as potential candidates based on their known actions and abundance in bone. IGF actions are modulated by IGF binding proteins (IGFBP). IGFBP-5, the most abundant in bone, fixes IGFs to the bone matrix and is itself a growth factor that acts independently of IGFs. We hypothesized that bone changes in OA FHs are mediated, in part, by increased production of IGFs and/or IGFBP-5. To examine this we have measured IGF-I, IGF-II and IGFBP-5 in extracts of FH cancellous bone powders. FHs were obtained at autopsy from elderly subjects with no bone disease (n=10) and after hip arthroplasty for OA (n=22). Since IGFs in bone are influenced by mechanical loading, bone was taken from 2 FH sites, the Superior (S) and Inferior (I) regions, which experience different loads. IGF system components were measured by RIA after extraction from bone with EDTA in 4M GnHCl and protease inhibitors. Data are expressed as median (range), ng/mg dry bone powder. Comparisons of groups were made using the Mann Whitney test * denotes p<0.05.

	IGF-I		IGF-II		IGFBP-5	
	S	I	S	I	S	I
Normal	0.05 (0.02-0.11)	0.06 (0.03-0.09)	0.21 (0.05-0.41)	0.21 (0.12-0.34)	0.73 (0.14-1.1)	0.98 (0.18-1.9)
OA	0.08 (0.02-0.24)	0.06 (0.02-0.18)	0.22 (0.11-0.32)	0.19 (0.09-0.32)	2.23* (0.7-4.99)	1.59* (0.7-3.19)

Extracts of cancellous bone contain about 3-fold more IGF-II than IGF-I. No sig. differences in levels of any of the components were found between S and I regions in either group. IGFBP-5 was increased in bone from both regions in OA (S p=0.0001; I p=0.009) compared with normals, and remained sig. when results were standardized using extractable protein as a referent. In conclusion, IGFBP-5 levels were significantly higher in extracts of cancellous bone from OA compared with age-selected normals. These findings are consistant with the hypothesis that increased IGFBP-5 production may contribute to changes in the cancellous bone network seen in end-stage OA through increased osteoblast proliferation and/or activity.

Perturbation of Fibronectin Inhibits Osteogenesis in Rat Cranial Suture. A. M. Moursi, P. L. Winnard,* A. V. Winnard.* Pediatric Dentistry, Ohio State University, Columbus, OH, USA.

Craniosynostoses are a group of congenital disorders which involve the premature fusion of the cranial sutures. A therapeutic agent which could prevent re-ossification of the excised sutures by transiently blocking osteogenesis would be an effective adjunct to surgery. Fibronectin (FN), an extracellular matrix molecule, has been shown to play an essential role in calvarial osteoblast osteogenesis. Antagonism of FN with anti-FN antibodies has been shown to selectively and reversibly block osteogenesis in rat calvarial osteoblasts. The purpose of this study was to determine if an anti-FN antibody (anti-FN Ab) could prevent osteogenesis in a rat cranial suture organ culture. The effect of anti-FN Ab was first evaluated in cell culture where fetal rat calvarial osteoblasts were plated on a 1 mm thick resorbable fibrillar collagen gel (Col), 65 mg/ml (NeuColl Inc., Palo Alto, CA), containing anti-FN Ab or IgG at dilutions of 1:40, 1;100 and 1:200. The media was changed every other day, no new anti-FN Ab or IgG was added. Anti-FN Ab released into the media was measured by ELISA. Cell attachment on plastic, Col+anti-FN Ab and Col+IgG was found to be similar at all dilutions, as determined by the alamarBlue dye technique. Proliferation was similar for all conditions at 1:100 and 1:200 dilutions. However, after 3 and 5 days in culture osteoblast proliferation was reduced by 79% and 88%, respectively, on Col+anti-FN Ab (1:40) compared to Col+IgG (1:40). Both Col conditions demonstrated less proliferation than plastic controls. Toluidine-blue staining of fixed cultures confirmed the proliferation data and showed that cells on Col achieved an osteoblastic morphology. The affect of FN perturbation on cranial suture fusion was investigated using a rat calvarial organ culture system in which postnatal day 15 rat calvariae were placed in serum-free, BGJ media. Col+anti-FN Ab (1:40) or Col+IgG (1:40) was placed sub-periosteally on the posterior frontal suture. After 5, 7 and 15 days in culture, histomorphometric analysis showed a decrease of 50%, 72% and 53%, respectively, in the fusion of sutures treated with Col+anti-FN Ab compared to Col+IgG. Together, these results indicate that the Col delivery vehicle can support osteoblast attachment, proliferation and promote normal morphology. They also demonstrate that the Col delivery vehicle can transfer the active antibody to cranial suture sites over time. In addition, the results show that Col+anti-FN Ab can inhibit fusion of rat cranial sutures suggesting potential clinical applications in the treatment of craniosynostosis. Morphological and Biophysic Study on the Effects of Disuse on Rat Femur Following Sciatic Nerve Neurectomy. H. Yonezu,*[1] S. Takata,[2] N. Yasui.*[2] [1]Orthopedic Surgery, Oe Kyodo Hospital, Oe-gun, Japan, [2]Orthopedic Surgery, The University of Tokushima, Tokushima, Japan

We studied the morphological and biophysic effects of disuse on rat femur following unilateral sciatic nerve neurectomy (USN) using peripheral quantitative computed tomography (pQCT), Fourier transformed infrared spectroscopy (FTIR) and calorimetric analysis in 15 growing Wistar-derived rats, 5 weeks of age. The rats were divided into two groups: operated group (right femur) and non-operated group (left femur). Bone mineral density (BMD) , bone mineral content (BMC), bone area, periosteal circumference, and endosteal circumference were measured by pQCT, and the mineral /matrix ratio was evaluated by FTIR. Furthermore, as for calorimetric experiment, the denatured temperature (Tm), half peak breadth (HPB) and transition temperature (TT) (mj/mg)of type I collagen of the femoral shaft were measured by calorimetry. The operated group showed a significant decrease in cortical BMC, bone area and periosteal circumference compared with the non-operated group ($p<0.05$). The cortical BMD did not vary significantly between the two groups. In the cancellous bone, the operated group showed a significant decrease in BMD and BMC at the metaphysis compared with the non-operated group ($p<0.05$). The mineral/matrix ratio of the cortical bone did no differ significantly between the operated and non-operated groups. The Tm and TT of the operated group were significantly higher than those of the non-operated group ($p<0.05$), whereas the HPB of the operated group was significantly lower than that of the non-operated group. We conclude that in cortical bone, disuse affected by USN inhibits periosteal bone formation but has no significant effect on the mineral/matrix ratio of cortical bone in femurs, and that disuse increases chemical stability of type I collagen.

Enhancing Detection Sensitivity of Skeletal Metastases with Green Fluorescent Protein. J. F. Harms,*[1] A. M. Mastro,*[2] C. V. Gay,[2] D. R. Welch.[3] [1]Jake Gittlen Cancer Research Institute, Penn State University College of Medicine, Hershey, PA, USA, [2]Biochemistry & Molecular Biology, Pennsylvania State University, State College, PA, USA, [3]Jake Gittlen Cancer Research Institute, Pennsylvania State University College of Medicine, Hershey, PA, USA.

PURPOSE: Skeletal metastases develop in the majority of breast cancer patients. Our objective was to develop improved models of breast cancer metastasis to bone. METHODS AND RESULTS: We observe metastasis to bone following injection of the human breast carcinoma cell lines, MDA-MB-231 and -435 into the left ventricle of the heart (i.c.) in female athymic mice. Osteolytic skeletal metastases localize predominantly to the trabeculae in femurs, proximal tibia, and vertebrae which are sites for metastases in humans. Development of bone metastasis has not been observed following i.v. (lateral tail vein) or orthotopic (mammary fat pad) injection, underscoring the impact of first-pass clearance in lung capillaries. In order to facilitate examination of tumor cell arrival and initial colonization events in the bone, we engineered 231 and 435 cells that constitutively express enhanced green fluorescent protein (GFP). Fluorescent subpopulations were selected by FACS. Following i.c. injection of 2 x 105 cells, all organs were examined grossly, radiographically and microscopically after 2-6 wk. Except at the latest time points, osseous metastases were not grossly apparent unless tumor replaced the marrow or if a fracture developed. Bones stripped of soft tissues are examined using a epifluorescence dissecting microscope and images digitized. Single fluorescing cells were visible through intact bone, allowing quantification of bone colonization before radiographic evidence of metastasis was apparent. Fluorescent tumors were visible in the bones even when no radiographic evidence of osteolysis was present. H&E sections confirmed osteolysis. GFP-tagging permitted convenient 3D examination of lesions and enables accurate distinction of adjacent, but separate, foci before they coalesced. Use of GFP-tagged cells also appears to be more sensitive than standard histologic examination. The number of femoral metastases per mouse was slightly greater using GFP (2.36 ± 0.65; mean ± SEM) than in H&E analysis (1.25 ± 0.40) in limited sample sets. CONCLUSIONS: In contrast to arduous histological sectioning, GFP-labeling also allows relatively rapid assessment of all skeletal sites. GFP tagging also appears to be more sensitive with regard to detection of boney metastases in these experimental models. Thus, analysis of skeletal metastases at early time points is now possible with increased sensitivity, improved counting accuracy and ease.

Mutational Analysis of Connexin 26 as a Candidate Tumor Suppressor Gene in Parathyroid Carcinoma. J. Costa,* T. M. Shattuck,* A. Arnold. Center for Molecular Medicine, University of Connecticut School of Medicine, Farmington, CT, USA.

One or more tumor suppressor genes critical to the pathogenesis of parathyroid cancers are expected to be present on chromosome 13q, based upon the finding of frequent loss of heterozygosity or deletion on 13q in parathyroid carcinoma. Connexins are encoded by a multigene family, one cluster of which is located on 13q. Connexins make up the functional unit of gap junctional intercellular communication by forming channels that allow the direct passage of small molecules and ions, such as Ca2+, between adjacent cells. Defects in connexin localization and gap junction channel formation have been observed in a variety of neoplastic cell lines and solid tumors. In addition, decreased expression of cyclin D1, an established parathyroid oncogene, has resulted from forced connexin expression in carcinoma cell lines. Furthermore, the rodent homolog of at least one such connexin gene on 13q, connexin 26 (GJB2), is known to be normally expressed in parathyroid tissue. Thus, given its attractiveness as a candidate parathyroid tumor suppressor gene, we rigorously examined the connexin 26 gene for possible inactivating somatic mutations in parathyroid carcinomas. High molecular weight genomic DNA from 6 primary parathyroid carcinomas, 2 recurrences and 2 metastases was analyzed by automated sequencing of the entire coding region of connexin 26. No mutations, insertions, or microdeletions were detected. One base change previously described as a polymorphism, resulting in a valine to isoleucine change at codon 27, was seen in one of the carcinomas and in that patient's corresponding peripheral blood leukocyte DNA. Based on the absence of identifiable inactivating mutations, it is unlikely that connexin 26 commonly functions as a classical tumor suppressor gene in the pathogenesis of parathyroid carcinoma.

PTHrP a Modulator of Breast Cancer Metastasis. R. J. Thomas,* A. M. Tester,* J. A. Sharp,* E. W. Thompson,* T. J. Martin, M. T. Gillespie. St. Vincent's Institute of Medical Research, Melbourne, Australia

The lytic lesions of breast cancer metastasis to bone result from osteoclast activity. PTHrP is commonly expressed by breast cancers and has been shown to enhance RANKL and inhibit OPG production by the osteoblast, which combined are conducive to osteoclast formation. However PTHrP production by breast cancer cells may also affect their tendency to intravasation and extravasation, influencing their metastatic spread. We have examined the expression of MMPs by breast cancers in response to PTHrP, since MMPs are crucial in the degradation of connective tissue for tumor invasion. MMP-2 (gelatinase A) and MMP-9 (gelatinase B) are specifically able to degrade type IV collagen, but also degrade elastin, fibronectin and gelatin.Each of the human PTHrP isoforms (139, 141 and 173aa) was overexpressed in MDA-MB-231 cells and stable clones selected. The anchorage-dependent growth rates of the cells did not alter in response to PTHrP production. MDA-MB-231 cells overexpressing each isoform of PTHrP demonstrated elevated levels of MMP-9 mRNA and protein by zymography, however their relative levels differed (139>>141>173). Recombinant PTHrP or PTHrP peptides when added to MDA-MB-231 cells (over a 48hr time course) did not increase MMP-9 mRNA or protein levels, suggesting that MMP-9 was regulated by intracrine actions of PTHrP. We then determined if MMP-9 production by MDA-MB-231 cells could be influenced by bone marrow cells and/or osteoblasts. Coculture of primary osteoblasts or marrow cells with MDA-MB-231 parental or PTHrP overexpressing cells at different cellular ratios did not alter MMP-2 or MMP-9 production, suggesting that marrow cells or osteoblasts do not effect MMP production by MDA-MB-231 cells.We then determined whether PTHrP production by MDA-MB-231 cells modified the ability of cells to migrate through a matrix, or their ability to undergo morphological change in a matrix. In migration assays performed in collagen type IV, no difference was noted in MDA-MB-231 parental cells and PTHrP overexpressing cells. In matrigel outgrowth experiments, MDA-MB-231 cells overexpressing each isoform of PTHrP showed increased outgrowth through the matrigel matrix, with significantly higher branching, which might be indicative of invasive potential, than the MDA-MB-231 parental cells. Notably, PTHrP also increases ductal branching morphogenesis during normal mammary gland development.These data suggest that PTHrP production by breast cancers has distinct roles. Firstly, it promotes outgrowth of cells in matrigel and enhanced MMP-9 production, two phenotypes associated with intravasation and extravasation. Secondly, in bone metastases, PTHrP promotes osteolysis.

Altered Expression of RANK in Human Osteosarcoma Tumors and Cell Lines. P. Bhatia,*[1] A. Deshpande,*[1] D. Ammerman,*[1] M. J. Nellissery,*[1] T. Johnson-Pais,*[2] R. J. Leach,*[2] M. F. Hansen.[1] [1]Molecular Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]Department of Cellular and Structural Biology, University of Texas Health Science Center, San Antonio, TX, USA.

RANK, a member of the Tumor Necrosis Factor alpha receptor superfamily has been shown to play a major role in mediating communication between osteoblasts and pre-osteoclasts during bone remodeling that results in the differentiation of pre-osteoclasts to mature osteoclasts. RANK is expressed on the pre-osteoclast while its ligand, RANKL, is expressed on osteoblasts. RANK maps to a region of human chromosome 18q21.3 that has been implicated in osteosarcoma tumorigenesis as well as predisposition to familial Paget's disease of bone. Using immunohistochemistry, RT/PCR and northern analysis, we examined RANK expression in primary osteosarcoma tumors and in the established osteosarcoma cell lines SAOS-2, U2-OS, OHS-50, and HT-148. We found that in all cases, RANK was strongly overexpressed. Further, in contrast to the observed pattern in pre-osteoclasts, RANK expression in the osteosarcoma tumors and cell lines was localized to the nucleus. RANK has been shown to activate both the NFkB pathway as well as the Akt1 pathway suggesting that aberrant expression and activation of RANK could lead to inhibition of apoptosis as well as misregulation of cell cycle control resulting in aberrant cellular growth. Thus RANK overexpression may play a critical role in osteosarcoma tumorigenesis.

Increased Bone Remodeling Due to Ovariectomy Dramatically Increases Tumoral Growth in the 5T2 Multiple Myeloma Mouse Model. H. Libouban,*[1] M. Moreau,*[1] M. Basle,*[1] M. Duquenne,[1] R. Bataille,*[2] D. Chappard.[1] [1]LHEA, Fac Medicine, Angers, France, [2]INSERM, Nantes, France

Multiple myeloma (MM) is a B cell malignancy characterized by the presence of osteolytic lesions. In man, MM cells produce local factors such as IL-6, which modulate the bone remodeling and promote bone resorption. IL-6 is also the major growth and survival factor of myeloma cells. Thus, there is a true "vicious circle" in which plasma cells stimulate bone cells, which in return stimulate the neoplastic growth. The graft of 5T2MM mouse plasma cells in the C57BL/KaLwRij mouse is the only model that mimics bone lesions observed in human. The cytokine network is also close to the human one. In this model, 16 weeks are necessary for the development of the disease. We hypothesized that an increased bone remodeling could influence the development of MM.Ovariectomy (OVX) is well known to stimulate bone remodeling and to increase IL-6 levels in the bone marrow. We have ovariectomized mice before injection of the malignant plasma cells (5T2MM). Two groups of mice were injected with 2.10^6 5T2MM cells: control and OVX. 5T2 cells were inoculated intravenously 7 days after OVX (a period necessary to reach a high bone turnover). The development of the disease was monitored from 7 weeks after cells injection by serum electrophoresis to detect the presence of the paraprotein. It was detected 7-8 weeks post injection in the OVX-5T2 group and 9 weeks post injection in the control-5T2 group. At 9 weeks, the concentration of paraprotein was 5 fold higher in the OVX-5T2 group than in the control group. All OVX-5T2MM mice developed a hind-limb paralysis after 9-10 weeks post injection and there were euthanazied due to ethical consideration. In contrast, control 5T2 mice were euthanazied 16 weeks post injection. Osteolytic lesions were quantified by numeric radiography, scanning electron microscopy and X-ray microtomography. At the time of euthanasia, we observed the presence of numerous bone lacunae in the long bones of the OVX-5T2MM mice. The lesions were localized in the metaphysis of the femur and tibia with a preferential localization in the tibial crest. In control animals, the development of bone lesions was followed by X-ray performed under anesthesia, at 10 weeks post injection and at the day of sacrifice. No lesions were observed at 10 weeks post injection; at 16 weeks, numerous lesions were observed in both femur and tibia.In this study, an accelerated bone remodeling (due to OVX) dramatically increased the growth of malignant plasma cells. This is, in turn, associated with an earlier bone destruction confirming the close relationships between bone and MM cells. The usefulness of a bisphosphonate therapy, that would help to limit both mechanisms, is under study.

Expression and Utilization of SDF-1/CXCR4 in Prostate Cancer Metastases. R. S. Taichman,* B. A. Wiedemer,* L. K. McCauley. Periodontics/Prevention/Geriatrics, University of Michigan Dental School, Ann Arbor, MI, USA.

Neoplasms have a striking tendency to metastasize or "home" to bone. Hematopoietic stem cells also "home" to bone during embryonic development where evidence points to the chemokine stromal-derived factor-1 (SDF-1) (expressed by osteoblasts and endothelial cells), and its receptor (CXCR4) as key elements in these processes. We hypothesized that metastatic prostate carcinomas also utilize the SDF-1/CXCR4 pathway to localize to the bone. To test the hypothesis the expression of CXCR4 in several human prostate cancer cell lines by RT-PCR and by Western Blotting was determined. Positive results were obtained with the PC-3 and DU145 cell lines, derived from malignancies which had spread to bone and brain, respectively. Hormone-refractory prostate carcinoma cell lines cloned from a lymph node (LNCaP) and marrow (LNCaP C4-2) also expressed CXCR4. To determine if prostate cancer cells migrate across endothelial cell monolayers in response to SDF-1, confluent bone marrow endothelial cells (Dr. S. Rafii, Cornell University, New York, NY.) were established on microporous membranes. Migrating cells were introduced into the upper chamber, and a gradient of SDF-1 (0 or 200 ng/ml) was established by placing the chemokine in the lower chamber. For LnCaP cells, random or chemokinetic migration accounted were 9,300 ± 3,000 and 7,300 ± 5,000 cells migrating through the endothelial layers/well, respectively. SDF-1 supported migration was significantly greater 35,000 ± 3,000/well ($P<0.05$). In in vitro adhesion assays, pre-treatment of the prostate cancer cells with SDF-1 significantly increased their adhesion to several osteosarcomas in a dose-dependent manor. In addition, invasion of the cell lines through basement membranes was also supported by SDF-1 and inhibited by antibody to CXCR4. Collectively, these results suggest that prostate cancers and perhaps other neoplasms (i.e. breast) may use the SDF-1/CXCR4 pathway during their spread to bone.

Androgen Deprivation Therapy in Patients with Prostate Cancer and Changes in Bone Mineral Density. M. G. Alferos,* S. Yaturu.* Endocrinology, OvertonBrooks VAMC/LSUHSC, Shreveport, LA, USA.

Androgen deprivation therapy in prostate cancer results in low androgen levels. Low androgen levels in men is a risk factor for osteoporosis. We studied the bone density changes in 146 patients who are on androgen deprivation therapy for prostate cancer. All patients received Goserelin injections.In addition to Goserlin, 50 (36%)of the 146 patients received other antiandrogens namely flutamide and casodex. The duration of the anti-androgen therapy ranged from 3 to 122 months. The results of the bone density studies were reviewed and correlated with the duration of the anti-androgen therapy. Osteoporosis was noted in 90 (62%), osteopenia noted in 36(24%) and only 20 patients(14%)had normal bone mineral density studies. Most of the changes were at hip, more so at the ward's triangle of the left hip which constitutes 49%(i.e.72) of the 146 patients.Osteoporosis was noted in either hip in 82 (56%) patients and either hip and or spine in 90 patients which constitutes 62%. The duration of anti-androgen therapy did not correlate with the degree of bone loss. We conclude that patients with prostate cancer on anti-androgen therapy are at high risk for osteoporosis.

SA074

Skeletal Involvement in 14 Advanced Prostate Cancer Patient autopsies, 5 of these Patients Treated by Pamidronate. M. P. Roudier,[1] C. S. Higano,*[2] L. D. True,*[3] S. M. Ott,[4] H. J. Vesselle,*[5] P. H. Lange,*[1] R. L. Vessella.[1] [1]Urology, University of Washington, Seattle, WA, USA, [2]Oncology, University of Washington, Seattle, WA, USA, [3]Pathology, University of Washington, Seattle, WA, USA, [4]Metabolism, Endocrinology and Nutrition, University of Washington, Seattle, USA, [5]Radiology, University of Washington, Seattle, WA, USA.

To better understand the progression of prostate cancer (CaP) into the bone, the anatomical and histological findings of 14 autopsied patients are described.14 advanced CaP patients underwent a necropsy, 12 of them had a least one bone scan taken during the disease and at least 17 bone biopsies taken during the autopsy. 5 patients were treated with pamidronate (BisP) 2 to 13 months before death. Bone biopsies were processed for histology and 6 patients had a second biopsy for histomorphometry analysis. Tumor volume, bone marrow volume, tumor glandular differentiation, PSA and Chromogranin A expressions were evaluated by two pathologists. One pathologist identified bone response to the invading tumor on each slide as either osteodense or normal. The bone histological and bone scan results were correlated to the tumor and clinical data.Bone metastasis ranged from 95% in pelvis to 70% in humeri. Mean number of bone metastasis in BisP-treated patients (BisPp) was 13 and 11.6 by histology and bone scan respectively and 14.57 and 14.28 respectively in non-treated patients. The mean tumor burden was 1097 cm3 with a quasi disappearance of the bone marrow in all cases. Histology detected more metastases than bone scan. The bone scan-histology concordance was nevertheless good (80.32%) and reduced in BisPp (63.38%). Prevalence of abnormality was decreased in the BisPp (0.75) compared to non-treated patients (0.88). The tumor glandular differentiation was low and PSA expression was high with a neuro-endocrine immunophenotype in three patients. Two patients had no histological bone change associated with the carcinoma metastasis; the other 12 were osteoblastic. One of the patients with no bone change was treated with BisP. No clinical or carcinoma features were found to independently explain the other case. Histomorphometric analysis data are underway for 5 BisP-treated patients.In our advanced CaPpatients, the overall skeletal tumor burden in bone is larger compared to earlier studies. This is probably due to a more complete propagation of the tumor that accompanies hormonal treatment of the CaP and prolonged life span. Bone marrow is generally replaced, which accounts for the anemia usually observed in late-stage patients. Bone metastases are generally osteoblastic. The prevalence of abnormality in bone CaP metastasis was decreased in BisPp compared to non-treated patients.

SA075

A Proteome Study of Prostatic Factors Affecting Osteoblastic Activity: Identification and Characterisation of Galectin-1 and Cyclophilin A. H. Andersen,[1] O. N. Jensen,*[2] E. P. Moiseeva,*[3] E. F. Eriksen.[1] [1]University Department of Endocrinology, Aarhus Amtssygehus, Aarhus, Denmark, [2]Protein Research Group, Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense, Denmark, [3]Department of Medicine and Therapeutics, University of Leicester, Leicester, United Kingdom

Prostate cancer cells metastasise to bone causing an osteosclerotic response. We have previously shown that the human prostatic tumour cell line PC3 secretes factors, which stimulate the mitogenic activity of human bone marrow stromal (hBMS) cells. The PC3 derived mitogens have been found to be proteins with a molecular weight of 20 to 30 kDa. The aim of this study was therefore to characterise the protein profile of conditioned medium (CM) from PC3 cells in the molecular weight area 5 to 30 kDa by proteome analysis. A protein profile of the CM from PC3 cells was performed by two dimensional polyacrylamide gel electrophoresis (2D-PAGE). 30 spots in the molecular weight area 5 to 30 kDa were analysed by matrix assisted laser desorption /ionisation time of flight mass spectrometry (MALDI-TOF MS). Two of these spots were identified as galectin-1 and cyclophilin A. Galectin-1 is a lectin that binds to specific carbohydrate structures, which can be

found on a number of glycoproteins (e.g. laminin and fibronectin). Cyclophilin A belongs to the family of immunophilins, which bind to cyclosporin A. We wanted to examine whether galectin-1 (10 and 1000 ng/ml with or without 10 ng/ml of IGF-I) or cyclophilin A (1, 10, and 100 nM with or without 10 ng/ml IGF-I) had any effects on the proliferation (determined by incorporation of [^{3}H]-thymidine) or differentiation (determined by measuring alkaline phosphatase activity) of hBMS cells. Furthermore, we tested whether adhesion of PC3 cells to laminin (10 μg/ml), fibronectin (5 μg/ml), and collagen type I (5 μg/ml) was influenced by lactose (0.1 M), which binds to galectin-1. Neither galectin-1 nor cyclophilin A increased the proliferation of hBMS cells. However, 10 and 1000 ng/ml of galectin-1 increased the differentiation of hBMS cells (Mean (stimulated/control) ± SEM: 1.37±0.08, and 1.31±0.11, $p<0.05$). Cyclophilin A did not have any effect on the differentiation of hBMS cells. Lactose inhibited the adhesion of PC3 cells to laminin (0.72±0.09, $p<0.05$), fibronectin (0.30±0.12, $p<0.01$), and collagen type I (0.86±0.04, $p<0.05$). In conclusion galectin-1 increases adhesion of prostate cancer cells to bone matrix constituents and stimulates osteoblastic differentiation. Thus, it may be involved in the osteoblastic response seen, when prostate cancer cells metastasise to bone. Cyclophilin A showed no such effects.

Why Don't Primary Care Physicians Screen for Osteoporosis? D. H. Solomon,[1] M. Connelly,[2] B. Dawson-Hughes,[3] C. J. Rosen,[4] D. P. Kiel,[5] S. L. Greenspan,[6] E. Leib,[7] A. H. Miguel,*[8] J. S. Finkelstein.[9] [1]Rheumatology and Pharmacoepidemiology, Brigham and Women's Hospital, Boston, MA, USA, [2]Ambulatory Care and Prevention, Harvard Medical School, Boston, MA, USA, [3]USDA Nutrition Center, Tufts University, Boston, MA, USA, [4]Maine Center for Osteoporosis Research, Bangor, ME, USA, [5]Aging, Harvard Medical School, Boston, MA, USA, [6]Medicine, University of Pittsburgh, Pittsburgh, PA, USA, [7]Medicine, University of Vermont, Burlington, MA, USA, [8]Proctor and Gamble, Cincinnati, OH, USA, [9]Endocrinology, Massachusetts General Hospital, Boston, MA, USA.

Data suggest that a large proportion of patients with osteoporosis are never diagnosed and never receive treatment. We examined what characteristics of practitioners are associated with low utilization of bone densitometry. We conducted a cross-sectional survey of primary care physicians (PCPs), including obstetrician-gynecologists (Ob-Gyn), internists (IM), and general practitioners/family practitioners (GP/FP), practicing in any of the six New England states who had a facsimile number listed with the American Medical Association. The questionnaire assessed their demographics, practice characteristics, use of bone densitometry, and attitudes regarding osteoporosis and health maintenance.Fourteen percent (N = 494) of all PCPs responded to the survey and respondents were very similar to non-respondents in terms of age and specialty though respondents were slightly more likely to be female (31% vs 23%). Respondents had a mean age of 51 years and their training included 51% IM, 24% Ob-Gyn, and 25% GP/FP. The mean number of self-reported bone densitometry referrals per month was 10 and 25% of respondents reported referring fewer than four patients per month. In adjusted logistic models, factors significantly associated with referring fewer than four patients per month were: 1) training as an IM (odds ratio, OR, 2.8, 95% confidence interval, CI, 1.5 - 5.0) or a GP/FP (OR 1.9, 95% CI 1.1 - 3.2) versus Ob-Gyn; 2) practicing in a rural (OR 2.1, 95% CI 1.3 - 3.8) or urban (OR 1.7, 95% CI 1.0 - 2.8) versus suburban setting; 3) the belief that calcium and vitamin D are adequate to treat osteoporosis (OR 2.1, 95% CI 1.0 - 4.5); 4) the belief that osteoporosis treatment should not be based on bone density results (OR 4.0, 95% CI 2.3 - 7.0); and 5) reporting confusion about the best anatomic sites for measuring bone density (OR 1.8, 95% CI 1.1 - 2.9).We conclude that several potentially modifiable factors, such as beliefs about adequate treatment and how to use bone densitometry, are associated with low referral rates for bone densitometry. Educational strategies aimed at improving use of bone density testing should consider these factors.

Effect of Two Different Hip Prostheses on Periprosthetic Acetabular Bone Density. G. Baccalaro,[1] A. Montesano,[1] P. Bertocco,[1] A. Pacico,[1] I. Guarducci,[2] A. Uderzo,[2] S. Ortolani.[3] [1]Unit of Rheumatologic and Metabolic Disorders, Istituto Auxologico Italiano, Verbania, Italy, [2]Divisone di Ortopedia Ospedale S. Biagio, Domodossola (Vb), Italy, [3]Istituto Scientifico Ospedale S. Luca, IRCCS, Milano, Italy

Dual X-Ray Absorptiometry (DXA) can be used in achieving the assessment of bone evaluation and density (BMD) around metal implants after total hip replacement (THR). Acute and persistent periprosthetic bone loss (BL) normally occurs after THR, and it can determine the decrease in local bone reaction and the consequent prosthetic failure. Local BL and reaction are controlled by bone turn-over, by local load applied and by prosthesis carachteristics, cemented (CP) and uncemented (UP). About UP normally used in THR, the cotile could be fixed (UPF) or not (UPU) to the acetabular bone, with differences in elastic and dynamic properties both in prosthesis and bone. The aim of this study was to evaluate the sovracetabular bone density after THR, both in UPF and UPU. Periprosthetic acetabular BMD by DXA was detected in 32 patients (9 M, 23 F), affected by primary osteoarthritis, who underwent THA, with two different prostheses.(see table). Time since surgery ranged from 13 to 46 months. An acetabular fixed region of interest (ROI) was evaluated and analyzed in order to define and assess a more precise weighted variable (RatioROI: BMD-ROI/ BMD total of the controlateral hip). Ratio ROIs of the two groups were compared by a T-Test.

	UPU		UPF	
N	**16 (3 M, 13 F)**		**16 (6 M, 10 F)**	
	Mean	**St. Dev.**	**Mean**	**St. Dev.**
BMD total control. hip	0.82	0.19	0.82	0.14
BMD ROI	1.20	0.36	1.29	0.42
Ratio ROI	1.50	0.34	1.58*	0.42
Age	72.25	5.72	67.00	6.87

*$p< 0.01$ RatioROI of the UPU-Cotex was significantly lower ($p< 0.01$) than UPF-ABG one. We can argue that local periprosthetic bone loss is higher in elastic and dynamic than fixed prosthesis after THR, suggesting that UPF could better control the local periprosthetic bone reaction than UPU. These preliminary data need to be confirmed by a longitudinal study on a larger sample size

Assessing Independent Changes in Bone Mineral Content and Cross-Sectional Area in the Rat Tibia by pQCT. C. S. Tam,[1] P. Cunniff,*[2] C. Gordon,*[3] C. E. Webber,[4] T. V. Sanchez.[2] [1]Osteopharm Limited, Oakville, ON, Canada, [2]Norland Medical Systems, Fort Atkinson, WI, USA, [3]McMasters University, Hamilton, ON, Canada, [4]Hamilton Health Sciences Corp, Hamilton, ON, Canada

Bone mineral density (bone mineral content divided by projectional area) in the rat tibia is often assessed by densitometry as a reflection of bone loss or gain in studies of bone disease. This study details the use of pQCT to independently assess changes of bone mineral content and bone cross-sectional area along the length of the tibia to show how these direct reflectors may better show what is occurring in the total, cortical and trabecular compartments during a treatment study. Tibia from three groups (group A--11 tibia from a test group, group B--11 tibia from a test group, group C--10 tibia from a control group) underwent evaluation of the midshaft and proximal tibia by pQCT. Scans were carried out using standard system settings. Bone mineral content and cross-sectional area were examined independently. Using group C results for content and area as the reference values, the relative content and area in groups A and B were calculated. Examining cross-sectional area, compared to Group C the tibia in Group A showed relative results at the midshaft and proximal tibia of 109% and 110% (Total area), 103% and 93% (Cortical area) and 137% and 88% (Trabecular area). Group B showed relative results at the midshaft and proximal tibia of 113% and 121% (Total area), 107% and 96% (Cortical area) and 126% and 110% (Trabecular area). Examining content, compared to Group C the tibia in Group A showed relative results at the midshaft and proximal tibia of 102% and 95% (Total content), 101% and 97% (Cortical content) and 80% and 42% (Trabecular content). Group B showed relative results at the midshaft and proximal tibia of 104% and 101% (Total content), 104% and 99% (Cortical content) and 78% and 51% (Trabecular content).Results show that while Group A and Group B show significant reductions in trabecular content, the tibia reach reference level total and cortical contents and exhibit cross-sectional areas greater than or equal to reference levels in the total, cortical or trabecular compartments. Independent evaluation of content and cross-sectional area may provide further insight into how the tibia responds to treatment or disease.

A New Approach to Peridental Bone Quality: pQCT Studies of the Human Mandible. E. J. A. Roldan,[1] V. Montangero,*[2] R. Capiglioni,*[2] T. V. Sanchez.[3] [1]Institute of Metabolic Research (IDIM) and Gador, SA, Buenos Aires, Argentina, [2]Institute of Metabolic Research (IDIM), Buenos Aires, Argentina, [3]Norland Medical Systems, Fort Atkinson, WI, USA.

Maxilla and mandible are the only human bones which, besides having muscle and endocrine influence, interact with another hard tissue--teeth. As such, local or systemic bone diseases may be screened and monitored with a differential approach. Low radiation volumetric analysis of maxillar and mandibular bone properties is now feasible by pQCT (Capiglioni, Radiología 1998,7:898), but interpretation of data has not always been manageable in the practice setting. To simplify interpretation we have related an anatomic classification of bone quality (Horner, Dentomaxillofacial Radiol 1998,27:17) to pQCT

measured bone mineral density in 71 cadaveric maxillar and mandibular samples. Methacrilate embedded maxillar and mandibular samples between 0.5 and 0.7 mm wide were fixed and scanned at 10 mm/sec with resolution set at 0.2 mm3 . Volumetric bone mineral density (vBMD) measurements were obtained for all sections (range for CV being 1.2-2.9; n=21x3). With Class I classified as dense bone and Class IV classified as severe osteopenia, bone sections were graded by an independent anatomist as Class I (10 samples), Class II (18 samples), Class III (22 samples) and Class IV (18 samples)--3 samples could not be graded. The pQCT vBMD ranged (in mg/cm3) between 444.5-1003.5 for Class I; 239.4-425.1 for Class II; 106.2-387.4 for Class III and 115.3- 0.0 for Class IV. No Class I sample showed a pQCT vBMD lower than 400mg/cm3, and no Class IV sample showed values above 200mg/cm3. To aid in interpretation each vBMD range could be further defined by a given colour in the software. Hence, a topographic distribution of bone qualities--color defined--within a bone section can be easily interpreted in a given patient.

Mineral Threshold Analysis of the Mandible by pQCT. A New Tool for Selective Diagnosis and Monitoring of Cortical Quality. E. J. A. Roldan,[1] R. Capiglioni,*[2] J. Amaro,*[2] T. V. Sanchez.[3] [1]Institute of Metabolic Research (IDIM) and Gador SA, Buenos Aires, Argentina, [2]Institute of Metabolic Research (IDIM), Buenos Aires, Argentina, [3]Norland Medical Systems, Fort Atkinson, WI, USA.

In order to quantify the cortical mineral composition of the human mandible, the labial, sub-alveolar cortex from 32 healthy adults was analysed using the XCT3000D pQCT system. Volunteers were free of current peri-odontopaties and mean (SD) age of 56 (11) years, body weight of 64 (10) kg and height of 161 (10) cm.. Patients were positioned as previously described (Capiglioni, Radiología 1998,7:898) using a 280mm gantry, 0.5mm3 voxel resolution, 60mm/sec scout-view speed and 20mm/sec measurement speed. A cortical region of interest was manually defined within the axial images. Volumetric bone mineral density (vBMD) using 710 and 900 mg mineral density thresholds, and section areas using 0, 400, 600, 700, 800, 900 and 1,000 mg thresholds were calculated. Mean(SD) and CI95% for cortical vBMD710 was 1008.8 (58.4) and 987-1030 mg/cm3 while cortical vBMD900 was 1128.9 (47.4) and 1111-1146 mg/cm3. CI95% of the area fraction for materials with a density below 400 mg was 26-36%, while between 400-600 mg the area fraction was15-18%, and between 600-700 mg area fraction was 6.7-8.8%. Area fractions for thresholds over 700 mg were minor. There were no significant differences when comparing cortex near dentate or edentate sites. Data suggest that between subjects of different ages and sex, without bone metabolic diseases, the natural variation of cortical material composition is less than 5%. The existence of teeth did not influence densities of cortex material. Hence, cortex and medullar bone behave differently, so that cortical and medullar bone should be evaluated separately by tomographic, not projectional, technology.

The Effect of Bone Density Information and Different Educational Interventions on Osteoporosis Knowledge in Premenopausal Women: Randomised Controlled Trial. G. Jones,[1] L. de Wit,*[1] S. Frendin,*[1] B. Oldenburg.*[2] [1]Menzies Centre for Population Health Research, Hobart, Australia, [2]School of Public Health, Queensland University of Technology, Brisbane, Australia

Preliminary uncontrolled data has suggested that bone density (BMD) feedback may be more effective than provision of information at changing behaviour in women in younger life. However, there is little information available about whether such programs will change knowledge. The aim of this study was to develop a measure of assessment of osteoporosis knowledge and assess the effect of BMD information and different educational interventions on short-term changes in knowledge. We studied 438 women aged 25-44 years who were randomly selected from the electoral role to take part in a three-year study (response rate 57%). Subjects were excluded if they were pregnant or lactating, had a previous BMD or had diseases or were taking medications that may affect BMD. Extensive data were collected at baseline including BMD (Hologic QDR2000) at the spine and hip. Those with a mean T-score at both sites less than zero (N=216) were told that they were at higher risk of fracture in later life while those above (N=222) were told that they were not at a higher risk of fracture. Subjects were also randomly assigned to a four-week small group osteoporosis and self-management course (OPSMC) or a comprehensive pamphlet. Osteoporosis knowledge was assessed by a newly developed 20-item questionnaire with true/false alternatives. This contained items on information contained in both methods of education and, in piloting, was shown to have content validity and exhibit a wide range of scores. All subjects completed the baseline knowledge questionnaire and an identical questionnaire at 6 weeks (without knowledge of the correct answers). In all groups, there was a significant improvement in scores during the 6 weeks (12.5 v 8.9, $p<0.001$). In terms of improvement in knowledge score, the OPSMC was superior to the pamphlet (mean difference 1.41, $p<0.001$) while low BMD was superior to normal BMD (mean difference 0.64, $p=0.049$). These effects were additive. In conclusion, this new instrument for assessing knowledge is sensitive to change in clinical trials and suggests that the best way to improve short-term osteoporosis knowledge is a combination of small group tutorials and BMD information. It remains to be determined whether short-term changes in knowledge will predict behaviour change and alteration in BMD in the longer term.

Development of Non-Invasive Diagnostics for Osteoporosis: A Model Based Approach. G. H. Gunaratne,*[1] K. K. Mohanty,*[2] S. J. Wimalawansa.[3] [1]Physics, University of Houston, Houston, TX, USA, [2]Chemical Engineering, University of Houston, Houston, TX, USA, [3]Internal Medicine, University of Texas Medical Branch, Galveston, TX, USA.

Controlling and managing osteoporosis requires the ability to determine the need and optimal time for therapeutic intervention. Non-invasive diagnostic tools are essential for this purpose. Surrogates for bone strength include bone mineral density (BMD), properties of ultrasound transmission through bone, and structural characteristics of a trabecular architecture (TA). Preliminary studies of their applicability requires the use of samples of animal bones (or their digitized images); it is difficult and time consuming to generate suitably uniform samples. A diagnostic tool is useful only if the range of applicability is large; i.e., it can be utilized for many different bones. Consequently, possible forms of diagnostic tools can be deduced via an analysis of a suitable mathematical model of a TA. Only the most promising diagnostic tools need to be subjected to further analysis involving animal bone.We have introduced a mathematical model of a TA which consists of a disordered network of elastic elements. Spatial variations in the structure of TAs motivate a random assignment of spring constants and analogous bond-bending constants. Osteoporosis is modeled by the random removal of elastic elements, and therapeutic regeneration is described by a rule similar to Wolff's law. This model exhibits analogues of several known mechanical features of bone including, (1) an initially linear stress vs. strain relationship that becomes nonlinear following yield, (2) an exponential decay of ultimate stress with a reduction of bone mass, and (3) a dramatic increase of bone strength following therapeutic intervention. Numerical analysis of the model exposes a fundamental difference between healthy and osteoporotic bone. Bonds taking part in stress propagation form a dense subset of the former, and consists of a few coherent pathways in the latter. This observation can be exploited to deduce possible forms of diagnostic tools of osteoporosis. The first example of such a diagnostic is the ratio of responses of the networkto stationary and time-periodic external strain. This ratio is seen to be bi-linearly related to the quantity essential to identify osteoporosis, namely the ultimate stress. The bilinear relationship holds for a wide range of parameters and external strain. Since periodic strain can be applied using ultrasonic techniques, we believe that this measure can be extended to a non-invasive diagnostic of osteoporosis.

Relationship Between Vertebral Morphometry and Angle of Kyphosis in Osteoporotic Women. D. Diacinti,* S. Minisola, E. D'Erasmo,* E. Tomei,* G. Mazzuoli. Department of Clinical Sciences, Rome, Italy

Hyperkyphosis and loss of height are common in the elderly population, particularly in osteoporotic women. The purpose of this longitudinal study was to evaluate with morphometric radiography (MRX) the contribution of decrease vertebral body heights to the thoracic kyphosis. We enrolled 170 postmenopausal women with an age range of 46-74 years after excluding vertebral fractures on lateral thoracic films centring on level T7 (tube-to-film distance of 115 cm). Lumbar spinal (L2-L4) bone mineral density (LS-BMD) was measured by dual-energy x-ray absorptiometry (DXA) using the Hologic QDR-4500 densitometer (Hologic, USA). On each lateral thoracic radiograph the kyphotic angle was calculated with the method of Fon et al. (1).The films were digitized by means of a scanner and then was performed the vertebral morphometry from T4-T12 using specified software (QR-Verona).The computer automatically calculated the anterior, middle and posterior vertebral bodies heights (Ha, Hm, Hp), the ratios of heights of single vertebrae (Ha/Hp, Hm/Hp, Hp/Hpp), as well as the sum of vertebral body heights (AHs, MHs and PHs). DXA examination and lateral spine radiographs were repeated after two years. After 24 month we observed a decrement of the vertebral heights respect to basal values in all women enrolled. In the group of osteoporotic women the mean vertebral heights loss was -6.5mm; higher in women with a new vertebral deformity (-10.5mm). Non-osteoporotic women had a smaller vertebral height loss (-4.1mm). The highest AHs decrement respect to PHs resulted in a significantly lower AHs/PHs average ratio in all postmenopausal women (0.991 versus 0.984; $p<0.001$). AHs/PHs average ratio correlated significantly with angle of kyphosis($r=-0.49$; $p<0.001$). This longitudinal study demonstrates that hyperkyphosis of osteoporotic women is related to vertebral deformity and the average ratio of the anterior to the posterior height of thoracic spine (AHs/PHs) may be used as index of anterior spine wedging and so of thoracic kyphosis. 1) Fon GT, et al. Biomechanical Parameters of Iliac Bone Biopsy Samples in Normal Premenopausal Women. Y. Chung,[1] Y. Won,*[2] K. W. Lee,*[1] H. Kim.*[1] [1]Endocrinology and Metabolism, Ajou University School of Medicine, Suwon, Republic of Korea, [2]Orthopaedic Surgery, Ajou University School of Medicine, Suwon, Republic of Korea

Bone microarchitecture is important in bone biomechanics. Biomechanical properties were investigated in iliac bone biopsy samples of Korean premenopausal women.Transiliac bone biopsies were performed in 5 young healthy premenopausal women using Rochester trephine (inner diameter of 7.5mm). Bone mineral densities (BMDs) were measured by DXA (Lunar Expert-XL, USA). Biomechanical parameters of the biopsy samples were analyzed by MicroCT scan (SkyScan 1072, Belgium).The results are expressed as mean(SD). The mean age of the subjects was 21.4(1.7)years, body mass index 22.1(1.7)kg/m2, and body fat 33.4(2.9)%. BMDs of L2-4 spine were 1.11(0.10)g/cm2, proximal femur 1.03(0.13)g/cm2, and total body 1.19(0.05)g/cm2. Bone volume was 25.1(7.7)%, trabecular thickness 0.041(0.011)mm, trabecular seperation 0.092(0.043)mm, trabecular number 8.45(2.97)/mm, trabecular pattern factor -0.14(1.33)/mm, Euler Number 14.7(59.0), mean intercept length 0.202(0.058)mm, degree of anisotropy 0.548(0.141), and structure model index 1.034(0.258). Bone volume and mean intercept length were correlated with total body BMD (r=0.952, p<0.05, and r=0.899, p<0.05, respectively). Trabecular number and trabecular seperation were correlated with proximal femur BMD (r=0.974, p<0.01, and r=-0.990, p<0.01, respectively). Trabecular thickness and trabecular pattern factor were not correlated with any BMD parameters.Biomechanical parameters were unique represents of bone microarchitecture, and some of the parameters were correlated with BMDs.

SA094

Glycosylation Differences Found Between Human Bone Alkaline Phosphatase Isoforms. P. Magnusson, J. R. Farley. Musculoskeletal Disease Center, Jerry L. Pettis Memorial VA Medical Center, Loma Linda, CA, USA.

High-performance liquid chromatography (HPLC) can separate three human bone alkaline phosphatase (BALP) isoforms in serum: a minor fraction, B/I, and two major isoforms, B1 and B2. The circulating levels of these BALP isoforms can vary independently during the pubertal growth spurt and in metabolic bone diseases. We postulated that structural differences between the BALP isoforms, which allow for HPLC separation, reflect different patterns of glycosylation. The three BALP isoforms were prepared from extracts of human osteosarcoma (SaOS-2) cells and separated by anion-exchange chromatography, using Q-Sepharose beads. Identities of the BALP isoforms were confirmed by HPLC. All three BALP isoforms were similar with respect to: freeze/thaw stability; solubility (100% soluble); heat inactivation; and inhibition by L-phenylalanine, L-homoarginine, and levamisole. The isoforms were also kinetically similar (i.e., no differences in maximal velocity or Michaelis constant at pH 8.8 and pH 10.0). The isoforms differed, however, with respect to sensitivity to precipitation with wheat germ lectin (WGL), p<0.001, but not concanavalin A (Con A). At 3.0 mg/mL, WGL precipitated about 20% of B/I but more than 80% of B1 and B2. At 10 mg/mL, Con A precipitated about 20% of B/I, B1, and B2. Together, these data suggest that B1 and B2 have more (or more reactive) sialic acid residues, compared with B/I, and that the isoforms do not differ with respect to accessible (reactive) mannosyl/glucosyl residues. Gel filtration chromatography appeared to show a difference in the molecular weights (MW) of the BALP isoforms, with B/I at 76 kd; B1 at 178 kd; and B2 at 184 kd. Further studies showed that this difference was also due to differential sialylation. Desialylation of B2 with neuraminidase decreased the apparent MW (to that observed for B/I), suggesting that desialylation results in non-specific interactions between uncharged carbohydrate residues on BALP isoforms and the agarose filtration beads, causing underestimation of the MW. All three BALP isoforms were similarly cross-reactive in the commercial Alkphase-B and Tandem-MP Ostase immunoassays, r = 0.944 and r = 0.985, respectively (p<0.001). Further studies are required to compare their immunoaffinities. In summary, our data indicate that B1 and B2 have more (or more reactive) sialic acid residues compared with B/I. The isoforms do not differ with respect to reactive mannosyl/glucosyl residues, reaction kinetics, or MW. A better knowledge of the molecular structures of these glycoproteins, and the difference between them, should advance our understanding of the function of BALP and of the clinical utility of measuring these isoforms in serum.

Biochemical Markers of Bone Turnover in Response to Dietary Salt. C. Palacios,*[1] K. Wigertz,*[1] B. R. Martin,*[1] M. Peacock,*[2] C. M. Weaver.[1] [1]Foods and Nutrition, Purdue University, W Lafayette, IN, USA, [2]School of Medicine, Indiana University, Indianapolis, IN, USA.

Biochemical markers of bone turnover and hormonal status were measured in 22 black and 14 white female adolescents during a controlled metabolic study. The study comprised 2 sessions of 3-week balances, at 2 levels of dietary sodium. Subjects were randomized to a low (1.3±0.6 g/d) or a high (4.0±1.0 g/d) sodium diet in a crossover design with calcium intake held constant at ~815 g/d. Age was 12±1 y in blacks and 12.9±1.2 y in whites (p<0.05). Subjects were matched by postmenarcheal age (9.5±12.7 months in blacks and 10.1±11.9 months in whites) and weight (55.8±12.7 kg in blacks and 56.3±16.2 kg in whites). Fasting biomarkers of bone turnover and hormonal indices measured and at the end of the study and last 2 weeks average 24-h urinary calcium are shown in the following table:

Biomarker	Dietary Na level	Whites	Blacks	p value
Serum				
25 OH Vitamin D	Low	39.8±7.1	26.6±7.5	0.0001
(ng/ml)	High	44.6±10.6	27.2±9.5	0.0001
1,25 OH Vitamin D	Low	37.7±10.9	44.1±15.1	0.05
(pg/ml)	High	39.3±10.3	46.8±15.4	0.05
Osteocalcin	Low	56.3±38.1	39.2±24.8	NS
(ng/l)	High	60±23.7	46.2±23.7	NS
Bone alkaline	Low	67.5±18.2	66.8±30.5	NS
phosphatase (ng/ml)	High	66.4±29.6	66.4±26.7	NS
Parathyroid hormone	Low	19.6±9.6	22.7±7.9	NS
(pg/ml)	High	22.2±10.7	26.2±10.9	NS
Insulin-like growth	Low	465±112	506±96.6	NS
factor I (ng/ml)	High	499±138	556±73.5	NS
Urine				
Average 24-h urinary	Low	62 ± 35	44 ± 39	NS
calcium (mg/d)	High	101 ± 41	48 ± 36	0.05
N-telopeptide	Low	345±124	320±161	NS
(nmol BCE/mmol Cr)	High	294±90	289±155	NS

* p-value refers to the difference between blacks and whites within dietary sodium level There were no significant differences in any of these parameters due to sodium intake except for urinary calcium. The white girls had significantly higher urinary calcium excretion while consuming the high sodium diet compared to the low sodium diet whereas blacks had no change in urinary calcium excretion due to the sodium intake. Despite the sodium induced urinary calcium output in the white girls, no changes in the bone turnover variables were observed. Whites had significantly higher 25-OH vitamin D but lower 1,25-OH vitamin D compared to blacks. Fasting biochemical markers of bone turnover did not reflect changes in calcium metabolism during a 3-week period in adolescents.

SA097

Sandwich CLIAs for the Variants of the Aminoterminal Propeptide of Type I Procollagen. E. Marjoniemi,*[1] L. Hakalahti,*[2] M. Immonen,*[2] S. Niemi,*[2] A. Novamo,*[2] J. Risteli.[1] [1]University of Oulu, Oulu, Finland, [2]Orion Diagnostica, Oulu, Finland

At least two variants of type I collagen are found in vivo. The classical form contains two different gene products, two α1-chain and one α2-chain of type I collagen, whereas the type I α1- homotrimer collagen contains three similar α1-chains. During the biosynthesis of these collagen variants also two different aminoterminal propeptides (abbreviated hetPINP and hotPINP) are formed. The presently available immunoassays for the intact PINP can not distinguish them. The ability to detect the synthesis of type I α1-homotrimer collagen would be interesting, since the Sp1 polymorphism of the COL1A1 gene has been suggest to lead to its synthesis e.g. in advanced age. The α1-homotrimer collagen is less mineralized and the stabilizing cross-links are also formed in a different way. The decreased tensile strength of the α1-homotrimer collagen fibers could explain the increased fracture risk.The hotPINP was purified from human ascitic and pleural fluids. It could be separated from the hetPINP by DEAE-chromatography in low pH (5.0), since the hotPINP contains 50% more negatively charged phosphate groups. Since there may be variation in the extent of phosphorylation, also other methods such as size exclusion and reverse phase chromatographies would be needed to totally remove the other variant from the standard preparations. After separation of these two forms, their consentrations can be estimated by the intact PINP radioimmunoassay, which measures both PINP variants equally. We selected a sandwich chemiluminescence immunoassay (CLIA) technology to distinguish if there is two or three similar α1-chains in the propeptide. At first thirteen differents monoclonals antibodies agaist the intact PINP were tested both in capture and reporter positions thus giving 169 different antibody combinations. The antibodies were biotinylated or labeled with an acridiniumester. The platform used was a 96-well plate coated streptavidin. A flash-type chemiluminescence was analyzed by a Victor[2] multilabel counter (PerkinElmer Wallac Inc). Thirty four antibody combinations gave an immunoassay which detected both the heterotrimer and homotrimer PINP and several assays measured them equally. A CLIA for the intact PINP gave a correlation of 0.953 (n = 100) with the intact PINP radioimmunoassay. Seven pairs were able to react preferentially with the hotPINP. Since our hetPINP preparations still seem to contain some hotPINP, the exact determination of the cross-reaction needs further work. Also the clinical significance of the presence of hotPINP in serum will be then evaluated.

Disclosures: Risteli J,7.

Quantitative Ultrasound and Its Association to Hormone Replacement Therapy - Results of the SEMOF-Study. F. C. Hartl,[1] J. Cornuz,[2] A. Tyndall,*[1] M. A. Krieg,[2] C. Ruffieux,*[3] P. Burckhardt.[2] [1]Rheumatology, University, Basel, Switzerland, [2]Internal Medicine, University, Lausanne, Switzerland, [3]Statistics, University, Lausanne, Switzerland.

Cross-sectional data of the SEMOF-study (7550 postmenopausal women, mean age 75.3 years ± 3) were used to analyse the association of hormone replacement therapy (HRT) and quantitative ultrasound measurements (QUS). SEMOF is a prospective, population based cohort study in Switzerland to asses the predictive value of QUS for hip fractures. QUS measurements were performed by trained personnel in 10 centres with 3 different ultrasound devices (Lunar Achilles, Hologic Sahara and IGEA DBM Sonic). Additionally a questionnaire regarding risk factors for osteoporosis was completed. 6225 subjects were eligible for further analysis after exclusion of individuals with missing information about HRT intake (n=139), unknown duration of HRT use (n=228), unidentified drug (n=401) and treatment with non-recognised drugs (n=557). Only subjects not indicating a diagnosis of osteoporosis in the questionnaire were further evaluated (n=5076). Of those, subjects with current use of HRT since at least 5 years or longer were regarded as current users (n=398 or 7.8%). Women never being exposed to such a treatment were defined as never users (n=4182 or 82.4%). All QUS measurements were significantly higher in current users compared to never users, this difference persisted after adjustment for confounding variables. It was observed that current users were significantly younger (73.7 vs. 75.5 years), had less weight (63.7 vs. 66.2 kg), were taller (160.2 cm vs. 158.5) and presented a lower BMI (24.8 vs. 26.4 kg/m²). Additional variables being associated with HRT were identified using a logistic regression analysis. Therefore current HRT users had a better formation, reported a higher rate of surgical menopause and were living more often with their husbands than never users. Bone status measured by QUS in elderly women seems to be preserved in current HRT users (HRT 5 years or longer), even so significant differences for health and socio-economic profiles were observed between never and current users in this large population based sample.

Table: Adjusted QUS variables of 4545 subjects in never and current users:

QUS device	Never users n=4156	Current >5 years. n=389	p-value current (>5 years) vs. never users
Achilles Stiffness	69.6 ± 12.3	79.0 ± 13.6	<0.0001
Achilles SOS	1511.5 ± 26.1	1530.3 ± 29.3	<0.0001
Achilles BUA	99.7 ± 9.5	105.9 ± 10.2	<0.0001
HologicQUI	74.8 ± 16.4	86.6 ± 18.5	<0.0001
Hologic SOS	1517.3 ± 26.5	1535.6 ± 30.6	<0.0001
Hologic BUA	57.9 ± 15.0	68.4 ± 16.0	<0.0001
DBM SOS* *Missing values in 47 subjects	1844.9 ± 98.7	1905.0 ± 100.9	<0.0001

Differential Effects of Multi-site SOS and DXA on Cortical Bone with HRT. K. M. Knapp,[1] G. M. Blake,[1] T. D. Spector,[2] I. Fogelman.[1] [1]Osteoporosis Unit, Guy's Hospital, London, United Kingdom, [2]Twin Research and Genetic Epidemiology Unit, St Thomas' Hospital, London, United Kingdom.

Hormone Replacement Therapy (HRT) is commonly used for the prevention and treatment of postmenopausal osteoporosis. The aim of this study was to investigate the effects of HRT use on speed of sound (SOS) measurements in cortical bone. A group of premenopausal women (n=278, mean age 38 ± 9 years), postmenopausal women (n=191, mean age 59 ± 7 years) and women receiving HRT (n=126, mean age 56 ± 7 years, mean HRT duration 7 ± 4 years) were recruited from Guy's and St Thomas' Hospitals. All women were normal healthy subjects as judged by the absence of any risk factors for osteoporosis. All patients had SOS measurements of their non-dominant third proximal phalanx, 1/3 radius, midshaft tibia and fifth metatarsal using the Sunlight Omnisense (Rehovot, Israel) and DXA measurements of the lumbar spine and proximal femur using Hologic QDR densitometers (Bedford, MA). T-scores were calculated using the premenopausal controls aged 20-40. Multivariate regression analysis was used to examine the effect of age, HRT usage, and their interaction on T-score values.

Site	Mean T-score Controls[a]	T-score difference[b]	p-value	Age coefficient[c]	p-value
RAD	-1.00	0.55	<0.001	-0.06	<0.001
TIB	-0.80	0.51	<0.001	-0.04	0.001
PLX	-1.09	0.29	0.053	-0.10	<0.001
MET	-0.65	0.26	0.055	-0.04	0.007
LS	-0.70	0.42	<0.001	-0.06	<0.001
THIP	-0.37	0.08	0.519	-0.05	<0.001

[a] = mean T-score at mean age for whole study group (58 years), [b] = mean increment in T-score due to HRT usage, [c] = mean decrease in T-scores per year. A positive effect of HRT usage on SOS T-scores was found at all four sites, although the effect at the phalanx and metatarsal was smaller and just failed to reach significance. The DXA T-scores for the lumbar spine are significantly different between the two groups, although the differences for the proximal femur are considerably smaller and insignificant. These results show that HRT has a positive effect on SOS measurements in cortical bone, which is greater than the effect found in the proximal femur using DXA. This suggests that SOS measurements may be measuring different aspects of bone than density (BMD) and that HRT may affect bone structure as well as BMD.

Changes in QUS and BMD Measurements with Antiresorptive Therapy: A Two-Year Longitudinal Study. M. L. Frost, G. M. Blake, I. Fogelman. Osteoporosis Screening & Research Unit, Guy's Hospital, London, United Kingdom.

The aim of this two-year longitudinal study was to assess whether calcaneal quantitative ultrasound (QUS) measurement variables respond to antiresorptive therapy and whether these measurements display adequate long-term precision to be useful for monitoring purposes. The study population consisted of 195 postmenopausal women who were placed into one of three groups: (i) 39 women treated with antiresorptive therapy who commenced treatment at baseline; (ii) 25 women treated with antiresorptive therapy who had been on treatment for at least two years at baseline; (iii) 131 women who did not taken antiresorptive therapy during the two year study period. Subjects had baseline and 12 and 24 months follow-up BMD measurements at the lumbar spine (LS), femoral neck (FN) and total hip (HIP) and calcaneal QUS measurements of broadband ultrasound attenuation (BUA) and speed of sound (SOS) on the Hologic Sahara. For women in Group 1, all BMD and QUS variables increased significantly from baseline after two years of treatment. For women in Group 2, only HIP BMD and BUA increased significantly after two years and the changes were less than those observed in women in Group 1. The overall treatment effect for each measurement variable, defined as the difference in the mean absolute changes between Group 1 and Group 3 after two years, was 0.08, 0.03 and 0.04 g/cm^2 for LS, FN and HIP BMD, and for BUA and SOS was 5.8 dB/MHz and 13.1 m/s respectively. When the overall treatment effect was expressed in T-score units, the effect was greatest for LS BMD (0.65 T-score units) and lowest for FN BMD (0.31 T-score units). QUS measurement variables yielded intermediate values of 0.43 to 0.52 T-score units. The average least significant change (LSC = precision error * 2.8) was 0.38 T-score units for BMD measurements, while the LSC for QUS measurements was three-times greater at approximately 1.20 T-score units. Ninety-four percent of the women in Group 1 showed changes in LS BMD that exceeded the LSC after two years, while the percentage was lower for the other measurement variables ranging from approximately 6% for FN BMD and SOS to 50 % for HIP BMD. A lower percentage of women in Group 2 and 3 displayed changes that exceeded the LSC for both BMD and QUS measurement variables. In conclusion, calcaneal QUS measurement variables were found to show a highly significant response to antiresorptive therapy. However, the precision of QUS measurements was not good enough to allow QUS to be used for monitoring response to treatment. Future improvements in the precision of calcaneal QUS measurements are required to increase the utility of QUS for monitoring purposes.

Normative Data for Ultrasound measurement of the Calcaneus within a Male Caucasian Population. H. J. Hinkley, I. P. Drysdale, D. Bird,* N. J. Walters.* British College of Naturopathy and Osteopathy, LONDON, United Kingdom.

After routine scanning of male subjects it was observed that a higher than expected proportion were diagnosed as being at risk of Osteoporotic fracture. This was seen particularly in younger age groups and suggests that the McCue normative data line may be too high.The purpose of this study was therefore to re-determine normative data for Caucasian men aged 29 to 80 years, using the McCue Cubaclinical II device.A questionnaire was used to determine handedness and eligibility for the study. Exclusions were use of Corticosteroids or Thyroxine for more than 6 months or a previous history of fracture. There were 276 men within the age range 20 to 80 years, recruited from various sources.Broadband ultrasound attenuation (BUA) was determined for the left and right calcaneus, each three times in succession. Both heels were re-positioned between each measurement to compensate for anatomical variation.There was a significant difference between non-dominant and dominant measures (P<0.05). For the purpose of normative data, the mean of the non-dominant BUA was used. Linear regression gave an R^2 of 0.089 (P<0.0001). The lin-

ear regression line resulting from this study was found to be lower than the MCCue line, with BUA values of 96 db/MHz as opposed to 113 db/MHz at age 20 and 77 db/MHz instead of 85 db/MHz at age 80.The same procedure was applied to 360 female Caucasians previously assessed (linear R^2 value of 0.143, P<0.0001). A significant difference was found between non-dominant BUA measurements for male and female, across all ages, with male being higher.

SA105

Maternal History of Osteoporosis Is a Major Determinant of Peak Bone Mass in Southern Chinese Premenopausal Women. A. Y. Ho,[*1] H. L. Lau,[*1] S. S. Yeung,[*1] J. L. Chan,[*1] A. W. Kung.[*1] [1]University of Hong Kong, Queen Mary Hospital, Hong Kong, Hong Kong Special Administrative Region of China.

Genetics influence is known to be a major determinant of peak bone mass and subsequent risk of osteoporosis in later life. To determine the role of genetic and environmental impact on bone mass, we measured bone mineral density (BMD) of the anterior-posterior lumbar spine and the hip in 464 premenopausal southern Chinese women by dual energy X-ray absorptiometry (DEXA, Hologic QDR 2000+). 265 of them had a maternal history of osteoporosis (Group A, maternal T-score hip/spine less than or equal to -2.5 or maternal history of hip/vertebral fracture) and 199 women were born to mother with T-score greater than -2.5 (Group B). Women in group A had significantly lower BMD at both the lumbar spine and the hip (L1-L4 BMD 0.958 ± 0.117 g/cm^2 vs 0.987 ± 0.116 g/cm^2, p = 0.01; Total hip BMD 0.816 ± 0.143 g/cm^2 vs 0.841 ± 0.103 g/cm^2, p = 0.04). The two groups were similar in their body weight, serum calcium, phosphate, total alkaline phosphatase, exercise levels (standing time and walking time per day) and daily calcium intake, but women in Group A were significantly shorter (p = 0.02) and older (p = 0.001). After adjusting for age and height using analysis of covariance, women in Group A still had significantly lower BMD at the lumbar spine (3.0 %, p < 0.05) and the hip (3.1%, p = 0.05) than those in Group B. Multiple regression analysis showed that body weight, maternal history of osteoporosis and serum total alkaline phosphatase were significant predictors of BMD at both lumbar spine and total hip. We concluded that genetic influence in terms of maternal history of osteoporosis is a major determinant of peakbone mass in southern Chinese premenopausal women.

Two Inbred Rat Strains Which Differ Substantially in Hip Fragility. Q. Sun,[*1] F. M. Hinant,[*2] C. H. Turner.[1] [1]Department of Orthopaedic Surgery, Indiana University, Indianapolis, IN, USA, [2]School of Medicine, Indiana University, Indianapolis, IN, USA.

One approach for identifying the genetic influences on skeletal phenotypes involves the creation and genetic mapping of a population of F2 offspring derived from a cross of two inbred strains of rodents. The two inbred strains should be chosen based upon a large difference in the phenotype of interest, e.g. bone fragility. We found previously that considerable variation exists in fragility phenotypes among inbred strains of rats, and the phenotypic variation was site specific. The aim of this study was to identify useful inbred rat strains for studies of genetic influences on hip fragility. Two inbred rat strains, Copenhagen 2331 (COP) and DA, were found to differ significantly in femoral neck size and strength as assessed by pQCT, biomechanics and geometry measurements. At six months of age, COP rats had 16 % greater proximal femur bone mineral content (BMC), 31% higher ultimate force (Fu), 47% higher ultimate displacement (du), 73% higher work to failure (U), and a significantly wider femoral head and neck, as compared to DA rats (Table 1). These data indicate that significant phenotypic variation at the femoral neck site exists between these two inbred strains, and COP rats appear to have genes that specifically enhance the femoral neck structure and strength. Therefore the cross of these two inbred strains, COP with DA, may provide a compelling model for the genetic studies of hip fragility.

Studies Using Congenic Mice Reveal That Chromosome 1 QTL Locus in Cast/EiJ Mouse Contributes to 30% Variation in BMD Difference Between CAST and C57BL Mice. W. Gu,[1] B. Edderkaoui,[1] W. Beamer,[2] X. Li,[1] H. C. M. Sheng,[1] J. Wergedal,[1] K. Shultz,[*2] K. H. W. Lau,[1] L. R. Donahue,[*2] C. Rosen,[*3] S. Mohan,[1] D. J. Baylink.[1] [1]MDC, Pettis VAMC, Loma Linda, CA, USA, [2]The Jackson Lab, Bar Harbor, ME, USA, [3]St. Joseph's Hospital, Bangor, ME, USA.

Peak BMD is one of the strongest determinants of subsequent osteoporotic fracture risk. More than 70% of variance in peak BMD is determined by genetic factors. In previous studies using F2 female mice generated from CAST/EiJ (CAST) and C57BL/6J (B6) mouse strains, which exhibit high and low peak BMD, respectively, we identified four statistically significant quantitative trait loci (QTL) that contributed to BMD variation between these two strains. In this study, we focused on the genetic effect of a QTL locus located on chromosome 1 because: 1) this QTL locus exhibited the highest LOD score of 8.0 among the 4 QTLs; and 2) this QTL is located on the syntenic region of human chromosome 1Q21-23, a region implicated in peak BMD regulation in humans. To determine whether chromosome 1 QTL contains biologically active gene(s) that contribute to a significant peak BMD difference between CAST and B6 strains, we generated congenic strains by transferring CAST chromosome 1 QTL region (donor) into the B6 strain (recipient). We found that the volumetric BMD at the mid diaphysis of the femur by PQCT was significantly higher in the congenic mice compared to age-matched B6 mice at 16 weeks of age (685±34 vs 638±41 mg/cm^3; P<0.05). In order to determine if this QTL exerts sex-specific effects, we evaluated BMD difference in both male and female mice. BMD was significantly increased in both male and female congenic mice compared to corresponding sex and age-matched B6 mice, thus suggesting that the effect of this QTL was not dependent on sex-specific hormones. To determine if the chromosome 1 QTL acted in a dominant or additive manner, we evaluated BMD difference between CAST/CAST homozygous and CAST/B6 heterozygous mice for this QTL. We found that, while the homozygous CAST genotype of the QTL locus contributed to 30% of the variation in BMD between CAST and B6 mice, the heterozygous genotype contributed to approximately 15% of the BMD variation, thus suggesting that chromosome 1 QTL acts in an additive manner. Conclusions: 1) The QTL region on mouse chromosome 1 contains a gene(s) that contributes to 30% of the variation in femur BMD between B6 and CAST strains. 2) Allele in CAST chromosome 1 QTL acts in a sex-independent and additive manner. 3) Congenic approach can be used to evaluate the relative contribution of a QTL to a phenotypic variation between the two inbred strains used for QTL mapping.

Areal and Volumetric Bone Mineral Density (BMD) and Bone Volume in Men with Primary Osteoporosis and Their First-Degree Male Relatives: Further Evidence for a Familial Effect. P. R. Ebeling,[1] B. Erbas,[*2] S. Ristevski,[*1] C. Poon,[*1] S. Yeung.[*1] [1]Diabetes and Endocrinology, The Royal Melbourne Hospital, Parkville, Australia, [2]General Practice and Public Health, The University of Melbourne, Parkville, Australia.

Osteoporosis in men is set to become an important public health problem. By 2010, 30% of all hip fractures will occur in men. While areal BMD is lower in daughters of women with postmenopausal osteoporosis, there are few data examining familial effects on areal and volumetric BMD, or bone volume, in relatives of men with primary osteoporosis. We assessed areal and volumetric BMD, and bone volume in men with primary osteoporosis and their first-degree male relatives (FDMR) to determine if there was a familial effect on the development of primary osteoporosis in men.Sixty-five normal, healthy men (Gp1); 113 men with primary osteoporosis (Gp2); and 66 of their FDMR were examined. FDMR were divided into 2 groups according to whether they had a t-score -2 (Gp 4). Participants were recruited by advertising through local newspapers; via a staff member, family, friends; and sporting clubs. BMDs at the spine (LS) and femoral neck (FN), and total body (BMC) were measured by DXA and vertebral and FN volumes were calculated by standard formulae. Values in all groups were corrected for age.Osteoporosis (t< -2) occurred in 41% of FDMR. BMD at all sites was lower in OP men and FDMR than in normal men. Age was negatively related to areal and volumetric BMDs at the FN and also to FN volume, while fat mass was positively related to age. All values were lower in OP men than in normal men, except fat mass and FN volumetric BMD. While LS and FN areal BMDs were both lower in FDMR only LS, but not FN volumetric BMD, was lower in FDMR.

Value	Gp1 vs Gp2	Gp1 vs Gp3	Gp1 vs Gp4
LS aBMD b	-0.25 (0.02)**	-0.21 (0.03)**	-0.04 (0.03) NS
FN aBMD b	-0.24 (0.02)**	-0.21 (0.03)**	-0.02 (0.03) NS
TBBMC b	-0.28 (0.10)**	-0.15 (0.13) NS	-0.14 (0.13) NS
% Fat	1.56 (1.12) NS	2.54 (1.47) NS	4.61 (1.44)**
Vert vol b	-0.06 (0.03)*	-0.04 (0.04) NS	0.010 (0.03) NS
LS vBMD b	-0.24 (0.03)**	-0.20 (0.04)**	-0.03 (0.03) NS
FN vol b	-0.17 (0.07)*	-0.12 (0.10) NS	-0.03 (0.09) NS
FN vBMD b	-0.12 (0.07) NS	-0.11 (0.10) NS	-0.02 (0.09) NS

Indicates Log to the base transformation of data; *, p < 0.05; **, p < 0.001.The high prevalence of low BMD in FDMR provides further evidence for a familial effect in primary osteoporosis in men. The familial effect may have a greater impact on spinal volumetric BMD, while age-related effects may predominate at the proximal femur

Extensive Screening of Candidate Genes for Ossification of the Posterior Longitudinal Ligament of the Spine. K. Furushima,[*1] T. Tanaka,[*1] S. Maeda,[2] K. Ikari,[1] T. Nobukuni,[*3] K. Shimo-onoda,[*2] T. Nakajima,[*3] S. Komiya,[*2] S. Harata,[*1] I. Inoue.[*3] [1]Dept. of Orthopaedic Surgery, Hirosaki Univ., Aomori, Japan, [2]Dept. of Orthopaedic Surgery, Kagoshima Univ., Kagoshima, Japan, [3]Division of Genetic Diagnosis ,The Institute of Medical Science,The University of Tokyo, Tokyo, Japan.

Ossification of the posterior longitudinal ligament of the spine (OPLL) showing ectopic bone formation in the posterior ligament is a common disorder among Asian populations, where an estimated prevalence of 2-4 % of the general population. Ectopic ossification

compresses the spinal cord and leads to various degrees of neurological symptoms from discomfort to severe myelopathy. OPLL is a hyperostotic disease with a pathology almost the opposite of osteoporosis, a typical bone loss disease. Despite the late onset, OPLL has a strong genetic background, as shown in the classical epidemiological study and by the estimated relative risk to siblings of ~10. Because genetic determinants appear to play a crucial role in the etiology of OPLL, we began a large scale screening for genetic loci linked with OPLL. In the present study, we performed an extensive non-parametric linkage study with 126 affected sib-pairs using markers for various candidate genes by two distinct analyses, SIBPAL and GENEHUNTER. 88 candidate genes were selected based on two distinct investigations: 1) genes identified by cDNA microarray analysis of systematic gene expression profiles during osteoblastic differentiation of human mesenchymal stem cells, and 2) genes known to be involved in bone metabolism. The newer technique using cDNA microarray-based technology provides a more extensive range of biological information on the interplay of genes. Of the 24 genes regulated during osteoblastic differentiation, only one, the alpha B crystalline gene, showed evidence of linkage (P=0.016, NPL=1.83). Of 64 genes known to be associated with bone metabolism, 6 showed weak evidence of linkage by SIBPAL analysis (P<0.05): BMP4, PRG1, TGFb3, OPN, PTHR1, and IGF1. Among these genes, BMP4 (NPL=2.23) showed evidence of linkage by GENEHUNTER. Because the functional role of BMP-4 in bone metabolism is well established, further investigation of molecular screening for BMP-4 is needed to detect the exact causality of OPLL.

Genetic Determinants of Osteoporosis Susceptibility in a Female Ashkenazi Jewish Population. V. Kantorovich,[1] D. H. Cohn,*[2] H. Yang,*[2] L. S. C. Cheng,*[2] S. Chen,*[1] J. I. Rotter,*[2] J. S. Adams.[1] [1]Burns and Allen Research Institute, UCLA/Cedars-Sinai Medical Center, Los Angeles, CA, USA, [2]Human Genetics, UCLA/Cedars-Sinai Medical Center, Los Angeles, CA, USA.

Although multiple environmental factors influence the development of osteoporosis, the major determinant for the disease is oligogenetic control of the achievement of peak bone mass. To identify loci that determine susceptibility to osteoporosis, we initiated the study of a single ethnic group, Ashkenazi Jews, where the incidence of osteoporosis is known to be high. Here we present bone phenotype data from 162 subjects in 56 different families in our Ashkenazi Jewish cohort and preliminary results from candidate gene linkage analysis. We also studied 69 control patients who included both non-Jewish and non-Ashkenazi subjects from families with osteoporosis/osteopenia, as well as Ashkenazi Jewish subjects without a family history of osteoporosis. Compared to the control population, Ashkenazi Jewish probands had significantly lower age- and sex-matched values of mean (±SE) bone mineral density at both lumbar spine (lumbar Z score 0.060±1.380 vs. -0.510±1.050; p=0.006) and femoral neck (hip Z score -0.400±0.900 vs. -0.900±0.620; p=0.0003). Variant Component Analysis, based on 94 sib-pairs and with adjustment for age, was used to estimate the genetic component of bone density. While heritability was found to be insignificant for lumbar bone mass, it showed high significance for both T and Z scores at the femoral neck, 0.34 (p=0.0001) and 0.38 (p=0.0017), respectively. We further carried out linkage analysis for candidate genes, starting with the genes that encode type I collagen. Genotypes were determined at microsatellite loci either tightly linked or within the COL1A1 and COL1A2 genes, respectively. Using SIBPAL, both qualitative and quantitative analysis of linkage to osteoporosis was calculated. No significant support for linkage was found with these markers. However, the proportion of allele sharing at COL1A2 among affected pairs was 0.62 (p=0.051) suggesting that the shared allele may contribute to disease susceptibility. We conclude that: 1] the Ashkenazi Jewish population shows significantly lower bone mass at the femoral neck and lumbar spine compared to our mixed-ethnicity control population; 2] there is significant inheritance of decreased bone density at the femoral neck; 3] with the initial number of families studied, there was no linkage between bone mineral density and the markers tested for the type I collagen; and 4] there was increased allele-sharing at COL1A2 among affected pairs, providing evidence that this locus may contribute to osteoporosis.

Geometry as a Heritable Determinant of Bone Strength. D. H. Goddard,[1] C. Goddard,*[2] J. Hecht,*[3] E. Kim,*[4] E. R. Myers,[4] R. D. Blank,[4] R. S. Bockman.[4] [1]New York Methodist Hospital & Arthritis & Osteoporosis Center, Brooklyn, NY, USA, [2]Arthritis & Osteoporosis Center, Brooklyn, NY, USA, [3]HAFTR High School, Lawrence, NY, USA, [4]Hospital for Special Surgery, New York, NY, USA.

Fracture susceptibility is determined by a combination of genetic and environmental factors, which act in concert to establish whole bone strength. Whole bone strength depends on the mineral and organic content as well as geometry and the integrity of the structural components of the bone. Recent studies have focused on bone geometry as a potential predictor of fracture risk in specific family groups with high fracture susceptibility. Hypothesizing that individuals with similar volumetric bone mineral densities (vBMD) might differ markedly with regard to bone geometry, we used peripheral QCT scans of the forearm to measure vBMD, bone diameters, and to calculate the maximum cross-sectional moment of inertia (I) in a 3-generation family. Typical scans of the radius using a Stratec XCT-2000, peripheral QCT are shown for the 68 year old father, the 67 year old mother and the 45 year old daughter in the figure below.

family	vBMD (mg/cc)	1 mm4
father	1140	1379
mother	1225	628
daughter	1215	356

While mother and daughter have similar vBMDs, they display considerable differences in the cortical diameters. This results in large differences in the calculated I. It is not possible to determine the contribution of aging to the mother-daughter difference in bone size from these data alone. A striking sexually dimorphic difference was observed in the I values for the father and mother. All members of this family have low BMD values, however, it is the striking difference in bone size that highlights the potential importance of geometry as a determinant of bone strength and in evaluating fracture susceptibility.

Genetic Regulation of the Bone Regenerative Capacity: Studies of 12 Inbred Strains of Mice. X. Li,* W. Gu,* G. Masinde,* C. Rundle,* S. Mohan,* D. Baylink.* Jerry L. Pettis VA Medical Center, Loma Linda, CA, USA.

Bone is one of the few tissues that has innate ability to regenerate upon damage. Based on the recent findings that ear-tissue regeneration in mice is genetically controlled, we hypothesized that bone regenerative capacity is different among the inbred strains of mice and that the variation in bone regeneration is determined by genetic factors. To evaluate this hypothesis, we have developed a "drill-hole" model in the tail vertebra of mice, a model which allows us to reproducibly introduce an injury with a defined boundary and quantify the rate of bone healing (CV≈6%) using the combination of high resolution Faxitron X-ray images and a ChemiImager^{TM} 4000 Low Light Imaging System. Using this model, we have found that bone regenerative capacity differs significantly among the inbred strains of mice (ANOVA, p<0.001). Of the 12 inbred strains tested, the order of bone regenerative capacity was Sencar/PtJ>129J>C3H/HeJ>DBA/1J>NZB/BinJ>LP/J>LG/J>KK/HiJ>RIIIS/J>C57BL/6J >FVB/NJ>CBA/J. Sencar/PtJ has been identified as a suitable model for the study of hard-tissue regeneration. It healed 3 times as fast as slow healer, CBA/J (70.7±14 relative density unit for Sencar/PtJ vs 23.6±5.5 for CBA/J. p<0.001). Heritability estimate revealed that 72% of variation in the healing of tail vertebra is genetically controlled. To determine if bone and ear tissue regeneration is under the control of common genetic mechanisms, we evaluated the correlation between the two phenotypes. We found no significant correlation in healing capacity between soft-tissue and bone-tissue among the 12 inbred strains (r=-0.08, p=0.67), suggesting that different set of genes may regulate the two phenotypes (the order of ear-healing capacity: LG/J>CBA/J>Sencar/PtJ>RIIIS/J>DBA/1J >LP/J> C3H/HeJ>KK/HiJ >C57BL/6J>FVB/J>NZB/BinJ>129J). We next determined if the ability to heal bone is correlated with the BMD phenotype. It was found that tail vertebral regeneration correlated positively (r=0.49, p<0.01) with total body BMD by DEXA, suggesting that BMD and bone regeneration may be regulated by some common genetic mechanisms. Conclusions: 1) Inbred strains of mice exhibit variation in the ability to heal drill hole in the tail vertebra. 2) 72% variation in bone healing capacity is genetically regulated. 3) Some common genetic mechanisms may regulate BMD and bone regeneration. 4) Different genetic mechanisms may regulate bone- and soft-tissue regeneration.

Genetic Heterogeneity in Familial Renal Magnesium Wasting. V. Kantorovich,[1] R. K. Rude,[2] J. E. Gaines,*[2] X. Guo,*[3] M. R. Pandian,*[4] D. H. Cohn,*[3] J. S. Adams.[1] [1]Endocrinology, Diabetes and Metabolism, UCLA/Cedars-Sinai Medical Center, Burns and Allen Research Institute, Los Angeles, CA, USA, [2]Endocrinology, Diabetes and Metabolism, USC/LA County Hospital, Los Angeles, CA, USA, [3]Human Genetics, UCLA/Cedars-Sinai Medical Center, Los Angeles, CA, USA, [4]Corning Nichols Institute, San Juan Capistrano, CA, USA.

Although Mg depletion is usually an acquired disorder, there are several rare inherited forms of isolated Mg deficiency. Two familial forms of primary hypomagnesemia due to renal Mg wasting have been described. One form (OMIM #248250) is inherited in an autosomal recessive fashion and results from mutations in the paracellin 1 gene (PCLN1) on chromosome 3. Another is an autosomal dominant form (OMIM #154020) originally described in two unrelated Dutch families. The related gene was localized to chromosome 11q23 and identified as the Na+, K(+)-ATPase gamma subunit gene FXYD2. Its product is expressed in the epithelial cells of the renal distal convoluted tubule and participates in Mg reabsorption. Here we describe an American family with a phenotype similar to OMIM #154020 but without linkage to 11q23. The index case, a 36 year old female, presented with paraesthesias, muscle weakness and seizures. Her evaluation showed hypomagnesemia and hypermagnesuria, which persisted despite aggressive Mg replacement. Prospective assessment revealed 6 additional subjects with frankly low serum Mg from a

total of 22 family members. Compared to unaffected relatives and normal controls, affected family members harbored significant reductions in serum (1.1±0.2 vs. 1.9±0.1, p<0.001 [normal 1.7-22 mg/dL]) and lymphocyte (1.0±0.2 vs. 1.5±0.4, p=0.01 [normal 1.2±0.2 µg/mg protein]) magnesium concentrations. The mean fractional clearance of Mg during a normomagnesemic clamp was significantly elevated in 7 affected subjects (proband and 6 family members) compared to unaffected family members (p<0.001) and controls (p<0.001). Bone mineral density at the femoral neck, but not at the lumbar spine, was significantly reduced (p=0.03) in affected family members. Genotypes were determined using reported markers: D11S4092, D11S4127, D11S4195, D11S1356, and D11S4104. Regardless of the level of penetrance specified, multi-point LOD scores for 5 different loci from the 11q23 region were less than 2.97 in all 22 individuals. We conclude that this hypermagnesuric hypomagnesemic pedigree differs from previously reported families in that 1] it shows no linkage to the 11q23 locus and 2] hypomagnesemia in this family is associated with low bone mass at the femoral neck.

The Relationship Between Serum Insulin-like Growth Factor-I(IGF-I),IGF-I Gene Polymorphism and Bone Mineral Density in Postmenopausal Korean Women. J. Kim,*[1] K. Roh,*[1] V. Yoo,[2] S. Moon,*[1] J. Lee.*[1] [1]Department of Obstetrics & Gynecology, Seoul National University Hospital, Seoul, Republic of Korea, [2]Cheongvak Primebeyond Hospital, Seoul, Republic of Korea.

The objectives of this study were to test the hypothesis that cytosine adenine (CA) polymorphism in insulin-like growth factor-I (IGF-I) gene is associated with serum levels of IGF-I and biochemical markers of bone turnover, and to investigate the relationship between this IGF-I gene polymorphism and bone mineral density (BMD) in postmenopausal Korean women.. IGF-I CA polymorphism was analyzed in 300 postmenopausal Korean women by GeneScan and direct DNA sequencing, and IGF-I was measured by radioimmmunoassay after Bio-gel P-10 preparation of serum samples. Serum bone alkaline phosphatase (BAP) and CrossLaps were measured by ELISA and BMD at the lumbar spine and proximal femur by dual energy X-ray absorptiometry. Ten IGF-I alleles were observed with product sizes ranging between 176-196 base pair (bp), and five most common allele distributions were as follows: 188 bp 26.2%, 194bp 19.8%, 186bp 18.2 %, 190bp 15.5%, and 192bp 14.3%. Guanine and adenine deletion were found following 3' end of CA repeats. After adjusting for age, years since menopause, and body mass index, serum IGF-I and BMD at most skeletal sites measured in women homozygous for 194bp allele among five major alleles were significantly higher than that in the 194bp heterozygotes or women who did not possess 194bp allele. A significantly decreased prevalence of 194/194 genotype in osteopenic and osteoporotic women was observed, compared with normal women. No correlation between IGF-I genotypes and adjusted biochemical markers of bone turnover was found. Compared with normal women, serum BAP levels were higher in osteoporotic women while no significant differences in serum crosslaps levels were observed. IGF-I gene CA polymorphism does not affect serum levels of biochemical markers of bone turnover and that this polymorphism is one of genetic factors which may affect circulating IGF-I levels and BMD at the lumbar spine and proximal femur.

SA121

Hyperthyroidism, Loss of Bone Mass, and their Relation to Vitamin D Receptor (VDR) Gene Bsm1 and Interleukin-1 Receptor Antagonist (IL-1RN) Gene VNTR Polymorphisms in Postmenopausal Women. E. Bajnok,* I. Takacs, A. Tabak,* G. Speer,* Z. Nagy, C. Horvath, P. Lakatos. 1.st Department of Medicine, Semmelweis University, Budapest, Hungary.

The genetic mechanisms on thyroid hormone-stimulated bone loss have not yet been established. Recently, an association has been found between the number of VNTR polymorphism of the IL-1RN gene and postmenopausal bone loss. Moreover, "allele A2" has been implicated in the development of Graves' disease (GD). The relationship between Bsm1 polymorphism of VDR gene and bone mineral density (BMD) has been reported in numerous population, however the results are controversial. Bsm1 genotypes seem to be associated with GD, and with BMD in hyperthyroidism (HT), too. In this study, we determined the previously described IL-1RN VNTR and VDR-Bsm1 polymorphisms to test their possible functional contribution to the pathogenesis of hyperthyroidism in 208 women. We genotyped 61 patients with GD (18-69 years) and 84 with toxic adenoma (TA) (27-78 years) and compared the genotype frequencies to that of 63 healthy controls (45-83 years). From this cohort, were investigated an association between these polymorphisms and BMD in 162 postmenopausal women. This group consisted of 62 healthy (mean age 56,2 ± 6,6 years) and 100 hyperthyroid subjects (mean age 53,7 ± 8,3) 40 patients with GD (mean age 50,1 ± 7,9 years) and 60 with TA (mean age 55,5 ± 8,1 years). BMD was measured by DXA at the lumbar spine and femoral neck. We found significant difference in the distribution of VDR genotypes, but not in case of IL-1RN. The bb genotype was significantly more frequent in TA than in the control and G group (p=0,015). No genetic polymorphism was associated with BMI and age adjusted BMD at any measured site neither in HT nor in control group. Our data do not support the hypothesis that IL-1RN gene VNTR or VDR Bsm1 polymorphism have an impact on BMD in hyperthyroid postmenopausal women. However, VDR gene might affect the development of toxic adenoma.

Lack of Association Between CaSR Gene A986S Polymorphism and Bone Density in Hungarian Postmenopausal Women. I. Takacs, G. Speer,* E. Bajnok,* Z. Nagy, A. Tabak,* C. Horvath, L. Kiss,* P. Lakatos. 1.st Department of Medicine, Semmelweis University, Budapest, Hungary.

Calcium-sensing receptor (CaSR) is an attractive candidate gene for osteoporosis susceptibility. CaSR A986S genotype has been shown to have an effect on serum calcium. Recently an association has been reported between the CaSR gene A986S polymorphism and the bone mineral density in healthy Caucasian girls. In this study, we examined whether CaSR gene A986S polymorphism is associated with decreased bone mass in 231 Hungarian postmenopausal women (age range:40-70). From this cohort, 109 osteoporotic (OP) patients (mean age:57.6±0.6) were compared with 122 (mean age:58.5±0.5) healthy control (C) women. Bone mineral density (BMD) was measured at the lumbar spine (L2-4) and femoral neck using DEXA method. Allele-specific PCR was used to amplify A986S polymorphisms of the CaSR gene. No significant effect of CaSR genotype on BMD was observed either in the whole population or in the subgroups. Our data do not support the idea that CaSR gene A986S polymorphism has an impact on bone mass in postmenopausal women.

SA124

Two Recently Described SNPs in a COL1A1 Regulatory Region Lie Within Nuclear Factor Binding Sites. N. Garcia-Giralt,*[1] A. Enjuanes,*[2] X. Nogués,*[3] L. Mellibovsky,*[3] A. Díez-Pérez,[3] D. Grinberg,*[4] S. Balcells.*[4] [1]Genetics, Universitat de Barcelona, Barcelona, Spain, [2]IMIM, Barcelona, Spain, [3]Hospital del Mar, Barcelona, Spain, [4]Dept. of Genetics, Universitat de Barcelona, Barcelona, Spain.

Polymorphisms in the regulatory region of the genes encoding type I collagen chains might be important for BMD variability. We have recently described two SNPs in the COL1A1 promoter and showed that they were associated to BMD in Spanish postmenopausal women. The aim of the present study was to analyze the binding of the regions containing the SNPs to primary osteoblast nuclear factors as a functional assay to contribute to the understanding of the molecular basis of this association.Electrophoretic mobility shift assays (EMSA) were used to detect binding of nuclear proteins to 25-30-mer oligonucleotides containing the polymorphic site in a central position. Both single and double-stranded DNA radiolabelled probes were used and competition assays with cold oligonucleotides containing known DNA binding site were performed. Nuclear extracts were prepared from 70% and 100% confluent primary osteoblast cells and from MG-63 osteosarcoma cell line. Southwestern studies were also carried out as a first characterization of the proteins bound to the probes. EMSA showed specific binding for both polymorphismic sites. For one of the SNPs, named PCOL1, only the forward ssDNA probe binds to the nuclear proteins. Competition assays allowed us to detect different binding capacities for the two alleles, the most frequent one having the highest. A Southwestern analysis performed to characterize the proteins involved in the binding, detected an 80 kD protein. A weaker band corresponding to a 48 kD protein was also seen.Nuclear factor binding to the other polymorphic site, PCOL2, was shown by EMSA both with ss-DNA (reverse) or ds-DNA probes, but was clearly stronger when the ss-DNA probe was used. The forward strand displayed a different higher molecular weight shift. Again, clear differences between the two alleles were observed. Southwestern studies for PCOL2 detected a protein in the 60-70 kD range and a smaller one of around 40 kD.In conclusion, we showed that the two SNPs lie within nuclear factor binding sites which preferentially bind proteins as ss-DNA. We also demonstrated differential binding capacities for the two alleles of each polymorphism. Finally, a preliminary characterization, in terms of molecular weight, was performed for the proteins binding to these COL1A1 regulatory regions.

Short Term Fibroblast Growth Factor-2 Treatment Increases Osteoblast Differentiation and Bone Nodule Formation, in Bone Marrow Cultures From Young and Adult Mice. M. M. Hurley, T. Sobue, X. Zhang. Endocrinology & Metabolism, University of Connecticut Health Center, Farmington, CT, USA.

Fibroblast growth factor-2 (FGF-2) has been shown stimulate bone formation in vitro and in vivo in rats. However, there are few studies in mice and only limited data on the mechanism (s) by which FGF-2 induces new bone formation. We therefore assessed whether short term treatment of bone marrow stromal cells from 2 month and 6 month old black swiss/129 mice with FGF-2 would increase alkaline phosphatase positive (ALP), mineralized colony formation as well as the expression of genes important in osteoblast maturation and bone formation. Bone marrow cells were plated at $3x10^6$ cell/well in complete media, αMEM with 10% heat inactivated fetal calf serum, 10 nM dexamethasone, 50 µg/ml ascorbic acid, and 8 mM beta-glycerophosphate in the absence or presence of varying concentrations of FGF-2 (0.01, 0.1, 1.0 nM). After 3 days, media were changed to control media without further additon of FGF-2. Cultures were stained for ALP and von-Kossa

for mineralization at 14 and 21 days. Colony area was measured using NIH IMAGE-1-61. Short term treatment with FGF-2 (0.01, 0.1, 1.0 nM) for 3 days increased the number and area of ALP colonies and colony at 14 and 21 days in marrow stromal cultures from 2 month as well as 6 month old mice. At 14 days, the maximum increase in colony number (14.7±1.4 vs 7.0±1.5) and colony area (0.26±0.03 vs 0.09±0.02) was observed in marrow stromal cultures from 2 month old mice treated with 0.1 nM FGF-2. There was also a significant increase in colony area (0.58±0.07 vs 0.24±0.05) in marrow stromal cultures from 6 month old mice that were treated with 1 nM FGF-2. Northern analysis of cultures from 2 month old mice treated with FGF-2 for the first 3 days of culture showed that FGF-2 (0.1 nM) increased type 1 collagen (COL1A1) mRNA by 152 and 134%; osteocalcin (OC) by 227 and 177%; core binding factor alpha (Cbfa1) by 123 and 121%; and insulin-like growth factor 1 (IGF-1) by 153 and 134% at 14 and 21 days respectively. Similar results were obtained in marrow cultures from 2 and 6 month old mice treated with 1 nM FGF-2 for the first 3 days of a 14 or 21 day culture period. In conclusion, short term exposure of bone marrow stromal cultures derived from young and older mice to FGF-2 significantly increased ALP colony number, size and mineralization. The increase in colony number probably represents enhanced recruitment of osteoblast progenitors by FGF-2. The increase in colony size is probably due to expansion of clones in response to FGF-2. Since these cultures showed increased expression of COL1A1, OC, Cbfa1 and IGF-1 mRNAs, we conclude that short term FGF-2 treatment can also enhance osteoblast maturation in vitro.

SA127

Basic Fibroblast Growth Factor (bFGF) Directly Stimulates Bone Pit Resorption by Isolated Osteoclasts (OC) and Promotes OC Recruitment, Development and Resorption in Association with Neoangiogenesis In Vivo. P. Collin-Osdoby, L. Rothe, S. Bekker,* F. Anderson, P. Osdoby. Biology, Washington University, St. Louis, MO, USA.

Increased local bone resorption coincides with regional angiogenesis in bone development, fracture healing, and pathological disorders such as inflammatory-related periodontal disease, rheumatoid arthritis, or tumor-associated osteolysis. Angiogenic stimulation facilitates delivery of hematopoietic precursor cells into tissues and causes the adhesion, activation, transmigration, and differentiation of cells via signals expressed on the surface of vascular endothelial cells (VEC). Thus, angiogenesis may enable greater numbers of pre-OC to emigrate from the circulation into bone and develop into resorptive OC. Recently, we showed that VEC can directly promote OC development in vitro from circulating monocytic or bone marrow precursors, and that inflammatory cytokines upregulate RANKL on human VEC thereby stimulating co-culture human OC formation and bone pit resorption. Here, we employed a chick chorioallantoic membrane (CAM) model of angiogenesis and OC development and function to investigate whether a potent angiogenic stimulator, bFGF, could promote OC recruitment, differentiation and resorption in vivo. Focal implantation of bFGF (0.5 ng) in an agarose plug adjacent to a bone chip on the CAM elicited an angiogenic response within 9 days. This was accompanied by significant increases (1.5 to 2.5-fold) in the mean number of OC formed, number of pits excavated, and total area of bone resorbed by OC in vivo. Increased resorption was a function of both increased OC numbers as well as OC activation since the area resorbed/OC was also increased (>1.5-fold), primarily due to OC initiating more resorption sites (pits/OC) rather than producing larger lacunae (area/pit). In vitro, bFGF also directly targeted mature isolated avian OC to stimulate their bone pit resorption. In contrast, bFGF did not directly influence in vitro pre-OC differentiation in avian bone marrow cell cultures. Thus, angiogenesis is an important component of bFGF stimulated OC development in vivo, and may involve bFGF-induced RANKL in VEC. Although bFGF has recently generated much interest as a potential bone anabolic agent, such effects may be transient and newly formed bone subsequently resorbed. Moreover, inflammatory elevated bFGF levels are directly linked to the extent of OC formation, joint destruction, and disease severity seen in rheumatoid arthritic patients. Our results therefore suggest that bFGF may contribute to inflammatory bone loss through direct and indirect mechanisms that stimulate angiogenesis and promote localized OC recruitment, formation and bone resorption.

Elevated mRNA Gene Expression of Fibroblast Growth Factor 23 (FGF23) in the Thymus of X-Linked Hypophosphatemic (*Hyp*) Mice. R. A. Meyer, M. H. Meyer. Department of Orthopaedic Surgery, Carolinas Medical Center, Charlotte, NC, USA.

Mutations of fibroblast growth factor 23 (FGF23) cause bone disease in autosomal dominant hypophosphatemic rickets (ADHR; Nature Genetics 26:345, 2000) as do mutations of *Phex* in X-linked hypophosphatemia. The similarities in physical symptoms and biochemical abnormalities in these two diseases suggest a common mechanism. To test whether FGF23 activity is altered in animals with mutation of the *Phex* gene, expression of FGF23 mRNA was measured in several organs of normal and X-linked hypophosphatemic (*Hyp*) mice. FGF23 has been reported to be expressed in the thalamus and thymus of the mouse (Biochem.Biophys.Res.Commun. 277:494, 2000). These organs were examined along with kidney and liver. In this study, primers were designed from the mouse cDNA sequence for FGF23 (GenBank Accession: AF263536). mRNA expression was measured by reverse transcription - polymerase chain reaction (RT-PCR) from mRNA prepared from individual mice at 4 weeks of age, normal and *Hyp*, male and female, on a C57BL/6J background. The amplimers were separated by electrophoresis and blotted to nylon membranes. The blots were probed with a ^{32}P-labeled internal oligonucleotide specific for FGF23. The ^{32}P was quantified with a phosphor imager in units of photo stimulated luminescence (PSL). No detectable amplimers were found for FGF23 in the diencephalon (epithalamus, thalamus and hypothalamus) or in the kidney. Amplimers of the predicted size were found in the liver and thymus. The mRNA expression in the liver was too variable to use for conclusions. However, the thymus had higher expression of FGF23 in the *Hyp* mice (2067 ± 217 (7) PSL, mean ± SEM (n)) than in the genetically normal mice (1275 ± 206 (7), P = 0.02). These data indicate that inactivation of *Phex* leads to up-regulation of FGF23 expression. There may be an interrelationship between these two genes in the regulation of phosphate homeostasis.

SA130

Recombinant FGF-23 Interacts in vitro with FGF Receptors 2 and 4. K. B. Jonsson,[1] M. Pragnell,*[2] T. Larsson,*[1] K. White,[3] M. Econs,[3] S. Schiavi.*[2] [1]Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA, [2]Applied Genomics, Genzyme, Framingham, MA, USA, [3]University of Indiana School of Medicine, Indianapolis, IN, USA.

Mutations in the gene encoding fibroblast growth factor 23 (FGF-23) are the most plausible cause of autosomal dominant hypophosphatemic rickets (ADHR) and high concentrations of its mRNA were recently identified in tumors that are associated with oncogenic osteomalacia (OOM). It remains uncertain, however, how ADHR-specific mutations or overexpression of FGF-23 in OOM tumors leads to phosphaturia or which receptor(s) mediates these effects. To address these issues, we expressed cDNAs encoding FGF-23 tagged at the C-terminus with a V5-epitope (FGF-23[V5]) and FGF-23 with one of the ADHR mutations (FGF-23[R176Q-V5]) in E. coli, Sf9, and COS-7 cells. Immunoblot analysis of supernatants from COS-7 and Sf9 cells expressing FGF-23[V5] revealed two distinct protein bands of =35 kD and =15 kD. In the presence of the R176Q mutation, the intensity of the lower molecular weight form of FGF-23 was dramatically reduced. Furthermore, purified recombinant, full-length FGF-23[R176Q-V5] was not cleaved when incubated with untransfected COS-7 cells. To investigate whether FGF-23 interacts with any of the known FGF receptors, we assessed binding of FGF-23[V5] to the recombinant extracellular domains of the FGF receptors 1-4 fused to the IgG-Fc fragment. Conditioned media from COS-7 cells expressing FGF-23[V5] was incubated with each of these FGF receptor-Fc chimeras and the resulting complexes were precipitated with immobilized protein A; FGF-1 and anti-FGF-1 antibodies served as positive controls. FGF4R-Fc showed the highest interaction with FGF-23[V5]. A weaker interaction was detected with FGFR2-Fc whereas binding to FGFR1-Fc and FGFR3-Fc was not detected. These results suggest that FGFR4, and possibly FGFR2 are receptors for FGF- however, an additional yet unknown receptor for FGF-23 cannot be excluded.

Different Signaling Pathways Are Involved in Runx2 Expression and RUNX2 Activation by FGF/FGFR Signaling. H. Kim,*[1] M. Park,*[1] J. Kim,*[1] S. Bae,*[2] H. Kim,*[3] H. Ryoo.[1] [1]Biochemistry, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea, [2]Biochemistry, School of Medicine, Chungbuk National University, Chungju, Republic of Korea, [3]Pediatric Dentistry, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea.

Fibroblast growth factor-2 (FGF-2) or FGF-4 strongly induced the expression of Runx2, a master transcription factor of osteoblast differentiation. However, underlying molecular signaling mechanisms involved in the FGFs-induced Runx2 expression haven't been clearly understood. We identified FGF-signaling not only induced Runx2 expression but also activated transcriptional function of the RUNX2 protein. Consistent with the result by FGFs, overexpression of constitutive active FGFR2 mutants (human Crouzon syndrome) also increased Runx2 expression and RUNX2 transactivational activity. FGF-signaling cascades were tested to determine their role in Runx2 expression and RUNX2 transcriptional function by using pathway specific inhibitors. PD98059, an Erk-specific inhibitor, and SB203580, a p38-specific inhibitor, didn't influence on FGF2-induced Runx2 expression but suppressed FGF2-induced RUNX2 transcriptional activity 5 folds and 2 folds, respectively. In contrast, blocking of JNK pathway didn't change Runx2 expression as well as its transcriptional activity. Calphostin C, a protein kinase C-specific inhibitor, strongly blocked FGF2-induced Runx2 expression and consequently almost completely suppressed RUNX2 transactivation function determined with 6XOSE2-Luc stable cells. Moreover, PKC pathway blocker also suppressed the transactivation function of exogenously expressed RUNX2 in Runx2-/- cells. These results indicate FGF/FGFR-induced Runx2 expression is resulted from the activation of PKC pathway, and the enhancement of RUNX2 transcriptional activity by FGF siganling is resulted from the activation of PKC pathway or Erk (for minor part by p38) MAP kinase. To analyze functional relevance of Runx2 in the pathogenesis of FGFR mutation-related craniosynostosis, we introduced mouse calvarial organ culture system. FGF2 beads placed directly on the osteogenic fronts of the sagittal suture of E15 mouse calvaria strongly accelerated the suture closure and Runx2 expression after 24 hours compared to control group. As expected in previous results, FGF2-induced acceleration of suture closure was blocked by PKC or ERK inhibitors. These results suggest expression of Runx2 and activation of RUNX2 by FGF/FGFR signaling employ different signaling machineries and provide the direct relevance of Runx2 in the pathogenesis of FGFR mutation related premature suture closure.

SA133

PDGF-CC A Novel Gene That Exhibits BoneAnabolic Activity. G. V. Krishnan,[1] S. Na,[2] L. Hammond,[2] A. Glasebrook,[2] W. Yeh,[2] L. Myers,[2] A. Kharitonenkov,[2] E. W. Su,[2] H. Song,[2] A. G. Geiser,[1] Y. L. Ma,[1] Q. Zeng,[1] E. C. Black,[1] C. A. Frolik.[1] [1]Gene Regulation, Bone & Inflammation, Eli Lilly and Company, Indianapolis, IN, USA, [2]Bio RT&P, Eli Lilly and Company, Indianapolis, IN, USA.

PDGF-CC is a novel cDNA encoding an N-terminal CUB-like domain with a C-terminal PDGF/VEGF motif. It is a member of the cysteine-knot family of proteins that includes NGF, TGF-β and VEGF. The 3.4 kilobase transcript of PDGF-CC is expressed in most tissues and it encodes a 354 amino acid protein with an approximate MW of 38 kDa. Full-length PDGF-CC shares approximately 26% identity with PDGF-B. PDGF-CC protein was purified to near homogeneity after over-expression in HEK293T cells. We have employed a rat neonate metatarsal organ culture model that measures increases in endochondral ossification in response to bone anabolic agents. PDGF-CC was shown to increase bone anabolic activity (17% ± 4) compared to PTH 1-38 (20% ± 3) in an ex-vivo organ culture model. PDGF-CC has been shown to target the PDGF-α receptor in vitro and co-treatment with Tyrphostin 1295 an inhibitor of PDGF-R tyrosine kinase, blocks its bone anabolic activity. PDGF-CC induces its bone anabolic activity in the organ culture model via a MAPK dependent step. Co-treatment with the MEK/ MEKK inhibitor U0126 results in complete loss of PDGF-induced bone anabolic activity. PDGF-CC does not directly induce osteocalcin promoter activity or expression and co-treatment of antisense Cbfa1/ Osf-2 oligonucleotides along with PDGF-CC results in minimal change in bone anabolic activity. In contrast, co-treatment with antisense c-fos oligonucleotides results in partial reversal of bone anabolic activity. In this report we have identified a novel target for bone anabolic activity that mediates its activity via the PDGF-α receptor.

SA135

Enhancement of Bone Induction by in-vivo Reduction of Proinflammatory Cytokines in the Rat. G. Voggenreiter,[1] M. Majetschak,*[1] M. Bardenheuer,[1] U. Obertacke,[1] F. U. Schade.*[2] [1]Department of Trauma Surgery, University Hospital Mannheim, Mannheim, Germany, [2]Clinical Research Group Schock & Multi Organ Failure, University Hospital Essen, Essen, Germany.

The influence of the reduction of proinflammatory cytokines on bone induction by demineralized bone matrix (DBM) was investigated. Cytokine synthesis was reduced by repeated injections of lipopolysaccharide (LPS). This constitutes a state of endotoxin tolerance with a consecutive reduction of the synthesis of proinflammatory cytokines. Materials and Methods: Prior implanting DBM (day 0) endotoxin-tolerance (ET) was induced by i.p. injection of LPS in concentrations of 0.1 mg/kg BW on day -7 and of 0.5 mg/kgBW on days -6, -5, -4 and -3. On day 0 50mg of DBM were implanted into the abdominal wall of adult Lewis rats in six groups (7 rats each): isogeneic (iDBM) and xenogeneic (xDBM) DBM (controls); iDBM and xDBM with short-term ET (SET) and iDBM and xDBM with long-term ET (LET). For LET injections of LPS (0.5mg/kgBW) were continued after surgery every other day. In-vitro cytokine synthesis was evaluated by TNF-alpha ELISA on days -7, 0, 7 and 28. Animals were sacrificed after 4 weeks and the bone remodeling of the proximal tibial metaphysis as well as the induced new bone were evaluated by quantitative histomorphometry (guidelines of the ASBMR). Comparisons between groups were done using unifactorial analysis of variance and with the Scheffè test. Linear regression analysis was used for correlation of TNF-synthesis and histomorphological parameters.Results: Implantation of iDBM and xDBM alone had no influence on TNF-synthesis. Induction of ET yielded in a significant reduction of TNF-synthesis on day 0 ($p < 0.05$). Furthermore in the LET groups the TNF-synthesis was reduced significantly at day 7 but no longer at day 28. However TNF-synthesis was reduced in 7 out of 14 rats at day 28. In all groups histomorphometry revealed no differences in the parameters obtained from the tibial metaphysis, but SET and LET showed a twofold increase of the induced bone volume. However it has to be marked that LET was only effective in 7/14 rats on day 28. The subgroup with effective LET demonstrated a threefold increase in bone volume compared to control animals. Based on the values of the isogeneic control group and the isogeneic SET and LET animals a significant linear relationship between the induced bone volume and TNF- synthesis was evident ($r=-0.68$, $P < 0.001$).Conclusion: Induction of endotoxin tolerance increases bone induction in isogeneic DBM. By means of TNF-alpha synthesis a linear relationship between the reduction of cytokine synthesis and bone formation has been detected.

Expression and Localization of VEGF and its Receptors in Osteoblasts and Bone Tissues. G. Hirata, K. Urabe, C. Li,* T. Shuto, A. Matsuo,* Y. Iwamoto.* Department of Orthopaedic Surgery, Kyushu University, Fukuoka, Japan.

Angiogenesis is an important process involved in normal bone growth and repair. Vascular endothelial growth factor (VEGF), an potent angiogenic factor, is reported to be involved in osteoclastogenesis. M-CSF and RANKL are essintial for osteoclastgenesis. VEGF substitutes for M-CSF in RANKL induced steoclast formation. Some osteogenic cytokines, BMP-4, BMP-7, TGF-β1 andFGF-2, and hormones, PTH and 1,25-$(OH)_2$Vit.D_3, induce the production of VEGF in osteoblasts. VEGF may be important in bone and mineral metabolism. However, the role of VEGF in osteoblastic bone formation is not well understood. We hypothesized that VEGF is expressed in osteoblasts and is involved in osteoblasic bone formation. The aim of the present study is to clarify the presence of VEGF in osteoblasts using various type of octeoblastic cells and bone tissues. Initially, we examined the expression of VEGF and its receptors in rat calvarial osteoblasts, human osteoblastic cell lines, rat and human bone tissues by RT-PCR. Fetal rat calvaria (FRC) cells were prepared as we previously reported (K. Urabe, J. Orthop. Res. 17:920, 1999). Rat calvaria for immunohitochemical study was obtained from 3 week old SD rats. Human trabecular bone was obtained from patients that underwent knee arthroplasty. Isoforms of rat VEGF, VEGF-122, 144 and 164, Flt-1/VEGFR1 and KDR/Flk-1/VEGFR2 were detected in FRC cells, and isoforms of human VEGF, VEGF-122, 165, 189 and 206, and Flt-1 were detected in SaOS2 and MG-63, human osteoblastic cell lines using RT-PCR. In order to localize VEGF and its receptor in bone tissues, immunohistochemical study was performed. Osteoblasts were positively stained with antibodies against VEGF and Flt-1 in rat calvaria and human trabecular bone. Because VEGF and its receptors are co-localized in osteoblasts and osteoblastic cells, VEGF may act on osteoblasts in an autocrine/paracrine fashion. It is possible that VEGF induces migration of osteoblasts to bone surface or regulates osteoblastic differentiation as is suggested previously. VEGF isoforms and its receptors may be important in regulation of bone metabolism.

SA139

Effect of TP508, A Synthetic Thrombin Peptide, on Growth Factor Expression During Femoral Fracture Healing. H. Wang, J. Convery,* J. T. Ryaby. OrthoLogic, Tempe, AZ, USA.

TP508 is a synthetic 23 amino acid peptide, representing a receptor-binding domain of human thrombin. When clots dissolve, thrombin fragments are released and act on thrombin receptors to initiate healing. The aim of this study was to determine the effects of a single percutaneous injection of TP508 on the expression of Cbfa1, Collagen type II and VEGF during femoral fracture healing in rats. Close fractures at the midshaft of the femurs were created in Sprague-Dawley rats. TP508 was injected percutaneously into the fracture site. The expressions of three genes in fracture calluses were analyzed in TP508 treated groups and PBS control groups on days 4, 7, 9, 11, 14, 17, and 21 after fracture by using Relative Quantitative RT-PCR. At 1μg/100ml, Cbfa1 expression increased 3-fold at 4 and 21 days. Collagen type II was expressed at 4 days in TP508 treated calluses but not in the controls, and was approximately 5-fold greater than controls at 14 and 17 days. The expression level of VEGF was increased at almost all time points. At 10μg/100ml, Cbfa1 although reduced at 4 days but increased at all other time points. Collagen type II expression was increased 2-3 fold at 14 and 17 days; this was less than the stimulation observed with 1mg/100μl. VEGF expression was increased more than 2 fold at 17 days. TP508 has the potential to promote fracture healing since it increases the expression of Cbfa1, VEGF, and collagen type II.

IGF-I Modulates Bone Resorption by Decreasing Osteoprotegerin/ RANKL Ratios in vitro and in vivo. J. Rubin,[1] L. Zhu,*[1] X. Fan,*[1] T. Murphy,*[1] C. Ackert,[2] W. G. Beamer,[2] C. J. Rosen.*[3] [1]Emory University and VAMC, Decatur, GA, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA, [3]Maine Center for Osteoporosis Research and Education, St. Joseph Hospital, Bangor, ME, USA.

Insulin-like growth factor-I (IGF-I) is considered a coupling factor for bone remodeling as it has a potent role in stimulating bone formation and collagen synthesis. By contrast, the effects of IGF-I on bone resorption are not well defined. We previously reported that growth hormone (rhGH) treatment in elders is associated with increased serum IGF-I, enhanced N-telopeptide (NTx) excretion, and bone loss at several skeletal sites. We thus hypothesized that IGF-I might induce resorption via changes in osteoprotegerin (OPG) and RANKL expression. Here we examined OPG and RANKL expression in response to IGF-I in mouse ST-2 stromal cells, and measured serum OPG levels in elderly women treated with placebo, low or high doses of rhGH. In ST2 cells we found a dose dependent decrease in OPG expression by RT-PCR such that IGF-I concentrations of ≥20 ng/ml were associated with a significant reduction in OPG in ST2 cells. Northern analysis confirmed that

OPG expression was maximally suppressed (37.0 ± 1.8%; p<0.002) by 100 ng/ml IGF-I at 24, 48 and 72 hours (p<0.01). Northerns also showed that IGF-I coordinately upregulated RANKL mRNA by 24 h to levels comparable to those achieved with 10 nM vitD in ST2 cells. To test the in vivo effects of IGF-I on OPG, we examined serum in 9 subjects from an earlier randomized trial of rhGH; 3 subjects were treated with placebo (P), 3 with 0.0025 mg/kg/day rhGH (LD-Rx), and 3 with 0.005 mg/kg/day rhGH (high dose-HD) for 1 year. At 3 and 12 mos in P, there were no changes in serum IGF-I, NTx or OPG, although serum IGF-I correlated inversely with OPG at all time points(r=-0.82, p=0.006). For the LD-Rx group, IGF-I increased significantly and there was an inverse relationship between change in NTx and change in OPG (r=-0.71,p=0.05). In the HD-Rx group, IGF-I levels increased two fold and were related to NTx (r=0.72,p=0.02); OPG levels declined nearly 25% (p<0.05) by 3 months with HD-Rx and correlated inversely with NTx (r=-0.60, p<0.09) at all time points. In summary, we report that IGF-I suppresses OPG and upregulates RANKL mRNAs in stromal cells in vitro and, in vivo, IGF-I is associated with decreased OPG and increased bone turnover. These data suggest that IGF-I may be important in coordinating OPG/RANKL expression both within the skeleton and in the circulation. This effect of IGF-I may have clinical significance with respect to rhGH as an anabolic agent in osteoporosis, and provide a possible mechanism for the observation that rhGH enhances bone resorption as well as formation.

Differential Promoter Use and Tissue Specific Expression of IGF-I in Inbred Strains of Mice: Implications for Understanding the Role of Circulating and Skeletal IGF-I in Modulating Bone Formation. M. L. Adamo,[1] C. Ackert,[2] L. Donahue,*[2] W. G. Beamer,*[2] D. Powell,*[3] C. J. Rosen.[4] [1]The University of Texas, San Antonio, TX, USA, [2]The Jackson Laboratory, Bar Harbor, ME, USA, [3]Lexicon, The Woodlands, TX, USA, [4]St. Joseph Hospital, Bangor, ME, USA.

We previously reported that a high BMD mouse strain C3H/HeJ(C3H) has 30% greater serum IGF-I concentrations than a low BMD strain C57B/6(B6). Although bone formation is greater in C3H mice than B6 mice, the relationship of serum IGF-I to skeletal production and function is not clear. Thus, we examined the expression of IGF-I in several tissues, and in association with ongoing genetic studies, identified QTLs for the circulating IGF-I phenotype. We performed RNase protection assays(RPA), to assess IGF-I mRNA transcripts synthesized from both the major (P1) and minor (P2) promoters. In the liver of both strains, promoter 1(P1) transcripts exceeded promoter 2(P2) by >2:1 a pattern not different from other species. But, hepatic P2 expression was 2 fold greater in C3H than B6 (p<0.01). By contrast, in calvarial bone cells, there was a nearly five fold increase in P1 transcripts for C3H compared to B6(p<0.005). P2 transcripts were also increased in C3H compared to B6, but there were low levels in both strains (<10% of total IGF-I mRNA). Heart, kidney, brain and intestine showed no differences in either P1 or P2 transcripts by strain. In calvarial bone cells, P1 nuclear RNA was increased threefold in C3H vs B6 and whole bone mRNA from the femur demonstrated that C3H had 40% greater exon 1 mRNA transcripts than B6(p<0.05). In conditioned media from C3H calvarial OBs, there was twice the amount of secreted IGF-I /cell than B6 (2.4ng/10^6 cells vs 1.2 ng/10^6 cells;p<0.05). Finally, preliminary experiments indicate markedly increased phosphoAKT levels in OBs from C3H vs B6, suggesting increased autocrine IGF-I activation of the PI3 kinase/Akt pathway. In summary, we report both tissue and promoter specific expression of IGF-I for 2 inbred strains that differ in bone acquisition. Overall, C3H has enhanced IGF-I P1 and P2 expression compared to B6, a pattern that mirrors strain differences in serum IGF-I. In conclusion, we believe interstrain differences in serum IGF-I are due to altered hepatic expression of the peptide. The influence of strain on IGF-I expression in bone reflects differences in serum levels, but promoter use(P1vs P2)remains tissue specific . Quantitative trait analysis of serum IGF-I regulatory determinants should identify the transcriptional regulators of IGF-I that are growth hormone independent, but promoter and tissue specific.

IGF-I Effects on Bone Accretion During Prepubertal Growth Phase Are Mediated Predominantly Via Mechanisms Independent of Growth Hormone (GH). S. Mohan,[1] L. R. Donahue,[2] C. Richman,[1] R. Guo,*[1] J. Wergedal,[1] D. Baylink.[1] [1]Pettis VAMC, Loma Linda, CA, USA, [2]The Jackson Lab, Bar Harbor, ME, USA.

Our data in mice show that prepubertal and pubertal growth periods are critical in the regulation of peak BMD. IGF-I knockout mice exhibited severe reduction in peak BMD, thus demonstrating that IGF-I is an important determinant of peak BMD. Based on the findings that IGF-I expression in bone is regulated by other osteoregulatory agents (estradiol, PTH), in addition to GH, we propose that IGF-I effects on peak BMD are mediated via a GH-independent mechanism, in addition to GH-dependent mechanism. Skeletal changes were evaluated at day 23 (prepubertal), 31 (pubertal), and 56 (postpubertal) in the whole femur by DEXA and in the mid-diaphysis by pQCT in mice lacking GH (*lit/lit*) and compared to mice lacking functional IGF-I. Bone strength was measured by 3-point bending. Values are % of corresponding age-matched control mice (mean; 8-20) and significant at p<0.01.

	Day 23 GH	IGF-I	Day 31 GH	IGF-I	Day 56 GH	IGF-I
Femur length (mm)	90	74	80	59	75	60
BMD (mg/cm^2)	93	61	76	54	68	44
BMD (mg/cm^3)	93	71	89	69	85	68
PC (mm)	92	62	86	58	75	57
Breaking strength (N)	73	38	53	26	45	20

The much larger deficit in length, BMD, periosteal circumference (PC), and breaking strength in mice lacking IGF-I compared to GH at day 23 suggests that skeletal changes during prepubertal growth is dependent on IGF-I expression largely independent of GH. To further evaluate the relative contribution of the GH-independent pathway during puberty, we determined the rate of gain in various parameters between day 23-31. The rate of gain in length was 35% and 32%, respectively, in mice lacking IGF-I or GH compared to control mice, thus suggesting that IGF-I effects on length are mainly mediated via GH. In contrast, PC increased by 50% in mice lacking GH compared to control mice during puberty while no increase in PC occurred in mice lacking IGF-I, thus suggesting that the increase in PC during puberty is IGF-I dependent and mediated equally via both GH-independent and GH-dependent mechanisms. Similarly, IGF-I effects on rate of gain in BMD and bone strength during puberty are mediated in part by GH-independent mechanism. Conclusions: 1) Mice deficient in IGF-I exhibit greater impairment in bone accretion than mice deficient in GH. 2) IGF-I effects on bone accretion during prepuberty are mediated predominantly via mechanisms independent of GH, while during puberty they are mediated via both GH-independent and GH-dependent mechanisms.

Skeletal Unloading Induces Resistance to Insulin-like Growth Factor I on Bone Formation. T. Sakata,[1] B. P. Halloran,[1] H. Z. ElAlieh,*[1] S. J. Munson,*[1] L. Rudner,*[1] L. Venton,*[1] C. J. Rosen,[2] D. D. Bikle.[1] [1]Medicine, University of California, Veterans Affairs Medical Center, San Francisco, CA, USA, [2]Medicine, Maine Center for Osteoporosis Research, Bangor, ME, USA.

Skeletal unloading results in an inhibition of bone formation associated with a decrease in osteoblast number, impaired mineralization of bone, and altered proliferation and differentiation of osteoprogenitor cells. Although such changes are likely to be mediated by multiple factors, resistance to the growth promoting action of insulin-like growth factor I (IGF-I) has been hypothesized to play an important role. To determine whether skeletal unloading induces resistance to IGF-I on bone formation, we examined the response of unloaded (hindlimb elevation) and normally loaded tibia and femur to IGF-I treatment. To eliminate the variable of endogenous growth hormone production and secretion during exogenous IGF-I treatment, we used growth hormone-deficient dwarf rats (dw/dw). Beginning at 3 months of age these rats were given IGF-I (2.5 mg/kg/day) or vehicle via osmotic minipumps during 7 days of unloading or normal loading. This increased the serum level of IGF-I from 233±19 and 225±22 ng/ml to 390 ±79 and 393±32 ng/ml in the normally loaded and unloaded rats, respectively.In the histomorphometric study: IGF-I treatment markedly increased the bone formation rate (BFR/BS) at the tibiofibular junction of normally loaded rats (196% of the control). Unloading decreased the BFR/BS at the tibiofibular junction in the vehicle treated rats, and blocked the ability of IGF-I to increase the BFR/BS (62% and 68% of the control, respectively). On the other hand, IGF-I treatment increased the BFR/BS at the mid point of the humerus (normally loaded in this model) in both hindlimb-elevated and normally loaded rats (293% and 262% of the control, respectively). In the bone marrow osteoprogenitor (BMOp) cell study: IGF-I treatment significantly increased the osteogenic colony number on day 7 and 12, the total ALP activity on day 12 and 21, and the total mineralization on day 21 in BMOp cells of normally loaded rats. Unloading reduced the osteogenic colony number, the total ALP activity, and the total mineralization in the vehicle treated rats, and blocked the ability of IGF-I to increase these parameters. Furthermore, IGF-I treatment (10 ng/ml) in vitro significantly increased the cell proliferation (bromodeoxyuridine incorporation) of the BMOp cells isolated from normally loaded bone, but not from unloaded bone. These results indicate that skeletal unloading induces resistance to IGF-I on bone formation.

Growth/differential Factor-5 Enhances Cellular Proliferation and Up-Regulates Its Receptor Transcript in Human Cementum-Derived Cell. M. Yamamoto,[1] T. Nakamura,[1] W. J. Grzeski,[2] J. Pohl,*[3] Y. Izumi.*[1] [1]Department of Periodontology, Kagoshima University Dental School, Kagoshima, Japan, [2]Dental Research Center, Department of Periodontics, School of Dentistry, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, [3]BIOPHARM GmbH, Heidelberg, Germany.

Growth/differential factor-5 (GDF-5), also designated cartilage-derived morphogenetic protein-1, is a member of TGF beta super family. Gdf-5 is expressed during the mesenchymal condensation and later localized in joint formation in axial skeletal development of limbs. Mutations in gdf-5 gene are known to be responsible for brachypodism in mice and chondrodysplastic diseases in human. In addition to biological roles in embryonic develop-

ments, recombinant human GDF-5 protein shows inductive activities such as an ectopic induction of tendon/ligament-like tissue in rat, ectopic cartilage and bone formation in rodents, and enhanced healing of long bone defect in primate. Previous in vitro study indicated that GDF-5 transduced these effects through the BMP receptor IB. Tooth is connected to alveolar bone in jaws, with attachment apparatus composed of alveolar bone proper, periodontal ligament, and cementum. This apparatus is derived from dental follicle, in which gdf-5, gdf-6 and gdf-7 are reported to be expressed strongly in root formation area. The purpose of this study was to examine the biological effects of recombinant human GDF-5 protein (rhGDF-5) on human periodontal ligament cells (PDL) and human cementum-derived cells (HCDC), both of which were isolated from teeth extracted on clinical demands. First, proliferation assay was performed in order to determine the effect of rhGDF-5 on the cells cultured in 96-well plate in the presence of various concentrations of the protein. The rate of cellular proliferation was significantly increased in both PDL and in HCDC at 200-1000 ng/ml of rhGDF-5 concentrations on day 1, and also in HCDC in same range of concentration on day 3. Second, the expressions level of osteogenesis markers such as parathyroid hormone receptor (PTHR), osteocalcin (OCN), and bone morphogenetic protein receptor (BMPR) IA, IB, II, were compared by semi-quantified RT-PCR. The total RNA was isolated from cells cultured with 200 ng/ml or 1000 ng/ml of rhGDF-5 for 3 days. Interestingly, the levels of IB receptor were increased only in HCDC at both protein concentrations tested. On the other hand, the expression levels of BMPR IA, II, PTHR, and OCN were not altered or slightly decreased in both of cells. These results indicate that rhGDF-5 protein affects on cellular functions of PDL and HCDC in an in vitro culture system. This suggests that GDF-5 may be possibly involved in maintenance and healing of periodontium.

Expression of GDF-7 mRNA During Endochondral Ossification and Tooth Development. Y. Miyoshi,* M. Yokozeki, K. Terai,* K. Hiura, K. Moriyama. The Univ. of Tokushima, Tokushima, Japan.

Bone morphogenetic proteins (BMPs) are secretory signal molecules which have a variety of regulatory functions during morphogenesis and cell differentiation. Growth and differentiation factor-7 (GDF-7), which is known as a member of BMP family, induces formation of tendon and ligament when is implanted at ectopic sites in vivo. Since tendon and ligament are attached to bones, these tissues might be closely related to early skeletogenesis. GDF-7 may also be a potent regulatory molecule in the tooth development since it was reported that the expression of GDF-7 mRNA was detected in the dental follicle. Therefore, the objective of this study is to analyze the expression of GDF-7 mRNA during endochondral ossification and tooth development in mouse embryo and to elucidate the roles of GDF-7 in skeletogenesis and odontogenesis. C57BL/6N mouse embryo at day 14.5 and 16.5 were used in this study. Reverse transcription polymerase chain reaction (RT-PCR) was performed using specific primers for 3'-untranslated region of mouse GDF-7 mRNA. In situ hybridization was performed using digoxigenin-labeled single stranded cRNA probes for GDF-7 and BMP-2, BMP-4 and osteopontin. RT-PCR analysis confirmed the expression of GDF-7 mRNA in developing mouse embryo at day 14.5 and 16.5. In situ hybridization analysis of mouse embryo at the day 14.5 and 16.5 showed that GDF-7 mRNA expression was observed in the periosteal cells around ossified ribs and chondrocyte of proliferating zone in the first rib cartilage where endochondoral ossification took place. Expression patterns of BMP-2 and BMP-4 mRNA were analogous with that of GDF7. The expression of osteopontin mRNA was not observed in periosteal cells expressing GDF-7, BMP-2, and BMP-4, but in osteoblasts within the ossified rib. In the developing tooth germ, GDF-7 mRNA was expressed in the dental papilla at the cap stage and the bell stage. GDF-7 mRNA expression was also observed in the preodontoblasts at differentiation stage. These results suggested that GDF-7 might be regulatory factor in skeletogenesis and odontogenesis during mouse development.

Serum Activin-A Levels in Metabolic Bone Diseases. R. Nuti,[1] G. Martini,[1] G. Florio,*[2] R. Valenti,*[1] S. Salvadori,*[1] A. Picchi,*[1] F. Petraglia.*[2] [1]Metabolic Disease Unit, University of Siena, Siena, Italy, [2]Obstetrics and Gynecology, University of Siena, Siena, Italy.

Activin is a dimeric protein that inhibits follicle-stimulating hormone secretion. It structurally belongs to the transforming growth factor beta family and shows some biological properties of growth factors. Increasing evidence suggests the involvement of Activin-A in the regulation of bone metabolism.Aim of the study was to evaluate the relationships between serum Activin-A levels and bone turnover, measured by serum markers of osteoblast and osteclast activity.We studied 58 subjects: 15 healthy postmenopausal women, 25 women with involutional osteoporosis characterized by one or more vertebral crushes, 10 patients with poliostotic Paget's disease of bone, 5 patients with multiple myeloma, and 3 patients with secondary osteoblastic bone lesions. All patients had normal renal function.Bone metabolism was evaluated by: serum and urinary calcium, serum phosphate (standard methods), serum bone alkaline phosphatase (BAP: Metrabiosystem), serum crosslaps (CTx: Osteometer), serum iPTH 1-84 (DRG-Int). Activin-A was measured using a specific two-site enzyme immunoassay (Oxford Bio-Innovation LTD).No differences among groups were appreciated as regards serum calcium, serum phosphate, urinary calcium excretion, serum iPTH. A statistically significant increase of CTx and BAP was found in Pagetic patients with respect to healthy postmenopausal women (10823±8158 pmol/l vs 4228±2528 pmol/l, $p<0.05$; 122.8±119 U/l vs 32.4±27 U/l, $p<0.05$ respectively). In postmenopausal women serum level of Activin-A was 0.628±0.2 ng/ml; increased but not statistically significant values, were detected in Paget's disease (0.700±0.15 ng/ml), in osteoporotic women (0.716±0.26) and in multiple myeloma (0.804±0.13). A dramatic increase of Activin-A (1.986±1.06) was found in three patients with solid cancer and osteoblastic metastasis.No relationships were found between Activin-A and bone metabolism parameters, while a positive correlation with age was confirmed ($r=0.42$; $p<0.05$).These preliminary data indicate that serum Activin-A levels may not actually considered a valuable marker of bone turnover.

SA153

Cell Swelling Activation of Membrane Currents, Ca2+ Transients and Regulatory Volume Decrease in Bovine Articular Chondrocytes (BAC). C. E. Yellowley,[1] J. C. Hancox,*[2] H. J. Donahue.[1] [1]Musculoskeletal Research Laboratory, Penn State College of Medicine, Hershey, PA, USA, [2]Department of Physiology, Bristol University, United Kingdom.

During mechanical loading, the osmotic environment of the chondrocyte is perturbed by changes in local proteoglycan concentration and, therefore, the ionic concentration and osmolarity. It is possible that cells may sense mechanical changes in their environment via changes in osmolarity. In this study we examined the effect of hypo-osmotic stress on early signaling events in chondrocytes by making measurements of intracellular calcium [Ca2+]i and of macroscopic ionic currents. In addition, we looked at the ability of BAC to regulate cell volume during a hypo-osmotic challenge. Cells were perfused with Tyrode's solution containing in mM; 140NaCl; 2MgCl2; 5K2ATP; 10 HEPES and 5 Glucose titrated to pH 7.4. For cell swelling external NaCl content was reduced to 100, 80 and 60mM, reducing osmolarity from 295mOsm (normal) to 220, 185 and 145 respectively. [Ca2+]i was quantified using the fluorescent dye fura-2 AM. Cell membrane ionic currents were recorded using perforated patch clamp. Relative changes in cell volume were measured by monitoring the fluorescence of calcein loaded cells. BAC continuously exposed to hypotonic solution (-150mOsm) swelled in size to a peak response at 4 min, with a mean decrease in dye fluorescence of 12.6±1.1% (±SEM), and recovered back to near normal within 30 min. Volume recovery was inhibited by Gd3+ (50mM), cell fluorescence decreased by 23.4±4.0% and showed no sign of recovery after 30min. When exposed to a decrease in osmolarity of -75mOsm, 28.7± 3.6% of cells responded with an increase in [Ca2+]i, 43.9±10.7% of cells responded to -110mOsm and 73.5± 6.7% to -150mOsm. The proportion of cells responding to -150mOsm (73.5± 6.7%) was not affected by nifedipine (20mM), (67.5±11.2%), but was reduced by Gd3+ (50mM) and thapsigargin (50nM) to 3.8± 2.6% and 8.1± 3.0% respectively. Inward and outward membrane currents increased over 4-fold when exposed to -150mOsm Tyrode's. These results indicate that BAC possess mechanisms by which they can regulate cell volume and that this mechanism may require Ca2+. The cell Ca2+i response to swelling was dependent on the magnitude of the hypotonic shock and was blocked by Gd3+ and thapsigargin suggesting roles for stretch activated channels and intracellular Ca2+ stores. Activation of ion channels and Ca2+i have been shown to play significant roles in volume regulation in other cell types, however, they may also play a role in transducing mechanical signals into cellular metabolic responses. These effects may be involved in a mechanism by which mechanical loads are transmitted to chondrocytes.

PTH potentiates Volume-sensitive Calcium Influx Pathways through the Activation of Adenyl cyclase in Mechanically Stretched Human Osteocytes. A. Miyauchi,[1] K. Naruse,*[2] M. Itoman,*[2] M. Goto,*[3] K. Notoya,[3] K. Okabe,[4] Y. Takagi,[1] K. Jinnai,*[1] Y. Yoshimoto,[1] T. Sugimoto,[5] K. Chihara,[5] T. Fujita,[6] Y. Mikuni-Takagaki.[7] [1]Medicine, National Hyogo-Chuo Hospital, Sanda, Japan, [2]Orthopaedic Surgery, Kitasato Univ., Sagamihara, Japan, [3]Takeda Chemical Industries Ltd., Osaka, Japan, [4]Oral Physiology, Fukuoka Dental College, Fukuoka, Japan, [5]Third Div., Med., Kobe Univ., Kobe, Japan, [6]Ca Res. Inst., Kishiwada, Japan, [7]Oral Biochemistry, Kanagawa Dental College, Yokosuka, Japan.

In mechanically loaded bone, osteocytes transduce signals that lead to bone formation. The mechanisms of mechanosensing and transduction, however, are not well elucidated especially in human cells. Previously, we have found that mechanosensing in rat osteocytes depends on a volume-sensitive calcium influx pathways that is regulated by activation of stretch activated cation channels (SA-Cat) (J. Biol. Chem. 275: 3335, 2000). These Ca^{2+} influx pathways are upregulated by PTH through the activation of adenyl cyclase. In this study, we found that the mechanosensing machinery operates similarly in human osteocytes. For this purpose, primary cultures of human long bone osteocytes were prepared from bone chips obtained during total hip replacement surgery. Cytosolic calcium concentrations, $[Ca^{2+}]i$, were measured using single cell video-image analysis with fura-2. Rapid and progressive increases (70±4nM above basal (n=11)) in $[Ca^{2+}]i$ were induced by stretch loading of human osteocytes in hypoosmotic solution (50% of normal osmolarity). Influx of extracellular Ca^{2+} is primarily responsible for the hypotonicity stimulated increase in $[Ca^{2+}]i$ as the response was abolished by Ca^{2+} free media containing EGTA. Gadolinium chloride (Gd^{3+}), a selective SA-Cat blocker, eliminated the $[Ca^{2+}]i$ increase caused by hypotonic solution. PTH(1-34) specifically potentiated the hypotonicity-induced $[Ca^{2+}]i$

increase in a dose dependent manner. The adenyl cyclase pathway appears to be involved in this potentiation, because dibutyryl cAMP had comparable stimulatory effects on the hypotonicity-induced $[Ca^{2+}]i$ increase. The $[Ca^{2+}]i$ increases induced by both PTH and hypotonicity were observed primarily in the cell processes of osteocytes. In cyclically stretched osteocytes on flexible-bottomed plates, PTH(1-34) or dibutyryl cAMP acted synergistically in elevating osteocalcin mRNA levels. Furthermore, Gd^{3+} inhibited the stretch-induced elevation of osteocalcin mRNA. The volume-sensitive calcium influx pathways of osteocytes, demonstrated here for the first time in human cells, represent a mechanism by which PTH potentiates mechanical responsiveness, an important aspect of bone formation.

Differential Expression of the AP-1 Protein Complex in Mechanically Strained Human Osteoblasts. M. Wozniak, K. A. Hruska. Internal Medicine, Washington University, St.Louis, MO, USA.

We have recently demonstrated the role of the $\alpha_v\beta_3$ integrin plaques in osteoblast differentiation and deposition of mineralizing extracellular matrix in response to mechanical strain (JBMR 2000). Our current goal is to further investigate the molecular signals, particularly the transcription factors, leading to osteoblast proliferation, differentiation and mineralization of matrix. The AP-1 (activator protein-1) transcription factor consists of either Jun/Jun homodimers or Fos/Jun heterodimeric complexes, and is formed by Fos (c-Fos, Fra-1, Fra-2, Fos B) and Jun proteins (c-Jun, JunB, JunD). Our hypothesis is that members of the AP-1 protein complex are differentially expressed during osteoblast proliferation, differentiation and mineralization of the extracellular matrix, and that mechanical strain affects their expression and cellular localization. Primary human osteoblasts were developed from bone marrow stromal cells and analyzed at distinct stages of differentiation (osteoprogenitor, preosteoblast and osteoblast) under conditions of chronic, repetitive mechanical strain. The magnitude of the non-uniform strain at the site of analysis was 70,000 με, applied in the form of a square wave at the frequency of 0.05 Hz for 48 hours. The results demonstrate that nuclear expression of Fra-1 is higher in preosteoblasts than in osteoprogenitors or in mineralizing osteoblasts, thus correlating well with previous studies of fra-1 mRNA levels, and that mechanical strain affects osteoprogenitor Fra-1 expression pattern. The Fra-1 protein was uniformly distributed throughout the nucleus of non-strained progenitors, but was confined to the endoplasmic reticulum following strain. In contrast to Fra-1, c-Fos expression was higher in osteoprogenitors than in preosteoblasts and osteoblasts. Accordingly, c-fos mRNA levels were previously shown to be high during the proliferative period of the osteoblast development. There was a shift in c-Fos localization pattern that occurred concurrently with the progression of osteoblastic differentiation - in progenitors c-Fos was present in the endoplasmic reticulum, later it was found in nuclear vacuolar structures and uniformly distributed throughout the nucleus in preosteoblasts and osteoblasts, respectively. We thus conclude that in ostoprogenitors c-Fos is synthesized in the endoplasmic reticulum, then transported into the nucleus during early preosteoblast stage, where it later (during the osteoblast stage) induces gene transcription (observed as uniform nuclear expression pattern). In summary, the proteins of the AP-1 transcription complex show osteoblast development stage-dependent expression and localization pattern.

Signaling Pathways for the Fluid Shear Stress Induction of Cyclooxygenase-2 in Murine Osteoblats. S. Wadhwa,[1] S. Godwin,*[1] L. G. Raisz,[2] C. C. Pilbeam.[2] [1]Oral Biology, University of Connecticut Health Center, Farmington, CT, USA, [2]Medicine, University of Connecticut Health Center, Farmington, CT, USA.

Anabolic effects of mechanical loading of bone can be abrogated by inhibition of prostaglandin (PG) production. Fluid shear stress (FSS), hypothesized to transduce mechanical loading into cellular signals, generates PGs in osteoblasts by inducing new gene transcription of cyclooxgenase-2 (COX-2). To examine signaling pathways involved in this induction, we used immortalized murine osteoblastic MC3T3-E1 cells stably transfected with -371/+70 bp of the murine COX-2 5' flanking DNA fused to a luciferase reporter (Pluc) and primary osteoblastic cells derived from calvaria of mice transgenic for Pluc. Cells were plated on collagen-coated glass slides, grown to confluence, and subjected to 10 dynes/cm^2 of steady laminar FSS in a parallel plate flow chamber. On Northern blot analysis, COX-2 mRNA was induced by FSS within 30 minutes and peaked at 4 h. An inhibitor of new protein synthesis, puromycin (10 μg/ml), did not affect the small FSS induction of COX-2 mRNA at 1 h but inhibited the large peak induction at 4 h by 90%. COX-2 promoter activity, measured as luciferase activity normalized to total protein, correlated with COX-2 mRNA expression. Inhibitors of the protein kinase A (PKA) signaling pathway, H-89 (30 μM) and PKI (1 μM), used at doses determined to be most specific for the PKA pathway, reduced FSS stimulated COX-2 mRNA expression and luciferase activity at 4-4.5 h by 60% and 66%, respectively. In contrast, a specific inhibitor of the protein kinase C (PKC) pathway, GF109203X (1.25 μg/ml), and down regulation of the PKC pathway by 24 h of pretreatment with phorbol myristate acetate (1 μM) had no effect on the FSS induction of COX-2 mRNA and luciferase activity at 4-4.5 h. On Western analysis, FSS induced phosphorylation of ERK1/2 within 5 min. A specific inhibitor of the ERK1/2 pathway, PD98059 (40 μM), reduced FSS stimulation of COX-2 mRNA and luciferase activity at 4-4.5h by 65% and 91%, respectively. We conclude that maximal induction of COX-2 by FSS requires new protein synthesis, involves the PKA but not the PKC pathway, and depends on activation of ERK1/2.

Surface Topography Modulates Osteoblast Response to Shear Force. F. Del Toro,[1] C. H. Lohmann,*[2] S. R. Bannister,*[3] Y. Liu,*[1] V. L. Sylvia,[1] D. L. Cochran,*[4] Z. Schwartz,[5] D. D. Dean,[1] B. D. Boyan.[1] [1]Orthopaedics, University of Texas Health Science Center, San Antonio, TX, USA, [2]Orthopaedics, Georg-August University, Goettingen, Germany, [3]Periodontics, Wilford Hall Medical Center, Lackland AFB, TX, USA, [4]Periodontics, University of Texas Health Science Center, San Antonio, TX, USA, [5]Periodontics, Hebrew University, Jerusalem, Israel.

Previous studies have shown that osteoblasts are sensitive to surface roughness and morphology. When cultured on titanium (Ti) surfaces, MG63 osteoblast-like cells exhibit decreased proliferation and increased differentiation with increasing roughness. To examine how the topography of the surface modulates osteoblast response to shear force, MG63 cells were cultured in a continuous flow device on glass disks (R_a < 0.2 μm) or Ti disks with three different R_a values and topographies (smooth [PT]: R_a = 0.60 μm; sand-blasted and acid etched [SLA]: R_a = 3.97 μm; and titanium plasma sprayed [TPS]: R_a = 5.21 μm). Flow rates were varied, resulting in shear forces of 0, 1, 5, 14, and 30 dynes/cm^2. Confluent cultures were exposed to fluid flow for one hour. After an additional 23 hours in culture under static conditions, cell number, alkaline phosphatase specific activity, and levels of osteocalcin, TGF-β1, and PGE_2 in the conditioned media were determined. Cell number on smooth surfaces (glass and PT) was unaffected by shear force. In contrast, there was a dose-dependent reversal of the decrease in cell number seen on rough SLA and TPS surfaces. On smooth surfaces alkaline phosphatase specific activity was unaffected by shear force, but shear force caused a biphasic reduction in the roughness-dependent increase on SLA and TPS that was maximal at 14 dynes/cm^2. There was a similar effect seen with TGF-b1 levels. Osteocalcin was unaffected on smooth surfaces; shear force caused a dose-dependent reduction in the roughness-stimulated increase seen on SLA and TPS. PGE_2 production was increased by shear force on all surfaces. There was a 2-fold increase on glass and PT in response to 14 dynes/cm^2, but on SLA and TPS, 14 dynes/cm^2 shear force caused a 9-10-fold increase. These results show that surface roughness and topography modulate osteoblastic response to shear force. The effect of shear force is greater on rougher surfaces. The shear force-mediated decrease in osteoblast differentiation seen in cultures on rough surfaces may be due to increased production of PGE_2.

Combined Estrogen and Exercise Completely Prevented Marrow Cancellous Bone Loss and the Elevated Intracortical Bone Remodeling Following Ovariectomy in the Femoral Neck. W. Yao, J. Chen,* C. Y. Li,* A. Mo,* R. B. Setterberg,* W. S. S. Jee. Radiobiology Division, University of utah, Salt Lake City, UT, USA.

The current study was designed to investigate the effects of estrogen (E_2) and exercise on the femoral neck (FN) of the ovariectomized (OVX) rats. Exercise was conducted by employing a raised cage (RC) model so as to make the rats rise to bipedal stance for feeding. Six-month-old female Sprague-Dawley rats were bilateral ovariectomy at day 0. They were housed in normal height or RC and injected twice a week with 10μg/kg of E_2 or vehicle for 8 weeks. We found that 1) Marrow cancellous bone (B.Ar) lost by 39% and intracortical porosity area (Po.Ar) increased by 108% while total bone area (TB.Ar) did not change significantly due to the periosteal expansion following OVX. 2) E_2 alone partially prevented the decrease of B.Ar and the increases of Po.Ar by inhibiting endosteal bone erosion (Es-E.Pm)and decreasing the periosteal bone formation (Ps-BFR). 3) RC alone also partially prevented the decrease of B.Ar by preventing the increased Es-E.Pm maintained the elevated Ps-BFR. 4) E_2 plus RC completely preserved the B.Ar and prevented the intracortical remodeling by having additive effect on reducing Es-E.Pm. RC helped to partially prevent decreased of Ps-BFR after E_2 administration (Table), as a result, TB.Ar increased. In conclusion, apart from inducing marrow cancellous bone loss, OVX also increase intracortical remodeling in the FN. Both E_2 and RC partially prevented these changes. Combination treatment completely prevented OVX-induced bone loss by having additive effect on reducing endosteal bone erosion and RC partially counteracted the

decrease of bone formation by E_2 treatment.

Age, Sex, and Grip Strength Determine Architectural Bone Parameters Assessed by Peripheral Quantitative Computed Tomography (pQCT) at the Human Radius. P. Schneider,[1] Y. Hasegawa,[2] C. Reiners.[2] [1]Clinic for Nuclear Medicine, University of Würzburg, Würzburg, Germany, [2]University of Würzburg, Würzburg, Germany.

The purpose of this study was to estimate the relation of some noninvasively derived mechanical characteristics of radial bone including architectural parameters for bone strength to grip strength and muscle cross-section. 63 males between 21 and 78 years of age and 101 females between 18 and 80 years of age were measured at the nondominant forearm using peripheral quantitative computed tomography (pQCT). We assessed volumetric bone mineral density (BMD) and content (BMC) by pQCT at the distal and at the midshaft radius. Bone area (Area), cortical thickness (C-th), and a newly proposed index for bone strength, the stress strain index (SSI) were also calculated. The dynamometrically measured maximum grip strength was taken as a mechanical loading parameter and muscle cross-section as a substitute for it.Sex, grip strength, BMC and BMD (distal radius) were identified in a multiple regression analysis to predict 81% of bone strength as expressed by SSI, after adjusting for all other independent variables. Further analysis showed grip strength closest related to age, sex, BMD and SSI of the distal radius. The cross-sectional area of muscle was not significantly determining the grip strength within the analysis model. The correlation between grip and SSI was 0.6.

Table

	Beta	St. Error of Beta	Partial correlation	p-level
BMC (distal radius)	0.693	0.068	0.488	<0.0001
BMD (distal radius)	0.281	0.052	0.378	<0.0001
grip strength	0.199	0.055	0.262	0.0003
Sex	0.134	0.058	0.177	0.02

The table shows the results of a forward stepwise regression (6 steps) with SSI of the distal radius as dependent variable. Sex was entered as 0=female, 1=male; with multiple R=0.910; p<0.0001; and adjusted R-square = 0.817.In conclusion, our results suggested that architectural parameters at the distal radius were better related to grip strength than to cross-sectional muscle area in both males and females. Only 19% capacity remained in our model to explain factors not investigated, such as bone genetics. A strong association between muscle and bone cross-section as found by others (JBMR 14, 1999, S495) could not be confirmed.

Bone Formation Decrease and Bone Resorption Increase with Decreased Activity Level. M. K. Karlsson,[1] C. Karlsson,*[1] S. Ljunghall,*[2] K. J. Obrant.*[1] [1]Department of Orthopedic Surgery, Malmö, Sweden, [2]Department of Medicine, Uppsala, Sweden.

The aim of this study was to (i) evaluate the relationship between bone formation, bone resorption and regional bone mineral density in elite male soccer players and controls and (ii) follow bone turnover with decreased and increased activity level. Bone formation was assessed by serum osteocalcin (OC) and carboxy-terminal propeptide of type I collagen (PICP). Bone resorption was assessed by carboxyterminal cross-linked telopeptide of type I collagen (ICTP). Bone mineral density (BMD; g/cm2) total body, lumbar spine, hip was measured by Dual X-ray Absorptiometry (DEXA) and BMD calcaneus by Quantitative Ultraosund (QUS; speed of sound (SOS, m/s), broadband attenuation (BUA, db/MHz) and stiffness index). Included were 12 male professional soccer players (mean age 23 years, range 17-34) exercising 12 hours/week, (range 8-15) for a mean of 5 years (range 1-15). The athletes were followed from full activity through four weeks of rest (weekly) between two seasons with recreational activity of mean 3 hours/week (range 1-7) into the new season. Twenty-seven age- and gender matched volunteers served as controls for the biochemical measurements and 24 individuals for the BMD measurements. Data is presented as mean ± SEM.Male soccer players had 22 ± 12 % higher OC ($p<0.05$), 13 ± 9 % higher PICP (NS) and 34 ± 17 % higher ICTP ($p<0.05$) compared to controls at the end of the season. Soccer players had also higher BMD than controls; 7 ± 1 % total body BMD, 15 ± 3 % lumbar spine BMD, 14 ± 2 % femoral neck BMD, 5 ± 1 % SOS, 13 ± 2 % BUA and 30 ± 3 % stiffness index (all $p< 0.001$, respectively). Bone formation (PICP) decreased by 21 ± 7 % ($p <0.05$) and bone resorption (ICTP) increased by 8 ± 10 % ($p = 0.07$) after two weeks rest and did not change during the rest of the resting period. Bone formation (PICP) increased by 26 ± 5 % ($p < 0.01$) and bone resorption (ICTP) decreased by 8 ± 2 % ($p<0.10$) after 10 days recommencing of seasonal activity level at the end of the study period. After this period, no differences was found in PICP- and ICTP values compared to baseline.In summary, exercising male soccer players have higher bone turnover conferring higher BMD in weight loaded skeletal regions compared to controls. Decreased activity level decreases bone formation and increases bone resorption within weeks. We conclude that decreased activity level with cessation of active career may confer a higher rate of loss of BMD in former athletes compared to controls with possibly no residual higher BMD to be found in old ages when fragility fractures occur.

Physical Activity Increases Bone Size in Prepubertal Boys and Bone Mass in Prepubertal Girls: A Combined Cross-sectional and 3-Year Longitudinal Study. M. Sundberg,*[1] I. Sernbo,*[1] P. Gardsell,[1] E. Ornstein,*[2] B. Sandstedt,*[2] O. Johnell,[1] M. K. Karlsson.[1] [1]Department of Orthopedic Surgery, Malmö, Sweden, [2]Department of Orthopedic Surgery, Hassleholm, Sweden.

The purpose of this study, following 44 boys and 42 girls from age 13 to 16 years, was to evaluate the skeletal effect of physical activity from age 9 to 13 and from age 13 to 16 years. The children were divided into two groups to achieve comparative numbers of children in each group, one high and one low activity group. Accrual of bone mass and growth in bone size were evaluated annually by dual-energy X-ray absorptiometry (DXA) from age 13 to 16 years. The outcome of discrepancies in physical activity from age 9 to 13 yeas were cross-sectionally evaluated at baseline (age 13) and the outcome of discrepancies in physical activity from age 13 to 16 years were longitudinally evaluated. Girls with a high activity level from age 9 to 13 years, had at age 13 years higher femoral neck (FN) bone mineral content (FN BMC; g) ($p = 0.07$), higher FN areal bone mineral density (FN aBMD; g/cm2) and higher FN volumetric BMD (FN vBMD; g/cm3) (both $p < 0.05$, respectively) compared with girls with a low activity level. FN width (cm) and head aBMD (an unloaded region) showed no differences when comparing the two groups. Three years of further high and low activity level (from age 13 to16) did not confer any increased differences when the two groups were compared, and the changes in bone mass and bone size during this period (adjusted for changes in height, weight and Tanner stage) showed no discrepancies when the high and the low activity group were compared.Boys with a high activity level from age 9 to 13 years had at age 13 higher FN BMC, FN aBMD and FN width (all $p < 0.05$, respectively) compared to boys with a low activity level. FN vBMD and head aBMD showed no differences in the comparison between the two groups. Three years of further high and low activity level (from age 13 to 16 years) did not confer any increased discrepancies when the two groups were compared, and the changes in bone mass and bone size during this period (adjusted for changes in height, weight and Tanner stage) showed no discrepancies when the high with the low activity group were compared.We summarize that exercise may confer gender specific skeletal benefits before age 13 years, and that three years of continued high or low activity level do not confer any increased discrepancies in bone size or bone mass in neither girls nor boys. In conclusion, the present study suggests that efforts by the community in order to enhance the skeletal bone status in the population by means of increased physical activity, should probably be initiated before the age of 13 years.

SA171

Phospholipids as Survival Factors in Osteoblastic Cells - A Role for Phosphatidylinositiol 3-Kinase. A. Grey, Q. Chen,* K. Callon, C. Xu,* B. Hill,* I. R. Reid, J. Cornish. Medicine, University of Auckland, Auckland, New Zealand.

The naturally occurring phospholipid growth factors lysophosphatidic acid (LPA) and sphingosine-1-phosphate (S1P) have been shown to influence fundamental cellular processes in a number of cell types in vitro. We and others have shown that both LPA and S1P are mitogenic to osteoblastic cells. In the current study, we examined the effect of these compounds on osteoblast survival in vitro. Using TUNEL and DNA fragmentation assays, we found that both LPA and S1P dose-dependently inhibit the apoptosis induced by serum withdrawal in cultures of primary rat osteoblasts or SaOS2 cells. This effect was observed

at concentrations between 0.01mM and 10mM, which are similar to those reported in the systemic circulation. LPA reduced osteoblast apoptosis by 74% at a concentration of 10mM, while 10mM S1P induced a 65% reduction. We further examined the signaling pathways involved in these anti-apoptotic effects using a DNA fragmentation assay. In primary rat osteoblasts, the ability of both LPA and S1P to prevent apoptosis was completely blocked by pertussis toxin (PTx, 10ng/ml). LY294002, a specific inhibitor of phosphatidylinositol 3-kinase (PI 3-K), dose-dependently inhibited the survival-promoting actions of each phospholipid. Neither PD-98059 nor U-0126, specific inhibitors of MEK, the kinase responsible for activating p42/p44 MAP kinases, abrogated the anti-apoptotic effect of either phospholipid. In Swiss 3T3 fibroblastic cells, PTx blocked the anti-apoptotic actions of LPA and S1P, but LY294002 had no effect on phospholipid-induced cell survival. We conclude that (a) the phospholipids LPA and S1P are potent survival factors in osteoblastic cells, (b) Gi proteins and PI 3-K, but not p42/44 MAP kinases, are involved in transducing the survival signal activated by LPA and S1P in osteoblasts and (c) the signaling pathways which mediate the pro-survival effects of LPA and S1P are cell-type specific.

The Role of IGF-I Receptor in Cell Survival of Trabecular Osteoblasts Derived from the Hypophysectomized Rat. J. F. Evans,* J. K. Yeh, J. F. Aloia. Medicine, Winthrop-University Hospital, Mineola, NY, USA.

It has been previously established that trabecular bone cells isolated from hypophysectomized (HX) animals 6-weeks after surgery have a higher rate of proliferation than their intact control counterparts when placed in culture. We have hypothesized that this increase is in part due to an up-regulation of the IGF-I receptor. Since active IGF-I receptor imparts an anti-apoptotic effect on the cell we compared the survival potential of HX vs control trabecular cells in response to the apoptosis inducing levels of inorganic phosphate and serum-free medium conditions. After a 72-hour incubation with an additional 9mmol/L inorganic phosphate as sodium phosphate in the medium, control cultures decreased in viability by 47% while the HX cultures experienced only a 12% decrease. When 200ng/ml of IGF-I was added to these cultures neither the control nor the HX cells experienced a decrease in viability after 72 hours, demonstrating that an increase in IGF-I receptor activity provides a protective effect. To further test cell survival we placed control and HX trabecular cells in serum-free medium with and without antibody to IGF-I receptor. After 48 hours of culture in serum-free medium 65% of cells survived in the HX cultures while only 50% remained in the control ($P< 0.01$), as assessed by the MTT viability assay. The addition of IGF-I receptor antibody decreased cell survival by 30% in the HX but only by 10% in the control, demonstrating that IGF-I receptor plays a role in their increased survival. In order to confirm whether or not the greater number of surviving cells in the HX cultures is due to a decrease in apoptosis, we examined the bcl-2/bax ratio in both groups using quantitative multiplex PCR. The bcl-2/bax ratio was 2X greater in the HX cultures than in the controls (3.03 vs. 1.54) indicating that the increased cell survival is through an anti-apoptotic effect. In conclusion the increased proliferation observed in trabecular bone cultures of the HX rat compared to those of the intact control is likely due to an increase in IGF-I receptor which imparts a resistance to apoptosis and therefore increases cell number. These cells provide a good model that can be used to further the study of anti-apoptotic effects induced through the IGF-I receptor.

SA174

Study of Cell Proliferation and Apoptosis During Fracture Healing. G. Li, G. White,* C. Connolly,* D. Marsh.* Department of Trauma and Orthopaedic Surgery, The Queen's University of Belfast, Belfast, United Kingdom.

Fracture repair is a complex physiological process during which bone shows the remarkable ability to mount a repair process, restoring its mechanical integrity and anatomical configuration by original osseous tissue. Programmed cell death, or apoptosis, is a naturally occurring cell suicide pathway with a homeostatic function in the maintenance of continuously renewing tissues. The present study investigated the relation between cell proliferation and apoptosis during fracture healing in a mouse femoral model.Left femoral osteotomies were performed in 20 male CFLP mice (35-45g), immobilised with uniplanar external fixators. 4 animals were sacrificed on days 2, 4, 8, 16 and 24 post-fracture and fracture callus collected for paraffin embedding. Localisation of cell proliferation was examined using immunohistochemistry with proliferating cell nuclear antigen (PCNA) monoclonal antibody. Apoptotic cells were visualised with the terminal deoxynucleotidyl transferase (TdT)-mediated dUTP-biotin nick end-labelling (TUNEL) method. Random images of each time specific specimen were captured via a digital camera and the positive labelling indices of PCNA and TUNEL labelling were calculated. Cell proliferation and apoptosis were found co-existing during the entire period of fracture healing studied. Cell proliferation was predominant in the early phases of fracture healing (days 2-8). PCNA positive labelling index peaked at day 8 and PCNA-positive cells were not limited to the fracture gap mesenchymal tissues but extended in the periosteum along most of the fractured femur. TUNEL positive labelling was minimal in the early stages (days 2-8). In later stages of fracture healing (days 16-24), PCNA expression declined as intramembranous and endochondral ossification spread within the fracture site and apoptosis was the dominant cell activity with the TUNEL positive labelling index peaked at day 16 and then declined sharply at day 24. The current study indicated that apoptosis was a normal concomitant during fracture repair, confirming programmed cell death in chondrocytes and bone cells, and that cell proliferation and apoptosis were tempero-spatially dependent. These findings support the view that apoptosis is a natural process, genetically programmed and active during fracture repair. The demonstration of a mixture of proliferative and apoptotic cell populations in the regenerating tissues of fracture callus, suggests that apoptosis and cell proliferation may be regulated by local factors during fracture healing.

Autocrine Glutamate Signaling Regulates Osteoblast Apoptosis. P. G. Genever, T. M. Skerry. Biology, University of York, York, United Kingdom.

Osteoblasts express functional receptors for the neurotransmitter glutamate that are similar to those located at synaptic sites in the central nervous system. We have shown that osteoblasts also accumulate glutamate using specific transporters and release glutamate constitutively under steady-state conditions to regulate extracellular glutamate concentrations. This continuous glutamate recycling in osteoblasts is in contrast to glutamatergic activity in neurons where prolonged exposure to glutamate has cytotoxic effects. We therefore investigated the functional role of constitutive glutamate signalling on cell survival in cultures of primary human osteoblasts. Using a fluorimetric assay we determined that osteoblasts release approximately 1-30μM glutamate into their incubation medium, though concentrations at the cell surface are likely to be much greater. Addition of riluzole, a pharmacological inhibitor of neuronal glutamate release, significantly inhibited glutamate release in osteoblasts. However exposure to riluzole at neuroprotective concentrations (25μM), induced biochemical and morphological characteristics of apoptosis in osteoblasts (membrane blebbing, DNA fragmentation, chromatin condensation, TUNEL). By western blot analysis of osteoblast lysates we demonstrated that riluzole (25μM, 24h) markedly increased the Bax/Bcl-2 ratio (+400%), a characteristic of cells beginning to apoptose. Riluzole treatment increased intracellular glutamate concentrations in these cells by approximately 50% compared to controls, however dimethylglutamate (5mM), a membrane permeable glutamate precursor, caused similar elevations in intracellular glutamate (+45%) but did not have proapoptotic effects. These findings suggested that riluzole-induced apoptosis was caused through decreased glutamate release and not merely increased intracellular glutamate accumulation. To test this hypothesis we cultured differentiated osteoblasts in glutamate/serum-free medium in the presence of varying concentrations of exogenous glutamate (0-500μM) for 24h. MTT assays revealed that glutamate significantly increased osteoblast viability, with 50μM glutamate causing an approximate 15% increase in viable cell numbers compared to untreated controls ($P<0.001$). Glutamate induced a marked dose-dependent decrease in the Bax/Bcl-2 ratio in these cells (-75%, 50μM glutamate) and rescued riluzole-induced increases in the Bax/Bcl-2 ratio, without affecting expression levels of PCNA, a protein involved in DNA replication and repair. These data suggest strongly that glutamate acts as an osteoblast survival factor and will impact significantly on our understanding of remodelling events and pathological bone disorders.

SA177

Retroviral Delivery of Genes to Transit Amplifying Osteoblast Progenitors: Inhibition of Apoptosis by Overexpression of Bcl-2. I. Gubrij, C. A. O'Brien, A. A. Ali, S. C. Manolagas, R. L. Jilka. Div. Endo/Metab, Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. of Arkansas for Med. Sci., Little Rock, AR, USA.

Murine marrow-derived colony forming unit-osteoblasts (CFU-OBs) are transit amplifying progenitors capable of both replication and differentiation into osteoblasts. Modulation of CFU-OB behavior influences bone homeostasis as shown by evidence that suppression of CFU-OB replication mediates the anti-remodeling effect of estrogen,and that decreased CFU-OB replication may contribute to age-related bone loss. To facilitate study of the regulation of CFU-OB using a genetic approach, we developed a strategy to transduce them with a replication defective murine retrovirus expressing genes of interest. A construct containing an internal ribosomal entry site was made to allow expression of two proteins from a single mRNA. For preliminary experiments, we made a construct expressing enhanced green fluorescence protein (EGFP) and neomycin phosphotransferase (neo). The former permitted nondestructive monitoring of transduction efficiency, and the latter allowed selection of transduced cells with G418. Marrow cells were obtained from mice expressing β-galactosidase under the control of an osteocalcin promoter so that osteoblast formation from CFU-OB could be detected by X-gal staining. The cultures were infected 4 days after plating, when CFU-OB are known to be dividing and thus susceptible to retroviral infection. Then, cells were subcultured and maintained for 20 days in medium containing 1 mM ascorbate-2-phosphate to induce osteoblast differentiation. We found that 40-60% of X-gal-positive colonies were composed exclusively of cells expressing EGFP, indicating efficient transduction of CFU-OB. After selection in G418, all such colonies expressed EGFP. To begin analysis of the role of apoptosis in CFU-OB behavior and fate, marrow cells were infected with a retrovirus expressing neo and human Bcl-2, which inhibits apoptosis. As a negative control, cells were infected with the EGFP/neo retrovirus. After G418 selection, all the cells in fibroblastic colonies that developed in cultures transduced with the Bcl-2/neo retrovirus, but not the EGFP/neo retrovirus, exhibited immunostaining for human Bcl-2. More important, only Bcl-2-transduced cells were resistant to apoptosis stimulated by etoposide, as determined by immunostaining for active caspase-3. These findings show that human Bcl-2 was expressed at levels sufficient for blockade of the death program in CFU-OB and their progeny; and they set the stage for investigation of the role of apoptosis in osteoblast differentiation and bone formation.

SA178

Bcl-2 Overexpression Prevents Glucocorticoid-induced Apoptosis in Osteoblasts from the H2K-BCL-2 Transgenic Mouse. G. Gronowicz,*[1] M. B. McCarthy,*[1] L. Aguila.*[2] [1]Orthopaedics, UCONN Health Center, Farmington, CT, USA, [2]Center for Immunotherapy, UCONN Health Center, Farmington, CT, USA.

The anti-apoptotic protein Bcl-2 has been shown to be inhibited by glucocorticoids, which increases apoptosis in primary osteoblasts. The transgenic mice (H2K-BCL-2) overexpresses human bcl-2 (hbcl-2) in all cells of the hematolymphoid system including spleen, thymus and lymph nodes (Domen,et al., 1998 Blood 91:2272). H2K is a major histocompatibility (MHC) class I promoter. We found that human bcl-2 is also expressed in mouse osteoblasts from this transgenic mouse, therefore the goal of this study was to use osteoblasts from the transgenic mouse to determine if overexpression of bcl-2 would prevent glucocorticoid-induced apoptosis. Primary osteoblasts were isolated by hyaluronidase/collagenase digestion (third digestion, fraction 3) of 1 month-old mouse calvaria from transgenic and control littermates. The transgenic osteoblasts expressed hbcl-2 as determined by Western blot with an antibody specific to the human isoform (Santa Cruz Biotechnology, Inc.) while osteoblasts from the nontransgenic littermate did not demonstrate hbcl-2. Treatment with 1 to 100 nM corticosterone caused a dose-dependent decrease in mouse bcl-2 levels in osteoblasts from the nontransgenic mice. Apoptosis assessed by acridine orange/ethidium bromide staining and TUNEL increased in a dose-dependent manner to a maximal 4-fold increase compared to control, untreated osteoblasts. In contrast, the osteoblasts from the H2K-BCL2 mouse demonstrated no changes either in hbcl-2 or mouse bcl-2 levels and did not undergo apoptosis in response to 1 to 100 nM corticosterone. Therefore, transgenic overexpression of bcl-2 driven by the H2-K promoter prevents glucocorticoid-induced apoptosis in calvarial osteoblasts.

SA179

Raloxifene Protects Osteoblasts from Apoptosis Induced by Sodium Nitroprusside and Low Serum Concentration. S. Olivier,*[1] C. Ribbens,*[1] B. Relic,*[1] P. Durez,*[2] M. P. Merville,*[3] M. Malaise,*[1] N. Franchimont.[1] [1]Rheumatology, CHU Sart-Tilman, Liège, Belgium, [2]Eli Lilly, Brussels, Belgium, [3]Chimie Médicale, CHU Sart-Tilman, Liège, Belgium.

Raloxifene is a selective estrogen receptor modulator (SERM) currently used for the treatment of postmenopausal osteoporosis. Raloxifene has agonist estrogen-like effects on bone remodeling and increases bone mass in osteoporotic women. Clinical studies revealed that raloxifene was even more potent in reducing vertebral fractures in osteoporotic women, suggesting additional positive properties on bone quality. However, the exact mechanisms of raloxifene effects on bone cells are not fully understood. We tested the hypothesis that raloxifene decreases osteoblast apoptosis induced by the nitric oxide (NO) donor sodium nitroprusside (SNP). It is believed that high concentrations of NO in response to proinflammatory cytokines inhibit proliferation and induce apoptosis of osteoblasts. For this purpose, we studied the effects of SNP at 1 to 4 mM in the presence or absence of raloxifene or estradiol on the survival of mouse osteoblastic cells MC3T3-E1. MC3T3-E1 apoptosis was evaluated by quantitative colorimetric cell viability assay, by DNA fragmentation and FACS analysis using Annexin-V labelling. The assays were conducted in 1% charcoal treated fetal calf serum (FCS) to reduce steroid interactions. We demonstrated significant levels of estrogen receptor-beta in MC3T3-E1 by Western blotting while levels of estrogen receptor-alpha were barely detectable.In 1% charcoal treated FCS, low levels of apotosis were observed in the absence of SNP, indicating that serum and/or steroids are required to prevent apoptosis in osteoblasts. Treatment with SNP at 2 mM for 24 h reduces cell viability to 30-40% of the control in both untreated and estradiol (10^{-6} M) treated cultures. In contrast, in the presence of raloxifene (10^{-6} M), 90% of the cell viability was sustained after treatment with SNP at 2 mM. Similar results were obtained whether the cells were pretreated with raloxifene for 48 h before SNP treatment or treated simultaneously with SNP. In addition, raloxifene positive effect on cell viability was dose-dependent, a significant effect being observed at a dose of 10^{-10} M. Interestingly, when using 10% non charcoal treated FCS, a dose of 4 mM SNP was required to induce a 50% cell mortality and raloxifene protective effect was abolished. In contrast, estradiol had a small positive effect on cell viability in 4 mM SNP treated cultures in the presence of 10% serum. These data suggest that raloxifene decreases SNP-induced apoptosis in conditions of low serum and/or steroid concentrations, possibly through mechanisms distinct from estrogen.

Cell Cycle Regulation During Osteoblast Differentiation, and the Role of c-Fos in Post-Confluence Growth Control. A. Sunters,* D. P. Thomas, D. Harmey, A. Tumber,* K. Beedles,* W. A. Yeudall,* A. E. Grigoriadis. Craniofacial Dev, KCL, London, United Kingdom.

The c-Fos proto-oncogene has been shown to play an important role in osteoblast differentiation, as exemplified by the formation of osteosarcomas in c-Fos overexpressing transgenic mice. We have demonstrated previously that alterations in the expression of key cell cycle regulators occur upon the expression of a c-Fos transgene *in vivo*. Furthermore, induction of exogenous c-Fos expression in primary mouse osteoblasts and in AT9.2 cells, a clone of MC3T3-E1 that expresses c-Fos under the control of a tetracycline (Tc) regulatable promoter, results in elevated cyclin A expression and accelerated S-phase entry. However, how cell cycle control is regulated during osteoblast differentiation and how c-Fos controls both these processes is unclear. Primary mouse osteoblasts were induced to differentiate by the inclusion of ascorbate and beta-glycerophosphate in the culture medium, which resulted in the expression of alkaline phosphatase and the formation of mineralised bone nodules after 15 days. We measured the expression of cell cycle control genes in differentiating compared to non-differentiating cultures (without ascorbate and beta-glycerophosphate) in order to determine what changes in cell cycle regulation were differentiation specific, and which were effects of long term culture. Early changes that were differentiation specific were upregulation of cyclin D3, prolonged expression of cyclin A, CDK1, CDK2, and p27, and a decrease in p57 expression. At later time points, we observed a dramatic increase in p16 expression in differentiating cultures. Expression of p16 is associated with senescence, and we also observed an increase in staining for senescence-associated-beta-galactosidase activity in differentiating cultures, suggesting a link between osteoblast differentiation, cell cycle regulation and senescence.Overexpression of c-Fos in primary mouse osteoblasts or in Tc-regulatable osteoblast-like clones caused a reduction in specific markers of osteoblast differentiation. Furthermore, whilst overexpression of c-Fos in AT9.2 cells did not result in an increase in prolliferation in exponentially growing cells, overexpression in post confluent cultures resulted in increased cell number and a higher number of cells in S-phase as determined by flow cytometry. The overexpression of c-Fos in postconfluent cells also resulted in prolonged expression of cyclin E.Taken together, these data show that osteoblastic differentiation is characterised by specific changes in cell cycle control, which are not observed in non-differentiating cultures, and that c-Fos can regulate post confluent growth in osteoblasts.

Effects of Estrogen on Human Osteoblast Gene Expression. D. C. Ireland,* S. Bord, S. R. Beavan,* J. E. Compston. University of Cambridge, Cambridge, United Kingdom.

Histomorphometric data in women given long-term, high-dose estradiol therapy show evidence of increased osteoblast activity whereas conventional HRT does not appear to have such an effect. We have investigated the effects of high (10^{-7}M) and physiological (10^{-10}M) concentrations of 17β-estradiol on the expression of genes for estrogen receptors (ERs), osteoprotegerin (OPG), RANKL, alkaline phosphatase (ALP), osteocalcin (OC) and type I collagen (COLIA1) in cultured low-passage, non-transformed human osteoblasts. Human osteoblasts were grown for two days in flasks coated with type I collagen in medium supplemented with vitamin C (100μM), hydrocortisone (200nM), β-glycerophosphate (7.5mM) and human male serum (10% v/v)and then treated with medium containing 10^{-7}M, 10^{-10}M or no added 17β-estradiol for 48 hours. RNA isolated from harvested cells was used for real-time, fluorescence-based quantitative RT-PCR. Following normalisation to GAPDH, mRNA levels relative to cultures with no added estradiol were calculated. Results shown in the table below demonstrate that estradiol increases levels of mRNAs for ER beta, OPG, RANKL, ALP and COLIA1 in human osteoblasts although the functional significance of the changes remains to be determined.

Relative ratios of mRNAs in estradiol-treated human osteoblasts

	no estradiol mean (std dev)	10-10M estradiol mean (std dev)	10-7M estradiol mean (std dev)
ER alpha	1.0 (0.3)	1.1 (0.2)	1.2 (0.1)
ER beta	1.0 (0.2)	1.4* (0.1)	1.5* (0.2)
OPG	1.0 (0.2)	1.3 (0.1)	2.6* (0.4)
RANKL	1.0 (0.3)	1.8 (0.8)	28.0* (3.0)
ALP	1.0 (0.2)	1.3 (0.4)	2.1* (0.1)
OC	1.0 (0.3)	1.1 (0.2)	1.2 (0.1)
COLIA1	1.0 (0.2)	1.4* (0.2)	2.4* (0.1)

Reduced Estrogen Influences Bone Remodeling by Delaying the Differentiation of Bone Marrow-Derived Osteoclast-Inductive Precursors into Osteoblastic Cells. J. Owens, M. Bouxsein, V. Rosen. Genetics Institute, Cambridge, USA.

Post-menopausal women who develop low bone density are at an increased risk of fragility fractures. In normal individuals, rhBMP-2 enhances fracture repair. However, it is not known whether rhBMP-2 would have the same positive effect on bone healing in estrogen deficient individuals. We addressed this question by comparing the response of bone marrow cells to rhBMP-2 stimulation before and after ovariectomy (ovx). We acquired bone marrow aspirates from ten skeletally mature female baboons before ovx and 6 and 12 months post-ovx. Compared to pre-ovx, the post-ovx samples had a 3 fold increase in the number of osteoblastic colonies which formed in our bone marrow cell cultures ($p<0.01$). RhBMP-2 increased alk phos activity in both pre- and post-ovx cells. However, the increase in alk phos activity in response to rhBMP-2 was 10 times lower post-ovx ($p<0.01$).The addition of estrogen to post-ovx cells for 14 days in vitro failed to restore the response to rhBMP-2 to pre-ovx levels. In contrast, increasing the exposure time to rhBMP-2, (from 14 to 21 days), restored alk phos activity to pre-ovx levels. These results suggest that without estrogen, the response to rhBMP-2 is delayed. Northern analysis of the type I BMP receptor, ALK3, showed decreased levels in post-ovx cells. The loss of

BMP receptors was not restored by the addition of estrogen in vitro.To test our hypothesis that ovx leads to a delay in the differentiation of bone marrow stromal cells, we investigated changes in RANKL and OPG expression using Northern analyses. We found that OPG mRNA levels increase and RANK-L mRNA levels decrease during osteoblast differentiation. The RANK-L:OPG ratio of mRNA expression was greater in our post-ovx samples compared to pre-ovx samples, indicating the presence of a greater proportion of osteoclast-inductive stromal cells and therefore, delayed osteoblast differentiation and increased osteoclast formation. In conclusion, these data suggest that the reduced response of post-ovx bone marrow to rhBMP-2 stimulation is due in part to a decrease in BMP receptor expression levels and in part to a delayed differentiation of osteoclast-inductive stromal cells into osteoblastic cells, resulting in increased osteoclastogenesis.

SA184

Participation of Signal Transducer and Activator of Transcription Proteins in Estrogen-induced Signaling. A. Maran, A. M. Kennedy,* R. T. Turner. Orthopedic Research, Mayo Clinic, Rochester, MN, USA.

Signal transducers and activators of transcription (STATs) transduce signals initiated by many growth factors and cytokines. Estrogen is important for the normal growth and remodeling of bone. While the physiological role of estrogen has been well defined, the signal transduction pathways utilized by estrogens in bone cells are largely unknown. To better understand the molecular mechanism of action of estrogens, we have studied the effects of 17-β estradiol on Janus Kinase (JAK)/STAT regulation in human fetal osteoblast (hFOB) cells in culture. 17-β estradiol stimulated various members of Stat family. The induction of Stat 1, -2, -3, -5a, -5b and -6 were noticed in estrogen treated human osteoblasts. Estrogen treatment resulted in the activation of Stat1 protein, which accompanied an increased binding to interferon-stimulated response element in the DNA. This provides first direct evidence that Stat 1 is a transducer for the estrogen signaling in bone cells. The estrogen receptor antagonist ICI 182, 780 blocked the regulation of Stat1 by estrogen indicating that this pathway is estrogen receptor dependent. Induction of Stat gene expression and activity by estrogens in osteoblastic cells suggests that components of JAK/STAT signal transduction pathway may mediate distinct estrogen mediated functional processes in skeletal system.

SA185

The Phytoestrogen Genistein Stimulates the Production of Osteoprotegerin by Human Trabecular Osteoblasts. V. Viereck,[1] C. Gruendker,*[1] S. Blaschke,*[1] H. Siggelkow,[1] G. Emons,*[1] L. C. Hofbauer.[2] [1]University of Goettingen, Goettingen, Germany, [2]University of Marburg, Marburg, Germany.

The anti-resorptive effects of estrogen on bone metabolism are thought to be mediated through modulation of paracrine factors produced by osteoblastic lineage cells that act on osteoclastic lineage cells. Receptor activator of nuclear factor-kappaB ligand (RANKL) is the essential factor for osteoclast formation and activation, and enhances bone resorption. By contrast, osteoprotegerin (OPG) which is produced by osteoblastic lineage cells acts as a decoy receptor that neutralizes RANKL, and prevents bone loss. Recently, 17beta-estradiol was found to enhance OPG mRNA levels and protein secretion in a human osteoblastic cell line through activation of the estrogen receptor (ER)-alpha. In this study, we assessed the effects of the phytoestrogen genistein on OPG mRNA steady state levels (by semiquantitative RT-PCR and Northern analysis) and protein production (by ELISA) in primary human trabecular osteoblasts (hOB) obtained from healthy donors. Genistein increased OPG mRNA levels and protein secretion by hOB cells by up to two- to six-fold in a dose- ($P < 0.0001$) and time-dependent ($P < 0.0001$) fashion with a maximum effect at 10-7 M. Co-treatment with the pure ER antagonist ICI 182,780 completely abrogated the stimulatory effects of genistein on OPG protein secretion, indicating that the effects observed were specific and directly mediated through the ER. Pre-treatment with genistein partially prevented the inhibitory effects of the glucocorticoid dexamethasone on OPG mRNA and protein production. The stimulation of OPG mRNA levels by genistein was not affected by the protein synthesis inhibitor, cycloheximide, and was shown to be due to enhancement of OPG gene transcription. In conclusion, these data suggest that the phytoestrogen genistein is capable of up-regulating the production of OPG by human osteoblasts. Thus, dietary sources of phytoestrogens may help to prevent bone resorption and bone loss by enhanced osteoblastic production of OPG.

SA186

Differential Effects of Genistein (GEN) and Daidzein (DIZ) on MC3T3-E1 Osteoblastic Cell Proliferation and Differentiation. X. W. Chen,*[1] S. C. Garner,[2] J. J. B. Anderson.[1] [1]Dept. of Nutrition, University Of North Carolina, Chapel Hill, NC, USA, [2]Dept. of Surgery, Duke Medical Center, Durham, NC, USA.

The mechanisms by which estrogen-like molecules, including isoflavones, improve bone retention in ovariectomized rodent models remain unclear. In this *in vitro* study, the effects of genistein (GEN) and daidzein (DIZ), two major isoflavones, were compared to 17β-estradiol (E_2) in MC3T3-E1 osteoblastic cells. Cell proliferation was evaluated by BrdU staining and by MTT assay. At high concentrations (~10^{-3} M), GEN or E_2, but not DIZ, strongly inhibited cell proliferation through stimulation of apoptosis ($P<0.05$). At nutritionally relevant concentrations (10^{-9} - 10^{-6} M), only slight stimulatory effects of GEN or E_2 were found; however, DIZ increased cell viability about 47%. In cell differentiation studies, MC3T3-E1 cells were cultured up to 16 days, and GEN or DIZ were added with fresh medium on either day 8 or day 12 for 8-day or 4-day treatments, respectively. Cells and culture medium were harvested for isolation of total RNA, and measurements of alkaline phosphatase (ALP), and interleukin-6 (IL-6). Although no significant effects of GEN, DIZ, or E_2 on ALP activities (adjusted for DNA) were detected during 4-day treatment periods, DIZ, but not GEN or E_2, significantly increased ALP activities 100%-120% during 8-day treatment periods ($P<0.05$). IL-6 synthesis (adjusted for DNA) was inhibited about 50%-70% by either GEN, DIZ, or E_2 during both 4-day and 8-day treatments, and the stronger inhibitory effects were found in the cells treated with DIZ or E_2. In addition, semi-quantitative RT-PCR was performed with gene-specific primers, and the predicted product sizes of 360 bp, 460 bp and 631 bp for osteoprotegerin (OPG)/osteoclastogenesis inhibitory factor (OCIF), receptor activator of NF-kB ligand (RANKL)/osteoclast differentiation factor (ODF), and GAPDH, respectively, were obtained. The ratios of OPG/OCIF mRNA to RANKL/ODF mRNA increased 282%, 254%, 218% in the MC3T3-E1 cells treated with GEN, DIZ, or E_2 at 10^{-8}M, respectively, in comparison to vehicle (control). In summary, because of the critical functions of IL-6, OPG/OCIF, and RANKL/ODF in osteoclast differentiation, the modulation of these three osteoblastic products by genistein and daidzein may be one important mechanism through which isoflavone molecules reduce the risk of osteoporosis. The differential effects of genistein and daidzein, compared to 17β-estradiol, suggest that two different pathways (estrogen receptor-dependent vs. estrogen-independent pathways) of regulation of osteoblastic functions may be involved.

SA188

Estrogen and Raloxifene Modulate the Expression of Osteoprotegerin (OPG) and RANK-Ligand (RANKL) in Human Osteoblast-like Cells at Supra-physiological/Pharmacological Concentrations. G. Hampson,[1] J. Cheung,[1] Y. T. Mak,[1] S. Papaioannou,*[2] B. Evans,*[3] I. Fogelman,[4] A. E. Grigoriadis.[2] [1]Chemical Pathology, St Thomas Hospital, London, United Kingdom, [2]Orthodontics and Paediatric Dentistry, Kings College, London, United Kingdom, [3]Child Health, University Hospital of Wales, Cardiff, United Kingdom, [4]Nuclear Medicine, Guy's Hospital, London, United Kingdom.

Oestrogen (E2) inhibits osteoclastic activity and resorption, at least in part, by regulating the production of IL-6, IL-1 and TNF by osteoblasts. It is now thought that the final step in the osteoclast regulatory pathway may be determined by the relative ratio of RANK-ligand (RANKL) to osteoprotegerin (OPG). The aim of the current study was to assess the regulation of IL-1, OPG and RANKL by E2 and the selective estrogen receptor modulator, Raloxifene (RAL). We studied an immortalised human bone marrow stromal cell line with osteoblastic characteristics (HCC1) and primary human osteoblastic cells (HOB). We tested physiological (10-8M) and supra-physiological (10-7, 10 -6 M) concentrations of E2. IL-1 alpha and beta and OPG were measured by ELISA. The expression of RANKL and OPG protein was also determined by immunolocalisation. Gene expression of OPG and RANKL in the HCC1 cells was measured using the SYBR Green PCR assay. IL-1 alpha and beta were significantly decreased following treatment with E2 and RAL at 10-7 and 10-6 M (E2 :73%, 66%. RAL : 69%, 73% of control, p =0.01). There was a significant reduction in OPG in the HCC1 and HOB cells at E2 and RAL concentrations of 10-6 M only (HOB, E2 : 63%, RAL : 55%. HCC1 , E2 : 54%, RAL : 39%, p=0.001). The same trend was observed when OPG expression was determined by immunolocalisation. The reduction in OPG was less than that found following treatment with Dexamethasone (DEX) at 10 -9, -8 and -7 M (HCC1 , DEX 10-9M : 15%, 10-8M : 16% , 10-7M : 25% of control p=0.001). There was also a decrease in RANKL protein expression in the HCC1 and HOB cells at E2 and RAL concentrations of 10-6M (HOB % RANKL positive cells Control : 12.3%, E2 : 3.8%, RAL : 2.8%. HCC1 , Control :12.9%, E2 : 4.6%, RAL : 7.1%). RANKL mRNA expression was significantly reduced following treatment with RAL at all concentrations tested (RAL 10-8 M : 52%, 10-7M : 62%, 10-6M : 53% of control p =0.001). However the ratio of RANKL/OPG mRNA did not differ significantly from control following either E2 or RAL treatment. E2 and RAL modulate the production of OPG and RANKL in human osteoblastic cells at supra-physiological/ pharmacological concentrations (10-6M). Although both E2 and RAL lead to a decrease in OPG and RANKL at this concentration, the ratio of these two factors remains unchanged.

SA189

The Orphan Receptor, Estrogen Related Receptor alpha (ERRα), May Regulate Bone Formation by Its Direct Effect on Bone Sialoprotein (BSP) Expression. V. Kung,* E. Bonnelye, J. E. Aubin. Dept of Anatomy & Cell Biology, University of Toronto, Toronto, ON, Canada.

The orphan estrogen related receptor alpha, ERRα, is known to be expressed by osteoblastic cells and, in promoter-reporter assays, to transactivate at least one osteoblast associated gene, osteopontin (OPN). This, together with its relationship to the estrogen receptors, ERα and ERβ, makes it an interesting and important potential regulator of bone formation and maintenance of bone mass. We recently described the expression of ERRα *in vivo*in sections of fetal (21 d. fetal rat calvaria (RC)) & adult (femur) bones, and in RC cell populations *in vitro*. To dissect further possible involvement of ERRα in bone development, we next blocked ERRα in differentiating RC cell cultures using phosphorothioate-modified antisense oligonucleotides. Concomitant with a dose-dependent total inhibition of bone nodule formation, we observed by RT-PCR and confirmed by immunocytochemistry a marked decrease in bone sialoprotein (BSP) expression in antisense-, but not in sense-, treated RC cultures. Interestingly, we found no evidence for changes in OPN expression levels in the same antisense-treated samples. BSP and ERRα were found to be co-expressed in very early osteoprogenitors *in vitro*(by PCR) and in mature osteoblasts *in vivo*(by immunocytochemistry). Given these observations, we next asked whether the effect of ERRα on BSP expression was direct or indirect. A sequence screen of the rat BSP promoter revealed a potential ERRα core binding site (-32 AAGAAGGGTT**TATAGGT-CA**GCAAGA -8). Moreover, by EMSA, we found evidence for potential interaction of

ERRα on this core binding site. Our data indicate that ERRα interacts with the BSP promoter, and strengthens the possibility that BSP is a potential target gene of ERRα, suggesting one pathway by which ERRα exerts its effect on osteoblast development.

Molecular Mechanisms of Osteoblastic Transformation in HumanOsteosarcomas. D. J. Papachristou,1 A. Bourli,*2 N. Arnogiannaki,*3 M. Assimakopoulou,*1 J. Varakis,*1 A. G. Papavassiliou.4 1Anatomy, University of Patras, School of Medicine, Patras, Greece, 2St. Olga Anticancer Hospital, Athens, Greece, 3St. Sabbas Anticancer Hospital, Athens, Greece, 4Biochemistry, University of Patras, School of Medicine, Patras, Greece.

Transcription factor AP-1 (a homo-/heterodimer comprised of c-Jun-and c-Fos-related proteins) binds to specific control elements in thepromoters of osteoblastic genes and modulates their expression. Thecomposition of AP-1 complexes, the phosphorylation status of c-Jun, andthe presence of auxiliary proteins dictate AP-1 activity in variouscontexts. AP-1-mediated gene expression contributes towards a diversityof important end-points, including proliferation, differentiation, andneoplastic transformation. Alpha-NAC (a-NAC) is an AP-1 co-activatorrestricted to osteoblasts, which is considered to be implicated in theregulation of gene expression during osteoblastic differentiation.Specifically, a-NAC augments the transcriptional potential of thehomodimeric c-Jun complex, but has no effect on the c-Jun/c-Fosheterodimer. Because AP-1 has a fundamental role in osteoblast geneprograming, it is plausible that alterations in theexpression/activation profile of AP-1 components/auxiliary factors mightbe involved in the biology of osteogenic tumors. We performedimmunohistochemical studies in paraffin sections of human osteosarcomas(anaplastic, intramedullary, periosteal, paraosteal) to investigate theexpression profile of a-NAC, in conjunction with theexpression/activation state of c-Jun and the kinases that are known tostimulate its transactivation potential (c-Jun N-terminal kinases[JNKs1/2]). In a high percentage of interspersed tumor cells of allosteosarcomas examined, there was a strong a-NAC immunoreactivity aswell as a co-localized enhancement in the expression of JNK1, JNK2, andtheir cognate substrate c-Jun. These inductive effects paralleled thepresence of the activated forms of c-Jun and JNKs and appeared tocorrelate with the histopathologic grading of the tumors. In accordancewith the minimal expression of the aforementioned proteins innon-proliferating osteoblasts in vitro, non-tumorous parts of thespecimens were devoid of the above immunoreactivities. Our resultsindicate the involvement of the JNK/c-Jun signaling cassette inosteoblastic transformation and imply that activation of c-Jun via theJNK pathway is a primary event in a cascade of changes related toincreased proliferative activity of human osteosarcoma cells. Our dataalso support the hypothesis that a high level of specific AP-1 complexes(i.e. c-Jun/c-Jun dimers) may play decisive role in the process of osteoblastictransformation.

The Decrease in Adipocyte Differentiation Observed In Vivo and In Vitro in Osteosclerotic ΔFosB Transgenic Mice Occurs at Early Adipocyte Commitment. M. Kveiborg, G. Sabatakos, M. Wu,* R. Baron. Yale University School of Medicine, New Haven, CT, USA.

Several members of the AP-1 family of transcription factors are known to play important roles in the regulation of bone cell differentiation. We have previously reported that overexpression of δFosB isoforms, naturally occurring splice variants of the *fosB* transcript, in transgenic mice resulted in a dramatic increase in bone density due to increased bone formation, shown to be cell-autonomous to the osteoblast lineage (Sabatakos et al. Nature Med 6: 985-990, 2000). In contrast, abdominal fat concentrations were decreased in δFosB transgenic mice, and marrow smears exhibited a reduced adipocyte number. In vitro, both bone marrow stromal cells and calvarial cultures from δFosB mice showed a significant decrease in adipocyte number and maturation, as opposed to increased expression of osteoblastic marker genes. The observation of decreased adipocyte differentiation in the presence of increased osteoblastogenesis in vivo and in vitro raised the possibility that the two events are linked. Therefore, the present study was aimed at determining whether the inhibitory effects of δFosB isoforms on adipocyte differentiation are the result of a direct action on adipocyte precursors or indirectly, via the effects of δFosB isoforms on osteoblasts. δFosB as well as δFosB mutants encoding only the full-length δFosB or the truncated δ2δFosB isoform were overexpressed in both the preadipocytic cell line 3T3-L1 and the mesenchymal cell line ST2, which has the potential to differentiate into both osteoblast- and adipocyte-like cells. Stably or transiently transfected cell lines were induced to differentiate into adipocytes by addition of adipogenic agents. Subsequent morphological and biochemical analysis demonstrated an inhibitory effect of δFosB on adipocyte differentiation, as revealed by reduced Oil Red O staining of lipid droplets and decreased induction of the adipogenic transcription factors PPARγ and C/EBPα. The repression of adipogenesis appeared to be mediated via the truncated δ2δFosB isoform and was more profound in the ST2 cell-line, representing an earlier stage of adipocyte differentiation, than in the already committed 3T3-L1 cell-line. Thus, these results suggest that δ2δFosB may exert cell autonomous inhibitory effects on adipocyte differentiation both at the level of early stem cell commitment, possibly via a decrease in the pool of adipocyte precursors as a consequence of increased osteoblast differentiation, and also on more committed adipocyte precursors.

Cbfa1- and Smad-binding Elements Mediate TGF-β Stimulation of Osteoprotegerin (OPG) Gene Expression. K. Thirunavukkarasu,*[1] R. R. Miles,*[2] D. L. Halladay,*[2] X. Yang,*[2] R. J. S. Galvin,[2] S. Chandrasekhar,[2] T. J. Martin,[3] J. E. Onyia.*[2] [1]Elanco Animal Health, Eli Lilly and Company, Greenfield, IN, USA, [2]Gene Regulation, Bone and Inflammation Research, Eli Lilly and Company, Indianapolis, IN, USA, [3]St. Vincent's Institute for Medical Research, Fitzroy, Victoria, Australia.

Transforming growth factor-β (TGF-β) regulates osteoclastogenesis and osteoclast survival, in part through the induction of osteoprotegerin (OPG), a protein known to inhibit osteoclast formation and function. To explore the molecular basis of TGF-β regulation of OPG expression, we evaluated the effects of TGF-β on osteoclast formation, OPG protein secretion, mRNA expression and gene transcription. The marked inhibitory effect of TGF-β on osteoclast differentiation was confirmed in a co-culture model utilizing murine stromal/osteoblastic BALC cells and bone marrow hematopoietic precursors. This inhibition in osteoclast differentiation was preceded by a decrease in RANKL mRNA expression (5-fold) and a reciprocal increase in OPG mRNA (6.1-fold) and protein (7.1-fold) expression in BALC cells. At the promoter/transcriptional level, TGF-β treatment resulted in a 3- to 10-fold increase in reporter gene activity directed by a 5.9-kb fragment of the human OPG promoter in transfection assays performed in UMR106 cells. The effect of TGF-β was mimicked by TGF-β2 and -β3, but not BMP-4, suggesting a TGF-β signal-specific effect. Deletion analysis revealed that a 183-bp region (-372 to -190) in the promoter was required for TGF-β responsiveness, and this region was sufficient to confer TGF-β inducibility to a heterologous (osteocalcin) minimal promoter. Substitution mutations that disrupted the Cbfa1- and/or Smad- binding elements present in the 183-bp region resulted in a decrease in baseline expression and in the responsiveness to TGF-β and Cbfa1. Collectively, these studies indicate the involvement and possible interaction of Cbfa1 and Smad proteins in mediating the effects of TGF-β on OPG transcription.

YKL-40 Gene Expression Is Inhibited by Cyclosporin A in Human Osteoblast-Like Cell Line MG63

E. Musacchio,* C. Valvason,* A. Pozzuoli,* G. Priante,* L. Punzi,* F. S. Netto,* L. Sartori. Department of Medical and Surgical Sciences, University of Padova, Padova, Italy.

YKL-40, also known as HC gp-39, is a human glycoprotein related in aminoacid sequence to the chitinase family, but shows no chitinase activity. It is a major secretory protein of human cartilage mainly produced, in vitro and in vivo, by chondrocytes and synoviocytes. It is also actively secreted in vitro by the osteoblast-like cell line MG63. YKL-40 mRNA is undetectable in normal human cartilage, but it is prominent in patients with rheumatoid arthritis (RA) and appears to play a role in cartilage remodelling perhaps as a glycosidic bond hydrolase with polysaccaride specificity. It has been identified as a target of the immune response in RA, while its circulating levels have been suggested to be used as a marker of inflammatory stage in several rheumatic disorders. The very effective immunosuppressant cyclosporin A (CyA) is widely used in the treatment of rheumatic diseases, yet nothing is known about its effect on YKL-40 release in patients. We have previously reported that CyA has several direct effects on osteoblast activity both at the phenotyipical and molecular level. The aim of the present study was to investigate the effect of CyA on YKL-40 gene expression in the human osteoblast-like cell line MG63 treated with CyA 0.1, 1.0, 2.5 and 5.0 ug/ml for either 48 or 96 hours. After treatments, total RNA was extracted, and gene expression was determined using the comparative semi-quantitative RT-PCR approach, glyceraldehyde-3P-dehydrogenase being the housekeeping gene. Our results indicate that CyA induces a marked down-regulation of YKL-40 gene expression in this cell line. The response was maximum after 96 hrs of treatment being 60% less than controls when the highest CyA dose (5 ug/ml) was used and showed a dose-dependent decreasing pattern, with a 25% down-regulation achieved already with CyA 0.1 ug/ml. The same trend was observed after 48 hrs with a decrease ranging from 20% (CyA 0.1 ug/ml) to almost 50% (CyA 5 ug/ml).To our knowledge, these results represent the first report of YKL-40 expression modulation in vitro by a pharmacological agent and may contribute to a better understanding of the role of this protein in rheumatic diseases.

Synergistic Induction of Transcriptional Activity of the cAMP Response Element Binding Protein by Parathyroid Hormone and Epidermal Growth Factor in Osteoblastic Cells. J. T. Swarthout,[*1] D. R. Tyson,[*2] S. C. Jefcoat,Jr.,[*1] N. C. Partridge.[1] [1]UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, United States, [2]University of California, Irvine, CA, United States.

We have previously shown that transactivation of the cAMP response element binding protein (CREB) by parathyroid hormone (PTH) requires both serine 129 (S129) and serine 133 (S133) in UMR 106-01 cells. Furthermore, while PKA is responsible for phosphorylation at S133, glycogen synthase kinase-3 (GSK-3) activity is also required and may be responsible for phosphorylation of CREB at S129. The AP-1 member c-fos has been implicated in the mitogenesis and/or differentiation of osteoblasts in the skeletal system, and CREB is a major activator of c-fos transcription. It is known that both epidermal growth factor (EGF) and PTH activate c-fos transcription in addition to phosphorylating CREB. The ability of EGF to stimulate CREB and the requirement for both S129 and S133 in the transactivation of CREB by EGF in osteoblastic cells is unknown. Here we show, using the GAL4-CREB reporter system, that EGF can transactivate CREB in UMR 106-01 cells in addition to PTH's effects. Furthermore, using mutational analysis we demonstrate that S129 and S133 are required for EGF-induced transcriptional activity of CREB. Furthermore, EGF activates both p38 and ERKs in UMR 106-01 cells and pre-treatment with either the p38 inhibitor (SB203580) or the MEK inhibitor (PD98059), respectively, prevented activation of p38 and ERKs by EGF. These agents also inhibit phosphorylation of CREB at S133 and transactivation of CREB by EGF, but not by PTH. In addition, treatment of UMR 106-01 cells with both PTH and EGF results in a greater phosphorylation of CREB at S133 than that seen with either PTH or EGF alone, and the synergistic transactivation of CREB. The latter effect is significantly reduced following pre-treatment with a PKA inhibitor (H-89) or by co-treatment with SB203580 and PD98059. Therefore, transactivation of CREB by EGF occurs following activation of p38 and ERKs, and requires both S129 and S133. Furthermore, co-treatment with both PTH and EGF results in the synergistic transactivation of CREB. This work emphasizes the different pathways that these two agents signal through and their possible synergistic effects in vivo on common endpoints.

Glucocorticoid Treatment Inhibits Gene Expression of Heparin Binding Growth Associated Molecule (HB-GAM) in Mouse Primary Osteoblasts. M. Lorentzon,[*1] C. Ohlsson,[*1] A. Bäckman,[*1] R. Lorentzon,[1] U. H. Lerner.[2] [1]Department of Surgical and Perioperative Sciences, Sports Medicine Unit, Umeå University, Sweden, [2]Department of Oral Cell Biology, Umeå University, Sweden.

Glucocorticoids are known to have deleterious effects on the skeleton. Suggested pathogenetic mechanisms include stimulation of bone resorption due to increased osteoclastogenesis and inhibition of osteoblastic bone formation. The molecular mechanisms, however, are poorly understood. Since the key cell in bone metabolism is the osteoblasts we have studied the effect of glucocorticoids on gene expression in mouse calvarial osteoblasts using cDNA expression arrays (Clontech, Paulo Alto, CA, USA) containing a total of 2352 cDNAs. Primary mouse osteoblasts were isolated from calvarial bones from 2 to 3 days old CSA mice, cultured in a-MEM containing 10% fetal calf serum, with or without dexamethasone (10-7 M). Cells were harvested, after 20 hrs, 40 hrs, and 16 days, and RNA was subsequently isolated. 32P -labelled first-strand cDNA probes were synthesized using Superscript II (Life Technologies, USA), hybridized to Atlas Array Mouse 1.2 and Mouse 1.2II (Clontech), and scanned on a Storm 860 PhophoImager (General Dynamics). Image analysis was performed using Atlas Array v1.5 software (Clontech). Heparin binding growth associated molecule (HB-GAM) gene expression was lower at 20 hrs (ratio 0.24), 40 hrs (ratio 0.26-0.36), and at 16 days (ratio 0.16) in cell cultures treated with dexamethasone (10-7 M), compared to controls. A reverse transcription (RT)- polymerase chain reacion (PCR) was chosen to, semi-quantitatively, verify the observed downregulation of HB-GAM gene expression at 40hrs. RNA from dexamethasone treated osteoblasts showed less intense RT-PCR fragments (ethidium bromide stained) for HB-GAM for all tested number of PCR cycles (28-36), while no differences could be detected for GAPDH (used as an internal control) RT-PCR fragments. Mineralization of bone nodules in 16-day-old cultures was significantly inhibited by dexamethasone demonstrating the inhibitory effect of glucocorticoids on in vitro bone formation. HB-GAM is an extracellular matrix-associated protein, believed to play an important role in osteoblast recruitment and attachment, processes necessary for bone formation. Most interestingly, transgenic mice overexpressing HB-GAM develop increased bone thickness [Imai, S. et al, J Cell Biol, 43: 1113-1128, 1998].The downregulation of HB-GAM gene expression following dexamethasone treatment suggests a role for HB-GAM in glucocorticoid-induced bone loss.

Thrombin Peptide TP508 Regulates BMP-2 and -7 Expression By Human Osteoblasts. L. X. Bi,* Y. Ji,* R. S. Crowther,* E. Mainous,* W. L. Buford.* The University of Texas Medical Branch, Galveston, TX, USA.

Previous studies have shown that osteoblastic cells express a non-proteolytically activated receptor (NPAR) that can be activated by a synthetic thrombin peptide (TP508). To investigate potential effects of TP508 on human osteoblasts, we examined expression of BMP-2 and -7, alkaline phosphatase activity (ALP) after treatment of cells with TP508. Human osteoblasts, obtained from Clonetics, Inc, San Diego, CA, were cultured in mineralizing-growth medium and treated with TP508 [10^{-6}M] for 3, 5, 7 days, respectively. The level of ALP and cell proliferation were assayed using a commercial kit (ALP and MTT, Sigma Chemical Co., St. Luis, MO). ALP activity was expressed on the basis of cell numbers. Expressions of BMP-2 (anti-rhBMP-2 monoclonal antibody, Genetics Institute, Cambridge, MA) and –7 (polyclonal antibody, Santa Cruz Biotechnology, Inc. CA) were examined using western blot analysis. The relative densities of different bands were quantified by Scion Image densitometry and normalized to a-tubulin. ALP activities were elevated (22-80%, $P<0.05$) within the first 5 days of culture by TP-508, compared to control group. BMP-7 expression was significantly increased at day 3 (68%, $P<0.05$) and day 5 (132%, $P<0.01$) after TP-508 treatment compared to control. There was increase in the level of BMP-2 protein (83%, $P<0.05$) within the first 3 days of culture, above the baseline. We conclude that thrombin peptide, TP-508, increases the expression of osteoblastic markers which play an important role in fracture healing in early stage. It may trigger the cascade of bone repair in vitro after fracture.

Microarray Analysis of Early Gene Expression Profile in Primary Human Osteoblast Cells Treated with Connective Tissue Growth Factor-Like Protein. C. R. Hanning,[*1] S. C. Tice,[*1] S. Ghosh,[*2] B. J. Votta,[1] M. W. Lark,[1] M. Gowen,[1] S. Kumar.[1] [1]Musculoskeletal Diseases, GlaxoSmithKline, King of Prussia, PA, USA, [2]Transcriptome Analysis Group, GSK, King of Prussia, PA, USA.

Connective Tissue Growth Factor-Like protein (CTGF-L) belongs to the CCN family of growth factors and has been shown to bind IGFs, promote adhesion of osteoblasts, and inhibit osteocalcin production. CTGF-L is expressed at high levels in primary osteoblasts and bone. We have examined the expression of CTGF-L during in vitro mineralization of primary osteoblasts. The expression of CTGF-L mRNA correlated with the expression of type I collagen and mineralization. CTGF-L mRNA was induced at day 14 and remained elevated up to day 28 when the mineralization was at maximum. We engineered a stable TF274 cell line expressing CTGF-L protein and examined their mineralization potential. TF274 cells expressing CTGF-L mineralized faster by day 9 compared to the wild type. These data suggest that CTGF-L protein is involved in mineralization of osteoblast cells. In order to understand the role of CTGF-L in osteoblast differentiation, we have utilized microarray technique to evaluate the effect of recombinant hCTGF-L on the expression of ~900 genes. Primary osteoblasts were treated with CTGF-L for 24 and 72 hours, total RNA was isolated, and microarray analysis was performed using 32P labeled cDNA probes. Two different blots were used; the first was a commercially available human Atlas Array with 588 genes. The second was a custom blot containing 277 genes known to play a role in bone and cartilage metabolism. Data was analyzed using Clontech's Atlas Image and other statistical and clustering software. Using criteria of a minimum 1.5-fold change in expression, we identified 54 (~9%) and 30 (~11%) genes on Atlas and custom blots, respectively, that were up or down regulated. Some of the genes with significant differential expression were BRCA2, MUC18 glycoprotein, glutaredoxin, APC, prothymosin alpha, cyclin D1, transferrin receptor, colon carcinoma kinase-4, integrin linked kinase, Prostaglandin G/H synthetase precursor, Cyr61 protein, Apolipoprotein E precursor, Hc-GP39 precursor, Interleukin 6, EGR-1, and Tumor necrosis factor receptor 1. The expression patterns of genes represented on the custom blot were further analyzed by a non-supervised clustering technique known as self-organizing maps (SOM). Eleven distinct patterns of expression were identified by SOM analysis with a dominant cluster (63 genes) representing genes with reduced expression at 24 and 72 hours post CTGF-L treatment. These results illustrate the utility of microarray technology to identify genes involved in the osteoblast differentiation process.

Osteoblastic Expression of the Rat Osteocalcin-EGFP Transgene in Mice and ex vivo. T. A. Owen,[1] S. L. Smock,[*1] C. Banerjee,[*2] K. S. Harrington,[*2] B. Lu,[*1] T. A. Castleberry,[1] L. C. Pan,[1] S. C. Marks,[2] A. J. van Wijnen,[2] J. L.

Stein,*[2] J. B. Lian,[2] G. S. Stein.[2] [1]Cardiovascular and Metabolic Diseases, Pfizer Global Research & Development, Groton, CT, USA, [2]Cell Biology, University of Massachusetts Medical School, Worcester, MA, USA.

Mice expressing a reporter gene that reflects the growth, differentiation and metabolic activity of osteoblasts would facilitate studies on bone anabolism. To provide a sensitive in situ marker of bone formation and examine osteoblast responses to physiologic mediators of bone formation in longitudinal studies, we fused the DNA sequence encoding enhanced green fluorescent protein (EGFP) to the 1775 bp proximal portion of the rat osteocalcin (OC) gene promoter to construct the OC-EGFP transgene. Transgenic mice were produced on the FVB background and weanlings were phenotyped by observation of EGFP expression in tail snips by fluorescence microscopy. Expression of EGFP was then analyzed in cryosections of calvaria, tibia, femur, lumbar spine, kidney and liver. We found that at 28 days of age, expression of EGFP as observed by fluorescence microscopy, was strong in cells lining both the periosteal and endosteal surfaces of the long bones and calvarium, as well as lining the trabeculae, especially in the lumbar spine. These cells were distinguished as osteoblasts based on morphology and on localization within the bone. Weaker staining was evident in osteocytes. No EGFP was observed in either kidney or liver of the transgenics and no EGFP was observed in any tissue from non-transgenic littermates. Bone marrow cultures initiated from 9 week old mice, as well as calvarial cell cultures initiated from newborn pups, formed bone-like nodules after approximately 14 days and expression of EGFP was observed in the cells on the nodules and in cells immediately surrounding the nodules. Temporally, the expression of EGFP correlated with the appearance of the nodules and, on the RNA level, EGFP was correlated with the onset of osteocalcin expression. Taken together, these data show that we have marked active osteoblasts in transgenic mice with EGFP, a marker that can be easily followed both in tissue sections and during longitudinal studies of differentiation in cell culture.

Smad3 Promotes ALP Activity and Mineralization of Osteoblastic MC3T3-E1 Cells: Involvement of Type I Collagen, Osteocalcin and p38 MAP Kinase. H. Sowa,* H. Kaji, T. Yamaguchi, T. Sugimoto, K. Chihara.* The third division, Department of Medicine, Kobe University School of Medicine, Kobe, Japan.

TGF-β, abundantly stored in bone matrix, appears to regulate bone metabolism in various ways, including skeletal development and bone remodeling. Although the diverse effects of TGF-β on osteoblasts have been reported, the local administration of TGF-β stimulates bone formation in vivo. On the other hand, the Smad family proteins are critical components of the TGF-β signaling pathways but the role of Smad3 in the expression of osteoblastic phenotype remains unknown. The present study was performed to clarify the role of Smad3 in the proliferation, expression of bone matrix protein and mineralization by employing stably Smad3-transfected mouse osteoblastic MC3T3-E1 cells. Smad3 stable transfection significantly inhibited [^{3}H]-thymidine incorporation and MTT-dye assay, compared to empty vector-transfection(control). Moreover, Smad3 significantly inhibited the level of osteocalcin mRNA, compared to control in Northern-blotting. Smad3 increased the level of type I procollagen, osteopontin, and matrix Gla protein mRNA, compared to control. TGF-β mimicked the effects of Smad3 on osteoblast prolifearation and the expression of bone matrix proteins in wild-type MC3T3-E1 cells. On the other hand, Smad3 greatly enhanced ALP activity (biochemical ALP asssay and ALP staining) and mineralization (Von Kossa and Alizarin Red-S staining) of MC3T3-E1 cells, compared to control, although TGF-β inhibited ALP activity and mineralization of wild-type MC3T3-E1 cells. Smad3δC, MH2 region-deleted Smad3 construct, stable transfection did not affect these phenotypes of MC3T3-E1 cells. Type I collagen synthesis inhibitor, L-azetidine-2-carboxylic acid, as well as osteocalcin and a p38 MAP kinase specific inhibitor, SB203580, significantly antagonized Smad3-stimulated ALP activity and mineralization in MC3T3-E1 cells. In summary, Smad3 inhibited proliferation and altered the level of bone matrix proteins in the manner similar to TGF-β. On the other hand, Smad3 enhanced ALP activity and mineralization through the synthesis of type I collagen, the reduction of osteocalcin, as well as p38 MAP kinase. We propose that Smad3 plays an important role in osteoblastic bone mineralization, and Smad3 may provide a beneficial clue for the investigation of transcriptional mechanism of bone formation and the development of bone-forming drugs.

Continuous Inhibition of MAPK Signaling Promotes Osteogenesis in Mesenchymal Cells. C. Higuchi,*[1] N. Hashimoto,*[1] A. Myoi,[1] K. Itoh,[2] H. Yoshikawa.[1] [1]Orthopaedic Surgery, Osaka University Medical School, Suita, Japan, [2]Biology, Osaka Medical Center for Cancer and Cardiovascular diseases, Osaka, Japan.

We screened the small molecule compounds which induce bone formation by themselves or promote bone morphogenetic proteins (BMPs)-induced osteogenesis. Final goal of our study will be clinical application of them. We found that a specific inhibitor for MAPK/ ERK kinase 1 (MEK1), PD98059 promoted the osteoblastic differentiation in C2C12 myoblastic cells treated with recombinant human BMP-2 (rhBMP-2). It also promoted the differentiation of MC3T3-E1 osteoblastic cells in the absence or presence of rhBMP-2. Alkaline phosphatase (ALP) activity was synergistically increased by the treatment with 25 to 100 microM PD98059 in C2C12 cells stimulated by 300 ng/ml rhBMP-2 in a dose-dependent fashion and it was also increased in MC3T3-E1 cells in the absence or presence of 50 ng/ml rhBMP-2. PD98059 reduced osteocalcin production of C2C12 cells stimulated with 300 ng/ml rhBMP-2, but increased osteocalcin secretion from MC3T3-E1 cells into the culture media. Twenty-five microM PD98059 also promoted mineralization of extracellular matrix in both C2C12 cells stimulated by 300 ng/ml rhBMP-2 and MC3T3-E1 cells. We also confirmed these biological phenomenon by introducing mutant MEK1 cDNA into C2C12 cells. C2C12 cells stably expressing constitutively-active MEK1 showed little ALP activity and osteocalcin production. In contrast, dominant-negative MEK1 transfectants represented higher ALP activity and lower osteocalcin production in the presence of rhBMP-2 than a mock transfectant did. These results were consistent with those of parent C2C12 cells treated with MEK1 inhibitor.Our results indicate that BMP-2-induced meneralization of mesenchymal cells and osteoblastic cells could be regulated by a fine tuning of MAPK signaling pathway and that MEK1 inhibitors would be useful in vivo for promotion of bone formation, for instance, fracture healing.

Potential Role of PPAR-γ in the Inhibition of Human Osteoblastic Cell Proliferation by Polyunsaturated Fatty Acids. A. C. Maurin,* P. M. Chavassieux, P. J. Meunier. INSERM Unit 403, Faculty R.T.H. Laennec, Lyon, France.

We have previously shown that the inhibitory effect induced by adipocytes on the proliferation of primary human osteoblastic cells derived from bone explants (hOB cells) may be mediated by polyunsaturated fatty acids (PUFAs) released by mature adipocytes. PUFAs have been reported to activate peroxisome proliferator-activated receptors (PPARs), specially PPAR-γ which has been implicated in cellular proliferation and differentiation. The purpose of the present study was to determine the role of PPAR-γ in the PUFA-induced inhibition of hOB cell proliferation. A PPAR-γ specific ligand 15-deoxy-prostaglandin J2 (15d-PGJ2) at a dose of 10 μM significantly decreased the hOB cell proliferation (- 50 %, $p < 0.01$). The inhibitory effects of 30 μM of docosahexaenoic and arachidonic acids were confirmed (- 27 and - 42 %, respectively). These effects were not related to cell apoptosis as shown by Hoechst dye staining. Immunofluorescence and western blot analysis showed the presence of PPAR-γ protein in the hOB cell nucleus. Besides the effect on cell proliferation, long-term (3 weeks) exposure of hOB cell cultures to PUFAs or 15d-PGJ2 induced morphological changes with the development of lipidic vacuoles in the presence of horse serum. Moreover, western blot experiments indicated an increase in PPAR-γ protein expression with PUFAs or 15d-PGJ2 treatment, markedly enhanced in the presence of horse serum, in hOB cells as in the 3T3-L1 preadipocytic cell line. In conclusion, as fatty acids, PPAR-γ specific ligands inhibited the proliferation of hOB cells, activated the expression of PPAR-γ in these cells, and also induced an adipocyte-like phenotype. These *in vitro* observations showed that fatty acids and their metabolites favor the commitment of bone-derived cells to the adipocyte pathway. These results raise the hypothesis that adipocyte-released compounds may initiate a switch between the osteoblast and adipocyte lineages. This mechanism may contribute to the age-related bone loss.

Cortisol Enhances the Expression of Notch 1 in Osteoblasts and Stromal Cells. R. M. R. Pereira,*[1] A. M. Delany,[2] E. Canalis.[2] [1]Saint Francis Hospital and Medical Center, Hartford, CT, USA, [2]Saint Francis Hospital and Medical Center and The University of Connecticut School of Medicine, Hartford, CT, USA.

Notch 1, 2, 3 and 4 are a family of closely related transmembrane receptors that mediate signaling mechanisms controlling cell fate decisions. Notch 1 is expressed by skeletal cells, but information about regulation and function of Notch receptors in osteoblasts is limited. Overexpression of Notch 1 in osteoblasts appears to decrease cell differentiation and functional markers of the osteoblast, such as type I collagen and Cbfa-1. These effects are similar to the reported inhibitory actions of cortisol on osteoblastic differentiation and function. Consequently, we postulated that cortisol might regulate Notch expression in cells of the osteoblastic lineage. Murine osteoblastic MC3T3 cells and primary bone marrow stromal cells were grown to confluence and then cultured in medium enriched with ascorbic acid and 5 mM beta glycerolphosphate in the presence or absence of cortisol at 1 μM for periods of 24 h to 4 weeks following confluence. Both MC3T3 and stromal cells expressed Notch 1, 2, 3 and 4 transcripts. Cortisol increased the expression of Notch 1 mRNA by 2 to 4 fold in MC3T3 and stromal cells, as determined by Northern blot analysis and densitometry. The effect was detected 24 h after exposure to cortisol, and it was sustained for 4 weeks, both in MC3T3 and stromal cells. In MC3T3 cells, the stimulatory effect on Notch 1 mRNA was observed with a cortisol dose as low as 10 nM. Cortisol also caused a modest increase in Notch 2 gene expression, but did not regulate Notch 3 or 4 mRNA levels. Supporting the inhibitory role of Notch 1 and cortisol on osteoblastic cell differentiation, bone morphogenetic protein 2, an inducer of this process, had an opposite effect to that of cortisol and suppressed Notch 1 expression. In conclusion, cortisol up-regulates Notch 1 and 2 expression in cells of the osteoblastic lineage, an effect that could mediate the inhibitory actions of cortisol on osteoblastic cell differentiation.

Coactivation of FAK After Hormone- and Growth Factor-Treatment in Osteoblastic Cells. A. Schroeder,* G. Delling,* E. A. Kaiser. Dept. Bone Pathology / Center for Biomechanics, University Hospital Hamburg-Eppendorf, Hamburg, Germany.

Aims: Physiological processes of osteoblastic cells, e.g. proliferation, differentiation or migration, are influenced by a wide spectrum of extracellular stimuli such as matrix proteins, growth factors and hormones. Their cognate receptors, i.e. integrins, receptor protein kinases or G-protein coupled receptors are linked to a variety of signal tranduction pathways that influence gene expression to allow the cells to react to changes in their extracellular milieu. Little is known about the signal transduction of PDGF and PTH in osteoblastic cells via the non-receptor protein-tyrosine kinase FAK. We observed an increase in FAK phosphorylation following stimulation of metaphyseal and diaphyseal derived marrow stromal cells with PDGF or PTH. Therefore we examined the pathways leading from the receptors to FAK using specific inhibitors to selected signal transduction molecules as, e.g. PI3K, PKC and PKA. Methods: Metaphyseal and diaphyseal marrow cells were isolated from 4 week old male Spraque Dawley rats; only cells of the first passage were used for the experiments. Cells were preincubated with the selected inhibitors for 30 min, then incubation with PTH or PDGF followed for 30, 60 or 90 min. Cells were lysed and lysates were subjected to western blot analysis with antibodies against FAK protein and FAK-autophosphorylation site. Results: PTH-stimulated diaphyseal marrow cells show a slight increase in FAK-autophosphorylation. This effect can be reduced by preincubation of the cells with H-89, a specific inhibitor of PKA. Preincubation with the PKC-inhibitor Calphostin C does not abolish the phosphorylation signal. PDGF-stimulation of metaphyseal marrow cells also leads to a FAK-autophosphorylation increase. This effect could be reversed by preincubation with LY294002, a specific inhibitor of phosphatidyl-inositol-3-kinase (PI3K). In this experiment preincubation with Calphostin C was again unable to decrease the activation of FAK after PDGF-incubation. Discussion: These results lead to the suggestion, that the signals following PTH stimulation in diaphyseal marrow cells are transduced by a PKA-dependent pathway. PDGF stimulation of metaphyseal marrow cells seems to activate a PI3K involving pathway.

SA218

Ionic Changes in Parathyroid-Stimulated Osteoblasts: Evidence for G-protein Activation. A. Chatoo,*[1] F. Arrebola,*[2] F. McDonald,[2] A. Warley.*[2] [1]GKT Schools of Medicine and Dentistry, LONDON, United Kingdom, [2]GKT School, London, United Kingdom.

Osteoblasts have well characterised receptors for parathyroid hormone (PTH); this ligand acts by heterotrimeric G protein activation. Its precise actions on osteoblasts are unclear although previous experiments suggest that PTH causes an increase in cell volume in osteoblasts. The current series of experiments were designed to further clarify the ionic component of the signalling pathway. Transformed human osteoblasts, derived from an osteogenic sarcoma cell line (Saos-2), were cultured in alpha modification Dulbecco's Modified Eagle's medium (DMEM), with 10% heat inactivated foetal calf serum, 100 U/ml penicillin, 10 µg/ml streptomycin, 2.5 µg/ml amphotericin B and 4 mM L-glutamine at 37°C in a humidified atmosphere with 5% carbon dioxide. Cells (2 x 10^4/ml)were seeded on to Pioloform covered gold electron microscopy grids contained in a 4-well tissue culture plate. Six hours prior to stimulation the culture medium was removed and replaced with DMEM containing 250 ng/ml cholera toxin (CTX). After incubation the cells were exposed to 2.5 µM PTH for 0, 5, 15, 30 and 60 seconds. They were then washed in ice-cold distilled water for 10 seconds; excess water was removed by blotting, and the cells cryofixed by immersion in liquid nitrogen (-210°C). The cells were freeze dried and coated with carbon. Areas of cytoplasm and nucleus (1x 2.5µm) were analysed for 60 seconds live time using a Zeiss electron microscope with a Link AN 10 000 microanalysis system. Cells (n=30) cultured in PTH showed a generalised decrease in the concentration of Cl^- and an increase in K^+/Na^+ ratio within the cytoplasm after 30 secs, which recovered towards control values by 60 secs (Table 1). In cells cultured with PTH + CTX concentrations of Cl- remained low, whilst K^+/Na^+ ratio was high after 30 secs and remained at this level (Table 1). Concentrations of Mg^{2+} were inconsistent but generally reduced and remained at a lower level.Table 1. Concentrations (mmol/kg dry weight; mean ± SEM; PTH; PTH + CTX) of Na^+ and K^+ in Saos-2 cells after stimulation with PTH or PTH + CTX

Time (s)/Ion	Mg^{2+}	Cl^-	K^+/Na^+
0	33.3 ± 1.3; 41.2 ± 2.6	93.8 ± 6.3; 84.7 ± 3.2	19.5 ± 0.7; 13.3 ± 0.4
30	12.6 ± 1.2; 24.6 ± 1.9	81.2 ± 4.3; 67.9 ± 5.2	21.9 ± 1.1; 24.1 ± 1.6
60	20.3 ± 1.6; 24.5 ± 1.6	99.4 ± 4.9; 68.7 ± 4.4	12.8 ± 0.6; 21.7 ± 1.1

Ionic changes of Cl- and K^+/Na^+ ratios induced by PTH appear to be linked to G-protein activation and can be modified by CTX.

Growth Factor Stimulation of Human Osteoprogenitor Proliferation Requires Activation of p70 S6 Kinase and Akt. L. R. Chaudhary, K. A. Hruska. Renal Division, Washington University School of Medicine, St. Louis, MO, USA.

The growth factors PDGF-BB and FGF-2 regulate the recruitment of osteoprogenitor cells, their proliferation and differentiation into mature osteoblasts, and play important roles in bone remodeling. We have shown PDGF to be a more potent stimulator of normal human osteoblastic (HOB) cell proliferation than FGF-2. However, the molecular mechanisms by which these growth factors differentially regulate osteoblast growth, bone formation and their signaling pathways have not been defined. We have demonstrated that while both growth factors activate ERK1/2, PDGF-BB but not FGF-2 stimulates PI 3-kinase and the cell survival signal, protein kinase B (PKB/Akt). These results demonstrate differential signal transduction by the two growth factors. Here, we analyze the importance of PI 3-kinase in the activation of p70 S6 kinase (p70S6K) responsible for stimulation of phosphorylation of S6 ribosomal protein, protein synthesis and cell proliferation. Quiescent HOB cells were treated with PDGF-BB (30 ng/ml) or FGF-2 (30 ng/ml). Cell lysates were subjected to SDS-PAGE, and activation of p70S6K was assayed by immunoblotting with two different anti-phospho-p70S6K antibodies that specifically recognize phosphorylation at Thr389 or Thr421/Ser424. Our results demonstrated that PDGF-BB treatment of HOB cells increased phosphorylation of p70S6K at both Thr389 and Thr421/Ser424 in a time-dependent manner, while FGF-2 failed to stimulate phosphorylation of p70S6K. The phosphorylation of Thr389 was mediated via PI 3-K and the mammalian target of rapamycin (mTOR) and was sensitive to the PI 3-K inhibitor, wortmannin or the mTOR inhibitor, rapamycin. The activation of p70S6K requires activation of both ERK1/2 and PI 3-K/PDK1/2. FGF-2 activated ERK1/2 but did not activate PI 3-K and p70S6K in HOB cells. Our results demonstrate for the first time differential activation of p70S6K by PDGF-BB and FGF-2. These results are of critical importance in understanding the mechanisms of PDGF and FGF-2 action in translational control of protein synthesis. PDGF-BB but not FGF-2 may be involved in the up-regulation of osteoblast protein synthesis by stimulating p70S6K. Taken together, our data demonstrate that the activation of Akt and p70S6K by PDGF-BB but not by FGF-2 contributes to increased proliferation of cells in the osteoblast lineage by PDGF-BB.

T Cell Induction of MMP-13 in Human Osteoblasts is Dually Regulated by p38 and ERK1/2 MAP Kinases. L. Rifas, S. Arackal.* Division of Bone & Mineral Diseases, Washington University School of Medicine & Barnes-Jewish Hospital, St. Louis, MO, USA.

T cells play a major role in the connective tissue degradation that occurs in chronic inflammatory diseases such as rheumatoid arthritis. We hypothesized that MMP-13 is induced in hOB by T cells and is regulated by MAP kinases. We have demonstrated that T cells induce the expression of MMP-13 in normal human osteoblasts (hOB). Using neutralizing antibodies and ELISA assays we have excluded TNF-alpha and IL-6 as mediators of MMP-13 production. To explore the mechanism of MMP-13 regulation by MAP kinases, hOB were treated with either the ERK 1/2 specific inhibitor PD98059 or the p38 specific inhibitor, SB203580, over a dose range of 0.1-40 µM. PD98059 induced, while SB203580 inhibited, MMP-13 in a dose dependent fashion demonstrating that p38 stimulates and ERK 1/2 inhibits MMP-13 expression. To further detail the MAP kinase signaling pathways regulating MMP-13 induction in hOB by activated T cell conditioned medium (ATCM), we examined the phosphorylation state of ERK 1/2 and p38 in the presence or in the absence of ATCM over a 16-72 hr period. Specific antibodies recognizing the phosphorylated forms of ERK 1/2, p38 and JNK were used in Western blots of whole cell extracts from untreated and ATCM treated hOB. ATCM slightly activated p38 and ERK 1/2 at 24 hours, an effect that lasted up to 72 hours. Interestingly, treatment with PD98059 did not inhibit phospho-ERK demonstrating that ERK is activated in resting, unstimulated osteoblasts and may play a role in maintaining the differentiated state. Although SB203580 dramatically inhibited MMP-13 production, it surprisingly increased phosphorylation of p38 while not affecting its protein level over the time course examined. Phosphorylated ERK 1/2 was also increased in the presence of SB203580 as well, but not ERK 1/2 protein. JNK protein was unchanged throughout the time course while phospho-JNK was not detected which indicates that this pathway does not play a role in MMP-13 regulation in hOB. Our data demonstrate that SB203580 inhibits the activity, but not the activation of p38 in human osteoblasts. Furthermore, SB203580 induces the activation of ERK 1/2. This process occurs through the activation of Ras and Raf-1, the upstream regulators of ERK1/2 activation. Thus, a crossover between the p38 and ERK1/2 pathways results in an increase in ERK1/2 and an inhibition of p38 activity, suggesting that this is the mechanism of inhibition of MMP-13 by SB203580. Our data show that MMP-13 is regulated by both the ERK pathway and the p38 pathway in response to T cell cytokines. Selective inhibition of p38 activity may offer a target for phamacological inhibition of bone loss in rheumatoid arthritis.

Effects of Risedronate, Alendronate and Etidronate on Viability and Activity of Rat Stromal Cells in vitro. K. Still,*[1] R. J. Phipps,[2] A. Scutt.*[1] [1]Children's Hospital, Sheffield, United Kingdom, [2]Procter & Gamble Pharmaceuticals, Mason, OH, USA.

The effects of bisphosphonates (BP) on osteoclasts (OC) have been studied extensively, and current evidence shows that BP suppress bone resorption by directly inhibiting OC activity. This BP-mediated inhibition of OC activity is achieved by (i) inhibition of OC differentiation from haematopoietic precursors, (ii) inhibition of activity of mature OC, (iii) stimulation of release of an osteoblast-derived OC inhibitory factor and/or (iv) by induction of OC apoptosis. In contrast, effects of BPs on osteoblasts have received less attention. It has recently been suggested that BPs may possess some mild anabolic activity that contributes to their efficacy in treating osteoporosis. This is based on the finding that long-term treatment with BPs increases wall thickness, which is considered to indicate a localised increase in osteoblastic activity. Consistent with this is the finding that BPs can prevent induction of apoptosis in murine osteoblasts and osteocytes, and can stimulate fibroblastic-colony formation by murine and human bone marrow. The purpose of this study was to investigate the effects of risedronate, alendronate and etidronate in two models of bone formation in rat stromal cells *in vitro*; high-density bone marrow cultures, and calcifying fibroblastic colony forming unit (CFU-f) cultures. Biphasic effects on bone formation were observed. In CFU-f cultures, high concentrations (10^{-5} to 10^{-4}M) of alendronate and risedronate inhibited colony formation and cell activity whereas etidronate had relatively little effect. At lower concentrations (10^{-9} to 10^{-7}M) all three drugs increased colony numbers suggesting a mild anabolic effect. These results were not entirely paralleled in the high-density cultures where all three drugs inhibited colony numbers and cell activity. Etidronate, however, was considerably less potent than the other two drugs. The inhibitory effects of alendronate and risedronate could be partially reversed by addition of geranylgeraniolpyrophosphate suggesting a similar mechanism to BP-induced apoptosis in OC. In contrast, the anabolic effects of alendronate and risedronate were augmented by co-incubation with geranylgeraniolpyrophosphate. Indeed, geranylgeraniolpyrophosphate, geranylgeraniol and farnesol all stimulated colony formation. These data suggest that high doses of BP can induce cell death in bone marrow-derived osteoprogenitor cells, by a mechanism similar to that seen in OC. However, at lower doses a mild anabolic activity is present which is not obviously mediated via inhibition of the cholesterol biosynthetic pathway.

Investigation into the Plasticity of Adult Human Mesenchymal Stem Cells. S. Ioannidou,*[1] K. Seehra,*[1] P. Wood,*[2] W. Staley,*[1] R. J. Byers,*[1] J. A. Hoyland,[1] A. J. Freemont.*[1] [1]Musculoskeletal Research Group, University of Manchester, Manchester, United Kingdom, [2]Department of Immunology, University of Manchester, Manchester, United Kingdom.

Osteoblasts and adipocytes are derived from the same stem cell (osteoprogenitor) in adult marrow and plasticity exists between the two lineages. However, the stage of adipocytic differentiation at which plasticity is lost and commitment is established is not known. Adult human mesenchymal stem cells (HMSCs) were investigated for the expression of STRO-1, a marker of osteoprogenitors, by fluorescence activated cell sorting. They were cultured in adipogenic medium (AM), osteogenic medium (OM) or mineralising medium (MM). After 2 weeks, morphology and histochemical staining for oil red O, alkaline phosphatase and alizarin red S was noted. Moreover, HMSCs cultured in AM for 8 and 16 days were switched to OM and MM and their ability to undergo osteoblastic differentiation and form mineralised calcium was determined by noting morphology and histochemical staining in these cells 8 and 16 days after medium switch. HMSCS were shown to be 82 per cent positive for STRO-1. These cells underwent adipocytic differentiation, osteoblastic differentiation and formed mineralised calcium upon appropriate stimulation. Moreover, HMSCs cultured in AM for 8 and 16 days could be stimulated to undergo osteoblastic differentiation and form mineralised calcium by medium switch. In conclusion, HMSCs are osteoprogenitors in their majority. They can undergo both osteoblast and adipocyte differentiation and there is plasticity of differentiation between early and late adipocytic precursors and osteoblasts as evidenced by morphology and histochemical staining. Future work will be centered on confirming these findings by specific PCR for known markers of osteoblast and adipocyte differentiation.

Human Dental Pulp Stem Cells (DPSCs): Characterization and Developmental Potential. S. Gronthos,*[1] P. Gehron Robey,[1] A. Boyde,*[2] S. Shi.*[1] [1]Craniofacial & Skeletal Diseases Branch, NIDCR, National Institutes of Health, Bethesda, MD, USA, [2]Department of Anatomy & Developmental Biology, University College, london, United Kingdom.

We have previously identified a clonogenic cell population, termed dental pulp stem cells (DPSCs), derived from adult human third molars. Ex vivo expanded DPSCs have the unique ability to regenerate a dentin-pulp complex following xenogeneic transplantation using hydroxyapatite/ tricalcium phosphate (HA/TCP) as a carrier vehicle. Transplants were composed of mineralized tubular structures lined with odontoblasts, and fibrous tissue containing blood vessels, analogous to normal human teeth. To further characterize the stem cell-like properties of DPSCs, we harvested cells from three-month old DPSCs transplants and expanded these populations in vitro. Human cells were isolated from these cultures based on their reactivity to a human specific anti-integrin b1 antibody using fluorescence activated cell sorting. These selected cells were then re-transplanted along with HA/TCP into immunocompromised mice. A mineralized dentin-like structure was formed following re-transplantation by the human donor cells. Moreover, regenerated dentin was also found to contain dentin sialophosphoprotein (DSPP) by immunohistochemical staining. Analysis of twenty individual colonies from primary cultured DPSCs demonstrated that only 10% to 15% of the clones showed a high proliferative potential in vitro. We next determined the ability of individually ex vivo expanded clones to form a dentin-pulp structure following xenogeneic transplantation. Approximately 20% of the transplanted clones showed the potential to develop a mineralized dentin-pulp structure in vivo. In conclusion, our data indicate that human DPSCs possess stem cell-like characteristics that include clonogenic potential, the ability to self-renew, and the capacity to differentiate into functiuonal odontoblasts. In analogy to bone marrow stromal stem cells, DPSCs represent another kind of mineralized tissue forming stem cell population, and may provide a potential resource for the regeneration of viable dental structures in vivo for clinical applications.

Cystatin C Inhibits Osteoclast Formation and Activation via Different Mechanisms. M. Brage,*[1] A. Grubb,*[2] M. Abrahamsson,*[2] M. Ransjö,[1] U. H. Lerner.[1] [1]Dept Oral Cell Biology, Umeå university, Umeå, Sweden, [2]Dept Clinical Chemistry, University of Lund, Lund, Sweden.

Cysteine proteases, particularly cathepsin K, have previously been shown to be key enzymes in the degradation of extracellular matrix in osteoclastic resorption lacunae. In line with this, we have reported that cystatin C, an inhibitor of papain-like cysteine proteases, inhibits bone resorption in mouse calvariae primarily by inhibiting the degradation of bone matrix proteins. This effect is mimicked by the amino-terminal segment Arg8-Leu9-Val10-Gly11 (RLVG) [Johansson et al. Bone 26:451, 2000]. We have previously reported that not only osteoclast activity but also osteoclast formation is dependent on cysteine protease activity. Thus, cystatin C, Z-RLVG-CHN2, E-64 and leupeptin inhibit osteoclastogenesis in mouse bone marrow cultures stimulated by PTH and D3. In the present study, we have studied the effect of cysteine protease inhibition on the expression of different phenotypic markers of osteoclast and osteoblast/stromal cell differentiation and in addition investigated the effect of cystatin C on bone resorption in vivo as assessed by decreased serum calcium. PTH did not stimulate osteoclast formation at 2 days but at and after 4 days of culture the number of osteoclasts increased with maximal number seen after 7 days. Addition of cystatin C at day 5 was sufficient to obtain inhibition of osteoclastogenesis. Using a semi-quantitative RT-PCR it was found that cystatin C did not inhibit the stimulatory effect of PTH on TRAP and cathepsin K mRNA expression at 2 or 9 days. After 9 days, cystatin C reduced PTH stimulated mRNA for calcitonin receptor and carbonic anhydrase II, without affecting that of RANK. Cystatin C did not affect osteocalcin, a1-procollagen and alkaline phosphatase mRNA. However, down regulation of OPG by PTH was abolished by cystatin C. Cystatin C and D were equipotent as inhibitors of bone resorption in mouse calvariae, whereas cystatin D was clearly less potent than cystatin C as inhibitor of osteoclast formation. Injection of cystatin C i.p. at 15 mg/100 g into rats fed a calcium deficient diet resulted in a transient inhibition of ionized blood calcium. These data show that cysteine proteinase inhibitors decrease bone resorption in mouse calvariae, inihibit osteoclast formation in mouse bone marrow cultures and decrease blood calcium in rats. The inhibition of osteoclast formation and activity seems to be due to different mechanisms (different sensitivities to cystatin C and D) and the inhibitory effect on osteoclast differentiation pathway may be mediated via effects on preosteoclast differentiation, rather than on osteoblast/stromal cell differentiation

Localisation of Collagen Fragments (CTx, ICTP, NTx, NTP and Dpd) in Resorption Sites: A 3D Confocal Study. S. A. Nesbitt,[1] S. P. Robins,[2] J. Risteli,[3] P. Qvist,[4] S. Apone,[5] D. R. Eyre,[6] M. A. Horton.[1] [1]Bone and Mineral Centre, University College London, London, United Kingdom, [2]Rowett Research Institute, Aberdeen, United Kingdom, [3]University of Oulu, Oulu, Finland, [4]Osteometer BioTech, Herlev, Denmark, [5]Ostex Int., Seattle, USA, [6]University of Washington, Seattle, USA.

During bone resorption osteoclasts liberate degraded bone matrix collagens and transport them through the cell before their release in the extracellular space. Herein, antibodies to the C telopeptides (CTx, ICTP), the N telopeptides (NTx, NTP) and the deoxypyridinoline collagen crosslinks (Dpd) have been used to assess the localisation of degraded collagens within resorption sites. The analysis was performed using an in vitro resorption model with fluorescence immunostaining and confocal microscopy with post hoc 3D image reconstruction. Human osteoclasts were cultured on biotinylated dentine slices for 24h. After fixation and permeabilisation, the cells were triple-stained for F-actin, biotinylated matrix and the degraded collagens. 3D images of osteoclasts and adjacent stromal cells were reconstructed from a series of 64 immunofluorescence xy optical sections (0.35 microns thick) taken by confocal microscopy to provide internal views of epitope distribu-

tion in the cells. Image analysis of the resorbing osteoclasts showed CTx and NTP in the resorption pit, across the ruffled border and forming discrete intracellular aggregates in the basolateral cell body. Minimal amounts of NTx were seen in osteoclasts compared to CTx, NTP and Dpd. Most NTx was localised along the ruffled border where Dpd and ICTP were absent. Furthermore, exposed pits were positive for ICTP, but negative for Dpd and NTx, and these sites were infiltrated with stromal cells. In summary, these data suggest that degraded collagen fragments NTx, NTP and CTx are liberated at the ruffled border and, in part, traffic through the osteoclast. Further intracellular degradation generates Dpd epitopes and, subsequently, ICTP is exposed following stromal cell modification of the resorption sites. Our data demonstrate that collagen fragments are generated both extracellularly and during transcytosis through osteoclasts; these findings will have implications for clinical tests of osteoclast activity that are based upon measurement of the levels of collagen fragments.

SA230

Development of Quantitative ELISAs to Pro- and Mature Cathepsin K: Their Utility in Mechanistic Studies of Osteoclastic Bone Resorption. C. J. Gress,*[1] I. E. James,*[1] N. Dada,*[2] M. Gowen,[1] M. W. Lark.[1] [1]Musculoskeletal Diseases, GlaxoSmithKline, King of Prussia, PA, USA, [2]diaDexus, Santa Clara, CA, USA.

Cathepsin K is the principal cysteine protease involved in osteoclast-mediated bone resorption(1). It has been proposed that small molecule inhibitors of this enzyme would be efficacious in the treatment of metabolic bone diseases such as osteoporosis. Indeed, small molecule, non peptide cathepsin K inhibitors have been described that inhibit osteoclast-mediated bone resorption both in vitro and in vivo. In an effort to understand the mechanisms of cathepsin K inhibition, it has been previously demonstrated, using Western blot analysis, that resorbing human osteoclasts treated with inhibitors of human cathepsin K cause a dose dependent accumulation of intracellular levels of mature enzyme(2). In this study we confirm and extend these observations using quantitative ELISAs specific for either pro- or mature cathespin K. In addition, we show that other classes of bone resorption inhibitors such as small molecule inhibitors of vATPase do not affect the intracellular levels of mature or pro-cathepsin K. Furthermore, in an in vitro human osteoclast resorption assay we show that normal osteoclastic resorption is resumed upon removal of the cathepsin K inhibitors. Importantly, preliminary studies suggest that this resumption of osteoclastic function does not appear to be accompanied by a resorption rebound effect from the accumulated mature cathepsin K. These data have important implications with regard to using cathepsin K inhibitors in the treatment of osteoporosis. Also, the development of the quantitative ELISAs may provide an important tool in the diagnosis and treatment of metabolic bone diseases such as osteoporosis.1) James et al., J Biol. Chem. 276: 11507-11511, 2001, 2) Rieman et al., J Bone Min. Res. 14: S357, 1999

Dissociation of Angiogenesis and Osteoclastic Resorption During Endochondral Bone Formation in Neonatal Mice. M. M. L. Deckers,*[1] G. van der Pluijm,[1] E. R. van Beek,*[1] A. Wetterwald,*[2] L. van der Wee-Pals,*[1] M. Cecchini,[2] S. E. Papapoulos,[1] C. W. G. Löwik.[1] [1]Endocrinology, LUMC, Leiden, The Netherlands, [2]Gene Therapy Laboratory, Department of Clinical Research & Urology Clinic, University of Bern, Inselspital, Bern, Switzerland.

Invasion of the mineralized cartilage by endothelial cells and osteoclasts is a key event in endochondral bone formation and is at least partly mediated by actvity of matrix metalloproteinases (MMP). Through the action of osteoclasts, the mineralized matrix in the center of embryonic bones is resorbed and a primitive bone marrow cavity is formed. During this process, endothelial cells invade the bone directing osteoblast progenitors to the cartilaginous scaffolds of the growth plate to form bone. To selectively examine the putative role of osteoclastic resorption and angiogenesis in this process we used an in vivo model of suppressed bone resorption and/or suppressed angiogenesis.Angiogenesis and osteoclastic resorption was examined in tails and long bones of newborne mice treated with bisphosphonates (BPs), osteopetrotic mice (c-fos knockout or op/op mice) and newborne mice treated with selective MMP inhibitors (MMPIs). The tail vertebrae of newborne mice, represent all stages of endochondral bone formation of which the most proximal vertebrae represent fully differentiated mineralized cartilage as opposed to immature non mineralized cartilage at the most distal vertebrae. During the next 7 days of postnatal development, all vertebrae in the tail reach their mature stage represented by the formation of a primitive marrow cavity.In control mice PECAM-1 positive sinusoids were detected in the vicinity of TRAcP positive osteoclasts. Treatment with BPs completely abolished bone resorption and eliminated TRAcP positive osteoclasts while angiogenesis remained unaffected. Similarly, bone sections of osteopetrotic mice revealed that capillaries invaded the mineralized cartilage. In contrast, in mice treated with a broad spectrum MMPI (marimastat) both processes were inhibited whereas a new selective MMPI solely blocked angiogenesis without affecting osteoclastic resorption.In conclusion we show that 1) endothelial cells invade the mineralized cartilage in the absence of osteoclasts. 2) BPs have no effect on angiogenesis. 3) a selective MMPI that has no effect on osteoclastic resorption strongly inhibits angiogenesis, suggesting that different MMPs are involved in osteoclastic resorption and angiogenesis. Together, these data strongly indicate that, during endochondral bone formation, invasion of cartilage by capillaries can occur independently of osteoclastic resorption and vice versa.

SA232

Expression and Role of Mannose Receptor/Terminal High Mannose on Osteoclast Precursors During Osteoclast Formation Via Cellular Fusion Events. S. Morishima,*[1] I. Morita,[2] T. Tokushima,[2] S. Enomoto,*[1] S. Murota.*[2] [1]Oral Surgery, Department of Oral Restitution,Division of Oral Health Sciences, Tokyo Medical and Dental University, Tokyo, Japan, [2]Celluler Physiological Chemistry, Tokyo Medical and Dental University, Tokyo, Japan.

It is well known that osteoclast is formed from hematopoietic precursors via cell-cell fusion. We have already presented that mannose residues wereexpressed on outer membranes of monocytes and that they were involved in the osteoclast formation via cellular membrane fusion events. In the present paper, we will demonstrate the mechanisms for expression of terminal high mannose (TM) and also show that mannose receptor, a counterpart of TM, is expressed on osteoclast precursor cells. Osteoclasts were formed by 3 different systems: 1) mouse bone marrow cells were incubated with 10-8M of PGE2 for 7 days, 2) mouse spleen cells wereco-cultured with stromal cells (TMS-14) in the presence of 10-8M of 1α,25(OH)2VitaminD3 (VitD3) for 7 days, and 3) RAW264.5 cells were cultured with 50 ng/ml of sRANKL in a spot culture for 4 days. The expression of TM was quantitatively determined by fluorescence intensity of cell membraneassociated FITC-conjugated pradimicine, which is recognized to bind TM, andthat of mannose receptor was immunostained with antibody against alveolar macrophage mannose receptor. During osteoclast differentiation the expression of TM increased graduallyand reached its maximum at the stage of fusion in the 3 different systems. The mannose receptor was not detected in bone marrow cells and spleen cellsin the absence of PGE2 or Vit D3, and gradually increased during osteoclastdifferentiation. In contrast, the expression of mannose receptor in RAW264.7 cells.was already detected without sRANKL and it was not changed during osteoclast differentiation. The expression of TM on outer membrane ofosteoclast precursor cells was abrogated by the addition of castanospermine,an inhibitor of glucosidase I, and was enhanced by the addition of either deoxymannojirimycin, an inhibitor of α-mannosidase I or swainsonine, aninhibitor ofα-mannosidase II. In parallel with TM expression, the number of osteoclast was inhibited by castanospermine, and stimulated bydeoxymannojirimycin or swainsonine. These results indicated that mannose receptor was expressed on the osteoclast precursor cells as a counterpart of TM, and the degradation of N-linked oligosacchadide regulates osteoclast differentiation via cellularfusion events. These data also suggest that the inhibitors of gluocidase I may be postulated as novel drugs against osteoporosis.

A Series of Echistatin Analogs Containing A Benzophenone Which Flanks the RGD Triad: Novel Tools in Photoaffinity Crosslinking Studies of the Osteoclast $\alpha_v\beta_3$ Integrin. D. Yahalom,* M. Rosenblatt, J. A. Alexander, M. Chorev.* Division of Bone and Mineral Metabolism, Charles A. Dana and Thorndike Laboratories, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA.

The benzopheneone (BP)-based photoaffinity scanning (PAS) methodology is employed by us to map the bimolecular interface between $\alpha_v\beta_3$integrin, the dominant integrin in human osteoclasts, and its RGD-containing ligands. We have previously identified the contact sites within the sequences β_3[99-118] {Bitan et al. Biochemistry (1999) 38, 3414-3420} and β_3[167-171] {Bitan et al. Biochemistry (2000) 39, 11014-11023} of the $\alpha_v\beta_3$ receptor for two small peptides, containing BP moieties at either the carboxyl or the amino terminal side of the RGD triad, respectively. More recently, we have employed an echistatin analog modified by insertion of a BP moiety on Lys^{45}, which is located within the C-terminus and removed from the $R^{24}GD^{26}$ triad {JBMR (1999) 14, S481}. We have identified β_3[209-220] as a putative auxiliary binding site for the C-terminus in echistatin. In order to identify the contact sites in $\alpha_v\beta_3$ for the residues flanking the RGD triad in echistatin and compare them with the analogous sites in small RGD-containing peptides, we have developed echistatin analogs containing *p*-benzoylphenylalanyl (Bpa), a BP-containing amino acid residue, in positions 21, 23, and 28. The [Bpa^{21},Leu^{28}], [Bpa^{23},Leu^{28}]and [Bpa^{28}]-Echistatin analogs bind with high affinity to the purified $\alpha_v\beta_3$ integrin. The radioiodinated analogs crosslink effectively to the recombinant human $\alpha_v\beta_3$ receptor overexpressed in HEK-293 cells. This photocrosslinking is blocked in the presence of excess echistatin. Unlike echistatin, the three new analogs are very poor ligands for the closely related $\alpha_{IIb}\beta_3$ receptor, suggesting high specificity toward $\alpha_v\beta_3$ integrin. We will present the results of the receptor binding assays and discuss them in the context of ligand structure-function relations. We will also report our photoaffinity crosslinking studies, and discuss their implications for the emerging experimentally-based model of the ligand-$\alpha_v\beta_3$ integrin bimolecular interface.

CpG Containing Oligodeoxynucleotide Modulates Osteoclastogenesis. W. Zou,*[1] H. Schwartz,*[1] G. Hartmann,*[2] S. Endres,*[2] Z. Bar-Shavit.[1] [1]Hebrew University faculty of Medicine, Jerusalem, Israel, [2]University of Munich, Munich, Germany.

The ability of the macrophage to distinguish bacterial from mammalian DNA is mimicked by single-stranded oligonucleotides containing unmethylated CG dinucleotides ("CpG" motifs) in specific sequence context (CpG ODN). CpG ODN interaction with the macrophage changes the transcription of a number of genes by activating nuclear translocation of nuclear factor κB (NF-κB). Activation NF-κB is also a key event in the differentiation of the osteoclast from its precursor cell, a member of the macrophage family. Therefore we examined the ability of CpG ODN to modulate osteoclast differentiation. We observed TRAP positive cells when CpG ODN (but not control GC ODN) was added to bone marrow macrophage (BMM) cultures in the presence of M-CSF. However. these cells did not fuse significantly, did not express calcitonin receptors and the intensity of the

TRAP stain was weak as compared to RANK ligand (RANKL)-treated cells. Furthermore, CpG ODN inhibited in a dose dependent manner the osteoclastogenic activity of RANKL. At 50 nM CpG ODN we observed 99.5% inhibition. On the other hand, a two fold enhancement of osteoclateogenesis was recorded if the CpG ODN was added to RANKL-containing cultures for the last 30 hours of a five day experiment. CpG ODN stimulated osteoclastogenesis in RANKL-pretreated BMMs, even in the absence of RANKL. CpG ODN treatment of BMMs increased the mRNA and protein levels of IL-1 and TNF-α. While these two cytokines show very little osteoclastogenic activity in BMMs, they are very effective in promoting osteoclast differentiation in RANKL-treated cells. The osteoclastogenic activities of IL-1 and TNF-a are inhibited by IL-1 receptor antagonist (IL-1ra) and antibodies to TNF-α, respectively. Induction of osteoclast differentiation in RANKL-pretreated BMMs by CpG ODN was not affected by IL-1ra, but was blocked by antibodies to TNF-a. In summary, CpG ODN is capable of modulating osteoclast differentiation. It exerts an inhibitory effect on the precursor, but markedly enhances osteoclastogenesis of RANKL-treated BMMs, namely cells which started to differentiate into osteoclasts. The enhancement of differentiation is mediated by TNF-a, while the inhibitory phase is may be due to reduction of M-CSF receptors caused by CpG ODN. Currently, potential target indications of CpG oligonucleotides comprise infections (current clinical trials as vaccine adjuvant) and malignancy (effective adjuvant for dendritic cell-based tumor therapy in animal tumor models). The present study suggests that CpG ODNs may be beneficial in treating osteoporosis.

Osteoclasts Generated from Cultures of Peripheral Blood Stem Cells from Human Osteopetrotic Patients after Stimulation with Interferon Gamma Resorb Bone. **P**. R. Madyastha,* W. L. Ries, L. L. Key. Pediatrics (Endocrinology), Medical University of South Carolina, Charleston, SC, USA.

Osteopetrosis is a metabolic disorder caused by the impairment of osteoclastic bone resorption. The chief manifestation is the accumulation of bone. Superoxide production, which appears to be necessary for normal osteoclastic bone resorption, is defective in osteoclasts (OCL) and white blood cells of osteopetrotic patients. We earlier have shown that in OCL generated from PBMC of osteopetrotic patients, IFNγ-stimulation increased the superoxide generation to levels present in control OCL. In the present study, we show that OCL generated from cultures of PBMC of four osteopetrotic patients were dysfunctional and failed to form resorption pits *in vitro* on bovine bone slices, representing the pathological features of osteopetrosis *in vivo*. In comparison, osteoclasts generated *in vitro* from non-osteopetrotic control subjects formed numerous resorption pits. When stimulated with IFNγ, the ability of osteopetrotic OCL to form resorption pits was improved (number of pits/experiment in triplicate bone slices: patient, unstimulated, 0; IFNγ -stimulated, 68; control, 121. The average total area resorbed was less (control, 549943 μm^2; osteopetrotic patient, 289449 μm^2), but the average resorption area per pit was similar (control, 4545±960 μm^2; osteopetrotic patient, 257±971 μm^2). These findings were complimentary to our earlier *in vivo* histomorphological data that demonstrated a decrease in trabecular bone volume on the bone biopsy specimens pre- and post-treatment with IFNγ. NBT staining, a marker of superoxide generation was significantly increased in IFNγ-stimulated OCL from osteopetrotic patients, compared to unstimulated OCL ($p<0.0001$). Our current data provide evidence that IFNγ-stimulated the generation of superoxide in osteopetrotic OCL, improving bone resorptive activity. In contrast to observations made in OCL harvested from non-osteopetrotic subjects where IFNγ exposure has suppressed OCL formation and bone resorption, the data from the current study suggest that IFNγ increases osteoclastic numbers in cultures of osteoclastic precursor cells harvested from osteopetrotic patients. This unique response may explain improved bone resorption seen in osteopetrotic patients treated with IFNγ.

TNFα Stimulates Osteoclast Differentiation Through Direct Effects on Osteoclast Precursors. J. L. Nalepka,* E. M. Greenfield. Orthopaedics, Case Western Reserve University, Cleveland, OH, USA.

Most bone resorptive agents stimulate osteoclast differentiation indirectly by increasing the RANKL:OPG ratio produced by stromal cells. In contrast, TNFα, in the presence of M-CSF, directly stimulates differentiation of osteoclast precursors in the absence of stromal cells. This study examined whether the primary effect of TNFα is through this direct pathway in the more physiological situation where both stromal cells and other cytokines are present. Osteoclast differentiation was assessed in co-cultures of precursors obtained from murine spleen and CIMC-4 cells, a conditionally immortalized murine calvaria cell line that supports osteoclast differentiation in response to 1,25-D3, IL-1, IL-6, IL-11, and TNFα. Addition of OPG (200 ng/ml) completely blocked formation of both TRAP+ multi- and mono-nuclear cells induced by 1,25-D3 and all of the cytokines, with the exception of TNFα. OPG also had no effect even in the presence of a wide range of TNFα concentrations and when a 10-fold higher concentration of OPG was studied. To confirm that TNFα primarily acts directly on the osteoclast precursors, spleen cells isolated from mice lacking both TNF-receptor-1 and TNF receptor-2 were studied. TNFα did not induce differentiation of osteoclast precursors that lack TNF receptors, even when they were co-cultured with CIMC-4 cells with normal TNFα responsiveness. Specificity of this effect was demonstrated since the TNF receptor-deficient precursors differentiate normally in response to 1,25-D3. Low concentrations of the cytokines synergistically stimulate osteoclast differentiation when added together and this effect was blocked by OPG. However, use of the TNF receptor-deficient osteoclast precursors shows that TNFα primarily acts directly on the osteoclast precursors even in the presence of the other cytokines. Thus, the cytokine mixture induced significantly less differentiation of TNF receptor-deficient osteoclast precursors than of control precursors. Moreover, the extent of differentiation of TNF receptor-deficient osteoclast precursors that is induced by the cytokine mixture is indistinguishable from that induced by the cytokine mixture lacking TNFα. Taken together, these results show that TNFα stimulates differentiation primarily by acting directly on the osteoclast precursors even in the presence of other cytokines and TNF responsive mesenchymal support cells. This mechanism is distinct from other resorptive agents that act through the RANKL pathway but does not imply that osteoclast differentiation induced by TNFα is completely independent of RANKL. Instead, it is likely that activation of RANK by RANKL is permissive for direct stimulation of osteoclast precursors by TNFα.

Flt3 Ligand Can Substitute for M-CSF in Support of Osteoclast Differentiation and Function. J. M. Lean,* K. Fuller, T. J. Chambers. Department of Cellular Pathology, St. George's Hospital Medical School, London, United Kingdom.

Although bone resorption and osteoclast numbers are reduced in osteopetrotic (op/op) mice, osteoclasts are nevertheless present and functional, despite absence of macrophage colony-stimulating factor (M-CSF). In fact, unresorbed bone is removed and a well-developed marrow cavity forms within a few weeks of birth. This suggests that alternative factors can compensate for the crucial actions of M-CSF in osteoclast-induction. We found that when non-adherent bone marrow cells were incubated in RANKL with flt3 ligand (FL) without exogenous M-CSF, tartrate-resistant acid phosphatase (TRAP)-positive cells were formed, and bone resorption occurred. Without FL, only macrophage-like, TRAP-negative cells were present. GM-CSF, stem cell factor, IL-3 and vascular endothelial growth factor could not similarly replace the need for M-CSF in these cultures. TRAP-positive cell induction by FL was not due to synergy with M-CSF produced by the bone marrow cells themselves, since FL also enabled their formation from the hemopoietic cells of op/op mice, which lack any M-CSF. FL appeared to substitute for M-CSF by supporting the differentiation of adherent cells that express mRNA for RANK and responsiveness to RANKL. FL did not compensate for M-CSF in precursor expansion, so that functional osteoclasts were formed, but in small numbers. To determine whether FL can account for the compensation for M-CSF-deficiency that occurs in-vivo, we blockaded FL signaling in op/op mice by injection of the soluble receptor for FL. We found that the soluble receptor induced a substantial decrease in osteoclast number, strongly suggesting that FL is responsible for the partial compensation for M-CSF deficiency that occurs in these mice. The actions that we have observed of FL on osteoclast progenitors are consistent with a role for FL in determining the natural history of osteopetrosis in the op/op mouse, in which the number of osteoclasts formed is adequate to cope with bone resorption except in early development, when the resorptive burden is greatest.

SA243

TNF Induces Osteoclast Formation Independent of NF-kB p50 and p52 Expression and Promotes the Formation of RANK-expressing Osteoclast Precursors. L. Xing,[1] J. Hofecker,*[1] Z. Tai,*[1] P. Li,*[1] T. Bushnell,*[1] E. Schwarz,[1] F. Young,*[1] M. Tondravi,[2] B. Boyce.[1] [1]Univ. Rochester, Rochester, NY, USA, [2]American Red cross, Rockville, MD, USA.

TNF is implicated in postmenopausal and inflammation-mediated bone loss. It stimulates RANKL production by stromal cells and like RANKL, activates NF-kB. NF-κB is required in osteoclast (ocl) precursors for ocl formation, it up-regulates TNF expression and thus mediates an up-regulatory osteoclastogenic cycle. Although TNF promotes ocl formation indirectly, it may also act directly on ocl precursors through or independent of NF-κB. To study this latter possibility, we treated wild-type (wt) and various NF-kB knockout (KO) mice, including p50KO, p52KO, and p50;p52 double KO (dKO) mice with TNF and examined its effects on ocl formation *in vivo* and *in vitro*. TNF injections (1μg 3/d x 3d): 1) increased ocl numbers (per mm^2 bone area) in calvarial sections: wt (55+/-12), p50KO (82+/-32) and p52KO (79+/-21) mice (vs 16+/-10 in PBS-treated wt mice) and eroded surface: wt (25+/-2%), p50KO (36+/-12) and p52KO (33+/-7.4%) mice (vs 7.6+/-4.7% in PBS controls). Importantly, ocls (which are absent in calvariae of untreated dKO mice) formed in dKO mice treated with TNF (7+/-1.5), but not with IL-1; 2) increased ocl formation from *ex vivo* cultures of splenocytes from TNF-treated mice: wt (626+/-32 ocl#/well); p50KO (730+/-155), p52KO (683+/-192) (vs 101+/-54 in PBS controls); 3) increased RANK+ve splenocytes from TNF-treated wt mice (8.1 vs 1.3% in PBS controls) and their proliferation response to RANKL/M-CSF (5 +/-0.1 fold increase vs 1.7+/-0.2 in an MTT assay), CFU-GM colony number (199+/-15 vs 39+/-5) from splenocytes and ocls formed from these colonies (460+/-23 vs 202+/-7) and resorption pit area per dentine slice (0.41+/-0.01 vs 0.17+/-0.03 mm^2). In addition, TNF promoted a 5-fold increase in CFU-

GM colony formation from wt, NF-kB p50KO and p52KO splenocytes, while spleen cells from untreated dKO mice formed 3-fold more CFU-GM colonies and 3-fold more RANK expressing cells than wt mice. Finally, splenocytes from TNF transgenic mice formed more ocls earlier in culture (5 days) than wt controls (441+/-13 vs 50+/-7), an effect that was not prevented by maximal doses of the TNF receptor blocker, hTNFR:Fc. Our findings indicate that 1) although the major osteoclastogenic effects of TNF are mediated by NF-kB, TNF, unlike IL-1, can promote ocl formation by an NF-kB independent pathway; 2) TNF primes RANK-positive ocl progenitor formation in vivo; 3) NF-kB expression is required for ocl formation in RANK-expressing cells beyond the CFU-GM stage. Thus, prevention of postmenopausal and inflammation-mediated bone loss is likely to require inhibition of both TNF and NF-kB signaling.

Impaired Osteoclastogenesis, but Normal Bone Resorption, in Mice Deficient in Tumor Necrosis Factor (TNF). W. Hofstetter,[1] R. Balga,*[1] J. Portenier,*[1] C. Mueller.*[2] [1]Department Clinical Research, University of Berne, Berne, Switzerland, [2]Department for Pathology, University of Berne, Berne, Switzerland.

Growth factors of the TNF family are essential for physiological bone metabolism. In the present study, osteoclastogenesis and bone resorption were investigated in mice deficient in TNFα and lymphotoxin (TNFβ) and in TNFα,β null-mice carrying a transgene encoding a transmembrane form of TNF (tmTNF). Mice of 3 months of age were ovariectomized (OVX). Bone density (BD) and bone mineral content (BMC) were measured by peripheral quantitative computer tomography (pQCT) in weekly intervals. After three weeks, bones were embedded in methylmetacrylate (MMA) for histological analysis and co-cultures of bone marrow cells (1.5 x 10^5 cells/well) together with primary murine osteoblasts from wt donors (10^4 cells/well) were prepared and cultured for 6 days. By pQCT, a significant decrease in total BMD and BMC was detected in the distal femur and the proximal tibia of TNF null mutants and of tmTNF transgenic mice within 3 weeks after OVX. Separation of total BMD and BMC into the cortical and trabecular compartments revealed a similar decrease in the cortical bone. Virtually no effect was detected in trabecular bone, which may be due to limited sensitivity and/or resolution. The data was confirmed by histological analysis of MMA embedded tibiae. In the metaphysis, total bone was reduced, and a significant reduction of trabecular bone was evident. TRAP staining of sequential sections revealed no obvious changes in the number and distribution of osteoclasts in the bones derived from the genetically different mouse strains. In co-cultures of total bone marrow with osteoblasts, the formation of osteoclasts was reduced by ca. 40% in marrow cells from TNF null-mice with respect to wt. A further decrease to ca. 20% as compared to wt was observed when the marrow cells were derived from tmTNF transgenic mice. The data demonstrates that in mice deficient in TNF or carrying a transgene for tmTNF, deficiency in estrogen induces an increase in bone resorption, which is not different to the increase in bone resorption observed in normal animals after OVX. While *in vivo* bone resorption is not affected by the mutations, the formation of osteoclasts in vitro is impaired by the deficiency in TNF, and is further reduced when only tmTNF is present. From the present data, it can be concluded that TNF is essential for the efficient formation of osteoclasts *in vitro*. In the regulation of physiological bone resorption, however, TNF is redundant and the increase in bone loss after ovariectomy can be mediated by other factors than TNF.

The Immunosuppressant Rapamycin, alone or with Transforming Growth Factor-β, Enhances Osteoclast Differentiation of RAW264.7 Monocyte-Macrophage Cells in the Presence of RANK-Ligand. C. Shui,* B. L. Riggs, S. Khosla. Endocrinology, Mayo Clinic, Rochester, MN, USA.

Immunosuppressant therapy has been shown to cause high-turnover osteoporosis both clinically and experimentally. Since this may result from direct or indirect stimulation of osteoclast development, we investigated whether cyclosporin A (CsA), rapamycin, or FK506 affect osteoclastic differentiation of RAW264.7 cells induced by RANK-ligand (RANK-L). Furthermore, since the rapamycin receptor protein binds TGF-β receptors, and TGF-β enhances osteoclastogenesis induced by RANK-L, we also examine potential synergistic effects of rapamycin and TGF-β_1. Cell proliferation was assessed using ^{3}H-thymidine incorporation and osteoclast differentiation was determined by tartrate-resistant acid phosphatase (TRAP) activity, TRAP-positive multinucleated cell (TRAP$^+$MNC) formation, and quantitative RT-PCR analysis of TRAP and calcitonin receptor (CTR) mRNAs. We found that rapamycin, in the presence of 50 ng/ml RANK-L and 5 ng/ml macrophage colony-stimulating factor (M-CSF), inhibited cell proliferation and stimulated TRAP activity in a dose-dependent manner (0.1-1000 ng/ml). At the optimal concentration of 10 ng/ml, it increased the number of TRAP$^+$MNC more than 20-fold and enhanced the expression of TRAP and CTR mRNAs 2.1- and 10-fold, respectively. CsA, at 125-2000 ng/ml, similarly inhibited proliferation, but at high doses (1000-2000 ng/ml) it decreased TRAP activity, TRAP$^+$MNC formation, and the expression of TRAP and CTR mRNAs. FK506 showed no detectable effect on cell proliferation or TRAP activity at concentrations up to 2000 ng/ml; however, similar to CsA, the addition of 1000 ng/ml FK506 inhibited TRAP$^+$MNC formation and the expression of TRAP and CTR mRNAs. The combination of rapamycin (10 ng/ml) and TGF-β_1(1 ng/ml) increased TRAP$^+$MNC 3.1- and 6.9-fold as compared to rapamycin or TGF-β_1 alone, respectively, and enhanced the CTR mRNA expression induced by TGF-β_1 by 1.9-fold. By contrast, both CsA and FK506 significantly antagonized the effect of TGF-β_1 or rapamycin on the expression of the osteoclast phenotype. These data thus indicate that rapamycin, alone or in synergy with TGF-β directly enhances osteoclastogenesis and may affect bone metabolism in vivo after long-term use. In contrast, CsA and FK506 seem to have an inhibitory effect on osteoclast development.

Isolation of a Human Homolog of Osteoclast Inhibitory Lectin That Inhibits Osteoclastogenesis. Y. S. Hu,*[1] D. Myers,[2] H. Zhou,[2] J. M. W. Quinn,[1] V. Kartsogiannis,[2] J. Elliott,*[1] C. Gange,*[1] W. J. McKinstry,*[1] M. T. Gillespie,[1] K. W. Ng.[2] [1]St Vincent's Institute of Medical Research, Fitzroy, Australia, [2]Department of Medicine, The University of Melbourne, St Vincent's Hospital, Fitzroy, Australia.

Murine and rat Osteoclast Inhibitory Lectins (mOCIL, rOCIL) are type II membrane C-type lectins expressed by osteoblasts and other extraskeletal tissues. The extracellular domain of mOCIL, expressed as a recombinant protein, inhibited osteoclastogenesis by adherent murine spleen cells treated with M-CSF and soluble RANKL (JBC, 2001).We have isolated the human homolog of OCIL (hOCIL) from a human fetal cDNA library using [32P] dCTP-labeled rOCIL as a probe under low stringency hybridisation conditions. hOCIL cDNA predicts a 191 amino-acid type II membrane protein, with the 112 amino-acid C-type lectin region in the extracellular domain having 54% homology to the C-type lectin sequences of rOCIL and mOCIL. The hOCIL gene, located in chromosome 12p, is 46.5 kb in length and comprised 6 exons, with evidence of 5' alternative splicing. Unlike mOCIL, hOCIL mRNA was not regulated in human osteoblastic cells (SaOS2 or MG-63) treated with calciotropic agents, PGE2, dexamethasone or calcitriol.The extracellular domain of hOCIL was expressed as a soluble recombinant protein in E. coli, and its biological effects were compared with recombinant mOCIL on human and murine osteoclastogenesis. Human osteoclastogenesis was performed with CD14+ cells separated from peripheral blood mononuclear cells. CD14+ cells were cultured on bone for 21d in the presence of hM-CSF (25 ng/ml), sRANKL (40 ng/ml) and three concentrations (2, 8 and 32 ng/ml) of hOCIL. 32 ng/ml hOCIL resulted in 90% inhibition of multinucleate osteoclast formation and 75% reduction in pit formation. In comparison, 32 ng/ml mOCIL also resulted in 90% inhibition of MNC formation and 80% reduction in pit formation.The effect of hOCIL on murine osteoclast formation was determined with spleen cells cultured for 7d in the presence of M-CSF and sRANKL. 50 and 500 ng/ml mOCIL caused near-complete inhibition of murine osteoclastogenesis, while hOCIL at these concentrations only inhibited osteoclast formation by 70%. This implies a degree of species specificity for OCIL action, with hOCIL having a higher affinity for human cells than murine cells: this is similar to growth factors such as M-CSF.In summary, hOCIL is highly conserved with mOCIL in its primary amino acid sequence, genomic structure, and activity to inhibit osteoclastogenesis. In contrast to mOCIL, hOCIL mRNA was not regulated by calciotropic factors. While there was cross-species efficacy in inhibiting osteoclast formation, hOCIL was more effective in blocking human osteoclastogenesis.

RAW264 Cell Clones are Transcriptional Osteoclast Precursors. B. L. Vincent,* A. J. O'Donoghue,* M. J. Glimcher, K. P. McHugh. Orthopaedic Research, Children's Hospital, Boston, MA, USA.

In this study we isolated and characterized osteoclast (Oc) precursors from RAW264 cells for studies of Oc transcriptional regulation. We cloned RAW264 cells which, with RANKL treatment, form functional phenotypic Ocs at high frequency. We also employed gene expression profiling of 1^o Ocs, their precursors, and Oc-genic RAW264 cell clones to characterize transcription in these cells. RAW264 cells have been used for >20 years, are well characterized as phagocytic macrophages, and have recently been shown capable of forming Oc-like cells when cultured with RANKL. While working with the RAW264 model we observed that not all cells give rise to Oc-like cells, demonstrating clonal variation. Thus we isolated Oc precursor clones for use in further studies of transcription. RAW264 cells (ATCC: TIB-71) were cloned by limiting dilution and random clones were grown +/- recombinant RANKL. After 5 days of culture, cells were fixed and stained for TRAP activity. All clones showed some degree of TRAP staining after RANKL treatment, while untreated cells did not. Approximately 1/4 of clones gave rise to TRAP positive multinuclear giant cells demonstrating various degrees of spreading. RNA was purified from parallel cultures and used as template for RT-PCR reactions for Oc markers (RANK, TRAP, cathepsin-K, calcitonin receptor (CTR), and β_3 integrin). All clones were found positive for RANK and, with RANKL treatment, for TRAP. All clones tested were capable of induced cathepsin-K expression, yet some clones constitutively express this Oc protease. CTR and β_3 were expressed in few clones with RANKL treatment. While all β_3 positive clones express CTR, not all CTR positive clones express β_3, making β_3 the most limited Oc marker. Clones were also assayed for their ability to form pits on dentine. We

found that pit formation correlated with cell spreading and β_3 expression. We also employed expression profiling using commercially available dense cDNA arrays to measure the steady-state expression levels of 1,200 known genes. As expected, the constitutive expression profiles of 1^o cells and RAW264 clones largely overlap. The genes coordinately repressed or induced by RAW264 clones and 1^o cells during Oc formation represent ~10% of the total detected, however the magnitude is not equal in all cases. Additionally, expression of some genes was specific to 1^o cells or RAW264 clones, perhaps reflecting the M-CSF dependent nature of 1^o cells or the transformed nature of RAW cells. We conclude that Oc-genic RAW264 clones represent osteoclast precursors that closely mirror the morphological, functional, and gene expression profile of 1^o Ocs, and are an appropriate model with which to study Oc transcriptional machinery.

Osteoblasts Prepared from LPS-Tolerant C3H/HeJ Mice Normally Support Osteoclast Formation in Response to LPS. K. Suda,*[1] M. Takami,[2] J. Woo,[1] N. Udagawa,[2] T. Suzawa,[2] K. Itoh,[2] N. Takahashi,[2] K. Nagai.*[1] [1]Bioengineering, Tokyo Institute of Technology, Yokohama, Japan, [2]School of Dentistry, Showa University, Tokyo, Japan.

Lipopolysaccharide (LPS), a major constituent of Gram-negative bacteria, is a potent stimulator of bone loss in inflammatory diseases such as periodontitis and some types of arthritides. We previously showed that LPS enhanced RANKL expression in osteoblasts and stimulated the survival and fusion of mononuclear osteoclasts. Recently, it was shown that C3H/HeJ mice, characterized by hyporesponsiveness to LPS, have a mutation within the Toll-like receptor (TLR) 4 gene. However, we have shown here that osteoblasts obtained form C3H/HeJ mice can support osteoclast formation in response to LPS similarly to those from C3H/HeN wild type mice.(1) When co-cultures of bone marrow cells and osteoblasts, both of which were prepared from C3H/HeJ mice, were treated with LPS, TRAP-positive osteoclasts were formed within 7 days. The number of osteoclasts induced by LPS in the co-culture of C3H/HeJ mice was similar to that in the co-culture of C3H/HeN normal mice. (2) OPG completely blocked LPS-induced osteoclast formation in the both co-cultures. (3) LPS stimulated RANKL mRNA expression in C3H/HeN wild type osteoblasts with two peaks; the first peak was observed at 3 hr, and the second peak at 48 hr. In osteoblasts prepared from C3H/HeJ mice, LPS stimulated RANKL mRNA expression with one peak at 48 h. LPS failed to induce RANKL mRNA expression at 3 hr in the mutant osteoblasts. (4) PD98059, a specific inhibitor of Erk1/2, inhibited RANKL mRNA expression induced by LPS at 3 h in normal osteoblasts, but had no effects on the LPS-induced RANKL mRNA expression at 48 h. In contrast, NS-398, a selective inhibitor of COX-2, inhibited LPS-induced RANKL mRNA expression at 48 h but not at 3 h in normal osteoblasts. (5) NS398 but not PD98059 completely blocked LPS-induced osteoclast formation in the co-culture. (6) LPS similarly stimulated COX-2 mRNA expression in both C3H/HeN and C3H/HeJ osteoblasts. These results suggest that LPS stimulates RANKL mRNA expression and induces osteoclast formation independent of TLR4-mediated signals. It is also suggested that RANKL mRNA expression induced by LPS in the late phase that depends on the prostaglandin E_2 production, plays important roles in LPS-induced osteoclast formation.

Induction of Osteoclastogenesis in Rat Bone Marrow Cultures by RANKL. W. Grasser,*[1] A. P. Baumann,*[2] V. Paralkar.*[2] [1]Pfizer Research Global Division, Groton, CT, USA, [2]Pfizer Global Research Division, Groton, CT, USA.

Osteoclasts differentiate from hematopoietic stem cell precursors of the monocyte/macrophage lineage. The terminally differentiated osteoclast is characterized as being large, multinucleated with phenotypic markers such as, tartrate-resistant acid phosphatase (TRAP), integrin ?vb3, calcitonin receptors and the ability to resorb calcified bone matrix. RANKL (receptor activator of NF-kB ligand)also known as TNF-related activation-induced cytokines (TRANCE), osteoprotegrin ligand (OPGL) or osteoclast differentiation factor (ODF) has been shown to be important in the formation differentiation and survival of osteoclasts from bone marrow cells. However, a majority of the in vitro studies carried out to study RANKl mechanism have been carried out using stem cells derived from either wild type or knockout mice. The rat has been used accepted as a preclinical model of choice osteoporosis. However, very little information has been generated on the role and action of RANKL in rat stem cell cultures. We have previously shown that in vitro cultures of adherent and non-adherent marrow cells from ovariectomized rats can be induced to form osteoclasts in the presence of platelet-derived growth factor (PDGF) and Vitamin D3. In this study we show that whole bone marrow from ovariectomized rats can be induced to differentiate in to osteoclasts in the presence of 25 ng/ml RANKL, 25 ng/ml M-CSF and 10-8 M Vitamin D3 after 6 days of culture. These cells express many of the phenotypic markers associated with osteoclasts. The addition of RANKL induces multinucleated osteoclats formation in a dose dependent fashion with optimal response at 25 mg/ml. We also show that estrogen can inhibit the formation of osteoclasts generated as a result of RANKL treatment. Our data shows for the first time that RANKL can be used to induce rat bone marrow differentiation into osteoclasts. Although rat has been the pre-clinical animal of choice in osteoporosis research majority of in vitro studies on osteoclasts have been carried out using murine cells. The relative ease of our culture conditions and the short time frame (six days) as a result of treatment with RANKL makes it possible to study rat osteoclasts formation and function in vitro.

Direct Negative Regulation of Bone Remodeling by Thyrotropin (TSH). Evidence from a TSH Receptor Knockout Mouse Displaying Increased Osteoblast and Osteoclast Formation, Osteosclerosis and Disordered Mineralization. E. Abe,[1] R. Marians,*[1] X. B. Wu,*[1] L. Sun,[1] H. C. Blair,[2] T. F. Davies,*[1] M. Zaidi.[1] [1]Endocrinology, Diabetes, and Bone Diseases; The Mount Sinai Bone Program; and the Bronx VA GRECC, Mount Sinai Medical Center, New York, NY, USA, [2]Department of Pathology, University of Pittsburgh, Pittsburgh, PA, USA.

Effects of thyrotropin (TSH) other than those on the thyroid gland itself are unknown. We report, for the first time, a direct, thyroxine-independent, effect of TSH on bone remodeling exerted *via* the TSH receptor. Thus, TSH receptor (TSH-R) null mice showed significant enhancements in osteoblast and osteoclast formation. Histostaining revealed foci of enhanced bone remodeling characterized by atypical osteoblasts and osteocytes, large osteocyte lacunae, focal osteosclerosis, and an increased diaphysial cortical thickness. Plain radiographs showed disordered mineral deposition in the femoral diaphysis and articular cartilage. To determine the skeletal localization of the TSH-R, we inserted Green Fluorescent Protein (GFP) at TSH-R gene deletion site. Multiple optical sections examined by dual photon confocal imaging revealed fluorescent periosteal mesenchymal cells in the inner table of the skull. Examination of bone marrow cultures showed intense green fluorescence in colony forming unit-fibroblast (CFU-F) colonies (at 10 days), as well as surprisingly, in osteoclast progenitors (between 4 and 6 days). This was consistent with TSH-R expression detected by RT-PCR in bone tissue and bone marrow cell cultures of wild type and not of TSH-R null mice. To understand the functional significance of TSH-R expression in bone, we examined osteoblast and osteoclast formation in bone marrow cell cultures. There was a significant, ~2-fold, enhancement of alkaline phosphatase-positive CFU-Fs, mineralizing CFU-OBs and TRAP-positive osteoclasts in both null and heterozygotic mice compared with wild type littermates. Finally, TSH-R null mice with or without thyroid supplementation showed essentially a similar phenotype. The main difference was that the femurs of those not given thyroid hormone were smaller, reminiscent of a hypothyroid state. It is notable that even the heterozygotes with normal circulating T3 and T4 displayed enhanced bone remodeling linking the observed phenotype to the TSH-R, rather than to circulating T3 or T4. We thus provide compelling evidence for the *negative, direct and simultaneous* regulation of osteoblastic bone formation and osteoclastic bone resorption by the TSH-R.

Inhibitory Effects of Minodronate (YM529) on Tumor-Induced Osteolysis in Mice with Bone Metastases. K. Shibasaki,*[1] M. Ito,[2] N. Amizuka,[2] S. Tanaka,*[1] H. Yuyama,*[1] U. Matsukawa,*[1] H. Asano,*[1] K. Miyata,*[1] H. Ozawa.[3] [1]Yamanouchi Pharmaceutical Co., Ltd., Tsukuba, Japan, [2]Niigata University, Niigata, Japan, [3]Matsumoto Dental University, Matsumoto, Japan.

The effects of minodronate (YM529), a potent third-generation bisphosphonate, on tumor-induced osteolysis caused by bone metastases in nude mice were investigated. Metastases were induced by intracardiac injection of the human breast cancer cell line MDA231 into BALB/c nu/nu mice. Minodronate was intravenously or orally given to mice after radiologically defined osteolytic metastases were observed. Histological examination confirmed that numerous osteoclastic (TRAPase-positive) cells appeared on the bone surface near the tumor. Either intravenous or oral administration of minodronate dose-dependently reduced both the number of osteoclasts and the ratio of osteoclast surface to bone surface at each tumor site. These effects were statistically significant at doses of 0.1 mg/kg i.v., 0.3 and 3 mg/kg p.o. In contrast, a dose of 10 mg/kg i.v. of pamidronate, the treatment currently available, was necessary to cause a significant decrease in the number of osteoclasts and the ratio of osteoclast surface to bone surface. The effects of minodronate on the total metastatic tumor area and ash weight of femurs were also evaluated. Minodronate at a dose of 0.1 mg/kg i.v. significantly reduced the total metastatic tumor area and slightly reversed the decrease in ash weight of normally seen in femurs with metastases. In conclusion, minodronate inhibits osteolysis in nude mice caused by bone metastases of MDA231 cells, regardless of its administration route. Consequently, minodronate holds promise as an intravenously and orally available treatment for bone lesions arising from metastases of breast tumors to bone, and may be a more effective treatment than the widely used treatment pamidronate.

Fc-Osteoprotegerin (Fc-OPG) Fusion Protein Reduces Osteoclast Numbers and Prevents Bone Destruction in Rats with Collagen-Induced Arthritis. E. Romas,[1] N. A. Sims,[1] D. Hards,*[1] M. Lindsay,*[2] P. F. J. Ryan,*[2] J. M. W. Quinn,[1] C. Dunstan,[3] T. J. Martin,[1] M. T. Gillespie.[1] [1]St. Vincent's Institute of Medical Research, Melbourne, Australia, [2]Medicine, Monash University, Melbourne, Australia, [3]AMGEN Corporation, Thousand Oaks, CA, USA.

DA rats in which collagen-induced arthritis (CIA) is induced by a single intradermal injection of type-II collagen (C-II) are a suitable model for analysis of experimental arthritis. These rats exhibit marked inflammation (paw swelling and massive leukocyte infiltration of the synovium) and skeletal damage (reduced bone mineral density and extensive bone and cartilage destruction) affecting many joints. Osteoclasts are present at sites of focal bone destruction in CIA and the infiltrating synovial cells express abundant RANKL mRNA.In this study, DA rats with CIA were treated with an Fc-OPG fusion protein (Fc-OPG) to assess whether blockade of RANKL would reduce osteoclast numbers, prevent focal bone erosion and joint destruction. Fc-OPG was administered by SC injection for up to 7 days at a dose of 3mg/kg daily beginning at the onset of paw swelling (day 14 after C-II inoculation). Osteoclasts were detected in joint tissue sections by TRAP staining. The mRNA for endogenous RANKL and OPG was detected by in-situ hybridization. Synovitis, bone erosion and osteoclast numbers were scored in a blinded fashion using a tiered, semi-quantitative grading scale. Compared to control human IgG1, Fc-OPG administration dramatically reduced numbers of osteoclasts in the juxta-articular bone. After 5 days of Fc-OPG treatment, osteoclasts were completely absent at sites of synovial/bone attachment, bone erosions were absent and joint structure was preserved. In contrast, the control animals exhibited extensive osteoclasts lying in erosive pits at the synovial-bone-cartilage junctions. The inflammatory synovitis, degree of leukocyte infiltration and levels of RANKL or OPG mRNA expression assessed by in situ hybridization within the synovial tissue were not affected by administration of Fc-OPG. Paw swelling was not significantly different between Fc-OPG and control rats with CIA. The low level of osteoclast-mediated joint destruction in the presence of continued inflammation in Fc-OPG treated CIA rats support the concept that osteoclasts principally mediate bone destruction in arthritis and indicate that Fc-OPG is able to protect bone integrity in CIA by regulating osteoclastogenesis.

Interleukin-4 Directly, and Indirectly Though TSA-1 Production by T-lymphocytes, Inhibits Osteoclast Formation. D. Mirosavljevic,* J. M. W. Quinn, N. J. Horwood,* B. J. Classon,* J. Elliott,* T. J. Martin, M. T. Gillespie. St. Vincent's Institute of Medical Research, Melbourne, Australia.

IL-4 is expressed by cells present in the bone microenvironment, in rheumatoid arthritis joints and is secreted by activated TH2 cells. IL-4 is a proliferation factor for both B and T cells, regulates macrophage differentiation and inhibits osteoclast formation. We examined the mechanism of IL-4 action on hematopoietic cells and on T and B cells to modulate osteoclast formation.To exclude potential effects of IL-4 on osteoblast/stromal cells, cultures of adult murine spleen cells from normal C57BL/6J mice were treated with M-CSF and RANKL for 7 days. IL-4 potently and dose-dependently inhibited osteoclast formation in these cultures as well as in M-CSF and RANKL treated adherent splenic cultures or spleen cultures established from Rag1 mice: both cultures are depleted of lymphocytes. The inhibitory actions of IL-4 occurred during the first and last three days of these cultures. This implied a direct effect of IL-4 on hemopoietic cells, which may result from PPARg action (PNAS 98, 2443, 2001). In contrast, in RANKL-stimulated cultures of the M-CSF independent RAW264.7 cells (ATCC) treated with IL-4, TRAP+ MNC formation increased 30% and nuclei number were also increased suggesting IL-4 may enhance cell fusion. All TRAP+ MNCs expressed CTR, confirming their osteoclast identity. Thus IL-4 has differential actions on osteoclast formation dependent upon the source of hemopoietic precursor. When T (Thy1.2+, CD4+ or CD8+), but not B, lymphocytes were added to RANKL-stimulated RAW264.7 cultures, IL-4 abolished osteoclast formation. The T cell-derived inhibitor elicited by IL-4 was concluded to be membrane associated since cultures where T cells were physically separated from RAW264.7 cells, IL-4 did not inhibit osteoclast formation, and conditioned media of T cells treated with IL-4 was also unable to inhibit osteoclast formation of RANKL-stimulated RAW264.7 cells. This contrasts with many of the known T lymphocyte-derived osteoclastogenesis inhibitors that are secreted. Using neutralising antibodies to potential candidate molecules, the membrane-associated factor was identified as TSA-1, a known osteoclast inhibitor. TSA-1 is a member of the Ly6 family and is bound to the cell surface through a GPI-anchor. Neutralizing antibodies to TSA-1 rescued osteoclast formation in RAW264.7 cultures containing T lymphocytes in response to IL-4.Thus, IL-4 has dual roles in that it can inhibit or enhance osteoclast formation depending on the cell system employed and mediates its inhibitory actions directly or through T-lymphocyte production of TSA-1.

Pyrrolopyrimidine Class Src Inhibitors Inhibit Osteoclast and Bone Metastatic Tumor Cell Functions. I. Recchia,*[1] N. Rucci,*[1] S. Migliaccio,*[1] A. R. MacKay,*[1] C. Festuccia,*[1] M. Bologna,*[1] D. Fabbro,*[2] M. Susa,[3] A. Teti.[1] [1]Experimental Medicine, University of L'Aquila, L'Aquila, Italy, [2]Oncology, Novartis Pharma, Basel, Switzerland, [3]Arthritis and Bone Metabolism, Novartis Pharma, Basel, Switzerland.

The discovery that c-Src is critical for osteoclast (OC) mediated bone resorption has had a profound impact on the field of bone biology. In this study we report the effects of novel Src inhibitors (SrcIs) of the pyrrolopyrimidine class, which reduce bone loss in ovariectomized animals, on OC and bone metastatic tumor cell behaviour. SrcIs CGP77675 and CGP76030 exhibited a concentration-dependent inhibition of OC maturation in a mouse bone marrow OC formation assay as determined histochemically and biochemically by TRAP activity. SrcIs also reduced the capacity of mature differentiated OCs to reabsorb bone in a bovine bone slice pit formation assay. SrcIs impaired OC adherence and spreading on a serum protein substrate, with a greater effect on mature vs immature cells. These two inhibitors also reduced dose-dependently proliferation of the human bone metastasis-derived prostate cancer cell line PC3 as assessed by the 3H-thymidine incorporation test. Crystal violet staining revealed that the two SrcIs reduced the capacity of PC3 cells to adhere to and spread upon a serum protein matrix in a concentration- and time-dependent manner. However, the SrcIs were modestly active at promoting PC3 cell detachment. When PC3 cells were previously attached to substrate prior to treatment with the inhibitors, crystal violet staining showed only 15% reduction of cell adherence at the highest concentration (20 uM). However, cells rounded up, confirming a role of Src on cell spreading. To evaluate the effect of SrcIs on cell invasion, we plated PC3 cells in transwells on porous membranes coated with recostituted Matrigel or gelatin substrates. Cells were then subjected to chemotaxis by inoculating in the lower compartment of the transwells culture medium previously conditioned by NIH3T3 cells. Results showed a potent concentration-dependent inhibition of PC3 cell ability to invade these substrates. In conclusion, these data highlight a role for Src activity in the regulation of OC and PC3 behaviour and, therefore, suggest a novel therapeutic avenue for Src inhibitors in osteopenic and cancer-induced bone diseases.

SA265

Tamoxifen Inhibits Acid Transport Activity and Binds Specifically to a 76kDa Protein in Isolated Osteoclast Ruffled Membranes. M. A. McKenna,*[1] J. P. Williams,[2] L. Zhang,*[1] J. M. McDonald.[1] [1]Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, [2]Department of Internal Medicine, University of Kentucky, Lexington, KY, USA.

Tamoxifen, a potent calmodulin antagonist, directly inhibits osteoclastic bone resorption by a mechanism independent of estrogen (*J Biol Chem* 1996; 271:12488-12495). However, the molecular events responsible for this inhibition are unknown. We have previously demonstrated that osteoclasts cultured on bone have increased intracellular calmodulin levels (*J Cell Physiol* 1994; 160:17-28). Furthermore, the inhibitory effects of tamoxifen on osteoclast activity are mimicked by the calmodulin antagonist, trifluoperazine. Chemical crosslinking was used to identify tamoxifen target proteins in osteoclast lysates and ruffled membrane preparations. Avian osteoclasts and ruffled membrane preparations were from egg-laying hens maintained on a calcium-deficient diet and mouse osteoclasts were differentiated from bone marrow cell preparations. Tamoxifen and trifluoperazine inhibit avian and mouse osteoclast bone resorption activity by 40-50% with IC50's of ~1.0µM, as measured by ^{3}H- proline release from labelled bone. Similarly, both agents inhibit acid transport in preparations of isolated ruffled membrane vesicles with IC50's of 0.5-2.0µM. These concentrations are similar to those that are reported to inhibit calmodulin-dependent activity in other systems. Chemical crosslinking was accomplished using tamoxifen aziridine, a modified, active tamoxifen molecule that acts as native tamoxifen, but binds covalently to tamoxifen target proteins. In intact avian osteoclasts and lysates from untreated avian and mouse osteoclasts, tamoxifen aziridine binds specifically to two proteins with molecular weights of 76 and 52 kDa. Using isolated ruffled membrane preparations from avian osteoclasts, the 76 kDa protein is the major, specific tamoxifen binding protein. The Kd for tamoxifen aziridine binding to the 76 kDa protein in isolated vesicles is ~1µM, similar to the concentrations at which tamoxifen half maximally inhibits acid transport and bone resorption. In conclusion, the direct inhibitory effects of tamoxifen on osteoclastic bone resorption and acid transport activity in isolated membrane vesicles are non-genomic and using chemical crosslinking we have identified a 76 kDa candidate protein as a potential molecular target through which tamoxifen exerts its inhibitory activity.

Fas-Mediated Apoptosis in Mouse Osteoclasts. X. Wu,* M. McKenna,* X. Feng, J. McDonald. University of Alabama at Birmingham, Birmingham, AL, USA.

The balance between bone formation and degradation is critical for maintaining bone mass. This balance is dependent upon both the number and activity of osteoblasts and osteoclasts. The cell number is determined not only by the rate of cell formation but also by the rate of apoptosis. Research in the past several years has provided greater insights into

the molecular mechanisms of osteoclast formation. However, the molecular mechanisms underlying osteoclast apoptosis remain largely unknown. Given that a) the Fas/Fas ligand (FasL) system is one of the most important systems regulating apoptosis in the development of the immune system and b) increasing evidence supports crosstalk between the immune system and bone homeostasis, we have initiated characterization of the Fas/FasL system in osteoclasts.To investigate whether Fas is expressed in osteoclasts, we generated mouse osteoclasts in vitro by treating osteoclast precursors (bone marrow macrophages) isolated from C57bl/6 mice with soluble mouse RANKL and M-CSF. RT-PCR using total RNA prepared from these osteoclasts demonstrated the presence of Fas transcripts in these cells. Furthermore, both Western analysis and immunohistochemistry showed that Fas proteins are also expressed in mature mouse osteoclasts. To determine whether Fas plays a role in regulating osteoclast apoptosis, mature mouse osteoclasts were treated with Fas activating antibody and apoptotic activity was determined by monitoring chromatin condensation by fluorescent nuclear staining. Fas activating antibody induced osteoclast apoptosis in time- and dose-dependent manners. Apoptosis of multinucleated osteoclasts was maximal at 0.5ug/ml of activating antibody with 40% of the cells undergoing apoptosis. Maximal apoptosis was seen at 18 hours after treatment with Fas antibody with no further increase at 24 hours. Interestingly, IFN-r up-regulated Fas expression dose-dependently in osteoclasts and induced osteoclast apoptosis by itself but did not sensitize the cells to Fas stimulation. IFN-r (10ng/ml) for 24 hours increased basal apoptosis 3 fold. In addition, FasL was also expressed in mouse osteoclasts as determined by both RT-PCR and immunohistochemistry, and its protein expression level could also be up-regulated by IFN-r.The observation of FasL expression and functional expression of Fas on mouse osteoclasts implies that the Fas/FasL system may play an important role in regulating bone remodeling. Furthermore, the regulation of apoptosis and Fas/FasL expression by IFN-r further supports a functional link between the immune system and bone remodeling.

Leupaxin Is a Cytoskeletal Protein in the Sealing Zone of the Osteoclast

A. Gupta,[1] B. S. Lee,[2] M. A. Chellaiah,[1] M. A. Khadeer,*[1] K. A. Hruska.[2 1]OCBS, University of Maryland, Baltimore, Baltimore, MD, USA, [2]Department of Medicine, Washington University, St. Louis, St. Louis, MO, USA.

Leupaxin (Leu), a novel cytoplasmic protein, was first identified in human (hu) macrophages, and was found to share homology with the focal adhesion protein paxillin. Leu was shown to associate with Pyk2, a member of the FAK family, and to be a substrate for a tyrosine kinase in lymphoid cells. Like other members of the paxillin superfamily, Leu possesses LIM and LD domains that have been implicated in targeting proteins such as focal adhesion kinase (FAK) to focal adhesions. Cross-species conservation of the LD motifs and sequence differences therein, are critical determinants of unique distribution and specificity of functions of these "adaptor" molecules. We have now cloned Leu from an osteoclast (OC) cDNA library (Leu-OC) as a 1.9 kb clone, comprising a 5' untranslated region of 72 bases, followed by 1161 bases of coding region, and 540 bases of 3' untranslated region. The overall amino acid identity between the OC and the hu-macrophage form of Leu was found to be 90%. In our preliminary studies, we have reported that Leu-OC is associated with Pyk2, similar to its association in macrophages. Although Leu-OC contains 10 tyrosine residues, sequence analysis of the Leu-OC amino acid sequence identified only tyrosines #9 and #10 as being potential phosphotyrosine sites. Treatment of osteoclasts (OCs) with TNF-alpha, a potent activator of osteoclastogenesis, and which is known to cause cytoskeletal rearrangements in macrophages, stimulated tyrosine phosphorylation of Leu-OC. We found Leu-OC to co-immunoprecipitate with the protein tyrosine phosphatase PTP-1B in murine OCs, although we have not determined whether Leu is indeed a substrate for PTP-1B. In hu-macrophages, both Leu and PTP-1B colocalized at the cell periphery. Furthermore, Leu-OC was also found to associate with FAK, the paxillin kinase linker p95PKL, and the ARF-GTPase PAK in murine OCs. In addition, Leu-OC was found to coimmunoprecipitate with the recently characterized focal adhesion protein called actopaxin, which has the ability to bind actin through its calponin-homology domains. Finally, we found that Leu-OC is distributed to actin-rich areas in the cell periphery of hu-OC, particularly those associated with the specialized adhesion structures known as podosomes. The localization of Leu to the OC podosomal complex may be explained by its putative association with actopaxin. These results indicate that Leu, which is a cytoskeletal protein preferentially expressed in hematopoietic cells, is likely to play a crucial role in adhesion and motility of the osteoclast.

Bone Mass in Women With Their First Acute Coronary Ischemic Episode. C. Valero,* J. A. Riancho,* L. Perera,* J. L. Olmos,* J. A. Amado,* J. González Macías.* Internal Medicine, Hospital Universitario Marques de Valdecilla, Santander, Spain.

Objective: To know if women with their first acute coronary ischemic episode have a low bone massPatients and methods: 28 women with first myocardical infarction or unstable angina and 47 normal women matched by age(range 40-75 y.) were studied. BMD at the spine and hip (Hologic QDR 4500) and QUS at the calcaneous (Sahara) were measured .BMI, smoking habit (considered as yes or no) and time since menopause were also noted. Results: No differences in age or time since menopause were found between both groups. However ,both BMI and smoking habits were higher among patients.BMD was similar in both groups (table 1).

*** T Student ** Chi2**

	Controls	Patients	P
Age (years)	59.7 ± 8.9	61.8 ± 10.0	0.34
BMI(Kg/m2)	25.4 ± 4.1	29.9 ± 5.3	<0.05*
Smoking habits	8/47	7/28	<0.05**
Years since menopause	10.8 ± 6.8	14.6 ± 10.1	0.21
Z-score spine	-0.08 ± 1.13	-0.01 ± 1.31	0.81
Z-score hip	0.35 ± 1.01	0.60 ± 0.97	0.30

After adjusting for BMI and smoking habit,the lack of difference persisted. Conclusion: We have found no differences in bone mass between women with their first acute coronary syndrome and normal women matched by age. However, they differed in BMI and smoking habits, and therefore new studies may be needed to further clarify the relationship between bone mass and atherosclerosis in wome

Recreational Physical Activities Are Associated With Increased Bone Mineral Density in Elderly Chinese in Beijing: Beijing Osteoarthritis Study. L. Xu,*[1] Y. Zhang,[2] D. Felson,[2] M. Qin,*[3] W. Yu,*[3] L. Lui,*[3] S. Cummings,*[4] M. Nevitt.*[4 1]Dept of Obstetrics and Gynecology, Peking Union Medical College Hospital, Beijing, China, [2]Rheumatology, Boston University School of Medicine, Boston, MA, USA, [3]Peking Union Medical College Hospital, Beijing, China, [4]University of California at San Francisco, San Francisco, CA, USA.

While several studies have shown that low levels of physical activity may contribute to decreased bone mineral density (BMD) in women, the epidemiologic evidence has not been consistent. To date, few studies have evaluated the effects of occupational and recreational physical activities simultaneously on BMD among elderly, especially elderly men. We examined the effects of these two types of activities on BMD among Chinese men and women in Beijing, China, a population with high levels of physical activity. Residents (age >60 years) were recruited door-to-door in randomly selected neighborhoods. Of those contacted, 82% (n=2,048) completed an interview and had BMD measured at hip and spine using a Lunar DPX-L or Lunar Prodigy. A cross-calibration study (40 subjects) was done to estimate Prodigy equivalent BMD from DPX measurements. For each subject, data was collected on past occupational physical activities performed daily, including walking >2 miles, standing >2 hours, digging >2 hours, kneeling or squatting >30 minutes, climbing up or down >10 flights, or lifting >10 kg objects. We also inquired into the nature of and time spent on current recreational physical activities. For each gender, we examined each activity in relation to total hip and spine (L1-L4) BMD adjusting for age, height, BMI, education, smoking, health status and densitometer using a linear regression model. There was little relation of past occupational activities on BMD at the hip and spine. In contrast, time spent on recreational activities was associated with an increased BMD in men and a threshold effect of recreational activities (> 10 min/day) on BMD in women.

Adjusted Mean of BMD

	Men (n=827)			Women (n=1221)		
Time spent on recreational physical activity (min/day)	N	Hip	Spine	N	Hip	Spine
None	484	0.920	1.079	823	0.803	0.890
10-30	76	0.931	1.088	61	0.825	0.922
31-60	135	0.939	1.095	85	0.824	0.917
>60	132	0.941	1.113	152	0.822	0.909
P for trend		<0.033	<0.049		<0.005	<0.012

The specific recreational activities related to an increased BMD were running, Taichi and stretching in men (differences in mean BMD ranging 2.2%-7.6% in hip, 2.5%-3.1% in spine), and Taichi and stretching in women (differences ranging 2.0%-2.5% in hip, 2.0%-3.8% in spine). In conclusion, time spent on current recreational physical activities instead of past occupational physical activities was associated with increased BMD among elderly men and women in Beijing

SA273

Study of Bone Health Among Middle-Aged Chinese Canadian Immigrants. A. M. Cheung,[1] G. Chan,*[2] E. Fuller-Thompson,*[1] J. Law,*[1] C. Chan,*[1] D. Lui-Yee,*[1] N. Forde,*[1] N. Diaz-Granados,*[1] R. Chaudhry,*[1] A.

Shik,*[1] L. Thompson.*[1] [1]University of Toronto, Osteoporosis and Women's Health, University Health Network, Toronto, ON, Canada, [2]Yee Hong Community Centre, Toronto, ON, Canada.

The purpose of this community-based cross-sectional study is to examine the risk factors for osteoporosis and osteoporotic fractures and the prevalence of osteoporosis among middle-aged Chinese Canadian immigrants. We recruited community-dwelling individuals aged 45 and over through newspaper, radio and television announcements, as well as posters in community centres in the Greater Toronto Area. Interviews were done in person at a community centre or hospital, and data were collected on demographics, risk factors for osteoporosis and osteoporotic fractures, calcium intake, physical activity, medication use, comorbid conditions, and fall and fracture history. Data was collected on height and weight and heel bone density measured using the Sahara ultrasound device (Hologic, Inc).A total of 491 individuals (334 women and 157 men) aged 44 to 94 (mean age = 60) were included in our study. Approximately 3/4 immigrated from Hong Kong, and the rest mainly from China and Taiwan. On average, the participants have been in Canada for 11.5 years (range = 2 months to 46 years). Less than 2% are current smokers and 10% are ex-smokers. Common reported comorbid conditions include hypertension (29%), hypercholesterolemia (18%), diabetes (9%), gastrointestinal diseases (8%), lung disease including asthma and COPD (7%), coronary artery disease (7%), liver disease (3%), and stroke (3%). Among the 334 women, 290 had children and 57% of these breastfed. Mean age at menarche was 13.6 years and over 70% of the women were postmenopausal (mean age at menopause = 48 years). Approximately a quarter of the participants have had at least one accidental fall and one fifth report a family history of osteoporosis. For women, average height and weight were 61 inches and 121 lbs, and average heel BMD was 0.509 g/cm2 with a T-score of -0.63. For men, average height and weight were 66 inches and 144 lbs, and average heel BMD was 0.511 g/cm2 with a T-score of -0.62. Overall, 4% of women and 2% of men had T-score at or below -2.5 and 39% of women and 41% of men had T-scores between -1 and -2.5.This is the first community-based study of bone health among Chinese immigrants in Canada. In this sample of Chinese Canadian immigrants, the prevalence of osteoporosis among men is similar to what has been described for the Canadian population in general, however, the prevalence of osteoporosis among Chinese Canadian women is less than would be expected. Further study is needed to compare the characteristics of this population to that of the general Chinese immigrant population in Canada.

Effects of Pregnancy, Risk Factors and Calcium Intake on Bone Mass in a Sample of Venezuelan Women. G. A. Galue, L. Mora,* C. Padron,* M. Camacho.* Centro de Ultrasonido Oseo, Maracay, Venezuela.

There have been conflictive reports on the effect of pregnancy and calcium intake on bone mass. This study aimed to elucidate the effects of pregnancy on bone mass ascertained by quantitative ultrasonometry (QUS) and on a basic biochemical profile in a group of healthy Venezuelan women. A group of 30 pregnant Venezuelan women (mean age of 26.23+/-7.26 SD years) in their second trimester underwent ultrasonometry at the heel (Achilles Express, Lunar Corp). Laboratory tests to determine serum calcium, serum phosphorus and total alkaline phosphate were performed at the beginning of the second trimester of pregnancy and during the third. A questionnaire on estimated calcium intake and risk factors for low bone mass was done. The ultrasonometry variables-speed of sound, broadband ultrasound attenuation, and Stiffness Index-were measured during the second and third trimester. Our results showed that the incidence of risk factors for low bone mass during the second and third trimester of pregnancy were: coffee intake of more than 3 cups/day (33 %), unspecified upper tract digestive disorders (33%), body weight under 45 kilograms (20%), family history of osteoporosis (20%), past use of glucocorticoids (20%). 43.3% of the women reported inadequate calcium intake. 46.6% had past history of oral contraceptive use and 60 % did not perform regular physical activity. There was a significant decrease in the total serum calcium (9.19 mg/dl vs. 8.39 mg/dl p<0,0001), increase of total alkaline phosphate (36 IU/l vs. 40,86 IU/l, p<0,0512) and decrease of the Stiffness Index (90,49 vs. 86,51, p<0,0379). Our study shows that in a sample of Venezuelan pregnant women there is a decrease in bone mass during the second and third trimester of pregnancy which can be safely assessed by quantitative ultrasonometry at the heel and that during this period there is a high bone turnover as can be inferred through a basic biochemical profile. Low calcium intake, sedentary lifestyle, high coffee intake and digestive disorders are frequent in this group of women.

SA276

The Hip Bone Mass of U.S. Adults Living in the First Half of the 20th Century. W. E. Duncan,[1] L. W. Poulsen,*[2] D. L. Stott,*[1] A. S. Chang.*[3] [1]Department of Medicine, Walter Reed Army Medical Center, Washington, DC, USA, [2]Department of Forensic Medicine, University of Aarhus, Aarhus, Denmark, [3]Department of Clinical Investigation, Walter Reed Army Medical Center, Washington, DC, USA.

Osteoporosis is a significant health problem for modern populations. The study of the bone mass of past populations may give insights into the influence of current lifestyles on bone health. Therefore, the bone mass of 293 femora (from 49 Black men, 96 White men, 51 Black women, and 97 White women) from a well-characterized and preserved group of American skeletons (the Terry collection, Smithsonian National Museum of Natural History) was measured by DEXA (Hologic QDR-2000). The bone mass was then compared to the hip bone mass of a recent (1988-1991) American population sample (NHANES III). The age of the Terry collection subjects was 52.6 ± 15.7 (mean ± 1SD) years (range: 20-89), the date of birth was 1885 (range: 1843 to 1934) and the date of death, 1938 (range: 1921 to 1965). The bone mass (gms/cm2) of the total hip was higher in the Black men (1.072 ± 0.159) and lower in White women (0.703 ± 0.149) than in Black women (0.887 ± 0.160) or White men (0.946 ± 0.127) (p<0.01). This trend was observed at the femoral neck, trochanter, intertrochanter, and Ward's triangle. Loss of bone mass with age was observed in all four gender/ethnic groups. Compared to the NHANES III reference population, the total hip bone mass of the Terry collection femora was 1.05 ± 0.10 SD lower for White women (p<0.0001), 0.42 ± 0.11 SD lower for Black women (p<0.001), 0.19 ± 0.08 SD lower for White men (p=0.03) and unchanged (+0.04 ± 0.12) for Black men. These differences were constant from the third through the ninth decade of life. Similar differences were observed at the other regions of the hip and could not be explained by differences among the study subjects in the date of death, body weight, cause of death or the size of their femurs. From 1938 to 1990, American women have significantly increased the bone mass of their femurs. This improvement was greatest for White women. While the explanation for these findings are likely to be multifactorial, the use over the last 60 years of hormone replacement therapy and possibly oral contraceptives is most likely the major reason for the observed improvement in bone health of American women.

SA277

Relationships between Anthropometric and Bone Mineral Density Variables Differ between Men and Women in the Early Adult Years. J. M. Beiseigel,* S. M. Nickols-Richardson. Human Nutrition, Foods and Exercise, Virginia Polytechnic Institute and State University, Blacksburg, VA, USA.

Osteoporosis prevention for both males and females is important; however, strategies for osteoporosis prevention among men and women may differ depending on relevant anthropometric and body composition variables. The purpose of this study was to investigate relationships between anthropometric measures, body composition variables, and bone mineral density (BMD) among men (n = 29; age = 22.7 ± 0.6 years; mean ± SEM) and women (n = 60; age = 20.3 ± 0.2 years) in their early adult years. Body height and weight were measured by an investigator. BMD of the total body (TB), lumbar spine (LS), nondominant total proximal femur [TPF, including Ward's triangle (WT), femoral neck (FN), and trochanter (Troch)] and nondominant forearm [including ultra-distal (UD), mid, and proximal regions] were measured by dual energy X-ray absorptiometry (DXA). Fat mass (FM), fat-free soft tissue mass (FFST), and percent body fat (%BF) were calculated from TB DXA scans. Correlation analyses showed that for men, height and FFST were positively associated with TB BMD ($r = 0.38$; $p < 0.05$ and $r = 0.31$; $p < 0.05$, respectively). In men, %BF was negatively associated with TB ($r = -0.37$; $p < 0.05$) and Troch BMD ($r = -0.42$; $p < 0.05$). Among women, body weight was positively associated with TB ($r = 0.28$; $p < 0.05$), LS ($r = 0.36$; $p < 0.01$), TPF ($r = 0.48$; $p < 0.001$), FN ($r = 0.34$; $p < 0.001$), Troch ($r = 0.40$; $p < 0.01$), and UD BMD ($r = 0.29$; $p < 0.05$). In women, FFST was positively associated with TB ($r = 0.38$; $p < 0.001$), LS ($r = 0.35$; $p < 0.01$), TPF ($r = 0.52$; $p < 0.001$), WT ($r = 0.26$; $p < 0.05$), and FN BMD ($r = 0.34$; $p < 0.001$). FM was positively associated with Troch ($r = 0.28$; $p < 0.05$) and UD BMD ($r = 0.31$; $p < 0.05$) in women, and %BF was positively associated with UD BMD ($r = 0.31$; $p < 0.05$) in women. Among these young adults, FFST was positively associated with measures of BMD for both men and women. In men, however, height was positively associated with TB BMD while for women, body weight, FM, and %BF were positively related to measures of BMD. These results suggest that for both men and women, maintaining or increasing FFST, such as skeletal muscle, appears beneficial for bone and osteoporosis prevention. For men, a lean body composition (i.e., lower %BF) may be beneficial, while among females, overall body weight, either from FM or FFST may be important to BMD and osteoporosis prevention.

Association of Weight with Bone Mineral Density in Older African Americans. J. Robbins,*[1] C. Hirsch,*[1] J. Cauley,[2] T. Harris.[3] [1]Internal Medicine, UC Davis, Sacramento, CA, USA, [2]Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, [3]Geriatric Epidemiology, National Institute on Aging, Bethesda, MD, USA.

Purpose: To assess correlates of bone mineral density (BMD) in African American (AA) men and women over the age of 64.**Methods:** Two sites of the Cardiovascular Health Study (CHS) (Pittsburgh PA and Sacramento CA) evaluated BMD by DEXA in 304 AAs. CHS is an observational study of older Americans. In 1995-6 DEXAs were obtained as well as medication usage, and multiple cardiovascular risk factors, demographic, physiologic variables, including estrogen use, diabetes, depression, alcohol use, self reported health. Correlation coefficients were calculated for multiple independent variables compared to BMD in the PA lumbar spine and total hip. Those that showed even marginal significance (p<0.1) were tested in sex stratified liberally configured linear regression models. (Backwards stepwise, p<0.1 to enter, 0.2 to remove.)**Results:** The study included 187 women and 119 men with an mean age of 75, range 67 to 96. The means and standard deviations for the BMDs were Spine: 1.11 (±0.26) gm/cm2, Total Hip: 0.92(±0.18)gm/cm2 . Gender was significantly associated with BMD (t-test, p<0.001). R2 for variables which stayed in the model are:

	TOTAL HIP	LUMBAR SPINE	TOTAL HIP	LUMBAR SPINE
	WOMEN		MEN	
WEIGHT	22%***	16%	27%***	

AGE	2%*		9%
IADL	1%		
ESTROGENS	1%		
FAMILY INCOME		2%	

Women only *p<0.05, **p<0.01, ***p<0.0001The mg/cm2 change in BMD per lb of weight ranged from: 2.4 to 3.1 **Conclusions:** As expected gender is associated with BMD. In this elderly population age is less important than might be predicted. In older AAs most of the identified variance in BMD is associated with weight. Fully 27% of BMD of the hip in AA men and 22% in women could be explained by weight. Thin older AA men and women are at significantly increased risk for low BMD and likely more risk for fracture

SA279

Mid-Life Muscle Mass Decrease. K. M. Davies,[1] R. P. Heaney,[2] R. Ryan,*[1] K. Rafferty.*[1] [1]Osteoporosis Research Center, Creighton University, Omaha, NE, USA, [2]John A. Creighton University Professor, Creighton University, Omaha, NE, USA.

A cohort of healthy, active, nulliparous white women (The Omaha Nuns) has been studied for 34 years to understand calcium metabolism, bone health, and menopause. For the first 25 years, participants had 8-day inpatient balance studies every five years with detailed analysis of diet on study. This period largely predated the scanner era, when body composition measurements have become routine. We have investigated urine creatinine as a surrogate of muscle mass in a subcohort of 131 women who averaged 4 visits each. Using a regression of urine creatinine on meat protein eaten (Urine creatinine = 0.909 + 0.00739 * Meat_Protein), we determined Residual Creatinine as Urine creatinine - 0.00739*Meat_Protein, which we took to be a better surrogate, and expressed all values in terms of each woman's peri-menopausal baseline value. Aggregating by age groups (40, 45, 50, etc) or by time with respect to menopause or including only those with natural menopause, we found virtually indistinguishable linear declines from age 45 to age 65 with no menopausal effect. The rate is -0.69 %/y (95%CL: -0.79,-0.59) The figure illustrates the linearity of the aggregate data. Conclusion: Muscle mass in these women decreased at the rate of -0.7 %/y.

More Evidence for the Beneficial Effects of Moderate Alcohol Intake and Adverse Effects of Caffeine Consumption on Bone Mass in Postmenopausal Women. J. Z. Ilich, R. A. Brownbill. University of Connecticut, Storrs, CT, USA.

It is well established that excessive alcohol and caffeine consumption, as well as cigarette smoking have detrimental effects on bone. Some studies however, report that moderate alcohol intake may be beneficial for bone, and moderate coffee consumption with, otherwise adequate calcium (Ca), may not adversely affect bone. The purpose of our study was to determine the relationship between alcohol, caffeine, cigarette smoking and bone mineral density (BMD) of different skeletal sites in healthy, Caucasian, women, n=136, age 68.6±7.1 y (mean±SD), not taking any medication known to affect bone. Alcohol and caffeine consumption was assessed using questionnaires designed to determine frequency, amount, and source of each. Additionally, 3-day dietary records were collected for more complete assessment and Ca intake. History of smoking was recorded and the years of smoke exposure (SE) calculated. BMD of various skeletal sites was measured by a Lunar DPX-MD densitometer (Lunar Corp., Madison, WI). Mean Ca intake was 834±365 mg/d (range 250-1857). Mean alcohol and caffeine consumption was 5.2±9.9 g/d and 210±188 mg/d, respectively. 46% women consumed wine as a main alcohol source, while 11% and 5%, consumed liquor and beer, respectively. 36% women did not drink any alcohol. 63% women consumed coffee as a main caffeine source, while 13% and 2%, consumed tea and soda, respectively. 20% women did not consume any caffeine. There were no current smokers and 54% of women never smoked. The average SE was 11.5±20.7 y*package, (range 0-102). Multiple regression models were constructed in which alcohol, caffeine and SE were regressed on BMD of different skeletal sites. Each model was corrected for age, weight and dietary Ca. The results showed statistically significant positive effect of alcohol and Ca intake and negative effect of caffeine intake on all regions of spine and total body BMD, with R2(adjusted) ranging from 19% to 35%. This effect was less significant in the models with forearm and non-existent in the models with hip BMD. SE did not show statistically significant effect on any of the skeletal sites examined. Our data indicate the beneficial effect of moderate alcohol, mostly consumed as wine, on BMD of spine and total body. The negative effect of caffeine could have been exacerbated by the relatively low Ca intake in our population (as Ca showed strong positive effect on BMD of all measured skeletal sites). The lack of association between SE and BMD could be due to the fact that majority of women have never smoked and those who have, were not heavy smokers. More investigation is necessary to clarify the above relationships.

Secondary Causes of Hip Fracture in Community-Dwelling Patients. L. A. Fitzpatrick,[1] J. Loftus,*[2] M. Faurot,*[1] M. Bolander.[2] [1]Department of Medicine, Mayo Clinic, Rochester, MN, USA, [2]Department of Orthopedics, Mayo Clinic, Rochester, MN, USA.

Mortality due to hip fractures can exceed 20% in one year and less than one-third of patients regain their independence. To determine the potential for prevention of hip fractures in a community population, we assessed laboratory values for bone loss in all patients sequentially admitted to our medical center for hip fracture. Patients with trauma as a cause were excluded and a total of 33 patients were tracked through the daily surgical list. Baseline demographics were collected by chart review and bedside interview. All patients had BMD measurements, basic laboratory parameters and a follow-up appointment with an endocrinologist, with a speciality interest in bone metabolism, at 6 to 8 weeks post fracture. Average age was 79±8 years with 30% male and 70% female distribution. Average serum calcium was 9.7±0.43 mg/dl, phosphorus 3.49±0.47 mg/dl, 25(OH)D 17.2±6.3 ng/ml, urinary Ca 114±96 mg/24h, PTH 3.5±3.0 pmol/ml, NTX 509±482, BMD LS 0.88±0.23 (T-score -1.9±1.6), BMD FN 0.49±0.15 (T-score -1.91±1.3). 55% of patients had had a prior fracture (12% ankle, 18% hip, 3% pelvic, 27% Colles'). In spite of this, only 9% of patients were aware that they had a diagnosis of osteoporosis. Only 3% were chair- or bedridden and could not ambulate without assistance. Regarding recognized secondary causes of bone loss, 3 patients had been on long-term glucocorticoids and 1 was hypogonadal (prostate cancer). Laboratory evaluation revealed that 4 patients were hypercalcemic and 4 had secondary HPT with elevated PTH levels. 13/33 had U_{CA} <100 mg/24h. One patient had an elevated TSH level. 22 of 32 (69%) patients had 25(OH)D levels ≤20 ng/ml and 5/32 (16%) had levels ≤12 ng/ml. In addition, 7/30 (23%) had $1,25(OH)_2D$ levels ≤15 pg/ml. By T-score criteria, (<-2.5), 11/30 at LS, 11/22 at FN and 27/30 (90%) at any site (LS, FN, Ward's, total hip Troch, Inter), who met criteria for osteoporosis. In community-dwelling subjects with hip fx, there is a high incidence of abnormal laboratory tests (77%) that are correctable with appropriate treatment. Patients with hip fx commonly have secondary causes of bone loss and require careful metabolic evaluation. Targeting patients with prior fx may provide an early intervention for reversal of secondary causes and prevent future hip fxs.

Predictive Demographics in 200 Consecutive Community-Dwelling Residents With Hip Fracture. L. A. Fitzpatrick,[1] J. Loftus,*[2] M. Faurot,*[1] M. Bolander.[2] [1]Department of Medicine, Mayo Clinic, Rochester, MN, USA, [2]Department of Orthopedics, Mayo Clinic, Rochester, MN, USA.

Hip fracture results in significant mortality and morbidity in elderly patients. In order to understand the risk factors for hip fracture in a community population, we evaluated all consecutive community hip fracture (fx) patients admitted to our medical center. Patients with trauma as a cause were excluded and 200 patients were tracked through the surgical register and cases confirmed by operative reports. Baseline demographics were collected by chart review and bedside interview. The average age was 73±12 and 67% of the patients were female. Average BMI was 26.09±7.62. Remarkably, 41% of the patients had a prior fracture. Previous Colles' fracture (25%) was predominant followed by contralateral hip fracture (13%), ankle fracture (9%), pelvic fracture (2%), and vertebral fracture (2%). In spite of the large number of prior fxs, only 16% of subjects had a prior diagnosis of osteoporosis. Baseline demographics revealed that 27% of the patients had dementia/chronic brain syndrome; 10% had a history of transient ischemic attacks and only 2% complained of vertigo. Only 1% of 200 patients had problems such as Parkinsonism or ataxia. Gait instability, focal cortical degeneration and functional gait problems were each less than 1%. Of the 122 patients with interview information regarding ambulatory status, only 2% were chair- or bedridden prior to fracture; 24% were community ambulators, 35% were home ambulators, and 23% of patients were fully active and brisk walkers.In summary, a large number (41%) of patients with hip fx had prior fx, especially Colles' fx (25%). Few patients were bed- or chair-bound prior to fx and vertigo was rare at the time of fx. Organic brain syndrome/dementia was associated with fracture in one-quarter of the cases. These data suggest that selective interventions for patients with dementia may also reduce hip fxs and early intervention in patients with a prior fracture may be important to prevent future

hip fractures.

SA288

Accuracy of Physical Examination for Detection of Thoracic Vertebral Fractures. K. Siminoski,[1] R. Warshawski,*[2] H. Jen,*[2] K. Lee.*[3] [1]Endocrine Centre of Edmonton and Medical Imaging Consultants, Edmonton, AB, Canada, [2]Medical Imaging Consultants, Edmonton, Canada, [3]Endocrine Centre of Edmonton, Edmonton, Canada.

Vertebral fracture is the most common type of broken bone in osteoporosis patients. Little information is available about the accuracy of physical examination in detecting such fractures. We have assessed two simple physical examination maneuvers for their accuracies in determining the presence of thoracic vertebral fractures. The maneuvers were measurement of (1) kyphosis angle (KA) from T4 to T12, quantified with a handheld digital inclinometer (in degrees), and (2) wall-occiput distance (WOD), quantified with a tape measure, as the distance from the wall to the occipital prominence with the patient standing, heels to the wall, looking straight ahead (in cm). A total of 216 women referred for assessment of osteoporosis were studied. The average age was 53 years (range: 18 to 92). Vertebral fracture was defined as a decrease in vertebral height of 20% or more on lateral radiographs (from T4 to T12 for the purposes of this study). One or more thoracic fractures were present in 29% of subjects. Among those with fractures, the average number of fractures was 1.9. KA and WOD were correlated ($r = 0.32$; $p<0.0001$). Both KA and WOD increased with age in those without fractures ($r = 0.29$ and 0.34; $p < 0.001$ for both) The areas under the receiver operating characteristic curves were 0.71 (95% CI: 0.61-0.80) for KA and 0.74 (0.66-0.83) for WOD. Accuracy results are shown in the first table. Likelihood ratios are in the second table. Upper cut-off points were present that produced very high LRs, but there were no lower cut-offs that produced very low LRs.The following applications can be made from this data. KA > 43^o or WOD > 7.0 cm rules in a fracture with a high degree of accuracy. KA < 20^o or WOD = 0 reduces the chance of fracture, but does not reliably rule it out These results show that physical examination of the thoracic spine using simple methods can produce clinically useful accuracy in detecting thoracic vertebral fractures. KA and WOD should be incorporated into the routine physical examination of osteoporosis patients.

KA (o)	Sens	Spec	PPV	NPV
>43	22	99	85	78
>30	63	81	55	86
>20	84	28	30	83
WOD (cm)	Sens	Spec	PPV	NPV
>7	21	99	92	76
>3	38	93	69	79
>0	60	87	65	85

Sens = sensitivity. Spec = specificity. PPV = positive predictive value. NPV = negative predictive value.

Predictors for Atraumatic Vertebral Fracture in Japanese Women as Assessed by Dual Energy X-ray Absorptiometry. T. Ogawa,*[1] S. Takata,[1] H. Yonezu,*[2] N. Yasui.*[1] [1]Orthopedic Surgery, The University of Tokushima, Tokushima, Japan, [2]Orthopedic Surgery, Oe Kyodo Hospital, Oe, Japan.

We clarified the characteristics of bone mineral density (BMD) and soft tissue composition in Japanese women with atraumatic vertebral fractures (AVF). Sixty-four women, 55 to 75 years of age, were divided into two groups: women with AVF (fracture group, n=30) and women without AVF (non-fracture group, n=34). The BMD of the 2nd to 4th lumbar vertebrae (L2-4BMD), the BMD of the head, arms, legs, ribs, thoracic vertebrae, lumbar vertebrae and pelvis as well as the lean mass and the fat mass of the head, arms, legs, and trunk were measured by dual energy X-ray absorptiometry. L2-4BMD, total body BMD and BMDs of the lumbar spine, thoracic spine and pelvis of the fracture group were significantly lower than those of the non-fracture group ($P <0.001$). The total as well as regional lean and fat mass did not differ significantly between the two groups. However, total lean and fat mass of the fracture group tended to be lower than that of the non-fracture group. We conclude that the BMD of weight-bearing bones, except for the bones of the legs of the fracture group, is significantly lower than that of the weight-bearing bones in the nonfracture group.

SA292

Cost of Hip Fractures and Estimate of Treatment Cost Effectiveness in Wisconsin Nursing Home Residents. M. E. Elliott,[1] L. D. Willsey,*[1] P. B. Beutel,*[2] D. R. Zimmerman,*[2] A. Gudmundsson,[3] P. D. Meek.*[1] [1]School of Pharmacy, University of Wisconsin, Madison, WI, USA, [2]Center for Health Systems Research and Analysis, University of Wisconsin, Madison, WI, USA, [3]Hrafnista Nursing Homes, Reykjavik, Iceland.

Residents in long term care facilities (LTCF's) have a 3-11 fold higher fracture risk than community-dwellers, but osteoporosis in LTCF's is rarely assessed. Economic constraints likely contribute to this lack of attention. It is unknown whether management of osteoporosis in LTCF's is cost-effective. Goals of this project were to estimate the cost of hip fractures occurring in Wisconsin LTCF's and the number needed to treat to prevent one hip fracture.To estimate hip fractures for 1999, we used fracture data from 95 not-for-profit LTCF's that constitute 30% of Wisconsin LTCF beds. Costs were obtained by combining hospital costs and LTCF charges above baseline after fracture. Fractured LTCF residents were assumed to incur hospital costs similar to Wisconsin community-dwellers. For incremental LTCF costs after fracture, mean daily cost for all non-Medicare residents ($109) was subtracted from the mean Medicare charge of $232 for the first 20 days post discharge to LTCF. To estimate number needed to treat (NNT), we assumed that there was a 20% annual death rate, that transfer independence and below-median bone density increased fracture risk 3-fold, and that alendronate reduced risk 50%.Based on a 2.8% annual hip fracture rate, an estimated 1120 hip fractures occurred in the 40,000 Wisconsin LTCF residents in 1999. Costs of $12,849 per fracture were based on hospital costs of $8477, in-hospital MD fees of $1912 and incremental LTCF costs of $2460. Total costs estimated for hip fractures for Wisconsin LTCF's in 1999 were $14,390,000. NNT for one year to prevent one hip fracture was 26. The model assumed that alendronate treatment of 100 high-risk residents (see above) reduced hip fractures from 8.4 to 4.2 per year. NNT to prevent any clinical fracture would be substantially lower than the estimate of 26.To our knowledge this report is the first to estimate combined cost of hospitalization, MD costs, and LTCF costs of hip fracture, as well as NNT in LTCF's. Direct medical costs for hip fracture were substantially less than that for hip fractures in community-dwellers (~$25,000). This is largely because estimates for community-dwellers include LTCF costs after fracture. Despite the lower figure of $12,849 per hip fracture occurring in LTCF's, the overall cost is considerable, because of the very high fracture risk in LTCF's.Given the high risk and high cost for hip fractures in LTCF's, and a relatively low number needed to treat, further research on assessment and treatment of osteoporosis in LTCF's is warranted.

Disclosures: Merck,2,5; Aventis,2; Novartis,2.

The Expected Cost of New Fractures in the Year Following a Vertebral Fracture. R. Lindsay,[1] R. T. Burge,*[2] D. M. Strauss.*[2] [1]Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Vertebral fractures are believed to be important predictors for future vertebral and other fractures, leading to at least a 4 to 5-fold increase in the risk of subsequent fractures. However, healthcare payers and providers generally view vertebral fractures as being relatively unimportant from a cost perspective. The purpose of this study was to estimate the expected costs of all new fractures occurring within one year of an incident vertebral fracture among osteoporosis patients. A probabilistic decision tree model was developed to identify the expected cost of all subsequent fractures emanating from an incident vertebral fracture event. A total of 381 subjects in the placebo arm (Ca + Vit D) in the risedronate VERT and HIP studies with incident vertebral fractures were identified and followed up for 1 year. Kaplan-Meier time-to-event models were used to estimate the cumulative incidence of new vertebral, hip, wrist, and other fractures occurring within one year of the incident vertebral fracture. Expected costs for each fracture type were obtained from published literature and national hospital discharge database analyses. The 1-year probability of any new fracture was 26.1% (17.3% vertebral; 3.6% hip; 3.5% other (humerus/leg); 1.6% wrist). The unit costs for each fracture type used in the analysis were $36,864 (hip), $1,880 (vertebral), $1,740 (forearm/wrist), and $3,950 (other). For patients with a subsequent fracture the weighted cost was $7,004 during the course of the year of follow-up. Overall the calculated cost of new fractures within one year of an incident vertebral fracture was estimated at $1,828 per patient (excluding the costs of the index vertebral fracture); a weighted average of fracture patients ($7,004; 26.1%) and non-fracture patients ($0; 73.9%). All patients were assumed to not receive any osteoporosis therapies in the model. All patients with incident vertebral fractures are at a 4-5-fold higher risk of a subsequent vertebral fracture within the following 12 months. This analysis predicts that the expected cost of subsequent fractures over the next 12 months following an incident vertebral fracture is $1,828 averaged over all vertebral fracture patients. These results should alert health care payers and providers to both the clinical need for, and economic benefits in, proactively treating vertebral fracture patients to prevent additional, costly fractures associated with osteoporosis.

SA296

Bone Loss Following Fracture of the Tibial Shaft. S. C. Findlay,* R. Eastell, B. M. Ingle. Division of Clinical Sciences, University of Sheffield, Sheffield, United Kingdom.

Delayed union and non-union are common complications after fracture of the tibial shaft. Healing of the fracture could be monitored non-invasively using techniques currently used in the study of osteoporosis. The aims of our study were 1) to evaluate the decrement in bone measurements made close to the fracture using dual x-ray absorptiometry (DXA), quantitative ultrasound (QUS) and peripheral quantitative computed tomography (pQCT); 2) to calculate the short term precision for BMD, QUS and pQCT and 3) to calculate the ratio of decrement to precision (response ratio) to determine the optimal test for monitoring changes after tibial fracture. We recruited 28 subjects (14 women, 14 men, ages 17 to 78 years, mean 41) following a fracture of the tibial shaft. BMD of the hip, ultra-distal tibia and fibula (UD) and heel were measured by DXA (Hologic 4500/A). pQCT of the distal tibia and fibula and proximal tibia and fibula (10% site) were measured using the Norland Stratec XCT 2000. Speed of sound (SOS) and broadband ultrasound attenuation (BUA) of the heel were measured using the Lunar Achilles + (LA+) and DMS UBIS 5000 (UB). SOS was also measured at the mid-tibia using the Sunlight Omnisense (SL). Two measurements were made 1 week apart to calculate the short-term coefficient of variation (CV) for the fractured limb. Paired t-tests were used to test for significant differences between the contralateral and ipsilateral limbs (the contralateral side acted as a control for measurements). Finally, we calculated a response ratio (RR) using the following equation: RR = % difference/% CV. The results are shown in the table (*P<0.05, **P<0.01, ***P<0.0001).

Measurement	Mean,diff	%, diff	CV, %	RR
UD tib/fib BMD, g/cm ^{2}	-0.13	-19.1***	6.8	2.8
Heel BMD, g/cm ^{2}	-0.05	-6.5***	4.7	1.4
Proximal trabecular, mg/cm^3	-36	-27.6**	3.0	9.0
Proximal cortical, mg/cm^3	-38.5	-7.7**	3.0	3.0
LA+ SOS, m/s	-14	-0.9***	0.6	1.5
UB SOS, m/s	-15	-0.9***	0.8	1.3
SL SOS, m/s	-109	-2.8*	1.8	1.6
LA+ BUA, dB/MHz	-2	-2.0**	2.8	0.7
UB BUA, dB/MHz	-2	-3.3**	4.8	0.7

The biggest decrement in BMD occurred at sites closest to the fracture when measured by DXA and pQCT. The response ratios were high for pQCT of trabecular bone and low for heel BUA. We conclude that pQCT of the trabecular regions of either the proximal or distal tibia and fibula should prove the most sensitive measurement for monitoring changes in bone adjacent to a tibial shaft fracture.

SA297

Does Cumulative Estrogen Exposure Explain the Association Between Osteoporosis and Coronary Heart Disease? B. I. Gulanski,[1] J. M. Robbins,*[2] A. L. Arnold,*[1] V. Vaccarino.*[3] [1]Department of Internal Medicine, Yale University School of Medicine, New Haven, CT, USA, [2]Population Studies Center, University of Pennsylvania, Philadelphia, PA, USA, [3]Department of Medicine, Division of Cardiology, Emory University School of Medicine, Atlanta, GA, USA.

The purpose of this study was to investigate the contribution of cumulative estrogen exposure, as measured by reproductive variables, to the association between osteoporosis and coronary heart disease (CHD) in women. We analyzed data from 2770 postmenopausal non-Hispanic White, African-American and Mexican-American women aged 40 or older who participated in the Third National Health and Nutrition Examination Survey and had a total-hip bone mineral density (BMD) scan performed. Logistic regression models were used to examine the association between BMD and CHD after adjusting for demographic factors, CHD risk factors, and reproductive variables. Mean total-hip BMD was lowest among non-Hispanic Whites and highest among African Americans. Age, hypertension, and HDL cholesterol were associated with lower BMD, while education, physical activity, BMI, early age at menarche, hormone use, ovariectomy and hysterectomy were associated with higher BMD. History of CHD showed a significant association with lower BMD in non-Hispanic Whites and a borderline association in Mexican Americans, but no association in African Americans. In multivariate analysis, reproductive variables did not explain the association between BMD and CHD in non-Hispanic Whites and Mexican Americans. When all the study factors were controlled for, non-Hispanic White women in the lowest BMD tertile, compared to the highest tertile, had 2.66 higher odds of a previous myocardial infarction, 1.98 higher odds of angina pectoris, and 2.03 higher odds of either myocardial infarction or angina pectoris. In conclusion, cumulative estrogen exposure may not explain the association between BMD and CHD. Further investigation of alternative mechanisms is warranted.

SA298

Model-Fitting and Its Validation of Bone Mineral Density Using an Exponential-Type Nonlinear Mixed-Effect Model in the Lumbar Spine of Postmenopausal Women After Natural Menopause Based on a Longitudinal Study. H. Watanabe,*[1] M. Fukunaga,[2] M. Shiraki,[3] Y. Ohashi.*[1] [1]Department of Biostatistics, University of Tokyo, Tokyo, Japan, [2]Department of Nuclear Medicine, Kawasaki Medical School, Okayama, Japan, [3]Research Institute and Practice for Involutional Diseases, Nagano, Japan.

An exponential-type nonlinear mixed-effect model was fitted to estimate and predict bone mineral density (BMD) at the lumbar spine - in 833 postmenopausal women. Years since menopause (YSM) and age at menopause (AAM) were used as explanatory variables. The model was assumed as $(BMD)_{ij}=a+a_i+(b+b_i)\exp(c(YSM)_{ij})+d((AAM)_i-AAM_{(mean)})+e_{ij}$ (i: subject; j: time point; a, b, c and d are the population means; a_i and b_i are the random effects among subjects; e_{ij} are random error). Because BMD decreases rapidly after menopause and changes slowly thereafter, an exponential model was assumed. The fitted model was $(BMD)_{ij}=0.838+a_i+(0.312+b_i)\exp(-0.0922(YSM)_{ij})-0.00175((AAM)_i-48.7)+e_{ij}$, $\sigma_a^2=(0.162)^2$, $\sigma_b^2=(0.112)^2$, $\sigma_e^2=(0.0290)^2$. The maximum likelihood model was done with a specific algorithm which took account of highly unbalanced data. These formulae were also used to derive a prediction formula for each individual using a Bayesian approach. This prediction formula was validated using other data, and found to be useful for BMD prediction except extremely abrupt change. This prediction formula makes it possible to predict the future BMD and to estimate the risk of osteoporosis accurately in individual subjects.

SA299

Menopausal Symptoms and Bone Loss in Chinese Perimenopausal Women. S. C. Ho,[1] S. S. G. Chan,[1] V. Yip,*[2] A. Sham,*[1] C. Chan,*[1] J. Woo.*[1] [1]Department of Community & Family Medicine, The Chinese University of Hong Kong, New Territories, Hong Kong Special Administrative Region of China, [2]Department of Nursing & Health Sciences, The Hong Kong Polytechnic University, Kowloon, Hong Kong Special Administrative Region of China.

Perimenopause is a period of transition from premenopausal to postmenopausal years. This transitional period is usually accompanied by an increase in reported symptoms. This period is also characterized by rapid bone loss. This study aims to investigate if increased number of reported symptoms at baseline is related to increased bone loss over 24month period. 438 women aged 45 to 55, not on hormonal replacement therapy, were recruited through random telephone dialing and family medicine clinic into a cohort study on bone changes. Standardized questionnaire, including a 22-item symptom check list, was administered at baseline. Five symptom clusters, namely psychological, musculoskeletal/gastrointestinal, non-specific somatic, respiratory, and vasomotor have been identified by the principal component analysis method. We had also obtained baseline measurements of bone mineral density (BMD) at the spine (L2-L4) and the hip with the use of dual energy x-ray densitometre (Hologic 2000). (Standardized questionnaires and measurements for dietary and lifestyle variables were also obtained at baseline.) Repeated measurements of BMD were obtained after 24 month followup.Analyses were carried out in 265 women with measurements at baseline and followup. The mean age of this study population was 49.9 y (sd = 2.65), and mean followup time was 2.56 y (sd= 0.09). Univariate analysis revealed that women with less than 5 reported symptoms had significantly higher percentage loss of BMD at the spine, femoral neck, trochanter, intertrochanter, wards and total hip, compared with women with fewer reported symptoms. The differences remained significant for intertrochanter and the wards after adjustment for age and menopausal status. Women with at least one reported symptom in the psychological symptom group had higher bone loss at the hip sites, while women with reported vasomotor symptoms had significantly higher bone loss at the wards.Our longitudinal data revealed that reported symptoms during menopause and possibility the accompanying stress level and or endocrine changes may be detrimental to bone health during menopausal transition. Such association is worth further investigation.

Endogenous Estrogen Levels and Its Relationship With Bone Mineral Density in Postmenopausal Women. A. Bagur,[1] M. Belotti,*[1] M. B. Oliveri,[1] A. López Cabanillas,*[1] D. Yankelevich,*[2] F. Sayegh.*[2] [1]División Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina, [2]Sección Climaterio, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina.

Postmenopausal women whose serum estradiol levels are between 5-25 pg/ml would have higher bone mineral density (BMD) and a lower prevalence of vertebral deformities than women with lower serum estradiol levels and these salutary effects would be moderated by reduced bone turnover. The aim of this study is to evaluate the effect of endogenous estrogens on BMD in healthy postmenopausal women. Upon completion, this cross sectional study will have included 100 healthy postmenopausal women from 55 to 75 years of age. The BMD of L2-L4, Total Femur (TF) and Total Body (TB) are measured by DXA (Lunar Prodigy). The following bone markers are measured in serum: calcium, bone alkaline phosphatase (BAP) and crosslaps (CTX), and in urine calcium. Estradiol and estrona

are measured with sensitive assays that detect lower limit at 5 pg/ml. To date, 48 women have been included in the study. The general characteristics of the population are as follows (Mean±DS): age 65.0±5.8 years, weight 63.2±9.7 kg, height 155±0.05 cm, BMI 26.2±4.2, onset of menopause 48.8±6.1 years, L2-L4: 0.99±0.02 g/cm2 (Z score -0.2), TF 0.85±0.10 g/cm2 (Z score -0.02), TB 1.01±0.02 g/cm2 (Z score -0.2), BAP 74.7±18.7 UI/l (Normal values: 31-95 UI/l) and CTX 522.9±267.8 ng/l (Postmenopausal Normal values: 80-590 ng/ml) , estradiol 8.5±5.7 pg/ml (Postmenopausal Normal values: up to 20 pg/ml), estrona 23.5±16.0 pg/ml (Normal values: 14-100 pg/ml).The 48 women were stratified into 4 groups according to their serum estradiol levels: 10 pg/ml and into 2 groups based on their serum estrona: 15 pg/ml. The results show no differences in BMD areas according to estradiol and estrona levels in these postmenopausal women (range L2-L4 from 1.02 to 0.98 g/cm2, TF from 0.84 to 0.89 g/cm2 and TB from 1.04 to 0.98 g/cm2).Bone alkaline phosphatase was significantly higher in group >10 pg/ml (p< 0.02). Estradiol and estrona did not correlate with BMD and bone markers. Estradiol only correlated significantly with estrona (p<0.02). These preliminary results obtained with 48 post menopausal women show: 1- No association between the low levels of estradiol and estrona determined using ultrasensitive assays and differences in BMD of L2-L4, Total Femur and Total Body. 2- The higher BAP levels observed in the group with the highest estradiol levels (>10 pg/ml) might indicate a positive influence of estrogens on bone mass.

SA302

Low Bone Mineral Density Is Associated With Low Serum Insulin-like Growth Factor-1 in Perimenopausal but Not in Premenopausal Women. D. H. Schussheim,[1] M. R. Rubin,*[1] C. A. M. Kulak,*[2] E. S. Kurland,[1] C. J. Rosen,[3] S. J. Silverberg,[1] J. P. Bilezikian,[1] E. Shane.[1] [1]Medicine, Columbia University, New York, NY, USA, [2]Medicine, Federal University of Parana, Curitiba, Brazil, [3]Maine Center for Osteo. Research, Bangor, ME, USA.

Although osteoporosis (OP) predominantly affects older postmenopausal women, unexplained low bone mineral density (BMD) also occurs in men and younger women. We have previously observed reduced IGF-1 levels in men, premenopausal (PreM) and perimenopausal (PeriM) women with unexplained OP, suggesting a possible pathogenic link between reduced IGF-1 and idiopathic low BMD. However, it is unclear whether this association in women is linked to changing estrogen status prior to menopause. We therefore compared 18 (15 PreM and 3 PeriM) women with a Z score <-2.0 at the lumbar spine (LS) and/or femoral neck (FN) and compared them with 32 (28 PreM and 4 PeriM) healthy volunteers. The PreM and PeriM patients and controls did not differ in age (PreM, 35+2 years vs. 38+1 years; PeriM, 50+2 years vs. 50+2 years, respectively). BMD (Z score) was significantly lower in patients than controls at the LS (-2.063+0.17 vs 0.726+0.13) and FN (-2.022+0.14 vs 0.743+0.16, both P<0.0001). A family history of OP was reported by 67% of patients vs. 37% of controls (P<0.05). Fragility fractures were reported by 44% of patients vs. 19% of controls (P=0.05). All patients had normal serum calcium, electrolytes, renal function, PTH and urinary calcium. Although serum osteocalcin and urinary N-telopeptide (NTX), were normal, NTX was higher in patients (37+3.8 vs. 26.8+2.2 ng/ml, P<0.05). Serum estradiol E2 levels, measured during the follicular phase of the cycle (days 1-5), were lower in PreM patients than in controls (31+4 vs. 50+7 pmol/L; P<0.05) but not in PeriM patients. Serum IGF-1 (168.9+15 vs. 158.7+8.3 ng/ml) and IGFBP3 did not differ between PreM patients and controls. However, in PeriM subjects, serum IGF-1 was lower in patients than controls (105.0+17.1 vs. 166.5+14.67 ng/ml; P<0.05), as were IGFBP3 levels (2815+191 vs. 4368+464 ng/ml; P<0.05). Serum IGF-1 values correlated inversely with age (r=-0.55, P<.0001) and directly with LS and FN BMD (r=0.72 and r=0.89, respectively, both P<0.05) in PeriM women but not in PreM women. Serum E2 did not correlate with IGF-1, LS or FN BMD. In summary, lower IGF-1 levels are associated with low BMD in PeriM but not PreM women. This observation, together with the lack of correlation between IGF-1 and E2, suggests that as E2 levels decrease during the perimenopause, IGF-1 may play a more important role in preserving BMD.

SA303

Are Bone Density and Mammographic Parenchymal Density Related? G. A. Greendale,[1] S. Carter,[2] B. Reboussin.*[2] [1]Department of Medicine/Division of Geriatrics, University of California, Los Aangeles, Los Angeles, CA, USA, [2]Public Health Sciences, Wake Forest University School of Medicine, Winston-Salem, NC, USA.

Women with breast cancer have higher bone mineral density (BMD) than those who do not have this disease; higher endogenous estrogens and/or greater estrogen responsiveness are postulated explanations. Higher mammographic density is an independent risk factor for breast cancer. We therefore conducted a study to explore whether mammographic density and BMD were positively associated. Between 1989-91, PEPI enrolled 875 postmenopausal women, aged 45-64 years, who were between 1-10 years postmenopause and not taking HRT within 2 months of screening. All women for whom we were able to retrieve baseline mammograms, and who did not have breast implants were eligible for this study, which included 594 participants (68% of original PEPI sample). BMD was measured using Hologic 1000-QDR densitometers. A computer-assisted method was used to assess mammographic density, the percent of the breast made up of dense tissue. Age and BMI averaged 56 years and 26.2 kg/m^2, respectively. 171 women (29%) were recent HRT-users (stopped for PEPI). Mammographic density ranged from 0-90%. Linear regressions were run with BMD as the outcome and mammographic density, age, and BMI as predictors (Model 1). Then baseline estrone was added (Model 2). The table below shows the β-coefficients (p values) for each of the predictor variables at each bone site among the 415 women who were not recent HRT-users.

Variable	Spine BMD (1)	Spine BMD (2)	Hip BMD (1)	Hip BMD (2)
Mammog. density	0.076 (0.07)	0.064 (.13)	0.059 (.06)	0.054 (.08)
Age	-0.006 (0.00)	-0.005 (.00)	-0.005 (.00)	-0.004 (.00)
BMI	0.012 (0.00)	0.010 (.00)	0.013 (.00)	0.013 (.00)
Estrone	N/A	0.001 (.00)	N/A	0.005 (.10)

Results were similar when estradiol was added to Model 1 (data not shown). In recent HRT-users, after adjustment for the same covariates, BMD and mammographic density were not significantly associated. We conclude that bone and breast densities are positively related in postmenopausal women who have not recently stopped HRT. Adjusting for baseline estrone or estradiol did not substantively alter this association, suggesting that the "common pathway" is more complex than higher circulating endogenous estrogens.

SA304

Effect of Menopause on Bone in Postmenopausal Women with High Bone Volume. S. Qiu,[1] S. Palnitkar,*[1] D. Rao,[1] A. M. Parfitt.[2] [1]Bone and Mineral, Henry Ford Hospital, Detroit, MI, USA, [2]Division of Endocrinology, University of Arkansas for Medical Sciences, Little Rock, MI, USA.

It has been claimed that some postmenopausal women suffer from increased bone fragility without obvious bone loss. There is little information, however, on bone histologic changes in such women. The current study was aimed at this problem.From our archived iliac biopsy sections, we included 94 healthy white women in whom the osteocyte density had been measured. Postmenopausal women with lower values of cancellous bone volume were excluded until the mean value for BV/TV was close to that in premenopausal women. Results of cancellous bone histomorphometry, in 38 premenopausal and 37 postmenopausal women, were compared. As well as standard measurements we added interstitial bone fraction [Ib.F = (Tb.Th-W.Th*2)/Tb.Th]. Additionally, 10 unbroken areas were randomly selected in each section stained with Goldner's trichrome for determination of osteocyte number per bone area (Ot.N/B.Ar). The results are shown in the following table.

	Pre	Post		Pre	Post
BV/TV	24.88(7.46)	24.81(4.58)	MS/BS	5.79(3.09)	8.50(5.55)
Tb.Th	140.56(23.57)	151.02(36.84)	MAR	0.58(0.19)	0.55(0.10)
Tb.N	1.76(0.37)	1.69(0.31)	Aj.Ar	0.31(0.19)	0.24(0.14)
Ib.F	46.32(9.59)	52.30(9.11)*	BFR/BS	12.71(6.94)	17.41(11.71)
W.Th	36.86(3.67)	34.86(5.51)	BFR/BV	14.68(8.90	18.57(12.81)
OS/BS	13.60(7.82)	21.95(12.17)***	Ac.f	0.35(0.19)	0.49(0.31)
ES/BS	6.63(3.17)	7.62(3.49)	Ot.N/BAr	416(57)	344(38)***

Pre: Premenopausal; Post: Postmenopausal. *p < 0.05; **p < 0.01; ***p < 0.001.

The increase in bone remodeling in the postmenopausal women without apparent bone loss was less clear than that shown in the complete data set. However, there was a significant decrease in osteocyte density and a significant increase in interstitial bone fraction in such postmenopausal women. Loss of osteocytes may impair detection of microdamage in bone matrix, and may also lead to focal hypermineralization. We have previously demonstrated that osteocyte loss is most prevalent in interstitial bone. Loss of osteocytes and increased interstitial bone fraction may contribute to enhanced bone fragility in some postmenopausal women without apparent bone loss. It needs to be emphasized that loss of osteocytes is more likely due to aging as we have previously reported

Testing and Validation of Simple Clinical Risk Indices to Identify Postmenopausal Women with Osteoporosis. M. C. Hochberg,[1] D. E. Thompson,[2] P. D. Ross.[2] [1]University of Maryland, Baltimore, MD, USA, [2]Merck Research Labs, Rahway, NJ, USA.

Several risk assessment tools have been developed for identifying postmenopausal women with osteoporosis, as defined by low bone mineral density (BMD), with the goal of targeting BMD measurements and reducing the number of tests and related health care costs. These tools include the Osteoporosis Self-assessment Tool for Asians (OSTA), SOFSURF, ORAI, and the Simple Calculated Osteoporosis Risk Evaluation (SCORE). The objective of the current study was to evaluate the performance of these indices among Caucasian women ages 45-93 who were screened for eligibility for the Fracture Intervention Trial (FIT). After completing a detailed questionnaire, BMD was measured. There were 17,572 women with age, weight, and BMD data; 3637 (21%) of these women had osteoporosis, as defined by a femoral neck BMD T score ≤ -2.5. Among the selected Caucasian women screened for FIT, at least 3 of the risk tools yielded reasonably good (>45%) specificity when sensitivity was set to approximately 90% for diagnosing osteoporosis (Table); similar results were obtained using T ≤-2.0 (data not shown). Likelihood ratios (LR) are provided for calculating the post-test odds (equal to LR*pre-test odds). Three risk categories have been previously reported using the OSTA index. A high risk subgroup was identified (OSTA score < -3, 1309 [7%] of women) that had a high prevalence of osteoporosis (59%). The prevalence of osteoporosis was 26% in a medium risk group (OSTA = -3 to 0, 9474 [54%] of women), and only 6% in a low risk group (OSTA > 0,

6789 [39%] of women). These results are very similar to those reported in the original Asian sample (Osteoporos Int 2000;11[Suppl 5]:S9), except that the risk category cutoffs were shifted by one unit among Caucasians compared to Asians. While the women who were screened for FIT may not be representative of the general population as they were selected on certain characteristics, the performance of these risk tools was similar to that in the original development populations. We conclude that these free and simple risk assessment tools could help clinicians target BMD testing among postmenopausal women.

Index	Cutoff	Sensitivity	Specificity	LR (+)	LR (-)
OSTA	<1 vs ≥1	89	46	1.65	0.24
ORAI	>10 vs ≤10	92	26	1.24	0.31
SOFSURF	>1 vs ≤1	82	55	1.82	0.33
SCORE	>10 vs ≤10	88	47	1.66	0.26

Effect of Smoking and Alcohol on Quantitative Ultrasound Parameters in the Elderly. R. J. Barr,*[1] A. Stewart,*[1] B. McDonagh,*[2] D. J. Torgerson,*[3] D. M. Reid.*[1] [1]University of Aberdeen, Aberdeen, United Kingdom, [2]Strakan Ltd, Galashiels, United Kingdom, [3]University of York, York, United Kingdom.

Background: Quantitative ultrasound assessment (QUS) of bone predicts hip fractures in elderly women. Few studies have investigated the relationship between lifestyle factors, such as smoking and alcohol consumption in elderly women and QUS parameters. Methods: This study investigated the association between smoking and alcohol consumption with the calcaneal QUS parameters broadband ultrasound attenuation (BUA) and speed of sound (SOS) in 712 women aged 70-98 years. Information about smoking habit and alcohol consumption were collected by questionnaire. BUA (dB/MHz) and SOS (m/s) were determined in the left heel using a McCue CUBA clinical system. Weight and height were also measured. Results: BUA was significantly associated with weight, height and age ($r=0.36$ $p<0.001$, $r=0.19$ $p<0.001$ and $r=-0.18$ $p<0.001$). SOS was significantly associated with age ($r=-0.112$, $p=0.003$) but not with weight and height. The BUA (mean±SD) of smokers was significantly lower than never and ex smokers (51.3±14.1, 56.7±16.2 and 56.3± 15.4; p=0.009 and p=0.019 unadjusted). However after adjustment for age, weight and height the BUA of smokers was significantly lower than the never smokers but not the ex smokers (p=0.003 and p=0.082). The SOS (mean±SD) of smokers, ex smokers and never smokers was 1581.6±48.7, 1577.7±48.6 and 1578.7±48.1m/s respectively, with none of the differences significant. Women who consumed alcohol 3-4 times a week had a significantly higher BUA (mean±SD) than women who consumed alcohol every day or less than 3-4 times a week (62.5±16.4, 53.4±16.5 and 55.9±15.6 dB/MHz; p=0.007 and p=0.01 unadjusted). After adjustment for age, weight and height women who consumed alcohol 3-4 times a week still had a significantly higher BUA than those who consumed alcohol every day (p=0.046) but not than those women who consumed alcohol less than 3-4 times a week (p=0.237). The SOS (mean±SD) of women who consume alcohol every day, 3-4 times a week and less than 3-4 times a week was 1585.4±54.3, 1573.7±42.4 and 1580.5±48.6m/s respectively. No significant difference was observed between the groups.Discussion: BUA, but not SOS, was linked to both smoking and alcohol consumption in elderly women. Interestingly the data on alcohol reflect BMD findings in a group of peri-menopausal women from Aberdeen1. Further work is needed to establish whether moderate alcohol consumption is related to a reduced incidence of hip fracture in elderly women.References: 1MacDonald HM et al., 2000. Nutritional influences on peri- and early menopausal bone loss: effects of alcohol and calcium intake. Osteoporos. Int. 11,(Suppl 1) S19.

Magnetic Resonance Image Analysis of Trabecular Bone Structure with Distance Transformation Maps. K. J. Hall,* A. Laib,* D. Newitt,* S. Majumdar. Radiology, University of California, San Francisco, CA, USA.

MR imaging of trabecular bone shows promise for predicting fracture risk, yet it has limited spatial resolution and signal-to-noise ratio. Laib et al (ASBMR 2000) presented a new image analysis technique in which characteristic distances in bone and bone marrow spaces are directly determined by Euclidean distance transformation. In this work, this technique is used to produce three-dimensional distance transformation maps of trabecular bone parameters Tb.Th (thickness), Tb.Sp (separation), and Tb.N (number). Two patient groups were analyzed: a mixed group of normal and osteopenic patients, and a group of patients with vertebral fractures. Qualitative analysis of these distance maps highlights differences among the normal, osteopenic, and fractured patients. The distance maps in the figure show the distance between the surfaces of neighboring trabeculae (Tb.Sp) of an axial slice from the distal radius. Lighter gray-levels represent areas of larger trabecular separation. The size of a sphere also yields information about the homogeneity of the local trabecular structure. Images whose distance maps have similarly-sized spheres have a more homogeneous structure than those whose distance maps are made up of a variety of sphere sizes. Normal subjects (A) typically have distance maps with even-sized spheres and a fairly homogeneous distribution of brightness, while osteopenic subjects (B) show more inhomogeneity in their distance maps. Subjects with vertebral fractures (C) have even more inhomogeneous distance maps that typically show greater separation between the trabeculae with increasing distance from the distal endplate. Valuable internal structural information can be extracted from the homogeneity of the distance maps, making their analysis a promising tool for studying trabecular bone structure. Further investigations will examine the distance maps for patterns in the radius and for assessing response to therapy and changes with age.

Magnesium Deficiency: Effect on Bone & Mineral Metabolism in the Mouse. R. K. Rude,[1] H. E. Gruber,*[2] L. Y. Wei,*[1] A. Frausto,*[1] B. G. Mills.*[1] [1]University of Southern California and Orthopaedic Hospital, Los Angeles, CA, USA, [2]Carolinas Medical Center, Charlotte, NC, USA.

Insufficient dietary magnesium (Mg) intake has been associated with low bone mass and/or increased bone loss in humans and in animals. The purpose of this study was to explore the hypothesis that inflammatory cytokines may contribute to alterations in mineral metabolism and to the Mg deficiency-induced bone loss in the mouse. BALB/c female mice were fed either a normal (.06%) or low (.002%) Mg diet for up to 6 weeks. Serum Mg, Ca and PTH, and bone mineral (Mg,Ca,PO4) content were determined. Histomorphometry was used to quantitate the effect on bone cells and immunohistochemical staining was used to localize the effect of substance P, TNFa, and IL1. Hypomagnesemia developed and skeletal Mg content fell significantly in Mg deficient mice within 3 weeks. Serum Ca in the Mg deficient mice was higher than in the control mice although serum PTH was not significantly different. Osteoprotegerin (OPG) inhibited osteoclastic bone resorption but did not prevent hypercalcemia in Mg deficient animals. However concomitant 50% reduction of dietary Ca prevented hypercalcemia suggesting that compensatory intestinal absorption accounted for the hypercalcemia. The growth plate width decreased by 33% in Mg deficient animals and the chondrocyte columns decreased in number and length. There was an increase of 135% in osteoclast number. The result was a decrease in trabecular bone volume in the metaphysis of the tibia. Osteoblast number was significantly reduced. Immunohistochemistry of cells in the medullary spaces revealed that substance P increased 227% and 200% in the megakaryocytes and lymphocytes respectively after 1 day of Mg depletion. IL-1 increased by 143% in osteoclasts by day 3, while TNFa increased in osteoclasts by 123% and by 500% in megakaryocytes at day 12. This study demonstrates a profound effect of Mg depletion on bone characterized by impaired bone growth, decreased osteoblast number, increased osteoclast number and loss of trabecular bone. Increased inflammatory cytokines in bone of Mg deficient animals may provide an explanation of increased osteoclastic bone resorption accompanying Mg depletion.

Short-Term, High Dose Vitamin A Does Not Affect the Skeleton. T. N. Kawahara,*[1] D. C. Krueger,[1] J. A. Engelke,*[2] J. M. Harke,[1] N. C. Binkley.[1] [1]Institute on Aging, University of Wisconsin, Madison, WI, USA, [2]Biochemistry, University of Wisconsin, Madison, WI, USA.

Excess vitamin A produces skeletal toxicity. While studies are limited, currently available data in humans and animals indicates that excess vitamin A stimulates bone resorption and inhibits bone formation. Although the animal studies have utilized extremely high doses, it has been suggested that unappreciated human subclinical vitamin A toxicity may be associated with high skeletal turnover and bone loss. If this is the case, vitamin A supplementation could be a heretofore unappreciated osteoporosis risk factor. To further evaluate this possibility, a prospective, randomized, single-blind pilot study was conducted in 80 healthy men age 18-50 utilizing the highest vitamin A supplement dose available over the counter. One half of study participants received 25,000 IU of retinol daily with their evening meal, the others received placebo. Screening laboratory parameters including complete blood count and serum chemistry panel were required to be normal for enrollment. Volunteers with a medical history of malabsorption, renal or hepatic disease were excluded from study participation. Fasting serum specimens were collected between 0730-1030 at baseline and following two, four and six weeks of supplementation. Serum bone specific alkaline phosphatase (BSAP) and n-telopeptides of type I collagen (NTx) were measured at all timepoints. At this time, 29 men (15 control/14 vitamin A supplemented, mean age 29 ± 1.4 years) have completed the study.Supplementation was well tolerated. Compliance was excellent (90%) with no difference between groups. At baseline, BSAP and NTx were higher ($p < .05$) in the placebo group. No differences in BSAP or NTx were demonstrated between the supplemented and placebo groups over the course of the study (Table 1).

Table 1: Markers of bone turnover

	Baseline	2 weeks	4 weeks	6 weeks
BSAP (U/L) Vitamin A	24.0 (1.6)	24.1 (1.5)	24.3 (1.6)	25.1 (2.3)
BSAP (U/L) Placebo	31.9 (3.0)	30.7 (2.9)	30.6 (2.7)	32.0 (2.4)
NTx (nM BCE) Vitamin A	17.1 (1.4)	16.6 (1.3)	15.4 (1.4)	16.5 (1.3)
NTx (nM BCE) Placebo	23.4 (1.6)	22.7 (1.8)	21.8 (2.2)	25.0 (1.8)

Data as mean (SEM)

In conclusion, short-term vitamin A supplementation, in a dose above the recently published tolerable upper intake level, but available over the counter, does not alter serum markers of skeletal turnover. Whether long term supplementation might have adverse skeletal effects remains to be determined

SA315

Potassium Citrate and Bone Metabolism in Rats. M. Horcajada-Molteni,*[1] B. Chanteranne,*[1] M. Davicco,*[1] V. Coxam,[1] S. Miller,[2] J. Barlet,*[1] C. Rémésy.*[1] [1]INRA, Theix, France, [2]Radiobiology Division, University of Utah, Salt Lake City, UT, USA.

The role of nutritional influences on bone metabolism remains undefined because most studies have focused attention on calcium intake. Consumption of nutrients found in abundance in fruits and vegetables is positively associated with bone health. Indeed, fruits and vegetables contribute to an alkaline environment due to their organic salts content (mainly potassium citrate). This study was thus undertaken to probe the hypothesis that potassium citrate, and then a high K/Na ratio in diet (as in fruits and vegetables) may influences ovariectomy-induced bone loss in rats. The experiment was carried out on forty 3-month old Wistar rats. Twenty of them were ovariectomized (OVX), while the remainings were sham-operated (SH). Among the OVX, ten were fed for 3 months after surgery (day 0) with the same diet (0.4% calcium ; 0.8% phosphorus ; K/Na = 2) as ten SH (10TSH, 10 TOVX). The twenty other rats (10 KSH, 10 KOVX) received the same diet in which K/Na = 14 ; K being given as citrate ($K_3C_6H_5O_7$, H_2O). The OVX rats were pair-fed to the SH. Urine of each animal was collected over 24h-periods from day 83 until day 89. At necropsy, on day 90, blood and femurs were collected. At the end of the experiment, the decrease in uterine weight was not different in TOVX and KOVX. On day 89, urinary pH was significantly increased by citrate potassium intake (KSH : 6.64 ± 0.06 ; $p<0.01$ vs TSH ; KOVX : 6.77 ± 0.06 ; $p<0.01$ vs TOVX). The lowest calciurias were observed in KSH and KOVX groups. Ovariectomy induced a significant decrease in femoral failure load (N) which was not prevented by potassium citrate consumption. In the opposite, total (T-BMD) (TSH : 0.2264 ± 0.0055 ; TOVX : 0.2142 ± 0.0025 ; $p<0.05$) and distal metaphyseal (M-BMD) (TSH : 0.2307 ± 0.0027 ; TOVX : 0.2163 ± 0.0032 ; $p<0.05$) femoral density ($g.cm^{-2}$) were significantly decreased by ovariectomy, this decreased being prevented by potassium citrate intake [(T-BMD : KSH : 0.2358 ± 0.0023 ; KOVX : 0.2281 ± 0.0025) ; (M-BMD : KSH : 0.2491 ± 0.041 ; KOVX : 0.2305 ± 0.0012)]. Moreover, on day 90, urinary deoxypyridinolin excretion (nM DPD.mmol creatinin-1) was higher in TOVX (164.8 ± 13) and TSH (121.9 ± 8.8) than in KSH (93.6 ± 10.3). In conclusion, this study allows the concept that organic salts with alcalinizing effects of the diet play a positive role in bone metabolism.

Do the Patients with Chronic Atrophic Gastritis Have Secondary Hyperparathyroidism? **C.** Lee,[1] Y. Jeon,[1] I. Park,[2] W. Choi.[3] [1]Department of Internal Medicine, Hanyang University Kuri Hospital, Kuri, Republic of Korea, [2]Department of Clinical Pathology, Hanyang University Kuri Hospital, Kuri, Republic of Korea, [3]Department of Internal Medicine, Hanyang University Seoul Hospital, Seoul, Republic of Korea.

It is well known that Hydrochloric acid is important factor for the absorption of calcium and the bone loss is often seen in human after total gastrectomy. Chronic atrophic gastritis causes a decrement of acid secretion of gastric mucosa. The aim of our study was to document the change of calcium metabolism in the patients with decreased gastric acid secretion. The study sample consisted of the gastritis group which had 19 post-menopausal females (age: 58.5 ±6.1 yr) followed in our hospital for chronic atrophic gastritis, and the control group which had 22 healthy females (age: 59.9 ±7.5 yr) with normal gastrofiberscopic findings. Serum levels of calcium, phosphorus, total alkaline phosphatase and intact PTH(IRMA, Nicol inc), were monitored in all the patients in both group before medication. There were no significant differences of calcium (9.1 ±0.9 vs 9.0 ±1.4 mg/dL, $p > 0.05$), phosphorus (3.5 ±1.1 vs 3.6 ±0.9 mg/dL, $p > 0.05$), alkaline phosphatase (60.5 ±34.6 vs 59.2 ±20.4 U/L, $p > 0.05$) between the gastritis group and control group. Serum intact PTH showed increased average value of the gastritis group comparing the control group (21.3 ±6.7 vs 17.0 ±3.7 pg/ml, $p = 0.09$). In conclusion, in patients who have decreased capacity of gastric hydrochloric acid secretion, there may be a possibility of abnormal calcium and bone mineral metabolism.

Vitamin K Depletion and Repletion in Postmenopausal Women Does Not Alter Biomarker of Bone Metabolism. L. Martini, S. Booth, E. Saltzman, R. J. Wood.* Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts Univeristy, Boston, MA, USA.

Vitamin K has been implicated in bone metabolism. Low dietary vitamin K intake and status has been associated in epidemiological studies with low bone mineral density and increased risk of hip fractures. The only known biochemical role of vitamin K is as a cofactor in an enzymatic reaction that post-translationally carboxylates specific glutamine residues in a small number of vitamin K-dependent proteins. Despite a potential role of vitamin K in osteoporosis, little is known about the effects of vitamin K status on the underlying components of bone metabolism. The aim of the present study was to assess the effects of vitamin K depletion and repletion on biomarkers of bone formation (serum osteocalcin) and bone resorption (serum and urinary type 1 collagen cross-link N-telopeptide (NTX)). Fifteen postmenopausal women participated in a 3-month in-house study that consisted of five dietary phases during which they were fed a low vitamin K depletion diet fortified with varying levels of vitamin K: 2-week “baseline” (65 mcg vitamin K/d) 4-week “depletion” (10 mcg vitamin K/d), 2-week “repletion –1” (65 mcg vitamin K/d), 2-week “repletion-2” (200 mcg vitamin K/d) and 2-week “repletion – 3” (500 mcg vitamin K/d). In addition, to test a possible interaction of vitamin K status with vitamin D, one-half of the subjects were randomly assigned to receive calcitriol (1,25 dihydroxyvitamin D3) supplementation (1 mcg/d) during the last 7d of baseline, depletion and repletion-3 dietary phases. Vitamin K depletion and repletion status was monitored by measurements of serum PIVKA-II, a measure of undercarboxylated prothrombin that increases in vitamin K deficiency states. There was a significant increase ($p<0.05$) in PIVKA-II during the dietary vitamin K depletion phase (1.5 ± 1 (baseline, mean±SD); 2.5 ±1.8 (depletion); 2.2 ± 1.7 (repletion-1); 1.7 ± 1.0 (repletion-2) and 1.0 ± 0.7 (repletion-3) ng/ml) confirming a functional vitamin K depletion state. However, there was no changes in bone metabolism during the study. Serum osteocalcin, a biomarker of bone formation, was similar in all dietary periods: 7.0 ± 2.0, 7.7± 2.7, 7.2 ±, 7.3 ± 1.5, 7.3 ± 2.0. Likewise, serum and urinary NTX, measures of bone resorption activity, were not affected by dietary vitamin K depletion: serum NTX (18 ± 3, 19 ± 4, 19 ± 4, 19 ± 5, 20 ± 5, 18 ± 3 nM BCE); urinary NTX (48 ± 14; 48 ± 15; 47 ± 13; 53 ± 15 and 44 ± 10 nM BCE/nM Cr). These findings suggest that short-term consumption of a low vitamin K diet can cause a functionally significant change in vitamin K status (increased PIVKA-II), but does not alter biomarkers of bone formation or resorption in elderly women.

SA318

Caloric Restriction Decreases Calcium Absorption in Mature Obese and Lean Rats. M. Cifuentes,* A. B. Morano,* H. Chowdhury,* S. A. Shapses.* Rutgers University, New Brunswick, NJ, USA.

Weight loss has been associated with loss of bone mass, however the mechanisms involved remain unclear. We hypothesize that weight loss reduces estrogen activity and alters intestinal Ca absorption thereby contributing to the negative effect on bone. Lean subjects who lose weight may be at greater risk of bone loss than heavier individuals. We investigated the effects of body weight (wt) and caloric restriction on Ca metabolism in mature female rats. Rats (n=56) were fed either a high fat (47%) or low fat (16%) diet to generate obese and lean animals, respectively. At 6 months of age, lean and obese groups were each divided into controls (CTL; fed ad-libitum) and calorie restricted (CR; at 40% restriction, matched for vitamins and minerals) to total 4 groups. Markers of bone turnover were measured before and after 10 weeks of CR or CTL diets. Traditional Ca balance method estimated net Ca absorption, whereas true Ca absorption, endogenous fecal Ca and intestinal Ca secretion also included the use of Ca45 radioisotopes (1). Uterine wt was measured, as a bioassay for estrogenic activity. At baseline, there were no differences between obese and lean rats in Ca balance, true absorption, endogenous fecal Ca or intestinal Ca secretion. Net Ca absorption, however, was slightly higher in obese compared with lean rats (33.6 6.5% and 29.1 7.0%, $p<0.05$). Lean rats presented higher serum osteocalcin levels and lower 24-h pyridinium crosslink excretion than obese rats ($p<0.001$). Caloric

restriction reduced body wt by -24.2 7.6% compared to CTL (+7.2 7.3%; p< 0.001) and decreased true intestinal Ca absorption (-23.7 16.3%) compared to CTL animals (-9.6 23.8%), regardless of body size (p 0.77 , p < 0.001), net absorption was not able to detect the effect of CR. Intestinal Ca secretion and endogenous fecal Ca also decreased due to CR (-29.3 28.5% and -15.4 29.5%, respectively; p<0.05). Uterine wts were lower in CR (249.9 0.1mg) than CTL rats (516.8 0.1mg, p< 0.0001), and these differences were greater in lean than obese rats (p<0.01). These data show that CR decreases true Ca absorption and may contribute to bone loss due to weight reduction. This may be due to a relative estrogen deficiency. The greater loss of estrogen activity, but not Ca absorption, in lean than obese animals suggests that other factors may be regulating Ca absorption during CR. In addition, lean individuals who lose weight may be more susceptible to bone loss than obese due to a greater loss of estrogen. 1. O'Loughlin PD & Morris HA. J Nutr 124:726-31, 1994.

Cancellous Bone Loss in Adult Rats Following Reduction in Chow Calcium and Vitamin D Contents to NRC-Recommended Levels. M. R. Allen, A. C. Currado,* S. A. Bloomfield. Health & Kinesiology, Texas A&M University, College Station, TX, USA.

In two separate studies, we have found evidence that alterations of rodent chow calcium and Vitamin D content, even if meeting the NRC-recommended levels, can lead to significant decreases in cancellous bone mineral density (cBMD) in skeletally mature male Sprague-Dawley rats. Animals for both experiments were fed a standard chow diet (Harlan Teklad Global Diet #2018) by the vendor until animals were shipped (5-months-old). After 1 wk acclimation, rats were then acclimated to their new diet for an additional 14 d prior to the start of each study. In Study 1, male rats were fed a Vitamin D-deficient diet (D-; n=4) (Purina Mills Test Diet) while in Study 2, male rats were fed AIN93-M chow (AIN; n=9) (Dyet) designed to provide adequate nutritional intake for adult maintenance (Reeves et al., J. Nutr., 1993). Both diets met the minimal daily requirement for calcium as defined by the NRC; however, these calcium contents were ~50% lower than the diet the animals were raised on. All animals were housed singly and allowed to eat ad lib. On day 0 of each study, baseline data were collected using in-vivo peripheral quantitative computed tomography (pQCT; Stratec Research-M) at the tibia proximal metaphysis (3 slices centered at 5.5mm from tibial plateau) and mid-diaphyseal shaft (1 slice at 50% total bone length). After 28d of normal cage activity, pQCT scans were repeated. Study 1: Over 28d, D- animals gained body mass (28 ± 7g) and consumed 24 ± 1.2 g of food/day over the final week of the study. In-vivo pQCT showed a significant (p < 0.05) loss (-21%) of cBMD over 28d (pre: 229 ± 12; post: 179 ± 7 mg/cm3) at the proximal tibia. There were also significant decreases in total BMD (-7%), while total area (+6%) and marrow area (+11%) both increased at the proximal tibia. There were no significant changes at the mid-diaphysis in D- animals over 28d. Study 2: AIN-fed animals gained body mass over 28d (32 ± 6g) and consumed 21 ± 1.1 g of food/day during the final week of the study. In-vivo pQCT showed a significant decline (-18%) in cBMD at the proximal tibia over 28d (pre: 198 ± 6.0; post: 162 + 5.7 mg/cm3). However, there were no significant changes in proximal tibia total BMD or area, nor in any variables at the tibial mid-diaphysis. Given similar losses in proximal tibia cBMD on both the D- and AIN diets, it appears that reduced calcium intake and not reduced Vitamin D-3 intake was the key factor affecting cBMD. Reducing exogenous D-3 intake did appear to impact on bone geometry at the proximal tibia. Possible confounders in these studies might be 1) reduced physical activity associated with single housing of rats and 2) alterations in the Ca:P molar ratio. Further studies are necessary to better control for these factors.

Cortical Bone Parameters for the Characterization of Asthmatic Patients with Glucocorticoid-Induced Vertebral Fractures. H. Tsugeno,*[1] B. Goto,*[2] T. Fujita,*[2] T. Sugishita,[3] T. Yokoi,*[1] S. Takata,*[1] M. Okamoto,*[1] K. Nishida,*[1] Y. Hosaki,*[1] K. Ashida,*[1] F. Mitsunobu,*[1] Y. Tanizaki,*[1] [1]Misasa Medical Branch, Okayama University Medical School, Tottori, Japan, [2]Calcium Research Institute, Kishiwada, Japan, [3]Third Division, **Dept of Medicine, Kobe University School of Medicine, Kobe, Japan.**

Despite a deepening understanding of the trabecular bone dynamics, little is known about glucocorticoids (GC)-induced cortical bone loss and fractures. Using peripheral quantitative computed tomography (pQCT), we have recently demonstrated oral GC-induced fall in cortical bone volume and density of adult asthmatic patients. For further study of the relationship between cortical bone loss and fractures, we examined the pQCT parameters and the presence of vertebral fractures in 83 postmenopausal (> 5 years after menopause) asthmatic patients on high-dose oral GC (> 10g of cumulative oral predonisolone) (oral GC group) and 194 age-matched controls. Cortical and trabecular bone was measured using pQCT (Stratec XCT960). Relative cortical volume was obtained by dividing the cortical area by the total bone area. Strength Strain Index (SSI) was calculated in the radius based on the density distribution around the axis. Spinal fracture was assessed on lateral radiographs. Fifty-four patients (65.1%) in oral GC group and 45 (23.2%) in the control group had at least 1 vertebral fracture. High-dose oral GC (> 10g of cumulative oral predonisolone) increased the risk of fracture (odds ratio, 8.64; 95% C.I., 4.11-18.1). In each group, diagnostic and predictive ability of vertebral fractures was determined by areas under the receiver operating characteristic (ROC) curves of the parameters. All parameters were significant predictor (p < 0.0001) in the control patients. Cortical bone mineral density (BMD) (p = 0.003), relative cortical volume (p < 0.0001) and SSI (p = 0.001) were significant predictors, but trabecular BMD was not (p = 0.242) in the oral GC group. Thresholds of all parameters for vertebral fractures were also calculated by Chi-square test, 90 percentile, 95% confidence interval and ROC analysis, and compared between the two groups. Although a rise of fracture threshold in GC group was suggested, variations depending on the method of calculation precluded a definite conclusion.We confirmed an outstanding risk of fracture on high-dose oral GC administration. Cortical bone parameters obtained by pQCT were good predictors of glucocorticoid-induced vertebral fractures.

Osteodensitometric, Biochemical and Histomorphometric Parameters of Bone after Longterm Corticosteroid Therapy. T. Eidner,* G. Lehmann,* G. E. Hein.* Dpt. of Internal Medicine IV, Friedrich-Schiller-University, Jena, Germany.

We investigated the influence of longterm corticosteroid therapy on osteodensitometric, biochemical and histomorphometric parameters of bone in postmenopausal women. Bone mineral density (BMD; DXA, QDR Hologic 4500A) at lumbar spine (LS) and femoral neck (FN), biochemical markers of bone turnover (serum osteocalcin - OC, urinary excretion of pyridinolin - Pyd and desoxypyridinolin - DPyd) and bone histomorphometric parameters from iliac crest biopsies were determined in 42 postmenopausal women. 25 patients (group A, Æ 62,6 y.) had primary osteoporosis. 17 patients (group B, Æ 63,0 y.) had longterm corticosteroid treatment (at least 7,5 mg prednisolon per day for more than one year) due to inflammatory rheumatic diseases (13), COPD (2) or chronic inflammatory liver diseases (2).

DXA, Bioch.	BMD LS	BMD FN	OC	Pyd	DPyd
	g/cm²	g/cm²	ng/ml	nmol/mmolKrea	
group A	0,73±0,12	0,65±0,09	8,1±2,4	54,7±29,7	20,8±8,2
group B	0,72±0,18	0,58±0,08	5,8±2,9	79,5±41,6	21,3±9,0
p (u-test)	n.s.	0,03	0,02	(0,06)	n.s.

group B	13,4±4,1	11,9±9,9	3,4±3,5	15,5±12,7	2,3±2,2	0,25±0,22	0,058±0,029
p (u-test)	n.s.	n.s.	n.s.	n.s.	n.s.	n.s.	n.s.

(BV bone vol., BS bone surf., OS osteoid surf., Ob.S osteoblast covered surf., ES erosion surf., Oc.S osteoclast covered surf., N.Oc number of osteoclasts, BFR bone formation rate, n.s. not significant)

In patients with longterm corticosteroid therapy (group B) we found a significantly lower BMD at FN (despite a comparable BMD at LS), a significantly lower OC-level as sign of reduced bone formation, an elevated Pyd-level as sign of increased bone and additional cartilage resorption (predominantly inflammatory rheumatic diseases) as well as a comparably elevated DPyd-level pointing towards increased bone resorption in both groups. Bone histomorphometry did not show any significant differences between both groups, but there was a tendency towards a lower bone volume, a lower bone formation rate and a lower osteoclast surface under corticosteroids. We conclude, that increased bone resorption can be found in postmenopausal women with osteoporosis relatively independent of longterm corticosteroid therapy, but there seems to be an additional inhibitory effect of corticosteroids on bone formation.

Prednisolone Administration Ameliorates the Increased Osteoclastogenesis But Aggravates the Loss of Osteocytes and Bone Strength That Follow Orchidectomy. R. S. Weinstein, C. C. Powers,* R. D. Landes,* A. M. Parfitt, S. C. Manolagas. Div. of Endo/Metab, Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Glucocorticoid excess causes decreased bone turnover and a profound depression in the numbers of both osteoblasts and osteoclasts due to inhibition of both osteoblastogenesis and osteoclastogenesis as well as to increased apoptosis of osteoblasts. Sex steroid deficiency also causes osteoblast and osteocyte apoptosis but, in contrast to glucocorticoids, results in upregulation of osteoblastogenesis, osteoclastogenesis and bone turnover. The two disorders could either aggravate or ameliorate each other. We used established murine models of glucocorticoid-induced osteoporosis and of androgen deficiency to examine the interactions of these conditions. Prednisolone or placebo was administered to 5-mo-old Swiss Webster mice for 28 days after sham operation or orchidectomy. Serial bone densitometry determinations revealed that bone loss was more rapid with prednisolone than after orchidectomy but, after 28 days, the amount of bone loss was similar in the orchidectomy and orchidectomy plus prednisolone groups. Vertebral compression strength was, however, less when both conditions were present. In the orchidectomized animals receiving prednisolone, the expected increases in CFU-F and in osteoclastogenesis were attenuated, as

determined in ex-vivo bone marrow cell cultures. Likewise, the orchidectomized animals receiving prednisolone failed to show the expected increase in cancellous osteoblasts and bone turnover. In addition, the prevalence of osteoblast apoptosis was less after orchidectomy plus prednisolone than after orchidectomy alone due to the decline in bone turnover. In contrast, *osteocyte* apoptosis was greatest when both conditions were present. These data demonstrate that glucocorticoid excess suppresses osteoclastogenesis in the marrow and the number of osteoclasts in cancellous bone, even in the face of the potent counter regulatory signals generated by orchidectomy. Moreover, they strongly suggest that changes in osteoblast and osteocyte apoptosis in glucocorticoid excess have graver consequences for bone homeostasis than the suppression of the rate of bone turnover. This latter contention is consistent with the evidence that whereas both bisphosphonates and glucocorticoids suppress turnover in sex steroid deficiency, the former increases while the latter, as shown here, further decreases bone strength–perhaps due to the combined effect of glucocorticoid excess and loss of androgens on osteocyte apoptosis.

SA324

Pre-receptor Activation of Glucocorticoids in Osteoblasts Increases With Age and Steroid Therapy. M. S. Cooper, E. R. Rabbitt,* P. Goddard,* P. M. Stewart,* M. Hewison. Medicine, University of Birmingham, Birmingham, United Kingdom.

The risk of glucocorticoid-induced osteoporosis increases substantially with age but is subject to considerable individual variation. We have proposed that this may be due to pre-receptor regulation of glucocorticoid responsiveness by the enzyme 11β-hydroxysteroid dehydrogenase (11β-HSD1): human osteoblastic cells (hOB) express 11β-HSD1 and synthesis of active cortisol by these cells is sensitively stimulated by inflammatory cytokines. In data presented here we have used a large number of primary hOB cultures to assess the effects of age on 11β-HSD expression and activity at different bone sites. In addition we show that prednisone is a target for 11β-HSD1 and that 'pre-receptor' activation of glucocorticoids via this enzyme is, in turn, induced by therapeutic steroids. HOB cells were generated from collagenase-digested trabecular bone chips obtained from orthopaedic specimens. Basal 11β-HSD1 activity (synthesis of cortisol from cortisone) increased significantly with age: e.g. 1.2 pmols/hr/mg protein age 11; 6.5 pmols/hr/mg protein age 63 ($r=0.59$, $p<0.05$). 11β-HSD1 expression and activity was also increased following treatment with various naturally occurring and synthetic steroids (eg. dexamethasone 2.1-fold ± 0.3; cortisol 1.7-fold ± 0.1 both $p<0.01$; $n=12$). Similar increases in expression of mRNA for 11β-HSD1 were demonstrated using real-time PCR (3.6-fold with dexamethasone; 2.5-fold with cortisol, both $p<0.01$). hOB as well as cells transfected with 11β-HSD1 also demonstrated the ability to convert prednisone to prednisolone, emphasizing that hOB cells have the ability to 'concentrate' active steroid through a pre-receptor mechanism. The significance of this *in vivo* was assessed by measuring circulating levels of steroids in normal males before and after treatment with oral prednisolone (5mg). 0900 cortisone levels were 110 ± 5 nmol/L and prednisone peaked at 78 ± 23 nmol/L 120 min. after administration of prednisolone. Thus therapeutic use of steroids has the potential to increase substrate availability for 11β-HSD1 in bone. These studies confirm that glucocorticoid availability in bone is dependent on the expression of 11β-HSD1. We propose that pre-receptor activation of glucocorticoids plays an important role in age-related decrease in bone formation and increased risk of steroid-induced osteoporosis.

Skeletal Effects of Ovariectomy in New Zealand White Rabbits. R. J. Colman,[1] M. Butz,*[2] N. C. Binkley.[2] [1]Wisconsin Regional Primate Research Center, University of Wisconsin, Madison, WI, USA, [2]Institute on Aging, University of Wisconsin, Madison, WI, USA.

Animal model utilization has played a major role in understanding osteoporosis pathogenesis and development of effective treatments. Ideally, animal models for skeletal research would possess bone remodeling processes similar to adult humans, i.e., Haversian remodeling. This is not the case with current small animal models. However, laboratory rabbits possess Haversian remodeling and many other attributes of an outstanding model including ready availability at modest expense and ease of handling. Despite these advantages, it is not established that another important animal model criterion, bone loss following estrogen depletion, occurs in rabbits. To this end, we conducted a study evaluating the effects of ovariectomy (oxv) on bone mass in eleven, 5-month old, New Zealand white rabbits (Oryctolagus cuniculus). Animals were individually housed and fed standard laboratory chow ad libitum. Baseline study was followed by randomization to receive bilateral ovx (n=6) or sham (n=5) surgery. Following surgery, animals were assessed, utilizing acepromazine and ketamine, at 0.5, 1, 1.5, 3 and 6 months. Assessments included blood sampling and bone density measurement by dual-energy x-ray absorptiometry (DXA). DXA consisted of lumbar spine (L1-L7) scans utilizing a Lunar DPX-L densitometer (GE/Lunar, Madison WI) with pediatric software, and distal femur/proximal tibia scans utilizing a Lunar PIXImus densitometer. Longitudinal data was analyzed by repeated measures analysis of variance. Body weight increased in both groups over time ($p<0.0001$). In the ovx group, lumbar spine BMD initially decreased and did not fully recover, leading to an ovx-sham difference of ~9% over time ($p<0.05$). Lumbar spine BMD increased 9% in the sham group during this study. Modeling of distal femur data showed a strong correlation with body weight and a difference between sham and ovx in the reaction to surgery ($p<0.05$). Although these animals were hypercalcemic (range: 11.8-13.1 mg/dl) and hypercalciuric relative to humans, both serum calcium and phosphorus were stable through 30 days post surgery, indicating tight homeostatic regulation. In summary, our findings, while preliminary, indicate that five month old rabbits have not reached peak skeletal mass. However, the development of relative osteopenia demonstrates promise for a rabbit model of estrogen-depletion bone loss. With its relative ease of handling and cost-effectiveness, we believe rabbits may possess many of the characteristics of an ideal animal model for osteoporosis research and, due to their Haversian remodeling, may be particularly useful for assessment of skeletal anabolic agents.

SA326

Evidence that Postmenopausal Women with Vertebral Fractures Due to Type I Osteoporosis Have Enhanced Responsiveness of Bone to Estrogen Deficiency. B. L. Riggs,[1] L. J. Melton, III,[1] E. J. Atkinson,*[1] W. M. O'Fallon,*[1] C. Dunstan,*[2] S. Khosla.[1] [1]Mayo Clinic and Mayo Foundation, Rochester, MN, USA, [2]Amgen Corporation, Thousand Oaks, CA, USA.

We have hypothesized that osteoporosis (OP) can be divided into type I and type II fracture syndromes (Am J Med 75:899, 1983). Type I osteoporosis occurs within 20 years after menopause and may be due to estrogen (E) deficiency plus some additional factor predisposing to excessive bone loss. One such factor might be a greater degree of sex steroid deficiency, which could not be excluded previously because assays were not sufficiently sensitive to measure low postmenopausal sex steroid levels accurately. Thus, we studied 40 women with typical high turnover type I postmenopausal osteoporosis and vertebral fractures and 40 normal postmenopausal women (controls) using new ultrasensitive assays with detection limits of 1 and 5 pg/ml for estradiol (E_2) and estrone (E_1), respectively, and 5 ng/dl for testosterone (T). Bone turnover was assessed by measuring serum osteocalcin (OC) and bone alkaline phosphatase (BAP) and 24-h excretion of urinary pyridinoline (PYD) and deoxypyridinoline (DPD).

Variable (mean ± SEM)	Controls	Type I OP	P (rank sum)
Age, yrs	64.8 ± 0.9	64.6 ± 0.8	NS
Yrs after menopause	16.7 ± 1.1	17.3 ± 1.4	NS
E_2, pg/ml	6.3 ± 0.8	6.1 ± 1.2	NS
E_1, pg/ml	15.9 ± 0.9	16.8 ± 2.2	NS
T, ng/dl	24.8 ± 1.6	27.6 ± 1.8	NS
OC, ng/ml	9.0 ± 0.3	10.2 ± 0.	<0.02
BAP, U/L	20.3 ± 1.0	30.4 ± 1.9	<0.001
PYD, nmol/mmol Cr	42.7 ± 2.1	55.5 ± 2.5	<0.001
DPD, nmol/mmol Cr	13.0 ± 0.6	18.8 ± 0.9	<0.001

Although levels of serum sex steroids were identical in both groups, bone turnover was increased by up to 50% in the women with type I osteoporosis. Moreover, compared with controls, the osteoporotic women had 13% lower ($P<0.05$) serum PTH and 53% higher ($P<0.01$) serum osteoprotegerin levels, which were likely compensatory responses to the increased bone turnover. Because many studies have shown that E replacement will normalize the elevated bone turnover in these patients, those postmenopausal women who develop type I osteoporosis may have a genetically-determined, increased responsiveness of bone to E deficiency that is evident in the presence of low E levels but is overcome by high E levels. This hypothesis is consistent with recent reports that postmenopausal women with polymorphisms of the E receptor genes have low bone density and fractures

Changes in Activation Frequency are More Influential Than Changes in Focal Bone Balance in Predictive Models of BMD Response to Estrogen Depletion and Replacement. C. J. Hernandez,* G. S. Beaupré, R. Marcus, D. R. Carter. VA Palo Alto HCS, Palo Alto, CA, Stanford University, Stanford, CA, USA.

The decreases in bone mass associated with estrogen depletion and replacement are the result of changes in bone remodeling. Bone remodeling is performed by the coupled activity of groups of cells in basic multicellular units (BMUs). Although changes in BMU activity such as increased activation frequency and decreased focal bone balance have been associated with estrogen loss there are conflicting reports regarding how these changes are associated with estrogen depletion and how they may be reversed through estrogen replacement. In this study we use a computational model of BMU activity to determine the changes in BMU activity that are most consistent with clinical bone mineral density (BMD) measurements made during estrogen depletion and replacement. In this analysis bone remodeling in the lumbar spine is simulated. Changes in BMU activity are applied in response to changes in serum estradiol concentrations. Changes in estradiol levels are considered to cause changes in: 1) activation frequency; 2) focal bone balance or 3) both. The magnitude of changes in BMU activity are determined by parametrically fitting simulation results to the changes in BMD observed in patients experiencing menopause or starting hormone replacement therapy (Recker et al. JBMR 2000 15(10):1965-73). All three simulation methods were able to predict the changes in BMD caused by estrogen depletion at menopause. Only simulations that considered both changes in focal bone balance and activation frequency gave predictions that were consistent with the BMD changes observed after hormone replacement therapy. Simulations that were consistent with both estrogen depletion and hormone replacement had only small changes in focal bone balance, suggesting that modification of activation frequency is the primary change in BMU activity that occurs in response to estrogen depletion and replacement. Since BMD changes resulting from modification of activation frequency are reversible, our finding that activation frequency is most likely the primary change in BMU activity implies that most of the bone mass lost due to estrogen depletion could be recovered with the appropriate estrogen

replacement therapy (although concurrent bone loss from factors like disuse or nutritional deficiencies would not be returned). Knowing the changes in BMU activity caused by estrogen depletion and replacement may help identify ways to modify BMU activity in postmenopausal women so that the greatest increases in bone mass can be achieved.

SA329

Number of Years Since Menopause: Spontaneous Bone Loss Is Dependent but Response to HRT Is Independent. N. H. Bjarnason,* P. Alexandersen, C. Christiansen. Clinical Dept., Center for Clinical and Basic Research, Ballerup, Denmark.

We wished to study the influence of number of years since menopause (YSM) on spontaneous bone loss and response to HRT in postmenopausal women under consideration for HRT. For this purpose we used data from 274 women within 20 years after menopause participating in 2 placebo-controlled mono-center trials of sequential, continuous and interrupted HRT in traditional and low doses without calcium addition. Both cross-sectionally at baseline in the total cohort (n=274) and longitudinally in the placebo group(n=71), bone loss in untreated women was greatest closest to the menopause and declined thereafter (r=0.34, p<0.01 for lumbar spine and r=0.25, p<0.05 for the femoral neck), such that the loss was eliminated in the femoral neck and bone mass increased in the spine in women more than 10 years after menopause.

Associations between YSM categories and BMD in untreated women

Cross-sectional (n=274 untreated women at baseline; mean(std))

	YSM<=2	YSM>2 and <=4	YSM>4 and <=7	YSM>7 and <=10	YSM>10
BMDspine(g/cm2)	0.99(0.13)	0.94(0.13)	0.92(0.13)	0.91(0.13)	0.84(0.11)
BMDneck(g/cm2)	0.76(0.10)	0.73(0.11)	0.70(0.09)	0.68(0.08)	0.68(0.11)

Longitudinal (n=71 placebo-treated women; mean(sem))

	YSM<=2	YSM>2 and <=4	YSM>4 and <=7	YSM>7 and <=10	YSM>10
aBMDspine(%/yr)	-1.54(0.38)	-0.33(0.22)	-0.18(0.53)	-0.04(0.47)	0.39(0.60)
aBMDneck(%/yr)	-1.50(0.26)	-0.63(0.25)	-0.44(0.51)	-0.24(0.92)	-0.01(0.91)

In contrast, bone turnover (S-OC and S-CTX) in untreated women was consistently elevated all through menopause, both cross-sectionally and longitudinally. The association between bone mass and YSM was counteracted both by 1 and 2 mg estradiol sequentially or continuously combined with gestodene, by piperazine estrone sulphate in combination with interrupted norethisterone and by a continuous combination of 2 mg estradiol and 1 mg norethisterone acetate. The response to the various HRT regimens was also independent of baseline bone mass.In conclusion, whereas bone loss was significantly related to number of years since menopause in untreated women, all HRT regimens arrested bone loss regardless of number of years since menopause. In addition, this effect seemed to be independent of type of estrogen, type of progestin and regimen chosen. Interestingly, the increase in spinal bone mass in women more than 10 years after menopause can not - as it has previously been suggested - be contributed to calcium supplementation, since calcium was not administered in our study. The constant difference between bone resorption and formation markers may be an essential component to explain the exponential pattern of bone loss in untreated women, but further experiments are needed to characterise this function which involves several compartments and eliminations

Bone Response to Estrogen Replacement in BRKO (Estrogen Receptor-β) Null Mice. M. A. Gentile, J. G. Seedor, G. A. Rodan, D. B. Kimmel. Bone Biology and Osteoporosis, Merck Research Laboratories, West Point, PA, USA.

α and β isoforms of the estrogen receptor (ER) exist, but their role in bone has not been fully defined. This study examined the skeletal effects of 17-β-estradiol (E2) in ovariectomized (OVX) ERβ null (BRKO) mice, obtained by F2 crosses of ERβ(+/-) females with ERβ(-/-) males.BRKO and wild type (WT) mice were OVX or Sham-OVX at age 26 weeks. OVX groups were given 0, 0.02, 0.04, or 0.2mg/kg 3X/wk E2 in sesame oil for eight weeks. Uterine weight (UWt, mg) and bone mineral density of distal 20% of femur (DF-BMD, mg/cm2, pDXA Norland) were measured after necropsy. The five groups of each genotype (see Table, all N=~12) were compared by Kruskal-Wallis ANOVA with Student Neuman-Keuls post-hoc test.

		Wild Type		BRKO	
Surg	**E2**	**UWt**	**DF-BMD**	**UWt**	**DF-BMD**
Sham	0	115±36#	62±7*	99±41#	65±4#
OVX	0	22±6	57±4	21±4	59±6
OVX	0.02	72±16#	60±7*	99±29#	65±7#
OVX	0.04	86±23#	64±3#	89±40#	67±6#
OVX	0.2	123±46#	66±4#	101±29#	67±7#

Mean±SD; #greater than OVX/same genotype (P<.01); *(P<.08)

There were no significant differences in UWt or DF-BMD between BRKO/Sh and WT/Sh mice. OVX reduced UWt (P<.001) and DF-BMD (P<.04) in both genotypes. All doses of E2 protected equally against loss of UWt and DF-BMD in WT and BRKO mice. We conclude that in the absence of ERb: 1) OVX induces bone loss; and 2) OVX-induced bone loss is prevented by E2. The similar protective action of E2 against loss of uterine weight and bone in OVX BRKO and WT, suggests that ERb is not required for these effects in mice

SA332

Effects of Ovariectomy on Bone Histomorphometric Parameters in Old Cynomolgus Monkeys. J. Legrand,[1] A. Bécret,[2] C. Fisch,[2] P. Persil,*[2] M. Attia,*[2] R. Forster,[2] J. Claude.*[3] [1]Beaufour-Ipsen, Paris, France, [2]CIT, EVREUX, France, [3]Faculty of Pharmacy, Paris, France.

Mature female cynomolgus monkeys from Mauritius, approximately weighing 4 kg, were randomly allocated to two groups. Seven animals were ovariectomized (OVX) and thirteen were sham-operated (SHAM). Bone mineral density (BMD) of lumbar vertebrae was measured by DXA before and 15 months after surgery. At this latter time, biopsies of the iliac crest and rib were obtained after dual calcein labeling (13-day interval). The bone samples were cut, undecalcified, stained with Goldner stain or examined under fluorescence to quantify the bone static and dynamic endpoints of bone formation and resorption histomorphometric parameters, using a validated image analysis software (Biocom). Fifteen months after surgery, the BMD of SHAM and OVX animals were respectively identical (99 ± 1 %) and decreased (93 ± 1 %) when compared to the BMD measured before surgery. Trabeculae could only be found in 4/13 rib biopsies of SHAM animals and in 5/7 rib biopsies of OVX monkeys. Trabecular tissue was lacking in only two iliac crest biopsies of the 20 animals (1 SHAM and 1 OVX). Histomorphometric parameters measured on trabecular bone of iliac crest and on cortex of both iliac crest and rib are summarized in the table (mean ± SEM,*: parameter quantified at iliac crest).

Parameter	SHAM	OVX	Parameter
BV/TV (%)*	18.93 ± 2.74	12.52 ± 1.72	MS/BS (%)*
Tb. Th. (μm)*	119 ± 8	98 ± 2	MAR (μm/day)*
Tb. N. (mm^{-1})*	1.53 ± 0.17	1.27 ± 0.16	BFR ($\mu m^2/\mu m$/day)*
Tb. Sp. (μm)*	634 ± 95	742 ± 88	
ObS/BS (%)*	5.86 ± 0.76	5.62 ± 2.00	Ct. Por. (%)*
OS/BS (%)*	16.70 ± 2.17	27.70 ± 4.57	Ct. Por. (rib) (%)
ES/BS (%)*	4.86 ± 0.66	6.62 ± 1.24	

Histomorphometric parameters in SHAM animals were similar to previously reported values in iliac crest of mature (10-15 years) cynomolgus monkeys. Most parameters of bone resorption and bone formation were higher in OVX monkeys than in SHAM animals. This reflects that the ovariectomy-induced bone turnover is still ongoing 15 months after surgery, a fact that should be considered when using the old OVX cynomolgus monkey as a model of established human osteoporosis.

SA333

The Relation of Renal Calcium Excretion and Bone Mineral Metabolism in Korean Postmenopausal Women. K. Oh,*[1] S. Lee,[1] D. Lee,*[1] E. Oh,*[2] W. Lee,*[2] M. Kang.*[2] [1]Miz Medi Hospital, Seoul, Republic of Korea, [2]St. Mary's Hospital, The Catholic University Medical College, Seoul, Republic of Korea.

Although all postmenopausal women are estrogen-deficient, women with postmenopausal osteoporosis may have some another defects, that explain for their higher rates of bone resorption and greater bone loss, compared to postmenopausal women without osteoporosis. In this cross-sectional study, we tested the hypothesis that one of the defects is an impairment of renal calcium conservation. In 177 postmenopausal women and 88 premenopausal women, we measured 24-hour urinary calcium levels, serum FSH, Estradiol (E2), intact PTH levels and bone tunover markers (serum osteocalcin and urine deoxypyridinoline). Bone mineral density using DEXA was also measured.Twenty-seven percent (47/177) of Korean postmenopausal women had urinary calcium excretion exceeding 4 mg/kg per day. The postmenopausal women had higher (p<0.05) values for mean urinary calcium to creatinine ratio (U cal/cr ratio) of 0.26±0.12 mg/mg of creatinine vs. 0.22±0.13 mg/mg of creatinine and higher (p<0.001) mean serum calcium level of 9.2±0.3 mg/dL vs. 9.0±0.3 mg/dL than the premenopausal women. Significant positive correlations were observed between U cal/cr ratio and both turnover markers (for serum osteocalcin, r=0.72, p<0.001; for urine deoxypyridinoline, r=0.213, p<0.01). However, there was no correlation with serum FSH level, E2 level, or intact PTH level. Although U cal/cr ratio was not significantly different according to bone mineral density status, there was increasing tendency of U cal/cr ratio in postmenopausal women with osteoporosis compared to women with normal bone mineral density (0.26±0.14 vs 0.22±0.13 mg/mg of creatinine). We suggest that some of Korean postmenopausal women have a defect in renal calcium conservation and bone turnover could be higher in postmenopausal women with a defect than those without this defect. Further studies are needed to identify the specific cause of the renal leak in cal-

cium in postmenopausal osteoporotic women.

Ovariectomy Dramatically Reduces Bone Innervation. B. Burt-Pichat,*[1] M. Lafage-Proust,[2] F. Duboeuf,*[1] C. Itzstein,*[1] P. D. Delmas,[1] C. Chenu.[1] [1]INSERM Unit 403, Lyon, France, [2]LBTO, INSERM-E9901, Saint-Etienne, France.

We recently demonstrated that sciatectomy induces a bone loss in rat tibia associated with a reduction of nerve profiles immunostained for several nerve markers, suggesting a link between bone innervation and remodeling. In order to rule out the effect of limb immobilization in these experiments, we studied the innervation in rat tibiae after ovariectomy and compared the results with the neurectomy model. A total of 27 female Wistar rats, aged 12 weeks, were randomly divided into 2 groups. 13 rats were sham-operated (SHAM) and 14 were ovariectomized (OVX). The rats were sacrified 14 days after surgery and infused with 1% glutaraldehyde in PBS by intracardiac injection. Bone mineral density (BMD) was measured by dual energy x-ray absorptiometry (DEXA) (Hologic 1000 plus) on the left tibiae, which were then processed for bone histomorphometry analysis. Right tibiae were fixed in 1% glutaraldehyde and processed for immunocytochemistry of nerve markers. BMD was significantly decreased in OVX tibiae compared to SHAM after 14 days ($P<0.005$, Mann-Whitney's Test). Bone histomorphometry analysis of tibiae demonstrated a significant reduction of trabecular bone volume (BV/TV) in both primary ($P<0.005$) and secondary ($P<0.0005$) spongiosa of OVX rats compared to SHAM. Immunocytochemistry of tibiae was performed using antibodies directed against the specific neuronal markers, neurofilament 200 (NF200) and synaptophysine (SY). We observed an important reduction of nerve profiles immunolabelled for both nerve markers in OVX tibiae. Quantitative image analysis (Osteolab, Biocom) of immunostaining for NF200 showed a 70% and 60% decrease of labelled profiles areas, respectively in primary ($P<0.0001$) and secondary spongiosa ($P<0.005$) of OVX tibiae compared to SHAM. A two-fold decrease of the percent area of immunolabelling for SY was also shown in primary spongiosa ($P<0.01$) and secondary spongiosa ($P<0.05$) of OVX Tibiae. While the decrease of innervation after sciatectomy was more marked in the modeling zone, ovariectomy lead to a strong reduction of nerve profiles in both modeling and remodeling zones. Our results indicate that ovariectomy of rat tibiae induces a bone loss associated with a marked reduction of nerve profiles density, similar to that observed after neurectomy. The decrease of innervation associated with bone loss in both models suggests that neural regulation may play a role in bone loss during immobilization and in osteoporosis.

SA336

Anabolic Effect of Vitamin K2 on Endocortical Bone in Orchidectomized Rats. J. Iwamoto,[1] T. Takeda,*[1] J. K. Yeh,[2] S. Ichimura,*[3] Y. Toyama.*[4] [1]Sports Medicine, Keio University School of Medicine, Tokyo, Japan, [2]Metabolism Laboratory, Winthrop-University Hospital, Mineola, NY, USA, [3]Orthopaedic Surgery, National Defense Medical College, Saitama, Japan, [4]Orthopaedic Surgery, Keio University School of Medicine, Tokyo, Japan.

The aim of the present study was to examine the effect of vitamin K2 on cortical bone loss in orchidectomized rats. Fifty male rats, 6 weeks of age, were randomized by stratified weight method into 5 groups with 10 rats in each group: baseline controls (BLC), age-matched controls (AMC), vitamin K2 administration (K), orchidectomy (ORX), and ORX+K. Vitamin K2 (menatetrenone) was administered subcutaneously at dose of 30 mg/kg on 2 days a week in the K and ORX+K groups. The experimental period was 8 weeks, and cortical bone histomorphometry was performed on double fluorescent labeled 40 um-thick sections of the tibial shaft. Total tissue area (Tt Ar) and cortical area (Ct Ar) were significantly higher in the AMC, K, ORX, and ORX+K groups that those in the BLC group (all $P<0.0001$). Tt Ar and Ct Ar were significantly lower in the ORX and ORX+K groups than that in the AMC group (all $P<0.05$), but they did not differ significantly between the AMC and K groups and between the ORX and ORX+K groups. Percent Ct Ar did not differ significantly between the AMC and K groups. Percent Ct Ar was significantly lower and percent marrow area (Ma Ar) was significantly higher in the ORX group than those in the AMC group (Ct Ar 83.1 % vs 84.9 %, $P<0.05$; Ma Ar 16.9 % vs 15.1 %, $P<0.05$). Percent Ct Ar was significantly higher and percent Ma Ar was significantly lower in the ORX+K group (84.9 % and 15.1 %, respectively) than those in the ORX group (both $P<0.05$), and they did not differ significantly from those in the AMC group. Endocortical eroded surface (ES/BS) and mineralizing surface (MS/BS), and periosteal MS/BS and mineral apposition rate (MAR) did not differ among any groups. However, endocortical MAR was significantly higher in the ORX group than that in the AMC group (1.20 um/day vs 1.02 um/day, $P<0.01$). Endocortical MAR was significantly lower in the ORX+K group (1.02 um/day) than that in the ORX group ($P<0.001$), and it did not differ significantly from that in the AMC group. These findings suggested that ORX increased MAR and subsequent bone turnover on the endocortical surface compared with age-matched controls, resulting in endocortical bone loss, and that vitamin K2 could prevent ORX-induced endocortical bone loss by normalizing MAR and subsequent bone turnover to the control level. Vitamin K2 could not prevent the ORX-induced reduction in the age-related gain in Tt Ar and Ct Ar. The present study provides evidence indicating the anabolic effect of vitamin K2 on endocortical bone in orchidectomized rats.

SA337

Sex Hormone and Adrenal Androgen Concentrations in Men with Idiopathic and Steroid-induced Osteoporosis. N. Bhargava,[1] J. Cheung,[1] S. Vaja,*[1] P. Seed,[2] I. Fogelman,[3] G. Hampson.*[1] [1]Chemical Pathology, St Thomas' Hospital, London, United Kingdom, [2]Obstetrics and Gynaecology, St Thomas' Hospital, London, United Kingdom, [3]Nuclear Medicine, Guy's Hospital, London, United Kingdom.

Changes in gonadal and/or adrenal steroids have been implicated in the pathogenesis of male osteoporosis and corticosteroid-induced osteoporosis. This study was undertaken to assess and compare adrenal androgen, testosterone and oestrogen status in a group of men with idiopathic and steroid-induced osteoporosis. We investigated 77 men (Group A, Idiopathic osteoporosis, n = 38 age (mean (SD) 57.7 (12.1) years, Group B, Steroid-induced osteoporosis, n = 39 age 55.3(13.1) years). The current steroid dosage was (mean (SD)) 14.3 (11.3) mg/day and the duration of oral steroid intake was 9.6 (8.1) years for the patients in Group B. There was no significant difference in bone mineral density (BMD) expressed as 'T' score at the spine, femoral neck and total hip between the 2 groups (Group A : spine -0.85 (0.83), femoral neck -1.56 (0.09), hip -2.54 (1.09), Group B : spine -0.89 (0.14), femoral neck -1.54 (0.81), hip -2.2 (.22)). However the prevalence of fragility fractures was higher in Group A (53% of patients in Group A v/s 23% in Group B, $p=0.0019$). Serum androstenedione, dehydroepiandrosterone sulphate (DHEAS), testosterone and and oestradiol were determined on all patients. The results were analysed by multiple regression with robust standard errors. Androstenedione and DHEAS were significantly reduced in Group B patients (Androstenedione:Group A 4.99(1.8), Group B 2.1 (1.6) $p = 0.0001$, DHEAS Group A 3.3 (2.4),Group B 1.4 (2.2) $p = 0.001$)). Serum DHEAS was undetectable in 23 (59%) patients in Group B compared with only 2 (5%) patients in Group A. We observed no significant difference in total and free testosterone and oestradiol between the 2 patient groups.Oestradiol/Sex hormone binding globulin (SHBG) ratio was significantly lower in Group A (Group A 1.24 (0.7), Group B 2.03 (1.3) $p = 0.007$). In the whole population studied, there was a significant positive association between serum oestradiol and BMD at the spine ($t = 2.622$, $p = 0.01$). The relation between serum oestradiol and spine BMD was more marked in Group B patients ($t = 2.974$, $p = 0.004$). In conclusion, this study confirms the association between serum oestradiol and BMD in men. Adrenal androgens production is significantly impaired in patients on steroids in contrast to sex steroids. Suppression of adrenal androgen synthesis may contribute, at least in part, to the reduction in bone formation observed in steroid-induced osteoporosis.

Densitometric Diagnosis of Osteoporosis in Men: Effect of Measurement Site and Normative Database. N. L. Vallarta-Ast,[1] D. C. Krueger,[2] N. C. Binkley.[2] [1]Department of Radiology, Wm S Middleton VAMC, Madison, WI, USA, [2]Institute on Aging, University of Wisconsin, Madison, WI, USA.

Controversy exists regarding which sites to measure, and the appropriate database to use, for the densitometric diagnosis of osteoporosis in men. While bone mineral density (BMD) measurement of the proximal femur (F) and lumbar spine (LS) is routine, LS osteoarthritis often elevates measured BMD in older men. Additionally, use of a male normative database is standard practice, however, recent data suggest a female database may be more appropriate. As such, the purpose of this cross-sectional study was to evaluate the effect of sites measured and normative database utilized on osteoporosis diagnosis in men. From 1997 to 2000, 647 male veterans were referred for initial BMD measurement; 52 were excluded based on inability to image a site. In the remaining 595 men (mean age 65 ± 12 years), DXA measurements were obtained at the LS, F and ultradistal radius (UD) using a Lunar Expert-XL densitometer. The manufacturers male normative database was used for initial analysis and World Health Organization (WHO) diagnostic criteria were applied. Osteoporosis (T-score < -2.5) was present at one or more sites in 282/595. The most sensitive single site was F identifying 75% of osteoporotic men compared to 56% and 37% at the UD and LS respectively. Combination of F plus UD was more sensitive (p 70, F plus UD detected 98% of men with osteoporosis. Of the 595 subjects, 129 had radiographically documented fractures (94 vertebral, 13 hip, and 28 other). In this group, scans were analyzed using male and female normative data. WHO diagnostic criteria and National Osteoporosis Foundation (NOF) treatment guidelines were applied. More men with prior fracture were diagnosed as osteoporotic ($p < .0001$), and NOF treatment indications were met more frequently ($p < .0001$), when a male normative database was utilized. Specifically, use of female normative data would lead to 29.5% of these men with prior fracture not meeting criteria for pharmacologic therapy. Furthermore, the percentage classified as having normal bone BMD was higher using female reference data (16%) than when male (10%) was used. In conclusion, BMD measurement at only the spine and hip leads to underdiagnosis of osteoporosis in men. This situation will be exacerbated by utilization of a female normative database. Many men with prior fracture will be categorized as not meeting a pharmaceutical intervention threshold or as having normal bone mass. Clinicians need to be aware of this impact on osteoporosis treatment recommendations if use of female reference data becomes standard densitometric practice in men.

The Effect of Chronic Estrogenic Treatment on the Bone Mineral Metabolism of the Man. M. Sosa,[1] E. Arbelo,*[2] M. Domínguez,*[3] D. Hernández,[4] A. Arbelo,*[3] J. Gómez.*[4] [1]Bone Metabolic Unit, University of Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain, [2]University of Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain, [3]Hospital University Dr. Negrín, Las Palmas de Gran Canaria, Spain, [4]Hospital University Insular, Las Palmas de Gran Canaria, Spain.

Background: There is a clear relationship between oestrogen deficiency and the decrease in bone mass among women, but the aetiology of osteoporosis in men in somewhat different. It has been described an excess of glucocorticoids, hypogonadism, and a variety of other systemic conditions, medications, and lifestyle factors, but often there is no obvious cause. It has also been linked with testosterone deficiency, and recently with serum estradiol levels. Taking into account that there is no ethically approved method to treat osteoporosis in men with estrogens -due to the feminisation caused-, we have searched for a population of men that self-administered estrogens, because they view themselves as women. They are transvestites. Not having found any reference to similar studies in Medline, we have studied the effects of a long-term estrogens intake in a middle-age male population on the bone mineralMethods: We studied 53 men (age 30-59) and divided them into two groups:Group 1: 27 transvestites that had been taking estrogens for a minimum period of 36 months. Group 2: 26 healthy men without any intake of estrogens as controls.To perform this study, we included men that received estrogens for a minimum time of 36 months. Those with chronic hepatitis, HIV and other diseases that affect the bone such as chronic renal failure, hepatic insufficiency, hyperparathyrodism, hypothyroidism, were excluded, the same as those transvestites that had undergone surgery in order to change their gender (transsexuals). Results: We found no statistically significant differences in biochemical bone remodeling markers and hormones between both groups with the exception of serum estradiol levels who were higher in transvestites and testosterone who were lower in this group compared to controls. Bone mineral density and bone mineral content values were similar in both groups (Table 1). Conclusion: Chronic treatment with estrogens dos not produce significant changes in bone mineral metabolism in men, either in biochemical bone remodelling markers or in bone mass.

	Transvestites	Controls	P values
BMD (g/cm^3)			
L2L4	1.068 ± 0.175	1.043 ± 0.145	0.59

Decrease in Serum Leptin by Troglitazone Is Associated With Preventing Bone Loss in Type 2 Diabetic Patients. S. Watanabe,*[1] Y. Takeuchi,[1] S. Fukumoto,[2] T. Nakano,*[3] T. Fujita.*[1] [1]Department of Medicine, University of Tokyo School of Medicine, Tokyo, Japan, [2]Department of Laboratory Medicine, University of Tokyo School of Medicine, Tokyo, Japan, [3]Tokyo Metropolitan Tama Geriatric Hospital, Tokyo, Japan.

Thiazolidinedione (TZD) class of antidiabetic drugs decreases the expression of leptin in adipocytes. Troglitazone, a member of TZD, often suppresses serum leptin level in type 2 diabetic patients. Less leptin can be associated with high bone mass based on analyses of mice deficient in leptin actions. Therefore, treatment with TZD may influence bone metabolism in diabetic subjects. The present study was undertaken to clarify effects of one year-treatment with troglitazone on bone mineral density (BMD) and bone metabolism in non-obese type 2 diabetic patients. Twelve male (mean 71.3 year-old) and 15 postmenopausal female (mean 72.6 year-old) with type 2 diabetes (HbA1c 8.4 +/- 0.5%) were enrolled in 1998-1999 to take 400 mg/day troglitazone for one year. Serum leptin decreased in 70% of subjects after one month-treatment. HbA1c significantly decreased after 3 months, while body mass index and %body fat did not change until 12 months in patients whose serum leptin level either increased or decreased. Although lumber BMD in each patient was equivocally changed during the treatment period, %change of BMD was significantly higher in the leptin-decrease group than in leptin-increase group at 6 and 12 months. Both of urinary excretion of type I collagen N-telopeptide (NTx) and serum bone alkaline phosphatase (ALP) decreased at one month but increased thereafter in either group. %Change of BMD was negatively correlated with %change of serum leptin, whereas it was not associated with that of other parameters including NTx, bone ALP, body mass index and HbA1c. There was no significant correlation between basal level of serum leptin and BMD. These observations suggest that the decrease in serum leptin with no change in body fat mass by troglitazone is involved in preventing bone loss in type 2 diabetic patients. Hence, TZD may have advantage for diabetic patients who have a risk for osteoporosis, and leptin may negatively affect bone metabolism in humans.

SA343

Role of Insulin-like Growth Factor-1 and Transforming Growth Factor b1 in Experimental Osteoporosis in Rat. X. Liang.* Shenzhen Institute of Geriatrics, Shenzhen, China.

Previous studies suggested that insulin-like growth factor-1 (IGF-1) and transformaing growth factor b1 (TGFb1) may involve in the development of osteoporosis. To document the their roles in the pathogenesis of osteoporosis, the levels of IGF-1 and TGFb1 were followed in the rats with experimental osteoporosis induced by the twin ovaries removal. The bone mineral density was measured by HOLOGIC dual energy X ray bone densitometer. IGF-1 and TGFb1 were measured by enzyme-linked immunosorbent assay. Osteoporosis was documented by the low bone mineral density in the experimental group (n=30 each group, P<0.01, compared to the control group with sham operation). Serum IGF-1 levels were lower in the experimental group (P<0.05, compared to the control group) 8 to 16 weeks after the operation. Experssion of TGFb1 by chondrocytes and osteoblasts was different in the experimental group compared to the control group. (P<0.05). These data suggests that both IGF-1 and TGFb1 may be important in the pathogenesis of the postmenopausal osteoporosis.

Trauma due to Fracture Reduces Biomechanical Properties of Non-Fractured Bone in the Aged Rat Model. S. Juma,[1] M. P. Akhter,[2] D. Chakkalakal,*[3] J. R. Novak,*[4] D. A. Khalil,[1] E. A. Lucas,[1] M. El-Osta,*[1] B. J. Stoecker,[1] E. D. Fritz,*[4] B. H. Arjmandi.[1] [1]Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, [2]Osteoporosis Research Center, Creighton University, Omaha, NE, USA, [3]Biomedical Engineering Center, Creighton University, Omaha, NE, USA, [4]VA Medical Center, Creighton University, Omaha, NE, USA.

Fracture healing involves various local and systemic factors. The purpose of this study was to investigate whether the process of fracture healing in one bone affects the bone density and biomechanical properties of other bones in sham and ovariectomized (ovx) aged rats. Fifty-six female 12-month old Sprague-Dawley rats were divided into four groups; two sham and two ovx groups. Animals in all groups were placed on a semi-purified diet for a period of 120 days to allow significant bone loss to occur in the ovx animals as confirmed by assessing whole body bone mineral density (BMD) using DXA. Thereafter, osteotomy was performed to create an experimental fracture model in both fibulae in animals from one sham and one ovx group. In this model a surgically created 4-mm-long defect was fitted with an 8-mm-long tubular specimen of demineralized bone matrix over the cut ends of fibula. Animals were killed 100 days after osteotomy and bone specimens were collected for BMD and biomechanical assessments. As expected, ovx significantly decreased 4th lumbar vertebra and femoral BMD and bone mineral content (BMC) but fracture had no significant effects on BMD and BMC of these bones in either the sham or ovx group. However, fibular fracture in sham animals significantly decreased structural properties of femur such as yield (25%) and ultimate load (27%) without affecting BMD and BMC. Thus, trauma in one bone and the repair response compromised the mechanical properties of distant bones without decreasing BMD or BMC. These findings suggest a disruption of bone remodeling characterized by dystrophic mineralization rather than ossification of newly formed matrix. In ovx rats, the higher rate of bone turnover may be responsible for overcoming this deficiency. These mechanisms are currently being investigated. Supported by USDA NRI grant No. 99-35200-7606

Serum Leptin Levels and Bone Mineral Density in Postmenopausal Women. Z. Nagy, G. Speer, I. Takács, É. Bajnok,* P. Lakatos. 1st Department of Medicine, Semmelweis University, Budapest, Hungary.

Leptin is secreted by adipocytes and regulates the bone formation via the receptor located in hypothalamus. Beside, leptin controlls the body weight and gonadal functions, which are also in connection with bone mineral density. Animal studies have shown that leptin inhibits bone formating function of osteoblasts and the leptin resistant animals have obesity, hypoganadism and high bone mass. In humans, the connection between serum leptin levels and bone mineral density (BMD) is controversial.In our work, we examined whether serum leptin levels, vitamin D receptor (VDR) gene BsmI, and estrogen receptor (ER) gene XbaI/PvuII polymorphisms are associated with BMD in 179 Hungarian postmenopausal women. From this cohort, 98 osteoporotic (mean age: 56.5±7.1 yr.) patients were compared with 81 healthy control women (mean age: 54.3±5.7 yr.). No one had been treated with hormone replacement therapy or other medication which could affect bone metabolism. Serum leptin levels were measured by RIA technique, while PCR was used to identify VDR and ER gene polymorphisms. BMD was measured at the lumbar spine (L2-L4) and at the femoral neck by dual X-ray absorptiometry (DEXA) and radius midshaft (SPA). Significant correlation was found between the BMD and the body mass index (BMI) ($p<0.0001$), also between the serum leptin levels and the BMI ($p<0.0001$). The VDR gene BsmI polymorphism shows a significant correlation with the femoral neck BMD ($p<0.05$). We found a negative correlation between serum leptin levels and BMD measured at radius ($p<0.03$) and femur ($p<0.05$) in the hole population. Subjects with BB genotype exhibited significantly higher serum leptin levels ($p<0.05$). No significant correlation was found between BMD and ER gene XbaI/PvuII polymorphisms and leptin levels. Our data raises the possibility that leptin plays a role in the regulation of bone metabolism

in humans.

Effects of Intravenous Zoledronic Acid on Bone Remodeling in Postmenopausal Osteoporosis: a Histomorphometric Analysis of Transiliac Biopsies after One Year. M. E. Arlot,[1] J. P. Roux,*[1] N. R. Portero,*[1] Z. Horowitz,[2] P. Richardson,[2] U. Trechsel,[2] P. J. Meunier.[1] [1]INSERM U403, Lyon, France, [2]Zoledronic Acid Study Group, Novartis, Basle, Switzerland.

The third generation bisphosphonate zoledronic acid (CGP 42446) is a very potent anti-resorptive agent. To assess its effects on human bone after menopause, intravenous bolus zoledronic acid were given in osteoporotic and osteopenic postmenopauseal women with DXA T score ≤ -2 and no more than one osteoporotic vertebral fracture in a Phase II study. Patients received placebo or zoledronic acid given every 3 months (0.25, 0.5, 1 mg), or every 6 months (2mg) or only once (4 mg) for one year. In addition, all patients received 1000 mg calcium daily. At the end of one year treatment, 7.5 mm transiliac biopsies were obtained from 43 patients aged 64 ±7 yrs (48 to 78 yrs), after double labeling with tetracycline. 27 biopsies were measurable. The sections were undecalcified and stained with Goldner's trichrome or remained unstained for tetracycline measurements.When compared to placebo, treated patients, whatever the dose, demonstrated a significant decrease in mineralizing surfaces, bone formation rate, adjusted apposition rate, activation frequency (- 71 to - 84 %; $p<0.05$) , and a borderline decrease in eroded surface (-39%; $p<0.06$) and volume (-48%; $p<0.07$). No change was noted for cortical thickness and porosity, cancellous bone volume, trabecular thickness, separation and number, wall width of trabecular packets, number of node/tissue volume and osteoid maturation time. No dose effect has been detected. No osteomalacia was diagnosed neither qualitatively nor quantitatively (osteoid thickness and volume, mineral apposition rate). Zoledronic acid did not induce any qualitative bone abnormalities.In conclusion, one year treatment with zoledronic acid markedly decreased the rate of bone remodeling without inducing osteomalacia and maintained bone quality without loss of the lamellar organization of bone.

Identical Acute Reduction in Bone Resorption are Obtained with Alendronate Administered on a Daily or Weekly Schedule in Patients with Baseline High Bone Resorption. J. R. Talbot,[1] M. Moran,*[2] G. Bollero,*[2] D. Mata,*[3] O. Messina.[3] [1]School of Medicine, UAP University, LSM, Argentina, [2]Endocrinology, British Hospital, Buenos Aires, Argentina, [3]CIRO, Rheumatology & Osteology Research Institute, Buenos Aires, Argentina.

We were concern to start a weekly dose of Alendronate (70mg/once/week) instead 10 mg/daily in patients who have extremely high bone resorption at their baseline determination. Therefore, we decided to compare the antiresortive acute effect of 70 mg of Alendronate administered during 4 weeks in a daily schedule of 10mg/day vs. a weekly schedule of 70mg/once/week. Fourteen patients with high bone resorption (i.e. deoxypyridinoline/ creatinina > 18 nmol/mmol) were randomized to receive Alendronate 10 mg/day (n=7) or Alendronate 70 mg/once/week (n=7). Second urinary morning void were collected to determine deoxypyridinoline and creatinina concentration (D-Pyr/Cr) at baseline and at the end of week 1, 2, 3 and 4. The baseline urinary concentration of D-Pyr/Cr was 22 ± 4 nmol/mmol decreasing »60% after Alendronate therapy in both groups ($p<0.001$), but in a similar pattern: -30% vs. -26 % at the first week; -51% vs. -49% at the second week; -51% vs. -65% at the third week and -60% vs. -65% at the fourth week (p=NS, between groups. Our results suggest that Alendronate 70mg-once-weekly is same effective as 10 mg daily to decrease acutely bone resorption on patient with baseline high bone resorption.

Once a Week Alendronate Therapy: A Convenient and Effective Way of Prevention and Treatment of Osteoporosis: A Four-Year Clinical Study. S. J. Wimalawansa. Department of Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ, USA.

Oral bisphosphonate therapy such as alendronate and residronate are highly effective in prevention and treatment of osteoporosis. The main aim of this study was to see whether the administration of alendronate once a week (i.e, infrequent dosing) has the same efficacy on bone mineral density (BMD), as the daily therapy. The secondary aims were to assess the adverse reaction profile and whether this regimen improves the compliance, in comparison with the daily administration of alendronate. A total of 180 patients with BMD <2.0 SD in the lumbar spine was included in this study. The first group of patients (n=89) received alendronate once a week (6 x 10 mg tablets) for two years. At the end of two years, they were given the choice of continuing the same dose of alendronate (60 mg once a week), or taking 40 mg of alendronate (one tablet) once a week for further two-years (a total follow up period of four years). This group was compared with a group of patients who received the original recommended dose of alendronate 10 mg taken once a day (n=91) for a four-year duration. BMD was measured by DXA in the lumbar spine and in the total hip at the beginning and then annually, and these data were compared between these three groups. Biochemical markers of bone turnover; serum osteocalcin and N-telopeptides were also measured. BMD increased significantly, and changes of both BMD and biochemical markers were remarkably similar in three groups over the four years duration of the study. Patients on both regimens had equal and significant suppression of biochemical markers; serum osteocalcin and urinary N-telopeptides. Patient compliance was 88% in the once a week regimen and 72% in the once daily regimen. Drop out rates due to adverse effects of alendronate were 8% for the once a week group and 14% for the once daily treatment group, respectively. All alendronate regimens that were tested significantly increased the bone mass in both lumbar spine and in hip, decreased markers of bone turnover, and generally well tolerated over the four-year duration. However, the compliance and the adverse effect profiles were better with the once a week regimen. This study gives an insight into a highly effective, safe and economical way of administration of alendronate to improve BMD in patients with established osteoporosis.

Bisphosphonate Incadronate Preserves Cancellous Bone Mass and Strength in Corticosteroid-treated Rats. N. Miyakoshi, T. Kudo,* Y. Tamura,* T. Tsuchida,* Y. Kasukawa, E. Itoi,* K. Sato.* Orthopedic Surgery, Akita University School of Medicine, Akita, Japan.

Corticosteroids have been used for treating a variety of diseases such as systemic lupus erythematosus, asthma, and rheumatoid arthritis. However, long-term corticosteroid administration results in significant bone loss. Although incadronate disodium (YM175) has been proved to be an effective drug in estrogen-deficiency osteopenia, little is known about its preventive effects on corticosteroid-induced osteopenia. The purpose of this study, therefore, was to evaluate the preventive effects of incadronate disodium on cancellous bone loss in rats treated with corticosteroid. The protocol was designed for the simultaneous or pre-treatment of incadronate disodium.Seven-month-old female Wistar rats were divided into six groups: the vehicle saline treated group, PSL group (prednisolone 2.5 mg/kg s.c., 6 times a week for 8 weeks), YM group (YM175 1 ug/kg s.c., 6 times a week for 8 weeks), YM+PSL group (YM175 1 ug/kg + prednisolone, 6 times a week for 8 weeks), pre-YM group (YM175 10 ug/kg, 3 times a week for 2 weeks prior to 8 weeks of vehicle injection), and pre-YM+PSL group (YM175 10 ug/kg, 3 times a week for 2 weeks prior to 8 weeks of prednisolone administration). At necropsy, their femurs, tibiae, and urine were collected. Histomorphometric studies of the proximal tibia revealed that PSL group exhibited a marked decrease in cancellous bone volume relative to vehicle group, as expected ($p<0.001$). In contrast, bone volumes in both YM+PSL and pre-YM+PSL groups showed significantly higher values compared to that in the PSL group ($p<0.01$). Bone formation and mineral apposition rates in the PSL, YM, YM+PSL, pre-YM, and pre-YM+PSL groups were significantly lower than those in the vehicle group ($p<0.05$). Eroded and osteoclast surfaces in the YM+PSL and pre-YM+PSL groups were significantly lower than those in the PSL group ($p<0.01$). Values in these histomorphometric parameters in YM+PSL or pre-YM+PSL groups were comparable with those in YM or pre-YM groups. Bone mineral density of the distal femur measured by DXA and metaphyseal strength of the femur were significantly lower in the PSL group than in other five groups. We also found that YM+PSL group and pre-YM+PSL group showed significantly lower urinary deoxypyridinoline compared to PSL group. We conclude that both simultaneous and pre-administration of incadronate disodium preserve cancellous bone mass and strength in corticosteroid-treated rats.

Alendronate as a Potential Countermeasure to Microgravity Induced Bone Loss. A. D. LeBlanc,[1] L. Shackelford,*[2] T. Driscoll,*[1] H. Evans,*[1] N. Rianon,*[1] S. Smith.*[2] [1]Baylor College of Medicine, Houston, TX, USA, [2]Johnson Space Center, Houston, TX, USA.

It is well documented that unloading the skeleton in microgravity or bed rest simulation results in rapid bone loss. Restoring the appropriate stimulus to the skeleton should, presumably, ameliorate bone loss in space. Exercise therefore is the logical countermeasure to restore physiological balance. Although preliminary results are encouraging, the appropriate type, amount and frequency of in-flight exercise is still unclear. Whatever the actual exercise prescription that is ultimately implemented, it will likely be time intensive and may not always be performed properly or effectively by in-flight crew members. All human data to date, indicate that space flight and bed rest dramatically increase bone resorption. Since the primary effect of bisphosphonates is to decrease bone resorption, their

use as a prophylactic agent during space flight is attractive. Earlier studies have indicated that during bed rest, bisphosphonates may reduce loss of urinary Ca and possibly bone. We report preliminary results of 10 mg/day of alendronate treatment in 8 subjects bed rested for 4 months compared to 8 control untreated bed rest subjects. Bone mineral density (BMD), bone resorption and formation markers were measured at the beginning and end of bed rest and at several intermediate time points. Subjects were maintained on a controlled metabolic diet and total urine and feces were collected throughout the study to determine Ca excretion and balance. Our preliminary results show that compared to baseline, formation markers were unchanged in controls while reduced 5-18% in the treated group. Resorption marker n-telopeptide, was increased 45% in the control group while decreased 24% in the treated group. Urinary Ca was elevated 53 mg/day in controls while decreased 22 mg/day in the treated group. No significant decreases, except for the calcaneus were observed in any bone regions in the treated group, while controls showed decreased bone density in the trochanter, intertrochanter, calcaneus, pelvis and legs. These data suggest that alendronate treatment may be an effective alternative countermeasure to exercise or more likely as an adjunct to in-flight exercise. The optimum dosage, bisphosphonate type, and dose schedule as well as the combined effects of exercise and alendronate have not been evaluated and need further study.

Daily (5 mg) vs. Weekly (30 mg) Dosage of the Bisphosphonate (BP) Risedronate (R): Effects on Markers of Bone Remodeling in Early Postmenopausal Women, With Consideration of Circadian Rhythm Effects. A. Shields,*[1] E. Laschansky,*[2] K. Beach,*[2] S. Downing,*[2] M. Burns,[3] C. H. Chesnut III.[2] [1]Radiology, Osteoporosis Research Group, Univ of WA Medical Center, Seattle, WA, USA, [2]Radiology, Univ of WA Medical Center, Seattle, WA, USA, [3]Procter & Gamble, Mason, OH, USA.

The BP R decreases bone resorption, increases bone density, and decreases vertebral and non-vertebral fractures. Weekly oral administration of R may be more acceptable than daily administration in terms of convenience and compliance; whether a higher weekly R dosage (30 mg) is biologically equivalent to a lower daily R dosage (5 mg) in terms of an effect on markers of bone resorption (and by extrapolation, an effect on BMD/fracture) remains unconfirmed. There is also concern regarding the magnitude of an observed circadian diurnal variability on bone markers, which may influence the timing of sample collection for distinguishing therapeutic effects on bone markers of differing dosing schedules. A six month randomized active-control parallel study group in 30 early postmenopausal women is currently underway, 1) to assess the biological equivalence, or lack thereof, of 6 months of daily or weekly oral R administration in terms of effect on BR markers, 2) to determine the 24 hour magnitude of circadian rhythm of such BR markers , and 3) to define the effect of circadian rhythm on such bioequivalence studies.Preliminary data (n=17) notes a 24 hr circadian rhythm of 30% in serum n-telopeptide (S-NTx), and 39% for urine NTx/creatinine (U-NTx). Percent changes in S-NTx / U-NTx for 5 mg daily and 30 mg weekly after the first 4 weeks of the 6 mo follow-up are:

R(n)	S-NTx (± SE)	U-NTx (± SE)
5 mg daily	(9) –30% ± 7.5	(7)–40.4% ± 8.6
30 mg weekly	(9) –24% ± 6.3	(9)–39% ± 8.5

The data available to date indicate the ability of this study design to compare 5 mg daily to 30 mg weekly R, and potentially to define the effects of circadian rhythm on such dosage comparability. A portion of this work was conducted through the Clinical Research Center Facility at the University of Washington and supported by the National Institutes of Health, Grant M01-RR-0037

SA360

Effect of Once Weekly Risedronate on Bone Density in Postmenopausal Osteoporosis. M. F. Delaney, J. Shaw,* S. Hurwitz,* M. S. LeBoff. Endocrine-Hypertension, Brigham and Women's Hospital, Boston, MA, USA.

Risedronate is FDA-approved as a daily treatment for postmenopausal osteoporosis. Risedronate 5mg daily increases bone density (BMD) at the spine (LS) by 5.4% and femoral trochanter (TR) by 3.3% (Harris et al, JAMA). Due to its long skeletal half-life, Risedronate may have a therapeutic effect if given as a once weekly dose. Risedronate 30mg once weekly decreases bone turnover (NTX) by 44% (Delaney et al, ASBMR 2000). 58% of patients had a previous history of GI symptoms and when treated with Risedronate once weekly, only 6% experienced GI symptoms (Delaney et al, Endo Soc 2001). In this retrospective study using Risedronate 30mg once weekly, we evaluate BMD changes in 60 postmenopausal women being treated for low BMD in the Osteoporosis Clinic at Brigham and Women's Hospital between 2/98 and 3/2001.Patients ages ranged from 46-85 years. After a baseline BMD (Hologic; QDR), follow up BMD was performed at 4-16 months of treatment (median 12months). Many patients (87%) had previous therapy with antiresorptive agents, Fosamax (F), Estrogen (E), Evista (Ev) and Calcitonin (C); 60% had previously taken Fosamax. During the study, 17% continued an additional baseline antiresorptive treatment (E, Ev, or C). Patients with secondary causes of bone loss were excluded (e.g. hyperparathyroidism, glucocorticoids, malignancy).

Percentage Change in BMD

BMD site	No. of patients	% change BMD	p value
FN	42	+1.1%	0.08
TR	40	+2%	0.009
LS	29	+1%	0.24
Total	42	+1.9%	0.002

We found an increase of 2% at the TR, 1.9% at the total hip and 1.1% at the FN, but no significant increase at the LS. In a small number of patients (n=14) never previously treated with a bisphosphonate, we found an increase of 2.7% at FN, 4.3% at TR, 2.3% at LS and 2.9% at Total hip. We conclude that once weekly Risedronate 30mg increased BMD at the total hip and trochanter ($p<0.01$). Risedronate 35mg may be the optimum weekly dose, however larger randomized controlled studies are necessary

Disclosures: Proctor and Gamble Pharmaceuticals,2,5.

Glucocorticoid Induces Osteopenia in Young and Adult Mice and Alendronate Partially Prevents this Bone Loss. C. Liu,[1] V. Shen,[1] M. Heggem,*[1] R. Leininger,*[1] H. Chen,*[1] P. Shao,*[1] M. Bailey,*[1] R. Velasco,*[1] G. Nickols,[2] M. Thiede,[2] S. Bain.[1] [1]Skeletech, Inc., Bothell, WA, USA, [2]Pharmacia, Inc., St. Louis, MO, USA.

Glucocorticoid (GC) excess is associated with osteopenia in humans. Although various animal models have been developed to study the mechanisms associated with GC-induced bone loss, most remain unsatisfactory or not fully characterized. Recently, a murine model has been developed in adult mice (JCI 102:274-282, 1998). As GC therapy in adolescents is also associated with osteopenia, the present study was undertaken to evaluate and compare the effects of GC and alendronate (ALN) on bone in young adult and adult mice. Swiss Webster mice, 3 and 7 mo old, were divided into 4 groups (n=7-10/group) and treated as follows for 4 wk: 1) vehicle-treated control, 2) low dose (LD) GC (0.7 mg prednisolone/kg/d), 3) high dose (HD) GC (3 mg prednisolone/kg/d), and 4) HDGC+alendronate (ALN). GC was given by slow release pellets, while ALN by oral gavage. GC caused dose-dependent decreases in lumbar vertebral total bone mineral density (BMD) (-5.5% and -11.8% in 3 mo old mice; -0.83% and -12.0% in 7 mo old mice) and comaprable changes in total bone mineral content (BMC) (-5.8% and -12.5% in 3 mo old mice; 1.8% and -12.9% in 7 mo old mice) (all significant at HD) as evaluated by DXA scans. Similar dose-dependent decreases in total BMD (-7.0% and -16.0% in 3 mo old mice; -11.9% and -20.9% in 7 mo old mice) and total BMC (-9.7% and -16.4% in 3 mo mice; -8.4% and -17.6% in 7 mo old mice) were observed in the distal femur as evaluated by pQCT. The above GC-induced bone changes were further confirmed by static histomorphometry at these bone sites. Co-administration of ALN partially prevented these bone changes. Our results suggest that the mouse model is an effective system for evaluating the skeletal effects of GC in both young and adult mice and has the potential for assessing the therapeutic efficacy of agents that may prevent GC-induced bone loss.

SA362

Comparison of the Efficacy of Alendronate With of Calcitriol in the Treatment of Postmenopausal Osteoporosis-3 Years' Data. Y. Kirazli, F. Erkisi, B. Durmaz. Physical Medicine, Ege University, Izmir, Turkey.

80 postmenopausal women with a mean age of 58.2 ± 4.2 were included in this study which was designed to compare the efficacy of alendronate with of calcitriol , which are widely used agents in the treatment of osteoporosis. The patients were randomly divided into two groups. Alendronate 10 mg+ elementary calcium 500 mg a day was given to the patients in the first group for three years while the patients in the second group took calcitriol 0.5 mg +elementary calcium 500 mg a day for the same period of time. The primary endpoint was bone mineral density(BMD) of the lumbar spine and the hip. The patients were evaluated with DEXA (Hologic) at baseline, at the end of the 1st, 2nd and the 3rd year.BMD values for the first group was 0.75 g/cm2 for the lumbar spine, 0.63 g/cm2 for the femoral neck, 0.53 g/cm2 for the trochanter region and 0.43 g/cm2 for the Ward's triangle. Baseline values were similar in the second group. All of the patients had gone through biochemical tests at baseline, and every three months through the treatment period. BMD values and T scores for the first group are presented in the Table. For the first group, there was statistically significant improvement in all areas except the Ward's triangle whereas the increase in BMD was significant in all areas at the end of the three yearsLumbar 2-4 Baseline 1st year 2nd year 3rd yearBMD 0.75 0.79* 0.78 0.81** T score -2.82 -2.51* -2.44 -2.37**Neck BMD 0.63 0.66* 0.65 0.65 T score -2.68 -2.28* -2.33 -2.04**Trochanter BMD 0.53 0.56* 0.57 0.58** T score -2.24 -1.79* -1.72 -1.51**Ward's triangle BMD 0.43 0.43 0.43 0.49** T score -3.28 -3.10 -2.19 -2.35***The difference between baseline and 1st year ($p< 0.05$)** The difference between baseline and 3rd year ($p<0.05$)There was statistically significant improvement in regards of BMD values also in the second group but alendronate was superior to calcitriol .It is concluded that both pharmacological agents are efficacious in the treatment of postmenopausal osteoporosis but alendronate is superior to calcitriol in regards of increasing BMD.

Combination Therapy with Ibandronate and Calcitriol Is Effective in Patients Following Liver Transplantation. A. Fahrleitner,[1] G. Prenner,*[2] G. Leb,*[1] K. Tscheliessnigg,*[2] C. Piswanger-Sölkner,*[1] H. Dobnig.[1] [1]Div. of Endocrinology, Graz, Austria, [2]Div. of Transplantation, Karl Franzens University, Graz, Austria.

Bone loss and fractures are common complications in patients following liver transplantation (LTX). Aim of this study was to evaluate the effectiveness of a combination therapy with ibandronate (1 or 2 mg iv./3mos) and calcitriol (0.5- 1.5µg/d) in 15 liver transplant recipients, as well as serum osteoprotegerin (OPG) at baseline and under therapy. The median age of the patients was 57 (37 – 71) years, the mean time since TX 21 (13 – 83) mos and none of the patients was on any osteoprotective therapy. DXA measurement of the hip and spinal X- rays were performed at baseline and after 12 months of therapy.

	Baseline	6 months	12 months
Current prednisolon dose (mg/d)	3.7 +/- 1.1	2.3 +/- 0.7	3.7 +/- 1
S-Creatinine (0.6-1.3 mg/dl)	1.5 +/- 0.1	1.6 +/- 0.	1.7 +/- 0.1
iPTH (10 - 65 pg/ml)	71 +/-14	59 +/- 10	51 +/- 8
S-Cross Laps (1.0 - 2.4 nmol/l)	8.4 +/- 1.7	5.6 +/- 1.3 *	3.4 +/- 0.5 **
S-Osteocalcin (1 - 35 ng/ml)	86 +/- 20	54 +/- 14 *	35 +/- 4*
S-Osteoprotegerin (pg/ml)	85 +/- 7	56 +/- 4*	63 +/- 4 **
Z-Score femoral neck (SD)	-1.32 +/- 0.35	NA	-0.76 +/- 0.31*
Bone mass femoral neck (g/cm²)	0.657 +/- 0.03	NA	0.710 +/- 0.03*

*p<0.05 vs baseline; ** p< 0.05 vs 6 months and baseline;At baseline 80 % of the patients fulfilled WHO criteria of having osteoporosis, 53% had at least 1 vertebral fracture (mean 2.1 + 0.5). Laboratory analysis further revealed a high prevalence of renal impairment (60%), vitamin D deficiency (60%), 2° HPT (40%) as well as elevated cross laps- (73%) and osteocalcin- (67%) values indicating high bone turnover. After one year of therapy a highly significant bone gain (p = 0.0007) could be shown at the femoral neck. The median increase of absolute bone mass was 9.2 percent (p = 0.001). The cumulative number of fractures didn´t change significantly. A significant correlation between OPG and cross laps (r=0.63;p=0.01) and osteocalcin (r=0.69;p=0.004) could only be seen at baseline, and the OPG decrease during the first six months correlated with the decrease of the bone markers, probably simply reflecting a normalisation of bone turnover. At later time points no correlation could be shown. Whereas the bone markers showed a further decrease during the second half of the year, OPG levels increased. As this increase correlated with the bone gain at the femoral neck (r=0.63;p=0.01), we postulate that the OPG increase under osteoprotective therapy (after normalisation of bone turnover) may be an independent predictor for treatment response. In summary we found calcitriol and ibandronate to be a successful well tolerated treatment option in patients following liver transplantation.

SA365

PTH and Bisphosphonates in the Treatment of Osteoporosis: The PTH and Alendronate (PaTH) Trial. D. M. Black,[1] C. Rosen,[2] S. Greenspan,[3] K. Ensrud,[4] J. Bilezikian,[5] J. McGowan.[6] [1]UC San Francisco, San Francisco, CA, USA, [2]U. Maine, Bangor, ME, USA, [3]U. Pittsburgh, Pittsburgh, PA, USA, [4]U. Minn., Minneapolis, MN, USA, [5]Columbia U, NY, NY, USA, [6]NIAMS, Bethesda, MD, USA.

Recent studies have shown that PTH use over 1-2 years can increase BMD and may decrease fracture risk. Antiresorptive agents, used in combination or following PTH therapy, could increase or sustain this effect but little is known about how best to combine PTH with antiresorptive agents. To examine this question, we are studying different combinations of PTH (RhPTH, 1-84, 100 microgm/day) with alendronate (ALN, 10 mg/day) in an NIAMS-funded randomized trial of 240 women. The study is being conducted at 4 clinical centers in the U.S. The main goal is to compare 1 year of PTH given concurrently with alendronate to 1 year of PTH followed by alendronate to 1 year of PTH with no bisphosphonate. Women must be between 55-85 years of age and have low BMD together with a risk factor for subsequent fracture. The women will be randomized into one of 4 treatment groups and followed for 2 years:

Treatment Group	Year 1 PTH	ALN	Year 2
1	yes	placebo	ALN
2	yes	yes	ALN
3	placebo	yes	ALN
4	yes	placebo	ALN placebo

Primary outcomes include change in BMD at the hip and spine by DXA and biochemical markers. In addition, we will use QCT to assess the impact of PTH and combination therapy on trabecular and cortical bone at the spine and the hip. Other endpoint measurements include calcaneal ultrasound, radiographic absortiometry and adverse experiences. As of April 15, the study had randomized 110 participants and we anticipate completing enrollment by September, 2001.

SA366

Effects of Continuous Combined HRT and Clodronate on Bone Mineral Density in Osteoporotic Postmenopausal Women. M. Tuppurainen,*[1] L. Sandini,*[2] E. Alhava,*[2] J. Jurvelin.*[3] [1]Dept. of Obstetrics and Gynecology, Kuopio University Hospital, Kuopio, Finland, [2]Surgery, Kuopio University Hospital, Kuopio, Finland, [3]Clinical Physiology and Nuclear Medicine, Kuopio University Hospital, Kuopio, Finland.

Recent studies suggest that adding bisphosphonates to HRT may improve the antiresorptive effects of HRT. In the Kuopio Osteoporosis Study a sample of 3200 women was selected for bone density measurement (BMD) by DXA in 1995-97. If the participants were osteoporotic according to WHO criteria at the lumbar spine and/or femoral neck, they were offered participation to an intervention trial. In absence of contraindications for HRT or bisphosphonates, they were randomized to estradiol hemihydrate (E2) 2 mg + noretisterone acetate (NETA) 1 mg (Kliogest®, Novo Nordisk, Denmark) + Boneplac. Boneplac consists of either 800 mg/day clodronate (Bonefos®, Leiras Ltd, Finland) or placebo. In case of contraindications or refusal of HRT, the woman was offered clodronate 800 mg/day. One and 3-year BMD follow-up measurements have been done. Full compliance and BMD values were available for 136 participants out of 168: Kliogest® + Bonefos® (KB, n=46), Kliogest® (K, n=44), Bonefos® (B, n=46). MANOVA was used to analyse BMD changes in time. After one year of treatment, the KB and K groups showed similar increases in lumbar spine BMD of 5.0±5.1 % and 5.3±3.5% respectively, while the B group showed an increase of 2.2±4.8%. After 3 years, the KB and K groups showed increases of 3.5±6.2% and 4.1±4.8%, while group B showed a decrease of -2.8±5.4% (p<0.01). After one year of treatment, the KB and K groups showed increases in femoral neck BMD of 3.1±4.5% and 3.1±3.6% respectively, while the B group showed a decrease of -0.1±5.6%. After 3 years, the KB and K groups showed increases of 2.9±6.0% and 2.9±5.9%, while group B showed a decrease of -3.1±5.8% (p<0.001). In a MANOVA analysis, after correction for age and BMI, there was a significant time effect on the femoral neck BMD (p<0.01). There was also a significant treatment group effect (p<0.001), suggesting that the effect of treatment was different in time. Post-hoc comparisons showed that the B group was constantly different from the others. There was no time effect on the lumbar BMD (p=0.34), but there was a significant treatment group effect (p<0.001), suggesting that the type of treatment was determinant. However, BMI has also a significant effect on the BMD changes in all groups (p=0.038). In conclusion, E2 2mg in combination with NETA 1 mg increases spinal and femoral BMD in patients with postmenopausal osteoporosis. However, the addition of clodronate 800mg does not increase further the BMD values. In contrast, 800 mg/day clodronate had no effect on BMD.

SA367

Anabolic Effect of Combined Estrogen and PTH (1-34) Therapy in OVX Mice Assessed by Micro-Computed Tomography. D. von Stechow,*[1] S. Fish,*[2] M. Chorev,[2] M. Rosenblatt,[2] R. Müller,[3] J. Alexander.[2] [1]Orthopedic Biomechanics Laboratory, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA, [2]Division of Bone and Mineral Metabolism, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA, [3]Institute for Biomedical Engineering, ETH and University, Zürich, Switzerland.

We have developed an ovariectomized (OVX) mouse model of osteoporosis to study the effects of anabolic and anti-resorptive agents. The aim of this study was to investigate the effect of a combined 17 beta-estradiol (E2) and parathyroid hormone [PTH(1-34)] therapy on bone in mice over a period of 9 weeks. 3-month-old Swiss-Webster mice underwent either OVX or Sham operation. 5 weeks post-OVX the mice were administered either E2,or E2 and PTH, or vehicle for 4 weeks. Animals were sacrificed after week 1 (Sham and OVX), week 5(Sham and OVX) and week 9 (Sham or E2 or , E2 & PTH or vehicle-treated OVX). Femoral bones were analysed by micro-computed tomography. The bone tissue was segmented using a global thresholding procedure. Morphometric indices, such as bone volume density (BV/TV), bone surface density (BS/TV), trabecular number (Tb.N), trabecular thickness (Tb.Th), trabecular separation (Tb.Sp) and cortical thickness (Ct.Th) as well as connectivity (Conn.D) were measured in three dimensions using direct 3D morphometry. OVX vehicle treated control mice showed a constant loss of metaphyseal trabecular bone over time (week 1 to week 9). This loss was associated with marked decreases in trabecular number and connectivity density. While E2 only treated mice showed a 7-fold increase of these parameters over vehicle-treated mice, the combination of E2 and PTH resulted in a 14-fold increase. Cortical endosteal bone formation under E2 treatment showed a 22 % increase while the combination of E2 and PTH showed a 45 % upregulation, resulting in significantly increased cortical thickness. Both E2 and the combination of E2 and PTH increased the numbers of trabecular and cortical bone indices above the level of the sham operated controls. Three-dimensional µCT of mouse trabecular and cortical bone offers quantitative structural endpoints that are highly correlated with static and dynamic histomorphometric parameters. We conclude that a combined E2 and PTH therapy has a highly beneficial effect on cancellous and cortical bone properties in OVX mice.

SA368

A Double-blind Placebo-controlled Prospective Study Comparing Active Absorbable Algal Calcium (AAACa) with CaCO3 on Spinal Fracture and Spondylotic Deformity. T. Fujita,[1] Y. Fujii,[1] A. Miyauchi,[2] Y. Takagi.[2] [1]Katsuragi Hospital, Calcium Research Institute, Osaka, Japan, [2]Medicine, National Hyogo-Chuo Hospital, Sanda, Japan.

The data obtained in the double-blind placebo-controlled study comparing the effect of Active Absorbable Algal Calcium (AAACa)on osteoporosis with that of CaCO3 reported in Calcif Tissue Int (1996) 58:226-230 by Fujita et al were reevaluated as to the fracture incidence assessed by X-ray morphometry and intraindividual variation of lumbar spine density and vertebral body area measured by DXA to assess the vertebral deformity due to compression fracture and spondylosis deformans quantitatively. In 57 women with a mean age of 80 admitted to a geriatric hospital randomly divided into 3 groups, 900mg/day Ca supplement was given as AAACa in Group A(18 subjects), the same amount of Ca as CaCO3 in Group B (19 subjects) and indistinguishable placebo containing no Ca in Gruop C (20 subjects) for 27 months, in addition to the hospital diet containing 600mg/day Ca. New fractures occurred in 0/1000 subjects-years in Group A, 357/1000 subjects-years in Group B and 500/1000 subjects-years in Group C. In addition to the significant increase of lumbar BMD in Group A over Group C, but not in Group B after the 6th month reported previously, intraindivudual variation of L1-L4 BMD was significantly lower in Group A than in Group C in the 18th month (p=0.0264,Fisher's PLSD) and than Groups B (p=0.0432 and 0.0454) and C and (p=0.0445 and 0.0390) in the 24th and 27th month respectively, suggesting an improvement of vertebral deformity mainly due to spondylosis deformans in response to AAACa, but not CaCO3 or placebo. Decrease of projected area of lumbar vertebral body to less than 80% of the previous value occurred in 4 of 18 subjects in Group A (22.2%),7 of 19 in Group B (36.4%) and 8 of 20 in Group C (40%). Decrease of vertebral body area by more than 20% occurred in 8 of 184 vertebral bodies in Group A (4.3%), 15 of 200 in Group B (7.5%) and 17 of 212 in Group C (8.0%). In addition to increasing spinal BMD, AAACa decreased the occurrence of vertebral body deformity as demonstrated by decreases of the intraindividual variation of both BMD and projected area of vertebral bodies significantly better than CaCO3 and placebo.

SA369

Effects of Repeated Ingestion of Calcium-Fortified Spring Water on Serum Ionized Calcium and Type I Collagen Cross-Linked N-telopeptide (NTx). J. Guillemant,*[1] C. Accarie,*[2] V. de la Guéronnière,*[3] S. Guillemant.[4] [1]Faculté de Médecine Pitié-Salpêtrière, Paris, France, [2]EPHE Pharmacologie et Nutrition Hydrominérale, Paris, France, [3]Pôle Expertise Eau, Bourg-la-Reine, France, [4]Faculté de Médecine Pitié-Salpêtrière and EPHE Pharmacologie et Nutrition Hydrominérale, Paris, France.

In a previous study (Am J Clin Nutr 2000) we showed that a single oral intake of calcium-rich mineral water could significantly increase the serum concentration of ionized calcium (iCa) and suppress serum concentrations of CTx for 4 hours demonstrating that calcium-rich mineral water could be considered as an efficient source of dietary calcium. Nevertheless, the availability of natural calcium-rich mineral water is limited and the possibility to fortify natural spring water with calcium salt is to be considered. Ten young adult males (21-26 y) ingested at three times (at 08.00, 11.00 and 14.00) 660 ml of either calcium-fortified (as bicarbonate, chloride and sulfate) spring water (300 mg/L of calcium) or calcium-poor (<10 mg/L) mineral water. Blood was collected at 08.00, 11.00, 14.00 and 17.00 referred as to P0, P3h, P6h and P9h, immediately before every intake of water for measurement of iCa and NTx. Oral intake of calcium-fortified water resulted in a progressive increase in serum iCa (from 1.252 to 1.319 mmol/L) while serum NTx decreased (by 19.3% at P3h, 24.7% at P6h and 23.1% at P9h) gradually. Since ingestion of calcium-poor mineral water induced a modest (-10.6%) but significant (P<0.01) decrease in NTx we compared the two sets of assays with repeated-measures two-factor ANOVA with interaction. Ingestion of calcium-fortified water resulted in a significant increase in serum iCa (time, P<0.0001; treatment,P<0.0001; time-by-treatment, P<0.0001) and a significant decrease in serum NTx (time, P<0.0001; treatment, P=0.006; time-by-treatment, P=0.09) demonstrating that usually drinking calcium-fortified water could efficiently lower the serum NTx concentrations throughout the day.

Vitamin K Status Does Not Affect Bone Loss in Ovariectomized Rats. N. C. Binkley,[1] J. A. Engelke,*[2] J. W. Suttie.[2] [1]Institute on Aging, University of Wisconsin, Madison, WI, USA, [2]Department of Biochemistry, University of Wisconsin, Madison, WI, USA.

Many reports suggest that vitamin K is important in bone metabolism. Notably, high dose vitamin K2 (menatetrenone, MK4) has been reported to reduce both ovariectomy (ovx) induced bone loss in Fischer 344 rats and osteoporotic fracture in postmenopausal women. However, it is unclear whether these reductions reflect a vitamin K physiologic effect or a direct pharmacologic result of MK4. To further evaluate this, we conducted three studies in which 6-month old nulliparous Sprague-Dawley rats were randomized to ovx or sham groups. All studies utilized a vitamin K deficient diet (Harlan-Teklad #93308, Madison, WI) containing 1% calcium, .55% phosphorous and 2.2 IU vitamin D/gram to which vitamin K1 (phylloquinone, [K1]) or MK4 was added as follows: study 1, 72 rats received diets containing low, control or high amounts of K1 (0.2, 1.37 and 500 mg per kg of chow respectively); study 2, 36 rats received diets containing 1.37 mg K1 or 500 mg MK4 per kg of chow; study 3, 56 rats received diets containing 1.3 mg K1, 882 mg K1 or 882 mg MK4 per kg of chow. Distal femur bone mineral density (DFBMD) in an eight mm region of interest was measured in vivo at baseline and one month post-operatively in all studies utilizing a GE Lunar (Madison, WI) DPX-L densitometer (studies 1 and 2) or a GE Lunar PIXImus densitometer (study 3). In study 1, no differences in ovx-induced DFBMD reduction versus baseline were observed in the control, low and high K1 groups (9.8%, 9.7% and 11.4% respectively). In study 2, no difference in ovx-induced bone loss was observing between the ovx control K1 (5.6%) and ovx high MK4 group (5.9%). Unlike studies 1 and 2, study 3 utilized paired-feeding to minimize the ovx-induced weight increase and also permitted direct comparison of K1 and MK4 effects on bone mass. Again, no effect of either K1 or MK4 on ovx-induced bone loss was observed. Specifically, DFBMD declined 10.5%, 9.2% and 11.2% following ovx in the control, high K1 and high MK4 groups respectively. In conclusion, in these studies of adult ovx rats, neither high dose K1 nor MK4 blocked the development of estrogen deficiency osteopenia. We conclude that for the relationship of vitamin K and ovx-induced bone loss, Sprague-Dawley and Fisher rats appear to give different results. It is possible that currently unappreciated strain and species differences in vitamin K metabolism explain why these data do not reproduce published work or reflect the reduced fracture risk observed in postmenopausal women.

Dose-Effect Relations of Loop- and Thiazide-Diuretics on Calcitropic Hormones and Biochemical Bone Markers in Postmenopausal Osteopenic Women: A Randomized Double-Blinded Latin Square Multiple Crossover Study. L. Rejnmark,[1] P. Vestergaard,[1] L. Heickendorff,*[1] F. Andreasen,*[2] L. Mosekilde.[1] [1]Aarhus Bone and Mineral Research Group, Aarhus University Hospital, Aarhus, Denmark, [2]Dept of Clinical Pharmacology, Aarhus University Hospital, Aarhus, Denmark.

Thiazide diuretics (TD) reduce whereas loop diuretics (LD) increase urinary calcium. We studied the effects of different doses of TD and LD on electrolytes, calcitropic hormones and biochemical bone markers. In a five period crossover study, comparing four active doses with placebo, 40 postmenopausal women with osteopenia were treated with different doses of the LD bumetanide (n=20, 0.5 to 2.0 mg per day) or the TD bendroflumethiazide (n=20, 2.5 to 10 mg per day). Each treatment period lasted one week. Urinary calcium decreased dose-dependently in response to bendroflumethiazide; 5 mg/day decreased urinary calcium significantly compared with placebo and 2.5 mg/day. Doses above 5 mg/day did not further decrease urinary calcium. Total plasma calcium levels increased, whereas ionized calcium at ambient pH-values decreased due to increased pH-values in response to bendroflumethiazide. Plasma PTH levels did not change, whereas a slight dose-dependent increase occurred in plasma 1,25(OH)2D levels. As a marker of bone formation, plasma osteocalcin levels increased. Conversely, bumetanide dose-dependently increased renal calcium losses with concomitant increased plasma PTH and 1,25(OH)2D levels. Bumetanide did not affect urinary NTx levels, whereas plasma osteocalcin levels increased and bone-specific alkaline phosphatase levels decreased dose-dependently. It makes a difference on calcium homeostasis whether a LD or a TD is chosen as diuretic therapy. An optimal hypocalciuric effect can be obtained by administrating bendroflumethiazide 5 mg/day. The effects of LD are potential harmful to bone. Further studies are needed to evaluate whether long term treatment with LD causes osteoporosis. Until than, we suggest that TD rather than LD are preferred, if possible, as diuretic therapy in order not to cause any deleterious effects on bone metabolism.

SA373

The Orthosis Spinomed Improves Posture, Lung Function, Trunk Muscle Strength, and Quality of Life in Postmenopausal Women with Spinal Osteoporosis: Results of a Prospective, Randomized, and Controlled, Cross-over Study. M. Pfeifer, B. Begerow,* H. W. Minne. Institute of Clinical Osteology "Gustav Pommer", Bad Pyrmont, Germany.

Thoracolumbar braces are widely used in the care of patients with vertebral fractures due to osteoporosis. Their usefulness, however, has never been tested under standardized conditions. To our knowledge, this is the first randomized, controlled study to determine the efficacy of an orthosis in the treatment of spinal osteoporosis. In this cross-over study, patients had been randomized into two groups: group A (n = 31) started with an intervention period of six months, while group B (n = 30) served as controls. After six months the groups changed. Measurements include trunk muscle strength, body sway, angle of kyphosis, pain, and limitations of everyday life and were performed at base-line and every three months thereafter. At baseline, we did not observe any differences between both groups concerning age (p = 0.77), height (p = 0.90), weight (p = 0.84), loss of height (p = 0.25), and number of vertebral fractures (p = 0.87).

Table 1 presents initial values and changes at 6 months in 61 study subjects:

	Initial value	Change	P-Value
Angle of kyphosis (°)			
Group A	-2.2 ± 4.1	-2.2 ± 4.1	
Group B	69.8 ± 9.9	1.4 ± 4.3	0.007
Back extensor strength (N)			

Group A	264 ± 131	122 ± 107	
Group B	262 ± 119	18 ± 55	<0.001
Abdominal flexor strength (N)			
Group A	165 ± 71	66 ± 61	
Group B	155 ± 64	25 ± 41	0.005
Body Sway (mm)			
Group A	84 ± 70	-14 ± 45	
Group B	78 ± 37	10 ± 43	0.045
Vital capacity (%)			
Group A	83 ± 21	0.5 ± 13	
Group B	93 ± 16	-8.2 ± 13	0.020
Pain (Score)			
Group A	4.0 ± 1.1	-0.9 ± 1.0	
Group B	3.9 ± 1.0	0.1 ± 0.9	<0.001
Limitations of daily living (Score)			
Group A	4.8 ± 1.9	-1.3 ± 1.4	
Group B	4.1 ± 1.7	0.2 ± 0.8	0.007

Spinomed improves posture, trunk muscle strength, lung function, body sway, and quality of life in postmenopausal women with osteoporosis. We believe that the efficacy of thoracolumbar braces needs to be investigated in prospective, randomized and controlled clinical trials prior to their introduction in patients' care.

Insulin-like Growth-Factor and IGFBP-3 Levels in Patients with Osteoporosis Before and After Physical Exercise. H. Franck,[1] F. Blum.*[2] [1]Internal Medicine, Center of Rheumatology, Oberammergau, Germany, [2]University of Tübingen, Tübingen, Germany.

IGF-1 and IGFBP-3 are known to influence bone turnover. The aim of our study was to examine whether patients with osteoporosis have different levels of IGF-1 or IGFBP-3 than patients with osteoarthritis.130 patients with osteoporosis (WHO-definition) (mean age 51,6 ± 15 years) and 90 patients with lumbar spine syndrome (mean age 50,8 ± 16 years) were included in the study. IGF-1 and IGFBP-3 were determined as described by Blum et al. Patients performed a standarized physical exercise program. All patients with osteoporosis and osteoarthritis were included in a randomized open controlled trial into two arms one group I: classic physiotherapy, group II: weight bearing exercise. Patients with osteoporosis presented with a significant increase of IGF-1 (121,8 ± 37,2 µg/l ® 128,9 ± 35 µg/l) after physical therapy. In contrast, patients with osteoarthritis didn't show a significant increase after physical therapy. There was no significant change in IGFBP-3 either.Looking at different therapy strategies in patients with osteoporosis and patients with osteoarthritis group I didn't show any significant increase in IGF-1 (102 ± 26 µg/l ® 101,7 ± 38 µg/l) in patients with osteoporosis and osteoarthritis (144 ± 48 µg/l ® 145 ± 47 µg/l). The same was evident for IGFBP-3 in patients with osteoporosis (2,7 ± 0,46 µg/l ® 2,87 ± 0,61 µg/l) and osteoarthritis (2,89 ± 0,7 ® 3,12 ± 0,61 µg/l). In contrast, in group II IGF-1 increase significantly from 103,8 ± 25 µg/l to 120,0 ± 27,6 µg/l (p > 0,01) in patients with osteoporosis with no significant change in patients with degenerative disease (135,6 ± 30® 135,2 ± 33 µg/l). Correspondingly there was a significant increase in IGFBP-3 (2,91 ± 0,18 ® 2,97 ± 0,18 µg/l, p > 0,0001).Weight bearing exercise leads to a significant increase of IGF-1 and IGFBP-3 in patients with osteoporosis.

SA376

Effects of Chronic Symptomatic Instability of the ACL on Bone Mineral Density, Soft Tissue Mass and Muscle Strength of the Leg. M. Kobayashi,*[1] S. Takata,[1] S. Kashiwaguchi,*[1] Y. Takeda,*[1] T. Matsuura,*[1] H. Yonezu,*[2] N. Yasui.*[1] [1]Orthopedic Surgery, The University of Tokushima, Tokushima, Japan, [2]Orthopedic Surgery, Oe Kyodo Hospital, Oe, Japan.

We studied the effects of chronic symptomatic instability of the ACL on bone mineral density, soft tissue mass and muscle strength of the leg in 33 patients (22 men and 11 women) aged 15 to 39 years with unilateral ACL injury. Bone mineral density, lean mass and fat mass were measured by dual energy X-ray absorptiometry, and the isometric and isokinetic muscle strength was assessed by an isokinetic machine. There was not significant difference in bone mineral density between injured and intact legs. Lean mass of the injured leg was significantly smaller than that of the intact leg (p =0.0001), whereas fat mass and %fat of the injured leg were significantly greater than those of the intact leg (p =0.0301, p =0.0001). The isometric and isokinetic muscle strength of hamstrings and quadriceps muscles of the injured leg was significantly smaller than that of the intact leg (p <0.05). We conclude that the unilateral ACL injury does not affect the bone mineral density of the injured leg, and that it affects muscle strength and muscle mass, predominantly that of quadriceps muscles, on the injured side, compared with hamstrings muscles.

SA377

Androgen Deficiency-induced Bone Loss Can Be Prevented by the Combined Intervention of Exercise and Genistein Administration in Mice. J. Wu,[1] X. Wang,*[1] H. Chiba,*[1] C. Miyaura,[2] Y. Ishimi.[1] [1]Food Science, The National Institute of Health and Nutrition, Tokyo, Japan, [2]Biochemistry, School of Pharmacy, Tokyo University of Pharmacy and Life Science, Tokyo, Japan.

Both estrogen and androgen deficiency caused by ovariectomy (OVX) and orchidectomy (ORX) result in a marked bone loss because of increased bone resorption. Estrogen administration completely restored it in both OVX and ORX animals. Recently, attention has been focused on nonsteroidal estrogen-like plant compounds called phytoestrogens that selectively act on bone without exhibiting substantial estrogenic action in reproductive tissues. We reported that genistein, one of the phytoestrogens, prevented bone loss caused by estrogen deficiency without substantial effects on the uterus in osteoporotic animal models. We also found that the combined intervention of moderate intensity of exercise and a sub-maximal dose of genistein exhibited cooperative effects on the prevention of bone loss in OVX mice. In this study, we investigated the effects of running exercise and genistein administration on bone mass in ORX mice to examine whether the both treatments exhibit cooperative effect on bone mass similar to that in OVX mice. Male ddY mice aged 7 weeks were either sham-operated or ORX and divided into six groups: (1) Sham; (2) ORX; (3) ORX, treated with genistein (0.4mg/day) subcutaneously (G); (4) ORX, exercised on a treadmill daily for 30min/day at 12m/min on a 10°uphill slope (Ex); (5) ORX, given genistein and exercised (ExG); and (6) ORX, treated with 17β-estradiol (0.03µg/day) in the same manner as genistein (E2). Four weeks after the intervention, weight of seminal vesicles was measured and bone mass was estimated by dual energy x-ray absorptiometry (DXA). The weight of seminal vesicles was strikingly decreased in ORX mice. Treatment with neither genistein nor estrogen recovered it at all. Bone mineral density (BMD) of the whole femur was significantly reduced by ORX, and restored by the combined intervention of exercise and genistein. Histomorphometric analysis showed that bone volume (BV/TV) and trabecular number (Tb.N) in the distal femoral cancellous bone were significantly lower in ORX group than those in Sham group, and these were completely restored in ExG group, as in the E2 group. These results indicate that the combined intervention of moderate exercise and genistein administration shows a cooperative effect in preventing bone loss in ORX mice similar to the case in OVX mice.

SA378

BMD Follow-up of Patients on Alendronate, Etidronate, Estrogens or Food Supplements; Significant Differences in Mean Response Between the Groups. A. Hoiseth.* Sentrum Rtg., Oslo, Norway.

Change in lumbar and femoral BMD among women being on no-medication, any systemic estrogen, or the bisphosphanate alendronate or etidronate, has been determined as part of an ordinary clinical follow up. The groups were sub-divided according to compliance and further according to the use of food supplements (calcium and/or vitamin D). The purpose of this on-going follow up of ordinary patient treatment is to reveal any systematic differences between the groups stratified according to the above criteria. A total of 1230 women, mean age 62.4 years (SD 10.8) had repeat BMD measurements made after at least 1 year. Mean age in the group on etidronate (n=123) was 70 years (SD 7.4), on alendronate (n=135) 66 years (SD 13), on an estrogen (n=474) 60 years (SD 8.1), on no medication (n=418) 61.5 years (SD 12.0) and on a combination of estrogen and a bisphosphanate (n=80) 64.8 years (SD 10.5). At baseline BMD (g/cm2, Hologic calibration) in the lumbar spine in the same groups were respectively 0.73, 0,74, 0,83, 8.87 and 0.78; in the total femur, respectively 0.68, 0.69, 0.76. 0.79 and 0.69. Mean (years) and SD of interval between measurements were in the same respective groups 2.2 (0.9), 2.1 (1.1), 3.2 (1.5), 2.9 (1.3) and 2.6 (1.1). In each medication group a substantial number of the women reported non-compliance (50% in the estrogen group). These had significant poorer response than the compliars. These non-compliars were removed from further analyses. In the etidronate and estrogen groups there was a slight tendency for a poorer response among those who did not report taking calcium. The groups not on an anti-resorptive medication had a statistically significant mean reduction in both lumbar and total femoral BMD (respectively 0.9% and 0.7% reduction). There were no differences depending on use or not use of calcium and/or vitamin D supplements in this group. The compliars on anti-resorptive medication had significant increase in lumbar and femoral BMD: Alendronate (5.9% and 2.9%); estrogen (4.0% and 2.3%); etidronate (3.1% and 1.4%); estrogen and a bisphosphanate in combination (5.0% and 4.0%). Several pertinent questions concerning anti-resorptive medical intervention are not addressed by randomized blinded clinical trials. Not least, few have compared different alternative medications or considered aspects related to monitoring the patients by means of repeat BMD measurements. This study indicates substantial differences in the effect by different medications, alendronate showing a superior effect to the other alternatives. Monitoring the individual patients by means of BMD measurements may be useful in patients on other medications; a poor response indicated by such measurements may call for a change in medication.

SA379

Fractures in Women Over 50yr: Implications for the Secondary Prevention of Osteoporotic Fractures of the Application of the NOF and RCPLondon Treatment Guidelines. A. R. McLellan,[1] M. Fraser.*[2] [1]Medicine & Therapeutics, Western Infirmary, Glasgow, United Kingdom, [2]Western Infirmary, Glasgow, United Kingdom.

Audit of demographic and bone mineral density (BMD) data from 1061 women over 50yr, who had sustained a fracture(fx) and who were referred consecutively to our Direct Access DEXA Service(for Primary Care) and to our Osteoporosis-Orthopaedic Liaison Service, is reported; this highlights the needs of the target population for the secondary prevention of osteoporotic fx and the implications of the application of current treatment guidelines for reducing fracture risk are reported.1061 women had sustained 1705 fx including fx of humerus(n=189), ankle(n=181), vertebra(n=177), hand/foot(n=171), hip(n=134) and other sites (n=147). 62.5% had a history of only one fx, while 25.4%, 8.7%, 2.4% and 1% had sustained respectively 2, 3, 4 or at least 5 fx in total (including the fx that led to referral). BMD was measured by Hologic QDR1000plus DEXA scanner: Z-scores (mean(SD)) in patients with 1 fx were -0.34(1.38) while those in patients who had sustained 2, 3, 4 and at least 5fx respectively were -0.54(1.22), -0.73(1.21), -0.84(1.03) & -1.31 (1.27), ANOVA p<0.0001. Similar trends were seen for absolute BMD, T-score and Z-scores at hip and spine. The prevalence of T-scores of '<-2.5', '<-2', '<-1.5' & '<-1.0' at Total Hip (and at Total Hip or Lumbar Spine L1-L4) among the 1061 women was also assessed and were as follows: 26.6(52.4)%, 41.9(67.2)%, 59.8(78.8)% & 74.7(87.9)%. Application of the Royal College of Physicians of London treatment guideline(http://www.rcplondon.ac.uk/pubs/wp_osteo_update) suggests that treatment should be offered to 87.9% of patients (based on hip+/-spine DEXA). Application of the NOF guideline(http://www.nof.org/physguide) suggests treatment should be offered to 59.8% of patients (based on hip DEXA) or to 70% (based on hip BMD if <70yr and treatment for all those >70yr).Osteoporotic fx are a recurring problem- 37.5% of our patients referred because of fx, had previously had a fx and those with a history of multiple fx had lower BMD, emphasising both the opportunity and need to offer treatment for the secondary prevention of fx. The proportion of our patients who would be offered treatment with the aim of reducing subsequent fx risk differs substantially depending on which current treatment guideline is employed.

Impact of Osteoporosis Health Beliefs on Preventive Behaviors in the Postmenopausal Post-fracture Patient. M. T. Cuddihy,[1] S. E. Gabriel,*[2] C. S. Crowson,*[2] J. A. Sloan,*[2] L. J. Melton.[2] [1]General Internal Medicine (Area), Mayo Clinic, Rochester, MN, USA, [2]Health Sciences Research, Mayo Clinic, Rochester, MN, USA.

To investigate the influence of osteoporosis health beliefs on preventive behaviors after fracture, the cohort of 343 postmenopausal women who sustained a minimal trauma distal forearm fracture in Olmsted County between 1993-97 and was previously identified using the resources of the Rochester Epidemiology Project, was sent written survey in 1999.Preventive behaviors included: exercise, calcium intake and osteoporosis medication use. The Osteoporosis Health Belief Scale (OHBS) provided 7 scores (health motivation, susceptibility and seriousness of osteoporosis, exercise barriers and benefits, calcium barriers and benefits). Fracture history, prior diagnosis of osteoporosis, bone densitometry after fracture, osteoporosis medication use, and Charlson co-morbidity index were determined by medical record review. Chi-square and rank sum tests were used for univariate comparisons, and multivariate procedures to identify predictors of preventive behaviors.Among 285 survivors, 168 (59%) responded (mean age 66 years). Only 20 (12%) exercised vigorously, while 98 (60%) exercised moderately and 46 (28%) little or none. Daily calcium intake was >1200 mg in 114 (68%) and <1200 mg in 52 (31%). Prior diagnosis of osteoporosis was associated (p1200 mg and ongoing use of medication for osteoporosis. Clinical factors correlated (p<.05) with higher OHBS susceptibility scores included education < high school, osteoporosis diagnosis, osteoporotic fractures, and bone densitometry; whereas health motivation correlated only with bone densitometry. Higher scores in health motivation, and perceived susceptibility to develop osteoporosis, correlated (p1200 mg. Higher exercise benefit score was correlated (p1200 mg, and a higher exercise barrier score with less frequent exercise (p<.001). Independent predictors of exercise were exercise benefit score (Odds Ratio [OR] 1.9, 95% confidence interval [CI] 1.1-3.1) and exercise barriers (OR 0.6, CI 0.4-0.9); and of calcium intake >1200 mg a higher susceptibility score (OR 1.5, CI 1.1-2.0).Some osteoporosis health beliefs are able to predict exercise behavior and calcium use, but not osteoporosis medication use. Patient perceived susceptibility to osteoporosis was associated with: prior osteoporotic fracture, past osteoporosis diagnosis, adequate use of calcium and osteoporosis medication use. Further work to clarify determinants of preventive behaviors, including medication use, will help focus our educational efforts.

Information Needs of Family Physicians for the Management of Osteoporosis. S. B. Jaglal,[1] G. Hawker,[2] J. Carroll,[3] W. McIsaac,[3] L. Jaakkimainen,[3] S. Cadarette,[3] D. Davis.[3] [1]Rehabilitation Science, University of Toronto, Toronto, ON, Canada, [2]Medicine, University of Toronto, Toronto, ON, Canada, [3]University of Toronto, Toronto, ON, Canada.

In Ontario, Canada which has a population of 10 million inhabitants, family physicians are largely responsible for managing osteoporosis. More than 80% of all BMD tests are ordered by family physicians. The objective of this study was to determine the information needs of family physicians for managing osteoporosis and their preferences for receiving this information. A needs assessment was conducted. Purposive sampling through community physicians was used to identify participants in communities that vary in population demographics and utilization rates of BMD testing. Focus groups were conducted between October and December 2000 with male and female physicians who represented a range of ages and practice types. The focus groups were audio-taped. Analyses were performed through independent identification of themes by the investigators. Saturation of themes was reached after 4 focus groups. A total of 32 family physicians (12 men, 20 women) participated from two urban and two rural areas. Average years in practice was 14.4, ranging from 2 to 50 years. Overall these physicians saw osteoporosis as an important issue in their practices with demand for testing often coming from their patients. However, major clinical themes that emerged were uncertainty about screening, BMD testing and treatment. Screening questions included: who to screen, when to start and how to handle the elderly. These physicians were uncertain about the workup for osteoporosis, how often a BMD test should be repeated and how soon you should expect to see a change with treatment. They would like to see better interpretation in the reporting of BMD test results from specialists. Information on what drugs to combine, what is best for preventing fractures, whether drugs work equally well at all sites, long-term safety and the efficacy of non-pharmacologic interventions were identified as needs. Another theme identified was that family physicians find it difficult to remain current. They want guidelines or information aids about osteoporosis with significant input from family physicians, developed by a credible source, which also reflects the reality of busy family practice. Patient education was identified as a key factor in information dissemination because educated patients prompt the physician to think about osteoporosis. In summary, these focus groups clearly indicated that the format of the current information available on the management of osteoporosis does meet the needs of family physicians or their patients.

Effect of Raloxifene on Osteoporosis in Rat. X. Liang.* Shenzhen Institute of Gerontology, Shenzhen, China.

Effect of Raloxifene on osteoporosis in rat. Xiaoping Liang. Shenzhen Institute of Gerontology, Shenzhen, Guangdong, People's Republic of China.In this study, the effect of Reloxifene on osteoporosis was investigated in an experimental osteoporosis model in rat. Experimental osteoporosis model was established by removing both ovaries. The rats were treated with Raloxifene at a dose of 1.2mg/kg/day (n=20) or saline (n=20) for three months starting from three months after operation. Bone mineral density was measured over time by dual energy X-ray bone densitometer. Serum insulin-like growth factor-1 (IGF-1) measured by enzyme-linked immunosorbent assay and expression of transforming growth factor beta-1 in the bone detected by immunohistochemistry were also followed. Raloxifene significantly increased the bone mineral density in the lumbar spine (Figure, P<0.01, compared to the saline control) starting 4 weeks after the treatment. Increased levels of serum IGF-1 were detected in the rats treated with Raloxifene between 4 to 8 weeks after treatment. Expression of TGF-beta by chondrocytes and asteoblasts were different in the treatment group compared to the saline control group. These data suggest that Raloxifene is effective in treating osteoporosis presumably through increasing the level of serum IGF-1 and the expression of TGF-beta in the bone. Raloxifene may be useful for the treatment of osteoporosis in human.

Near Complete Prevention of Musculoskeletal Losses in Hind-limb Suspended Rat Model, using the Combination Therapy with Alendronate and Testosterone

S. M. Wimalawansa,*[1] S. J. Wimalawansa.[2] [1]Department of Medicine, Robert Wood Johnson Medical School, New Brunswicck, NJ, USA, [2]Robert Wood Johnson Medical School, New Brunswick, NJ, USA.

Disuse or the lack of gravity (as encountered during space flights) is known to cause rapid loss of musculoskeletal tissues. Hindlimb-elevated rat model has been validated as a ground-based model to simulate microgravity (i.e., it simulate the musculoskeletal changes observed in rats in space flight). Using this animal model, previously we demonstrated a significant decrease of serum testosterone levels ($p<0.001$) in male rats (International Congress of Endocrinology, 1996; Endocrine, 10:253-60, 1999). Although testosterone replacement and bisphosphonate therapies by themselves have been shown to significantly decrease these losses, neither drug prevented it completely (Journal of Applied Physiology, 86: 1841-6, 1999). These experiments led us to hypothesize that it may be possible to alleviate musculoskeletal losses to near completeness by administering appropriate doses of the combination of these two agents. Rats were hindlimb suspended (n=10 per group) and treated with either vehicle (placebo control), alendronate (30 microgram/kg, twice a week, s.c.), or depot testosterone 6 mg/kg, i.m.). Additional 10 rats (non-suspended) were used as ground controls. In all rats, a loose ligature was placed around the inguinal canal to prevent testes from moving into the abdominal cavity. Bone mineral density (BMD) was measured by dual energy X-ray absorptiometry (DXA) and the muscle mass by magnetic resonance imaging (MRI). A significant losses of BMD (12% decrease, $p<0.01$), and muscle mass (a decrease of 25%, $p<0.01$) were seen in these 26 week old male Wistar rats after 12 days of hindlimb suspension (n=10 each group). Rats treated with alendronate had a 75% lesser bone loss, but there was no protection against the muscle losses. Testosterone treated rats, bone loss was decreased by 65%, and the muscle losses by 70%. However, the group of rats treated with testosterone and alendronate together had 95% protection against the bone loss and 70% protection against the muscle losses. These data suggest in male rats that the combination therapy with androgen, testosterone, and bisphosphonate, alendronate (at their optimum combination) may completely alleviate the musculoskeletal lossse associates with weightlessness conditions.

Cenestin® (Synthetic Conjugated Estrogens, A) Maintains Trabecular Bone Mass, Structure And Bone Strength; Suppresses Bone Turnover; And Maintains Estrogenic Uterine Effects In Ovariectomized Rats. N. E. Lane, MD,[1] J. Kumer,*[1] M. Khan,*[1] R. Klein, MD,*[2] R. E. Stevens, Ph.D.,[2] K. V. Phelps.[2] [1]Department of Medicine, University of California at San Francisco, San Francisco, CA, USA, [2]Department of Clinical & Medical Affairs, Duramed Pharmaceuticals, Inc., Cincinnati, OH, USA.

Estrogen products, when given in adequate doses, reduce the risk of osteoporosis through their anti-resorptive effect on bone. This study evaluated the effect of Cenestin, a synthetic conjugated estrogens product synthesized entirely from plant source, on the maintenance of trabecular bone micro-architecture, bone strength, suppression of bone turnover, and uterine effect in the ovariectomized (ovx) rat model. Two doses of Cenestin were chosen in an attempt to approximate the equivalent human oral doses of 0.3- and 0.625mg. Fifty, 6-month retired female breeder Sprague Dawley rats were randomly assigned to one of four groups; 1) sham-operated, 2) ovx + vehicle, 3) ovx + day 1 post-ovx Cenestin, 8.12 mg/kg, 4) ovx + day 1 post-ovx Cenestin, 16.24 mg/kg, for 8 weeks. Trabecular structure of the right proximal tibia of each rat was imaged non-invasively by microCT. A strength failure test determined the mechanical properties of the tibial plateau. Bone markers, Deoxypyridinoline crosslink (DPD) and Osteocalcin (OC), were analyzed by ELISA. Uteri were removed at sacrifice, were thin sectioned, and H & E stained. The sections were scored by 2 readers for uterine myometrial hypertrophy and endometrial cell height (score ranges 0-4). Measurements of trabecular bone mass, structure, and connectivity density in the Cenestin-treated groups were not statistically different ($p>0.05$) from the sham rats, but were all significantly higher ($p<0.05$) than the ovx treated rats. Cenestin-treated rats Structure Model Index (SMI), which measures trabecular morphometry, maintained a more equal mix of plate- and rod-like structure similar to the sham, while the ovx group had predominantly rod-like trabeculae. Fracture load from the Cenestin-treated group (16.24mg/kg/d) was 31% ($p<0.01$) higher than the sham and 61% ($p<0.05$) higher than the ovx animals. Cenestin-treated groups showed significantly lower biochemical markers of bone turnover (OC and DPD) than the ovx group. Uterine histology showed that Cenestin-treated groups had uterine cell hypertrophy and cell lining changes that were similar to the estrogenic uterine effects as the sham group, and significantly different than the ovx group ($p<0.05$). Cenestin, given at the time of ovariectomy, prevented the increase in bone turnover from estrogen deficiency, maintained trabecular bone volume, structure and strength, and exhibited estrogenic effect on rat uteri.

Effects of Raloxifene on the Severity of New Vertebral Fractures in Postmenopausal Women with Osteoporosis: Results from the MORE Trial. E. Siris,[1] G. Crans,*[2] S. Sarkar,*[2] M. Wong,[2] K. D. Harper.[2] [1]Columbia University, New York, NY, USA, [2]Lilly Research Laboratories, Indianapolis, IN, USA.

The 4-year MORE (Multiple Outcomes of Raloxifene Evaluation) trial studied the effects of placebo (PL), or raloxifene (RLX) at 60 or 120 mg/day in 7705 postmenopausal women (≤ 80 years old) with osteoporosis, with or without prevalent vertebral fractures (VF). New VF were identified in radiographs taken at 2, 3, and 4 years [JAMA 282(1999): 637]. Semiquantitative criteria defined VF severity as normal (no VF) or mild, moderate or severe VF, based upon the percent reduction in vertebral height [JBMR 8 (1993): 1137]. The table shows relative risks (RR) and 95% confidence intervals (CI) for new moderate or severe VF at 4 years in women with or without prevalent VF. RLX decreased the risks of at least one new moderate or severe VF in women without prevalent VF by 40 to 51% and in women with prevalent VF by 37% to 47%, with no significant differences between the RLX doses in either group of women. Both RLX doses decreased the risk of multiple new moderate or severe VF by 88% in women without prevalent VF. The 3-year risk reductions for moderate or severe new VF were similar to the 4-year reductions in each RLX group.

Relative Risk (95% CI)

No Prevalent VF	At least one new VF	RLX60	0.49 (0.27, 0.78)
		RLX120	0.60 (0.35, 0.98)
	Multiple (≥2) new VF	RLX60	0.12 (0.00, 0.35)
		RLX120	0.12 (0.00, 0.39)
With Prevalent VF	At least one new VF	RLX60	0.63 (0.50, 0.79)
		RLX120	0.53 (0.40, 0.68)
	Multiple (≥2) new VF	RLX60	0.58 (0.32, 0.91)
		RLX120	0.47 (0.26, 0.80)

RLX60 and RLX120 decrease the risk of moderate or severe new VF at 3 and 4 years, in women with and without prevalent VF.

Dose-Dependent PTH Effects in Young, Intact, Female Rats After 9 Months of Treatment. M. Sato, A. Schmidt,* L. Y. Ma, S. Smith,* E. Rowley,* H. Cole,* M. Westmore. Lilly Research Labs, Indianapolis, IN, USA.

The long-term, dose-dependent, skeletal effects of human recombinant parathyroid hormone PTH (1-34) in ovary-intact Fischer 344 rats were evaluated for up to 9 months of treatment. Young females (1.5 month-old) were subcutaneously administered 0, 0.03, 0.3, 5, 30, or 75 ug/kg/day PTH and evaluated longitudinally by DXA for whole body composition and computed tomography (QCT) for skeletal effects in the proximal tibia metaphysis. No consistently significant differences in body weight or whole body lean mass were observed between groups; however, 30 and 75 ug/kg PTH elevated whole body bone content for the duration of the study after 1 month of treatment. Volumetric bone mineral density (BMD) for the proximal tibia became elevated for 5, 30 and 75 ug/kg after 3-4 months of treatment. After 9 months, dose-dependent increases in BMD were observed for vertebra and femora, with BMD = 1.2 g/cc (75 ug/kg PTH) for the whole femur diaphysis in cross-section which was due to a dose dependent 86% increase in BMC. Biomechanical analyses confirmed substantial, dose dependent increases in the strength and stiffness of the vertebra, femoral midshaft and proximal femur. Interestingly, the optimal dose for vertebral toughness was 30 ug/kg, indicating that duration is an under appreciated aspect of PTH efficacy. Serum osteocalcin levels for all groups were considerably lower than for baselines, consistent with an age dependent reduction in osteoblastic activity. PTH dose-dependently increased osteocalcin levels compared to vehicle controls, confirming PTH stimulation of osteoblastic activity. PTH at 30 ug/kg and above substantially increased whole body BMC, and BMD in the proximal tibia, femoral midshaft and vertebra to well beyond normally attained peak levels. Midshaft analyses showed that the rat cortical bone is as responsive to PTH treatment as cancellous bone with long-term administration, although with slower kinetics. Rat cortical bone and its responsiveness to PTH represent a significant physiological difference between rodents and primates, based on the cortical bone data of PTH effects in cynomolgus macaques and humans. The data taken together showed that treatment duration is an under appreciated aspect of PTH skeletal efficacy.

Dramatic Skeletal Effects of PTH in Male and Osteopenic Ovariectomized Rats after 1 Year of Subcutaneous Administration. Y. L. Ma,[1] M. Westmore,[1] C. Turner,[2] J. Hock,[2] J. Vahle,*[1] M. Sato.[1] [1]Lilly Research Laboratories, Indianapolis, IN, USA, [2]Indiana University Medical Center, Indianapolis, IN, USA.

Skeletal effects of PTH were evaluated in intact male and osteopenic, ovariectomized F344 rats, after 1 year of treatment with 0, 8, or 40 ug/kg/day sc PTH. Males and females were about 6 months of age at baseline, but the females were ovariectomized (Ovx) for 5 weeks prior to initiation of PTH treatment. To ascertain PTH effects on longitudinal growth, femoral length was measured and found not to differ between male groups; but PTH slightly increased femoral length of Ovx rats. No significant differences in femoral

length were observed between Sham and Ovx controls. Histomorphometric analysis of the proximal femur showed a dose-dependent 84-91% increase in trabecular bone volume (BV/TV), 122-189% increase in cortical thickness, 170-189% increase in trabecular number, and 325-664% increase in connectivity for males and Ovx females, respectively. The substantial increase in trabecular and endocortical apposition coincided with a -74% and -61% loss of marrow space for males and females, respectively. Failure analysis of the femoral neck showed 140% and 180% increase in strength for males and Ovx females. QCT analyses of the femoral midshaft showed dose-dependent 200% and 70% increases in BMC, 67% and 55% increases in BMD, and 22% and 10% increases in cross-sectional area, which resulted in 104% and 47% increases in moments of inertia for males and Ovx females, respectively. 3-point-bending analyses of the midshaft showed substantial, dose-dependent increases in strength and stiffness, but a reduction in ultimate strain was observed, which may reflect the significantly altered geometry. Histologic evaluation of sections from the proximal tibia and kidneys showed no treatment related anomalies after 1 year of PTH treatment, indicating that the bone structural changes occurred without histologic lesions or abnormalities. Therefore, 1 year (nearly half-a-lifetime) of PTH treatment substantially increased bone mass and strength to beyond normally attained levels. The data show that treatment duration is an under appreciated aspect of PTH skeletal efficacy.

SA395

The Response of the Mouse Skeleton to Estrogen-Deficiency and Parathyroid Hormone (PTH) Treatment Differs According to Skeletal Sites. A. Iida-Klein,[1] S. S. Lu,[1] M. Ducayen-Knowles,*[1] K. Yokoyama,*[1] J. Nieves,[2] D. W. Dempster,[1] R. Lindsay.[2] [1]Regional Bone Center, Helen Hayes Hospital, West Haverstraw, NY, USA, [2]Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

We have previously demonstrated that the anabolic action of parathyroid hormone (PTH) is skeletal-site specific in intact mice (ASBMR, 2000). However, the effects of PTH in mice with estrogen-deficiency are not defined. To determine whether ovariectomy (ovx)-induced bone loss is also skeletal-site specific in mice, and whether the PTH response in ovx mice is similar to that in intact mice, we initiated PTH treatment (hPTH 1-34, 40mcg/day, 5 days per week) in 16 week-old, female, sham-operated and ovx C57BL/J6 mice at 4 weeks of post operation for an additional 7 weeks (11 weeks total ovx). BMD was longitudinally measured in vivo by DEXA. At 4 weeks post-ovx, BMD was significantly reduced at all the skeletal sites examined. The magnitude of bone loss at 4 weeks was 9.8%, 5.3%, 5.1% and 3.8%, (all $p<0.05$) in the lumbar spine, total body bone, femur, and tibia, respectively. Lumbar spine BMD further decreased with time in ovx-control animals and was 17.8% below that of sham-control at 11 weeks after ovx. From 4 to 11 weeks post-ovx, age-related slight increases in BMD were evident at other skeletal sites in both sham and ovx animals. PTH partially reversed the ovx-induced bone loss in the spine in a time-dependent manner, but at the dose used failed to completely reverse bone loss after 7 weeks of treatment. However, PTH did reverse the ovx-induced bone loss completely in the tibia, the femur, and total body by 1, 3 and 7 weeks of treatment, respectively. The lumbar spine was the most sensitive site to estrogen deprivation, while the tibia was most sensitive to the anabolic action of PTH. In summary, ovx-mice are a good model of estrogen-deficiency bone loss and PTH alone reverses ovx-induced bone loss at most skeletal sites in mice. However, there is clear heterogeneity among skeletal-site response to both estrogen and PTH.

Effects of Parathyroid Hormone on Bone Formation in a Rat Model for Chronic Alcohol Abuse. M. Zhang,* R. T. Turner, G. L. Evans,* J. D. Sibonga.* Orthopedic Research, Mayo Clinic, Rochester, MN, USA.

Alcohol is a risk factor for osteoporosis and it is not clear whether the detrimental effects of alcohol on bone are reversible. Parathyroid hormone (PTH) is a potent stimulator of bone matrix synthesis and is being investigated as a therapeutic agent to reverse bone loss. The present investigation was designed to determine the effects of PTH on bone formation in a rat model for chronic alcohol abuse. Alcohol was administered in the diet of female rats (35% caloric intake) for two weeks. Human (I-34) PTH (80 µg/kg/d) was administered sc during the second week of the study. Alcohol resulted in a transient reduction in steady-state mRNA levels for the bone matrix proteins type 1 collagen, osteocalcin, and osteonectin compared to rats fed an alcohol-free (control) diet. As expected, alcohol decreased and PTH increased histological indices of bone formation and two-way ANOVA demonstrated that alcohol antagonized PTH-induced bone formation. In spite of antagonism, bone formation and mRNA levels for bone matrix proteins in alcohol-fed rats treated with PTH greatly exceeded the values in rats fed the control diet. The results of this study contribute to a growing body of evidence that alcohol-induced bone loss is primarily due to reduced bone formation. We conclude that alcohol does not prevent the stimulatory effects of PTH on bone formation. This is evidence that the effects of alcohol on the skeleton are reversible. Additionally, the positive effects on bone formation in rats consuming high concentrations of alcohol suggest that PTH may be useful as an intervention to treat alcohol-induced osteoporosis.

SA398

Effects of Basic Fibroblast Growth Factor on Bone Gene Expression in Aged Ovariectomized Rats. R. A. Power, T. J. Wronski. Physiological Sciences, University of Florida, Gainesville, FL, USA.

Histomorphometric studies indicate that basic fibroblast growth factor (bFGF) has a strong anabolic effect on bone. Treatment with bFGF in ovariectomized (OVX) rats results in markedly increased osteoblast surface compared to vehicle-treated OVX rats. Osteoblast, mesenchymal stem cell, and osteoprogenitor cell culture studies have yielded varied results regarding mRNA levels for bone matrix proteins in the presence of bFGF. The purpose of this study was to examine the effects of bFGF therapy on gene expression for osteocalcin (OC), type I collagen (COL I), and several growth factors and cytokines (IGF-I, TGF-β, IFN-γ), *in vivo*, in OVX Sprague Dawley rats. Animals were ovariectomized at 3 months of age, and maintained untreated for one year after surgery. At 15 months of age, catheters were inserted in the jugular veins of all rats for IV injections. One group of OVX rats was treated daily with bFGF (Chiron Corp., CA) for 14 days, at a dose of 200 µg/kg, then euthanized. Another OVX group was injected daily with vehicle. At necropsy, lumbar vertebrae were collected for RNA analyses. Total RNA was isolated from vertebral bodies using a guanidine thiocyanate-phenol-chloroform extraction method. Following northern blot analysis for mRNAs encoding bone matrix proteins, and RNase protection assay for mRNAs encoding growth factors and cytokines, mRNA levels were quantified by densitometric scanning of phosphor images. mRNA levels for OC and COL I, relative to 18S rRNA, were significantly higher in bFGF-treated OVX rats than in vehicle-treated OVX rats by a factor of greater than 10 ($P < 0.05$). IGF-I mRNA levels, relative to rL32 housekeeping gene, were also significantly higher, by nearly a factor of 3, in the bFGF-treated OVX rats ($P < 0.01$). Treatment of OVX rats with bFGF did not appear to affect message levels for TGF-β and IFN-γ. These *in vivo* results suggest that bFGF treatment upregulates gene expression for IGF-I, which may mediate, at least in part, the increased gene expression for bone matrix proteins and the bone anabolic effects of bFGF in aged OVX rats.

Statin Lipid-Lowering Drugs and Bone Density. D. H. Solomon,[1] J. S. Finkelstein,[2] P. S. Wang,*[3] J. Avorn.*[3] [1]Pharmacoepidemiology and Rheumatology, Brigham and Women's Hospital, Boston, MA, USA, [2]Endocrinology, Massachusetts General Hospital, Boston, MA, USA, [3]Pharmacoepidemiology, Brigham and Women's Hospital, Boston, MA, USA.

HMG Co-A reductase inhibitors (statins) have been associated with a reduced rate of fractures in some observational studies but not others. We are defining the relationship between statin use and bone mineral density (BMD) among 400 patients referred for DXA scans by their local physicians. After scanning, participants responded to a telephone survey assessing a range of known osteoporosis risk factors, use of anti-resorptive agents, and statin exposure. Among the first 245 patients enrolled in the study, 69 (28%) patients reported current or recent use (last 3 months) of statins. Mean age of respondents was 60 ± 11 years and 90% were female. Statin users and non-users were similar with respect to: age, gender, menopausal status (statin users 95% postmenopausal vs non-users 94%, P = 0.81); prior fracture history (statin users 42% vs non-users 33%, P = 0.16); use of an anti-resorptive agent (statin users 45% vs non-statin users 50%, P = 0.56); current or recent oral glucocorticoid use (statin users 3% vs non-statin users 8%, P = 0.15); ≥ 1 alcoholic drink per day (statin users 16% vs non-statin users 20%, P = 0.48); and current cigarette smoking (statin users 6% vs non-statin users 6%, P = 0.95). BMI was significantly higher in statin users vs non-users (27.2 ± 5.7 vs 25.0 ± 4.7, P = 0.005). Total BMD of the lumbar spine and proximal femur did not differ between statin users and non-users in crude analyses (see Table) or after adjustments for the above variables.

	Statin Use	No Statin Use	P
Total femoral BMD, mean (g/cm^2)	0.897 ± 0.144	0.867 ± 0.146	0.35
Total lumbar BMD, mean (g/cm^2)	0.946 ± 0.165	0.938 ± 0.135	0.82

These preliminary data fail to demonstrate a significant difference in lumbar spine or total hip BMD between statin users and non-users, though spine BMD was slightly higher in users. Our data suggest that if statin use is associated with a reduced risk of fractures, then factors other than BMD may be responsible for this effect. However, we cannot yet exclude the possibility that differences in BMD may be demonstrated with a larger sample size.

Long-Term Strontium Ranelate Administration in Monkeys: Effects on Mineral Crystals and on the Degree of Mineralization of Bone. G. Y. Boivin,[1] D. Farlay,*[1] G. Panczer,*[2] I. Dupin-Roger,*[3] C. Simi,*[1] A. Buffet,*[1] I. Tupinon-Mathieu,*[3] P. J. Meunier.[1] [1]Laboratoire d'Histodynamique Osseuse, Faculté de Médecine R. Laennec, Lyon, France, [2]LPCML, CNRS UMR 5620, Université C. Bernard, Villeurbanne, France, [3]Institut de Recherches Internationales Servier, Courbevoie, France.

The analysis of the interactions of Strontium Ranelate (Protos®) with bone mineral is of interest as this agent has a dual effect on bone remodeling by increasing bone formation and decreasing bone resorption leading to prevention of bone loss and increase of bone

mass and strength in normal and ovariectomized rats. Strontium (Sr) has already been shown to be heterogeneously distributed in the bone of normal monkeys receiving Strontium Ranelate (SR) for 13 weeks with higher concentrations in new than in old bone (Boivin et al. 1996, JBMR 11:1302-11). Similar findings have been reported in post-menopausal osteoporotic women treated for 2 years with SR (Boivin et al. 2000, JBMR 15 suppl.1:S305). The interactions of Sr with bone mineral were investigated in monkeys after a long-term SR treatment and at the end of a recovery period. Iliac bones were obtained from 30 monkeys: 7 untreated controls, 12 sacrificed at the end of a 52-week SR treatment (200, 500, 1250 mg/kg/day PO) and 11 sacrificed 10 weeks after the end of a 52-week SR treatment (same 3 doses of SR). Sr uptake and distribution in bone mineral were quantified by X-ray microanalysis, changes at the crystal level were evaluated by X-ray diffraction, and the degree of mineralization of bone (DMB) was measured by quantitative microradiography. In monkeys sacrificed at the end of a 52-week SR treatment, Sr was uptaken in a dose-dependent manner into compact and cancellous bone, with higher contents (1.6 times) in new bone than in old bone. Sr content greatly decreased (1.7-2 times) in animals sacrificed 10 weeks after the end of treatment but this affects almost exclusively new bone and not old one. After SR treatment, there were no significant changes in crystal characteristics. Easily exchangeable in bone mineral, Sr was slightly linked to crystals by ionic substitution (generally less than 1 calcium ion substituted by 1 Sr ion in each unit cell). DMB was not significantly different in the various groups of monkeys. In conclusion, at the end of a long-term SR treatment and after a period of withdrawal, Sr was uptaken in a dose-dependent manner into new bone without alteration of DMB and with no major modification of bone mineral at the crystal level. These findings confirm the safety of Strontium Ranelate usage at the mineral level and of its potential interest as anti-osteoporotic treatment which simultaneously increases bone formation and decreases bone resorption.

Effect of Melatonin on Bone Metabolism in Ovariectomized Rats. Dependence with Estradiol Serum Levels. M. G. Ladizesky,*[1] R. A. Cutrera,*[2] V. Boggio,*[2] J. Somoza,*[1] M. Centrella,*[2] C. A. Mautalen,[1] D. Cardinali.*[2] [1]División Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina, [2]Departamento de Fisiología, Facultad de Medicina, Universidad de Buenos Aires, Buenos Aires, Argentina.

The objective of this work was to assess the effect of pharmacological dose of melatonin on bone metabolism in ovariectomized (OVX) rats. Animals received melatonin in the drinking water (25 ug /ml water) or drinking water alone. Baseline and secuential determinations of urinary deoxypyridinoline (UD PYR) (a marker of bone resorption), calcium excretion, as well as circulating levels of calcium, phosphorous and bone alkaline phosphatase (BAP) activity (a marker of bone formation), were measured in adult rats for up to 60 days after OVX. At this time, the animals were killed, and bone mineral density (BMD), bone mineral content (BMC) and bone area (BA) of total body, were measured. UD PYR increased significantly after OVX by 51% (30 days after surgery) and by 47% (60 days after surgery) ($p<0.01$, anova dunnet´s t test). Melatonin treated OVX rats, showed a significantly decrease in UDPYR, 30 days after surgery, compared with values detected at the same time, in OVX rats drinking water, indicating a diminution in bone resorption. ($p<0.001$, anova dunnet ´s t test). Urinary calcium concentration was similar in the 4 experimental groups studied, as was the circulating calcium concentration at every time interval examined. Fifteen days after surgery, a significant increase in serum BAP levels occurred in OVX rats receiving melatonin as compared with their controls, indicating an increase of bone formation. Sixty days after surgery , BMD, BMC and BA decreased significantly in OVX rats, an effect not modified by melatonin. Serum estradiol decreased significantly by 30 days after OVX to attain values close to the limit of detection of the assay by 60 days after OVX. In summary, post-OVX disruption of bone remodeling (a highly regulated process in the mammalian skeleton) could be prevented in rats by administering a pharmacological amount of melatononin in a way apparently related to the levels of circulating estradiol. Further studies are needed to define the precise roles that melatonin plays in bone development and in formation and degradation of bone and their dependence of circulating estrogen concentration

SA403

Adenovirus-mediated VEGF-A Gene Transfer Induces Bone Formation In Vivo - A Preliminary Report. J. Huuskonen,[1] M. O. Hiltunen,*[2] M. Ruuskanen,*[3] A. Mähönen,*[2] A. Herranen,*[2] A. Mahonen,*[4] H. Kroger,[3] S. Ylä-Herttuala.*[2] [1]Department of Surgery, University of Kuopio, Kuopio, Finland, [2]A.I. Virtanen Institute, University of Kuopio, Kuopio, Finland, [3]Department of Surgery, Kuopio University Hospital, Kuopio, Finland, [4]Department of Biochemistry, University of Kuopio, Kuopio, Finland.

We tested the hypothesis that vascular endothelial growth factor (VEGF-A) transfer is an appropriate way to enhance recruitment of osteoblasts in vivo. We used adenovirus vectors (1.4x1010 particles) for targeted gene therapy in six sixteen weeks-old female New Zeland White rabbits. Adenovirus vectors (2 ml per injection) containing VEGF-A and lacZ genes were injected locally into three right distal femurs. Saline was injected into all six contralateral distal femurs. One week after the injections the femurs were collected for analyzes. X-Gal staining was used to quantify transfected bone marrow cells. Trabecular bone hard tissue histomorphometry of the distal femurs was performed to study the effect of gene transfer on trabecular bone turnover.Up to twenty percent of the bone marrow cells were transfected. Compared to contralateral saline injected side, VEGF-A injected trabecular bone had 7 % lower bone volume, 157 % higher osteoblast number, 155 % higher osteoblast surface, 61% higher osteoid volume and 32 % higher total erosion surface. When compared to unilateral bacterial lacZ received trabecular bone, VEGF-A bone had 17 % lower trabecular bone volume, 150 % higher osteoblast number, 137 % higher osteoblast surface, 171 % higher osteoid volume and 66 % lower total erosion surface.We have demonstrated that injection of adenovirus vector is capable of transfecting bone marrow cells in vivo with high efficiency. Our preliminary results suggest that adenovirus-mediated VEGF-A gene transfer induces bone formation via increasing osteoblast activity.

Long-Term Treatment with Strontium Ranelate (S12911) Increases Vertebral Bone Mass Without Deleterious Effect in Mice. P. Delannoy,*[1] D. Bazot,*[2] B. Robin,*[3] Y. Tsouderos,[3] P. J. Marie.[1] [1]Inserm U349 affiliated CNRS, Lariboisiere Hospital, Paris, France, [2]Biologie Servier, Gidy, France, [3]Institut de Recherches Internationales Servier, Courbevoie, France.

It has been shown previously that strontium salts modulate bone metabolism in rats and mice. In this study, the effect of a long term treatment with strontium ranelate (S12911 - PROTOS®), has been investigated on bone metabolism in mouse caudal vertebrae. Strontium ranelate (200, 600 or 1800 mg/kg/d, i.e. 0.78, 2.34 or 7.03 mmol Sr^{2+}/kg/d) or vehicle, was given orally in the diet to normal 6-week old $B_6C_3F_1$ male and female mice over 104 weeks. Histomorphometric analysis of indices of bone formation and resorption were determined in the endosteal caudal vertebrae of 20 male and 20 female animals per group. A 104-week treatment with strontium ranelate dose-dependently increased the trabecular bone volume (BV/TV) by 25% and 59% in females treated with 600 and 1800 mg/kg/d, respectively ($p<0.05$ *vs* controls in both cases). This increase of BV/TV was linked to a similar increase in the mineralized bone volume (Md.V/TV): +27% and +62% in the same animals ($p<0.05$ *vs* controls in both cases). An increase of BV/TV was also observed in males treated with 200 and 1800 mg/kg/d (+17% and +38%, respectively, $p<0.05$ *vs* controls in both cases). In parallel, a dose-dependent increase of the osteoblastic surface (Ob.S/BS) was observed in treated males (+131% for the highest dose group, $p<0.05$ *vs* controls). In addition to this stimulatory effect on bone formation, strontium ranelate decreased histomorphometric indices of bone resorption in males and females. Osteoclast surface (Oc.S/BS) was decreased in a dose-related manner in females and was significantly different from the control group at the highest dose (-52%). Furthermore, the number of osteoclasts (N.Oc/T.Ar) was dose-dependently diminished by 30% to 47% in female mice ($p<0.05$ *vs* controls for each dose group). Osteoid thickness remained unchanged in all treated groups as compared with control animals, suggesting that strontium ranelate, even at the highest dose tested (1800 mg/kg/d), had no deleterious effect on bone mineralization. These findings show that, in mice, strontium ranelate simultaneously increases indices of bone formation and decreases indices of bone resorption. This results in increased vertebral bone mass in mice without deleterious effects on bone mineralization.

Disclosures: IRI Servier,2.

Growth Hormone (GH) Decreases Bone Mineral Mass and Bone Strength in Adult Female Rats Fed a Low Protein Diet. P. Ammann,[1] L. Rodriguez,[1] M. L. Aubert,[2] J. P. Bonjour,[1] R. Rizzoli.[1] [1]University Hospital, Div of Bone Diseases, Geneva, Switzerland, [2]University Hospital, Div of Pediatric Endocrinology and Diabetology, Geneva, Switzerland.

Isocaloric protein undernutrition is associated with accelerated bone loss and decreased bone strength. This seems to be related to a decrease in GH and/or IGF-I production and/or action. Whether GH administration can reverse the protein undernutrition-induced alterations in bone turnover, bone mineral mass and bone strength when the diet is low in protein, a dietary situation frequent in elderly, is not known. Six-month old female rats were fed isocaloric diets containing 2.5% (Low Protein, LP) or 15% (Normal Protein, NP) casein for 2 weeks. Then, GH (0.5 or 2.5 mg/day x kg BW) or its solvent were given subcutaneously to rats on either diet twice daily for 4 weeks. Proximal and midshaft tibia bone mineral density (BMD) and ultimate strength, together with serum osteocalcin and IGF-I were measured. In rat fed the NP diet, 4 weeks of GH did not significantly influence proximal tibia BMD (254.4±5.0 and 263.0±4.5 for 0.5 and 2.5 mg GH vs 253.1±4.9 mg/cm2 in controls, n=8 per group, x±SEM) nor bone strength (209.9±5.4 and 191.1±14.9 vs 208.0±11.9 N). In contrast, GH dose-dependently decreased BMD (248.8±6.4 and 234.0±4.7 vs 262.7±3.5, $p<0.05$ ANOVA) and bone strength (199.7±12.2 and 139.9±13.9 vs 225.7±9.4, $p<0.05$) in rats fed the LP diet. On both diets, GH caused a dose-dependent increase in IGF-I in NP and LP diets (585±17, 709±20 for 0.5 and 2.5 mg GH vs 476±22 ng/ml in controls, $p<0.05$, and 450±30, 556±29 vs 304±19, $p<0.05$, respectively). GH increased serum osteocalcin in rats on both NP (17.5±1.1, 25.7±2.5 vs 16.2±1.6 ng/ml, $p<0.05$) and LP (13.5±0.7, 18.7±1.6 vs 10.9±0.9, $p<0.05$) diets. Thus, whereas GH treatment increased IGF-I and osteocalcin levels on both NP and LP diets, it was associated with a negative bone balance and with a lower bone strength when administered to animals on a low protein diet. These results emphasize the major importance of dietary protein intake in the bone response to GH administration.

Simvastatin Did Not Prevent Bone Loss In Ovariectomized Rats. W. Yao,[1] C. Y. Li,*[1] R. W. Farmer,*[2] J. L. Chen,*[1] A. Mo,*[1] R. Cooper,*[2] P. Chmielewski,*[2] R. B. Setterberg,*[1] W. S. S. Jee,[1] M. W. Lundy.*[2] [1]Radiobiology Division, University of Utah, Salt Lake City, UT, USA, [2]Bone Biology, Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Statins decrease the hepatic biosynthesis of cholesterol and thereby reduce serum cho-

lesterol concentration. Some recent reports showed that they could also stimulate bone formation *in vivo* and *in vitro*. To investigate whether statins have beneficial effects on bone metabolism, we designed a study in which Sprague-Dawley rats were ovariectomized (OVX) at 6 months of age, allowed to lose bone for 60 days and followed with oral administration of Simvastatin at dose levels of 0.3, 1, 3 and 10 mg/kg/d for 60 days. Study endpoints included bone histomorphometry on the proximal tibial metaphysis (PTM) and the tibial diaphysis (TX) and mCT on the 5th lumbar vertebra (LV). As expected compared to sham, 60 days of OVX decreased cancellous bone volume in the PTM (41%) and LV (15%); with a continued bone loss 120 days post-OVX (PTM, 80%; LV 18%). The OVX-induced bone loss was accompanied by increased bone formation and resorption. Simvastatin did not cause significant changes in bone volume, bone formation rate or bone erosion surface when compared to 120d-OVX animals (Table).

Groups	**Sham**	**OVX**		120d	**Simvastatin**	
Parameters	60d	0.3mg	1mg	3mg	10mg	
PTM	BV/TV	10.6±3.3*#	7.6±1.7	3.1±1.9	4.0±1.4	3.7±1.5	4.6±1.8
BFR/BS	23.7±4.5*	35.7±1.7	31.5±3.5	27.9±2.0	30.6±2.9	31.4±1.5	28.7±5.9
ES	3.4±1.4*	12.9±3.4	12.2±3.9	10.3±3.0	10.5±1.0	10.76±0.76	10.7±2.3
TX	Ps-BFR	15.4±19.0#	74.9±28.1	30.5±23.2	30.1±4.3	37.0±18.1	13.5±10.4
Ec-BFR	6.6±12.7*#	19.4±6.9	28.1±11.8	20.2±6.9	34.4±7.5	27.9±8.5	24.7±8.9
Ec-ES	5.5±2.7*#	14.1±4.3*	9.4±6.4	10.4±1.8	7.5±2.9	9.1±3.2	11.3±8.1
LV	BV/TV	41.0±1.9*#	34.8±2.8	33.5±2.1	33.2±1.8	31.5±2.4	33.0±2.1
CortTh	201.5±17.1*#	172.1±17.2	177.6±6.3	175.6±2.8	167.6±12.7	174.1±11.7	174.5±8.7

Mean ± SD; *p < 0.01 vs 120d-OVX; # p < 0.01 vs 60d-OVX; BV/TV, bone volume (%); BFR, bone formation rate ($\mu m^3/mm^2/d$); ES, eroded surface (%); Ps, periosteal surface; Ec, endocortical surface; CortTh, cortical thickness. In conclusion, this study demonstrated that Simvastatin did not prevent cancellous bone loss and did not stimulate cancellous and cortical bone formation following ovariectomy in the PTM, TX and LV.

SA408

Statins and Bone Mineral Density. S. Yaturu,*[1] M. G. Alferos,*[1] C. Deprisco,*[2] J. Tynes,*[3] S. Wade.*[4] [1]Endocrinology, OvertonBrooks VAMC/ LSUHSC, Shreveport, LA, USA, [2]OvertonBrooks VAMC/LSUHSC, Shreveport, LA, USA, [3]Medicine, LSUHSC, Shreveport, LA, USA, [4]Pharmacy, OvertonBrooks VAMC, Shreveport, LA, USA.

Treatment of osteoporosis remains a major challenge despite an increase in the choice of therapeutic agents. Experimental evidence has shown that the statins, the cholesterol lowering agents, increase the bone formation. We reviewed the bone density studies of patients who were on statins for at least one year (12-15months). Additionally, twenty-seven of them were on other antiresorptive agents like estrogens or bisphosphonates or calcitonin. We compared the changes in the bone density of those on statins alone with the changes in the bone density (BMD) of those on statins and other antiresorptive agents.

Change in BMD±Standard error

Site	Statins alone	Statins+antresorptive	*p*
Spine:Total	0.009±0.02	-0.005±)0.002	0.22
RightHip:Total	0.004±0.01	-0.004±0.004	0.16
Left Hip:total	-0.01±0.01	3.7±0.004	0.17

We did not observe any significant differnce between the changes in BMD whether they were on statins alone or other antiresorptive agents in addition to statins.We conclude that addition of antiresorptive agents to statins may not improve the BMD further

SA409

Short-Term Treatment With Atorvastatin Does not Change Bone Turnover in Patients With Hypercholesterinemia: A Randomised, Controlled Study. P. Salbach,*[1] J. Kreuzer,*[2] M. J. H. Seibel,[3] [1]Dept. of Cardiology, University of Heidelberg, Heidelberg, Germany, [2]Cardiology, University of Heidelberg, Heidelberg, Germany, [3]Dept. of Endocrinology, University of Heidelberg, Heidelberg, Germany.

Osteoporotic fracture risk has been reported to be significantly lower in patients treated with statins than in subjects treated with non-statin lipid lowering drugs or non-users. In one study, the statin effect was already observed after short-term treatment. So far, however, no data are available regarding the acute and short-term effect of statins on bone turnover.In a prospective study, 54 patients with hypercholesterinemia (mean age: 65.5 ± 9.7 yrs) were randomised to either 40 mg Atorvastatin (AS) b.i.d. or a low fat diet. Blood and urine samples were collected 0, 3 and 30 days into the study. Serum bone specific alkaline phosphatase (bALP) and osteocalcin (OC; ng/mL), and urinary carboxyterminal telo-peptide (CTX-I, pmol) were determined in 23 male (mean age 62.8 ± 8.8) and 11 female (mean age 64.5 ± 12.1) patients treated with AS, and in 13 male (mean age 65.9 ± 8.4) and 7 female (mean age 67.4 ± 9.5) patients receiving diet. All values were expressed as mean ± SD.In the AS treated group, bALP decreased significantly (p< 0.01) from day 0 to day 3 (19.2 ± 8.3 to 16.8 ± 7.2 U/L), and returned to baseline levels at day 30 (19.4 ± 8.8 U/L). These changes were more pronounced in males than in females. In the diet group, bALP decreased non-significantly and remained at that level over 30 days. Serum OC levels remained unchanged in both groups. Urinary CTX excretion decreased significantly (p< 0.05) from day 0 to day 3 (2914 ± 1454 to 2585 ± 1287 pmol) and remained at that level until day 30. Again, changes were more pronounced in males than in females. In contrast, no significant changes were observed in the group receiving diet.We conclude that except for minor (though statistically significant) changes 3 days after initiating AS treatment, no systematic changes in bone turnover were observed in this study. Therefore, neither AS nor a fat modified diet seem to affect bone metabolism on a short term basis. This does not exclude alterations in bone turnover over longer periods of time.

SA410

Statin Increases Cortical Bone in Young Male Rats by Single, Local Administration but Fails to Restore Bone in Ovariectomized (OVX) Rats by Daily Systemic Administration. D. T. Crawford, H. Qi, K. L. Chidsey-Frink, H. A. Simmons, D. D. Thompson, H. Z. Ke. Pfizer Global Research and Development, Groton Labs., Groton, CT, USA.

HMG-CoA reductase inhibitors (statins) are widely used as cholesterol-lowering agents. It was recently reported that statins may protect against skeletal fractures. We attempted to characterize the local and systemic skeletal effects of one of the statins, lovastatin, in young male rats and in an established osteopenic, OVX rat model. In the first study, a single injection of either vehicle (n=8) or lovastatin at 3 mg/kg (n=8) was given locally through the cortex into the bone marrow cavity of the proximal tibial metaphysis of 6-week-old male rats. Seven days post-injection, the rats were necropsied and the injection site was analyzed by pQCT and bone histomorphometry. Compared with vehicle controls, lovastatin significantly increased cortical bone area (+17%), cortical thickness (+13%) and axial area moment of inertia (+29%). In addition, a non-significant increase in total content (+12%) and area (+11%), trabecular content (+30%) and periosteal circumference (+5%) was found in lovastatin-treated rats compared with vehicle-treated rats. Histomorphometric results showed that periosteal and endocortical bone formation increased in lovastatin-treated rats compared with vehicle-treated rats. In the second study, S-D female rats were sham-operated or OVX at 3.5 months of age. The OVX rats were untreated for 6 weeks to allow development of osteopenia. Thereafter, OVX rats were treated with either vehicle (n=10) or lovastatin at 10 mg/kg (n=10) by daily s.c. injection for 4 weeks. Compared with sham controls, OVX significantly decreased total content and density, trabecular density, cortical content and cortical thickness in the distal femoral metaphysis as determined by pQCT analysis. The above parameters in lovastatin-treated OVX rats did not differ significantly from vehicle-treated OVX controls, indicating no skeletal effect of lovastatin on bone in this OVX rat model. Similarly, lovastatin had no effect on trabecular bone volume, trabecular number or bone turnover parameters in proximal tibial metaphyseal cancellous bone in OVX rats. In conclusion, we found that lovastatin increases cortical bone in young male rats by single, local administration to the bone marrow cavity but fails to restore bone in OVX rats by systemic, daily administration. The mechanism for the different response to local and systemic administration of lovastatin is not clear.

Disclosures: Pfizer Inc.,3.

Decreased Bone Turnover in Postmenopausal Women Treated with Statins: A Cross-Sectional Study. L. Rejnmark,[1] N. H. Buus,*[1] P. Vestergaard,[1] F. Andreasen,*[2] M. L. Larsen,*[3] L. Mosekilde.[1] [1]Dept of Endocrinology and Metabolism, Aarhus University Hospital, Aarhus, Denmark, [2]Dept of Clinical Pharmacology, Aarhus University Hospital, Aarhus, Denmark, [3]Dept of Medicine and Cardiology, Aarhus University Hospital, Aarhus, Denmark.

Statins have been suggested as potential agents in the management of osteoporosis. In a cross-sectional design, we compared 140 postmenopausal women who had been treated with a statin for more than two years (median 4 years) with 140 age- and gender-matched population based controls.We studied the effects of treatment with statins on calcium homeostasis, bone turnover, bone mineral density, and body composition. Plasma PTH levels were 16% higher in the statin treated subjects than in the controls (p<0.01). Conversely, plasma levels of biochemical bone markers were lower in the statin treated subjects than in the controls: osteocalcin (-9%, p=0.03), bone-specific alkaline phosphatase (-14%, p<0.01), and CTx (-11%, p<0.01). No correlation could be demonstrated between changes in biochemical quantities and dose or duration of statin use. Moreover, body composition and BMD at the lumbar spine, hip, forearm, and whole body did not differ between the two groups. Our data suggest that statins reduce bone turnover and exert an antiresorptive effect on bone metabolism. Prospective studies are needed in order to resolve whether this effect is clinical relevant in the management of osteoporosis.

Fluvastatin and Cerivastatin Are Not Anabolic for Bone After Local or Systemic Administration of Non-Toxic Doses in Mice and Rats. J. A. Gasser. Arthritis & Bone Metabolism, Novartis Pharma AG, Basel, Switzerland.

The purpose of the experiments was to extend the knowledge on the proposed bone anabolic properties of HMG Co-A reductase inhibitors (statins) following their local administration over calvaria in mice (fluvastatin) or daily oral administration in rats (cerivastatin).Male Swiss mice were injected locally twice daily over the central calvaria with fluvastatin at concentrations ranging between 0.001 and 100mM or with 100nM hPTH(1-34) for 5 consecutive days, and sacrificed on day 14 for histomorphometric analysis of fluorochrome labels.Seven month old skeletally mature intact or ovariectomized vir-

gin Wistar rats were administered daily by gavage with 0.01 or 0.1mg/kg of cerivastatin for 4 weeks and changes in cancellous and cortical bone parameters monitored in the proximal tibia metaphysis by pQCT.Local administration of fluvastatin at concentrations between 1 and 100mM led to acute local capillary damage and visible bleeding forcing the termination of the highest dose. Treatment with lower doses did induce formation of woven bone but only at doses where histological hemorrhage was detected (1 and 10mM). The increase in the mineral apposition rate was statistically significant at 10mM ($p<0.01$, Dunnett-test). Our results suggest that the measured bone activity may represent a damage repair response rather than a direct anabolic property of the compound.In estrogen competent rats, daily oral administration of cerivastatin did not induce any change in cancellous or cortical bone mass, density or structural cortical parameters as measured by pQCT which would be indicative of a bone anabolic response. Similarly, the significant decrease in cancellous bone mineral density (-15.3%, $p<0.01$) and cortical thickness (-14.5%, $p<0.01$) or any of the other bone parameters in OVX-rats was not reduced by daily administration of cerivastatin. Total serum cholesterol was reduced significantly in OVX-rats at 0.01 (-14.6%, $p<0.01$) and 0.1mg/kg (-19.8%, $p<0.01$).Taken together, these studies in mice and rats are not supportive for the proposed anabolic activity of statins in bone and suggest, that disruption of capillary integrity and local bleeding may explain some of the previously reported bone responses in the mouse calvaria model.

Effect of Statins on Bone Mass and Turnover in Ovariectomized Rats. P. Masarachia, G. Wesolowski, J. G. Seedor, C. Weiss,* B. L. Pennypacker,* M. A. Gentile, G. A. Rodan, D. B. Kimmel. Bone Biology and Osteoporosis, Merck Research Laboratories, West Point, PA, USA.

Statins, cholesterol controlling drugs, have been reported to reduce fractures in humans and prevent cancellous bone loss in ovariectomized (OVX) rats, via stimulation of bone formation. The object of this study was to compare skeletal effects of simvastatin (SIM) and atorvastatin (ATOR) to those of alendronate (ALN) and PTH in adult OVX rats.Eight months old virgin female rats were OVXd or Sham-OVXd. OVX rats were treated for 35 days with: vehicle; 10mg/kg/d po SIM; 10mg/kg/d po ATOR; 0.01mg/kg SC 3X/week ALN; or 0.08mg/kg SC 3X/week PTH(1-34). We measured: urinary deoxypyridinoline/creatinine (uDPD); static and dynamic histomorphometry of proximal tibial metaphysis using dual fluorochrome labeling; including cancellous bone volume (BV/TV, %), osteoclast surface (OcS/BS, %) and mineralizing surface (MS/BS, %); and distal femoral metaphyseal bone mineral density (DF-BMD, mg/cm2) by DXA (Hologic 4500A). Groups (N=13) were compared by ANOVA with Fisher PLSD post-hoc test. Results show that:

Variable	Sham	Vehicle	SIM	ATOR	ALN	PTH
DF-BMD	180±19*	160±14	169±11	163±18	180±12*	185±12*
BV/TV	24±6*	14±6	20±5&	18±7#	24±5*	27±7*
uDPD	20±5*	48±12	55±15	47±14	22±8*	52±23
OcS/BS	3.6±1.3&	5.2±2.3	5.1±1.6	4.9±1.0	3.6±1.3*	6.0±1.6
MS/BS	20±9*	37±7	30±6&	31±4#	15±4*	46±15&

Mean±SD; #diff from OVX (P<.11); &diff from OVX (P<.05); *diff from OVX (P<.001)

1) ALN or PTH fully prevented OVX-induced bone loss; SIM was partially effective [BV/TV]; 2)Only ALN lowered uDPD and osteoclast surface; 3)ALN suppressed and PTH augmented, the OVX-induced rise in formation; and 4)SIM and ATOR partially reduced that rise in formation. We conclude that SIM but not ATOR partially prevented OVX-induced bone loss. Although no suppression of uDPD or osteoclast surface occurred, SIM's modest bone loss prevention effect here seems likely due to inhibition of bone resorption, since both statins tended to reduce fluorochrome labeled surface (MS/BS) below OVX+VEH.

Effects of Short-term Cerivastatin on Bone Turnover. F. Cosman, J. Nieves, M. Zion,* J. Cruz,* S. Gordon,* R. Lindsay. Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

Since statin drugs share a common mechanism of action with bisphosphonates in the cholesterol synthesis pathway was hypothesized that statins could also affect the skeleton. In vitro and in vivo animal data suggested that statins could stimulate bone formation and inhibit bone resorption but observational studies on statins and fracture risk have been mixed and the few clinical trial data are not definitive. To help settle the controversy, we performed a short-term randomized blinded clinical trial to determine if cerivastatin (Becol, Bayer Corp) could increase biochemical variables of bone formation and/or reduce biochemical indices of bone resorption. Fourteen postmenopausal, healthy women, mean age 58, on no medications known to influence bone metabolism, were randomly assigned to receive cerivastatin 0.4 mg/d or an identically appearing placebo for 12 weeks. Biochemical indices of bone formation (propeptide of Type I procollagen, PICP and osteocalcin, OC) as well as bone resorption (urinary N-telopeptide, NTX and C-telopeptide, CTX) were obtained in the AM in the fasting state at baseline, and 1, 2, 4, 6, 8 and 12 weeks after treatment assignment. Compliance with medication was >90%. There were no demographic differences (years from menopause, height, weight, baseline BMD) between groups and mean baseline biochemical indices were the same in both groups. During the 3-month follow up, there were no significant differences in either variable of bone formation in the cerivastatin group compared to baseline or compared to the placebo group. However, biochemical indicators of bone resorption were modestly reduced within 6 weeks by <20% in the cerivastatin group (NTX, P = 0.08; CTX, P = 0.19). These results suggest that in vivo cerivastatin does not substantially stimulate bone formation, and therefore, is unlikely to produce a significant anabolic effect on bone mineral density. However, cerivastatin might have modest anti-resorptive potential.

SA416

Effect of Simvastatin on Three-Dimensional Trabecular Architecture of Ovariectomized Rats. Y. Jiang,[1] J. Zhao,[1] G. Gutierrez,[2] G. R. Mundy,[2] I. R. Garrett,[2] H. K. Genant.[1] [1]Osteoporosis and Arthritis Research Group, University of California, San Francisco, CA, USA, [2]OsteoScreen, San Antonio, TX, USA.

The statins, orally bioavailable drugs that decrease hepatic cholesterol biosynthesis, are commonly prescribed and administered to patients to reduce serum cholesterol concentrations and lower the risk of heart attack, and have shown to be bone activation agents by enhancing the expression of BMP-2 gene in bone cells. This study evaluated effect of the statin simvastatin, administered systemically on trabecular structure and connectivity of ovariectomized (OVX) rats after oral administration, using µCT, a non-destructive advanced imaging technique. Unlike traditional histomorphometry based on 2D sections parallel plate model, µCT directly measures three-dimensional (3D) trabecular architecture without stereological model assumption, which may improve our ability to understand the pathophysiology of osteoporosis and to estimate bone biomechanical properties as the mechanical competence of trabecular bone is a function of its apparent density and 3D distribution. Thirty 3-month old virgin female SD rats were equally divided, based on body weight, into 3 groups: 1) Control: sham-OVX rats receiving vehicle (sham rats), 2) OVX: OVX rats receiving vehicle (OVX rats), and 3) OVX treated: OVX rats receiving simvastatin at a dose of 10 mg/kg/day by oral gavage for 35 days. Treatment with the statin started one day post-OVX. Animals were pair fed. After 5 weeks the animals were sacrificed by anesthetic overdose, and the left femur was dissected and scanned using a µCT scanner with isotropic resolution of 11 µm. 3D trabecular structure in the secondary spiongiosa in the distal femur was directly measured. There was a significant change in 3D trabecular bone volume fraction (BV/TV, -51%), trabecular number (Tb.N, -49%), trabecular thickness (Tb.Th, -34%), trabecular separation (Tb.Sp, +68%), structure model index (SMI, +30%), degree of anisotropy (DA, +2.5%), and connectivity density (CD, -58%) in OVX rats (group 2), compared with those in sham rats (group 1). Compared with OVX treated with vehicle (group 2), simvastatin treatment (group 3) caused a significant change in 3D BV/TV (+81%), Tb.N (+32%), Tb.Th (+52%), Tb.Sp (-22%), SMI (-22%), DA (-3.4%), and CD (+62%). 3D trabecular thickness was preserved at the sham level after simvastatin treatment. Thus, OVX induces deterioration of 3D trabecular structure in rats. The trabeculae become more rod-like (indicated by structure model index) and more isotropic after OVX. Simvastatin treatment appears to prevent OVX-induced bone loss.

Effect of Disodium Pamidronate on the Interface of External Fixation Half Pins and Fracture Healing. K. Yang,* J. Jahng, J. Park,* E. S. Kang.* Orthopaedic Surgery, Yonsei University College of Medicine, Seoul, Republic of Korea.

The purpose of this study was to evaluate the antiresorptive effect of the bisphosphonate around the metal implant, which was inserted in the bone and its influence on fracture healing and stress-shielding effect. Twelve dogs were divided into 2 groups; Six dogs were treated with disodium pamidronate (0.5mg/kg, im injection) every two weeks for 6 weeks (Group 1) and the other six dogs were treated with placebo (Group 2). External fixators with 6 pins were applied on both tibiae. Perpendicular osteotomy was performed at mid shaft of the right tibia and gap of one millimeter was made in all 12 dogs. Right side was for evaluation of fracture healing and pin bone interface in unstable situation. Left side was for evaluation of stress-shield effect. Torque strength (extraction torque of the pin) could not be measured in 4 cases of 72 pins in Group1 and in 12 cases of 72 pins in Group 2 ($p<0.01$). It was due to pin loosening and infection at pin bone interface. The means of torque strength in measureable pins were 0.97 ± 0.50Nm in Group 1 and 0.94 ± 0.51Nm in Group 2. It was statistically insignificant. Results of maximal breakage strength of the right tibia, which was measured by 3 point bending test, showed no difference between Group 1 (227 ± 129Nm) and Group 2 (256 ± 45Nm). That means that pamidroanate had no deteriorative effect on fracture healing. Three point bending test in left tibia showed 202 ± 25Nm in group 1 and 68 ± 16Nm in group 2. Stress-shielded left tibia showed significantly higher ultimate strength in Group 1 ($p<0.01$). Disodium parmidronate, an aminobiphosphonate, could decrease the incidence of severe pin loosening and prevent bone loss in stress-shielded tibia. It did not deteriorate fracture healing process.

A Herbal Extract and its Major Component Induce Growth Hormone Release and Prevent Bone Loss in Ovariectomized(OVX) Rats. C. Kim,[1] H. K. Ha,[1] J. H. Lee,*[1] J. S. Kim,*[1] K. Y. Song.*[2] [1]Korea Institute of Oriental Medicine, Seoul, Republic of Korea, [2]College of Medicine, Chung-Ang University, Seoul, Republic of Korea.

Estrogen deficiency after menopause induces bone loss and results in osteoporosis. To

find any estrogen replacement from herbs, effects of herbal extract (F4) and BB, a major compound from the F4 extract, were investigated on growth hormone (GH) release in a pituitary cell culture and on osteoporosis in vivo and in vitro models. Proliferations of osteoblast (MG-63, Saos-2) were tested with MTT and alkaline phosphatase (ALP) assays. Adult OVX SD rats (10 weeks old) were divided into eight groups; sham, control, 17-beta-estradiol at 1 micro-g/kg/day (E2), OVX and various concentrations of F4 and BB (F41, F42, F410, BB1, and BB10). Animals were given an i.p. injection everyday for 9 weeks. Trabecular bone areas (TBA) of tibia and lumbar spine were measured by bone histomorphometry. Plasma levels of ALP, calcium, inorganic phosphate, cholesterol and HDL-cholesterol were analyzed. In results, extract F4 and BB were induced GH release upto 157% and 166% of control corresponding to 407 nM and 446 nM of GH-releasing factor (GRF) using rat pituitary cells. F4 increased cell proliferations of MG-63 and Saos-2 and BB stimulated ALP activity of Saos-2. And F4 inhibited osteoclast activity a little less than genistein, a phytoestrogen. Plasma levels of HDL-cholestrol decreased and those of LDL-cholesterol inceased during the study in both F4 and BB treated groups. Plasma concentrtions of ALP decreased following ages. TBA of tibia in control group was reduced 58.1% compared to sham ($P<0.01$). The TBAs of tibia in F41, BB1, and BB10 groups were increased upto 143% of control ($P<0.01$) which was similar to that in E2 group. But TBAs of tibia in F42 and F410 groups were not increased. Interestingly, TBA of lumbar in BB1 and BB10 groups were increased significantly ($P<0.01$). In conclusions, herbal extract F4 and BB, a major compound of F4, prevent OVX-induced cancellous bone loss for 9 weeks in OVX rats.

Melatonin Could Prevent Cancellous Bone Loss in Ovariectomized Rats. Y. Hattori,* T. Kaku, H. Koyama, O. Nakade.* Health Sciences University of Hokkaido, Ishikari-Tobetsu, Japan.

We have recently demonstrated that daily I.P. injection of melatonin (aMT) could increase cancellous bone mass in young growing mice in vivo, mostly through suppressing bone resorption. The present study was to determine whether aMT could prevent bone loss in ovariectomized (OVX) rats. Female rats were sham-operated or OVX at 6 months of age and treated for 4 weeks with vehicle or aMT. Sham-operated control rats (CON + VEH) and one group of OVX rats (OVX + VEH) were injected I.P. with vehicle between 3 and 5 p.m. The remaining OVX rats were injected I.P. with either 10 (OVX + 10 aMT) or 50 (OVX + 50 aMT) mg aMT / kg BW / day at the same time with vehicle-injected groups. The proximal tibial metaphyses were processed undecalcified for quantitative bone histomorphometry osteopenic with a cancellous bone volume at only 50 % of vehicle-treated control level. This bone loss was derived from increased indices of bone turnover such as osteoclast surface, osteoid surface and bone formation rate. Compared to vehicle-treated OVX group, aMT treatment with low dose (10 mg/kg /day) increased cancellous bone volume by 80 % and decreased osteoclast surface, osteoid surface and bone formation rate. However, these effects by aMT treatment were minimized at high dose (50 mg/kg/day) and increased osteoid surface without a significant effect on mineral apposition rate was apparent, suggesting that aMT treatment could exert to increase bone formation at high dose. These results indicate that melatonin treatment could prevent bone loss in OVX-rats through decreased bone resorption activity, although melatonin would induce diverse effects on bone depending on its dose.

SA421

Combined Assessment of Both Bone Formation and Bone Resorption for Improved Prediction of Long-Term Skeletal Effect of Anti-Resorptive Therapy. P. Qvist,[1] E. G. Henriksen,[1] N. Bjarnason,*[2] P. Ravn,*[2] C. H. Christiansen.[2] [1]Osteometer Biotech, Herlev, Denmark, [2]CCBR, Ballerup, Denmark.

Markers of bone turnover have been applied for monitoring of anti-resorptive therapy, partly because they, in contrast to image technologies, respond rapidly to medical intervention. Several studies have demonstrated that early change in markers following anti-resorptive therapy predict treatment efficacy as assessed by measurements of bone mineral density over several years. Recently statistical models have been developed to improve both sensitivity and specificity of the biochemical prediction of the long-term BMD response to treatment (1-3). However, none of the models included both a bone resorption marker and a bone formation marker and we therefore investigated if such a combined model could improve prediction of the long-term skeletal effect of anti-resorptive therapy.We performed the data analysis on prospective studies of hormone replacement therapy (HRT) (2) and alendronate (4) in prevention of postmenopausal osteoporosis. In brief, the calculations included data from individuals receiving either 2 mg estradiol (combined sequentially with gestodene) or placebo (n=56), or for the bisphosphonate study either 1, 5, 10 or 20 mg of alendronate or placebo (n=67).The data analysis demonstrated that Serum CrossLaps and N-MID Osteocalcin ELISA were independent predictors of change in bone mineral density of the spine in postmenopausal women receiving bisphosphonate or HRT. In a logistic regression analysis combining the change of Serum CrossLaps and N-MID osteocalcin during 6 months of therapy the sensitivity and specificity was in the range 85-95% for early prediction of bone gain (alphaBMD>0) and bone loss (alphaBMD<0), respectively, which was better than each of the markers alone.(1) Garnero et al., Bone (1999) 24:603-609. (2) Bjarnason and Christiansen, Bone (2000) 26:561-569. (3) Delmas et al., Bone (2000) 26:561-569. (4) Ravn et al., Bone (1999) 24:237-244.

Osteoprotegerin (OPG) Abrogates Chronic Alcohol Ingestion-induced Bone Loss in Mice. J. Zhang,[1] J. Dai,*[2] D. Lin,[2] P. Habib,*[2] P. Smith,*[2] J. Murtha,*[2] Z. Fu,*[3] E. T. Keller.[4] [1]Department of Pathology, University of Michigan, Ann Arbor, MI, USA, [2]ULAM, University of Michigan, Ann Arbor, MI, USA, [3]Department of Immunology, University of Michigan, Ann Arbor, MI, USA, [4]Pathology, ULAM, Immunology, University of Michigan, Ann Arbor, MI, USA.

Alcoholism is a widespread problem accompanied by many pathophysiological manifestations. For example, a large proportion of chronic alcoholics have osteopenia. There is evidence that alcohol (ethanol) induces bone loss through both inhibition of osteoblast activity and induction of osteoclast activity. Osteoclastogenesis occurs through the binding of receptor activator of NFkB (RANK) ligand, which is present on osteoblasts, to RANK, which is found on the osteoclast precursors. Osteoprotegerin (OPG), a protein produced by osteoblasts and bone marrow stromal cells, binds RANK ligand, effectively blocks RANKL from binding to RANK, and thus inhibits osteoclastogenesis. We have previously documented that alcohol induces osteoclast activity and bone resorption in mice. In addition, we showed the ethanol-induced osteoclast activity was associated with increased RANKL mRNA expression in bone marrow cells. Thus, we hypothesized that inhibition of RANKL should diminish ethanol-induced bone loss. Accordingly, the purpose of this study was to determine if the RANKL inhibitor, OPG, could inhibit alcohol-mediated bone loss in a murine model. To investigate the role of osteoprotegerin (OPG) on alcohol (ethanol)-mediated osteoporosis, we measured a variety of bone remodeling parameters in mice that were either on a control diet, an ethanol (5%) diet, or an ethanol (5%) diet plus OPG administration. OPG diminished the ethanol-induced decrease of bone mineral density as determined by dual-energy densitometry. OPG also abrogated (1) ethanol-induced decrease of cancellous bone volume and trabecular width and the increase of osteoclast surface as determined by histomorphometry of the femur, (2) increased urinary deoxypyridinolines as determined by ELISA, and (3) increased colony forming unit-granulocyte monocyte (CFU-GM) formation and osteoclastogenesis as determined by ex vivo bone marrow cell cultures. Additionally, OPG diminished ethanol-induced decrease of several osteoblastic parameters including osteoblast formation and osteoblast culture calcium retention. These findings were supported by histomorphometric indices in the distal femur. Taken together, these data demonstrate that OPG diminishes ethanol induced bone loss. Furthermore, they suggest that OPG achieves this through it ability to abrogate ethanol-induced promotion of osteoclastogenesis and promote osteoblast proliferation.

SA424

Anti-Resorptive and Survival Actions of Selective Integrin Peptidomimetics on Authentic Human Osteoclasts. P. Collin-Osdoby,[1] F. Anderson,[1] L. Rothe,[1] X. Yu,[1] Y. Huang,*[1] W. Maloney,*[2] W. Westlin,*[3] G. A. Nickols,[3] P. Osdoby.[1] [1]Biology, Washington University, St. Louis, MO, USA, [2]Orthopedics, Washington University, St. Louis, MO, USA, [3]Pharmacia, St. Louis, MO, USA.

Mature osteoclasts (OC) undergo functional cycles of migration and resorption, processes dependent upon specific cell surface integrins. The integrin $\alpha v\beta 3$ becomes highly expressed in OC development, mediates OC motility and attachment to RGD-containing extracellular matrix proteins, and is crucial for OC bone resorption and survival in vivo and in vitro. Conversely, RGD ligands and $\alpha v\beta 3$ antagonists inhibit OC function and prevent bone loss in ovariectomized animals. However, the precise mechanisms of action and specificity of integrin antagonists for human OC (HOC) have not been well characterized. Here, we investigated two integrin peptidomimetics designated S787 and S783, with S787 ($IC50 = 0.7$ nM) being a more potent inhibitor than S783 ($IC50 = 14.7$ nM) for human $\alpha v\beta 3$ binding, for their effects on HOC function and survival. Authentic HOC were isolated from femoral heads obtained during hip replacement surgery, cultured (10 days) on ivory with or without S783 or S787 (0.01 to 10 uM), and the ivory analyzed for TRAP stained HOC and resorption pits. Both peptidomimetics dose-dependently inhibited HOC pit resorption via decreasing the mean number of HOC remaining attached to the ivory, the number of pits formed per HOC, the area resorbed per HOC, and the size of individual pits. Inhibition was more pronounced with S787 than S783 and was maximal (up to 95%) at 1 uM of either S787 or S783. Attachment assays using in vitro RANKL-induced monocyte-generated OC (HMN-OC) demonstrated that the number of HMN-OC binding to ivory within 1 h was reduced by 55% or 65% in the presence of 1 uM S787 or S783, respectively, compared to the number of HMN-OC that attached in the absence of these agents. Whether decreased HOC numbers also reflected increased apoptosis was evaluated using HOC or HMN-OC treated with S787 or S783 (0.01 to 10 uM, 20 h) and then stained with annexin V-FITC. Both peptidomimetics elicited HOC and HMN-OC apoptosis (but not necrosis), S787 was more potent than S783 for inducing apoptosis, and maximal HOC apoptosis (2 to 4-fold over control levels) occurred with 0.1 uM S787 or 10 uM S783. An RPA multiprobe kit was used to quantify potential changes in bcl family gene expression during peptidomimetic-induced apoptosis of HMN-OC (at 6 and 24 h) and revealed decreases in anti-apoptotic bclx (6 h) and bfl1 (6, 24 h). Thus, integrin peptidomimetics potently and dose-dependently inhibit HOC bone pit resorption, induce HOC apoptosis via a bcl-related pathway, and may exert differential effects as a function of their $\alpha v\beta 3$ potency.

Celecoxib Does Not Prevent Osteopenia or Impair the Action of Anti-resorptive Therapies in Ovariectomized Rats. S. L. Settle,*[1] R. K. Rader,*[1] S. Hornby,[2] G. A. Nickols,[1] M. A. Thiede.[1] [1]Discovery Pharmacology, Pharmacia Corporation, St. Louis, MO, USA, [2]SkeleTech Inc, Bothell, WA, USA.

Prostaglandins play a role in bone cell function, and several studies have suggested that administration of COX nonselective NSAIDs can influence skeletal metabolism. New selective inhibitors of COX-2 now make it possible to test the role of COX-2 in high turnover bone loss associated with ovarian hormone deficiency. The study aims were to determine the effect of selective COX-2 inhibition on ovariectomy (OVX)-induced bone loss and COX-2 selective inhibition on anti-resorptive therapy in this model. Sprague-Dawley rats (6 mo) underwent either OVX or sham-operation (S). In study 1, treatment (TX) was begun on post-op day 14. In study 2, TXs were initiated on the day of surgery. Groups of rats (n=8) were administered vehicle (V) (0.5% methylcellulose, 0.025% Tween-20), celecoxib (C, 10 mg/kg/d), 17a-ethynylestradiol (EE, 30 ug/kg, PO) or combinations thereof by gavage. Alendronate (A, 28 ug/kg) was administered sc 2 twice weekly. Calcein (10 mg/kg, BID) was injected on days 49 and 56. BMD of the left proximal tibia was determined by pQCT on days 0, 14, 28, 42 and 56. TBD of the lumbar spine was measured by DEXA on day 56. Trabecular bone strength of the distal femur was measured by an indentation method.

	Study 1 Tx	Study 2 Prevention	Study 1 Tx	Study 2 Prevention
Group	Day 56 Tibial BMD (mg/ccm)	Day 56 Tibial BMD (mg/ccm)	Day 56 Maximum Load (N) (n= 6-8)	Day 56 Maximum Load (N) (n= 6-8)
1. Sham +V	386 +/- 23	346 +/- 36	5.5 +/- 3.2	6.7 +/- 6.1
2. Ovx +V	233 +/- 28	191 +/- 18	1.5 +/-1.2	1.5 +/-1.2
3. Ovx +EE	323 +/- 34	306 +/- 18	6.3 +/- 7.3	5.9+/-6.4
4. Ovx + A +V	342 +/- 28	424 +/- 23	5.6+/- 6.1	10.5+/-9.1
5. Sham + C	419 +/- 21	357 +/- 17	6.7 +/-5.3	6.2 +/-3.4
6. Ovx +C	201 +/- 23	168 +/- 15	3.2 +/-2.3	1.4 +/-1.5
7. Ovx + EE +C	305 +/- 25	315 +/- 20	4.0+/-3.6	4.5 +/-2.9
8. Ovx + A + C	325 +/- 12	423 +/- 19	3.4 +/-2.5	9.0 +/-6.7

Changes in BMD and trabecular bone strength following OVX and anti-resorptive TX were as expected for the model. Concomitant TX with C had no measurable effect on the response of the skeleton to OVX or the response to Tx. Static and dynamic histomorphometry was performed on proximal tibiae with similar findings. Together these data suggest that anti-inflammatory doses of celecoxib do not prevent bone loss associated with OVX, but that its use to treat pain and inflammation during the post-menopausal period is not likely to impact the benefits of current anti-resorptive therapies either.

Disclosures: Pharmacia Corporation,3.

Current Opinion of Experts About the Prevention and the Treatment of Postmenopausal Osteoporosis. S. Rozenberg,[1] A. Peretz,*[2] H. Ham.[1] [1]Interdisciplinary Group on Osteoporosis, St Pierre Hospital, Brussels, Belgium, [2]CHU Brugman, Brussels, Belgium.

The National Institutes of Health (NIH) convened a consensus conference about the diagnosis, prevention and therapy of osteoporosis. A consensus has the merit to reflect the opinion of a panel of experts, but this view is not necessarily shared by others. We conducted an opinion survey on the therapy of osteoporosis. One physician not familiar with this subject reviewed the titles of all papers published during the last 5 years in major journals. Fourty papers were found to be closely related to the therapy of osteoporosis and a questionnaire was then sent to the first authors of these papers. They were assured that their participation would remain anonymous, and that the study would not be commercially exploited. They were asked what effect they thought that some medications (HRT, Biphosphonates, SERMS, Calcium and vitamin D) have in modifying the future risk of either vertebral- or hip fracture. After 1 months, we had obtained 20 returns (1 blank and 19 filled returns). The results show that the surveyed experts are quite critic towards the proposed treatments. If we consider that only a risk modification superior to 20% is clinically relevant, only 12 (63%) and 10 (53%) experts considered that HRT has a favourable effect on prevention and 14 (74%) and 11 (58%) on treatment of vertebral or hip fracture. Others considered that there were not enough data to conclude. For the biphosphonates, 10 (53%) experts considered that these drugs have a favourable effect on vertebra or hip prevention and 18 (95%) and 15 (79%) on vertebral or hip fracture treatment. About half of the expert think that the efficacy of the biphosphonates on prevention of osteoporosis has not been proven, while it has as a treatment of established osteoporosis. Only respectively 10 (53%) and 7 (37%) experts considered that SERMS has a favourable effect on prevention of vertebral or hip fracture, and 16 (84%) on treatment of vertebral and 6 (32%) on treatment of hip fracture. Concerning the calcium plus vitamin D, 4 (21%) and 6 (32%) experts considered this regimen has a favourable effect on prevention and 9 (48%) and 10 (53%) on treatment of vertebral or hip fracture. These data suggest that some experts are much more critical in their views than the views which appeared in the consensus conference.

SA428

A New Active Vitamin D Analog, ED-71, Increases Bone Mass with Preferential Effects on Bone in Osteoporotic Patients. T. Matsumoto,[1] T. Miki,[2] T. Sugimoto,[3] R. Teshima,*[4] Y. Kato,*[5] S. Okamoto,[6] H. Tsurukami,[7] Y. Tanigawara,*[8] T. Nakamura,[7] M. Shiraki,[9] Y. Hayashi,*[10] M. Fukunaga.*[11] [1]University of Tokushima, Tokushima, Japan, [2]Osaka City University, Osaka, Japan, [3]Kobe University, Kobe, Japan, [4]Tottori University, Yonago, Japan, [5]Shimane Medical University, Izumo, Japan, [6]Sanyo Osteoporosis Research Foundation, Oita, Japan, [7]University of Occupational and Environmental Health, Kitakyushu, Japan, [8]Keio University Hospital, Tokyo, Japan, [9]Research Institute and Practice for Involutional Diseases, Nagano, Japan, [10]Tokyo Metropolitan Tama Geriatric Hospital, Tokyo, Japan, [11]Kawasaki Medical School, Kurashiki, Japan.

ED-71 [1α,25-Dihydroxy-2β-(3-hydroxypropoxy)vitamin D_3] is a potent analog of active vitamin D, 1α,25$(OH)_2D_3$, bearing a hydroxypropoxy substituent at the 2β-position. In ovariectomized rats, ED-71 prevented the reduction in bone mass and strength without causing hypercalcemia by inhibiting bone resorption and enhancing bone formation. These results suggested that ED-71 preferentially acts on bone to increase bone mass with less effect on intestinal calcium absorption. We therefore conducted a randomized controlled clinical trial in 108 osteoporotic subjects (101 females and 7 males) 49 to 81 years of age (mean 65.0 years). The patients were randomly assigned to either 0.25, 0.5, 0.75 or 1.0 μg/day of ED-71 administered orally. They were treated for 6 months, and bone mineral density (BMD) and bone markers were evaluated. ED-71 treatment increased the BMD at L_{2-4} in a dose-dependent manner (0.34±0.73, 0.50±0.91, 3.00±0.65 and 2.66±0.71% in the 0.25, 0.5, 0.75 and 1.0 μg groups, respectively, mean±SE). The percentages of patients that showed an increase in the L_{2-4}BMD over 3% after 6 months also increased dose-dependently (21.7, 26.1, 54.2 and 45.5% in the 0.25, 0.5, 0.75 and 1.0 μg groups, respectively). Although 24 patients (23.3%) showed serum 25(OH)D levels below 20 ng/mL, the effect of ED-71 on the L_{2-4}BMD was not affected by the serum 25(OH)D level. ED-71 also exhibited a dose-dependent suppression of urinary deoxypyridinoline and Crosslaps excretion as well as serum bone-type alkaline phosphatase, whereas serum osteocalcin was not suppressed, suggesting a maintenance of bone formation with a suppression of bone resorption. ED-71 was well tolerated without causing hypercalcemia, and no patient exhibited sustained postprandial hypercalciuria over 0.4 mg/dL GF. These results demonstrate that ED-71 can effectively increase bone mass without causing hypercalcemia possibly via its preferential effects on bone, and suggest that ED-71 is a new modality that may be a candidate for the treatment of osteoporosis.

Alfacalcidol in the Prevention of Bone Loss After Heart Transplantation. H. U. Stempfle,[1] C. Werner,*[1] S. Florian,*[1] R. Frost,*[1] W. A. Rambeck,*[2] R. Gärtner.*[3] [1]Cardiology, Medizinische Klinik Innenstadt, Munich, Germany, [2]Tierärztliche Fakultät, Munich, Germany, [3]Endocrinology, Medizinische Klinik Innenstadt, Munich, Germany.

Background: Immunosuppressive therapy induced osteoporosis is a well known complication after heart transplantation (HTx). The aim of this prospective, placebo-controlled study was to assess the effect of alfacalcidol (1 μg) in the prevention of bone loss after HTx. Methods: Study patients (n=56) received a triple-drug immunosuppression including FK506, azathioprine or mycophenolate mofetil and glucocorticoids. Patients were treated with elemental calcium (500 mg/d) and sex hormone replacement in hypogonadismus. 38 patients (mean age: 48±9 yrs.; 5±1 months post HTx) received alfacalcidol and were compared to 18 cardiac transplants with placebo (age: 54±12 yrs.; 5±4 months post HTx) at baseline and 12 months. 16 and 9 patients completed already a 24 months treatment intervall. Bone mineral density (BMD) was measured at the lumbar spine (LS) and at the femoral neck (FN) with DEXA (Lunar Expert, g/T-score %). Fractures were assessed by X-rays of chest, thoracic and lumbar spine. Biochemical markers included gonadal hormones, gonadotropins, urinary and serum para-meters of calcium metabolism, intact PTH, 25OHVitD3 and renal function. Results and Conclusions: Calcium supplemention and sex hormone replacement in hypogonadism proved a sufficient therapy to increase BMD and to prevent fractures after HTx. The additional dose of 1 μg Alfacalcidol demonstrated a significant extra benefit regarding BMD (see table).

Alfacalcidol Restores Vertebral Bone Mass in Ovariectomized Rats. M. Li, Y. Li,* D. R. Healy,* H. A. Simmons, D. D. Thompson. Pfizer Global Research and Developemt, Groton, CT, USA.

Vitamin D has been demonstrated to reduce vertebral and hip fractures in elderly patients. However, the role that vitamin D play in reducing fractures in the elderly is unclear. Some in vitro and in vivo pre-clinical studies have suggested that the vitamin D may effectively stimulate osteoblastic activity and exert an anabolic effect on bone. The current study was designed to further explore the ability of active vitamin D to restore bone in a skeletal site with established osteopenia in ovariectomized (OVX) rats. Female Sprague-Dawley rats at five months of age and 8 weeks after sham ovariectomy (OVX) or

OVX were randomly divided into 7 groups with 10 per group. At the beginning of the treatments, one group of sham-operated rats and one group of OVX rats were sacrificed to serve as baseline controls. Another group of sham operated rats and one group of OVX rats was treated with vehicle for 4 weeks. The OVX rats in the remaining groups were treated with 0.05, 0.1 or 0.2 mg/kg/d body weight of alfacalcidol [1a(OH)D3] by daily oral gavage, 5 days/week for 4 weeks. As expected, estrogen depletion caused high bone turnover and cancellous bone loss in lumbar vertebra of OVX rats. Alfacalcidol treatment at 0.1 or 0.2 but not 0.05 mg/kg/d increased serum calcium and phosphorus in OVX rats as compared with vehicle treatment. In addition, serum parathyroid hormone was suppressed, whereas serum osteocalcin was increased by alfacalcidol at all dose-levels. Furthermore, histomorphometric data of lumbar vertebra revealed that cancellous bone volume in OVX rats treated with alfacalcidol at 0.1 or 0.2 mg/kg/d was increased to the level of sham-controls treated with vehicle. This increment in cancellous bone mass was accompanied by increases in trabecular number and thickness and a decrease in trabecular separation. Moreover, osteoclast surface was decreased, whereas bone formation variables such as mineralizing surface and bone formation rate were increased in alfacalcidol-treated OVX rats compared with those of vehicle-treated OVX rats. Finally, a linear regression analysis showed that alfacalcidol treatment dose-dependently altered most of the variables measured in the current study. In conclusion, alfacalcidol completely restores cancellous bone by stimulating bone formation and suppressing bone resorption in lumbar vertebra of OVX rats. Increased serum calcium and decreased serum parathyroid hormone accompany such effects of alfacacidol on bone. These results support the use of active vitamin D analogs for the treatment of osteoporosis.

An Unusual Pattern of Bone Formation by Alfacalcidol Treatment in Aged Male Rats. M. Li, D. R. Healy,* Y. Li,* H. A. Simmons, D. D. Thompson. Pfizer Global Research and Development, Groton, CT, USA.

Vitamin D is an essential component for maintenance of health. Further, it has been demonstrated to prevent vertebral and hip fracture in elderly patients. The role that vitamin D play in preventing fractures in the elderly is unclear. Calcitriol [1a25(OH)2D3] and alfacalcidol [1a(OH)D3] have been reported to increase bone mass and bone strength in relative young rats. However, these effects of vitamin D have not been assessed in aged animals. Therefore, we sought to investigate the effects using aged male rats to understand the relationship between changes in bone mass and bone strength. Eighteen-month-old male Sprague-Dawley rats were treated with 0, 0.1, or 0.2 mg/kg/d body weight of alfacalcidol by daily oral gavage, 5 days/week for 12 weeks. At the end of the study, the second lumbar vertebrae were processed for standard bone histomorphometric analysis and the fourth lumbar vertebrae were subjected to a compression test. The results of current study confirmed the previous finding of increasing bone mass and improving bone strength by alfacalcidol in aged male rats. However, an atypical pattern of bone formation on trabeculae was observed in the rats treated with alfacalcidol. The atypical bone formation was characterized by small, focal packets of newly formed bone on trabecular bone surfaces. This gave the appearance of the formation of "bone buds" emanating from trabecular surfaces. The "bone buds" appeared to be randomly scattered along the surfaces. Also they were fully mineralized and demonstrated significant fluorochrome label indicating recent mineralized and their lamellae did not run parallel to those of the trabecular plate to which they are attached. No evidence of osteomalacia was observed in these animals. In summary, alfacalcidol treatment increased cancellous bone and improved bone strength of lumbar vertebrae in aged male rats. However, a unique pattern of bone formation was observed in this study, a finding not previously recorded. Further study will be necessary to assess if these effects are restricted to the aged.

Disclosures: Pfizer Inc,3.

SA433

Lack of Significant Toxicity of a Daily Supplementation of 1 g Elemental Calcium and 880 IU Vitamin D in Postmenopausal Women. J. P. Devogelaer,* G. Depresseux.* Rheumatology Unit, Cliniques Universitaires Saint-Luc, Bruxelles, Belgium.

Calcium and vitamin D deficiencies are relatively common in elderly population, leading to secondary hyperparathyroidism potentially detrimental for bone.Vitamin D and calcium supplementations are more and more frequently recommended. However, blind systematic supplementation could potentially be at risk of toxicity. We have, therefore, administered physiologic doses of elemental calcium (1 g) and vitamin D (880 IU) daily for 2 months to 30 ambulatory postmenopausal women with osteopenia [T-score = - 1.5 (1.2)], aged 67.7 (6.4 SD) whose 25OHD level was lower or equal than 30 ng/ml. Following therapy, 25OHD level increased from 14.7 (7.0) to 29.2 (7.0) ng/ml, 50 % of patients reaching levels higher than 30 ng/ml. Serum calcium (total and corrected) and creatinine clearance did not change significantly. iPTH decreased significantly from 34.1 (14.8) to 25.5 (8.7) pg/ml ($p < 0.01$). 24-H urinary calcium excretion (both total and body weight-corrected) increased from 173 (83) to 223 (93) mg and from 2.7 (1.2) to 3.5 (1.6 mg/kg), respectively ($p < 0.01$). 24-H urinary N-telopeptide (NTx)/creatinine and NTx/whole body BMC decreased non significantly. 13.3 % of patients increased their total serum calcium and 24-H urinary calcium/body weight over 10.4 mg/dl (up to 10.9 mg/dl) and 5 mg/kg (up to 6.6 mg/kg), respectively, and 20 % developed 24-H urinary calcium excretion superior to 300 mg (up to 444 mg).In conclusion, calcium and vitamin D supplementations in elderly patients are able to induce a significant decrease in serum iPTH and a non-significant decrease in urinary NTX excretion, potentially favorable for bone mechanical resistance. However, 24-H urinary calcium excretion should ideally be checked after 2 months in order to detect frank hypercalciuria which can occur in up to 20 % of patients. This could be of some clinical significance in a minority of patients.

SA434

A Vitamin D Analog, ED-71, Is a More Potent Anti-Osteoporosis Drug than Alfacalcidol in an Estrogen-deficient Rat Model of Osteoporosis. S. Takeda,[1] Y. Uchiyama,[1] Y. Higuchi,[1] T. Masaki,[1] A. Shiraishi,[1] K. Sato,[1] N. Kubodera,[1] K. Ikeda,[2] E. Ogata.[3] [1]Chugai Pharmaceutical Co., Ltd., Shizuoka, Japan, [2]Dept. of Geriatric Res., Natl. Inst. for Longevity Sci., Aichi, Japan, [3]Cancer Inst. Hosp., Japanese Foundation for Cancer Res., Tokyo, Japan.

Although active vitamin D is used in certain countries for the treatment of osteoporosis, the risk of causing hypercalcemia/hypercalciuria results in a narrow therapeutic window, and has precluded worldwide approval. The results of our previous animal studies suggested that the therapeutic effect of active vitamin D on bone loss after estrogen deficiency can be dissociated at least partly from its effect of enhancing intestinal calcium absorption and suppressing parathyroid hormone (PTH) secretion. In the present study, we compared the effects of ED-71, a propoxy derivative of 1α,25-dihydroxyvitamin D_3, with alfacalcidol on bone mineral density (BMD) and the bone remodeling process as a function of their effects on calcium metabolism and PTH secretion, in a rat ovariectomy (OVX) model of osteoporosis. Eight-month-old female Wistar rats were subjected to OVX and treated p.o. with ED-71 (0.05-0.2 micro g/kg BW) or alfacalcidol (0.1-0.4 micro g/kg BW) for 12 weeks. ED-71 increased BMD in the lumbar vertebra to a greater extent than alfacalcidol, while enhancing calcium absorption (reflected by urinary calcium excretion) and decreasing serum PTH levels to the same degree as alfacalcidol. ED-71 lowered the biochemical and histological parameters of bone resorption, such as urinary deoxypyridinoline and osteoclast surface (Oc.S/BS), more potently than alfacalcidol, while maintaining bone formation markers such as serum osteocalcin and bone formation rate (BFR/BS). These results suggest that active vitamin D exerts an anti-osteoporotic effect by inhibiting osteoclastic bone resorption while maintaining osteoblastic function, and that these anti-catabolic/anabolic effects of active vitamin D take place independently of its effects on calcium absorption and PTH secretion. The demonstration that ED-71 is more potent in these properties than alfacalcidol makes it an attractive candidate as an anti-osteoporotic drug.

SA435

Measurement of Tartrate-Resistant Acid Phosphatase (TRAP) and the Brain Isoenzyme of Creatine Kinase (CK-BB) Accurately Diagnoses Type II Autosomal Dominant Osteopetrosis but Does Not Identify Gene Carriers. S. G. Waguespack,[1] S. L. Hui,[1] K. A. Buckwalter,*[2] M. J. Econs.[1] [1]Medicine, Indiana University School of Medicine, Indianapolis, IN, USA, [2]Radiology, Indiana University School of Medicine, Indianapolis, IN, USA.

Autosomal dominant osteopetrosis, Type II (ADO2) is a metabolic bone disorder that results from ineffective osteoclast-mediated bone resorption. The diagnosis is typically made on radiographs, which demonstrate the pathognomonic findings of osteosclerosis and endobone formation. Individuals with ADO2 also have elevated serum levels of TRAP and CK-BB. In the current study, we tested the utility of these enzymes in making or refuting the diagnosis in asymptomatic patients at risk for ADO2. Furthermore, because ADO2 has incomplete penetrance, we examined whether TRAP and CK-BB were helpful in identifying gene carriers. We studied eight families and measured serum levels of TRAP and CK-BB in 44 affected patients and 12 obligate carriers (individuals with normal radiographs, but who have an affected descendant as well as another relative with the disorder). We then compared their values to age-matched controls without osteopetrosis (Table). The reference ranges for TRAP are 4.3-21.1 U/l in children <18 years of age and 3.5-9.1 U/l in adults. CK-BB should be undetectable in adults whereas in children, small quantities of CK-BB activity may normally be observed.

	Affected <18 yrs	Controls <18 yrs	Affected >18 yrs	Controls >18 yrs	Obligate Carriers
N	**14**	**23**	**30**	**89**	**12**
Age (yrs±SD)	9.0±4.1	7.1±3.3	45.3±17.2	44.3±16.0	41.3±9.8
M / F	9 / 5	13 / 10	13 / 17	44 / 45	4 / 8
TRAP (U/L±SD)	81.4±17.3*	21.2±4.8	49.5±18.4*	9.62±2.9	11.3±5.4#
CK-BB (U/L±SD)	190.6±96.0*	1.2±2.4	59.6±43.7*	0.0±0.0	0.8±2.6#

*$p < 0.0001$ vs controls; #$p > 0.3$ vs controls

Our results demonstrate that affected patients have significantly elevated levels of both TRAP and CK-BB. In contrast, gene carriers have values that are no different from controls. In our study population, TRAP is 100% sensitive and 94% specific when a cutoff of 1.5X the age-appropriate upper limit of normal is used. In children, using a CK-BB value of 15 U/L gives a sensitivity and specificity of 100%. In the adult group, a cutoff of 0 U/L gives a diagnostic sensitivity and specificity of 93% and 100%, respectively. From this large study of ADO2 patients and carriers, we conclude that: 1) TRAP and CK-BB are significantly and consistently elevated in patients with radiographically-proven ADO2, 2) gene carriers cannot be adequately identified by measurement of these analytes, and 3) TRAP and CK-BB are highly sensitive and specific diagnostic tests that can efficiently and effectively screen high risk individuals who have not had previous radiographic assessment

Intravenous Pamidronate Improved Bone Mineral Density and Diminished Bone Turnover in Patients with Fibrous Dysplasia. M. S. Parisi,*[1] M. B. Oliveri,[1] C. Gómez Acotto,[1] C. Tau,[2] F. Solís,*[1] C. A. Mautalen.[1] [1]División Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina, [2]Metabolismo Cálcico y Óseo, Endocrinología, Hospital de Pediatría J. P. Garraham, Buenos Aires, Argentina.

We report the effect of one year treatment with intravenous Pamidronate (APD) on bone mineral density (BMD) and bone turnover in six patients with Fibrous Dysplasia (FD), 5 women and 1 man. Mean age was 37.3 years (r:21-79). A complete clinical, biochemical and radiographic follow-up was performed. BMD of Total Body (TB) was assessed by DEXA at baseline and one year after the onset of treatment. In patients with unilateral location of the disease, areas of FD (aFD) (3 located in the arms, 5 in legs and 1 in pelvis) were delimited by ROI analysis and compared with their contralateral non-affected side (C). The difference in BMD was calculated as a percentage where the healthy side was taken as 100%. The same analysis was performed in 6 sex and age matched controls. Bone alkaline phosphatase (BAP) and urinary cross-laps (CTX) were measured at baseline and at 3 months intervals. A 60mg/day dose of iv APD was administered on 3 days every 6 months.At baseline, TB BMD values were in the normal range, except for one postmenopausal woman who presented diminished BMD. Mean difference in BMD (ROI analysis) between aFD and C was -8.4% (r:-36.2 to +4.6). The difference in BMD between right and left sides in control subjects was +0.5±4.3(X±SD). BAP and CTX levels were above the normal range in 5 and 3 patients respectively.After one year, we observed 2.6% increments in mean TB BMD ($p<0.05$), while mean BMD of aFD and C increased 6.9% and 1.9% respectively. The mean difference between aFD BMD and C BMD diminished to –4.8% (r:-31.5 to +19.5). BAP levels were found to decrease an average 30% in the five patients presenting abnormal baseline values, but were still above the normal range. CTX levels decreased in the three patients presenting abnormal baseline values. Only one patient with markedly high baseline values still showed high levels of CTX after one year of treatment, although a 40 % reduction was observed. CTX and BAP levels remained unchanged in the patients with normal baseline values.Whereas TB BMD was mostly within normal ranges, BMD of FD areas was lower than their corresponding healthy contralateral side. Treatment with iv APD produced an increase in Total Body and areas of FD BMD and diminished markers of bone turnover. Our results lead to the conclusion that specific densitometric evaluation of areas of FD by means of ROI analysis, together with determinations of specific markers of bone turnover allow to assess the effectiveness of one year treatment with iv APD in most patients with FD.

Identification of EDR3, a Candidate Gene for the Cornelia - de Lange Syndrome (CDLS). A. M. Deshpande,*[1] M. J. Nellissery,*[1] X. Reveles,*[2] S. L. Naylor,*[2] L. G. Jackson,*[3] R. J. Leach,[2] M. F. Hansen.[1] [1]Center for Molecular Medicine, Univ. Connecticut Health Center, Farmington, CT, USA, [2]Department of Cellular and Structural Biology, Univ. Texas Health Science Center, San Antonio, TX, USA, [3]Department of Medical Genetics, Thomas Jefferson University, Philadelphia, PA, USA.

CDLS is a syndrome characterized by pre- and post-natal growth delay, mental retardation, microbrachycephaly, synorphrys, hirsutism, delayed skeletal maturation especially upper limb abnormalities and a characteristic facies. Ireland et al. first described a [3:17] balanced translocation in a classical case of CDLS. This and other studies suggest localization of the gene(s) involved, to the region 3q26 - q27. We have identified a candidate for CDLS, a novel member of the polycomb group of proteins, which we have named EDR3. Southern and FISH analyses reveal that EDR3 is triplicated in cell lines derived from CLDS patients even in the absence of gross cytogenetic abnormalities. Northern and RT-PCR analyses indicate that EDR3 is expressed in mesenchymal stem cells (MSC), but is expressed at very low levels in normal human osteoblasts and adult bone. The gene has an ORF of 2748 bp and a 5'- and 3'- UTR. The mouse homologue of EDR3 is approximately 92% homologous to the human EDR3 protein. The EDR3 protein is similar to other members of the polycomb protein family including human EDR2 (48%) and mouse mPh2 proteins (52%). Members of the PcG family regulate gene expression through protein-protein and protein-DNA interactions. These proteins play an important role in axial patterning of organisms through regulation of expression of homeotic genes. PcG proteins antagonize the function of trithorax group of proteins and mediate long term lineage-specific silencing of genes. Mutations in polycomb proteins [e.g.: Ezh2, BmiI] cause shifts in the boundaries of homeotic gene expression, which result in anterior or posterior transformations and skeletal dysmorphogenesis. Based on the observed localization of the EDR3 gene and its potential role in regulation of skeletal dysmorphogenesis, we propose that overexpression of EDR3 caused by triplication gives rise to the skeletal phenotype associated with CDLS.

Bone Marrow Triglyceride Accumulation and Hormonal Changes During Chronic Alcohol Consumption. F. H. Wezeman,*[1] Z. Gong.*[2] [1]Orthopaedic Surgery, Loyola University Medical School, Maywood, IL, USA, [2]Loyola University Medical School, Maywood, IL, USA.

The relationship between chronic alcohol consumption and bone marrow fat content was studied in a rat model. Clinical observations during orthopaedic surgical procedures frequently note an increase in bone marrow fat content in chronic alcoholics. Chronic alcohol consumption may influence the metabolism of adipocytes, the most abundant stromal cell phenotype in bone marrow, and promote increased bone marrow triglyceride. Male and female rats 35 days old were fed the Lieber-DeCarli liquid diet containing 36% of the calories as ethanol and were compared to pair-fed rats (weight-matched to ethanol-fed rats) given an isocaloric liquid diet in which maltose-dextrin substituted for the calories supplied by ethanol. Other control rats were fed chow ad libitum. The rats were maintained on these diets for 64 days, after which the femurs were recovered. Individual femur marrow triglyceride content was quantified after lipid extraction and alkaline hydrolysis. Serum concentrations of insulin, insulin-like growth factor-1, testosterone, estradiol, progesterone, and leptin were determined by radioimmunoassay at the time of sacrifice. End-weights of male and female ethanol-fed rats were significantly lower than both control groups. Femur marrow triglyceride levels were significantly increased in ethanol-fed male and female rats compared to both control groups. Femur marrow cavity diameters were significantly increased and cortical thickness was significantly decreased by alcohol in both males and females. Serum insulin levels were significantly decreased by alcohol only in female rats compared to the ad libitum but not the pair-fed control group, and insulin-like growth factor-1 levels were significantly reduced in male and female rats given the ethanol diet compared to both controls. Male testosterone and female estradiol levels remained unchanged. Male estradiol levels were significantly elevated by ethanol compared to both controls, and female progesterone levels were significantly reduced by ethanol compared to pair-fed rats. Whereas female leptin levels were unchanged by ethanol, male leptin levels were significantly increased by ethanol compared to pair-fed rats. Hormonal and growth factor changes during chronic alcohol consumption accompany triglyceride accumulation in bone marrow, and may parallel the effects of alcohol on mesenchymal stem cells and the balance between osteogenic and adipogenic lineages and their cellular progenies.

Bone Mineral Impairment and Body Composition Evaluated by DXA (Dual-Energy X-Ray Absorptiometry) in Black HIV-Positive Patients. S. Daens,*[1] M. Guillaume,[2] P. Bergmann,[3] M. Fuss,*[2] R. Karmali,*[2] A. Peretz.*[1] [1]Rheumatology, CHU Brugmann, Brussels, Belgium, [2]Internal Medicine, CHU Brugmann, Brussels, Belgium, [3]Clinical Chemistry, CHU Brugmann, Brussels, Belgium.

Background. The aim of the study was to determine the influence of HIV infection and its treatment on bone mineral density and body composition in African black patients.Methods. 24 HIV-positive (HIV+) black patients (9 men and 15 women) and 16 HIV-negative black control subjects (C) were consecutively enrolled. All patients were already treated with an anti-retroviral therapy with two third of them receiving in addition a protease inhibitor (PI). Nutritional status and hormonal functions were evaluated at the initiation of the study and one year later. Body composition, lumbar (BMDL) and whole body BMD (BMDW) were assessed using DXA (Hologic, QDR 1000).Results. No differences were found between HIV+ and C in anthropometric parameters or nutritional status. HIV+ had significantly higher TSH level than C ($p<0.001$) indicating perhaps a lower thyroid activity. BMDW and BMDL were similar in female HIV+ and C. However in HIV+ men the BMDL, the bone mineral content (BMC) and the lean mass (LM) were respectively 9%, 16% and 11% lower than in C ($p<0.05$). After a year of follow up, DXA measurements and endocrine functions did not change. In the patients who were also treated with PI, fat distribution remained unchanged a year later.Conclusions. Male black HIV+ had a significantly lower LM, BMC and BMDL when compared to C. In addition, treatment with PI did not change fat distribution.

Diffuse Crippling and Disfiguring Bone and Skin Lesions as a Presentation of Systemic Mastocytosis. A. Halabe,[1] R. Shor,[1] I. Tolatov,[2] E. Rachmilewitz.[2] [1]Department of Internal Medicine and Metabolic Bone Diseases, The Edith Wolfson Medical Centre, Holon, Israel, [2]Hematology, The Edith Wolfson Medical Centre, Holon, Israel.

Mastocytosis is a disease characterized by an abnormal increase in mast cells associated usually with skin lesions (urticaria pigmentosa) and systemic bone involvement. We report a 77-years-old Russian male who was referred to our clinic because of intractable pain in his vertebral column and lower extremities. His past medical history included severe chronic dermatitis diagnosed as vasculitis, following a skin biopsy in Russia. The patient was treated with high dose of corticosteroids without any improvement in his skin lesions. On physical examination the most evident finding was a severe disability affecting mainly the thoracic and lumbar vertebral regions, causing inability to flex the spine and maintain an upright position (the patient was forced to use a metal corset). A maculo-papular skin eruption was also observed over his trunk. Laboratory tests including CBC, chemistry analysis and serum protein electrophoresis were within normal range. An Osseous CT and MRI revealed severe osteoporosis with diffuse large lytic lesions in the iliac bones and in the spinal area at the level of L4-L5. CT guided FNA from one of the bone lesions and bone marrow biopsy, were not diagnostic. An open biopsy from the iliac area demonstrated focal paratrabecular mast cell infiltration compatible with the diagnosis of systemic mastocytosis. A repeat biopsy from one of the skin lesions supported the diagnosis of mastocytosis-urticaria pigmentosa. The patient was treated with monthly I.V. Pamidronate 90 mg, alpha interferon 3 X 10-6 U/weekly and H2 receptors blockers.Three months later, his bone pain subsided considerably and the skin eruption was very much improved. A repeat MRI showed improvement in the extent of the lytic lesions of the iliac region. This is an interesting case of a rare disease, which responded dramatically to treatment. The most striking feature was an improvement in the quality of life of one who suffered for two decades from a crippling and disfiguring disease.In conclusion, mastocytosis is a rare disease with protean manifestations; very seldom considered in the differential diagnosis of osteoporosis and possibly even overlooked.

Specificity of DSL Salmon Calcitonin ELISA. N. Khaja,*[1] S. K. Durham,*[1] J. Mistry,*[1] M. Nicar,[1] A. Consalvo,*[2] A. Sturmer,*[2] N. Mehta.*[2] [1]DSL, Inc, Webster, TX, USA, [2]Unigene Laboratories, Fairfield, NJ, USA.

Calcitonin plays a major role in calcium homeostasis by inhibiting osteoclast-mediated bone resorption. Salmon calcitonin (sCT), a 32-amino acid polypeptide, is used clinically in the treatment of bone disorders such as Paget's disease, hypercalcemia and osteoporosis in humans. Unigene has developed a dual recombinant process for the cost-effective, large-scale production of bioactive sCT. The technology involves production of a glycine-extended sCT precursor in *E. coli*, followed by *in vitro* amidation. An enzyme-linked immunosorbent assay (ELISA) was recently developed by DSL to measure sCT in human serum. This ELISA was used to study the specificity of the assay towards synthetic and recombinant full-length sCT as well as various peptide fragments of sCT including amino acid 1-11, 12-18, 19-24, 25-32 NH_2, 1-15, 16-32 NH_2, 1-24 and 12-32 NH_2. The synthetic and recombinant intact antigens showed equal immunoreactivity in the ELISA throughout the dynamic range (10-500 pg/mL) of the assay. Peptide fragments 1-11, 12-18, 19-24, 25-32 NH_2, 1-15, 16-32 NH_2 (at concentrations 0.06-500 ng/mL) displayed insignificant cross-reactivity (<2%) whereas, fragment 12-32 NH_2 showed minor (3.3-16.9%) cross-reactivity at 0.06-1.95 ng/mL. The only peptide fragment that cross-reacted in the assay was sCT 1-24, and the extent of cross-reactivity was greater than 100% in the linear range of the assay. Human calcitonin (up to 500 ng/mL), katacalcin (up to 1 ng/mL), CGRP (up to 1 ng/mL), ACTH (up to 2 ng/mL) and PTH (up to 0.2 ng/mL) did not display any cross-reactivity in the assay. We conclude that the DSL Active™ Salmon Calcitonin ELISA is species-specific; the pair of antibodies used in this sandwich ELISA do not recognize peptide fragments of sCT (except for sCT 1-24). The availability of this highly specific ELISA provides a useful tool for monitoring treatment and dosage of salmon calcitonin in human serum or plasma.

Predictive Value of Bone Markers in the Long-Term Response to Bisphosphonates in Paget's Disease. N. Guanabens, L. Alvarez, P. Peris, S. Vidal-Sicart,* I. Ros,* A. Monegal,* J. Bedini,* R. Deulofeu,* F. Pons,* A. M. Ballesta,* J. Muñoz.* Metabolic Bone Diseases Unit, Hospital Clínic, University of Barcelona, Barcelona, Spain.

The purpose of this study has been to evaluate if short-term changes in bone marker levels predict long-term Paget's disease activity after bisphosphonate treatment.This prospective study was carried out in 15 patients with Paget's disease of bone treated with tiludronate (400 mg/day for 3 months). The activity of the disease was determined by quantitative bone scans (scintigraphic activity index -SAI), at baseline and after 9 and 21 months. Biochemical markers of bone turnover, including serum levels of total alkaline phosphatase (TAP), bone alkaline phosphatase (BAP) and procollagen type I N-terminal propeptide (P1NP) and urine levels of hydroxyproline (HYP) and N-terminal telopeptide of type I collagen (NTx) were measured at the same times.According to the SAI changes between 9 and 21 months, the patients were divided into two groups: group I: no changes or reduction (9 patients), and group II: increased SAI (6 patients). Short-term changes (0-9 months) in the markers of bone formation were similar in both groups (I vs II. TAP -48 ± 7 % vs -68 ± 6%; BAP: - 63 ± 9% vs -81 ± 3%; PINP: -67 ± 6 % vs -75 ± 4%). By contrast, long-term changes (9-21 months) in the markers of bone formation were clearly associated with the SAI, since the patients with high scintigraphic activity had significant increases of TAP (69 ± 20% vs 9 ± 4%, $p<0.01$), BAP (120 ± 18% vs 33 ± 12%, $p<0.01$) and PINP (105 ± 10% vs 23 ± 12%, $p<0.05$). No significant changes in the markers of bone resorption were observed between both groups.In conclusion, the short-term changes in bone markers did not predict the long-term response to tiludronate. Changes in bone formation markers, measured between 9 and 21 months, provide the best biochemical approach for assessing long-term response to treatment.

SA454

Paget's Disease of Bone with Normal Serum Alkaline Phosphatase Activity - Effects of Bisphosphonates on Clinical Symptoms and Bone Markers. F. F. A. Bandeira,[1] G. J. C. Caldas,*[2] L. H. M. Griz,*[2] C. H. C. Bandeira.*[2] [1]Dept. of Endocrinology/UPE/CpqAM, Centro de Osteoporose, Recife, Brazil, [2]Dept of Endocrinology, Centro de Osteoporose, Recife, Brazil.

In most series the majority of patients with Paget's disease of bone are asymptomatic and are usually accidentally discovered during a clinical,radiological or biochemical evaluation for an unrelated condition. For many years serum alkaline phosphatase(AP) activity has been used as the most common index of activity of the pagetic lesions. In a serie of 77 consecutive patients seen at our Institution we identified 6 patients with normal serum AP activity but high levels of deoxypiridinoline(DPD) or N-telopeptide(NTX) excretion. The patients were 4 males and 2 females with mean+/-SD age 74.5+/-6.7 and 74.3+/-9.5 years respectively, all of them with poliostotic disease and 2 of them asymptomatic.Mean serum AP was 86.8+/-15.8 U/L(normal up to 110).One patient had urinary DPD 82% above the upper limit of normal, and 5 patients had NTX 123.2+/-72.3% above the upper limit of normal, with absolute levels of 125+/-66.7 nmol/mmol creatinine(range 107.2 to 188).In 4 patients with symptomatic disease treatment were offered, oral alendronate(ALN)in 2 patients and intravenous pamidronate(PAM)in 2 patients. There was great improvement in pain after treatment and the changes in serum AP were -48+/-9.7%.One patient had 70% decrease in DPD excretion with ALN, and the other 3 had 63+/-18.6% decrease in NTX (-50% with ALN,-82% with PAM,-87% with PAM respectively).In conclusion in 8 % of a our patients with Paget's disease of bone basal serum AP activity were unable to express the disease activity in comparison with markers of bone resorption.In at least the symptomatic patients, treatment with bisphosphonates induced a significant decreases in serum AP,and more pronounced decreases in urinary DPD and NTX along with clinical improvement.

SA455

Symtomatic and Scintigraphic Improvement Following Pamidronate Treatment of Paget's Disease with Normal Serum Alkaline Phosphatase. G. Ang,* A. Moses. Medicine, SUNY-Upstate Medical University, Syracuse, NY, USA.

Pamidronate is well known to be effective in the treatment of patients with mild to moderate Paget's disease of the bone. It relieves pain and induces prolonged remissions. We report 3 cases of patients with symptomatic Paget's disease who presented with normal serum alkaline phosphatase (SAP). All had typical x-ray findings, abnormal bone scans and had pain in the involved area. They were treated with IV pamidronate 60 mg once weekly for 2-3 consecutive weeks. SAP and urinary markers of bone resorption were monitored every 3 months post-treatment. Bone scans were repeated after symptomatic improvement was achieved. Vitamin D deficiency was ruled out with appropriate laboratory tests. The first case is a 79 year-old man who had Paget's disease of the left pelvis with associated pain and bone scan revealed intense uptake in the involved area. Pretreatment SAP was 88 (normal 21-129 U/L) and urine deoxypyridinoline (d-pyr) was 15 (normal 2-7 nmol/mmol creatinine). He was treated with 180 mg of pamidronate. Post treatment SAP was 56 and d-pyr was 3.7. He remained symptom free for 6 years. At that time, SAP was 63 and bone scan did not show any increased uptake in the left pelvis. The second case is a 78-year old woman who had Paget's disease of the left iliac bone, vertebrae L2 and L4 who initially presented with pain the left hip and lower back. Her pre-treatment SAP was 124 and NTX was 124 (normal 15-110 nmol BCE/mmol creatinine). She became asymptomatic soon after treatment and at 6 months the SAP decreased to 84. Bone scan showed marked improvement six months after treatment. She was asymptomatic for 17 months, at which time the SAP rose to 122 and NTX was 177. She was retreated and 3 months later, the pain disappeared, the SAP was 76 and NTX was 61. The third case is a 67 year-old man with Paget's disease of the right proximal femur and complained of pain in the right hip. The pagetic femur was bowed. He received 180 mg of pamidronate. Pre-treatment SAP was 120 and NTX was 68. Three months post-treatment SAP was 97 and NTX was 36. He was asymptomatic after treatment. Bone scan repeated after one year showed marked decrease in radiotracer uptake. Conclusion: There are little data on the treatment of Paget's disease with normal SAP, which occurs in a small percentage of symptomatic patients. We observed that pamidronate is effective treatment for these individuals. It afforded symptomatic relief and decreased the levels of SAP and urinary markers of bone resorption. A normal SAP does not rule out active Paget's disease and in such patients, urinary markers of bone resorption and bone scans should be used to assess and monitor the activity of the disease.

New England Registry for Paget's Disease of Bone. M. Seton,[1] R. Sebaldt,[2] C. Cooper.[3] [1]Arthritis, Massachusetts General Hospital, Boston, MA, USA, [2]McMaster University, Hamilton, ON, Canada, [3]MRC Environmental Epidemiology Unit, Southampton, United Kingdom.

Paget's disease of bone (PDB) is a focal disorder of bone re-modeling, with clinical complications resulting from the location, extent of affected skeleton, and activity of the bony lesions. Some scientists postulate that PDB is the late expression of a viral infection of osteoclasts; others contest the theory of antecedent viral infection and explain the familial and geographic clustering that is reported in PDB by genetic predisposition. They point to genetic studies in some families with PDB where a candidate gene on the long arm of chromosome 18 has been identified. The New England Registry for Paget's Disease of Bone was established in 1999, designed to be the platform for a national / international database of patients with Paget's disease. The goal of the Registry is to provide clinical investigators with data to assess the prevalence, epidemiology and treatment outcomes; and to provide scientists with tissue for correlative science. Enrollment began February 2001, with completion of the database. Enrollment is voluntary, initiated by a patient questionnaire exploring the distribution and determinants of disease frequency. This information is linked to a clinical database and banked tissue in selected patients. Data from the first 100 patients entered into the registry show a familial incidence of Paget's disease of 13%; 5 patients were second generation PDB, with maternal history positive in all cases. In one, both parents had PDB. These mothers came from Scotland, Italy and Ireland, with no correlate to birth date or year of immigration; the proband reported measles infection in each case, but no consistent pet ownership. 8 patients had siblings with PDB; one was his twin sister, 4 reported more than one sibling affected. Overall, PDB affected the 1st in birth order 27%, 2nd 24%, the 3rd 19%, the 4th 11% and the 5th 12%, with 7 affected in later birth order. The most common ancestral country was Italy (Sicily) 42%, USA 36%, England (Scotland) 13% and Canada 16% with the Middle Eastern countries, Germany, central Europe (Poland, Czech) and Russia next in frequencies. Two patients emigrated from the Cape Verde Islands. 61% of patients were male. A summary of skeletal distribution of PDB: 42% hip, 41% skull, 31-34% lower back and pelvis, 26% tibia. Further correlative studies will help to define this focal disorder of bone. www.massgeneral.org/pagetregistry

Treatment of Paget's Disease of Bone with Alendronate 60mg. G. M. Tsoukas,[1] A. Arzoumanian.[2] [1]Endocrinology, McGill University, Montreal, PQ, Canada, [2]The Montreal General Hospital, Montreal, PQ, Canada.

One of the aims of treatment of Paget's disease should be the normalization of the activity of the disease with the shortest possible exposure to the drug. Alendronate has demonstrated effectiveness in the oral treatment of of Paget's disease of bone. With a 40mg daily dose for 6 months, 63% of treated patients normalized their serum alkaline phosphatase,(Siris,et al. J Clin Endocrinol Metab 1996). The aim of our study was to examine the effects of a higher treatment dose of alendronate (60mg per day) over a shorter period (3 months). There were 28 patients with Paget's disease, 18 male and 10 female, with a mean age of 69 years, who were treated with an oral alendronate at a dose of 60mg per day for 3 months. Ten patients had never been treated before and 18 had previously received anti-osteolytic drugs. The mean period without treatment prior to alendronate 60mg was 14 months. Baseline alkaline phosphatase levels fell from 266.6 to 82.2 (mean difference 183.8, P=0.000). Osteocalcin levels fell from a baseline of 25.62 to 16.53 (mean difference 9.1, P=0.017). PTH levels rose from a baseline of 5.1 to 8.7 (mean difference 3.6, P=0.0002). All patients normalized their alkaline phosphatase levels. Follow-up was carried out on all 28 patients two years later. All but three were in remission, for a rate of 89.2%. No side effects noted in any of the patients treated. In summary, a three month course of treatment with alendronate 60mg proved to be very effective and well tolerated for the treatment of Paget's disease.

A Novel Tandem Duplication Identified in the TNFRSF11A Gene in Two Unrelated Patients with Familial Expansile Osteolysis. F. R. Singer,[1] T. L. Johnson-Pais,*[2] H. G. Bone,[3] M. J. Nellissery,*[4] C. T. McMurray,*[5] M. F. Hansen,[4] R. J. Leach.*[6] [1]Skeletal Biology, John Wayne Cancer Institute, Santa Monica, CA, USA, [2]Pediatrics, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, [3]Michigan Bone and Mineral Clinic, Detroit, MI, USA, [4]Center for Molecular Medicine, University of Connecticut, Farmington, CT, USA, [5]Department of Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic and Foundation, Rochester, MN, USA, [6]Cellular and Structural Biology, University of Texas Health Science Center, San Antonio, TX, USA.

Familial expansile osteolysis (FEO) is an autosomal dominant disorder that is characterized by dramatic bone remodeling. It is extremely rare, with only three families reported in the literature. Last year, Hughes et al. (2000) identified identical mutations in the first exon of the TNFRSF11A gene in all published families with FEO. The TNFRSF11A gene codes for RANK, which has been demonstrated to be important in bone remodeling and the differentiation of pre-osteoclasts to osteoclasts. The mutation appears to arise as a tandem duplication of 18 bases in the sequence coding for the signal peptide of RANK. The resulting mutation causes an increase in RANK-mediated NF-6B signaling, consistent with a gain-of-function mutation. We have identified two additional FEO patients. One has no family history of FEO, but presented with classic symptoms including bilateral hearing loss at an early age, deterioration of teeth by the late 20's, and severe pain and swelling in distal tibia before the age of 20. The second patient had an extensive expansile tibial lesion, which was first noted in adolescence, and less prominent lesions in one humerus and a phalanx. Her hearing deteriorated after age 10, as did her teeth in her 20's. Her father also had skeletal involvement, hearing loss, and loss of dentition. Mutational analysis of the TNFRSF11A gene in these patients demonstrated an 18 base pair tandem duplication in the first exon, one base proximal to the tandem duplications reported by Hughes et al. (2000). This novel mutation results in the addition of the same 6 amino acids to the RANK signal peptide that has been observed in all other FEO patients. Further analysis of this sequence in this region demonstrated that it has the ability to form stable secondary structure. Formation of this secondary structure may facilitate the generation of these tandem duplications. Although the mutations we described are not identical on the DNA level to those previously described, the resulting proteins are identical. Thus, it appears that the mutations in the TNFRSF11A that give rise to FEO are highly specific.

SA461

Compound Heterozygous Mutations of the AIRE-1 Gene Causing Autoimmune Polyendocrinopathy Type 1. M. R. Bowl, J. J. O. Turner,* M. A. Nesbit,* B. Harding,* R. V. Thakker. Nuffield Department of Clinical Medicine, Oxford University, Oxford, United Kingdom.

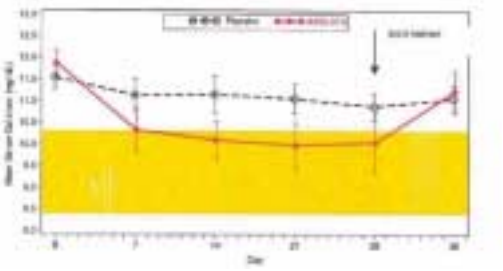
Autoimmune polyendocrinopathy type 1 (APS1) is an autosomal recessive disorder characterised by hypoparathyroidism, adrenocortical failure, mucocutaneous candidiasis, pernicious anaemia, alopecia (totalis or areata) and vitiligo. The gene causing APS1, which is located on chromosome 21q22.3, is referred to as the autoimmune regulator (AIRE-1) gene and consists of 14 exons that encompass a 1635bp coding region. The AIRE-1 protein, which consists of 545 amino acids, contains two plant homeodomain (PHD) zinc-finger motifs, a proline rich region and four LXXLL motifs, and these features suggest that it may have a role as a transcription factor. Over 20 different AIRE-1 mutations have been reported and two of these account for more than 85% of the mutations observed in APS1 patients. These two mutations are a nonsense mutation, Arg257Stop, that occurs in >80% of Finnish and >30% of USA patients, and a 13bp deletion (1094-1106del) that occurs in

>70% of British and >55% of USA patients. We have therefore investigated a 7 year old boy with APS1 for AIRE-1 mutations. The patient, whose parents are non-consanguineous, presented at 3.5 years of age with carpo-pedal spasms and investigations revealed hypocalcaemia (serum calcium = 1.58mmol/L) with an undetectable circulating PTH concentration. In addition to the hypoparathyroidism, he also developed moniliasis and alopecia totalis. Adrenocortical and thyroid function are normal. Treatment with alfacalcidol has restored normocalcaemia. Leukocyte DNA was utilised together with 14 pairs of primers to amplify, by use of PCR, the 14 exons and their respective exon-intron boundaries. The DNA sequences of the PCR products were then determined. This revealed the presence of two mutations which were the Arg257Stop mutation that was inherited from his mother, and the 13bp deletion (1094-1106del) that was inherited from his father. The nonsense mutation was confirmed by Taq I restriction enzyme analysis, and the deletion by agarose gel electrophoresis of the PCR products. The nonsense mutation predicts a truncated AIRE-1 protein of 256 amino acids, and the 13bp deletion predicts a frameshift with 50 missense amino acids followed by a premature termination signal at codon 372. Both of these mutations will result in the loss of the zinc-finger motifs, the proline rich region and two of the four LXXLL domains, and hence a loss of AIRE-1 activity. Thus, the patient is a compound heterozygote for inactivating AIRE-1 mutations, whilst the parents, who are phenotypically normal, are heterozygous carriers. These findings are consistent with an autosomal recessive inheritance for APS1.

SA462

An Evaluation of the Calcimimetic AMG 073 in Patients with Hypercalcemia and Primary Hyperparathyroidism (PHPT). D. M. Shoback,[1] A. F. Firek,[2] R. B. Mims,[3] T. A. Binder,*[4] T. Graves,*[4] S. A. Turner,*[4] M. Peacock.[5] [1]SF Veterans Affairs Med Ctr, UCSF, San Francisco, CA, USA, [2]Jerry L. Pettis VAMC & Loma Linda Univ Med Ctr, Loma Linda, CA, USA, [3]Diabetes and Endocrinology Associates for Research, Santa Rosa, CA, USA, [4]Amgen Inc., Thousand Oaks, CA, USA, [5]Indiana Univ Sch Med, Indianapolis, IN, USA.

Calcimimetics reduce PTH secretion and, subsequently serum Ca, by increasing the sensitivity of the parathyroid calcium-sensing receptor to extracellular Ca. In a prospective, double-blind, 5 week trial, 10 patients (6 AMG 073, 4 placebo) with PHPT and Ca levels ≥ 11.0 mg/dL were randomized to receive twice daily oral doses of 65 mg AMG 073 or placebo for 4 weeks of treatment and a 1 week follow up period (no drug administered). The effects of AMG 073 and placebo on serum Ca are shown below. The normal range for serum Ca is shaded.All but one (83%) of the AMG 073-treated patients experienced a reduction in serum Ca to the normal range (≤ 10.3 mg/dL) as compared with only 1 of 4 (25%) of placebo-treated patients. Serum Ca returned to predose levels 1 week after cessation of AMG 073 treatment. Baseline mean (SD) PTH was 189.9 (± 89.6) pg/mL in the AMG 073 group and 92.7 (± 25.3) pg/mL in the placebo group. Maximum reductions from baseline in mean PTH were observed in the AMG 073 group at 2 to 4 hours post-dose (approx. 39%). On day 28, mean (SD) PTH was reduced by 14.5 (± 7.62)% at 12 hours post-dose in the AMG 073 group as compared with an increase of 10.6 (± 7.57)% in the placebo group.AMG 073 was generally well-tolerated at this dose. In this 5-week study of patients with moderate to severe PHPT, 65 mg bid AMG 073 was efficacious in reducing serum Ca with concurrent reductions in PTH.



Disclosures: Amgen Inc.,3,5.

Genetic Analysis of the MEN1 Gene and HPRT2 Locus in 2 Kindreds with Familial Isolated Hyperparathyroidism. F. Cetani,[1] E. Pardi,*[1] E. Vignali,[1] A. Giovannetti,*[1] F. Golia,*[1] L. Cianferotti,[1] A. Picone,*[1] E. Ambrogini,*[1] P. Viacava,*[2] A. Pinchera,*[1] C. Marcocci.[1] [1]Endocrinology, University of Pisa, Pisa, Italy, [2]Oncology, University of Pisa, Pisa, Italy.

Familial hyperparathyroidism may occur as part of hereditary syndromes, including MEN1 and MEN2A), hyperparatyroidism-jaw tumor (HPT-JT) syndrome, and familial isolated hyperparathyroidism (FIHPT). It is unclear whether FIHPT represents a distinct genetic entity or is a variant of MEN1 or HPT-JT. We describe 2 unrelated Italian kindreds with FIHPT, in whom the clinical, histopathological and genetic analysis of the MEN 1 gene and HPRT2 locus at 1q21-32 suggest that both represent a variant of MEN1 or HPT-JT syndromes. Genomic DNA was isolated from peripheral blood leukocytes from all family members and from parathyroid tissues of subjects submitted to parathyroidectomy. Ionized calcium and PTH were measured in all family members. The coding sequence of the MEN1 gene were PCR-amplified and sequenced. Parathyroid glands were obtained from 5 subjects submitted to parathyroidectomy (III-2 and IV-4 of family 1; II-3, III-2 and III-4 of family 2). LOH at 11q13 and 1q21-32 was analyzed using polymorphic DNA markers PYGM and D11S449, and D1S212, D1S222, D1S428, D1S412, D1S413, respectively. Forward primers were conjugated with 5' fluorescent dye. PCR products were subjected to ABI PRISM 310 sequencer. Five members of family 1 and 2 of family 2 had biochemical evidence of primary hyperparathyroidism. A heterozygous deletion of 1 bp (1785delA) was found in exon 10 in affected members of family 1. The mutation was confirmed by subcloning in pCR4-TOPO vector. No MEN1 gene mutation was found in any member of family 2. LOH at 11q13 was observed in the tumors of family 1 members (PYGM in III-2; PYGM and D11S449 in IV-4) but not in tumors of family 2 members. Studies at 1q21-32 showed LOH at D1S428 and D1S212 markers in the tumors of the 2 affected members of family 2, whereas a retained heterozygosity was found in the remaining family 2 member (II-3) and in any tumor of family 1 members. The histological diagnosis in the 2 affected members of family 1 was chief cell hyperplasia with diffuse-nodular pattern of growth. Cut surface showed no cystic structures. Typical parathyroid adenoma was diagnosed in 1 member of family 2 and atypical adenoma in the remaining 2. All tumors showed cystic structures. We describe two unrelated kindreds clinically diagnosed as FIPHPT, which, on the basis of histological and genetic studies, can be classified as variants of MEN1 syndrome and HPT-JT. Therefore an extensive analysis of these genes should be performed in FIHPT families to identify the subset which are linked to MEN 1 gene or HPRT2 locus.

Increased RANKL Expression and Osteoclast Numbers, but No Change in Osteoblast Number or Apoptosis in a Murine Model of Sustained PTH Elevation: Mechanism of Decreased Bone Density and Strength. C. A. O'Brien, R. S. Weinstein, C. Powers,* S. C. Manolagas. Div. of Endo/Metab, Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

Whereas intermittent administration of PTH results in net bone gain possibly via inhibition of osteoblast apoptosis, sustained elevation of PTH results in net bone loss. However, the cellular and molecular mechanisms by which continuously elevated PTH leads to bone loss remain unclear. In vitro studies reported elsewhere in this meeting show that PTH directly stimulates RANKL gene expression. To determine whether sustained PTH elevation stimulates RANKL in vivo and to quantitate the cellular changes associated with this condition, we induced secondary hyperparathyroidism in mice via a calcium-deficient diet. Five-month-old C57BL/6 mice were stratified into two groups (n = 4) with equal spinal bone mineral density and one group was placed on normal mouse chow (0.97% calcium, 0.85% phosphorus, Harlan/Teklad) and the second group on a calcium-deficient chow (<0.01% calcium, 0.4% phosphorus diet, ICN) for 7 days. Body weight was similarly maintained in the two groups but spinal density (BMD by DEXA) decreased by 8.4% and compression strength of L5 by 36% in the calcium-deficient group. As expected, calcium-deficiency raised serum intact PTH levels by 3-fold (18.2±4.7 vs 53.7±7.7 pg/ml, P <0.003) and there was an inverse relationship between PTH and BMD (r = -0.85, P <0.01) and between PTH and compression strength (r = -0.78, P <0.05) reflecting the role of the increased PTH in loss of skeletal assets. In contrast to the decrease in osteoblast and osteocyte apoptosis and anabolic effects seen with intermittent PTH administration, longitudinal thin sections of L1-4 vertebra showed no change in the prevalence of osteoblast or osteocyte apoptosis. However, the group fed the calcium-deficient diet had decreased cancellous bone area and trabecular width as well as increased cancellous osteoclasts, mineralizing perimeter and bone formation rate without a significant increase in cancellous osteoblasts. Consistent with the increased number of osteoclasts, Northern blot analysis of tibial RNA revealed increased RANKL mRNA expression. Based on these results we propose that dietary calcium deficiency and the resultant continuous elevation of PTH cause bone loss by increasing osteoclast number and bone turnover, via RANKL, without altering osteoblast production or lifespan, thereby resulting in an inadequate number of osteoblasts to reconstitute the increased number of resorbed cavities.

Dynamics of Bone Resorption Changes in Pediatric Patients with Osteogenesis Imperfecta Treated with Cyclical Pamidronate. J. Marowska,* E. Jelonek,* M. Olszaniecka,* M. Kobylinska,* M. Lebiedowski,* R. Lorenc. The Children's Memorial Health Institute, Warsaw, Polandn

Osteogenesis imperfecta (OI) is an incurable heterogenous group of genetic disorders of collagen type I, characterized by osteopenia and recurrent fractures. Recently, administration of aminobisphosphonates to children with OI has been reported to improve bone mass and reduce fracture incidence with no significant adverse effects.The purpose of our study was to investigate rapid and long-term changes of bone resorption in children with OI treated for 12 months with pamidronate given according to two regimens, with special emphasis on the safety of treatment, considered as the absence of excessive and/or permanent inhibition of bone resorption.Seven patients with OI type I, III and IV, aged 7-16 yrs, with low L2-L4 BMD by DEXA (z score: -5.41±2.08) and high bone resorption as measured by urinary pyridinoline (ZS: 3.23±2.40) and deoxypyridinoline excretion (ZS: 2.53±2.88), entered the study. Pamidronate was administered iv in cycles of 3 consecutive days with 4 month intervals at a dose of 1 mg/kg/d (6 patients with OI type III and IV) or once a month (1 patient with OI type I) at a dose of 30 mg/m2 body surface. Urinary Pyr

and DPyr was measured by HPLC and L2-L4 BMD by DEXA (Lunar DPX-L) before and after 1 year of treatment.Three days of pamidronate infusion caused a profound, but transient, suppression of bone resorption, with maximal response observed around day 7 (% change from baseline: -56±9% and -70±6% for Pyr and DPyr, respectively; p<0.0001), corresponding with the decrease of Pyr ZS to -0.32±1.77 and DPyr ZS to -1.30±1.30, followed by the gradual gain (within 30 days) of new plateau, maintained till the end of the cycle at the level 20-30% lower as compared to baseline. The pattern of bone resorption changes was similar during all cycles. Pamidronate treatment in one-month cycle resulted in less profound maximal suppression of bone resorption (-36±11% for Pyr and -45±12% for DPyr), which was returning to baseline values within 30 days, up to the end of the 3rd cycle. Beginning from the 4th cycle, however, urinary excretion of crosslinks at day 30 of each cycle stabilized at the level 20-30% lower than baseline.One year pamidronate treatment resulted in relief of bone pain, improvement of mobility and decreased fracture incidence (from 2.3 to 1.3 per year), whereas L2-L4 BMD increase was observed only in a patient under 1 month cycle of bisphosphonate administration (ZS improvement from -5.21 to -3.50).It is suggested that pamidronate treatment of pediatric patients with OI does not result in excessive and prolonged suppression of bone resorption, which could be deleterious to bone health.

Use of Representational Difference Analysis to Identify Candidate RFLPs Linked to Modifiers of the Murine *Cola2$^{oim/oim}$* Osteogenesis Imperfecta Phenotype. A. N. Patani,*[1] A. Pincavage,*[2] J. Bankston,*[2] N. P. Camacho,[2] R. D. Blank.[1] [1]Endocrinology/Medicine, University of Wisconsin, Madison, WI, USA, [2]Research Division, Hospital for Special Surgery, New York, NY, USA.

The *Cola2$^{oim/oim}$* mouse harbors a nonsense mutation in the gene encoding the a2 chain of type I collagen and consequently produces type I collagen composed of α1 homotrimers rather than $(\alpha1)_2$(a2) heterotrimers. This mutation is maintained on an outbred B6C3 background, but we have noted that inbreeding results in attenuation of the bone fragility phenotype that is characteristic of *oim/oim* mice. Notably, there is considerable phenotypic heterogeneity among these animals. The outbred animals averaged 3.2 ± 1.6 long bone fractures each under normal cage activity while the partially inbred animals averaged 1.0 ± 1.1 long bone fractures. In an attempt to identify loci whose segregation modifies the *oim/oim* phenotype, we used pools of genomic DNA prepared from outbred and partially inbred *oim/oim* animals to perform representational difference analysis. This PCR-assisted subtraction method results in preferential amplification of restriction fragments present exclusively in one of the two DNA sources. We amplified representative populations of BamH1 restriction fragments from the outbred and inbred DNA pools by PCR to generate "amplicons." We iteratively subtracted outbred from inbred amplicons and amplified the difference products. Following 3 rounds of subtraction and amplification, difference products were cloned into a plasmid vector and analyzed. Unique, polymorphic clones obtained by this method are putative markers for genes that modify the *oim/oim* phenotype. Representational difference analysis provides a complementary approach to linkage mapping in localizing genes of interest.

Early Treatment Improves Prepubertal Growth in X-linked Hypophosphatemic Rickets. O. Makitie,* E. Sochett.* Division of Endocrinology, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada.

X-linked hypophosphatemic rickets (XLH) is a disorder of renal phosphate wasting characterized by hypophosphatemia, defective bone mineralisation, rickets and impaired growth. Treatment with oral phosphate (Pi) and calcitriol is usually started in infancy and results in improved blood biochemistry, resolution of the skeletal changes and improved height gain. However, even with optimal medical treatment, many patients do not achieve normal stature; one contributing factor may be the height loss occurring prior to diagnosis and onset of treatment. To assess whether the time of inititation of treatment impacts on pre-pubertal growth, we retrospectively examined the growth data in 17 well controlled patients with XLH followed regularly at our clinic. Individual growth curves were drawn using growth data obtained in clinic until puberty. Heights at 6-monthly intervals (until 9.5 yrs) were interpolated and transformed into SD scores (SDS). Height SDS for males and females were pooled and medians calculated for the two groups separately at each age. Treatment was started in 8 patients (3 girls) in the first year of life (median age 0.35 years, range 0.15 - 0.58 years, Group 1) and in 9 patients (8 girls) after one year of age (median 2.0 years, range 1.3 - 8.0 years, Group 2). All in Group 1 and 4 patients in Group 2 had a positive family history of XLH. At the start of treatment the median height SDS for Group 1 was -0.76 SDS (range -1.4 - +0.14 SDS) and for Group 2, -1.7 SDS (range -2.8 - -1.0 SDS) (P=0.0028). The median height SDS for Group 1 remained > -1.0 SDS (range for median -0.96 - -0.50 SDS) and for Group 2, <-1.3 SDS (range for median -1.9 - -1.3 SDS) throughout childhood. The height SDS at commencement of treatment correlated significantly with the height SDS later in childhood (at 9.5 years P<0.02 for each group). There was no significant difference in the rate of treatment-related complications i.e. secondary and tertiary hyperparathyroidism and nephrocalcinosis between the two groups. We conclude that patients commencing oral Pi/calcitriol treatment before a year of age experience improved pre-pubertal growth overall when compared with those starting after a year of age. Our data also suggest that height lost prior to treatment may not be completely recovered and may contribute to the poor stature outcome in some patients.

Retarded Gene Expression for Cartilage-related Proteins During Fracture Healing in Experimental Diabetes. A. Ogasawara,* M. Yamazaki,* F. Nakajima,* S. Shimizu,* A. Nakajima,* H. Moriya.* Chiba Univercity, Chiba, Japan.

INTRODUCTION: Diabetes mellitus (DM) is a condition which clinicallyÅ@impairs fracture repair. Little has been analyzed, however, how DM condition influences the gene expression in chondrogenesis during fracture healing. In this study, we produced the standardized fracture in experimental DM rats, and analyzed the spatial and temporal expression of genes encoding cartilage-related proteins by means of in situ hybridization and northern blot analysis.MATERIALS AND METHODS: Fracture model: A closed middiaphyseal fracture was created after intramedullary pinning of the right femur in both streptozotocin induced DM rats and control rats. Animals were euthanized at 4, 7, 14, 21 and 28 days postoperatively, and the fractured femora were fixed, decalcified and embedded in paraffin. Measurement of cartilage area: Sections were stained with toluidine blue, and the cartilage area showing metachromasia was calculated using a public domain NIH image program. In situ hybridization: Sections were hybridized with DIG-labeled cRNA probes for pro-a1(II) collagen (COL2A1), pro-a1(X) collagen (COL10A1) and osteopontin (OP). Northern blot analysis: Total RNAs were extracted from DM and control calluses, and the mRNA levels were determined using 32P-labeled probes for COL2A1 and COL10A1. RESULTS: In the soft calluses of DM rats, the cartilage tissues were apparently smaller than those of control rats. In both DM and control rats, COL2A1 signal was detected in proliferative chondrocytes from day 4, and COL10A1 signal in hypertrophic chondrocytes from day 7. By quantification, expression of COL10A1 reached the peak value on day 14 in both types of rats. But expression of COL2A1 in DM rats reached peak level later than in control rats. In DM rats the amounts of COL2A1 and COL10A1 were markedly decreased on days 21. OP signal was detected in terminally differentiated chondrocytes at the front of endochondral ossification. In DM rats, the number of OP mRNA expressing cells was decreased and the structure of primary spongiosae was immature.DISCUSSION: The results demonstrated that the diabetic state suppressed the gene expression for cartilage extracellular matrices and differentiation of chondrocytes in fracture calluses. Especially, the matrix synthetic activity was apparently decreased in later stages of fracture healing. The diabetic state also suppressed the replacement of hypertrophic chondrocytes by primary spongiosae. We suggest that, in DM condition, the retarded gene expression for the cartilage-related proteins in later stages of fracture healing plays some important role(s) on the impairment of fracture repair.

SA472

Risedronate But Not Alendronate Slows Disease Progression in the Guinea Pig Model of Primary Osteoarthritis. J. M. Meyer, R. W. Farmer,* M. C. Prenger.* Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Most animal models of osteoarthritis involve chemical or surgical initiation of the disease, although the majority of human OA is considered primary. The Duncan-Hartley guinea pig is a model of primary OA and mimics human disease in many aspects. Cartilage lesions begin at about 3 months of age or 750g weight. They are bilateral and begin primarily on the medial tibial plateau (MTP). Chondrocyte cloning, osteophytes and tidemark duplication can also be seen. Disease severity progresses as the animals age and gain weight. This may be a useful model for testing potential structure modifying OA drugs. Animals were randomized into the treatment groups shown in Table 1. The bisphosphonates risedronate (Actonelä) and alendronate (Fosamax™) or sterile isotonic saline (vehicle control) were administered via subcutaneous injection 5 consecutive days/week for 12 months. At sacrifice, the left tibia of the stifle joint was disarticulated and stained with Evan's blue dye. Joints were then placed in 10% neutral buffered formalin and digitally photographed. These images were analyzed using a BDS Image Analysis System (Oncor Image, Gaithersburg, MD). Lesion, MTP and osteophyte areas were manually outlined by a single blinded grader, and area calculated by the software program. A non-parametric Friedman's rank sum test was used to compare treatment groups to control. Median scores are reported.

Treatment & Dose (mg/kg)	Lesion area mm^2	% Lesion area	Osteophyte area mm^2	% Osteophyte area
Vehicle ---	8.3	35.2	12.1	42.8
Risedronate 0.004	8.6	36.1	9.5	41.1
Risedronate 0.012	8.4	28.4*	8.6	34.1*
Risedronate 0.03	6.2*	26.9*	7.2*	24.4*
Alendronate 0.005	11.0	43.2	12.4	47.1
Alendronate 0.012	9.6	36.8	11.7	40.1
Alendronate 0.03	12.2	41.1	11.7	41.5

*=p<0.05 vs vehicle, two sided testRisedronate but not alendronate had a statistically significant effect on cartilage lesion and osteophyte size in the guinea pig model of primary OA. This is consistent with previous data (unpublished) suggesting not all bisphosphonates are effective at slowing disease progression in this model. These data suggest risedronate may be efficacious as a structure modifying drug in OA.

SA473

Prognostic Value of Serum Bone Markers and Hand Bone Densitometry in Very Early Rheumatoid Arthritis : Preliminary Results of the VERA Study. A. Daragon,[1] O. Vittecoq,*[1] M. Brazier,[2] O. Mejjad,[1] P. Fardellone,[3] K. Krzanowska,*[1] P. Boumier,[4] C. Zarnitsky,[5] A. Phan Van,[6] A. Gayet,[7] J. F. Menard,[8] X. Le Loet.[1] [1]Rheumatology, CHU, Rouen, France, [2]Biochimie, CHU, Amiens, France, [3]Rheumatology, CHU, Amiens, France, [4]Collège des Rhumatologues, Amiens, France, [5]Rheumatology, CHG, Le Havre, France, [6]Collège des Rhumatologues, Tours, France, [7]Collège des Rhumatologues, Rouen, France, [8]Biostatistiques, CHU, Rouen, France.

The aim of the study was to determine the prognostic value of serum bone markers and hand bone densitometry in very early rheumatoid arthritis (RA).From a population-based recruitment, 66 patients with very early (median duration: 4.3 months [1-6 mo]) peripheral arthritis (swelling >=2 joints for > 4 weeks) were studied. Patients were steroid and DMARD naive. After a year, patients were classified as RA or non RA. Assessments were performed at entry (T1), after 9 (T2) and 12 (T3) months. Serum bone markers were C telopeptide (sCTX) by ELISA test, free pyridinoline (Pyr) and free deoxypyridinoline (Dpyr) by HPLC. Other investigation : hand bone densitometry (DEXA), hands and feet X Rays. Prognosis was defined as the progression of radiological damage from T1 to T3 (van der Heijde modified Sharp's method).At T3, 26 patients had radiological progressive disease, and 40 no progressive disease. 50/66 patients fulfilled ACR criteria for RA (75% in non progressive group, 77% in progressive group, NS). At T1, no difference was found between progressive group and non progressive group, excepted for rheumatoid factors more frequent in progressive group ($p < 0,03$). Bone mineral density (BMD) of both hands decreased significantly from T1 to T3 in the progressive group ($p < 0,03$), whereas it remains unchanged in the non progressive group. Furthermore, sCTX, Pyr and Dpyr levels at T1 were negatively correlated to the evolution of hand BMD from T1 to T3 ($p < 0,02$, and $p < 0,01$ respectively).In patients with early RA, a structural bone damage progression after 12 months duration is associated with a decrease of hand BMD. Moreover, this decrease was negatively correlated with levels of serum bone markers at entry. These preliminary results of the VERA study need to be confirmed on a larger population.

Osteoclast Inhibitory Lectin (OCIL), RANKL and OPG Expression at Sites of Inflammation and Joint Destruction in Rheumatoid and Collagen-Induced Arthritis. N. A. Sims, H. Zhou, T. J. Martin, M. T. Gillespie, K. W. Ng, E. Romas. St Vincent's Institute of Medical Research and Department of Medicine, University of Melbourne, Fitzroy, Victoria, Australia.

Rheumatoid arthritis (RA) has been shown recently to be associated with a high level of RANKL expression in synoviocytes, which are able to induce osteoclastogenesis in vitro. Ostoclast inhibitory lectin (OCIL) is a type II transmembrane C-type lectin also shown recently to inhibit osteoclast formation in vitro. In normal tissues, OCIL expression in normal tissue parallels that of RANKL and OPG, being highly expressed in osteoblasts and pre-hypertrophic chondrocytes.OCIL expression in rheumatoid arthritis was studied by in situ hybridisation and immunohistochemistry in human synovectomy samples and in the rat collagen-induced arthritis model (CIA). In human synovectomy samples OCIL was expressed in the synovial lining of normal, osteoarthritic (OA) and RA samples. This expression was similar to, but not identical with, RANKL and OPG which were abundant in a higher number of synovial cells. In RA samples, OCIL protein and mRNA were also expressed at high levels in TRAP positive osteoclasts at sites of erosion at the articular cartilage-bone interface. In serial sections, this expression co-localised with both RANKL and OPG mRNA expression. OCIL expression was also high in follicular lymphoid aggregates in RA samples and co-localised with RANKL and OPG in serial sections. In the CIA rat model, in which joint inflammation and destruction are induced by a single intradermal injection of type II collagen, OCIL, RANKL and OPG were also highly expressed in lymphoid aggregates at sites of inflammation. While OCIL was expressed in periosteal and trabecular osteoblasts, it was not expressed in trabecular osteoclasts in control rats or after arthritis was induced. In contrast, both immunohistochemistry and in situ hybridisation revealed high levels of OCIL in TRAP positive osteoclasts at sites of joint destruction in CIA. Osteoclastic OCIL expression co-localised with RANKL and OPG. The expression of mRNA and protein for OCIL and mRNA for RANKL and OPG all appeared to be greater in osteoclasts actively resorbing at sites of disease than in normal bone. Expression of OCIL in osteoclasts only at sites of rheumatoid joint destruction and in inflammatory tissue suggest that OCIL may be a novel target for therapeutic intervention in both the inflammation and joint destruction associated with rheumatoid arthritis.

Post-transcriptional Regulation of Calcitonin Receptor Gene Expression in Mouse Osteoclast-Like Cells. S. Yasuda,* S. Wada,* S. Kitahama,* S. Suda,* T. Nagai,* M. Iitaka,* S. Katayama.* Fourth Department of Internal Medicine, Saitama Medical School, Iruma-gun, Japan.

Using mouse osteoclast-like cells (OCs), we have shown that short exposure to calcitonin (CT) resulted in prolonged reduction of CT binding by inhibiting de novo CT receptor (CTR) synthesis. This mechanism of CTR regulation is specific for particular target cells. Experiments to explore the molecular basis of the CTR gene expression in mouse OCs suggested that GCs up-regulate CTR by increasing transcription of CTR gene. Studies on mRNA turnover in the presence of transcriptional inhibitors suggest that the action of CT to destabilize the CTR mRNA predominates over increased transcription by GC. The mRNA stability observed in mouse OCs required ongoing transcription, suggesting the involvement of a labile protein mRNA-degrading factor. In this study, we subcloned the 3' untranslated region (UTR) of mouse CTR gene using nested PCR technique from mouse DNA library. Nuclear extracts of mouse osteoclasts srrongly degraded in vitro transcript of the 3'UTR labelled with 32P UTP, whereas the extracts did not act on the transcript of GAPDH. The treatment with RNase inhibitor and trypsin could not diminish this mRNA degrading capacity. Interestingly, the nuclear extracts from mouse hypothalamus and osteoblastic cells (MC3T3E1) did not show any degrading capacity, which may suggest that this effect is specific for particular target cells. When nuclear extracts of MC3T3E1 cells were incubated with labelled transcripts of the CTR 3'UTR, the bands were shifted to the upper portion. This may suggest that a certain nuclear factor would bind to 3'UTR of the CTR gene. It has bee shown that the AUUUA motifs, as well as other A/U-rich sequences, determine the stability of other mRNA transcripts through binding with multiple proteins in this region As we have shown, multiple copies of the AUUUA motif have been identified in the 3' UTR of CTR gene in various species. We are currently investigating the factors involved in CTR regulations and roles of the 3'UTR in the CTR gene.

Regulation of Osteoclasts by Novel Orally Bioavailable Calcitonin Conjugates: Role of Cytosolic Calcium. S. V. Komarova,*[1] L. A. Paige,*[2] S. M. Sims,*[1] S. J. Dixon.[1] [1]Department of Physiology, University of Western Ontario, London, ON, Canada, [2]Nobex Corporation, Research Triangle Park, NC, USA.

The effects of salmon calcitonin and orally bioavailable conjugates of calcitonin were tested on isolated rat osteoclasts and HEK-293 cells transfected with the calcitonin receptor. Time-lapse video microscopy was used to record osteoclast morphology and motility, and retraction was quantified as changes of planar area. The concentration of cytosolic free Ca^{2+} ($[Ca^{2+}]_i$) was monitored by spectrofluorimetry in single fura-2-loaded osteoclasts or in suspensions of indo-1-loaded HEK-293 cells. Addition of calcitonin or conjugates (CT-001 or CT-002) at 1 nM caused immediate arrest of osteoclast membrane ruffling and subsequent retraction to ~50% of initial area. The effects on retraction were concentration-dependent, with calcitonin and the conjugates causing retraction at concentrations as low as 10 pM. As a control, the same amphiphilic polymer attached to an unrelated protein was tested and shown to have no effects on osteoclast morphology and motility. Since it has been suggested previously that osteoclast retraction in response to calcitonin is mediated by Ca^{2+} signaling, we investigated the effects of calcitonin and its conjugates on $[Ca^{2+}]_i$. In osteoclasts, calcitonin-induced elevations of $[Ca^{2+}]_i$ were variable and relatively small. Therefore, we studied Ca^{2+} signaling in HEK-293 cells transfected with the C1a isoform of the calcitonin receptor. In these cells, calcitonin and the conjugates caused concentration-dependent elevations of $[Ca^{2+}]_i$. However, the rise of $[Ca^{2+}]_i$ occurred at concentrations of agonists 100 to 1000 fold higher than those required to elicit retraction. Although the rise of Ca^{2+} and retraction were quantified in different cell types, the data suggested that retraction of osteoclasts may not be due solely to rise of $[Ca^{2+}]_i$. To further investigate a requirement for Ca^{2+} in retraction, we preloaded osteoclasts with BAPTA to buffer changes of $[Ca^{2+}]_i$. Surprisingly, calcitonin (1 nM) continued to elicit retraction of osteoclasts after BAPTA treatment, although at a slower rate than in controls. Prolonged stimulation with calcitonin (3 h) resulted in comparable retraction in control and BAPTA-treated cells. We conclude that orally available calcitonin conjugates cause retraction of osteoclasts in a manner similar to that elicited by salmon calcitonin. This response is indicative of functional calcitonin receptor signaling that leads to inhibition of bone resorption. Moreover, the extent of osteoclast retraction induced by calcitonin is independent of $[Ca^{2+}]_i$, although $[Ca^{2+}]_i$ does modulate the rate of retraction.

SA479

Effects of Age and Amylin Treatment on Long Bones in Growing and Mature Mice. V. L. Ferguson, L. K. Hermann,* E. E. Smith,* T. A. Bateman, S. J. Simske. BioServe Space Technologies; University of Colorado, Boulder, CO, USA.

This study examines the effects of amylin on cortical bone properties in growing mice. Male C57BL/6J mice, aged 5- (n=30), 11- (n=36) and 40-weeks (n=45) were equally divided into three groups: baseline controls were killed at the start of the study, and vehicle (saline) and amylin (0.42 mg/kg rat amylin) treatment groups were killed on day 28. Injections were administered s.c. daily. Immediately following sacrifice, mice were weighed and the liver, thymus and spleen were removed from the treatment groups. Right femora

were measured for length and composition in all groups. Left femora were analyzed via quantitative histomorphometry at the mid-diaphysis in the 11- and 40-week old groups. Amylin treatment resulted in increased body mass (5.5%, 5.2%, and 1.3% (N.S.) for 5-, 11- and 40-week old mice, respectively), increased liver mass in the two youngest groups (10.8%, 10.4% and -0.6% (N.S.)) and decreased thymus mass (10%, 14.7% and 18.3%) in all groups from control levels. Spleen mass increased with age but was unaffected by treatment. Femur length, mass and percent mineralization were also unaffected by treatment with amylin, but increased with age. Femur cross-sectional morphology showed significant alterations with age and amylin treatment. The periosteal surface of the femur-mid-diaphysis significantly decreased in perimeter (1.3% and 3.2% in 11- and 40-week old groups) and total cross-sectional area (2.1%, 6.2%) in amylin treated animals. Cortical area tended to decrease in young animals (1.1%) and significantly decreased in old animals (7.1%) in amylin treated mice. The medullary cavity was significantly smaller in animals treated with amylin, resulting in decreased endocortical perimeter (1.7%, 2.3%) and cross-sectional area (2.9%, 5.5%), reflecting a statistically significant increase in endosteal formation compared to controls. Decreased cross-sectional area at the femur mid-diaphysis reduced the cross-sectional moment of inertia in the 11-week old (5.2%, N.S. and 2.9% for Ix and Iy, respectively) and 40-week old mice (13.8% and 16.2%), and resulted in moments that were lower than those in baseline mice. This was coupled with decreased periosteal perimeter and total cross-sectional area in both ages. Amylin did not appear to stimulate normal bone formation, and affected more mature bone at least as much as younger bone.

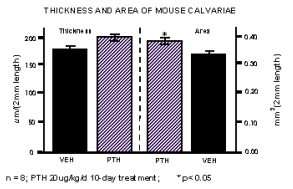
Calcitonin Induces the Transcription of Early Response Genes. M. Nakamura,[1] N. Segawa,*[2] Q. Yang,*[1] Y. Nakamura,*[1] H. Yamasaki,*[3] I. Mori,*[1] K. Kakudo.*[1] [1]Department of Pathology, Wakayama Medical University, Wakayama, Japan, [2]Department of Urology, Osaka Medical College, Osaka, Japan, [3]Department of Biology, Wakayama Medical University, Wakayama, Japan.

Calcitonin (CT), a polypeptide hormone, regulates urinary calcium excretion. The purpose of this study is to identify potential downstream gene regulatory mechanisms induced by CT and analyze their associations with the MAPK pathway. By cDNA subtraction hybridization method, we identified three immediately early (IE) genes: connective tissue growth factor (CTGF), IL-3 promoter transcriptional activator (NF-IL3A), and urokinase-type plasminogen activator (uPA). The effects of CT on the expression of IE mRNA were confirmed by Northern blot analysis. CT increased CTGF mRNA levels in a time-dependent manner, reaching a maximum after 1 hr (5.7 fold), NF-IL3A mRNA levels reaching a maximum after 1 hr (3.2 fold), and uPA mRNA levels after 5 hrs (17.5 fold). In order to exclude the possibility that CT regulates these genes expression through *de novo* protein synthesis of cytokines or transcription factors, the cells were treated for 3 hrs with CT and cycloheximide, a protein synthesis inhibitor. Addition of both CT and cycloheximide increased mRNA levels of the three genes, as compared to CT or cycloheximide alone. These data suggest that the stimulation of expression of these genes by CT is not induced by increased synthesis of regulating proteins. We also found that treatment of LLC-PK1with CT led to the phosphorylation of ERK1/2. Therefore, we examined whether the regulation of CT on the expressions of these IE genes involve ERK1/2 pathway. We demonstrated that PD98059, a MEK inhibitor, inhibited mRNA expressions of CTGF and uPA induced by CT, but had no obvious influence on the NF-IL3A expression. Our present findings suggest that the transcriptions of the CTGF, NF-IL3A and uPA are induced by CT pathway and might be important mediators of CT function in renal cells. Furthermore, we also elucidated the regulation of CTGF and uPA by CT involve RAS-ERK pathway.

SA481

Local Anabolic Effects of Parathyroid Hormone in a Mouse Calvarial Model. W. Zhao, R. J. Murrills, M. Tarby,* V. Dell,* Y. Kharode,* F. J. Bex. Bone Metabolism and Osteoporosis Research, Wyeth-Ayerst Research, Radnor, PA, USA.

PTH is well known to have anabolic effects when administered systemically but its local effects are less well documented. Female Swiss-Webster mice were injected daily directly onto the calvarium with hPTH(1-34) and bone was quantified by histomorphometry following H+E staining. Osteoblast apoptosis was visualized by TUNEL staining and CBFA expression by immunohistochemistry. An initial experiment explored various doses of PTH, using a 5-day course of injections followed by a 21-day no-treatment "chase" period. BMP-2 at 20ug/kg, a positive control, produced a clear increase in calvarial thickness. With PTH, an increase in calvarial thickness was noted at 10 and 20ug/kg, but at 40ug/kg and 80ug/kg there was no increase and at 80ug/kg there was histological evidence of increased resorption. At 20ug/kg, fewer apoptotic osteocytes and periosteal osteoblasts or stromal cells were noted whereas at 80ug/kg, an increased number of apoptotic osteoblasts were observed. CBFA expression was increased by BMP-2 in the periosteum and sagittal suture, but the effect of PTH on CBFA expression was less convincing. In a time-course study using a 5-day or 10-day course of daily injections of 20ug/kg PTH (with no "chase" period), increased periosteal cellularity was noted at 5 days and an increase in calvarial area was evident at 10 days.



The effect was most prominent on the hemicalvarium that had the injection site, indicating a local effect of the peptide. We conclude from this that PTH can, at certain doses, have a local anabolic effect when injected directly onto mouse calvaria. The effect appears to be related to an increase in osteoblast number, at least partly a consequence of a decrease in osteoblast apoptosis.</p

In Vitro Inhibition of Bone Resorption by Human PTH(7-84). P. Divieti, M. R. John, H. Juppner, F. R. Bringhurst. Endocrine Unit, Mass General Hospital, Harvard Medical School, Boston, MA, USA.

Intact PTH from different mammalian species comprises 84 amino acids and shows high sequence conservation within both its amino (N)-terminal and carboxyl (C)-terminal regions. The N-terminal 34 amino acids are sufficient for classical actions of intact PTH in the regulation of mineral ion homeostasis and bone metabolism, which are known to be mediated through activation of the type 1 PTH/PTHrP receptor (PTH1R). C-terminal PTH (CPTH) fragments, analogous to those known to be released into blood during peripheral proteolysis of intact PTH or via direct parathyroid secretion, exert biologic effects in osteoblastic and chondrocytic cells and bind specifically to a putative CPTH receptor in such cells. Recently large CPTH fragments, minimally truncated at their N-termini and cross-reactive with most commercially available intact PTH immunoassays, were detected in normal plasma and, at higher levels, in plasma of patients with advanced renal failure. These fragments exhibit chromatographic properties similar to synthetic PTH(7-84). Moreover, hPTH(7-84) recently was shown to inhibit the calcemic actions of PTH(1-84) and PTH(1-34) in parathyroidectomized rats.To determine if hPTH(7-84) might antagonize the calcemic response to PTH(1-84) in vivo via direct effects on bone, we tested hPTH(7-84) for inhibition of in vitro assays of osteoclast formation (murine marrow cultures) and bone resorption (release of 45Ca from intact murine calvarial bone). Addition of hPTH(7-84) alone (300nM) reduced basal 45Ca release by approximately 50% (control: 17.8±5.7%; hPTH(7-84): 9.6± 1.9% ; p,< 0.001), an effect comparable to that of salmon calcitonin. HPTH(7-84) also inhibited agonist-induced bone resorption caused by a variety of agents, including intact PTH(1-84), PTH(1-34), 1,25(OH)2D3 (1,25D), prostaglandin E2 and interleukin-11. In murine marrow cultures, 1,25D (10 nM) stimulated the formation of TRAP positive cells by 13.9 fold; in the presence of 300nM PTH(7-84), this response was reduced by 65%. It is unlikely that this inhibitory effect of PTH(7-84) was due to an antagonistic effect at the PTH1R, as neither hPTH(3-34) nor [L11,DW12]PTHrP(7-36), both potent PTH1R antagonists in these systems, inhibited bone resorption induced by PTH(1-34) or 1,25D-induced osteoclast formation. We conclude that hPTH(7-84), acting via receptors (probably CPTH receptors) independent of the PTH1R, can exert a generalized antiresorptive effect that may involve both inhibition of osteoclast recruitment and reduction in formation or activation of mature osteoclasts.

Effect of Intermittent Low Dose Treatment of Human Parathyroid Hormone (1-34) on Fracture Healing in Rats. A. Nakajima,[1] M. Yamazaki,*[1] N. Shimoji,*[2] K. Shiomi,*[2] S. Shimizu,*[1] K. Goto,[1] H. Moriya.*[1] [1]Orthopaedic Surgery, Chiba University School of Medicine, Chiba, Japan, [2]Institute for Medical Research & Development, SUNTORY Limited, Gunma, Japan.

Recent reports have shown that intermittent PTH (1-34) treatment increases callus formation and mechanical strength in healing experimental fractures. In this study, we tested whether an intermittent low dose treatment of hPTH (1-34) could increase callus formation and mechanical strength, then analyzed the molecular mechanisms of the effect by PTH (1-34). Closed mid-diaphysial fractures were created in the femora of 7-week-old male SD rats. The rats were divided into two groups: rats injected daily with 10 µg of PTH (1-34)/kg subcutaneously (PTH group), and rats injected daily with vehicle subcutaneously (vehicle group). Samples harvested at 4, 6 and 8 weeks after fracture were used for DXA and mechanical testing, and those from 2, 4, 7, 14 and 21 days after fracture were analyzed for molecular assays. It was found that at any point both BMD and ultimate load were significantly increased in the PTH group as comparison to the vehicle group ($p<0.01$). In the PTH group, the hard calluses consisted of well-developed trabeculae with less bone marrow, and the number of osteoclasts were significantly increased compared to the vehicle group. In the earlier stages, the number of PCNA-positive cells was increased in the osteoprogenitor cells of the periosteum in PTH group. Northern blot analysis demonstrated that mRNA expression levels of relatively immature osteoblast-lineage markers such as type-I collagen, ALP and osteonectin, were elevated even in the later stages of fracture healing in the PTH group. Up-regulation of IGF-I mRNA was only found in the early stage in the PTH group. The expression profiles of type-II and -X collagen, which are chondrogenic differentiation markers, showed similar results for the PTH group and vehicle group. These findings suggest that PTH stimulates the proliferation of osteoprogenitor cells, contributing to the formation of hard calluses, and that PTH modulates not only callus formation but also callus resorption, presumably accelerating callus remodeling. We speculate these molecular mechanisms lead to the increase of BMD and ultimate load of fracture calluses. In conclusion, intermittent treatment of low dose hPTH (1-34) increased callus formation and mechanical strength by simultaneously modulating osteoblast and osteoclast function.

SA486

Parathyroid Hormone Induces Cyclooxygenase-2 in Osteoblasts via a Composite NFAT/AP-1 Binding Site. D. Chikazu,[1] O. S. Voznesensky,[1] B. E. Kream,[1] X. Li,[1] H. R. Herschman,[2] C. C. Pilbeam.[1] [1]Medicine, University of Connecticut Health Center, Farmington, CT, USA, [2]Biological Chemistry, UCLA School of Medicine, Los Angeles, CA, USA.

The nuclear factor of activated T-cells (NFAT) family of transcription factors plays a central role in the regulation of cytokine gene transcription in immune cells but has not yet been implicated as a mediator of gene transcription in osteoblasts. Cyclooxygenase-2 (COX-2) is an inducible gene that is expressed not only in immune cells but also in osteoblasts. PTH, a potent transcriptional inducer of COX-2 in osteoblasts, was previously shown to act via the -150/-40 bp 5'-flanking region of the murine COX-2 gene. Sequence analysis identified three NFAT core consensus sequences (5'-GGAAA-3') at -111/-107 bp, -90/-86 bp and -77/-73 bp in the COX-2 promoter. The -77/-73 bp sequence (NFAT77) is adjacent to the AP-1 site (5'-AGAGTCA-3') at -69/-63 bp. NFAT and AP-1 (Fos/Jun) proteins interact cooperatively in other systems to mediate transcription, and the -77 to -63 bp sequence, GGAaagacagagTCA, is consistent with the minimum consensus sequence, GGA(N)9TCA, reported for NFAT/AP-1 composite sites. To determine whether the NFAT/AP-1 site at -77/-63 bp mediates PTH induction of COX-2 in osteoblasts, murine osteoblastic MC3T3-E1 cells were stably transfected with -371/+70 bp of the COX-2 5'-flanking region fused to a luciferase reporter (Pluc) or with Pluc carrying 2 bp mutations of NFAT77 (5'-ttAAA-3'), the AP-1 site (5'-AGAGTtg-3'), or both. Mutation of the AP-1 binding site, the NFAT77 site, or both NFAT77 and AP-1 decreased PTH stimulated-luciferase activity by 41%, 58%, or 92%, respectively. On electrophoretic mobility shift analysis, PTH stimulated binding to a radioactively labeled oligonucleotide spanning -85 to -57 bp of the COX-2 5'-flanking region. Binding was supershifted or inhibited by both an antibody for NFAT (specifically NFATc1) and antibodies for c-Fos / c-Jun but not by a non-specific IgG antibody. In summary, we have demonstrated that a composite NFAT/AP-1 binding site in the murine COX-2 promoter mediates PTH induction of COX-2 promoter activity in osteoblastic cells. This site is likely to be involved in prostaglandin responses to other physiological and pathological stimuli in bone.

A New High-Affinity Parathyroid Hormone 1 Receptor Antagonist, Mouse Tuberoinfundibular Peptide (7-39). S. R. J. Hoare, T. B. Usdin.* Laboratory of Genetics, NIMH, National Institutes of Health, Bethesda, MD, USA.

The parathyroid hormone 1 (PTH1) receptor mediates the pathophysiological effects of PTH-related protein (PTHrP) in hypercalcemia of malignancy and PTH in hyperparathyroidism. A PTH1 receptor antagonist might prove useful for treating these conditions. Remarkably, one of the highest-affinity PTH1 receptor antagonists identified is an analogue of the PTH2 receptor's endogenous ligand, human/bovine tuberoinfundibular peptide of 39 residues (h/bTIP39): h/bTIP(7-39) binds with an affinity of 6.2 nM to the human PTH1 receptor. We have now prepared mouse (m) TIP(7-39), and tested it's effectiveness as an antagonist of the rat PTH1 receptor, since rodents will likely be used to test the in vivo effects of the ligand. (Cloning and sequencing of mTIP39 cDNA revealed four differences of amino-acid sequence between mTIP39 and h/bTIP39 (h/b residue in parentheses) – Arg24 (His), Asp27 (Asn), Gln31 (His) and Leu35 (Val)). mTIP(7-39) antagonized PTHrP(1-34)-stimulated cAMP accumulation via the rat PTH1 receptor with higher potency (Kb = 44nM) than h/bTIP(7-39) (210nM), PTHrP(7-34) (640nM) and bPTH(7-34) (>3000nM). mTIP(7-39) was 21-fold more potent as an antagonist of the rat PTH1 receptor than the rat PTH2 receptor. The effect of rat plasma on the bioactivity of mTIP(7-39) was tested by pre-incubation of [125I]mTIP(7-39) with plasma (50% v/v) at 37C followed by measuring binding of the radioligand to the human PTH1 receptor. Plasma pre-treatment reduced [125I]mTIP(7-39) binding with a t1/2 of 1.8 hours, an effect blocked by protease inhibitors. In radioligand binding assays mTIP(7-39) bound the human PTH1 receptor with high affinity (2.9nM), comparable with h/bTIP(7-39) (6.2nM) and greater than [D-Tryp12]bPTH(7-34) (45nM) and PTHrP(7-34) (65nM). mTIP(7-39) dissociated from the human PTH1 receptor (t1/2 of 6.3 min) much more slowly than [D-Tryp12]bPTH(7-34) (13 sec) and PTHrP(7-34) (9 sec). [125I]mTIP(7-39) also detectably bound the human PTH2 receptor, providing the first radiolabeled antagonist for this receptor. In summary, mTIP(7-39) displays higher potency for the rat PTH1 receptor than previously described antagonists, is PTH1 receptor-selective, reasonably stable in plasma, and binds with a relatively high-affinity and slow off-rate. This ligand should be useful to test the effectiveness of PTH1 receptor antagonism in rodent models of hypercalcemia.

SA489

PTH-Mediated Receptor Desensitization: Kinetics and Properties Are Influenced by Peptide Size. S. A. Morris, Q. Sun,* E. Dworakowski,* J. P. Bilezikian. College of Physicians & Surgeons, Columbia University, New York, NY, USA.

PTH receptors stimulate both adenylyl cyclase (ACA) and phospholipase C (PLC) in SaOS2 cells. In both these and other PTH responsive cells, prolonged exposure to the agonist results in loss of the ability to demonstrate PTH dependent activation of ACA, a process known as receptor desensitization. Since ACA is preferentially associated with PTH containing native residues through 29-34, we tested the hypothesis that progressive loss of amino acids at the C-terminal end of these fragments would alter patterns of receptor desensitization. PTH dependent ACA was determined in homogenates of SaOS 2 cells previously incubated with several different PTH peptides for varying time periods, and ACA in response to PTH[1-34] determined. When preincubated with PTH[1-34] at 5x10-8 M, virtually maximal (75%) receptor desensitization was observed at 2 minutes with no additional increase even after 24 hours of further preincubation. In contrast, preincubation with PTH[1-29] at 5x10-8 for 2 min was associated with only 25% receptor desensitization, with a progressive increase in magnitude reaching a maximal level of 75% only after 16 hours, ultimately identical to that achieved with PTH[1-34]. Consistent with previous reports, we determined that PTH[1-29] at any concentration demonstrates no PLC activity in contrast to PTH[1-34] which harbors clear actions on this messenger system. Accordingly, Calphostin C, a PkC inhibitor, produced an approximately 40% reduction in the magnitude of receptor desensitization observed following preincubation with PTH[1-34] for 2 min whereas this compound had no effect on the magnitude of desensitization observed with PTH[1-29] under otherwise identical conditions. H-89, a PkA inhibitor, had no influence on the magnitude of receptor desensitization following 2 min incubation with either PTH peptide. We conclude that C-terminal amino acids of PTH(1-34) participate in enhancing the kinetics of receptor desensitization, possibly through a PLC linked pathway.

Bpa at Position 28 of PTHrP(1-36) Crosslinks to the Amino-terminal Extracellular Domain of the PTH/PTHrP Receptor and Thereby Assists in Predicting a Tertiary Structure for this Receptor Region. R. C. Gensure, T. J. Gardella, H. Jüppner. Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Leucine at position 28, in the carboxy-terminal portion of PTH(1-34) (Ile in PTHrP), is critical for high affinity binding to the PTH/PTHrP receptor. We therefore prepared an analog of PTHrP(1-36) with p-benzoyl-L-phenylalanine (Bpa) substituted at position 28 (Bpa28-PTHrP(1-36)) to identify the receptor contact site of this ligand residue. When tested with LLC-PK1 cells stably transfected with human P1R (hP1R), the apparent binding affinity (IC50 8.1+/-2.4 nM) and agonist-stimulated cAMP accumulation (EC50 7.8+/-0.1 nM, Emax 152+/-8 pmol/well) for this analog were similar to those of the parent compound, indicating that substitution of this ligand residue with a larger but similarly hydrophobic amino acid derivative was well tolerated. Bpa28-PTHrP(1-36) showed weak but specific crosslinking to the hP1R. Digestive mapping with CNBr and LysC defined the crosslink interval as being located between residues 64-95 of the hP1R's amino-terminal extracellular domain. This crosslink interval lies within the region encoded by exon E2, which has been shown to be non-essential for ligand interaction. Crosslinking of this critical ligand residue to a non-essential receptor domain was not expected, and implies that proximity to this receptor region is not related to the role of residue 28 in ligand binding. Another possible role for the hydrophobic group at position 28 may be to facilitate ligand association with the cell membrane, as postulated in the two-dimensional diffusion model of ligand-receptor interaction. However, the apparent proximity between PTHrP(1-36) residue 28 and the E2-encoded P1R region does provide an important structural constraint on the receptor amino-terminal extracellular domain. The combination of these new data and previously reported mapping of P1R crosslinking sites for ligand residues 13, 23, 27 and 33, together with the recently proposed pattern of disulfide bridging in this receptor region, provides a high degree of constraint on models of the structure of the P1R's amino-terminal extracellular domain when bound to PTHrP(1-36). These constraints are easily accommodated by a putative configuration in which the amino-terminal extracellular domain assumes a spiral shape that wraps around the ligand's carboxyl-terminal helix.

Correlation of Growth and Maturation in Roosters with Magnitude of Nongenomic Responses to 1,25(OH)2D3. B. Larsson,[1] I. Nemere.[2] [1]Nutrition and Food Sciences, Utah State University, Logan, UT, USA, [2]Nutrition and Food Sciences and The Biotechnology Center, Utah State University, Logan, UT, USA.

$1,25(OH)_2D_3$ is known to regulate calcium metabolism through a genomic mechanism mediated by nuclear receptors (nVDR). The hormone is also capable of activating the transport pathway by interacting with a membrane receptor (pmVDR). It is our hypothesis that the non-nuclear receptor is important in maintaining calcium homeostasis. In this study we investigate the correlation of growth and maturation in roosters with magnitude of non-genomic responses of $1,25(OH)_2D_3$. White leghorn roosters were raised for 7, 14, 28 and 58 wk (mean body weights; 0.56±0.02, 0.96±0.03, 1.28±0.03 and 2.53±0.05 kg respectively), prior to experiment. These age-ranges cover growth of young animals, adulthood and roosters with declining reproductive functions. Measurements of hormone responsiveness as a function of age were performed by *in vitro* perfusion studies, where the transport of ^{45}Ca from the intestinal lumen to the vasculature, in response to exogenous $1,25(OH)_2D_3$ (130 pM), was measured. ^{45}Ca in venous effluent (expressed as treated/average basal) after 40 min exposure to vehicle was 0.96±0.1, while exposure to $1,25(OH)_2D_3$ in 7, 14, 28 and 58 wk roosters resulted in values of 2.43±0.15, 1.83±0.37, 1,89±0.36 and

1.54±0.18 respectively. This decrease in intestinal Ca^{2+} transport with age indicates an involvement of the non-genomic response and the pmVDR. Further, Western analyses on isolated basal lateral membranes (BLM) showed a decreased expression of the pmVDR with increasing age, supporting the results obtained in the perfusion studies. [^{3}H]1,25$(OH)_2D_3$ binding to BLMs gave K_d values of 0.59, 1.03, 0.99 and 2.65 nM and B_{max} values of 188.9±18.2, 250±13.3, 185.9±10.8 and 640±160.1 fmol/mg protein for 7, 14, 28 and 58 wk old roosters respectively. The obtained results show a significant increase in K_d indicating a decreased affinity of the receptor for hormone with age. Increasing B_{max} values with age may be due to nonspecific binding as a result of decreased pmVDR affinity. Binding characteristics for [^{3}H]1,25$(OH)_2D_3$ to nVDR gave K_d values of 0.35, 0.38, 0.29 and 0.30 nM and B_{max} of 31.1±3.93, 36.35±5.17, 31.0±5.08 and 22.7±2.61 fmol/mg protein for 7,14, 28 and 58 wk roosters respectively. No significant changes in affinity were seen for nVDR, indicating that this pathway is not involved in the age-related changes in hormone responsiveness. In conclusion, our experiments demonstrate that there is a decrease in responsiveness to exogenous 1,25$(OH)_2D_3$ in rooster intestines as a function of age. This decrease can be explained both by a decreased affinity for 1,25$(OH)_2D_3$, and a reduced expression of pmVDR with age.

A Novel Chromatin Remodeling Complex Function as a Transcriptional Modulator of Vitamin D Receptor (VDR). H. Kitagawa,[1] J. Yanagisawa,*[1] S. Ogawa,*[1] T. Matsumoto,[2] S. Kato.[1] [1]Institute of Molecular and Cellular Biosciences, University of Tokyo/ CREST, Tokyo, Japan, [2]The First Department of Medicine, Tokushima University, Tokushima, Japan.

Many complexes interact with nuclear receptors for their ligand-dependent transactivation through modulating chromatin structure in the promoters of a set of target genes. Distinct classes of co-regulator complexes like DRIP/TRAP complex are shown to interact with nuclear receptors in a ligand-dependent way. For such transcriptional controls, complexes to modulate chromatin structure are also considered essential. As one class of such complexes, several ATP dependent chromatin remodeling complexes have been identified, but still other unknown chromatin remodeling complexes are supposed to exist. We provide an evidence here to support possible existence of a novel complex by biochemical purification of complexes associated with VDR. Using GST fused VDR ligand binding domain (LBD) as a bait, we purified nuclear complexes associated with liganded VDR-LBD from HeLa nuclear extracts and identified complex components by mass fingerprinting method and Western blotting with specific antibodies to detect known componets in the chromatin remodeling complexes and co-activator complexes. The components of DRIP/TRAP complex were included, confirming importance of this complex for VDR transactivation. We found that some of the components of the novel complex harbor several conserved motifs which are mapped in essential components of a known ATP dependent chromatin remodeling complex. We further showed that one component of this complex interacts with VDR in ligand independent way by co-immunoprecipitation and can activate ligand-dependent transactivation of VDR by transient transfection assay. From these results, we suppose that this complex is a novel ATP dependent chromatin remodeling complex which associates with VDR and have some important role in the target gene regulation of VDR. Now we are trying to identify all components of the complex and explain how they function in the VDR transactivation by an in vitro chromatin assay.

Calcitriol Increases VDR and CaR Expression in Peripheral Blood Mononuclear Cells (PBMC) and Decreases Monocytes Apoptosis. J. M. Quesada-Gomez,[1] F. Luque Recio,[1] G. Dorado.*[2] [1]UMM, Hospital Reina Sofia, Cordoba, Spain, [2]Departamento de Biología Molecular, Universidad Córdoba, Córdoba, Spain.

In postmenopausal osteoporotic women in spite of normal serum calcitriol levels has been reported a decrease in intestinal calcium absorption. Intestinal calcitriol receptors (VDR) are difficult to study on clinical settings, but VDR have been found in PBMC. PBMC seem to represent well other target tissues of vitamin D, and are also potential targets for the immunomodulatory actions of calcitriol.Vitamin D insufficiency has been reported in elderly subject with osteoporotic hip fracture, with a decrease in the intestinal calcium absorption. This vitamin D insufficiency through a modification of VDR could influence the intestinal calcium absorption and immune response.Purpose of the study: In elderly patients with hip fracture and a vitamin D insufficient status to evaluate baseline VDR&CaR expression in PBMC and the effect of calcitriol on VDR/CaR regulation and on monocyte apoptosis. We study 22 elderly subjects with hip fractures and controls, pre and after calcitriol treatment (IV administration during a week of 2 mg calcitriol each other day. Serum calcium, phosphorus and alkaline phosphatases were determined by standard autoanalyser. PTH was measured using the allegro inmunoradiometric assay (Nichols Institute. San Juan Capistrano. CA. USA)25OHD3 and Calcitriol was determined by RIA (modified Reinhart method) PBMC were separated by centrifugation on a Ficoll-Hypaque discontinous gradient (1.076).Apoptosis were assessed by flow cytometry (FACscan, Beckton Dickinson). Apoptotic cells are characterized by hypodiploid DNA peak. mRNA was isolated (Trizol Reagent,Life-Technologies) and the amount of VDRand CaR mRNA were studied by quantitative RT-PCR. The quantitation of the different amplicons were accomplished by laser induced fluorescence (ABI 373 A Strech Sequencer from P-E Biosystems).The study confirms vitamin D insufficiency in elderly subjects with hip fractures.In PBMC calcitriol treatment increase VDR/actine from 1.43 to 1.61($p<0.01$)and CaR mRNA from 0.18 to 0.25 ($p<0.05$), but decreases apoptosis in monocytes from 3 to 0.1%($p<0.001$)Vitamin D insufficiency, a determinant factor in the elderly hip fracture, also could contributes to decreased VDR expression and CaR. Calcitriol treatment increases VDR and CaR expression in PBMC and decreases monocytes apoptosis. These results support the role of vitamin D endocrine system as a regulator of the immune response and are relevant to explain the immune dysfunction in elderly subjects with hip fracture.

Vitamin D3 Dimer: A Potential VDR-Inhibitory Molecule. A. Gacio-Fernandez,*[1] N. Swamy,*[2] R. Ray.[2] [1]Universidad de Santiago de Compostela, Santiago de Compostela, Spain, [2]Medicine, Boston University School of Medicine, Boston, MA, USA.

Vitamin D receptor (VDR) binds to its cognate ligand, 1,25-Dihydroxyvitamin D3 [1,25(OH)2 D3] with high fidelity, followed by the heterodimerization of holo-VDR with RXR to bring about the transcription regulation of vitamin D dependent genes. According to this mechanism VDR-1,25(OH)2 D3-RXR is a functional unit; and any disruption in the interaction among its components would result in impairment of gene-regulation by 1,25(OH)2 D3. We hypothesized that a dimer of 1,25(OH)2 D3, in which two 1,25(OH)2 D3 molecules are coupled via a long tether, might bind with low affinity to two VDRs, and this might impair the binding of RXR by steric interaction between VDR and RXR. Such a process would bring about inhibition of VDR-mediated transcriptional regulation. Such a molecule may hold promise for treating diseases like idiopathic hypercalcuria where VDR is expressed at an elevated level in intestine and kidney, thus resulting in hypercalemia and spontaneous formation of kidney stones at normal 1,25(OH)2 D3 levels. In the present study we synthesized such a dimer (of 1,25(OH)2 D3), and carried out VDR-binding studies. These results will be discussed.

Estratriene-3-ol, an Activator of Non-genomic Estrogen-Like Signaling (ANGELS), Does Not Stimulate Bone Growth in Ovariectomized rats. J. F. Whitfield,*[1] P. Morley,*[2] G. Willick,*[2] J. Barbier,*[2] S. MacLean,*[3] V. Ross.*[2] [1]Institute for Biological Sciences, National Research Council of Canada, Ottawa, ON, Canada, [2]National Research Council of Canada, Ottawa, ON, Canada, [3]National Research Council of Canada, Ottawa, ON, Canada.

Osteoblasts can respond to estrogens through both nuclear 'genomic' and 'non-genomic' surface receptors. When activated, these surface receptors, like PTH, cause an influx of Ca^{2+} and a flurry of kinase activities by stimulating adenylyl cyclase and phospholipase-C. Because of the similarity between their signaling and the osteogenic PTHs, estrogens that have a preference for non-genomic rather than genomic receptors (ANGELS) could be anabolic agents rather than just antiresorptives and thus be ideal candidates for treating osteoporosis. Indeed Manolagas [(1)] and Manolagas et al [(2)] have reported that one of these estrogens, EOL (estratriene-3-ol), is as potent a stimulator of bone growth in intact and OVXed (ovariectomized) mice as PTH-(1-34). We have compared the abilities of EOL and Ostabolin-C™ ([Leu^{27}]cycloGlu^{22}-Lys^{26} hPTH-(1-31)NH_2) to stimulate bone growth in 3-months-old OVX Sprague-Dawley rats. We injected sc. 0.1 mg of EOL (in sesame oil)/g of body weight every other day and/or 0.8nmole of Ostabolin-C/100 g of body weight once every day starting at the end of the 2nd week and ending at the end of the 6th week (8th week after OVX). This dose of EOL was high enough to reduce the OVX-induced weight gain to the weight gain in sham-operated control rats and to drop the Ostabolin-C™-stimulated serum TRAP (tartrate-resistant acid phosphatase) activity to a value below the level in the untreated sham controls. OVX dropped the BV/TV in the distal femurs to 37.1% of the sham value by 8 weeks ($p<0.01$). EOL injections did not significantly stop the BV/TV drop, but Ostabolin-C™ kept the BV/TV value at the sham value. Neither OVX nor treating the OVX rats with EOL affected the mean trabecular thickness while Ostabolin-C™ increased it from the sham value of 72.3 ± 2.2 mm to 121.7 ± 7.1µm ($p<0.01$). Thus, while EOL can stimulate bone growth in OVX mice as effectively as PTH[1], it cannot stimulate bone growth when given in a dose that otherwise fully replaces estrogen functions in OVX rats. 1. Effects of Estrogen Receptor α/β Heterodimers and Steroid Receptor Coactivator Overexpression on Transcription in Osteoblasts. D. G. Monroe,[1] D. J. Rickard,[1] M. Subramaniam,[1] B. L. Riggs,[2] S. Khosla,[2] T. C. Spelsberg.[1] [1]Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, [2]Endocrinology, Mayo Clinic, Rochester, MN, USA.

Estrogen (E) is a major sex steroid that affects the growth, maintenance and homeostasis of the skeleton. Two isoforms of estrogen receptor (ERα and ERβ) have been discovered which mediate the transcriptional effects of E. Although studies in our laboratory and others have demonstrated that endogenous ERα and ERβ are present and functional in some human osteoblast (OB) cell lines, there are few reports on the differential regulation of gene transcription by ERα and ERβ acting either as homodimers or as heterodimers. Recent gene deletion experiments in mice suggest that the ERα and ERβ isoforms may have antagonistic actions on bone. Antagonism by ERα and ERβ could be caused by differential action of ERα/β heterodimers acting through different DNA elements in gene promoters or by the differential recruitment of steroid receptor coactivators (SRCs). We have investigated the effects of ER homodimers (ERα/α and ERβ/β) in cells transfected with ERα or ERβ alone, ER heterodimers (ERα/β) in cells transfected with both receptors, and the effects of SRC overexpression on E-dependent transcription in OBs. Using FLAG-tagged ERα and ERβ expression constructs that express functional and quantifiable receptors when transiently transfected into OBs, our data demonstrate that following E treatment of the cells, ERα/β displays an antagonistic effect on transcription of a cotransfected synthetic ERE-reporter construct in both normal human OBs and MG63 osteosarcomas, compared to either ER isoform alone. Interestingly, the data also demonstrate that coexpression of SRC1 in OBs preferentially potentiates ERβ/β signaling, whereas the coexpression of SRC2 preferentially potentiates ERα/α signaling. Coexpression of SRC3 has no differential effect on ERα/α and ERβ/β. These experiments suggest that in OBs, individual SRC family members differentially enhance transactivation by the two ER isoforms. Studies are currently underway to elucidate the 1) molecular mechanisms of ERα/β antagonism at the level of ER binding to elements in endogenous gene promoters, 2) the relative proportion of ERα/β heterodimers versus homodimers at different ratios of transfected ERα and ERβ, and 3) the preferential association of SRCs with a particular ER dimer in human OB cells. We conclude that ERβ, acting through heterodimer formation with ERα, decreases the transcriptional responsiveness of OBs to E and that SRCs may play a role in mediating the ER isoform-specific transcriptional activities.

Transcriptional Profiling of Estrogen Induced Osteogenic Differentiation of Mouse Marrow Mesenchyml Stem Cells (MSCs) In Vitro. S. Zhou,[1] S. McLarney,*[2] B. Komm,*[2] P. Bodine,*[2] D. Gazit.[1] [1]Molecular Pathology, Hebrew University-Hadassah Medical and Gene Therapy Center, Jerusalem, Israel, [2]Women's Health Research Institute, Wyeth-Ayerst Research, Radnor, PA, USA.

We have previously reported that in vitro treatment of MSCs from ovariectomized ICR mice with 100 nM 17b-estradiol (17b-E2) for 8 days promoted osteoblastic differentiation. Under these conditions, mRNA expression of the osteoblastic markers Cbfa1, alkaline phosphatase (ALP), type I collagen, transforming growth factor (TGF)-b1, bone morphogenetic protein (BMP-2) and estrogen receptor (ER)-a are increased with 17b-E2 treatment, while the expression of ER-b message is suppressed. We hypothesized that transcriptional profiling of differentiating MSCs induced by 17b-E2, may lead to the discovery of novel genes, which may be pivotal in the anabolic effect of estrogen in osteogenic tissues. We performed robotic high-throughput differential display polymerase chain reaction (RADE) and gene chip analysis with RNA samples isolated from MSCs that were treated with 17b-E2 as described above. From 3 separate experiments, we identified the following estrogen regulated genes (up = up regulated, down = down regulated). From RADE we identified a6-intergrin (up), integral membrane protein CII-3 (up), proteosome regulator PA28 (up) and 4 novel cDNAs (ESTs). From gene chip analysis, we identified ALP (up), the calcium-binding proteins MRP-8 and - 14 (both down), transglutaminase (TG) (up) and the adipocyte marker adipsin (down). All of these results were subsequently confirmed by RT-PCR analysis of new RNA samples. Although the function of most of these genes in osteoblast differentiation is as yet unknown, the up-regulation of ALP and down-regulation of adipsin is consistent with 17b-E2 promoting osteogenesis while suppressing adipogenesis. The novel ESTs are currently being characterized in order to obtain full-length cDNAs, human analogues, and for functional analysis. These ESTs may play an important role in the anabolic effects of estrogens on the murine skeleton. Thus, this approach has the potential to greatly expand our understanding of the molecular mechanisms by which estrogens regulate skeletal homeostasis, and to identify novel gene targets for estrogen action in bone.

Disclosures: Wyeth-Ayerst Research,3.

DHEA Stimulates Osteoblast Differentiation in Human Marrow Cultures. J. Simon,[1] A. Mascarenas,[1] M. S. LeBoff,[2] J. Glowacki.[1] [1]Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA, [2]Endocrinology, Brigham and Women's Hospital, Boston, MA, USA.

Dehydroepiandrosterone (DHEA) is an adrenal steroid that circulates in high concentrations in humans. Previously, we and others showed DHEA to have anti-osteolytic actions. DHEA has been reported to stimulate osteoblast proliferation and activity in vitro, but little is known about its effects on osteoblast differentiation. Bone marrow stromal cells include a subset of cells capable of osteoblastic differentiation, a process known to be stimulated by 1,25-dihydroxyvitamin D (1,25D). This study tests the hypothesis that DHEA promotes the differentiation of osteoblasts from human marrow precursors/progenitors, in the presence and absence of 1,25D. Human marrow from elderly subjects (62-79 y) and a line of human marrow stromal cells (KM101) were used in a 96-well assay for development of alkaline phosphatase (AlkP)-positive cells. Fresh marrow was obtained from subjects undergoing total hip replacement for non-inflammatory osteoarthritis. Low-density mononuclear cells were precultured for collection of adherent cells. Both the marrow-derived cells and the KM101 cells were cultured in phenol red-free α Minimum Essential Medium with 10% charcoal/dextran-stripped fetal bovine serum, 5 mM b-glycerophosphate, 0.05 mM L-ascorbic phosphate, 100 U/ml penicillin, 100 µg/ml streptomycin, and 292 mg/ml L-glutamine. AlkP activity was measured colorimetrically after 6 d for human bone marrow and after 4 d for KM101 cells. Constitutive AlkP activity in human marrow stroma was low. DHEA significantly increased AlkP activity in a dose-dependent manner for all samples to 242% at 10 nM ($p<0.0001$). Comparison of the effects of 10 nM DHEA, 17-estradiol (E2), or dihydrotestosterone (DHT) showed greatest stimulation by DHEA. In KM101 cells, DHEA increased AlkP activity in a dose-dependent manner to 311% at 10 nM ($p<0.0001$). Further, DHEA stimulated AlkP to the greatest extent at 350%, with DHT at 273% and E2 at 147%. 1,25D stimulated AlkP in marrow and in KM101 cells in a dose-dependent manner. Combinations of DHEA and 1,25D showed greater AlkP than either alone, but combinations of 1,25 with DHT or E2 were not greater than with 1,25D alone. In sum, DHEA is more potent than DHT or E2 in promoting osteoblast differentiation in human marrow stromocytes and is unique in enhancing 1,25D's stimulation. Thus, DHEA or its metabolites may be useful for treating bone diseases because of its anabolic and anti-osteolytic actions. Supported by a grant from the Dept. of Defense (US Army - Bone Health and Military Readiness)

Synthesis of 1,25-dihydroxyvitamin D_3 by Human Endothelial Cells Is Regulated by Inflammatory Cytokines: A Novel Autocrine Determinant of Vascular Cell Adhesion. D. Zehnder,* R. Bland,* D. C. Wheeler,* P. M. Stewart,* M. Hewison. Division of Medical Sciences, The University of Birmingham, Birmingham, United Kingdom.

Recent studies have shown that increased circulating concentrations of active vitamin D, 1,25-dihydroxyvitamin D_3 ($1,25D_3$), reduce the risk of coronary calcification of atherosclerotic vessels. Furthermore, low $1,25D_3$ serum levels in patients with renal failure appear to increase vascular calcification. The precise mechanism for this remains unclear, although data have highlighted a possible role for $1,25D_3$ as a modulator of cell adhesion and angiogenesis. Previous studies have demonstrated the presence of vitamin D receptors and the enzyme 1α-hydroxylase (1-HYD) in bovine endothelial cells. Here we have used immunohistochemical, and in situ hybridization analyses to show for the first time the expression of 1-HYD mRNA and protein in human endothelial cells from kidney, spleen and lymph nodes. RT-PCR and Western analyses using primary cultures of human umbilical vein endothelial cells (HUVEC) confirmed expression of mRNA and protein corresponding to the reported renal 1-HYD. Enzyme activity assays in HUVEC using $3H\text{-}25D_3$ as substrate showed basal conversion of 318 ± 56 (±SD) fmoles $1,25D_3$/hr/mg protein which increased 3-4-fold following 24 hr treatment with TNFalpha (1054 ±166) or lipopolysaccharide (1381 ±88). Forskolin (554 ±56) increased only slightly the production of $1,25D_3$, and incubation with $1,25D_3$ itself (475 ±111) did not suppress 1-HYD activity, as is classically observed with the renal enzyme. Functional analyses showed that exogenously added $1,25D_3$ or precursor $25D_3$ significantly increased monocyte adhesion to HUVEC in a similar fashion to inflammatory agents such as TNFα; parallel ELISA studies revealed that this was not due to increased expression of ICAM-1 or VCAM-1. These data suggest that vitamin D metabolism and function in human endothelia is similar to that described previously for macrophages, with inflammatory cytokines showing greater up-regulation of endothelial 1-HYD activity than classical calcitropic regulators. We therefore propose that endothelial cell 1-HYD acts as a novel autocrine/paracrine immunomodulatory mechanism. In particular, the synthesis of $1,25D_3$ by blood vessels during inflammation may play an important role in leukocyte adhesion. Further analysis of this process may help to elucidate a mechanism for the impact of vitamin D on cardiovascular disease.

Rapid Effects of 25-Hydroxyvitamin D on Calcium Uptake by Isolated Chick Enterocytes. R. Phadnis,*[1] I. Nemere.[2] [1]Nutrition and Food Sciences, Utah State University, Logan, UT, USA, [2]Nutrition and Food Sciences, and the Biotechnology Center, Utah State University, Logan, UT, USA.

25-Hydroxyvtiamin D_3 [25(OH)D_3]is a metabolite of vitamin D_3 that has long been considered to be an inactive precursor; consequently very few studies have addressed its biological activity. However it is known that 100 nM 25(OH)D_3 increases calcium transport in the perfused duodenal loop of the chicken to 200% of controls within 20 minutes. It is our hypothesis that 25(OH)D_3 may be a hormonally active metabolite and its effects can be studied in isolated chick enterocytes.In the current work, we investigated the time course of ^{45}Ca uptake in isolated intestinal cells (from 7 week chicks) as influenced by a range of 25(OH)D_3 concentrations. After establishing the basal uptake of ^{45}Ca for 5 minutes, cells were treated with vehicle (ethanol) or 25 nM, 50 nM, 100 nM or 300 nM 25(OH)D_3 and samples were taken at T=1,3,5,7 and 10 min. In the first series of studies, 100 nM 25(OH)D_3 decreased enterocyte ^{45}Ca to 54% of controls within 1 min (P<0.001), and 70% of controls at T=3, 5, and 7 min (P<0.01 to <0.05, relative to controls). These results suggested that 25(OH)D_3 might stimulate the extrusion of ^{45}Ca from the cell. Comparing the 7-min time point, 25(OH)D_3 appeared to yield a biphasic dose-response curve with values of ^{45}Ca observed to be 99 % (*NS*, not significant), 75% (P<0.05), 70% (P<0.01), and 80% (*NS*) of controls for 25 nM, 50 nM, 100 nM, and 300 nM metabolite, respectively. In an additional series of experiments, we found that physiological levels of 24,25-dihydroxyvitamin D_3 [24,25(OH)$_2$$D_3$, 6.5 nM]inhibited the actions of 100 nM 25(OH)D_3 in isolated chick enterocytes. Similar time course studies with isolated enterocytes from 14 week and 28 week chickens treated with 100 nM 25(OH)D_3 showed decreased responsiveness. Comparisons at T=1 min revealed ^{45}Ca levels in 7 week, 14 week and 28 week to be 54% (P<0.001), 83% (*NS*) and 80% (*NS*) of controls, respectively. We then investigated the effect of pharmacological agonists for selected signal transduction pathways. Experiments with the calcium channel activator, BAYK 8644 (2 υM), and protein kinase (PK) A activator, forskolin (20 υM), revealed enhanced levels of ^{45}Ca to 132% and 140% of controls, respectively (each, P<0.05 at T = 10). These pathways are therefore not likely to be the major ones activated by 25(OH)D_3. In conclusion, our experiments demonstrate that 25(OH)D_3 is biologically active in isolated chick enterocytes with relation to calcium uptake and that 24,25(OH)$_2$$D_3$ inhibits the action of this metabolite. There is a decrease in the response to exogenous 25(OH)D_3 as a function of age and the metabolite does not act primarily through activation of calcium channels or the PK A pathway.

Effect of 1,25-Dihydroxyvitamin D on Intestinal Cell Phosphate Uptake. B. Zhao,*[1] I. Nemere.[2] [1]Nutrition and Food Sciences, Utah State University, Logan, UT, USA, [2]Nutrition and Food Sciences and the Biotechnology Center, Utah State University, Logan, UT, USA.

1,25-dihydroxyvitamin D_3 [1,25(OH) $_2$$D_3$] promotes phosphate transport in the perfused duodenal loop (Treated/Av Basal at T = 40min,1.82 ± 0.42, relative to controls, 1.11 ± 0.21). It is our hypothesis that direct effects of 1,25(OH) $_2$$D_3$ can be observed in isolated intestinal cells by either increases in uptake or extrusion. In this study we used isolated enterocytes to investigate (1) A range of 1,25(OH)$_2$$D_3$ concentrations to identify an optimal time and dose for 1,25(OH)$_2$$D_3$ mediated changes in ^{32}P uptake; (2) The effect of a combination of 1,25(OH)$_2$$D_3$ at optimal concentration and 24,25(OH)$_2$$D_3$ to determine whether the latter seco-steroid exerts an inhibitory effect on phosphate uptake; (3) Activators of protein kinase A, protein kinase C, and calcium channels for their effects on phosphate uptake in cells to obtain insights regarding signal transduction pathways; (4) The effect of age as a function of responsiveness to 1,25(OH)$_2$$D_3$. In time course studies, with 4-8 wk chicks, 130 pM 1,25(OH)$_2$$D_3$ increased ^{32}P uptake in enterocytes to 157% of controls after 10 min, while 300 pM 1,25(OH)$_2$$D_3$ produced an increase of 122% of controls (each R<0.05). 24,25(OH)$_2$$D_3$ exerted an inhibitory effect on phosphate uptake by 130 pM 1,25(OH) $_2$$D_3$. For signal transduction studies, isolated enterocytes were incubated with 20 µM forskolin, 100 nM phorbol ester or 2 µM BAY K 8644. Enhanced ^{32}P levels relative to controls were found for phorbol ester (150% of controls at T = 7 min, P<0.05) and BAY K 8644 (127% of controls at T = 7 min, P<0.05) but not for forskolin. Both BAY K8644 and phorbol ester, but not forskolin, also stimulated transport in perfused duodenal loops. These results suggest that PKC and calcium channel signal transduction pathways may be involved in uptake (at the brush border). For aging studies, white leghorn roosters were raised for 7, 14, and 28 weeks prior to experiment. These ages cover growth (a period of rapid bone formation) and adulthood when demand for bone mineralization decreases. These studies showed a 1,25(OH)$_2$$D_3$ mediated increase in ^{32}P uptake in isolated cells at 7wk, but not at 14 or 28 wk. In conclusion, our experiments demonstrate that 1,25(OH)$_2$$D_3$ increases phosphate uptake in isolated intestinal cells; 24,25(OH)$_2$$D_3$ exerts an inhibitory effect on phosphate uptake by 1,25(OH) $_2$$D_3$. PKC and calcium channel signal transduction pathway maybe involved in uptake (at the brush border). And that there is a decrease in 1,25(OH)$_2$$D_3$ mediated ^{32}P uptake in isolated intestinal cells with age.

Delineation of Vitamin D Deficiency Based on Pth and Muscle Function Tests: What Is the Lower Limit for 25(oh)d? H. Glerup,[1] E. Eriksen.[2] [1]Dept V, Aarhus University Hospital, Aarhus, Denmark, [2]Dept C, Aarhus University Hospital, Aarhus, Denmark.

The diagnosis of vitamin D deficiency is primarily based on the assessment of serum (S) 25(OH)D. Which cutoff to use is, however, still subject to debate. In order to approach this problem further, we tested muscle function and measured S-PTH, S-25(OH)D, and S-1,25(OH)2D in 102 subjects with varying degrees of vitamin D deficiency. The first subjects with secondary hyperparathyroidism were detected at S-25(OH)D=25 nmol/l. Some patients, however, displayed normal PTH levels (< 7.6 pmol/l) even at 25(OH)D levels down to 5 nmol/l. At S-25(OH)D < 5 nmol/l all subjects exhibited secondary hyperparathyroidism. Muscle testing consisted of a standardized assessment of maximal voluntary contraction (MVC, newton) and muscle contractility after electrical stimulation (twitch, newton). The first abnormal values for MVC and twitch (defined as values below the 95% confidence limits for normals) were already detectable at S-25(OH)D=60 nmol/l, and 50% of subjects displayed abnormal MVC- and twitch-values at S-25(OH)D < 50 nmol/l. A few patients, however, exhibited normal muscle function even at S-25(OH)D< 5nmol/l. At S-25(OH)D < 40 nmol/l twitch correlated significantly to S-25(OH)D (r=0.43, p 40 nmol/l was r = -0.01. MVC at S-25(OH)D < 40 nmol/l the correlated to S-25(OH)D (r = 0.23, p 40 nmol/l. S-1,25(OH)2D did not correlate to neither MVC nor twitch. In conclusion, S-PTH is a rather insensitive marker of vitamin D deficiency. The first cases of elevated PTH levels were not detectable until S-25(OH)D was below 25 nmol/l, while muscle function suffers significantly at S-25(OH)D < 40 nmol/l. Based on these results we therefore suggest that individuals exhibiting S-25(OH)D < 40 nmol/l should be considered vitamin D deficient.

Seasonal Variations of 250H Vitamin D in Young Adults and Elder Outpatients From an Overpopulated City. L. Plantalech,*[1] J. Fassi,*[1] M. F. Russo Picasso,*[1] M. Glerean,*[1] L. Camera.*[2] [1]Division of Endocrinology, Hospital Italiano, Buenos Aires, Argentina, [2]Department of Internal Medicine, Hospital Italiano, Buenos Aires, Argentina.

The aim of this study wasto assess the level of 250h vitamin D (250HD) and to determine winter (W) and summer (S) prevalence of hypovitaminosis in young (Y) and elder (E) oupatients from the city of Buenos Aires. We studied 49 E (37 women) and 44 Y (26 women) during W (June to September) and 34 E (25 women) and 32 Y (30 women) in S (December to April) were analyzed. Ages x 71.8 ± 6.5 and 29,8 ± 6,5 years old respectively, without any medication that might affect bone metabolism. Serum levels resulted in 250HD, middle molecular PTH (vn 20-100 pg/ml), Calcemia, Alkaline Phosphatase (APH) (vn:< 190Ul/l), tartrate-ressistant Acid Phosphatase (TRAP) (vn:1.8 -4.4 Ul/l). Patients were subdivided according to 250HD by McKenna criterium (Osteop. Int.:1998:Supl:8:3). The results are defined as x ± sd and analized with Student´s t test.(Table 1). Calcemia was normal in both groups (E in W and S 9,65 ± 0,4 mg/dl and 9,5 ± 0,53 mg/dl respectively ; Y in W and S 9,5 ± 0,7 mg/dl and 9,6 ± 0,5 mg/dl respectively)

	E W	E S	p	Y W	Y S	p
25OH D ng/ml	17,30 ±7,5	28,6 ±10,1	<0,001	17,1± 8,1	32,5± 12,8	<0,001
PTH pg/ml	75,2± 43,2*	63,6± 34,8 **	ns	37,6± 17,9 *	28,9± 18,7 **	ns
APH UI/l	134,7 ±34,3*	101,3± 131***	<0,001	96,2± 21,1 *	84,0± 27,1***	0,05
TRAP UI/l	3,90± 0,72*	2,7 ± 0,84	<0,001	3,20± 0,9 *	2,50± 0,6	<0,001

* p E-Y in W < 0,001 ; ** p E-Y in S < 0,001 ; *** p E-Y in S =0,007 Thirty one E analyzed in W and 20.5% analyzed in S showed secondary hyperparathyroidism.

25OHD	E in W	E in S	Y in W	Y in S
Desirable.>40ng/ml	2%	20,5%	2,3%	28,1%
Hypovitaminosis D :40-20ng/ml	36,7%	64,8%	27,3%	56,2%

Vitamin D Insufficiency 20-10 ng/ml	51%	14,7%	54,5%	15,6%
Vitamin D deficiency:<10ng/ml	14,2%	0%	15,9%	0%

A high prevalence of hypovitamin D during summer and insufficiency during winter are found in both groups. During W an increase of bone turnover was observed, higher in elders without important changes of PTH. Elders showed higher levels of PTH than young adults, therefore, secondary parathyroidism was found. Big cities lifestyle would determine this observation.

VitaminD Regulates Phex Expression During Embryonic Development: Study in VitaminD Receptor Null Mice. M. Shinohara,[1] H. Tanaka,[1] S. Kato,[2] Y. Seino.[1] [1]Department of Pediatric Medicine, Okayama University, Okayama, Japan, [2]Institute of Molecular and Cellular Biosciences, Tokyo University, Tokyo, Japan.

Phex a new gene whose mutation causes X-linked hypophosphatemic vitamin D resistant rickets (XLH). The mechanism how Phex mutation causes hypophosphatemia is still unclarified. Moreover Phex gene expression shows clear age dependence. Namely, Phex expression is high in calvaria from embryo when ossification is very active and become low with aging., which may be related to the age dependent change in serum phosphorus concentration. However, the mechanism of this developmental regulation of phex has not been clarified. It was reported that 1,25-$(OH)_2D_3$ down-regulates Phex expression of mouse osteoblast in vitro. The aim of this study is to clarify the role of vitamin D in the regulation of phex gene expression in vivo. To this aid, we examined phex mRNA expression in vitamin D receptor knockout mice (VDRKO) at different age. The mice were bred by mating hetero type males and females in our animal facilities. The genotypes of the fetus were identified by performing multiplex PCR for exon 2 of VDR gene and neomycin resistant gene in DNA extracted from fetal liver. The calvaria, lung, liver and brain were taken from VDRKO and its brethren wild-type mice(WT) at embryonic 18.5 days , newborn(0 day), 2weeks, and 4 weeks after birth. Total RNA for RT-PCR was extracted from each tissue by AGPC method. Using the reverse transcribed product, quantitative PCR was done on Phex. and GAPDH as an internal control by SYBR Green technology in Light Cycler whose lower detection limit is 10 copies. Phex expression in calvaria was highest in embryo and decreased rapidly after birth in both mice. In 18.5 day emdryonic calvaria, phex expression in VDRKO mice were about three times to five times higher than that in WT mice. And the similar results were obtained at 0 day. But at 2 weeks after birth, there was no significant difference between VDRKO and WT. Moreover, at 4 weeks after birth, Phex expression itself is hardly detectable in both mice. On the other hand, the expression of phex gene in lung showed contradictory pattern. Phex expression in WT lung was three fold higher than that in VDRKO lung. These results indicate that vitamin D receptor is involved in the regulating system of Phex gene in embryonic development. And the regulatory mechanism may be bone specific. Vitamin D is an important regulator of Phex gene during embryonic development.

Dietary P Regulation of Renal 25-Hydroxyvitamin D3 1 Alpha-Hydroxylase (1-OHase) Protein and mRNA Expression in Young and Adult Rats. M. Wong,*[1] M. Favus,[2] W. Lai,*[1] T. Chau.*[1] [1]Department of Applied Biology And Chemical Technology, The Hong Kong Polytechnic University, Hong Kong, Hong Kong Special Administrative Region of China, [2]Department of Medicine, The University of Chicago, Chicago, IL, USA.

The increase in renal 1,25(OH)2D3 production in response to dietary phosphorus restriction (LPD) was lost in 12 weeks old adult rats. The present study is undertaken to investigate if the loss of LPD stimulation of renal 1,25(OH)2D3 production is due to a decrease in renal 1-OHase protein and mRNA expression with age. Young (150-175g, 6 weeks old) and adult (325-350g, 12 weeks old) male Sprague Dawley rats were fed either normal (0.6% Ca, 0.6% P) or low P (0.6% Ca, 0.1%P). The expression level of renal 1-OHase protein in renal proximal tubules isolated from young and adult rats were characterized by immunoblotting using sheep anti-human 1-OHase antibody. The mRNA expression level of renal 1-OHase and glyceraldehydes-3 P dehydrogenase (GAPDH) were studied using reverse-transcriptase polymerase chain reaction (RT-PCR). 1-OHase protein and mRNA expression level increased upon LPD feeding in young rats ($p< 0.05$ and $p< 0.01$, respectively). Adult rats had higher basal 1-OHase protein expression than young rats ($p< 0.0001$) but did not increase 1-OHase protein expression in response to LPD. Renal 1-OHase mRNA expression in adult rats was lower than that of the younger rats and its upregulation by LPD was lost in adult rats. The results indicated that the inability to increase renal 1-OHase mRNA and protein expression in adult rats might be partly responsible for their blunted response of renal 1,25(OH)2D3 production during LPD.

Serum 25-OH Vitamin D3 in Chronic Rheumatic Patients. O. Di Munno,*[1] A. Delle Sedie,*[1] M. Mazzantini,*[1] S. Frigelli,*[1] M. R. Metelli.*[2] [1]Internal Medicine, University of Pisa, Pisa, Italy, [2]Experimental Pathology and Biotechnology, University of Pisa, Pisa, Italy.

Serum 25-OH vitamin D3 (25-OH D3) levels play a fundamental role in bone mineralization. Vitamin D3 deficiency is a underestimated problem. Low levels of 25-OH D3 (i.e. < 12 ng/mL) have been documented in both general population and internistic hospitalized patients. A recent Italian study on 799 postmenopausal women, who had been referred to 43 Centers for Osteoporosis (February-March) for their first densitometric test, showed that 74% had 25-OH D3 < 12 ng/mL. Aim of our study is the assessment of 25-OH D3 in patients with chronic rheumatic diseases, referred for hospitalization to the Rheumatologic Unit of the University of Pisa. Exclusion criteria were vitamin D supplementation in the previous 6 months and concomitant diseases or drugs that could interfere with bone metabolism, with the exception of glucocorticoids. We measured 25-OH D3 serum levels (25-Hydroxyvitamin D 125I RIA Kit, DiaSorin), 1,25-(OH)2 D3 (Gamma-B 1,25-Dihydroxy Vitamin D RIA Kit, Immunodiagnostic Systems), PTH (Intact PTH IRMA Kit, Nichols Institute Diagnostics), Osteocalcin (ELSA-OST-NAT, CIS Bio International), bone Alkaline Phosphatase (Ostase, IRMA, Beckman Coulter), N-telopeptide of type I collagen (NTx) (Osteomark NTx serum enzyme-linked immunoassay, EIA, Ostex). So far we have examined (November-May) 100 patients (78 females, 22 males), aged 58.8 years (range 22-82), affected with rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, osteoarthritis, systemic lupus erithematosus, polimyositis, Sjögren syndrome, polimialgia rheumatica and vasculitis. Mean 25-OH D3 values were 14.9±10 ng/mL (range 0.3-69.1); 44 patients (44%) had 25-OH D3 < 12 ng/mL and 13 of them had PTH above the upper normal limit; 18 patients (18%) had values < 6 ng/mL,. Significant correlations were found between 25-OH D3 and PTH ($r=-0.27$, $p<0.01$), age and PTH ($r=0.45$, $p<0.0001$), NTx and PTH ($r=0.39$, $p<0.005$), and age and NTx ($r=0.41$, $p<0.002$). Our preliminary data show that in chronic rheumatic patients serum levels of 25-OH D3 are frequently low. Many factors may play a role in such patients, including age, low sun exposure and low-fat diet. Present data show also that serum levels of 25-OH D3 are an important parameter to be evaluated in the study of bone turnover, particularly in the case of densitometric evidence of reduced bone mass.

SA526

Post-Maturational Decline in Intestinal Calcium Transport in C57BL/6 Mice. H. J. Armbrecht, M. A. Boltz,* T. L. Hodam.* Geriatric Center, St. Louis VA Medical Center, St. Louis, MO, USA.

Studies have suggested that mice undergo bone loss with age. Intestinal absorption of dietary Ca is an important factor in maintaining bone mass in humans. Therefore, the purpose of this study was to determine whether there were age-related changes in Ca transport by the small intestine of the mouse. Intestinal Ca transport was measured in C57BL/6 female mice aged 2, 6, 12, and 24 months old. Mice were fed regular rodent chow. Transport was measured in the duodenum, since this is the site of active Ca absorption. Duodenal segments (5 cm) were everted, filled with buffered saline, and tied off into sacs. The sacs were incubated in vitro for one hour in buffered saline containing 0.25 mM Ca with radiolabeled Ca on the outside of the sac (mucosal side) only. The amount of radioactivity that moved into the sac (serosal side) during the one hour incubation was taken as a measure of Ca transport. There was no change in Ca transport between 2 and 6 months of age. However, Ca transport declined in an almost linear fashion between 6 and 24 months of age. It declined 24% between 6 and 12 months of age and 19% between 12 and 24 months for an overall decline of 43%. In parallel experiments, the mRNA levels of calbindin D-9k, the vitamin D-dependent Ca binding protein, were measured by ribonuclease protection assay. Duodenal mRNA levels did not change over this age range. Using pooled plasma samples, intact plasma PTH showed an overall increase with age, and plasma 1,25(OH)2D levels did not change with age. These studies demonstrate that Ca absorption declines markedly from midlife onward in the mouse. This is unlike the rat, where the decline in Ca absorption is mostly maturational. The decline in the mouse is not explainable by a decline in calbindin mRNA levels or by a decline in serum 1,25(OH)2D. This suggests that it may be vitamin D-independent. The age-related rise in plasma PTH in the mouse may be in response to the decline in Ca absorption. This rise may contribute to the loss of bone reported in the mouse.

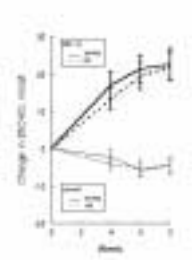
Plasma 25-Hydroxyvitamin D Responses of Young and Old Men to Supplementation with 800 IU/day of Vitamin D. S. S. Harris,* B. Dawson-Hughes.* Jean Mayer USDA Human Nutrition Research Center, Tufts University, Boston, MA, USA.

We recently reported that, compared with young men, older men had smaller plasma 25-hydroxyvitamin D (25OHD) responses to supplementation with 1800 IU/d of vitamin D for 3 weeks. The present study was conducted to determine whether this age difference would occur in men given a smaller vitamin D dose (800 IU/d) and followed for a longer time (8 weeks). Twenty-six young (18-35) and 26 old (62-79) white men were randomized to 800 IU/d [20 µg] cholecalciferol or to no intervention. Subjects lived in the greater Boston area, had no medical conditions known to affect vitamin D absorption or metabolism,

and had usual vitamin D intakes ≤200 IU/d. Two control subjects were excluded because of southern travel during the study. Study visits were conducted in February through April to minimize effects of sun exposure on 25OHD. Plasma 25OHD was measured by competitive protein binding assay. Baseline 25OHD did not differ by age in the supplemented men (60±16[SD]nmol/L in young, 62±16 in old, P=0.797) or in the control group (50±17 nmol/L in young, 54±18 in old, P=0.514). Changes in 25OHD during the study are shown in the Figure:

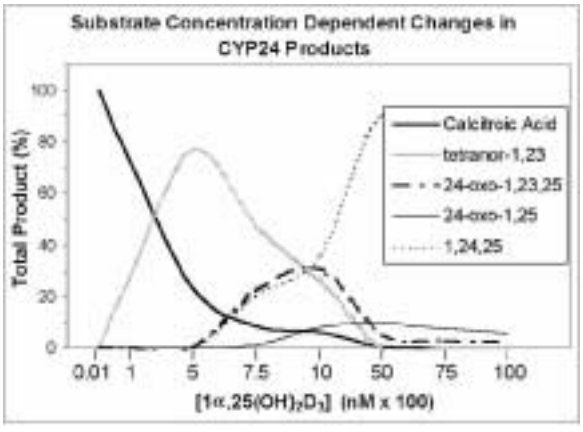


By the end of the study, the 25OHD concentrations of the young and old supplemented men had risen significantly (P<0.001) and nearly identically (22±15 nmol/L in young and 22±13 in old, P=0.948). In contrast, there were modest and similar decreases in 25OHD of the young and old controls. We conclude that young and old men have similar increases in plasma 25OHD during eight weeks of daily oral supplementation with 800 IU of cholecalciferol

SA529

LC-MS Based Enzyme Kinetic Analysis of CYP24 Confirms That 1α,25(OH)$_2$D$_3$ Is a Physiologically Relevant Substrate. M. Kaufmann,* S. Masuda,* G. Jones. Biochemistry, Queen's University, Kingston, ON, Canada.

1α,25(OH)$_2$D$_3$ is metabolized in vitamin D target cells by a 5-step, inducible, 24-oxidation pathway catalyzed by CYP24 culminating in the excretory form, calcitroic acid. Recent reports [Taniguchi *et al.*, JBMR 16: 57. 2001] have challenged this hypothesis claiming that the apparent K_m for 1α,25(OH)$_2$D$_3$ was 20μM when they used a new assay procedure based upon 1α,24,25(OH)$_3$D$_3$ production. The objective of this investigation was to study the catabolism of [1β-^{3}H]1α,25(OH)$_2$D$_3$ by CYP24 in the human keratinocyte cell line, HPK1A-*ras* over a broad substrate concentration range from 1nM to 10μM and assess activity based upon both *substrate loss* and *total* product formation using a combination of diode array, ^{3}H and LC-MS detection. Metabolite quantitation was based upon UV_{265} or [^{3}H] measurements while peak identification was based upon LC-MS using both positive and negative electrospray modes. Mass spectra for all vitamin D catabolites featured characteristic molecular ions (MH^+ or MH^-), their dehydration products and sodium adducts. Studies of substrate disappearance reveal highly efficient metabolism of 1α,25(OH)$_2$D$_3$ in the 1-100nM range whereas above 100nM intermediates start to accumulate. Studies revealed an altered distribution pattern (see figure below) of the intermediates of C-24 oxidation pathway of 1α,25(OH)$_2$D$_3$ across the substrate concentration range used, such that at low substrate concentration 1-100nM, calcitroic acid [MH^-=373] was the major product whereas at higher substrate concentrations, more proximal pathway intermediates predominated. At 100nM-1μM substrate, tetranor-1α,23(OH)$_2$D$_3$ [MH^+=361] and 24-oxo-1α,23,25(OH)$_3$D$_3$ [MH^+=447] were maximally produced and at 1-10μM both 1α,24,25(OH)$_3$D$_3$ [MH^+=433] and 24-oxo-1α,25(OH)$_2$D$_3$ [MH^+=431] were the major products. Above 1μM substrate 1α,23,25(OH)$_3$D$_3$ [MH^+=433] was also detected as a major product. Thus using LC-MS techniques, we have shown that CYP24 efficiently metabolises1α,25(OH)$_2$D$_3$ to calcitroic acid via a saturable pathway operating down to the picomolar range. Our data shows that methods which purport to measure CYP24 activity solely based upon 1α,24,25(OH)$_3$D$_3$ production underestimate total enzyme activity especially at low substrate concentrations. We conclude that one of the physiological roles of CYP24 is target cell catabolism of 1α,25(OH)$_2$D$_3$.



SA530

Bone Cyp27b1 mRNA Is Regulated by Dietary Calcium and not Vitamin D Status. P. H. Anderson,*[1] S. Iida,*[2] A. J. Moore,*[2] M. Cochran,*[2] P. D. O'Loughlin,*[2] B. K. May,*[3] H. A. Morris.[2] [1]Department of Physiology, University of Adelaide, Adelaide, Australia, [2]Institute of Medical and Veterinary Science, Adelaide, Australia, [3]Department of Biochemistry, University of Adelaide, Adelaide, Australia.

Regulation of renal 1,25-dihydroxyvitamin D3 (1,25D) synthesis by 25-hydroxyvitamin D-1alpha-hydroxylase (Cyp27b1) has been identified for 20 years, however, regulation of bone cell Cyp27b1 activity remains largely unknown. We have compared the effects of vitamin D status and dietary calcium (Ca) on Cyp27b1 mRNA expression levels in kidney and bone tissues. Vitamin D-deplete female Sprague-Dawley rats were raised on a vitamin D-deficient, 1% Ca diet and housed in a UV-free environment from birth. Six month old vitamin D-replete and vitamin D-deplete rats were fed either the 1% Ca diet (high) or a 0.1% Ca diet (low) for 3 months. Total RNA was extracted from one femur and kidneys by phenol/chloroform extraction. Real-Time RT-PCR quantified mRNA for Cyp27b1. The second femur was processed for histology and in situ hybridisation for Cyp27b1. Vitamin D-deplete rats on a low Ca diet developed hypocalcaemia, secondary hyperparathyroidism and showed a significant increase in osteoid consistent with osteomalacia. In these rats, kidney Cyp27b1 mRNA levels were increased 100-fold compared with kidneys levels in vitamin D-replete rats fed a low Ca diet($p<0.001$). Bone Cyp27b1 mRNA levels were similar to low Ca/vitamin D-replete kidney levels but unlike kidney CYP27b1, were unaffected by vitamin D depletion. In rats on a high Ca diet, bone Cyp27b1 mRNA levels were increased 5-fold independent of vitamin D status ($p<0.01$), while kidney Cyp27b1 mRNA levels were slightly suppressed. Additionally, there was a strong correlation between bone mRNA levels for Cyp27b1 and the catabolic enzyme for 1,25D, 25-hydroxyvitamin D-24-hydroxylase (CYP24). There was, however, no association between bone Cyp27b1 and kidney CYP24. Most interestingly, the high-Ca challenge in low-vitamin D rats normalised serum Ca and PTH levels as well as reduced osteoid and normalised mineralisation lag time. Preliminary identification of bone Cyp27b1 by in situ hybridisation indicates that the majority of the signal-positive cells are bone marrow derived normoblast-type, haematopoietic progenitor cells. It is evident from these rat studies that unlike kidney Cyp27b1 mRNA, bone Cyp27b1 levels are up-regulated by dietary calcium and unaffected by vitamin D depletion. This up-regulation of bone Cyp27b1 is associated with correction of the mineralisation defect and bone structural changes.

SA531

C-3 Epimerization Pathway is a Common Metabolic Pathway of Vitamin D Metabolites and Inversely Interacts with C-24 Oxydation Pathway in Mammalian Cells. T. Okano,[1] M. Kamao,*[1] S. Tatematsu,*[1] S. Hatakeyama,*[2] K. Ozono,[3] N. Kubodera.*[4] [1]Kobe Pharmaceutical University, Kobe, Japan, [2]Nagasaki University, Nagasaki, Japan, [3]Osaka Medical Center for Maternal and Child Health, Osaka, Japan, [4]Cugai Pharmaceutical Co. Ltd., Tokyo, Japan.

1α,25-Dihydroxyvitamin D_3 [1α,25-D_3] is metabolized into its epimer of hydroxyl group at C-3 of the A-ring beside side-chain cleaved products through the C-24 and C-23 oxidation pathways. In the present study, we investigated the C-3 epimerization of 25-hydroxyvitamin D_3 [25-D_3] and 24*R*,25-dihydroxyvitamin D_3 [24,25-D_3] in cell culture system to clarify whether C-3 epimerization pathway is common to vitamin D compounds. In addition, we examined further metabolism of 3-epi-25-D_3 and 3-epi-1α,25-D_3.Ten μM of 25-D_3, 24,25-D_3 or 1α,25-D_3 were incubated with UMR-106 (rat osteosarcoma), MG-63 (human osteosarcoma), Caco-2 (human colon adenocarcinoma), HepG2 (human hepatoblastoma) and LLC-PK_1 (porcine kidney) cells for 48hr. Metabolites were purified by HPLC and structural analyses were performed by ^{1}H-NMR and LC-MS. Metabolism of 3-epi-25-D_3 and 3-epi-1α,25-D_3 were examined by the same method.In all the cells tested, 25-D_3 and 24,25-D_3 were metabolized into their C-3 epimers. Although the differences existed in the amounts of the products. UMR-106, MG-63, Caco-2 and HepG2 cells generated 3-epi-25-D_3 from 25-D_3 as a major metabolite. In contrast, LLC-PK_1 cells produced 24,25-D_3 from 25-D_3 predominantly. C-3 epimerization occurred more preferentially in 25-D_3 and 1α,25-D_3 than 24,25-D_3. These findings suggest that putative C-3 epimerase can recognize side-chain structure of vitamin D_3. Biological activities of each C-3 epimer of 25-D_3, 24,25-D_3 and 1α,25-D_3 with respect to vitamin D receptor binding, transcriptional activity, regulatory activities of human leukemia (HL-60) cell proliferation and differentiation were lower than those of 25-D_3, 24,25-D_3 and 1α,25-D_3, respectively. 3-epi-25-D_3 and 3-epi-1α,25-D_3 were metabolized into their C-24 hydroxylated metabolites, 3-epi-24,25-D_3 and 3-epi-1α,24,25-D_3. Interestingly, an inverse relationship between the production rates of C-3 epimer and 24-hydroxylated metabolites was observed in 25-D_3 and 1α,25-D_3. Our results suggest that the C-3 epimerization pathway is involved in metabolism of vitamin D_3 widely and C-3 epimers are further metabolized through the C-24 oxidation pathway similar to their parent compounds.

Targeted Ablation of the 25-Hydroxyvitamin D 1a-Hydroxylase Enzyme: Evidence for Skeletal, Reproductive and Immune Dysfunction. D. K. Panda,[1] D. Miao,[1] M. L. Tremblay,*[2] J. Sirois,*[2] G. N. Hendy,[1] D. Goltzman.[1] [1]Dept. of Medicine, McGill University, Montreal, PQ, Canada, [2]Dept. of Biochemistry, McGill University, Montreal, PQ, Canada.

The active form of vitamin D, 1α,25-dihydroxyvitamin D [1α,25(OH)$_2$D], is synthesized from its precursor 25 hydroxyvitamin D [25(OH)D] via the catalytic action of the 25(OH)D-1α-hydroxylase [1α(OH)ase] enzyme. Many roles in cell growth and differentiation have been attributed to 1,25(OH)$_2$D, including a central role in calcium homeostasis and skeletal metabolism. To investigate the in vivo functions of 1,25(OH)$_2$D and the molecular basis of its actions we developed a mouse model deficient in 1α(OH)ase by targeted ablation of the hormone-binding and heme-binding domains of the1α(OH)ase gene. After weaning, mice developed hypocalcemia, secondary hyperparathyroidism, retarded growth and skeletal abnormalities characteristic of rickets. These abnormalities are similar to those described in humans with the genetic disorder vitamin D dependent ricket type1 (VDDR-1). Altered non-collagenous matrix protein expression and reduced numbers of osteoclasts were also observed in bone. Female mutant mice were infertile and exhibited uterine hypoplasia and absent corpora lutea. Furthermore histologically enlarged lymph

nodes in the vicinity of the thyroid gland and reduction in CD4- and CD8- positive peripheral T lymphocytes were observed. Alopecia, reported in vitamin D receptor (VDR)-deficient mice and in humans with VDDR-11, was not seen. The findings establish a critical role for the 1α(OH)ase enzyme in mineral and skeletal homeostasis as well as in female reproduction and also point to an important role in regulating immune function.

SU001

The Increased Bone Mass for Age Observed in Childhood Obesity Is Due to Increased Height and Bone Width, but not Increased Bone Density. M. B. Leonard,* B. S. Zemel, A. M. Tershakovec.* Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Obesity has been associated with increased areal-BMD as measured by DXA, and with decreased fracture risk. Because DXA is a projectional technique, it does not distinguish between large bones (increased patient height, or increased bone width) vs. increased volumetric-BMD as an explanation for increased areal-BMD. The purpose of this study was to evaluate these alternative explanations for the increased bone mass observed in obese children compared with healthy controls. Whole body (WB) and lumbar spine (LS) DXA scans (Hologic, Inc, QDR-2000) were performed in 96 healthy controls and in 67 obese children, ages 4-21 yr. The obese children were recruited from the weight management clinic and were otherwise healthy. Pubertal stage was classified according to Tanner. Weight (Wt) and height (Ht) were converted to age, gender-specific z-scores, using NCHS data. Models for bone parameters were constructed using the healthy controls, and then a dummy variable for the obese group was entered to test for group effects. DXA WB bone area adjusted for patient height was used as an estimate of bone width, while LS BMC adjusted for LS bone area was used as an estimate of bone density (Molgaard, et al, Arch Dis Child 1997). All models were adjusted for gender, race and pubertal stage. The obese subjects had significantly increased Ht-z and Wt-z scores compared with healthy controls (all $p < 0.001$). WB BMC for age was significantly increased in the obese subjects, as expected. WB BMC, adjusting for patient Ht, was still significantly increased in the obese, suggesting that the increased bone mass is not entirely due to tall stature. WB bone area for height was also significantly increased in the obese, suggesting markedly increased bone width for patient height (i.e. broad bones). Finally, LS BMC, adjusting for bone area was not significantly different between healthy controls and obese.

	Ht-z Mean (SD)	Wt-z Mean (SD)	WB-BMC for Ht*	WB-area for Ht*	LS BMC for area*
Control	0.2 (1.0)	0.2 (1.0)	-	-	-
Obese	1.2 (1.1)	4.4 (1.9)	↑ p<0.001	↑ p<0.001	NS

*Decreased compared to healthy controls, adjusted for puberty, gender, and race

SU002

Bone Turnover During Adolescence and Young Adulthood. Y. M. Henry, A. C. Eagleton, D. Fatayerji,* R. Eastell. Bone Metabolism Group, University of Sheffield, Sheffield, United Kingdom.

Biochemical markers of bone turnover may help in understanding the physiology of skeletal growth and maturation. Bone turnover markers are elevated during puberty but it is unclear when they are maximal. Bone markers stabilise during young adulthood but the time when minimal levels are achieved remains ambiguous. Therefore, the aims of the present study were to examine the effects of age and gender on different biochemical markers of bone turnover and to study the effect of puberty on bone markers in children. One hundred and thirty two healthy Caucasian children (63 boys and 69 girls, ages 11 to 19 years) and 134 healthy Caucasian adults (66 men and 68 premenopausal women, ages 20 to 50 years) were studied. Bone ALP, OC and PINP were measured as indices of bone formation, and NTX and i-free DPD as indices of bone resorption. Bone resorption markers were expressed as a ratio to urinary creatinine. One-way ANOVA followed by a Scheffé test were used to test the significance of the difference between results at various pubertal stages and between the decades (20 to 50 years) in which adult levels were achieved. The magnitude of the pubertal increase was estimated by expressing mean level in Tanner stages II and III in girls and III and IV in boys as a ratio to the mature adult (MA) reference range (30 to 50 years). We observed that all markers were maximal at mid-puberty (M-P), Tanner stages II and III in girls, and IV in boys. During young adulthood bone markers were minimal in women between 20 to 50 years but later in men during 30 to 50 years.

Marker	M-P Mean[1]	MA Mean[1]	Female Ratio	M-P Mean[2]	MA Mean[2]	Male Ratio
OC, ng/ml	104	26.1	4.0	140	21.7	6.4
PINP, ng/ml	481	43.5	11.1	728	46.1	15.8
Bone ALP, µg/l	50.4	9.16	5.5	75.8	12.3	6.2
NTX/Cr	328	29.9	11.0	438	41.3	10.6
i-free DPD/Cr	22.7	5.99	3.8	26.2	3.5	7.5

[1] Females. [2] Males.

To conclude: (1) all markers were elevated in children (boys more than girls) compared to adults, and were maximal at mid-puberty followed by a decline in late puberty. This pattern of change parallels growth height velocity; (2) the magnitude of the increase was specific for each gender and marker because they reflect growth, modelling and remodelling of trabecular and cortical bone and (3) adult reference ranges should take into account the later maturation of the male skeleton.

SU003

Alendronate in the Treatment of Osteogenesis Imperfecta. V. Vyskocil.[1] [1]Charles University Hospital, Plzen, Czech Republic.

Osteogenesis imperfecta is relatively rare disease which causes fractures. Previous therapeutic procedures consisting of calcitonin and vitamin D had only limited effect on the bone density. According to our results the increase in BMD was only 4,6% per year. They had no significant effect on the number of fractures. Out of these reasons we started (after agreement with parents of our patients) treatment with bisphosphonates. We evaluated 30 children with osteoporosis imperfecta (mean age 13,7) treated orally with bisphosphonates. During one year therapy the children older than 10 years were given 10 mg of alendronate daily and children from 4 to 10 years used 5 mg daily. The Z-score of L1-L4 DXA at the onset of therapy was - 2,56 in all our patients a they had more than 2 fractures per yer. After one year of alendronate therapy we have noticed significant increase in spinal bone density 14,5 %, other location of measurement (hip, forearm) were not evaluated because of frequent deformities. During the first year of the therapy we observed only one fracture caused by adequate trauma (ankle fracture due to skiing). No adverse events occured in children treated with alendronate. There were no signs of gastrointestinal inconvenience and no negative influence on bone evaluated by X.rays in our patients. We recommend to continue the alendronate therapy of these children.

SU004

Bone Size Corrections: Application to Children Born Preterm. C. M. Smith,[1] R. C. Coombs,*[2] A. T. Gibson,*[2] R. Eastell.[1] [1]Bone Metabolism Group, University of Sheffield, Sheffield, United Kingdom, [2]The Jessop Hospital for Women, Sheffield, United Kingdom.

Several methods have been proposed to correct bone mass for bone size. Our aim was to evaluate the spine bone mineral content (BMC) status of children who were born preterm, by separating BMC into its two components, volume and volumetric density. Fifty prepubertal children (25 preterm, 25 age and sex matched term controls) had posterior-antero lumbar spine BMC and bone area (BA) measured using dual energy x-ray absorptiometry (DXA, Hologic QDR 4500A). Bone mineral apparent density (BMAD) was calculated using the equation BMC/Bone Volume (BV). BV was calculated using the formula $BA^{1.5}$ (Carter, 1992). BV was adjusted for body size by dividing it by height (BV:Ht). A z-score was calculated for all these variables based on their mean and standard deviation in the term group.

	Preterm mean (SD)	Term mean (SD)	p	Preterm z-score
BMC, g	12.3 (2.87)	14.5 (4.18)	<0.01	-0.80
BMAD, mg/cm^3	82.0 (8.96)	89.1 (9.68)	<0.05	-0.73
BV, cm^3	149.9 (33.9)	161.3 (37.6)	<0.05	-0.37
Height, cm	104.9 (8.84)	110.43 (9.85)	<0.01	-0.44
BV:Ht, cm^3/cm	1.41 (0.23)	1.44 (0.24)	0.43	0.46

Bone mineral content was reduced in the preterm group. This reduction resulted from a reduction in both bone volume and volumetric bone density. However, bone volume was appropriate for height in the preterm group. Thus, children born preterm have a bone volume that is low for their age but not for their size. They also have a reduced volumetric bone density. If these deficits are not recovered during puberty this could result in a low peak bone mass.

SU005

The Bone Mass Pattern in 9-Year Old South African Black Children Is Similar to That Found in Their Mothers, but Is Different to Those in African-Americans. S. A. Norris,[1] L. Vidulich,*[1] N. Cameron,*[2] J. M. Pettifor.[3] [1]Mineral Metabolism Research Unit, Johannesburg, South Africa, [2]University of Loughborough, Loughborough, United Kingdom, [3]Paediatrics, University of the Witwatersrand, Johannesburg, South Africa.

In the USA, ethnic bone mass and body composition patterns are evident before puberty and persist through adulthood; African-Americans have similar height to that of Caucasian-Americans, but have greater site-specific bone mineral density (BMD, g/cm^2), total bone mineral content (g), lean body mass (g), and body fat (g). We investigated ethnic differences in site-specific BMD, bone mineral content (BMC, g), bone area (BA, cm^2) and body composition of a cohort of prepubertal (aged 9) white (males=47; females=52) and black (males=159; females=139) children and their mothers living in Johannesburg using DXA (QDR-4500). Black children were significantly shorter than white children, and black mothers were shorter than white mothers. Correcting for body size, there were no ethnic BMD, BMC or BA differences at the lumbar spine or radius for both children and mothers, however, black children and mothers had greater hip BMD associated with decreased bone area and similar or greater BMC. Furthermore, there were no significant ethnic differences in body composition for both children and mothers. This study confirms earlier South African findings that there is no ethnic difference in radial bone mass after adjusting for body size in prepubertal children, and is similar to findings from premenopausal women in whom no ethnic differences at the lumbar spine and radial sites were found, but where ethnic differences of the hip was evident with black women having greater hip BMD than white women. These results might explain the lower hip fracture rate in postmenopausal black women, and may suggest that black South African women are not protected against vertebral fractures as anticipated. This study further highlights that ethnic bone mass and body composition differences found between black and white children and

adults in the USA cannot be assumed to be true for other countries. Unadjusted means ± SD

Variable	White males	Black males	White females	Black females
Child hip BMD	0.704 ± 0.079	0.747 ± 0.114 [a]	0.609 ± 0.065	0.670 ± 0.079 [b]
Maternal hip BMD			0.904 ± 0.123	0.964 ± 0.121 [b]
Child spine BMD	0.549 ± 0.052	0.535 ± 0.054	0.528 ± 0.065	0.555 ± 0.083
Maternal spine BMD			1.017 ± 0.131	1.008 ± 0.110
Child radial BMD	0.407 ± 0.030	0.397 ± 0.047	0.386 ± 0.031	0.379 ± 0.048
Maternal radial BMD			0.565 ± 0.045	0.561 ± 0.049

SU006

Calcium Absorption and Bone Mass in Lactating African-American Adolescents. K. O. O'Brien,*[1] A. N. Geer,*[1] F. R. Witter.*[2] [1]Center for Human Nutrition, Johns Hopkins School of Public Health, Baltimore, MD, USA, [2]Gynecology and Obstetrics, Johns Hopkins School of Medicine, Balitmore, MD, USA.

The impact of adolescent pregnancy and lactation on bone mineral density and the ability of adolescents to modify calcium absorption in response to these increased requirements are largely unknown. We addressed this issue by measuring calcium (Ca) absorption during the third trimester of pregnancy (34-36 wks gestation) and again 3-4 weeks postpartum in a group of 14 African-American adolescents (ages 16.3 ± 1.5 y), 8 of whom were breastfeeding their infants during the second study. Total body and lumbar spine bone mineral content were measured in each adolescent 3-4 weeks post-delivery using DXA (Hologic QDR 4500A). Ca absorption was determined during each study following the administration of oral (^{44}Ca or ^{46}Ca) and intravenous (^{42}Ca) stable Ca isotopes. Cumulative excretion of the oral to the intravenous isotope in a 24-hr urine collection post-dosing was used to determine Ca absorption. Percent Ca absorption (-21.4%, p<0.0001, paired t-test) and urinary Ca excretion (-190 mg/d, p<0.0001) were significantly decreased in these adolescents 3-4 weeks post-delivery. A total of 36% of this population (5/14) had evidence of osteopenia (lumbar spine z-scores < -1, n=3) or osteoporosis (lumbar spine z-scores < -2, n=2) 3-4 weeks following the delivery of their infants. Lumbar spine z-scores were on average 0.770 SD lower in lactating compared to non-lactating adolescents (-0.489, n=8 vs. +0.282, n=6) although the magnitude of this difference did not reach statistical significance in this population. Further studies are needed to address the ability of adolescents to regain bone mineral conent once menses resume.

SU007

Analysis of Skeletal Development on the Basis of Body Mass and Bone Resorption. D. L. DeMoss,[1] W. D. Geng,*[2] G. L. Wright.*[2] [1]Biology, Morehead State University, Morehead, KY, USA, [2]Physiology, Marshall University School of Medicine, Huntington, WV, USA.

Regression analysis was utilized to define the relationships among body weight, whole skeleton bone resorption (^{3}H-tetracycline method), and the development of skeletal mass. The results indicated that skeletal development (% body weight) of slowly growing, 24-week-old rats consisted of two major components, one directly ($r = 0.985$, $P < 0.001$) and one inversely ($r = 0.977$, $P < 0.001$) related to body weight. It was further noted that the skeletal resorption rate was inversely correlated to body weight ($r = 0.879$, $P < 0.05$) and directly related to skeletal development ($r = 0.865$, $P < 0.05$), suggesting that whole skeleton bone resorption and formation were highly correlated in the slowly growing animal. A third small component of skeletal development identified in the analysis of data from 24-week-old animals showed no direct relationship to either body weight or resorptive activity. The model presented enables the separation of skeleton mass into major components, which may represent mechanically and metabolically driven bone formation.

SU008

Bone Mineral Mass in Overweight and Obese Children: Diminished or Enhanced? K. J. Ellis,* R. J. Shypailo,* W. W. Wong,* S. A. Abrams. Children's Nutrition Research Center, Dept. Pediatrics, Baylor College of Medicine, Houston, TX, USA.

The purpose of this study was to determine if overweight and obese children have enhanced or diminished bone mineral mass. We have examined whole-body bone mineral content (BMC) in 918 healthy children (ages 5 -18 y) representing a full range of body fatness. Dual-energy x-ray absorptiometry (DXA) was used to obtain whole-body BMC, body fatness (%Fat), and lean tissue mass (LTM). The %Fat cutpoints for 'overweight' and 'obese' status were 25% and 30%, respectively. A reference model for BMC in children (Ellis et al, J Bone Min Res 2001; 16: in press) was used to obtain a standardized Z-score rating for each child. Additional statistical analyses included linear regression, analysis of variance, and unpaired t-test. There were ethnic and gender differences for BMC vs body weight (Wt) and height (Ht), but not for BMC vs LTM. BMC, adjusted for height (Ht), was increased for children with an 'obese' classification.

	Normal (<25%)	Overweight (25%-30%)	Obese (>30%)
N = male (female)	318 (188)	37 (96)	66 (160)
BMC (g)	1480 (1242)	1556 (1504)	1607 (1616)
BMC/Ht (g/cm)	9.55 (8.36)	10.11 (9.74)	10.36 (10.50)
BMD (g/cm2)	0.944 (0.984)	0.951 (0.939)	0.944 (0.965)

Furthermore, when evaluated using a Z-score model, the obese and overweight children usually had positive Z scores indicating above average BMC values. Overweight and obese children also tended to have a higher Tanner rating than leaner children of the same age, indicating possible hormonal influence, and not obesity *per se*. We conclude: (1) the lower bone mineral mass previously reported for overweight and obese children (Goulding et al, Int J Obs 2000; 24: 627; Goulding et al, J Bone Min Res 1998;83: 3469; Weiler et al, Bone 2000; 27: 203) was not evident when the anthropometric reference index was height; and (2) obese children have increased BMC compared with leaner children, when adjusted for Ht, age, gender, and ethnicity.

Osteoporosis Prevention in Young Women: Application of the Health Belief Model. L. S. Wallace. The University of Texas at Tyler, Tyler, TX, USA.

The purpose of this study was to examine personal characteristics and Health Belief Model (HBM) constructs associated with the practice of osteoporosis protective behaviors among a random sample of nontraditional college women. Two hundred and seventy-three women (mean age=24.81±10.23 years, mean BMI=24.81±6.56, 87.7% Caucasian) completed a valid and reliable written mail questionnaire assessing osteoporosis knowledge, HBM constructs, weight-bearing exercise (EX), and dietary calcium intake (CA). On average, women were able to correctly answer 65% of questions assessing general osteoporosis knowledge (e.g., risk factors, preventive measures). Women reported an average of 2.36±2.03 days of weight-bearing activity per week. Current daily calcium was 997.97±517.78 mg (median=922.0, range=46.7-3595.3 mg). Adequate (=) CA was defined as the consumption of >1200 mg/day, while adequate EX was defined as > 90 min/wk. Those falling below the adequate criterion were considered low (Ø) for both CA and EX. A high proportion of women did not meet current guidelines for EX (50.7%) or CA (67.8%). Subjects were classified into one of four categories based on their current calcium intake and weight-bearing exercise participation. The following CA and EX categories emerged: 1) ØCA/ØEX (n=100, 38.9%); 2) ØCA/=EX (n=81, 31.5%); 3) =CA/ØEX (n=38, 14.8%); and, 4) =CA/=EX (n=38, 14.8%). Those in =CA/=EX and ØCA/=EX had significantly higher health motivation and exercise self-efficacy than those in =CA/ØEX or ØCA/ØEX. Multiple stepwise discriminant analysis revealed exercise self-efficacy, barriers to exercise, and perceived susceptibility to osteoporosis as significant predictors of CA/EX category. On the basis of these data, it was concluded that a need exists to increase awareness of osteoporosis risk factors and encourage young women to meet recommended guidelines for both calcium intake and weight-bearing activity. Intervention activities should be developed to foster increased self-efficacy and decreased barriers to calcium intake and physical activity. Many young women are at risk of developing osteoporosis later in life, and more education on this subject is warranted.

SU010

Precision of DXA Measurements of the Spine and Total Hip in Adolescents. C. G. Miller,[1] J. Pak,*[2] J. N. Caminis.[3] [1]Bio-Imaging Technologies Inc., Newtown, USA, [2]Medical Affairs, Roche Laboratories inc., Nutley, USA, [3]Roche Laboratories Inc., Nutley, USA.

Non-invasive techniques such as DXA has made it possible to determine, with very low radiation exposure, bone mineral accumulation, at various skeletal sites during childhood and adolescence. Currently, there are no published data for total hip cross-sectional data in normal pediatric populations. The purpose of this is to evaluate the contribution of triplicate DXA measurements to precision in adolescent patients between 12 and 18 years of age. 204 children (mean age 16.55 +/- 1.3 years) (approximately 66% male) were enrolled in this trial at 19 centers. All subjects and their guardians signed informed consent, which had been approved by each local IRB. Each subject had 3 AP spine (L1 to L4) and 3 left hip DXA measurements taken within 24 hours (1 subject had right femur measurements). All measurements were obtained on GE Lunar densitometers. The %cv's for each site were then calculated as the mean of the individual's precision.The mean, minimum, maximum and median precision (%cv) for the AP Spine was 1.31%, 0.715, 2.09, 1.29 and for Total Hip was 0.653, 0.259, 1.551, 0.629, respectively. The %cv obtained in this group of pediatric subjects was less than 1% at the spine at 18 of 19 sites. The Total Hip precision (%cv), while expectedly poorer, was still very small and demonstrates the ability to obtain good data on pediatric subjects. This level of precision enables the detection of most clinically significant changes in this population. These are the first published data of Total Hip BMD in these age groups on an axial densitometer. This is important with the increasing, regulatory mandated need for more pharmaceutical studies in pediatric populations. Pediatric BMD studies are not only possible but can be conducted ethically with precision and with minimal radiation exposure (approximately 3 to 3.7 micro Sv per scan per anatomical site).

Oral Contraceptive Inhibition of Bone Growth in Young Female Rats: The Role of Androgens. T. Register,[1] M. J. Jayo.[2] [1]Comparative Medicine, Wake Forest University School of Medicine, Winston-Salem, NC, USA, [2]Pathology Associates, Charles River Laboratories, Advance, NC, USA.

Previous studies demonstrated that treatment of intact young adult female monkeys with an oral contraceptive (OC) resulted in inhibition of normal gains in whole body and lumbar spine bone mineral content and density (Register et al., Osteoporosis Intl 1997;7:348). OC treatment also caused a marked suppression of serum testosterone and androstenedione levels. The purpose of the present study was to determine whether hypoandrogenemia might explain the inhibitory effects of OC on bone metabolism and the attainment of peak bone mass in young adult females. Intact, 70-day old adolescent/young adult virgin female Sprague-Dawley rats were treated with placebo (Control), an OC containing ethinyl estradiol and levonorgestrel (OC), OC supplemented with the aromatization-resistant androgen methyltestosterone (OC+MT), or the anti-androgen bicalutamide (BC) for 15 weeks. OC treatment inhibited gains in bone mass relative to Controls, similar to the previous findings in cynomolgus monkeys, and also caused a reduction in tibial length. Addition of MT to the OC treatment did not prevent the adverse effects of OCs on the bone mass or tibial length, suggesting that hypoandrogenemia was not solely responsible for the OC effects. Anti-androgen (BC) treatment had no effect on the growing skeleton of young rats compared to Controls, suggesting that androgens may have a limited involvement in acquisition of bone mass in young adult females. Histomorphometry of the cancellous compartment of proximal tibias indicated that the OC and OC+MT groups had reduced bone surface, non-labeled surface, and trabecular number, and increased trabecular separation relative to Control and BC groups. Histomorphometric data suggested that double-labeled surface perimeter, bone formation rate/bone surface ratio, and mineralizing surface were higher in the OC+MT group compared to the OC group. Nevertheless, OC and OC+MT groups were not different from one another in bone density or tibial lengths. No treatment effects on the cortical compartment were observed. Taken together, these results suggest that while androgens may influence bone metabolism, hypoandrogenemia was not the underlying cause of OC inhibition of bone mineral acquisition in this study.

SU012

Bone Histomorphometry in Older Men. A. M. Kenny,*[1] K. M. Prestwood,[1] M. Gunness,[2] L. G. Raisz.[3] [1]Center on Aging, University of Connecticut, Farmington, CT, USA, [2]Portland Veterans Administration Hospital, Portland, OR, USA, [3]General Clinical Research Center, University of Connecticut, Farmington, CT, USA.

Osteoporosis is a significant problem in the aging male, resulting in 30% of hip fractures that occur worldwide. While increasing evidence suggests that estrogen and testosterone are important to skeletal integrity in men, few studies have related these hormones to bone architecture in older men. We obtained bone biopsy samples from 28 older men (x= 72.3 ± 4.6, range 65-82 years) to assess histomorphometric parameters and correlated them with sex and calcium regulating hormone levels, markers of bone turnover, lumbar spine, femoral and total bone mineral density, calcium intake, physical function, muscle strength and power. Mean static and dynamic parameters of bone histomorphometry and normative numbers are outlined in the table. Bioavailable testosterone levels correlated positively with cancellous bone volume (BV/TV) [r=.52, p=.006] and trabecular thickness (TbTh)[r=.51, p=.007]. Using linear regression analysis, bioavailable testosterone predicted BV/TV and TbTh (R2=.25, p<.01). Bone formation rates (BFR/BV, BFR/TV, BFR/BS) and mineralizing surface (MS/BS) were inversely correlated with calcium intake (r= -.38 to-.48, p<.05) and estrogen/SHBG levels (r= -.47 to-.59, p<.05) and positively correlated with muscle power (r=.44 to.55, p<.05). Using linear regression analysis with calcium intake, muscle power and estrogen as independent variables, muscle power predicted MS/BS (R2=.40, p<.012), estrogen predicted BFR/BS (R2 =.47, p=.007), calcium intake and muscle power predicted BFR/BV (R2=.68, p=.002) and estrogen and muscle power predicted BFR/TV (R2=.66, p=.003). No significant associations were found between parameters of bone histomorphometry and parathyroid hormone, markers of bone turnover, bone mineral density or physical activity. Conclusion: In healthy older men, bioavailable testosterone levels predicted cancellous bone volume and trabecular thickness. Increased mineralization surface and bone formation rates are associated with lower calcium intake, lower estrogen levels and increased muscle power.

Effect of Total Knee Arthroplasty on Patients' Bone Quaity: Five to Ten Years Followup. Y. Ishii,*[1] Y. Matsuda,*[1] S. Sakata,*[2] K. Ichimura.*[3] [1]Ishii Orthopaedic & Rehabilitation Clinic, Gyoda, Japan, [2]Sado General Hospital, Kanai Sado, Japan, [3]Toyama Kyoritsu Hospital, Toyama, Japan.

Introduction: Poor bone quality is considered as a major risk factor for hip fracture in the aged population. Eighty seven percent of patients with hip fracture are reported over 65 years old. Patients aged over 65 years who suffer from osteoarthritis of the knee are good candidates for total knee arthroplasty (TKA). The purpose of this study is to compare the bone quality between patients who underwent TKA, patients who suffered from hip fracture, and age matched controls with ultrasonographic heel measurement.Materials and Methods: Characteristics of three groups shows as follows. Each group shows ,heels/ patients,Gender, and average age respectively. Group A; TKA, 70/ 57, Female 48;Male 9,76±7years. Group B;Hip Fracture,107/104, Female 86;Male 18, 83±9years. Group C; Controls, 70/ 70, Female 59;Male 11, 76±6yrs. In TKA patients, the mean follow-up was 92 months (range, 62 to 113), and all patients had the preoperative diagnosis of osteoarthritis. The average HSS Score was 93±7. Broadband Ultrasound Attenuation (BUA; dB/MHz) through the os calcis was measured to access the bone quality of patients. Group A and B were evaluated on the affected side. ANOVA (Scheffe's methods) were used for statistical analysis.Results: There were no TKA patients who suffered from hip fracture during follow-up period. BUA of Group A, B, and C showed 42.2±15.5, 22.9±13.3 and 40.2±14.9 respectively. Group B showed significant differences compared to both A and C (p<0.0001). Although TKA group had better BUA than controls, there is no significant difference between both groups (p=0.712). Discussion and Conclusion: The results suggest that the increase in activity level after artificial replacement of arthritic joint might improve the bone quality, because of pain relief. BUA is reported to be a better discriminator of hip fracture than dual-energy x-ray absorptiometry. Early TKA might be protective against later hip fractures, by allowing increased mobility and improved bone quality.

SU014

Gender and Age-Related Effects on Bone Formation in a Human Osteoblast Implant Culture System. H. Zhang, G. Gronowicz. Orthopaedics, UCONN Health Center, Farmington, CT, USA.

Gender-related differences are found in bone geometry and strength, especially in the older population. Women also have a higher fracture rate compared to men. Implants are used extensively in orthopedic surgery and dentistry, particularly in the elderly. To investigate if gender and age affect bone formation on implant materials, we examined the response of primary human osteoblasts (HOBs) to orthopaedic Ti-6Al-4V (Tiv) implant disks (Zimmer, Warsaw, IN) by using a novel in vitro osteoblast/implant culture system. HOBs were cultured from bone chips obtained in corrective orthopedic surgery from healthy men and women; Young (Y) <15, Middle (M) = 30-50 and Old (O) >60 years old (4-6 patients per group). These cells were identified as HOBs by their ability to produce a1(I) procollagen and osteocalcin mRNA and high levels of alkaline phosphatase message and protein. HOB attachment to Tiv was examined at 4 h. HOB from female patients showed an age-related decrease in adhesion, with O females showing statistically lower attachment of cells (31.1%) compared to O men. No differences were found between females and males in Y or M groups. Collagen synthesis, assayed by ^{3}H-proline incorporation at 24 h, demonstrated a small but significant age-related decrease in both genders in the O group vs. Y and M groups. Cell proliferation determined by ^{3}H-thymidine incorporation did not show any differences at 24 h of culture. Mineralization, determined by biochemical and morphological calcium content assays, demonstrated age-dependent decreases in female patients (O<M<Y) but no differences in male patients' HOBs at 4 wks of culture. In the O group, females had significantly less calcification (26.5%) compared to males. DNA content in each group was similar. In conclusion, female patients demonstrated a significantly decreased ability for their osteoblasts to attach to implants, to synthesize collagen and to mineralize matrix in response to implant materials. However, HOBs from male patients demonstrated no significant changes among different age groups. These results suggest that elderly female patients may have decreased osseointegration of their implants. In addition, we have developed a reproducible human system in which to study age- and gender-related changes in the osteoblast's ability to form bone.

SU015

Mechanisms of the Sequential Occurrence of Two Types of Bone Loss in the Lumbar Vertebra of Male Sprague Dawley Rats During Aging. L. Wang, J. Banu, D. N. Kalu. Physiology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA.

We previously demonstrated that the intact male Sprague Dawley (SD) rat experiences age-related bone loss that has the characteristics of the bone loss that occurs in aging men (L. Wang, et al. Bone: 2001, in press). In this study, male SD rats aged 3, 6, 8, 9, 10, 11, 12, 15, 18, 21, 24 and 27 months were studied at the L4 vertebral bone using peripheral quantitative computed tomography, histomorphometry and biochemical analyses. From 9 to 21 months of age, cancellous bone mineral content (BMC) decreased by 30% (p<0.0001) and cancellous bone mineral density (BMD) decreased by 35.2% (p<0.0001). Vertebral trabecular bone thickness and trabecular number decreased significantly during this period. From 3 months of age and on, mineral apposition rate (MAR) and bone formation rate (BFR) in the male SD rats decreased rapidly until 9 months of age. From 9 to 24 months of age, MAR and BFR decreased further and remained at the much lower level than the levels for 3-month-old rats (p0.05) and cancellous BMD had decreased by 10.7% (p>0.05) compared to the levels at 21 months of age. However, cancellous BFR increased significantly in the 27-month-old male SD rats compared with the level for 9-month-old rats (p<0.05). Osteocalcin and Dpd also increased at 24 and 27 months of age, but the increase was significant only at 27 months of age (p<0.05). In conclusion, it was found in this study that decreased bone formation rate preceded increased bone resorption rate in male SD rats from 9 to 27 months of age while bone mass decreased progressively. Decreased bone formation appeared to contribute primarily to the early phase of age-related bone loss while the bone loss that occurred later in the life of the male SD rats was possibly due primarily to increased bone resorption.

SU016

Risk Factors for Low Bone Mineral Density and the Six-Year Rate of Bone Change Among Pre- and Perimenopausal Women. K. E. Bainbridge,* M. F. Sowers. Epidemiology Department, University of Michigan, Ann Arbor, MI, USA.

The purpose of this population-based prospective cohort study was to determine risk factors for pre- and perimenopausal bone mineral density (BMD) as well as the rate of bone loss among women aged 24-50 years. The specific aims were to 1) estimate measures of association between anthropometric, reproductive, dietary, lifestyle, and medical history variables with BMD, and 2) evaluate which of these variables are associated with the rate

of BMD change (either gain or loss). We followed 614 women, between the ages of 24-44 at baseline, for six years beginning in 1992/93. BMD measurements of the lumbar spine (L_{2-4}) and the femoral neck were obtained using dual x-ray absorptiometry (DXA) during up to five physical examinations conducted between 1992/93 and 1998/99. Anthropometric measurements were also obtained during these examinations. Dietary information was collected over four consecutive years from 1992/93 to 1995/96 using the NCI Health, History, and Habits Questionnaire. History of chronic illness, medication use, and family history of osteoporosis as well as physical activity, alcohol use, and smoking behavior were assessed through interviews or self-administered questionnaires. Reproductive factors were also assessed including self-reported frequency of menstrual bleeds per year from which menopausal status was derived. Linear mixed models were developed to identify independent risk factors for BMD at a given time while simultaneously identifying risk factors for BMD change over the six years. Body weight was positively associated with BMD (p = .0001) and with bone change (.0001) at both the lumbar spine and femoral neck. At the lumbar spine, history of fracture at any skeletal site (p = .005) and surgical menopause (p = .03) were associated with lower BMD. Natural and surgical menopause and reproductive cancers were associated with greater lumbar spine bone loss (p = .0001, for each). At the femoral neck, family history of osteoporosis was associated with lower BMD (p = .01). Alcohol consumption (p = .0003) and high school sports participation (p = .002) were associated with greater BMD. Surgical menopause (p = .007) and reproductive cancers (p = .0008) were associated with greater femoral neck bone loss. Calcium intake, smoking, and current physical activity were not associated with BMD or bone loss at either skeletal site. Risk factors that are associated with BMD at a given point in time are not necessarily associated with rate of BMD change.

SU017

Effect of Orchidectomy and Salmon Calcitonin in Fracture Healing on Cortical Bone from Rat Femur. Bone Mass and Mechanical Strength. J. C. Koulouris,* I. Dontas, G. Trovas, E. Kataxaki, P. Raptou, G. P. Lyritis. Laboratory for the Research of the Musculoskeletal System, Athens, Greece.

Aim of this study is to investigate changes in bone mass and biomecanical competence in relation to effect of salmon Calcitonin (sCT) in healing of fracture in normal, orchidectomized and orchidectomized treated wirh sCT rats. We used 56 male Wistar rats. We orchidectomized 28 rats in the age of 2 months and we performed a half-osteotomy(OT) of the diaphysis of the femurin the age of 3 months. We divided the rats to 8 groups of 7 animals. A(2 weeks) a (4 weeks) nonorchidectomized, B(2 wks) b(4 wks)nonorchidectomized+sCT,G(2wks)g(4wks)orcidectomized,D(2wks)d(4 wks) orchidectomized+sCT. We treated the groups(B,b,D,d)immediately after OT with 5UIsCT subcutaneously daily. Rats of groups a,b,g,d were killed 2 weeks and those of A,B,C,D 4 weeks after OT. At the fracture callus we assesed the corticalBMD,TOTALBMD,CORTICALBMD,IPcort.area (polar moment of inertia) with pQCT (Stratec-960).

	2 WEEKS				4 WEEKS		
CORTICAL BMD	TOTAL BMD	CORTICAL CONTENT	IP cortical area	CORTICAL BMD	TOTAL BMD	CORTICAL CONTENT	IP cortical area
b>a (p=0.01)	ns	ns	ns	B>A (p=0.002)	B>A (p=0.01)	ns	ns
d vs g ns	ns	ns	ns	D vs G ns	ns	D>G (p=0.002	D>G (p=0.001)
				A vs G ns	ns	ns	A>G (p=0.006)

We concluded that treating fracture with sCT for 4 weeks improved the parameters of pQCT (content, density) and mecanicalbone strenght (polar moment of inertia) in the callus for the rats of group D compared with group g

SU018

Rate of Bone Loss in Perimenopausal and Early Postmenopausal Women: Role of Body Composition, Hormonal History and Environnemental Factors. S. Malochet,*[1] J. M. Ristori.[2] [1]Rheumatology, CHU Clermont Ferrand, Clermont Ferrand, France, [2]Departement of Rheumatology, CHU de Clermont Ferrand, Clermont Ferrand, France.

The object of this study was to evaluate the role of body composition, hormonal history and environnemental factors on the rapid bone loss that occure in perimenopausal and in early postmenopausal period. We espacially study the impact of food that are rich in polyphenols wich could influence bone metabolism (fruit, vegetable, red wine an tea).Sixty five women (7 pre-, 22peri-, 36 postmenopausal between 12 and 36 month since their last menstrual period), aged 43-58 years participated in a longitudinal study of bone mineral density (BMD). BMD was measured by dual-energy X-ray absorptiometry (DXA) at the lumbar spine and four femur sites and the time between the two bone scans was on average 26.4 months. Rate of bone loss was expressed as a percentage of the baseline value per year and as the bone mineral density slope in grams per cm ^{2} per year.At the time of the second bone density scan, 51 women were postmenopausal and 14 perimenopausal, and 71% of the postmenopausal women had taken Hormone Replacement Therapy (HRT) since the first measurement.Baseline BMD measures were highly predictive of the follow-up BMD values (r^2 from 0.87 to 0.95). The annual percentage change in BMD of the whole group was different compared with zero at the lumbar spine (-0.5, p=0.02), the femoral neck (-0.8, p=0.001) and the Wards'triangle (-1.5, p<0.001).Factors significantly associated with slower rate of bone loss were : longer time since last menstrual period at the spine, the trochanter and intertrochanteric site; the use of HRT at all sites except the femoral neck; shorter duration of contraceptive use and of breast-feeding only at the trochanter; greater weigth at the trochanter for the whole group and at the intertrochanteric site for the women without HRT; greater body mass index at the intertrochanteric site only in women without HRT; red wine intake at the femoral neck and at the Ward's triangle only in women without HRT. Factors significantly associated with greater rate of bone loss were smoking at the femoral neck and regular physical activity at the Ward's triangle. Calcium, fruit and vegetables, coffee and tea intake were not related to bone mass change.In conclusion, HRT seems to have the greater protective effect on the rate of bone loss . These data suggest that body composition and environnemental factors exert only little effect on the rapid bone loss in perimenopausal and early postmenopausal women.

SU019

Effects of Menopause on Femoral and Vertebral Bone Loss: A 5-year Prospective Population Based Cohort Study. J. Sirola,*[1] R. Honkanen,*[1] H. Kröger,[2] M. Tuppurainen,*[3] J. S. Jurvelin,*[4] S. Saarikoski.*[3] [1]Research Institute of Public Health, University of Kuopio, KUOPIO, Finland, [2]Dpt. of Surgery, Kuopio University Hospital, KUOPIO, Finland, [3]Dpt. of Obstetrics and Gynaecology, Kuopio University Hospital, KUOPIO, Finland, [4]Dpt. of Clinical Physiology and Nuclear Medicine, Kuopio University Hospital, KUOPIO, Finland.

This longitudinal study investigated the effects of natural menopause on vertebral and femoral bone mineral density (BMD) . The study population, 409 women aged 47-56 years, was selected from a random sample (n=2025) of the Osteoporosis Risk Factor and Prevention study population (n=14 220) Kuopio, Finland. Spinal (L) and three areas of femoral (neck (N), Ward's triangle (W) and trochanter (T)) BMDs were measured with dual X-ray absorptiometry at baseline (BL) in 1989 and at five year in 1994. Characteristics were obtained with postal inquiries. Pre- and postmenopause definitions were based on amennorhea of under or over 12 months, respectively. Of the 409 women 13 were premenopausal at both measurements, 116 perimenopausal (premenopausal at BL, postmenopausal at 5-year), 172 early postmenopausal (under 5 years postmenopausal at BL) and 108 late postmenopausal (over 5 years postmenopausal at BL). Table presents the mean annual BMD loss (%) (95% CI) according to menopausal status. The greatest annual bone loss was seen in all four areas in perimenopausal women. The annual bone loss was decreased in early and late postmenopausal women being close at the premenopausals' level. These differences were found significant between the pre- and perimenopausal as well as peri- and early postmenopausal in all areas and between early post- and late postmenopausal in lumbar spine.In linear regression model a significant positive correlation was seen in all areas between the annual BMD loss and the duration of menopause (p<0.001 (L), p=0.008 (N), p=0.006 (W), p=0.007 (T)). In conclusion after an acceleration phase of bone loss during menopausal years the bone loss rate is gradually decreased. Thus, the preventive hormonal therapy should be initiated as early as possible at the beginning of the menopause.

Activation of PPARγ2 by Rosiglitazone Causes Bone Loss Associated with Increased Marrow Adiposity and Decreased Osteoblast Number in Mice. R. L. Jilka, B. Lecka-Czernik, A. A. Ali, C. E. O'Brien,* R. S. Weinstein, S. C. Manolagas. Div. Endo/Metab, Center for Osteoporosis and Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, Univ. of Arkansas for Med. Sci., Little Rock, AR, USA.

The osteoblast deficit that characterizes age-related bone loss is associated with increased marrow adiposity. Osteoblasts and marrow adipocytes are derived from a common mesenchymal progenitor, and lineage selection is governed in part by specific transcription factors - Cbfa1 for osteoblasts and PPARγ2 for adipocytes. Previous studies have shown that the PPARγ2 ligand rosiglitazone irreversibly blocks osteoblast differentiation while promoting adipocyte differentiation of a murine marrow-derived osteoblastic cell line expressing PPARγ2. Addition of rosiglitazone to murine bone marrow cultures also inhibited osteoblast differentiation, and promoted adipocyte differentiation, within the fibroblastic colonies that develop from their common mesenchymal progenitor, CFU-F. These findings suggest that age-related bone loss may be due to increased synthesis and/or activation of PPARγ2 in these early progenitors and/or their uncommitted progeny. Therefore, we examined the effect of rosiglitazone on the skeleton of adult (5 month old) Swiss-Webster mice. The animals were pair fed with normal rodent chow, or chow containing rosiglitazone, such that those receiving the drug ingested 25 µg per gram body weight per day - a dose previously shown to stimulate formation of peripheral adipose tissue in rats. None of the animals exhibited changes in food intake or weight during the 28-day course of the experiment. As expected, mice receiving rosiglitazone exhibited a 3-fold increase in the weight of interscapular brown fat. More important, the ligand caused a 7.3 ± 3.8% reduction in BMD. Histomorphometric studies revealed a reduction in cancellous bone area that was associated with a decrease in bone formation rate and osteoblast number; and an increase in the number, but not diameter, of marrow adipocytes. Consistent with the latter, there was a significant increase in the expression of mRNA for aP2, an adipocyte-specific protein, in tibiae of rosiglitazone-treated mice. However, rosiglitazone had no effect on the number of CFU-F, as detected in ex-vivo marrow cultures. Thus, activation of PPARγ2 reduces cancellous osteoblast number by acting on the differentiation rather than the replication of uncommitted progenitors of osteoblasts and adipocytes. These findings

support the contention that the decline in osteoblast number, and the bone loss, that occurs with aging may be due in part to activation of PPARγ2, resulting in the development of adipocytes at the expense of osteoblasts.

SU021

The Role of Reproductive Factors in Bone Mineral Density: Clues from Medieval Female Skeletons. S. C. Agarwal,[1] M. D. Grynpas.[2] [1]Department of Anthropology and Samuel Lunenfeld Research Institute of Mount Sinai Hospital, Toronto, University of Toronto, Toronto, ON, Canada, [2]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada.

It is generally agreed that pregnancy and lactation are high bone turnover states. However, the effects of parity and lactation on the maternal skeleton, and their contribution to bone fragility in post-reproductive years, is not fully understood. From an evolutionary perspective, it seems maladaptive that the female skeleton be incapable of efficient bone maintenance under the normal conditions of pregnancy and lactation. Human females do share similar reproductive patterns with our genetically closest non-human primate relatives. For example, life cycles of females from non-industrialized societies are typically characterized by late menarche, frequent pregnancies, prolonged lactation, and early menopause. However, reproductive patterns have changed substantially within the last century, causing a dramatic shift in the hormonal milieu of modern western females. The study of female skeletons in historical past populations gives us a unique opportunity to examine the skeletal effects of reproductive patterns that are more consistent with those found throughout the majority of female evolution. A study was made of bone mineral density (BMD) in British medieval skeletons excavated from the historic village, Wharram Percy, located in North Yorkshire, England. The burials represent primarily ordinary peasants with reproductive practices that would have included high parity and prolonged periods of lactation. A total of 55 individuals (m=24, f=31) were examined that were aged with established age determination techniques and divided in three age categories (18-29yrs, 30-49yrs, 50+yrs). 5mm thick coronal sections were removed from the fourth lumbar vertebrae and scanned in a specialized DEXA scanner (PIXImus, GE Lunar Corp.) where BMD could be measured specifically for the trabecular region of the section. Significant differences in female BMD were found between the youngest and two later age groups (ANOVA, $p<0.05$). Medieval females specifically showed significant decrease in bone mineral density at an early age, and no significant change between middle and old age. Further, the female skeletons showed few fragility fractures. Although the males demonstrated more typical age-related patterns of bone loss, the patterns of bone loss in the females contrast with those seen modern populations. We hypothesize that the patterns of bone loss found in females from archaeological populations may reflect the many changes that have occurred in reproductive behavior.

Changes of the Femur Trochanter in Women With Aging. H. Barden,[1] R. Mazess.[2] [1]GE Medical Systems - Lunar, Madison, WI, USA, [2]Department of Medical Physics, University of Wisconsin, Madison, WI, USA.

We have previously reported reference data on about 11,000 to 12,000 adult white women for spine and femur [1]. Those results showed femur neck area was constant from young adulthood through old age, but that trochanteric area increased by 20% from youth to age 80. As a consequence, the area of the "total" femur site increased about 5%. Trochanteric BMC actually increased from age 20 to age 55 (by 15%), and by age 80 it had lost this "premenopausal" gain and was identical to the BMC at age 20. The slow diminution of BMD at the trochanter from young adulthood to old age (only -15%) masks large and distinctive changes in bone area and BMC. We examined the interrelationship of trochanteric BMC and area in a large US subsample (n=1854) of the above database. Conclusion: Peak BMC at the trochanter is not reached until age 55, and peak area until age 80. The increase of trochanteric bone area and BMC may offer a biological protection against impact forces from falls. Patients with hip fracture have a smaller trochanteric area and BMC.

		Neck			Trochanter		
Age	n	BMD (g/cm^2)	BMC (g)	Area (cm^2)	BMD (g/cm^2)	BMC (g)	Area (cm^2)
20-29	81	0.983	4.69	4.79	0.787	8.57	10.76
30-39	118	0.970	4.59	4.74	0.780	9.27	11.77
40-49	286	0.936	4.37	4.67	0.774	9.60	12.33
50-59	443	0.880	4.12	4.67	0.749	9.87	13.10
60-69	454	0.814	3.80	4.67	0.712	9.70	13.53
70-79	374	0.744	3.48	4.66	0.658	9.24	13.88
80-89	98	0.675	3.15	4.65	0.597	8.47	13.88

Differences in the Ratio of Trochanteric BMD to Femoral Neck BMD in Women Across the Lifespan. K. B. Gunter,*[1] J. M. Shaw,[2] C. M. Snow.[1] [1]Exercise and Sport Science, Oregon State University, Corvallis, OR, USA, [2]Exercise and Sport Science, University of Utah, Salt Lake, UT, USA.

Approximately 80-90% of all hip fractures occur at either the femoral neck or the trochanteric regions of the hip. Trochanteric fractures are associated with greater blood loss and higher mortality rates than fractures at the femoral neck and it has been reported that lower trochanteric BMD or a higher femoral neck BMD is associated with an increased risk of trochanteric hip fractures in the elderly. This indicates that a higher ratio of trochanteric to femoral neck BMD may provide protection against fractures. Our aim was to examine BMD changes at the femoral neck and trochanteric regions of the hip with age. We examined the ratio of trochanteric BMD to femoral neck BMD in 308 women ranging in age from 19-91 y. Participants were categorized by age into 5 groups (Group 1= 18-28; Group 2= 29-45; Group 3= 46-60; Group 4= 61-70; Group 5= 71 and older). Bone mineral density of the proximal femur was assessed by DXA and reported as mean +/- standard error (Table 1). We found the ratio of trochanteric to femoral neck BMD (TR/FN BMD) increased with each age category with significant differences between the oldest 2 age groups and the youngest 3 age groups ($p<.03$) (Table 1). In multiple regression analyses age was a significant predictor of TR/FN BMD ($r=.42$; adjusted $R2=.17$). In the older age categories estrogen use resulted in a significant differences in the ratio among 46-60 year olds. In this age category, the TR/FN ratio was .895 in estrogen users compared to .847 in non-estrogen users ($p=.009$). There were no differences in the TR/FN ratio between estrogen and non-estrogen users in the oldest age categories (4 and 5).

Table 1

Group	FN*	TR*	Ratio*
1 (18-28)	.926 (.020)	.734 (.017)	.796 (.715)
2 (29-45)	.849 (.011)	.717 (.010)	.848 (.008)
3 (46-60)	.769 (.013)	.662 (.011)	.874 (.010)
4 (61-70)	.691 (.015)	.612 (.013)	.891 (.012)
5 (71+)	.635 (.013)	.582 (.011)	.918 (.010)

Our results demonstrate a discordant loss of bone density at the femoral neck and trochanteric regions of the hip with age. The implications of these findings warrant further investigation.

SU024

Differential Response to BMPs in Immortalized Tendon-Derived Cell Lines Which Express Scleraxis/Six1 Genes and Form Hard Connective Tissues in Ovo. R. Salingcarnboriboon,[1] Y. Maeda,[1] H. Yoshitake,*[1] M. Takamoto,[1] K. Tsuji,[1] A. Nifuji,[1] V. Rosen,[2] M. Noda.[1] [1]Dept of Molecular Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, [2]Genetics Institute, Cambridge, MA, USA.

The development of musculoskeletal system requires coupled development of distinct types of tissues, including muscle, tendon, cartilage, and bone. Until now, molecular biology aspects of muscle, cartilage and bone have been extensively studied. However, both cell and molecular biology of tendon has not been well understood. The purpose of this study is to construct and characterize the tendon cell lines to be utilized as a model for further studies on tendon biology and also to understand the mechanism that differentiates these cells from the cells in osteoblastic and chondrocytic lineages. Three lines of tendon-derived cells (E4, G11, and D6) were cloned from the Achilles tendon of the transgenic mice harboring SV40 large T antigen gene according to limiting dilution technique. The cells were further cultured in alpha-MEM supplemented with 0.5% FBS, at 33°C, under 5% CO2 atmosphere for over one year. The proliferation of these 3 lines was significantly increased by the treatment with bFGF ($p<0.01$). Proliferation of E4 and G11 cells was also enhanced by TGF-beta ($p<0.01$) whereas BMP2 did not show any significant effect on proliferation. D6 cells grew at the slowest rate in 0.1% serum but it grew faster than the other two cell lines at 10% serum. Scleraxis and Six1, markers of tendon cells, were expressed in these cell lines. Northern blot analysis indicated the expression of osteopontin and type I collagen mRNAs, but not osteocalcin and alkaline phosphatase mRNAs, markers for osteogenic cells. However, interestingly, these cells did express all these genes when examined by a more sensitive technique such as RT-PCR. Alkaline phosphatase levels were enhanced by 100-300 % in all the tendon cell lines after the treatment with BMP2. D6 cells were characterized further to examine their behavior both in vitro and in vivo. Unlike BMP2, BMP12 and BMP13 did not show any significant effect on proliferation and alkaline phosphatase expression in D6 cells. Interestingly, dexamethasone suppressed the growth of D6 cells (about 40%) while it still significantly induced alkaline phosphatase expression ($p<0.05$). Formation of hard connective tissue mass was observed when D6 cell pellets were cultured on chorioallantoic membrane (CAM) in ovo. These observations indicated that D6 cells could serve as a tendon cell line and they possess capabilities to differentiate into osteoblasts/chondrocytes suggesting that these cells contain stem cell like features as common progenitors.

Regulation of BMP Expression by Thyroid Hormone in Differentiating Chondrocytes. M. C. Stewart, Y. Wang. Orthopaedics, Case Western Reserve University, Cleveland, OH, USA.

The induction of hypertrophic differentiation in chondrocytes by thyroid hormone is believed to be mediated through autocrine expression of BMPs. This study was conducted to identify the specific BMP family members that are upregulated in differentiating mammalian chondrocytes, in response to thyroid hormone.Chondrocytes were isolated from the proximal humeral epiphyses of neonatal rats and cultured under non-adherent conditions in defined, serum-free medium in the presence or absence of 100 ng thyroid hormone (T3)/ml of culture medium. Total RNA was isolated from samples on days 1 through 7. Changes in gene expression were monitored by semi-quantitative RT-PCR. Induction of the hypertrophic phenotype was monitored by expression of collagen type X (ColX) and ALP. Specific primers were developed to assess expression of BMPs 2, 3, 4, 5, 6 and 7. Expression was standardized to that of beta actin and GAPDH.Collagen type X expression was not detected in Control samples at any stage but was evident by Day 4 in T3-treated samples. ALP expression was detected in all samples, but expression was increased threefold in T3-treated samples after Day 5. In Control cultures, BMP-2 expression declined over time. However, T3 treatment maintained BMP-2 expression throughout the experiment. BMP-2 expression was 2-3 fold higher in T3-treated samples from Days 4-7. BMP-6 expression was stable in Control cultures but was increased approximately twofold in T3-treated samples from Days 4-7. This increase corresponded to, but did not preceed, the induction of hypertrophic-specific markers. BMP-7 expression declined throughout the course of the experiment and was not affected by T3 treatment. BMP-4 expression was not infuenced by T3. BMP-4 expression showed a transient increase from days 1-3, then dropped through the second half of the experiment in both Control and T3-treated samples. Expression of BMPs 3 and 5 were not affected by T3 treatment, nor did the levels of expression alter during the course of the experiment.These findings indicate that BMPs -2 and -6 are specifically responsive to thyroid hormone in differentiating chondrocytes. Direct treatment of chondrocytes with rhBMP-2 (50 ng/ml) resulted in strong induction of ColX and ALP expression. In contrast, there was minimal induction of hypertrophic markers in response to BMP-6. These data suggest that BMP-2 is a primary autocrine mediator of hypertrophic differentiation in mammalian chondrocytes, in response to thyroid hormone.

Dysregulation of BMP Receptor IA in Fibrodysplasia Ossificans Progressiva. L. Serrano de la Peña,* P. C. Billings,* J. Ahn,* F. S. Kaplan, E. M. Shore. Orthopaedic Surgery, University of Pennsylvania, Philadelphia, PA, USA.

Fibrodysplasia ossificans progressiva (FOP) is an autosomal dominant disorder of heterotopic ossification. The gene responsible for FOP has not yet been identified. The first molecular insights into the disorder arose from observations of increased BMP4 mRNA and protein expression in lymphoblastoid cell lines (LCLs) and pre-osseous fibroproliferative lesional cells obtained from FOP patients. These findings suggested that altered BMP4 regulation and/or signal transduction pathways in affected individuals could induce ectopic bone formation. In this study, we examined specific components of the BMP signal transduction pathway. Using Fluorescence Activated Cell Sorting (FACS) analysis, we observed that levels of BMP receptor type IA (BMPRIA) are 10 fold higher on the surface of FOP LCLs compared with LCLs from unaffected individuals. This surprising observation of overexpression of both ligand and receptor, has led us to question the integrity of the BMP4 signaling pathway in FOP cells. The activation of BMPRIA by phosphorylation in BMP4-treated and untreated cells was examined by BMPRIA immunoprecipitation followed by immmunodetection of phosphothreonine. In the absence of BMP4 stimulation, BMPRIA is endogenously phosphorylated at a relatively high level in FOP cells, in contrast to normal cells which show little phosphorylation. Following BMP4 stimulation, the level of BMPRIA phosphorylation does not change in FOP cells, but increases in normal cells. We are currently examining whether the apparent chronic activation of the BMP4 pathway in FOP cells results from endogenous over-production of BMP4 protein, or from defects in a BMP receptor(s) and/or elements of the downstream signaling pathway. Our findings demonstrating overexpression and basal hyperphosphorylation of BMPR1A, together with insensitivity to exogenous BMP4 protein, provide further evidence of alterations in the BMP4 pathway in the pathogenesis of FOP.

BMP-7 Induces Both Chondrogenesis and Osteogenesis in the C3H10T1/2 Mesenchymal Stem Cell Line. C. M. Shea,*[1] G. L. Barnes,[2] T. A. Einhorn,[2] L. C. Gerstenfeld.[2] [1]Department of Periodontology, Harvard School of Dental Medicine, Boston, MA, USA, [2]Department of Orthopaedic Surgery, Boston University Medical Center, Boston, MA, USA.

Bone morphogenetic proteins (BMPs) have been shown to be instrumental in promoting cellular differentiation of mesenchymal stem cells into skeletal lineages. In order to elucidate the temporal pattern of differentiation from uncommitted mesenchymal to mature skeletal cell, C3H10T1/2 mesenchymal stem cells were treated with BMP-7 and examined for transcription factor and matrix gene expression and transcription factor DNA-binding by RNase Protection Assays (RPAs) or Electromobility Shift Assays (EMSAs) respectively. C3H10T1/2 cells were treated with rmBMP-7 at 0, 80, or 250 ng/ml in either the nutrient-rich growth media BGJb or DMEM. Additional experiments independently analyzed the effect of ascorbic acid supplementation. The results of these studies indicate that the mesenchymal stem cell line C3H10T1/2 can be induced to undergo both chondrogenesis and osteogenesis when treated with BMP-7. Furthermore, this induction is dose-dependent and occurs in a temporal pattern with chondrogenic differentiation preceding osteogenesis as determined by the expression of matrix-related genes and skeletal cell-associated transcription factors. These studies also demonstrate a default to the adipogenic phenotype upon removal of BMP-7 from the culture media demonstrating a role for BMPs in the maintenance of the skeletal cellular phenotype. Finally, our results demonstrate that the nutrient-rich media BGJb enhances both chondrogenic and osteogenic gene expression in BMP-7 treated cells by approximately two-fold and suggest that additional environmental factors may enhance BMP-7 induced chondrogenic and osteogenic differentiation.

Prostate Cancer Cells Induce Osteoblastogenesis Through Bone Morphogenetic Proteins. J. Dai,*[1] J. Zhang,[2] D. Lin,*[3] E. Keller.[3] [1]Unit for Laboratory Animal Medicine, University of Michigan, Ann Arbor,, MI, USA, [2]Department of Pathology, University of Michigan, Ann Arbor, MI, USA, [3]Unit for Laboratory Animal Medicine and Department of Pathology, University of Michigan, Ann Arbor, MI, USA.

Human prostate cancer (CaP) frequently metastasizes to bone resulting in osteoblastic metastases at the site of metastasis. The exact factors mediating the osteoblastic response remain unknown. Bone morphogenetic proteins (BMPs), the members of the transforming growth factor-ß (TGF- ß) superfamily, play an important role in regulating the osteoblast differentiation and function. Accordingly, the present study was designed to explore if BMPs contribute to formation of osteoblastic metastases. To determine if prostate cancer tissue expressed BMPs, we performed immunohistology. BMPs-2, -4, -6, and -7 were expressed in prostate cancer tissue. To define if prostate cancer cells express functional BMPs, we evaluated if a bone metastatic LNCaP-derivative prostate cancer cell line, C4-2B, produces osteoblastic factors. C4-2B cells were grown for 48 h both the C4-2B cells and their conditioned media (CM) were collected. Western analysis revealed that C4-2B cells expressed BMP-2, -4, -6 and -7. To determine the production of functional osteoblastic activity by C4-2B cells, MC3T3-E1 cells, murine osteoprecursor cell line, were incubated in C4-2B CM or control media. CM had no effect on cell proliferation, but increased alkaline phosphatase (ALPase) activity and mineralized nodule formation (von Kossa positive). To determine if these effects were mediated through BMPs, noggin, a factor known to block BMPs, was added to the cultures in addition to the C4-2B CM. The presence of noggin inhibited the ALPase activity and mineralized nodule formation. Finally, a previous study had suggested that BMP-7 is regulated by androgens. Thus, to determine if androgens regulate BMP production in prostate cancer, we tested the ability of dihydrotestosterone (DHT) to regulate BMP-7 mRNA levels. In the androgen-dependent LNCaP cells line, DHT reduced BMP-7 mRNA expression. However, in the androgen-independent C4-2B cell line, DHT had no effect on BMP-7 expression. These data suggest that C4-2B BMP-7 expression is dysregulated in C4-2B cells and the increased production of BMPs, leads to osteoblastic activity. These findings suggest a possible mechanism through which prostate cancer cells produce osteoblastic lesions.

Impact of rhBMP-2 on Prognostic Risk Factors for Delayed Fracture Healing and Related Secondary Interventions in Open Tibial Shaft Fractures. M. F. Swiontkowski,*[1] P. Peeters,*[2] P. Bacquet,*[2] R. Mallick,*[3] C. Csimma,*[4] A. Valentin-Opran,*[4] S. Govender.*[5] [1]Department of Orthopaedic Surgery, MMC # 492, University of Minnesota, Minneapolis, MN, USA, [2]Quintiles, Levallois Perret Cedex, France, [3]Wyeth-Ayerst Research, Radnor, PA, USA, [4]Genetics Institute, Cambridge, MA, USA, [5]Department of Orthopaedics, University of Natal, Durban, South Africa.

Open tibial fractures are associated with delayed fracture healing (DH) and a correspondingly high rate of secondary interventions (SI) to accelerate healing. We evaluated the relative impact of risk factors for DH and associated SI, and assessed potential risk reduction with recombinant human bone morphogenetic protein-2 (rhBMP-2; dibotermin alfa).Data were analyzed for 450 open tibial fracture patients who were randomly assigned to receive rhBMP-2 (1.50 mg/mL or 0.75 mg/mL) plus standard of care (SOC; reamed or unreamed intramedullary [IM] nail fixation), or SOC alone. Multivariate logit models were estimated to evaluate relative importance of risk factors and generate corresponding predicted risks for the 6-month rate of clinically determined DH and the 12-month rate of SI (invasive and non-invasive).Predicted 6-month DH risks and 12-month SI risks varied considerably between risk factor combinations, but were consistently lower in the 1.50 mg/mL rhBMP-2 group than in the SOC group (Table I). Independent of risk factors, the 1.50 mg/mL rhBMP-2 group, compared with the SOC group, was more likely (adjusted odds ratio [OR] = 1.83; P = .005) to attain 6-month fracture healing and less likely (OR = 0.60; P = .048) to require SI.

Predicted Risk By Treatment Group

Risk Factors	SOC	rhBMP-2 (1.50 mg/mL)
	DH (predicted risk)	
Gustilo-Anderson (G-A) IIIA/B, unreamed IM nails	69%	55%
G-A I/II, reamed IM nails	33%	21%
	SI (predicted risk)	
G-A IIIA/B, unreamed IM nails, multiple fractures	51%	39%

G-A I/II, reamed IM nails, single fractures	11%	7%

Gustilo-Anderson IIIA/B fracture grade and unreamed IM nail fixation were significant risk factors for 6-month DH. Multiple fractures were an additional risk factor for SI. rhBMP-2 treatment was associated with reduced risk across all groups.Prognostic modeling to identify risk factors for DH and associated SI may facilitate optimal risk management in fractures through new treatments such as rhBMP-2

Transcriptional Regulation Of The Cloned Human Cbfa1 Gene Promoter By Bone Morphogenetic Protein-7. L. Tou,* N. Quibria,* J. M. Alexander. BIDMC/Harvard Medical School, Boston, MA, USA.

It is well established that core binding factor cbfa1 is required for osteoblast recruitment and differentiation from mesenchymal stem cells. However, little is known regarding the effects of osteogenic factors such as bone morphogenetic proteins (BMPs) on transcriptional regulation of the Cbfa1 gene. BMP-7 is a member of the transforming growth factor beta (TGF-b) superfamily and induces osteoblast differentiation from mesenchymal precursor stem cells in vitro and bone formation in vivo. This study examines the effects of BMP-7 on markers of osteoblast differentiation and specifically on human cbfa1 gene transcription. Recombinant human BMP-7 induced both alkaline phosphatase (ALP) and cbfa1 mRNA and protein biosynthesis in a mouse C2C12 myoblast cell line. To further understand the mechanisms of human cbfa1transcriptional regulation by BMP-7, we cloned 3.0 kb of the human cbfa1 gene 5'-upstream flanking region and created a promoter deletion series of cbfa1 in luciferase-based reporter vectors (cbfa1/Luc). Sequence data revealed 6 copies of the osteoblastic cis-acting element (OSE2) in the proximal promoter region. In C2C12 cells transiently transfected with a 1.2 kb cbfa1/Luc DNA construct, transcriptional activity of cbfa1 was upregulated by 2-fold after 24 hours of BMP-7 treatment. Electromobility shift assays with C2C12 cellular extracts indicate that BMP-7 increases binding of OSE2 promoter sequences. Supershift assays with anti-cbfa1 antibodies demonstrate that cbfa1 is part of the nucleoprotein complex binding OSE2. Co-transfection studies with both a cbfa1 cDNA expression vector and cbfa1/Luc decreased basal transcription level of cbfa1/Luc, while BMP-7 reversed cbfa1-induced repression in C2C12 cells. These data suggest that cbfa1 can attenuate its own transcription in a classic negative feedback manner, and this repression is reversible by BMP-7. Together, transfection and gel shift studies indicate that BMP-7 can upregulate cbfa1 gene expression in C2C12 myoblast cells, and that cbfa1 may bind to OSE2 elements within its own promoter to suppress cbfa1 gene transcription in a classic negative feedback loop fashion.

SU031

Development of a Standardized System for Assessing the Osteogenic Activity of BMP Gene Transduced Mouse Embryonic Fibroblast. S. Yang,* D. Wang,* D. Wei,* R. Franceschi. University of Michigan, Ann Arbor, MI, USA.

Gene therapy represents a new alternative for regenerating bone. Previous studies showed that adenoviruses expressing BMPs can induce ectopic bone formation at subcutaneous and intramuscular sites and repair bony defects. An osteogenic response was observed regardless of whether virus was directly implanted in experimental animals or used to transduce dermal fibroblasts before implantation (Franceschi et al. J Cell Biochem 78:476, 2000; Krebsbach et al., Human Gene Therapy 11:1201, 2000). However, lack of a standardized system for comparing the osteogenic activity of different virus constructs prevents clear comparisons between various BMPs and other osteogenic factors. To provide such a system, we used an inbred mouse strain (C57BL6 mice) and a clonal (syngeneic) embryoic fibroblast cell line derived from this strain (BLK cells). Cells were transduced with control (lacZ) adenovirus or adenovirus expressing BMPs 2, 4, or 7 as well as constitutively active BMP receptors 1A and 1B. In this study, we investigated the effect of different BLK cell numbers (105,106,2x106, 5x106, 107), different adenoviral titres (500, 1000, 1500, 2000, 2500pfu/cell) and different times (2, 3, 4, 6, 8 weeks) on bone formation with Ad-BMP7. After transduction, cells were suspended in a collagen hydrogel carrier (type I rat tail, 3mg/ml) and implanted into subcutaneous sites of mice. Histologically distinguishable bone begins to form at the edge of the collagen implant as early as 2 weeks following cell implantation. After 3 weeks, mature bone marrow elements were detected. The optimal time for forming bone was 3 to 4 weeks based on assay of implant alkaline phosphatase, calcium and phosphate. Increasing transduced cell number also increased bone formation. Using a saturating adenovirus titer (1000 pfu/cell), the weight of bone in 107cells groups was 27.3, 20.5, 6.3, 3.5 times of those in 105, 106, 2x106, 5x106 cells groups. When cell number was held constant, an adenovirus titer of 500 pfu/cell was best for bone formation with higher titer being toxic to cells. To follow the fate of virus-transduced cells in vivo, we generated BLK cell stable clones carrying a lacZ reporter gene. These cells are being used to assess the degree to which implanted cells contribute to the new bone formed which is known to be composed of both implanted and host cells. These studies validate use of the BLK/C57BL6 system for quantitatively evaluating the osteogenic activiy of various adenovirus constructs.

Discovery of an Effective Natural Product Carrier of Demineralized Bone Matrix. A. Fujiwara,*[1] M. P. Tippen,*[2] A. J. Marchosky,*[3] W. J. Maloney,*[1] J. Feder,*[2] K. A. Hruska,[4] H. D. Adkisson.[2] [1]Orthopaedic Surgery, Washington University School of Medicine, St. Louis, MO, USA, [2]Isto Technologies, Inc., St. Louis, MO, USA, [3]Neurosurgery, St. Lukes' Hospital, St. Louis, MO, USA, [4]Internal Medicine, Washington University School of Medicine, St. Louis, MO, USA.

Introduction: Failure of some commercial demineralized bone matrix (DBM) products to repair large bone defects has raised concerns regarding variable efficacy and possible allograft migration. This study compared the ability of DBM formulated with either high molecular weight hyaluronic acid (HMWHA) or polymerized alginate to heal 5mm femoral gap defects in rats. Methods: Fourty 5mm defects were created in twenty female athymic nude rats aged 12-16 wks. Five treatment groups were randomly assigned: Group 1 (negative control), untreated defects; Group 2 (positive control), fresh human cancellous bone chips; Group 3, DBM alone (AlloSource, Englewood, CO); Group 4, DBM in 14 mg/ml HMWHA (Healon GV); and Group 5, DBM in 3% alginate in saline. Alginate grafts were polymerized in situ with calcium. All DBM was from a single donor and delivered in carrier at the same dose. Animals were euthanized at 12 wks for radiographic and histomorphometric analysis of bone healing. A three-point scale was adopted for radiographic scoring (0 = no bone formation; 1 = partial bone formation; 2 = complete union). Percent new bone formation was expressed as percent of total bone (DBM + new bone) observed in the defect. Data were treated statistically for determination of variance between groups.Results: Bilateral surgery was well tolerated; rats demonstrated increased weight gain over the 12-week evaluation period. Fourteen (2 in Group 2, 6 in Group 3, and 6 in Group 4) of 40 defects demonstrated complete radiographic healing. Histomorphometric analysis showed 48.3 ± 8.5 % new bone in Group 4 defects vs. 37.5 ± 12.1 in Group 3. Alginate/DBM produced only 1.6 ± 2.2 % new bone, with little evidence of osteogenic/chondrogenic differentiation. Histologic evidence for chondrogenic differentiation to bone was greater in Group 4 vs. Group 3 treated defects. Histomorphometric analysis of new bone formation showed statistical significance between Group 1 vs. 5 ($p<0.05$), Group 2 vs. Groups 1 and 5 ($p<0.001$), and Group 4 vs. Group 2 ($p<0.05$). No significant difference in % new bone formation was observed between either Group 4 vs. Group 3 or Group 3 vs. Group 2. Discussion and Conclusions: HMWHA displayed good handling characteristics and supported osteoinductive growth when combined with DBM. Although alginate has been used successfully to culture osteoblasts and chondrocytes, in vivo use for bone grafting is contraindicated because it limits migration of osteogenic precursor cells.

SOST, a BMP Antagonist Expressed in Mature Osteoblasts, Regulates Bone Formation. M. S. Kung Sutherland, J. Geoghegan,* D. G. Winkler,* T. Hayes,* R. J. Ursino,* K. Staehling-Hampton,* L. Zhao,* J. A. Latham. Celltech R&D, Inc., Bothell, WA, USA.

We previously reported that null mutations in the SOST gene are associated with the sclerosteosis phenotype typified by excess deposition of bone (Amer J Hum Genet 2001, 68: 577-589). To further characterize the SOST gene product, Sclerostin, human mesenchymal cells were used to evaluate Sclerostin expression and to determine its biological activity. Human mesenchymal cells were cultured to induce the formation of osteoblastic or chondrocytic cells. Sclerostin was expressed in committed and mature osteoblasts but not in chondrocytes. We evaluated the biological function of Sclerostin by measuring alkaline phosphatase activity, synthesis of collagen type I and mineralization after the addition of partially-purified preparations of baculoviral-expressed Sclerostin protein. Sclerostin significantly decreased the activities and levels of these osteoblastic markers. In contrast, alkaline phosphatase activity, synthesis of collagen type I and mineralization were increased upon treatment of osteoblastic cells with anti-Sclerostin monoclonal antibodies. In a rodent culture model, the mouse mesenchymal C3H10T1/2 cells, Sclerostin displayed a dose-dependent decrease in BMP-6-induced alkaline phosphatase activity. These findings support the premise that Sclerostin plays an important role in controlling osteoblast function.

Sclerostin, the Protein Product of the Sclerosteosis Gene (SOST) and a Key Regulator of Bone Matrix Formation, Binds to BMPs and Antagonizes their Function. D. G. Winkler, T. Hayes,* J. Geoghegan,* J. Skonier,* R. Ursino,* M. Kung Sutherland, J. Latham.* Gene Function and Target Validation, Celltech R & D, Inc., Bothell, WA, USA.

Null mutations in the SOST gene in humans results in Sclerosteosis. This disease causes an increased bone deposition throughout life. We have expressed and partially purified Sclerostin from SF9 cells. Sequence analysis of Sclerostin has established homology to the DAN family of BMP antagonists. We tested the ability of Sclerostin to bind to BMPs directly, and found that the protein binds to a subset of BMPs with high affinity. This interaction antagonizes BMP induced akaline phosphatase in C3H10T1/2 cells. We hypothesize that blocking the Sclerostin /BMP interaction may increase bone deposition and could lead to anabolic treatments for osteoporosis.

Delivering BMPs by Thermoreversible Biomaterials for Increased Local Retention. H. Uludag,* T. Gao,* N. Kousinioris.* University of Alberta, Edmonton, AB, Canada.

This study was conducted to investigate the feasibility of enhancing local retention of BMPs by thermoreversible biomaterials. The latter exhibit temperature dependent solubility, where the biomaterials are water-soluble at a low temperature but become insoluble at

the physiological temperature. In that way, the biomaterials can be formulated with BMPs as a liquid at a low temperature (4 oC), but become insoluble and retain the protein in body. An enhanced retention of BMPs is expected to result in an enhanced osteoinductive activity. To investigate the feasibility of this approach, we prepared several thermoreversible biomaterials with predictable changes in their properties. Among the factors investigated were: presence/absence of protein reactive N-acryloxysuccinimide (NASI) group in the biomaterials, the lower critical solution temperature (LCST: solubility transition temperature) and molecular weight (MW) of the biomaterials. All biomaterials were based on N-isopropyacrylamide (NiPAM) and were synthesized by a free-radical polymerization process. The LCST of the biomaterials were controlled by incorporating alkylmethacrylates into the biomaterials. The MW was controlled by the choice of the polymerization conditions. The biomaterials were characterized as described elsewhere [Uludag et al., (2001) Biotech. Bioeng., in press.]. To determine the BMP retention, BMP-2 was 125I-labeled and either implanted (with a collagen sponge) or injected intramuscularly into Sprague-Dawley rats. Rats were periodically sacrificed and the radioactive count at the injected site was determined.To explore the LCST effect on BMP-2 retention, biomaterials with high (~25 oC) or low (~15 oC) LCST was used. The rhBMP-2 retention was similar on day 1 (40-50%, irrespective on the biomaterials' LCST and the animal model. By day 7, differences among the biomaterials were not that significant in the implant model, whereas biomaterials with low LCST gave an increased retention in the injection model. Incorporating protein-reactive NASI groups into the biomaterials further improved the retention of BMP-2 (irrespective of LCST). To determine the MW effect, the biomaterials were chosen where the MW was either ~50 kD or 400 kD. Biomaterials with a higher MW gave a higher retention of BMP-2 after 14 days. Taken together, the results indicated that delivering BMP-2 with thermoreversible biomaterials increased the protein retention as much as 200-fold in the chosen animal models. This was achieved by physical entrapment as well as chemical conjugation of the protein within the biomaterials. Studies to correlate the retention results with bone tissue induction are currently underway.

Bone Morphogenetic Protein-2 Enhances Statement of the Inorganic Phosphate (Pi) Transporter Pit-1 and Matrix Mineralization in Osteoblast-like Cells. A. Suzuki,[1] I. Sato,*[1] J. Guicheux,*[2] A. Kakita,*[1] Y. Miura,*[1] Y. Oiso,*[1] J. Bonjour,[3] J. Caverzasio.[3] [1]1st Department of Internal Medicine, Nagoya University School of Medicine, Nagoya, Japan, [2]INSERM 99-03, School of Dental Surgery, Nantes, France, [3]Division of Bone Diseases, Department of Internal Medicine, University Hospital of Geneva, Geneva, Switzerland.

Bone morphogenetic proteins (BMPs) play an important role in the development of bone and cartilage. BMP-2 is produced by osteogenic cells including osteoblasts and stimulates the differentiation of preosteoblasts and the activity of osteogenic cells. Inorganic phosphate (Pi) is an important element for the calcification of the bone matrix. Previous in vitro studies in osteoblast-like cells suggested a possible role of the Pi transport system Pit-1 in initial events of matrix mineralization and recent observations indicate that BMP-2 selectively enhances statement of Pit-1 in MC3T3-E1 cells. The aim of the present study was to investigate the role of Pit-1 in matrix mineralization induced by BMP-2 in MC3T3-E1 cells. BMP-2 time- and dose-dependently stimulated Na-dependent Pi transport in confluent MC3T3-E1 cells. This response was preceded by an increased statement of mRNA encoding Pit-1 after 2 hours BMP-2 exposure. In addition to its effect on Pi transport, BMP-2 dose-dependently enhanced both ALP activity and the formation of mineralized bone nodules in differentiating MC3T3-E1 cells in presence of 5 mM beta-glycerophosphate (13 x) in the culture medium. This latter effect of BMP-2 was also observed in MC3T3-E1 cells cultured in presence of a high phosphate containing (2.5 mM) medium. Phosphonoformic acid (0.1 mM), a selective inhibitor of Pi transport, suppressed BMP-2-induced enhancement of mineralization . In conclusion, the results of this study indicate that associated with the stimulation of Pit-1 statement in osteoblast-like cells, BMP-2 enhances bone matrix mineralization and that this effect is prevented by a selective inhibitor of Pi transport further suggesting a role of Pit-1 in initial events of bone matrix calcification.

Is Calcification closely Associated with Ossification during Atherogenesis? H. H. T. Hsu,[1] O. Tawfik,*[1] F. Sun.*[2] [1]Pathology, University of Kansas Medical Center, Kansas City, KS, USA, [2]University of Kansas Medical Center, Kansas City, KS, USA.

Several studies demonstrated that specific bone makers contributing to the regulation of calcification are present in atherosclerotic lesions. These findings are consistent with a number of clinical observations that ossification and calcification can occur in atherosclerosis. To determine whether calcification is a result of ossification during high lipid-induced atherosclerosis, a rabbit model was used. Rabbits were fed 0.25% high cholesterol and 1% peanut oil for up to 6 months. As a result of 3 months of dietary interventions, rabbits developed characteristic atherosclerotic lesions without Alizarin red positive calcification. At 6-month period, calcification was predominantly present in the area between intima and media. H & E histochemical staining indicates that neither bone cells nor chondrocytes were present throughout the entire period of the study. The fatty streaks and calcification were more abundant in proximal regions of the aorta exiting from the heart and became progressively less to the distal part of aortas. The structural irregularity of the ascending aorta close to the heart caused by the high lipid diet are more subjected to the impact of blood flow than are the distal part of aortas. This may contribute to high incidence of calcification since calcification is frequently associated with tissue injury. Thus, it is concluded that aortic calcification induced by high cholesterol diet is in part a result of local damage caused by the impact of blood flow to the abnormal aortic structure rather than a mere end result of ossification.

Environmental Fluoride Exposure, Bone Quality, and Osteoarthritis. D. Chachra,*[1] H. Limeback,*[1] D. Zukor,*[2] M. Schwartz,*[2] A. E. Gross,*[1] C. H. Hutchison,*[1] M. D. Grynpas.[1] [1]Mount Sinai Hospital and University of Toronto, Toronto, Canada, [2]Jewish General Hospital and McGill University, Montreal, Canada.

The purpose of this study was to characterize bone quality with respect to environmental fluoride exposure. Femoral heads were obtained at hip arthroplasty from 92 individuals, residing in regions with fluoridated (n=53) or non-fluoridated (n=39) municipal water. The femoral heads were primarily removed because of osteoarthritis (75) or osteoporosis (9). The fluoride content of a cancellous core from the centre of the femoral head was measured by neutron activation analysis. This sample was tested in compression. Image analysis and backscattered electron imaging (BSE) were performed on samples from the superior (weightbearing) and inferior (nonweightbearing) surfaces of the femoral head. The microhardness was determined at four sites. The fluoride content of the cancellous bone increased logarithmically with age ($R2=0.09$, $p<0.005$). The mechanical properties did not vary with the fluoride content, independently of age. The amount and connectivity of the cancellous bone were not related to the fluoride content. However, more bone was present at the superior site than at the inferior site of osteoarthritic specimens ($p<0.05$); this was not observed in the non-osteoarthritic specimens. Similarly, the amount of bone present at the superior, but not the inferior, surface of the osteoarthritic specimens was greater than that of the non-osteoarthritic specimens. These data indicate increased local bone formation associated with osteoarthritis. The degree of mineralization was lower for the superior surface of osteoarthritic samples than the inferior surface or the superior surface of the non-osteoarthritic specimens ($p<0.05$). However, for the osteoarthritic samples, the degree of mineralization of both the subchondral and the cancellous bone increased with the fluoride content ($R2=0.137$ and $R2=0.145$, respectively; $p<0.05$) at the superior surface. Consistent with this, the microhardness of the subchondral and cancellous bone at this site also increased with the fluoride content ($R2=0.414$, $R2=0.138$, respectively; $p<0.05$). These relationships were not observed at the inferior surface. In conclusion, fluoride incorporation due to environmental fluoride exposure does not have a systemic effect on bone quality. However, incorporated fluoride is positively associated with the degree of mineralization of bone in regions affected by osteoarthritis. This suggests that exposure to environmental fluoride and its subsequent incorporation may influence bone remodeling in the subchondral bone of osteoarthritic patients.

In Situ Identification of a Ca-Organic Phosphate Complex by 31P Solid State NMR Spectroscopy at Onset of Mineralization. Y. Wu,*[1] J. L. Ackerman,*[2] M. J. Glimcher.[1] [1]Orthopaedic Surgery, Harvard Medical School and Children's Hospital, Boston, MA, USA, [2]Dept of Radiology, Massachusetts General Hospital, Boston, MA, USA.

To investigate proposals that phosphoproteins play a critical role in calcification of bone, we have developed 31P solid state NMR spectroscopy techniques which permit the direct identification of Ca-free phosphoproteins, phosphoproteins complexed with Ca and Ca-P apatite crystals in intact, 8-19 d embryonic chick bone. Ca-free and Ca-complexed phosvitin and beta-casein were used as standards. To distinguish the NMR characteristics of Ca-free phosphoprotein from phosphoproteins complexed with Ca, we introduced a new parameter, δ, the sideband pattern index, which clearly distinguishes Ca-free from the Ca-complexed phosphoproteins. However it was not possible to accomplish this in moderately calcified embryonic bone because the 31P NMR spectra were overwhelmed by the mineral. Similarly, it was not possible to identify the rare organic spin species in the earliest stages of mineralization because the 31P NMR spectra were essentially identical to those of standard Ca-free phosphoproteins. The problems were solved by using a differential cross polarization (DCP) 31P NMR technique and the new index parameter δ. DCP 31P NMR of 8 day chick embryo bone generated a sideband pattern identifying the very major component as phosphoprotein (phosphoryl groups) not complexed with Ca. However, a very small signal was also generated by a Ca-phosphoprotein complex coincident with the detection of a trace of apatitic mineral phase. Additional mineral phase was identified in 10 and 12 day chick embryo bone. Phosphoproteins synthesized and excreted into the extracellular organic matrix in the very early stages of ossification are for most part not complexed with Ca. At the onset of mineralization, very few molecules of Ca-complexed phosphoproteins are detected at a time when a trace of a Ca-P mineral phase of apatite is also observed. These are the first structural data of in situ bone which support the critical role for phosphoproteins in the initiation of calcification.

Osteoinductive Potential of DBM/collagen Product Is Affected by Product Preparation Rather Than Collagen Matrix Preparation. L. Masinaei,*[1] K. Crouch,*[1] D. Softic,*[2] A. Wilson,*[2] L. Wolfinbarger.[2] [1]Center for Biotechnology, Norfolk, VA, USA, [2]LifeNet, Virginia Beach, VA, USA.

Over the past few years, human collagen has been used as a carrier for demineralized bone matrix (DBM) to improve the handling characteristics and maintain the osteoinductive potential of DBM. The purpose of this study was to determine the appropriate techniques for preparation of a collagen/DBM product that would fulfill the above criteria. The study was divided into two phases. In the first phase, different collagen preparation methods were examined and factors such as extraction acid (0.5N Acetic acid, 0.1N HCl, 0.01N HCl, and 2N Citric Acid), extraction time (1hr, 2hr, and 24hr) and heat (65°C, 50°C, and 25°C) were varied. The DBM was manually mixed with the collagen matrix to produce

composite products. The maximum amount of DBM for any one product was 27% by weight. A total of 11 different products were produced by these variations. Enough material to contain 20mg of DBM was implanted into gluteal muscle pouches of male athymic mice (three mice/product). The materials were explanted after 28 days and analyzed for new bone formation as shown by histomorphometric analysis and remineralization as shown by calcium deposition. All the results from the experimental groups were compared to a positive DBM control. In phase two of the study, the best method of collagen preparation (extraction of tendon with 0.5M Acetic Acid, pH1.67 for 2 hours at 25ºC) was used to produce the collagen matrix for all the remaining implantation studies and the methods of addition of bone to the collagen were varied. Different methods of mixing bone with the collagen (homogenization of the bone/collagen matrix, dehydration of the product at 40ºC for 24hr, and rehydration of sample), weight:weight ratio of DBM to collagen (40% DBM, 50% DBM, and 60% DBM), and different solutions for hydration of the product (saline and glycerol) were changed for producing the samples. A total of 12 products were produced and assayed as described for phase one. The products from the first phase formed less bone and deposited less calcium than a positive DBM control and did not have the desired handling characteristics. The products from the second phase provided for better sample handling characteristics and were at least as osteoinductive as the positive control. The important factors that should be taken in consideration for producing a successful collagen/DBM matrix are bone to collagen ratio and the method of mixing bone with collagen.

Bone Density Changes in Pamidronate Treatment of Paget's Disease: Enhanced Increase in the Nonpagetic Spine with Calcium plus Calcitriol Supplement. R. I. Price,[1] L. Ward,*[1] D. H. Gutteridge,[1] R. W. Retallack,[1] G. O. Stewart,[2] R. L. Prince.[1] [1]Sir Charles Gairdner Hospital, Perth, Australia, [2]Fremantle Hospital, Perth, Australia.

We reported (Price et al [1993]) that intravenous pamidronate disodium (ivAPD) was associated with forearm bone loss, arising from secondary hyperparathyroidism. We also showed (Stewart et al [1999]) that the loss was abolished by calcium (Ca) plus calcitriol (1,25D) supplement (SUP). This study reports effects on bone mineral density (BMD) of ivAPD treatment, with and without SUP, in the lumbar spine (LS), hip and whole body (WB). Forty-nine patients were stratified by disease severity into; (i) a "moderate" (M, n=27) group with Hyp_E = 5-10µmol L GF, and; (ii) "severe" (S, n=22) with Hyp_E> 10mmol/L GF. Patients were randomised within-group to Ca plus 1,25D SUP or unsupplemented (UNSUP). S received 360 mg ivAPD as 6 doses of 60mg once-weekly; M received 240 mg as 4 weekly doses of 60mg. SUP received oral Ca 1.0-1.2 g/day for 6 months (mo) plus 1,25D 0.25mg twice daily for 4 weeks, starting at first ivAPD infusion. BMD was measured at 0, 3, 6, 12 & 24 mo using DXA (Hologic QDR2000 array) on the LS, hip and WB. Pagetic bone was assessed separately in the spine and hip. Only patients completing the 24 mo study were included in the analysis. WB BMD of all groups rose significantly (sig.) by 6 mo, notably in S-SUP (2.2-8.9% [(95%CI], p<0.005). All groups were elevated at 12 mo, but only M-SUP was still sig. above baseline at 24 mo (1.1-4.4%, p<0.005). SUP and UNSUP in S or M were not sig. different at any time. Spinal Pagetic BMD rose dramatically by 3 mo (see Table), but SUP and UNSUP were not different at any time in S or M. Indeed, in the combined M plus S groups, Pagetic LS BMD of SUP and UNSUP were elevated equally at 24 mo (see Table). SUP LS BMD in nonpagetic vertebrae rose mildly compared with Pagetic, but markedly compared with UNSUP, as shown below (95%CI, in units of % increase in LS BMD. * = p<0.05 , SUP vs UNSUP at same time point).

SPINE	UNSUP(M+S)	UNSUP(M+S)	SUP(M+S)	SUP(M+S)
	3mo	24mo	3mo	24mo
Pagetic	5.2-23.3 (n=9)	-1.40-18.9	10.5-25.2 (n=14)	1.7-16.6
Nonpag	-1.5-1.7 (n=15)	-0.3-4.41	0.4 -13.6 (n=11) *	-0.1-10.3

Hip Pagetic BMD responded similarly to the spine, with increases about one half. Nonpagetic hip BMD showed neither a treatment nor SUP effect. We conclude that (i) UNSUP bone loss is confined to the forearm; (ii) Ca plus1,25D SUP does not enhance Pagetic BMD or its retention at 24 mo, relative to UNSUP; (iii) SUP markedly and rapidly increases BMD in the nonpagetic spine, relative to UNSUP, suggesting a role for SUP in treatments for osteoporosis using parathyroid hormone. Price R et al (1993) J Bone Miner Res 8:210; Stewart G et al (1999) Bone 24:139.
